Progressive demineralization is defined as ► dental caries, a condition which passes through different stages, starting with chalky white spots and leading to a ► cavity. When reaching the underlying dentine, pain usually occurs because dentine is sensitive to thermal, physical, and osmotic stimuli. If the process still continues, it can spread to the ► pulp and then along the ► root canals to the ► alveolar bone, causing an inflammation or even a dental abscess. These progressions cause spontaneous and intense pain and discomfort, often of longer duration. As a consequence, the tooth frequently has to be extracted (tooth loss).

Periodontal Diseases

► Periodontal diseases have been prevalent throughout human history. They cover a group of inflammatory diseases that arise in the gum sulcus, the crevice between the gum and the tooth, as a response to dental plaque. Even in healthy mouths, the gum sulcus is teeming with bacteria, but they tend to be harmless varieties. If dental plaque remains in the sulcus, the population of the microorganisms changes and these bacteria and their waste products (exo- and endotoxins) attack the crevicular epithelial cells. Some of the microorganisms can even pass through the epithelium. In order to eliminate the detrimental bacteria and their toxins, the body activates an immune response to infection. This reaction passes through different stages. Due to these reactions, periodontal diseases are generally divided into two groups: ► gingivitis and ► periodontitis.

Gingivitis is an inflammatory process exclusively affecting the gingiva (gum). The inflammation of the gingiva is characterized by tender, red, swollen gums that bleed on gentle provocation like cleaning the teeth.

In most cases, gingivitis causes no pain. The junctional epithelium remains attached to the tooth at its original level. Gingivitis is nearly always chronic, but occurs infrequently in an acute form, the most severe being acute necrotizing ulcerative gingivitis (ANUG).

Periodontitis is the consequence of progressive gingivitis, although not every gingivitis leads to periodontitis. It is characterized by loss of clinical attachment of the ► periodontal ligament and by loss of bony support of the tooth. This occurs because exotoxins and endotoxins, as well as decomposition products of the host, represent a stimulus. They encourage the activation of osteoclasts, which are responsible for purposeful decomposition and reconstruction of bony tissue in order to protect the surrounding tissue and to prevent deeper infection. As a result, the supporting bone starts to atrophy. This loss of attachment manifests by deepening of the pockets between the gingiva and teeth and by recession of the gingiva. In severe cases, the supporting structures are so depleted that the teeth become loose. All things considered, periodontal destruction arises directly as a result of pathogenic bacterial components and indirectly via host destructive mechanisms. In most cases, this oral disorder is chronic with recurring acute phases. Pain only occurs in cases of exposed ► roots and during acute inflammation. It can be severe in the event of an abscess of the pocket or alveolar bone. Whereas gingival bleeding, ► calculus, and mild ► periodontal pocketing are highly prevalent among adult populations all over the world, advanced disease with deep ► periodontal pockets ($\geq$ 6 mm), leading to severe loss of supporting periodontal tissues and tooth loss, affects 10–15% of adults worldwide (Petersen 2003). ► Dental plaque does not seem to be the only cause for periodontitis, since destructive diseases only occur in a minority of people although dental plaque is ubiquitous. Research has shown that the appearance of periodontal diseases is affected by genetic and environmental factors, for example smoking and stress.

The influence of periodontitis on other medical subjects has become a point of research within the last few years. Periodontitis as a risk for bacteraemia has been described. This is especially important for patients suffering from certain cardiac diseases who are at high risk of endocarditis. Furthermore, not only an influence of diabetes and its risk factors on periodontitis, but also the influence of periodontal diseases on progression of diabetes, is also being discussed at the moment. Periodontitis has also been linked to preterm birth and low birth weight.

Oral Cancer

Oral cancer is the eighth most common cancer in the world, showing marked geographic variation. In most cases, oral malignancies are squamous cell carcinomas. Many are painless until they get large. The carcinomas appear as ulcers, swelling, or red or white patches. They can arise on the lip, tongue, gum, mouth floor, salivary glands, pharynx, or on other unspecified parts of the mouth, and often emerge from premalignant lesions as *leukoplakias* and *erythroplakias*. Malignant change of oral *lichen planus* and hyperplastic *candidiasis* occurs less frequently. Hence, as oral cancer quite often goes through initial benign states, it is largely preventable. The major risk factors are tobacco, alcohol, exposure to sunlight, and poor diet (Pine 1997). The single risk factor most consistently associated with oral cancer is the use of tobacco in its various forms (Burt and Stephen 2005). Oral malignancies are high among men. Their incidence increases with age.

Dental Trauma

Dental trauma is an injury to the teeth, lips, gum, tongue, or ► jawbones. The most common dental trauma is a fracture or a bodily movement of the tooth, including complete avulsion. Tooth fracture can affect the crown and/or the ► root of the tooth. The anteriors, which are also the most visible teeth, are primarily involved. In ► primary dentition, the incidence is greatest at the toddler age of 2 to 3 years, when motor coordination is developing (especially finding one's feet; Flores 2002). ► Permanent teeth are most frequently affected in the event of falls, followed by traffic accidents, violence, and sport activities. Depending on the location of the fracture, the tooth may cause toothache pain (e. g. crown-root fractures). Broken teeth often have a sharp edge that may cut the tongue and cheek. If the upper and lower teeth no longer fit together properly (malocclusion) or if there is jawache accompanied by a limited ability to open and close (mobility) the mouth, a jawbone may be broken.

Congenital Malformations

Within the possible congenital malformations of the digestive system, craniofacial anomalies (CFA) are

a highly diverse group of irregularities in the growth of the head and facial bones. There are many factors that may contribute to their development, including the combination of genes, environmental factors, and folic acid deficiency. They affect a significant proportion of the global population and still remain a major cause of infant mortality and morbidity in many countries. Their impact on speech, hearing, appearance, and cognition has a prolonged and adverse influence on health and social integration. One of the most common types of CFA is a cleft lip and/or cleft palate which occur in around 1 per 600 births (WHO 2002). The rate varies substantially across ethnic groups and geographical areas.

Dentofacial Anomalies

Temporomandibular Disorder Temporomandibular disorder (TMD), also called temporomandibular joint syndrome (TMJ) or craniomandibular disorder (CMD), comprises a group of painful and distressing conditions related to the ► jaw joint (*temporomandibular joint*) and the surrounding facial muscles that control chewing and moving the jaw, or both (Okeson 1996). The three most common types of temporomandibular disorders are ► myofascial pain and ► dysfunction, internal derangement of the joint, and degenerative joint disease (osteoarthrosis). Among them, myofascial pain and dysfunction is by far the most common form (Dimitroulis 1998).

TMD are ubiquitous in cultures around the world. Signs and symptoms vary in their presentation and can be very complex, for example headache pain, neck pain, noises or ringing in the ear, problems in biting, popping sounds during biting (joint noises), and many more. The three cardinal features of temporomandibular disorders are orofacial pain, joint noises, and restricted jaw function (Dimitroulis 1998). TMD primarily affect young adults, especially women aged 20–40 years (Dworkin 1990).

The etiology of the most common types of temporomandibular disorders is multifactorial and still largely unresolved. Beside occlusal (bite) interferences, psychological stress, depression, and the presence of other somatic complaints have been shown to influence the course of these disorders considerably (predisposing factors). Psychosocial variables have been found to be more strongly associated with pain intensity and activity interference than clinical examination findings have (Turner and Dworkin 2004). Trauma and parafunctional habits (e. g. clenching and bruxism) are often cited as possible initiating factors, the latter being the most frequent cause of myofascial pain and dysfunction. Hence, both the assessment and the management of TMD require a multidisciplinary perspective with strong emphasis on psychosocial variables (Rollman and Gillespie 2000).

Malocclusion Occlusion of the teeth means the meeting of upper and lower teeth. Malocclusion is therefore the term used to describe states in which the occlusion departs from the normal (Osborn 1981). Malocclusion is not a disease but rather a set of dental deviations which, in some cases, can influence quality of life. It refers to a misalignment of teeth or may be caused by a disproportion between the size of the upper and lower jaws or between jaw and tooth size. Hence, it can range from gross disfigurement to minor irregularities in the alignment of the teeth. Most people have some degree of malocclusion, although it isn't usually serious enough to require treatment. Those who have more severe malocclusion may require orthodontic treatment. Correction of malocclusion can reduce the risk of tooth decay and periodontitis. Under certain conditions, it may help relieve excessive pressure on the temporomandibular joint, avoiding dysfunctions known as temporomandibular disorders (TMD). However, besides the medical rationale, the growing significance of aesthetics contributes considerably to the very high demand for orthodontic treatment.

Oral Health

Definition

Oral health means more than just having healthy teeth. It comprises chewing and eating the full range of foods, speaking clearly, having a socially acceptable smile and dentofacial profile, being free from pain, and having a fresh breath.

Oral Health Behavior

Synonyms

Dental health behavior; Health belief

Definition

The term "oral health behavior" describes the complex effect on individual oral health of oral hygiene habits, nutritional preferences and the pattern of a person's utilization of dental services. Since these behaviors exist in a social framework of lifestyles typical of the relevant culture, not only these direct parameters but also the indirect influences on people's oral health need to be taken into account. These are determined principally by the social opportunity structure offered by a society, which underlies the distribution of access to knowledge about oral health, the availability and utilization of dental services and the provision of the necessary funding. Empirical studies have repeatedly shown that the distribution of oral morbidity in industrial societies is unequal, with persons lower down the social scale on the whole exhibiting oral health problems more frequently than those in higher social categories.

Definition

Oral health means more than just having healthy teeth. It comprises chewing and eating the full range of foods, speaking clearly, having a socially acceptable smile and dentofacial profile, being free from pain, and having fresh breath. Due to changes in the importance of these factors, the prevalence of oral diseases varies with regard to age, sex, and culture.

Basic Characteristics

Background

Oral health depends on a range of individual factors such as socio-economic, socio-cultural, and nutritional conditions. Other characteristic factors influencing oral health are, for instance, the individually available number of teeth, consequences of traumatic injuries, and oral cancer. There are still wide discrepancies between the availability of medical care and health care utilization in developed countries and between the availability and access to Oral Health Care in developing countries. Worldwide, these discrepancies lead to differences in the distribution of oral diseases, varying not only between different regions but also between different age groups. The two main oral diseases of public health importance are dental caries and periodontitis (gingivitis and periodontitis), followed by oral cancer and dental trauma.

Dental caries is a common chronic disease occurring at any age. It is a process of demineralization of the ► hard tooth tissue caused by products of bacterial metabolism and leading to cavities in the teeth. Untreated caries can give rise to infection of the dental ► pulp, which can spread to the supporting tissues and the jaws, culminating in advanced disease conditions that are often painful. In Thailand for example, recent surveys of a sample of 12-year-old children revealed that 53% had suffered from pain or discomfort from their teeth over the past year (Petersen et al. 2001). The corresponding figures in China were 34% for 12-year-olds (Peng et al. 1997) and 74% for adults. ► Dental caries is the single most common childhood disease in the United States (U.S. Public Health Service 2000). These figures demonstrate that tooth decay is a public health problem worldwide.

The prevalence of dental caries is measured by the ► DMF(T)-index (Klein et al. 1938). This Index-system describes the lifetime-caries-experience of an individual. Every tooth is given one of the following categories:

D	Decayed	Tooth with a cavity (decay)
M	Missing	Tooth is missing (because of caries)
F	Filled	Tooth with a filling (has had a cavity)

The sum of the three figures forms the DMFT-value, which ranges from 0 (no caries) to 28 (all teeth affected) for each person. If a tooth has both a caries lesion and a filling, it is calculated as D only. Wisdom teeth are not counted.

Periodontal diseases are an inflammation either of the gingiva (► gingivitis) or of the gum, periodontal ligament, and alveolar bone (► periodontitis). The prevalence of gingivitis and periodontitis is measured by the ► CPI-Index (Table 1). According to this index, the mouth is divided into sextants, each sextant having special index teeth. The index teeth are examined and assigned to a certain score. The highest score per sextant is recorded.

For examining differences between several ages, the World Health Organization, in their manual for oral health surveys, suggests five age-groups as representative index ages for monitoring disease trends and enabling international comparisons (Table 2).

Children

Dental Caries In early childhood, a very severe kind of Early Childhood Caries (ECC) of the ► primary dentition is the so-called nursing-bottle syndrome (NBS)

Oral Health in Different Age Groups, Table 1 CPITN-Index (Ainamo et al. 1982)

Code	Status	Sign of
0	Healthy gingival and periodontal conditions	Healthy conditions
1	Gingival bleeding on probing	Gingivitis
2	Calculus or iatrogenic marginal imperfections and gingival bleeding	Gingivitis
3	Depth of the gingival pocket: 4–5 mm	Periodontitis
4	Depth of the gingival pocket: 6 mm or above	Severe periodontitis

Oral Health in Different Age Groups, Table 2 Representative WHO index age groups (WHO 1997)

Index age	Description	Main examination goals
5	Children (complete primary dentition)	– Caries in primary dentition
12	Children (complete permanent dentition) (except third molars)	– Caries monitoring
15	Adolescents	– Caries monitoring – First assessment of periodontal disease indicators
35–44	Adults	– Caries monitoring – Status of periodontal diseases – Evaluating effects of oral health care
65–74	Elderly	– Planning and evaluating effects of oral health care

which is more and more common in developed countries. NBS results from calming a child down by giving sweet sugar-containing drinks in light plastic bottles frequently and for any length of time, leading to massive destruction of the hard tooth tissue. This kind of rampant tooth decay can either destroy the milk tooth or have negative effects on eating, speaking, and the permanent dentition (▶ permanent teeth). Its prevalence differs between developed countries (1% to 12%) and developing countries (e. g. 70% among Native Americans; Milnes 1996; Broderick 1989).

Looking at the 12-year-old children worldwide, a substantial decline in dental caries levels can be identified. In several regions, prevention programs show good effects in this age-group. The WHO and the FDI World Dental Federation formulated goals for oral health in 1981 to be achieved by the year 2000. The global average was committed to be no more than 3 DMFT at 12 years of age. In 2001, the global weighted mean DMFT value for this age group was reported to be 1.74, and is continuing to decrease (global weighted mean DMFT = 1.61 in 2004). Although efforts have been made, dental caries is still a public health concern. There are still countries which suffer from a high rate of caries, for instance Lebanon (DMFT score of 3.4 in 2000) and Bulgaria (DMFT score of 4.4 in 2000). Only 74% of the nations reached the formulated goal, representing 86% of the world population in 2004. In several developing countries, a trend toward higher levels of dental caries has even been reported. Dental caries still affects between 60 and 90% of 12-year old children.

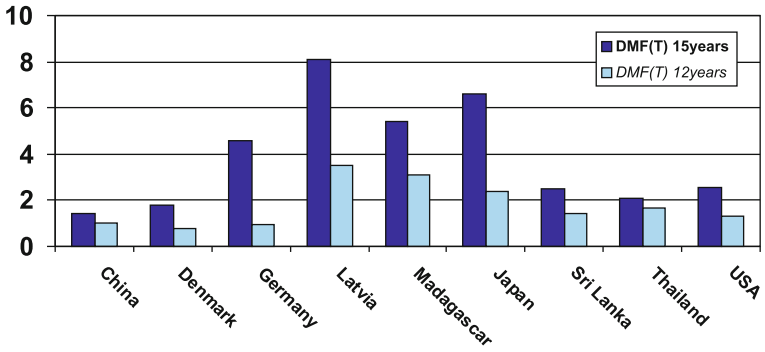
Periodontitis In the young population, the frequency of gingivitis is nearly 100%. The prevalence increases from primary dentition onwards, and reaches highest scores in puberty (Stamm 1986; Jenkins and Papapanou 2001). Periodontal diseases are very seldom identified in children; CPI-codes 3 and 4 are normally not found in this age group. However, chronic gingival inflammation could be a potential risk for periodontal diseases in later age.

Other Diseases Dental trauma occurs very often to toddlers. In the 0–6-year-old group, the prevalence of traumatic injuries varies from 12–30% (Flores et. al. 2002). In general, a child's activities bear an unavoidable risk of accidents.

Adolescents

The DMF(T) rates at the age of 15 are naturally higher than at the age of 12 in nearly every country worldwide. The decreasing prevalence of caries within children (5 years, 12 years) does not continue in adolescents (Fig. 1).

Periodontal Diseases Beside the high prevalence of gingival inflammation (nearly 100% with CPI-code 1 or 2), the first signs of elevated probing depths can



Oral Health in Different Age Groups, Figure 1
Mean DMFT-values of 12- and 15-year-olds in selected countries

already be recorded in young people. Although CPI-code 4 is only measured in a small portion of adolescents, the prevalence of code 3 is up to two thirds in this age group. Two percent of adolescents suffer from an aggressive periodontitis, which is also called "juvenile periodontitis". This severe type leads to a tremendously fast loss of the tooth supporting structure.

Other Diseases The different kinds of oral cancer and premalignant lesions have nearly no importance in adolescence.

Adults

Dental Caries A large majority of adults suffer from dental caries. The severity depends on many life circumstances and environmental factors and can be very different between individuals of the same population. Such factors include the socio-economic status and nutritional factors, as well as personal oral hygiene or even cultural traditions. In general, the increase in the prevalence of caries is lower than at younger ages. Complications of dental caries, kinds of pulpitis (inflammation of the dental pulp), and periodontitis are very common in adults with untreated caries lesions. Although caries lesions themselves seldom cause pain, the inflammatory complications can lead to very severe pain and sick leave.

Periodontal Diseases Mild forms of periodontal diseases affect nearly every adult person. Only with perfect personal oral hygiene may it be possible to diagnose a patient with no forms of gingivitis. Periodontitis – a chronic loss of tooth supporting tissues – is on one hand a reaction of an untreated gingivitis. On the other hand, there are individual dispositions that even make patients with perfect oral hygiene suffer from aggressive loss of periodontal attachment. Therefore, periodontitis is a multifactorial process depending, for example, on hygiene, plaque-retention, and professional periodontal treatment but also on genetic dispositions and environmental factors.
Periodontitis is mainly divided into an aggressive and a chronic form.

Other Diseases Dental trauma occurs not only at a young age. Sports injuries, traffic accidents, or other accidents may cause very serious damage to oral structures. The potential for regeneration of tissues, however, decreases during the aging process, so that regeneration becomes more difficult.

Elderly

Dental Caries Dental caries is a major public health problem at older age and is closely associated with social and behavioral factors. There is a tendency among elderly people with lower incomes to miss regular dental examinations and treatments and neglect regular ► oral hygiene. In addition to this, they frequently consume too much sugar and smoke, and therefore suffer more often from dental caries. The prevalence of coronal and ► root caries in older people is very high worldwide. In developed countries, the number of filled and decayed tooth (crown) surfaces ranges from 22 to 35, the filled and decayed root surfaces from 2.2 to 5.3.

Periodontal Diseases Because of discrepancies between aggressive and chronic types of periodontitis, the differences in prevalence and progression between adults and the older ages are not that big in comparison to dental caries. The prevalence of CPI-codes 3 and 4 in elderly people in Western Europe are 15–30% and 30–60%, respectively (Miyazaki et al. 1991).

Oral Health in Different Age Groups, Figure 5 Prevalence of edentulousness (%) in elderly people (65–74 years) in selected countries. (WHO Oral Health Database)

Other Diseases Not a disease itself, *tooth loss* and *edentulousness* is worth mentioning as a consequence of oral diseases. The main reasons are caries and periodontitis.

Edentulousness is mainly a problem in older people. However, there are big regional differences worldwide. The highest rate is found in Bosnia and Herzegovina (78% of all persons over 65 are edentulous) – the lowest rate in Gambia (6%) (WHO 2002). Besides chewing problems, there is a psychological component to tooth loss. Persons without teeth are regarded as old because in most cultures, white, good-looking teeth are a symbol of youth and health. The consequence is an objective and subjective treatment need, especially in developed countries, which also has big implications for health economics.

The different kinds of *oral cancer* are most common in older people. First time diagnoses of carcinoma are predominantly found in the above 60 age group. Oral cancer and premalignant lesions are associated with several risk factors such as high alcohol consumption, low education levels, and smoking.

Older men in France, for example, suffer from oral cancer significantly more often than those in other European regions, which may be due to more excessive consumption of wine and cigarettes (Menegoz et al. 2002). Women's rates are still lower. Consequently, the measures to minimize the risk of a malignant disease have to be started at younger ages. The prevalence of oral cancer has increased in several European countries such as Germany, Denmark, and Scotland, but also in New Zealand, Japan, and the United States (WHO). Treatment of oral cancers is not easy in most cases and often leads to an esthetically and functionally compromised outcome. The 5-year-survival-rates are below 50% (WHO 2003).

Oral health plans; Oral health programs

Definition

Oral health policies are oral health-related formal statements or courses of action that affect institutions, organizations, services, funding arrangements, groups and individuals. Oral health policy statements set overall guidelines and outline future directions.

Basic Characteristics

Oral health policies can take the form of explicit written documents, but they may also be implicit or unwritten (Schou 1995). In this sense, health policies refer to what health agencies actually do, although their decisions or actions may not be intended or even recognized as policy. Health policies include actions of both public and private organizations inside and outside the health system.

The terms policy, programs and strategy are sometimes used interchangeably. A strategy can be defined as to outline the content of policies more specifically (Fig. 1). Taking part in policy development is an important task for oral health facilitators. Practical considerations and steps have been described to guide those who are unfamiliar with this kind of work (Freire 2006).

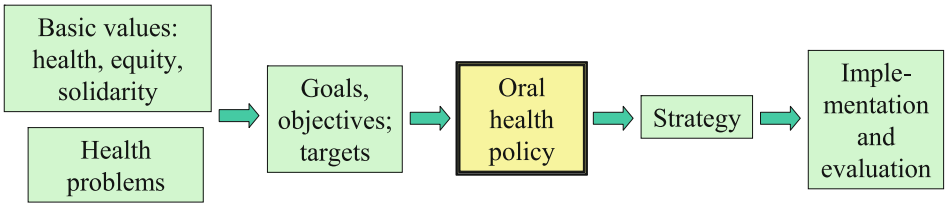
Values, Policy Fields and Objectives

The WHO (2005) has described that a basic policy value is equity, which means that everyone should have a fair opportunity to attain his or her full health potential. Closely linked is the value of solidarity: everyone contributes to the health system according to his or her ability. A health policy that promotes solidarity is better able to counterbalance social inequities.

Oral health policies can be applied to a wide range of issues, e. g. to training dental personnel or the planning of oral health education programs. A much contested policy field is the extent of coverage of dental services by public health care. In the United Kingdom, the availability of dental services is regarded a core element of the national health service (NHS). However, as a result of government decisions, some dentists became dissatisfied with NHS conditions and no longer offered NHS services, which caused access problems for patients. Dental care *de facto* became a private service in these areas, and the process was regarded as "rationing through the back door" (Ham 2004). The failure of subsequent governments to respond to this development is an example that public policy is not only what governments choose to do, but also what they choose *not* to do.

In the US, many oral health policies put improved access for disadvantaged populations high on the agenda. The polices refer e. g. to the access to fluoridated water, to enhancing public health infrastructure, and to integrating primary care providers into early life oral programs. Health boards in rural Australia recommend vocational training for dental graduates and the expanded use of therapists and hygienists. Policies in Cambodia refer to supporting dental materials and equipments, cooperating with other sectors, oral health service delivery, and quality standards. In the UK, oral health strategies on the regional level relate to a national oral health plan.

On the international level, global oral health objectives have been presented, one of which is to promote evidence-based policies. The targets relate to disease and disability indicators and have to be adapted by local authorities (Hobdell et al. 2003). For the European region, one target is that by the year 2020 at least 80% of children aged 6 years should be free of ► caries. The strategy is built around the twin goals of improving population health and reducing health inequalities.



Oral Health Policies, Figure 1

Policies for Tackling Health Inequalities

Disadvantaged people experience much higher levels of oral disease than well-off people. An example is ► noma (cancrum oris), which is a disfiguring and deadly gangrenous condition of the oral and facial tissues, particularly found in Sub-Saharan Africa (Bratthall et al. 2006). Poverty has been identified as the single most important risk indicator. Accordingly, improving the overall socio-economic conditions can prevent noma.

A number of specific innovative approaches to reduce health inequalities has been employed in various European countries, examples of which are active labor market policies for chronically ill citizens, preventive interventions at annual occupational check-ups, the serving of low-fat food products through catering in schools and workplaces and comprehensive health strategies for deprived areas (Mackenbach 2006). Concerning oral health, the widening of the gap between children with caries and the majority without caries has been described as "polarization". Community water fluoridation remains an ideal public health measure because it decreases the gap (USPHS 2005). Whether targeting high-risk populations is an effective strategy remains a matter of debate (Batchelor and Sheiham 2002). Screening programs fail to reduce inequalities in dental services use.

Content of Oral Health Policies

With regard to the content of oral health policies, the WHO proposes to address the following priority action areas:

- Fluorides
- Diet and nutrition
- Tobacco
- Health promoting schools
- Young people
- The elderly
- Oral health, general health and quality of life
- Oral health systems
- HIV/AIDS
- Oral health information systems
- Evidence for oral health policy
- Research for oral health.

One of WHO's practical policies is to support the widespread use and the promotion of affordable fluoridated toothpaste in developing countries. This is particularly important in the light of a changing diet.

In industrialized countries, a diet which is compatible with the maintenance of oral health means to substantially reduce the intake of sugars. Authoritative and non-commercial nutritional guides and guidelines are extremely valuable. Such recommendations should be integrated into the national agriculture, nutrition and health policies (Freire 2006). Not only educative strategies but also regulation, replacement and pricing strategies should be used.

Some countries have emphasized secondary rather than primary prevention. They will still be faced with high ► DMFT levels.

Health Policy: Process and Power

The process of health policy making refers to the way in which policies are initiated, formulated, negotiated, communicated, implemented and evaluated (Buse et al. 2005).

Trying to influence oral health policy requires maintaining a strong oral health unit within health agencies. Opportunities for funding may arise in conjunction with key policy developments currently taking place. Oral health policies should explicitly relate to policies in the health and social sectors. Partners have to be found among policy makers, professionals, organizations, groups and the public.

The framework for policy development has been described: to outline gathered information by means of a mapping exercise, to set an agenda, to draft the policy, to present the case to all interested parties, to set up a working group, to consult others, to finalize the

policy and eventually to implement and to monitor it. But policy making is seldom a linear, rational process. Frequently it resembles "muddling through". A reason is that policy making is the result of power struggles between competing groups of actors.

Interest groups try to influence public policy on particular issues at various stages of the policy process. Companies and for-profit-organizations are powerful interest groups. But also organizations registered as not-for-profit may not be independent. For instance, the International Life Sciences Institute (ILSI), which was established in 1978 with funding by soft drink manufacturers, gives the impression of a learned society, but the commercial interests of its Assembly of Members cannot be overlooked (James 2002). Similarly to ILSI-supported publications by dentists, the Center for Food and Nutrition Policy goes to great lengths in order to question the association between sugar and caries (Storey and Forshee 2004). As a counterbalance, a voluntary network of health professionals – Action and Information on Sugars – claims to confront disinformation about sugar and to provide clear information. This is an example of how health professionals who strive for health promotion can use their legitimacy and expert status powers to lobby for particular causes.

Policy as Option-Setting: Healthy Public Policy

A health-making policy deals effectively with the environments and ways of living. The concept of "healthy public policy" has been described as follows (Milio 1989): Personal behavior patterns are not simply "free" choices about "lifestyle", isolated from the social and economic context. Lifestyles are patterns of choices made from the alternatives that are available to people according to their socio-economic circumstances and to the ease with which they are able to choose certain ones over others.

Choice options available to the population and to social groups do not simply "happen". Rather they are themselves the result of policy choices: governmental and corporate decisions concerning technology, income maintenance, taxation, health care and other services. These policies represent the scope of health-making policy. Policy, from this perspective, is *option-setting*. A health-making strategy eliminates those options that result in health-damaging situations, or increases the cost of those options. It provides new, easier opportunities, or reduces the costs of these options. This approach emphasizes neither prohibition nor prescription, but rather new opportunities for choice-making. Individuals and organizations that want to continue to choose health-damaging options would be able to do so. However, they would pay higher costs than if they made health-promoting choices.

An impressive example for the strength of option-setting is the fluctuation of sales of fluoridated table salt in Switzerland. Originally, fluoride salt had been marketed successfully in economic 1kg packets, the price being slightly subsidized by the other types of salt. But in 1992 the producer changed the content of the 1kg packets from fluoridated to non-fluoridated salt. Immediately the market share of fluoride salt dropped. Dental researchers were alarmed and intervened. Subsequently, fluoride salt was sold again in 1kg packets and non-fluoridated salt in half-kilo packets only. The result of this deliberate pricing strategy was that the market share of the caries-preventive salt increased again and reached nearly 90%. This example from trade and industry shows that for a health-making policy several sectors should be linked conceptually within a concept of an ecological health framework.

Healthy public policy is extremely efficient. The caries decline in the industrialized countries was due to the public health measure of adding fluorides to various substrates. The largest proportion of the caries decline had occurred before practice-based professional prevention was introduced. This shows that oral health policy interventions have much more potential for effectiveness than individualized preventive measures (Strippel 2004).

In the developing countries, the promotion of health is intimately related to "big politics": a process of ending underdevelopment. In the developed world, progressive oral health workers could show that any struggle for social change policies and equity is also a struggle for health (Sanders 1985). These tasks can be supported by researchers who perform analysis-for-policy and analysis-of-policy.

Synonyms

Promotion of oral health

Definition

Oral health promotion is any combination of oral health education and legal, fiscal, economic, environmental, organizational and technical interventions designed to facilitate the achievement of oral health and the prevention of disease. Oral health promotion directs multi-sectoral actions to the determinants of health in order to ensure that the environment is conducive to health. A key concern is the achievement of equity in health. Methods are community involvement, multi-sectoral working, empowerment, advocacy and mediation.

Basic Characteristics

The consumption of sugars in processed food and drinks is the major cause of ► dental caries. Smoking and oral hygiene are the major influences related to periodontal health. Further factors are the optimal exposure to fluoride and the appropriate use of good-quality dental care. Excess alcohol consumption predisposes for oral cancer. Dental and facial trauma are influenced by traffic management and occupational safety. All of these factors are shaped by culture, economy and politics, which means that the fundamental determinants of oral health are socio-economic. Individuals have only a limited control over these determinants, but oral health promotion is a way to deal effectively with them (Sheiham and Watt 2003).

People with low income and migrants show a consistent pattern of high oral disease levels, compared to the majority populations (Chen 1995). Tackling such health inequalities has become a key policy objective. There is an argument that health inequalities can only be addressed through a significant redistribution of income, e. g. by tax and benefit reform. But programs

can also aim directly at oral health. For instance, school dental services are valuable in promoting equity of oral health outcomes.

Oral health education is a part of oral health promotion. But health education can only develop its full potential if it is supported by structural measures – legal, environmental, regulatory etc. Peoples' environment has to be changed in order to enable them to transform new knowledge into action. Nancy Milio (1981) formulated the core concept of health promotion: *Make the healthy choices easy choices*.

Multi-Sectoral Approach

Many sectors in society have a significant influence on health, for instance industry, commerce, agriculture, education and the health service. Oral health promotion uses techniques for multi-sectoral working and develops partnerships across agencies. Potential partners are not only doctors, pediatric nurses, pharmacists and midwives, but also teachers, parents, social workers, food producers, the advertising industry and local, national and international government (Daly et al. 2002).

► Advocacy is a means by which health professionals can influence the creation of policies supporting oral health. Community advocacy is a powerful tool because it fosters problem ownership and empowers people when they adopt advocacy roles.

Key Areas for Action

Sustainable improvements in oral health can be achieved through:

- Applying fluoride
- Reducing sugar intake to a maximum of 6–10% of food energy or four times daily (Moynihan and Petersen 2004)
- Improving nutrition in young children with regard to breast and bottle feeding
- Reducing smoking and alcohol consumption
- Using fissure sealants
- Reducing dental injuries: a safer environment should be established; seatbelts, child restraints, mouth protectors and helmets should be used
- Increasing early detection of mouth cancer.

Oral health should be improved by activities in all five areas delineated in the Ottawa Charter of Health Promotion.

Building Healthy Public Policy

The addition of fluoride to table salt and to salt used for the food production is an example of healthy public policy. A further example is offered by legislation which has banned smoking in the workplace and public areas including bars and restaurants. This acts to support those who aim to reduce or give up smoking (Schou and Locker 1998).

In the target group of young children, local initiatives would seek to set up oral health and nutrition policies and work with child carers to implement them. Practical steps in a nursery may start with establishing an alternative policy for the celebrating of birthdays to make the birthday child feel special and finish with a reappraisal of contracts for meal suppliers (Munday 1999).

Creating Supporting Environments

An example for the creation of political, legal, educational, social and economic environments which support health is the fluoridation of water supplies.

On the local level, supportive environments can be created in settings, for instance by implementing "sugar-free morning and afternoons" in schools. Further support can be provided by fluoridated school milk. Healthy options have been offered at tuck shops, and a healthy vending machines policy in schools, colleges and youth centers has been pursued. In areas of relative deprivation, families may receive fluoride toothpaste/brush kits on a continuing basis.

Companies can act on oral health of their employees by pursuing policies concerning healthy eating, smoking, alcohol, oral hygiene and attendance at dental services. They can buy toothbrushes and fluoride toothpaste in bulk and ensure that hygienic facilities are available for ► oral hygiene. Health education at work-sites and preventive and screening services have been shown to improve oral hygiene status and reduce the amount of work-time lost.

For older people or those who are handicapped, ► organizational change at care homes, day centers and day care facilities have been induced which lead to the establishment of healthy catering and to improved oral hygiene.

Strengthening Community Action

Experience shows that change is best achieved and sustained when the people it affects are involved in initi-

ating this change by social action (Nutbeam and Harris 2000). Essential elements of community development are the importance of participation and "starting where people are at" and the creation of critical consciousness among a community. Health professionals will take on the role of a facilitator. Liasing with stakeholders in the community is a method, as is instructing other professionals who access risk groups, e. g. maternal and child care nurses, meals on wheels managers or youth workers. A lack of preventive dental knowledge and skills in some migrant populations can be addressed by training oral health advocates from minority groups.

Developing Personal Skills

The plaque biofilm develops within days, which means that it has to be removed on a daily basis by effective oral self-care. Dentists and auxiliary personnel are well acquainted with teaching the necessary personal skills to their clients.

In the community, skills development can mean to train teachers and classroom assistants to encourage improved brushing and diet. By this, the oral health workforce is multiplied.

Reorienting Health Services

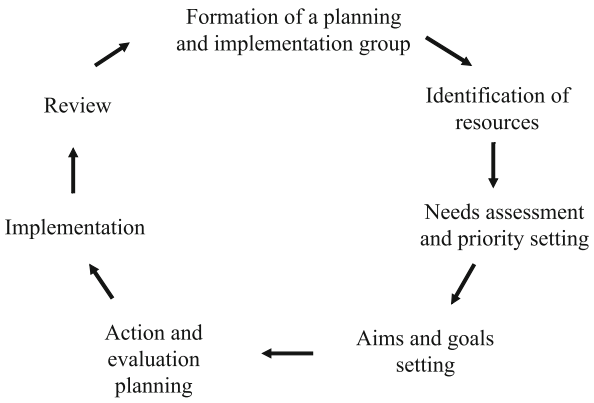
Reorienting health services means to shift resources from curative towards preventive services. There is a necessity to include health promotion in the dental curriculum and to train specialized oral health promotion personnel. Employing community dental nurses who facilitate change and visit people at home or in the workplace means to recognize fully that health is created where people live, work, study and play. Auxiliaries can apply fluoride varnish in risk-group settings.

Reorienting dental practice in a health promoting way means to encourage high-quality oral care. This will strengthen secondary and tertiary prevention. The access to dental sealants has to be improved, especially for high caries risk individuals.

Program Planning and Implementation

The development, implementation and evaluation of oral health promotion strategies can be divided into stages (Fig. 1).

Programmed planning starts with assessing the preconditions. Epidemiological, social, behavioral, educational and administrative diagnoses are performed. Predisposing factors (e. g. knowledge and perceptions), enabling factors (e. g. skills and barriers), and reinforcing factors (like rewards) are identified (Green and Kreuter 2004).



Oral Health Promotion, Figure 1 Oral health promotion strategic planning model (modified from Watt and Fuller 1998)

For assessing needs, both normative and lay measures are used. Normative need is interpreted as the quantity of dental health care which dental expert opinion judges necessary. Lay measures may simply consist of asking people for their priorities in oral health. Additionally, ► sociodental indicators can be used.

It is inspiring to create a matrix as a planning tool and to complete it with options for activities. The row headers relate to potential settings or target groups. The column headers relate to potential oral health promotion interventions: health education, community development, organizational change, legislation/regulation, fiscal/economic and service reorientation (Daly et al. 2002).

Health promotion identifies existing effective interventions and adapts them to the present situation. There is a call for evidence-based public health. But there is also a growing critique concerning the use of systematic reviews as the only research basis for health promotion (Asthana and Halliday 2006). It has to be taken into account that some interventions will work for certain groups, under certain conditions, and in certain context, but may not work in others. They are conditionally effective.

If political agreement and high scientific certainty support the planned intervention, the field is ready for the development of control mechanisms, such as guidance,

application of standards of practice, and performance management. Where agreement and certainty are low, there will be room for experimentation, local innovation and reflective learning of those who implement the programs.

Evaluation

Evaluation of health promotion is important as a means of developing effective interventions, for sharing and disseminating examples of good practice and for providing feedback to funding agencies, staff and participants. Outcome measures should measure change in inequalities. Samples, control and test groups have to be chosen properly. It is recommended to include information about the intervention design, the contextual circumstances in which the intervention was implemented, and information on how the intervention was received. Process evaluation is as important as outcome evaluation. Both qualitative methods (like focus group discussions) and quantitative methods should be used. This multi-method approach corresponds to the multidimensional nature of health itself – physical, mental, and spiritual.

Definition

Oral Health-related Quality of Life (OHRQoL) characterizes a person's perception of how oral health influences their overall well-being and ability to perform the activities of daily life.

Basic Characteristics

Importance of Oral Health

► Oral health is often a low priority for individuals, policy makers, and public health specialists. In fact, oral health is an important public health concern because ► oral diseases have a significant impact on society and individuals. They restrict, for example, activities in school, at work, and at home, causing millions of lost school and work hours worldwide each year. Oral health influences how people grow, enjoy life, look, speak, chew, taste food, and socialize, as well as their

feelings of social well-being (Locker 1997). A cross-sectional survey in London (UK) showed, for instance, that one in six 8-year-olds had experienced toothache that caused them to cry (Sheperd 1999).

Oral health is integral to general health. This interrelationship is proven by evidence. Severe ► periodontal disease, for example, can be influenced by diabetes or increases the risk of a cardiovascular disease. Furthermore, the role of bacteraemia as a sequela of oral disease and treatment is well known in the etiology of bacterial endocarditis. Oral lesions may also be the first signs of other life threatening diseases such as HIV/AIDS.

All things considered, oral health affects people's life physically *and* on a psychosocial level, can often diminish quality of life, and therefore means more than just having healthy teeth. In recognition of this, oral health has been more broadly defined as "the ability to chew and eat the full range of foods native to the diet, to speak clearly, to have a socially acceptable smile and dentofacial profile, to be comfortable and free from pain, and to have fresh breath" (Sheiham 1997). Hence, the impact of oral diseases can range between initial ► dental caries and effects on general health and quality of life.

Oral Health and Quality of Life

Quality of life (QoL) and not just survival has become a core issue in public health. QoL has been defined by the World Health Organization (WHO) as "an individual's perception of their position in life in the context of the culture and value systems in which they live and in relation to their goals, expectations, standards and concerns. It is a broad ranging concept incorporating in a complex way the person's physical health, psychological state, level of independence, social relationships, personal beliefs and their relationship to salient features of the environment" (WHO 1997). According to this definition, QoL is closely related to health aspects. It is a concept that brings together the multidimensional and widespread character of health status. A broader understanding of health was expressed in the WHO definition of health in 1946, which states "Health is a state of complete physical, mental and social well-being and not merely the absence of disease or infirmity". A patient based assessment of health status is, therefore, essential to the measurement of health. Involving the individual perspective (for instance the worries about and expectations of a new denture) can lead not only to greater patient satisfaction but also to a more effective use of the available resources. Hence, in recent decades, patients' awareness of health has become more important (patient centeredness).

Oral Health-Related Quality of Life

Health, one domain of well-being, includes OHRQoL as a subset of Health-Related Quality of Life (HRQoL). OHRQoL is based on *self-ratings* and comprises the patients' perceptions of their illnesses and the resulting limitations to their daily activities, and assesses the success of the therapy after treatment from the patients' point of view.

In the past, aspects concerning quality of life were an integral part of medical care and were not regarded as something independent. During treatment, the patients' subjective awareness regarding their health status has only been considered by rather broad inquiries about their current health state (e. g. How are you?). Studies have, however, revealed that objective diagnostic findings in dentistry often differ from the patients' subjective views (Heydecke et al. 2003a). Within the frame of health needs assessment as one part of ► health services research, a high objective need for dental treatment is often contrasted by considerably lower subjective need. Whereas restorations after tooth loss in the posterior region are required from most professionals' point of view, leaving untreated open spaces in the ► premolar and ► molar regions is often accepted by patients of different age groups even in countries with highly developed oral health care systems. Furthermore, discrepancies between diagnostic findings and patients' health status have been recognized. A comparison, for example, between HIV infected dental patients and general patients receiving public-funded care showed that, despite similar clinical indices, the occurrence of pain, functional limitations, and social disability was significantly more frequent in HIV infected patients (Coates 1996). This emphasizes that assessments of Oral Health Status should cover more than merely clinical-somatic components.

As a consequence, measuring OHRQoL as an indicator of patient's well-being and the quality of health care services has become accepted as an explicit criterion of evaluation. The rehabilitation of QoL can be regarded

as one of the main goals of medical interventions. Within the context of oral health, some authors consider the improvement of QHRQoL as the most important contribution of dentistry. OHRQoL is an essential component within the assessment of outcomes of oral health care, as it captures the outcomes of public health programs.
Additionally, because of increasing life expectancy, more health professionals have to identify therapies that preserve or even enhance the patient's quality of life effectively in order to keep the patient well and fit over a long period of their life (reduction of morbidity).

Measurement

When trying to quantify the consequences of disease, it has been recognized that objective measures of disease provide little insight into the impact of oral disorders on daily living and an individual's QoL. In studies that have assessed the association between objective measures of dental disease and patient based ratings of oral health status, objective measures did not accurately reflect patients' perceptions. They only reflect the endpoint of a specific disease process and give no indication of the impact of the disease and its course on function or psychosocial well-being.
A search for more appropriate concepts and indicators that integrate oral and general health and identify the multifactorial impacts on quality of life has therefore been started. Generic measures of health status are not useful, because they are not sensitive to all oral health problems (e. g. effects of tooth loss and edentulousness; see also Heydecke et al. 2003b).
As a consequence, a number of OHRQoL measures have been developed to assess the functional, psychological, social, and economic implications of oral health problems, recording the patient's own assessment of health by using questionnaires (Table 1).
Objective measures of dental disease (such as the presence of dental caries or periodontal attachment loss) and patient based measures are not conflicting but complement one another in collecting clinical findings and diagnostic data, in formulating the aim of the therapy, and in assessing the therapeutic success.
In general, patient-based measures of oral health status can be used for:

- Screening and monitoring for psychosocial problems in individual patient care
- Clinical trials
- Population surveys of perceived health problems
- Medical audit
- Cost-utility and cost-effectiveness analyses
- Outcome measures in health services or evaluation research.

The best-documented and most popular instrument for measuring OHRQoL is the Oral Health Impact Profile (OHIP; Slade, Spencer 1994). This questionnaire has been widely used in population based studies and clinical research and is available in different languages such as English, French, Spanish, German, and even Chinese. Forty-nine questions capture seven conceptually formulated dimensions: functional limitation, physical pain, psychological discomfort, physical disability, psychological disability, social disability, and handicap. A major advantage of this measure is that the statements were derived from a representative patient group, and were not conceived by dental research workers. Short versions of this instrument with 20 and 14 items have also been published.

Oral Health Status

► Oral Health Related Quality of Life

(Oral) Health System Performance

Synonyms

(Oral) health indicators

Definition

To permit international comparability of the efficiency and performance of health care systems, clearly defined and operational criteria are essential. The principal criterion for assessing the quality of a health care system's outcomes is the state of health of the population, which can be determined empirically from morbidity and mortality statistics. The most important indicators commonly used in dentistry and oral epidemiology are the DMFT value for the caries burden and the CPI for the population's periodontal status. Other aspects to be considered in a performance analysis are the fairness of distribution of health benefits among the various population strata and, increasingly, the extent of patient orientation and responsiveness. Comparative performance analyses of this kind can identify weak points in national health care systems. However, the methodological problems associated with such comprehensive performance analyses should not be underestimated.

Oral Hygiene

Definition

All methods suitable to keep up clean conditions in the oral cavity such as tooth, gum and tongue brushing, flossing, and denture cleaning. An appropriate oral hygiene is essential for oral health. Oral hygiene should be a daily routine. Certain measures as plaque and calculus removal and hygiene instructions can be delivered by dental professionals (dental hygienist, dentist).

Oral and Maxillofacial Surgery

Definition

Oral and maxillofacial surgery covers a wide spectrum of diseases, injuries, and defects in the head, neck, face, jaws, and the hard and soft tissues of the oral and maxillofacial region. Oral and maxillofacial surgery is at the bridge of dentistry and medicine, and can therefore be recognized as either a medical specialty or a dental specialty as it addresses problems like the extraction of wisdom teeth, misaligned jaws, tumors and cysts of the jaw and mouth, and dental implant surgery. Oral and maxillofacial surgeons are highly qualified and usually spend more aggregate time in training than other surgical specialties.

Organisation for Economic Co-Operation and Development

► OECD

Organizational Change

Synonyms

Organizational development

Definition

Organizational change is a health promotion approach that seeks to develop policies within local organizations such as kindergartens, schools, workplaces and hospitals in order to promote the health of clients and staff. The underlying concept is that health is "created" in the places where people live, work and play. Organizations are a promising setting for health promotion efforts, because their core activities, administrative structures, policies and regulations can facilitate health promotion. The aim of organizational change is to make changes in organizations that are conducive to better health. Organizational change involves activities like lobbying for support, negotiating with management, supporting policy development, developing skills and partnerships and making organizational plans. There are conceptual links to workplace health promotion. Examples for organizational change activities include the establishment of non-smoking areas or catering services with an offer of healthy food choices such as low-calorie or sugar free foods and drinks.

Original Inhabitants

► Autochthonous Population

Orphan Diseases

Definition

Orphan diseases are diseases, including those of genetic origin, that are life-threatening or chronically debilitating diseases which are of such low prevalence that special combined efforts are needed to address them. As a guide, low prevalence is taken as prevalence of less than 5 per 10 000 in the community. Orphan diseases are treated with ► orphan drugs.

Orphan Drug

Definition

Orphan drugs depicts a status of a drug that is granted by regulatory authorities for drugs (e. g. the Food and Drug Administration in US or the European Agency for the Evaluation of Medical Products – EMEA in Europe) to medications developed for rare diseases. Orphan drug status gives the drug's manufacturer a right to exclusively market the drug substance. This protection of orphan drugs encourages their development since there are few financial incentives for drug companies to develop therapies for diseases that affect few people.

Orthodox Medicine

► Western Medicine

Orthodox Medicine Treatment

► Conventional Treatment

Orthopedic Surgery

Definition

Orthopedic surgery is the branch of surgery that is broadly concerned with the skeletal system (bones).

Some orthopedic specialists maintain a general practice; others specialize in sub-specialties like joint replacements or disorders of the spine. Orthopedic surgery addresses acute and chronic disorders, and sports medicine is a rapidly growing area. The range of treatments is wide and includes traction, amputation, hand reconstruction, spinal fusion, and joint replacements.

Osteoporosis

Definition

Osteoporosis refers to the loss of bone mass and density. Osteoporosis increases the risk of fractures. Primary osteoporosis may be postmenopausal or age-related (senile). Osteoporosis may also be caused by genetic defects, metabolic disorders, cancer, medical treatment, inadequate nutrition and immobility.

OTC Drugs

► Over-the-Counter Drugs

Otolaryngology

Definition

Otolaryngology is both a medical and surgical specialty which is concerned with the diagnosis, management, and treatment of diseases and disorders of the ear, nose, throat, and related structures of the head and neck, which includes the sinuses, larynx (voice box), oral cavity, and upper pharynx (mouth and throat). Otolaryngology is commonly called ENT.

Ottawa Charter

ANDREAS FUCHS
Forschungsverbund Public Health Sachsen-Sachsen Anhalt e. V., Medizinische Fakultät, Technische Universität, Dresden, Germany
andreas.fuchs@mailbox.tu-dresden.de

Definition

The Ottawa Charter was developed in the eighties of the last century and depicts the main concepts and principles of health. It was adopted at the 1st International Conference on Health Promotion in Ottawa/Canada in 1986. The Charter, based originally on the policy statement ► health for all of the ► World Health Organization (WHO), encompassed numerous developments in ► health policy. It built on the progress made through the Declaration on Primary Health Care at Alma Ata, the World Health Organization's Targets for Health for All document and the recent debate at the World Health Assembly on intersect oral action for health The Ottawa Charter defines health promotion as a process enabling people to increase control over, and to improve, their health (WHO 1986).

Basic Characteristics

Development of the Ottawa Charter

After they were developed as a program for action to achieve the general goal "Health for All 2000" by the European regional office of the WHO, the core elements, aims and goals, as well as the principles of the Ottawa Charter on health promotion, were summarized in a discussion paper in 1984. The development of the Ottawa Charter was based on a resolution of the ► World Health Assembly in Geneva 1977. The Assembly aimed at enabling "health for all" in order to provide all citizens with the possibility of leading productive and socially rewarding lives. This overall goal was adopted as the general strategy "Health for All" in 1979 and it has so continued (Declaration "Health for All in the 21st Century", adopted 1998).

The Ottawa Charter is the key document and it describes both the basic fields of action (► health promotion fields of action) and basic strategies of health promotion. The Charter was translated into many languages and disseminated widely in the eighties. It is the basic program for governmental and non governmental ► health promotion actors. Important terms of health promotion are defined and characterized in the Charter and a resolution adopting the Charter was carried at the 1st International Conference on Health Promotion (WHO in collaboration with the Canadian Public Health Association) in Ottawa in November 1986 (Kaba-Schönstein 2003).

Content

The Ottawa Charter highlighted the three basic essential strategies for health promotion: advocacy for health (► advocate) to create the essential conditions for health in general; to ► enable all people to achieve their full health potential; and to ► mediate between the different interests in society in the pursuit of health.

Action areas in health promotion were also outlined and support the implementation of the three basic strategies of health promotion. The participants of the conference in Ottawa have committed to be active in the following five action areas in health promotion:

- To build healthy public policy.
- Create supportive environments for health.
- Strengthen community action.
- Develop personal skills (► life skills).
- Re-orient health services.

Further Development of the Charter

A differentiation of the above mentioned fields of action took place at the following successor global conferences on Health Promotion (WHO 1997):

- 2nd Global Conference on Health Promotion: Adelaide in 1988
- 3rd Global Conference on Health Promotion: Sundsvall in 1991
- 4th Global Conference on Health Promotion: Jakarta in 1997
- 5th Global Conference on Health Promotion: Mexico in 2000
- 6th Global Conference on Health Promotion: Bangkok in 2005.

The conference in Adelaide paid further attention to the detail of the Ottawa Charter. Confirming that health promotion demands a collaboration at all levels of society, people and primary health care, further fields of action were defined. Discussion was directed towards the health of women since it was perceived that this section of the population is characterized by few opportunities in health promotion due to poor access to resources and information. Moreover, further topics emphasized the need to eliminate hunger in the world and to make it possible for all people to have healthy nutrition. It was also decided that health risks had to be minimized, particularly those associated with the consumption of alcohol and tobacco products. In spite of the enormous economic importance of these products, all participants agreed that the influences of advertising of these products had to be decreased. The creation of health promoting living conditions and environment were identified as a further field requiring action.

The 3rd Conference on Health Promotion in Sundsvall in 1991 was a joint conference of the WHO and the Environmental Programme of the ► United Nations with the participation of developing countries and industrial nations. This Conference considered to a larger extent the interests of the developing countries since health promotion in the industrialized nations had been the main topic of discussion up to this point.

"New Players for a New Era: Leading Health Promotion into the 21st Century" was the title of the 4th International Conference on Health Promotion held in Jakarta in 1997. The experiences and results since the adoption of the Ottawa Charter in 1986 were reflected on. The 5th Health Assembly of the WHO adopted the 1st Resolution (on health promotion with the statements of the Ottawa Charter and the conference of Jakarta) (WHO 1997):

- Promoting social responsibility for health.
- Increasing community capacity and empowering the individual.
- Expanding and consolidating partnerships for health promotion.
- Increasing investment for health development.
- Securing an infrastructure for health promotion.

The 5th International Conference on Health Promotion with the title "Health Promotion: Bridging the Equity Gap" was held in Mexico City in 2000. The content of the conference was twofold; one part of the conference was addressed to the representatives of health ministries, the second part to the scientific community. The Conference adopted a declaration on health promotion which was signed not only by the invited representatives but also by the health ministries from 87 countries. Concerning this declaration, health ministries undertook to put programs for health promotion into national action.

The declaration of the conference in Mexico emphasized three key aspects in health promotion: improvement of ► health determinants, reduction of risk factors and consideration of all population groups and settings as well as at all levels of society. It was also stated that health promotion had not been implemented in all areas and needed further consistency. The Ottawa Charter was also discussed at the 6th International Confer-

ence on Health Promotion held in Bangkok 2006. The new "Bangkok Charter for Health Promotion in a Globalized World" is complementary to the Ottawa Charter but additionally considers new aspects arising from globalization and the new demands in public health. It identifies major challenges, actions and commitments needed to address the determinants of health by reaching out to people, groups and organizations that are critical to the achievement of health. Health promotion is mentioned as the core function of public health. Further important documents that mention the importance of public health in the new millennium like the ► Millennium Development Goals (abbreviation: MDG) were also compiled (UN 2000).

The Declaration states that to further advances in implementing strategies, all sectors and settings are necessarily involved and consideration should be given on how to:

- advocate for health based on human rights and solidarity;
- invest in sustainable policies, actions and infrastructure to address the determinants of health;
- build capacity for policy development, leadership, health promotion practice, knowledge transfer and research, and health literacy;
- regulate and legislate to ensure a high level of protection from harm and enable equal opportunity for health and well being for all people;
- partner and build alliances with public, private, non governmental and international organizations and civil society to create sustainable actions (► sustainability).

Synonyms

Epidemic investigation

Definition

"An outbreak can be defined as an increase in the number of cases for a given period and place, clearly in excess of normal expectancy" (Last 2001).

Basic Characteristics

A report of a suspected outbreak may be received in a variety of ways (active or passive ► surveillance systems, healthcare workers, patients, media, law enforcement, etc.). Outbreak investigation requires the col-

lection and processing of a great deal of information. This includes determining that an outbreak has in fact occurred and defining the extent of the ► population at risk, determining the ► mode of transmission and ► reservoirs, and characterizing the agent. The urgency of the outbreak investigation depends upon the severity of the disease, the rapidity of transmission, the number of affected persons, and the need to control further spread of the disease.

To satisfy all requirements, the ten basic steps commonly used in an outbreak investigation are the following (Gregg 2002):

- Determine the existence of the epidemic
- Confirm the diagnosis
- Define a case and count cases
- Orient the data in terms of time, place, and person
- Determine who is at risk of becoming ill
- Develop a hypothesis that explains the specific exposure that caused disease and test this hypothesis by appropriate statistical methods
- Compare the hypothesis with the established facts
- Plan a more systematic study
- Execute control and prevention measures
- Prepare a written report

These steps are listed in logical order, but they may be carried out simultaneously or in a different order in practice. It is important to highlight that control measures should be implemented as soon as a potential mode of transmission is known in order to prevent additional cases.

Determine the Existence of the Epidemic

Most outbreaks are recognized by clinicians, through regular analysis of surveillance data, or through calls from concerned citizens. One of the first tasks in an outbreak investigation is to evaluate the quality of information from various sources and to verify that a suspected outbreak is a real outbreak. Thus, it is necessary to compare the number of cases in the outbreak with the number of cases from a previous period (this can be a few weeks, months, or years). The major source of these data for a notifiable disease is health department surveillance records. An increased number of cases may be the result of pseudo epidemics that occur because of laboratory error, changes in case definition, diagnostic and reporting procedures, or increased interest in a certain disease.

Confirm the Diagnosis

It is important that the diagnosis be confirmed early in the investigation. Clinical findings (the symptoms and features of the illness) and laboratory results should be reviewed. Those investigating an epidemic must be aware of laboratory errors as the basis for an increase in diagnosed cases. Additionally, the investigator should visit several of the ill people to gather important information about their exposure before they became ill.

Define a Case and Count Cases

A case definition is needed to decide whether an individual should be classified as having the health condition of interest. The initial case definition may include simple and objective clinical criteria, laboratory findings, and information about the time and place of exposure. Later, this definition can be refined in order to exclude unrelated cases.

All cases can be classified as "► confirmed", "► probable", or "► possible cases" (CDC 2006). The process of case finding includes reviewing existing surveillance and laboratory data, surveying physicians' offices, and hospitals, and questioning known cases in order to identify other exposed cases. Identification and demographic information, and clinical and laboratory data, as well as information about exposure to different sources, (► source of infection) should be collected for every affected person.

Orient the Data in Terms of Time, Place, and Person

The organization of data in terms of time, place, and person is called descriptive epidemiology.

Time. Traditionally, the time course of an epidemic is shown by a graph, called an epidemic curve, in which the cases of a disease are plotted according to the time of onset of illness.

An epidemic curve gives information about the magnitude of the outbreak, its possible mode of transmission, and the time trend. If the ► incubation period of the disease is known, a probable time period of exposure can be estimated. The shape of the curve is determined by the pattern of the epidemic—whether it is a ► common source outbreak, ► person-to-person transmission (propagated outbreak), or both.

Place. Assessments of an outbreak by place often become more useful when a map is used. A spot map is usually used to plot location of cases' residence, their place of work, or the place where they may have been exposed.
Person. The characteristics of the ► host (age, sex, and race) and opportunities for exposure (occupation, use of medication, etc) are related to disease risk.

Determine Who is at Risk of Becoming Ill

The investigator should determine what populations are at risk for the disease and should look carefully to identify other affected cases not known at the time of the initial report.

Develop a Hypothesis that Explains the Specific Exposure that Caused Disease and Test this Hypothesis by Appropriate Statistical Methods

The next conceptual step in an investigation is formulating hypotheses about the source of the agent, mode of transmission, and the exposures that caused the disease. In practice, the investigator should begin to formulate the hypothesis at every stage of the investigation. Sometimes the evidence obtained from descriptive epidemiologic techniques obviously supports the hypothesis that formal testing is unnecessary. In other circumstances, when the cause is less clear, the ► analytic method should be used to quantify the relationship between various exposures and the disease.

Compare the Hypothesis with the Established Facts

When analytic epidemiological studies do not confirm hypotheses, they must be reconsidered. Sometimes, it is necessary to obtain more specific exposure histories or a more specific control group in order to test a more specific hypothesis.

Plan a More Systematic Study

When an outbreak occurs, whether it is routine or unusual, some questions may remain unanswered about that particular disease. Additionally, the investigator may perform studies that are more detailed in order to expand knowledge of the disease. Such studies can improve the sensitivity and specificity of case definition and improve the quality of numerators and denominators.

Execute Control and Prevention Measures

Control measures should be implemented as soon as possible when the investigator knows the mode of transmission and the source of an outbreak. Control measures should be aimed at the weak links in the chain of infection. In some cases, control measures should be aimed at the specific agent, source, or reservoir of the agent. In other situations, control measures might be directed at interrupting transmission or exposure.

Prepare a Written Report

The final task in an investigation is to prepare a written report to document the investigation with the usual scientific format (background, methods, results, discussion, conclusion, and recommendations).

Outbreak Management and Surveillance of Infectious Diseases

MONIKA KORN
Friedrich-Ebert-Krankenhaus GmbH,
Neumünster, Germany
hkorn80663@aol.com

Synonyms

Registration of infectious diseases; Evaluation of infectiological data; Surveillance of transmissible diseases; Measures in case of outbreak of communicable diseases

Definition

Surveillance of infectious diseases involves the registration and evaluation of data collected on infections as well as the transmission of the results to regional, national and international institutions that are responsible for preventing and combating these diseases. Outbreak management subsumes all measures that are instituted to control an infectious disease and prevent its spread.

Basic Characteristics

Basics of the Surveillance of Infectious Diseases

Surveillance of infectious diseases involves the registration and evaluation of data with the aim of using the results to prevent and control any transmission of infection. To judge the extent of the spread of an infectious disease, mathematical epidemiological models can be utilized. The rate of spread of an infectious disease is characterized by its ► basic reproduction rate (R_o). Various factors have to be considered when utilizing this formula: the registration of the vaccination status, suspicion of an infectious disease, a manifest infection or death. Another significant factor may be the source of infection. This factor plays an important role in infections that are transmitted fecal-orally (► fecal-orally transmitted diseases) with food or ► drinking water. If data concerning infectious diseases are registered by public institutions, the time and the economic costs involved in gathering the information have to be reasonable and justified by their usefulness. Surveillance of infectious diseases can be performed on regional, national or international levels. In industrial countries there are legal rules concerning the announcement of infectious diseases and the specific procedures to be followed. The occurrence of certain infectious disease has to be notified to the responsible health institution (for example, the local public health department) which then takes the necessary measures or procedures for the detection of the source and the mode of transmission of the infectious disease and for giving hygienic advice. To achieve a maximum surveillance, a complete registration of all the notifiable infectious diseases is necessary. Modern documentation and communication techniques considerably facilitate this data interchange. However, in developing countries, the fight against infectious diseases is impaired by a lack of financial resources and skilled staff, by a weak health care systems and an absence of support from local authorities and governments. The World Health Organization is the global coordinating authority for the surveillance of communicable diseases. World Health reports provide extensive data and statistical evaluations about infectious diseases (http://www.who.ch). Other national and international institutions of surveillance exist, for example, the European Center for Disease Prevention and Control (ECDC, Stockholm, Sweden), the Centers for Disease Control (CDC, Atlanta, USA), the Communicable Disease Control Section (Public Health Branch, SDCS, Melbourne Victoria, Australia), the National Institute of Infectious Diseases (NIID, Tokyo, Japan) or the Robert-Koch-Institute (RKI, Berlin, Germany).

Surveillance on Regional and National Level

In general, regional health authorities are the first level of surveillance where the registration of infectious diseases data is centered. It depends on the specific infectious disease whether or not further procedures have to be undertaken. Some tasks may remain a regional responsibility, like the supervision of communal services with regard to infectious diseases, the detection of the source of food-borne infection, or the training of hygiene inspectors. The surveillance of ► endemic infectious diseases can be carried out on a regional or national level.

Education plays an important role in the prevention of infectious diseases. A basic knowledge and the availability of basic social and medical services are indispensable to implementing the recommendations and rules of hygiene within a population. Improvement in children's health in the developing countries is only possible through the education of the female population, particularly mothers. The social position of females in these countries needs to be strengthened and improved. Active vaccinations (► vaccination, active) are one of the piers in the prevention of infectious diseases. In industrial nations, immunization programs are carried out by family doctors or pediatricians.

Some countries control vaccination status by refusing to enroll children into kindergarten or elementary school without evidence that they have been vaccinated. In order to reach as many children as possible in developing countries, national immunization days (NIDs) are organized; announcements by radio or megaphone draw people's attention to these events; immunization teams travel around and even reach outlying villages.

Surveillance at International Level

After cardiovascular diseases, infectious diseases rank as the second cause of death worldwide. Due to the significance of infectious diseases, worldwide migration and the general increasing mobility of people, data interchange and international cooperation are important. Under the leadership of WHO, international health regulations have been developed, the latest version being made in May 2005. Various topics regarding infectious diseases cause worldwide interest, for example, the spread of /► AIDS and the problems concerning ► tuberculosis, with the development of multiresistant germs making consistent treatment difficult. The latter was the reason for the introduction of ► DOTS-strategy. As for AIDS and tuberculosis, successful therapy is difficult due to a lack of the availability of effective drugs or financial capacities. Because of an extensive use of antibiotics the development of resistances has become a global concern. For this reason, there is an international data interchange that specifically includes ► nosocomial infections. Efforts to make antibiotics only available on prescription could help to minimize this uncritical use. Another topic of interest is influenza surveillance (► WHO influenza surveillance program) and the development of vaccines. As there is a discrepancy between the immunization status of industrial and developing countries, ► GAVI, Global Alliance for Vaccines and Immunization was instituted to try to close this gap. In the fight against ► malaria, in 1998, Unicef, WHO, United Nations Development Program (UNDP) and the World Bank Group started the campaign Roll Back Malaria. This campaign aims to improve health services by the distribution of mosquito nets. Other internationally organized surveillance programs of infectious diseases include WHO Surveillance Programme for Control of Foodborne Infections and Intoxications in Europe and the Partners for Parasite Control (PPC, http://www.who.int/wormcontrol/en/). Various organizations and institutions engage in the surveillance of HIV-infections and AIDS. Among others are: UNAIDS, the Joint United Nations Programme on HIV/AIDS (http://www.unaids.org/en/HIV_data/default.asp), EuroHIV (http://www.eurohiv.org/) and the CDC'S HIV/AIDS surveillance system in America (http://www.cdc.gov/hiv/topics/surveillance/index.htm).

Eradication of Pathogens

To be able to control a disease various factors have to be known and understood. In infectious diseases the pathogens, their contagiousness, their incubation periods, their effects, their modes of transmission as well as the prophylactic and therapeutic possibilities have to be ascertained. The more a germ is spread, and the more it is resistant against environmental influences, the less is the chance of eradication. However, if humans are the only reservoir of a pathogen, an eradication of the disease is possible; this can be assumed for ► measles and ► polio. ► Smallpox, was declared eradicated in 1980, and poliomyelitis seems to be within our grasp as, to date, North and South America, South Africa, Europe and East Asia are declared to be free of polio, complying with the requirements that no cases of polio have been registered for at least 3 years. However, polio still occurs in India, Nigeria, Pakistan and Afghanistan. Vaccination campaigns are made difficult by social and political instability. If poliomyelitis was eradicated, 1.5 billion dollars could be saved worldwide every year – money, which still has to be spent on vaccination campaigns, therapy, rehabilitation and surveillance systems. Unfortunately, measles eradication has not even been achieved in the industrial nations yet, not least of all due to an increase of what has been termed vaccination fatigue. Currently, measles, a preventable infectious disease, causes the most deaths worldwide.

Outbreak Management at Regional Level

To prevent the spread of an infectious disease, an early diagnosis, which is confirmed quickly, is essential. In industrial nations, the responsible health institution (for example, the public health department) is informed about any case of an infectious disease that is legally notifiable. The health authority then institutes the necessary measures and procedures; it is responsible for the detection of the source of infection and providing

advice on appropriate hygienic methods to be undertaken. The closure of schools or other public institutions is only reasonable when diseases are transmitted by droplets, fecal-orally or by contact with blood. There might be restrictions concerning jobs dealing with teaching, training, nursing or supervising people. Furthermore, outbreaks of infectious diseases may have consequences for employees in the food industry; they may not be allowed to work with open foodstuff. These restrictions especially concern ► permanent shedders of fecal-orally transmitted infectious diseases. Isolation of infected people may be necessary and their contacts may require special monitoring. In infections with meningococci, close contacts should receive a prophylactic antibiotic therapy. After exposure to particular pathogens, active or passive vaccination (► immunization, active; ► immunization, passive) may be necessary to prevent outbreaks, for example, possible infection with ► tetanus, ► rabies or ► hepatitis B.

Management of Catastrophe

► Epidemics or even ► pandemics present not only medical difficulties, but also organizational and ethical problems. If effective preventive or therapeutic measures are to be possible then the question of sufficient resources arises. Supplies can fail due to production related, logistical or financial problems.

Whenever resources are restricted, decisions have to be made about how they should be distributed. In 1994, a declaration was published by the World Medical Association (WMA) concerning the medical ethics of catastrophe (http://www.wma.net/e/policy/d7.htm). The first aim in such a state of emergency should be the reduction of morbidity and mortality of the whole population. As the maintenance of the health care system is very important, and as medical staff faces a high risk of infection, a decision has to be made about whether or not the involved professionals should be given preferential prophylactic therapy when stocks are scarce. Another important consideration is the effects of public policy and security on individual rights. Those facing the highest risk of infection, according to current medical knowledge, deserve compassionate care but in a catastrophic situation, when the rest of the population may be at risk, they may suffer a restriction of their personal rights – maybe due to quarantine (► quarantine diseases) measures – that cannot be avoided. The recommendation of the Council of Ethics and Judical Affairs of the American Medical Association can help to weigh up public and individual interests (http://www.ama-assn.org/ama1/pub/upload/mm/31/quarantine15726.pdf).

It is very important to inform people about the necessary measures involved in a pandemic prior to its outbreak. The reasoning behind the pandemic plan, in which there may be a distribution of resources to particular groups and possible restrictions on individual freedom, has to be understood, otherwise, the emergency plan could be put in jeopardy.

In conclusion, the process of surveillance holds a significant position in the fight against infectious diseases. A sufficient health service, extensive preventive measures, a precise registration and evaluation of infection data and an active data interchange – maybe even on international levels – are the basic conditions for dealing with infectious diseases successfully. An exact and fixed procedure is essential to achieve a quick barrier to the spread of infectious diseases. In epidemics or even pandemics professional outbreak management is indispensable, even if the acceptance of individual restriction is inevitable.

Outcome Evaluation

► Summative Evaluation

Outcome (Health Economics)

Synonyms

Benefits; Consequences

Definition

In ► health economics, the term outcome describes the results and the general benefit of the use of a health care technology as a defined measure. As outcome measures adequate medical parameters such as blood pressure reduction or improvement of a symptom score, epidemiologic parameters such as events avoided or life years gained, or utilities such as ► quality-adjusted life years can be chosen. The type of outcome measure defines the type of ► health economic evaluation. The choice of the outcome measure in health economic evaluation studies can strongly influence the result.

Cross-References

► Event
► Outcome Research Variable

Outcome Intervention Effect

Synonyms

Effectiveness

Definition

Effectiveness is the extent to which an intervention produces favorable outcomes under usual or everyday conditions. Using different terminology, effectiveness studies must have a high degree of external validity. The end-points of clinical trials and effectiveness studies tend to differ. Usually, clinical trials are focused on end-points such as mortality and clinical symptoms. Effectiveness studies often include these end-points but there is now movement towards including outcome measures that are more meaningful to patients.

Outcome Measure

Definition

Measure which assesses relevant endpoints of any intervention.

Outcome Research Variable

Synonyms

Resulting variable; Result; Outcome; Dependent variable

Definition

Each measurement or observation relevant to the researched phenomenon and which is noted with the experimental unit. All possible results that can be derived from exposure to the trigger (causative) factor.

The result of the experiment or another situation that implies uncertainty.

Outliers

Definition

An outlier is an unusually small or unusually large ► data value. For every such value an assessment should be as to why it has occurred, e. g. ► measurement error, data error, data from another population, or a value that represent an abnormality of some unit of observation and which lies in the tail of assumed theoretical ► probability distribution. A value indicates a possible outlier if it is 2.5 ► standard deviations from the mean. The most common reason for outliers is data error, and when such outliers are identified they must be corrected. If correction of erroneous data is not possible, outliers must be removed from the analysis. Deciding to eliminate an outlier from analysis must be done carefully because retaining a wrong value may be misleading while removing a correct value may produce an underestimated measure of variability. It may be useful to perform the statistical analyses twice, the first time with all the data and the second time without the outliers, and then estimate the impact the outliers had on the results and statistical inferences.

Outline of Dental Public Health

MICHAEL WALTER
Dental School, Department of Prosthetic Dentistry, University Hospital, University of Technology, Dresden, Germany
michael.walter@uniklinikum-dresden.de

Synonyms

Public health dentistry; Community dentistry

Definition

Dental public health is an interdisciplinary field of research, work and activity with special focus on ► oral health and oral and dental diseases. The paradigms of public health apply likewise. Basically, dental public health aims at sustaining the oral health of the population by using structured community based measures for oral health promotion and organized efforts of society.

Basic Characteristics

In the United Kingdom and North America, dental public health has a long tradition. Many universities offer postgraduate programs in dental public health. In other countries including many European, however, this field is still evolving, its potential being not yet fully utilized. Still, many dental professionals have difficulties in understanding and implementing the public health paradigm. It can be best described by a population-based view on oral health and ► oral diseases. This perspective can considerably contribute to a better and broader understanding of oral diseases and oral health promotion. The significance of oral and dental diseases as common chronic diseases with extremely high prevalence rates in the population is apparent and underlines their relevance for public health. Like public health in general, dental public health has shifted from old public health to new public health. The scope of "old" public health covers prevention, oral health in high risk groups (e. g. deprived children, institutionalized elderly or migrants), sociology, psychology, environmental health, and epidemiology. "New" public health additionally focuses on health policy, health system research, economics, political and management sciences and thereby even more acknowledges the significance of interactions between oral health and basic conditions and society related parameters.

► Caries and ► periodontitis are among the most common diseases. The sequelae of these diseases with tooth loss on top affect all health dimensions. Still, tooth loss has very high incidence rates in adults. In many industrial countries the prevalence of edentulism is over 25% in people over 65 years of age. To a relatively high extent, caries and periodontitis are preventable diseases. They are associated with ► bacterial plaque and sugar consumption. Caries is a sugar dependent infectious disease. On the average, more than half of the teeth can be decayed, filled or missing in a middle aged adult. Periodontitis is an infectious disease leading to inflammation of the ► periodontium, the formation of gingival pockets and bone loss. In adults aged 40 years and older, periodontitis is responsible for more tooth loss than caries.

An array of measures at individual, professional and community levels is available for the prevention of oral diseases. Measures at the individual level are regular ► oral hygiene, fluoride applications, healthy food choices and smoking cessation. Services delivered by dentists or auxiliaries include professional oral hygiene procedures, topical fluoride applications and ► fissure sealing. Caries prevention for groups can be offered in schools or kindergartens and encompasses healthy food choices, the use of fluoridated salt, and oral health education. Community level measures are water fluoridation, campaigns for healthy food choices and actions suitable to reduce common risk factors.

Dental diseases can be successfully treated. In many cases restorative procedures are part of the treatment. However, most ► dental restorations have a more or less limited lifespan. Most important are the successful management of the underlying disease and the compliance of the affected patient. Defects due to caries are commonly treated by removing the affected tooth structure and depending on their size by fillings or crowns. In advanced cases, a root canal treatment becomes necessary. Periodontitis is most commonly treated by cleaning the root surfaces for infection control. Tooth loss is compensated for by different prosthetic means like ► bridges, removable prostheses or ► dental implants.

The World Health Organization's definition of health encompasses a state of complete physical, mental and social well being that enables a person to lead a socially and economically productive life and not merely the absence of disease or infirmity. Transferring this definition to oral health means a high oral health related quality of life in the absence of oral diseases. The importance of sound good looking teeth and fresh breath for a person's well being is apparent. Considering oral health a multi-dimensional construct increasingly becomes a widely accepted perspective. Oral health related quality of life has physical, psychological and social dimensions. We know from many studies that there is a significant discrepancy between subjective perception and objective views (as seen by dental professionals) on oral diseases and treatment need. Moreover, there is a great diversity of views among patients. A good example for this is the loss of ► molars (back teeth). Whereas some people might feel uncomfortable with a situation without back teeth others might hardly feel any discomfort. Most professionals, however, recommend molar replacement.

There has been a considerable ► caries decline in most industrial countries in the last decades. This decline has been found predominantly in children and adolescents. The foundation of this improvement of oral health is not quite clear and multi-causal. The situation in the adult population is much less straightforward. There is some concern that the effect of prevention in children and youth can be equally transferred to higher age groups. Periodontitis is not declining in a similar way. Still, the prevalence rates are high or even increasing. Oral health and the epidemiology of oral diseases are strongly affected by demographic changes. Most analysts expect a shift of tooth loss towards higher age groups. Because of the increase in life expectancy, dental treatment need will most probably not decrease as expected by many health politicians. Most experts are of the opinion that treatment need might be even higher because of a high number of remaining old teeth in high age groups. Treatment cases might become more complex and affected by non-carious lesions and tooth wear that occur in old age even after lifelong absence of dental caries and periodontitis. Reacting to both epidemiological and demographic changes will be the main challenge of public health dentistry in the future.

Risk factors for oral diseases are unhealthy diet with high sugar consumption, poor oral hygiene and smoking. In addition, low social status and low income have been shown to be associated with an increased risk. Many common risk factors like smoking have a high significance. The ► common risk/health factor approach aims at reducing risk and promoting health factors, no longer focusing on single diseases but rather aiming at an improvement of health conditions for the whole population. Common risk factors are unhealthy diet, obesity, stress, lack of exercise and smoking. They affect the incidence of heart disease, cancer and oral diseases. Smoking has a significant influence on the onset and progression of periodontitis and also on the success of dental implants. Associations between cardiovascular diseases, diabetes and periodontitis are assumed.

In many surveys and studies, caries, periodontitis and tooth loss had a significant association with a person's social status. Looking at caries for example in children and adolescents shows that there is a considerable polarization of the disease. A high portion of dental caries occurs in a relatively small group of socially deprived people. Caries in deprived portions of a pop-

ulation in children and adolescents might be accompanied by high prevalence rates of early onset type II diabetes, obesity and malnutrition. Seen from this angle, only an interdisciplinary approach under consideration of society related public health principles can be appropriate. Mere patient centered prevention in the dental office will not be effective.

Depending on national characteristics, dental services are delivered by private dentists, policlinics or non-academic professionals as ► dental hygienists or ► denturists.

Health system and reimbursement policies have a considerable impact on the access to dental services, treatment modalities, and social disparities. Dental services demand a considerable portion of health expenses. Therefore, oral health policies are often in the focus of public interest. Among the different parties concerned with health services there are frequent controversies about the most feasible allocation of the available resources. For political reasons changes are very often implemented hurriedly and without any appropriate scientific background. Rules of national insurance plans strongly affect treatment modalities especially in those countries in which the reimbursements for dental services are high. Changing those rules can lead to under-, over- or false treatment at the population level. In many ways a health service system resembles a black box in which the impact of change is hardly predictable. ► Health services research can deliver data that improve our knowledge in this field.

A core competency of dental public health is health promotion. The respective WHO goals include reducing the disease burden and disability, especially in poor and marginalized populations, promoting healthy lifestyles and reducing risk factors that arise from environmental, economic, social and behavioral causes and developing oral health systems that equitably improve oral health outcomes, respond to people's legitimate demands, and are financially fair.

Outpatient Care

GERNOT LENZ
Forschungsverbund Public Health Sachsen-Sachsen Anhalt e. V., Medizinische Fakultät, Technische Universität, Dresden, Germany
gernot.lenz@gmx.de

Synonyms

Ambulatory care

Definition

Outpatient care services are the health care services that are provided to patients who are not hospitalized for an overnight stay. The outpatient care services are delivered in different settings like a physician or therapist's office, a clinic, or a day surgery center. Outpatient care covers diagnosis, observation, treatment, and rehabilitation. It is usually provided to persons that are able to ambulate or walk about.

Basic Characteristics

Providers of Outpatient Care

The expenditures for outpatient care in the Organisation for Economic Co-operation and Development (OECD) countries average at 33%, ranging from 21% in the Slovakia Republic to 51% in Denmark. The USA also has a very high share of outpatient care expenditures, with 47% of the total health care expenditures. Outpatient care is provided in different settings and in different proportions depending on the health

care system and infrastructure in the respective country. Medical practitioners and therapists with private practices are the key providers of outpatient care. Other providers of outpatient care are ambulatory departments within hospitals as well as day surgery centers, where patients can go for minor surgical interventions allowing them to return to their homes the same day. The outpatient care in private practices is offered by personal ► primary care physicians (specialized in ► internal medicine, ► family medicine, and ► pediatrics), subspecialty physicians (gastroenterologists or cardiologists), and non-physicians (e. g. nurse practitioners, physical therapists). The practices are either single practices or collaborations in clinics or group practices, which can consist of physicians of similar or different medical specializations. The primary care physician, often a ► general practitioner, plays a vital role in many countries' outpatient care settings. The primary care physician is the first point of contact of the patient with the health care system and offers services for acute and chronic diseases as well as preventive medicine. She or he coordinates the patient's journey through the health care system by acting as gatekeeper when it comes to referring the patient to outpatient medical specialist practices, clinics, or hospitals.

The Physician-Patient Relationship

The relationship between the physician and the patient is of high importance, which is particularly the case for the primary care physician. The relationship should be understood as an interaction where each party influences the other, as well as the process of consultation. The consultation can also be described as a negotiation process, where the patient is the expert on his or her own health and life and the physician is the expert on medical conditions and possible treatment paths. There are an increasing number of physicians shifting from a disease-centered practice towards a more patient-centered one that integrates biomedical knowledge of disease with personal knowledge of the patient's illness experience in the context of the patient's and physician's environment.

Integrated Care

The gatekeeper model described above is one element of a more integrated care approach. Integrative approaches like ► managed care will be further enforced in the mid-term future, primarily driven by cost constraints but also quality of care objectives. A more integrated model aims at better coordination of all the elements of a health care system, be it inpatient care, outpatient care, long-term care, rehabilitation, or prevention. Barriers between the different sectors will be dissolved by better aligning the outpatient and inpatient services to avoid double-work, and shifting more services to the outpatient sector. The increasing prevalence of chronic diseases will be addressed by integrated disease management programs, which are systems of coordinated health care interventions and communications for people with conditions that require significant self-monitoring. Disease management programs include collaborative practice models, evidence-based practice guidelines, patient self-management education, process and outcome measurement, and routine reporting.

Conclusion

As it is expected that health care costs will absorb larger and larger parts of national economies worldwide, there will be ongoing cost pressure on the different sectors of care. Primary care-led health care systems have proven to be cheaper than systems with direct access to outpatient medical specialists and hospitals. It is therefore a realistic scenario that additional countries will refine their outpatient care delivery towards a more primary care based approach. It can be assumed that this transition towards primary care models will go along with the evolution towards more integrated health care delivery models that can also address the challenge of a rising share of chronic diseases more efficiently and effectively.

Overnutrition

Synonyms

Supernutrition

Definition

Excessive food consumption over a long period of time leads to an increased energy intake (► nutrition).

Over-the-Counter Drugs

Synonyms

OTC drugs; ► Non-Prescription Drugs

Definition

Over-the-counter (OTC) drugs are preparations that may be sold to consumers without a physician's prescription. Unlike their name would suggest, in many cases these items are openly placed on the shelves of stores and can be bought like any other packaged product. Prescription drugs are only available at the pharmacy counter. The most common over-the-counter medication are supposed to treat aches and pains, allergies, cold and influenza symptoms. They also often address coughs and sore throats, constipation and diarrhea. OTC drugs aim at treating a condition where a direct supervision by a doctor is not required and it needs to be proved that the OTC drugs are reasonably safe, well-tolerated and have little or no abuse potential. In cases where prescription drugs, over time, prove to be safe and appropriate for self-medication they might then be switched to OTC.

Ozone Depletion

Synonyms

Ozone holes

Definition

Ozone depletion is the process of decline of the total amount of ozone in the Earth's stratosphere during the past few decades, especially over Polar Regions (the ozone holes). The cause of this trend is catalytic destruction of ozone by atomic chlorine and bromine, originating from chlorofluorocarbon (CFC) compounds, called freons, and bromofluorocarbon compounds, known as halons. Depletion of the ozone layer leads to an increase in ultraviolet light passing through the Earth's atmosphere, which is known to induce skin cancer, damage to plants, and reduction of plankton populations in the ocean's photic zone. The Montreal Protocol, adopted in 1987, bans the production of CFCs, halons, and other ozone-depleting chemicals such as carbon tetrachloride and trichloroethane.

Paediatric Palliative Care

Synonyms

Palliative care in children; Hospice care in children

Definition

As the spectrum of malignancies is dissimilar between adults and children, the palliative treatment of adults and children differs. In children, leukemia, cerebral tumors and sarcomas predominate, whereas carcinomas are seldom observed. The response to chemotherapy in childhood cancer is fast and effective. However, because of the stage of cognitive development, the reaction in children to palliative measures, such as pain treatment, is often difficult to manage. This had led to the creation of authorative guidelines for systemic pain pharmacotherapy in combination with an interdisciplinary team approach in pediatric palliative care.

Paedophilia (or Pedophilia)

► Paedo-Sexual Behavior

Paedo-Sexual Behavior

Synonyms

Paedophilia (or pedophilia); paedo-sexuality

Definition

Paedo-sexual behavior is the more appropriate term for the commonly used term paedophilia (or pedophilia) which literally means "being fond of children". Paedo-sexuality refers to the notion of being sexually attracted primarily or exclusively to children and adolescents, potentially leading to child sexual abuse with its profound harmful effects for the child. According to international conventions, a person below the age of 18 years is considered a child and the various forms of sexual exploitation of underage girls and boys constitute violations of human rights.

Pain

Definition

The International Association for the Study of Pain defines pain as an unpleasant sensory and emotional experience associated with actual or potential tissue damage, or described in terms of such damage. The intensity of pain may range from slight to agonizing and there are different specifications for pain like sharp, throbbing, dull, nauseating, burning, and shooting. Pain has, in most cases, both an emotional quality and a sensed bodily location, which is the basis for the determination of the pain receptor. Pain can be acute or chronic, and the most common types of pain are somatic pain (originating from ligaments, tendons, bones, blood vessels, and nerves), visceral pain (orig-

ination from the body's viscera or organs), and neuropathic pain (resulting from injury or disease to the nerve tissue).

gernot.lenz@gmx.de

Synonyms

Terminal care; Hospice care

Definition

Palliative care is an approach or a philosophy of care that emphasizes the quality of life of patients and their families. Palliative care addresses the problems associated with life-threatening illness through the prevention and relief of suffering by early identification, assessment, and treatment of ► pain and other physical, psychosocial, and spiritual problems. Although palliative care has been predominantly connected with cancer patients, it is now increasingly used in conjunction with other diseases like chronic heart failure or progressive neurological conditions. Furthermore, there is a growing field of pediatric palliative care services driven by the fact that more than 11 million children under the age of 5 die worldwide each year. Palliative care should be offered by a multidisciplinary team, often with the primary health care team in the lead and supported by specialist practitioners and specific palliative care units or hospices.

Basic Characteristics

Background

It can be observed that life expectancy is increasing in at least most of the developed countries, with more and more people living beyond 65 years of age. As a consequence of this population ageing, there is a shift in the patterns of diseases people suffer and die from. Increasingly, people nowadays die at older ages after suffering from serious chronic conditions, which often cause physical, psychological, and social problems. In the past 20 years, there has been a significant shift towards stronger focusing on the patient's quality of life. Today, in the United States, 55% of the hospitals with over 100 beds offer a palliative care program –

amongst the ► community hospitals there is still one fifth having a palliative care program. Palliative care is no longer restricted to hospice care; however, that is where palliative care actually began. The first ► hospices for the dying were established by religious orders in the 19th century in England and Ireland. The modern hospice is a relatively recent concept that originated and gained momentum in the UK after the founding of St. Christopher's Hospice in 1967. St Christopher's Hospice was founded by Dame Cicely Saunders and her extraordinary contribution to alleviating human suffering has resulted in the hospice being considered a center of innovation and insight ever since. She is widely acknowledged as the pioneer of the modern hospice movement. The hospice movement has grown tremendously since its beginning. Whereas the hospices focus on dying patients, palliative care programs in hospitals offer care for non-terminal patients well as hospice patients. Palliative care programs in hospitals are often difficult to be funded due to the multiple employees that constitute a palliative care team and the time-intensive involvement without adequate reimbursement. As a consequence, most strategies for funding palliative care programs focus on cost-savings as opposed to revenue-generating models.

Pain Management

Pain can be described as an extraordinary experience that has a severe impact on the psychology and physiology of the person affected. Pain includes a combination of sensory, affective, and cognitive dimensions that are different for each person. The perception of pain and the resulting description varies according to the sufferer's reaction and there is often a discrepancy between the pain subjectively perceived by the affected person and the objective charting by the doctor.

As pain is one of the most dreaded elements of dying for many patients and their families. Therefore pain management constitutes the cornerstone of good palliative care, as a minimization of pain increases the patients' quality of life and reduces their fears. As pain is entirely subjective, pain management has to be tailored to each patient's needs. This requires an accurate determination of the cause and nature of the pain, a decision upon appropriate medication and non-medication pain relief measures, and a regular reassessment of the pain control.

Dr. Cicely Saunders developed the concept of total pain associated with the dying process. Total pain consists of four elements: physical noxious stimuli, affect or emotional discomfort, interpersonal conflicts, and non-acceptance of one's own dying. All these elements may effect the patient's perception of the total pain. Physical pain is the most familiar component of total pain. In terms of its temporal nature, it can be differentiated into acute and chronic pain and it is usually categorized into three types: somatic pain, visceral pain, and neuropathic pain.

From a temporal perspective, acute pain is time-limited and results from nociceptor stimulation, like from an acute injury. Chronic pain is often differentiated from acute pain from a temporal perspective, meaning that pain that lasts beyond 3 months after an acute injury is described as chronic pain. More recent distinctions see acute pain as pain that serves as protection after an injury, with acute pain being defined as the symptom of pain. Chronic pain, in contrast, is defined as the disease of pain, which represents a completely different challenge to the patient and physician. The treatment objectives for such patients are the reduction of related symptoms and the restoration of maximal function.

When comparing the three types of pain, somatic pain results from the activation of nociceptors in the skin and deep musculoskeletal tissues. Potential sources of somatic pain are bone pain caused by metastases, arthritic joints, osteopathic lesions, fractures, and abscesses. Visceral pain arises from stretching or activation of nociceptors in the linings or serosa of organs. In contrast to somatic pain, visceral pain is often poorly localized, dull, aching pain which is difficult to describe. Exemplary descriptions of the pain are "deep pressure", "cramping", "spasms", or "squeezing". It is frequently associated with sensations like bloating and nausea. Neuropathic pain originates from damage to the ► peripheral nervous system (PNS) or the ► central nervous system (CNS), or both. The pain is often described as "sharp", "electric", or "burning" pain.

Besides those three types of pain, there also exist the terms breakthrough pain and incident pain. Breakthrough pain describes a temporary increase in pain from the basal, acute, or chronic pain level, which is not relieved by the scheduled dose of medication, it "breaks through" regular analgesia. Incident pain can occur during diagnostic or therapeutic procedures, or be associated with voluntary physiologic maneuvers like walk-

ing or sitting up. Physicians should anticipate the pain before the provoking activity takes place and have the appropriate pain management in place, which is often a challenge.

Practice

The options for the location of terminal care differs by country and comprises the patient's home, a long-term care setting, a hospice, a palliative care inpatient unit in an acute care hospital, or acute in-hospital care. Whereas in the 1980s, 70–90% of deaths occurred in hospitals, the scale began to move back towards deaths occurring at home by the turn of the millennium. The most anticipated causes of deaths are chronic diseases like cancer, cardiovascular disease, neurologic disease, chronic obstructive pulmonary disease, and AIDS.

In most countries, palliative care is provided by interdisciplinary teams consisting of physicians, nurses, social workers, hospice chaplains, physiotherapists, occupational therapists, complimentary therapists, volunteers, and last but not least, the family, as one of the most important elements. As palliative care covers a wide array of conditions in patients at varying stages of their illness, palliative care teams have to offer a broad range of care. A large part of the work involves helping patients with complex or severe physical, psychological, social, and spiritual problems. Clear and accurate communication to the patient is always important but of specific relevance in the phase where the patient is approaching death.

Conclusion

Due to the advancements in treatment and supporting technology as well as social changes, life expectancy has increased significantly in the last century. As a consequence of this development, medicine has devoted its effort and resources to preventing and postponing death and put less focus on the care of dying, which in medicine is often interpreted as failure. Furthermore, in many societies, death is seen as a taboo. All of these aspects affect patients, their families, carers, friends, and children, and staff in health, social, and other services. Although every individual has to die and death is an inevitable part of life, the suffering of the patients and their families is often covert and best practices to treat and support those individuals are not yet universally available. Yet, progress can be observed, with changes in medical treatments and technologies. They are now more often targeted at increasing survival or improving quality of life of the severely ill. Going forward, the elements of successful palliative care are assessment, accurate diagnosis, skilled management, and anticipatory care. This implies a consistent review of the medications for the dying and cessation of those that are not essential, in conjunction with a provision of nursing care and communication. Family and friends of the patient have to be included and educated both practically and psychologically. This is reinforced by the fact that home death has turned out to be a common preference amongst terminal patients.

Palliative Care in Children

► Paediatric Palliative Care

Palliative Medicine

Synonyms

Palliation; Palliative care

Definition

Compared with palliative care and hospice care the term palliative medicine is a more general concept. Palliative medicine does not only describe the tasks of attending and caring for the severely ill patient, who is suffering an end-stage disease with corresponding symptoms, but also implies ethical aspects, health economic considerations, quality of life (QOL) research and patient education.

Cross-References

► "A Safe Place to Suffer"

Palliative Medicine and Hospice Care

GABRIELE KIRCH
Hospice Worker, Kitzeberg/Kiel, Germany
annessa@t-online.de

Synonyms

Palliative care; Hospice; "A safe place to suffer"

Definition

According to a report of the World Health Organization (WHO 2006) palliative care is defined as "the active total care of patients whose disease is not responsive to curative treatment." This definition underlines the ► end stage of the diseases. However, palliative medicine as term can also be used more generally for the alleviation of symptoms, even if there is also hope of a cure by other treatment. In a more recent WHO statement ► palliative medicine is described as "an approach that improves the quality of life of patients and their families facing the problems associated with life-threatening illness." Palliative care may also be used to ease the unwanted effects of curative treatments, such as improving certain symptoms associated with chemotherapy.

Basic Characteristics

Correspondingly palliative care (from Latin *palliare*, to cloak) is any kind of medical treatment or help that reduces the severity of the symptoms of an illness, or slows the disease's progress, rather than to cure it. However, it may occasionally be used in combination with curative therapy, when the latter does not cause additional morbidity. Palliative care is supposed to improve ► quality of life (QOL), by reducing or eliminating pain and other symptoms, helping the patient to better deal with psychological problems (► psychological distress and palliative care), and supporting partners and family. Recently the concept of having a good quality of life has gained ground, although many assume that there is still a long way to go to improve the palliative medicine issue. A relatively new development is the concept of ► health care teams in palliative care that is entirely focused on palliation; this is often called hospice and/or palliative care. Though the concept of palliative care has been known for hundreds of years, in the past physicians have often aggressively tried to treat patients, so that the idea of making a patient comfortable was supposed as "giving up" on him.

The term palliative care principally does not refer to the care of patients with chronic diseases such as diabetes mellitus which, although actually incurable, has effective enough treatments so that it is not considered as a progressive or life-threatening disease like cancer (► cancer palliative care). It is, however, more often used regarding other life-threatening illnesses, such as progressive pulmonary disorders, terminal renal insufficiency, advanced heart failure or progressive neurological diseases. Additionally, the field of ► pediatric

P

palliative care is rapidly growing. Furthermore, cancer survival is considerably increasing with many patients living far longer than patients with, for example, progressive neurological conditions.

The hospice movement started in the 1980s and 1990s indicating that the issue had become more significant to health care professionals (Husebo and Klaschik, 2000). It was driven by the debate on ► euthanasia, following liberal legislation in certain countries, such as the Netherlands (Jansen-van-der Weide et al. 2005); "good" palliative care is considered as an alternative to euthanasia (Lennert 2003).

There is an ambiguity in the term palliative care: most oncologists consider any treatment that is not curative as palliative. Thus a therapy that leaves a patient in comfort rather than dying in pain, without changing the duration of life, is palliative. And a treatment that lets a patient live ten years longer is also palliative.

History

Hospices were originally places of rest for journeymen in the 4th century CE. In the 19th century hospices were established for the dying in Ireland and London. The modern hospice is a relatively new concept that gained momentum after the founding of St. Christopher's Hospice in 1967 (United Kingdom). Since its start, the hospice movement has grown fast. For example, in the UK there were just fewer than 1700 hospice services in 2005 consisting of inpatient units for adults, inpatient units for children, home care services, hospice at home services, day care services and hospital teams. In the United States the first hospice was established in 1974. Medicare reimbursement for hospice treatment has greatly enforced hospice usage in the United States. Today, there are roughly 4100 hospice services operated in the United States (NHPCO) (http://nhpco.org/files/public/2005-facts-and-figures.pdf). The first United States Hospital-based palliative care programs started in 1989, at the Cleveland Clinic. Thereafter adequate care for seriously ill and dying patients was established in more than 1200 new acute care hospitals (www.capc.org). The service is always free to patients. In Germany meanwhile about 200 hospice units and 956 ambulant hospice services have been reported to contribute to palliative medicine.

Palliative Medicine and Hospice Care, Figure 1 Hospice Care Room

Aims

According to dictionary.com (http://dictionary.reference.com/search?query=hospice&db=*) a hospice is defined as "A program that provides palliative care and attends to the emotional and spiritual needs of terminally ill patients at an inpatient facility or at the patient's home," and according to Cancer Web Internet site a hospice is "An institution that provides a centralized program of palliative and supportive services to dying persons and their families, in the form of physical, psychological, social, and spiritual care; such services are provided by an interdisciplinary team of professionals and volunteers who are available at home and in specialized inpatient settings. Origin: L. Hospitium, hospitality, lodging, fr. Hospes, guest" (http://cancerweb.ncl.ac.uk/cgi-bin/omd?query=hospice&action=Search+OMD).

Palliative care does not try to hasten or postpone dying. It aims for symptom relief (► symptom relief in palliative medicine) and promotion of general well being and psychological and social comfort for the person with a life-threatening or life-limiting disease. For palliative medicine quality of life has become more and more important not only in the dying stages, but also in the last weeks, months and years of life. As already pointed out palliative care deals not only with cancer, but also with patients (adults and children) suffering from ter-

LIVING WILL

PERSONAL DETAILS

Name _____

Address _____

Date of birth _____

Doctor's details _____

National Health Number _____

I, _____, am of sound mind and make this Advance Directive now on my future medical care to my family, my doctors, other medical personnel and anyone else to whom it is relevant, for a time when, for reasons of physical or mental incapacity, I am unable to make my views known.

INSTRUCTIONS

Medical treatment I DO NOT want:

I REFUSE medical procedures to prolong my life or keep me alive by artificial means if:

(1) I have a severe physical illness from which, in the opinion of _____ independent medical practitioners, it is unlikely that I will ever recover; ☐

or

(2) I have a severe mental illness which, in the opinion of _____ independent medical practitioners, has no likelihood of improvement and in addition I have a severe physical illness from which, in the opinion of _____ independent medical practitioners, it is unlikely that I will ever recover; ☐

or

(3) I am permanently unconscious and have been so for a period of at least ___ months and in the opinion of ___ independent medical practitioners there is no likelihood that I will ever recover. ☐

Medical treatment I DO want:

I DO wish to receive any medical treatment which will alleviate pain or distressing symptoms or will make me more comfortable. I accept that this may have the effect of shortening my life. ☐

If I am suffering from any of the conditions above and I am pregnant, I wish to RECEIVE medical procedures which will prolong my life or keep me alive by artificial means only until such time as my child has been safely delivered. ☐

Palliative Medicine and Hospice Care, Figure 2b Advance directive : Living Will (Continuation)

minal kidney, liver or neurological diseases including Alzheimer's disease. In palliative medicine the patient **and** his family have to be paid attention to.

Palliative care was called "► a safe place to suffer" in 1987 by the Oxford psychiatrist Averil Stedeford and involved measures of building the patient's trust, good symptom control and listening in a therapeutic relationship. These are the focal points of effective palliative medicine. Thus *a safe place to suffer* may be one of the best descriptions of palliative care.

Practice

Hospice and palliative care are two different aspects of end stage medicine with different locations of care. Palliative care services are most often based in hospitals with interdisciplinary consultation services and, possibly, with an inpatient palliative care ward. Palliative care may also be in dying persons' homes or in long-term care facilities. Hospice care is given in patients' homes or in long-term care facilities. In contrast to the US, in the UK no differentiation is made between 'hospice' and 'palliative care.'

In most countries hospice and palliative care are the responsibility of interdisciplinary teams consisting of physicians, registered nurses, ► hospice chaplains, social workers, physiotherapists, occupational therapists (► occupational therapy in palliative care), complimentary therapists, volunteers and, most importantly, the family. In addition, home health care aides, volunteers from the community (largely untrained but some being skilled medical personnel as well), and housekeepers are team members. The aim of the team is to optimize the patient's comfort. Family members and volunteers are crucial to the palliative care system and may find themselves under severe emotional and physical stress. As there is a wide range of conditions that may occur in patients at varying stages of their illness, palliative care teams offer very differing kinds of care: managing the physical symptoms in patients receiving active treatment for cancer, treating depression and attending patients in their last days and hours. This means the teams have to help patients with complex and/or severe physical, psychological, social and spiritual problems.

In many countries *board certification* in palliative medicine has been established for physicians following specialty training for 1 or 2 years. The mode of payment or funding for hospice and palliative care services varies widely throughout the world.

Conclusion

Concerning the definition and the tasks of palliative care and hospice the World Health Organization has published the following statement: "The primary goal of palliative care is to optimize the Quality of Life (QOL) of patients with advanced incurable illness through control of physical symptoms and through attention to the patient's psychological, social and spiritual needs" (WHO Technical Report Series No. 804). Thus palliative medicine is provided for patients with incurable illnesses, such as relapsed cancers, other chronic diseases in end stage situations like cardiac, renal or hepatic failure, diabetes mellitus, the acquired immunodeficiency syndrome (AIDS), and chronic progressive neurological disorders. Palliative care concentrates on issues like management of symptoms such as pain, cachexia, intestinal obstruction, nausea and vomiting, neutropenic infections, dyspnea, and depression. Themes like ► ethics in palliative medicine, health economics, quality of life (QOL) research and patient education also have to be given consideration when devising care schemes. So the quality of the team members is crucial. Carers require an understanding of the fundamental mechanisms of symptoms in patients who are undergoing palliative or hospice care. Available information should be integrated into any care plan so that obstacles to better palliation can be overcome, and the knowledge and system of collaborative work developed in palliative medicine must be expanded to a multinational level for the benefit of all who require such care.

► Cancer Palliative Care

Pandemic

Synonyms

Widespread epidemic

Definition

The term "pandemic" stems from the Greek and means "all people." A pandemic infectious disease spreads without local restriction, extending over large regions, or even worldwide. Although pandemics ignore frontiers and reach nearly all corners of the globe, some regions can be spared due to their isolated location; these can be lonely mountain villages, islands or particular regions of the jungle.

Cross-References

► Infectious Diseases
► Widespread Epidemic

Panic Disorder

Synonyms

Episodic paroxysmal anxiety

Definition

A panic disorder is characterized by repeated, sudden bouts of anxiety that reach maximum intensity in a very short period of time. The panic attack is distinguished from other forms of anxiety by its intensity and its sudden, episodic nature. Panic disorders are associated with numerous somatic and cognitive symptoms. Symptoms include tachycardia, sweating, trembling, shortness of breath, chest pain, nausea or gastrointestinal distress, dizziness or lightheadedness, tingling sensations, and fear of dying. The attack typically has an abrupt onset, building to maximum intensity within 10 to 15 minutes, it rarely lasts longer than 30 minutes. The experiences generally provoke a strong urge to escape or flee the place where the attack begins and, when associated with chest pain or shortness of breath, frequently results in seeking aid from a hospital emergency room or other type of urgent assistance.

Cross-References

► Anxiety Disorders

Paper-Based Patient Record

Definition

A paper-based patient record is a collection of data on a patient's health status, stored in the formats in which they are collected (as text, numbers, images, biosignals and codes). It is the oldest and most widely applied type of patient record because it is fast, portable, unbreakable, easy to use, and provides health professionals with great freedom in entering various types of data. The disadvantages of paper-based patient records include vulnerability to ► data errors – loss, incompleteness or incomprehensibility, and chronological orientation of data, which makes retrieval and research difficult.

Paradigm Shift

Definition

The term *paradigm shift* was introduced by Thomas Kuhn in his book *The Structure of Scientific Revolution*, published in 1962. Kuhn shows how almost every significant break-through in the field of scientific endeavor is first a break with tradition, with the old way of thinking, and with old paradigms. For Ptolemy, the great Egyptian astronomer, the earth was the center of the universe. However, Copernicus created a paradigm shift, by placing the sun at the center, and suddenly everything was viewed differently. Paradigm shifts move us from one way of thinking to another, from one way of seeing the world to another, and create powerful change. They create a revolution, a transformation, or a sort of metamorphosis.

Paralysis agitans

► Parkinson's Disease

Parameter

Definition

Value of a population characteristic, unknown by definition, which consequently needs to be evaluated, i. e. population mean is a value usually used as an indicator of a mean value of a quantity. In a population, a parameter is a fixed value that does not vary. Each sample of the population has a statistical value, which is used for grading the parameter. Numerical property of a population. The unique number that depicts a population of measurements of the resulting variable and depends on it.

A parameter is a summary value (numerical quantity measuring some aspect of a population values) which in some way characterizes the nature of the population in the variable(s) under study. Often, it is a mathematical function of the population values of the variable(s) (e. g. the population mean, the population variance, the population proportion, the population correlation coefficient). Parameters are represented by Greek letters (μ ,σ^2, π, ρ, respectively). The parameters are rarely known and they have to be estimated.

Parametric Test

Definition

Inferential statistical method that is based on the specific assumptions regarding one or more of the population parameters that characterize the underlying distribution(s) for which the test is employed. In general it is designed to be used with normally distributed quantitative (interval or ratio) variables.

Parasites

Synonyms

Leech; Sponge; Sponger

Cross-References

► Zoonotic and Parasitic Infections

Parasitic and Zoonotic Infections

Synonyms

Parasitoses and zoonoses; Infections transmitted by parasites; Infections transmitted by parasitic organisms; Infections transmitted by animals

Cross-References

Parens patriae Power

Definition

Parens patriae power stands for the legal authorization of states entitling them to act paternalistically on behalf of and for the benefit of an individual in order

to save the individual from harm. Particularly, mentally ill persons and children are subject to public health actions based on the state's parens-patriae-power (e. g., by hospitalizing mentally ill persons even against their expressed will). In such situations, states through their public health agencies act, metaphorically speaking, as parents of the country and of the endangered individuals.

Parenting

Synonyms

Child-rearing; Raising children

Definition

All of the activities involved in raising a child, for the child to become a healthy and functional adult. Parenting begins during pregnancy and may continue until either the parent dies or the child dies. Three general types of parenting styles are: (1) the authoritarian parenting style (strict enforcement of rules; frequent use of punishment) (2) the permissive parenting style (leniency in the enforcement of rules; little or no actual use of punishment), and (3) the authoritative parenting style (considered the "ideal" parenting style), the enforcement of rules necessary to maintain discipline and clearly telling children why the rules are necessary.

Pareto Efficiency

Definition

Pareto efficiency describes a condition that implies that it is impossible to improve the level of individual welfare of one individual without reducing the level of individual welfare of other individuals. If it is possible to improve the individual welfare of one individual without hurting the individual welfare of other individuals by reallocating resources, this reallocation is desirable from a Paretian point of view. It is important to note that the Pareto criterion does not include any notions about the distribution of income, which is considered to be given.

Pariser

► Condom

Parity

Synonyms

Number of children born alive

Definition

Parity represents the number of children born alive to a woman. For example, a primiparous woman has given birth to one child, while a nulliparous has not had a live birth.

Parity Progression Ratio

Definition

Parity progression ratios represent the proportion of women at a given parity level who progress to the next higher parity level; for example, the percentage of women with one child who go on to have a second child. This measure is useful for studying tempo versus quantum changes in ► fertility patterns, and can be specific to a cohort or time period.

Parkinson's Disease (PD)

Synonyms

Paralysis agitans; Shaking palsy

Definition

Parkinson's disease is a chronic, progressive neurological disease, which is characterized by a fixed inexpressive face, tremor (shaking), rigidity in some muscles, slow movements, and problems with maintaining normal posture. This is caused by degeneration of brain cells in a part of the brain known as the substantia nigra (SN) which controls many types of muscular movement by releasing a neurotransmitter called dopamine. Dopamine is needed to carry nerve messages from one brain cell to another. The majority of patients are older than 50 but at least 10% of patients are under 40. The

basic cause for Parkinson's disease has not been discovered, yet it is assumed that the disease is hereditary. There are also researchers who think that environmental factors may be the reason for damage of the SN brain cells. There is no cure for Parkinson's disease, but the symptoms can be reduced by drug therapy and surgery supported by exercise, good nutrition, and ► physical therapy.

Criteria for Parkinson's disease include the motor symptoms bradykinesia, rigidity, rest tremor, and postural instability. Additionally, mental symptoms like psychotic disorders or depression may occur as well as autonomic and gastrointestinal dysfunction. PD is one of the most prevalent neurodegenerative diseases and its relentless progression results in severe disability.

Parochialism

Definition

Parochialism means ignoring the impact of cultural concepts and diversity on organizations, professions, policies, procedures and programs. One's own concepts are perceived as culture-free and the only and universal way of thinking and acting. Diversity is trivialized or considered as irrelevant. When problems occur, the underlying role of culture or diversity is denied. Parochialism is a limiting view because it precludes options for managing diversity effectively. The term parochialism is derived from 'parish', which has both religious and governmental connotations (compare ► ethnocentrism).

Partial Removable Dental Prosthesis

Synonyms

Removable partial denture

Definition

A dental prosthesis that replaces some or all teeth in a partially dentate arch. It can be inserted and removed from the mouth by the patient.

Participation

Synonyms

Involvment; Commitment; Engagement

Definition

Involvement in a life situation.

Participation Restrictions

► Impairment and Disability

Particulate Matter (PM)

► Suspended Particles

Partnership

► Alliance

Parvovirus B 19 Infection

► Erythema Infectiosum

Passive Smoking

Synonyms

Secondhand smoke; Involuntary smoking; Involuntary inhalation of tobacco smoke; Environmental tobacco smoke

Definition

Passive smoking refers to the involuntary inhalation of a mix of mainstream and sidestream smoke (smoke given off the burning end of a cigarette) by a non-smoker. There is evidence that passive smoking causes diseases in the fetus, the newborn, children, adolescents, and adults.

Passive Surveillance

Definition

In this context, passive surveillance means that physicians are required to report to the health department certain diseases, when they are diagnosed, by filling out a form with information about the patient (name, age, sex, race and residential address), the diagnosed disease, the date of diagnosis, and the reporting physician.

Pasteurization

Definition

In 1856, the technique of pasteurization was developed by Louis Pasteur. The French scientist is accepted as one of the fathers of microbiology. He recognized that heating for a short period of time killed the microorganisms contained in a product without relevantly changing the characteristics of the product itself. Pasteur revealed that when milk was heated to a temperature of 72 to 75 °C for 15 to 40 seconds, 99.5% of the germs were killed. If afterwards the milk was stored in a refrigerator (which was invented nearly at the same time as pasteurization), it remained drinkable for 6 to 10 days.

Cross-References

► Tuberculosis and Other Mycobacterioses

Patent

Definition

A patent is an intellectual property right that is granted to an inventor to allow him to exploit exclusively an invention he has made. Patents are time limited and granted by states. They are territorially effective in the countries where the right has been granted. Patents provide a defense and damage claim against anyone who makes use of the patent without the permission of the patent holder. Patents can be obtained for invented products and procedures.

Paternalism

Definition

Paternalism, etymologically, simply means treating one in a fatherly way, taking decisions on an individual's behalf, just like a father who knows better than his child what is in his child's best interest. Applied to the doctor–patient relationship, its meaning was intended to be a positive one; the doctor really thought that taking decisions on behalf of his patients and withholding information from them or their legal guardian was the best he could do, in a fatherly way. Paternalism has been strongly criticized because it interferes with patients' freedom and right over their own bodies. Applied to public health practice, it refers to coercive measures over the individual taken by government on account of protecting the common good.

Pathogen Organisms

Definition

The pathogen organisms in water are bacteria, viruses, protozoa and helminths which may cause diseases that vary in severity and sometimes have fatal outcomes.

Pathogens that Cause Tuberculosis

► Mycobacterium Tuberculosis

Pathologising

Synonyms

Demonizing; Victim blaming

Definition

Pathologising refers to the tendency to make someone or something into a problem without remainder. It focuses on disease or disfunction rather than health. While it is appropriately used of processes whereby tissue becomes diseased, it is typically demeaning when used with reference to people. Blaming the victim for their reduced circumstances without taking into account other factors is one form of pathologising practice.

Pathology

Definition

Pathology is the scientific study of the essential nature of disease and its causes, processes, development, and consequences. A medical doctor who specializes in pathology is called a pathologist and is an expert at interpreting microscopic views of body tissues.

Patient-Care Information System

► Health Information System

Patient-Centred Approach

Definition

The patient-centered approach refers to the way the physician approaches patients, being committed to the individuals rather than to their diseases. It aims at understanding the meaning diseases may have for specific patients; this implies understanding patients' feelings and fears about their conditions, and their expectations of the consultation process.

Patient Confidentiality

► Consumer Confidentiality

Patient Data

Definition

Patient data are data about an individual patient and potentially relevant to decisions about his/her current or future health or illness. Patient data include clinical measurements, laboratory values, medication dosages, treatments etc. Patient data should be collected using methods that minimize systematic and random error.

Patient Empowerment

Definition

In ► health promotion, empowerment is a process through which people gain greater control over decisions and actions affecting their health. It may be a social, cultural, psychological or political process through which individuals and social groups are able to express their needs, present their concerns, devise strategies for involvement in decision-making, and achieve political, social and cultural action to meet those needs. Patient empowerment includes collective ► advocacy of patients' rights as well as enabling processes on the individual level (e. g. patient education, enhancement of ► health literacy) that improve patient participation, self-determination in treatment and patient-centred health care. Together, they help patients to take an active role in the improvement of their health and to diminish psychological and social consequences of disease.

Patient Orientation

Definition

Patient orientation means the concept of shared decision-making, i. e. the participation of the patient regarding the selection of therapeutic goals and treatment options. The quality of patient care must not only be measured by the professional standards of the medical, nursing, and other staff, but also by the patients' satisfaction with their medical care. Patient orientation means that all the parties involved in patient care try to get to know and meet the expectations and needs of the patients within the framework of therapeutically correct medical care.

Patient Preferences

Definition

Patient preferences result from deliberation about specific elements, such as anticipated treatments or health outcomes. Patient preferences refer to the individual's evaluation of dimensions of health outcomes and are one of a large number of preferences that may influence

health care choices. These judgments are expressed as statements or actions. Patient preferences result from cognition, experience, and reflection; and exist as the relatively enduring consequences of values. In order for patient preferences to be effectively used in the delivery of health care, it is important that patients are able to formulate and express preferences, that these judgments are made known to the clinician at the time of care, and that these statements meaningfully inform care activities.

Patient Privacy

► Consumer Privacy

Patient Protection

► Consumer Protection

Patient Record

► Health Record

Patients

Definition

Patients are people with defined medical conditions seeking treatment. The term is usually used for individuals participating in clinical trails to determine the efficacy of a treatment or therapy by comparison with historical data (efficacy in a previously treated cohort within the same medical setting and with previous standard therapy), or by direct comparison with standard therapy, or, if no standard therapy is available, by direct comparison with placebo administration. In patients, the risk of an intervention has to be compared with the risk of the disease, the risk of standard treatment and the potential benefit of a successful therapy, so that a final risk–benefit evaluation can be given. Because such patients need therapy anyway, usually only the expenses incurred by the trial regimen are financially compensated (e. g. travel expenses).

Patient Safety

► Consumer Safety

Patient Safety HTA

ULF MAYWALD
Abteilung Ärzte/Apotheken, AOK Sachsen, Dresden, Germany
ulf@maywald.com

Definition

Patient safety technologies are any that reduce the risk of ► adverse events related to exposure to medical care, either by directly reducing the probability of injury or by reducing errors that may lead to injury. Patient safety practice is defined as a type of process or structure whose application reduces the probability of adverse events resulting from exposure to the health care system across a range of diseases and procedures (Shojania et al. 2001). Patient safety Health Technology Assessment (HTA) is the use of HTA methods to rate patient safety technologies and to prepare decisions on their implementation.

Basic Characteristics

HTA is a process used to evaluate the clinical ► effectiveness and ► cost-effectiveness of health technologies by systematic review of clinical, economic, and utilization research. HTA can also be applied to patient safety projects and approach-respective technologies. There are four categories of patient safety HTA, including HTA for existing safety technologies, underutilized safety technologies, emerging safety technologies, and safety aspects of technologies with a non-safety primary purpose.

The rapid rise of patient safety to the attention of policymakers and the public left healthcare providers and researchers little time to evaluate the effectiveness of many patient safety technologies. In the case of patient safety technologies, HTA is urgently needed to evaluate the clinical and economic effectiveness of existing technologies and to prioritize their implementation in health care practice (Mulcahy and Walley 2005).

In the context of patient care, safety issues can emerge in traditional clinical areas (e. g. adverse drug events and complications of surgery), less traditional clinical areas (e. g. ► provider fatigue and in information transfer), and from non-medical approaches to safety (e. g.in► information technology and human factors research) (Shojania et al. 2001).

Most patient safety issues involve both an error and physical or psychological harm. The patient safety literature distinguishes between two approaches to patient safety; one is minimizing injury and the other is minimizing error. It seems clear that healthcare should strive to minimize as many errors and injuries as possible (Cole 2000).

Patient Safety Technology

This term is reserved for technologies with patient safety as their primary purpose. However, many other technologies with a therapeutic or diagnostic primary purpose can affect patient safety. They can indirectly influence the impact of patient safety by raising or lowering the risk of injury or error in health care.

Patient safety technologies are already used in some health care settings. They are mostly developed by following the US safety reports created by The Agency for Healthcare Research and Quality (► AHRQ), which include drug bar-coding, computerized order entry, and work hour regulations. Additional well known and widely implemented patient safety technologies are, for example, patient self-management of anticoagulation and pressure relieving bedding materials to prevent pressure ulcers.

Emerging patient safety technologies are new technologies with a probable improvement for patient safety. An example are drug-eluting coronary artery stents.

However, most technologies that will probably affect patient safety have not been implemented. Different reasons lead to the underutilization of these technologies, such as high capital cost, lack of knowledge, lack of evidence, or investment in other technologies. Policy makers have to weight the potential patient safety and quality benefits against the costs of these technologies.

Patient safety has received increased attention in recent years, but mostly with a focus on errors and adverse events, rather than on practices that reduce such events. Efforts to introduce a patient focus in HTA programs are therefore necessary, because most HTA programs today focus only on clinical and economic effectiveness. Patient safety is considered indirectly as a factor in effectiveness (impact of adverse events or errors on clinical outcome) and in cost effectiveness (costs of adverse events). HTA rarely considers the social, political, and ethical aspects of health technologies, despite their inclusion in the definition of HTA. These factors are particularly critical in the assessment of patient safety technologies, where ethical, legal, and political dimensions and the concept of patient safety closely guide decision makers (Mulcahy and Walley 2005).

Implementation of Patient Safety HTA Results

The implementation of patient safety technologies is often prioritized lower than the implementation of new treatment technologies. This is due to limited resources in most healthcare systems. However, economic pressure in healthcare systems makes patient safety HTA important.

Ignoring HTA safety evidence risks adopting improvements that are not cost-effective; this could prevent investment in other patient safety interventions and limit resources available for actual patient care and services. Linking HTA evidence to patient safety guidelines like the US National Quality Forum's Patient Safety Practices may be the best way to provide healthcare providers with reliable HTA information to decide which patient safety technologies to implement.

Patient Satisfaction

Definition

Patient satisfaction serves as an indicator to evaluate ► health care quality. To obtain this measurement, patients report their perception of received health care services in hospitals, doctors' offices or other provider settings by means of ratings or questionnaires.

Patient's Comfort

Synonyms

Quality of Life (QOL); Well-being; Wellness

Definition

The concept of a measure of good quality of life for each patient has gained popularity recently. Quality of life may be determined by so-called Qualys which are a measure of the state of well being. A better quality of life for patients undergoing palliative care is affiliated to the alleviation of certain physical symptoms, like pain, nausea, vomiting and dyspnea, etc., and to improvements in their psychological situations and social contacts (trust, listening, therapeutic relationship).

Payer's Perspective

Definition

The most common perspective besides the societal perspective is the payer's perspective. It refers to all expenses of the public payer, e. g. a sickness fund, government health service, or private health insurance company, for reimbursed health care due to a defined health care intervention or disease. From a payer's perspective, only the health care described in the catalog of reimbursed items is relevant and to a large extent the reimbursement rates directly reflect the costs.

Pay-for-Performance

Synonyms

P4P

Definition

Pay-for-performance payment systems associate part of the physician's payment with performance indicators such as clinical outcome and patient satisfaction.

Pearson's Correlation Coefficient

Definition

Pearson's correlation coefficient (r) is a measure of the linear association of two variables. Correlation analysis usually starts with a graphical representation of the relation of data pairs using a scatter diagram. The values of correlation coefficient vary from –1 to +1. Positive values of correlation coefficient indicate a tendency of one variable to increase or decrease together with another variable. Negative values of correlation coefficient indicate a tendency that the increase of values of one variable is associated with the decrease of values of the other variable and vice versa. Values of correlation coefficient close to zero indicate a low association between variables, and those close to –1 or +1 indicate a strong linear association between two variables. The square of the correlation coefficient is the coefficient of determination, which gives the proportion of the variation in one variable that can be explained from the variation of the other variable. The assumptions for applying Pearson's correlation coefficient are (a) linear relationship between variables, (b) continuous random variables, (c) variables must be normally distributed, and (d) variables must be independent of each other. Nonparametric counterparts of Pearson's correlation coefficient, such as Spearman's rank correlation coefficient,

Kendall's tau, and Goodman–Kruskal gamma, can be applied when data are presented as ranks or when data come from an ordinal scale of measurement.

Formation of soil; Soil genesis

Definition

Pedogenesis or soil formation (evolution) is the natural geobiological process by which soil is created. Formation of the lithosphere as well as the whole biosphere is influenced by factors classified as: a) abiotic factors: climate, edaf (physicochemical properties of the soil), and orograf (the relief) factors; and b) biotic factors, which consider the influence of all living beings: microbes, flora, fauna, and anthropogenic influence. Soils are more developed in areas with higher rainfall and more warmth, and the rate of chemical weathering increases 2–3 times when the temperature increases by 10 °C. The final composition of the soil depends mostly on the base on which the soil is formed (for example via hydration, hydrolysis, ion exchange, oxydoreduction, or calcification). Previously, soil was considered to be a product of physicochemical transformations of rocks, a dead substrate from which plants derive nutritious mineral elements. The soil is now considered to be a natural body having its own genesis and history of development, with complex and multiform processes that take place within it.

Pedometer

Step counter.

Peer Education

Definition

Peer education is defined as involving people from a similar societal group, age group, or specific ► community who inform and educate each other to achieve positive health outcomes. It can be conceptualized as learning from one's peers. Peer educators are not professionally trained educators, but usually undergo a special training. The term peer education is often used to describe young people teaching young people. However, the peer education approach has also been successfully used with other groups, e. g. homosexuals in terms of HIV/AIDS prevention. The advantages of this approach are that peers are insiders in a certain culture, have a history of shared experiences and consequently are especially sensitive to the needs and atti-

tudes of other individuals from the ► target group. The insider status may also allow peers to gain a better access to the people in question. Peer education may also effect change at the group or societal level by modifying norms and stimulating collective action that contributes to individual change as well as changes in programs and policies.

Education that is offered by trained people who are members of the same group (or at least fit similar criteria, such as age or educational level) as the relatively homogeneous group they are educating. This type of intervention aims at increasing acceptance of messages through avoiding hierarchy or socio-cultural traps between counselors and those seeking advice. This method is often used with groups such as young people or sex workers. Peer education is used widely in the US and is part of the academic curricula. Positive experiences exist for the following topics: Primary prevention of smoking and substance and alcohol abuse; counseling and information on eating disorders; HIV prevention and prevention of unintentional pregnancy; and coping with stress.

Peer Group

Definition

A peer group consists of male and female people of about the same age and status. It is regarded as a type of sociological group with a homogeneous system of values. Adolescent behavior, both positive and negative, can be influenced by membership in peer groups. Peer-based intervention programs, especially school-based programs have been used as a preventive strategy for a range of adolescent risk behaviors.

Pelvic Inflammatory Disease (PID)

Definition

Pelvic inflammatory disease (PID) is an infection of the upper genital tract (the uterus, fallopian tubes and/or ovaries) that results from an initial infection, often beginning at the cervix. If severe or left untreated, the result of PID can be extensive scarring of the fallopian tubes leading to tubal occlusion and infertility.

Penetrance

Definition

Penetrance is defined as the fraction of the ► mutation carriers that develops the given phenotype of the ► allele. In most hereditary disorders, penetrance is below 100%, i. e. not every mutation carrier becomes affected throughout life.

Penicillin

Definition

Penicillin, the first antibiotic available, is produced by different species of the fungus *Penicillum*. Penicillin's can be given orally or parenterally. They are bactericidal, that means they kill bacteria by interfering with the synthesis of the bacterial cell wall. Penicillin's are effective against gram positive and gram negative germs. Some pathogens have an enzyme called penicillinase (a particular type of β-lactamase), which is able to inactivate penicillin. By chemical alteration penicillin's can be produced that cannot be inactivated by penicillinase. They are called penicillinase-stable penicillin's. The structure of cephalosporins and penicillin's is similar. In allergic reactions both groups of substances can be involved. This phenomenon is called cross-allergy.

People

► Nation

Per Capita Payment

Synonyms

Capitation payment

Definition

Per capita payment is a payment method by which physicians are paid per patient treated. This payment method aims to assure time efficient treatment of each patient and creates incentives for physicians to treat as many patients as possible. This payment method contrasts with the ► fee-for-service payment where payment depends on the number of services provided. As payment systems of physicians are seen as mechanisms to achieve policy objectives, such as controlling health care cost or improving ► health care quality, the per capita payment seems to save more health care costs than the fee-for-service payment method. But still little is known on the impact of different methods of payment (per capita, salary, fee-for-service) on the clinical behavior of the physicians.

Per-Case Payment

Definition

Per-case payment is a financing method of hospitals in which hospitals receive a payment according to the 'medical case' they treat. These cases are based on ► Diagnosis Related Groups (DRGs), determining the level of payment according to the principal diagnosis, age, ► co-morbidities and other criteria of a patient. This financing method of hospitals has become popular as a measure to contain costs in contrast to the method of ► prospective budgets.

Perinatal Health

Heena Brahmbhatt
Department of Population and Family Health Sciences, Bloomberg School of Public Health, Johns Hopkins University, Baltimore, MD, USA
hbrahmbh@jhsph.edu

Definition

The ► perinatal period refers to the period about 5 months before and right after a birth. External risk factors and the in-utero environment can impact birth outcomes, and adversities during pregnancy can impact the health of the newborn as well as the trajectory of long-term health and development of the infant.

Basic Characteristics

Preterm Labor and Birth

► Preterm Delivery (PTD) is defined as a birth before 37 weeks of pregnancy, and occurs in approximately 10% of births. PTD continues to increase in most western countries, and is associated with 75–80% of all ► perinatal mortality, and increased morbidities. Preterm labor can result from spontaneous labor or prolonged rupture of membranes (PROM) resulting in spontaneous preterm births (SPB), or due to medical indication (► prolonged or preterm rupture of membranes). There are several pathways that lead to SPB: 1) premature activation of the fetal hypothalamo-pituitary-adrenal (HPA) axis which could lead to elevation of prostglandins, 2) ascending genital tract infections, 3) decidual hemorrhage, or 4) uterine overdistention (Aagaard-Tillery et al. 2005). Sociodemographic and biologic risk factors associated with PTD include maternal age, race and ethnicity, low socioeconomic status, stress, drug abuse, family genetics, and poor nutritional status. History of PTD and past history of miscarriages in the second trimester also increase the risk of PTD (Goldenberg et al. 1993). Risk factors for PTD during the current pregnancy include multiple gestation, uterine anomalies, cervical abnormality, bleeding and infection (Halbreich 2005) .

Infants that survive are at higher risk for damage to the central nervous system, and increased rate of hypertension, cardiovascular disorders and diabetes.

Current methods to identify women at high risk for PTD include detection of vaginal secretion of fetal fibronectin (fFN), and use of cervical sonography to detect funneling and shortening of the cervix. Due to the multiple and overlapping risk factors for PTD, advances in prevention have been modest. Current successful approaches include antibiotic treatment of bacterial STIs, progesterone intake, and identification of early labor and transport of mothers to a delivery facility before onset of early labor and rupture of mem-

branes. Hence it is crucial to continue to find additional methods to prevent PTD, screening to identify women at high risk of PTD, and continue to work on designing effective interventions to prevent and better manage PTD (Ancel 2004).

Intrauterine Growth Retardation (IUGR)

IUGR is defined as a process that leads to limited potential for intra-uterine growth of the fetus, resulting in low birth weight (► intrauterine growth retardation (IUGR)). It occurs in about 5% to 7% of pregnancies, and results in babies being born at birth weights that measure less than 3% to 10% using standard growth curves. The growth restriction is caused by inadequate supply of nutrients and/or limited oxygen supply to the fetus. A majority of fetal growth retardation occurs in the 3rd trimester (~70% to 80%) resulting in an 'asymmetrical' growth restriction, whereas in about 20% to 30% of babies, the growth restriction occurs in the 1st or 2nd trimesters, resulting in a 'symmetrical' growth restriction. Symmetrical IUGR is typically caused by chromosomal and congenital malformations, early fetal infections, drugs or early onset of severe preeclampsia, and results in a greater rate of morbidity and mortality compared with asymmetrical IUGR, that is typically caused by placental-cord abnormalities and maternal vascular factors, as well socioeconomic and nutritional factors (Brodsky, Christou 2004).

Growth restricted fetuses have been shown to be at a higher risk of morbidities as well as ► fetal mortality. Some perinatal effects associated with IUGR include an increased prevalence of perinatal depression, hypoglycemia, hypothermia, prematurity and infection. Long-term effects include growth problems (prevalent in about 10% of IUGR children), and some studies have also shown an increase in adult onset of hypertension, type 2 diabetes and coronary artery disease associated with in-utero growth restriction.

It is crucial to improve the early detection and management of fetuses experiencing growth restriction. Once the IUGR is diagnosed, the cause of the growth restriction has to be determined, followed by more specific tests and regular monitoring of the mother and fetus so as to determine optimal timing and method of delivery. Umbilical Doppler flow measurements that show blood flow in fetal arteries and veins are recommended to diagnose sick IUGR fetuses and have been shown to improve perinatal outcomes. At delivery, it is important to have a neonatology team present to diagnose the effects of IUGR on fetal outcomes. Since IUGR fetuses are more likely to be born preterm, they are exposed to the same risks as preterm births. Prevention strategies should continue to focus on prevention of smoking during pregnancy, optimal maternal nutrition, and in developing countries, malaria prophylaxis during pregnancy.

Low Birth Weight (LBW)

► Low birth weight infants are born weighing 2500 gms or less, measured within the first hour of birth. Within the category of LBW infants, infants can be born premature or preterm (born before 37 weeks gestation), at term (born between 37 and 42 weeks gestation), or post-term (born after 42 weeks gestation). '► Very low birth weight' infants weigh between 1000 to1499 gms and ► 'extremely low birth weight' infants weigh between 500 to 999 gm (Carroll et al. 2005). The incidence of LBW ranges from 5–8% in developed countries to 25% in some developing countries, and after premature births, is the 2nd leading cause of perinatal morbidity and mortality. The impact of LBW on subsequent development of these infants depends on the cause leading to fetal growth restriction, timing of this risk exposure, and the duration of the impairment (Lawn et al. 2005).

Sociodemographic risk factors include low SES, maternal age (less than 19 years and over 35 years), ethnicity (African Americans), marital status (single mothers), and decreased educational level. Medical history of risk factors that can increase the risk of LBW include chronic hypertension in the mother, glucose metabolism disorders, chronic cardiorespiratory disease (any complication that limits oxygen to fetus), obstetrical history (higher risk with 1st pregnancy), and history of low birth weight. Risks during the current pregnancy include gestational hypertension (development of high blood pressure after week 20 weeks gestation), ► pre-eclampsia (high blood pressure and proteinuria and edema), gestational diabetes, low weight gain during pregnancy, maternal malnutrition, short birth intervals, multiple pregnancies, alterations in the placenta and umbilical cord that could impair oxygen to the fetus, bleeding during pregnancy, extremes of hemoglobin concentrations (less than 9 g/dl or more than 12 g/dl), infections (such as STIs, HIV), and fetal

congenital anomalies (such as trisomy 21). Some environmental and behavioral risk factors are over-work, stress or physical/sexual abuse, smoking, moderate to heavy alcohol consumption, caffeine consumption, illicit drug use, exposure to toxic substances, and ionizing radiation.

Ways to prevent LBW include improved access to health services and adequate prenatal care to improve detection of LBW and identify causes of the fetal growth restriction, counseling mothers on risks associated with smoking, alcohol and drug use, as well as use of family planning to increase birth spacing over 2 years, and educating mothers about adequate nutrition during pregnancy.

Perinatal Mortality

Perinatal mortality is the sum of fetal and neonatal mortality. Fetal mortality is defined as still births or fetal deaths after 20 weeks gestation. ► Early neonatal mortality is defined as mortality within the first 7 days of life, whereas ► late neonatal mortality is a death between 7 and 29 days of life. More than 70% of deaths occur in the 1st week of life and the highest risk of mortality is in the first day of life. There are an estimated 8 million perinatal deaths globally per year, with 4 million fetal and an equal number neonatal deaths. Globally, the main causes of neonatal deaths are preterm births (28%), severe infections (26%), asphyxia (23%), tetanus (7%), congenital abnormalities (7%), and diarrhea (3%) (Lawn et al. 2005).

Maternal health and care, are important determinants of neonatal health, with obstetric outcomes during the intrapartum period which include complications during labor, having the most significant impact on neonatal survival. Complications of pregnancy and childbirth are the leading cause of death and disability among women of reproductive age in less developed nations. Over 90% of maternal mortality is in developing countries and the main causes of mortality are bleeding, chronic anemia, hypertensive disorders, infections, obstructed labor, and unsafe abortions. The most common causes of perinatal deaths are early childbearing, poor maternal health, and lack of appropriate and quality health services.

Interventions to reduce the burden of maternal and perinatal mortality need to focus on maternal education, access to health services (with a focus on prenatal and labor and delivery services), nutrition during and after the pregnancy, as well as opportunities to improve her socio-economic status (Moss et al. 2002).

Perinatal Mortality

Synonyms

Perinatal death

Definition

Perinatal mortality is the sum of fetal and neonatal mortality.

Perinatal Period

Definition

The perinatal period is the period between 5 months gestation to about 4 weeks after birth.

Periodical Health Examination

Synonyms

Periodic medical examination; Periodical medical examination

Definition

Periodical health examinations are carried out as a type of follow-up health examination at regular intervals. The periodicity of these examinations should depend on the type and the level of the health risk assessed, and the probability of adverse health effects occurring. Periodical health examinations are usually carried out on employees that are at risk of exposure to a known health hazard. They are required by legislation for employees placed in high-risk workplaces. There are two types of periodical health examinations, general health examinations and specific health examinations. The general health examinations are routine comprehensive medical evaluations aimed at the ascertaining the health status of employees. The specific periodical health examinations are aimed at detecting the effects of any specific exposure to a known health hazard, or to detecting functional impairments which may affect ability to meet work demands.

Between different countries there are considerable differences in the organization and contents of this kind of workers' health examination.

Periodontal Diseases

Synonyms

Periodontal inflammation

Definition

Periodontal diseases cover a group of inflammatory diseases that arise in the gum sulcus, the crevice between the gum and the tooth, as a response to dental plaque. Even in healthy mouths, the gum sulcus is teeming with bacteria, but they tend to be harmless varieties. If dental plaque remains in the sulcus, the population of the microorganisms changes. These bacteria and their waste products attack the crevicular epithelial cells. In order to eliminate the detrimental bacteria and their toxins the body activates his immune response to infection. This reaction passes through different stages. Due to these reactions periodontal diseases are generally divided into two groups: ► gingivitis and ► periodontitis.

Periodontal Inflammation

► Periodontal Diseases

Periodontal Ligament

Definition

Teeth are not embedded in bone directly but suspended in the socket on elastic fibers which attach the tooth by bridging the space between the ► root cement and the surrounding alveolar bone. This specialized connective tissue is called periodontal ligament.

Periodontal Pocket

Definition

In healthy conditions, there is a crevice between the gum and the tooth (gum sulcus) of about 2 mm in size. In the case of periodontitis, the alveolar bone housing the ► roots of a tooth is being resorbed and the periodontal ligament is destroyed. This loss of attachment clinically manifests as recession of the gum and deepening of the gum sulcus into the periodontal ligament to the original level of the resorbed alveolar crest, causing a periodontal pocket.

Periodontal Pocketing

► Periodontal Pocket

Periodontitis

Definition

Periodontitis is a disease involving inflammation and infection of the ligaments and bones that support the tooth. In most cases, the course of the disease is chronic. Periodontitis is the primary cause of tooth loss in adults.

Periodontium

Definition

The tissues that surround and support the tooth, including the gum, the root cement, the periodontal ligament, and the supporting ► alveolar bone.

Peripheral Nervous System

Definition

The peripheral nervous system (PNS) is the part of the nervous system that is outside the brain and spinal cord. The nerves in the PNS connect the ► central nervous system (CNS) to the sensory organs, other organs of the body, muscles, blood vessels, and glands. In contrast to the CNS, the PNS is not protected by bone. The PNS comprises the 12 cranial nerves, the spinal nerves and roots, and the automatic nerves for the automatic body functions of the body (e. g. heart muscle).

Permanent Carriers of Pathogens

► Permanent Shedders

Permanent Dentition

► Permanent Teeth

Permanent Shedders

Synonyms

Permanent carriers of pathogens; Chronic carriers of pathogens

Definition

In infections with fecal-orally transmitted pathogens, the germs are shed through the stool of the infected individual. In a small percentage of people the shedding of germs persists over a longer period of time, sometimes over months or even years. These people are called permanent shedders or chronic carriers. In general, they are asymptomatic, but they are a source of infection for other individuals. In industrial nations permanent shedders are supervised and controlled by responsible authorities and institutions. Chronic carriers have to be informed about the required hygienic rules. There may be restrictions concerning different professions: permanent shedders are not allowed to work with open food, in different sectors of the health service or in public institutions, like homes or children's nurseries.

Cross-References

► Food-Safety and Fecal-Orally Transmitted Infectious Diseases

Permanent Teeth

Synonyms

Permanent dentition

Definition

The permanent teeth replace the baby tooth (milk tooth). Usually adults have 32 permanent teeth: 8 incisor teeth, 4 canine teeth 8 ► premolar, and 12 ► molars.

Persistent Anxiety Depression

► Dysthymia

Persistent Somatoform Pain Disorder

Definition

Persons with persistent somatoform pain disorders suffer from a persistent, severe, and distressing pain, which cannot be explained fully by a physiological process

or a physical disorder, and which occurs in association with emotional conflict or psychosocial problems that are sufficient to allow the conclusion that they are the main causative influences. The result is usually a marked increase in support and attention, either personal or medical.

Personal Care Home

► Assisted Living Facilities

Personal Factors

Synonyms

Individual factors

Definition

The particular background of an individual's life and living.

Personal Health Factors

► Individual Health Factors

Personal Hearing Protection

Definition

A personal hearing protector is a device, or pair of devices, designed to be worn over, or inserted into, the ears of a person to protect hearing. It should be used if the ► noise level at a workplace exceeds 85 dB(A). There are three types of hearing protectors: earplugs, earmuffs, and helmets. Earplugs are inserted to block the ear canal. They may be premolded (preformed) or moldable (foam earplugs). Earplugs are sold as disposable products or reusable plugs. Earmuffs consist of sound-attenuating material as soft ear cushions that fit around the ear, and hard outer cups. They are held together by a headband. Helmets are worn in the noisiest conditions (by pilots and astronauts, and for weapons testing) and also provide mechanical protection for the head. In order to get full benefit, hearing protectors must be worn all the time during noisy work.

Personal Identity

► Identity

Person-to-Person Transmission Outbreak

Synonyms

Propagated outbreak

Definition

This type of outbreak does not have a common source and arises from the introduction of an infection into a susceptible population with subsequent transmission from person to person and a progressive increase in incidence.

Persons Providing Medical Treatment and Care

► Health Care Professionals

Perspective

Definition

The perspective of a health economic analysis defines the point of view of the analysis. The perspective affects the costing process but also the outcome measurement. The most common and most important perspectives are the ► societal perspective and the ► payer's perspective. Further perspectives are the health care system perspective, provider's perspective (e. g. a hospital) and patient's perspective.

Perspective Taking

► Role Taking

Pertussis

► Whooping Cough

Pertussis Vaccination

Synonyms

Pertussis immunization; Whooping cough vaccination; Whooping cough immunization

Definition

A ► vaccine against pertussis has been available since 1954. In 1960, its combination with the vaccines against diphtheria and tetanus (DPT) was introduced. Up until the 1990s, whole germ vaccines were common. These were then replaced by better tolerated vaccines, which only contain certain pathogen antigens, acellular vaccines. Pertussis immunization is generally implemented as part of the 6-fold vaccination, starting from the third month of age, with 3 inoculations at intervals of at least 4 weeks, followed by a further vaccination after 4–12 months. Only after the third injection, and not before the age of 7 months, a relatively good protective effect is achieved. The protective rate is 80–95%. Due to its decreasing effectiveness, a fifth vaccination at the age of 9–17 years is recommended. Contraindications for the pertussis vaccine are, apart from acute illness with fever and a known severe allergic reaction to components of the vaccine, the appearance of a central nervous system's disease of unknown origin within 7 days of the vaccination.

Pharmaceutical Industry

► Health Care Profession

Pharmaceutical Products

► Drugs

Pharmacodynamics

Definition

Pharmacodynamics describes what a pharmacological drug does to the body.

Pharmacoeconomics

Definition

Under the scientific discipline pharmacoeconomics, assessment of the value of pharmaceutical products and health care programs involving pharmaceuticals is carried out. Clinical, economic, and ethical issues are addressed. The most important methodological approach of pharmacoeconomic analysis is ► health economic evaluation. The field of pharmacoeconomics is interdisciplinary and covers health technology assessment, health economics, outcomes research, risk analysis, clinical research, epidemiology, decision sciences, and others.

Pharmacoepidemiology

Tatjana Pekmezović
Institute of Epidemiology, School of Medicine, University of Belgrade, Belgrade, Serbia
pekmezovic@sezampro.yu

Definition

Pharmacoepidemiology can be defined as the study of the utilization and effects of drugs in large numbers of people, such as a country's population. "To accomplish this study, Pharmacoepidemiology borrows from both Pharmacology and Epidemiology. Thus, Pharmacoepidemiology can be called a bridge science spanning both Pharmacology and Epidemiology" (Strom 2000). In general, pharmacoepidemiology (often called drug epidemiology) can be considered as the application of epidemiological methods to pharmacological issues.

Basic Characteristics

Although pharmacoepidemiology is one of the youngest epidemiological disciplines, only 20–30 years old, it has shown progressive improvements in methodology and the development of new approaches to the investigation of drug safety and effectiveness.

"Doing the studies needed to provide an estimate of the probability of beneficial effects in populations, or the probability of adverse effects in populations and other parameters relating to drug use, epidemiological methodology is essential" (Strom 2000). Some-

times, pharmacoepidemiology focuses primarily on techniques for conducting ► drug safety studies. These techniques can also be applied to pharmacoeconomic and outcome research studies.

Methodological Aspects of Pharmacoepidemiological Studies

Similar to other areas of epidemiology, in pharmacoepidemiology, both clear case and exposure definitions are critical for the success of a study. However, in pharmacoepidemiology, providing these clear definitions is more complex than in classic epidemiology, due to the following reasons: a) drug exposures are constantly varying and are thus difficult to define precisely; b) outcomes are often associated in some way to the exposure, creating biases and confounding the results and requiring essential adjustments to the study design to be fully understood (Garbe and Suissa 2005).

It is well known that new drugs must be investigated through preclinical animal studies followed by three phases (phase I, II, and III) of clinical trials in humans. But, because of flaws in design, crucial answers to questions of drug safety cannot be provided even by the most valid and complex phase III studies. Keeping in mind these facts, different types of epidemiological studies should be involved in the ► postmarketing investigation of drugs. The case-control design (► case–control studies) is the method of choice for the investigation of rare drug risks, while ► cohort studies are used to assess the risk of more frequent events or if several outcomes need to be followed simultaneously.

Confounding by Indication

Special attention in pharmacoepidemiological studies has been paid to the control of ► confounding factors, especially ► confounding by indication. This occurs when the drug investigated is selectively used or not used by those who developed the outcome of interest. Although confounding by indication is often difficult to control, there are several methods for avoiding this type of bias. One option is to restrict the study to a group of patients homogeneous with respect to disease severity. Another option is to compare two medications prescribed for the same indications, with evaluation of their relative and absolute effectiveness (Rothman and Greenland 1998).

Potential confounding variables are: changes in drug use from one part of the world to another, variations between men and women, differences in age, variations in length of time of treatment. Therefore, age, sex, geography and calendar time, must be controlled in drug-epidemiological studies.

Data Sources

Several sources of data can be used to identify both harmful and beneficial effects of drugs as well as provide information for pharmacoepidemiological studies. They are spontaneous reporting systems, multipurpose cohorts, administrative databases, large health databases (record linkage studies), physician-based databases, etc. All of these sources of data have some advantages as well as certain limitations. Intensive development of powerful computer technologies (e. g. neural networks) facilitates using large databases in pharmacoepidemiological research.

Spontaneous reporting systems were developed in the early 1960s in many Western countries especially after the "thalidomide disaster", with the aim of providing a systematic collection of information about adverse drug reactions. These systems are based on the spontaneous reporting of suspected adverse drug reactions by physicians, dentists, pharmacists, and other health professionals. Trained reviewers then analyze every report to estimated the likelihood that the drug intake is causally linked to the adverse reactions (Wiholm et al. 1994).

Multipurpose cohorts are usually used to investigate two or more different research hypotheses at the same time. Today, these cohorts (for example, US Nurses' Health Studies I and II) have been extensively used to investigate a specific pharmacoepidemiological research question, such as, for example, the association between nonsteroidal anti-inflammatory drugs and Parkinson's disease (Chen et al. 2003).

Administrative databases (for example, Health Databases in Saskatchewan in Canada) "consist of patient-level information from two or more separate files which can be linked via a unique patient identifier contained in each file" (Garbe and Suissa 2005).

Drug Utilization Studies

► Drug utilization studies are also an important tool in pharmacoepidemiology. They are conducted to improve

rational drug use and to provide data for ► cost-benefit analyses. Both qualitative and quantitative approaches are used in these studies. In qualitative studies, the appropriateness of drug prescribing is estimated, while quantitative ones are undertaken for various purposes, such as, providing information about the quantities of drugs consumed in a specific period of time and/or in a specific geographical area. Additionally, these studies can be used to determine trends in drug use according to the demographic characteristics of populations, etc. (Garbe and Suissa 2005).

Department of Medicine, University of Pittsburgh,
Pittsburgh, PA, USA
romkes@dom.pitt.edu

Definition

Pharmacogenetics is the study of the inter-individual differences in responses to drug treatment resulting from polymorphisms or mutations in DNA sequence. In these studies the differences among individuals with regard to the clinical responses to individual drugs are determined. Pharmacogenomics expands upon this definition to include the study of the genome and its products, both RNA and proteins.

Basic Characteristics

With the recent advances in the human genome sequencing project, one of the initial applications is the emerging field of pharmacogenomics. Pharmacogenomics encompasses both the prediction of disease susceptibility and drug response. Given the fact that the underlying mission of public health is to prevent disease and improve health, tools which can be used as biomarkers of disease susceptibility and outcome are critical. Currently, the majority of pharmacogenomics based assays are focused on identifying individualized drug therapy strategies for treatment of disease, but as current translational research efforts continue, pharmacogenomic endpoints have the potential to provide a vast array of tailored intervention targets to prevent disease.

The human genome is made up of approximately three billion nucleotides that code for all the macromolecules necessary for human life. The most common human genetic variations are ► single nucleotide polymorphisms (SNPs), which are defined as DNA sequence variations that occur when a single nucleotide (A, T, C or G) in the genome sequence is changed (Cooper et al. 1985). It is estimated that only one in every thousand bases is different, or that the DNA code is

approximately 99% identical between human subjects. The SNPs may occur in coding and noncoding regions, and may or may not result in altered gene expression or gene products. Even SNPs that do not themselves change protein expression and cause disease may be close on the chromosome, i. e. in ► linkage disequilibrium (LD) to deleterious mutations. Recently, it has been recognized that the genome is organized into largely invariant DNA fragments at the population level characterized by rare recombination events intermingled with "hotspots" of recombination and designated as "haplotype blocks". These haplotype blocks can be determined by creating a dense map of SNPs across the gene of interest and analyzing population level LD. A few SNPs can then be selected which designate ("tag") each haplotype block and these htSNPs can be screened to comprehensively assess disease associations across the entire gene. Applying this approach to multiple genes in pathways critical to disease development and assessing combinations of genes is likely to increase the power to discover genetic associations with specific disease risk. Haplotype-based association studies are powerful procedures for detecting genetic influences on complex diseases (Daly et al. 2001; Gabriel et al. 2002; Stram 2004). Such markers help unearth the mutations and accelerate efforts to find therapeutic drugs.

Applications

Using cancer as an example of the disease model, pharmacogenomic based tests can be used in three important ways as markers to predict drug response and efficacy, to screen for markers of disease susceptibility and as markers of disease prognosis and outcome. The initial emphasis in identifying cancer susceptibility biomarkers focused on association studies evaluating both phase I and II metabolic enzymes, particularly among tobacco smokers. More recently, the panel of candidate markers has extended to screening for genetic polymorphisms in DNA repair enzyme pathways, immune response genes and a variety of growth factor signal transduction pathways. Although multiple risk factors have been characterized in several large scale genetic epidemiological studies, further studies are ongoing and required prior to translation to routine clinical screening tests. The discovery of common low-penetrant genes that are associated with cancer risk, either directly or through interaction with environmental exposures, particularly smoking, would be of great importance, and would open new avenues of prevention. Studying the relationship between a gene and disease has evolved into haplotype-based approaches to provide greater information about genes and pathways and to evaluate how variation relates to cancer risk (Wu et al. 2004; Spitz et al. 2005; Buch et al. 2005).

Not only are these pathways relevant in determining risk of cancer or other diseases, they may also represent markers of disease prognosis and outcome. A growing number of studies are evaluating these potential associations. For example, it is well known that the nucleotide excision repair (NER) pathway is important in the repair of chemical carcinogen, induced genotoxic damage including that induced by tobacco carcinogens. There are several ongoing studies evaluating the association of NER gene polymorphisms and haplotypes with tumor recurrence and overall survival and initial data has shown poorer survival among individuals carrying NER gene polymorphisms associated with reduced DNA repair capacity (Wu et al. 2004; Spitz et al. 2005; Buch et al. 2005).

In addition to these studies of pharmacogenomic endpoint and disease risk and prognosis, the possibility of using these markers in the search for improved chemotherapeutic efficacy is growing. Many cancer chemotherapeutic agents, including cis-platinum, cause interstrand breaks and consequently cytotoxicity. Several recent studies have shown that reduced NER DNA repair capacity may be associated with enhanced response and survival with platinum-based chemotherapy. Despite the frequency of resistance, the use of platinum based therapies will remain the current practice for chemotherapeutic regimens for some time to come, until novel agents that target specific therapeutic targets are available. In the meantime, however, it would be highly beneficial to develop strategies to identify subjects most and least likely to benefit from platinum based agents to reduce the frequency of adverse side effects and improve outcomes (Wu et al. 2004; Rosell et al. 2003; Gurubhagavatula et al. 2004).

Several of the first US Food and Drug Administration (FDA) approved pharmacogenomic tests are in fact tests that are relevant for cancer treatment. In August 2005, the FDA approved a test marketed by Third Wave, the Invader *UGT1A1* Molecular Assay, to screen for polymorphisms in the UDP-glucuronosyltransferase enzyme, which is involved in the metabolism of a num-

ber of drugs, including irinotecan, a drug used in colorectal cancer treatment. *UGT1A1* genetic variations can modulate a patient's ability to metabolize irinotecan, which may lead to increased blood levels of the drug and a higher risk of adverse side effects. For patients with specific *UGT1A1* genetic polymorphisms, a dose of irinotecan that is safe for another person might be too high for these patients, raising the risk of certain side effects. The Invader assay joins a growing list of genetic tests used by clinicians to personalize treatment decisions, including the Roche AmpliChip, used to individualize dosage of antidepressants, antipsychotics, beta-blockers, and some chemotherapy drugs (Food and Drug Administration 2005).

The FDA has also approved the product label for 6-mercaptopurine (Purinenthol and Imuran) to include information about the pharmacogenetics of thiopurine methyltransferase (*TPMT*)(Food and Drug Administration 2005). Patients with low or absent TPMT activity are at an increased risk of developing severe, life-threatening myelotoxicity if receiving conventional doses of 6-MP (Huang et al. 2006). As noted above, there is a growing awareness that it is not only important to consider pharmacogenomic tests, such as *TPMT*, in the context of optimal treatment in the short-term and avoidance of adverse events, but also to consider the overall risk/benefit of such testing in the context of overall drug efficacy and disease outcome. Relling et al. have studied this question for TPMT and found that individualization of 6-mercaptopurine dose based on *TPMT* genotype could be used to avoid toxicity without compromising efficacy (Rocha et al. 2005). This may not be true for all pharmacogenomic tests however.

As additional pharmacogenomic endpoints are characterized and validated as markers of disease susceptibility and outcome and particularly as markers of drug response, it is important to also consider the implications of such genetic testing in the context of public health. While many of the recent technological advances make it more economical and simple to perform these tests for a given individual, there are many potential barriers to the implementation of these tests. These barriers include possible privacy or discrimination issues not only with reference to insurance and employment questions, but also in terms of general societal acceptance. It is also important to consider who will pay the associated test costs and the availability of the tests for ethnically and geographically diverse populations. A third significant barrier is possible negative psychosocial consequences. Currently there are several commercial laboratories in the US which have made several genetic tests available to the general public. However, the results of these tests are provided directly to the patient in the absence of clinical and genetic counseling. This may lead to significant confusion and misuse of the genetic results. For example, one test currently available is for *CYP2D6*, an enzyme involved in the metabolism of up to 20% of commonly prescribed medications including antidepressant/psychotics, antiarrhythmics, and beta-blockers. However, some of these drugs are active as prodrugs, for others, the metabolites are the active agent, so the fact that an individual is a *CYP2D6* poor metabolizer means that they may be at increased risk of adverse events for some *CYP2D6* drugs, but not all *CYP2D6* drugs. Further, over 70 allelic variants in the human *CYP2D6* gene have been identified, many of which are associated with either decreased or enhanced metabolic activity. Unless the genetic test screens for all of these variants, even though some variants may be very rare, there is the potential for misclassification. For the average patient, these implications may not be understood when the results are provided without professional counseling. Both the Human Genome and HapMap projects have identified these and other ethical, legal and social issues, but clearly society as a whole will need to consider these issues as the science of genetics and its applications continues to rapidly move forward. Increased education of both the clinical professionals and the lay public are required before the promise of pharmacogenomics as a tool for improved public health and individualized medicine can be achieved.

Pharmacokinetics

Definition

Pharmacokinetics describes what the body does to a pharmacological drug.

Phenotype

Definition

Phenotype describes the (clinical) consequences of a certain ► genotype (► mutation) or, in general, the observable characteristics of an individual as a whole. Depending on the pathophysiological level, the phenotype can be described as biochemical changes (e. g. altered protein level) or on a morphological level (appearance).

Philosophy

Synonyms

Love of Wisdom

Definition

In philosophy, there is an attempt to analyze ones own thoughts on a rational self-examination basis. A moral contemplation with a tendency to determine the reason behind the world's existence and also that of mankind. The science of philosophy was defined as "something you can not talk about" without first becoming involved in its work.

Phobic Anxiety Disorder of Childhood

Definition

Fears in childhood that show a marked developmental phase specificity and arise (to some extent) in a majority of children, but that are abnormal in degree.

Phoniatrics

► Speech Therapy

Phtisis

► Morbus Koch (Koch's Disease)
► Tuberculosis and Other Mycobacterioses

Physical Activity

CHRISTINE GRAF, DIRK STEINBACH
Deutsche Sporthochschule Köln, Köln, Germany
c.graf@dshs-koeln.de, steinbach@dshs-koeln.de

Synonyms

Fitness; Sport; Exercise

Definitions

Physical activity covers all muscular activities that go hand in hand with a verifiable increase in energy expenditure. It includes the wide-ranging possibilities of enhancing energy consumption. In literature, the following terms are generally used to describe it: ► *exercise, non-exercise-activity thermogenesis (NEATs), sports and exercise.* The boundaries are seamless, the definitions are not clear.

Physical activity is a broad term that encompasses all forms of muscle movements. These movements can range from sports and exercise to lifestyle activities. It is frequently referred to as movement involving a minimal increase in energy expenditure. In another definition, however, physical activity means repetitive, structured movement aimed at enhancing a person's fitness.

Sports and exercise can be distinguished as subcategories of leisure-time physical activity in which planned, structured and repetitive bodily movements are performed to improve or maintain one or more components of ► physical fitness (Hardman and Stensel 2003). Exercise may be classified in one of two categories, anaerobic and aerobic, depending on where energy is derived from depending on intensity and duration. There is a distinct difference between the two, and specific training techniques are needed to enhance both. As such, *physical fitness* can be construed as a subcategory of a person's global fitness which is determined by exertion and effort processes involved in certain sporting activities. Fitness is also determined by mental, emotional and psychosocial factors.

► Non-exercise activity thermogenesis (NEAT) describes the energy consumption of all physical activities other than volitional sporting-like exercise. It includes all the activities that render us vibrant as working, posture, etc.

Basic Characteristics

Recommendations

Regular moderate training will provide optimal health benefits. In addition, it has become apparent that there is a positive dose-response relationship between frequency and intensity, in other words the more exercises, the more benefit. An increase in physical fitness reduces the risk of cardiovascular disease and mortality. To this end, more than 700 kcal (► Kcal – kilocalories) per day should be burnt off through exercise. The guideline for adults is to participate in physical activity for 30 minutes each day, children should spend 60 minutes each day engaging in physical activity, either en bloc or in "single 10-minute doses". The focus here is on endurance training. It can be controlled through the ► heart rate, among other things, and should be carried out at around 50 to 70% of the maximum heart rate or 40 to 60% of maximum oxygen intake capacity. Perception of exertion can also be used to control intensity with the help of the BORG scale (► BORG scale / RPE scores). In this case, training should be carried out in such a way that the intensity is perceived as low to moderately hard (Borg scale 11–13). In addition, moderate strength training should be carried out at least two days per week. The resistance level should be set so that the respective exercise can be repeated 10 to 12 times.

Epidemiology

In Germany, around one third of men (37.3%) and women (38.4%) do not engage in any kind of physical activity, 20.9% of men and 28.4% of women engage in some kind of sporting activity for more than 2 hours per week. As such, there is an inverse correlation between a person's age and their socio-economic status. Similar data is also found in Europe where around 40% of people are physically inactive (HEPA), with the definition of physical inactivity apply to those who spend less than 3.5 hours per week engaging in physical activity. Eurobarometer came up with similar results. The World Health Organization assumes that approximately 60% of the global population do not participate in the recommended 30 minutes of physical activity each day.

Benefits

The benefits of physical activity have meanwhile been proven through a large number of studies. Some of the health benefits include improved ► carbohydrate metabolism and ► lipometabolism, reduction in weight and blood pressure, positive influence on the blood coagulation. The key benefit in terms of prevention is that a person who exercises lowers the risk of developing cardiovascular disease by approximately 30%, and lowers the risk of suffering a stroke by 40%. They can also lower their risk of cardiovascular disease (e. g. arterial hypertension, diabetes mellitus, obesity, etc.). Persons who engage in physical activity are 30 to 40% less likely to develop cancer, particularly colon and

breast cancer and are 20% less likely to suffer fractures caused by osteoporosis. Regular physical activity also has a positive impact in relation to the aforementioned diseases in terms of secondary and tertiary prevention.

Methods of Analysis and Parameters

It is difficult to record the methods used to measure physical activity which is always prone to errors. As a rule, people are asked about their participation in physical activity in writing and verbally (type of sport, frequency and intensity of physical activity). However, this method is always dependent on the interviewer's subjective rating; observations and video monitoring are more objective, but they depend to an even greater extent on the situation being observed. This explains why measuring methods that record the fitness parameters are more objective, such as those used, for instance, within the framework of ergonomics (bike, treadmill, relating to specific types of sport). They included the maximum oxygen intake (peakVO2) once the maximum level of exertion has been reached (VO2max is the maximum value that can be reached, even if the level of exertion is increased once a plateau is reached) as well as the maximum wattage. These values are always measured against a person's weight. Additional rating variables are the maximum running speed (usually in m/sec) as well as the so-called ► metabolic equivalents (METS). Metabolic equivalents are the factor by which the oxygen intake at rest is increased by certain physical activity. METS can also be converted into kilocalories (factor 1.2). Exertion of less than 3 METS (or 4 kilocalories = 15 kilojoules consumption per minute) is considered to be low, between 3 and 6 METS (4 and 7 kilocalories or 15 to 29 kilojoules) as moderate physical activity and over 6 METS (7 kilocalories; 29 kilojoules) as ► vigorous physical activity. ► pedometers and ► accelometers are frequently used to determine calorie consumption and/or METS. The so-called BORG scale represents one possibility of quantifying a persons' rate of perceived exertion. The so-called rate of perceived exertion or RPE scores begins with very, very light = 7 and ends at 19 = very, very hard. The intensity perceived by the subject at a certain level of exertion is indicated as an average as the heart rate divided by 10. Anyone who perceives the activity to be "easy" or 11 has an average heart rate of 110.

An average exertion of between 3 and 6 METS corresponds more or less to an ergonomic exertion of 75 to 100 watts. Intensive physical activity refers to a rate of perceived exertion of 15 or more, a metabolic equivalent of more than 6 MET or a thermogenesis of more than 29 KJ/min and 7 kcal/min. If the person engages in this level of physical activity on a regular basis, this is equivalent to five days of moderate or mild activity or several days of intensive exertion.

Definition

Specification of consequences of disasters in the physical, environmental, and social domains.

Basic Characteristics

The consequences of a disaster (► hazards, natural; ► hazards, technological) fall into categories of physical, environmental, and socio-economic damage.

After a major disaster, such as an earthquake, many buildings are damaged (e. g. totally ruined or deprived of windows, roofs, and walls) or rendered unsafe, hence uninhabitable. Settlements and towns may turn into a sea of rubble, large dumping sites with disordered remnants of infrastructure and human belongings, and human bodies (or parts thereof). Utilities are typically discontinued. There may be no electricity, gas, telephone, or safe water, and food supplies can be spoiled. There is often severe damage to infrastructure, including public buildings, health care buildings, clinics and hospitals, schools, and post offices, etc. Transport infrastructure may also be damaged, disabled, or destroyed: roads, railways (and railway stations), bridges, airports, and vehicles – cars, trains, and planes. Levees and irrigation channels may be damaged, affecting large croplands, and agriculture and horticulture farms themselves. There can be vast damage to industrial installations, commercial buildings, and to personal property.

The environment can be contaminated by floating chemicals, e. g. fuel oil, animal carcasses, and other toxic debris. Water pollution may accompany both floods (flush of agricultural chemicals to rivers and lakes, causing fish kill) and droughts (little water available for dilution under low water stage and discharge situation).

Socio-economic impacts can be represented by several indices. The principal two classes of indices are the number of fatalities and the aggregate economic damage.

Consequences of disasters can be divided into direct ones (caused directly by disasters) and indirect ones, which may occur over a longer period of time (e. g. health effects emerging years after a nuclear accident). Detection of changes in the time series of health-related indices and attribution of the changes (e. g. to a disastrous event) are very difficult. Even identification of "disaster-related deaths" (additional or excess deaths) in a region devastated by a disaster causes considerable methodological problems.

Disasters kill and wound people and ruin their livelihoods and life perspectives. There is a lot of disaster-related suffering (e. g. due to loss of loved ones, disaster-related starvation, being wounded), morbidity (e. g. infectious diseases), hardship, stress, and feelings of helplessness and humiliation. The accustomed sense of security disappears. Some people's only remaining possessions are the clothes on their backs. Survivors leave their communities for the relative safety of displacement camps.

Since disasters ruin the domiciles of many of those evacuated, the problem of homelessness arises. Disasters paralyze social systems. Many businesses are damaged to different extents, and all are closed in the immediate aftermath. There is a temporary loss of many jobs, some of which may disappear permanently. Yet, reconstruction creates an emerging opportunity for employment, economic growth, and better disaster preparedness.

In the disaster aftermath (► Disaster aftermath), a new image of the community emerges from the disaster. Municipalities that functioned very well in normal conditions may fail completely after disasters strike. Urban areas in the developed world may temporarily lose their modern infrastructure and may be downgraded below the level of rural Third World communities.

Typical conveniences such as immediate repair of a damaged power line, mail delivery, or a functioning public phone or automatic teller machine become difficult to access. House repair services cannot meet the demand; hence, some residents may endure life without a roof or a cooked meal for months.

In some cases, disasters may lead to mobilization of dangerous chemicals from storage or remobilization of chemicals already present in the environment, e. g. pesticides. Hazards may be greater when industrial or agricultural land adjoining residential land is affected. Increases in population density and accelerating industrial development in areas subject to natural disasters increase the probability of future disasters and the potential for mass human exposure to hazardous materials released during disasters.

Physical Fitness

Definition

Sub-category of a person's global fitness which is determined by exertion and effort processes involved in certain sporting activities. Fitness is also determined by mental, emotional and psychosocial factors.

Physical Maturation

Synonyms

Physical development

Definition

Physiological changes, such as increase in height and weight, pubertal and sexual maturation, changes in body composition (the quantity and distribution of fat and muscle), and changes in circulatory and respiratory systems (which lead to increased strength and tolerance for exercise), occur between 9 and 16 years of age. The growth spurt occurs about 2 years earlier in girls compared with boys.

Physical or Mental Impairment

► Disability

Physical and Social/Cultural Environments

► Setting

Physical Therapy

Definition

Physical therapy is a branch of rehabilitative care that uses specially designed exercises and equipment to help patients develop, restore, and preserve their physical function. Physical therapy is characterized by the examination, treatment, and instruction of the patient

to detect, evaluate, prevent, correct, mitigate, and minimize physical disability, movement dysfunction, bodily dysfunction, and pain from injury, disease, and other physical or mental conditions. Physical therapists usually work with patients from all ages, including infants born with musculoskeletal birth defects, adults suffering from the after-effects of injury, and elderly post-stroke patients.

Physiological Functions

Definition

Body functions and systems (including psychological functions).

Cross-References

► Body Function

Phytoremediation

Definition

Phytoremediation describes the treatment of polluted soils or other environmental problems through the use of plants able to contain, degrade, or eliminate metals, pesticides, solvents, explosives, and crude oil and its derivatives. Phytoremediation comprises efficient, inexpensive, and non-environmentally disruptive processes like phytoextraction—uptake and concentration of substances into the plant biomass; phytostabilization—reduction of the mobility of substances in the soil; phytotransformation—(phytostabilization, phytodegradation) chemical modification of substances; phytostimulation—enhancement of soil microbial activity for degradation (rhizosphere degradation); and phytovolatilization—release of less polluting substances into the air. Phytoextraction (or phytoaccumulation) uses plants to remove contaminants from soils or sediments and turn them into harvestable plant biomass. The plants also absorb contaminants and store them in the root biomass, so the growth/harvest cycle must usually be repeated through several crops to achieve a significant cleanup. Examples of phytoextraction from soils are cleanup of arsenic and uranium using sunflowers, cadmium and zinc using Alpine Pennycress, and lead using Indian Mustard, Ragweed or Poplar trees. Evidence shows that the metals in hyper-accumulating plants give them protection from various bacteria, fungi, and/or insects. In the case of organic pollutants, such as pesticides, explosives, solvents, industrial chemicals, and other xenobiotic substances, certain plants, such as Cannas, render these substances less toxic. The limitations of phytoremediation include applicability only on the surface and depth occupied by the roots, the long-term commitment required due to slow growth, and possible bioaccumulation of contaminants, which then pass into the food chain.

► Psychogenic Loss of Appetite

Piggy-Back Analysis

Definition

A piggy-back trial is an economic analysis, in most cases an economic evaluation study, which is embedded in a clinical trial. Additional economic cost and outcome data are collected and analyzed, but the trial itself is designed according to clinical issues.

Pigmy Peoples (Central and Western Africa)

► Indigenous Health – Africa

Ping Pong Disease

► Ping-Pong Infection
► Trichomoniasis

Ping-Pong Effect

Synonyms

Re-infection

Definition

The phenomenon in which sexual partners re-infect each other with the same sexually transmitted disease (STD). First, an individual who has the STD infects his or her partner. The partner may then re-infect the individual, after the individual has been cured from that particular STD. Individuals and their partners may or may not be aware that they have an STD, since symptoms are not always present. To prevent the ping-pong effect, both partners should be treated for STDs simultaneously.

Ping-Pong Infection

Synonyms

Ping Pong effect; Reinfection in sexually transmitted diseases; Reinfection in social diseases; Reinfection in veneral diseases

Definition

In all cases of sexually transmitted diseases, which can be treated medicinally, it is recommended that all sexual partners be treated. This recommendation is given due to the fact that the partners, most probably, will be infected as well. As sexually transmitted diseases do not give immunity, a new infection is possible at any time. Without consequent therapy, a recurrent infection from one partner to the other can easily take place.

Pinworm Infection

► Enterobiasis

Placebo

Definition

A placebo is a dose that looks like the medicine being tested but, in fact, contains no medical ingredients. It is given in ► clinical trials to a control group in order to have some sort of comparison for the medicine being tested.

Placebo Controlled

Definition

Placebo controlled describes a method of research in which an inactive substance (a placebo) is given to one group of participants, while the active treatment (usually a drug or vaccine) that is being tested is given to another group. A placebo is a medicine without any inherent pertinent pharmacological activity, but which is effective only by virtue of the factor of suggestion attendant upon its administration. The results obtained in the two groups are then compared to see if the investigational treatment is more efficacious than the placebo.

Placebo Effect

Definition

A placebo effect is the psychological effect that a medical treatment can have on patients. The perceived effects of placebo are usually but not always beneficial. They are due to the power of suggestion.

Plague Sepsis

Synonyms

Septic course of infection with Yersinia pestis; Black Death sepsis

Definition

Plague sepsis is caused by the hematogenic spread of *Yersinia pestis*. The onset of the disease is characterized by high fever and shivering fits. Without treatment the course is lethal within 36 hours.

Planned Behavior Theory

Synonyms

Theory of health behaviors

Definition

The theory of planned behavior is an extension of the theory of reasoned action. Both models may be considered as information processing models. It is hypothesized that behavioral decisions are based on careful evaluation of all available information. The theory of planned behavior introduces the concept of compatibility. This is based on the assumption that each attitude and behavior has elements of action, target, context and time. The congruence between attitudes and behavior is assumed to be greatest if both have the same level these elements.

► Dental Plaque

Plasmodia

Synonyms

Germs that cause malaria; Malaria causing parasites

Definition

Plasmodia are single-celled eukaryotes of the class Sporozoea, which cause malaria. They depend on the biosphere of the *Anopheles* mosquito. For their cycle of development they need warm temperatures. Among the more than 120 species of plasmodia, 4 are transmitted to humans and can cause malaria: *Plasmodium ovale* (causing malaria tertiana), *Plasmodium vivax* (malaria tertiana), *Plasmodium malariae* (malaria quartana) and *Plasmodium falciparum* (malaria tropica). Depending on the species, the incubation period varies between 7 and 24 days. While *Plasmodium ovale* is primarily found in West Africa, the other species appear in all regions endemic for malaria. With an incidence of >95%, *Plasmodium vivax* is the predominant species in Central America, parts of South America, and the southeastern countries of Africa. The percentage of *Plasmodium falciparum* varies considerably in different regions; it is the predominant species in Haiti, the Dominican Republic, Africa and Papua New Guinea.

Plasticity

Synonyms

Multilineage potential

Definition

By definition, stem cells can differentiate into various cell lineages. This property is termed plasticity or multilineage potential. For instance ASC derived from the bone marrow are able to differentiate into parenchymal cells of different organs, like hepatocytes.

Plastic Surgery

Definition

Plastic surgery is the branch of surgery that covers the reduction of scarring or disfigurement that may be the result of accidents, birth defects, or treatment for diseases. Many plastic surgeons also offer cosmetic surgery, which is unrelated to medical conditions and has been a growing field in developed countries in recent years.

Pleasant Taste

Synonyms

Enjoyment of food

Definition

The enjoyment of food is a sensual experience associated with eating. Enjoyment is connected with seeing, hearing, tasting, smelling and touching and assumes a certain sensory perception.

Pluripotency

► Multipotency

Pneumococcal Vaccination

Synonyms

Pneumococcal immunization

Definition

In 1977 the first pneumococcal ► vaccine was licensed, containing 14 serotypes. For children aged 2–23 months, the pneumococcal conjugate vaccination (PCV) is recommended, which recognizes seven forms of the capsule (heptavalent). Starting from the third month of age three inoculations are given at intervals of at least four weeks (preferably at 2, 4 and 6 months of age). A fourth dose in the series should be applied at the age of at least 12 months. From two years of age, the pneumococcal polysaccharide vaccination (PPV), which recognizes 23 forms of the capsule, can be used. Its protective efficacy reaches 60–70%. Pneumococcal vaccination is recommended for people facing a high risk of serious pneumococcal disease. Such groups include persons with HIV-infection, chronic organ failure, sickle-cell disease, splenectomized patients, and the elderly population, particularly those living in institutions. Booster vaccination should be given every six years. Contraindications for the pneumococcal immunization are acute illness, including febrile illness, a known allergy to any component of the vaccine or an allergic reaction to a previous dose of pneumococcal vaccine.

Pneumoconioses

Definition

According to the ILO definition, this is the accumulation of dust in the lungs and the tissue reactions to its presence. For the purpose of this definition, 'dust' is an aerosol composed of solid inanimate particles. In American literature pneumoconiosis has been defined as lung disease resulting from the chronic inhalation of inorganic dust. The pneumoconioses make up a class of respiratory diseases attributed solely to occupational exposures. They include the major fibrotic lung diseases such as asbestosis, coal workers' pneumoconiosis, and silicosis as well as rarer interstitial diseases such as siderosis and berylliosis. Some authors include byssinosis in this category, though it differs substantially in its pathology and clinical manifestations.

Pneumonia

Definition

Pneumonia is an inflammation of the lung caused by infection with bacteria, viruses, and other organisms. Pneumonia that is contracted within the hospital is called hospital or nosocomial pneumonia. The most important risk factor for hospital pneumonia appears to be mechanical ventilation and tracheal intubation. Pneumonia is the most common infection in intensive care units. Gram-negative bacteria and staphylococci are the predominant causes of hospital pneumonia.

Podiatrists

Synonyms

Chiropodist

Definition

A podiatrist is a physician specialized in assessment and treatment of diseases of the foot, ankle, and in some cases lower extremities like the knee and leg. The treatment methods might be conservative or via surgery. Potential subspecialties are reconstructive foot and ankle surgery, diabetic foot and wound care, rheumatology, gerontology, and sports medicine.

Poisson Distribution

Poisson distribution is a probability distribution of the number of random events occurring over a fixed period of time or fixed space. The probability function is given by:

$$P(X = x) = \frac{e^{-\lambda}}{x!}\lambda^x,$$

where x is number of random event, e is approximately 2.72, λ is the mean frequency of random events in a fixed period of time or fixed space. The occurrence of an event over any fixed period of time or fixed space is independent on the occurrence of an event over any other period of time or space. The Poisson distribution depends on one parameter, λ. This value is identical to the mean and the variance of Poisson distribution.

Poisson distribution is often used to describe probability models for a number of discrete events which are considered as rare for a given period of time or space. For example, a number of errors in a medical record, a number of phone calls in an emergency unit, or the number of bacterial colonies in a certain area. Poisson distribution can be used to approximate the binomial distribution when the number of observations is great and the probability of the event of interest is small, for example, congenital malformation.

Police Powers

Synonyms

Danger defense powers

Definition

Police powers denote the constitutional powers of states deriving from the people that are designed to avert dangers and to defend the population from harm as well as from violations of law and order. Based on the police powers, the state and its institutions are entitled to take measures to safeguard and promote the public's health and to protect the legal and social order.

Policy

Definition

A policy is a plan of action to guide decisions and actions. The term may apply to government, private sector organizations and groups, and individuals. The policy process includes the identification of different alternatives, such as programs or spending priorities, and choosing among them on the basis of the impact they will have. Policies can be understood as political, management, financial, and administrative mechanisms arranged to reach explicit goals.

Policy Analysis

Ulf Maywald
Abteilung Ärzte/Apotheken, AOK Sachsen, Dresden, Germany
ulf@maywald.com

Definition

Policy analysis is the systematic evaluation of alternative means of achieving social goals. It is frequently deployed in the public sector but is equally applicable to other kinds of organizations, like the healthcare system. Policy analysis refers to the analysis of existing or prospective policies with the intention of improving social welfare. Policy analysis is methodologically diverse using both qualitative (► qualitative research) and ► quantitative research methods, including ► case studies, ► surveys, ► statistical analysis, and ► model building, among others.

Basic Characteristics

In the context of this definition, health technology assessment (HTA) has been defined as "a form of ► policy research that systematically examines the short- and long-term consequences (in terms of health and resource use) of the application of a health technology, a set of related technologies or an technology related issue" (Henshall et al. 1997). HTA focuses on policies, especially policies related to regulation, quality, and payment for care. The target is to develop assessments useful for health policy makers and policymaking. Different groups in health care systems may require health policies and HTA (Banta, Oortwijn 1999):

- Research and Development
- ► Regulation of pharmaceuticals and equipment
- Regulation of numbers and location of services
- Payment for services
- Quality assurance
- Education and training of providers
- Consumer education
- Implications

These topics are differently weighted in the particular health care systems of different countries. In Germany, for example, HTA plays an important role when deciding on the payment for services, whereas it is de facto irrelevant for decisions on pharmaceuticals prepared

by the ► IQWiG (the German institute for quality and economic viability in the healthcare system). However, in the UK, the opposite is true regarding decisions by the ► NICE (National Institute for Health and Clinical Excellence).

All the assessment reports mentioned intend to allow the transfer of knowledge produced in scientific research to the decision-making process. HTA collects and analyzes evidence from research in a systematic and reproducible way, to make it accessible and usable for decision-making purposes.

Policy Question

At the origin of an assessment, there is a decision to be made. Decision-makers have to pose a policy question and this is then transformed into the correct research questions by the commissioners. Formulating research questions is a crucial part of the assessment; they transpose the original decision-making problem, the policy question, into questions that can be answered by evaluating scientific evidence. Different factors of the health care system concerned with defining the policy question can be involved in the assessment, like politicians, health care providers, hospital managers, etc.

HTA in Decision-Making Processes of Health Care Institutions in Germany

The development of the German HTA system and the corresponding HTA law began in the year 2000. In 2004, the law on the modernization of statutory health insurance established two new institutions, the Federal Joint Committee (G-BA) and the IQWIG. They are the most important institutions for the assessment of health services in the German Health Care System. Beside these political institutions, other associations like the medical review board of the SHI, hospital owners, or private health insurers use HTA as a basis for decision-making. However, like in any other country, problems in the identification of appropriate HTA authors without ► conflicts of interests exist.

Output of Health Technology Assessment

HTA can provide input into the decision-making process of the health system. It can be applied to assess the potential consequences of medical interventions, organizational interventions, and even of health care reforms. HTA can show decision makers the potential effects on health and the consequences for the health system, as well as those for the economy and the society into which a technology is to be introduced or excluded (Velasco-Garrido, Busse 2005).

Policy Networks

Definition

The concept of policy networks is based on clusters of actors, each with an interest, or 'stake' in a given policy sector and the capacity to help determine policy success or failure. It has been developed and refined as a way to try to describe, explain and predict the outcomes of policy-making.

Policy Research

Definition

Policy research means research and education on issues of government, politics, economics, and social welfare.

Policy relevant research should facilitate public dialog to assist policymakers in understanding the impacts of public policies and programs.

Polio

Synonyms

Poliomyelitis; Infantile paralysis; Cripple disease; Heine-Medin disease

Cross-References

► Infectious Diseases in Pediatrics

Poliomyelitis

Synonyms

Polio; Infantile paralysis; Cripple disease; Heine-Medin disease

Definition

Poliomyelitis, which is caused by the poliovirus, can be transmitted fecal-orally as a smear infection, by droplets as an aerosol infection or by contaminated articles. Up to 95% of the infections are asymptomatic, but the infected person sheds the virus in feces and thus can transmit the disease to other individuals. The symptomatic course is similar to a flu-like infection, but sometimes the meninges (meningitis) are involved. In 0.1% infected persons, mostly in children younger than five years of age, polio takes a paralytic course. Usually, flaccid paralysis involves the legs. The onset is sudden, sometimes within a few hours – the child, who had been healthy the evening before, shows the typical "morning paralysis." In most cases, paralyses vanish within one year, but damage may be long term causing permanent invalidity. Poliomyelitis may cause uneven growth of the extremeties. Paralysis can be lethal in up to 20% of cases. The virus can be detected in stool, pharyngeal secretions and cerebrospinal fluid. The most important preventive measure is active poliomyelitis-vaccination (► immunization, active). A worldwide eradication of poliomyelitis is possible (► surveillance and outbreak management of infectious diseases). This is due to two facts: humans are the only reservoir for polioviruses (monkeys are possible transmitters, but this can be neglected), and, the virus cannot survive outside the human organism for any length of time.

Polio Vaccination

Synonyms

Polio immunization; Poliomyelitis vaccination; Poliomyelitis immunization

Definition

In 1955, an inactivated poliomyelitis ► vaccine (IPV) was developed and introduced, followed in 1962 by an oral vaccine with weakened viruses (OPV). The effectiveness of the vaccination is almost 100%. In rare cases after oral vaccination, a "vaccine-associated paralytic poliomyelitis" (VAPP) may develop, which is observed as flaccid paralysis. For this reason, IPV has become the treatment of preference. From the third month of age, basic immunization is generally implemented three times as part of the 6-fold vaccination, or twice when no pertussis component is involved, at intervals of at least 4 weeks, followed by a further vaccination after 4–12 months. Booster vaccinations should be given every 10 years thereafter. Contraindications for the polio vaccine are acute illness with fever, and a known severe allergic reaction to components of the vaccine.

Politics

Definition

The word politics stems from the Greek word Polis, referring to Town or Community. Political science is partly involved in the humanities field with well-established political structures and political content with political processes.

Politics has been defined in many ways. In general, politics is a process by which groups make decisions. Although the term is generally applied to behavior within governments, politics is observed in all human group interactions, including corporate, academic, and religious institutions.

Polity

Definition

Polity is usually a general term that refers to the political organization of a group. It is used to describe a loosely organized society such as a tribe or community, but can mean any political group including a government or empire, corporation or academy.

Polluted Water

► Contaminated Drinking Water

Pollution

Synonyms

Contamination; Toxic waste

Definition

Pollution is the release of chemical, physical, biological or radioactive contaminants into the environment. Principal forms of pollution include: air pollution, water pollution, radioactive contamination, noise pollution and light pollution. It is undesirable that the natural environment should be contaminated with harmful substances as a consequence of human activities.

Pollution Prevention Hierarchy

Definition

Pollution prevention is efforts that reduce or eliminate the toxicity of wastes. The Pollution Prevention Act of 1990 set up a hierarchy of preferred approaches to protecting the environment. First and foremost, pollution should be prevented at the source whenever feasible. If waste streams cannot be prevented, they should be reused, recycled, or treated. Disposal should be the last resort.

Polymorphisms

Synonyms

Genetic variants; DNA variants

Definition

In genetics, a polymorphism is any genetic unit which exists in several different common forms or variants, called alleles, across different members of a species. One classic definition of polymorphism, put forth by British ecological geneticist E.B. Ford, is "the occurrence in the same habitat of two or more forms of a trait in such frequencies that the rarer cannot be maintained by recurrent mutation alone." Therefore, a unit of the genome which is known to vary must meet a minimum minor allele frequency in a population to be defined as polymorphic. One criterion proposed to define polymorphism is that any genetic unit with two alleles must have a minimum minor allele frequency of 1% to be considered polymorphic in a given population. The majority of identified polymorphisms are non-functional. Portions of the genome that are highly conserved and do not appear to vary are called monomorphic. In humans, several different types of polymorphisms exist, such as ► single nucleotide polymorphisms (SNPs), ► short tandem repeats (STRs), variable number tandem repeats (VNTRs), and even mobile elements like short interspersed nuclear elements (SINEs), the most common of which in the human genome is the Alu repeat.

Polypharmacy

Synonyms

Polypragmasy

Definition

The use of multiple drugs by the same patient is denoted as polypharmacy. However, there is no general accepted definition of how many medications have to be taken simultaneously. Often, at least five drugs used simultaneously are referred as polypharmacy. Especially the elderly use more medications than any other age group. Polypharmacy has been associated with ► adverse drug reactions, medication errors and increased risk of hospitalization.

Polypragmasy

► Polypharmacy

Population

Definition

A population is a collection of like objects. Demographers and population health scientists refer to populations as a collection of people who share important characteristics; often these are people living at the same time within defined geographic boundaries. Populations are frequently delineated further into subgroups, (e. g. regional, age, sex, or ethnic groups) in order to understand important health patterns or differentials. A population – like the population of Europe – can also be conceptualized as existing over long periods of historical time. In this sense, we can study historical population trends and we can project population trends forward to understand the consequences of current mortality, fertility, and migration levels for this future hypothetical population.

The overall total of subjects used to derive a sample; can be people, hospitals, data, or events. The sample should give results that represent the entire population. It can be a target group – the group from which a study population was chosen, or a study group – the group chosen for research. Often, population is also used to designate all the inhabitants of a country or a region when viewed altogether. The more precise term implies a group of values or forms of a variable of interest within a baseline statistical group.

Population (or universe, or target population) is any finite or hypothetical collection of observational units (persons, things, or measurement values) for which there is an interest at a particular time. In general, the different numerical characteristics of the population are of interest. We get them in the form of parameter – information on statistical characteristics about populations. The population on which we are seeking information is called the target population. The population to be sampled is called the sampled population.

Cross-References

► Nation

Population Age Distribution

Synonyms

Age composition of population

Definition

The ► population age distribution measures the proportionate contribution of each age group to the overall population. Where mortality and fertility are high, a large percentage the population will be concentrated in young ages (more than 40 percent are under age 15 in Africa). Where fertility and mortality are low, then the population will be concentrated in older ages (20 percent of the population is 65 or older in Japan). Changes in the population age distribution (e. g. population aging) reflect historical shifts in the mortality, fertility, or migration patterns.

Population Aging

Definition

Population aging is the demographic process by which older persons become a proportionally larger share of the total population.

► Population aging is a function of two distinct yet interconnected demographic processes. A decline in the rate of mortality in childhood and early adulthood increases the number of people who survive to old age, while reductions in the ► fertility rate lead to an increase in the relative proportion of older people in the population. Population aging is now a demographic reality in both high and low-income nations. Population aging is fundamentally a mark of human success in reducing undesired fertility, improving living conditions and curbing the risks of premature death through innovations in public health and medical treatment. However, it also presents a challenge for societies and governments that must reconsider and restructure their health and human service systems to accommodate a new profile of need.

Population Attributable Risk (PAR)

Synonyms

Attributable risk proportion

Definition

Population attributable risk (*PAR*) is the proportion of the incidence of a disease in the population (exposed

and unexposed) that is due to exposure. It is the incidence of a disease in the population that would be eliminated if exposure were eliminated.
The PAR is calculated by subtracting the incidence in the unexposed from the incidence in the total population (exposed and unexposed).
PAR is usually expressed as a percentage. The *PAR%* is calculated by dividing the population attributable risk (PAR) by the incidence in the total population and then multiplying the product by 100 to obtain a percentage.
PAR measures the potential impact of control measures in a population, and is relevant to decisions in public health.
In order to calculate PAR, the prevalence of exposure in the study population must be known or estimated (PAR = AR × prevalence of exposure to ► risk factor in the population).

Cross-References

► Attributable Risk Fraction
► Attributable Risk Proportion

Population-Based Services

Definition

Population-based services are ► health services targeted at populations of patients with specific diseases or disorders (e. g. patients with asthma or diabetes). Population-based services are based on the concept that health care can be better administered if patients are examined as a population, as well as being considered as specific cases.

Population Characteristics (Demographics)

Definition

Population characteristics include race, age, gender, income, location of residence, mobility, socioeconomic status, religion, educational attainment, ownership (home, car, etc.) employment status, marital status, language, and location of residence and even life cycles (fertility, mortality, migration). Demographics are primarily used in social science research, especially in economic research.

Population Genetics

Synonyms

Genetic epidemiology

Definition

Traits which are inherited from the transmission of genes in families following Mendel's laws of heredity. A science which deals with the study of the genetic composition and characteristics of populations. Population genetics involves the study of ► allele frequencies within a population and the attempt to explain the given distributions through the forces of natural selection, genetic drift, mutation and population expansion, contraction and migration.

Cross-References

spencer.polley@lshtm.ac.uk, richard.pearce@lshtm.ac.uk

Definition

Population genetics involves the study of ► allele frequencies within a population and the attempt to explain the given distributions through the forces of ► natural selection, genetic drift, mutation and population expansion, contraction and migration.

Basic Characteristics

Variability and Selection

The initial requirement for any ► population genetics based study is the ability to characterize and quantify the level of genetic diversity either within a population or between populations. The characterization

of diversity was initially performed at a phenotypic level, since this was the level at which genetic variation could be easily observed. The discovery of micro- and mini-satellites, coupled with advances with DNA sequencing has allowed variability to be assayed at the genotypic level. The progression of these technologies to a high throughput easily attainable technology has allowed ever increasing amounts of ► single nucleotide polymorphisms (SNPs) and micro-satellites to be analyzed, producing genome wide maps of sequence variability at a population level.

Numerous loci in the human ► genome have been shown to be under the influence of ► positive selection (where the frequency of a novel allele increases within the population due to the selective advantage it provides). Many of these have direct roles in human health through processes such as host-parasite interactions, recombination rates, fertility, salt-sensitive hypertension and sensitivity to prescribed drugs (Carlson et al. 2005; Voight et al. 2006). Therefore the identification of novel loci under apparent selection offers the potential to highlight genes of significance to human health for subsequent molecular and epidemiological investigation.

The Neutral Theory of Evolution and Frequency Based Analyses for Detection of Selection

► Frequency based analyses of selection make use of the ► neutral theory of evolution, which states that changes in allele frequency within a population occur through stochastic events not related to the organisms fitness (genetic drift). The ability to model these processes allows the expected distribution of allele frequencies for a locus to be predicted under neutrality in a panmictic (non segregated) population of constant size. Investigators can therefore compare the predicted and observed allele frequencies to detect deviations most likely caused by natural selection. Analyses to detect non neutral patterns of allele frequencies which have so far been applied to human genomic sequences include: The Hardy Weinberg equation, Tajima's D test, Fu and Li's D and F tests, the McDonald and Kreitman test, the Ewen Watterson test on observed homozygousity, Fay and Wu's H statistic and Weir and Cockram's FST.

The Tajima's D test compares the level of allelic diversity at a locus calculated from two different indices: the average pair wise diversity ($\Theta\pi$) and the number of segregating sites (ΘS). Under neutrality both will result in roughly the same estimate of diversity. However, where balancing selection (a form of positive selection) operates it will tend to increase the frequency of mutations to intermediate levels. This will increase the estimate of $\Theta\pi$ without affecting ΘS (seen as positive Tajima's D values). This is the case for Chemokine Receptor 5 (CCR5), which encodes a receptor used as an invasion ligand by HIV-1. Polymorphisms within CCR5 have been associated with reduced susceptibility to HIV-1 and significantly positive D values are seen in non-African populations, showing that these polymorphisms are at higher frequencies than would be expected under neutrality. Interestingly the apparent age of the CCR5 mutations predates the emergence of HIV-1 and a more ancient pathogen may have shaped allelic diversity at this locus (Bamshad et al. 2002).

The balancing selection apparent on CCR5 mutations prevents any single allele going to fixation in the population (possibly due to a deleterious effect of reduced chemokine activity in those alleles selected for reduced pathogen susceptibility). Positive selection that is directional (rather than balancing) will tend to drive novel alleles to fixation. This results in a decrease in allelic diversity (such that ΘS will tend to be greater than $\Theta\pi$) resulting in negative Tajima's D values. An example of this is seeb at the *LCT* locus, which encodes the enzyme lactase-phlorizin hydrolase (required for the digestion of lactose) and shows strongly negative D values in European populations (Carlson et al. 2005). It is postulated that the force for positive directional selection at this locus was produced by the introduction of diary lactose into human diets following the domestication of livestock (Bersaglieri et al. 2004).

Whilst the functional importance of CCR5 and LCT had already been identified before population genetics were performed on these loci, the ability to perform genome wide scans of polymorphism has identified numerous additional loci that show non neutral patterns of distribution for future bio-informatic, molecular and epidemiological characterization (Carlson et al. 2005). Increasingly complex models can take into account factors such as population changes and background ► negative selection (known to have shaped the genetic landscape of the human genome) resulting in an increased sensitivity and robustness of these analyses (Reed et al. 2005).

Haplotype Based Analyses

In addition to the frequency of SNPs within a population, the analysis of ► haplotype structure (measured by linkage disequilibrium – the non-random association of polymorphism within the genome) can also provide evidence of natural selection. Recombination through meiosis will tend to break down linkage disequilibrium, however, when a single polymorphism is driven to fixation quickly enough to minimize this effect the surrounding polymorphisms (termed hitch hikers) in the genetic locality will also be driven to fixation. This process homogenizes haplotype structure (evident as linkage disequilibrium) until it is broken down by recombination and new mutation. Evidence of ► selective sweeps are seen around many loci in the human genome, including *LCT* (Bersaglieri et al. 2004). Linkage disequilibrium also has the ability to identify loci under recent balancing selection such as *G6PD* (Glucose-6-phosphate dehydrogenase) and B-globin that may not be detectable by any standard nucleotide diversity test (Saunders et al. 2005). As with genome wide analysis of Tajima's D, the ability to analyze whole genomes has allowed population wide linkage disequilibrium studies to be performed. Such studies highlighted many genes under apparent selection, including genes known to be associated with disease risk such as *DPP10* (encoding dipeptidyl peptidase 10, associated with asthma susceptibility) and *COL4A3* (encoding the alpha3 chain of collagen type IV, associated with Alport syndrome) and numerous candidates for future characterization (Nielsen et al. 2005; Voight et al. 2006).

Important Human Pathogens Can also Be Investigated by Population Genetics

It is important to note that the populations under study need not be composed of human beings in order to identify genes of direct importance to human health. For many pathogens the strongest driving forces for balancing selection and directional selection will be the host immune response and chemotherapeutic drugs. The study of major human pathogens at the population genetics level has provided important information concerning the genetic determinants of virulence/pathogenicity, epidemiology and emergence of drug resistance in these organisms.

The human malaria parasite *Plasmodium falciparum* is a major cause of mortality in the developing world and widespread drug resistance is severely limiting the effectiveness of many front line antimalarial chemotherapies. The drug Fansidar contains two active ingredients: sulphadoxine and pyrimethamine. Pyrimethamine inhibits the parasite enzyme dihydrofolate reductase (DHFR), but amino acid substitutions at four key residues in DHFR alter the conformation of the active sites of this enzyme resulting in differing levels of drug resistance. Researchers have shown a large scale selective sweep around the *dhfr* locus in the genomes of parasites in southeast Asia and southeast Africa (Pearce et al. 2005). Comparing the sequence haplotype flanking different *dhfr* alleles in samples taken across a number of southeast Asian countries showed that each resistance allele shared a common flanking sequence haplotype indicating shared ancestry and the occurence of a stepwise accumulation of point mutations in the gene (Nair et al. 2003). In addition, in southeast Africa the *dhfr* allele present which confers the highest resistance to pyrimethamine was shown to have originated not in Africa but in southeast Asia, indicating that resistance alleles in *dhfr* arise very infrequently but can migrate rapidly to spread drug resistance (Roper et al. 2004). These population genetics studies show that like many emerging human pathogens, drug resistant malaria has to be considered on a global scale when designing intervention and treatment policies.

The Future of High Throughput Sequence Analysis and Population Genetics?

The future of High Throughput Sequence Analysis and Population Genetics. New developments in sequencing technology are resulting in higher throughput and lower cost applications for generating SNP data. These developments are coupled with the rapid development of statistical frameworks and computing technology to allow the analysis of larger, more complex datasets. The result of this will undoubtably be an increase in the number of genomes from humans and pathogens to be sequenced for signatures of selection. The ability of bioinformatics to rapidly analyse loci of interest to determine putative functionality will allow these techniques to play an ever increasing role in helping researchers to understand (and therefore counteract) the genetic basis of human diseases.

Population Mean Value

Synonyms

Confidence interval

Definition

Population mean value is an interval within which the population parameter is expected to lie with a given degree of certainty (95% or 99%). In strict terms the confidence interval is a range of values that is likely to cover the true but unknown population value. The confidence intervals for means can be derived by adding and subtracts 1.96 (95%) or 2.575 (99%) times the standard error from mean. The confidence interval is based on the concept of repetition of the study under consideration. Thus if the study were to be repeated 100 times, of the 100 resulting 95% confidence intervals, we would except 95 of these to include the population parameter. In deriving confidence intervals for rates and ratios assumptions have to be made about these distributions. If rates and ratios are not within normal distribution, it is preferable to consider the standard error of the logarithm of the rate.

Population Nadir

Definition

Population nadir denotes the lowest number of certain population members in defined time and on defined territory. It usually refers to Indigenous populations in regions where the number of indigenous inhabitants drastically decreased due to illness, or repressive behavior of colonizers.

Population (Prevention) Strategy

Definition

Population strategies represent prevention approaches that target the whole population or large subgroups of it. This strategy rests on the observation that many risk factors and risk behaviors (e. g. blood pressure, smoking) exhibit a continuum of severity and associated risk for disease. Therefore the greatest benefit to the community will be achieved by shifting the whole distri-

bution curve (e. g. lower the blood pressure across the whole population), even if this may offer only little benefit to each participating individual ("prevention paradox"). Population strategies are used where there is mass exposure to risk, even if that risk is at a low level. Examples for this approach are the iodinization of household salt, the compulsory use of car seat belts or increasing tax on tobacco products.

Population Related Death Number

Synonyms

Mortality

Definition

Population related death number refers to the quality of being mortal. It measures the rate of death from a disease within a given population (e. g. cancer mortality rate) or the number of expected deaths in a population or population group (e. g. infant mortality) for a given time period. Statistical mortality rates based on historical data are represented in so-called mortality tables and are usually broken down by age and gender.

Cross-References

► Mortality

Population at Risk

Definition

In ► epidemiology, the population at risk is the part of the total population who would be counted as cases if they had the disease being studied.

Population Trends and Family Health

► Demographic Perspectives on Family Health

Positive Income Elasticity

► Superior Good

Positive Predictive Value

► Screening

Positive Selection

Definition

The process by which advantageous ► alleles are increased in frequency in the gene pool due to an increase in the fitness of an organism which carries them in its ► genome. Positive selection can be directional or balancing in nature. Directional selection will tend to drive a single allele to fixation, thereby removing all other alleles from the gene pool. Balancing selection will increase the frequency of a ► polymorphism to an intermediate frequency, but not to fixation due to some deleterious effect of the polymorphism which "balances" the advantageous effect it confers. An example of balancing selection is found in heterozygous advantage: The allele *HbS*, offers increased resistance to ► malaria in humans who are heterozygous for this allele (*HbSA*) compared to those homozygous for the normal version of the allele (*HbAA*). *HbS* has been selected for in populations exposed to the human malaria parasites (most probably *Plasmodium falciparum*), however, humans who are homozygous for this allele (*HbSS*) suffer from a lethal disease known as sickle cell anemia and often die before reaching reproductive age, thereby preventing the HbS allele reaching fixation. By contrast, null mutations in the Duffy receptor (required for invasion of red blood cells by the malaria parasite *Plasmodium vivax*) have no apparent fitness cost, and thus directional selection has driven these to fixation in West Africa.

Possible Case

Definition

A case classified as probable in an outbreak usually has fewer of the typical clinical features of the disease than a probable case.

Postcode Lottery

► Postcode Prescribing

Postcode Prescribing

Synonyms

Postcode lottery

Definition

The term postcode prescribing refers to regional variations of prescription patterns. As a consequence of postcode prescribing, access to therapeutic procedures and pharmaceuticals depends on place of residence instead of other criteria such as clinical effectiveness or ► cost–effectiveness.

Post-Coital Contraception

► Emergency Contraception

Postexposition Prophylaxis

Synonyms

Postexposure prophylaxis

Definition

Post exposition prophylaxis is the administration of specific ► antibodies against a particular pathogen the individual is not immune to. The aim of this post exposure measure is to prevent the infected person from becoming ill. To be successful, it is important to give the immune globulins as soon as possible after the contact with the pathogens.

Postexposition Prophylaxis (PEP) in HIV-Infection

Synonyms

Postexposure prophylaxis in HIV-infection; Prophylactic measures following HIV-exposition

Definition

After contact with potentially infectious material, various measures are indicated. On the one hand, there are general procedures, like disinfection or squeezing out the wound after a needle stitch injury; on the other hand, a specific antiviral therapy may be necessary for some weeks. Medicinal postexposure prophylaxis has to be started within 48 hours. Directly after contact with contaminated material, infection can only be ruled out by identification of the virus itself (by PCR). As antibodies are not present at that point in time, the HIV-test will be negative. Nevertheless, in the case of professional exposition, the individual might need proof that his or her HIV-status was negative at the time of the accident as evidence in a possible lawsuit.

Postexposure Prophylaxis

► Post Exposition Prophylaxis

Postexposure Prophylaxis in HIV-Infection

► Postexposition Prophylaxis (PEP) in HIV-Infection

Post Hoc Test

► Fisher LSD

Postmarketing Investigation of Drugs

Definition

Postmarketing investigation of the effects of a drug is undertaken at the stage when the drug is generally available on the market. It includes an active postmarketing surveillance system, which is essential for registration of any drug adverse effects. Besides that, evaluation of these effects is possible through several types of observational epidemiological studies, especially ► case-control studies.

Post Primary Tuberculosis

Synonyms

Reactivation tuberculosis; Adult tuberculosis

Definition

Post primary tuberculosis is the reactivation of old foci with a following outbreak of the disease. Primarily, the lungs are concerned; other organs become involved less frequently. In most cases, the reason for the reactivation is a decline in the status of personal health, especially an impairment of the immune system.

Post-traumatic Stress Disorder (PTSD)

Definition

Psychological damage that develops after a traumatic experience as a delayed reaction to the trauma.
PTSD arises as a delayed or protracted response to a stressful event or situation (of either brief or long duration) of an exceptionally threatening or catastrophic nature, which is likely to cause pervasive ► distress in almost anyone. Predisposing factors, such as personality traits (e. g. compulsive, asthenic) or previous history of neurotic illness, may lower the threshold for the development of the syndrome or aggravate its course, but they are neither necessary nor sufficient to explain its occurrence. Typical features include episodes of repeated reliving of the trauma in intrusive memories ("flashbacks"), dreams or nightmares, occurring against the persisting background of a sense of "numbness" and emotional blunting, detachment from other people, unresponsiveness to surroundings, anhedonia, and avoidance of activities and situations reminiscent of the trauma. There is usually a state of autonomic hyperarousal with hypervigilance, an enhanced startle reaction, and insomnia. Anxiety and depression are commonly associated with the above symptoms and signs, and suicidal ideation is also common. The onset follows the trauma with a latency period that may range from a few weeks to months. The course is fluctuating but recovery can be expected in the majority of cases.

Potable Water

Synonyms

Drinking water

Definition

Potable water is water intended for human consumption and others domestic purposes including personal hygiene, which must be safe without any significant risk to health over a lifetime of consumption.

Cross-References

► Drinking Water

Pott's Disease

► Morbus Koch (Koch's Disease)

Poverty Line

Synonyms

Poverty threshold

Definition

Worldwide the definition and calculation of poverty lines are controversial. The World Bank fixes the *absolute (extreme) poverty line* at 1 US-Dollar per person per day. According to this criterion, the poverty line is an income limit and below this limit the purchase of vitally necessary resources is no longer possible for an individual; such an individual is then classified as poor. *Relative poverty (risk) lines* however refer to a statistical standard for a society (e. g. the average or mean income). Thus, since 2001 the Member States of the EU have classified an individual with less than 60% of the average of an equivalent net monthly income as poor, i. e. a per capita-income modified according to relevant necessity aspects. This applies to a single-person household or to the senior person of a large household. In order to avoid any confusion or distorted interpretation, the top and the bottom 10% of the income are not taken into account. In Germany, the relative poverty line was at 856 EURO/month/person in 2004. The poverty lines

are fixed in concordance with standard political criteria as they cannot be proved or justified without prejudice.

Poverty Threshold

► Poverty Line

Power

Definition

The power is the probability of detecting a treatment effect of a given magnitude when a treatment effect of at least that magnitude truly exists. For a true treatment effect of a given magnitude, power is the probability of avoiding type-II-error, and is generally defined as $(1-\beta)$, where β is the probability of a type-II-error (false-negative). In hypothesis testing, β is the probability of concluding incorrectly that an intervention is not effective when it has true effect.

Power Analysis

Synonyms

Statistical power analysis; Sample size estimation

Definition

Performing power analysis and sample size estimation is an important aspect of experimental design. Software for Power Analysis is a comprehensive, general purpose tool of computer programs aiding the planning of research studies so that the sample size is appropriate for the objectives of the study. It also provides a wide variety of tools for analyzing all aspects of statistical power and sample size calculation. In some power analysis software programs, a number of graphical and analytical tools are available to enable precise evaluation of the factors affecting power and sample size in many of the most commonly encountered statistical analyses. This information can be crucial to the design of a study that is cost-effective and scientifically useful.

PPP

► Public-Private Partnership
► Purchasing Power Parity

Pragmatic Aspect of the Information

Definition

The pragmatic aspect of the information refers to the value of the information, the media that carries it, the resolution and precision that it was written with, and the quantity in which it was produced, transferred and received.

Pragmatic Trial

Definition

In contrast to controlled explanatory clinical trials, which aim to maximize the internal validity by rigorous control of all variables except the intervention, pragmatic trials seek to maximize external validity and to achieve a large degree of generalizability of the results. Elements that distinguish pragmatic trials from controlled clinical trials are, for example, wider inclusion and exclusion criteria and a less strict blinding of patients or physicians.

Prayer-Singers

► Indigenous Health Care Services

Preadmission Review

Definition

In the context of ► managed care, a preadmission review is the practice of reviewing claims for ► inpatient admission before the patient enters the hospital. The objective is to assure in advance that the admission is medically necessary. If there is no preadmission review carried out or it is not accepted by the insurer, the insurer can, depending upon contract provisions, deny or pay reduced benefits for the admission.

Prebiotics

Definition

Prebiotics are special indigestible substances which enhance the growth of bifiobacteria and possibly oth-

er microorganisms. They lead to a positive health effect in the intestine.

Precautionary Principle

Definition

The precautionary principle implies that when an activity raises a reasonable suspicion of causing harm to the environment or human health, though there is no scientific evidence, precautionary measures should be taken just as if proofs of its damage actually existed.

Precede-Proceed Model

Definition

The precede–proceed health promotion planning model proposes a clear understanding of the social, epidemiological, behavioral, environmental, educational, organizational, administrative, and policy aspects of a problem area during the needs assessment or planning stage; for evaluation, there is a distinction between process evaluation, impact evaluation and outcome evaluation. Precede (Acronym for Predisposing, Reinforcing, and Enabling Constructs in Educational Diagnosis and Evaluation) outlines a diagnostic planning process to assist in the development of targeted and focused public health programs. Proceed (Acronym for Policy, Regulatory, and Organizational Constructs in Educational and Environmental Development) guides the implementation and evaluation of the programs designed using precede.

Preciseness

Synonyms

Accuracy

Definition

Accuracy is the extent to which a measurement or an estimate based on measurements agrees with the true value. Accuracy is distinguished from precision, because a measurement can represent a true value without details. For example a temperature of 37.5 °C is accurate, but is not precise if a more refined thermometer registers a temperature of 37.543 °C.

Precision

Definition

Precision is the quality of being sharply defined. One measure of precision is the number of distinguishable alternatives from which a measurement was selected, sometimes indicated by the number of significant digits in the measurement. If it is expressed numerically, person's height could be stated to the nearest millimeter. Precision does not imply ► accuracy. A measurement can be precise but inaccurate. For example a faulty thermometer records the body temperature to be 36.67 °C when it is 37.10 °C.

In statistics, precision is defined as the inverse of the variance of a measurement or estimate.

Precision refers to the consistency of repeated results. Minor differences among repeated measures means that the measurement of precision is larger. Precision is quantified by ► measures of dispersion (variance, ► standard deviation, coefficient of variation) and ► confidence intervals. These measures are called imprecision measures, as higher variation means less precision. High precision is necessary for high ► accuracy, but the reverse does not hold. Despite high precision and low variability of results, ► accuracy may be low because of significant systematic error.

In statistical estimations, precision is the variation of an estimate of the true population value (parameter value) which is measured by the standard error of estimate.

Precision Attachment

Definition

An interlocking device, one component of which is fixed to an abutment or abutments (matrix), and the other (patrix) is integrated into a removable dental prosthesis in order to retain it.

Preclinical Phase of Disease

Synonyms

Presymptomatic phase of disease

Definition

The natural history of disease consists of preclinical and clinical phases of disease. The period from the pathologic onset of disease to the development of the first symptoms and/or signs of disease is the preclinical phase. During the preclinical stage of disease, it is possible to detect the disease by using available ► screening tests. The period in which the symptoms develop is the clinical phase of disease.

Prediction

Definition

A prediction is a rigorous (often quantitative) statement forecasting what will happen under specific conditions. Statistical regression models are frequently used to both describe the behavior of something, and predict its future behavior. Prediction methods based on objective mathematical and statistical calculations are called quantitative prediction methods, while methods based on expert opinions are called qualitative prediction methods. The first group includes, from the simplest methods to the most complicated, the Box–Jenkins methodology, fuzzy logic and neural networks, etc. The second group includes, for example, the Delphi method.

Predictive Toxicology

Definition

Predictive toxicology can use genomics, ► proteomics or ► metabolomics information from known toxicants to predict the toxicological class of an unknown agent. Genomics assays and single nucleotide ► polymorphisms can also be integrated to generate predictive models that are used to predict toxicological responses to specific agents. Prevention of environmentally-induced cancers is a health issue of unquestionable importance. Obtaining empirical evidence from animal-model based bioassays is costly and extremely time-intensive. This has resulted in an urgent need for carcinogenicity models that could generate reliable toxicity predictions for chemicals. These models would also enable low cost identification of hazardous chemicals and refine and reduce the reliance on the use of large number of laboratory animals.

Predictive Value

Definition

Predictive value describes the prognostic power of a test result and depends on ► penetrance and frequency of the disease. It is defined as the portion of clinically affected persons among all individuals tested positive for the ► mutation (positive predictive value) or the portion of non-affected (healthy) persons among all individuals tested negative for the mutation, respectively (negative predictive value).

Predictive Value Positive of a Surveillance System

Definition

Predictive value positive (PVP) is defined as the proportion of persons identified as case-patients who actually have the condition being monitored through the surveillance system. Calculating the PVP requires confirmation of all cases.

A low PVP means that non-cases are being investigated and there may be false positive reports of epidemics. This can lead to costly investigations and unnecessary interventions. On the other hand, a surveillance system with high PVP leads to less unnecessary and inappropriate expenditure of resources.

Sensitivity and PVP are inversely related. The balance between high sensitivity (assuring that almost all cases are identified) and high PVP (few false positive are identified) must be based on the level of importance accorded to identifying all cases (e. g. for rabies, or spinal cord injuries).

Pre-Eclampsia

Definition

Pre-eclampsia is one of the most common serious medical complications during pregnancy that is defined by the presence of the following symptoms: hypertension (high blood pressure of more than 140/90 taken at 2 time points 6 hours apart), presence of proteinuria (protein levels of 300 mg or more in urine) and edema (swelling, especially of hands and feet). It is incurable and has serious consequences for the health of the mother and baby and the only treatment is delivery of the baby, which depending on the gestational age, could have severe health consequences for the baby. The presence of hypertension without proteinuria is referred to as pregnancy induced hypertension.

Pre-Employment Health Examinations

Definition

Pre-employment health examinations are carried out prior to employment if the job entails health hazards or if it involves special health requirements. In most countries there are legal regulations on the provision of such health examinations in situations where workers are exposed to specific hazardous substances or physical agents involving special risk.

Preferred Risk Selection

Synonyms

Cherry-picking; Cream-skimming

Definition

Traditionally the term refers to selection that occurs because health insurers prefer low-risk enrollees to high-risk enrollees within the same risk group. Preferred risk selection may occur even if health insurers are required to accept all enrollees.

Pregnancy

Synonyms

Maternity; Gestation

Definition

Pregnancy is the state of carrying a developing embryo or fetus within the female body. This condition can be indicated by positive results on an over-the-counter urine test, and confirmed through a blood test, ultrasound, detection of fetal heartbeat, or an X-ray. Pregnancy lasts for about nine months, measured from the date of the woman's last menstrual period. It is conventionally divided into three trimesters, each roughly three months long.

Cross-References

► Gravidity

Pregnancy Loss

► Abortion

Pre-Implantory Blastocysts

Synonyms

Morula

Definition

A fertilized oocyte, termed zygote, starts to divide and proliferate, thereby giving rise to a blastocyst. A blastocyst is an early embryo not yet implanted into the uterus, containing 8 to 32 cells. At day five to six of embryogenesis, the blastocyst adheres to the mucosa of the uterus and penetrates in the second week of pregnancy. After implantation, the primitive cells differentiate into the trophoblast and embryoblast, the latter giving rise to the organism. ESC are isolated from blastocysts which have not yet adhered to the uterus' mucosa. ESC are omnipotent, being able to give rise to cells from embryo- and trophoblast.

Prejudice

Synonyms

Favoritism; Inclination; One-sidedness; Bias

Definition

There may be systematic underestimation or overestimation of the true value of an attribute bias. For example, prejudice in questionnaire data may occur from a variety of other factors, including choice of words, sentence structure, and the sequence of questions.
It represents either human choices or any other factors beside the treatments being tested that affect a study's results. Clinical trials use many methods to avoid bias, because biased results may be missleading.
Prejudice is basically an affective and cognitive response. It leads to social ► discrimination, the behavioral reaction. Prejudice yields emotional responses (e. g., fear) to stigmatized groups and involves a generally negative component.

Preliminary Injunction

Synonyms

Provisional injunction; Interim injunction

Definition

The term depicts a preliminary but nevertheless binding court order, which is regularly issued in urgent matters. With preliminary injunctions, courts order, prohibit, or allow acts or conditions that are relevant in the particular case in order to assure a claim or right for the time being until a regular court judgment of the lawsuit has been given.

Premolar

Definition

The premolars – eight in all – are located in pairs on each side of the upper and lower jaw, behind the canines and in front of the molars.

Pre-placement Health Examinations

Definition

Pre-placement health examinations are carried out when work tasks or working conditions essentially change; after periods of illness affecting the employee's work ability; when an employee may have deficient work capacity; when an employee is to be transferred to a high-risk place. These kinds of medical examinations are similar to pre-employment health examinations, but not exactly the same. In most countries there are legal regulations on the provision of such health examinations.

Preponderance

Synonyms

Prevalence

Definition

The ponderance of a disease is defined as the total number of cases of a given disease in a specified population at a specified time. It also may be defines as the ratio of the number of cases of a disease present in a statistical population at a specified time and the number of individuals in the population at that specified time.

Cross-References

► Prevalence

P

Prepsychotic Schizophrenia

► Schizotypal Disorder

Presbyacusis

Definition

Presbyacusis is hearing loss in elderly people. It is the most common cause for hearing loss in people over 55. The hearing loss comes on gradually, often over several years. Loss of hearing sensitivity due to aging occurs mainly at the higher audiometric frequencies and is bilateral and usually symmetrical. An affected person has difficulty using the telephone or following a conversation in a group. Presbyacusis is caused by a degeneration of nerve hair cells in the cochlea as a part of the aging process. The severity of hearing loss varies from person to person of the same age but most people do not go completely deaf.

Presence of Microorganisms

Synonyms

Colonization of microorganisms

Definition

Colonization is a term used to denote the presence of microorganisms in certain regions of the body which do not cause the symptoms of an infectious disease. Such colonization, does not require systemic antibiotic therapy. However, when multiresistant germs are present, elimination might be useful in order to avoid spread of the pathogens to hospital staff or other patients.

Preservation of Food

Synonyms

Conservation of food

Definition

Various physical and chemical methods can be used to lengthen the shelf life of food. These methods can prevent the foodstuff from rotting due to the influence of light, humidity, chemical reactions or microorganisms (bacteria, fungi). Physical methods include thermic treatment (like cooling, freezing, pasteurization and sterilization), withdrawal of water by drying or freeze-drying as well as radiant exposure (UV light, electron radiation, X-ray, gamma radiation). Chemical methods of preservation are smoking, salting, pickling, leavening and the addition of conserving agents. An alcoholic content of > 14% has a conserving effect as well. Among other things, sorbic acid (E200) and its salts (potassium sorbate E202), benzoic acid (E210) and sulphites (E221–E228) are compounds used as food preservatives.

Presumptive Therapy of Malaria

► Self-Therapy of Malaria

Presymptomatic Phase of Disease

► Preclinical Phase of Disease

Preterm Delivery (PTD)

Synonyms

Premature birth

Definition

Preterm delivery is the birth of an infant before 37 weeks gestation, occurring in about 10% of births.

Prevalence

Synonyms

Disease frequency, measures

Definition

Prevalence is used in ► epidemiology. It refers to the total number of people affected by a certain condition at a given point in time. It can be given as a total number, or as a percentage (referred to the total population), or as a ratio referred to 1,000/10,000/100,000 (e. g. the prevalence in town of lung cancer is 478 patients, which is equal to. It encompasses the number of all new and old cases of this disease.

Nicole.Wolfram@tu-dresden.de,
Andreas.Fuchs@tu-dresden.de

Introduction

Most health professionals as well as medical professionals will have formed their own opinions about the meaning and pretensions of prevention and health pro-

motion. There is some confusion about the precise interpretation of these two interrelated concepts since they can have a multitude of meanings and underlying philosophies. This chapter intends to clarify these conceptual uncertainties.

Accordingly, this chapter aims to discuss the input that human behavior has on health and illness. More particularly, the authors of each essay will consider how health might be promoted and disease prevented by the cautious application of health strategies in different settings.

First, prevention and health promotion are basically understood as two different public health science strategies. Prevention is essentially a medical action that deals with the individual or risk groups as well as the observance of physical health. In contrast with this, health promotion is concerned with the whole population in its daily life and not only selected individuals or groups (von Troschke 2004).

The differences between those two concepts have been worked out comprehensively by Badura (1992): Health promotion and prevention stand for two completely different conceptions of health care policy. The term prevention derives from the social hygienic discussion of the 19th century, at a time when, due to industrialization and urbanization, social problems were large, the medical treatment of diseases was still underdeveloped, and the detection and containment of contagious diseases was considered as predominant. In contrast with prevention, the idea of health promotion is still very new and was introduced to the discussion on health policy and science issues by the European World Health Organization (WHO) office and Aaron Antonovsky, an Israeli sociologist and stress researcher.

Health promotion aims to increase the means of self-determination for all people and their state of health in order to enable them to strengthen their health situation [Ottawa Charta 1986]. The WHO definition clearly places its emphasis on the term self-determination; it also focuses on self-reliance as well as self-help of individuals and groups, and participation and political influence (...). In that context, the emphasis is placed on the promotion of health – the salutogenetic approach in contrast to the pathogenetic approach of prevention research (...). The idea of health promotion is unspecific, whereas the idea of prevention is health specific, i. e. oriented on the International Classification of Diseases (ICD). Prevention starts with well-defined medical end-points and works back to identify possible risk factors.

Health promotion applies to living conditions of human beings. The point is to activate biological, mental, and social resistibility and safety factors as well as to set up living conditions that allow positive thoughts and feelings and which permit an optimal amount of physical strain and relief.

To summarize in only one sentence: prevention can be seen as reduction of risks whereas health promotion can be seen as increase of resources (Waller 2006).

Prevention

The most well known prevention act in public health in the past can be illustrated by the persistent effort of Dr John Snow (1813–1858) to determine how cholera was spread and the statistical mapping methods he initiated. Snow is a legendary figure in the history of public health, epidemiology, and anesthesiology.

The background for the public health act of Snow was the Asiatic cholera epidemic in the summer of 1854 in England. Whenever cholera broke out, nothing whatsoever was done to contain it, and it rampaged through industrial cities leaving tens of thousands dead. Snow had recently published a report speculating that it was spread by contaminated water – an idea that was dismissed by the authorities and the rest of the medical profession.

The number of fatal attacks and the death rate in Soho (the surrounding area of Broad Street) was more than double that for the rest of London. That it did not rise even higher was thanks only to JSnow. His previous research had convinced him that cholera, which, as he had noted, "always commences with disturbances of the functions of the alimentary canal", was spread by a poison passed from victim to victim through sewage-tainted water.

He patrolled the district, interviewing the families of the victims. His research led him to a pump on the corner of Broad Street and Cambridge Street, at the epicenter of the epidemic. "I found", he wrote afterwards, "that nearly all the deaths had taken place within a short distance of the pump". Snow took a sample of water from the pump, and, as he was convinced that this was the source of infection, he took his findings to the Board of Guardians of St. James's Parish, in whose parish the pump fell. Though they were reluctant to believe him,

Prevention and Health Promotion, Figure 1 The Broad Street Pump (Source: English, 1990)

they agreed to remove the pump handle as an experiment. When they did so, the spread of cholera dramatically stopped (Summers 1989).

Even though the findings of Snow were not accepted as a reason for the cholera epidemic (because of different unsolved deaths), his intervention to avoid further spread of cholera was the first documented public health act in (disease) prevention.

Prevention may be divided into several subdisciplines. In this field, we will take a close look at: ► prevention primary, ► prevention, secondary, ► prevention, tertiary, and ► prevention, starting points, as well as ► intervention concepts in prevention and ► intervention strategies in prevention.

Primary Prevention

Primary prevention (► prevention, primary) is a health management strategy that aims at prevention of the onset of clinical risk factors or even preclinical changes (US Preventive Services Task Force 1996). Primary prevention encompasses measures to reduce risk behavior or risk factors for disease (e. g. action on smoking to prevent lung cancer and coronary heart disease) and to reduce the risk of acquiring a pathogen (e. g. immunizations).

Measures of primary prevention can act on several levels: individual behavior on one hand and wider socioecological conditions on the other. The latter form the context for individual behavior and encompass important determinants of health. Traditionally health education is one of the main instruments of the behavioral approach. Regarding the target group of prevention measures, a population strategy targeting the whole population or large subgroups of it and a high risk strategy in which efforts are focused on those deemed most likely to develop disease can be distinguished.

Against a background of increasing demand for evidence-based practice, this lack of evidence may put primary prevention at a disadvantage in resource allocation decisions. The development of quality management and good quality criteria for primary prevention interventions are one attempt to address this issue.

Secondary Prevention

Secondary prevention (► prevention, secondary) is a health management strategy that aims at the identification and treatment of asymptomatic persons who have already developed risk factors or preclinical disease but in whom the condition has not become clinically apparent (US Preventive Services Task Force 1996). Secondary prevention aims at the early detection and treatment of a condition with superior cure rates compared with the treatment of clinically apparent cases.

Secondary prevention relies on early and reliable identification of cases, and swift, effective, and acceptable treatment. Regarding the identification of cases, two strategies need to be distinguished: screening and case finding. While screening is the testing of a population or population subgroup within a program, case finding relates to the identification of cases within routine systems of health care delivery.

Although great progress has been made towards the identification of meaningful measures of secondary prevention, their implementation frequently fails in practice. Causes can be attributed to the patient (the target person), the provider, and the payer (the health care system).

Tertiary Prevention

Tertiary prevention (► prevention, tertiary) is a healthcare strategy that aims to prevent the progression of disease, to alleviate symptoms, and to prevent subsequent disability after initial clinical diagnosis. Tertiary prevention may simply be the treatment of an already diag-

nosed health condition and thus overlaps with medical care. Aims of tertiary prevention vary with the status of the health condition. The outcome of acute illness or injury depends not only on the provision of appropriate medical and surgical care, but also on the early recognition of patients' needs with respect to functioning. The main characteristic of tertiary prevention is the coordinated, multidisciplinary team approach for evaluation and intervention. Typically, this team consists of physicians, nurses, physical therapists, occupational therapists, speech therapists, clinical psychologists, social workers, and others. Patient and family/caregivers are involved as closely as possible in decision making and planning.

Starting Points of Prevention

Starting points for prevention are basic ideas for preventive efforts. They form the foundation for the development of the concept and the strategy of a preventive program or intervention. Numerous starting points for preventive initiatives exist. They can be classified according to different criteria, e. g. according to the risks, diseases, and/or conditions tackled (priorities); the individuals or populations addressed (target groups); or according to the theory underpinning the initiative and general strategies chosen (theoretical concept).

Focusing on risks to health or significant health issues and diseases is an effective starting point for prevention. With regard to the target group, there are two starting points for preventive efforts. The first is to seek to reduce risks in the entire population regardless of each individual's level of risk and potential benefits (population-based strategy). The second is to focus the intervention on the people likely to benefit, or benefit most, from it (individual-based or high-risk strategy).

Different psychological, sociological, and socio-ecological theories and models have emerged within recent decades that can serve as starting points for designing a preventive intervention. The classic preventive intervention aims to change individual health behavior and can draw upon several different change theories. With the development and worldwide acceptance of the health promotion concept since the 1980s, the role of environmental support for actions and conditions of living has gained increasing importance in the field of prevention.

Intervention Concepts

An intervention concept is a scheme for the different elements and activities that are required to achieve the intended outcome of a program. A concept is usually developed in the beginning of a health promotion and prevention activity, and it maps out detailed steps that have to be taken to design, implement, and evaluate a prevention program. A concept usually encompasses the whole program cycle: analysis, strategy, implementation, evaluation, and sustainability.

Several frameworks for a systematic planning process in prevention and health promotion have been developed since the 1980s. The models for intervention concepts are procedural resources that map the path from recognition of a need or problem to the identification of a solution. They are designed to enhance quality management of health promotion and prevention programs, but cannot provide off the shelf solutions.

Intervention Strategies

In health promotion and prevention activities, strategies are a set of decisions and actions that determine the long-term performance of an intervention. An intervention strategy is usually an umbrella plan encompassing a number of smaller plans and elements targeted at a defined population in order to prevent a specific health problem. An intervention's strategy aims to reach a target group in order to initiate and effect changes in their ideas and preventive behavior. As health literacy is a necessary condition for preventive behavior, health education and information form an essential part of almost any preventive intervention. Communication of health-related facts and promotion of the intended preventive behavior are thus important strategic aspects of an intervention.

In health promotion and prevention, the process of establishing a system's ability to perform or produce desired outcomes is known as "capacity-building". Therefore, in addition to mapping out strategies in order to reach the target group, planners of an intervention also need to build the necessary infrastructure and problem-solving capabilities.

Health Promotion

The concept of health promotion is not clearly defined: it has a variety of meanings and is thus used to describe

a number of different activities. In the beginning of the 1980s, as "health promotion" acquired wider prevalence, several different individuals and organizations provided their own definitions. The term was selectively interpreted, and as a result of this, every stakeholder set up their own agendas, philosophies, and constructions of reality. In general, health promotion is described as a process or an activity directed towards enabling people to take action. Correspondingly, health promotion is not something that is done *on* or *to* people; it is done *with* people, either as individuals or as groups (Nutbeam 2001). For this purpose, behavioral health approaches are used with individuals in relation to personal health behavior and in relation to compliance with health care interventions. Lalonde (1974) described in the "Health Field Concept" that health behavior is obviously one of the key determinants of health and disease. This simple model of a health territory characterizes four main inputs to individual health:

- Lifestyle and behavior
- Health, social, and other service provision
- Socio-economic and physical environment
- Biological processes.

Three of these inputs are involved in health promotion. Health promotion advertises health in the quest of influencing lifestyle, health services, and, furthermore, the environment. Apart from some passing consideration for genetic counseling, the 'inherited' aspects of health receive little attention (Tones 2003).

In the context of the determination of health, health promotion comprises actions directed toward changing both the determinants within the more immediate control of individuals, such as individual health behaviors, and those outside the immediate control of individuals, such as social, economic, and environmental conditions that influence health.

As well as prevention, health promotion may be divided into several other subdisciplines. To explain the nature and demands of health promotion more specifically, the ► Ottawa charta will be considered closely as the fundamental description of the term "health promotion". Contemplation of ► health goals, the ► actors and models of health promotion, and the ► fields of action of health promotion will be continuously discussed. Besides this, the principles of ► health education, ► motivation, and ► sustainability will be described. To have a complete view of health promotion, it is necessary to present the ► models of evaluation, the ► settings, and the ► target groups.

Ottawa Charta

The core elements, aims, and goals, as well as the principles of health promotion were first summarized in the Ottawa Charta in November 1986 at the 1st International Conference on Health Promotion in Ottawa, held by the Canadian Public Health Association in collaboration with the WHO. It was directed as a basic program for governmental and non-governmental actors. Essential terms of health promotion were first defined and characterized in this Charta.

The development of the Ottawa Charta was based on a resolution of the World Health Assembly in Geneva in 1977. The assembly aimed at enabling health for all in order to allow all citizens to have the possibility of leading a productive and social life. This goal became a general goal, "Health for all", in the declaration of the International Conference on Primary Health Care and is still considered a primary goal. The Charta was translated into many languages and disseminated widely in the 1980s.

Further differentiation of the above-mentioned terms on health promotion took place at the successor conferences in Adelaide (Australia) in 1986 and Sundsvall (Sweden) in 1991, at the 4th International Conference on Health Promotion (New Players for a New Era: Leading Health Promotion into the 21st Century) in Jakarta in 1997, at the 5th International Conference on Health Promotion (Health Promotion: Bridging the Equity Gap) held in Mexico City in 2000, and the 6th International Conference on Health Promotion (Bangkok-Charta for Health promotion in a globalized world) held in Bangkok in 2006.

Health Promotion – Fields of Action

The Ottawa Charta is the key document in health promotion and it describes both fields of action in health promotion and basic strategies of health promotion. These basic strategies are advocated to create essential conditions for health in general, enabling all people to achieve their full health potential and mediating between the different interests of society in the pursuit of health. These strategies are supported by five priority action areas as outlined in the Ottawa Charta for health promotion:

- to build healthy public policy,
- create supportive environments,
- strengthen community action,
- develop personal skills, and
- reorient health services.

According to the understanding of the WHO, health promotion describes the concepts of analyzing and increasing the resources and potential for health on all policy and social levels. This led to identification of the above-mentioned five important fields of action in health promotion. The fields of action were also confirmed at the 4th International Conference on Health Promotion, which took place in Jakarta in 1997, 11 years after the Ottawa conference. Furthermore, most elements and terms of the Ottawa Charta, like health policies, were added. In particular, the contents of the Ottawa Charta were developed into new priorities in the following fields:

- promote social responsibility for health,
- increase investments for health development,
- expand partnerships for health promotion,
- increase community capacity and empower the individual, and
- secure an infrastructure for health promotion.

Health Goals

Health goals arose in the reorientation of health policy with new aims in health promotion and disease prevention in the mid 1970s. Health goals are general statements of intent and aspiration, intended to reflect the values of the community in general, and the health sector in particular, regarding a healthy society. The achievement of health goals is supported by using health targets to define a change in the health status of a population that can be reasonably expected within a defined time period. On the basis of firm evidence, health goals are used for creating recommendations and cataloging measures to be undertaken in special sectors and population groups.

The WHO advocated the development of health goals and adopted its first worldwide program of health goals at the conference of Alma Ata. This program was followed by the European program with the title "Health for all 2000" in 1984. It encompassed 38 health goals amongst other general goals like "for better health" or "for promoting healthy life styles". It was also agreed to measure the attainment of health goals regularly and to publish the results of these measurements. Therefore, 65 indicators were developed for measurement purposes. In the course of time, health goals underwent further development in 1991; after that, the program was transferred into the health goal program "Health for all in 21st century – health 21".

Actors of Health Promotion

The conception and implementation of the complex aim "health promotion" demands the collaborative work of many actors, not only those in the medical field but also representatives from numerous societal sectors. Acting on the creation of health promotion is the responsibility of political decision markers at both national and international levels. This acting includes regulations and measures by law as well as sustainable funding for continuous and long-term support of flexible mediating and advising structures in health promotion. Actors come from governmental and non-governmental sectors, the education and welfare system, and the work environment as well as the health care system.

Models of Health Promotion

Models or theories in health promotion are systematically built and validated constructs with clearly defined and interconnected concepts covering a wide range of phenomena related to health behaviors or health conditions. The best-known and most often applied health promoting models have four different orientations: the first, from the 1930s–1950s, examined health behaviors and behavior changes by focusing solely on the individual and her/his characteristics. While these theories substantially contributed to the understanding of human health practices, the attention to and the inclusion of the broader environmental and socio-economic context led to a second generation of theories that focus also on the influence and competence of a community, or "setting", in which individuals live, work, play, and learn. These theories might also include the individual as one focus of intervention, but they additionally address issues beyond the control of the individual, such as the increased availability of supporting devices (e. g. provision of condoms free of charge or a health center in the neighborhood).

A third group of theories clusters around raising awareness and transmitting knowledge through communication and action-motivation. Here, the targets might

be individuals, (risk) groups, communities, or even whole nations, addressed by mass communication campaigns or social marketing strategies (e. g. BZgA's HIV-prevention campaign "Mach's mit"). A fourth group of theories focuses on the analysis of organizational structures and structural change mechanisms and their health impact by means of general policy or "healthy public policy" development (Nutbeam and Harris 2004).

Many projects have been conducted successfully without theory – solely based on experience or intuition. However, the likelihood of success and effectiveness has been proven to be higher when the conceptualization had been theory-led.

Health Education

Health education plays a significant role in health promotion and represents one principle of the implementation of intervention strategies of primary, secondary, and tertiary prevention. Health education deals with mediating health information that influences social, economic, or environmental related determinants of healthy lifestyles and health promoting behavior. The regional European office of the WHO aims to strengthen knowledge and experience of individuals on health and illness and the organism and its functions, as well as disease prevention. It emphasizes strengthening of knowledge and experience of individuals regarding the utilization of health services and understanding of the functions of these services. The objective of these efforts is to give the individuals responsibility for their health and the ability to use the offerings of health care systems. Furthermore, the idea of health education is based on the principle of human rights, allowing people to gather complete information in the field of health and illness.

Motivation

In psychology, motivation refers to the initiation, direction, intensity, and persistence of behavior, as well as being the desire and willingness to do something. Motivation in the sense of health promotion and disease prevention means the willingness of individuals to participate in health promotion interventions and to implement the recommendations of health promotion in daily life. Motivation is an essential element required for individuals to follow the suggestions of health promotion campaigns. Motivation for participating in and implementation of health promotion issues is generated by health education.

Sustainability

The term was originally applied to natural resource situations in a long-term perspective. In general, sustainability represents the concept of meeting the needs of the present without compromising the ability of future generations to meet their needs (Brundtland Commission). Today, it applies to many disciplines, including economic development, the environment, food production, energy, and social organization.

Sustainability refers to doing something while considering the long-term consequences. Today's decisions are made under consideration of sustaining activities into the long-term future. Sustainable development includes two key concepts: the concept of "needs", in particular the essential needs of the world's poor, to which overriding priority should be given; and the idea of limitations imposed by the state of technology and social organization on the environment's ability to meet present and future needs.

Sustainable development does not focus solely on environmental issues. More broadly, sustainable development policies encompass three general policy areas: economics, the environment, and society. It incorporates many elements, and all sectors, including the health sector, which must contribute to achieve sustainable development. Human beings are at the center of sustainable development. Sustainable development refers to the use of resources, direction of investments, orientation of technological development, and institutional development in ways that ensure current development and use of resources do not compromise the health and well-being of future generations. In the context of health promotion and disease prevention, sustainability is considered to be the realization of sustainable health through development of a healthy environment and the support of health-conscious decisions of individuals. The current health program of the WHO is "Health 21" and is connected with the program on sustainable development of "agenda 21". Health promotion intervention can be classified as sustainable if effects are achieved after the project's end and developed processes have a continued and lasting effect.

Models of Evaluation

In terms of health promotion, evaluation contributes to both consideration of a project's course (implementation of empowerment or participation) and results at the end of the project. It depicts a basic element of quality assurance and contributes to the success and the sustainability of a health promotion intervention. Evaluation is therefore an essential part of each intervention. Surveillance of goal attainment, formulation of reachable and observable goals, definition of target groups, documentation, legitimization, and improvement of the project's course are fundamental elements of evaluation. Evaluation helps in the understanding of the causes of success or failure of a project and gives valuable contributions to strengthen the interventions idea. Planning of an intervention and evaluation of a project are closely connected. Essentially, evaluation is using diverse methodology approaches that include qualitative methods and quantitative methods (e. g. case studies, survey research, statistical analysis, and model building). It is estimated that more than 100 approaches for evaluation measures exist. The principal approaches are outlined in the essay on evaluation models.

Settings

Settings are places or social conditions in which humans spend a huge part of their lives and which have a great influence on their health. Working conditions, leisure areas, and schools depict typical settings for individuals. The concept of health promotion that is described in the Ottawa Charta emphasized the importance of settings in which interventions are carried out. Moreover, the Ottawa Charta demanded the creation of health promoting settings in one of its area of activity, "create supportive environments". Regarding health promoting activities, the setting also describes a well-defined social environment that is needed for analyzing, defining, and implementing health promotion interventions. In this context, individuals belong to various settings and are influenced by various settings. The setting approach in primary prevention and health promotion, which was first put forward by the WHO (WHO 1986), denotes a systemic intervention that aims to change structures and processes in a setting, rendering it more conducive to health. The formulation of the setting approach was an important step in the development of health promotion activities. Examples of settings are numerous and there are widespread programs and interventions, mainly initiated by the WHO.

Target Group

Target groups are an important element of all health education and information measures in health promotion and disease prevention. A clear and well thought-out definition of the group at which an intervention is targeted is an important condition for formulating realistic objectives and for reaching those objectives as well as for reaching the group itself. Strategies and measures have to correspond to the lifestyles of the target groups if lasting individual or structural changes are to be achieved.

If the health behavior and living conditions of target groups will be changed and improved sustainably in settings, strategies have to be geared to the way of life of the target groups. Settings also have to be defined in this context. Target-group orientated work is regarded as standard in health promotion activities since a lack of it is associated with an undifferentiated and inefficient appeal of the intervention to all people. In order to evaluate the attainability of target groups, projects in the field of health promotion are characterized with respect to the participants and recipients.

P

Summary

The term "health" means, in its plain form, the absence of disease. In the first definition, the WHO outlined health as the state of complete physical, emotional, and social well-being, not merely the absence of disease or infirmity. In further definitions, this was extended and additional fundamental terms were integrated: intellectual, environmental, and spiritual health. The well-balanced interplay of all named components is finally established on the principle of self-responsibility.

Health promotion and prevention provide the pathway or process to achieve this balance. As the introduction explained, a pointed and clear distinction between (disease) prevention and health promotion should be made. Disease prevention focuses on protecting as many people as possible from all consequences of a threat to health. In contrast, health promotion consists of the development of lifestyle habits that healthy individuals and communities can adopt to preserve and increase their state of well-being. The final aim is to optimize the health status.

Prevention of Mental Disorders

Definition

Prevention of mental disorders has as its target the reduction of symptoms, incidence, prevalence, recurrence of mental disorders, or the risk condition for a mental illness, preventing or delaying recurrences and also decreasing the impact of illness in the affected person, their families and the society and ultimately of mental disorders. It uses mental health promotion strategies as one of the means to achieve these goals. Prevention of mental disorders can be considered as one of the aims and outcomes of a broader mental health promotion strategy.

Prevention of Occupational Diseases

Definition

Prevention of ► occupational diseases includes policies and actions to eliminate or reduce occupational ► risk factors, thus reducing or eliminating occupational diseases and injuries, work-related diseases and premature deaths. Several levels of prevention are defined. **Primordial prevention** includes elimination of any predisposing risk factor, for example substitution of asbestos with another less harmful substance in the production process. **Primary prevention** includes protection from exposure to an occupational factor, e. g. enclosed machinery that does not allow spread of solvents or use of adequate protective equipment. **Secondary prevention** includes the use of screening tests, for example detection of early signs of occupational exposures and symptoms during the preventive check-ups. **Tertiary prevention** includes interventions aimed at slowing the progress of already established occupational or ► work-related disease.

Coping with the demands of prevention is difficult without appropriate legislation and regulation and a centrally directed articulation of the process and work instructions.

Prevention of Oral Diseases

Definition

In dentistry, prevention is any activity by which an individual avoids the development of an ► oral disease or condition (primary prevention), diagnoses oral diseases at an early stage or prevents its reoccurance (secondary prevention), and improves or maintains a person's functional status (tertiary prevention).

Prevention can be directed to all individuals (i. e. the whole population), sections of the population (for example school children), or the individual patient. Prevention can include measures for all people independent of their individual risk (mass prevention) or measures only for high risk groups.

Basic Characteristics

Background

Oral diseases are the most prevalent noncommunicable chronic diseases (NCDs). From a dental public health point of view the following oral diseases are relevant: ► dental caries, ► periodontal diseases, dental trauma and oral cancer, because these diseases are linked to common, preventable (modifiable) and lifestyle related risk factors (e. g. unhealthy diet, tobacco use, risky lifestyle; Daly 2002). The burden of oral diseases for the individual patient (pain, limited functioning and appearance) and the society (treatment costs) is substantial. It is therefore beyond dispute to prevent these conditions.

The majority of oral diseases do not cause life-threatening conditions. It was therefore difficult in the past to implement dental prevention in the health care system. Current research has shown that oral diseases have a considerable impact on oral health related quality of life. In the western world, the loss of teeth (caused by caries, periodontal diseases, dental trauma or other reasons) has a wide range of psycho-social consequences for the affected individuals (eg. problems with finding a job or partner). This is also the case for subjects with severe orthodontic problems or oral cancer with their disfiguring consequences. This made it easier to establish measures for the prevention of oral diseases.

Measures of Primary Prevention

Primary prevention focuses on maintaining good habits. The most important measures of primary prevention for oral diseases are:

- tooth brushing based on the practical experience that ► plaque-free teeth do not or less frequently develop caries or periodontal diseases. The positive effect of tooth brushing for oral health is evidence-based.
- use of fluorides. There are more than 10 systematic reviews/meta-analyses in the *Cochrane Library* (The Cochrane Collaboration) about the caries-preventive effect of fluoridation. Fluorides can be given as topical (tooth paste, varnish, mouth rinses) and/or systemic preparations (tablets, salt, water). Current research has shown that the caries-preventive effect of fluoride is mainly attributed to the effects on demineralization/ remineralization at the tooth oral fluids interface (ten Cate 1999).
- healthy diet. The relationship between sugar-rich diet and oral health is well-known. All programs to improve diet (i. e. to reduce fat or sugar) automatically help to improve oral heath.
- ► fissure sealants in children and teenagers in order to prevent the development of dental caries in pits and fissures of ► permanent teeth.
- consultations for pregnant women to improve the knowledge regarding oral health of their children.
- safety precautions to reduce the risk of dental and maxillofacial trauma or to reduce the resulting sequelae: using seat-belts in cars, gum-shields in dangerous sport, Dentosafe® (boxes for shortterm storage of fully avulsed teeth) in ambulances and first-aid kits etc.
- campaigns against tobacco and alcohol consumption to reduce the risk of oral cancer.

Measures of Secondary Prevention

Screening, early detection, and early treatment of oral diseases are the most important focus areas of secondary prevention:

- yearly dental check up in the dental office or in the dental public health service (this allows to screen the population for early stages of oral diseases: white spots, bleeding gum, precancerous changes of oral mucosa etc.),
- special diagnostic and therapeutic procedures in risk groups and prescription of tailored preventive mea-

sures for example in subjects with juvenile progressive periodontal diseases or immunosupressed patients,
- treatment of early disease stages (for example treatment of baby teeth caries to prevent caries development in the permanent dentition, sealants and preventive fillings in dark-colored pits and fissures to prevent more extended tooth decay),
- treatment of malpositions of teeth for example to reduce the risk of dental trauma in protruded front teeth.
- early treatment of dental trauma because prognosis depends on time between accident and treatment.

Measures of Tertiary Prevention

Tertiary prevention includes all measures for oral rehabilitation. This includes fillings of decayed teeth, the treatment of periodontal diseases, the replacement of lost teeth (► dentures, implants), and the complex treatment of oral cancer. The recall period for the patient depends on the individual risk situation and the disease progress.

Limitations of Dental Prevention

Even optimal prevention cannot completely avoid the development of oral diseases. Only the extent and severity of these diseases can be reduced. In addition to specific risk factors like bad oral hygiene, sugar-rich diet, no fluoridation or heavy smoking further factors are included in the etiology of oral diseases (systemic illnesses, habits). Tooth loss caused by diabetes mellitus associated periodontitis can serve as an example. Other examples are tooth decay caused by parafunctional habits (bruxism), nutritional disorders (bulimia) or genetics (amelogenesis imperfecta). However, the major part of oral diseases is lifestyle-related. Furthermore, prevention has to be free of any risks for the individual to reach a wide acceptance of preventive measures (for example avoidance of dental fluorosis by supervised use of systemic fluoridation).

Implications for the Health Care System

Effective dental prevention requires sufficient structural and political conditions:
- political support for a "healthy environment",
- wide acceptance of preventive measures in the society,
- sufficient financial and personnel resources,
- cooperation between all members of the health care system (dentists, dental public health service, health insurances etc.),
- more competences in the dental education to prevent oral diseases (Plasschaert 2004)
- implementation of dentist's knowledge in the educational system,
- implementation of an incentive scheme within the dental care system focusing on preventing instead of treating oral diseases.

Conclusion

In most of the cases prevention of oral diseases does not lengthen life, but improves oral health related quality of life for large parts of the population and may reduce socially determined inequalities. Finally, it should be born in mind that prevention of oral diseases always has a positive effect on general health and vice versa all measures to improve general health also improve oral conditions.

Prevention Paradox

Definition

Primary prevention involves two strategies that are often complementary. It can focus on the whole population with the aim to reduce average risk of particular disease (population strategy), or on people at high risk as a result of particular exposure (the high-risk individual strategy). The major advantage of the population strategy is that it does not require identification of the high-risk group and its main disadvantage is that it offers little benefit to individuals because their absolute risks of disease are quite low. In other words a preventive measure that brings large benefits to the community but may offer little to most participating persons. This phenomenon is known as prevention paradox.

For example, most people will wear seat-belts while driving for their entire life without being involved in a crash. The widespread wearing of seat-belts has produced benefits to many societies but little benefit to most individuals.

Prevention, Primary

Definition

Primary prevention is the health management strategy that aims at the prevention of the onset of clinical risk factors or even preclinical changes (U.S. Preventive Services Task Force 1996). The term prevention is derived from the latin verb "praevenire" which means "coming before". It denotes that something is effectively done *before* a targeted condition has evolved. Primary prevention encompasses measures to reduce risk behavior or risk factors for disease (e. g. action on smoking to prevent lung cancer and coronary heart disease) and to reduce the risk for acquiring a pathogen, respectively (e. g. immunizations). In contrast, secondary prevention (► prevention, secondary) aims at the identification and treatment of asymptomatic persons who have already developed risk factors or preclinical disease but in whom the condition has not yet become clinically apparent. Tertiary prevention (► prevention, tertiary) refers to an intervention that aims to mitigate health consequences of a clinical disease (Commission on Chronic Illness 1957). Primary prevention can include elements of, but is distinct from ► health promotion, which is "the process of enabling people to increase control over, and to improve, their health" (WHO 1986). The latter process, which is characterized by ► participation and ► empowerment, ► advocacy, ► enablement and ► mediation is not restricted to a specific phase of the health or disease history.

Basic Characteristics

Value of Primary Prevention

The particular value of primary in contrast to secondary and tertiary prevention lies in the reduction of risk exposure leading to a reduction of the number of episodes of ill health over time and extension of the healthy life span. There are a number of examples of successful primary prevention, e. g. immunization programs, breast feeding or child safety car seats in childhood, regular physical activity and bicycle helmets in the general population, and pneumococcal vaccine or avoidance of excess sun in high risk populations (U.S. Preventive Services Task Force 1996). For clinicians and the general population primary prevention often appears as an abstract concept because it is directed towards a healthy population. More difficulties are encountered if the potential value of a primary intervention has to be balanced against the interests of other societal or economic sectors, including even the health sector: successful primary prevention may be detrimental to the economic interests of e. g. the tobacco or alcohol industry and the distributors of their products.

Key Concepts of Primary Prevention

Behavioral Versus Contextual Approach Measures of primary prevention can act on several levels: the individual behavior on one hand and the wider socio-ecological conditions on the other. The latter form the context for individual behavior and encompass important determinants of health. Some primary prevention measures also intervene on the individual biomedical level, for example immunizations. Traditionally ► health education is one of the main instruments of the behavioral

approach (e. g. a safe sex media campaign aiming to change individual risk behaviors regarding HIV/AIDS), whilst policy and legislative measures aiming to reduce risks in the living environment belong to the mainstays of the contextual approach (e. g. smoke protection laws creating smoke free public places; introduction of compulsory car seat belts).

Population Versus High Risk Strategy Regarding the target group of prevention measures, a ► population strategy targeting the whole population or large subgroups of it (e. g. all sexually active persons) and a ► high risk strategy in which efforts are focused on those deemed most likely to develop disease, can be distinguished. The population strategy rests on the observation that many risk factors and risk behaviors (e. g. blood pressure, smoking) exhibit a continuum of severity and associated risk and that the greatest benefit to the community will be achieved by shifting the whole curve (e. g. lower the blood pressure across the whole population), even if this may offer only little benefit to each participating individual ("prevention paradox") (Rose 1992). Issues with the high risk strategy are the need to (easily) identify the target group and develop interventions which are tailored to that particular group. The high risk strategy falls mainly in the domain of secondary prevention (screening).

Setting Approach A ► setting is a confined social system with a certain set of conditions for and influences on health and the opportunity to shape these conditions for a better health. The setting approach in primary prevention and health promotion, which was first put forward by the WHO (WHO 1986), denotes a systemic intervention that aims to change structures and processes in a setting rendering it more conducive to health. This approach accounts for the contextual nature of individual behavior, is non-discriminatory (all individuals in a setting are reached) and has great potential for a sustainable change in health related outcomes through action on setting innate determinants of health. Examples of settings include kindergartens, schools, workplaces, hospitals, prisons, neighborhoods and communities.

Primary Prevention and Health Promotion

Health promotion as a process can be found both within and outside the confines of primary prevention. According to a World Health Organization definition, health promotion is "the planned and managed process of encouraging and assisting improvement in the health of a population as distinct from the provision of health care services" (WHO 1998). Health promotion overlaps and complements prevention strategies aiming at the sole reduction of risk factors. It has been suggested that the risk-reduction context of prevention relates to both a reduction of risk factors and a strengthening of resources, while the context of the health promotion process is predominantly resource-oriented (Rosenbrock 2004). While health promotion is said to encompass wide if not all domains of life, disease prevention frequently is regarded as emanating from the health sector only and dealing with risk factors and risk behavior. It is important therefore to realize that disease prevention and health promotion are complementary activities towards the public health goal of "ensuring conditions in which people can be healthy" (Institute of Medicine 1988).

Limitations and Challenges

The quest of primary prevention coexists and may be in conflict with issues of personal choice and preferences on an individual level, cultural stereotypes, industrial interests, political power or democratic decision making to name but a few on a larger level. The building up of an evidence-base, in particular for complex contextual interventions with a long time horizon (for potential benefits as well as damage), represents an ongoing methodological challenge. Against a background of increasing demand for evidence-based practice, this lack of evidence may put primary prevention at a disadvantage in resource allocation decisions. The development of quality management and good quality criteria for primary prevention interventions are one attempt to address this issue. Although some primary prevention measures can be worthwhile in monetary terms (e. g. small pox eradication), others are not or may never be able to prove it, making the economic argument for primary prevention a dangerous one to embark on. Despite the sometimes large costs and uncertain cost-effectiveness, prevention is a primary public health obligation because it prevents suffering and improves quality of life (Rose 1992).

Sustainable Primary Prevention

Despite their profound impact and its great successes, primary prevention activities are also subject to disappointment. Health gain in populations requires health promotion and disease prevention activities over years and decades. Evidence-based activities at the base of health promoting policies across sectors which shape the social and physical environment in which people live are potentially sustainable (Smith et al. 2006). Consistent with this analysis, the Institute of Medicine has issued recommendations (Institute of Medicine 2002) which include:

- Overhaul of the Public Health Infrastructure and competency building within and outside the Public Health services
- Focus on sustainable change by support of ongoing community engagement
- Recognition of communication as a critical core competency including dialogue with the mass media
- Development of a research agenda and build up of an evidence-base that will guide policy making
- Inclusion of age-appropriate preventive services into insurance plans

Synonyms

Early detection and treatment of diseases

Definition

Secondary prevention is the health management strategy that aims at the identification and treatment of asymptomatic persons who have already developed risk factors or preclinical disease but in whom the condition has not become clinically apparent (U.S. Preventive Services Task Force 1996). The term prevention is derived from the latin verb "praevenire" which means "coming before". Its meaning is that something is effectively done *before* a disease state evolves in order to make this disease state impossible or less likely. Whereas *primary* prevention refers to an intervention before clinical risk factors or preclinical changes have evolved, and tertiary prevention refers to an intervention that aims to mitigate health consequences of a clinical disease, *secondary* prevention aims at the *early detection and treatment* of a condition with superior cure rates compared to the treatment of clinically apparent cases (Commission on Chronic Illness 1957). Because of difficulties in the diagnosis of mental disorders, the Institute of Medicine redefined prevention for the *mental*

health field and suggests the terms prevention, treatment, and maintenance instead for its core activities (Institute of Medicine 1994). In this terminology, prevention is restricted to the classical concept of primary prevention, while secondary prevention is part of the activities treatment and maintenance and relates both to the index condition and co-occurring disorders.

Basic Characteristics

Value of Secondary Prevention

There are a number of examples of successful secondary prevention, e. g. in early childhood screening for inborn metabolic errors, vision and hearing screening in the general population and especially in high risk populations hemoglobin measurement, HIV and tuberculosis testing (U.S. Preventive Services Task Force 1996). Generally clinicians and the general population find it easier to understand the value of secondary prevention than that of primary prevention. This is easily understood as secondary prevention is a less abstract concept and requires many of the skills that clinicians are trained for (and people are used to): screening, diagnostic work-up and therapeutic interventions. More difficulties are encountered if the potential value of a secondary intervention at the individual level of preclinical disease has to be balanced against its value at a population level with a mix of healthy and diseased persons. This affects the context and biometrical properties of screening tests, questions of efficacy and effectiveness and the allocation of resources under conditions of restraint. An example is the discussion on which inborn errors of metabolism should be included in screening programs for newborns: while many conditions could easily be tested for, only some can be treated and hence are meaningful for secondary prevention. Care must be taken not to put clinical enthusiasm over the best interest of the patient or parent and their rights to know, but also not to know.

Key Elements of Secondary Prevention

Secondary prevention relies on early and reliable identification of cases, and swift, effective and acceptable treatment. Regarding the identification of cases two strategies need to be distinguished: screening and case finding. While ► screening is the testing of a population or population subgroup within a program, ► case finding relates to the identification of cases within routine systems of health care delivery, e. g. during a visit at the doctor's office for some related or unrelated cause. Classical criteria for meaningful screening programs have been formulated by Wilson and Jungner (1968), see Table 1. These have been extended to account for developments in both science (e. g. genetic testing) and society (e. g. consumer movement) (Goel 2001; UK National Screening Committee 2003). These extensions include that

- all the cost-effective primary prevention interventions should have been implemented as far as practicable,
- if screening is for a mutation the program should be acceptable to people identified as carriers and to other family members,
- there should be a plan for managing and monitoring the screening programme and also an agreed set of quality assurance standards,
- all other options for managing the condition should have been considered (e. g. improving treatment, providing other services), to ensure that no more cost

Prevention, Secondary, Table 1 Wilson and Jungner criteria for screening programs (1968)

Knowledge of disease:	• The condition should be important.
	• There must be a recognizable latent or early symptomatic stage.
	• Natural course of condition, including development from latent to declared disease, should be adequately understood.
Knowledge of test:	• Suitable test or examination.
	• Test acceptable to population.
	• Case finding should be continuous (not just a "once and for all" project).
Treatment for disease:	• Accepted treatment for patients with recognized disease.
	• Facilities for diagnosis and treatment available.
	• Agreed policy concerning whom to treat as patients.
Cost considerations:	• Costs of case finding (including diagnosis and treatment of patients diagnosed) economically balanced in relation to possible expenditures on medical care as whole.

effective intervention could be introduced or current interventions increased within the resources available,
- evidence-based information, explaining the consequences of testing, investigation and treatment, should be made available to potential participants to assist them in making an informed choice,
- the benefit from the screening programme should outweigh the physical and psychological harm (caused by the test, diagnostic procedures and treatment).

Efficacy, Effectiveness, Side Effects

► Efficacy relates to the positive effects of prevention programs that have been reported from studies, while ► effectiveness tries to make a statement to its performance in routine care. Evidence bases have been developed in the context of the evidence-based medicine movement (EBM) and health technology assessment (HTA reports), e. g. by the ► Cochrane Collaboration (see www.cochrane.org), the National Institute for Health and Clinical Excellence in the UK (► NICE, www.nice.org.uk) or the U.S. Agency for Health care Research and Quality (► AHRQ, www.ahrq.gov).

► Cost-effectiveness is an important aspect of the economic evaluation of secondary prevention. To this purpose, the effectiveness of prevention programs is weighed against expenses and potential savings (Wildner 2001; Drummond et al. 2005).

Screening can contribute to the reduction of the risk of developing a disease, it cannot guarantee however protection. Moreover, adverse events of an inevitable minimum of false positive and false negative results have been reported (Brett 2001). Psychological side effects of false-positive rates of programs of secondary prevention deserve careful consideration. In order to contribute to the evidence base, the development of a culture of documentation and evaluation as part of secondary preventive service delivery is essential.

Barriers to Service Delivery

Although great progress has been made towards the identification of meaningful measures of secondary prevention, their implementation frequently fails in practice. Causes can be found at the side of the patient resp. target persons, the provider, and the payer resp. the health care system. Examples are to little or inadequately framed information of the target group (e. g. inadequate language for migrant populations), counterproductive activities or myths within the target group (e. g. inadequate perception of the risk of side effects), inadequate reimbursement and fragmentation of health services (e. g. losses of clinical important information), neglect of socially disadvantaged groups (e. g. losses to follow-up), refusal to build necessary structures (e. g. screening capacities) and deficits in medical training with respect to preventive services (e. g. prioritization of treatment).

Recommendations for Clinical Preventive Services

The U.S. Preventive Services Task Force has reflected on its experience with successful secondary prevention within clinical service delivery. Their principal findings are (www.ahrq.gov/clinic/cpsix.htm):
- Interventions that address patients' personal health practices (behavior) are vitally important.
- The clinician and patient should share decision-making.
- Clinicians should be selective in ordering tests and providing preventive services.
- Clinicians must take every opportunity to deliver preventive services, especially to persons with limited access to care.
- For some health problems, community-level interventions may be more effective than clinical preventive services.

Prevention, Starting-Points

JULIKA LOSS
Institute for Health Care Sciences and Management in Medicine, University of Bayreuth, Bayreuth, Germany
julika.loss@uni-bayreuth.de

Definition

Starting points for prevention are basic ideas for preventive efforts. They form the foundation for the development of the concept and the ► strategy of a preventive program or intervention. Starting points encompass general elementary decisions:

- what health issue the intervention should concentrate on,
- what group or community the intervention should target,
- what basic theory or model the intervention should draw on.

Basic Characteristics

Before a preventive initiative is planned and developed, some elementary decisions on the character of the intervention have to be made. These decisions constitute the general starting points. Numerous starting points for preventive initiatives exist. They can be classified according to different criteria, e. g. according to the risks, diseases and/or conditions tackled (priorities), the individuals or populations addressed (target groups), or according to the theoretical underpinning and general strategies chosen (theoretical concept).

Setting Priorities: Risks to Health, Diseases and Conditions to be Prevented

Focusing on risks to health or significant health issues and diseases is an effective starting point for prevention. Epidemiology can provide the rationale and quantitative basis for decisions on preventive interventions in individuals and communities.

In general, priority should be given to controlling those risks that are well known, common, substantial and wide-spread, and for which effective and acceptable risk reduction strategies are available. When considering efforts in secondary prevention, e. g. ► screening tests, different criteria apply to the condition sought and the screening test used. For example, there should be an accepted treatment or useful intervention for patients with the disease, there should be a latent or early symptomatic stage, facilities for diagnosis and treatment should be available etc.

The leading risk factors for developed countries are tobacco consumption, high blood pressure, alcohol consumption, high cholesterol, overweight and obesity, low fruit and vegetable intake, physical inactivity, illicit drugs and unsafe sex. This evidence, however, should be only one input to the decision about the priority of an intervention. For regional approaches, a needs assessment in the target population can identify special local concerns and risks which are more important than general public health data.

For example, the starting point for the comprehensive UK Government action plan “Saving Lives: Our Healthier Nation”, which was launched in 1998 and outlined the strategy to improve the nation’s general health, was to concentrate on fighting the four “main killers”. These biggest killers were defined as cancer, coronary heart disease and stroke, accidents, and mental illness. All of the Government’s policies, strategies and interventions developed for “Our Healthier Nation” draw on these four conditions that have been identified as a starting point for the action plan.

Defining the Target Groups

With regard to the ► target group, there are two starting points for preventive efforts. The first is to seek to reduce risks in the entire population regardless of

each individual's level of risk and potential benefits (*population-based strategy*). The second is to focus the intervention on the people likely to benefit, or benefit most, from it (*individual-based* or *high-risk strategy*).

The *population-based approach* aims to make healthy behaviors or cancer screening behaviors a social norm, or to reduce exposures, and thus lower the risk in the entire population. Population-wide prevention applies to everyone, is usually easy to put into practice, and mostly consists of health education or legislation. Examples are the promotion of seat-belt use or increased consumption of fruit and vegetables.

With the *high-risk approach*, a target group that benefits most of the intervention is selected. For example, one approach to promoting colorectal cancer screening can be to primarily educate and motivate people who are at higher risk to develop colorectal cancer, i. e. individuals aged 50 years or older, or with a family history of colorectal cancer. Preventive measures for high-risk individuals are usually more specific and complex and sometimes require additional support and guidance. Focusing on people who are more likely to benefit has a significant impact on the health of a nation only when there are large numbers of them.

Individual-based efforts that can be performed by a clinician in a practice or hospital setting are also referred to as *"clinical prevention"*. Clinical prevention is aimed at individual patients and patient groups, and includes screening, counseling, ► immunization, and ► chemoprevention.

A key challenge is finding the right balance between population-wide and high-risk approaches. Combinations of these two starting points are likely to be the best ways of improving health in many cases. For example, a high-risk strategy for melanoma prevention might seek to identify target individuals with three or more risk factors (number of moles, blond or auburn hair, and a family history of skin cancer) by asking primary health care professionals to provide special advice to those persons. Simultaneously, a population-wide strategy using ► mass media communication would aim to make sun protection a social norm, so that the whole population is less exposed to risk.

Choosing a Theoretical Underpinning

Different psychological, sociological, and socio-ecological theories and models have emerged within the last decades that can serve as starting points to design a preventive intervention. The classic preventive intervention aims to change individual health behavior, and can draw upon several different change theories. With the development and worldwide acceptance of the health promotion concept since the 1980s, the role of environmental supports for actions and conditions of living has gained increasing importance also in the field of prevention.

Approaches to Behavior Change Theoretical background of most models that explain individual behavior is the assumption that health behavior depends on voluntary intentions, and that changing knowledge, attitudes, beliefs, and social norms can help to change intentions and behaviors. Three of the theories most commonly cited in prevention literature and most often used as starting point for interventions are outlined below: the Health Belief Model, the Stages of Change, and the Social Cognitive Theory.

The *Health Belief Model* attempts to explain and predict health behaviors by focusing on the attitudes and beliefs of individuals. It was developed in the 1950s by Becker et al. to explain the lack of public participation in prevention and screening programs. They assumed that people feared diseases, and that health actions were motivated in relation to the degree of fear (perceived threat) and expected fear-reduction potential of actions and behavior (perceived benefits), as long as that potential outweighed practical and psychological obstacles to taking action (perceived barriers). Since then, the model has been adapted to explore a variety of health behaviors, including screening and sexual risk behaviors. A preventive intervention based on the Health Belief Model model needs to target the individual's perception of the levels of susceptibility and seriousness, and must also provide incentives to take action and provide a clear course of action to acceptable costs.

The *Stages of Change Theory*, developed by the psychologists Prochaska and DiClemente in 1982, conceptualizes the process of change as entailing five stages:

1. precontemplation (no intention to change behavior in the foreseeable future),
2. contemplation (awareness of a problem and seriously thinking about overcoming it),
3. preparation for action (intention to take action in the next month, history of failed action in the past year),

4. action (modification of behavior, experiences, or environment in order to overcome the problems),
5. maintenance (preventing relapse and consolidating the gains attained during action).

The rationale behind "staging" people is to tailor preventive efforts to a person's needs at his/her particular point in the change process. A variety of health-related behaviors have been explored in populations using the Stages of Change Theory, and the theory has been applied in the development of countless preventive interventions, such as smoking cessation, weight control efforts and mammography screening. For example, the American Centers for Disease Control and Prevention suggest the model as a starting point for HIV/AIDS counseling at clinics, so the counseling provided will be based on the client's particular stage.

The *Social CognitiveTheory* was launched by Bandura in 1986. According to this theory, a person's individual reality and behavior is formed by the interaction of the environment and his or her cognitions. A key construct of the theory is the concept of *self-efficacy*. Self-efficacy refers to the confidence in one's ability to behave in such a way as to produce a desirable outcome. A person with a high level of self-efficacy expects to succeed and will persevere in an activity until the task is completed. A person with low self-efficacy anticipates failure and is less likely to persist in challenging activities. Self-efficacy develops as a result of a person's history of achievement, from observations of successes and failures of others, from the persuasion of others, and from one's own physiological state (such as nervousness or anxiety). Bandura's theory has been extremely fruitful in developing techniques for promoting behavior change, and has been applied to a wide range of health problems, e. g. alcohol abuse or ► immunizations. Focusing on self-efficacy can be an effective starting point for preventive actions. Smoking cessation, for example, has been one of the most common health-related behaviors that self-efficacy has been linked to. The concept is also used in lifeskills training, especially for social and refusal skills in children and adolescents with regard to drugs.

Approaches to Context and Environmental Change

Over recent decades, evidence of the need to tackle the wider environmental and social issues that shape individual choices but are beyond individuals' control has emerged. This socio-ecological vision of individual change has been embraced by health promotion for two decades since the ► Ottawa charter, and it has influenced preventive efforts as well. The starting point of interventions based on this vision would be to focus on creating supportive environments for health, by changing context and structure in order to facilitate preventive behavior.

For example, providing health insurance coverage for breast cancer screening, improving access to screening facilities, and reducing waiting times for mammographies are structural changes that can positively influence utilization of ► screening tests. In terms of the prevention of childhood overweight and obesity, changing the school settings in ways that make the consumption of unhealthy and fatty food more difficult for the students can be very effective, e. g. by removing vending machines, preparing healthy breakfast in class, or modifying the canteen menu. Classical environmental approaches with positive preventive effects are reducing the exposition to environmental risk factors, e. g. by improving air and water quality, food safety and safety in traffic.

Definition

Tertiary prevention is a healthcare strategy that aims to prevent the progression of disease, to alleviate symptoms and to prevent subsequent disability after initial clinical diagnosis. After an acute event tertiary prevention interventions aim to reduce the risk of subsequent events, to prevent complications, and to avoid negative consequences. In chronic disease, interventions are designed to ease the consequences, such as preventing the occurrence of skin lesions in bed-bound persons. Tertiary prevention in fatal disease aims at the alleviation of symptoms. This definition, however, is not as clear cut as it seems. In particular, the distinction from secondary prevention is controversially discussed, e. g. in cardiology. To avoid further ambiguity several authors have recommended the redefinition of the terminology or even to cease using the term tertiary prevention. Moreover, tertiary prevention may simply be the treatment of an already diagnosed health condition and thus overlaps with ► medical care.

Basic Characteristics

Tertiary Prevention and the Concept of Functioning, Disability and Health

Tertiary prevention targets the consequences of a health condition and in particular aims at the maintenance or reestablishment of ► functioning and the minimization of ► disability. An internationally accepted framework and common terminology for the understanding of functioning and disability has been provided by the World Health Organisation (WHO) with its ► international classification of functioning, disability and health (ICF) (World Health Organization 2001). According to the ICF, functioning is an umbrella term encompassing ► body functions and ► body structures as well as ► activities and ► participation in society. Loss of functioning and therefore onset of disability occurs when an individual is impaired in body functions and structures, limited in carrying out activities such as carrying objects, or restricted in social participation such as having a job. Functioning and disability are influenced not only by the health condition, but also by ► environmental factors such as technologies or societal attitudes, and ► personal factors such as coping styles or health related behavior. Functioning and disability are universal experiences, i. e. everyone may experience disability at a certain point in his or her life e. g. due to a health condition or with aging. Moreover, two individuals of the same age with the same health condition can substantially differ in their level of functioning, depending on degrees of bodily impairment, activity limitations and participation restrictions as well as the influence of environmental and personal factors (Stucki 2005). Thus, tertiary prevention aims at the functioning of an individual in the context of his or her environment in conjunction with personal factors.

Value and Timing of Tertiary Prevention Interventions

The goals of tertiary prevention vary with the status of the health condition. The outcome of acute illness or injury depends not only on the provision of appropriate

medical and surgical care, but also on the early recognition of patients' needs with respect to functioning. Patient groups such as the elderly, people with a chronic condition and people already experiencing disability may even have an increased risk of additional loss in functioning. The goals of tertiary preventive intervention in the acute situation are to maintain and restore functioning, to prevent disability and to avoid the need for long-term care (Stucki, Stier-Jarmer et al. 2005). To give an example, patients in the acute hospital may be encouraged to regain mobility with the help of walking aides, or to participate in exercises in order to enhance muscle strength.

In chronic conditions, tertiary prevention strategies are to be applied as early as possible in order to halt progression of the disease process, to maintain or to minimize the loss in functioning, to facilitate recovery and to promote independence. The ultimate goal is to prevent disability becoming permanent (Pope and Tarlov 1991).

In health conditions with potentially fatal prognoses such as cancer or progressive neurological disease, medical and rehabilitative management may not lead to recovery. However, tertiary prevention is nevertheless of major importance to alleviate symptoms and to enhance participation and quality of life. To give an example, progressive muscular degradation in amyotrophic lateral sclerosis leads to irreversible respiratory failure. Appropriate tertiary preventive interventions aim at the support of respiratory function and prevention of pneumonia.

Main Issues of Tertiary Prevention

Symptom Control An acute and chronic health condition entails a wide array of primary and secondary symptoms and complications on the level of body structures and functions. In spinal cord injury, for example, lesions are associated with various dysfunctions of the nervous system and metabolic changes which in turn may cause e. g. urinary tract infections, respiratory infections, osteoporosis and insulin resistance (Biering-Sorensen, Scheuringer et al. 2006). These symptoms are often perilous and exert negative effects on functioning, including participation and quality of life. Thus, tertiary prevention tries to understand how these symptoms are affected by and affect other biomedical and psychosocial factors, and how they can be reduced or controlled.

Health Maintenance Despite the good survival prospects of certain acute diseases or injuries, health maintenance may require a significant effort. In spinal cord injury, for example, premature death is associated with level and severity of injury as well as with secondary complications and ► co-morbidity like diabetes mellitus and cardiac disease, but also with unhealthy lifestyles like smoking or physical inactivity, and poor economic status and participation (Krause, Devivo et al. 2004). To give another example, there is substantial evidence that increased mortality in patients with acquired brain injury persists even after the main event has been survived (Shavelle, Strauss et al. 2001).

Participation Human functioning and disability can be described as experiences of people with a health condition in the context of their resources, e. g. their personal abilities to cope with disease, and in the interaction with the environment (Stucki 2005). Against this background, participation is the societal aspect of functioning (World Health Organization 2001). Participation is a basic need of people with a health condition and of major importance to society. Tertiary prevention in chronic disease therefore ultimately aims at the maintenance or restoration of participation in major life areas, such as intimate relationships or work. In doing so, tertiary prevention strategies not only address the disease process but equally provide a facilitating environment and try to develop the performance of individuals in the interaction with their environment. Appropriate means, e. g. to support employability, may include the use of specially designed devices or the provision of adequate transport services.

Key Elements of Tertiary Prevention and Recommendations for Service Delivery

The main characteristic of tertiary prevention is the coordinated, ► multidisciplinary team approach for evaluation and intervention. Typically, this team consists of physicians, nurses, physical therapists, occupational therapists, speech therapists, clinical psychologists, social workers, and others. Patient and family/caregivers are to be involved as closely as possible in decision making and planning.

Recent clinical practice guidelines, e. g. for early post-acute and post-acute stroke care, emphasize the following essential key points (Duncan, Zorowitz et al. 2005):

- early assessment and intervention
- standardized evaluations
- ► evidence-based interventions grounded on functioning goals
- care provided by an experienced ► rehabilitation team
- patient, family and caregiver as part of the rehabilitation team
- patient and family education
- utilization of community resources for community reintegration
- ongoing medical management of ► risk factors and co-morbidities

Effectiveness of Tertiary Prevention

The ► effectiveness of tertiary prevention is assessed by human functioning and rehabilitation research. Since tertiary prevention interventions are extremely multifaceted, research aims not only towards single intervention products and procedures but also on the efficacy, effectiveness and efficiency of intervention programs and policies including health services organization, plus delivery and financing (Brandt and Pope 1997). There is a large body of evidence for the effectiveness of timely tertiary prevention. Appropriate rehabilitation management decreases mortality, dependency and hospitalization rates. Protocols to standardize tertiary preventive measures and follow-up (► disease management) have been developed for many chronic conditions. There are numerous groups who review the literature on medical treatment in order to advise clinicians on the optimal way to treat chronic conditions.

Barriers to Service Delivery

Although there is no doubt about the potential efficacy and effectiveness of tertiary prevention, its implementation often fails in clinical practice. This may have several underlying causes. Firstly, reimbursement systems are mainly based on diagnosis, not on functioning, resulting in inadequate funding of services aimed at the prevention of disability. Secondly, health care delivery is fragmented with little collaboration between the different service providers. Thirdly, the relative effectiveness of different interventions is often unclear, making it difficult to decide on those which are most appropriate. As interventions are typically a team effort of several health professional groups and related professions aiming at a multitude of functioning aspects, difficulties occur regarding the agreement upon the selection of ► outcome measures as well as the planning and realization of ► randomized controlled trials and ► observational studies.

Preventive Screening

► Disease Screening Practices

Preventive Services

Definition

Preventive services constitute the core of ► health services. They include primary prevention services (counseling and immunization), which are interventions undertaken before the onset of disease; secondary prevention services, such as screening tests and examinations for early detection, eradication and control of diseases; and tertiary prevention services, which involve treatment and counseling (rehabilitation) for symptomatic diseases to prevent progression and development of complications.

Primaquine

Definition

Primaquine is derived from the alkaloids of the bark of the South American cinchona tree (quinine and quinidine). In cases of infections with *Plasmodia ovale* and *P. vivax*, parasites can remain dormant in the liver (so-called 'hypnozoites'). As primaquine impairs the cellular function of the parasites, this substance should be administered to prevent relapses. Treatment lasts for 14 days. Side effects are gastrointestinal symptoms, like a loss of appetite, nausea, vomiting or stomach ache. Prior to the administration of primaquine, a deficiency of glucose-6-phosphat-dehydrogenase has to be excluded, as hemolysis would otherwise occur.

Primary Care

Synonyms

General practice

Definition

There is no single definition of primary care. In general, it can be described as the provision of integrated, comprehensive, and accessible health care services by physicians who are responsible for addressing the majority of an individual's health care needs that are not performed on an emergency basis. Except for emergencies, the primary care practitioner is the enrollee's first point of contact with the health care system and develops a partnership with his or her patients in the context of the community and the family.

Basic Characteristics

History and Context of Primary Care

One of the key institutions that influenced thinking about primary care was the World Health Organization (WHO). Although primary care was already mentioned in several publications, especially in the Anglo-American countries, the definition that was developed by the WHO at the International Conference on Primary Health Care in 1978 enhanced interest in primary care on an international level. Yet, the definition was not interpreted similarly by each country due to differences in industrialization, philosophy of government, health

care services, and wealth. Thus, one key issue around primary care in those days was the fact that it was considered differently throughout the world. In different studies, primary care was interpreted as, for example, "whatever a certain group of health care providers did", "a set of activities", "a level of care or setting", "a set of attributes", or "an organizational strategy". This resulted in a refined definition by the Institute of Medicine of the United States, which is close to the definition stated above. This refined definition clearly stated primary care as a function to which health care professionals contribute by using their expertise and skills. The objectives of primary health care are to achieve a high quality of care and desired ► health outcome, to ensure high levels of patient satisfaction, and to use the resources efficiently. As many countries are facing increasing health care costs, primary care is seen as one key element for an affordable, effective, and sustainable health care system. Within managed care, the focus was put on the cost containment element of primary care, with the primary care physician acting as a gatekeeper. This gatekeeper role sometimes contradicts with the objectives of establishing trusting relationships with patients and balancing between the best interests of patients and the best interests of those working in the health care system.

Primary Care Delivery

Different forms of primary care delivery evolved depending on the health care system and other contextual factors in the respective country. In general, health care systems can be differentiated into systems that are based on primary care, and systems and that are often more hospital based. In many of the primary care based systems, like in the UK or the Netherlands, the primary care physician, in most cases a ► general practitioner, is in a gate-keeping role as he or she can refer the patient to the ► secondary care system of specialists and hospitals. This is different in pluralistic systems like Germany and France where access to general practitioners and medical specialists exists in parallel, although this is about to change in the German statutory health system where ~ 90% of Germans are health insured.

The provision of primary care is performed by physicians who are educated and trained for delivering comprehensive first contact and continuing care for persons with any undiagnosed sign or symptom. The responsibilities of primary care physicians include health promotion, disease prevention, health maintenance, counseling, patient education, and diagnosis and treatment of acute and chronic illnesses in various health care settings. The primary care physician often collaborates with other health professionals and utilizes consultation or referral whenever appropriate. The primary care physician is a generalist physician or general practitioner who is based in the community as opposed to the hospital in most countries. However, in the recent past there has been a tendency towards offering more primary care oriented responses at emergency departments as well. This is driven by the fact that a large number of patients attend hospital emergency departments with minor injuries and conditions that would have been suited to the capabilities and facilities of a primary care setup.

Primary care physicians often work in partnerships of different sizes and have a different number of employees to provide clinical and non-clinical support. The size and composition of those general practice partnerships differs significantly between countries. In the UK, only around 10% of practices are single-handed practices, whereas in the Netherlands, around 54% are solo practitioners. Reasons for the increase of larger teams instead of solo practice are a desired improvement in quality in combination with constraining costs by utilizing ► economies of scale and ► economies of scope.

Public Health Elements Within Primary Care

As primary care physicians are often located in the community or—when based in the hospital—at least have to remain connected with the community, they can play a vital role in addressing some of the future health problems. Some examples for those future health issues that are currently the focus of public health efforts are the aging society, the resulting burden of ► degenerative diseases, high-risk behavior of many individuals, unhealthy habits, high rates of population growth, and increasing poverty in large parts of the world. Public health aims at preventing diseases, prolonging life, and promoting health in the society. Traditionally, the primary care physician's perspective is restricted to the care of his or her individual patients and there is a focus on medical interventions and care of the sick, with prevention playing only a minor role. To bridge the gap

between primary health care and public health, across-the-board cooperation seems inevitable. This could produce better results and more value for the individual as well as for the community. As general practitioners also live in the area where they have their practice in many cases, they also get insights about the community from their patients. This qualitative information, in combination with the patients' registration data, could be used by public health doctors for their epidemiological research and health care planning. By collecting and assessing community information received from different general practitioners, the public health doctors could also support the primary care physicians.

Conclusion

Due to differing health care systems across the world and the different evolutionary stages of these systems, each country has a distinct setup of primary care and faces different challenges within this context. As primary care is one key element of each health care system, it is usually affected by all major policy changes within the health care system. However, there are also overarching topics that apply on an international level. Modern health care systems aim at being safe, effective, efficient, patient-centered, and equitable. As primary care is an essential part of each health care system, those objectives are most relevant for primary care. To improve primary care further, it has to be developed and enhanced to be an integral part of each health care system, especially when they are still evolving.

Primary Care Case Management (PCCM) (U.S.)

Definition

In the US, Primary Care Case management (PCCM) is the most prevalent form of running ► medicaid ► disease management programs that lies between traditional ► fee-for-service payment of providers and risk-based managed care of ► health maintenance organizations (HMOs). Under PCCM, patients choose a Primary Care Provider (PCP) who coordinates their health care services, provides preventive health care services and acts as a gatekeeper to expensive specialty services. They include among others primary care physicians, clinics and group practices. PCPs are generally paid on a fee-for-service basis and receive compensation for their case management tasks. Medicaid offers PCPs professional education programs, medical treatment guidelines and other support systems.

Primary Care Information System

Definition

A primary care information system is an ► information system for processing ► data, information and knowledge in the context of primary health care. Primary

care systems are used for keeping electronic patient records, organization of administration, financial activities, reporting, statistics, and research. They have been developed in countries with strong primary health care systems, such as the Netherlands, Great Britain and Scandinavian countries.

Primary Care Physician

► General Practitioner

Primary Complex of Tuberculosis

Synonyms

Tubercle

Definition

Within 6 weeks of infection a so-called primary complex of tuberculosis develops as an infection of the site of entry and local lymph nodes. As these inflammatory foci are surrounded by the cells of the body's defense mechanism (macrophages), rounded nodules ("tubercles") appear. Within the tissues calcifications develop and can be seen on X-ray. Inside these encapsulated areas mycobacteria can remain dormant for several years.

Primary Dental Care

Definition

Primary dental care is provided by dentists or dental auxiliaries who have the first contact with a patient demanding dental treatment or care. These first contacts occur in a dentist's office, in dental clinics, public dental services, dental wards of the hospitals, in universities or in home visits. About 90% of the demands for dental treatment can be met by the primary care provider. These include treatment of acute and chronic oral illnesses, preventive care and oral health education for all ages and both sexes.

Primary Dentition

Definition

The primary dentition comprises 20 milk (baby) teeth, which are replaced by 32 permanent teeth.

Primary Health Care

Synonyms

Universally accessible care

Definition

Primary health care is concept of health care that was introduced after an international conference in Alma Ata in 1978 organized by the World Health Organization and the UNICEF.

The Alma Ata conference defined primary health care as follows:

"Primary health care is essential health care based on practical, scientifically sound and socially acceptable methods and technology made universally accessible to individuals and families in the community through their full participation and at a cost that the community and the country can afford to maintain at every stage of their development in the spirit of self-determination".

WHO member countries accepted primary health care as the key to achieve the goal of "Health for all".

Basic principles of primary health care include equitable distribution, community participation, intersectoral cooperation and appropriate technology. Health services must be accessible to all irrespective of their ability to pay and regardless of place they live (urban, rural). Community must participate in planning, implementation and maintenance of health services. Cooperation with other sectors such as agriculture, food, industry, education, communication is needed for successful provision of health services. Appropriate technology means primarily technology that is scientifically approved, affordable and adaptable to local needs.

Primary Patient Data

Definition

Primary patient data are those obtained from the original data source – all documentation in the patient's

health record, as well as hospital reports, daily ward census etc. Primary data are usually detailed, poorly structured, incomplete and inaccurate.

Primary Research

Definition

In primary research, data are collected specifically for the study at hand. Data can be obtained by the investigator either observing the subject or phenomenon being studied or communicating directly or indirectly with the subject.

Primitive

► Indigenous

Principal

► Employer

Principal Component Analysis

Definition

A statistic dimensionality reduction technique that chooses new coordinate systems for the data so that the first axis will have the largest variance, the second axis the second largest, to capture the greatest variance in the model with the fewest axes. This is used in gene expression analysis to determine which characteristics of gene expression are important to divide genes into significant groups.

Principal component analysis is an advanced statistical method for examining the relationships among a set of variables without identifying a specific response variable. It explains as much variability (expressed by their correlation or covariances) as possible in terms of a few linear combinations (principal components) of the variables. This technique is often used when there are large numbers of variables, and there is a need to reduce them to a smaller number of variable combinations by combining similar variables (ones that contain much the same information). It is a linear dimensionality reduction technique, which identifies orthogonal directions of maximum variance in the original data, and projects the data into a lower-dimensionality space formed of a sub-set of the highest-variance components. Principal component analysis of qualitative data is a synonym for correspondence analysis.

Principle of Equal Treatment

► Equality

Principle of Equivalence

Definition

The principle of equivalence is employed in private ► health insurances to calculate the premiums. Each person insured contributes according to his or her individual risk profile determined by age, sex and ► health status. The premium is in this sense equivalent to the individual risk situation. In contrast to the principle of equivalence, there is the ► principle of solidarity employed by social insurances. Contributions in social insurances represent the same percentage of the income and all contributors receive the same provisions of health care.

Principle of Fair Treatment

Synonyms

Equity

Definition

The principle of fair treatment is about "fairness". Fairness and being equal are not necessarily the same things. Inequality can be fair if there are differences in need, or differences in contribution, effort or deserve. Scarcity is – the same as for efficiency – the reason why equity is interesting. If resources were not scarce, it would be fair for people to consume as much as they want or need of any particular commodity, including health care. However, because of scarcity, we have to judge what a fair allocation might be.

Equity is the principle of being fair to all persons, with reference to a defined and recognized set of values.

Cross-References

► Equity

Principles of Genetics

► Genetic Principles and Genetic Variations

Principle of Solidarity

Definition

The principle of solidarity is employed in social ► health insurances to calculate the contributions of the insured. Each person insured pays the same percentage of its income into the health insurance; children and unemployed family members are typically free of any contribution. The principle of solidarity balances the different economic situations of its members as they all receive the same kind of treatment. This principle is the major point of difference between social health insurances and private health insurances. Private health insurers calculate their premiums according to the ► principle of equivalence taking into account only the individual risk situation without considering any economic aspects.

Privacy

Synonyms

Confidentiality; Data protection; Private sphere protection

Definition

Privacy refers to the right of the individual to do certain things without anyone seeing or interfering. In a public health context, it refers to the right of the individual to control the disclosure of personal information. In many countries it is now regulated by specific laws. It is based on the principle of ► autonomy and it is meant to protect the individual's right over his own personal information. In public health practice it brings about ethical conflicts when such information would be needed for programs aimed at protecting the common good.

Privacy is a human right of individuals and aims to protect their personal sphere. The Universal Declaration of Human Rights states, "no one shall be subjected to arbitrary interference with his privacy". The privacy right allows a person to control, limit or exclude others from access to his private personal sphere and to information about this sphere.

Privacy Rights

Definition

Privacy rights in health care describe the right of each patient that all information concerning his health is kept confidential by all providers of health care. In most countries providers of health care, i. e. physicians, laboratories, etc, are not allowed to disclose medical information to a third party unless the patient has explicitly granted access. Privacy rights protect patients against discrimination on the grounds of certain medical conditions in the workplace or in other areas of society.

Private Health Insurance

Synonyms

Voluntary health insurance

Definition

Private health insurance calculates actuarially fair premiums. Three functions of private health insurance can be distinguished: alternative, supplementary, and complementary or double-cover private health insurance. In many countries, private health insurance is regulated heavily in order to avoid problems of ► adverse selection and to obtain comprehensive coverage. In these cases, the borderline between private health insurance and ► social health insurance becomes blurred.

Private Health Insurance, Alternative

Definition

Private health insurance schemes may be the only system of coverage available for some part of the population. Private health insurance thus performs the function of an alternative to ► social health insurance.

Private Health Insurance, Complementary

Synonyms

Double-cover private health insurance

Definition

Individuals who are entitled to benefits elsewhere may purchase complementary private health insurance that covers at least partly the same benefits.

Private Health Insurance, Supplementary

Definition

Supplementary private health insurance schemes offer coverage for services not covered or not completely covered elsewhere.

Private Law

Synonyms

Civil law

Definition

Private law consists of the legal rules that govern the individual rights and legal relationships between legal subjects on the assumption of a co-equal interrelation. Private law typically governs the relationship between two individuals when concluding a contract (e. g., a purchase agreement). In addition, private law is also applicable if an administrative agency enters into a legal relationship with individuals and other private subjects on the premise of a co-equal relationship (e. g., agreement on the purchase of office materials). As particular areas, private law includes the law of obligations (which includes contracts and tort law), the law of property, the law of succession and family law.

Private Sphere Protection

► Privacy

Probability

Definition

Probability is the measure of how likely an event is – a quantitative description of the likely occurrence of a particular event. Probability is conventionally expressed on a scale of zero to one. A rare event has a probability close to zero. A very common event has a probability close to one. The classical definition of probability states that probability is shared equally between all the possible outcomes and works well for situations with only a finite number of equally likely outcomes. Frequentists defines that the probability of an event is its relative frequency over time. This implies that the probability can be determined only by repeated trials in which the observed result converges to the underlying probability in the long run. Subjectivists, also known as *Bayesians*, give the notion of probability a subjective status by regarding it as a measure of the degree of belief of the individual assessing the uncertainty of a particular situation. In biostatistics, the term probability is most frequently used to describe the likelihood that an event will or will not happen, the degree of certainty regarding the relationship of two or more variables and the level of confidence that what you think is real actually is real.

Probable Case

Definition

A case classified as probable in an outbreak usually has the typical clinical features of the disease but does not have laboratory confirmation.

Probiotics

Definition

Probiotics are defined as living microorganisms which, if present in sufficient amounts in the intestine, have a positive effect.

Problem Behavior

Definition

A set of co-occurring behaviors in adolescence that is associated with a common set of precursors and a common set of later life outcomes. The problem behaviors include substance use (alcohol, tobacco, marijuana, and other drug use), risky sexual behavior (early adolescent sexual initiation, multiple sexual partners, non-condom use), problems at school (e. g. truancy, school drop-out, fighting), and problems in the community (e. g. gun violence, gang participation).

Process Evaluation

► Formative Evaluation

Prodromal Schizophrenia

► Schizotypal Disorder

Product Evaluation

► Summative Evaluation

Professional Care Giving

Definition

When treatment or care for a medical, psychological or other problem is provided by a paid professional (e. g. physician, nurses, therapist, social worker) versus a family member.

Professional Ethics

Definition

Professional ethics is concerned with the ethical dimensions of a specific profession, including the development of a code of conduct for the health professionals themselves. More and more, the professional ethics of different countries conform to universally accepted values.

Prognosis

Definition

It is generally accepted that prognosis can be regarded as a set of outcomes and their associated probabilities following the occurrence of some defining event or diagnosis that can be a symptom, sign, test result or disease. Prognostic factors are those which are associated with outcomes, and come in many varieties, such as clinical signs, symptoms, test results, medications, demographic factors, or lifestyle behaviors. For acute diseases, prognosis is usually expressed as a case fatality ratio and for chronic diseases, as a probability of survival.

Prolonged or Preterm Rupture of Membranes (PROM)

Definition

Premature (before 37 weeks) or prolonged rupture of membranes refers to cases where the amniotic membranes of a pregnant women rupture before labor contractions begin.

Promotion of Mental Health

ISABEL HACH
Klinik für Psychiatrie und Psychotherapie,
Klinikum Nürnberg-Nord, Nürnberg, Germany
isabel.hach@klinikum-nuernberg.de

Definition

Activities of mental health promotion imply the creation of individual, social and environmental living conditions that enable optimal psychological and psychophysiological development. Such initiatives involve individuals in the process of achieving positive mental health, enhancing quality of life and narrowing the gap in health expectancy between countries and groups.

Basic Characteristics

Introduction

Mental disorders are highly prevalent, their treatment is expensive and the lost quality of life of their sufferers is enormous. Hence, successful ► prevention of mental disorders is urgently required. Recent reports focusing on prevention research (e. g., WHO 2004) showed a strong endorsement of the need for continued exploration of the interface between

- potentially modifiable biological and psychosocial risk and protective factors,
- outcome prevention research focused on risk reduction, and
- broader collaboration among scientific disciplines and the dissemination of existing approaches.

Risk Factors and Protective Factors

Prevention of mental ill health and promotion of mental health address individual, family, community, and social determinants of mental health by reducing risk factors and strengthening protective factors. For children and adolescents schools are crucial settings for prevention procedures, accordingly for adults workplaces, because people spent large parts of their time in those places. Brown and Sturgeon (2005) named different risk factors as well as protective factors that are relevant in mental health (see Table 1).

Noteworthingly, showing different risk factors has not automatically and directly, the consequence of suffering from a mental illness during lifetime. Risk factors also can indirectly influence the environmental circumstances of their sufferers and, so, advantage the onset of a mental disorder.

Taking all identified risk factors into account, there are biological, emotional, behavioral, cognitive, interpersonal or related to the family context determinants that have an impact on mental health. This impact might be stronger during sensitive periods across the life span (e. g. early childhood, see Tables 2 and 3).

Prevention Strategies and Prevention Research

► Universal prevention strategies (i. e. macro strategies) can improve mental health and reduce the risk of mental disorders. There are some successful major macrostrategies, for example, improving nutrition (most successful was the combination of improving nutrition with counseling and psychosocial care); improving housing; improving access to education (low levels of education tend to be more prevalent in women, especially in South Asia and sub-Saharan Africa), reducing economic insecurity; strengthening community networks (e. g. Community that Cares, CtC programs, which have been successfully implemented in several hundred communities of the USA); multimodal school programs (e. g., Seattle Social Development Project); and reducing the harm from addictive substances (tax increases can reduce the incidence and prevalence of nicotin and alcohol abuse and of related medical illness, e. g., liver disease) (WHO 2004).

However, universal strategies need much more resources and are often less effective than selective and indicated prevention programs. Therefore, recent programs focused mainly on ► selective prevention or ► indicated prevention. The NHI recommends that attention be paid to smaller, focused, and intensive longitudinal prevention studies, informed by basic research. For selective prevention, a target population (showing a higher risk for mental disorders than the average) has to be identified. The home-visiting-program (i. e., two-year period of home visits by trained nurses) represents a very successful selective prevention program. Impoverished adolescents pregnant for the first time were the target population at risk. Randomized controlled trials showed benefits for the newborns in reducing low birth weight (increase of up to 400 grams), a 75% reduction in preterm delivery, more than a two-fold reduction in emergency visits and a significant reduction in child abuse among unmarried teens. Both children (higher IQ scores than control group, less likely to have problems with alcohol or drugs at the age of 15 years) and their mothers (e. g., increased employment) did benefit from the intervention. Families were better off financially. Last, the reduced government's costs for such families com-

Risk factors	Protective factors
Access to drugs and alcohol	Empowerment
Displacement	Ethnic minorities integration
Isolation and alienation	Positive interpersonal interactions
Lack of education, transport, housing	Social participation
Neighborhood disorganization	Social responsibility and tolerance
Peer rejection	Social services
Poor social circumstances	Social support and community networks
Poor nutrition	
Poverty	
Racial injustice and discrimination	
Social disadvantage	
Urbanization	
Violence and delinquency	
War	
Work stress	
Unemployment	

Promotion of Mental Health, Prevention of Mental Illness, Table 1 Risk factors and protective factors in mental health

Promotion of Mental Health, Prevention of Mental Illness, Table 2 Risk factors for mental health

Biological	Low birth weight, perinatal complications, neurochemical imbalance, physical illness or organic handicaps, sensory disabilities
Emotional	Low self-esteem, emotional immaturity and dyscontrol
Cognitive and behavioral	Academic failure, scholastic demoralization, reading disability, attention deficits, poor work skills
Interpersonal	Social incompetence, loneliness, isolation, communication deviance
Related to the family and environment	Parental mental illness (incl. substance abuse); child abuse and neglect; early pregnancies; family conflict or family disorganization; low socioeconomic status; exposure to aggression, violence, and trauma; personal loss-bereavement

Promotion of Mental Health, Prevention of Mental Illness, Table 3 Protective factors for mental health

Psychological constitution	Autonomy, feelings of security, literacy, intelligence
Emotional skills	Problem-solving skills, sufficient stress management, adaptability, pro-social-behavior
Related to the family and environment	Social support of family and friends, good parenting, early cognitive stimulation, positive parent-child-interaction, social and conflict management skills, socioemotional growth

pensated for the program's cost (Brown and Sturgeon 2005). However, the translation of this very successful program did not work. Olds et al. (1999) tried to replicate the program using paraprofessionals (instead of trained nurses) in a large effectiveness trial but found less dramatic and less significant results. The authors pointed out that the nurses have to be the key to the effort of the program. Another successful program was "First step", a school multimodal program for children at risk (Walker et al. 1998).

The difference between selective prevention programs and indicative prevention is fluent. Existing studies often do not use standardized instruments to distinguish between subclinical and clinical symptoms, as Durlac and Wells in an analysis of 130 studies showed. The authors found out that behavioral and cognitive-behavior programs for children with subclinical disorders (i. e., target group for indicative prevention) appear as effective as psychotherapy for children with established problems (i. e., secondary prevention) and more effective than attempts to prevent adolescent smoking, alcohol use, and delinquency (i. e., universal prevention).

To optimize prevention research, a new emphasis is needed on prevention effectiveness trials, prevention services, and costeffectiveness of preventive strategies. Research on relapse prevention and naturally occurring prevention is of high importance as well.

Prophylaxis of Insect Bites

Synonyms

Prevention of insect bites; Prophylaxis of insect stitches; Prevention of insect stitches

Definition

To avoid insect bites, covering clothing should be worn, that means, longs trousers, long sleeves, socks and closed shoes. Light colors should be preferred as mosquitoes are attracted by dark colors. In areas at risk of insect bites, exposed and uncovered parts of the body should be treated with repellents (diethyltoluamid, DEET). As many mosquito species are night-active, going out of doors cannot be recommended in the evening and at night. In tropical regions people should sleep under a mosquito net, the protective effect of which can be increased by an impregnation with 1% permethrin. It is important that the mosquito net does not have any holes, it should be kept close and the entrance parts should overlap sufficiently in order to prevent the insects from entering. As mosquitoes can also bite through the net, it must not rest directly on the skin. The net has to be carefully tucked under the mattress to avoid it slipping out due to movements during sleep.

Proportion

Definition

A proportion is the ► ratio of the absolute frequency (x) of a unit of observation that possesses a certain

specific characteristic (belonging to a specific category or class interval) and the total number (n) of units of observations: $p = x/n$. This relative frequency can be expressed as a percentage: $p(\%) = x/n \cdot 100$. A proportion is a type of ratio in which the numerator is a component of the denominator. Proportions can be interpreted as the equivalent of ► probability, because one of the definitions of probability (empirical probability) is based on relative frequencies. Proportion, like probability, always has values between zero and one.

Proportion of Agreement

Definition

Proportion of ► agreement represents the simple proportion of an identical measurement made by two or more raters or measurement procedures for categorical data, such as diagnosis. In contrast to ► kappa coefficient, simple proportion of agreement can be misleading because it does not take into consideration the amount of inter-rater agreement expected by chance.

Proportional Hazard Regression

► Cox Proportional Hazards Regression

Proportional Mortality Ratio (PMR)

Definition

Ratio calculated in a method analogous to that for SMR but when, in each age group, the population size is replaced by the number of all-cause deaths. Thus, the rates are replaced by the proportions of all deaths due to the cause of interest.

Propositus = Client

► Consulter in Genetic Counseling

Prospective Budgets

Definition

Prospective budgets are a method of financing hospitals based on historical spending. According to historic budgets and the specific functions of a hospital, prospective budgets are annually established to reimburse hospitals for the treatment of their patients. Prospective budgets do generally not incorporate incentives for the hospital to spend less than the budget fixed before. Under the persisting financial constraints in the hospital sector, many countries changed during the last 20 years their financing method for hospitals towards ► per-case payments based on ► Diagnosis Related Groups (DRGs).

P

Synonyms

Projections

Definition

Projections of future developments

Basic Characteristics

The human and material damage caused by many disasters can be reduced if adequate measures are taken (► disaster response; ► mitigation strategies; ► recovery strategies). Alone, extension of the temporal horizon of forecasts of extreme events (e. g. floods and droughts); improvements in their accuracy and reliability; and progress in warning, its dissemination and penetration, and response to warnings (► health warning systems) could save many lives and considerably reduce human suffering and material damage. Changes in the risk of natural disasters (► hazards, natural) depend on the population, economic growth and the quality of the preparedness system.

However, humankind will never be free of natural disasters generated by extreme geophysical (climatic, hydrological, seismological, volcanic) events and disasters caused by man (► hazards, technological). Potentially, the most disastrous event could be collapse of a large man-made infrastructure object, such as a large dam break, jeopardizing people living downstream. In some areas, population density in the vicinity of the river downstream from large dams is high (including large cities).

The September 11 tragedy (opening a new, post-9/11 era in security precautions) unveiled the possibility of emergence of new man-made disasters – "innovative" and inhuman acts of violence, aimed at massive killing, where maximizing the number of anonymous fatalities is the terrorists' target. This was also the terrorists' objective behind the use of the deadly sarin nerve gas in the Tokyo subway, and the bombs in the Madrid and London transportation systems.

Possible causes of hypothetical future disasters are: a gigantic asteroid colliding with the planet Earth, a mega-tsunami (the record consequences of the tragic event of 26 December 2004 are not the absolute limit and can be exceeded), and global climate change, which – in the long-term – may severely and adversely affect the life support system in many areas. Climate change itself can indeed generate a disaster. Ultimate changes due to the finite Sun's lifetime are expected but not in the time scale of human perception (of the order of billions of years). Changes in solar activity and in parameters of the trajectory of Earth's movement around the Sun generate climate changes at large time scales (e. g., many thousands of millennia – like glaciation periods). In the past, sudden climate change, e. g. induced by the fall of a large meteorite or strong volcano eruption, caused severe effects such as extinction of the dinosaurs or – more recently – hunger during and after "the year without summer" (1816), respectively.

There is an increasing body of evidence regarding the ongoing planetary climate change (global warming) that is attributable to human activities, such as the rising emission of ► greenhouse gases (carbon dioxide, methane, nitrous oxide, etc) leading to buildup of greenhouse gases in the atmosphere and enhancement of the ► greenhouse effect, and land-use changes (e. g. deforestation in tropical areas). The global climate system has been driven out of the stable, natural variability mode. Consequently, every single year from the period 1997–2006 made it to the list of ten warmest years globally in the global instrumental temperature observation records, which date back to 1860. Future warming depends on scenarios of socio-economic development and on the mitigation policy (curbing the greenhouse gas emissions). Projected temperature changes differ regionally, being model- and scenario-specific, with a global mean temperature for 2100 predicted to be 1.0 to 6.3°C higher than 1980–1999. Article 2 of the United Nations Framework Convention on Climate Change (UNFCCC) defines international policy efforts in terms of avoidance of a level of greenhouse gas concentrations beyond which there is "dangerous interference with the climate system".

There have been ongoing changes in other climate-related variables, such as precipitation (growth in some areas, decreases in other areas of the Globe), river flow, glacier extent, and sea level. The area of the Globe's surface with very wet or very dry status has been increasing and the water cycle has accelerated. Various extreme events are expected to change in magnitude and/or frequency and location with global warming. In some cases, significant trends have been observed in recent decades.

In many areas, an increase in intense precipitation has been observed, which can be translated into increased flood hazard. Even stronger changes are projected for the future.

The Intergovernmental Panel on Climate Change (IPCC) Third Assessment Report identified five "reasons for concern" about climate change, whose seriousness increases with global warming (Table 1).

Any regional increases in climate extremes (storms, floods, cyclones, droughts, etc.) associated with climate change are likely to cause physical damage, population displacement, and adverse effects on food production and freshwater availability and quality. Adverse health effects would increase, particularly the risks of infectious disease epidemics in developing countries. Already at present, diarrheal diseases attributable to unsafe water and lack of basic sanitation cause numerous (nearly 2 million) deaths a year worldwide. The projected increase in frequency and severity of droughts would exacerbate the situation. Malnutrition affects every third human, dwarfing most other diseases. The increased risk of extreme events caused by climate change is likely to worsen the situation and exert an adverse human health impact.

Prospects for the Future, Table 1 Reasons for concern related to projected climate change

Reason for Concern	Specification
Unique and Threatened Systems	Warming harms several such systems, in particular coral reefs, glaciers, and polar ecosystems, some of which are already adversely affected by the temperature increase to date.
Extreme Events	The frequency and magnitude of many extreme climate-related events (e. g., heat waves, intense precipitation, and tropical cyclones) are likely to increase.
Distribution of Impacts	Developing countries are more vulnerable to climate change than developed countries. Even a small warming has negative impacts on some regions (many developing countries), while large warming would have negative impacts on most regions.
Aggregate Impacts	Due to a small warming, most people of the Globe are likely to be adversely affected. For large warming, the impacts are likely to be negative in all metrics.
Large-Scale Singularities	Climate change may trigger large-scale singularities, such as deglaciation of the Greenland ice sheets and the West Antarctica Ice Sheet (WAIS), and slowdown of thermohaline circulation.

The 2003 European heat wave killed many thousands of people, showing that even developed countries may not be adequately prepared to cope with extreme heat. There were 10 days with temperatures over 35°C in Paris, and mortality in the time period from 1 to 20 August increased by 55%, as compared with earlier years. Occurrence of a heat wave as extreme as the one in Europe in August 2003 would be unlikely in the absence of anthropogenic climate change. An individual extreme event, such as extreme flood or heat wave, cannot be directly attributed to climate change. However, the probability of an extreme event of a given intensity (magnitude) is likely to increase in the future. Hence, these excess deaths, caused by heat wave, can be linked to climate change. An increase in the frequency or intensity of heat waves in the future, warming, climate will increase the heat-caused risk of mortality and morbidity, particularly in older age groups (sick people, lonely people) and among the urban poor.

Potentially disastrous effects can be caused by transmission of infectious diseases. Despite modern health care, a re-emergence of ► tuberculosis has been observed and there is ubiquitous occurrence of the ► HIV/AIDS pandemic. Even if the consequences so far have not been disastrous, recent emergence of avian influenza (virus H5N1) and Severe Acute Respiratory Syndrome (► SARS), with confirmed cases of infections (and deaths), quarantine, and material losses, have raised considerable concern. Globalization and human mobility in the global village have led to connectivity between remote regions and continents at unprecedented levels. While in the past, the incubation period (between exposure to a pathogen and the development of disease symptoms) was substantially shorter than a long-distance journey, now, with contemporary air speeds, travel times are shorter. If H5N1 mutates into a virus that can be transmitted among humans, it can be disseminated worldwide with potentially ravaging effects, leaving no place on Earth potentially safe from emerging infectious disease.

Protease-Inhibitors (PI)

Synonyms

Drugs to treat AIDS; AIDS-therapeutics; Anti-HIV medications; Antiretroviral medications

Definition

Protease-inhibitors (PI) interfere with the production of infectious viral particles. Due to their short plasma half-life they have to be taken thrice daily. By combination with ritonavir (RTV, Norvir™) the plasma half-life can be lengthened, which is why ritonavir is called a "booster". Ritonavir is only licensed as a booster. Available protease-inhibitors are nelfinavir (NFV, VIRACEPT®), amprenavir (APV, Agenerase®), indinavir (IDV, CRIXIVAN®), saquinavir (SQV, FORTOVASE®, INVIRASE®), lopinavir/ritonavir (LPV/RTV-booster, Kaletra®), atazanavir (ATV, REYATAZ®), fosamprenavir (FPV, Telzir®) and tipranavir/r (TPV, Aptivirus®). Long-term treatment with protease-inhibitors has a negative influence on fat metabolism.

Protection Motivation Theory

Definition

Protection motivation theory has originally been proposed to provide conceptual clarity to the understanding of fear appeals. Later the theory has been extended to a more general theory of persuasive communication, with an emphasis on the cognitive processes mediating behavioral change. It describes coping with health threat as the result of two appraisal processes: a process of threat appraisal and a process of coping appraisal, in which the behavioral options to diminish the threat are evaluated. The appraisal of the health threat and the appraisal of the coping responses may result in the intention to perform adaptive responses (protection motivation) or may lead to maladaptive responses i. e. not participating in breast cancer screening.

Protein Folding Problem

Definition

The prediction of the tertiary three-dimensional structure of a protein from the primary sequence of amino acids in a protein. This unsolved problem derived its complexity from the large number of possible configurations each bond angle can have.

Proteome

Definition

Two possible definitions. The complete proteome is the complete set of proteins that can be produced by one or a group of cells. This is more related to the static characteristic of genome. The cellular proteome is the set of proteins that is present in the cell at a specific time point under a specific environmental condition. This is more related to the dynamic nature of the ► transcriptome.

Proteomics

Definition

Proteomics is the collective study of protein products. Proteomics also includes the study of the structure and

function of proteins, including the way proteins function and interact. Using high throughput technologies, such as PAGE followed by mass spectrometry, thousands of proteins can be resolved and identified in a single experiment.

Protozoa

Synonyms

Single-celled eukaryotes; Unicellular organisms

Cross-References

► Zoonotic and Parasitic Infections

Provider

Definition

The term provider refers to a hospital, licensed health care professional, or group of hospitals of health care professionals that provide health care services to patients. Providers may also include medical supply firms and vendors of durable medical equipment.

Provider Fatigue

Definition

The daily demands of critical care nursing, including psychosocial stressors, heavy patient workloads, and noxious sensory stimuli make healthcare staff particularly vulnerable to fatigue, and subsequently to accidents and errors. The study of health care provider fatigue is therefore of crucial importance to the promotion of safe patient care environments.

Psychiatric Sociology

► Social Psychiatry

Psychiatry

Definition

Psychiatry is the medical specialty that addresses the prevention, diagnosis, and treatment of mental illness and substance use disorders. There is usually extensive training required after medical school to become

a psychiatrist, especially for further sub-specializations like adolescent psychiatry, geriatric psychiatry, forensic psychiatry, psychopharmacology, or psychoanalysis. The psychiatrist is in most cases the best-qualified physician to differentiate between physical and psychological causes of both mental and physical distress.

Psychoeducational Intervention

Definition

A psychoeducational intervention is an intervention, often for families with a chronic illness or disabled member, which provides education, skills training and emotional support for individuals and/or family members.

Psychogenic Loss of Appetite

Synonyms

Pica in adults

Definition

Psychogenic loss of appetite is characterized by a loss of appetite due to stressful events.

Psychological Distress and Palliative Care

Synonyms

Spiritual concerns

Definition

Alleviation of psychological distress in patients receiving end stage care is the key to effective palliative care; a safe way has to be found to address the individual's physical and/or psychological problems. While some patients want to explore their psychological or spiritual problems, some do not, so it is essential to determine patients', partners' and families' wishes regarding this type of help. Alleviating psychological distress is complex in end stage care as hospice and palliative care requires interdisciplinary teams consisting of physicians, registered nurses, hospice chaplains, social workers, physiotherapists, occupational therapists, complimentary therapists, volunteers and, most importantly, the family. Furthermore, home health care aides, volunteers from the community, housekeepers, family members and volunteers, are crucial to the palliative care system. Anyone of the members of this extensive team, let alone the patient, may find themselves under severe emotional and physical stress whilst being involved in palliative care.

Psychoneuroimmunology

Synonyms

Neuro-endocrine immune-network

Definition

Psychoneuroimmunology studies the interaction of behavioral, neural, and endocrine factors and the functioning of the immune system. The premise is that a patient's mental state influences diseases and healing. The term psychoneuroimmunology was coined by Robert Ader, a researcher in the Department of Psychiatry at the University of Rochester Medical Center in Rochester, New York. In the 1970s, studies by Ader and other researchers opened up new understandings of how experiences such as stress and anxiety can affect a person's immune system.

Psychosis

Synonyms

Psychotic disorders; Dementia praecox; Auditory hallucinations; Thought disturbances; Distorted thinking

Definition

A cluster of psychotic phenomena that occur during or following psychoactive substance use but that are not explained on the basis of ► acute intoxication alone and do not form part of a ► withdrawal state. Psychotic disorders are characterized by hallucinations (typically auditory, but often in more than one sensory modality), perceptual distortions, delusions (often of a paranoid or persecutory nature), psychomotor disturbances (excitement or stupor), and an abnormal affect, which may range from intense fear to ecstasy. The sensorium is usually clear but some degree of clouding of consciousness, though not severe confusion, may be present.

Cross-References

► Substance Induced Disorders

Cross-References

► Psychotic Disorders

Psychosocial Development

Synonyms

Psychosocial maturation; Psychosocial transition

Definition

Psychosocial development includes the ability of the adolescent to seek and/or gain social acceptance and integration from peers and adults.

Psychosocial Maturation

► Psychosocial Development

Psychosocial Transition

► Psychosocial Development

Psychosocial Work Environment

Definition

A psychosocial environment is defined as the socio-structural range of opportunities that is available to an individual person to meet his or her needs of well-being, productivity, and positive self-experience, in particular self-efficacy and self-esteem. With respect to work, this environment concerns central features such as fair employment conditions, skill and career development, adequate demands, and safety measures. Theoretical models are being developed to identify health-promoting or health-adverse components of a psychosocial work environment. Widely tested examples are the demand-control model and the effort-reward imbalance model.

Psychostimulants

Synonyms

Stimulants

Definition

Stimulants are psychotropics which enhance brain activity and in turn increase alertness, attention and energy. Historically, psychostimulants were used to treat a variety of ailments (e. g. asthma, obesity). Now, they are prescribed for the treatment of only a few diseases, especially narcolepsy and attention deficit hyperactivity disorder. Drugs such as caffeine and amphetamines belong to this category, too.

Psychotic Disorders

Uwe Ruhl
Institut für Psychologie, Universität Göttingen, Göttingen, Germany
uruhl@uni-goettingen.de

Synonyms

Dementia praecox; Auditory hallucinations; Thought disturbances; Distorted thinking; Psychosis

Definition

► Schizophrenia, ► schizotypal disorder, and persistent ► delusional disorders are classified, according to ICD-10, as schizophrenic or psychotic disorders. The psychotic disorders are characterized in general by fundamental and characteristic distortions of thinking and perception, and affects that are inappropriate or blunted. Clear consciousness and intellectual capacity are usually maintained although certain cognitive deficits may evolve over the course of time. The most important psychopathological phenomena include "positive symptoms", for example, thought insertion or withdrawal; delusional perception and delusions of control; influence or passivity; hearing internal, hallucinatory voices commenting or discussing the patient in the third person; assigning unusual significance or meaning to normal events or holding fixed false personal beliefs (► delusions); and "negative symptoms" (i. e., reduction in the range and intensity of emotional expression, poverty of speech, and reduction, difficulty, or inability to initiate and persist in goal-directed behavior). ► Schizoaffective disorders are characterized by both schizophrenic and affective symptoms.

Basic Characteristics

Introduction

The German psychiatrist Emil Kraepelin was the first person to catalog the symptoms of schizophrenia in the late 19th century (Andreasen 1997). Initially, Kraepelin named schizophrenia "dementia praecox". Eugen Bleuler introduced the term schizophrenia in 1911. Multiple interactions are involved in the causation of schizophrenia. Genetic risk factors (the risk of schizophrenia in first-degree relatives of people with schizophrenia is 10%) interact with environmental exposures (e. g., fetal hypoxia, obstetric complications, season of birth [individuals born in the winter half-year are significantly more often affected by schizophrenias than individuals born in the summer half-year], stress in daily life, cannabis use). There is still a discussion over whether the use of cannabis increases the risk of schizophrenias or, vice versa, if the use of cannabis is an attempt to therapy the first symptoms of schizophrenic disorders. Early onset of illness, family history of schizophrenic disorders, and prominent negative symptoms are suggestive of poor prognosis, whereas an acute stress-related onset of schizophrenias, higher social class, better premorbid social development, and no history of cannabis use are associated with a better course of the illness (Kelly et al. 2001). The onset of psychosis is associated with increased risk of suicidal behavioral or aggression.

Epidemiology

The lifetime prevalence rate of schizophrenic disorders is estimated to be about 1 percent (e. g., Jablensky 1995). According to Wittchen and Jacobi (2005), the 12-month-prevalence of psychotic disorders in European countries is 2.6% (women: 2.5%, men: 2.6%). Hallucinatory and delusional symptoms, especially, ► illusions, show a much higher prevalence in the general population than manifest psychotic disorders (10–15%, Johns and van Os 2001).

Pathophysiology/Etiology

Schizophrenia affects men and woman with equal frequency. Up to date research has failed to uncover any definite causes. Psychological theories attribute unfavorable social and emotional experiences (i. e. double-bind/expressed emotion); biological theories prefer to see schizophrenia as a physical disease of the nervous system. Schizophrenia may be associated with chemical defects or physical abnormality of the brain.

Consequences

Onset of psychotic disorders typically occurs during young adulthood, although earlier and later onset does occur as well. Onset may be abrupt or gradual, but most people experience some early signs, such as increasing social withdrawal, loss of interest, unusual behavior, or decreases in functioning prior to the beginning of active positive symptoms. The course of psychotic disorders can be continuous, episodic with progressive or stable deficit, or there can be one or more episodes with complete or incomplete remission. However, full recovery is unusual. According to the World Health Report (2001), schizophrenia causes a high degree of disability and is listed as one of the leading causes of lost disability adjusted life years (DALYs). Early onset of schizophrenic disorders (i. e., prior to 25 years of age) is associated with more gradual development of symptoms, more prominent negative symptoms, and more neuropsychological problems (Basso et al. 1997;

Symonds et al. 1997). Patients with schizophrenia have lower rates of employment, marriage, and independent living than other people. Patients suffering from schizophrenias have a 10% risk of suicide. Psychotic disorders are often associated with comorbid substance use disorders. The burden of psychotic disorders affects not only patients but also their families. Distress and changes in the relationship between family members and the psychotic patient during acute phases of illness are a particular burden on relatives (Lauber et al. 2003).

Treatment

Although some patients with psychotic disorders can be treated as outpatients, acutely disorganized psychotic people frequently need hospitalization in order to be stabilized. In the acute stage, a person suffering from a psychotic disorder is treated with antipsychotic medication. Antipsychotics are used to diminish the positive symptoms of schizophrenia and help organize the person's thinking and, therefore, his/her behavior. Antipsychotics do not change the patient's personality. Antipsychotic maintenance medications have repeatedly been shown to prevent relapses. Novel antipsychotic medications are associated with fewer extrapyramidal adverse effects and are probably more effective in treating the negative symptoms and cognitive impairment of schizophrenia than conventional antipsychotic agents are. Antipsychotics may be associated with weight gain, thus, nutritional counseling and increased physical activity can be helpful for the patients and increase their compliance.

Patient education is another important part of treatment. It includes teaching about the importance of medication compliance, abstinence from alcohol and other drugs of abuse, and the recognition of early signs of a decompensation (e. g., insomnia or increased irritability). Psychosocial interventions help patients and their families to cope with the illness and reduce relapse rates (i. e. expressed emotion concept). Rehabilitation can support the reintegration of patients into the community.

Many types of psychotherapy, including individual, group, and family therapy, may be used at some point in the illness to help support the person suffering from a psychotic disorder.

Pubertal Maturation

Synonyms

Sexual maturation; Sexual maturity

Definition

Pubertal maturation describes physical development to the state when sexual reproduction first becomes possible (sexual maturity). This includes further development of reproductive organs and development of secondary sexual characteristics such as breast development in girls, genital development in boys, and pubic hair in both.

Pubic Lice

Synonyms

Pediculosis pubis

Definition

Most frequently, pubic lice are transmitted during sexual intercourse; infection is also possible if clothing, towels or bedlinen are shared. Pubic lice primarily live in pubic hair, but they can also be found in the hair of the armpit or the head, in beards, eyebrows or eyelashes. The parasites, which feed on blood, are specific to humans; outside their hosts they usually die within 24 hours. At the site of the bite, little blue-gray spots and strong itching occur. Due to scratching, inflammation of the skin and bacterial superinfection can ensue. To cure the infection, local treatment is necessary, using lindane, pyrethrum or permethrin. Clothing and bedlinen should be washed at a temperature of at least 60°C. Lice, eggs and nymphs can be killed by freezing or by keeping clothing or other articles in plastic bags for a couple of days.

Cross-References

► Sexually Transmitted Diseases

Publication Bias

Definition

Publication bias is the tendency on the parts of investigators, reviewers, and editors to submit or accept manuscripts for publication based on the direction or strength of the study findings. Publication bias is the tendency to produce results that appear significant, because negative or near neutral results are almost never published. Prevention of publication bias is important both from the scientific perspective (complete dissemination of knowledge), and from the perspective of those who combine results from a number of similar studies (► Meta-Analysis). If treatment decisions are based on the published literature, then the literature must include all available data that is of acceptable quality.

Public e-Health

Definition

Public ► e-health is the use of the ► Internet by public health organizations and departments to provide ► public health services. Public health services have a great role in health promotion and prevention, adoption of healthy life styles, prevention of non-communicable diseases, and environmental protection, etc.

Public Health

Synonyms

Preventive medicine; Community medicine; Hygiene

Definition

Public health is field of medicine and hygiene dealing with the prevention of disease and the promotion of health. It encompasses different fields primarily epidemiology, hygiene, biostatistics and social medicine. Public health is one of the efforts organized by society to protect, promote, and restore the people's health, the goals being to reduce the amount of disease, premature death, and disease-produced discomfort and disability in the population. It is the combination of sciences, skills, and beliefs that is directed to the maintenance and improvement of the health of all the people through collective or social actions. Public health is thus a social institution, a discipline, and a practice.

Synonyms

Public health agencies

Definitions

Public health is the art of applying science in the context of politics in order to reduce inequalities in health while ensuring the best health for the greatest number (WHO 1998). A more specific definition is that public health is the organization and analysis of medical knowledge in such a way that it may be utilized by society in the making of decisions regarding health related questions (Forsetlund 2001).

Public health departments are organizational units within the public health infrastructure that perform public health goals. Public health departments are dependent upon public funding and are delegated public authority by a government body to provide preventive functions. These characteristics are crucial to the definition of public health agencies, since they distinguish them from private organizations that may perform similar health promotion and prevention functions.

Basic Characteristics

Public Health Infrastructure and Functions

The ► infrastructure of public health is the underlying foundation that supports the planning, delivery, and evaluation of public health activities and practices. The three components of basic public health infrastructure are: 1) the workforce (► workforce in public health) – professionals and public health agencies, 2) information and data systems – systems that monitor disease and enable efficient communication among public and private health organizations, the media, and the public, and 3) the organizational capacity – the consortium of local and state public health departments and private partners (CDC 2001).

The main function of public health is to address the determinants of health in a community, protect a population's health, and treat disease (WHO 2003a).

Since ► functions of public health represent public goods, it is in the best interest of governments to ensure the provision of these essential functions, not necessarily implementing and financing them on the state level, but providing an approach for intersectorial action with other public health partners.

Public health practitioners collaborate with other members of the health team and with several other professional groups in the community, and thus hold an important position in the local decision-making process. The evidence-based health care approach implies that decisions should be based on a systematic appraisal of the best available evidence, combined with an assessment of existing resources and values in society.

In 1988, the Institute of Medicine suggested three core functions for public health:

1. surveillance functions (► public health surveillance) that detect and monitor disease and injury patterns (assessment – figuring out what the important health problems are),
2. developing policies that promote health, and prevent disease and disability (policy development – deciding what to do),
3. ensuring that data-driven interventions address the health issues identified through assessment activities (assurance – doing it well, or making sure someone else does it well).

These core functions were further delineated into more specific essential services (► essential public health services; ► public health services; ► health information) (Institute of Medicine 1988).

Public Health Law

The recognition that public health protection requires the positive intervention of the law is not new. Even the earliest known civilizations founded their public health activities, such as enforcing sanitation codes, regulating the food supply, and caring for the sick, on some kind of law – either religious beliefs or civil authorities. Even today, public health departments depend on the laws that establish their offices, provide their authority, and support them financially (Goodman et al. 2003). It is impossible to deny the fact that law is essential to public health, because it is a tool of

social ordering, which in turn affects the well-being of individuals and communities (► law in public health; ► ethics).

The relationship between public health and law is certainly interdependent. Law can be a powerful mechanism for changing the course of public health. It is expected that strict legislations on smoking and cigarette marketing will lead to a decrease in the incidence of smoking-related diseases and thus support public health in many populations. However, law can create barriers to public health, such as in cases where the law protects the interest of industries and places economic interests above health. On the other hand, law depends on public health. Since public health is among the most ancient of all administrative agencies, its policy was used as a model for the organization and development of many bureaucratic organizations and administrative law.

Public health law can be seen as the authority and responsibility of the government to prevent disease and promote the population's health, at the same time respecting the rights of the person's privacy and property, as well as the rights of all groups in the society (Gostin 2000). Public health authorities traditionally have a variety of powers to regulate persons, professionals, and businesses in order to safeguard the common good in a well-regulated society:

a. Regulation of persons – in order to prevent transmission of communicable diseases, public health authorities have the power to compel individuals to submit to testing or medical examination, especially in certain occupations, such as food handlers, nurses, or teachers. Compulsory immunization or isolation and quarantine of persons with infectious diseases are other examples of public health policies that put public health above individual autonomy and privacy.
b. Regulation of professions and businesses – public health authorities have the power to control licensure for a profession, occupation, or business of choice, thus limiting the person's liberty and the use of his property, while at the same time protecting public interests for health, safety, and welfare. Similarly, public health laws may prohibit public facilities that pose a significant threat to health, such as factories producing air pollution, activities emitting excessive noise, and wastes contaminating water or soil (Goodman et al. 2003).

Current Operational Problems in Public Health Departments

Public health departments use information collected from surveys and reports collected within a community. Some diseases are regularly reported to public health departments, such as the occurrence of infectious diseases, cancer, cardiovascular diseases, diabetes, injuries, etc.; while health related issues (smoking patterns, alcohol consumption, physical exercise, dietary habits, etc.) are collected by conducting national health surveys. Public health departments use these sets of information for the production of statistical information on the health status of the community, which in turn is used by the government to assist in formulating, monitoring, and evaluating health politics in the provision of health care services (WHO 2003b).

Public health departments are facing various barriers in their work, which can be summarized as:

- Problems with workforce – lack of formal training of public health professionals. These individual skills are described as ► core public health competencies, and ► core legal public health competencies;
- Financial problems – limited or unstable funding due to low priority among policy makers in general;
- Problems with information technology – limited use of advanced technology such as electronic information systems and telecommunication;
- Organizational problems – lack of knowledge and organizational capacity to respond to public health threats, e. g. ecological changes, bioterrorism attacks;
- Problems with ► data quality – incomplete and inaccurate data collection, lack of standards for reporting statistical data, and dysfunctional reporting procedures (US Department of Health and Human Services 1997; WHO 2003b; Baker et al. 2005).

Challenges for the Future

Many public health authorities suggest that some changes in public health priorities must be made in order to meet the health challenges we are facing at present:

1. Institutional changes – strengthening the governmental public health infrastructure that forms the backbone of the public health system is of prime importance. Furthermore, a rational health system organized toward primary health care must be insti-

tutionalized, and systems of accountability must be developed to assure the quality and availability of public health services. New intersectoral partnerships are needed, and communication within the public health system must be established (e. g., among all levels of the governmental public health infrastructure and between public health professionals and community members). Public health departments must engage more health professionals, who need to be well educated and properly trained in this field.

2. Adopting a population health approach that considers the multiple determinants of health: elimination of health disparities (better access to health care), focusing on longer lifetime and healthy lifestyles, fighting non-communicable diseases through intervention regarding risk factors, protection of the environment, and preparedness to respond to emerging infectious threats such as new diseases, bioterrorist attacks, and resistance to antibiotics. Public health must promote good mental health in communities; and help to reduce violence in society through interventions in schools, workplaces, and communities, and the use of mass media (Koplan 2000; Institute of Medicine 2002; Kirch 2004).

Conclusion

We are living in a period of major transitions in the health of populations. On one hand, accelerated economic growth and technological advances have enhanced health and life expectancy in many populations. On the other hand, the erosion of social and environmental conditions has led to impairment of the health of many populations. The scope of contemporary public health must therefore encompass a reduction in social and health inequalities and strive for health-sustaining environments. The goal to make people live longer and healthier than before should be used as a base point for establishment of a modern public health system. Further research is required to focus on the needs of policy and practice in order to make public health services more effective in providing health to the community.

Introduction

For centuries humans have known that heredity affects health (Adams 1886). In the 1850s Gregor Mendel systematically studied the genetic transmission of observable traits in sweet peas and described different modes of inheritance for traits as the product of the transmission of ► alleles from parent to offspring (Mendel 1866). Based on Mendel's experiments the distinction between genotype and ► phenotype was established. Several decades later, ► deoxyribonucleic acid (DNA) was characterized as the medium in which ► genetic information is encoded. The development of recombinant DNA technologies in the early 1970s facilitated studies on the functionality and structure of genetic information. The Human Genome Project (HGP) was initiated in 1986 to map the human ► genome to the nucleotide level and has attained 99% completion by 2003. The HGP has sequenced approximately three billion base pairs and identified approximately 30,000 genes (The National Human Genome Sequencing Consortium 2003).

Except for monozygotic twins, each person's genome is unique. The International HapMap Project is an initiative to identify genetic similarities and differences in human beings. Its goal is to identify genes that affect health, disease, and individual responses to medications and environmental factors. The initiative started in October 2002 and already contained information on about six million ► single nucleotide polymorphisms (SNPs) in March 2006 (The International HapMap Consortium 2003).

This short historical overview highlights that genetics is among the most rapidly emerging fields in science. Whereas genetics is the study of single genes and their effects, genomics is the study of the functions and interactions of all the genes in the genome. The science of genomics, which was established about 15 years ago, applies not only to monogenetic conditions, most of which are rare, but also to common disorders, which typically are caused by interactions of multiple genes and environmental factors (Guttmacher 2002). For decades, genetics played a large role in the health of few individual patients, but was less important at the general population level. Today, we are about to enter a transition period in which specific genetic knowledge is becoming critical to the delivery of effective health care for everyone. Therefore, every public health professional will soon need to understand the concept of genetic variability, its interactions with the environment, and its implications for patient care and population health.

We are about to enter an era in which the individual patient's genome will help determine the optimal approach to medical care (Guttmacher 2002). In key public health tasks and disciplines, such as prevention, risk assessment, ► epidemiology, and environmental health issues related to genetics, already play a central role and are likely to gain even more impact in the near future.

In the following key aspects of the discipline of public health genetics will be outlined. More detailed information on these issues is provided in the corresponding essays.

Genetic Principles

DNA is the basic molecule in which genetic information is encoded. Individual DNA units, or nucleotides, consist of one of four nucleic acids [Adenine (A), Cytosine (C), Thymine (T), or Guanine (G)] bound to a molecule of the ringed sugar 2′-deoxyribose. These nucleotides are in turn bound to one another by covalent bonds between phosphate groups attached to the 5′ and 3′ positions of the ribose sugar backbone, and form a strand, going from 5′ to 3′. Each nucleic acid has an affinity for another nucleic acid (A for T, G for C, and vice versa), and aligns with another strand which has a 'reverse complement' of the sequence of the first strand. This double-strand relaxes to a low-energy state wherein the DNA coils and forms a double-helix.

Genes are sections of functional units of double-helical DNA strands. Alternative forms of a gene are termed alleles. Individuals who possess two different alleles of a particular gene (one inherited from each parent) are

called heterozygote, whereas homozygote refers to having two identical alleles of a particular gene.

Long continuous DNA strands are referred to as ► chromosomes. Chromosomes contain hundreds to thousands of genes plus non-functional DNA sequences. The human genome consists of 22 unique autosomal chromosomes plus two X chromosomes in females and one copy each of an X and Y chromosome in males, respectively. Somatic cells are termed diploid, because they have two homologue copies of each chromosome (46 chromosomes). Germ cells are termed haploid as they only have one copy of each chromosome.

Each cell undergoes a cellular cycle of DNA and cell duplication. Within each cellular cycle the whole DNA is duplicated (replication), transcribed into single-stranded ribonucleic acid (RNA) (► transcription), and translated into polypeptide chains (► translation). At the end of each cellular cycle each diploid somatic cell divides into two diploid daughter cells (► mitosis). In somatic cells identical copies of the chromosomes are made before cell division. In germ cells, however, DNA sequences are exchanged along the arms of homologous chromosomes (recombination, crossing-over). The division of germ cells (► meiosis) consists of two sets of cell division: firstly, the diploid cell gives rise to two diploid daughter cells, secondly, the two diploid daughter cells each produce two haploid daughter cells with only one copy of a homologous chromosome in each cell. ► genetic principles and genetic variations.

Genetic Variations

It is a basic genetic principle that cells use DNA to encode RNA, and RNA to encode proteins. Thus, errors in any of the processes with which DNA and/or RNA is involved may alter the type, functionality, and/or the amount of protein products produced by cells.

Large-scale alterations such as chromosomal abnormalities are rare. Chromosomal abnormalities usually cause severe diseases or are lethal. Potential causes include non-disjunction (the failure of chromosomes to separate during cell division), or anaphase lagging (the loss of chromosomes during cell division). The resulting chromosomal number abnormalities affect all genes on the affected chromosomes, and thus can lead to multi-symptom syndromes, such as Down's syndrome (Trisomy-21). Other chromosomal abnormalities can include chromosomal rearrangements such as translocations, large-scale insertions and deletions, or inversions of chromosomal arms. These changes can result in errors of ► recombination.

Smaller-scale variations include local changes to the genomic sequence such as ► polymorphisms and ► mutations. Polymorphisms are common variants of particular segments of DNA. Mutations are by definition infrequent, and can often be redefined to be polymorphisms if they achieve sufficient frequency in the population. Small-scale variations are much more frequent than chromosomal abnormalities. They may have a protective or a pathologic role in the expression of diseases. The former variations are referred to as gain-of-function mutations. However, as approximately 95% of DNA is noncoding, mutations at most points in the genome are unlikely to have any effect (silent mutation).

Single nucleotide polymorphisms (SNPs) are variations where a single nucleotide in the genome may differ from individual to individual. Single changes in the nucleic acid at a particular position may have effects on zero or one amino acid encoded, whereas SNP insertion/deletion polymorphisms may shift the entire sequence of amino acids encoded by the DNA radically by changing the frame of reference in which the coding information is read.

Monogenic diseases are caused by a mutation in a single gene. However, it has to be considered that a mutation in a recent generation can either have been passed down to an individual, or can have occurred during the lifetime of the affected individual. Somatic cell mutations, due to errors in replication or DNA alterations by external stimuli, can be lethal and preclude transmission by affecting individuals' reproductive health; similarly, germline transmissions may affect a person's offspring without affecting the individual himself.

Genetic defects may be inherited defects or accidentally created changes arising from cells that are aging or are exposed to environmental factors such as radiation, chemicals, and some toxic pollutants. ► genetic principles and genetic variations.

Molecular Technologies to Detect Genetic Variations

A basic understanding of molecular techniques is necessary to envision potential applications of genetics and genomics in public health. Since the develop-

ment of recombinant DNA technologies in the early 1970s molecular technologies have quickly emerged as a central field of biomedical research. Polymerase chain reaction (PCR) and related technologies facilitate studies on both the functionality and the structure of DNA.

PCR was developed in the 1980s by Kary B. Mullis, who was awarded the 1993 Nobel Prize in chemistry for his work. PCR is an in vitro technique for amplifying defined DNA sequences by separating the DNA into two strands and incubating it with oligonucleotide primers and DNA polymerase. It can copy a specific sequence of DNA up to one billion times. Advantages of this universally applicable method are its robustness, specificity, and sensitivity. Slightest traces of DNA can be detected and made available for diagnostic purposes. Restriction Fragment Length Polymorphism (RFLP) is a common technique to recognize and cut DNA specifically at a defined sequence of nucleotides. Applications for RFLP include the detection of known SNPs and mutations. As a result of mutations restriction sites may either be lost or additional restriction sites may emerge. Thus, in the case of a mutation, the length of the DNA fragments produced will differ from the wild type fragments. Other popular methods to detect known SNPs, mutations, and/or polymorphisms include 5′ nuclease assay and melting curve analysis. In contrast to RFLP, the latter methods may not only be used for detection of certain mutations but also for allelic differentiation.

► DNA microarrays (DNA chip technology) allow the simultaneous analysis of many known DNA alterations such as heterozygous base-pair polymorphisms or mutations, insertions, and deletions (Strachan 2004). Dideoxynucleotide sequencing is an elaborated method to detect unknown mutations. DNA sequencing enabled initiatives like the HGP; the basic principle being sequencing DNA after amplification by PCR. This technique utilizes DNA polymerase, the four deoxynucleotide-triphosphates (dNTPs) and fluorescing dideoxynucleotide-triphospates (ddNTPs). The ddNTPs compete with dNTP and terminate DNA chain elongation. Gel electrophoresis can be used to separate the fragments by size and the base at the end of each fragment can be identified by laser light stimulation. After combining the fragment sizes the DNA sequence can be read digitally (Strachan 2004). ► molecular technologies to detect genetic variations

Bioinformatics

In response to the ascertainment of huge amounts of biological data, computer scientists and biologists collaborated in creating a new discipline named ► bioinformatics. Besides modern molecular technologies elaborated computational tools and algorithms facilitated the genomic revolution. The main aims of bioinformatics include: acquisition, storage, and management of large-scale biologic data; development of algorithms and computational tools to analyze and classify the data; integration of the data to make conclusions and predictions. Within the last decades huge databases have been established for proteomic, genomic, phylogenetic, chemical, structural, phenotypical, functional, ontological, and transcriptomic information.

In sequence analysis, bioinformatics is applied to execute the alignment and comparison of DNA sequences. In transcriptomics, another new discipline, computational tools are used to measure gene expression on a large-scale. A large set of different algorithms has been developed to analyze these expression data.

With the availability of large amounts of information at all levels, biological research is no longer confined to experimental methods based on single genes. The new challenge is to consolidate, integrate, evaluate, and obtain data from established sources to generate hypotheses or produce a set of targets that can then be validated and investigated using experimental methods. With more available computation resources and data, researcher can now start to think of genes and proteins in relation to a vast network of interactions within the genome and think more in terms of pathways and systems. Just like biotechnological advances such as PCR have revolutionized biology, future biological research will be intimately involved with bioinformatics databases, tools, and analyses.

Genetic Epidemiology

► Genetic epidemiology may be defined as the study of the joint action of genetic and environmental factors in disease causation and their patterns of inheritance in families (Thomas 2004). Like all other disciplines contributing to public health genetics, the field of genetic epidemiology is still quite young. It came up in the second half of the 20th century evolving from the disciplines of epidemiology and (population) genetics. Whereas genetics dismisses the environment

as noise and epidemiology dismisses genes as an unnecessary and unfamiliar complication, genetic epidemiology treats both as legitimate contributors to disease (Thomas 2004).

Until the 1970s, etiological studies of human disease were carried out in terms of latent ► genotypes through statistical analysis of family data. Investigations pertaining to the genetic basis of human diseases have been confined to simple Mendelian diseases which, for the most part, did not involve environmental effects.

As emphasis shifted from Mendelian to complex disorders such as coronary heart disease, hypertension, and diabetes, population geneticists faced new challenges because familial effects were no longer entirely genetic. Within the past decades elaborated methods of data analysis have been developed to identify genes involved in specific conditions, their variation within the population and across populations, and their interaction with each other and with environmental factors. Principle study types include aggregation analysis, segregation analysis, linkage analysis, and association analysis.

Aggregation studies frequently are the first step if a genetic etiology of a disease is hypothesized. Aggregation studies explore whether the disease (phenotype) tends to be observed in families more than would be expected by chance alone. Appropriate designs for aggregation studies include case-control comparison, migrant studies, twin studies, and adoption studies.

The next step is to determine whether the pattern of disease among relatives is compatible with their genotype. Segregation studies examine how alleles at a gene segregate from parents to children. Studies of the families of a population-based sample of cases are appropriate for this purpose.

If a genetic etiology appears likely due to the result of aggregation and segregation studies, linkage analysis is frequently the next step in determining the causal gene(s). Linkage analysis examines whether a trait locus and a genetic marker co-segregate within families. Usually, blood samples are collected from informative members of multiple case families and genotyped for markers at known locations. Beginning with a widely spaced array of markers scattered over the whole genome, the region of the presumably causal gene is further narrowed down. This process is frequently termed genome scan.

Frequently, the linked region contains many potentially relevant genes for the disease under study. Association studies are used to compare the genotypes between cases and controls and thus to test hypotheses about whether certain genes are actually associated with disease occurrence. However, even if a certain gene appears to be associated with the disease under investigation, the observed association is not necessarily causal (Thomas 2004).

The same genes may express differently in different environments and the environmental effect may vary with the person's genotype; this is known as gene-environment interaction. In industrialized societies most conditions with high prevalence, e. g. obesity, chronic heart disease, ► diabetes mellitus type II, cancer, atopic eczema, and depression have a ► multifactorial etiology, i. e. are caused by interactions of multiple genes and environmental factors. Genetic variations in multifactorial disorders may have a protective or a pathologic role in the expression of diseases (Guttmacher 2002).

In the field of genetic epidemiology different study designs have been applied to test interactive effects like gene–environment interaction. Partial-collection designs (e. g. case-only, partial case–control, case–parent trio studies) have been suggested to efficiently study hypotheses regarding gene–environment interaction. However, common problems in genetic epidemiology studies, including gene–environment correlation in the population, population mixture, and genotyping error, may reduce the validity of partial-collection designs. Therefore, the case–control design appears to be the best choice to study gene-environment interaction (Liu et al. 2004).

Population Genetics and Human Health

The human genome is made up of approximately three billion nucleotides that code for all the macromolecules necessary for human life. ► Population genetics involves the study of allele frequencies within a population and the attempt to explain the given distributions through the forces of ► natural selection, genetic drift, mutation and population expansion, contraction, and migration. The requirement for any population genetics based study is the ability to characterize and quantify the level of genetic diversity. The progression of DNA sequencing to a high throughput easily attainable technology has allowed ever increasing amounts of SNPs and micro-satellites to be analyzed,

producing genome wide maps of sequence variability at a population level.

The principle of evolution is positive selection. Therefore, the identification of novel loci under apparent selection offers the potential to highlight genes of significance to human health for subsequent molecular and epidemiological investigation.

In frequency based analysis, observed patterns of allele frequencies in a population are compared with predicted frequencies under the ► neutral theory of evolution, which states that changes in allele frequency within a population exclusively occur through stochastic events. For example, polymorphisms within chemokine receptor 5 (CCR5), which encodes a receptor used as an invasion ligand by HIV-1 are associated with reduced ► susceptibility to HIV-1. In non-African populations, these polymorphisms are at higher frequencies than would be expected under neutrality. Interestingly, the apparent age of the CCR5 mutations predates the emergence of HIV-1 and a more ancient pathogen may have shaped allelic diversity at this locus (Bamshad 2002).

It is important to note that the populations under study need not be composed of human beings in order to identify genes of direct importance to human health. For many pathogens the strongest driving forces for selection are the host immune response and chemotherapeutic drugs. The study of major human pathogens at the population genetics level has provided important information concerning the genetic determinants of virulence/pathogenicity, epidemiology, and emergence of drug resistance in these organisms.

With the increase in high throughput and decrease in costs potentially offered by new sequencing platforms, coupled with the rapid development of statistical frameworks to analyze these results the future offers a greater potential to screen the human and pathogen genome for signatures of selection. With the rapid bioinformatics analysis of loci under apparent selection these approaches will offer an increasingly powerful molecular tool box to complement other approaches such as molecular epidemiology that attempt to understand the genetic basis of human disease. ► population genetics and human health

Genetic Susceptibility of the Individual

The genetic make-up of an organism determines the individual irritability to environmental factors and thus the risk of certain diseases. Genetic variants may lead to an increased or decreased susceptibility to external factors. It is these genetic variations that have made evolution possible.

Because of the contribution of multiple genetic factors in most conditions, some of which have major effects and others have modulatory effects, the identification of susceptibility genes is frequently complex. For example, the genetic basis of type 2 diabetes is quite a complex, which may evolve into different outcomes of the disease. Atherosclerosis and retinopathy, for instance, are complications of type 2 diabetes that arise from different genes. Environmental factors, such as nutrition and physical inactivity contribute to the disease complexity and consequences like obesity and insulin resistance. Another important example where genetic susceptibility determines the individual risk of disease after a defined exposure is lung cancer from cigarette smoking. One of the cellular processes explaining the inter-individual difference in risk of lung cancer from smoking is DNA repair capacity. Genetic susceptibility also determines the individual's risk to experience harm caused by chronic low-level exposures like air/water pollutants or radiation.

Markers of disease susceptibility are now being increasingly used in the assessment of risk factors among individuals and populations. Detailed knowledge of biomarkers for disease susceptibility may have high relevance for public health, as it may enhance effective primary prevention programs among particularly vulnerable subgroups. Susceptibility markers can be grouped into three categories (Suk 2002):

- Chemical alterations by enzymes leading to a decrease or an increase in the ability of the chemical to interact with DNA, RNA or proteins.
- Genetic differences of DNA repair capacity secondary to environmental insult.
- Pre-existing hereditary defects.

Some diseases have common genetic determinants. For example, the apolipoprotein E epsilon-4 (APO E-e4) genotype is associated with an increased risk for both Alzheimer's disease and coronary heart disease (Rienzo 2005).

Genetic susceptibility to ► asthma is attributable to multiple genes interacting with one another and the environment. Present findings indicate that genes near a major locus regulating serum IgE levels on chromosome 5q cause susceptibility to asthma (Bleecker et al.

1997). People with this kind of gene are also more susceptible to the effects of ozone and other air pollutants. In the future, early ► genetic susceptibility testing might serve as a major public health tool to avoid diseases and dramatically prevent morbidity and mortality.

Pharmacogenomics and Toxicogenomics

Pharmacogenomics and toxicogenomics are related fields applying new evidence from ongoing human genome sequencing initiatives.

Although the terms ► pharmacogenetics and ► pharmacogenomics are frequently used as synonyms, there are by definition distinct differences.

Pharmacogenetics focuses primarily on the role of genetic variation in drug response. In the 1950s it has been shown that hemolytic reactions after use of certain drugs (e. g. the antimalarial agent primaquine) are associated with mutations in the enzyme glucose-6-phosphate dehydrogenase. A variety of other monogenetic pharmacogenetic traits have been described since then.

Pharmacogenomics expands upon this definition to investigate the whole genome and its products, both RNA and proteins. Currently, most pharmacogenomic studies focus on identifying individualized drug therapy strategies for prevalent conditions. But pharmacogenomic endpoints additionally have the potential to provide tailored intervention targets for primary prevention programs.

Using cancer as an example of the disease model, pharmacogenomic based tests can be used as markers to predict drug response, to screen for disease susceptibility, and as markers of prognosis. Gene polymorphisms that are associated with reduced DNA repair capacity like the nucleotide excision repair (NER) polymorphism have been shown to increase the risk of tumor recurrence and to decrease overall survival (Spitz et al. 2005). Additionally, enhanced response to platinum-based chemotherapy has been observed in individuals carrying the NER polymorphism (Rosell et al. 2003). In the near future, strategies to identify subjects most likely to benefit from certain (chemotherapeutic) agents might help to improve survival and quality of life in individual patients and also to reduce adverse drug reactions and associated economic burden.

A high proportion of the pharmacogenomic tests that have already been approved is relevant for cancer treatment. However, it has to be considered that many immunosuppressive and immunomodulatory drugs are not only applied in patients with cancer, but also in many highly prevalent chronic inflammatory and autoimmune disorders. Therefore, not only patients suffering from cancer will benefit from the pharmacogenomic tests in question. The lower the thiopurine methyltransferase (TPMT) activity the higher is the risk of developing severe myelotoxicity if receiving conventional doses of 6-mercaptopurine or its prodrug azathioprine (Huang et al. 2006). In both children with acute lymphoblastic leukemia and patients with atopic dermatitis individual dosing regimens of 6-mercaptopurine respectively azathioprine based on the *TPMT* genotype significantly improved drug safety without compromising efficacy.

The science of ► toxicogenomics aims to understand causal relationships between various gene products and biological effects of environmental toxicants. Toxicogenomic research combines gene, transcript, protein, and metabolite profiling with conventional toxicology. Recent advances in biotechnology and high-throughput genomic technologies have facilitated the rapid emergence of the field of toxicogenomics. According to Waters and Fostel (2004) the main goals of toxicogenomic research are:

- to understand the relationship between environmental stress and disease susceptibility;
- to identify markers of disease and exposure to toxic substances; and
- to elucidate the molecular mechanisms of toxicity.

Another important goal of toxicogenomics is the identification and discovery of safer drugs in a quicker, more cost-effective manner. Toxicogenomics could contribute to early prediction of the toxic nature of compounds, avoiding animal tests and time-consuming pre-clinical trials.

Toxicogenomics also aims to increase the global understanding of cellular mechanisms of toxicity and disease causation. In order to achieve this aim, structures of networks including protein–protein, protein–DNA, and transcriptional regulatory mechanisms will need to be determined under a variety of different conditions to better understand cellular responses to stress.

Genetic Testing, Screening and Counseling

► Genetic testing and counseling are among the most important applications of genetic knowledge for the public's health.

Until recently, medical genetics involved the study and treatment of rare monogenetic disorders. The public health component of genetics was limited to newborn screening programs for the early detection and treatment of a small number of conditions. Parallel to the rapidly growing knowledge in molecular genetics, individual genetic testing and ► genetic counseling are increasingly integrated into health service delivery.

Prenatal diagnosis may involve non-invasive and invasive methods. Particularly in Europe, ultrasonic examination is routinely performed in each pregnancy. Abnormal fetal growth as well as several birth defects can be detected by ultrasound. Additionally, α-fetoprotein, chorionic gonadotropin, and unesterified estriol (triple-marker screening) may be measured in the blood of pregnant women to assess the risk of several fetal malformations including neural tube defects, Down's syndrome, and others. Problems may arise from high rates of false-positives and false-negatives. If an increased risk for a fetal malformation is detected invasive tests like amniocentesis and chorionic villus sampling are recommended. Other reasons for invasive prenatal diagnosis are advanced maternal age, chromosomal aberration or neural tube defect in a previous child, balanced translocation in a parent, and monogenetic hereditary disease in a parent (Vogel and Motulsky 2002).

In general, screening involves the study of a large proportion of a population for the presence of a certain disease or predisposition. Tests for untreatable and treatable diseases should not be combined. Screening is recommended if prevention and/or effective treatment are available. ► Genetic screening of children should only be considered if effective treatment or preventions during childhood are available. Neonatal screening of newborns for phenylketonuria is a good example. Profound mental retardation caused by accumulation of phenylalanine can be effectively prevented by phenylalanine restrictive diet. Most European countries and the US have introduced neonatal screening for phenylketonuria. There is an ongoing discussion on whether or not a population based screening for hemochromatosis is recommendable (Aretz et al. 2006). Cystic fibrosis testing of newborns has not shown to significantly affect the course of the disease and is therefore currently not recommended (Vogel and Motulsky 2002).

Heterozygote testing in clinically healthy individuals may be indicated in the case of positive family history of a severe and not adequately treatable recessive disorder with onset in early childhood. Examples for such disorders are β-thalassemia and Tay–Sachs disease.

Recessive disorders manifest in homozygotes, whereas heterozygote carriers are usually clinically not affected. If both parents are heterozygote for the same condition the disease risk for their children is 25%. The disease risk for sons of heterozygote mothers for a X-chromosomal recessive disorder is 50%. Fathers cannot pass the X-chromosomal recessive mutation on to sons, but any daughter will be at least a carrier of the mutation. If an autosomal recessive disease manifests in a child, its parents usually are both carriers. Genetic testing is therefore not necessary to determine the disease risk of their future children, but is indicated for family members of the child's parents. Heterozygote testing without adequate genetic counseling is ethically not acceptable (Aretz et al. 2006).

In populations with high prevalence of severe recessive conditions heterozygote screening may be useful. Heterozygote screening involves genetic testing of the whole population or a population subgroup irrespective of family history. Among Ashkenazi Jews, 3 to 5 percent of the population are heterozygotes for the autosomal recessive Tay–Sachs disease. In the US and Israel heterozygote screening prior to and during pregnancy led to a rapid reduction in the prevalence of Tay–Sachs disease among Ashkenazi Jews. Heterozygote screening also effectively reduced the prevalence of β-thalassemia in the islands of Sardinia and Cyprus (Vogel and Motulsky 2002).

Like heterozygote testing predictive testing is usually performed in clinically unaffected family members of patients with severe monogenetic disorders. The goal is to identify mutations in persons at risk for severe genetic diseases with late onset.

Huntington's disease and other treatment resistant neuro-degenerative diseases are typical disorders that are subject to predictive testing. Knowledge of an increased risk of a severe, untreatable disease in later life interferes with the most private issues (e. g. family planning). Any person has the right to decide about whether to know or not to know their own genetic constitution. Therefore, predictive testing should always be voluntary, only performed after informed consent, and limited to adults (Aretz et al. 2006).

To date, molecular genetic diagnosis has limited clinical relevance for complex genetic disorders. Howev-

er, in the near future extended genetic screening not only for monogenic, but also for multi-factorial conditions may be both technically possible and recommendable.

A clear indication is required for any genetic test. Nevertheless, several commercial laboratories have recently made genetic tests available to the general public. Primarily in the US, but also elsewhere, the results of these tests are sometimes provided directly to the patient without professional clinical and genetic counseling. Genetic counseling is critically important to guarantee responsible application of genetic knowledge in clinical practice; it is, therefore, an essential component of all prenatal and predictive diagnostic procedures, otherwise, significant confusion and misuse of genetic tests may result.

Common reasons for genetic counseling include possible genetic disorder in a close relative, advanced parental age, consanguinity, multiple pregnancy loss, stillbirth, infertility, distinctive features diagnosed before birth, possible mutagenic and/or teratogenic exposure.

Adequate genetic counseling should provide information on the nature of the disorder, the probability of getting the condition and/or passing it on, and measures available for prevention and treatment. The genetic counselor has to be sensitive to potential psychological aspects raised by the genetic problems. Allowing the client to make an autonomous, but informed decision is a basic principle of genetic counseling. This characteristic is frequently referred to as the ► non-directiveness of genetic counseling (Baker et al. 1998).

Possible Therapeutic Applications: Gene Therapy, Stem Cell Therapy

Gene therapy involves the transfer of one or more genes or nucleic acid elements to a patient in order to counteract a naturally occurring deficiency in gene function. Whereas traditionally only monogenic conditions were amenable to ► gene therapy, complex genetic diseases recently also became subject to this therapeutic method. However, study results were mixed: in a subset of patients genetic defects could be effectively treated, in others, serious adverse events including insertional effects such as malignancy were observed (Hacein-Bey-Abina et al. 2003). The challenge of gene therapy will be to find the optimal tools to introduce disease-modifying genes and to attain adequate levels of long-term gene expression. There are significant public health implications for human gene therapy, since many common diseases including cancer, depression, Alzheimer's disease, and diabetes have a strong genetic component which may be modified or treated by gene transfer.

Stem cells are characterized by their ability for long-term self-renewal and their multilineage potential. Two main categories are distinguished: embryonic and adult stem cells. In many countries, stem cell research is a priority area for multidisciplinary funding. Stem cell research provides new insights in genetic, molecular, and cellular events during early development, e. g. chromosomal abnormalities. Transplant therapy is a field in which stem cell therapy might help to improve medical care. It is also hoped that stem cells may be used in novel treatments for Parkinson's disease, multiple sclerosis, and other chronic degenerative conditions. Additionally, stem cells represent a very useful model to test candidate therapeutic drugs, extending information from animal model testing. Although stem cell therapy does not play an important role in current public health practice, it is possible that it will gain significant impact on the health of the general population in the future. ► stem cell research and therapy

Ethical and Legal Considerations

The intersection of public health and genetics is a domain that is particularly complex from an ethical and legislative perspective. Genetic information is inherently individuating, as it describes individual risk, potential, and even identity. Genetic information implicates the most intimate kinds of family and reproductive relationships and decisions. It has an impact not only on social stigma, but also personal self-esteem. Disclosure of associations between race and genetics may also adversely affect the self-perception and definition of ethnic groups and communities.

Due to its particular ethical sensitivity, policies and programs in the area of public health genetics must be especially careful to adhere to ethical guidelines. ► ethical framework for public health genetics

Potential conflicts may arise between the rights and interests of individuals and the health and interests of society. Therefore, certain legislative, administrative, and ethical issues must be considered when plan-

P

ning for and developing policies regarding public health genetics.

Legislation and administrative regulations emphasize the importance of an individual's right to specific, written informed consent prior to genetic testing. To allow patients to make informed decisions, they are entitled to explanations of the nature and scope of the information to be gathered, the meaning of positive test results, the underlying disease, and any appreciable risks involved in the testing or activities following a positive result. Some public health initiatives involving genetic data, such as mandatory newborn screening programs, are justified by public health officials without consent through legal principles allowing the state to protect the health of children. ► legal issues in public health genetics

Together with the increasing ability to identify and store individual genetic information concerns about the privacy of identifiable data have been raised. Unauthorized uses or disclosures of genetic information can lead to discrimination through insurers, employers, government agencies, and others. Therefore, personal identifiers should be carefully protected in databases of genetic information.

Both, in Europe and the US, anti-discrimination laws attempt to limit stigmatization of individuals on genetic bases. However, public health officials conducting surveillance also have legitimate claims to access an individual's genetic data. Such communal needs for individual genetic information are supported by normative principles of beneficence or justice, but can impinge the privacy rights of individuals. Effectuating an appropriate balance between respecting individual interests and communal public health is particularly critical when concerning genetic data (Hodge 2004).

The current state of public understanding of the significance of genetics is poor. Misunderstanding about purported genetic determinism evokes the danger of serious social stigma and discrimination against particular individuals or groups.

Within the past years, individual privacy and anti-discrimination concerns relating to genetic testing have led many states in the US and elsewhere to adopt genetic-specific privacy and anti-discrimination laws. This legal trend is often referred to as ► genetic exceptionalism. Laws treat genetic information differently from other personally identifiable health information and typically establish heightened protections. The premise underlying genetic exceptionalism is that genetic information needs special protections, as it frequently identifies increased risks of future diseases in otherwise healthy individuals.

Irrespectively of their socio-economic position individuals should have equal access to genetic services. Otherwise the described scientific and technological advances will produce a system of genetic benefit for some and genetic disenfranchisement for others. In addition, it is a public health responsibility to contribute to increasing the genetic literacy of the population and to increase the social acceptance and equal rights of those with impairments and disabilities.

Public health is not immune to social or racial prejudice. It may mistake the individual who suffers from (genetic) disease for a ► vector responsible for the spread of this disease. Its mission to rid society of disease can be misconstrued as a mission of eliminating the genetic factors contributing to disease from the population (negative eugenics). It may also mistake its mission of promoting human health and welfare for the task of enhancing the traits and biological properties of individuals and populations (positive eugenics). Fortunately, forced sterilization and euthanasia are almost unthinkable today. Improvement of human individuals by manipulation of normal germ cells meets with many ethical problems. The purpose of public health genetics is not the genetic improvement of humans (eugenics). Therefore, public health must be aware particularly of subtle methods and inducements (financial, social, and cultural) that might be associated with future goals of public health genetics. Here the safeguards of autonomy, freedom of choice, informed consent, and nondirective genetic counseling are important hallmarks of ethical public health programs.

Summary

Public health genetics involves the application of genetics, genomics, and biotechnology to improve the public's health and to prevent disease.

The mapping and sequencing of the human genome has already begun to transform medical practice, and it promises greatly increased insight into the causes and potential prevention and treatment of many conditions of significant public health importance.

To date, most practical applications of molecular genetics relate to monogenetic disorders. However, in the

near future extended genetic testing and screening for multi-factorial conditions may be both technically possible and recommendable. Additionally, genetic susceptibility testing might serve as a major public health tool to avoid diseases and dramatically prevent morbidity and mortality. This would help to further improve the public health significance of the discipline.

Genetic knowledge is currently used to develop effective individualized therapies for prevalent disorders. The development of a vast array of new genetic tests appears to offer a precise, objective approach to identifying individuals at risk for certain diseases, thereby permitting earlier and better-targeted interventions. This may greatly enhance the knowledge base of public health beyond the level of epidemiological studies based on phenotype and the presence of symptomatic disease alone.

Due to its particular ethical sensitivity, policies and programs in the area of public health genetics have to strictly adhere to ethical guidelines.

Public Health Informatics

Definition

Public health informatics is defined as the systematic application of information and computer science and technology to public health practice, research, and learning. The scope of public health informatics includes the conceptualization, design, deployment, refinement, maintenance, and evaluation of communication, surveillance, information, and learning systems relevant to public health. Public health informatics requires application of knowledge from information science, computer science, management, organizational theory, psychology, communications, political science, and law. Knowledge from epidemiology, toxicology, and statistics is of prime importance.

Public Health Information System (PHIS)

Definition

The public health information system is a branch of ► health information system that deals with ► data, information and knowledge from the perspective of the population. Its purpose is continuous monitoring of public health events, planning and surveillance of public health programs, financing and management in public health and health research.

Public Health Interventions

Public Health Law

ADEM KOYUNCU
Mayer Brown LLP, Cologne, Germany
akoyuncu@mayerbrown.com

Introduction

Law makes public health possible. Law is of vital importance for public health theory and practice. The analysis of the interrelationship between law and public health documents that the theory and practice of public health significantly relies on law (Parmet 2007). Therefore, leading scholars characterize the interrelation between law and public health as strong. As such, Frank Grad states that "the field of public health is firmly grounded in law" (Grad 1990); Wendy Parmet describes the fact that even historically law has been the "chief tool of public health" (Parmet 2007) and Lawrence Gostin regards law as "a very important tool

in furthering the public's health" (Gostin 2000a). Similarly, law is highly valued as "fundamental to the practice of public health" (Lopez and Frieden 2007), "indispensable to the public's health" (Moulton et al. 2002), or "vital to public health" (Gostin et al. 2007) or for its "central role in contemporary public health" (Moulton et al. 2007). This synopsis and the subsequent essays aim to enlighten the reasons for law's importance to the theory and practice of public health and to highlight a few practice areas covered by public health law.

Most of the milestone accomplishments of public health and many successes against public health threats were obtained through the impact of law. In 1999, the Centers for Disease Control and Prevention (CDC) in Atlanta, USA, published a list of ten great public health achievements in the 20th century in the United States (CDC 1999), which included:

1. Safer workplaces
2. Control of infectious diseases
3. Motor vehicle safety
4. Family planning
5. Fluoridation of drinking water
6. Safer and healthier foods
7. Healthier mothers and babies
8. Vaccination
9. Recognition of tobacco use as a health hazard
10. Decline in deaths from coronary heart diseases and stroke.

Law has contributed significantly to all of these milestone achievements (Moulton et al. 2002). For example, the legal provisions providing for occupational health and safety at the workplace and allowing agencies to set safety standards for workplaces and impose obligations of employers have laid the basis for the aforementioned achievement "safer workplaces". This is also true for the laws that provide for worker's compensation after occupational injuries and illnesses and, particularly, for those laws that have created, funded and authorized occupational safety agencies.

Further, the great public health achievement "control of infectious diseases" relies heavily on law. The numerous laws dealing with the control, detection and treatment of infectious diseases – one of the oldest practice areas of public health and public health law – have provided public health practitioners with legal authorities to enforce community protection measures like isolations, quarantines and mandatory vaccinations. In addition, these laws have assured the funding of these costly activities and the engaged public health agencies. Therefore, the "control of infectious diseases" would not have been achievable without law and the corresponding legal means.

Regarding the great public health achievement "motor vehicle safety", no public health officer would seriously doubt that obligatory seat belt use in cars, mandatory helmet use for motorcyclists and criminal laws sanctioning drunk driving have substantially contributed to motor vehicle safety. Additionally, law contributed to this achievement by assuring higher vehicle safety standards, imposing regular technical check-ups and enforcing speed limits (*See* Moulton et al. 2007 for further remarks on the role of law in the ten achievements presented by the CDC).

Law and Public Health Authority

As a tool of public health, law is complementary to the scientific tools of public health, like epidemiology and statistics. These form the scientific-analytical part of public health, known as "public health analysis" (Hall 2003). In addition, public health practice has a legal-regulatory part encompassing the regulatory infrastructure as well as the legal authorities. The latter are referred to as "public health authority" (Hall 2003). Public health law focuses and supports the legal-regulatory branch of public health practice. Both "public health analysis" and "public health authority" are indispensable for the pursuit of public health activities.

The importance of law in public health practice results from the legal means (► public health law, legal means) necessary for safeguarding the public's health. Public health actions need sufficient legal authorization as they regularly affect or infringe individuals' rights and freedoms. Public health practice must operate in legally sensitive territories as demonstrated by the following examples:

- The protection of the public from infectious diseases regularly necessitates measures against individuals like the above-mentioned mandatory isolation or quarantine. Such actions can be directed against the infected person as well as potentially infected contact persons. However, isolations, quarantines or compulsory examinations and compulsory treatments of an individual encroach on the individual's basic rights to bodily integrity, freedom of movement, freedom of assembly and freedom of profes-

P

sion, among others. Such encroachments of individual rights by the public health department, however, are not allowed if there is no sufficient legal authorization. Without such legal authorization, public health departments would be prohibited to undertake these protection measures even if medically justified. Therefore, the grant of legal authority to restrict personal rights by public health actions enables the departments to carry out such effective conduct.

- After suspicion of an outbreak of avian influenza A (subtype H5N1) on a number of farms, the health department considered the order of a local quarantine around the affected farms. In such constellations in Germany, controversies arose with respect to the legal authorization of these measures. Arguments regarding human rights violations as well as economic arguments with respect to the consequences of such actions to the touristy image of the affected regions were made. Therefore, in addition to the affected farmers, the tourism industry also complained about the violation of their interests and argued against the public health measures. This example also enlightens the legal explosiveness of public health measures that can be directly or indirectly tangent to a broad range of personal and economic rights and interests. Again, the encroachment of such rights and interests by public health departments is only allowed if there is sufficient legal authorization. Otherwise, the public health department may become liable for damages vis-à-vis the affected persons and companies based on the allegation of unauthorized conduct.
- Public health practice depends on the existence and functioning of administrative agencies, which include federal regulatory agencies, state and municipal health departments and scientific agencies, as well as the police. The creation and financial funding of such agencies need a legal basis. Such agencies can only be created and funded by virtue of a legal authorization. Therefore, law is also necessary to institute the organizational infrastructure of public health.

The three examples should have additionally highlighted the interdependency and close relationship between public health operations and law. Law grants powers to the states and governments and distributes these powers among the state institutions. Law grants authorities to the legislator, the government and the courts. Based on these underlying authorities, the state is entitled to institute specific public health agencies and to fund them with financial resources, thus to spend the taxpayers' money for these purposes. Law also bestows these agencies with coercive powers vis-à-vis citizens, companies and the community to pursue their public health mission. As such, law authorizes public health agencies and their officers to infringe private rights and to invade private spheres if they deem necessary to assure the population's health. As in many jurisdictions, such infringements of private rights by state agencies can only take place when explicitly legally authorized. Law makes these public health actions possible. Overall, law is essential for both the establishment of the institutional public health infrastructure and for its effective functioning (Gostin 2000a). In addition to such a direct type of public health practice, the range of legal means (► public health law, legal means) within public health law also encompasses a variety of tools with indirect positive effects on the public's health as well as tools that do not involve an official public health agency (e. g., ► tort law and public health, ► criminal law and public health).

In the following, the legal basics, characteristics and some specialized working fields of public health law will be discussed. In addition, the functioning and legal means of public health law will be depicted. Prior to this, it is necessary to attempt to define public health law.

Definition of Public Health Law

At the beginning of the 20th century, public health law was defined as

"that branch of jurisprudence which treats of the application of common and statutory law to the principle of hygiene and sanitary science" (Tobey 1926).

The definition of public health law can be accentuated from the legal scientist's or the practitioners's perspective. On the other hand, public health law has always been a branch of law with a practical root that grew through practical application. Accordingly, the definitions of public health law vary in their emphasis depending on the perspective considered. From the academic scholar's perspective, public health law is defined as

"the study of the legal powers and duties of the state, in collaboration with its partners, to assure the conditions for people to be healthy (e. g., to identify, prevent, and ameliorate risks to the health in the population) and the limitation on the power of the state to constrain the autonomy, privacy, liberty, proprietary, or other legally protected interests of individuals for the common good. The prime objective of public health law is to pursue the highest possible level of physical and mental health in the population, consistent with the values of social justice" (Gostin 2007).

From a rather practical viewpoint, public health laws are defined as

"any laws that have significant consequences for the health of defined populations" (Moulton et al. 2007).

The latter definition focuses primarily on the practical impact of the respective laws and all-embracingly includes all legal provisions with significant practical impact on the public's health. Despite their varying perspectives, the three definitions cited above pursue the same idea of public health law and its practical function. With a focus on its legal objectives, the common features and legal characteristics of public health law can be summarized in the following definition of the term:

Public health law is the sum of all legal rules which directly or indirectly aim to safeguard or promote the population's health. These rules may arise from statutory law, administrative regulations and acts, customary law, case-law and common-law. Public health law also includes laws which provide for the establishment and funding of corresponding administrative agencies.

In addition to the features mentioned in the definitions above, this definition highlights some characteristics in order to facilitate the understanding of the legal context; these are explained in the following:

- As with the definitions above, this definition articulates that the population's health is the target of public health law. In this respect, public health law is substantially different from medical law. Unlike public health law, medical law does not target the population's interest but the individual patient's health outcome (see below).
- Public health law can be subdivided into the group of legal rules that establish the administrative agency infrastructure and a second group of legal rules which equip the public health practitioners with the necessary operational legal means to safeguard and promote the community's health.
- The definition in this synopsis also stresses the fact that public health laws may unfold public health effects either *directly* or *indirectly*. Based on their mechanisms and teleology, in the following sections primary public health laws (intending direct effects) and secondary public health laws (indirect effects) will be differentiated.
- This definition documents that public health law comprises codified (written) law, judge-made case-law as well as unwritten customary laws. All of these sources of legal rules formed the ► legal basis of public health and still play significant roles in the practice of public health.

Constitutional Basis of Public Health Law

With respect to the sources of public health, a differentiation seems appropriate between "foundational public health laws", which form the ► legal basis of public health practices, and "operational public health laws", which supply public health practice with legal means (► public health law, legal means).

The foundations of public health practice as well as public health laws regularly lay in the national constitutions. To understand this legal context, the following simplified connection may be helpful: According to the principles of self-defense, each individual has the right to protect himself from harm to his health. Correspondingly, as the population is formed by the sum of individuals, the population also has the immanent right to protect itself from threats to its health, i. e. the population's health. The population thus has the right to protect itself from harm to its health. In addition, the population has – as each individual has – the right to take measures to promote its health. In democratic nations, the populations delegate these rights through their constitution to the state powers. Therefore, all state powers derive from the population. In a nutshell, this is the constitutional base of a country's foundational legal public health powers.

In summary, public health activities and correspondingly public health laws are rooted in the population's natural right to protect itself from harm to its health. This right, as well as the population's right to promote its

health, is delegated via the constitution to the state. The constitution distributes this authorization among several state institutions and authorizes

- The parliament to legislate the laws ("law-making power");
- The government to execute the laws ("law-executing power"); and
- The courts to judicially review, interpret and enforce the laws.

The state is empowered as the guardian of the common welfare and the rights of the individuals. All these powers derive from the population as the people. As mandated by the people, the state has the power to protect the population from harm as well as to promote its health and well-being. The main part of these powers is (in many jurisdictions) denominated as the "police powers" or "the danger defense powers" (in German speaking jurisdictions "*Gefahrenabwehrrecht"*). Based on this legal background of public health and by virtue of the constitutionally granted powers and authority, the state has to take all necessary measures to protect the public's health.

In summary, all constitutional powers derive from the people. These powers are distributed among the legislative power ("law-maker"), the executive power ("law-executor"), and the judiciary power ("law reviewer, interpreter and enforcer"). These three powers play relevant roles in the realm of public health.

Primary Public Health Laws

The foundational source of public health laws is the constitution. In addition to constitutional law, public health laws encompass numerous laws that should be regarded as operational public health laws. They provide for the scope, limits, administrative infrastructure and the legal means in a particular field of public health. Thus, *primary public health laws* are such legal rules that have a direct impact on the population's health by intending direct outcomes on the population's health. Depending on the various fields of public health practice, such laws *inter alia* include ► infectious diseases control laws, occupational safety laws (► labor and occupational safety laws), sanitation and hygiene laws and environmental health laws (e. g., air pollution prevention or clean water laws). Some of these primary public health laws are presented in separate essays in this encyclopedia.

Secondary Public Health Laws

In contrast to primary public health laws, *secondary public health laws* focus primarily on objectives other than population health outcomes. However, pursuit of these goals influences public health relevant behavior and, thus, indirectly affects public health outcomes. As an example of such secondary public health laws, tort law should be noted. Tort law *inter alia* encompasses medical malpractice and product liability law, which have intersections with each other. Tort law primarily intends to attribute legal responsibilities for the compensation of damages due to tortious acts (► tort law and public health). However, the risk of being convicted relative to damage payments deters individuals as well as companies and influences safety related behavior (McClurg et al. 2007). Tort law may also be applicable against the state if public health officers act unlawfully and, in doing so, violate personal or property rights (state liability). In addition, tort law develops doctrines for consumer information and advertising; both indirectly affect public health (e. g., rules for patient's informed consent). Tort law is elucidated in an explicit essay in this encyclopedia. Another legal area that influences human behavior and has indirect effects on the population's health is criminal law (► criminal law and public health). This legal field also falls under the scope of the secondary public health laws. As with tort law, criminal laws may apply against public health practitioners when they exceed their authorities and excessively encroach individual rights. The nature, functioning and specifics of criminal law are the subjects of a separate essay.

Nature of Public Health Law

Public health law is not medical law. These fields of law must not be confused and mixed up. As mentioned above, medicine and medical law focus on the health of the individual patient whereas public health and public health law focus on the health of the whole population. Medical law is patient-centered whereas public health law is population-centered. In the realm of medical law, typical subjects include medical malpractice, patient-informed-consent or delivery of medical services (*See* also Gostin and Jacobson 2006). Medical law is substantially targeted on the Latin principle "*salus aegrotii suprema lex*", what translates to "the health of the patient is the highest law". In recent years,

this command is being rivaled by the principle "*voluntas aegrotii suprema lex*", which asserts that "the will of the patient is the highest law". The latter has led to patient-informed-consent rules in many jurisdictions (*See* Koyuncu 2006; Koyuncu 2004). For public health, this sentence has to be "*salus populi suprema lex*", emphasizing that "the health of the population is the highest law". Against this background, it goes without saying that public health law is concerned about other legal issues than medical law and needs different legal means to overcome public health threats. In summary, despite certain overlaps and similarities, public health law and medical law are two distinct legal disciplines with different scopes. Medical law focuses on the legal side of individual patient care whereas public health law focuses on the legal aspects of population-oriented public health practice.

With respect to its nature, public health law is regarded as a part of administrative law (Gostin et al. 2007; Grad 1990). As administrative law (▶ administrative law and public health) itself is part of public law, public health law necessarily is a part of public law (Reynolds 1995). Public law is one of the three main legal branches. The other two are formed by private law and criminal law. Within public law, administrative law and enforcement is one major legal field supplementing other public law fields like, for example, constitutional law, tax law or social law. Some of the characteristics of administrative law and enforcement will be presented in a separate essay on this legal field. Therein, the principles of administrative law, the role of the administrative agencies as well as the role of the courts in the practice of administrative law will be elucidated.

Despite its attribution to administrative law, public health law is not precluded from using private law or criminal law elements. Agencies may – and regularly do – enter contractual agreements with private persons and companies and, by this means, involve private entities in the provision of public health services. On the other hand, agencies may request criminal prosecution if their administrative investigations indicate criminal offenses. Therefore, it is important to understand that the branches of law do not act in complete isolation. The opposite is the case. The actors of the different legal branches influence each other in manifold ways and to a certain extent share their tools.

Public health actions can also be grounded in other legal areas than administrative law. As such, *tax law* is widely used to influence individual or corporate behavior in the interest of public health. States may impose additional taxes on behavior that they want to eliminate and vice versa. In addition, *commerce and trade law* provide influential means for assuring and promoting the public's health. Particularly, these legal areas provide for the control and limitation of the flow of potentially harmful goods and products within a country and into a country from outside. *Social insurance laws* also have significant relevance to the public's health. They build the legal fundament for the financing and provision of health insurances as well as for the supply of health care services for the community.

It is also noteworthy that public health law is a *dynamic field of law*. Interrelated with public health, the law must cope with different and continually changing public health challenges. The public health threats of today are not the same as those 100 years ago (e. g., bioterrorism, chronic diseases, behavior-induced health risks). The subject of contemporary public health practice in the 21st century includes many additional tasks when compared with the realm of public health at the beginning of the 20th century (e. g., health information and promotion). Public health law must take on these new challenges and provide the public health practitioner with sufficient legal infrastructure as well as appropriate legal means to intervene when necessary.

In conjunction with its dynamic nature, it is important to understand that public health and, thus, public health law are "*highly political*" fields (Gostin 2000a). This is because public health practice has to protect and promote the population's health and well-being as the core goods of a society. To achieve this, public health practice may come with personal restrictions. Public health measures can significantly affect human rights. As such, if public health officers order a quarantine or the isolation of an individual because of an infectious disease or if they revoke the license of a health professional or order the market recall of a pharmaceutical, they restrict personal and corporate rights. Such personal restrictions are subject to political debate. Such aspects, including the accompanying ethical and cultural bearings, must be discussed on the political level, for example in the forefront of a legislation proposal.

Public health laws could be qualified as *population-centered risk-management laws* . Like other risk-management subjects, public health laws also provide mechanisms to prevent, detect, assess, mitigate and elimi-

nate risks to the public health. The legal means provided by public health law cover the range from incentives for voluntary behavior up to severe compulsory measures against individuals, objects and businesses. The range of legal means (► public health law, legal means) provided by public health law will be presented in an essay where the restrictive intensity of some public health instruments will be highlighted. Traditionally linked with the character as a legal area to avert dangers ("police powers"), public health pursues an interventionist approach (Gostin 2000a) therefore public health law has to provide practitioners with sufficient intervention means.

In conclusion, the legal characteristics and nature of public health law may be summarized as follows:

- Public health law is mainly a part of administrative law which itself is part of public law. However, public health law is interrelated with and influenced by other legal fields.
- Public health law is not the same as medical law. These legal areas must not be confused. Medical law is patient-centered whereas public health law is population-centered.
- Public health laws are *population-centered risk-management laws*.
- Public health law is a highly political field.
- Public health law is a very dynamic field of law.

In this sense, public health law has to accompany the far-reaching and dynamic scope of public health practice and provide it with the legal-regulatory infrastructure as well as the necessary legal means for interventions.

Mechanisms of Public Health Law

The mechanisms and functioning of public health law are based on the interplay of four kinds of legal rules that represent primary or secondary public health laws. As such, the mechanisms of public health law are based on

- Constitutional granting of legal power and authority to the government and its administrative agencies;
- Primary public health laws which create, fund and regulate the infrastructure of public health practice – "infrastructural" public health laws (*See* also Gerberding et al. 2003);
- Primary public health laws which provide for the legal authorization and legal means for public health activities to eliminate public health threats – "interventionist" public health laws (Gerberding et al. 2003; Gostin 2000a);
- Secondary public health laws which influence behavior without direct public health interventions (e. g., tax law, criminal law, tort law, commerce law, trade law).

These categories of law have different scopes and mechanisms. However, in public health practice they are interwoven and have to interplay to protect and promote the population's health. One of the core functions of public health laws is to arrange the legal relationships between the involved persons and administration entities (Childress et al. 2002). This includes the attribution and delineation of competencies, responsibilities and missions within the administration (i. e., the government and the public health agencies). It also comprises the clarification of the interrelationships between the population, the public health agencies and the individuals/legal entities posing health threats. Such clarifications are made by grant of circumscribed authorities to the public health agencies in the scope of their legal mission to act in the interest of the population. In doing so, they encroach the individual's sphere (*See* Gostin et al. 2007, with further explications).

In effect, the mechanisms of public health laws particularly include instruments to:

- Fund health promotion and education activities;
- Fund, promote and enforce prevention measures (e. g., vaccination);
- Promote voluntary healthy behavior by providing incentives (e. g., by tax law);
- Prohibit harmful behavior and promote healthy behavior by sanctioning harmful behavior (e. g., seat belt laws, criminal law);
- Coercively mitigate and eliminate health threats (e. g., by compulsory isolation and quarantine);
- Set standards and rules that provide legal guidance (e. g., technical rules, air pollution or noise level standards).

It becomes clear that law provides for *individual case-related means* as well as for *abstract general legal means* like standards or prohibitions. One advantage of the latter tools and their mechanism in pursuing public health goals is that they become effective and binding for the whole population. They are broader in their reach.

Codified public health laws provide guidance for public health practitioners and the public. Particularly, practitioners are relieved from the burden of resolving ethical conflicts, which they are regularly exposed to in daily practice (Bernheim et al. 2007). Many legal provisions are the result of the prior process of parliamentary weighing and ► legal balancing of conflicting rights that include ethical considerations. As noted above, public health and public health law are very political fields.

Additionally, public health laws set forth the procedural steps and the substantive criteria of the decision-making process before an intrusive public health action can be enforced. As typical for administrative law, public health agencies must take into account a number of procedural (formal) requisites which are legally instituted to protect the individual's rights vis-à-vis the state. In addition, codified public health laws as well as their judiciary interpretation by court decisions urge the public health practitioner to undergo a substantive process of weighing and balancing the protected good (population's health) and the rights they infringe with their public health actions. These procedural and substantive requirements for the public health agencies are part of the administrative decision-making process and, all together, they ensure an adequate legal balancing of conflicting rights.

Law as Limit to Public Health Practice

Law not only enables public health practice it also limits public health actions. The reason for this constellation is grounded in the fact that law is not only protecting the population's health interests but also the interests of those persons who impose risks to the public. The human rights (► human rights and public health) of the latter persons protect them from governmental intrusions into their personal sphere and are not be dispensed even if they cause a public health threat. It is up to laws to protect these persons from public health measures that are excessive or lack the necessary legal balancing. Therefore, law is not always "necessarily an ally" of public health (Parmet 2007).

By protecting human rights (which are regularly implemented in national constitutions or bills of rights), law can impede public health agencies and ensure that public health officers respect the rights of the endangering individuals (or other endangering legal entities like companies). Thus, law endows public health agencies with authority to restrict personal rights in the interest of the community and – at the same time – law guarantees the protection of these rights. As Lawrence Gostin put it, with respect to public health powers, the constitution "acts as a fountain and a levee" at the same time because it "originates the flow of powers to preserve the public health, and it curbs that power to protect individual freedoms" (Gostin 2000b). Therefore, public health law indeed has to mediate and navigate between two "separate ends" where one stands for the population's interest in a functioning public health practice assuring its safety and the other end represents the individual's human right to be "treated non-instrumentally" (Bloche 2003).

Law enables and limits public health at the same time. The relationship between individuals, the public and public health administration is complex and it is a burden of public health law to govern these complex relationships.

Particular Fields of Public Health Law

As with public health, public health laws have a far reach. They must govern all areas of life where public health risks may result. As such risks are multifaceted and may arise from individual conduct, objects, the environment, corporate conduct as well as state activities, the starting points for public health protection are manifold. Public health laws must cover this multitude of causes of public health risks. Therefore, the scope and range of public health laws is as manifold as the risks they aim to prevent and mitigate. In the following, a list of some public health laws exemplifies the broad range of this legal field:

- Public Health Services Laws;
- ► Labor and Occupational Safety Law;
- Anti-Discrimination Laws;
- Youth and Child Protection Laws;
- Mother Protection Laws;
- Family Protection Laws;
- Laws Protecting Disabled;
- ► Infectious Diseases Control Law;
- Quarantine and Isolation Laws;
- Vaccination Laws;
- ► Environmental Law and Public Health;
- Clean Drinking Water Laws;
- Air Pollution Prevention Laws;

- Surveillance and Data Collection Laws;
- Traffic Safety Laws;
- Zoning and Planning Laws;
- Laws for the ► Legal Regulation of Professions;
- Laws for the Regulation of Businesses (► Legal Regulation of Professions, Businesses and Products);
- Laws for the Regulation of Products (► Legal Regulation of Professions, Businesses and Products)
- General Product Safety Laws;
- Food Laws;
- Drug Safety Laws;
- Chemicals Laws;
- Pharmaceuticals Laws;
- Medical Devices Laws;
- Motor Vehicle Laws;
- Genetically Modified Substances Laws;
- Toxic and Hazardous Substances Laws;
- Waste Disposal Laws;
- Urgent Safety and Emergency Laws;
- Rescue Laws;
- Mentally Ill Persons Laws;
- Social Security Laws;
- Health Insurance Laws;
- Organ Transplant Laws;
- Health Promotion Laws;
- Prevention Laws.

This non-exhaustive list provides an insight into the heterogeneity and far-reaching scope of public health law. Several subsequent essays will further address some of these public health law fields. As such, one essay will highlight the particulars and methods of the legal regulation of professions, businesses and products. It will particularly demonstrate the measures and means of the legal regulation of professions (e. g., registration, licenses, regulatory supervision). It is noteworthy that this area of public health not only involves health professionals but also numerous further professions that may impact the population's health. For public health, the legal regulation of businesses and products is as important as the regulation of professions. This section of legal regulation not only encompasses health products as the range of product risks to the public health by far extends purely health-related products. Several specialized public health authorities are established for the legal regulation of professions, businesses and products. Among these, the food and drug regulatory agencies may be highlighted.

- Infectious Disease Control Laws
  Governmental activities to control and combat infectious diseases build on the "oldest field of public health" (Grad 1990). Correspondingly, the infectious diseases control laws are probably the oldest field of public health law. Many of the earliest public health interventions relate to the control of infectious diseases. Infectious diseases control laws encompass the legal rules that aim at the prevention, detection and abatement of infectious diseases and the health risks resulting from such diseases. These laws regulate a central field of public health law. Many of the earliest public health interventions relate to the control of infectious diseases. Infectious diseases are still a major concern of contemporary public health practice. All jurisdictions have taken measures to combat infectious diseases and prevent epidemics. Constitutions in some countries (e. g., in Germany) even grant explicit authorization to control and abate communicable diseases. As with all other branches of public health law, infectious disease control laws have certain characteristics that need further explication.
  Infectious diseases control laws have always been and will remain a major part of public health laws. Contemporary infectious diseases control laws increasingly focus on disease prevention in addition to the traditional public health actions, which are aimed at the combat and treatment of infectious diseases. Contemporary infectious diseases control faces new challenges from new pathogens and new disease mechanisms (e. g., SARS, HIV, avian influenza-virus, Ebola-virus). Particularly, recent suspected cases of avian influenza have led to controversies in some jurisdictions; thus, if a statute allows the agency to impose a cordon sanitaire and to a certain extent a quarantine on a farm or other area in order to control avian influenza, this needs legal grounding and justification.
- Labor and Occupational Safety Laws
  Occupational safety is one of the oldest areas and still a central practice area of public health practice. Law is essential for this section of public health. Labor and occupational safety laws comprise the legal rules that govern three aspects. Labor law regulates the legal relationship between employers and employees (including worker unions) with respect to the employment, including the corresponding rights

and duties resulting therefrom. Occupational safety laws encompass the body of law that provides for both the safety and health of employees at the workplace and the compensation of employees in cases of work induced injuries and diseases.

- Environmental Law
  Public health practice has always been strongly linked with environmental legislation. Environmental law can be defined as those legal rules that aim at the protection and development of the environment and its compartments as well as the protection of the public health from harm, risks and nuisances arising from the environment and the human-made interaction with the environment. Environmental laws can be differentiated into "environmental protection laws" (protection of the environment and its compartments as natural habitats) and "environmental health laws". Environmental health laws are aimed at the protection of human health from risks arising from the environment. This approach includes those "human-made" risks that developed as a result of interactions between human beings and the environment (e. g., air and water pollution). The environmental health laws should be attributed to the body of public health law. The practice and legal means of environmental health law are significantly different from those in other areas of public health law.
- Public Health Related Information and Communication (► public health law, information and communication)
  The heading "information and communication" in the realm of public health law encompasses several distinct topics. Three shall be depicted here. First, the surveillance, data collection and evaluation of information by public health agencies. Second, the information of the population on health aspects by the public health administration (e. g., health promotion campaigns, public health warnings). Third, the regulation of the information practices and contents provided by commercial companies with respect to their products and services (regulation of commercial speech). Both information and communication play crucial roles in contemporary public health. However, in all three branches, critical legal questions are raised which deserve attention in public health practice. The importance as well as the legal relevance of "information and communication" in public health practice is continuously increasing and deserves particular legal attention.

Future of Public Health Law

The future of public health law is linked with the development of public health. The scope, contents, challenges and measures of public health have undergone an alteration and diversification process even though not all public health threats are new and many of the challenges of the previous century remain up-to-date. However, today's public health practice faces some new threats and new tasks that need legal undercoating.

First, public health law in the 21st century faces new threats. These include public health concerns caused by:

- New infectious diseases (e. g., SARS, avian influenza);
- Worldwide globalization and increased mobility and travel, which facilitates the spread of (old and new) communicable diseases;
- New technologies and new products with unknown risk potential (e. g., mobile phone radiation, nanotechnology, genetically modified organisms);
- Environmental threats with yet unknown dimensions (e. g., climate change, hurricanes, flood disasters and other extreme weather events, *See* Kirch et al. 2005;
- Chronic diseases (Moulton et al. 2007);
- Terrorist attacks, including bioterrorism (e. g., anthrax attacks);
- Lifestyle and unhealthy behavior (Moulton et al. 2007). Particularly, obesity has been described as "the new frontier of public health law" (Mello et al. 2006).

Law has to provide public health practice with sufficient legal authorities, infrastructure elements and legal means to cope with the new threats. Some of the new threats (e. g., terrorism) have already led to national and international discussions on the legal limits of newly introduced public health protection measures in light of the human rights they intrude. In Germany, a recent law allowing the shooting down of a hijacked aircraft was repealed by the Constitutional Court. The Court held that the law was in breach of the German constitution as allowing the aircraft to be shot down violates the basic rights of the passengers. A deeper discussion of this judgment would go beyond the scope of this synopsis. In conclusion, the Court forbids the legislator to bal-

ance the public's safety against the lives of the passengers (Bundesverfassungsgericht 2006). Legal balancing must not charge lives against the public's health. Such discussions about the limits of legal measures in answer to new public health threats are ongoing in many countries. They will also shape the public health laws of the 21st century.

Second, in addition to new public health threats, contemporary public health has to take on new tasks and deliver new public health services, which need sufficient legal coverage:

- To cope with the new lifestyle and behavior-induced public health threats, activities of public health are shifting towards information and education and, thus, towards health promotion. These health promotion activities are also targeted to support patients with chronic diseases. The classical police powers activities of public health agencies no longer stand alone for public health practice. Nowadays, public health practice has to influence behavior at an earlier stage and prevention is increasingly emphasized (*See* Kirch et al. 2008; Kirch and Badura 2006, with pertinent contributions). For these new activities, states need to create and fund appropriate public health infrastructures.
- The new public health tasks will necessitate the inclusion of private service providers in the supply of such new public health services as health promotion activities. Public health law must provide for the legal embodiment of the arrangements between administrative bodies and private entities. This will lead to a co-existence of administrative law and private law elements in the provision of public health services.
- Public health practice methodologically has new scientific possibilities with new prospects. Among others, the potentials of public health genetics and stem cell research raise legal and ethical concerns that will be subject of future public health law.
- Public health is increasingly becoming subject to health policy and becomes involved in the provision of health care for the population and the corresponding securing of health insurances (Grad 1990; Schütte and Walter 2008). A form of co-existence between public health law and social (insurance) law will emerge. Connectedly, public health law will have to handle questions of financing adequate health care and will need to become familiar with the appending new methods (e. g., evidence-based-medicine, health technology assessments).
- Many of the new public health threats increase the need for international public health cooperations. Therefore, the importance of international organizations will increase (e. g., WHO, UNEP, WTO). However, such activities in the sense of a "global public health" (Fidler and Cetron 2007) will necessitate sufficient legal authorization and funding so that international public health laws will become necessary even though today's public health law already encompasses international legal rules.

The new public health threats as well as the new range of activities of public health practice will challenge public health law. These developments will extend the classic scope of public health law. In addition, the new global public health threats will speed up the globalization of public health law.

Conclusion

Law is an essential element and one of the most powerful tools of public health practice. This synopsis underscored the importance of law in public health practice and outlined the nature, means and mechanisms of public health law. Law will continue to play a central role in public health as it creates and funds the infrastructural fundaments of public health practice and provides it with the necessary operational legal means.

In addition, law will keep playing a central role in public health practice as it also limits the reach of public health measures and protects the (personal and property) rights of community members who are affected by public health actions. Therefore, the careful legal balancing of conflicting rights must remain a basic element of all actors in the realm of public health.

Even though not all public health challenges of the 21st century are new, public health is a dynamic field facing new threats, subjects, obligations and methods. Likewise, the field of public health law is dynamic too, as both are interrelated. Therefore, public health and law are characterized as "sibling fields that develop in close interrelation with each other" (Moulton et al. 2007). Probably, in this century "law will make at least as great a contribution to the public's health as it did in the century just ended" (Moulton et al. 2007).

Public health law is not only relevant for lawyers but also for public health practitioners. As law authorizes

and limits their actions, they should understand the role of law as well as how law is made, enforced and interpreted. This can enable them to use legal means in a more targeted way and influence the development of public health policy and public health law (Grad 1990). In many jurisdictions around the world and from various perspectives, there is a "renewed interest in public health law" (Coker and Martin 2006). Particularly but not only in the United States, public health law is widely recognized as a core element of public health practice and has become subject to the curricula of a number of law schools (Goodman et al. 2002). Many aspects of public health law and their interrelation with public health and medical practice are discussed in numerous articles and need further elaboration. The subject and discussion of public health law is transcending borders into other countries, which will help to strengthen the legal basis of public health practice. Law will remain indispensable and vital to public health and continue to make public health possible.

Synonyms

Health information and education; Health promotion

Definition

In the field of public health law, "information and communication" encompasses numerous topics. Most of them can be attributed to three major subjects. *First*, surveillance, data collection and evaluation of information by public health agencies. *Second*, the public health administration informing the population on health aspects (e. g., health promotion campaigns, public health warnings). *Third*, the regulation of commercial information practices and contents provided by companies and professionals with respect to their products and services (regulation of commercial speech).

Basic Characteristics

Many aspects of public health law are discussable under the title "information and communication". Most of them can be aggregated under three major subtitles, which will be further elucidated in the following.

Surveillance, Data Collection and Evaluation

Public health practice needs information. Information is essential for the theory and functioning of public health. Risk reduction measures undertaken by public health agencies must be grounded on sufficient and carefully evaluated information. This, however, raises the need to gather information on present or potential public health risks and developments. Therefore, surveillance and information gathering are fundamental to the functioning of public health and, thus, core activities of public health agencies. Such activities include surveillance of infectious diseases by gathering information from doctors and laboratories. Regularly, doctors have mandatory reporting obligations with respect to certain diseases. The collection of safety-relevant information on pharmaceuticals by imposing mandatory notification and reporting obligations on pharmaceutical companies (pharmacovigilance) is another example of a regulatory information collection activity. Such health information is "indispensable for virtually all public health activities" (Gostin 2000).

Public health surveillance and information gathering are also necessary for the subsequent assessment of the effectiveness of public health risk reduction measures that have been undertaken and for gathering follow-up information. Information collection is also an element of regulatory supervision of industries, workplace safety, product marketing and professional conduct. Information enables efficient regulatory supervision by the administration and government. The surveillance and information gathering activities of public health agencies raise some legal questions:

- As the data collected by the public health administration regularly contains sensitive information on individuals and companies (e. g., status of infections, product related information), its collection is a bur-

den on the ► privacy rights of the individuals as well as the commercial rights of the companies (e. g., intellectual property rights).

- The data collection procedure is associated with restrictions of professional and commercial rights: Medical doctors who must report to agencies as well as companies (product surveillance) and employers (workplace safety) are affected in their freedom to conduct their profession and business. Therefore, the imposition of such mandatory reporting obligations must be balanced with these conflicting rights of the professionals and companies.
- The mandatory reporting and notification obligations of physicians or other health professionals lead to an infringement of the ► confidentiality between the physicians and their patients. This confidentiality within the physician-patient-relationship is a necessary and legally protected good. Therefore, public health agencies have to be aware of the burden they cause with surveillance activities in such sensitive relationships.
- In light of the sensitivity of the data, administrative agencies must ensure safe, confidential and secure handling of the obtained information. With respect to these data, the administration must ensure data security and protect privacy rights (e. g., the information about an existing HIV-infection of a person). The protection of sensitive information is the state's mirrored duty in contrast to the right to collect these data.
- Any disclosure of such information must be based on rational and public health related reasons. Public health officers who fail to ensure security and confidentiality violate the rights of persons and companies. These officials are at risk of being sentenced to criminal culpability and tort liability and of paying damages to the affected persons and companies.

Like most public health activities, surveillance and data evaluation practices also generate legal conflicts that need to be balanced with the material importance of the information for the protection and promotion of public health.

Health Communication and Promotion

Public health agencies not only collect but also use obtained information to protect the population from health threats. Regulatory agencies evaluate information to assess health risks resulting from products and techniques. As a consequence of detected risks, agencies issue warnings and public health advice and, in this vein, inform and warn the public about health threats. Additionally, public information includes recommendations on healthy behavior. Drug regulatory agencies make intensive use of their competencies to inform and warn the public about health risks of pharmaceuticals and medical devices (*See* the webpages of the FDA, EMEA or BfArM). Public warnings by state agencies about product risks are effective tools in regulatory supervision.

The information and communication activities, thus, the "government speech" (Gostin 2000) comprise more than product-related warnings. The government and its agencies also warn and inform about upcoming or present health risks resulting from natural disasters or infectious diseases. As an early example, in the 14th century in Europe, the local administration informed the population about the right behavior in cases of plague, and about how to prevent plague. In the "*Pestschriften*" (a German term that translates to "the Plague Writings"), the administration provided, among others, instructions to avert the risks of an epidemic (Schumacher and Meyn 1992). Such health information and education campaigns are even more relevant in contemporary public health.

Another growing field of public health practice is *health promotion*. These activities conducted by agencies (or in cooperation with specialized private institutes) cover a wide range of health topics. By this means, the government intends to influence behavior. These activities pursue health education goals. Examples of health promotion activities include campaigns for safer sex in order to prevent sexually transmitted diseases. Other health promotion campaigns educate on nutrition aspects and try to prevent drunk driving. Furthermore, the reduction of tobacco smoking was significantly promoted by the anti-smoking campaigns of public health agencies (CDC 1999). There are numerous other examples, including regular vaccination campaigns. Overall, health promotion campaigns influence individual behavior by convincing, persuading, motivating and creating awareness of the upsides and downsides of a behavior. Today, many public health concerns result from individual behavior and lifestyle, and health promotion will remain a useful tool of public health practice (Reynolds 1995).

As public health agencies are also involved in the supply of health services and the securing of health insurances, their activities also include the analysis and communication of the quality of care and cost-benefit-ratios of medicinal products and medical treatments. For the latter, many countries have established particular agencies that are in charge of cost-benefit-assessments and health-technology-assessments. Among these institutions, the "National Institute of Clinical Excellence" (NICE) in the United Kingdom is a prominent example. Agencies inform the public about the quality and other features of medical treatments and supply recommendations and therapy guidelines. These communication activities continue to play an important role in contemporary public health. Their importance will probably increase as new communication means (e. g., internet, e-mail) enable agencies to reach out more effectively to the general public.

Legal concerns arising from public health agencies' communication and health promotion activities are manifold. As such, health-related communication by the government influences consumer behavior with respect to several types of products (e. g., food, dietary products). These activities interfere with the economic rights of manufacturers and product distributors. Similar concerns arise with respect to public health advisories issued by the administration that warn the public against certain products. Here again, a relevant interference with economic, professional and personal rights of health professionals and product manufacturers cannot be excluded. Overall, public health agencies need sufficient authorizations to conduct such information campaigns. Despite legal authorization, public health agencies must carefully balance all personal and economic rights that might be impacted by their health communication activities. If agencies conduct such activities wrongfully, they may be liable to companies, health professionals and other individuals (► state liability).

Regulation of Commercial Information

As a third branch of "information and communication", public health law comprises the regulation of information, communication and advertising of companies and service providers (including health professionals). This regulation of commercial speech is part of the legal regulation of professions, businesses and products. Commercial speech is characterized as the provision of information that directly or indirectly aims to support the marketing and sale of products or services. Therefore, courts also refer to the fact that commercial speech proposes a commercial transaction, which means that this type of communication and information is aimed at sales promotion or merchandising. The public health regulation of commercial speech has several starting points as such communication may endanger the public health in different ways when left unregulated:

- *First*, in most jurisdictions, commercial speech with wrong, inaccurate or misleading information is prohibited.
- *Second*, states may prohibit certain content in commercial communication. Accordingly, laws in many countries limit advertising, information or product-related commercial communication for a number of products. Among these, tobacco, alcohol and pharmaceuticals are prominent examples.
- *Third*, commercial speech may be restricted with respect to the type of content, addressees or the media used. In Europe, commercial information to consumers for marketing of prescription drugs is prohibited whereas it is allowed vis-à-vis health professionals. In addition, the content and channels of such commercial speech is regulated. In this alternative, public health regulates when, how, where, with whom and with which content commercial speech is allowed (*See* Gostin 2000, with a case study on tobacco advertising in the U.S.).
- Public health regulation of commercially motivated communication also includes "compelled commercial speech" (Gostin and Jacobson 2006). Here, governments force industries to provide the consumers with specific information on product ingredients or risks. Again, the pharmaceutical industry is a good example. When placed on the market, drugs must be labeled with certain information. They must be marketed with a package leaflet containing particular information including unfavorable product information, which must also be disclosed (e. g., side effects, interactions). Additionally, companies must disclose safety-relevant information obtained during the marketing to authorities and the public (*See* Koyuncu 2006, for pharmaceutical information). Similar compelled communication measures exist for other goods (e. g., food, chemicals). In addition to consumer products, occupational safety laws prescribe that workers need to be informed about

the risks of the substances processed at work. Here, public health laws function as so-called "right-to-know laws" (Judson et al. 2006). They grant workers a right to know the risks of substances and materials they handle. These rights-to-know are analog to the informed-consent-rules in medical law where the patient has the right to know the risks of a medical treatment or medicinal product (Koyuncu 2006).

Regulation of commercial speech has different manifestations among which some were highlighted above. Public health law allows different stages of commercial freedom and restricts some types of commercial communication. These regulation measures are part of the regulation of professions, businesses and products.

Both information and communication play crucial roles in contemporary public health. However, in all three branches highlighted above, critical legal questions are raised that deserve attention. The importance as well as legal relevance of "information and communication" in public health practice is increasing.

Synonyms

Legal tools of public health; Legal instruments of public health

Definitions

Legal means of public health encompass the instruments applied in public health practice that are provided by law. In contrast to the legal means, public health practice also applies scientific means rooted in epidemiology, medicine, microbiology, and statistics, among others. The range of legal means includes legal rules legislated by parliaments as well as individual administrative orders to protect and promote the public's health.

Basic Characteristics

The legal means of public health can be differentiated depending on the actor who uses them (e. g., the government, legislator, courts, or private entities and individuals). On the other hand, the legal means can be differentiated depending on the addressee of the means (e. g., individuals, companies, objects, the general public). In the following, some of the means are presented.

Legal Means Depending on Public Health Actors

All state powers as well as individuals and private entities are involved in the assurance and promotion of public health. Based on the assigned legal powers, the legal means of the actors differ remarkably.

The *legislator* (i. e., parliaments/congress) particularly uses the following means:

- Enacting statutes assuring and promoting public health purposes;

- Enacting statutes defining public health terms (e. g., definition of "emergency", "natural catastrophes")
- Enacting statutes providing for policy objectives;
- Enacting statutes with indirect effect on public health (e. g., tax law, criminal law);
- Enacting statutes establishing procedural rights within public health administration;
- Granting legal authorization to the government;
- Granting funds to the government for public health policies and actions;
- Creating, funding and defining the mission of public health agencies;
- Enacting statutes governing the competencies and relations between agencies.

The *administration* (i. e., government and administrative agencies) as the key actor of public health practice has the most legal means at its disposal. The administrative agencies are part of the government. All together form the state administration. As legal means, they may, among others:

- Promulgate regulations;
- Issue ordinances (e. g., air pollution ordinances, zoning ordinances);
- Create administrative agencies;
- Set standards and guidelines (e. g., air pollution, noise level thresholds);
- Supervise authorities;
- Carry out surveillance and data collection;
- Release and enforce administrative acts;
- Perform administrative physical acts;
- Release public information, including health promotion campaigns;
- Mandate private entities to supply public health services;
- Carry out public health litigation, including obtaining court injunctions;
- Impose civil sanctions;
- Impose administrative fines;
- Initiate criminal investigations.

In addition to the administrative agencies, the military may effectively contribute to the public's health, which is regularly the case in emergencies and natural disasters (*See* Matthews et al. 2007).

The *court system and judges* also have specific legal means in the realm of public health. Courts are increasingly involved in public health matters. It was noted that since the 1970s, litigation has been increasingly used to pursue public health goals and that this new type of "Public Health Litigation" to promote public health outcomes is particularly used by individuals and non-governmental organizations (Parmet and Daynard 2000; Teret 1986). The court's function is to judge legal disputes and provide guidance by reviewing, interpreting, and enforcing laws. As a result, courts release judgments, intermediate and ▶ preliminary injunctions, and impose penalties. In doing so, they establish case law as well as legal doctrines, particularly where no codified laws exist. In addition to such case-related work, courts influence legislatures and policies. As commentators note, numerous policies of contemporary public health are the result of an "interactive dialog between courts and the legislatures" (Parmet and Daynard 2000). The court's powers and influence avenues must not be underestimated.

Other actors in public health practice include individuals, private entities (e. g., companies), and other institutions (e. g., non-governmental organizations, international organizations). These actors may also make use of specific legal means to pursue public health objectives. As a basic legal tool, individuals and organizations may apply for administrative agency actions against public health threats. Further, public health litigation has already been mentioned and can be a powerful instrument. For example, in Germany, an individual obtained a judgment of the Federal Administrative Court against the local administration, which ruled that in that particular case the administration had to take public health measures against significantly elevated air pollution with micro dust in a particular area. The administration initially refused such actions. Individuals can also influence public health relevant developments by private law litigation against companies, state authorities, and medical service providers. As such, product liability litigation has influenced the product safety level as well as the manufacturers' duties (information, instruction, record-keeping) and safety relevant behaviors (McClurg et al. 2007; Parmet and Daynard 2000; Gostin 2000). Medical malpractice litigation improved the patient's legal status vis–à–vis medical doctors (Koyuncu 2007; Koyuncu 2006a). This has not only produced deterrent effects but also enhanced the development of patient empowerment and contributed to the public's health (Koyuncu 2006b). Similarly, pharmaceutical product liability litigation led to the establishment of information and instruction obligations of drug manufacturers (Koyuncu 2004).

Legal Means and Their Mechanisms

The legal means can also be subdivided with respect to their mechanisms. As such, the following means can be differentiated, where the degree of coercion through the administration is a further criterion:

- Legal means to inform, educate, and induce voluntary healthy behavior of individuals and legal entities (e. g., health promotion, standard setting);
- Legal means to influence behavior and sanction misconduct (e. g., criminal laws, tort liability) and to provide incentives for voluntary healthy behavior (tax law);
- Legal means to supply public health services (e. g., health insurances);
- Legal means enabling the intrusion of individual privacy (e. g., surveillance);
- Legal means to impose preconditions for the conduct of certain activities and businesses (e. g., licenses) and regulation of such conduct (e. g., mandatory notifications);
- Coercive measures without affecting bodily integrity (e. g., isolation, destruction of objects, closure of businesses or buildings);
- Coercive measures with bodily integrity affection (e. g., compulsory medical examination, vaccination, and treatment).

These legal means can be further differentiated with respect to their targets. The set of tools provided by public health law can be subdivided depending on the target of the action, which can be (1) persons, (2) objects, (3) companies and businesses, and (4) the general public. Public health can ensure and promote the population's health by starting at different points and targets and by applying different levels of coercion. The legal tool to combat a public health risk must always be selected on a case-by-case basis. Therefore, the following lists present a selection of means provided by law and which stand for a wider spectrum of potential legal means.

Legal Means Against Persons

These legal means regularly entail personal restrictions but not necessarily, as many of them also intend to influence behavior and induce voluntary healthy behavior. However, many public health means provided by law allow coercive actions and, thus, substantially affect personal rights:

- Information and health promotion campaigns;
- Provision of health services;
- Provision of social/health insurances;
- Providing incentives for healthy behavior (e. g., tax law);
- Surveillance and data collection, including inquiries and questionnaires;
- Registration of persons;
- Regulation of professions (e. g., licensures, permits, prior notification);
- Mandatory professional obligations (e. g., mandatory reporting of infectious diseases);
- Conditions, restrictions of professional speech, and advertising;
- Revocation of licenses and ban from professions or businesses;
- Mandatory use of private property and administrative condemnation of private property;
- Isolation, quarantine, and cordon sanitaire;
- Compulsory commitment and hospitalization;
- Compulsory examination and medical treatment;
- Civil sanctions and tort liability;
- Administrative fines and penalties;
- Criminal prosecution and punishment.

This non-exhaustive list demonstrates that to a certain extent personal restrictions are an inevitable part of public health practice. Therefore, particular emphasis is necessary on the legal balancing of conflicting rights prior to the selection of the means of practice in a particular case. Public health officers must understand that each act causing a personal restriction may lead to personal criminal culpability of the public health officer and cause the liability of the administration if the order was issued without sufficient legal balancing.

Legal Means Against Objects

Many public health threats are related to objects. Therefore, several public health actions target objects. These include:

- Legal regulation of products and regulatory supervision;
- Surveillance (e. g., reporting duties, inspections, inquiries, questionnaires);
- Trade restrictions (e. g., an ► embargo);
- Product-related public health advisories, public product warnings, and recalls;

- Restriction of access and prohibition of the use of products/goods;
- Closure of buildings, streets, tunnels, bridges, etc.;
- Inspections (in criminal law: searches), takings, and seizures;
- Administrative condemnation and destruction of objects.

Legal Means Against Companies and Businesses

A considerable part of public health practice includes the regulation of businesses and products. Among these businesses, health-related product manufacturers and service providers (e. g., pharmaceutical companies, medical device producers, hospitals) as well as businesses with a less direct connection to the public's health (e. g., motor vehicle producers, construction business) have to be regulated. Legal means with respect to these targets include:

- Restriction of the access and conduct of businesses;
- Legal regulation and regulatory supervision of the business and workplaces (e. g., licenses, permits, prior notification/registration);
- Occupational safety measures;
- Surveillance (e. g., reporting, inspections, inquiries, hearings, questionnaires);
- Restrictions of advertising and marketing of certain products (e. g., alcohol, tobacco, pharmaceuticals) and recall orders for products;
- Trade restrictions and embargos;
- Suspense and revocation of licenses and prohibition and closure of businesses;
- Administrative sanctions and criminal prosecution and punishment including forfeit of gain;
- Tort liability and civil sanctions.

Legal Means Targeting the General Public

Public health practice additionally applies a set of tools that is rather addressed to the general public. These measures effectuate through influencing voluntary behavior, prescribing behavior, and defining state-of-the-art standards, thresholds, and prohibitions with subsequent sanctioning. These instruments also intend to influence, develop, and form social norms (Bernheim et al. 2007) and, thus, induce and promote healthier behavior. Among them, regulations, ordinances, and guidance documents governing particular fields as well as the setting of standards (e. g., air pollution thresholds, workplace safety standards) must be noted. Particularly, nuisance abatement is a crucial public health action (Gostin and Jacobson 2006) in addition to zoning and planning activities with respect to land use, construction, and traffic. Furthermore, health information, education, and health promotion campaigns conducted by the public health administration are directed to the general public. The latter include statistics and other publications of public health agencies. As the basis for such publications, public health agencies must be entitled to conduct their own research; this includes public funding of the research activities.

In summary, law provides the public health practice and state powers with a broad range and a flexible set of legal means. The acting public health officer will have to select the applicable legal means on a case-by-case basis as the legitimacy and admissibility of the tools always depend on the result of the case-specific legal balancing of the conflicting rights. Many of the legal means presented above will be further discussed in the essays regarding the field of public health law and the corresponding specialized public health fields in this encyclopedia.

Public Health Legal Rules

Definition

Public health law is the sum of all legal rules that directly or indirectly aim to safeguard or promote the population's health. These rules may arise from statutory law, administrative regulations and acts, customary law, case-law and common-law. Public health law also includes laws which provide for the establishment and funding of corresponding administrative agencies.

Public Health Programs

Synonyms

Public health interventions; Public health system

Definition

Governmental or other collective efforts to prevent disease, prolong life, and promote physical and mental health among the population as a whole. These programs primarily emphasize the prevention of disease and the promotion of health-enhancing resources such as screening programs for early detection of disease, immunizations, monitoring of health standards, and health education.

Public Health Services

Forschungsverbund Public Health Sachsen-Sachsen Anhalt e. V., Medizinische Fakultät, Technische Universität, Dresden, Germany
wolfgang.boecking@web.de, dtrojanus@gmx.net

Definition

Public health services are services, goods or facilities provided to promote and improve the ► health status of populations in a country, region or community as distinct from personal health care services improving the health status of an individual. Public health services are designed to prevent diseases, to promote, protect and improve health by means of preventive medicine, health education, control of ► communicable diseases, sanitary measures, and protection against ► environmental hazards. The organization and scope of public health services depends on the country-specific concept of public health, its health care system as well as on the available financial resources.

Basis Characteristics

The Concept of Public Health

The concept of public health emphasizes the health needs of a population as a whole. Goals of public health are the prevention of disease, the reduction of the amount of disease and of health inequalities, and the reduction of premature death, disability and discomfort in the population.

To assess the health status and health trends in a population, basic sciences such as ► epidemiology and ► vital statistics are applied. Epidemiology is used to identify causes and calculate risks to health; vital statistics help to assess the conditions influencing health. Other sciences such as ► toxicology and ► microbiology are used to assess chemical and biological risks in the environment. Even social sciences are increasingly impor-

tant as social factors and behavioral aspects also contribute to the risk of diseases, premature death or disability.

The effort put into public health services, institutions and programs to fulfill specific public health goals determines the design and scope of public health services in a country.

Organization and Scope of Public Health Services Throughout the World

In most industrialized nations with well developed health care systems, public health services are organized on a three-level basis: national, regional and local levels.

- National public health services are typically in charge of collecting national health statistics in order to set, monitor and maintain health standards and to promote good health. They also support and perform research on diseases relevant to public health.
- Regional public health services are mainly responsible for larger health protection activities such as providing safe water and food supplies as well as early detection of diseases. They may also provide health care for certain groups such as the chronic mentally ill.
- Local public health services in cities or communities deal with various public health services on a more personal level, for example, health education and health control in schools, immunization programs, advice in mother-child care as well as health care for the elderly and long-term sick. As local health services are close to the people they also investigate and control epidemics and other communicable diseases such as those transmitted sexually.

On an international level, there is an exchange of information between national public health services in order to control diseases of international importance. Under the guardianship of the World Health Organization (WHO), national public health services collaborate in the field of major ► epidemic diseases and set standards for protection against environmental hazards.

In most developing countries, public health services are weak due to several factors: lack of responsibility for public health in the government; weak leadership and vested interests; lack of investment in health and lack of infrastructure to deliver health services as well as poor training and career structures. Since its creation in 1948, the WHO, as the United Nation's specialized agency for health, mainly concentrates its efforts on the promotion of health in developing countries. Through various programs, the WHO Regional Offices try to help these countries to strengthen their public health workforce as well as their public health education and research by developing training programs, building partnerships and mobilizing new health funds. Despite WHO efforts over the years, the organization, scope and quality standards of public health services in developing countries are far behind the services provided in well developed industrial nations (see country example of the United States).

Country Example: Public Health Services in the United States

The system of public health services in the United States serves as an example for all industrialized high-income nations with well developed health systems which organize their public health services in a similar way. In the United States, the principal agency for public health is the US Department of Health and Human Services. It covers a wide spectrum of services provided at the local level by state or county agencies, or through private sector grantees. Its global mission is to promote physical and mental health and prevent diseases, injury and disability in all communities of the country. The Department's programs are administered by the following 11 operating divisions, including 8 agencies in the US Public Health Service and 3 Human Services Agencies.

Public Health Service Agencies:

1. National Institutes of Health (NIH) is a medical research organization, conducting extensive research nationwide in neurology, cancer, diabetes, heart diseases and AIDS
2. Food and Drug Administration (FDA) assures the safety of foods and cosmetics, and the safety and efficacy of pharmaceuticals, biological products, and medical devices
3. Centers for Disease Control and Prevention (CDC) provide a system of health surveillance to monitor and prevent disease outbreaks (including ► bioterrorism), implement disease prevention strategies, immunization services, workplace safety, and environmental disease prevention

4. Agency for Toxic Substances and Disease Registry as part of CDC helps prevent exposure to hazardous substances from waste sites and develops toxicological profiles of chemicals at these sites
5. Indian Health Service (HIS) provides health services for American Indians and Alaska Natives living in Federally recognized tribes
6. Health Resources and Services Administration (HRSA) provides access to essential health care services for people having a low income, being uninsured or who live in rural areas or urban neighborhoods where health care is scarce
7. Substance Abuse and Mental Health Services Administration (SAMHSA) works to improve the quality and availability of substance abuse prevention, addiction treatment and mental health services
8. Agency for Healthcare Research and Quality (AHRQ) supports research on health care systems, health care quality and cost issues, access to health care, effectiveness of medical treatments and quality of care (► health care quality).

Human Service Agencies:

1. Centers for Medicare & Medicaid Services (CMS) administers the Medicare and Medicaid programs, which provide health care for the elderly and disabled (► medicare) and for low-income persons including children (► medicaid)
2. Administration for Children and Families (ACF) is responsible for programs that promote the economic and social well-being of children, families and communities
3. Administration on Aging (AoA) supports a nationwide aging network, providing services to the elderly, such as home delivered meals, transportation and at-home services to enable them to remain independent

Public Health Surveillance

Slavenka Janković
Institute of Epidemiology, School of Medicine, University of Belgrade, Belgrade, Serbia
slavenka@eunet.yu

Synonyms

Surveillance; Epidemiologic surveillance; Health monitoring; Continuous control

Definition

According to the ► Centers for Disease Control and Prevention (CDC), "public health surveillance is the ongoing systematic collection, analysis, and interpretation of outcome-specific data essential to the planning, implementation, and ► evaluation of public health practice, closely integrated with the timely dissemination of these data to those who need to know. Outcomes may include disease, injury, and disability, as well as risk factors, vector exposures, environmental hazards, or other exposures. The final link of the surveillance chain is the application of these data to prevent and

control human disease and injury" (Thacker and Birkhead 2002).

Surveillance of ► drinking water quality is a continuous process of public health assessment and review of the safe quality and quantity, accessibility, coverage and continuity of drinking water supplies.

Surveillance can be distinguished from ► monitoring by the fact that it is continuous and ongoing, whereas monitoring is intermittent or episodic (Last 2001).

Basic Characteristics

Historical Background

Surveillance concepts in public health practice were first used to monitor contacts of persons with serious communicable diseases, such as bubonic plague and smallpox, in order to detect early symptoms and prompt isolation. Two prominent names in the development of public health surveillance activities in the 19th century were Lemuel Shattuck and William Far. In the middle of the 20th century, Alexander Langmuir and his colleagues began to broaden the concept of surveillance. They emphasized rapid collection and analysis of data on a particular disease. The 1968 World Health Assembly focused on national and global surveillance of communicable diseases, applying the term to the diseases themselves rather than to the monitoring of individuals with disease. It also addressed the application of the concept of surveillance to public health problems other than communicable disease, such as leukemia, congenital malformations, injuries, behavioral risk factors, etc. (Thacker 2000).

Purposes of Surveillance

Public health surveillance is a management tool and the cornerstone for public health practice. It provides the scientific and factual database that is essential for informed decision-making, conduction of public health prevention and control programs, evaluation of public health efforts, and allocation of resources. There are many uses of surveillance. The most important are:

- estimation of the health status of populations,
- portrayal of the natural history of disease,
- detection of epidemics,
- testing of hypotheses,
- evaluation of control and prevention measures,
- monitoring of changes in infectious agents,
- detection of changes in health practice,
- designing and planning public health programs, and
- planning and conducting research (Thacker 2000).

The overall purpose of surveillance is to prevent disease, disability, and death, thereby improving public health.

Elements of Surveillance Systems

Case Definition Explicit case definition is at the core of a surveillance system. It should be as clear and as simple as possible. When the definitions apply to diseases, they generally combine laboratory criteria with clinical manifestations. For some diseases, definitions may be stratified by the levels of confirmation (e. g., confirmed and possible cases). During an epidemic investigation, when laboratory data are often not available, the case definition is usually broad (Thacker and Birkhead 2002).

Population Under Surveillance All surveillance systems target specific populations, which may range from individuals at specific institutions (e. g., schools, hospitals) to residents of nations.

Types of Surveillance

Active surveillance is a system employing staff members to contact health care providers or the population (by telephone calls or visits to physicians) regularly in order to seek information about health conditions. Active surveillance provides the most accurate and timely information, but it is expensive.

Passive surveillance means that the organization conducting the surveillance does not contact potential reporters but rather leaves the initiative for reporting to others. Passive surveillance is relatively inexpensive, but data quality and timeliness are difficult to control.

Population-based surveillance systems include ► notifiable disease reporting systems and systems based on the use of vital statistics, which register almost all births and deaths and provide information on the causes of deaths.

Laboratory-Based Surveillance Using diagnostic laboratories as the basis for surveillance can be highly effective for some diseases. The future in food borne disease surveillance is in laboratory-based surveillance. A collaborative World Health Organization (WHO)

program – Global Salm-Surv – promotes the international use of Salmonella serotyping.

Sentinel Surveillance Surveillance for ► sentinel events can be used to identify situations where public health investigation or intervention is required. An example of sentinel surveillance is networks of private physicians reporting cases of influenza.

Syndromic Surveillance Syndromic surveillance uses case definitions that are based entirely on clinical features without any clinical or laboratory diagnosis (e. g., collecting the number of cases of diarrhea rather than cases of cholera). It can detect potential disease outbreaks quickly and can provide useful tools to assist in outbreak investigation.

Evaluation of Surveillance System

Evaluation of public health surveillance systems should be performed regularly to assess the following:

- the public health importance of the health event;
- the usefulness and cost of the surveillance system;
- the characteristics of the surveillance system that contribute directly to its ability to meet its specific objectives, such as simplicity, flexibility, acceptability, ► sensitivity, ► predictive value positive, ► representativeness, and ► timeliness (Romaguera et al. 2000).

The Future of Public Health Surveillance

The vision of the future of surveillance assumes transformation of surveillance from dusty archives of data collected after-the-fact to meaningful measures that provide accountability for health status or that deliver timely early warnings for outbreaks of serious diseases. Realization of this future vision of surveillance requires information technology that is already feasible, the political will to develop and coordinate the needed systems and standards, as well as the removal of the financial and logistical barriers to broadband Internet access (Nsubuga et al. 2006).

In a time when we are confronted with SARS and avian influenza, the need to integrate global surveillance networks is unquestionable. The global infectious disease surveillance network that has been adopted by the WHO links regional, national, and international networks of laboratories and medical centers. Government centers of excellence, such as the CDC, together with military networks, Internet discussion sites (for example ProMed), and collaborative WHO programs such as the WHO Global Salm-Surv, also supplement the reporting networks. The Global Outbreak Alert and Response Network has more than 120 partners around the world. One of the most important aspects of the new ► International Health Regulations (IHR 2005) is the establishment of a global surveillance system for public health emergencies of international concern (Nsubuga et al. 2006).

Conclusion

Public health surveillance is an essential tool for estimating the health status and behavior of populations, and is useful for measuring both the need for interventions and the effects of interventions. The key objective of surveillance is to provide information to guide intervention.

Public Health System

► Public Health Programs

Public Law

Definition

Public law is the body of law that governs the relationships between private subjects (individuals and private legal entities) and the state with its institutions. This includes the relationships between individuals and the legislative powers, the judiciary powers and the executive powers (i. e., the state administration). Subdivisions of public law include constitutional law, court procedure laws and administrative law. Public health law is a branch of administrative law and, thus, a part of public law.

Publicly-Financed Health Systems

Synonyms

Health care system; Governmental health care

Definition

The health care delivery and payment system financed by a government, which includes all the actors, institutions and resources that government employs to promote access, quality, affordability, and value of health care.

Introduction

According to the World Health Organization (WHO), mental health is a state of well-being in which the individual realizes his or her own abilities, can cope with the normal ► stresses of life, can work productively and fruitfully, and is able to make a contribution to his or her community. Tudor (1996) described mental health as multifaceted with six dimensions: affective, behavioral, cognitive, spiritual, socio-political, and psychological. The Mental Health Foundation stated that an individual with good mental health is defined as one who can

- Develop emotionally, creatively, intellectual, and spiritually;
- Initiate, develop and sustain mutually satisfying personal relationships;
- Face problems, resolve them and learn from them;
- Be confident and assertive;
- Be aware of others and empathize with them;
- Use and enjoy solitude;
- Play and have fun;
- Laugh, both at themselves and at the world. (http://www.mentalhealth.org.uk)

Mental health is broadly defined. It includes vastly different beliefs about human natures and how to relief mental suffering. The determinants of mental health occur at three main levels- the individual, the group and the environment. Mental health and mental illness are not two different poles on a single continuum. Mental disorders are one of a number of possible obstacles to the individual's utilization of inner strengths and resources (other obstacles are, for example, physical illness, poverty or negative social circumstances). Public mental health is public health in relation to mental health and mental disorders. The Diagnostical and Statistical Manual of mental disorders (DSM-IV; APA 1994) defines a mental disorder as a clinically significant behavioral or psychological syndrome or pattern that occurs in an individual and that is associated with present distress or disability with a significantly increased risk of suffering, death, personal disability, or an important loss of freedom. The DSM-IV's definition seems quite broad, for example, it suggests that a mental disorder must be a manifestation of a behavioral *or* biological *or* psychological dysfunction. Psychological disorders can be episodic, chronic or recurrent. They cover a broad range of conditions. ► Substance use disorders (e. g., alcohol dependence, illicit substance dependence), ► psychotic disorders (e. g., schizophrenia), ► affective disorders (e. g. major depression, dysthymia, bipolar I and II disorder), ► anxiety disorders (e. g. panic disorder, agoraphobia,

generalized anxiety disorder, social phobia, obsessive-compulsive disorder), ► somatoform disorders (e. g., somatization disorder, pain disorder, hypochondriasis) and ► eating disorders (e. g. anorexia nervosa, bulimia nervosa) are "major mental disorders" and show a high public health relevance. Mental disorders are common diseases. Over 80 million people of all ages in the EU are estimated to suffer from mental disorders. At any time, one adult in six suffers from mental problems of varying severity. Despite being common mental disorders are underdiagnosed by doctors. Mental health is fundamental to overall health. Mental disorders typically have adverse effects on school and academic career, somatic health, and social functioning. According to Murray and Lopez (1996), the burden of mental illness has been seriously underestimated by traditional approaches that focus on mortality rates as the primary measure of adverse health outcomes. Projections used in The *Global Burden of Disease* show that psychiatric and neurological conditions could increase their share of the total global burden of disease from 10.5% in 1990 to 15% in 2020. Mental disorders are real. People with mental disorders are not just thinking that they are ill, people with mental disorders are as disabled as people suffering from coronary heart disease or cancer in terms of lost productivity (e. g., disability days) and premature death (e. g., caused by suicide, the affects of associated risk factors, and comorbidity). Mental disorders are associated with total costs of over 290 billion Euros. Those costs are related to diagnostic assessment and treatment but mainly to indirect costs (Andlin-Sobocki et al. 2005). There is a strong need for economic research in mental health (► mental health economics). As research has improved our ability to diagnose and treat mental disorders, the recognition of mental disorders should be improved as well. However, probably less than half of individuals suffering from frequent mental illnesses are recognized in primary care settings. And, even if mental disorders are recognized, only about half of affected patients get effective treatment. The earlier a mental disorder is diagnosed and treated, the higher the changes for achieving recovery. Non-treatment, however, supports chronicity and comorbidity of mental disorders.

Mental health problems can be both a cause and a consequence of social exclusion. Common mental disorders are significantly more frequent in socially disadvantaged populations (e. g., people with low education or unemployment). Mental illness can lead to social stigmatization. Stigma in relation to mental illness (► stigma of mental disorders) contributes negatively to social inclusion and equality. Moreover, a stigma deters treatment significantly. Mental health problems are an important contributor to the burden of disease and can cause significant loss of quality of life (by e. g. causing disability and increasing social exclusion and mortality), hence, mental health problems are of major importance to all societies and to all age groups worldwide. Mental health and psychiatry research in the enlarged European Union varies. Especially in the new central and eastern European member states (Hungary, Estonia, Poland, the Czech Republic, Slovenia, Latvia, Lithuania, and Slovakia), the publication rate in the psychiatric field (i. e. an indicator of scientific research) is low. As Marusic (2004) stated, the low number of internationally recognized psychiatric publications might reflect the restricted mental health research in these countries which is mainly a result of the small economic capacity. Inspite of their small populations, Ireland (publication rate in the year 2000: 22.18 per 10^6 inhabitants), Finland (10.24 per 10^6 inhabitants), Denmark (7.18 per 10^6 inhabitants), and Sweden (6.09 per 10^6 inhabitants) show the most psychiatric research publications in the European Union, whereas Italy (0.68), Poland (0.36), Portugal (0.29), and Slovakia (0.19) show the lowest rate.

Prevalence, Severity, and Treatment of Mental Disorders

For examining and comparing the prevalence of mental disorders in different countries, the use of the same diagnostic instrument is an important factor. In epidemiological surveys, the lack of common methods is the fundamental problem. Of course, the advantages and disadvantages of the different instruments can be argued, but unless agreement is reached on a very few standardized and validated instruments, comparisons will be impossible. Moreover, for comparison, age groups targeted, sampling methods, interviewing techniques, methods and categories of analysis, and presentation of results need to be standardized. In 1988, Robins et al. published the World Health Organization (WHO) Composite International Diagnostic Interview (CIDI) which was more elaborated than other

Ukraine	7.1 [5.6–8.6]	9.1 [7.3–10.9]	3.2 [2.2–4.0]	6.4 [4.8–8.1]	20.5 [17.7–23.2]
USA	18.2 [16.9–19.5]	9.6 [8.8–10.4]	6.8 [5.9–7.8]	3.8 [3.2–4.5]	26.4 [24.7–28.0]

* anxiety disorders include agoraphobia, generalized anxiety disorder, obsessive compulsive disorder, panic disorder, posttraumatic stress disorder, social phobia, and specific phobia; mood disorders include bipolar I and II disorders, dysthymia, and major depressive disorder; impulse control disorders include bulimia, intermittent explosive disorder, and reported persistence in the last 12 months of symptoms of 3 child- and adolescent disorders (attention deficit hyperactivity disorder, conduct disorder,and oppositional-defiant disorder); Substance disorders include alcohol or drug abuse or dependence.

interviews used before. The CIDI shows the prevalence of mental disorders (with the exception of disorders of personality and behavior) but includes also detailed questions about disorders severity, impairment, and treatment. There are explicit algorithms for International Statistical Classification of Diseases, 10th Revision (ICD-10) and Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition (DSM-IV) diagnoses (APA 1994). Many cross-national psychiatric surveys using the CIDI were carried out in the following years. As a limitation of those surveys, most of them were carried out in developed countries, making it impossible to assess generalizability of results. WHO established the World Mental Health (WMH) Survey Consortium in 1998 which coordinated the implementation of surveys in 28 countries, including less-developed countries.

Table 1 displays the twelve month prevalence rates of mental disorders in seven European countries and in the United States (WHO-WMH 2004).

In all but one European countries (i. e., Ukraine) and in the USA ► anxiety disorders are most common (12 months prevalence rates between 5.8% in Italy and 12.0% in France), followed by ► affective disorders (12 months prevalence rates between 3.6% in Germany and 9.6% in the USA). Overall prevalence rates of mental disorders vary widely, from 8.2% in Italy to 20.5% in the Ukraine and 26.4% in the United States.

As an example, it can be seen in Table 2 that mental disorders affect a substantial proportion of the population during their whole lifespan (lifetime prevalence of mental disorders in the German population = 43%). German lifetime prevalence rates of The German National Health Interview and Examination Survey (GHS-MHS; Jacobi 2002) show a strong concordance with other lifetime prevalence studies (e. g. Kessler et al. 1994).

However, it is also important to recognize that many mental disorders are mild and often self-limiting, i. e. people suffering from mild mental disorders usually do not need treatment. Therefore, in the WMH surveys each mental disorder was classified in different severity grades (“mild”, “moderate” or “serious”, for details s. WMH Consortium 2004). Mild mental disorders are significantly more frequent than moderate and serious mental disorders (Table 3).

Patients suffering from serious mental disorders show higher probability for receiving treatment than patients with moderate mental disorders. A significant proportion of individuals with mental disorders do not seek professional help. The help-seeking behavior of patients with mental disorders varies and it is unclear why some patients with mental disorders seek help and others do not. The severity of mental disorder is proposed as one possible reason. Table 4 displays the association between mental disorders severity and the probability of treatment. Treatment was assessed by seeing

Public Mental Health, Table 2 Lifetime prevalences of mental disorders in the German Population (GHS-MHS; N = 4181)

Disorders (DSM-IV)	total		male	female

USA	7.7 [7.0–8.4]	9.4 [8.5–10.3]	9.2 [8.1–10.3]

a professional (i. e. mental health professionals, general medical professionals, religious counselors, and traditional healers) either as an inpatient or outpatient for problems with emotions, nerves, mental health, or use of alcohol or drugs.

However, it is notable that a remarkable proportion of people with even serious mental disorders do not receive treatment (36% in Spain—80% in the Ukraine were untreated). The way to treatment is for people with mental disorders much longer than for people with somatic diseases. It is easy to imagine that individuals with mental disorders, for example major depression, who may be fatigue, who may have sleeping problems, who may have guilty conscience, are not able to seek treatment, especially if they experience barriers to care. In depressed patients individual judgments about the current distress (e. g., feeling hopelessness, self-criticism) and social support (particularly living with a partner) seem to predict more the help seeking behavior than somatic manifestations (e. g., sleep disorders, tension). The non-treatment-seekingbehavior of people with mental disorders is the main barrier to diagnosis and treatment. Other barriers may be the unawareness of health care providers, non sufficient treatment options, inadequate mental health care in the region, antiquated family beliefs about mental illness, the stigma related to mental disorders, and the fear of possible side effects of psychopharmacological treatment. Despite more openness about mental disorders in the media within the last decade, skeptical views about psychopharmacotherapy still prevail. One reason for this negative view can be attributed to fears associated with psychoactive medication: most people believe psychoactive drugs to be addictive and that they change one's personality. Accordingly, the most favored treatment of mental disorders, in the eyes of the public, is psychotherapy. However, particularly in serious mental disorders, not psychotherapy but psychopharmacological treatment has to be the first-choice-treatment. Thus, to realize the patient's basic beliefs about best treatment, to improve compliance to treatment, and to do psychoeducation should be major issues of health care professionals' work (e. g., primary care physicians, psychiatrists, psychotherapists).

Because of the lack of valid EU-wide information about the prevalence of mental disorders, the total burden of mental disorders in the EU is unknown, as well as the total direct and indirect costs. Most individuals suffering from one mental disorder show comorbid another mental disorder, hence, it is not possible just to add up prevalence rates and estimate the costs and unmet needs of the affected persons (due to comorbidity thus adding up prevalences would lead to overestimation of mental disorders prevalence). Wittchen and Jacobi compared 27 epidemiological studies on mental disor-

Any mental disorder	33.2	21.7	27.4

ders conducted in European regions (EU countries, Iceland, Norway, and Switzerland). For inclusion, those studies had to use a population based approach (i. e. community based sample). The following table displays median 12-months prevalence rates of mental disorders in the EU (for details of the statistical procedure and the results, s. Wittchen and Jacobi 2005). Anxiety disorders, somatoform disorders, and affective disorders are most frequent mental disorders. About one in three women and one in five men fulfills diagnostic criteria of a mental disorder in a twelve months period.

As mentioned above, there is a substantial degree of comorbidity. Among the individuals with at least on mental disorder, 68% have only one diagnosis, almost 20% have two, and 14% have more than two 12-month diagnoses of mental disorders.

Women and Mental Health

Women suffer significantly more often from mental disorders than men (exception: substance abuse disorders, i. e. opposite relationship, and psychotic disorders, i. e. similar estimates in both men and women, s. Table 5). Estimated median major depression rates for women, for example, are twice as high as compared for those to men. According to Murray and Lopez (1996) unipolar depression will be the second most important cause of disability burden in the world by the year 2020. As women in many countries are approximately twice as likely as men to experience depression, any significant reduction in the overrepresentation of women who are depressed would make an important contribution to lessening the global burden of disease. Since suffering from mental disorders seems to be more "female" than "male", it is still controversial whether gender differences in depressive disorders are real or an artefact. Three main issues are discussed that might affect not real but artificial gender differences in rates of depression:

- The definition of caseness and measurement procedures. Females show a tendency to report more criterion symptoms associated to depression compared to men. However, findings available from population based surveys suggest that this does not account entirely for those significant gender differences in prevalence rates of depression.
- Recall bias. Women might recall more past depressive episodes compared to males. Although there is

evidence for the instability of recall of depressive episodes in both men and women over time, the gender difference is not entirely responsible for the gender differences in rate of depression.
- Mortality rates. There are suggestions that the relation between depression and premature death is more pronounced in males what might contribute to higher prevalence rates of depressive disorders in women. Two population based epidemiologic surveys show a significantly increased mortality risk in men.

Assuming that different prevalence rates are real, there are some determinants that might influence the higher mental disorder rates in women:
- Women are confronted with more devaluation and discrimination than men.
- Men show a better material well being compared to women.
- Women make less decisions about their lives than men.
- Women show more frequent a low socioeconomic status compared to men. Socioeconomic status and social class, respectively, are negatively associated with the prevalence of mental disorders.

Otherwise, there are factors which are protective against depression. In particular, having sufficient autonomy to exercise some sense of control in response to severe events reduces the likelihood of depression developing. Access to adequate material resources is also needed to underpin the possibility of making choices when confronted with severe life events. All of those protective factors seem to be more pronounced in men.

One of the most consistent findings of epidemiological research is the relationship between low socioeconomic status or social class and increased rates of mortality and morbidity. A more than a two-fold increase in risk has typically been found for those in the lowest social class compared with the highest, for psychological as well as physical morbidity. Previous research has documented the relationship between various objective measures of rank and the increased likelihood of depression and anxiety. Low educational status, unemployment or low employment status, homelessness and insecure housing tenure, inadequate income and poor social support including unsatisfactory interactions with neighbors and relatives have all been found to be associated with increased rates of depression and anxiety and often interact with one another in reciprocal relationships. In this context, it has to be mentioned that single mothers show a notably lower socioeconomic status and income situation as well as lower social support than married mothers. The proportion of single mothers in western countries is large and continuously growing. Recent studies found increased psychological distress of single mothers and their children. However, the US National Comorbidity Survey determined that separated or divorced mothers were more likely to experience psychiatric disorders (e. g., depression, dysthymia, general anxiety disorder) compared to both never married and married mothers. This finding suggest that being a single mother per se is not associated with a higher risk of mental disorders. Single mothers are a heterogeneous group, hence, single marital status groups should be studied separately. There is some evidence that the social factors involved in recovery or restitution may differ from those implicated in the onset of depression and anxiety. Thus, the relationship between low socioeconomic status and a high prevalence of psychiatric disorders has been subject to two quite different explanations. Individuals with mental disorders, or with other personal characteristics predisposing towards mental disorders might be selected down into lower socioeconomic groups. The second explanation asserts that the relationship explained in terms of the greater environmental and psychological adversity accompanies lower socioeconomic status and, in turn, produces high levels of depression. Evidence related to the second view is clearly more congruent with a social view of health. Yet good quality evidence on this relationship for women remains variety of reasons. One general difficulty has been the lessening of research attention paid to social, structural analyses of psychological disorders.

Mental Health Indicators

Carrying out population based surveys for the examination of population mental health is very elaborately. Macro indicators collected routinely from institutional sources such as the World Health Organization (WHO) European Regional Office for Europe (www.who.dk) or the Organization for Economic Co-Operation and Development can provide a synthetic description of mental health status.

The rate of deaths from suicide is a routinely collected public mental health indicator. Suicide rates and life satisfaction, as well as happiness, are inverse associated. According to WHO estimates for the year 2020,

approximately 1.5 million people will die from suicide worldwide. The suicide rates differ in the European countries but it has to be recognized that worldwide the highest suicide rates for both men and women are found in Europe, more particularly in Eastern Europe (i. e. Estonia, Latvia, Lithuania). Those high rates underline the need for developing a sufficient mental health care system in the Eastern European Member States. The annual rate of suicide in the Mediterranean countries and Ireland is, for females, below the EU mean (i. e., 5.2 per 100 000) (compare Chisti et al. 2003). Suicide rates in men are consistently higher than in women (ratio: 3.6 : 1 in 1995). Previous research has produced evidence that suicides are more likely early in the course of certain severe mental illnesses and that persons who have required hospitalization for severe mood disorders have a substantially increased lifetime risk of suicide compared to individuals with less severe illnesses. Yet, only a minority of persons with those mental or substance use disorders seek professional help. The literature suggests that up to two-thirds of those who die by suicide are not receiving mental health or substance abuse treatment at the time of their death and that half had never seen a mental health professional. Suicide rates increase with age (e. g., suicide rate in men aged 15–24 years = 19.2 per 100,000; suicide rate in men aged 65–74 years = 41.5 per 100,000). Older people have the highest rates of suicide in most countries, but, in absolute numbers, young people are significantly more often dying from suicide than elderly people. Worldwide, 55% of suicides (N = about 900,000 deaths from suicide) are committed by people < 45 years. Last, the prevalence of a religion in a country determinates suicide rates. Atheist countries show significantly higher suicide rates than religious countries (e. g., the total suicide rate in China is 25.6, whereas the total suicide rate in Italy is around 10 per 100,000 population).

Alcohol consumption in a population and/or in special age groups (e. g. in teenagers) is another important public mental health indicator. Use of alcohol is common in European countries, particularly in the Czech Republic, Denmark, Ireland, Malta, and the United Kingdom. The proportion of alcohol consuming students, for example, in central and eastern Europe (i. e., Lithuania, Poland, Slovenia, and Slovakia) did clearly increase in the last decades. Drinking by Norwegian teenagers did also increase. The highest frequency of alcohol consumption was reported for Denmark, where 59% of the respondents reported drinking alcohol on at least 40 occasions. Students in Denmark reported highest rates of drunkenness, followed by teenagers in Finland, Ireland, and the United Kingdom, with nearly one in four teenagers indicating that they had been drunk at least 20 times. Boys reported much more frequently that they had been drunk than girls. Binge drinking (defined as having five or more alcoholic drinks) was most common in Luxembourg, the Czech Republic, Ireland, Germany, and Croatia. There is a tendency found that teenagers follow adult drinking patterns with greater overall alcohol consumption in southern Europe (e. g., Spain, Italy, France), but more binge drinking in northern Europe. Table 6 shows the alcohol consump-

Public Mental Health, Table 6 Pure alcohol consumption (100%) in liters per capita in Europe, age 15+

tion in selected European countries. The majority of nations who were high consumer between 1970 and 1980 (e. g. France, Spain, Italy), showed a progressively decreased consumption until 2003, with the exception of Luxembourg. On the other hand most of the "low consumer" nations in 1970 (e. g. Finland, Norway) showed a progressive increase until 2003, with the exception of Sweden (decreasing trend). Ireland and Finland had the highest increase in alcohol consumption (1980–2003).

The rate of alcohol-related deaths is an important macro indicator as well. Finland (139.0 alcohol-related deaths per 100,000 inhabitants), France (132.2), Germany (97.1) and Ireland (88.5) showed the highest rates in alcohol-related deaths in 2000. Other (macro) mental health indicators are, for example, the rate of psychiatric hospital beds per 100,000 inhabitants, the incidence and prevalence of mental disorders, the number of mental patients staying in hospitals, the number of cigarettes consumed per person per year, and the incidence of alcohol psychosis (for more information s. European health for all database: http://data.euro.who.int/hfadb/).

Evidence Based Practice and Continuity of Care in Mental Illness

According to Sackett et al. (1996), evidence based medicine is the conscientious, explicit, and judicious use of the current best evidence in making decisions about the care of individual patients. For questions about medical therapy, the best source of evidence is the randomized controlled trial (RCT), which provides experimental findings as does no other study design. However, while the placebo effect in somatic diseases is about 30%, it varies in depressive disorders in randomized controlled trials between 30–50%. An analysis of 75 double-blind trials in major depressive disorder (published 1981–2000) showed a substantial response to placebo (average: 30%, range 12 to 52%, Walsh et al. 2002). Evidence based mental health adheres to the same principles as evidence based medicine (EBM). However, it is almost impossible to define what the best evidence of mental health practice is. In contrast to somatic diseases, as for example an appendicitis, no health care professional can predict, how long a depressed patient, even with evidence based treatment, will suffer from his actual depressive episode. There is still too little knowledge about how specific treatments affect specific mental disorders. Particularly assuming that a mental disorders diagnosis is specific and, therefore, needs a specific treatment, is nearly impossible on the ground that comorbidities are the rule and conditions overlap. Persons with mental disorders need a variety of treatments and treatment settings, depending on their illness and the phase of their illness. In the beginning of mental disorders, a valid diagnosis of a health care professional and, better, mental health care professional, respectively, is most relevant. Despite widespread initiatives to improve the management of mental disorders (e. g., depression) in primary care, it appears that the links between primary care and mental health care management, as well as the use of evidence based approaches to managing patients are rare and ineffective. During increased symptomatology (e. g. during first manifestation of a psychotic disorder or other acuteness of mental illness) patients may need the structure and also enhanced protection of a hospital (e. g., due to possible dangerousness to others or self). The continuity of care is for people with serious and persistent mental illness (e. g. schizophrenia) of particular importance, because their illnesses usually show many different stages. Giving continuity of care is one step in the process of implementing managed care strategies. The implementation of managed care can control costs but also correct traditional delivery system problems, such as inappropriate matching to level of care, barriers to receiving care, as well as poor quality of care. About one third of individuals with schizophrenias is chronically ill. During better times they may be able to live with their families and even to work without support. Family work is an integral part of care for those patients. Mentally ill persons and their families are confronted with many emotional and socioeconomic challenges and some specific economic and social costs. Those costs are, for example, lost production from premature deaths caused by suicide or from inability to work or from family members caring for the mentally ill person. Thus families caring for a mentally ill person have higher direct and indirect financial costs. Moreover, often they may show diminished quality of life and a high emotional burden. All individuals with mental disorders but especially those with serious and persistent mental illness need a continuum of care that includes, psychosocial rehabilitation, (hospital) day treatment, crisis intervention, psy-

cho-educational approaches, the assistance of a case manager and/or a legal guardian and others. Not only during different stages of mental illness but also in different stages of life, a continuum of care is of high importance, (e. g. for adolescents during transitioning into adulthood). Severely and persistently mentally ill persons (► social psychiatry) have been a target population for public mental health services. The level of severity is a major determinant of treatment utilization and cost. The main goal of psychiatric reform in the late 1970's has been closure of large asylums and a shift of service provision towards community settings. Without doubt, deinstitutionalization has been a revolutionary success story but the classical paradigm of social psychiatry postulating that dehospitalization automatically generates social integration has proven to be wrong. Large psychiatric institutions (e. g. state hospitals) had also fulfilled essential functions beyond treatment for people suffering from severe mental illness. For many of those patients, asylums were "places where one is safe and secure". A comprehensive network of community services should result in declining rates of psychiatric admission (including compulsory admission) and in reduction of cost. Implementing services that support recovery mainly outside of hospital settings are innovations of the managed care system, for example, diversions of psychiatric hospitalization, hospital day treatment, outreach and prevention services, special services addressing the unique needs of children, adolescents, and their families. But despite such successful implemented services, there will probably always be a need for some "asylum" placements, particularly for people with serious and persistent mental illness. The Substance Abuse and Mental Health Services Administration (SAMHSA) and its Center for Mental Health Services (CMHS) have determined that there are six evidence-based practices in community mental health that are proven effective. These are: 1) Programs for illness magement and recovery (e. g., learning facts about the stress-vulnerability model, reducing relapses, coping with stress), 2) programs for assertive community treatment (i. e., helping people stay out of the hospital and to develop skills for living in the community), 3) family psychoeducation (i. e., involves a partnership among consumers, families and supporters, and practitioners), 4) supported employment (i. e. a well-defined approach to helping people with mental illnesses find and keep competitive employment within their communities), 5) skills development (in managing aspects of mental illness), 6) integrated treatment for people with co-occurring mental illness and substance use disorders (for details s. http://www.mentalhealth.samhsa.gov/cmhs).

Independently of the patient's age, the treatment of an existing mental disorder is both secondary prevention of the existing mental disorder (e. g. relapse) and primary prevention of another new mental disorder (e. g. an existing major depression increases the risk for comorbidity of anxiety disorders). As most mental disorders develop in adolescence and early adulthood, prevention must start as soon as possible. Children and adolescents (► mental health in children and adolescents) should be a special target population for prevention programs. If childhood problems were not sufficiently well addressed, affected children will not be able to benefit fully from the education available. Programs that enhance the quality of the relation between psychosocial and cognitive development of infants on the one hand and their interaction with their parents, on the other hand, can improve substantially the emotional, social, cognitive and physical development of children. Particularly in children, *systems of care* are important (i. e. mental health, education, child welfare, juvenile justice, and other agencies work together to ensure that children and adolescents with mental, emotional, and behavioral problems and their families have access to the services and supports they need to succeed). Schools are a crucial social institution for the education of children in preparation for life and they need to be more involved in a broader educational role fostering healthy social and emotional development of pupils. There seems to be a large gap between the mental health needs of youth and effective programs to meet those needs. All young people experience challenges (e. g., leaving home, starting to work, studying, having children) that might cause a higher vulnerability and risk for mental disorders. Due to those challenges young people do not typically identify mental health as a high priority. Youth unemployment is another significant issue. In this area, mental health promotion strategies seek to improve employment opportunities, for example, through programs to create jobs, provide vocational training, and social and job seeking skills. As mentioned before, mental health interventions are more effective, the earlier they start. However, broad based approaches that address problems

before they begin are very expensive. Hence, most prevention programs are secondary interventions (i. e., targeting "at risk" people) or tertiary care (i. e., assessing and treating people with more serious mental problems). Many treatment programs for young people are geared to children and adolescents with a pattern of problem behavior as a result of longstanding emotional disturbance. It should be a goal to change the start of health promotion programs towards an earlier time.

Summary

As it could be shown, the promotion of mental health and the prevention of psychological disorders is of great importance for various reasons. Mental health programs have and should have, respectively, several objectives:

- Collection of good quality data on mental health (e. g. studies on the prevalence of mental disorders and of therapy, and studies that allow the derivation of mental disorder specific criterias of diagnostical and treatment options). Although in Europe a diversity of national prevalence studies exists (i. e., studies in single countries or regions), a direct comparison of data and estimating of European prevalence rates is still difficult (e. g. due to different methods or different approaches). The underlying samples of nationwide representative examinations should be so large that the heterogeneity of the population with respect to its life situation and probable mental health problems is sufficiently represented. There is, moreover, a strong need for epidemiologic studies in children and adolescents as well as for studies in older adults (► mental health in older adults). Research efforts should aim mainly Europe-wide representative examinations carried out at regular intervals (e. g., every 10 years). Finally, descriptive studies are missing informing about recognition and treatment of mental disorders in the various European health care systems.
- Reduction of inequities within the European Union (e. g. between new memberstates and old memberstates).
- Assessment of needs for development of the mental health care system of Eastern Europe.
- Supporting of evidenced based mental health (although it is more difficult to define what evidenced based means than in somatic diseases) and giving persons suffering from mental illness access to treatment (it seems impossible to deliver care to everybody but the implementation of diagnostic and treatment algorithms could help to find the best therapy for each patient).
- ► Promotion of mental health and prevention of mental illness (both promotion and prevention should start as soon as possible, i. e. in children and adolescents and in persons at risk, respectively, and continue during the whole life span).
- Integration of persons with mental illness, especially those with persistent and severe mental illness, into society.

Public-Private Partnership

Synonyms

PPP

Definition

The term public-private partnership stands for a focused and circumscribed type of contractual relationship between a public institution (e. g., government, administration agency) and a private organization. Public-private partnerships are entered into with respect to the realization of a particular project or the supply of particular services. Services subject to public-private partnerships include public health services vis-à-vis the population.

A variation of privatization in which elements of a service (usually run solely by the public sector) are provided through a partnership between the government and one or more private sector companies. Usually entered into via a long-term contract, the private sector typically provides the infrastructure for delivery of a particular governmental service. But, the government remains at least partial responsibility for the delivery of the service.

Public Stigma

Definition

Public stigma is the reaction of the general population for example towards people with mental illness. Three different public stigma components can be distinguished: ► prejudice, ► discrimination, and ► stereotypes.

Pulp

Definition

The inner structure of a tooth is the pulp, formed by connective tissue containing nerves and blood vessels. The pulp is subdivided into a coronal and root pulp.

Purchasing Power Parity

Synonyms

Currency conversion rates

Definition

The term Purchasing Power Parity refers to currency conversion rates that convert to a common currency – mostly US$ – and equalize the purchasing power of different currencies. In other words, they eliminate the differences in price levels between countries in the process of conversion.

Purification

Synonyms

Self-cleaning of the soil

Definition

Purification is the process of cleaning the soil of foreign elements or pollutants, i. e. to render the soil back

to a pure state. Self-cleaning of the soil is influenced by characteristics like mechanical structure, physical and chemical characteristics of the soil, and type and quantity of microflora, flora and fauna. The most important factor is the main constituent of waste substratum in the soil. Natural-borne ground microbes and saprophytes perform decomposition of proteins to nitrogen and simple compounds. Some plants, in symbiosis with bacteria, can fix nitrogen compounds into glutamate. Decomposition of large quantities of cellulotic and other carbohydrate biomass is influenced by cellulolitic bacteria and fungi. In the case of low oxygen concentration, decomposition is directed into humification, and if oxygen is lacking, putrefaction caused by anaerobic bacteria occurs. If such is the case, malodorous gas is released.

Purifying Selection

► Negative Selection

p Value

Synonyms

Significance probability

Definition

The p value gives the probability that the null hypothesis is correct; therefore, if it is a small value (like < 0.05), the null hypothesis is rejected. More technically, it is the probability that the observed data or more extreme outcome would have occurred by chance, i. e., departure from the null hypothesis when the null hypothesis is true. However small, a p value does not indicate the size of an effect. A p value > 0.05 does not necessarily mean lack of association. It does so only if there is enough power to detect an association. Most statistical insignificance is due to lack of power to detect an association (poor experimental design).

Qualitative Overview

Synonyms

Narrative synthesis

Definition

A qualitative overview is research that concentrates on the investigation of definitions, concepts, and issues, often performed through interview unrestricted by structure, and reported in terms of words or descriptions. Key elements of the qualitative approach for assessing ► effectiveness include consideration of the following characteristics: people who were part of the study intervention delivered, setting where the technology was applied, and other modifying factors such as personal skills, environmental factors that may influence compliance, nature of the outcome measures used, their relative importance and robustness, and their comparability. It should include the total number of research reports, studies, and independent samples that contributed to tests of comparison or relationships (descriptive statistics). Effect size estimates should be calculated if the studies contained the necessary data, but the effect sizes should not be combined statistically.

Qualitative Research

Definition

Qualitative research involves exploratory studies (to explore an unknown sector, identify the main dimensions of a problem, draw assumptions, or understand motivations) or operational studies based on in-depth analysis of interviewee responses (in a group or individually), typically in "focus groups". It most often deals with a restricted sample of individuals that does not necessarily need to be representative. It may be the preliminary phase of a quantitative study or stand-alone research.

Quality

Definition

Quality refers to the inherent or distinctive characteristics or properties of a person, object, process or other thing. Such characteristics or properties may set a person or thing apart from other persons or things, or may denote some degree of achievement or excellence.

Quality-Adjusted Life Years (QALY)

Definition

In cost-utility analyses in the field of health economics, a recurring problem is to find an appropriate way of expressing and quantifying the health-related effects of medical interventions. The QALY concept was developed in health economics as an important standard measure for describing the outcome of medical interventions in a manner allowing comparability. QALYs, or "quality-adjusted life years", basically constitute a pragmatic approach to description of the health-related effects of medical interventions and assessment of the efficacy of a given therapy, in terms both of quality (improvement of the patient's quality of life) and of quantity (prolongation of life). Both effects are combined in QALYs, life expectancy being weighted by a factor q, a standardized quality index in which 1 represents perfect health and 0 death. The QALY concept also permits comparison of different interventions:

QALY tables set out the comparative cost of various interventions per incremental QALY thereby obtained. Quality-adjusted life years (QALY) are ► outcome measures of cost-utility analysis (► value, human life – utilities). QALYs are constructed by estimating the remaining lifetime weighted according to a health-related quality of life score. Thus, a defined time period spent with a higher quality of life represents more QALYs gained compared with the same period spent with a low quality of life. The QALY is seen as a measure that represents the outcome from a patient's perspective. The QALY construct makes it possible to compare health care interventions that mainly affect survival with interventions that improve the health-related quality of life.

Quality Assurance

Definition

► Quality assurance (QA) is defined as part of ► quality management that is directed to assure demands on reaching quality. QA covers all activities from design, development, production, installation, servicing to documentation. It introduced the saying "fit for purpose and do it right the first time." It includes the regulation of the quality of raw materials, assemblies, products and components; services related to production; and management, production, and inspection processes. The term of quality assurance is an important term and is used for comparing the reality (instantaneous value) and the must have value of a measurement.

Quality of Care

Synonyms

Health care quality

Definition

There are several definitions for quality of care. One of the most cited definitions was formulated by the Institute of Medicine in the 1990s. It defines quality of care as "The degree to which health services for individuals and populations increase the likelihood of desired health outcomes and are consistent with current professional knowledge". Unlike other definitions, this definition includes both the technical perspectives of quality and the individual perspective of the patient, by referring to the desired outcome. Quality of care is often categorized into the three dimensions structure, process, and outcome. The structural elements refer to the quality of the facilities and the environment where the health care services are delivered (e. g. buildings, equipment, and skill level of health care professionals). The process quality refers to the correctness and appropriateness of the treatment that is provided. The overarching dimension is the quality of the health care outcomes like improvement of health, patient satisfaction, and reduced pain. The quality of health outcome can be operationalized by calculating and comparing complication rates, mortality rates, or readmission rates, for example.

Quality of Health Indicators

Definition

Quality of health indicators are measured by several criteria: validity, objectivity, sensitivity, specificity, relevance for health policy, and cost-effectiveness, etc. In order to achieve this, an ► indicator must be simple and understandable, data needed for each indicator must be easily obtainable through routine health services, and data collection and processing must follow ethical principles.

Quality of Life

Synonyms

Health-related quality of life (HRQOL); HRQL

Definition

Although the term quality of life is widely used in the public health context, there is still no commonly accepted definition. In the research and clinical area, quality of life often stands for anything except death and mortality rates. Others see quality of life as an overarching concept that covers all aspects of a person's life, which includes, amongst others, physical health, psychological well-being, social well-being, financial well-being, family relationships, friendships, work, and

leisure. Other approaches focus on the social and psychological aspects of quality of life and contrast it with ► quality of care. The quality of life that is supposed to be affected by health care intervention is often defined as health-related quality of life. Quality of life can be interpreted as the ultimate marker of success for both preventive measures and health care delivery. The impact on quality of life is often taken into consideration when discussing different treatment choices. This is especially relevant for the terminally ill, where quality of life can be used to weigh the benefits and costs of life-extending measures. In the context of deciding about the relative value of health expenditures, the concept of quality-adjusted life years (QALY) is often applied. It estimates the effect of an intervention on prolonging life and the quality of that prolonged life. It is used in cost-utility analyses to calculate the ratio of cost to QALYs saved for a particular health care intervention, which is then utilized to allocate healthcare resources accordingly.

Quality-of-Life Studies

Definition

Quality of life is an area of study that has attracted an ever-increasing amount of interest over the past two decades, particularly in the areas of health, rehabilitation, disability studies, and social services, but also in medicine, education, and others. The study of quality of life is an examination of influences upon the satisfaction and meaning in life, as well as people's happiness and well-being. The ultimate goal of a quality-of-life study and its subsequent applications should be to enable people to live quality lives – lives that are both meaningful and enjoyable.

Quality Management

Definition

Quality management depicts all activities of a project's ► quality assurance policy which determines the aims, goals and responsibilities as well as the resources needed for planning of ► quality, quality assurance and improvement.

Quantification

► Evaluation Models
► Measurement
► Measurement: Accuracy and Precision, Reliability and Validity

Quantitative Research

Definition

Quantitative research studies aim to quantify attitudes or behaviors, measure variables on which they hinge, compare, and point out correlations. They are most often conducted via a survey on a sampling that must be representative so that the results can be extrapolated to the entire population studied. It requires the development of standardized and codifiable measurement instruments (i. e. structured questionnaires).

Quantitative Research Synthesis

Definition

Quantitative research synthesis is used in research which concentrates on describing and analyzing phenomen by using numerical data and empirical models. There are some statistical methods that can help synthesists summarize research results. This quantitative procedure is called meta-analysis. Among the techniques there are counting study outcomes, combining probabilities from inference tests, averaging ► effect sizes, and examining the variability in effect sizes across studies. Quantitative research synthesis is an extension of the same rules of inference required for rigorous data analysis in primary research. If primary researchers must specify quantitatively the relation of the data to their conclusions, the next users of data should be required to do the same. Before using quantitative synthesis, it is important to take a closer look at some of the unique features off accumulated research results.

Quarantine

Synonyms

Isolation of persons to prevent transmission of diseases

Definition

Quarantine in the public health context refers to the restriction of the activities of healthy individuals who have been exposed (or are thought to have been exposed) to a communicable disease. The restriction is for a specific period of time, till investigations or clinical signs/symptoms have clarified the infectiousness status of the individual.

Cross-References

► Outbreak Management and Surveillance of Infectious Diseases

Quarantine Diseases

Synonyms

Infections of quarantine; Infectious diseases requiring isolation

Definition

Quarantine is a measure of isolation that is performed in order to avoid the spread of an infectious disease. The term stems from the 14th century when travelers and merchants were isolated for a period of 40 days in order to avoid plague (Black Death) epidemics. Nowadays, quarantine is used to contain yellow fever, Ebola, plague and cholera. The duration of isolation is adapted to modern requirements and depends on the incubation periods of the different pathogens.

Cross-References

► Outbreak Management and Surveillance of Infectious Diseases

Questionnaire

Definition

A questionnaire is considered to be the written document used to obtain information from respondents. It consists of a predetermined set of questions used to collect data (clinical data, social status, etc.). There are two main types of questionnaires: structured (closed-ended, standardized, formal) and unstructured (unstandardized, informal). Closed-ended questions will refer to those in which all possible answers to a given question are listed on the questionnaire, whereas the term open-ended will apply to questions in which the possible answers are not listed in advance. The three common ways of obtaining information are: by sending a questionnaire by mail to individual to fill out and return, by having an interview by phone or in person. Sometimes combinations of these methods are used.

Quetelet Index

► Body Mass Index (BMI)

Quinine (Quinora®, Quinerva®, QM-260®)

Definition

Quinine, which is the oldest anti-malaria drug, is an alkaloid of the bark of the South American cinchona tree. Its effect results from the impairment of metabolic processes in plasmodia. Quinine is used for the treatment of infections with *Plasmodium falciparum*, in complicated cases it is combined with doxycycline or clindamycin. Treatment is performed for 7 days and can also be carried out throughout pregnancy. Side effects involve the central nervous system (tinnitus, visual defects, headache, cerebral seizures) or the gastrointestinal tract (nausea, vomiting). In cases of long-term and high-dosage therapy, a summation of side effects can occur, which is called ‘cinchonism’.

Rabies

► Acute Life-Threatening Infections

Rabies Immune Globulin

► Rabies Vaccination, Active
► Rabies Vaccination, Passive

Rabies Immune Prophylaxis

► Rabies Vaccination, Active
► Rabies Vaccination, Passive

Rabies Vaccination

Synonyms

Rabies immunization

Definition

The first rabies ► vaccine was introduced as early as 1885 by Louis Pasteur. Since 1967, a vaccine produced from human diploids has been available. The rabies vaccination containing a vaccine made from dead viruses is suitable for persons who are at high risk for infection due to their profession or due to traveling. The vaccine is well tolerated, and is given on days 0, 7 and 28, producing almost 100% protection. The first booster is given one year later, followed by further boosters every 2–5 years.

Rabies Vaccination, Active

Synonyms

Rabies immunization, active

Cross-References

► Immunization, Active

Rabies Vaccination, Passive

Synonyms

Application of rabies immune globulin; Rabies immune prophylaxis

Definition

The application of rabies-immune globulin is performed as a prophylactic passive vaccination after a contact with an animal which is suspected of being infected with rabies or which suffers from rabies. In this regard, contact is not only defined as a bite, but also as a touching of the animal or a licking by the animal.

Cross-References

► Immunization, Passive

Race

Synonyms

Subspecies

Definition

Race is socially defined population based on visible, genetically transmitted physical characteristics. People who belong to a race are distinguished in some way from other humans. The most widely observed races are those based on skin color, facial features, ancestry, and genetics. Conceptions of race, as well as specific racial groupings, are often controversial due to their impact on social identity hence identity politics.

Radiation

ZORAN MARMUT
Institute of Hygiene and Medical Ecology, Faculty of Medicine, University of Belgrade, Belgrade, Serbia
zmarmut@eunet.yu

Definition

Radiation is the transmission of energy through space, both in the form of waves (electromagnetic radiation, EMR) and in the form of streams of atomic particles (particulate radiation). Each of the several kinds of EMR spectrum is characterized by its own wavelength or frequency. Gamma rays have the shortest wavelength followed by, in increasing order, X-rays, ultraviolet radiation, visible light, infrared radiation, ► microwaves, and radio waves. Some of the forms of particulate radiation are alpha particles, protons, neutrons, and electrons (e^-, β^-, β^+). A narrow meaning of the term radiation is the transmission of energy by waves.

Basic Characteristics

The whole electromagnetic spectrum (EMR and particulate radiation altogether) is divided into two major regions—ionizing and nonionizing, according to wavelength and energy potential. Ionization means disruption of a molecule or atom's structure by removing one or more electrons. Ionizing radiation is more potent, with greater energetic potential, and higher frequencies, but shorter wavelengths than nonionizing radiation. Nonionizing radiation is more benign—of lower and insufficient ionizing potential.

Ionizing Radiation

Ionizing radiation has wavelengths shorter than 100 nanometers (nm; $1\,\text{nm} = 10^{-9}\,\text{m}$), with energies sufficient to produce ionization in matter (both nonliving and living).

Natural radioactivity on Earth may be of cosmic origin (protons and alpha particles from outer space or the Sun), originate in the atmosphere under the influence of cosmic radiation, or, finally, from Earth's crust; these are decay products of uranium and thorium, a trace constituents of some types of rocks and soils. During its natural decay, beside solid radioactive pollutants, ► radon gas is released. Artificial sources of ionizing radiation included detonations of nuclear devices until they were banned. Recent sources include accidents in nuclear power generating plants, uncontrolled release of energy by spent-fuel reprocessing plants, radioactive material from waste sites, some industrial and mining operations, and diagnostic and therapeutic procedures in nuclear medicine and radiology.

Ionizing radiation can produce extremely harmful effects in humans. Acute somatic effects occur within a few weeks of irradiation as *acute radiation syndrome*. The form of syndrome manifestation depends both on the route of contamination (external or internal) and on the contaminated body area. During the intrauterine embryonic period, developmental (teratogenetic) effects are possible. In *chronic radiation syndrome* in adults, genetic mutations and chromosomal aberrations are described after several years of exposure. Late somatic effects also occur in the form of various forms of cancer. According to the International Agency for Research on Cancer, all forms of ionizing radiation (neutrons, alpha and beta particles-emitting radionuclides, gamma radiation, and X-rays), are ranked as group 1 human carcinogens.

Nonionizing Radiation

Nonionizing radiation has wavelengths longer than 100 nm. It is further subdivided into ultraviolet radiation (A), visible light (B), infrared radiation (C), microwaves, and radiofrequencies. The final outcome of this radiation may be quite negligible, beneficial, healthful, or even harmful in different degrees.

A) Ultraviolet Radiation (UVR) Ultraviolet radiation is nonionizing and invisible EMR with wavelengths from 10 to 400 nm. It has longer wavelengths than the ionizing radiation spectrum, but shorter wavelengths than visible light. The borderline between the

two main EMR regions is not clear, therefore the shortest wavelengths of nonionizing UVR (< 100 nm) may produce ionization of matter.

According to main biological effects, the whole UV spectrum is further subdivided into three regions:

- UVA—between 400 and 320 nm (longwave or near ultraviolet radiation),
- UVB—between 320 and 280 nm (middle or sunburn ultraviolet radiation), this is the most biologically damaging UVR to the skin and eye,
- UVC—between 280 and 100 nm (shortwave, far, or germicidal UVR), this is only present from artificial sources on Earth.

UVR may be produced when a body is heated over 2500 K (incandescence) or when electrons are excited (gas discharge). As a large incandescent body, the Sun is the main natural source of UVR. Of the total solar energy on Earth's surface, only 5% falls into the ultraviolet region. There is no solar UVR below 290 nm on Earth because of its high absorption by the ozone layer in the ► stratosphere. Artificial sources of UVR have been used in industry (arc welding), science, medicine (therapy of some skin diseases, or germicidal lamps effective in killing microbes in air), cosmetic enterprises (special sun-tanning lamps), and even in everyday surroundings, like unshielded tungsten-halogen lamps used for lighting.

The Sun is the main source of human exposure to UVR. All outdoor workers are greatly exposed, but other population groups (mostly tourists) are also affected during prolonged unprotected exposure to sunlight. The amount of UVR depends on solar angle, altitude, air pollution, stratospheric ozone, cloudiness, and reflection from surfaces. The amount of UVR is expressed by the ► UV Index. One of the main beneficial health effects of UVR is vitamin D_3 synthesis in skin. However, in general population groups, prolonged exposure to UVR sources results in increased incidence of various cutaneous damages (e. g. erythema, sunburns, solar keratosis, premature skin aging, and malignancies), ocular impairments (photokeratitis, photoconjunctivitis, and possibly cataract formation), and changes in human immune system defense.

B) Light (Visible Light) Light is a form of nonionizing radiation with wavelengths in the range between 400 and 780 nm, and is the only visible part of the whole EMR spectrum. Light can be detected by highly differentiated retinal cells, rods and cones. Through the process of vision, the human eye receives about 80% of all sensations from outside space, e. g. concerning the size and shape of objects, movement, color, illumination and luminance. A certain quantity of light is always necessary because without light, we cannot see, but quality of light is also essential. To prevent deficiencies, both in daylight and artificial ► lighting, collaboration between architects, engineers, lighting designers, and occupational hygienists is needed from the beginning of interior space projects.

Sources of light are both natural and artificial. The greatest natural source of light on Earth is the Sun. The two main ways for producing light by artificial sources are incandescence (heating of solids above 1000 K), and electrical discharge in some gases or vapors. Both of these are based on conversion of electric energy into light. Visible light is the only desired component of artificial lighting sources output, though it is not possible that for this to be the only output obtained. Much of the energy input is dissipated as thermal radiation, by conduction or convection, and a small amount as UVR. A ► laser is a device that produces coherent EMR in any part of the UVR or infrared region, or visible light spectra.

C) Infrared Radiation Infrared radiation (IR) is nonionizing and invisible EMR with wavelengths in the range between 780 nm and 1 mm. The IR radiation spectrum is located between visible light and microwaves. Synonyms for IR are thermal radiation and radiant heat. Due to different biological effects, the IR spectral band is further subdivided into three regions:

- IRA—between 780 and 1400 nm (near or shortwave IR),
- IRB—between 1400 nm and 3 μm (middle IR),
- IRC—between 3 μm and 1 mm (far or longwave IR).

Infrared radiation is emitted from any warm object. There are natural and artificial sources of IR, and the Sun is the main natural source. Occupationally exposed individuals are outdoor workers, e. g. farmers, construction workers, seafarers, fishermen, and fire-fighters. Non-occupationally exposed people are general population groups that stay unprotected under sunlight for prolonged periods.

In industry, artificial sources include objects or technical processes of thermal curing of various materials, e. g. in smelteries, foundries, steel mills and oth-

er heavy industrial plants, and in glass factories. The general population is slightly exposed to IR from radiant heating devices in homes, or from incandescent lighting sources (tungsten filament or halogen lamps). In hospitals, IR lamps are used for heat treatment in physical medicine and pediatric departments (incubators).

Two main properties of IR are important for health considerations. First, the low penetration ability of IR means that surface tissues such as skin and eyes are endangered. Second, the thermal mechanism of its interaction means that heating of the affected tissues is the main consequence. Adverse health effects may be ocular lens opacities and cataract formation during chronic exposure and burns of the skin during acute irradiation. If the unprotected head is exposed, even sunstroke is possible. IR is also a contributing factor of other general adverse health effects like misbalance of thermoregulation and heat stroke.

Radiation Oncology

Synonyms

Radiation therapy; Radiotherapy

Definition

Radiation oncology is concerned with the use of high-energy rays to damage cancer cells and stop them from growing and dividing. It is usually a local treatment targeted at the cancer cells in the affected area. The ► side effects of radiation therapy depend on the dose of treatment and part of the body treated, and might include tiredness, skin reactions, loss of appetite, decrease in white blood cells, and inflammation of tissues and organs in and around the body site irradiated.

Radiation Therapy

► Radiation Oncology

Radioactive Wastes

Definition

Radioactive wastes contain radioactive chemical elements that have no practical purpose. They are normally classified as low-level, medium-level or high-level wastes, according to the amount and types of radioactivity in them. Low-level waste (LLW) includes radioactively contaminated protective clothing, tools, filters, rags, medical tubes, and many other items. High-level waste (HLW) is "irradiated" or used nuclear reactor fuel. Uranium mill tailings are the residues remaining after the processing of natural ore to extract uranium and thorium. The approvals required for disposal of radioactive wastes are granted by regulatory authorities and/or other government agencies in individual countries. There are currently a number of organizations around the world which operate licensed disposal facilities for radioactive wastes. Waste characterization (WC) is the determination of the physical, chemical and radiological properties of the waste to establish the need for further adjustment, treatment, conditioning, or its suitability for further handling, processing, storage or disposal. "Health physics" is

the science of radiation protection – protecting people from exposure to radiation, monitoring the effects of any exposures, and recording any radiation dose received by the person.

Radiology

Definition

Radiology is the field of medicine that is concerned with the use of ionizing and non-ionizing radiation for the diagnosis and treatment of disease. The historic methods, which are still frequently used, are X-rays for diagnosis of disease and X-rays and gamma rays for the treatment of disease, both based on the use of ionizing radiation. Radiology furthermore comprises the use of isotopes and non-ionizing radiation like ultrasound waves and nuclear resonance imaging (MRI).

Radiotherapy

► Radiation Oncology

Radon

Definition

Radon (chemical symbol Rn, ^{222}Rn) is a chemically nonreactive noble gas, and a radioactive chemical element with an atomic number of 86 (in the periodic table) and an atomic weight of 222. It is one of the products of spontaneous uranium decomposition (^{238}U), and directly issues from radium alpha decay (the name radon is from radium, ^{226}Ra). Uranium is a natural trace constituent of some types of rocks and soils in the Earth's crust. Like radium, radon is also an alpha particle emitter, and has a half-life of 3.85 days. Humans are exposed to radon and its decay products, called radon daughters, either professionally in underground mines, or unprofessionally from the ground under and around buildings, from ground water, or from some building construction materials. From the ground, radon gas diffuses through cracks or holes and beside pipes, easily penetrating basements, ground floors, and other spaces of buildings; with penetration facilitated by low pressure. Good isolation and poor ventilation of indoor spaces prevent radon gas from leaving those interiors, and it can easily be inhaled. In such cases, irradiation of surrounding tissues can occur, with possible harmful consequences like lung cancer. Smokers are more susceptible than are non-smokers. Although radon is carcinogenic to humans (group 1, according to IARC—International Agency for Research on Cancer), a higher incidence of lung cancer has only been observed in uranium miners.

Random

Definition

Something that is random is unpredictable and governed by chance. The opposite of random is determined. The chief importance of randomness in research is that by using it to select or assign subjects, researchers increase the probability that their conclusions will be valid. Random numbers are used to select random samples or assign subjects randomly. Random assignment increases internal validity. Random sampling increases external validity.

Randomization

Synonyms

On chance distribution

Definition

Randomization is a technique of assigning patients to treatment and control groups in ► experimental studies that is based only on chance distribution. It is used to diminish confounding in clinical trials. Proper randomization of patients is an indifferent yet objective technique that tends to neutralize patient prognostic factors

by spreading them evenly among treatment and control groups. Randomized assignment is often based on computer-generated tables of random numbers.
Randomization is the process of making something random. In biostatistical theory of design of experiments, it is a core principle that involves random allocation of the experimental units across the treatment groups. Thus, if the experiment compares a new drug against a standard drug used as a control, the patients should be allocated to new drug or control by a random process. This ensures that the different treatment groups are statistically equivalent, i. e. such that there should be no foreseeable possibility of any systematic relationship between the data and any measurable characteristic of the procedure by which the data was sampled. In generating the randomization sequences the questions of balance, selection bias and accidental bias should be considered. The randomization can be complete or restricted, algorithmic or non-algorithmic.

Cross-References

► Experimental Studies

Randomized Clinical Trials

Synonyms

Clinical studies

Definition

In a Randomized Clinical Trial (RCT), a group of patients is randomized into an experimental group and a control group. These groups are followed up for the variables or outcomes of interest. A RCT is, after ► meta-analysis, the highest form of evidence. Advantages are the unbiased distribution of confounders and the randomization, which facilitates statistical analysis. Disadvantages are the time, expense, and ethical problems in indications with an established therapy standard different from placebo.

Randomized Controlled Trials

Synonyms

Controlled studies

Definition

Study design comparing outcomes in intervention and control group. Participants are randomized to either intervention or control group in order to minimize selection effects.

Randomized Experimental Trial

► Experimental Studies

Random Variation

Definition

Variability of a process caused by many irregular (and individually unimportant) fluctuations or chnace factors that (in practical terms) cannot be anticipated, detected, identified, or eliminated. As such, random variation represents the sum of many small variations, arising from real but small sauses that are inherent in — and part of — a process, which cannot be tracked back to a root cause. Random variation follows the laws of propability — behaves statistically as a random propability function. Also, the tendency for the estimated magnitude of a parameter (e. g. based upon the average of a sample of observations of a treatment effect) to deviate randomly from the true magnitude of that parameter.

Rapid Disaster-Response

Definition

Activities in rapid disaster-response are designed to minimize loss of life, to organize the temporary removal of people and property from a threatened location and

facilitate timely and effective rescue, ► relief and rehabilitation. Disaster-response is the sum of decisions and actions taken during and after ► disaster, including immediate relief, rehabilitation and ► reconstruction after the issuance of a state of emergency upon the occurrence of a large-scale calamity in order to activate measures aimed at the reduction of the disaster's impact.

Rate

Definition

A measure of a part with respect to a whole. Epidemiological rates can be broken into three general categories: crude rates, specific rates, and adjusted rates. A rate measures the probability of occurrence of some particular event. A rate is expressed as: $x \times k/y$

x = Number of times an event has occurred during a specific interval of time.

y = Number of persons exposed to the risk of the event during the same interval.

k = 100; 1000; 10.000; 100.000; etc.

Rating

► Measurement

► Measurement: Accuracy and Precision, Reliability and Validity

Ratio

Definition

A ratio shows the relative magnitude of one quantity to another, obtained by dividing one quantity by the other. This can be expressed by formula a/b, where a is the numerator and b is the denominator. A ratio is dimensionless if these two quantities have the same unit, otherwise the ratio has dimension. In the mathematical meaning of the word, ratio is equivalent to quotient a/b, i. e. to division of numbers a (dividend) and b (divisor). If this expression is left unevaluated, it is called a fraction.

Examples of ratios include ► odds-ratio and ► risk ratio. A specific type of ratio is ► proportion, in which the numerator is part of the denominator, and with restricted values between 0.0 and 1.0. Proportion is equivalent to a proper fraction. ► Rate is a type of ratio, in which the numerator is represented by the number of events, and the denominator by the population at risk.

Rationing

Definition

Rationing is the controlled distribution of scarce goods and services. In health care, the term rationing describes the process by which choices are made when the demand for health care exceeds the resources available. Rationing involves strategies to allocate scarce health care resources under budget constraints such as rationing by denial, selection or deterrence. The reason for rationing in health care is the continuous upward spiral of medical expenses in all health care systems (► cost containment).

Reading and/or Spelling Disorder

Synonyms

Specific developmental disorder of scholastic skills

Definition

The main feature is a specific and significant impairment in the development of reading and/or spelling that is not solely accounted for by mental age, visual acuity problems, or inadequate schooling. Reading comprehension skill, reading word recognition, oral reading skill, and performance of tasks requiring reading may all be affected. Spelling difficulties are frequently associated with specific reading disorder. During school age, emotional and behavioral problems are often associated with these disorders. The disorders often continue into adolescence.

Reasoned Action Theory

Definition

The theory of reasoned action was first proposed by Ajzen and Fishbein (1980) to predict an individual's intention to engage in a behavior at a specific time and place. The theory was intended to explain virtually all behaviors over which people can exert self-control. Factors that influence behavioral choices are mediated through the variation of behavioral intent. In order to maximize the predictive ability of an intention to perform a specific behavior, it is critical that measures of the intent closely reflect the measures of the behavior, corresponding in terms of action, target, context and time. The predictive power of the model depends significantly on the identification of most or all of the salient outcomes associated with a given behavior for any particular target population.

Recombination

Synonyms

Crossing-over

Definition

Recombination is the biological process of the exchange of genetic information between homologous chromosomes, leading to genetic variability on the chromosomes transmitted from parents to offspring. Recombination or crossing-over results in the production of chromosomes some of whose alleles at multiple polymorphic sites differ from alleles at those same sites on the chromosome of the parent organism. Recombination occurs during prophase of the first round of meiotic cell division (prophase I), and occurs between duplicated homologous chromosomes. Recombination is one of two sources of genetic variation in offspring, the other being independent assortment. Independent assortment denotes the principle of transmission that, after recombination, either homologous chromosomes has an approximately equal probability of being transmitted or not transmitted (50–50%). Recombination and independent assortment are the reasons for why any two offspring of the same two parents share 50% of their genetic code on average. However, there are several constraints on the probability of transmitting a particular variant at random. One constraint is that, on any given chromosome, recombination is most likely to occur near the ends of the chromosomal arms, and least likely to occur near or at the centromere. Another constraint is that the probability of recombination between any two ► polymorphisms that are very close to one another on a chromosome is relatively low, and if as a result, these adjacent polymorphisms are frequently co-transmitted, it is said that they are 'linked' or in 'linkage disequilibrium' meaning that the probability of recombination between them is less than 50%.

[2] Potsdam Institute for Climate Impact Research, Potsdam, Germany
zkundze@man.poznan.pl, zbyszek@pik-potsdam.de

Synonyms

Back-to-normal

Definition

Strategies of re-establishing order, life support systems, and human livelihoods in the area affected by a disaster. The aim of the recovery phase is to restore such an area to its previous (or better) state, if feasible.

Basic Characteristics

Recovery strategies should make it possible to re-establish order and continuity gradually after a natural or technological disaster (► hazards, natural; ► hazards, technological), to build life support systems, and human livelihoods. Recovery efforts mean much more than just rebuilding houses – they are concerned with actions that involve rebuilding destroyed property, but also re-employment and the repair of other essential infrastructure.

After the 1755 Lisbon disaster, Marquis de Pombal led the recovery action based on three principal tasks, formulated as follows: to take care of survivors, to bury the dead, and to rebuild the city. In general, none of these tasks is easy in a post-disaster landscape.

► Disaster responses are focused on immediate needs – providing emergency medical help, food and drinking water, warmth, shelter, and further medical assistance (*cum* psychological help) to survivors. Normal health care systems would not be functioning, yet the needs can be very serious. In the case of the 2004 tsunami, it was necessary to rescue survivors and try to care for millions of homeless, increasingly threatened by disease amidst the rotting corpses. It was also necessary to treat specific syndromes such as ► acute stress disorder, depression, and other anxiety disorders. After the 2004 tsunami, it was not easy to bury the dead. There were not enough body bags to accommodate the many bodies. There were not enough coffins and those available were too small for the bloated bodies of foreigners.

The recovery phase starts when the immediate threat to human life has subsided, after the phase called ► disaster response. The recovery efforts are concerned with issues and decisions that must be made after immediate needs are addressed. In the disaster aftermath, a decision has to be made whether the strategy of retreat is feasible and acceptable. If endangered locations have been developed (people built in the floodplain), a remedy is that humans, and infrastructure, move out of harm's way. Citizens from the disaster-struck area are more likely to accept mitigative measures that might otherwise be unpopular (e. g. permanent relocation) when a recent disaster is in fresh memory. After the Great Midwest Flood of 1993, the US Interagency Floodplain Management Review Committee (IFMRC 1994; Galloway 1999) recommended that the administration fund acquisition of land and structures at risk from willing sellers in the floodplain. The number of families relocated from the vulnerable floodplain locations in the USA was of the order of 20,000 (Galloway 1999).

In some disaster sites, wrecked, roofless, derelict buildings and piles of unidentifiable wreckage are not leveled

to the ground level – they keep the memory of disaster alive. If destruction is beyond repair (or if repair is not recommended, as above), then evacuees permanently move away from the area and the area is abandoned. In history, cases of disappearing settlements after a disaster are well known, e. g. after the eruption of the Vesuvius Volcano, which destroyed Stabies, Herculanum, and Pompeii on 23 August 79.

When the decision of rebuilding settlements is made, masses of refuse, composed of remains of human property, have to be removed to landfills. The homeless family problem has to be addressed, e. g. by establishing a tent city (climate permitting), temporary container-based accommodation, or trailer housing. Services, such as electricity, gas, water, telephone; legal and medical services; sanitation; transportation; postal services; and day care have to be re-established. It is necessary to help the population recover their livelihood, e. g. via temporary employment (possibly related to disaster recovery work, hence the important role of job counseling), to secure money flow and financial support.

In the reconstruction, it is recommended that the location and construction material of the property be reconsidered. An important aspect of effective post-disaster recovery efforts is taking advantage of a unique opportunity to build better. After a disaster, the building codes are carefully examined and strengthened, new housing is monitored and inspected far more stringently, and developers are more accountable. This is unlike before the disaster, when many areas may have experienced rapid, unplanned growth. Disasters unveil that existing structures may not have met building codes (e. g., use of plastic straps attaching roofs to walls), with poor workmanship, use of cheap materials, and temporary fixes.

In some long-term disasters, confinement may last for several months (or years). In this situation, the recovery takes place inside the home. The issue is to have a supply of water and bulk foods and appropriate storage and preparation equipment, and then to construct a simple balanced diet, including vitamin pills, cereals, beans, milk powder, and fat (oil) plus vegetables, fruits, spices, and meats, both prepared and fresh-gardened, when possible.

In the disaster aftermath, when the shelters close, the tent cities fold, the media spotlights turn off, and high-ranking decision makers leave the disaster area to go back to their time-consuming routine duties, continuation of assistance to disaster survivors is less spectacular, but nevertheless badly needed. There may be little available housing for the displaced populations. Rents increase and landlords take advantage of a scarce market. For a long time, a large number of inhabitants may live in substandard, or even unsafe, housing. The economic recovery can last a long time, since many jobs will have been lost and many small businesses destroyed or relocated. Unemployment may remain a critical concern for years. There is also a need for long-term medical assistance, including mental health and health monitoring.

The solidarity and altruism of individuals and groups is crucial for recovery efforts. Ad-hoc aid organizations are formed that do home repair for the uninsured and provide legal or medical advice. Joint initiatives arise to deal with the overwhelming task of moving toward recovery and becoming better prepared for the possibility of another disaster.

Recruitment and Retention Schemes

Definition

Recruitment and retention schemes are systematic approaches of organizations to fill vacancies and to

keep personnel from leaving the organization. Such approaches may also apply to professional training schemes leading to graduation. Recruitment means to identify potential candidates and to convince selected persons to take up the job or training. Incentives offered to (future) personnel may be financial/material or non-material in nature. Examples include the improvement of physical working conditions, salary increases, facilitation of return after 'family breaks', policies for promotion, training opportunities, special conditions for insurance schemes, or support for housing and transport.

Recurrence Risk

Synonyms

Fix heritability recurrence risk

Definition

The term recurrence risk refers to the estimate of the probability that a relative (especially a child) will be affected by the same disorder as an affected individual. It describes the probability that a disease present in one family member will occur again in other family members in the same or following generations is known as recurrence risk. In general, for fixed heritability, the recurrence risk is approximately a linear function of prevalence when plotted on a logarithmic scale. In practice, it is necessary to offer some estimation of recurrence risk for counseling purposes even in the absence of any defined mechanism of inheritance.

Recurrent Depressive Disorder

Definition

A recurrent depressive disorder is characterized by repeated episodes of depression. The first ► depressive episode may occur at any age from childhood to old age, the onset may be either acute or insidious, and the duration varies from a few weeks to many months.

Recycling

Synonyms

Reusing

Definition

Recycling is a series of activities that include collecting recyclable materials that would otherwise be considered waste, sorting and processing recyclables into raw materials such as fibers, and manufacturing raw materials into new products. It is the act of processing used or abandoned materials for use in creating new products. For many years direct recycling by producers of surplus and defective materials constituted the main form of recycling. However, indirect recycling, the recycling of materials after their use by consumers, became the focus of activity in the 1990s. For some time, most waste has been deposited in ► landfills or dumps. Landfills are filling up, however, and disposal of wastes in them has led to environmental problems. A growing alternative to such disposal is recycling. The individual consumer plays a large part in recycling. Products that are recycled in large quantities include paper and paperboard, ferrous metals, aluminum and other nonferrous metals, glass, plastics, and yard wastes. Recycling is a key concept of modern ► waste management.

Reduction of Health Expenditure

Synonyms

Cost containment

Definition

Reduction of health expenditure implies a wide variety of strategies and measures to reduce overall health care expenditure, the growth rate of expenditure or certain costs of health care services. These measures include

for example enhanced government regulation of the prices of health care services through changes in the payment method of providers, co-payments, managed care programs, patient education, etc. The reason for the trend of cost containment in health care is the upward spiral of medical expenses in all health care systems due to medical progress and an improvement of technology, the expansion of coverage by public health systems and aging populations in the industrial world with higher levels of ► chronic diseases and ► disability.

Cross-References

► Resource Allocation

Refugee

Synonyms

Displaced person; Fugitive

Definition

A refugee is a person who has left or has been forced to leave his country or native place in order to escape persecution, war, terrorism, extreme poverty, famines or natural disaster.

Refugees and Internally Displaced People

JOACHIM GARDEMANN
Fachhochschule Münster, Münster, Germany
gardemann@fh-muenster.de

Definition

A refugee is any person fleeing to a place of safety and being outside the country of his or her nationality (UNHCR 1996). In contrast, internally displaced people (IDP) are those who have fled to a place of safety within the national borders of their country of origin. Both refugees and IDP are at-risk populations in terms of health. Recent international activities try to integrate both subgroups using the unifying concept of forced migration.

Basic Characteristics

Refugees and Relief Organizations

The United Nations High Commissioner for Refugees (UNHCR) is the UN organization caring for refugees. In the year 2005, the total population of concern to UNHCR increased to 20.8 million persons worldwide (UNHCR 2005). Of this endangered population, about 40 percent are regarded as being refugees, 32 percent as being internally displaced persons (IDP) and 11 percent as being stateless (► stateless person). These figures are estimates and the true numbers might be even higher (UNHCR 2006, 2). The International Organization for Migration is reporting 30 to 40 million unauthorized migrants for 2005, 6.6 million internally displaced persons and 8.4 million refugees worldwide (IOM 2006). In 2001, the World Health Organization released a fact sheet concerning emergency and humanitarian action (WHO 2001). Within the WHO, the Department of Emergency and Humanitarian Action is co-ordinating efforts of WHO with other humanitarian organizations worldwide. Assessment of health risks, health co-ordination, surveillance and prevention in the light of the human rights to health constitute the core elements of WHO's activities in emergency and humanitarian action.

Legal Situation in Forced Migration

On 28 July 1951 the United Nations adopted the Convention relating to the Status of Refugees that has been the comprehensive international codification of the rights of refugees down to the present day (UNHCR 1996). Article 1 (Definition of the term "refugee") of Chapter 1 (General Provisions) of the Convention constitutes a refugee being any person fleeing to a place of safety and being outside the country of his or her nationality. Hence, the crossing of an international border has been the legal precondition for full protection by the UN Refugee Convention, thus depriving the major population of internally displaced people (IDP) of the complete shelter of international law worldwide. There are attempts at international level to integrate both subgroups under the unifying concept of forced migration (University of Oxford 2006).

Health Hazards in Forced Migration

Refugees as well as internally displaced persons always constitute a population at elevated risk of severe dam-

age to health and life, morbidity and mortality being seriously elevated especially in refugee camps. Their forced migration might have been stirred up by natural, man-made or complex ► disasters (Gardemann 2002). At the place of refuge major health hazards are constituted by structural or individual violence, by trauma and psychosocial distress, by overcrowding of accommodation facilities or unfamiliar climatic conditions, by lack of shelter, food, of safe drinking water, by unfamiliar infective agents or by lack of basic medical prevention and treatment. To alleviate these major health hazards, the principles of Primary Health Care as stated in the Alma Ata Declaration of the World Health Organization in 1978 have to be followed.

Humanitarian and Technical Standards

As a consequence of the disastrous situation in camps after the Rwanda Genocide in 1994, the major humanitarian agencies founded an open source of humanitarian and technical standards for emergency situations (The Sphere Project 2004). UNHCR is also providing standard references for all aspects of humanitarian assistance (UNHCR 2000). The International Committee of the Red Cross, in its function as a body of international law impartially officiating humanitarian assistance within armed conflicts, has been making major contributions to all aspects of public health in wartime (Perrin 2001). In addition to the UN Convention relating to the Status of Refugees in all cases of international or non-international armed conflicts, the international humanitarian law is also applicable (Haug 1993). The United Nations Office for the Coordination of Humanitarian Affairs is operating "► reliefweb" as a global hub for time-critical humanitarian information on complex emergencies and natural disasters (UN-OCHA 2006).

Disaster Relief and Public Health

Recent media focus on forced migration movements after natural or man-made disasters worldwide has shifted public awareness and concern somewhat away from long-term international development cooperation to humanitarian disaster response. An earmarking of donations after circumstantial media coverage in particular is restricting the options of humanitarian agencies in their ► relief operations for refugees. Funds may be re-routed away from structural development projects into acute humanitarian relief operations. Moreover, isolated actions of disaster response may counteract long-term development projects by generating a price rise in local markets, by poaching local health staff or by privileged medical treatment in comparison with the resident population of the host country (Razum, Gardemann and Will 2006). From the very first day of action, any reasonable project of short-term disaster response and relief for refugees has to blend well, and co-operate extensively, with the local system of health and administration in the affected countries and societies. Examples of ► rapid disaster-response with the option of full and sustainable integration into local health structures are demonstrated by the Emergency Response Units of the International Federation of Red Cross and Red Crescent Societies (IFRC 2006).

Registration of Occupational Injuries

Definition

Registration of occupational injuries is the process of collecting and recording data on ► occupational injuries. Registration could be organized on the enterprise, local community, regional, state, or national level. National laws specify the procedures for registration of ► occupational accidents as well as identifying persons responsible for submitting the information on occupational accidents. In most countries, the employer is responsible for submitting data on occupational accidents. Each country decides on the amount and the structure of data in the occupational accident reporting form. This huge variability among countries means that only basic comparison is possible on an international level.

Registry

Definition

A registry is a ► database and associated applications that collect a minimum dataset on a specified group of patients (often those with a certain disease or who have undergone a specific procedure), health professionals, organizations, or clinical trials. Registries can be used to explore and improve the quality of care or to support research; for example, to monitor long-term outcomes or rare complications of procedures.

Regression Analysis

Regression analysis is an inferential statistical method that develops equations (regression models) from empirical random samples to make predictions about the values of a dependent variable (outcome, response) based on the values of one or more independent variables (covariates, explanatory variables, predictors) with known probabilities of accuracy. If there is more than one independent variable the method is referred to as multiple regression. There are two major classes of regression – parametric and non-parametric. Parametric regression requires choice of the regression equation with one or a greater number of unknown parameters. Linear regression, in which a linear relationship between the dependent variable and independent variables is posited, is an example. The aim of parametric regression is to find the values of these parameters which provide the best fit to the data. The number of parameters is usually much smaller than the number of data points. In contrast, the nonparametric regression requires no such a choice of the regression equation. In regression analysis, there are several methods for variable-selection procedures aimed at selecting a reduced set of the independent variables: step-wise regression, forward selection and backward selection.

Regulated Competition

Synonyms

Managed competition

Definition

Regulated competition models are supposed to increase the efficiency of health care markets by increasing competitive pressure for health insurers and health care providers. A comprehensive set of regulatory instruments is supposed to counteract unwanted consequences of competition in health care markets.

Regulation of Pharmaceuticals (Drug Regulation)

Definition

Effective drug regulation has many aims. It promotes and protects public health by ensuring that medicines are of the required quality, safety and efficacy; and it ensures that health professionals and patients have the necessary information to enable them to use medicines rationally. It also ensures that medicines are appropriately manufactured, stored, distributed, and dispensed; that illegal manufacturing and trade are detected and adequately sanctioned; that promotion and advertising is fair, balanced, and aimed at rational drug use, and that access to medicines is not hindered by unjustified regulatory work.

National governments are responsible for establishing strong national drug regulatory authorities (DRAs) with a clear mission, solid legal basis, realistic objectives, appropriate organizational structure, adequate number of qualified staff, sustainable financing, capacity to exert effective market control, and access to technical literature, equipment, and information.

Regulation

Definition

Market failures would be imminent in most unregulated health care markets. Thus, regulatory mechanisms influence the way health care systems are financed and the way demand and supply in health care systems are determined. On the supply side, regulatory mechanisms strive to solve agency problems in the relationship between patients and health care professionals by introducing payment systems. However, little progress has made in designing payment schemes that encourage physicians to act as perfect agents for their patients as well as for third-party payers.

Basic Characteristics

Designers of health care systems around the world use a variety of regulatory mechanisms in order to overcome market failures that would be imminent in unregulated health care markets. Competitive health insurance systems need to overcome ► adverse selection. Comprehensive coverage leads to ► moral hazard and a relationship between patient and physician that has severe agency problems (► agency theory), which may lead to ► supplier-induced demand. The basic domains of regulatory action by designers of health care systems are health care financing, regulation of demand, and regulation of supply. For regulation of health care financing and regulation of demand, see ► health financing, ► health insurance markets,

► consumer choice, and ► competition, health care. This essay is therefore only concerned with the regulation of supply. More specifically, we explore regulatory mechanisms that are intended to reduce agency problems in the relationship between health care professionals and patients.

Patients rely on health care professionals to reduce information asymmetries and to support them so that they can make informed choices. This assumes that health care professionals act as perfect agents for their patients and refrain from pursuing self-interests that might be divergent from the interest of the patient. However, in practice physicians are quadruple agents. They pursue the interest of the patient, their own self-interest, the interest of the ► third-party payer, and the interest of society as a whole (Rice 2006). The key for aligning the interests of patients, physicians, third-party payers, and society as a whole is the development of physician payment systems. Before the introduction of third-party payers, health care professionals faced no external obstructions in treating their patients. They negotiated the price for their services individually with the patient and had a rather strong bargaining position in the physician-patient relationship. However, third-party payers intervene in this relationship and change the balance of power – most physician payments nowadays are determined by payment schemes, which are administered by a third-party payer in most cases. Traditionally, payment systems for physicians have been based on ► fee-for-service, ► capitation, ► salary, or some combination of these.

Fee-for-Service

Fee-for-service payment systems are intended to allow physicians to react in a flexible manner to patients' needs and also grant the physicians a high degree of autonomy. Financial rewards are directly connected with work performed; therefore, they are popular with the medical profession. Under fee-for-service payment systems, physicians tend to delegate fewer tasks to other health care professionals than under capitation or salary payment systems (Greß et al. 2006). This is not surprising since fee-for-service payment systems contain incentives to maximize income by maximizing self-produced services, which also entails longer working hours. Third-party payers try to counteract the trend for the expansion of services under fee-for-service systems by setting budgets for the volume of services. They also try to steer provider behavior by changing relative prices for services, e. g. by reducing relative prices for technical procedures and by raising relative prices for time-consuming individual counseling. While fee-for-service payment systems increase the activity of physicians, they also allow for a high degree of flexibility (Engström et al. 2001).

In fee-for-service systems, patients tend to consume more health care services than in capitation- or salary payment systems. However, without evidence on patient health status and clinical outcomes it is unclear if the increased consumption of services itself is hazardous or beneficial for patients (Gosden et al. 2001).

Capitation

Capitation is intended to reduce incentives for supplier-induced demand and to increase incentives for continuity of care. While there may be "under-delegation" in fee-for-service systems, there may be "over-delegation" in salary and capitation systems. In capitation, there are incentives to encourage physicians to withhold care, which may result in under-treatment of patients. Physicians can reduce their workload without reducing their income by referring their patients to other providers and can increase income by increasing the number of patients on their lists (Lynch 1998). For physicians in capitation systems, it may be profitable to dump patients (► dumping) in order to attract favorable risks (health care costs of the individual are lower than capitation payments for the individual), and to actively discourage non-favorable risks (health care costs of the individual are higher than capitation payments for the individual). However, this kind of behavior is severely restricted by ethical restraints. While risk-adjusted capitation payments are technically and administratively complex, they greatly reduce incentives for risk selection in situations where ethical restraints against risk selection may be less effective (Hutchinson et al. 2000).

Salary

A salaried payment system is intended to combine basic income security for physicians with high accessibility for patients. However, in salaried systems, patients sometimes complain about discourteous physicians. This behavior probably reflects low motiva-

tion of providers who have limited opportunities to increase income. Moreover, private practice may be more rewarding, not only financially but also professionally. However, a study from the UK shows that job satisfaction does not necessarily have to be lower in salaried systems than in capitation/fee-for-service systems (Gosden et al. 2002).

Mixed Payment Systems/Pay-for-Performance

"There are many mechanisms for paying physicians; some are good and some are bad. The three worst are fee-for-service, capitation, and salary. Fee-for-service rewards the provision of inappropriate services, the fraudulent upcoding of visits and procedures, and the churning of "ping-pong" referrals among specialists. Capitation rewards the denial of appropriate services, the dumping of the chronically ill, and a narrow scope of practice that refers out every time-consuming patient. Salary undermines productivity, condones on-the-job leisure, and fosters a bureaucratic mentality in which every procedure is someone else's problem (Robinson 2001: 149)."

This statement reflects the fact that little progress has so far been made in designing payment schemes which encourage physicians to act as perfect agents for their patients as well as for third-party payers (Rice 2006). However, a number of new payment schemes in the US may provide promising solutions. ► Pay-for-performance schemes associate part of the physician's payment to performance indicators such as clinical outcomes and patient satisfaction (Rosenthal et al. 2004; Rosenthal et al. 2005).

Rehabilitation Delivery

GERNOT LENZ
Forschungsverbund Public Health Sachsen-Sachsen Anhalt e. V., Medizinische Fakultät, Technische Universität, Dresden, Germany
gernot.lenz@gmx.de

Definition

The World Health Organization defines rehabilitation as an active process by which those disabled by injury or disease achieve full recovery, or, if full recovery is not possible, realize their optimal physical, mental, and social potential and are integrated into their most appropriate environment. This refers to people with chronic illnesses, after trauma, and with congenital disabilities.

Basic Characteristics

Background

There are around 600 million people with disabilities worldwide. The disabilities may be physical, sensory, and/or mental conditions and limit the way the disabled persons carry out their daily activities. Many disabled people live in developing nations and do not have access to rehabilitation services of any kind. Internationally, there have been efforts to improve the quality of life for disabled people and their families in recent year, which are reflected in a stronger emphasis on social elements instead of predominantly the medical perspective. ► community based rehabilitation services emerged, especially in developing countries with only limited rehabilitation infrastructures. As rehabilitation aims to restore full independence by eliminating or at least reducing a handicap and by improving ability to participate in social life, it covers medical, psychological, occupational, and social aspects.

Approaches of Rehabilitation Delivery

Rehabilitation delivery aims at helping a disabled person to regain or acquire knowledge and skills, thus generating maximized ► functional ability and minimizing disability and handicap. This will allow for activity and participation by improved physical, psychological, and social function. There are three approaches towards rehabilitation. The first approach aims at reducing or eliminating disability by providing appropriate treatment and using medication control, for example. The second approach has the objective of acquiring new skills and strategies that will reduce the impact of disability such as enabling a disabled person to use a wheelchair for longer distances. The third approach helps to alter the physical and social environment to facilitate living with a given disability. An example could be the alteration of the work environment. In many cases, two or all of the approaches are pursued.

Types of Rehabilitation

Rehabilitation delivery covers a wide field of different services offered. The major categories of rehabilitation services are medical rehabilitation services, vocational rehabilitation services, and residential/community rehabilitation services. Medical rehabilitation is still a key element of rehabilitation delivery. It aims at minimizing physical, intellectual, and social consequences of disease, illness, injury, aging, and congenital factors. Amongst the most common health conditions targeted by medical rehabilitation are stroke, ► spinal cord injury, ► traumatic brain injury, ► arthritis, amputation, spinal pain, respiratory dysfunction, cardiac/pulmonary dysfunction, ► multiple sclerosis, ► Parkinson's disease, ► motor neuron diseases, and ► cancer. The objectives of medical rehabilitation are to maximize ► functional ability, restore or enhance vocational ability, improve ► quality of life, and avoid or reduce the need for ► long-term care. Vocational rehabilitation aims to enable temporarily or permanently disabled persons to enter, return, or remain in employment. Vocational rehabilitation offers a wide range of employment and pre-employment services to disabled persons. These services include, for example, ► sheltered work and supported employment. Vocational rehabilitation programs offer, amongst other services, career exploration, skill and potential assessment, advice and counseling on job selection, training in prevocational skills, training for particular jobs, and assistance in finding a job. Residential/community rehabilitation services offer informal services for disabled persons in residential settings like group homes, supported living, or assisted living settings. The objective is to enable persons with physical, cognitive, mental, or sensory disabilities to live and function as independent-

ly as possible at home, at work, and in the community.

Delivery Settings

Rehabilitation services are offered in a wide range of rehabilitation facilities and multidisciplinary and interdisciplinary ► rehabilitation teams are usually involved in providing the different services. With regard to medical rehabilitation, the first phase of rehabilitative care is usually provided to patients at acute care hospitals, general medical or surgical wards, trauma centers, or intensive care units. This sub-acute rehabilitative care – also called ► short-term rehabilitation – is either delivered in the rehabilitation unit of the hospital, in a dedicated rehabilitation hospital, or by outpatient rehabilitation services. The rehabilitation hospitals provide close medical supervision and have physicians, nurses, and therapists available. The therapies offered include ► physical therapy, ► occupational therapy, and ► speech therapy. At the end of the stay in the rehabilitation hospital, the patient is either moved home with – if required – outpatient rehabilitation services or transferred to another, longer-term, facility, which could be a skilled nursing facility or a long-term care hospital. Skilled nursing facilities and long-term care hospitals offer services for people with more severe disabilities who need to stay longer term but sometimes have less intense rehabilitation needs (especially relevant for skilled nursing facilities). Those facilities usually offer the whole range of rehabilitative therapies. Patients that are sent home can continue their rehabilitation in outpatient rehabilitation settings. The facilities focus on providing diagnostic, therapeutic, and restorative services for persons who periodically require rehabilitation services. They might offer the whole range of those services or specialize on specific areas e. g. physical therapy or speech therapy. The patients come either from home or from residential settings. There are also residential/community rehabilitation services that are offered for disabled persons in residential settings like group homes, supported living, or assisted living settings.

Benefits of Rehabilitation Delivery

There are several proven benefits of rehabilitation delivery on an individual level. Rehabilitation improves and optimizes both the physical and social functioning of the affected individual. It furthermore reduces the risk of unnecessary complications. Rehabilitation improves the chances and accelerates the speed of living independently at home and returning or starting to work. Rehabilitation also enforces the concentration of therapy and thus decreases the length of hospital stay and results in improved outcomes. On a micro- and macroeconomic level, rehabilitation can lead to cost reductions by reduced length of hospital stay, fewer complications, fewer unnecessary hospital admissions and readmissions, less sickness absence, lower early retirement, increased productivity, continued tax payment, and reduced payment of state benefits.

Conclusion

Rehabilitation efforts have grown significantly over the last 25 years and several delivery models have emerged and developed. Formal training programs have been established worldwide for the education of specialists in the different fields and areas of rehabilitation. Rehabilitation is commonly accepted as an important field in health care and public health. Rehabilitation is now shifting from its traditionally reactive focus towards a more proactive one yet there are still too few studies of rehabilitation that specifically address the future challenges and implications. The scientific, technological, and communications revolutions underway have to be utilized worldwide to better serve the needs of people that require rehabilitation services in the most integrated way possible.

Rehabilitation Teams

GERNOT LENZ
Forschungsverbund Public Health Sachsen-Sachsen Anhalt e. V., Medizinische Fakultät, Technische Universität, Dresden, Germany
gernot.lenz@gmx.de

Definition

The rehabilitation team consists of professionals from different disciplines that are involved in the rehabilitation process. The multidisciplinary and interdisciplinary team agrees on explicit objectives that have an impact on team setup and function. It is a key success factor that the skills and roles are clearly defined and understood by each team member. The rehabilitation team works with the disabled person and their family and defines an appropriate, realistic, and timely treatment plan embedded in an integrated rehabilitation program.

Basic Characteristics

Team Structures

Successful rehabilitation teams have to be more than a mere collection of different health professionals from multiple disciplines. What actually differentiates an interdisciplinary team from only a multidisciplinary team is that the interdisciplinary team pursues a client centric approach. This means that the goals are set in cooperation with the disabled person and their family and for each single discipline. Such an integrative approach requires the team to define common actions and work cross-boundaries, with each individual bringing in their specific experiences, skills, and expertise. The rehabilitation teams are often led by a physician, which is primarily driven by historical or political reasons, but still makes sense as the physician often has the broadest view of the patient as a whole as well as of the contribution of the different team members. The core members of a rehabilitation team are usually the rehabilitation physician, a rehabilitation nurse, a clinical ► neuropsychologist, an occupational therapist, a physiotherapist, and a speech and language therapist. Depending on the specific case, there might be other specialists involved like, for example, social workers, ► dieticians, or ► podiatrists. In some cases, a key worker or case manager is assigned to act as liaison between the rehabilitation team, the disabled person, and the family, by providing information about the rehabilitation process and feeding back the thoughts and aspirations of the disabled person and their family to the team. The rehabilitation teams are usually established in all rehabilitation settings, which can be hospital-based and other inpatient settings as well as outpatient rehabilitation services.

Key Benefits of Rehabilitation Teamwork

There are several benefits that arise from establishing interdisciplinary and multidisciplinary rehabilitation teams. A rehabilitation team allows for improved communication and knowledge sharing between the representatives from the different disciplines. Tackling a case as a team enables a consistent, client centric, and goal-oriented approach and improves continuity of care. The stimulating environment has positive effects within the team by enhancing the contribution of each member, improving their motivation and passion, and allowing for a more effective working style. If the team is set up correctly, with clear rehabilitation objectives for the patient, the output of the team is usually higher than the sum of the individual professional inputs as experiences and workload are shared.

Outcome Measures

Outcome measurement has gained increasing importance in recent years in the health care industry. There is a wide range of different outcome measures in rehabilitation. The outcome measures have to be defined accurately to ensure that they do not only reflect the goal that has been set for the rehabilitation effort but also the process by which the goal is achieved. Outcome measures are a tool to evaluate the service but it is always

crucial to examine the underlying process as well, and get a detailed understanding of the whole context of the situation. When it comes to evaluating the work of rehabilitation teams, at least the following three standards concerning multi-professional working should be fulfilled. 1) The rehabilitation team should work according to written criteria for seeing and treating their patients. 2) The teams should define appropriate outcome measures, document at least one at admission of the patient, and review its fulfillment at discharge. 3) There should be a detailed rehabilitation plan for each patient with clearly defined goals that have been aligned with the patient and the family.

Conclusion

Rehabilitation will face constant changes in upcoming decades. There will be changes in the structure and function of the rehabilitation systems worldwide. To deliver rehabilitation services in the most efficient and effective way, there will be further efforts to enhance networking and integration both within the rehabilitation industry but also with other stakeholders involved in or close to the process. Furthermore, continuous learning and education is required to meet the changing needs of patients and society. The establishment and enhancement of rehabilitation teams, especially for more specialized rehabilitation services, will contribute to facing the future challenges by providing a coordinated source of information, advice, and treatment, thus facilitating minimization and prevention of disability and handicap.

Rehydration

Synonyms

Replacement of fluids; Substitution of fluids; Fluid therapy

Cross-References

- ► Therapy of Infectious Diseases

Rehydration Solution

Synonyms

Replacement of fluids; Substitution of fluids; Fluid therapy

Definition

In oral rehydration the loss of fluids and electrolytes is replaced without intravenous infusions. The amount of an oral rehydration solution (ORS) depends on the assumed loss of fluids (or weight) and the requirements of the organism. To compensate the loss properly, the solution has to provide an optimal composition of salts (electrolytes) and sugar (glucose). This is achieved by an uptake of 60 mmol sodium, 20 mmol potassium and 90 mmol glucose (16.2 g) per liter and an osmolality of 240 mosmol/l. Osmolality means the amount of dissolved particles per liter of the solution. A number of products, which follow these recommendations, are available. A simple and easily self-made oral rehydration solution should contain eight teaspoons of sugar (40 g) and one teaspoon of salt (5 g) in one liter of boiled water. Cola or fruit juices are not suitable for rehydration because their content of sugar is too high and that of electrolytes too low. Furthermore, the osmolality of these beverages is too high.

Reimbursement

Definition

Reimbursement in health care refers to the reimbursement of all types of health care services provided. Med-

ical services and drugs in the ambulatory sector or in hospitals are reimbursed by the health insurance of a patient. The reimbursement may be 100% or lower according to the service received and the health insurance contract. If a patient is not fully reimbursed for a treatment or drug he has to make a direct payment or co-payment in order to fill the gap between the price of a service and the reimbursement.

Relationship

Definition

A relationship is a connection between two or more variables usually assessed by a measure of association. Informally a term that describes a case where one variable is depending on the other, or a case where values of one variable vary together with values of the other variable(s). The relationships may be causal, meaning that the changes in one variable depend on the changes in another; or they may be correlational, meaning that the variables tend to change at the same time, but there is not necessarily a causal relationship between the two variables. A relationship between two variables that can be described by a straight line when variable values are plotted on a graph is a linear relationship.

Cross-References

► Association

Relative Odds

Synonyms

Odds ratio (OR); Cross-product ratio

Definition

The odds ratio is a measure of association, in which a value of "1.0" means that there is no relationship between variables. The value of an odds ratio can be less than or greater than 1.0. The magnitude of any relationship is measured by the difference (in either direction) from 1.0. An odds ratio less than 1.0 indicates an inverse or negative association. An odds ratio greater than 1.0 indicates a positive correlation.

Cross-References

► Odds Ratio (OR)

Relative Outcome Risk

Synonyms

Cumulative incidence ratio; Relative risk

Definition

The risk ratio (RR) of an event is the risk of the outcome in the treatment group (or exposed group) divided by the risk in the control group (or unexposed group). RR is an example of exposure effects used in connection with dichotomous outcomes. When the exposure factor under study is a risk factor RR $>$ 1. RR $=$ 1 when there is no association between exposure and disease. RR $<$ 1 corresponds to a protective exposure. In relative risk regression models, where regression coefficients for main effects exposure variables have an interpretation of log relative risk, a significant interaction between exposure and a second variable means that the second variable is an effect modifier. Logistic regression and multiplicative Cox regression are all examples of multiplicative models for which the relative risk is the implicit measure of effect. Relative risk is the same as the cumulative incidence ratio which represent the ratio of the risk of disease in an exposed cohort over a defined time interval to the risk of disease in an unexposed cohort over this same time interval.

Cross-References

► Risk Ratio

Relative Ratio (RR)

► Relative Risk

Relative Risk

Synonyms

Cumulative incidence ratio; Relative ratio (RR)

Definition

The relative risk quantifies how many times more or less likely the disease is in "exposed" people compared to "unexposed" people. Traditionally, exposure has been considered in terms of environmental agents, but in genetic studies exposure can refer to the underlying genotype or allele. A null value of 1.0 indicates that the disease is equally likely in exposed and unexposed people; a value greater than 1.0 indicates that the disease is more likely in exposed people; and a value less than 1.0 suggests that the disease is more likely in unexposed people. Usually, a relative risk is given in percent.

Cross-References

► Risk Ratio (RR)

Reliability

Definition

Reliability indicates the degree to which the measurement instrument is consistent, free from random error, and the measurements of the characteristics of individuals under different conditions yield similar results. There are three ways to analyze reliability: internal consistency reliability, test-retest reliability and inter-rater reliability. Internal consistency reliability is the degree of congruence of items on the questionnaire or scale. Congruence between them suggests that all items measure the same thing as the instrument as a whole. Inter-rater reliability measures the agreement of two or more raters that use the same information on the same analyzing unit. Test-retest reliability is an estimation of the scale of stability over time that is measure of result congruency obtained by repeated measurement on the same objects, under the condition that there was no change in the condition of those objects.

Relief

Definition

Relief is assistance or intervention from outside during or after ► disaster to meet the life preservation and basic subsistence needs.

Relief Organization

► Humanitarian Agency

ReliefWeb

Definition

ReliefWeb is an independent, internet-based source of information on humanitarian emergencies and ► disasters. It is administered by the UN Office for the Coordination of Humanitarian Affairs (OCHA). ReliefWeb has been started in 1996 and has been designed to assist the international humanitarian community in evidence-based delivery of emergency assistance. ReliefWeb maintains three offices in three different time zones (New York, Geneva, and Kobe) to update the web site around the clock, posting some 150 maps and documents daily from over 2,000 sources from the UN system, governments, NGOs, the scientific community and the media.

Religion

Synonyms

Faith; Devotion; Spirituality

Definition

Religion is commonly defined as belief concerning the supernatural, sacred, or divine, and the moral codes, practices and institutions associated with such belief. It may also be understood as the sum total of answers given to explain humankind's relationship with the universe.

The relation of human beings to God or the gods or to whatever they consider sacred or, in some cases, merely supernatural.
A belief in God with the knowledge and observation of religious Cults in their abundance, sacred songs, and artistic representation of pictures of churches or temples.

Religion and Health

jelgud@gmail.com

Definition

There are many different definitions of ► religion. One of the most commonly used defines religion as a set of beliefs, values, and practices based on the teaching of a ► spiritual leader. Religion is a system of thought, feeling, and action shared by a group. Also, religion is an acknowledgment of the extraordinary, the mysterious, the supernatural. The religious consciousness generally recognizes a sacred order and elaborate a technique to deal with the inexplicable or unpredictable elements of human experience.
Most languages have no word for religion but this does not mean their speakers are not religious.

Basic Characteristics

Types of Religious Systems

Religion is an essential part of the human experience.
Main concerns of every religion are health, wealth, and the pursuit of happiness. Through religion people express their desire for a better life. How "better", "healthy", "wealthy" or "happy" are understood varies from one community to another as well as from one individual to the next. The ways in which it is appropriate to express one's desire for the above attributes also vary. Sometimes wealth or the good life are not defined by human desire but by divine dictate. People adjust their views, beliefs, and actions to what is acceptable to their source of authority.
Indigenous religions are the majority of the world's religions. They are as diverse as are languages, cultures, traditions, and the ways of life of people living in a variety of settings all over the world. *Indigenous religions are co-operative activities in which individuals often have considerable freedom.* There is considerable diversity of indigenous religions. Each indigenous religion is unique to a specific ethnic group or part of a group. However, several groups may share elements of belief and ritual because of common ancestry or mutual influence. Believing and acting in a religious mode is incorporated in every day life and is part of the social, cultural as well as economic and political actions and relationships of the group.
Due to growth and spread of transcultural or global religions (Buddhism, Christianity and Islam) some indigenous religions have been rejected, abandoned or destroyed. Others have accepted the arriving religion on their own terms slotting it into an indigenous understanding. Many have adapted to the presence of more powerful dominant religions, but many people have returned to their 'traditional' religion or are engaged in both indigenous and newer religion.
Many beliefs and practices of indigenous religions are not systematized. The distinction between the natural and the supernatural or divine usually is not relevant to the traditional religions. In many indigenous religions spirits may have much greater power than humans. Their powers are perceived not as altering the way the world commonly works but as explaining occurrences in nature or in the social world.

Religion and Health

Understanding and explanation of causes and consequences of illness and health very often are different from the evidence based medical viewpoint. In some indigenous religions it is believed that illness is a result of spirit possession. Spirit possession is found in virtually all religions of humankind from earliest times until now. Its forms and belief content, show an amazing diversity, for example shamanism (Arctic, Siberian and other) and zar and bori cults in Africa.
Approaches to healing are different as well. Very often in indigenous religions we encounter men and women who are believed to have extraordinary powers. Understanding regarding the way these powers have been acquired and exercised varies from group to group. In general, however, some people are thought to have inherited the capacity to harm others and to have a dis-

position to do so. Typically they are accused of inflicting illnesses on specific individuals. On the other hand, very often it is believed that some men and/or women have powers of healing which is an important issue in terms of acceptance of medical care and provision of health service.

Religious practices may be beneficial for human health as proved in some investigations. For example, many indigenous religions forbid the use of certain food types during specific times of the year.

Is religion related to better health? Research in this area is obscure but not entirely absent. Australian studies for example have found greater marital stability, less alcohol and illicit drug use, lower rates of and more negative attitudes toward suicide, less anxiety and depression, and greater altruism among the religious. Religiosity has also been associated with less cigarette smoking, more conservative sexual practices (reducing risk of sexually transmitted diseases), lower cortisol and catecholamine levels (for meditators), lower blood pressure, lower cholesterol, and even lower risk for colon cancer. Health practitioners should consider a patient's religion or spirituality in clinical practice.

Religious practices have to be considered in terms of either health benefits or a possible disturbing factor in utilization of health care, depending on the features of specific indigenous group.

Health professionals working in indigenous communities have to be aware of the religious practices and beliefs of indigenous groups. What is more they should be trained to react accordingly if they estimate religious issues might interfere with the treatment. Further research of the relationship between spirituality and health of indigenous groups is needed for better understanding of causes as well as more successful implementation of treatment.

► Rehydration Solution

Replication

Synonyms

Repeating

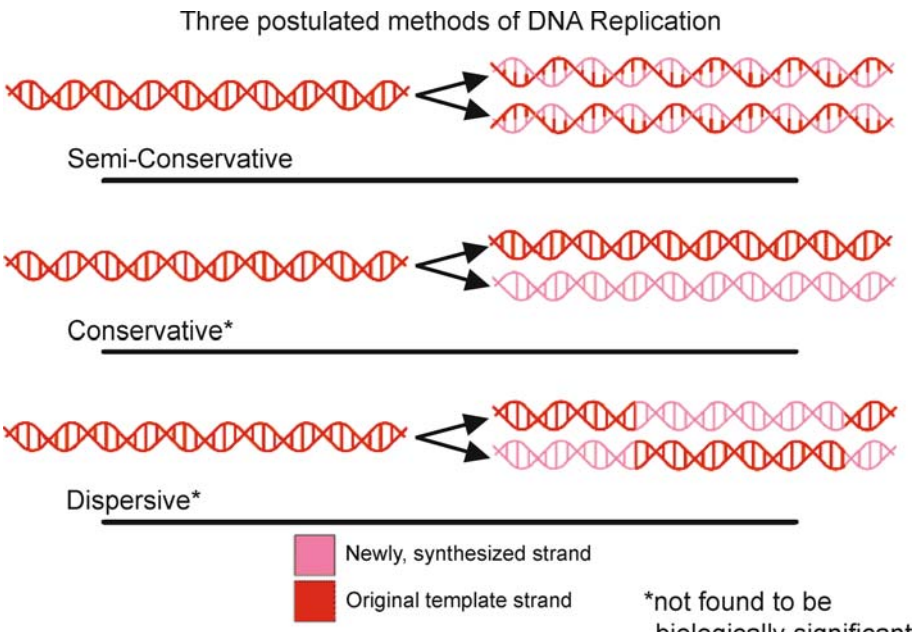
Definition

Replication is performing the same treatment combination more than once to increase confidence in those findings; repetition of the same research procedures (usually by a second researcher) for the purpose of determining if earlier results can be duplicated; the collection of two or more observations under a set of identical experimental conditions. Repeating the creation of a phenomenon, so that the variability associated with the phenomenon can be estimated. If affordable, replication should be part of every design. Replication allows us to compute a model-independent estimate of the process standard deviation. Such an estimate may then be used as a criterion in an objective goodness of fit test to assess whether a given model is adequate. Such an objective test can be employed only if the design has built-in replication. Some replication is essential; replication at every point is ideal.

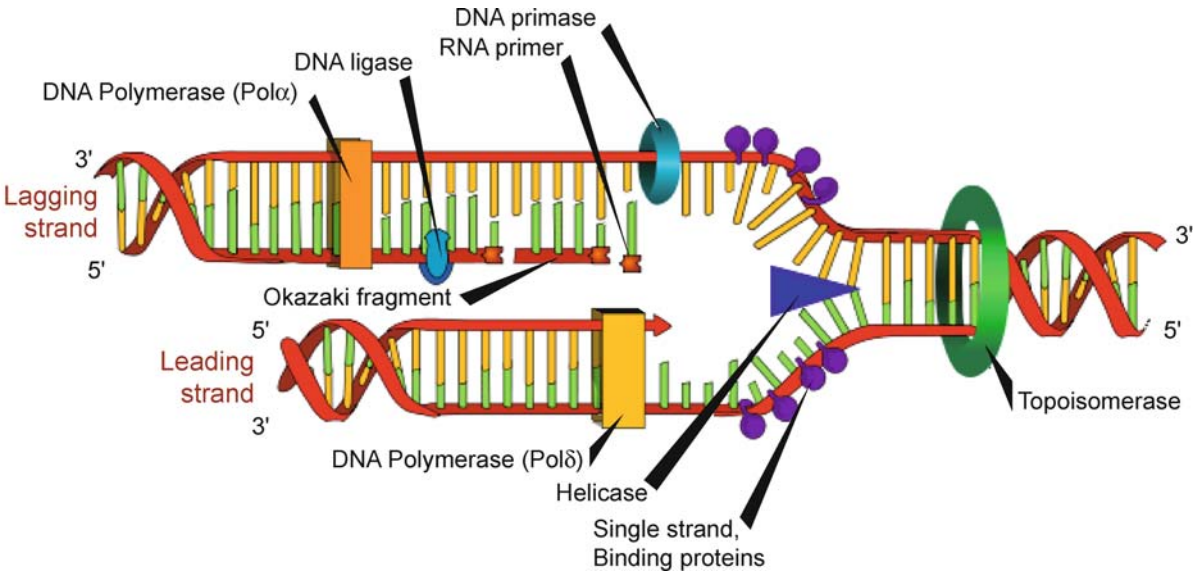
Replication (DNA)

Definition

Replication is the process by which DNA is copied, producing two new double-stranded DNA sequences from one original. Each new double-stranded sequence is made of one strand which initially served as a template, and one strand which was constructed on that template; hence, it is therefore said that DNA replication is 'semi-conservative' (Fig. 1). Several complicated steps transpire in order for DNA to replicate. The first step is the separation of the DNA double-strand. In this first step, several enzymes perform key functions: topoisomerase 'nicks' one strand at a specific site, the origin of replication, breaking a bond between two adjacent nucleotides to lower torsional stress and permit uncoiling; helicase unwinds and separates the two strands, dissociating the base pairs; and single-strand binding proteins attach to the separate strands, holding them open. With this newly opened 'replication bubble', the enzyme primase reads the exposed single strand and attaches short segments of ribonucleotides ('primers' of RNA) at various specific sequences in order to create sites from which to begin replicating the DNA. It is then that the enzyme DNA polymerase begins the process of attaching their 5′ ends to the 3′ ends of the RNA primers by removing phosphate ($-PO_4$) groups from deoxynucleotide triphosphates (dNTPs) to extend a new duplicate strand along the template. At a replication origin, replication will proceed bidirectionally on each strand, towards both the 5′ and 3′ ends. DNA polymerization, however, always goes from the 5′ to 3′ direction. On one of the two strands, a single primer will be used to start the addition of nucleotides from 5′ to 3′; on this strand, replication proceeds continuously as the DNA double-strand is unwound and separated into individual strands. The strand which is continuously duplicated is called the leading strand. However, on the complementary strand, and on the 5′ side of the replication origin, the template is being opened in a 5′ direction. As



Replication (DNA), Figure 1 Illustration of semi-conservative vs. conservative replication



Replication (DNA), Figure 2 Illustration of replication at the site of uncoiling and opening of the template

a result, primase attaches RNA primers at multiple sites along the single strand as the distance from the origin of replication increases (Fig. 2). At each primer, DNA polymerase attaches nucleotides until it encounters the end of that segment of DNA at another primer. Thus, the strand opposite the leading strand, the lagging strand, is made by continuously duplicating short stretches in the 5′ to 3′ direction as the bubble expands. These short stretches of replication on the lagging strand are collectively called Okazaki fragments. After a section of strand has been duplicated, the sequence is proofread to ensure both correct duplication of the strand and the removal and replacement of the RNA primers with the appropriate deoxyribonucleotides. Finally, any remaining nicks or separations in the strand are sealed using the enzyme DNA ligase.

Reportable Disease

► Notifiable Disease

Representativeness of a Surveillance System

Definition

In order to generalize findings from surveillance to the target population at large, the data from a surveillance system should reflect the population characteristics related to time, place, and person. Representativeness is assessed by comparing the characteristics of health events detected through a surveillance system with those of all such health events in the target population. A lack of representativeness may lead to misallocation of health resources.

Reproductive Health

BEATE SCHÜCKING,
BRIGITTE BORRMANN,
SUSAN ERIKSON
Forschungsschwerpunkt Maternal Health, FB 8 Humanwissenschaften/Gesundheitswissenschaften, Universität Osnabrück,
Osnabrück, Germany
beate.schuecking@uos.de, bborrman@uos.de, slerikson@sfu.ca

Definitions

Reproductive health refers to the complete physical, mental and social well-being in all matters concerning the reproductive system, its functions and processes. Reproductive morbidity may be divided into three categories: obstetric/maternal morbidity (related to pregnancy and childbirth), contraceptive morbidity (complications with methods of birth control) and gynecologic morbidity (endocrine disorders, infertility, cancer, sexual dysfunction, symptoms related to the ► menstrual cycle and ► menopause, sexually transmitted infections).

Healthy sexuality and reproduction involves safe, satisfying behavior and experience. Reproductively healthy people are able to reproduce, and enjoy the freedom to decide if, when, and how to reproduce. Both sexual and reproductive health is influenced by the availability of necessary resources, individual decision-making, and environmental contexts. Sexuality and reproductive concerns change over a person's lifetime; thus, gender and lifestages affect sexual and reproductive health.

Basic Characteristics

Sexual and reproductive health are vital elements of physical and emotional well-being. But while sexual and reproductive health are sometimes synonymous, healthy sexual expression need not always lead to reproduction. Healthy reproduction includes a problem-free conception, normal pregnancy and birth, and easy postpartum recovery. Gender-specific reproductive health information is essential for informed consent, and should include information about sexual and reproductive behavior that is preventative in nature. Loving relationships in early childhood and later life also support sexual and reproductive health. Access to adequate and affordable health-care is essential for safe pregnancy, childbirth, and postpartum recovery. Sexual coercion and violence, genital cutting, inadequate child-spacing and child trafficking all threaten individual health, especially of women and children. Sexual and reproductive health are closely related to the realization of human and reproductive rights.

Adolescence, Sexuality and Reproductive Health

Adolescence is typically a time of sexual experimentation. Ideally, good sex education cultivates understanding and awareness of a broad range of human sexual expression, as well as the long-term risks of some behaviors. Adolescents may be sexually vulnerable because of family history and relationships, cultural norms and societal pressures. Statistically, adolescents are at comparatively high risk for unintended pregnancies and ► sexually transmitted diseases, including ► HIV/AIDS. Half of all new HIV-infections take place among people under the age 25, and girls and women are disproportionately affected.

About 10 percent of all newborns worldwide have teenage mothers. Impaired access to family planning services and basic sex education has led to a worldwide increase in the number of young single mothers. Pregnant teenagers often experience poor nutrition, inad-

equate weight gain, and high rates of smoking, thus experiencing higher risk pregnancies.

Reproductive Responsibilities, Family Planning and Abortion

Sexual pleasure as well as sexual risk goes hand-in-hand with reproductive responsibility, and men and women alike are responsible for healthy sexual and reproductive praxis. Sexual and reproductive coercion, on the other hand, can take different forms: Most extreme forms would include being forced to have sex, or to carry an unwanted child. Lesser forms include overmedicalization of normal reproductive practices like pregnancy. Further, the prevention of unintended pregnancies requires access to a wide range of family planning methods including abortion. Unsafe abortion can lead to maternal morbidity and mortality and can potentially cause later infertility.

Childlessness and Infertility

Many couples choose to remain childless. Other couples have trouble conceiving. There are about 80 million infertile men and women worldwide, and many causes of ► infertility are preventable. For example, the most common cause of infertility are sexually transmitted diseases, which the use of condoms could prevent. Likewise excessive use of toxic substances (e. g. caffeine, tobacco, alcohol, drugs), ► environmental pollutants, excessive exercise, and weight loss or weight gain can result in abnormal ovulation and sperm production. Additionally, an increasing number of women working in formal economies are postponing childbearing until the age of 35–45, when the chance of becoming pregnant is reduced.

Pregnancy

Pregnancy is a normal condition for a reproductively healthy woman. At the same time, pregnancy may induce conditions the woman might not otherwise experience, like hypertension, ► gestational diabetes, ► anemia, and ► depression. Effective pregnancy management can minimize these conditions. Access to information about the physiological changes of pregnancy, good nutrition, proper exercise, stress reduction, and working during pregnancy, as well as access to the assistance of a trained birth attendant should be available and affordable for all women. Having many children and lacking control over child-spacing can also threaten women's long-term health. Additionally, other factors over which women do not have control – exposure to ► environmental toxins, economic and cultural stressors, and violence (4–20 percent of women worldwide experience violence during pregnancy) – affect the health and wellness of mother and fetus.

Childbirth

Experiencing an uncomplicated delivery can contribute to a women's overall good physical and mental health, and can simultaneously be an empowering experience. Women choose to give birth at home, in birthing centers, and in hospitals. Despite worldwide improvements in childbirth outcomes – fetal and maternal mortality and morbidity rates – contemporary public health initiatives focus on the disparities of childbirth outcomes throughout the world. Adverse socio-economic conditions, inadequate care during pregnancy, lack of good childbirth support, smoking, drinking, and drug use contribute to childbirth-related death and disability. Many women in developing countries lack medical and midwifery care, while in most European and North American countries there is an overmedicalization of birth (high tech – low touch). Despite the rising prevalence of induced labour, epidural anesthesia, and c-section deliveries (in some countries, as high as 30 percent cesereans or more), research does not support the overall efficacy of these high intervention rates for women's and children's long-term health.

Postpartum Period

After birth, women require rest and quiet. At this time, the well-being of the mother and child is closely linked. Opportunities for parents and children to bond will increase the likelihood of long-term physical and mental health. Some women are vulnerable to postpartum depression, not only in the days immediately following birth, but also for as long as a year afterward. Social support can help alleviate the stress and challenges of adding a new family member. Long-term successful ► breastfeeding can be faciliated by consultations from experts as well as family support and cultural acceptance. There are some long-term physiological advantages for women who bear children, especially for those who are young at first birth and breastfeed for pro-

longed periods of time. These include lower incidence of breast and ovarian cancer, reduced risk of fibroids, and less incidence of mental illness, particularly in old age.

Reproductive and Sexual Health of the Elderly

Like ► menarche (the onset of menstruation), ► menopause (the cessation of menstruation) does not require medical intervention. In recent years, however, many women in industrialized countries have been encouraged by their doctors to take hormone treatments as anti-aging antidotes. These hormone treatments have been shown to increase cardiovascular risk and estrogen-induced cancers. Menopause is the cessation of reproductive but not sexual capability. Improving male sexual performance by taking drugs is efficient but also adds (e. g. cardicovascular) health risk. Maintaining healthy sexuality can positively affect all aspects of physical health and emotional well-being. The need for intimacy does not disappear with aging, although physiological changes in hormone secretion may alter sexual functioning of men and women.

Reproductive Health Care and Health Promotion

Important reproductive health indicators are: contraceptive prevalence rate, maternal and perinatal mortality ratio, antenatal care coverage, births attended by skilled health personnel, low birth weight prevalence, prevalence of anemia in women, maternal morbidity and mortality owing to abortion, reported prevalence of women with ► female genital mutilation (FGM), prevalence of infertility in men and women, STD and HIV prevalence among pregnant women and knowledge of STD and HIV related prevention practices.

Improving antenatal, perinatal, postpartum and newborn care; providing high-quality services for family planning, including infertility services; eliminating unsafe abortion; combating sexually transmitted infections including HIV, reproductive tract infections, cervical cancer and other gynecological morbidities; and improving sexual health are fundamental aspects of reproductive and sexual health care. Well-designed, comprehensive, community-based sexual and reproductive health services can empower women and men to make safe and satisfying sexual and reproductive health choices (WHO 2004).

Reproductive Tract Infection (RTI)

Definition

Reproductive tract infections are infections of the genital tract. They affect both men and women. Some RTIs (such as syphilis and gonorrhea) are sexually transmitted, but many are not. RTIs include endogenous infections, such as bacterial vaginosis, or iatrogenic infections that appear as a result of unsanitary medical procedures.

Reservoir of Infection

Definition

The reservoir is the natural habitat of the infectious agent. It may be any person, animal, plant, soil, or substance in which an infectious agent normally lives and multiplies. The reservoir typically harbors the infectious agent without injury to itself and serves as a source from which other individuals can be infected. The infectious agent depends primarily on the reservoir for survival.

Residential Care Facility

► Assisted Living Facilities

Residential Health Care Facility

► Nursing Homes

Residual

Definition

The difference between the predicted value (often from a regression equation) and the actual or observed value is termed the residual value. Residuals reflect the overall badness of fit of the model. Examination of residuals in regression analysis will identify atypical cases. Ideally, the residuals should have constant variance along the line. A normal probability plot of the residuals can check this. In the plot of residuals against the explanatory variable (or the fitted values), there should not be any pattern if the assumption of constant variation is met, i. e. residuals do not tend to get larger as the variable values get larger or smaller.

Residual and Late-Onset Psychotic Disorder

Definition

A disorder in which alcohol- or psychoactive substance-induced changes of cognition, affect, personality, or behavior persist beyond the period during which

a direct psychoactive substance-related effect might reasonably be assumed to be operating. Onset of the disorder should be directly related to the use of the psychoactive substance. Cases in which initial onset of the state occurs later than episode(s) of such substance use should be coded here only where clear and strong evidence is available to attribute the state to the residual effect of the psychoactive substance. Flashbacks may be distinguished from psychotic state partly by their episodic nature, frequently of very short duration, and by their duplication of previous alcohol- or other psychoactive substance-related experiences.

Cross-References

► Substance Induced Disorders

Resiliency

Definition

Resiliency is a property of a system that describes its smooth and fast recovery from a state of failure.

Resistance

Synonyms

Resistibility; Insensitivity

Definition

Resistance means insensitivity. In connection with microorganisms resistance is understood as the insensitivity for antibiotics or chemotherapeutics. One has to differentiate between natural and acquired resistance. In cases of natural resistance the characteristics of bacterium make the drug ineffective. These characteristics can either lie in the structure of the bacterium or their enzymes, which are able to neutralize the drug. As for acquired resistance, a bacterium, which has once been sensitive for an antibiotic becomes insensitive due to changes in its structure or its metabolic capabilities. The increased, and sometimes uncritical, use of antibiotics supports the development of resistant bacteria and diminishes the number of antibiotics that are effective against particular pathogens. The mismanagement of antibiotic treatment leads to the development of multiresistant bacteria.

Resistibility

► Resistance

Resource Allocation

Synonyms

Cost containment

Definition

Resource allocation describes the process of decision to use available resources selectively between competing projects. In health care, resources are allocated in order to achieve the defined ► health policy goals in the future. Generally resources should be allocated to achieve the highest ► health outcomes in terms of disease prevention and therapy. The basic allocation is made once a choice has been made on which health care areas and projects are to be funded and what level of funding each of these areas should receive. As health care systems are always subject to cost containment, resource allocation also involves a decision on which areas or projects must be sacrificed to lower the overall funding.

Cross-References

► Scarity of Resources

Respect for Persons

Definition

As a basic ► ethical principle in research, respect for individuals was clearly defined in the ► *Belmont report* in 1979 in the USA by the National Commission for the Protection of Human Subjects of Biomedical and Behavioral Research. Respects for persons incorporates two ethical considerations:

a) respect for ► autonomy, which requires that those who are capable of deliberation about their personal choices should have their capacity for self-determination respected; and

b) protection of persons with impaired or diminished autonomy, which requires that those who are depen-

dent or vulnerable be afforded security against harm or abuse.

Respiratory-Syncytial-Virus (RSV) Infection

Definition

For RS-viruses, humans are the only reservoir. These viruses, which are spread by droplets, are the most common cause of respiratory tract infections during the first two years of life. RSV-infections are mainly seen in the winter months. After an incubation period of 3–6 days the infection leads to bronchiolitis, obstructive bronchitis, pneumonia and otitis media. The virus can be detected in nasopharnyngeal secretions. For special groups at risk (like premature babies and children with chronic pulmonal diseases) passive immunoprophylaxis is recommended during the first two years of life.

Respite Care

Definition

Respite care services are usually provided for functionally disabled or frail individuals in their homes, at a ► day care center or by temporary placement in a nursing home or residential home. Respite care allows for occasional or systematic relief for the informal caregivers, often members of the family. Most respite care programs offer their services on a fee scale with hourly or daily rates. Depending on the type of respite care that is available in the community, services can range from several hours of care to several months. Some respite care programs aim at a specific disability or illness.

Response

► Event

Restriction

Definition

Restriction is straightforward, convenient and inexpensive means to control confounding. It is a process of limiting the entrance into the study to individuals who fall within a specified category of a confounder. For example if sex is potential confounder, the study could include only men or only women. Similarly, control of age could be achieved by restricting admissibility to those within o narrow range that corresponds to a relatively homogeneous rate of disease incidence.

► Recycling

Revealed Preferences

Definition

The revealed preferences approach is an indirect determination of the ► willingness to pay by observing the behavior of individuals and estimating the willingness to pay for a specific health care service by observed choices in other but comparable contexts. Revealed preferences have a strong foundation in the utility theory. The results of revealed preference measurements can be used as outcome measure in a cost-benefit analysis.

Revision

► Evaluation, Models

Right-to-Know

Synonyms

Risk communications

Definition

Many workplace chemicals and other substances are referred to only by brand names or code numbers. The right-to-know movement, initiated in the late 1970s in many countries, resulted in the development of right-to-know laws in the early 1980s, which are the legal rights and obligations that govern the transfer of workplace information on toxic substances. According to those laws, employers have a duty to inform workers of the identity of substances with which they work through labeling the product container, and the workers should be counseled on the importance of personal hygiene and the use of protective equipment to reduce exposure.

Rights of Indigenous Peoples

► Indigenous Rights

r Index

Definition

The *r* index is the most appropriate metric for expressing an ► effect size when the researcher is interested in describing the relationship between two continuous variables. It is simply the Pearson product-moment correlation coefficient. Very often we do not have presented variances and covariances in primary research. If only the value of the $t-$test associated with *r* index is given, formula for its calculation is:

$$r = \sqrt{\frac{t^2}{t^2 + df_{\text{error}}}}$$

Risk

Synonyms

Absolute risk

Definition

There are two commonly used terms associated with ► risk assessment. They are ► hazard and risk. A risk is the likelihood that exposure to a hazard will result in injury or disease. In risk assessment, risk combines the probability of an event occurring with the impact that event would have under different circumstances. The level of risk can be viewed as a function of probability and severity of impact.

Risk is the probability that a risk event, such as disease, injury, disability, or death, will occur during (over) a specified time period. For calculation of risk, the numerator contains the number of persons experiencing the risk event during the time period. The denominator contains the population at risk, i. e. the number of persons who are free of the risk event at the beginning of the time period, but capable of having disease.

Variables associated with an increased or decreased risk are the risk factor or protective factor, respectively. The risk factor and protective factor are any characteristics, such as personal behavior, inheritance, or environmental conditions, that are considered to be associated with occurrence of the risk event.

Risk Adjustment

Synonyms

Risk equalization

Definition

Risk adjustment refers to the use of information to calculate expected health care expenditures of consumers and to determine subsidies to health insurers to neutralize incentives for ► preferred risk-selection.

Risk Analysis

Synonyms

Risk assessment

Definition

Risk analysis consists of risk assessment, risk management and risk communication. ► Food safety risk

assessment is a process of identifying food borne hazards, assessing risks, gauging severity and potential health effects. Through risk assessment the likelihood of an undesirable event occurring and the consequences of this event are estimated. The mathematical model for calculating the probability of an undesirable effect occurring and the magnitude of the impact of the hazard are calculated. Risk management is a process of regulating the risks to acceptable levels. Risks should be transparently communicated to the public and they should be educated on how to avoid food borne diseases.

Cross-References

► Risk Assessment

Risk Assessment

SRĐAN BORJANOVIĆ
Institute of Occupational Health, Belgrade, Serbia
drsrle@sezampro.yu

Definition

A risk assessment is a systematic procedure to identify potential health hazards, evaluate the extent of exposure and to establish the need for, and effectiveness of existing control measures. It is an organized look at what, in work activities and the workplace, can cause harm to employees. In the context of occupational health, risk assessment is the process of quantifying the probability of a harmful effect to individuals or populations from certain activities at the workplace.

Basic Characteristics

Determination of Risk

The risk assessment is a part of four interrelated activities including risk research, risk management and risk communication. The concept of the risk assessment is not new – we make decisions about risks in our daily lives. What is new is the shift from concern for immediate hazards with readily discernable linkages between a specific hazardous situation and an adverse outcome to situations where there are only probabilistic linkages between exposure to an agent and the occurrence of an adverse effect over a long period of time.

Risk assessment estimates the risk to humans of a specified hazard, based on the availability of exposure data. There are two commonly used terms associated with risk assessment. They are hazard and risk. A ► hazard is a source of potential harm. A ► risk is the likelihood that exposure to a hazard will result in injury or disease. The outcome is the result of when the hazard causes harm. Mathematically, the level of risk can be viewed as a function of: probability x severity of impact. Hence, risk assessment is measuring two quantities of the risk, the magnitude of the potential harm, and the probability that the harm will occur. The difficulty of risk assessment is that measurement of both of the quantities in which risk assessment is concerned can be very difficult itself. Uncertainty in the measurement is often large in both cases. Also, risk assessment would be simpler if a single metric could embody all of the information in the measurement. However, since two quantities are being measured, this is not possible. A risk with a large potential loss and a low probability of occurring must be treated differently than one with a low potential loss but a high likelihood of occurring. In theory both are of near equal importance but in practice it can be very difficult to choose which one to prioritize.

Risk Assessment Phases

There are no fixed rules about how a risk assessment should be carried out. It will depend on the nature of the undertaking and the type and extent of the hazards and risks. Various models for conducting occupational health risk assessment provide step-by-step guidance and assist in producing risk assessment reports. In particular, a risk assessment should:

- ensure that all relevant hazards and risks are addressed, with the aim of identifying significant risks in the workplace;
- address what actually happens in the workplace, including non-routine operations;
- ensure that all groups of employees and others who might be affected are considered;
- identify groups of workers who might be particularly at risk (women and young workers are of special concern);
- take account of existing preventive measures

Risk assessment should be performed by competent occupational safety and health professionals with appropriate theoretical and practical knowledge and

experience of relevant systems. To be able to identify all hazards and events, it may be necessary to split them into manageable parts. A risk assessment is performed by considering types of hazards, extent of exposure to the hazard and the relationship between exposures and responses, including variation in susceptibility. In general, risk assessment consists of the following four components:

1. Hazard identification;
2. Dose-Response Assessment;
3. Exposure Assessment;
4. Risk Characterization.

► Hazard identification evaluates the weight of evidence for adverse effects in humans based on assessment of all available data on health impact and mode of action. This step aims to determine the probability that an individual receiving a specific dose of the contaminant (chemical, radiation, noise, etc.) will develop an adverse effect. This is done, for chemical hazards, by drawing from the results of the toxicology and combining them with the data from epidemiological studies. The appropriate pathways and route of exposure are established for each chemical, its effect on body tissues and the type of effect. For different kinds of hazard other disciplines are involved. The complexity and uncertainty of this step derives mainly from the need to extrapolate results from experimental animals to humans, and from high to lower doses. The hazard may be higher for particular groups, called the susceptible populations, due to their special vulnerability to a given contaminant, greater exposure, age, sex or genetics.

The ► dose-response assessment identifies the relationship between the exposure level and the magnitude of risk. It determines whether the adverse effect increases with increasing exposure to the hazard. The result of the dose-response assessment provides either a reference dose or a threshold limit value (TLV), below which the threshold contaminant is expected to pose little or no hazard, or a risk-specific dose below which a non-threshold contaminant poses a tolerably low probability of an adverse effect. These respected values are referred to as exposure limits.

The exposure quantification determines the amount of a contaminant (dose) that individuals and populations will receive. This is done by examining the results of the ► exposure assessment. The exposure assessment determines how much exposure causes how much of a given effect in how many of the exposed persons. As different location, workload, lifestyles and other factors likely influence the amount of contaminant that is received, a range of possible exposures for different exposure scenarios and different subpopulations is generated in this step. Typical exposure is also determined. Particular care is taken to identify the magnitude of exposure for those groups that are either particularly vulnerable to a contaminant (e. g. children to lead and methyl mercury) or that are expected to be exposed to higher levels than the rest of the population.

The results of the previous three steps are then summarized and integrated into quantitative and qualitative characterizations of risk.

Risk Characterization

A ► risk characterization is the final step in risk assessment. It is the estimation of the incidence and severity of the adverse effects due to actual or predicted exposure including risk estimation or calculation, i. e. the quantification of that likelihood. The calculation of the risk is made by combining the severity of consequence with the likelihood of occurrence in a risk rating matrix. This can be expressed mathematically as a quantitative assessment (by assigning low, medium and high likelihood and severity with integers and multiplying them to give a risk factor), or as a description of the circumstances by which the harm could arise i. e. qualitative (Table 1). Risks that fall into the 'unacceptable' category (e. g., high severity and high probability) must be mitigated by some means to reduce the level of safety risk.

Risk acceptance criteria are an important part of safety management and reflect the targeted safety level. They should be established prior to performing risk assessment analysis. The results of risk assessment are then compared with established risk acceptance criteria to determine whether the risk level is acceptable or not. Occupational health professionals may be tempted to

Risk Assessment, Table 1 Risk rating matrix

	Probability		
Severity	**1**	**2**	**3**
3	MEDIUM	HIGH	HIGH
2	MEDIUM	MEDIUM	HIGH
1	LOW	MEDIUM	MEDIUM

6,9: High Risk; 2–4: Medium Risk; 1: Low Risk

advocate the adoption of a zero-risk policy. Although in some cases risk can be eliminated, in most cases a certain degree of risk must be accepted. Some accepted degrees of risk are specified by laws, regulations and standards and may change as knowledge of the risks grow and safety techniques improve. Some risks we accept as part of normal living. Most would consider such conditions to be 'safe'. Other risks we tolerate because we consider the benefits outweigh the risks (e. g. driving a car). Some risks are considered intolerable and most would consider conditions 'unsafe'. The region in between the unacceptable and the broadly acceptable level of risk is where the risks need to be reduced as low as reasonably practicable (ALARP). In the interest of occupational and environmental health, the risks vs. costs and benefits of the possible alternatives must be carefully considered. In practice however, a true zero-risk is possible only with the suppression of the risk-causing activity. Until technological developments offer superior methods, the choice based on risk assessment must be that of the lesser evil.

The risk assessment is a dynamic process and should be reviewed periodically and whenever there is a significant change to work practices. This is an ethical and legal responsibility of both industry and government.

Risk-Benefit Analysis

Definition

Risk-benefit analysis is the comparison of the risk of a situation to its related benefits. For research that involves more than minimal risk of harm to the subjects, the investigator must assure that the amount of benefit clearly outweighs the amount of risk. Only if there is a favorable risk-benefit ratio may a study be considered ethical. The Declaration of Helsinki, adopted by the World Medical Association, states that biomedical research cannot be done legitimately unless the importance of the objective is in proportion to the risk to the subject. The Helsinki Declaration and the ► CONSORT-statement stress the importance of a favorable risk-benefit ratio.

Risk-Benefit Evaluation

Definition

Prior to medical experiments or clinical trials, the potential risks and benefits for the participants have to be analyzed and evaluated. Depending on the medical condition to be treated, different risks may be taken depending on the potential benefit. For instance, it is obvious that a substance or procedure intended to treat a headache after a social event and a substance or procedure intended to cure leukemia have to be evaluated differently because the risks of both conditions differ so widely.

A risk–benefit evaluation has to be updated as new data become available (e. g. after each adverse reaction occurring during a trial, because as this may increase the potential risk it has to be ensured that the potential benefit of the procedure still outweighs the new risk status).

Risk Characterization

Definition

A risk characterization combines information on exposure and toxicity to estimate the risk of a particular substance in a particular situation. The risk characterization step combines the information on toxicity and exposure

to describe what is likely to happen to people. It is the estimation of the incidence and severity of the adverse effects due to actual or predicted exposure including risk estimation or calculation, i. e. the quantification of that likelihood.

Risk Determinant

Synonyms

Risk factor

Definition

Any aspect that may increase the chance of developing a disease.

Risk-Equivalent Premiums

► Risk-Related Premiums

Risk Factor

Synonyms

Determinant of disease

Definition

A risk factor is an aspect of behavior or life-style, such as an habitual pattern of diet, exercise, cigarette and alcohol use, etc., or a biological characteristic, an inborn or inherited characteristic, or a health-related condition or environmental exposure with predictable effects on the risk of disease due to a specific cause, including in particular an increased likelihood of an unfavorable outcome. Another meaning of this term is that a risk factor is a determinant of disease that can be modified by specific actions, behaviors, or treatment regiments. Risk factors can be categorized as genetic, physiological, behavioral and socioeconomic characteristics of individuals that place them in a cohort of the population that is more likely to develop a particular health problem or disease than the rest of the population. Usually applied to multifactorial diseases for which there is no single precise cause, they have been particularly useful in identifying candidates for primary preventive measures and in assessing the effectiveness of the prevention program in controlling the risk factors being targeted. A risk factor may be directly related to disease outcomes (proximal risk factor) or may have indirect effect on outcomes (distal risk factor).
Risk factor is clearly defined occurrence or characteristic that has been associated with the increased rate of a subsequently occurring disease. Risk factors are defined as factors influencing health in a way that causes health impairment. Risk factors may be genetic (e. g. inherited susceptibility to certain ailments) (► disease, ailment), psychologic (e. g. psychosomatic illness), behavioral (e. g. smoking, etc.), socioeconomic status (e. g. hygiene, proper nutrition, clothing, availability and accessibility of ► health care), environmental (e. g. different types of pollution), etc.

Cross-References

► Risk Determinant
► Risk Marker

Risk Factor Information System

Definition

The risk factor information system is a new branch of ► health information system designed to produce estimates of risk factors leading to serious diseases, injuries, and death. Risk factor information systems support public health practice by assessment of population health, and comparisons across states and geographic regions over time. Risk factor systems focus on factors such as smoking, environmental risk factors, nutrition, behavioral risk factors, some health conditions, etc. They provide information for implementation of prevention programs and monitoring of the impact of public health prevention programs on a national level.

Risk Factors and High Risk Groups

CHRISTIAN HIRSCH
Abteilung für Kinderzahnheilkunde und Primärprophylaxe, Poliklinik für Kieferorthopädie und Kinderzahnheilkunde, Universität Leipzig, Leipzig, Germany
christian.hirsch@medizin.uni-leipzig.de

Synonyms

Causal factors; Etiological factor; Risk indicator

Definition

In dentistry a risk factor is a variable associated with an increased risk of an ► oral disease. However, risk factors are not necessarily causal. Risk factors include aspects of a person's condition (genetics), lifestyle or environment. Various combinations of risk factors lead to the disease. The more risk factors are involved in the disease process the more complex is the etiology of the disease. Risk factors with dental public health importance should contribute a considerably attributable risk for the disease process and should be modifiable by public health measures. Subjects of high risk groups show more often such patterns of risk factor combinations which lead to an earlier disease onset and – in consequence – to a higher disease prevalence.

Basic Characteristics

Specific or Common Risk Factors for Oral Diseases

For a long time research in dentistry was aimed at specific biological risk factors (bacterial or micro-structural causes) for oral diseases. The reason was to clear up the etiology of these diseases. For the most prevalent chronic oral disease – ► dental caries – the following specific risk factors are known: plaque accumulation on the teeth and frequent intake of simple sugar (instead of complex carboanhydrates). The production of organic acids in ► plaque leads to the demineralization of dental hard tissue (enamel). In an early stage, this process can be reversed (re-mineralization) by continuous plaque removal (tooth brushing, flossing). The bacterial plaque also damages the ► periodontium – initially by an inflammation of the gum (► gingivitis) followed by the chronic destruction of the attachment apparatus (► periodontitis). The etiopathogenetic mechanisms of this process in relationship to the genetic and immunological background are not fully clear in detail. However, it is well known that the destruction of the attachment apparatus can be reduced by continuous plaque and ► calculus removal.

Current research in dentistry is more directed towards a wider risk concept including biological and psychosocial determinants. It became obvious, that a core group of modifiable risk factors is common to many chronic diseases and injuries. The four most prominent noncommunicable chronic diseases (NCDs) – cardiovascular diseases, diabetes, cancer and chronic obstructive pulmonary diseases – share common risk factors with oral diseases, preventable risk factors that are related to lifestyle. For example, dietary habits are significant to the development of NCDs and influence the development of dental caries. Tobacco use has been estimated to account for over 90% of cancers in the oral cavity, and is associated with aggravated periodontal breakdown, poorer standards of oral hygiene and thus premature tooth loss (Petersen 2003).

Available data from population based studies show, that lifestyle problems as well as chronic (oral) diseases are more prevalent in disadvantaged and socially marginalized populations. Members of these social strata are characterized by:

- an unhealthy and risky lifestyle (smoking, obesity, frequent alcohol consumption, more violence),
- inability to change unhealthy behavior (because it often results in only a brief need satisfaction),
- bad oral hygiene (no daily tooth brushing, no flossing, no use of fluorides),
- bad self-assessment of health (oral and general),
- non-participation in prevention programs even if they are free of charge,
- low social support (unemployment, difficulties in family, migrants),
- no resources for rehabilitation.

The consequence is a higher prevalence of oral diseases in these subjects. That is the case for all oral diseases with public health importance: dental caries, periodontal diseases, oral cancer, and dental trauma (Daly et al. 2002). The poorer oral health of disadvantaged and socially marginalized subjects becomes manifest in early childhood and youth and is present for the whole life (Micheelis and Reich, 1999).

Problems with Prediction of Risk and Risk Groups

There has been an intense search for risk indicators for oral diseases in the past. However, because of the complex etiology of chronic oral diseases it is difficult to predict the disease in an individual subject using an isolated risk factor. Sensitivity, specificity, and predictive values are not sufficient. Only a certain probability for the onset of a disease can be given if a risk factor is present. Ultimately, the use of a dentist's clinical judg-

ment to identify people at risk of oral diseases has been shown to be as good as other selected methods because it includes not only aspects of the oral situation, but also aspects of lifestyle and environment (Kay 1999).
Moreover, the care of risk groups requires a clear risk definition. However, the definition of risk factors and risk groups is context-sensitive. An example might be the changes of "risk definition" for dental caries against the backdrop of caries decline: In the past 10 years of the last century a mean caries index (► DMFT-Index: number of decayed, missed, and filled teeth) of 4 was considered as "normal" for 12-year-olds in Europe. Today – the mean caries index is between 1 and 2 – such a child belongs to the high risk group with "need" of special care. The question is whether all subjects or only the risk groups should be included in prevention programs? In the end, the care of risk groups is limited by the available resources in the health care system.

Risk Groups for Oral Diseases

There are specific risk groups for oral diseases:

- In industrialized countries up to 10% of infants and preschool children suffer from the so-called ► nursing-bottle-tooth-decay (a special type of early childhood caries) caused by long-lasting use of baby bottles with sweet content and sugar-rich diet.
- Dental caries occurs mainly in disadvantaged and socially marginalized populations (Micheelis and Reich 1999; Pieper 2004). Caries risk subjects have less ► fissure sealants compared to others. They also have more orthodontic problems and dental trauma due to less frequent orthodontic treatment and a more risky lifestyle.
- Periodontal diseases occur more often in smokers and in subjects with poor general health.
- People with frequent tobacco and alcohol use show an increased risk for oral cancer.
- Physically disabled and mentally handicapped subjects as well as immobile subjects show a higher risk for oral diseases.

Special Care for Risk Groups

To improve oral health of risk groups the following specific measures are useful in addition to common preventive measures for the whole population:

- giving specific information to risk groups (for example information about nursing caries and fluoridation to pregnant women and young parents with low socioeconomic status),
- taking care of risk groups in special settings (family welfare service, fluoridation programs in schools of poorer communities, organized dentist visits to old-age-homes, special care for periodontal conditions in immunosupressed patients etc.),
- reducing the barriers for participation of risk subjects in prevention programs,
- making risk subjects "regular attenders" in dental practices and establish a monitoring for risk groups (for example for handicapped subjects or those with precancerous changes of oral mucosa).

Conclusion

The care of risk groups in dentistry should be directed to the change of their unhealthy and risky behavior. This can be successful on the individual level which is often observed in daily practice. Lower plaque indices and less bleeding gum show that tooth brushing exercises are useful to improve oral health in youth. However, the non-participation of risk subjects in individual and community prevention programs limits the wide success of that approach. Therefore, it seems more useful to influence common risk factors for oral diseases related to lifestyle and environment. A major benefit of the common risk factor approach is the focus on improving health conditions for the whole population as well as for high risk groups, thereby reducing inequalities.

Risk Identifying

Synonyms

Risk analysis

Definition

Risk identifying is a scientific tool for identifying and evaluating the potential health hazard posed by exposure of humans to physical, chemical and/or biological entities present in the environment; such as that of a school building contaminated with PCBs (polychlorinated biphenyls). In order to gain this information, risk analysis includes such varied research methods as toxicological animal trials, epidemiological surveys, exposure modeling, etc. In addition to assessing acute exposure, risk analysis also is used to predict and compare risks (e. g., prospective testing for potential hazards posed to human health and the environment). Amongst others, the results are used to set threshold values, standards and reference points for environmental toxins. Furthermore, risk assessment also provides a scientific basis for political decisions relating to the environment and public health, and hence risk management.

The usual problem with risk assessment is that it is restricted by the data available and methodological limitations. A further problem is that for the most part, only the adverse effects of single substances (such as anthropogenic chemicals) in the various parts of the environment are known, while the effects of combinations – which comprise most types of exposure – remain largely unknown. Scientific risk assessment can therefore never eliminate a residual risk, especially regarding particularly susceptible groups (e. g., children, pregnant women), thus allowing only a partial assessment of the actual health risk.

School of Medicine,
Andrija Stampar School of Public Health,
University of Zagreb,
Zagreb, Croatia
jmustajb@snz.hr

Synonyms

Safety management; Hazard management; Hazard reduction; Hazard information; Guidance sheets

Definitions

Risk Management is the process of minimizing risk to an organization by developing systems to identify and analyze potential hazards in order to prevent accidents, injuries, and other adverse occurrences; and by attempting to handle events and incidents which do occur in such a manner that their effect and cost are minimized. Effective risk management has its greatest benefits in application to insurance in order to avert or minimize financial liability.

Communication is the transfer of information regarding workplace exposure to toxic substances from employer to workers.

Basic Characteristics

History

In the early 1970s, basic principles about occupational risks had been regulated and managed. In the late 1970s, the trend for managing risk at work was to merge and centralize the authorities responsible for occupational health and safety, and to clarify responsibilities in criminal law for managing risks in particular circumstances through the establishment of regulatory regimes, whereby broad general duties are explicitly put on those who are best placed to do something about preventing or controlling the risks. The broad duties are supplemented by specific regulations. Many of these regulations place absolute duties on the duty holders: on employers, the self-employed, employees, designers, manufacturers, importers, suppliers, and people in charge of premises. Associated legislation places additional duties on owners, occupiers, licensees, and managers. However, in order to avoid the imposition of duties that no one can fulfill – because absolute safety cannot be guaranteed – and in order to ensure that preventive and protective actions are commensurate with the risks, others, like broad general duties are qualified by expressions such as 'as low as reasonably achievable' (ALARA), 'as low as reasonably practicable' (ALARP), and 'so far as is reasonably practicable' (SFAIRP).

Many workplace chemicals and other substances are referred to only by brand names or code numbers. The ► right-to-know movement, initiated in the late 1970s in many countries, resulted in development of right-to-know laws in the early 1980s, which are the legal rights and obligations that govern the transfer of workplace information on toxic substances (communication). According to those laws, employers have a duty to inform workers of the identity of substances with which they work through labeling the product container, and the workers should be counseled on the importance of personal hygiene and the use of protective equipment to reduce exposure.

In 2004, a Global Implementation Strategy was established under the auspices of the ► International Programme on Chemical Safety (IPCS). This Global Implementation Strategy aims to build and implement an Occupational Risk Management Toolbox, containing toolkits to manage different workplace hazards. The first such toolkit is the ► International Chemical Control Toolkit.

Risk Management and Communication Scope

The terms hazard and risk are used interchangeably in everyday vocabulary. Risk Management involves the employer looking at the risks that arise in the workplace and then putting sensible ► health and safety measures in place to control them. By doing this they can protect their most valuable asset, their employees, from harm, as well as members of the public. The law requires an employer to assess and manage health and safety risks. There are three basic steps in managing the risk from workplace hazards: eliminate hazards, control the hazard, and protect workers from the hazard.

There are a number of tools used in risk management: ► environmental engineering, ► economic analysis in toxic substances control, and ► pollution prevention hierarchy.

Communication is the transfer of information regarding workplace exposure to toxic substances from employer to workers. It is mandatory sharing between management and labor, and mandates that workers receive training and information on all potentially hazardous chemicals with which they work. They provide information through ► material safety data sheets as the foundation of a successful safety and health program, which can be on paper and/or in electronic form.

The Chemical Toolkit of the Global Implementation Strategy is available on the Internet through the ILO SafeWork Website. The hazard information employed by the Toolkit is either European Union (EU) label Risk (R) phrases or the hazard statements of the Globally Harmonized System for Classification and Labeling (GHS). The target for global implementation of the GHS is 2008.

Risk Marker

Synonyms

Risk factor

Definition

An aspect of personal behavior or lifestyle, an environmental exposure, or an inborn or inherited characteristic, which on the basis of epidemiological evidence is known to be associated with health-related condition(s) considered important to prevent. Not necessarily a causal factor but an indicator of an increased probability of occurrence of a disease or other specific outcome–a risk marker.

Risk of Natural Disasters

► Hazards, Natural

Risk Perception

Definition

Subjective judgment that people make about risk, including its severity and characteristics.

Risk and Protective Factors of Psychological Health and Well Being

► Health Determinants, Psychological

Risk Ratio (RR)

Synonyms

Relative risk

Definition

The *Relative Risk (RR)* of an event, such as the occurrence of a specified disease or a death from a specified cause, is the ratio of the risk of a disease or death among those exposed to a specified factor to the risk among those not exposed to this factor. It is calculated from the incidence of the specified disease or the death rate due to the disease.

If the level of risk in both the exposed and unexposed group is the same, the RR will equal 1. If an exposure is harmful (e. g., cigarette smoking), the RR is expected to be greater than 1. If an exposure is protective (e. g., vaccine), the RR will be less than 1. The RR is used in randomized controlled trials and cohort studies.

The RR is less relevant to making decisions in risk management than attributable risk. Nevertheless, relative risk is the measure of association most often used by epidemiologists.

► Mitigation Strategies

Risk-Related Premiums

Synonyms

Actuarially fair premiums; Risk-equivalent premiums

Definition

Health insurers calculate risk-related premiums if expected health care expenditures of individuals are equivalent to premiums paid by individuals. As a consequence, high-risk individuals pay higher premiums than low-risk individuals.

Risk Sharing Plans

Definition

The distribution of financial risk among two or more parties furnishing a particular service. By establishing a formal arrangement between health care providers, managed care organizations and another entity such as a governmental health care program, these plans protect the parties from excess risk.

Risk Solidarity

Definition

The term risk solidarity refers to redistribution from individuals with low health risks toward individuals with high health risks.

Risk Solidarity, ex-ante

Definition

Ex-ante risk solidarity implies redistribution from those individuals who are expected to be healthy to those who are expected to be sick.

Risk-Solidarity, ex-post

Definition

Ex-post risk solidarity implies that there is limited redistribution from the unexpectedly healthy towards the unexpectedly sick.

River Blindness

► Onchocerciasis

Role Taking

Synonyms

Perspective taking

Definition

A mental process that enables an individual to understand the point of view of another person or group of people. Specifically, role taking allows the individual to understand why others have certain attitudes and beliefs, and why others behave as they do. To accomplish role taking, the individual imagines himself or herself as that person (or group of people). A key period for the development of role taking abilities is between the ages of 4 to 12 years, and role taking is vital to the development of social skills.

Root

Definition

The root is the invisible part of the tooth that anchors the tooth in the jaw. Inside every root, there is a root canal with nerves, blood vessels, and connective tissue.

Root Canal

► Root

Root Canal Treatment

Synonyms

Endodontic treatment

Definition

Inside each tooth is the pulp consisting of blood vessels, nerves, and connective tissue. When the pulp is infected or injured, the pulp tissue dies. During a root canal treatment, the pulp is removed, the pulp cavity is cleaned and sealed using a root filling.

Rubella

Synonyms

German measles; Three-day measles

Definition

Rubella is a common communicable disease of childhood, which is spread by oral droplets; humans are the only natural hosts. The incubation period lasts 14–21 days, and it has to be assumed that it remains contagious for seven days before and seven days after the appearance of the rash. Rubella's exanthem is maculopapulous. It starts in the face and spreads quickly. Furthermore, there is a lymphadenopathy, which is typically located behind the ears (retrooauricular), in the neck (posterior cervical) and at the back of the head (postoccipital). In most cases there is only a mild elevation of body temperature. In up to 50% the course of the infection is asymptomatic. An arthritis can appear, further complications (encephalitis, thrombocytopenic purpura) are rare. An infection during pregnancy has to be feared as the transmission of the virus to the unborn child can cause severe congenital anomalies, the ► congenital rubella syndrome. Rubella infection can be prevented by an active rubella-vaccination (► immunization, active).

Rubella Vaccination

Synonyms

Rubella immunization; German measles immunization; German measles vaccination; Three-days measles vaccination; Three-days measles immunization

Definition

The course of rubella is harmless for the patient, both in childhood and in adulthood. However, if the first infection occurs during pregnancy, it represents a great threat to the embryo. For this reason, the number of rubella antibodies (antibody titer) in women in the early stage of pregnancy is checked in order to determine their immunity to rubella. The rubella vaccination was introduced in 1969/1970. Nowadays, it is generally applied in combination with the vaccination against measles and mumps (MMR). The patient receives the first inoculation at a minimum of 11 months of age and a second vaccination at an interval of at least 4 weeks later. The protection rate is 95%. Contraindications for rubella or MMR vaccination are immunodeficiency, acute illness with fever, pregnancy and a known severe allergic reaction to components of the ► vaccines or the carrier protein.

Rubella Vaccination, Passive

Synonyms

Application of rubella immune globulin; Rubella immune prophylaxis; Application of German measles immune globulin; German measles immune prophylaxis; Three-day measles immune globulin; Three-day measles immune prophylaxis

Definition

In general, German measles is an infectious disease with a harmless course, but for unborn babies in the womb it is very dangerous. Prenatal infection can lead to the congenital rubella syndrome (CRS or Gregg's syndrome), which is associated with low birth weight, deafness, cataract and heart defects. At the beginning of a pregnancy the woman's immune status against rubella is checked by determination of the amount of ► antibodies (titer). In the case of a low or a missing immune status a passive rubella vaccination should be given when the pregnant woman has come into contact with German measles.

Rubeola

Synonyms

Rubella; Measles

Definition

Measles or rubeola is a highly contagious disease of young children, caused by a virus and spread by droplet spray from the nose, mouth, and throat of individuals in the infective stage. This period begins 2 to 4 days before the appearance of the rash and lasts from 2 to 5 days thereafter. The first symptoms of measles, after an incubation period of 7 to 14 days, are fever, nasal discharge, and redness of the eyes. Characteristic white spots appear in the mouth, followed by a rash on the face that spreads to the rest of the body. The symptoms disappear in 4 to 7 days. One attack of measles confers lifelong immunity. Complications are possible such as bronchial pneumonia and encephalitis. Common measles in pregnant women can be a threat to the unborn child, and ► vaccination of women well before pregnancy is recommended. Immunization by injection of live measles-virus vaccine.

Sackett, David

Definition

As the founder of Canada's first department of clinical epidemiology at McMaster University in Hamilton, Ontario in 1967, Dr. Sackett has made significant contributions to how we measure the presence of diseases in populations, and in particular how we assess the effectiveness of various forms of treatment. By employing precise models and innovative approaches, Dr. Sackett has emphasized the importance of clinical trials and other forms of objective evidence in evaluating what the various possible forms of treatment accomplish, and how they can be made more effective for the patient's benefit. His textbook "Clinical Epidemiology: A Basic Science for Clinical Medicine" has gone through several editions and is a classic in the field.

SAE

Definition

SAE is an abbreviation for serious adverse event. Adverse events are undesirable experiences associated with the use of a medical product (drug or device) in a patient. Such events are classified as serious if the event meets at least one of the following criteria:

- death of the patient;
- life-threatening (substantial risk of dying, or suspicion that continued use of product would result in the death of the patient);
- hospitalization (due to the event, or prolonged stay in hospital due to the event);
- disability (events resulting in a significant, persistent or permanent change, impairment or damage in the patient's body function or quality of life);
- congenital anomaly (adverse outcome in a child due to exposure to the medical product prior to conception or during pregnancy);
- requires intervention to prevent impairment or damage (use of the medical product results in a condition which requires medical or surgical intervention to preclude permanent impairment or damage to the patient).

Serious adverse events should be reported to the competent authorities (e. g. FDA in the US).

"A Safe Place to Suffer"

Synonyms

Palliative medicine; Palliative care; Hospice

Definition

Hospice and palliative care may not be described by anything better than by the term 'a safe place to suffer.' This expression was first used in 1987 by Averil Stedeford a psychiatrist working at a hospice in Oxford, UK in order to illustrate palliative care (place = relationship between a patient and his person in charge; suffer = rest distress after palliative help).

Salary

Definition

In salaried payment systems, the physician is paid for units of time. Remuneration is independent of the volume of services and independent of the number of patients. Salaried providers work within a defined schedule; in some countries, they are allowed to treat patients privately after hours. Physician income is determined by the content of the employment contract. Salaries mostly depend on the physician's qualification and his or her task profiles and provide a high degree of income security to physicians.

Saldana

► Leishmaniasis, Cutaneous

Salutogenic

Synonyms

Health generating; Health creating

Definition

This is a composite word coined by the medical sociologist, Aaron Antonovsky. In seeking to reorient health professionals from a ► pathologising approach to the discussion of health related issues and processes, he chose a Latin word for health, *salus*, and a Greek word for generation or origin, *genesis*. The combination resulted in the word *salutogenesis*, or health generation. The adjectival form, *salutogenic*, emphasizes the health generating propensities of processes and mechanisms.

Sample

Definition

A set of subjects or objects from a population. For a sample to be useful in drawing inferences about the larger population from which it was drawn, it must be representative of the population. Thus, typically (although there are exceptions), the ideal sample to employ in research is a random sample. In random sampling, each subject or object in the population has an equal likelihood of being selected as a member of that sample.

Sample Size

Definition

The sample size represents the number of persons who should be included in the ► experimental study before the investigation commences. The sample size should be large enough to keep the chances of statistical errors low. Several factors are considered in the calculation of sample size. For dichotomous outcome studies, these factors are event rate in the control group, expected benefit from the intervention, level of adherence to the control regimen, alpha level, and power. For continuous outcome studies, the mean and variance of the control and intervention groups, plus the level of adherence, alpha level, and power are the relevant variables.

Sample Size Calculation

► Sample Size Determination

Sample Size Determination

Belgrade, Serbia
nika4@eunet.yu

Synonyms

Sample size calculation

Definition

One of the major steps in research design is sample size determination, meaning determination of the exact number of subjects (i. e. sizing the ► sample as necessary for reaching the expected ► research goal). The quality of the estimate ultimately depends on the quality of the information used to derive it. Care should be taken to avoid overestimating the likely event rate and the feasible effects of treatment.

Basic Characteristics

To make this crystal clear from the very beginning, the "magic number" as an optimal size of a sample simply does not exist. The optimal number depends on the research characteristics and the characteristics of the ► population used as the sample source. These demands can be summarized as follows:

1. Measuring or using knowledge of the outcome variable's variability (► outcome research variable)
2. Identifying the research aim (whether it is regarding estimation of a population ► parameter, p, or a combination of parameters, $p_1 - p_2$, or hypothesis testing regarding a parameter or a group of parameters)
3. Establishing the size of the effect, i. e. conciliating statistical and research (problem-based, medical) significance, and
4. Whether the issue at stake is ► repeated measurements or not?

Variability of the Outcome Variable

Measuring ► variability usually encompasses a practical assessment of the real variability of the outcome variable (σ), irrelevant of the statistical procedure: estimation of a population parameter or hypothesis testing.

Example

Effects on subjects' heart rate (defined as beats per minute, bpm) were tested for two drugs (A and B). Five subjects were given drug A and another five were given drug B, and their results were:

Drug A: 55, 55, 55, 55, 55
Drug B: 60, 60, 60, 60, 60.

It can easily be concluded that the average heart rate in subjects taking drug A was lower than that of those taking drug B.
In reality, these values will never be obtained, therefore the second possible scenario could be:

Drug A: 59, 51, 60, 50, 55
Drug B: 56, 49, 60, 71, 64.

In both cases, the mean value derived from the Drug A group is 55 bpm and that from the Drug B group is 60 bpm. Of course, in the case of the latter, it is more difficult to state whether there is a real difference in heart rate in subjects treated with Drug A or Drug B. The variability of the value itself blurs the possible existence of the real difference between the two.
Generally, the greater the variability of the outcome variable, the harder it is to answer certain research questions, meaning that the relationship between variability and sample size is directly proportional. If the variability of the population is unknown – which is practically a rule – it is acquired through available literature or from pilot studies. If a pilot study is the case, the following approximation is recommended:

$$\sigma \approx (\text{max value} - \text{min value})/4\,,$$

where σ is the standard deviation in the population; the denominator can be 6 instead of 4, although rarely.

Estimation of a Population Parameter

The research aim is often an estimate (► estimation) of one or more parameters or their linear combination. Research aims of this type include estimating the mean length of treatment for myocardial infarction (μ), estimating the mean difference ($\mu_1 - \mu_2$) of heart rate values in subjects receiving the same drug in different doses, and estimating the population of patients suffering from multiple sclerosis, etc.
The estimate of parameters is based on ► standard error (SE), which measures the difference of the sample

statistics from the real population parameter. Its relation to sample size is as follows:

SE is proportional to $1/\sqrt{n}$.

What the aforementioned shows is that the greater the sample size (n), the lesser the standard error. Furthermore, SE is inversely proportional to the square root of the sample size, meaning that by doubling the sample size, standard error is reduced only by the factor that is the square root of 2, i. e. 1.41. Similarly, a nine-fold increase of sample size is followed by only a triple-size increase in the sample error.

In any case of parameter estimation, the researchers have to determine point estimation and interval estimation (confidence interval) when they wish to determine the ► probability level – accuracy and precision. The width of the interval estimate, together with the knowledge of the variability of the outcome variable, determines optimal sample size.

Determining the number of subjects required is done by calculations using the aforementioned formulas or, more often, using particular tables, depending on what is estimated: the population proportion (π), difference of population proportions ($\pi_1 - \pi_2$), population mean (μ) or difference of $\mu_1 - \mu_2$ (actually, the most frequent mean difference of the outcome variable between the two factor categories). Naturally, together with these, there are also other population parameters: cross relation in case-control research, relative risk, incidence, size effect, etc.

Example

Determine the sufficient number of subjects for estimating the proportion of diabetics in a given population.

The following formula can be used:

$$n = \left(Z^2_{1-\alpha/2} \times \pi \times (1-\pi)\right)/E^2.$$

First, it is assumed that the proportion of diabetics in the entire population is roughly 3%, and the solutions for various confidence levels and different estimate precision are provided:

1. We choose $E = 0.5\%$ for the assumed proportion of the entire population. For an accuracy of 95%, $z = 1.96$:

$$n = \left(1.96^2 \times 0.03 \times (1-0.03)\right)/0.005^2 = 4472$$

2. For $E = 2\%$ and $z = 1.96$, we get the following:

$$n = \left(1.96^2 \times 0.03 \times (1-0.03)\right)/0.02^2 = 279$$

3. For $E = 1\%$ and $z = 2.575$ (99% accuracy), we get the following:

$$n = \left(2.57^2 \times 0.03 \times (1-0.03)\right)/0.01^2 = 1922$$

Consequently, the change of estimate precision from 0.5% to 2% diminished the sample size from the initial 4472 to 279, while the change in confidence level from 0.95 to 0.99 changed the sample size from 279 to 1922.

Hypothesis Testing

The research aim can take the form of a question:

Is the frequency of epileptic seizures less in patients taking Drug A or in those taking Drug B?

In this case, the hypothesis involves testing the difference between parameters.

When determining the sufficient number of subjects for the situation of ► hypothesis testing, the key information is provided by:

1. The level of significance (α; or the probability of making a Type I error)
2. β (or the probability of making a Type II error)
3. $1 - \beta$, which is the power of the statistical test.

Prior to beginning the investigations, α and β, which – together with the estimates of variability of the outcome variable – affect sample size, are chosen. The chosen Type I and Type II errors not only influence sample size, but they are important in interpreting the reach of the statistical conclusions. Type I error represents a "false alarm", while Type II error is a "miss".

Reducing the odds of a Type I error is achieved by choosing an acceptable level of significance, α – usually of 0.05 or less. This convention helps the "false alarm" to be reduced to a rate lower than 1/20 (i. e., 5/100). A sole repetition of the finding by independent researchers provides important evidence that the original decision of rejecting the null hypothesis was correct.

Reducing the odds of a Type II error is achieved by increasing the size of the sample, n; reducing measurements' variability; using one-sided testing; and lowering the criteria regarding α.

Example

The difference between parameters π_1 and π_2, meaning μ_1 and μ_2, in a sole test is assessed. In both cases, the researcher decides the size of the difference between the two parameters is worth determining. For example, for a 4% difference, besides the usual values of $\alpha = 0.05$ and $\beta = 0.20$ ($1 - \beta = 0.80$, the power of the test), with the assumption that P_1 and P_2 are 5% and 9%, respectively, using one of the Tables, we determine an n value is 552. Therefore, 552 subjects are necessary for each group to show a 4% difference between the two parameters.

Size Effect

► Statistical vs. Clinical Significance.

Instead of tables, we can use various formulas for sample sizing as shown in Table 1.

Consequently, in a controlled clinical trial aiming to assess the efficiency of a given substance (parallel groups: control group with placebo and experimental group with the substance) in asthma patients, in the procedure of determining necessary sample sizes of the two groups, an accord should be reached regarding the following values:

1. Therapy efficiency – the outcome (measured by the forced expiratory volume of the first second, FEV_1);
2. Clinically relevant difference – of 150 ml minimum when compared to placebo;
3. σ (assumed standard deviation of the outcome) is 420 ml;
4. α (probability of Type I error providing the null hypothesis [H_0] is correct) is 0.05, and
5. β (probability of Type II error providing H_0 is wrong) is 0.2.

Replacing these values in the table's formula, we find:

$$n = 2 \times (1.96 + 0.84)^2 \times 420^2/150^2 = 122.9$$

The result shows that each group should encompass 123 patients.

The numerous formulas from the previous Table are, actually, adequate for getting initial information on the sample size. Practically speaking, there is a myriad of problems one should be bear in mind before applying them. The most common is unknown variability of the outcome, which is usually shown through standard deviation. To evade it partially, a new element of incertitude can be introduced, which is the approximation of the unknown variability with a reasonable estimate derived from previous research and/or pilot studies. The remaining, equally important, issues are lack of standard clinically relevant differences, robustness or sensitivity of the chosen statistical methods, and the arbitrary level of chosen errors' probabilities. Disregarding these, this (classical) approach to sample sizing is used more frequently than the sequential approach, where the sample size is not determined in advance but the measurements and analyses are preformed in sequences (a couple of subjects – each one belonging to a different group) and the procedure is repeated until the null hypothesis for the assigned probabilities is accepted or rejected.

Statistical Software Packages

There are several commercial statistical software packages capable of being used for sample size calculation. They include EGRET-SIZ by Cytel Software Corporation, SamplePower by SPSS Inc., nQuery Advisor by Statistical Solutions, and PASS by Number Cruncher Statistical Systems. Most of the software packages pro-

S

Sample Size Determination, Table 1 Approximate formulas for sample size determination in some empirical situations

Statistical methods for testing the significance of difference between:	Necessary size of a sample (n)
Mean value of a group (e) and standard value (sg)	$[(Z_{1-\alpha/2} - Z_\beta)\sigma/(\mu_e - \mu_{sg})]^2$
Two mean values (e and k)	$2[(Z_{1-\alpha/2} - Z_\beta)\sigma/(\mu_e - \mu_{sg})]^2$
Proportions of a single group (e) and the standard value (sg)	$[Z_{1-\alpha/2}(\pi_{sg}(1-\pi_{sg}))^{1/2} - Z_\beta(\pi_e(1-\pi_e))^{1/2}/(\pi_e - \pi_{sg}))]^2$
Two proportions (e and k)	$[Z_{1-\alpha/2}(2\pi_k(1-\pi_k))^{1/2} - Z_\beta(\pi_e(1-\pi_e)_+\pi_k(1-\pi_k))^{1/2}/(\pi_e - \pi_k))]^2$

where Z is standardized normal value – z score, while σ, μ and π are parameters of the population – standard deviation, mean, and proportion respectively

vide sample size estimates for a broad range of statistical models including tests for means, proportions, analysis of variance, regression, and survival analysis. Other "freeware" may be found in public health service organizations or from individual statisticians.
In all cases, it is important to understand the statistical procedures by which a computer package is calculating the sample size. Otherwise, the calculated sample size can be erroneous and lead to an underpowered or overpowered study.

Sanitation

Synonyms

Sanitization

Definition

Sanitation refers to principles of health preservation, including hygiene on an individual level and public health on a communal level. Sanitation is aimed at elimination or reduction of health hazards associated with the water supply, the collection and disposal of solid and liquid waste, and the prevalence of rodents and insects. It also refers to noise, air pollution, and improper food handling. Disposal of toxic, medicinal or radioactive waste is also important.

SARS

Synonyms

Severe acute respiratory syndrome

Definition

SARS is an infection with the coronavirus, which appeared for the first time at the end of 2002, and which became the first big epidemic of the 21st century, mostly involving China, Hong Kong, Singapore and Canada. Initially, the disease was transmitted from animals to humans by the civet cat, which is a popular food in South China. SARS can also be transmitted between humans by direct contact as a droplet infection. After an incubation period of 2–7 (maximum 12) days the infected person suffers from fever, sore throat, bad cough and difficulties in breathing; an atypical pneumonia develops. Lethality of SARS is about 10%. A specific therapy is not available. Persons with SARS have to be isolated; people who come into contact with the patient should wear protective clothing and use a face-mask. These face masks (covering nose and mouth) can also be used outside of hospitals for infection prophylaxis.

Saved Young Live Equivalent (SAVE)

Definition

The concept of saved young life equivalent attempts to estimate the limitations to the individual by defined changes of health in relation to life expectancy and the quality of life of young people. The concept has not been used in larger empirical studies so far.

SBRI

► Specific Building- and Home-Related Illnesses

SBU

Definition

The Swedish Council on Technology Assessment in Health Care (SBU) is an independent governmental agency promoting the rational use of health care resources in Sweden. It assesses clinical, economic, social, and ethical implications of new and established health technologies. It reviews and synthesizes data and disseminates its assessments widely to help decision-making that promotes the efficient delivery of high quality care. It also houses the headquarters of the International Network of Agencies for Health Technology Assessment (► INAHTA) and European Collaboration for Health Technology Assessment (► ECHTA).

Scabies

Synonyms

Infection with *Sarcoptes Scabiei*; Itch

Definition

Scabies is caused by the mite *Sarcoptes scabiei*. The infection is transmitted by close contact. As the parasites can survive outside their host for about 4 days, transmission can also take place by bedlinen, clothing or soft-toys. While the male mite stays on the surface of the skin, the female parasite penetrates the skin and tunnels into the stratum corneum, where it releases eggs. On the skin, papules and slightly prominent aisles are visible. Besides the genital region, the umbilical area and the nipples are involved as well as the interdigital region of the fingers and the toes. A characteristic symptom is strong itching, especially at night (due to the warmth of the bed); scratching can cause a bacterial superinfection of the affected parts of the skin. Medicinal treatment, which often has to include people in close contact, is performed as a local therapy; lindane, benzylbenzoat (10%), permethrin (5%), crotamiton (10%) or malathion can be used. As a supporting hygienic measure, bedlinen and laundry should be washed at temperatures of at least 60°C. Mites on soft-toys can be killed by freezing or by keeping them in plastic bags for about two weeks.

Cross-References

Scale of Measurement

► Level of Measurement

Scarcity

Synonyms

Limited resources

Definition

The fact that goods are scarce while needs are in principle infinite is the reason why budgeting is necessary. Hence scarcity is the basic axiom of economics, which is concerned with the efficient distribution of scarce resources. The scarcity of resources in the healthcare system calls for prioritization – i. e. the setting of (oral) health goals – and in certain cases also implies the rationing of medical benefits. Decisions on the efficient allocation of resources can be placed on a rational foundation by the use of the models and data of health economics. For instance, the various possible applications of scarce funds can be evaluated by means of the "opportunity cost" approach. The opportunity cost is the value to society of the resources appropriated for a given medical program if they were to be used for an alternative purpose.

Scarity of Resources

Synonyms

► Resource Allocation

Definition

The basic assumption of health economics is that resources for health care are limited (scarcity of resources). From a health care system's perspective or a public payer's point of view, the consequence of that assumption is the necessity to decide where to allocate the resources; or in other words: which health care technologies should be reimbursed and to what extent. One criterion for resource allocation decision making can be cost-effectiveness.

Scarlet Fever

Synonyms

Scarlatina

Definition

Scarlet fever, which is caused by group A streptococci, is spread by droplets. Following an incubation period of 3–4 (–8) days, there is an acute onset with fever, headache, pharyngitis, vomiting and an inflammation of the tonsils. The rash which is fine, red and rough-textured (like sandpaper), appears first on the chest, in the axilla and behind the ears and afterwards generalizes. The cheeks are flushed, the area around the mouth is pale. A characteristic symptom is the inflammation of the papillae of the tongue, called "red strawberry" or "raspberry tongue." Streptococci can be detected by throat culture and treatment consists of antibiotic therapy. Scarlet fever is followed by a desquamation of the skin, which is characteristic on the palm of the hands and the sole of the feet. Possible complications are otitis, myocarditis, arthritis and nephritis. Scarlet fever usually induces immunity, but recurring attacks may occur.

Schistosome dermatitis

Schizoaffective Disorder

Definition

Individuals with schizoaffective disorders show both affective and schizophrenic symptoms. However, the symptoms do not justify a diagnosis of either ► schizophrenia or depressive or manic episodes.

Schizophrenia

Definition

According to ICD-10, schizophrenic disorders are characterized in general by fundamental and characteristic distortions of thinking and perception, and affects that are inappropriate or blunted. Clear consciousness and intellectual capacity are usually maintained although certain cognitive deficits may evolve over the course of time. The most important psychopathological phenomena include thought echo, thought insertion or withdrawal, thought broadcasting, hallucinatory voices commenting or discussing the patient in the third person, thought disorders, negative symptoms, and delusional perception and ► delusions of control, influence or passivity. Paranoid schizophrenias are the most prevalent form; other forms of schizophrenia are hebephrenic (only in adolescents and young adults), catatonic, simple, and residual schizophrenias.

Schizotypal Disorder

Synonyms

Latent schizophrenic reaction; Borderline schizophrenia; Latent schizophrenia; Prepsychotic schizophrenia;

Prodromal schizophrenia; Pseudoneurotic schizophrenia; Pseudopsychopathic schizophrenia; Schizotypal personality disorder

Definition

A schizotypal disorder is characterized by eccentric behavior and anomalies of thinking and affect which resemble those seen in ► schizophrenia, though no definite and characteristic schizophrenic anomalies occur at any stage. The symptoms may include a cold or inappropriate affect; anhedonia; odd or eccentric behavior; a tendency to social withdrawal; paranoid or bizarre ideas not amounting to true ► delusions; obsessive ruminations; thought disorder and perceptual disturbances; occasional transient quasi-psychotic episodes with intense ► illusions; auditory or other ► hallucinations; and delusion-like ideas, usually occurring without external provocation. There is no definite onset and evolution and course are usually the same as those of a personality disorder.

Schizotypal Personality Disorder

► Schizotypal Disorder

Science-Based Medicine

Synonyms

Evidence-based medicine; Evidence-based clinical practice; Evidence-based health care practice

Definition

Evidence based medicine is a term used to denote a recent movement to establish the most effective practice through the use of the scientific method and modern information technology. As the result, standard protocols for diagnosis and treatment are delivered to health care providers.

Cross-References

► Evidence Based Medicine

Scientific Evidence

Definition

Scientific evidence is evidence that serves to either support or counter a scientific theorem or hypothesis. Such evidence is expected to be empirical and properly documented in accordance with scientific methods that are applicable to the particular field of inquiry. Standards for evidence may vary according to whether the field of inquiry is among the natural sciences or social sciences.

Screening

Sandra Šipetić Grujičić
Institute of Epidemiology, School of Medicine, University of Belgrade, Belgrade, Serbia
sandragru@ptt.yu

S

Definition

Screening can be defined "as the presumptive identification of unrecognized disease or defect by the applications of tests, examinations or other procedures which can be applied rapidly. Screening tests sort out apparently well persons who probably have a disease from those who probably do not" (Last 2001).

The aim of the screening test is to detect disease in the preclinical phase (► Preclinical Phase of Disease), when it is more easily curable. A screening test is not a diagnostic test. All persons who screen positive must be referred to their physicians for diagnosis and necessary treatment (Gordis 2004).

Basic Characteristics

Diseases Appropriate for Screening

To be appropriate for screening, a disease should be an important health problem, the treatment should be more beneficial in terms of reducing morbidity or mortality when given before rather than after symptoms develop, the ► natural history of the disease should be well known, and the ► prevalence of the preclinical phase of the disease should be high among the population screened (Miller 2005).

Characteristics of a Good Screening Test

A suitable screening test must be available, inexpensive, quick and easy to administer, impose minimal discomfort on patients, and have good validity and reliability (Webb et al. 2005).

Validity of Screening Test

The validity of a screening test is defined as the ability of a test to distinguish individuals who have a disease, as test-positive, from those who do not have a disease, as test-negative. Sensitivity and specificity are two measures of the validity of a screening test. These two components of validity are determined by comparing the results obtained by the screening test with those derived from some "► gold standard" (Table 1).

Sensitivity is the ability of the test to identify all screened individuals who actually have the disease; it is the percentage of individuals with disease who test positive (Table 1).

Specificity is the ability of the test to identify only disease-free individuals who do not actually have the disease; it is the percentage of individuals without disease who test negative (Table 1) (Gordis 2004).

Screening, Table 1 Sensitivity, specificity and predictive value of the screening test

	EXAMINATION	
Screening test	**Disease present**	**Disease absent**
Positive	A (true positives)	B (false positives)
Negative	C (false negatives)	D (true negatives)
Total	A + C	B + D

Sensitivity (%) = A / (A + C) × 100
Specificity (%) = D / (B + D) × 100
Predictive value (+) = A / (A + B) × 100
Predictive value (–) = D / (C + D) × 100

True Positives

True positives are individuals with the disease who are correctly screened "positive".

True Negatives

True negatives are individuals without the disease who are correctly screened "negative".

The Importance of False Positives

False positives are individuals who screened positive but do not really have the disease. The problems with *false positive results* are firstly that they pose a burden to the health system, and secondly that they cause anxiety and worry in individuals who have been told that they have tested positive.

The Importance of False Negatives

False negatives are individuals who screened negative but actually have the disease.

Individuals with *false negative results* usually start interventions late and, because of that, the ► effectiveness is reduced.

Correlation of Sensitivity and Specificity

An ideal screening test would be 100 per cent sensitive and 100 per cent specific. In practice this does not occur. Sensitivity and specificity are usually inversely related.

The Cutoff Level Between Sensitivity and Specificity

For many screening tests, there are some people who are clearly ► normal, some clearly abnormal, and some who fall into the gray zone between the two. In these situations, the ► cutoff level between normal and abnormal is an arbitrary decision. Lowering the criterion of abnormality will mean that more people who actually have the disease will be test-positive (increased sensitivity), but the number of people who do not have the disease but test positive will also increase

(decreased specificity). Conversely, making the criterion more stringent leads to increased specificity and decreased sensitivity.
One way of addressing the problem of the cut-off between sensitivity and specificity is to use the results of several screening tests together (Gordis 2004).

Predictive Value of Screening

The predictive value of the screening test can be positive or negative. It measures whether or not an individual actually has the disease. *Predictive value positive* is the percentage of individuals who test positive and who actually have the disease. Analogously, *predictive value negative* is the percentage of individuals who test negative and who are actually disease-free. The calculations of these measures are illustrated in Table 1.
The predictive value of a screening test is determined not only by factors that determine the validity of the test itself, but also by the prevalence of preclinical disease. When the prevalence of preclinical disease is low, the predictive value positive will be low even using a test with high sensitivity and specificity (Bhopal 2002).

Reliability (Repeatability) of Screening

The reliability of a screening test is the ability of a measuring instrument to give consistent results when a measurement is repeated under ideal conditions. Two major factors that affect the consistency of the results are the variation of a method and observer variation. The variation of a method depends on such factors as the stability of the reagents used and fluctuations in the substance being measured (e. g. blood pressure). Observer variation can stem from differences among observers (*interobserver variation*) and also from variation in readings taken by the same observer on separate occasions (*intraobserver variation*) (Gordis 2004).
The best quantitative measure for reliability is *kappa*. Kappa is used to measure agreement between two observers. It is defined as the agreement beyond chance divided by the amount of possible agreement beyond chance.

Different Types of Screening

Mass screening (population screening) refers to screening on a large scale, consisting of total population groups.

Selective screening (targeted screening) is applied to subsets of the population who are at high risk for disease or certain conditions as the result of family, age, or environmental exposure.
Multiple screening is defined "as the use of two or more screening tests on a single occasion" (Last 2001). Multiple screening tests can be *sequential (two-stage)* or *simultaneous*. Sequential screening is carried out in stages, and only initially positive individuals undergo the second stage. Simultaneous screening means that two or more tests are used simultaneously to detect disease. The individual is generally considered to have tested positive if he has a positive result for one or more of the tests.
Opportunistic screening is screening of individuals who visited their doctor regarding a condition unrelated to the screening (Gordis 2004).

Study Designs for Evaluation of Screening

A number of epidemiological design strategies are utilized to evaluate the ► efficacy of a screening program, including ► observational studies (such as correlation, case-control, and cohort studies), as well as ► experimental studies.
► Correlation studies are used to examine trends in disease rates in relation to screening frequencies within a population, or to compare the relationship between the frequencies of screening and disease rates in different populations. In ► case-control studies, participants with and without the disease are compared with respect to their past exposure. Using ► cohort studies, the case-fatality rate of those who chose to be screened is compared with the comparable rate among those who were not screened. ► Randomized experimental trials can provide the best and most valid evidence concerning the efficacy of a screening program (Webb et al. 2005).

Biases in Evaluation the Benefits of Screening

Biases (► Bias; ► Confounding and Interaction) of particular relevance to the evaluation of screening are lead-time bias, length/time bias, and selection bias.
Lead-time bias is the perception that the screen-detected case has a longer survival simply because the disease was identified earlier in the natural history of the disease. Lead-time is the period of time from the detection of a medical condition by screening to the

appearance of symptoms. When lead-time is very short (e. g. lung cancer), the treatment of medical conditions picked up by screening is likely to be no more effective than treatment after symptoms appear. On the other hand, when lead-time is long (e. g. cervical cancer), treatment of the medical condition found by screening can be effective.

Length/time bias is an error that occurs because the proportion of slow-growing lesions diagnosed during screening programs is greater than proportion of fast-growing lesions. The effect of including a greater number of slow-growing cancers makes it seem that the screening is more effective.

Selection bias (volunteer bias) is an error due to differences in characteristics between people who are screened and those who are not. In general, volunteers tend to have better health and are more like to comply with medical recommendations. On the other hand, volunteers may represent people who are at high risk of developing the disease because they have anxieties based on a positive family history or lifestyle characteristics. The problem is that we do not know in which direction the selection bias might operate and how it might affect the study results (Gordis 2004).

Secondary Association

Definition

When a factor C and a disease A are associated only because both are related to some common underlying condition B, this is a non-causal type of association. Alteration in factor C will not produce alteration in the frequency of disease A unless the change also affects the common underlying condition B as well.

Secondary Care

Synonyms

Specialized health services; Ambulant or inpatient service

Definition

Secondary care describes all health care services provided by medical specialists generally not having the first contact with patients such as dermatologists, cardiologists, urologists, etc. On referral from ► primary care patients have access to the specialized services in secondary care which are provided either in ambulatory settings or in inpatient services such as emergency rooms, intensive care medicine and surgery services. In some health care systems patients may have direct access to secondary care through specific health insurance, but in most health care systems this direct access is limited due to cost containment reasons. Secondary care does not include highly specialized, technical ► inpatient health care services; those are part of tertiary care.

Secondary Channels

Definition

Secondary channels provide information about primary research documents, and some even contain the documents. The major secondary channels are bibliographies, research registers, and references databases, including citation indexes. They are constructed by third parties for the explicit purpose of providing literature searchers with a relatively comprehensive list of studies relating to a topic. Secondary channels have summarized accounts that often include just research abstracts, research summaries, bibliographic information, or all three, which can be used to obtain the full reports.

Secondary Dental Care

Definition

Secondary dental care services are provided by dental specialists in their offices, in local community hospitals or universities for a patient referred by a primary care provider who first diagnosed or treated the patient. Referrals are for those patients who require the specific expertise or treatment measures performed by specialized dentists. These include both outpatient dental care and inpatient services, oro-maxillo-facial surgery services, orthodontic services, periodontal services, services for people with disabilities, diagnostic laboratory and dental imaging services, etc. Some primary care providers may also take care of hospitalized patients.

Secondary Patient Data

Definition

Secondary patient data are derived from primary data – including disease and procedure indexes, health care statistics, and disease registries. Secondary data are created in a highly standardized way. For this reason, the information derived from secondary data are comparable to other sources.

Secondary Plant Compounds

Definition

Secondary plant compounds are a group of approximately 60 000–100 000 substances which can be classified according to their chemical structures and functional properties into different sub groups. The main groups are carotenoids, phytosterole, glucosinolate, flavonoids, phenolic acid, protease inhibitors, monoterpens, phyto estrogenes and sulfur compounds. They are found in plants as plant pigments, growth regulators, pest and parasite repellents and aromas and scents. So far only a little group of approximately 100 substances has been investigated. Approximately 1.5 g of secondary plant compounds are absorbed daily in a mixed diet.

Secondary Research

Definition

Secondary research means research using data that already exist in some form, having been collected for a different purpose, perhaps even by a different organization, and which might be useful in solving a current problem.

Secondhand Smoke

► Passive Smoking

Secrecy

Synonyms

Privacy; Health data protection

Definition

Secrecy means the legal duty of a person or a legal entity (including public health agencies) to keep certain information secret (thus, confidential) and not to reveal it to any other person or entity. Such confidentiality duties may result from contracts, statutory laws or other express warranties. Public health agencies as well as health professionals have regular statutory confidentiality duties with respect to personal and other sensitive information obtained during the course of their professional conduct. Breaches of confidentiality may be punished under criminal law and lead to contractual or tort liability under private law.

Cross-References

► Confidentiality

Secularization

Definition

Recognized in all forms of worldly religions, with particular reference to the explanation of the processes by which earlier religious practices were formed and used as the basis of human behavior.

Security Council

► United Nations Security Council

Sedentary Lifestyle

Synonyms

Inactivity

Definition

Sedentary lifestyle is defined as way of life that includes little or no physical activity. It is often associated with different ailments of the contemporary age such as obesity, cardio- and cerebrovascular diseases, spinal deformities, etc. It is common in urban areas whereas in rural areas people tend to be much more physically active, for example walking to and from work, gardening, etc.

Segregation Analysis

Definition

Segregation analysis is a complex statistical technique which is used for investigation of the pattern of disease occurrence within pedigrees. It is focused on elucidation of the types of genetic effects that underline familial aggregation of the disease or trait. In this analysis, the most likely mode of inheritance is determined through comparison between the observed familial distribution and the distribution expected from various specific genetic models.

Selection Bias

► Observational Studies

Selective Prevention of Mental Disorders

Definition

Interventions target individuals or subgroups of the population whose risk of developing a mental disorder is significantly higher than average, as evidenced by biological, psychological or social risk factors.

Selective Sweep

Definition

The fixation of an ► allele in a gene pool can also result in neighboring alleles being swept to fixation where it occurs sufficiently rapidly that the effects of recombination can not oppose it. The resultant reduction in allelic and ► haplotype diversity around this locus is known as a selective sweep and can be used to identify loci under positive selection.

Self-Cleaning of the Soil

► Purification

Self Concept

► Self-Identity

Self-Determination

Synonyms

Sovereignty; Self-rule

Definition

Self-determination denotes determination of ones own fate or course of action without compulsion. It is a principle in international law that a people ought to be able to determine their own governmental forms and structure free from outside influence. Self-determination refers to a number of distinct human rights. These include the right to equality under the law, the right to a nationality, the right to freely leave and return to a person's country of origin, the right to freedom from persecution because of race, religion, or gender, and a host of others.

Indigenous peoples do not have rights based on their knowledge per se, but on the recognition of their rights to self-determination as peoples. This is clearest in settler societies, in there was a distinct and massive colonizing event, such as happened in Australia, New Zealand, Latin America, and North America. In most of these countries, indigenous peoples are recognized as a distinct class of people with "dual citizenship". They are members of their nation states, but they are also members of indigenous collectives (first nations, clans, tribes) that governed themselves prior to contact and through the Law of Nations retained sovereign powers not ceded or lawfully terminated. The dual citizenship has given rise to very complex rules of laws which recognize spheres of rights to self-governance and self-determination.

Cross-References

► Self-Government

Self-Direction

Synonyms

Autonomy

Definition

Personal governance of the self that is free from controlling interferences.

Self-Government

JELENA GUDELJ RAKIĆ
Department of Food and Nutrition, Institute of Public Health of Serbia, Belgrade, Serbia
jelgud@gmail.com

Synonyms

Sovereignty; Self-determination; Self-rule

Definition

The most widely accepted definition of self-determination is: ones right to participate in the democratic process of governance and to influence ones future – politically, socially and culturally.

Self-determination or the right to self-determination is defined as freedom of the people having the characteristics of a nation to decide whether they will be independent (choose their own government) or (continue) to be part of another state. It is important to stress that self-determination for indigenous peoples does not necessarily imply secession from the state.

Self-determination has been defined by the International Court of Justice, as the need to pay regard to the freely expressed will of peoples.

Basic Characteristics

History

The principle of self-determination has been recognized since 1919, when the League of Nations, precursor of the United Nations, was established. At that time focus was on the "principle" not the "right" of self-determination. It was only after the foundation of the United Nations in 1945 that "principle" evolved into "right" under international law.

The primary aim of the right to self-determination in international law was to allow the former colonies that existed before World War II to have their say in their future. So far the United Nations have been reluctant to recognize any further extension of the right beyond the traditional de-colonization context and this is still a matter of dispute and controversy. However, efforts are being made to further evolve this process.

Right of Self-Determination Under International Law

The right of self-determination is a fundamental principle and right under international law. It is incorporated in the Charter of the United Nations and the International Covenant on Civil and Political Rights and the International Covenant on Economic, Social and Cultural Rights. Common article 1, paragraph 1 of these Covenants says:

1. "All peoples have the rights of self-determination. By virtue of that right they freely determine their political status and freely pursue their economic, social and cultural development.
2. All peoples may, for their own ends, freely dispose of their natural wealth and resources without prejudice to any obligations arising out of international economic co-operation, based upon the principle of mutual benefits, and international law. In no case may a people be deprived of its own means of sustenance.
3. The States Parties to the present Covenant, including those having responsibility for the administration of Non-Self-Governing and Trust Territories, shall promote the realization of the right of self-determination, and shall respect that right, in conformity with the provisions of the Charter of the United Nations".

The right of self-determination has also been recognized in many international and regional human rights instruments such as Part VII of the Helsinki Final Act 1975, Article 20 of the African Charter of Human and Peoples' Rights and Declaration on the Granting of Independence to Colonial Territories and Peoples. The International Court of Justice has endorsed it. The scope and content of the right of self – international human rights experts have elaborated upon determination.

Right of Self-Determination of Indigenous Peoples

► Indigenous peoples consider the right to self-determination as one of the fundamental conditions for the enjoyment of all the individual human rights (civil, political, economic, social or cultural). The right of self-determination is equal for all people.

The United Nations has an important role in protecting and promoting the rights of indigenous peoples. The Working Group on Indigenous Populations (WGIP) adopted the United Nations Draft Declaration on the Right of Indigenous Peoples in 1994. It is divided into nine parts and each part addresses particular thematic concerns. The ninth part refers to miscellaneous provisions.

Part I includes General principles (Articles 1–5), which proclaim the rights of indigenous peoples to equality, freedom from adverse discrimination and nationality. Article 3 says that "indigenous peoples have the right to self–determination", and Article 4 recognizes the right of indigenous peoples to maintain and develop their distinct characteristics and legal systems, while participating fully in the life of the State. Part II of the Declaration (Articles 6–11) addresses the right of indigenous peoples to physical existence, integrity and security and a full guarantee against genocide, including removal of indigenous children. Part III (Articles 12–14) refers to rights in relation to cultural, spiritual and linguistic identity of indigenous peoples. Educational, information and labor rights are incorporated in Part IV of the Draft Declaration (Articles 15–18). These refer to the right to all forms and levels of education including indigenous peoples' own education institutions, the right to establish media in their own languages and equity in terms of international labor law and national labor legislation. Part V (Articles 19–24) includes participatory rights, the right to development and other social and economic rights. In Part VI (Articles 25–30) refers to land, water and other resources. Part VII (Articles 31–36) contains rights relevant to exercise of self–determination and formation of indigenous peoples' institutions. Part VIII (Articles 37–45) includes issues regarding Declaration implementation as well as UN cooperation and a special UN indigenous Body among other issues.

The Draft Declaration provides a solid framework for indigenous peoples' rights as well as a basis for mobi-

lizing resources. The majority of indigenous peoples who took part in the UN work on the Draft Declaration emphasize that their goal is to gain greater control over their lives by having the right to participate in the decision making, not secession and independence through the establishment of independent nation states.

Ever since its adoption the Draft Declaration has had considerable impact on the lives of indigenous peoples worldwide.

There is an increasing number of State delegations supporting the right to self-determination provided that it poses no threat to the territorial integrity of the States. These include Argentina, Bolivia, Canada, Chile, Colombia, Denmark, Finland, Mexico, New Zealand, Norway, Peru and Switzerland.

Right of Self-Determination and Indigenous Peoples Health

Being the fundamental right of all peoples and, as such, firmly established in international law, the right of self-determination is one of the cornerstones of health issues of ► indigenous peoples worldwide.

By the right of self-determination in terms of health, the right to influence decisions regarding health care system provisions is fundamental. Cultural, traditional and religious beliefs all influence both health knowledge and health practices of indigenous peoples. Understanding of illness as well as methods to overcome different ailments varies greatly not only between indigenous and other population groups but also within different indigenous communities. An holistic approach to health and disease provides a basis for health practices in indigenous communities. However, very often indigenous peoples are deprived of proper medical care due to the negligence of the national health care services towards the specific needs of indigenous groups. Access to health services and to health promotion and prevention programs for indigenous people are limited, inadequate and frequently culturally inappropriate. Therefore, sustainable solutions to indigenous health problems must address and acknowledge the right of self-determination which needs to be implemented in the health care systems. Otherwise, in the future, we will witness a rise in differences in morbidity as well as mortality between indigenous and non-indigenous peoples.

Self-Help

Definition

The primary focus of self-help is to provide emotional and practical support and an exchange of information. Usually, self help actions are taken by non-health professionals to mobilize the necessary resources to promote, maintain, or restore the health of individuals or communities. They are carried out in a participatory process to provide opportunities for people to share knowledge, common experiences, and problems (i. e. on diseases). Self-help can be carried out on an individual or an organized level. It is depicted as an important element for coping with diseases; supporting competences in health and empowerment.

Self-Identity

Synonyms

Self concept

Definition

Self-identity (► identity) sums total of being's knowledge and understanding of his or her self. Integral part

of self-identity are physical, psychological, and social attributes. They may be influenced by the individual's attitudes, habits, beliefs and ideas.

Self-Organizing Maps

Definition

A neural-network unsupervised learning algorithm to analyze high dimensional data. SOMs are used for dimensionality reduction for gene expression in reducing the large dataset into groups of genes that are similar.

Self-Regulation

Synonyms

Regulating oneself

Definition

Self-regulation is a concept that derives from cognitive social learning theory, and it includes what is commonly named willpower. Self-regulation includes cognitive and behavioral processes that involve the initiation, termination, delay, modulation, modification, or redirection of a person's emotions, thoughts, behaviors, physiological responses, or environment.

Self-Rule

► Self-Determination

Self-Stigma

Definition

Self-stigma is the ► prejudice which people (e. g., suffering from mental disorders) turn against themselves.

Self-Therapy of Malaria

Synonyms

Presumptive therapy of malaria; Standby therapy of malaria

Definition

Standby therapy of malaria is self-therapy practiced by travelers when they develop symptoms suggestive of malaria (fever, flu-like symptoms) in an endemic region where there is no chance of consulting a doctor soon. Due to the specific circumstances and the risk of infection, chemoprophylaxis or standby therapy is preferable. Depending on the region and the resistance of the plasmodia, ► mefloquine (Lariam®, Mephaquin®), ► atovaquone + proguanil (Malarone®) and ► artemether/lumefantrine (Riamet®) are recommended for self-therapy.

Semantic Aspect of Data/Information

Definition

The semantic aspect refers to the meaning of the message carried by the data. The interpretation of data, and creation of information from it, can be made only if the data have some meaning and the context of production of the data is taken into consideration.

Semantic Errors

Definition

A semantic error is a type of ► data error referring to the meaning of data.

Semen Quality

Definition

Semen quality refers to the structure/morphology and motility of the sperms. Semen quality and sperm count (the total number of sperm cells per ml of semen) as well as quantity and quality of the ejaculate predict male fertility.

Senescence

Definition

Senescence should be distinguished from aging. The term "aging" refers simply to the accumulation of chronological time and maturation. Senescence, in contrast, refers to the increasing vulnerability or decreasing capacity of an organism to maintain homeostasis as it progresses through its life span. Previously thought to be synonymous, it is now increasingly understood that while the two terms are related, aging refers generally to changes over time while senescence describes a process of degeneration.

Theories explaining biological senescence can generally be divided into two categories. Programmed senescence theories imply that senescence is regulated by biological clocks operating throughout the life span. This regulation would depend on changes in gene expression that affect the systems responsible for maintenance, repair and defense responses. Error theories see senescence as the outcome of accumulated environmental impacts that induce damage at various levels on an organism.

Sensitivity

Synonyms

Operating characteristics of diagnostic tests

Definition

The sensitivity is the operating characteristic of a diagnostic test that measures the ability of a test to detect a disease (or condition) when it is truly present. Sensitivity is the proportion of all diseased patients for whom there is a positive test, determined as: [true positives ÷ (true positives + false negatives)], in contrast to specificity.

Sensitivity Analysis

Definition

Sensitivity analysis is a technique or methodological approach to describe the ► uncertainty around the estimated results of health economic evaluation studies, especially decision analytic modeling. The influence of plausible changes of one or more parameters of the analysis on the results when the other parameter is kept constant is described. Sensitivity analysis is a key standard element of health economic evaluation.

Sensitivity of a Surveillance System

Definition

Sensitivity of a surveillance system is defined as the proportion of the total number of cases of a disease or health condition in the target population that are detected by the system (the completeness of case reporting). For assessing the impact on health, high sensitivity is required. A surveillance system with low sensitivity can still be useful in monitoring trends if sensitivity and predictive value positive (PVP) are consistent over time.

Sensoric Quality of Food

Definition

Sensory experiences such as taste, color, shape and consistency defines the quality of food.

Sentinel Events

Definition

A sentinel event is an unexpected occurrence involving untimely death, preventable disease, serious injury, or disability, whose occurrence serves as a warning signal that the quality of preventive and/or therapeutic medical care may need to be improved. Sentinel events (such as cases of certain communicable diseases, e. g., influenza cases, adverse drug reactions, etc.) are harbingers of broader public health problems. Surveillance for such events can be used to identify situations where public health investigation or intervention is required.

A Sentinel Event Alert identifies the most frequently occurring sentinel events, describes their common underlying causes, and suggests steps to prevent occurrences in the future.

Sentinel Surveillance

Definition

Sentinel surveillance is a type of ► active surveillance. It implies that department of health officials regularly call a sample of physicians' offices to ask if they have identified any cases of a particular disease; in this instance, information required is very detailed because the disease often is not well understood and this surveillance system provides a means of collecting information that may help identify its causes or risk factors.

Separation Anxiety Disorder of Childhood

Definition

This disorder should be diagnosed when fear of separation constitutes the focus of the anxiety and when such anxiety first arose during the early years of childhood. It is differentiated from normal separation anxiety when it is of a degree (severity) that is statistically unusual (including an abnormal persistence beyond the usual age period), and when it is associated with significant problems in social functioning.

Sepsis

Synonyms

Bloodpoisoning; Septicemia

Cross-References

► Acute Life-Threatening Infections

Septic Course of Infection with Yersinia pestis

► Plague Sepsis

Septic Course of Meningococcal Infection

► Waterhouse–Friederichsen Syndrome

Septicemia

► Sepsis

Septic Infection

► Bloodpoisoning

Serial Analysis of Gene Expression

Definition

A method to monitor large-scale gene expression within a cell or group of cells by sequencing short sequence tags from the population of mRNA. Unlike microarray, this sequence based technique does not need a priori knowledge of the mRNA population and thus can be used to find novel transcripts. Furthermore, absolute levels can be measured and thus comparison between different experiments is easier. However, the cost of production is higher than microarray.

Serpent Worm Infection

► Dracunculiasis
► Guinea Worm Infection

Serum Electrolytes

Synonyms

Blood salts

Definition

In any given fluid compartment of an organism there is a particular composition of electrolytes. These are salts, acids and bases, which – in watery solution – disintegrate to ions, loaded atoms. Electrolytes play an important role in the excitation of cells, closely related to the body fluid balance. It is necessary to keep the electrolytes in balance to maintain the optimal pH-value in arterial blood. If there is a relevant alteration of the levels of the electrolytes the fluid volumes of the cells change. Thus different metabolic processes might be influenced.

Service Provision and Infrastructure

► Infrastructure and Service Delivery

Setting

Synonyms

Physical and social/cultural environments; Microenvironments

Definition

The term 'settings' goes back to the Ottawa Charter for Health Promotion of 1986, which outlined the need for creating a health-promoting environment. Going further afield, the World Health Organization (WHO) explicitly called for setting-based health promotion in its 'Health 21' plan (► health goal no. 13) in 1999. With its holistic nature, the setting approach moves away from the one-sided focus on individual risk-prone behavior and takes a broader view by looking at social systems and organizations – settings – such as companies, schools, hospitals, neighborhood, etc. where the necessary conditions for good health can be created, shaped and maintained. The setting strategy is seen as the core strategy of health promotion since it takes into account living conditions and behavior, and so can accommodate the specific requirements of widely different ► target groups.

Furthermore, since it allows incorporating health promotion into everyday activities, the setting approach has been particularly successful at low-level communication with otherwise hard-to-reach target groups (e. g., socially disadvantaged segments of the population). Examples of setting-based international and national projects as well as integrated programs addressing both human health and the environment include the Healthy Cities Network and the Health Promoting Hospitals Network.

Cross-References

► Environment
► Setting Concept

Setting Concept

Synonyms

Setting; Settings for health promotion

Definition

The setting concept (orientated towards lifestyle and different areas of life) includes measures of health promotion in the most common and frequently visited areas in the life of an individual (workplace, office, school, family, place of residence, etc.) which have a great impact on the individual's health. This type of health promotion is regarded as being very promising from the viewpoint of health science. Thus, health-orientated basic conditions may be improved within delimited social systems by the inclusion and participation of the individual.

Settings for Health Promotion

Seven-Day Fever

► Dengue Fever

Severe Acute Respiratory Syndrome

► SARS

Severe Overweight

► Obesity

S

Sewage Disposition

Definition

Sewage disposition is the disposal of human excreta and other waterborne waste products from houses, streets, and factories. In an urban environment, sewage disposal is collection of sewage by the sewerage system and the disposal of the sewage, with or without treatment. The determinants commonly included in sewage analysis are tests measuring organic matter, biochemical oxygen demand, nitrogen, chlorides, hardness, alkalinity, pH, dissolved oxygen, hydrogen sulfide, carbon dioxide, and living organisms including bacteria and larger organisms. By appropriate processes, sewage and industrial waste water can be treated so that the decomposable organic matter is removed or oxidized and the bacteria and other organisms removed or killed. The fundamental processes of sewage treatment are: separation of the suspended matter from the liquid sewage; destruction of the putrescible organic matter in the liquid sewage looking to final mineralization by processes of biological action; transformation of the sewage sludge to a condition of stability and inertness by biological action; and destruction of the bacteria and other microorganisms in the liquid effluent or their removal from it.

Sex

Definition

A biological characteristic that differentiates people on the basis of X-chromosome versus Y-chromosome linked attributes. It is a dichotomous outcome, i. e. sex is defined as either male or female.

Sex Differences and Health

► Gender Differences and Health

Sex/Gender

Synonyms

Male; Female; Masculinity; Femininity

Definition

Sex refers to whether one is biologically a male or female. Gender refers to masculinity, the expected social behaviors for men in society, and femininity, the expected social behaviors of women in society. What constitutes masculinity and femininity varies from culture to culture, and can change over time. Although sex and gender are conceptually different, they are often used interchangeably in everyday discourse.

Sexism

Definition

An institutionalized practice of denying rights, responsibilities, and/or resources to a specific individual on the basis of his or her ► sex.

Sex Ratio at Birth

Definition

The sex ratio at birth represents the number of male live born infants per 100 female live born infants in a given year. In humans the sex ratio at birth is commonly assumed to be 105 boys to 100 girls. However, sex ratios at birth or among infants may be considerably skewed by sex-selective abortion and infanticide. Even in the absence of such practices, a range of "normal" sex ratios at birth of between 103 to 107 boys per 100 girls has been observed in different societies, and among different ethnic and racial groups within a given society, though more extreme ratios documented in some populations should be attributed rather to cultural preferences than to biological variation in the propensity to bear boys or girls.

Sexual Behavior

► Sexual Practices

Sexual Contact

Synonyms

Sexual intercourse; Sexual activity; Physical intimacy

Definition

Physical intimacy that includes a broad range of behaviors such as kissing and touching breasts or genitalia through clothing or direct contact. Sexual contact also includes sexual intercourse, which refers to the occurrence of one person penetrating a body part or an object into another person's genital or anal opening.

Sexuality

Definition

The set of behaviors that allow an individual to express his or her sexual identity in a manner consistent with his or her ► gender. It involves giving and receiving sexual pleasure, and may or may not involve reproduction and reproductive biology.

Cross-References

hkorn80663@aol.com

Synonyms

STDs; Sexually transmissible diseases; Veneral diseases; Veneric diseases; Social diseases

Definition

Sexually transmitted diseases (STDs), which can be caused by different pathogens, are primarily transmitted from one human to another by sexual intercourse or by close contact. Most frequently, the symptoms of these infectious diseases manifest in the genital region.

Basic Characteristics

Introduction

Sexually transmitted diseases can be caused by viruses, bacteria or other microorganisms. Frequently, mixed infections occur. All pathogens causing STDs prefer a warm and moist climate. Therefore, they grow best on the mucous membranes of the genitals, the mouth and the rectum. Outside a humid milieu, the germs quickly die. Infectious diseases, which belong to the classic STDs, are syphilis, gonorrhea, ► ulcus molle (soft chancre) and ► lymphogranuloma venereum (LGV). Syphilis and gonorrhea are the most dangerous and widest spread social diseases. Besides HIV-infection, which is treated separately, the STDs considered here are ► granuloma inguinale, ► trichomoniasis, *Chlamydia trachomatis* infection, ► *Ureaplasma urealyticum* infection and ► herpes genitalis infections, ► condyloma, ► hepatitis B, ► scabies as well as infestation with ► pubic lice. Having a veneral disease does not confer immunity; thus reinfections are frequent.

History

Veneric diseases have been known since ancient times. Due to its possible severe or even deadly course, syphilis holds prime position. Remnants of skeletons, showing syphilitic changes, can prove that syphilis has occurred in Europe throughout antiquity. However, it achieved a special significance in 1495, when the French king Charles VIII conquered Naples. After the victory, 80-days festivities were held, which were followed by a syphilis epidemic, which spread all over Europe within five years. The origin of the name syphilis has been associated with a poem of Girolamo Fracastoro written in 1530; in the poem the shepherd Syphilis, as punishment for an act of impropriety, suffers from a disease with the symptoms of syphilis. For a long time, veneral diseases have been regarded more as a moral than a medicinal problem. They were thought to be the rightful punishment for wantonness. As tougher moral attitudes were adopted, social taboos prevented discussion about sexually transmitted diseases, and, especially, it was thought better that young people should not know too much about these kinds of diseases. In 1879, Albert Neisser determined that the bacterium *Neisseria gonorrhoe* was the cause of gonorrhea. In 1909, Fritz Schaudinn and Erich Hoffmann identified *Treponema pallidum* to be the cause of

syphilis. For centuries, mercury had been the treatment for syphilis but in 1909 Paul Ehrlich and Sahachiro Hata developed the first real therapeutic breakthrough, Salvarsan. Using Salvarsan reduced primary and secondary stages of syphilis by more than 60%. Since 1953, penicillin has been used for therapy, which – in most cases – can cure the disease if it is administered at an early stage.

Transmission

Usually, transmission of veneric diseases takes place during sexual intercourse. As the germs cannot survive outside the humid milieu for any length of time, transmission by toilet seats or – lids or by other objects of sanitary equipment is quite improbable. Although it is not a common way of transmission, infection is possible by the use of contaminated toothbrushes, washclothes, towels, bedlinen or sex toys. In rare cases, transmission can also take place by kissing. In every unprotected vaginal sexual intercourse, the risk of syphilis infection is 30–60%; as for gonorrhea, in every heterosexual intercourse with an infected partner the risk is 20–35% for men and 50–70% for women. Social diseases can also be transmitted by oral or anal sex. Furthermore, transmission is possible by contaminated blood conserves or by the re-use of contaminated needles. As for syphilis, an infection during pregnancy can be transmitted to the unborn child via the placenta, causing ► congenital syphilis. Hepatitis B can also be subject to intrauterine transmission. Moreover, a number of veneral diseases can be transmitted during the birth process.

Syphilis (Lues, French Disease)

Syphilis is caused by the bacterium *Treponema pallidum*. Half of the transmissions lead to an outbreak of the diseases, 30% of which heal spontaneously. The course of lues is made up of 3 (or 4) phases. During the primary stage, the germs can be detected in slide preparations from skin lesions, but diagnostic determination of antibodies is preferred in the following stages. Following an incubation period of 2–3 weeks (maximum 3 months), at the site of infection (at the male glans or at the female labia) a small nodule appears; this nodule develops into a hard-edged ulcer. Ulcer secretions are colorless and highly contagious. Additionally, there is a swelling of the regional lymph nodes. The ulcer and the swollen lymph nodes form the so-called primary complex. Four to ten weeks after the ulcer heals, the secondary stage starts, which heals without consequences after about 2 years. During this stage, different symptoms can be present. At the beginning, the symptoms are similar to a flu-like infection with fever and rheumatic pains; exanthemas and swellings of the lymph nodes can appear. Later on, nodulous efflorescences, lesions of the mucous membrane of the oral cavity and inflammation of the tonsils can appear. Moreover, at locations of skin-to-skin contact (under the breasts, in the armpits, in the groins) hard nodules develop, the so-called condylomata lata. Tertiary syphilis, which can involve all organs, occurs in about 25% of infected people; the latency phase prior to this late-stage of syphilis is variable and can last months to years or even decades. Soft nodules (gummas) ulcerate; widening of the blood vessels (aneurysms) can develop, which can rupture and cause a lethal hemorrhage. Neurological complications are often called the forth stage of syphilis. They are characterized by paralyses, difficulties in the coordination of muscle movements and cerebral seizures; frequently psychoses occur. Finally, there is a loss of intellectual capacities, resulting in dementia. Without treatment, the progressive paralyses lead to death within 4–5 years. Involvment of the posterior part of the spinal cord is called tabes dorsalis. In this case, the patients suffer from episodes of intense pain in the legs and disturbed sensation. Lues is treated antibiotically with ► penicillin. In the stages I and II benzathine penicillin is administered intramuscularly once a week for 3 weeks. If penicillin is not tolerated, tetracyclines or erythromycin can be used. Neurosyphilis demands intravenous treatment with penicillin G for 3 weeks. At the onset of antibiotic therapy, a ► Jarisch–Herxheimer reaction can appear. As a reactivation of the infection is possible, serologic controls should be performed after the end of treatment. The tests should be carried out after 3, 6 and 12 months, and once yearly thereafter.

Gonorrhea

Gonorrhea, also called “drip”, is caused by the bacterium *Neisseria gonorrhoe*. It is the most common sexually transmitted disease worldwide. According to estimations of WHO, there are 12 million new infections every year, primarily in men. Asymptomatic courses

are found in 15–30% of infected men and in up to 80% of infected women. Following an incubation period of 2–7 days, there is an inflammation of the urethra (urethritis); discharge and a burning sensation during micturition occurs. A typical symptom of gonorrhea is the so-called "bonjour-drop", a purulent secretion from the urethra, which appears after a long pause in urination. Gonorrhea can spread locally and cause inflammation of the tubes, the prostata or the peritoneum. Moreover, there is the risk of a general spreading by the blood (hematogenic) with the development of fever, joint pain and arthritis. In severe cases, inflammation of the meninges or the cardiac muscle can occur (menigitis, myocarditis). Infection can lead to adhesions in the tubes or the seminal vessels, thus causing infertility. Transmission during birth can cause a ► congenital gonorrhea. Usually, *Neisseriae* can be detected by slide preparation or culture. Before the onset of therapy, the possibility of infection by other STDs should be investigated; frequently, a simultaneous infection with *Chlamydiae* is present. Due to possible resistances against penicillin and tetracyclines, gonorrhea should be treated with intramuscular ceftriaxon or oral gyrase inhibitors (ofloxacin, levofloxacin). In uncomplicated cases, a single shot is sufficient, systemic infections have to be treated for 7 days. The sexual partner (or partners) should also be treated, otherwise ► ping pong infections could appear.

Prophylaxis

The most effective prophylaxis for sexually transmitted disease is sexual abstinence. The Catholic Church demands the restriction of premarital sex. Some institutions organize campaigns for marital faithfulness and against promiscuity. In Uganda, the so-called ABC-program was propagated; **a**bstinence, faithfulness (**b**e faithful) and safer sex (**c**ondoms). Even if there is no absolute security and protection, the risk of transmission of STDs considerably declines with the use of ► condoms (http://en.wikipedia.org/wiki/Condom). People with multiple partners should regularly be checked for the presence of veneric diseases. Sexually active persons should be informed about the risks of transmission, effective protective measures, symptoms and the urgency of immediate treatment (http://kidshealth.org/teen/sexual_health/contraception/contraception_condom.html).

Current Problems

The World Bank Group calculates that sexually transmitted diseases' costs, due to the treatment of the 15 to 44 years age group, ranks second worldwide. Thus, STDs have far-reaching health, political, social and economic significance. The introduction of modern methods of contraception caused a decrease in the use of condoms; while the rate of unintended pregnancies declined, sexually transmitted diseases were spread more easily and more quickly. An increased risk of transmission is present when anal sexual intercourse in homosexual men occurs. Immediate treatment of infected individuals is still hindered by their sense of shame and their fear of stigmatization. In the developing countries these factors are complicated by a lack of medical care. Especially in young people, there often is an insufficient knowledge about causes and symptoms of sexually transmitted diseases. Frequently, parents are not aware of the sexual activity of their children and, fearing discovery, teenagers are afraid to seek treatment. If the disease is transmitted by a third party, the fear of conflicts within the original partnership can lead to concealment of the infection. A further problem arises with long-distance tourism, which – under special conditions – can be designated as "sex tourism". On such journeys the travelers repeatedly have brief sexual contacts, often without the use of condoms. The risk of the transmission of sexual diseases is high.

Procedures in Case of Infection

Because sexually transmitted diseases are still taboo, public institutions have been established which perform diagnostic and therapeutic measures confidentially. When diagnosis is confirmed, not only is the infected person immediately treated, but also his or her sexual partner (or even partners). Until complete healing of the infection is achieved, individuals should undertake sexual abstinence. As the occurrence of social diseases is rare before the onset of puberty, the appearance of STDs in young children should give rise to suspicion of possible sexual abuse.

Sexually Transmitted Diseases and Family Health

MICHELE MOUTTAPA[1], DEBRA A. MURPHY[2]

[1] Department of Health Science, California State University Fullerton, Fullerton, CA, USA

[2] University of California Los Angeles, Los Angeles, CA, USA

mmouttapa@fullerton.edu, dmurphy@mednet.ucla.edu

Synonyms

Venereal diseases (VD); Sexually transmitted infections (STI)

Definition

Sexually Transmitted Diseases (STDs) refer to a broad category of infections that can be transmitted from person to person through sexual contact and from mother to child during birth. There are 20 known STDs. Common STDs include Chlamydia, genital warts, gonorrhea, hepatitis B virus, herpes, syphilis, Human Papilloma Virus (HPV), and ► human immunodeficiency virus (HIV). Acquired Immune Deficiency Syndrome (AIDS) is a condition in which HIV reaches an advanced stage (Berger 1998).

Family health refers to the concept that each individual can affect the health of his or her family members. For example if one family member becomes infected with an STD, he or she may infect other family members with the disease as well. Secondly, the experience of a family member having an STD may have a negative social and psychological effect on individuals, especially children, regardless of whether or not they contract the disease themselves. Denham (1999) suggested that HIV may have an especially negative impact on the lives of family members as it is a life-threatening disease to those infected. In such circumstances, family members can sustain each other's health through effective communication, cooperation, and care giving.

Basic Characteristics

Transmission Through Sexual Contact

Once an individual becomes infected with an STD, he or she may infect others through ► sexual contact. However symptoms appear only after an incubation period has passed. Incubation periods vary depending upon the STD – 2 to 8 days for Gonorrhea and up to 8 months for genital warts (Daugirdas 1992). During this time individuals may unknowingly infect their sexual partners. Sexual partners may also re-infect each other with the

same STD. This is known as the ► "ping-pong effect"; the disease travels back and forth between two partners.

Transmission from Mother to Child

Pregnant mothers who have STDs may pass the infection to their child before or during vaginal childbirth. The child may suffer serious health consequences. For example Chlamydia can cause serious eye and lung infections and Herpes can cause death or major damage to the central nervous system. These infections can be prevented by cesarean section delivery. Syphilis microbes, however, can infect the fetus after the first 3 months of pregnancy and result in death or lasting damage to major body organs (Daugirdas 1992).

HIV/AIDS

An STD on the rise: The prevalence of HIV and AIDS has steadily risen since the 1980s. The United Nations Programme on HIV/AIDS 2003) estimated that approximately 40 million people are infected worldwide. Furthermore the Centers for Disease Control and Prevention stated in a 2003 report that HIV and AIDS are increasing among women of childbearing age. In the United States alone, at least 200,000 children live with at least one parent who has HIV or AIDS (Murphy et al. 2006). HIV and AIDS may especially impact the family if the mother is infected, since mothers are generally the main caregivers of the family.

The Social and Psychological Impact of Mothers' HIV/AIDS on Their Children

The extent to which children are affected by their mother's illness varies greatly, and depends upon several factors including demographics, mothers' physical and mental health, the mother-child relationship, and unique characteristics of the child.

Demographics

Children's age and the ► socioeconomic environment that they are raised in largely determine how they are affected by their mothers' HIV/AIDS status. Masten and colleagues (1990) suggested that youner children are especially dependent on caregivers for protection. Therefore they are more likely to suffer the consequences of poor ► parenting due to their mothers' declining health. On the other hand, older children can more fully comprehend their mother's illness, have more developed psychological ► coping mechanisms, and can more easily draw upon the support of people outside of the immediate family when needed. Poverty is an added stressor for children that makes coping with their mothers' illness even more difficult.

Mothers' Physical and Mental Health

Although HIV-positive individuals are infected with the virus, they may still be in good health and have few or no symptoms. Nevertheless 30 to 40% of HIV-positive women have clinical levels of anxiety and depression, which in turn are risk factors for poor parenting, lower resilience among children, and less ability for family members to cope, support each other, and solve problems (Murphy et al. 2006). When mothers' disease progresses from HIV to AIDS, children often take on adult roles that they often may not be prepared for (► role taking). Physical and mental health enables HIV-positive mothers to properly care for and monitor their children, and assists children to effectively cope with their mother's illness.

Mother-Child Relationship

The manner in which HIV-positive mothers communicate with their children about their HIV status may also affect their children's health. Murphy and colleagues (2006) suggest that if HIV-positive mothers try to cope with their disease by simply avoiding it, their children are more likely to experience adjustment problems. They also suggest that HIV positive mothers inform and educate their children about their disease, they will have better relationships with their children, can more easily access resources to effectively cope with the family's situation, and will lead to better child adjustment (Murphy et al. 2006). Nagler and colleagues (1995) found that children who do not know about their mother's HIV-positive status often feel distressed because they are aware that something is wrong but feel unable to ask what is wrong.

Family Health Prevention

It is clear that the health of one family member can impact the health of other family members. Therefore preventing, diagnosing, and treating diseases such as STDs are important not only for the individual who has

the disease, but his or her family members as well. An ideal family health program should incorporate activities that promote behaviors directly related to physical health as well as improve communication among family members. Murphy and colleagues (2006) believe that to date, little is known about how to effectively provide services to families affected by HIV/AIDS. Providing services to promote family health are often a challenge because it requires the motivation and cooperation of several family members as well as a substantial amount of resources.

Sexual Practices

Synonyms

Sexual behavior; Sexuality

Definition

Sexual relationships and practices are complex to investigate, but their study is important because infectious disease has always been a possible outcome of sexual relationships, as has unwanted pregnancy. Concern about AIDS has been an important motivation for recent studies of sexual behaviors. Sexually transmitted infections are behavior-linked diseases that result from unprotected sex. Safe sex is sexual activity in which safeguards, such as the use of a condom and the avoidance of high-risk acts, are employed to reduce the chance of acquiring or spreading a sexually transmitted disease.

Sexual and Reproductive Health

Definition

Sexual and ► reproductive health addresses, within the framework of WHO's definition of health as a state of complete physical, mental and social well being, and not merely the absence of disease or infirmity, the reproductive processes and functions at all stages of life. Sexual and reproductive health hence implies that people are able to have a responsible, satisfying and safe sex life and that they have the capability to reproduce and the freedom to decide if, when and how

often to do so. This implies certain rights, firstly that of men and women to be informed of and to have access to safe, effective, affordable and acceptable methods of fertility regulation of their choice. Secondly, the right of access to appropriate health care services that will enable women to go safely through pregnancy and childbirth and provide couples with the best chance of having a healthy infant.

Sheltered Work

Definition

Sheltered work facilities provide paid employment and educational and therapeutic programs to people with disabilities. Usually, employment in a sheltered work setting is transitional. However, it should lead to a regular job placement. The sheltered aspect ensures that the disabled persons are protected from some elements of real business life while nevertheless having the opportunity to build or rebuild job skills and experience a work environment. Workers with severe physical or mental impairments are offered employment where productivity is far less important. The focus is put on the therapeutic activities offered in a work like setting. For those cases, transition to the outside is often not considered a feasible alternative.

Shift Work

Definition

Shift work means any method of organizing work in shifts whereby workers succeed each other at the same workstations according to a certain pattern, including a rotating pattern, and which may be continuous or discontinuous, entailing the need for workers to work at different times over a given period of days or weeks.

Shift work is an employment practice designed to make use of the 24 hours of the clock, rather than a standard working day. Different kinds of work schedules and changing shifts are used. For example, from three shifts, each of eight hours, to four or more sets of employees who work twelve-hour shifts over a 48-hour period and take the subsequent 48 hours off. Shift work is known as a risk factor of work-related stress with the consequence of disturbing natural circadian sleep rhythms as well as the risk of behavioral changes.

Reasons for shift work are its clear effect on economy (increasing use of capital equipment and production compared to an eight-hour day) and the growing needs of modern 24-hour society. In present times, up to 30% of workers are exposed to different kinds of shift work, with an increasing trend.

Health effects of shift work may be summarized as follows: a reduction in the quality and quantity of sleep; widespread complaints of "fatigue"; anxiety, depression, and increased neuroticism; increasing evidence of adverse cardiovascular effects; possible increase in gastrointestinal disorders; and increased risk of spontaneous abortion, low birth weight, and prematurity.

A different but related concept of work shift means the time period during which a person is at work.

Short Tandem Repeat (STR)

Synonyms

Microsatellite DNA

Definition

A short tandem repeat (STR) is a type of polymorphism characterized by the repetition of two or more nucleotides (for example, 'CA') in multiple copies directly adjacent to one another in a DNA sequence. The lengths of the repeated sequences can vary from 2 to 10 nucleotides in length and are typically non-functional sequences of DNA present in the non-coding intronic regions of genes, thereby reducing the probability of their directly affecting gene function. Alleles of STRs are often characterized by the number of repetitions of the short sequence (e. g., 36 vs. 38) and can often have multiple alleles with relatively high frequency in the population. Beyond their use in research on the genetics of populations, forensic scientists often examine several STR loci in genetic materials and, by counting how many repeats are present within a specific STR sequence at a given locus, and doing this over a set of STRs, a unique genetic profile for an individual can be established, allowing forensic scientists to genetically 'fingerprint' individuals. For this reason, STR analysis is the most common method of identification employed in forensic cases. There are currently over 10,000 published STR sequences in the human genome.

Short-Term Rehabilitation

GERNOT LENZ
Forschungsverbund Public Health Sachsen-Sachsen Anhalt e. V., Medizinische Fakultät, Technische Universität, Dresden, Germany
gernot.lenz@gmx.de

Synonyms

Sub-acute care

Definition

Short-term rehabilitation follows an acute illness, injury, or surgical procedure like a hip replacement. Short-term rehabilitation is considered appropriate when there is a reasonable medical expectation of a significant functional improvement within 2 to 3 months after initial treatment. It focuses on establishing the prior level of function that will allow the patients to return home; however, there are also cases where transfer to a long-term rehabilitation setting is required. The services are performed either in the rehabilitation unit of a hospital, in specialized rehabilitation hospitals, or in outpatient settings. Depending on the rehabilitation requirements, the services are performed by the respective specialist, e. g. a physiotherapist after a broken leg, or by an interdisciplinary ► rehabilitation team.

Basic Characteristics

Delivery Process and Setting

Short-term rehabilitation covers the first phase of rehabilitative care following acute illness or injury. It usually starts in the hospital setting under the supervision of the admitting physician or surgeon. It is then often continued in a rehabilitation hospital due to the increasing pressure on hospitals to discharge their patients early. The objective of the delivery process is to get the patients to the point where either a more definitive rehabilitation can occur or the patients are able to return to home and resume their lives in the community. Short-term rehabilitation is characterized by a timeframe of 2 weeks to 3 months and is impairment driven. It can be observed that short-term rehabilitation services are increasingly being shifted to inpatient or outpatient community settings. Similar to medium and long-term rehabilitation delivery, short-term rehabilitation often uses a comprehensive, interdisciplinary team approach with the patient and their family being at the center of the treatment plan.

Services Offered

Although the focus of short-term rehabilitation is put on the recovery aspect, the full range of rehabilitation services might be applied. This includes ► physical therapy, ► occupational therapy, ► speech therapy, and other daily therapies like aquatic therapy, massage therapy, or recreational therapy. The services are usually provided to patients of all ages with the goal of achieving maximum physical, social, and emotional independence. Inpatient rehabilitation units or hospitals ensure

close medical supervision, with physicians available 24 hours a day. There are also registered nurses and therapists to allow comprehensive rehabilitation program to be offered.

Conclusion

In many health care systems worldwide, there are still inefficiencies at the interface of acute care and short-term rehabilitation, which might result in prolonged disease states and additional costs for the system. Going forward, additional focus should therefore be put on the integration of inpatient acute care, the rehabilitation unit, and outpatient care. This implies that the rehabilitation efforts have to be started early, ideally in parallel to the curative measures, to ensure an integrated and holistic treatment approach.

Sick Building Syndrome

Synonyms

Indoor air quality

Definition

The term "Sick building syndrome" (SBS) is used to describe situations in which building occupants experience acute health and comfort effects that appear to be linked to time spent in a building, but no specific illness or cause can be identified. Causes of SBS are inadequate ventilation, poor heating, bad acoustics, chemical contaminants from indoor sources, chemical contaminants from outdoor sources, and biological contaminants. Building occupants complain of symptoms associated with acute discomfort. These symptoms include headaches; eye, nose, and throat irritation; a dry cough; dry or itchy skin; dizziness and nausea; difficulty in concentrating; fatigue; and sensitivity to odors. With SBS, no clinically defined disease or specific chemical or biological contaminant can be determined as the cause of the symptoms. Most of the complainants feel relief soon after leaving the building. This spectrum of specific and non-specific complaints, when tied to a particular building, became known as the "sick building syndrome." It is important to note that "sick building syndrome" is not the same as "building related illness" which refers to a specific airborne building contaminant. One well known example of this is Legionnaires' Disease.

Sick Leave

Synonyms

Sickness pay; Sick pay

Definition

Sick leave is a paid form of sickness absence. Provisions (levels of compensation or duration of leave) for employee sick leave vary from country to country and depend on legislation or social security systems. Usually, it covers leave due to personal illness or injury certified by medical doctors or other types of authorized body. The term sick leave, in some countries, covers absence of an employee from work to care for or support ill family members.

Sick leave is better understood as an interplay between the individual's health contra the social insurance system; levels of benefits; type of work; flexibility at work by lowered working capacity; attitudes towards work; and other medical, social, and psychological factors.

Sickness Pay

► Sick Leave

Sick Pay

► Sick Leave

Side Effect

Synonyms

Adverse drug reaction; Adverse events; Adverse effect

Definition

Side effects are problems that occur when the medical treatment goes beyond the desired therapeutic effect or that occur in addition to the desired effect. In many countries, law requires side effects to be reported and they have to be researched in clinical trials. Drug manufacturers have to list all the known side effects of their products in patient information leaflets supplied with the drugs. As side effects are a function of dosage or drug level at the target organs, they may be decreased or avoided by adjusting the dosage. Another potential cause of side effects is drug interactions. It is therefore crucial that a physician checks all the medicaments a patient takes for potential harmful interactions. In some cases, side effects might be reduced by the use of a second medication or a change in lifestyle or diet. In the case of cancer treatment, characteristic side effects are fatigue, nausea, vomiting, decreased blood cell counts and hair loss.

Cross-References

► Adverse Drug Reaction
► Adverse Effect

Significance

Definition

Statistical significance is the conclusion that an intervention has a true effect, based upon observed differences in outcomes between the treatment and control groups that are sufficiently large such that these differences are unlikely to have occurred due to chance, as determined by a statistical test. Statistical significance indicates the probability that the observed difference was due to chance if the null hypothesis was true, it does not provide information about the magnitude of a treatment effect. Statistical significance is necessary but not sufficient for clinical significance. Clinical significance is the conclusion that an intervention has an effect that is of practical meaning to patients and health care providers. Even if an intervention is found to have a statistically significant effect, this effect might not be clinically significant.

Single Nucleotide Polymorphism (SNP)

Synonyms

Simple nucleotide polymorphism

Definition

A single nucleotide polymorphism (SNP, pronounced '*snip*') is a variation in DNA occurring when a single nucleotide (A, T, C, or G) at a particular site in the genome differs between members of a species. An example might be that if two stretches of DNA sequence at the same site in two different individuals were sequenced and revealed to be TTGC*T*ATT in the first individual and TTGC*A*ATT in the second, they would contain a difference in a single nucleotide. In this hypothetical example, if both the A allele and T allele at this site were sufficiently frequent on the chromosomes of the population of interest, the variants at this genomic site would be designated as a biallelic SNP. SNPs have been identified throughout the genome: within genes in both coding and noncoding regions, as well as in the regions between SNPs. SNPs can manifest functional effects on the final protein product if they alter ► transcription, post-transcriptional splicing, or the actual mRNA transcript. Among SNPs which fall in coding regions, SNPs which alter coding sequence incorporated into mRNA transcripts are said to be synonymous coding SNPs if the ribonucleotide they change does not change the amino acid incorporated (due to degenerate coding); SNPs which alter both the coding sequence and the amino acid incorporated are said to be non-synonymous coding SNPs. SNPs make up 90% of all genetic variations in the human genome, and SNPs with a minor allele frequency greater than 1% occur an average of once every 100 to 300 bases in the human genome. Also, approximately 66% of SNPs include substitutions of the nucleotide cytosine (C) with thymine (T). Currently, the largest collection of identified SNPs is of the 2.4 million SNPs which have been identified by the International HapMap Project. SNPs are useful in the genetic research of populations for their ability to characterize variability over large portions of the genome.

Sleeping Sickness

Synonyms

African trypanosomiasis; Infection with Trypanosoma brucei (T. brucei gambiense and T. brucei rhodesiense)

Definition

Sleeping sickness, which is found in Africa, is caused by *Trypanosoma brucei gambiense* and *Trypanosoma brucei rhodesiense*. It is transmitted by the bite of the tsetse fly. After an interval of 10 days, a red papule develops at the place of the bite. A generalized infection, with fever, flue-like symptoms, pressure pain over the long bones, splenomegaly and cardiac arrhythmias, occurs 3–10 days later. During the following chronic stage, central nervous system symptoms appear with epileptic seizures, sensory and motor impairments and a progressive dementia. Without treatment the disease takes a lethal course due to the progressive degeneration of the central nervous system. A quick onset of therapy is important. In the early stage pentamidine (Pentacarinat®) or suramin (Metaret®) are effective, in later stages very toxic arsenic compounds (like Arsobal®) have to be used in combination with steroids. Tsetse flies are exterminated with insecticides and flytraps; moreover, prophylaxis of insect bites is useful.

Sleep Stage

Definition

Several stages of sleep can be identified from EEG responses. On relaxing prior to sleep, the EEG pattern changes from rapid, irregular waves to a regular pattern – the alpha rhythm. This is followed by sleep stage 1, which is characterized by prolonged reductions in wave amplitudes and frequencies. Later, in sleep stage 2, the pattern changes to consist of bursts of waves (spindle waves) mixed with single, slow waves of relatively large amplitude (K-complexes). About 30–45 minutes later, periods of slow, high amplitude waves (delta waves) appear in the EEG (stage 3). When the delta waves occur for about 50% of the recording period, the deepest stage, sleep stage 4, has been reached. About an hour and a quarter later, the EEG pattern resembles that found in stage 1, but electrodes placed near the eye reveal joint rapid eye movements (REM). In this sleep stage most dreaming occurs.

Smallpox

Synonyms

Smallpocks; Variola

Definition

Smallpox, which have been known for thousands of years, is a viral infectious disease transmitted by droplets. Humans are the only reservoir of the virus. Following an incubation period of 1–2½ weeks the outbreak of the disease is characterized by fever and shivering fits. Later, vesicles develop all over the body, which on healing leave scars. Without treatment, the outcome is lethal in about 30% cases, complications are blindness, deafness, pareses and brain damage. At the end of the 18th century, Edward Jenner developed a vaccine against smallpox. Thanks to a WHO vaccination program, which was started in 1967, smallpox have been eradicated; in May 1980 WHO certified the world to be free of smallpox. Variola viruses are stored at two places, in a research center of the CDC in Atlanta and in a Russian research center near Novosibirsk. The devastating use of variola viruses in biological warfare can only be imagined.

Smog

Definition

Smog is a contraction of the words smoke and fog, suggested by a London physician, and it has been in common usage since the beginning of the 20th century. It is a common term that indicates the presence of an enormous amount of pollutants in the air around a large human settlement. Two different types of smog have been described – winter smog (London smog or industrial type of air pollution), and summer smog (photochemical smog or Los Angeles type), depending on the period of year in which it appears, and the presence or relative absence of solar UV radiation. Originating merely during the daytime, Los Angeles smog is a phenomenon characterized by a high concentration of ozone, haze, a characteristic odor, eye irritation, and plant damage. London smog, not related only to Great Britain's cities but also to other parts of the industrialized world, is a phenomenon produced by the unrestricted use of coal, primarily that containing large amount of sulfur. For this extreme atmospheric air pollution (smog episodes), numerous diverse sources and a variety of pollutants may be responsible (► Air Quality and Pollution), but major pollutants are carbon monoxide (CO), hydrocarbons, nitrogen oxides (NO_x), sulfur dioxide (SO_2), suspended particles, and ozone (O_3). Almost all disastrous smog episodes observed have occurred during certain unfavorable weather conditions such as cloud, dense fog, temperature inversion and dead calm lasting several consecutive days. In sufficient concentrations, accumulation of these substances leads to poor air quality, and affects human health, living matter and other materials. Considering health effects during smog episodes, increased morbid-

ity and mortality rates (an unusually large number of deaths) have been reported among vulnerable population groups – premature infants, newborns, the elderly, the infirm, and those with chronic pulmonary and/or heart diseases. Commonly registered diseases and complaints are as follows: a) acute upper respiratory tract illnesses, and complaints – nasal and throat irritation; b) lower respiratory tract illnesses (bronchitis, asthma, pneumonia), and corresponding symptomatology like chest constriction and pain, cough, shortness of breath; c) ocular mucous membrane symptomatology – eye irritation and lacrimation; and d) other complaints – headache, nausea and even vomiting.

Smoking

► Tobacco Consumption

Smoking Behavior

Synonyms

Nicotine use; Tobacco use

Definition

Cigarette-smoking leads to an increased risk of heart disease, cancer, both leading causes of death in Northern Europe and the United States. Although smoking declined steadily in the 1970s and 1980s, it levelled off in the 1990s. Men are more likely to smoke than are women – 27 per cent and 22% respectively in the United States although those rates are changing. Smoking is so addictive that fewer than 20 per cent who desire to quit are successful in doing so. Nausea, constipation or diarrhoea, drowsiness, lack of concentration, insomnia, headache and irritability are withdrawal symptoms frequently occurring in nicotine dependence who quit smoking. The prescription of bupropion has shown some success in helping smokers quit. This drug does not contain nicotine and was originally developed as an antidepressant drug. Other alternatives to alleviate withdrawal symptoms and craving include nicotine replacement therapy in the form of gum, patches, nasal sprays, and oral inhalers.

Smoking and Family Health

HEATHER WIPFLI

Synonyms

Tobacco and Family Health

Definition

The health and financial impact of tobacco use on families.

Basic Characteristics

Worldwide, nearly half of middle-school students report being exposed to secondhand tobacco smoke from others in their home. Students in Meghalay, India, report the highest exposure in the home at 79.8 percent (Global Youth Tobacco Survey Collaborative Group 2002). In the United States, where public policy has largely eliminated exposure to secondhand smoke in public places, 43% of children continue to live with at least one smoker (CDC 2003). Parental smoking results in numerous negative consequences on child and family health, as well as on the financial welfare of families.

Smoking and Pregnancy

Smoking reduces the fertility of women. Studies have shown that smokers take longer to conceive than non-smokers, and this includes women exposed to passive smoke. Smoking impairs the normal function of the fallopian tubes, alters the normal physiological levels of the reproductive hormones, reduces the chances of embryo implantation and increases the risk of pelvic inflammatory disease by altering the immune function. In men, some research has shown that cigarette smoking is associated with modest reductions in ► semen quality including sperm density (the total number of sperm cells per ml of semen) and motility (USDHHS 2004).

If a smoker does become pregnant, the rate of ► ectopic pregnancy doubles as well as the likelihood of many other pregnancy complications, including decrement in

birth weight, low birth weight and premature labor. In the US, some 20 percent of ► low birth weight births, eight percent of ► preterm deliveries, and five percent of all prenatal deaths are linked to smoking during pregnancy, making smoking the most important modifiable cause of poor pregnancy outcome (USDHHS 2004).

Non-smoking women exposed to tobacco smoke during pregnancy also are at risk for complications. Secondhand tobacco smoke is causally associated with decrement in birth weight, low birth weight, and preterm delivery. Other perinatal health effects that are possibly associated with secondhand smoke exposure are ► intrauterine growth retardation, congenital malformations and spontaneous ► abortion (IARC 2004).

Impact of Smoking on Child Health and Behavior

For young children, the major source of tobacco smoke is smoking by parents and other household members. Maternal smoking is usually the largest source of tobacco smoke exposure because of the cumulative effect of pregnancy and close proximity to the mother during early life. Furthermore, children of smokers are more likely to take up the habit themselves because they copy the behavior of adults and will perceive smoking as the norm if they grow up in a household where adults smoke (USDHHS 2000).

Exposure to tobacco smoke results in numerous childhood illnesses. Maternal smoking during and after pregnancy is causally associated with ► sudden infant death syndrome (SIDS), otherwise known as cot-death – the unexpected death of a seemingly healthy infant while asleep (USDHHS 2004). Infants of mothers who smoked during pregnancy are three times more likely to die of SIDS than those whose mothers were smoke-free; exposure to secondhand smoke doubles a baby's risk of SIDS. Investigations throughout the world have also shown significant increases in the frequency of bronchitis and pneumonia during the first year of life of children with parents who smoke (IARC 2004). Data from numerous surveys demonstrate greater frequency of the most common respiratory symptoms: cough, phlegm, and wheeze in the children of smokers (IARC 2004).

Exposure to tobacco smoke also reduces the rate of lung function growth during childhood. Having parents who smoke across the childhood years is estimated to reduce the maximum level of lung function reached by several percent. Evidence also indicates that exposure to tobacco smoke causes the onset of new asthma among children. Studies have found a significant excess of childhood asthma if the mother or both parents smoke. Exposure to tobacco smoke also worsens the severity of asthma in children already with it. In this regard, exposure to smoking in the home has been shown to increase emergency room visits and medication use by asthmatic children. There is also a causal relationship between exposure to tobacco smoke and otitis media (middle-ear disease or glue-ear) in children. Exposure to secondhand smoke has been evaluated as a risk factor for childhood cancers, however the evidence is limited and does not yet support conclusions about the nature of the observed associations between exposure and any childhood cancer (IARC 2004).

Impact of Passive Smoking on Spouse

► Active smoking by a parent also has negative health consequences for the non-smoking spouse. The first major studies that reported on ► passive smoking and lung cancer in non-smoking adults were based on studies of nonsmoking women married to cigarette smokers (USDHHS 1986). The excess risk of lung cancer in non-smokers married to smokers is currently estimated at 24% (IARC 2004). Besides lung cancer, exposure to tobacco smoke is also associated with coronary heart disease and data suggest that exposure may play a role in the genesis of chronic respiratory symptoms and produce small, but measurable, decrements in pulmonary function (IARC 2004).

Impact of Active Smoking on Smoker

Smoking is now identified as a major cause of heart disease, stroke, several different forms of cancer, and a wide variety of other health problems (USDHHS 2004). The vast majority of deaths caused by smoking occur through development of heart disease and lung cancer, followed by chronic bronchitis, stroke, peripheral vascular disease and other circulatory diseases, and cancers other than lung (USDHHS 2004). If cigarette smokers commence smoking as teenagers and do not quit, then eventually about half of them are killed by tobacco in middle or old age. This excess burden of death falls particularly heavily upon the 45–64 year old age group. Smokers between these ages are three times more likely to die prematurely than lifelong non-

smokers of the same age, and in the 65–84 age group, smokers are around twice as likely to die compared to lifelong non-smokers (WHO 2002). Illness and death caused by active smoking during these key years in which individuals are typically involved in raising children result in direct financial and emotional distress in families.

Impact of Smoking on the Family Finances

Smoking results in multiple financial costs for families. Money spent on cigarettes represents resources that could have been spent on other products for the family, such as food or education. Health care costs also rise in families with at least one smoker. Studies from the US indicate that the expected health care costs related to respiratory symptoms for children from households where one person smoked increase by 13% while if 2 or more smoked, the health care costs are 25% higher than non-smoking households. In total, exposure to parent smoking is estimated at $4.6 billion in annual direct medical costs (Aligne, Stoddard 1997). Health care costs for the smoker also rise dramatically. Family income is also reduced due to lost wages from absenteeism caused by illness. In many countries smokers must also now pay more for life insurance.

Smoke-Free Homes

In many countries, public policy has successfully reduced exposure to second-hand smoke, especially among working adults (USDHHS 2002). Public policy and educational campaigns have also resulted in an increasing number of households implementing voluntary bans. However, homes remain a primary location of tobacco smoke exposure for many children and non-smoking adults. Second-hand smoke in the home is a major source of exposure because children spend most of their time at home and indoors. Unlike adults who can choose whether or not to be in a smoky environment, children have little choice. They are far less likely to be able to leave a smoke-filled room if they want to: babies cannot ask; some children may not feel confident about raising the subject; and others may not be allowed to leave even if they do ask. Public education and interventions, in addition to stronger public smoking restrictions, can be implemented in order to improve family health.

SNP (Single Nucleotide Polymorphism)

Definition

Any polymorphic variation at a single nucleotide (single base substitution). Although the term polymorphism is used, SNPs are considered to be the most important genetic basis of complex (multifactorial) diseases. Thus, the term variant instead of polymorphism would be more appropriate.

Social Action Theory

Definition

The social action theory attempts to integrate social contextual factors which builds on social cognitive learning theory, models of self regulation, processes of social interdependence, social interaction, and underlying biological processes to predict health-protective behaviors and outcomes. It views the person as influenced by environmental contexts or settings to which he or she brings a particular temperament and biological context. Thus, a person's capacity to practice healthy eating habits and to exercise is influenced by access to health-enhancing foods and safe places to exercise and by internal goal structures, self-efficacy beliefs, and problem-solving skills.

Social Anxiety Disorder

► Social Phobia

Social Anxiety Disorder of Childhood

Definition

In this disorder, there is a wariness of strangers and social apprehension or anxiety when encountering new, strange, or socially threatening situations. This category should be used only where such fears arise during the early years, and are both unusual in degree and accompanied by problems in social functioning. This is an avoidant disorder of childhood or adolescence.

Social Control

Definition

The social processes that govern individual actions such that they are consistent with group norms, values, and rules. In addition to explicitly institutionalized rules and governing structures (e. g. a criminal justice system), social control is maintained through the interpersonal interactions as part of social monitoring and social reinforcement. Individuals in relative positions of power (e. g. parents, teachers, peer leaders) display appropriate behavior and attitudes, monitor the extent to which other group members display similar behavior and attitudes, and reinforce behavioral norms and accepted values and attitudes through positive reinforcement (social sanctioning) and negative reinforcement (social stigma).

Social/Emotional Support

Synonyms

Mentoring; Caretaking; Advising; Providing

Definition

There are three primary categories of social support: emotional support, guidance support, and tangible support. Emotional support includes behaviors that express physical affection and concern for well-being. Guidance support is the provision of knowledge, advice, or mentoring on how to achieve a goal. Tangible support is the provision of any type of resource including money, food, housing, transportation, etc.

Social Factors

Synonyms

Social determinants

Definition

Health is influenced by genetic, psychological, and social factors, in addition to factors related to health care provision. Social factors are defined as influences produced by macrosocial and/or microsocial environments that are mediated either by health-related behaviors or by emotional and stress-related reactions. A macrosocial environment is characterized by societal features such as class structure, labor market, income distribution, and social integration. A microsocial environment relates to settings of everyday life, including family and neighborhood, social networks, schools, and workplaces. These influences impact on health by either protecting or promoting health, or by deteriorating well-being. In general, health adverse social factors follow a social gradient, with poorer health among people with lower socioeconomic status, as measured by education, income, or occupational standing.

Social Health

Definition

Social health refers to the ability of an individual to form relationships with his or her social environment, including parents, peers, superiors and society.

Social Health Insurance

Definition

The term social health insurance refers to health insurance schemes that are heavily regulated (most importantly premium rate restrictions, standardized benefits, and mandatory coverage) in order to avoid problems of ► adverse selection and provide comprehensive coverage. Premiums in social health insurance are either community-rated, income-dependent, or a mix of both.

Social Identity

Synonyms

Group identity

Definition

Social identity refers to psychological and sociological elements of behavior and attitudes derived from belonging to a particular group. Each individual has both social and personal identity, each informing the individual of who he is and what this identity entails. Which of these many identities is most salient for an individual at any time will vary according to the social context. Social identity may explain when and why individuals identify with, and behave as part of, social groups.

Cross-References

► Cultural Identity

Social Inequalities in Dentistry

SEBASTIAN ZILLER
Head of Dept. of Prevention and Health Promotion, German Dental Associationy, Berlin, Germany
s.ziller@bzaek.de

S

Definition

Social inequality refers, on the one hand, to a distinction between sections of the population according to typical features: education, income and professional status. These features also permit a subdivision of the population into a "top section" and a "bottom section" (so-called vertical social inequality). With these data a relatively correct estimate of the "socio-economical status" of an individual is possible so that this individual can be categorized in a hierarchical scale or a "social stratum". On the other hand, the population can be classified according to further features: age, sex, marital status and nationality. Between these two groups, too, social inequalities may exist. Where the differentiation between these groups crosses the differentiation of the vertical social inequality, an estimation of an individual's status can be made; the term horizontal social inequality is used in this respect (Mielck 2005). Social inequality has a lifelong impact on people's general health and, therefore, on their oral health: lower socio-economical status equates with more susceptibility to (oral) diseases, less (oral) health and shorter life expectancy.

Basic Characteristics

General Background

To What Extent is this a Problem in Germany? In Germany approximately 9% of the population live below the ► poverty line. The Advisory Council on the Assessment of Developments in the Health Care System states in the "Socio-economical Status and Health" chapter of its report dated 2005:

If the population living in Germany is classified into five strata equal in size according to the features Income, Education and Professional Status (Quintile), the group of the population of the lowest "quintile" of each age – from birth to death – has, at a rough guess, a double risk to fall seriously ill compared with the group of the population of the top "quintile". This refers to all major diseases, including ► oral diseases, except breast cancer, alcoholism and allergies. The social inequalities in matters of health chances, (oral) health, and life expectancy decrease continually the lower the income and education and the lower the social status of the individual are (SVR 2005).

However, it becomes rather evident that even the lowest social stratum benefits from the overall increase in the population's health, e. g. a longer life expectancy which is per decade a bit more than a year. In addition, the lowest social stratum also benefits in that the elderly, in general, now maintain better health as they grow older. But these so-called benefits in health have an unequal distribution within the population and the social inequality continues to increase in most European countries (Rosenbrock 2006 with further evidences).

Specific Background

The Social Determinants of Oral Health (SDOH) For a long time the (oral) health status of the population has mainly been defined by the delivery and financing of medical care. However, scientific surveys show that in highly developed countries the groups which have the highest risk of falling ill or dying young have:

- the lowest income;
- the lowest education level;
- the least possibilities to structure their lives;
- the lowest social assistance by small social networks (social support); and
- the lowest political influence – as an individual and also as a group (Rosenbrock 2006; Mielck and Bloomfield 2001).

In short: the poor have a shorter life and fall ill more frequently than the rich. Due to this finding science and politics are more and more interested in the fact that health, including *oral diseases*, reacts very seriously to social environmental influences, the so-called *social determinants of oral health (SDOH)* (Bund, 2005). The most important SDOHs with a lifelong impact on health are (WHO 2004):

- education and care in early life,
- social exclusion/inclusion,
- job security and working conditions,
- income inequality,
- stress,
- social support,
- general access to medical care,
- housing and food security,
- physical environment.

Thus, socio-economical conditions influence the health status of individuals more than personal health behaviors and medical care. However, not only the objective stresses on an individual need to be considered but also the individual's possibilities and capacities to accept

these strains and to deal with them need to be considered (Sense of Coherence). Thus, the health strain per se is not the important factor: it is the individual's coping resources that matter. In this context, the personal health behavior of an individual is influenced by this interaction and also by the kind of health care provided. Marmot and Wilkinson (1999) have written an extensive and recommendable paper on Social Determinants of Health.

Social Inequality and Oral Health Many surveys on the prevalence of oral disease in the population have been made in Germany and internationally and they show that ► dental caries is the most investigated dental disease, particularly in children and young adults. Comparative cross-section studies carried out in the industrialized countries of western Europe and in the USA show that since the 1970s there has been a continual decrease in the frequency of caries (caries decline). Of particular interest is the improvement in the oral health of the 12-years-age group in Germany. This is a real success story of the efforts made in dental prevention in children and young adults. The scientific studies show that, in addition to the effects of poor eating habits and poor oral hygiene, there is a series of biopsychological and behavioral disease risks which support the formation of caries. The vertical as well as the horizontal social inequality has visible influence on the caries prevalence in the population. Thus, the vertical social risks (poor education, low income) are, amongst others, the cause of – in comparison with other countries of similar standard – poor dental health in the lower social stratum, compared to the upper stratum of the population. This example of the 12-year-olds in Germany shows that the major caries frequency is concentrated in a relatively small group of individuals. In 1997, 61% of all DMF-Teeth (► DMFT-Index) of the 12-year-olds were diagnosed at 22% of the children of this age group (IDZ 1999). In 2005, 10% of the 12-year-olds had 61% of all DMF-Teeth. Although these figures indicate that the risk group has decreased, in fact – on the contrary – the polarization of caries has increased (IDZ 2006). Table 1 shows the influence which social strata (here: school education of the parents) exerts on the oral health of children and young adults. The proportion of naturally healthy dentition in children and young adults in the upper class is quite above the proportion in the social underclass.

Social Inequalities in Dentistry, Table 1. Percent naturally healthy dentition in 12-year-olds dependent on the school education of the parent

Year	Naturally healthy dentition by 12-year-olds (%) School education of the parents		
	Low	Average	High
1989 (First German oral health study DMS I)	9.5%	13.0%	28.6%
1997 (Third German oral health study DMS III)	44.8%	34.3%	50.1%
2005 (Fourth German oral health study DMS IV)	68.0%	67.3%	75.4%

Source: German oral health surveys 1989, 1997, 2005

For dental public health these findings are of great political significance regarding the prevention and care of a very high proportion of children and young adults of lower social class (caries polarization). An analysis carried out in connection with the Third German oral health study made clear that caries is particularly frequent in the young adult age group:

- who do not see a dentist for regular check-ups;
- who do not brush their teeth twice per day after the meals; and
- who have never had a professional instruction on correct tooth brushing (IDZ 1999).

However, caries polarization is not only observed in children and young adults. This socio-medical problem exists in all age groups and at different levels of severity. The second major oral disease, periodontal disease (periodontitis), shows clear stratum-specific differences with regard to its frequency in the population (Micheelis 2001). Thus, in the group of the 35–44-year-olds 32.9% of low education level, 19.1% of average education level and only 13.4% of high education level in the population suffer from a severe periodontitis (► CPI level 4) (IDZ 2006).

It is also evident that although the bottom social strata profits from prevention measures, these advantages and benefits of oral health care are, of course, less marked and significant than in the top social strata.

Consequences

Strategies Oral health promotion strategies can be orientated either towards the population as a whole or

towards groups or individuals at risk of disease. The risk of suffering from many chronic diseases can be reduced by actions to reduce smoking and alcohol consumption and improve diets. These approaches also have an impact on the prevalence and severity of oral diseases. In addition, the use of fluorides reduces the prevalence of tooth decay. This strategy focuses on the whole population with an additional emphasis on some of the more vulnerable groups (e. g. ► setting concepts). The absolute objective is to reduce inequalities in oral health. On the one hand, it is, therefore, of great importance in public health research to draw the attention to societal responsibility, i. e. that a multitude of economical and social decisions also include very important decisions concerning health matters. On the other hand, the health resources of the population must be strengthened. The most important ressources are self-consciousness and self-confidence, self-efficiency, education, income, participation, involvement in social networks and possibilities for relaxation and recovery. Reducing stress and increasing resources are potential strategies to reduce social inequalities in oral health matters and life chances. Generally formulated strategies to strengthen the social determinants of health are: Promotion of employment, job security and healthy working conditions; protection of universal access to a quality health system; expansion of early childhood education and care programs; provision of adequate housing and food; reduction of income disparities; support of social networks.

Conclusion

Poor oral and general health are more common in areas of relative deprivation and poverty. The wider social determinants of health have, of course, an impact on oral health. All fields of politics, explicit health policies, primary and secondary prevention as well as health promotion and the curative and rehabilitation fields, are influenced by the interaction and correlation of social situation and health status. Therefore, those involved in politics, public health research, health care research and prevention and health care in Germany must deal with the social determinants of oral health (SDOH) in order to analyze the causes of health deficits and to develop strategies orientated per se towards better general and oral health. Priority should be given to social inequality as a primary determinant of health status.

Socialization

Synonyms

Acquiring social identity

Definition

Socialization is the process by which individuals learn to adopt the behavior patterns of the community in which they live. This process is typically thought to occur during the early stages of life, during which individuals develop the skills and knowledge necessary to function within their culture and environment. However, this also includes adult individuals moving into an environment significantly different from one(s) in which they have previously lived and must thus learn a new set of behaviors. Socialization for social agents refers to all learning regardless of setting or age of the individual. In every group one has to learn the rules, expectations, and knowledge of that group, whether the group is your family, the army, or the state (nation). Socialization is the process whereby people acquire a social identity and learn the way of life within their society.

Social Justice

Definition

In the field of public health social justice refers to reducing differences in current health status and ensuring equal opportunities and resources to enable all people to achieve their fullest health potential. It is a big concern in as much as increased costs of health care have brought along disparities in its distribution and accessibility within a specific population and at global level.

Social Learning Theory

Synonyms

Social cognitive theory; Cognitive social learning; Cognitive learning theory

Definition

The social learning theory, also called Social Cognitive Theory, not only explains how people "learn" and maintain certain behavioral patterns, but also explicates factors influencing health behaviors and thereby provides the basis for intervention strategies for the promotion of behavioral change. Human behavior is explained in terms of a triadic, dynamic, and reciprocal model, in which behavior, personal factors (including cognitions), and environmental influences all interact.

The Social Learning Theory is widely used since its concepts are easy to operationalize for health promoting interventions: role models can be used to model positive outcomes, to correct misconceptions, to demonstrate self-reward, to reflect mastery, to point out opportunities, to signal social support, etc.

Social Marketing

Definition

The term "social marketing" is defined as "the application of commercial marketing technologies to the analysis, planning, execution, and evaluation of programs designed to influence voluntary behavior of target audiences in order to improve their personal welfare and that of their society". Social marketing began as a formal discipline in 1971, with the publication of "Social Marketing: An Approach to Planned Social Change" in the Journal of Marketing by marketing experts Philip Kotler and Gerald Zaltman. Speaking of what they termed "social change campaigns", Kotler and Roberto introduced the subject by writing "A social change campaign is an organized effort conducted by one group (the change agent) which attempts to persuade others (the target adopters) to accept, modify, or abandon certain ideas, attitudes, practices or behavior". Social marketing is distinguished from other management approaches by six basic principles: (1) the marketing conceptual framework is used to design behavior change interventions; (2) there is recognition of competition; (3) there is a consumer orientation; (4) formative research is used to understand consumers' desires and needs; (5) there is a segmentation of populations and careful selection of target audiences; and (6) continuous monitoring and revision of program tactics help to achieve desired outcomes.

Social Maturation

► Social Transition

Social Networks

Definition

Social networks are the social relations and links between individuals which may provide access to or mobilization of social supports for health. They are long-lasting but non formalized structures and relations between individuals and/or groups. As opposed to the cooperation of organizations and institutions, social networks provide support to the individual who needs to cope with stressful living circumstances (e. g. diseases), and promotes health at an individual level. Social networks can be divided into primary social networks (e. g. family, relatives and friendships), secondary social networks (e. g. self help organizations) and tertiary social networks (professional advice centers, hospitals, physicians, etc.).

Social Phobia

Synonyms

Social anxiety disorder

Definition

Social phobia is characterized by a permanent and exaggerated fear of one or more social situations in which a person might be confronted with strangers or might be evaluated by other people. Transition to social anxiety, a common phenomenon known by virtually all people, is smooth. Characteristically, people fear to show a behavior (e. g. trembling, blushing, sweating) that could be humiliating or embarrassing to them. Other typical fears are that people could notice halting or rapid speech. Fears of fainting, losing control of bowel or bladder function, or having one's mind going blank are also not uncommon. Social phobias generally are associated with significant anticipatory anxiety for days or weeks before the dreaded event, which in turn may further handicap performance and heighten embarrassment. This fear occurs when anticipating a situation that is perceived as threatening, usually leading to avoidance of the situation.

Social Psychiatry

ISABEL HACH
Klinik für Psychiatrie und Psychotherapie,
Klinikum Nürnberg-Nord, Nürnberg, Germany
isabel.hach@klinikum-nuernberg.de

Synonyms

Cross-cultural psychiatry; Psychiatric sociology; Community psychiatry

Definition

Social psychiatry is concerned with the relationships between mental disorders and sociocultural processes. Social psychiatry has the aim to view the patient and the context in which he or she lives or works as a field in which one element affects all others in circular fashion. One of the main goals of social psychiatry is to reintegrate the patient into society (► socialization). The label social psychiatry is often used to include other labels, i. e., transcultural psychiatry; cross-cultural psychiatry; crossnational, transnational, or international psychiatry; intercultural psychiatry; ethnopsychiatry, and comparative psychiatry. ► community psychiatry is practiced social psychiatry.

Basic Characteristics

Introduction

At the turn of the 19th century, the "moral treatment" for hospitalized psychiatric patients in Europe was introduced. The positive relations among the patient's environment and humane social interactions, on the one hand, and an improvement in patients' functioning on the other hand, were recognized. The importance of social psychiatry became obvious in the United States

at the beginning of the 20th century with the work of A. Meyer. He became well-known for emphasizing many important social factors and integrating social work into his psychiatric treatment settings (Brady 1975). Many American psychiatrists and other mental health professionals followed in Meyer's footsteps: Among them, K. Horney, who wrote about personality as it interacts with other people (1937); E. Erikson, who discussed the influence of society on life development (1950); and Cornell University's Midtown Manhattan Study, which looked at the prevalence of mental illness in Manhattan (e. g., Srole 1975). In Germany, Fischer stated in 1919 that there is no psychiatry without social psychiatry (Berger 1999). However, ► euthanasia of mentally ill patients (>100,000 patients were killed) destroyed all social psychiatric developments in Germany for a long time. World War II and the psychiatric casualties from trauma made worldwide the influence of social stress more apparent. The success of crisis resolution on the war front and in other outpatient interventions, along with a moral concern over hospital warehousing, led to ► deinstitutionalization and a new social system of care in the guise of the community mental health care movement of the 1960s in the U.S.A. and England (Bühring 2001). Franco Basaglia is widely recognized as the Italian leader of the democratic psychiatry movement in Europe. His political and social agenda involved, for example, decriminalizing mental illness and the importance of voluntary psychiatric treatment. In Germany, dehospitalisation started late as a consequence of the "Psychiatrieenquete" 1975 (a fundamental report of the situation of psychiatry in Germany). By the 1980s, social factors had a presence in the Diagnostic and Statistical Manual of Psychiatric Disorders III (DSM-III) in the Axis IV and V categories.

Severe and Persistent Mental Illness

People with severe and persistent mental illnesses (SPMI) have been a special target population for social psychiatry and public mental health. People with SPMI suffer from major mental illnesses such as schizophrenia or major affective disorders (with psychotic symptoms). Severe mental illnesses cause their sufferers dismal functional impairment. People affected with schizophrenia might have difficulties in thinking coherently, interacting with others normally, problems in managing of work, strange beliefs, extraordinary physical complaints, carrying out responsibilities and expressing emotions appropriately. Even simple everyday tasks like personal hygiene can become unmanageable and neglected. Thus, the disease can impact every aspect of affected people's work, family, and social life. Though not affected directly, family members also frequently become distressed and overwhelmed by the difficulties involved in providing care and in coming to terms with the transformation of their relatives into patients suffering from serious chronic illness.

Principles and Goals of Social Psychiatry

The goals of social psychiatry were always broad, for example: To include all social, biological, educational, and philosophical considerations which may come to empower psychiatry in its striving towards a society which functions with greater equilibrium and with fewer psychological casualties (Jones 1968). For social psychiatrists, it was obvious that the individual could not be treated as separate from the society and that the society contributed greatly to mental disorders. Social psychiatry is a scientific approach that is influenced by different historical dimensions. Hence, social psychiatry criticizes traditional psychiatric concepts and has a social theory of mental disorders. Social psychiatry consists of different treatment dimensions and therapy strategies (e. g., social network, medical treatment, structuring of daily activities, complementary care in the living and work area).

Carleton and Mahlendorf (1979) summarized the principles of social psychiatry in six postulates:

1. Human behavior can only be understood in the context of the total social and other energies (including living and inert physical matter) of this universe.
2. A person should always be a subject and never an object of an interpersonal transaction.
3. There is meaningful interrelationship, a relativity, between the behaviors of one individual and all social and mythological institutions and groups.
4. Social problems, including individual, institutional and group deviant behaviors, cannot be solved without collaboration between all the institutions and disciplines of human knowledge, influence, and action.
5. Values of compassion, caring, and consideration for all human beings are essential to the operations of social psychiatry.

6. Human behavior acquires purpose and meaning in reference to and by virtue of adherence to these postulates.

Those aims of social psychiatry are still up to date. In Germany, mental health care research clearly dominates social-psychiatric research. While in the beginning, most research was devoted to the conceptualization and description of psychiatric services, in recent years more studies on outcome evaluation and quality assurance were carried out. More and more the subjective perspective of patients and relatives becomes relevant. Topics such as treatment satisfaction, subjective illness theory, and subjective quality of life enjoy growing interest. The same holds for *stigmatization* of mentally ill people. By contrast, studies investigating psycho-social influences on the development and the course of mental disorders are still very rare (Holzinger and Angermeyer 2002). Another important related field are the treatment costs of severe and persistent mental illnesses. The prevalences rates of psychotic disorders are significantly lower than those of affective or anxiety disorders. However, Löthgren showed in a recent published literature review that more research has been conducted across Europe for schizophrenia than for the mood disorders. There are marked differences in variation among European countries regarding service provision, resource use, and costs for schizophrenia treatment, for example range the direct and non-direct medical cost estimates per patient per year from €2152 in Spain to €8188 in Italy and €14 927 in Denmark (Knapp et al. 2002).

Last, research in transcultural psychiatry with potential clinical or social applications has covered such themes as, for example, similarities and differences in the form, course, or manifestation of mental illness in different societies and cultures; the occurrence, incidence, and distribution of mental illness in relation to sociocultural factors; sociocultural factors predisposing to mental health or to optimal function or to increasing vulnerability to or perpetuating or inhibiting recovery from mental illness or impaired function; the relationship between culture; and the psychological and social adaptation of migrants, voluntary or involuntary, within or across national boundaries especially insofar as their cultural traits or those of the receiving society are significantly involved.

There is a broad consensus on principles and aims of social psychiatry in European countries. However, the implementation of mental health reforms has been slow. According to Cooper (2001), progress is subject to constraints imposed by service infrastructures, reductions in state responsibility, changing public attitudes, and growth of relative poverty. Much inferential evidence has accumulated on the importance of social risk factors such as unemployment and socio-economic deprivation, but most studies have had to rely on analysis of ecological correlations, based on administrative data. There is an urgent need for more direct research in the field of social psychiatry making use of case-control and cohort study designs.

Social Regulation

► Cross-Sector Efforts

Social Relations

Synonyms

Communication; Interpersonal relations

Definition

Social relation refers to a multitude of social interactions, regulated by social norms between two or more people. It may be relation between individuals, groups of people or between an individual and group of people. Group in this context, refers to an ethnic group, social institution or organization, nation, gender, etc. Social relations form the basis of concepts such as social structure, social organizations or social system. By "social" is understood association, co-operation, mutual dependence and belonging.

Cross-References

► Human Relations

Social Resources

Synonyms

Social capital

Definition

These are goods that derive from inter-personal relationships with other individuals. There are direct psychological goods, such as social support that develop from inter-personal relationships. In addition, there are the material goods (e. g. money) that individuals are provided the right to request in light of the nature of the inter-personal relationship and history of returning similar requests. Inter-personal relationships through which exchange relationships develop are based on friendship, family ties, political connections and other social relations.

Social Stigma

Definition

An organized process by which a group denies material and psychological privileges to individuals who do not display – or are not considered by the group to display – the characteristics, beliefs and behavior the group has defined to be important to group membership.

Social System and Organization

► Health Setting

Social Transition

Synonyms

Social maturation; Social development

Definition

Social transition is characterized by the adolescent's expansion of their social circle of significant others from parents/family to include peers and other adults.

Social Welfare Policy

Synonyms

Social policy

Definition

A broad term encompassing a range of government policies enacted to protect citizens from economic risks, insecurities, and dependency. These policies include income support policies, educational systems, treatment of mentally ill, rehabilitation of criminals, provision of health care and health insurance, and the care of destitute adults.

Societal Perspective

Definition

The most comprehensive perspective of health economic analysis is the societal perspective. From the perspec-

tive of the society, all costs and benefits of a health care intervention or illness are taken into account. With regards to the costing process in a calculation from a societal perspective, the direct medical and non-medical costs (► direct cost) for all health care payers and the patient as well as the ► indirect cost due to lost productivity are included. Most recommendations for ► health economic evaluation studies suggest choosing the societal perspective at least in addition to other perspectives.

Society

Definition

In general, society is seen as life within a living community. On closer examination, society means structures with organized systems in which human beings live and work together.

Cross-References

► Nation

Socio-Cultural Barriers

Definition

In health care settings, socio-cultural barriers prevent specific population groups such as migrants from utilizing services sufficiently and efficiently. A lack of local language skills can create a socio-cultural barrier. Gender issues, differing knowledge and information systems and problems with interpreting subtle, non-verbal signs in the context of health, disease and therapy might act as further barriers that can hinder migrants from making competent and appropriate use of available services.

Socio-Cultural Definitions of Old Age

Definition

Old age is a biological fact and a socio-cultural construct. In different cultures, the classification of old age can vary substantially and be at variance to a person's actual age. In some ethnic groups, for instance, to belong to the group of the aged is defined by having grandchildren, independent of a person's actual age. For several decades, gerontological research has held the belief that modernity created negative images of old age whereas so-called traditional societies valued persons of old age. Currently, the picture of inter- and intracultural variation regarding concepts of old age is more diverse. Appreciation and discrimination may coexist in societies with regard to gender, economic power or other status indicators such as education.

Sociodemography

Synonyms

Population characteristics

Definition

The study of populations, especially with reference to size and density, ► fertility, ► mortality, growth, age distribution, migration, and vital statistics, and the interaction of all these with social and economic conditions.

Sociodental Indicators

Synonyms

Socio-dental indicators

Definition

Sociodental indicators are measures for the psychological and social impact of dental diseases. They assess the extent to which dental and oral disorders disrupt normal social functioning. Sociodental indicators reflect the quality of life of the individual and the well-being of society. They are subjective measures, related to a biopsychosocial model of health. They should be used to supplement clinical (normative) measures like the ► DMFT, which depend on professional opinions of what constitutes a disease. Sociodental indicators relate to the following biophysical and sociomedical parameters: Death, disease, impairment, functional limitation, discomfort, disability and disadvantage. The majority of sociodental indicators are "problem indices" that can be used to understand the population's experiences and perceptions and to demonstrate the need for oral health promotion. Sophisticated new needs assessment tools

integrate normative and subjective estimates of treatment need, taking into account the severity of diseases and the willingness of the respective patient to get treatment.

Socioeconomic Environment

Synonyms

Socioeconomic status; Socioeconomic position

Definition

The social and the economic characteristics of both the work environment and the home environment, for given person or a group of people. Some examples of social characteristics include literacy level, ► social support, physical safety, and connectedness in the community. Economic characteristics include income and the distribution of income within a community. Some researchers believe that the health of a community is dependent upon a relatively equal distribution of wealth among its individuals.

Socioeconomic Indicators

Definition

Socioeconomic characteristics include measures that affect health status, such as income, education, employment, household conditions, lifestyles, and environment, and measure the proportion of the population represented by various levels of these variables.

Socioeconomic Influences

► Health Determinants, Social

Socioeconomic Position

► Socioeconomic Environment

Socioeconomic Status

► Socioeconomic Environment

Sociopolitical Culture

Synonyms

Welfare culture

Definition

The health care systems of the industrial nations differ appreciably in their funding models, levels of benefits and forms of organization. The reasons for this situation are studied by the methodological approach of sociopolitical culture, which describes and analyses the historical and cultural place of social security systems within a country's prevailing body of social values. In the context of international comparative welfare state research – specifically, research on health care systems – the genesis, development and configuration of national welfare state institutions are traced back to a society's prevailing attitudes, norms and interpretative patterns (such as ideas of social justice). The importance of the sociopolitical culture emerges in particular in relation to the social acceptance of reform measures in the field of social security.

Socrates

Definition

A highly regarded philosopher, recognized as one of the main contributors to Greek history within wider Europe.

Soil Degradation and Erosion

Definition

Types of soil degradation are erosion, desertification, acidification, and salination. Desertification is a natural process of ecosystem degradation in arid regions. It can result from continued human land abuse during droughts. Increased population and livestock pressure on marginal lands also accelerates desertification. Erosion of the soil is caused by wind, water, ice, and land movement in response to gravity. Erosion is an intrinsic natural process, but in many places, it is increased by human exploitation. When the total ground surface is stripped of vegetation and then seared of all living organisms, the upper soils are vulnerable to both wind and water erosion. One of the main causes of soil erosion is slashing and fire treatment of tropical forests. Poor land use practices include deforestation, overgrazing, and improper construction activity. Improved management can limit erosion by using techniques like restricting the disturbance during construction, avoiding construction during erosion prone periods, intercepting runoff, terrace-building, use of erosion-suppressing cover materials, and planting trees or other soil binding plants. Soil acidification is a problem in many regions of the world due to acid rain deposits, which change the chemical properties of the soil. Soil salination might be a natural process that results from high levels of salt in the soil, features that allow salts to become mobile, or climatic trends that favor salt accumulation.

Soil Genesis

► Pedogenesis

Soil Pollution

Dušan Backović
Institute of Hygiene and Medical Ecology, Faculty of Medicine, University of Belgrade, Belgrade, Serbia
dbacko@ptt.yu

Synonyms

Land pollution; Soil contamination

Definition

Pollution of the soil is physical, chemical, biological, or radiological modification of the surface layer of the earth's crust by accumulation of a large quantity of natural materials or occurrence of new synthetic materials that disturb the composition of the soil, influence the natural balance of the ecological system, and disable the ► purification process (self-cleaning) of the soil. The consequences of soil pollution depend on the kind, quantity, and dynamics of disposal of harmful materials, and also on soil composition, structure, and its physical and chemical characteristics.

Basic Characteristics

Characteristics of the Soil Pollutants

Soil pollution may be the result of disposal of solid waste materials, overflowing waste water, or deposition of air pollution sediments. According to the source of emission, soil pollution can originate from communal and industrial environments, and according to the nature of pollutants from inorganic or organic chemicals, radioactive nuclides or infective agents. It is also possible that the soil is polluted with combinations of pollutants from different sources.

Pollution with organic waste, especially components of animal and human tissues and excreta, bears a high risk due to the possibility of microbiological contamination and infections in humans and animals. Pollution of cultivable soil represents a serious hazard, and pesticides and fertilizers carry the risk of intoxication of people and animals through contaminated food.

Among industrial waste materials, the most dangerous are synthetic organic compounds, due to their biopersistence (resistance to degradation), accumulation in biological species, and even ► bioconcentration in the food chain.

Characteristics of the Soil

In most cases, pollution of the soil is reversible, and decomposition of the pollutants is continuous, occurring simultaneously with decomposition of the soil. The self-cleaning ability of the soil mostly depends on the mechanical structure of the soil, physical and chemical

characteristics (such as oxygen and moisture, pH), and composition of microflora, flora and fauna (types and quantities), which often become damaged as a result of excessive pollution. It is important that there are zones of unpolluted soil from which the living species may recolonize a damaged area and initiate the natural process of purification. The process of decomposition of waste in the soil depends on the type and quantity of natural or artificial waste substrate (carbohydrates, fats and proteins, chemical products). If the soil is polluted with large quantity of organic waste materials, there are adverse conditions for their decomposition, and they can leave by-products and gases of unpleasant odor.

The structure of the upper layers of the soil is constantly being changed by physical factors:

1. sun radiation, warming, and cooling, which causes mechanical weathering of bedrocks
2. atmospheric influences and the influence of the climate, especially heavy precipitations cause ► soil degradation and erosion
3. deep layer movements and earthquakes

Formation of the soil or ► pedogenesis is also a permanent geobiological process influenced by all living organisms and humans, particularly by anthropogenic pollution important in soil degradation. The structure and texture of soil depends on the size, shape, and type of connection of particles. Within the solid structures of soil, cavities can be found which result from the activity of atmospheric water, and even the activity of animals. The porosity of soil determines the quantity of water and air that the soil can absorb. Air contained in the pores of the soil determine the physical and chemical characteristics, plant growth, activity of bacteria, and self-cleaning properties of the soil.

Out of all the chemical elements that make up the surface of the earth's crust, oxygen and silicon are present in the highest proportion (over 80%), followed by aluminum, calcium and iron. Minerals originating from the soil are classified into two main groups according to quantity and physiological function in the human organism:

- ► major elements (macronutrients) constitute up to 80% of the minerals in the human body, as well as 99% of the minerals in the soil (O, H, C, N, Ca, Na, K, P, S, Cl, Mg)
- essential ► trace elements, like micronutrients (Fe, Se, Cu, Zn, Co, F, I, Mn, Cr), are found in concentrations of about 10–100 ppm, some with known physiological functions and others without.

Deficiency of some trace elements (such as iodine, fluorine, and selenium) in regions with naturally anomalous distribution of them is manifested in the disturbance of health in the form of enzootic and/or endemic disease; this area is investigated by ► geomedicine. The global problem of shortage or reduced bioavailability of some trace elements in the soil is slowly spreading to many regions of the world due to acid rain (deposited sulfates and nitrates) changing the chemical properties of the soil.

Health Effects of the Soil Pollution

There is a very large set of health consequences from exposure to soil contamination, which depend on pollutant type, pathway of spreading, and vulnerability of the exposed population. In cases of pollution with organic waste from hospital and laboratory environments, the highest risk is due to possible microbiological contamination. The most frequent and widely spread microbiological agents that can be found in the soil are those that cause typhoid fever, cholera, tularemia, leptospyrosis, tetanus and gaseous gangrene, and anthrax, and parasites like Trichocephalus, Ankylostoma, and Ascaris. Pollution of cultivable soil represents a serious danger, especially for agricultural workers. In communal environments, the people who are in direct contact with polluted soils such as in residences, parks, schools, and playgrounds (children) have the greatest health risk. Other contact mechanisms include contamination of drinking water or inhalation of soil contaminants that have vaporized.

Heavy metals like chromium and a number of pesticides are carcinogenic to all populations. Lead is especially hazardous to young children, a group with a high risk of developmental damage to the brain and nervous system. Mercury is known to induce higher incidences of kidney damage, and PCBs and cyclodienes are linked to liver toxicity. Chronic exposure to benzene is known to be associated with a higher incidence of leukemia. Many chlorinated solvents induce liver and kidney changes and depression of the central nervous system. Organophosphates and carbamates can induce acute intoxication, leading to neuromuscular blockage.

Assessment and Control of Soil Pollution

Soil pollution can be investigated by means of toxicological, radiological, bacteriological, and parasitological methods, while the final evaluation and conclusions are made on the basis of data analysis of the results from all of the mentioned methods. Chemical methods test the quantity of materials belonging to the normal composition of the soil, which occur in excess during decomposition of waste (organic nitrogen and carbon, ammonium, nitrates, and chlorides), and also test qualitatively synthetic materials that are unusually present in the soil like heavy metals and pesticides. Bacteriological tests consist of determination of the total number of bacteria, number of coliform bacteria, and *Clostridium perfrigens* in a volume unit of the soil.

Large projects related to the prevention of chemical pollution of the soil include implementation and control of the production process, aiming at a decrease in production, and increase in recycling and neutralization (dechalogenation and burning of the plasma of dangerous PCBs, for example), as well as efficient disposal and protection of non-decomposable waste materials. The next large project is implementation of a program of disposal of and protection from infectious waste materials (from veterinary and public service facilities). Continued measures of maintenance of quality of the soil are also important, as follows: building of facilities for waste disposal and permanent collection and removal of waste, construction of corresponding water supply and sewerage systems, waste water purification, construction of drainage systems for precipitation, and growing plants on all cultivable surfaces. Strategies for reducing soil degradation and erosion in some regions include planting of cover crops, establishment of windbreaks, strip cropping, terracing, and minimum-tillage farming. Recent projects have developed successful new methods in artificial purification of the soil like ► georemediation (accelerated geochemical remineralization) ► phytoremediation and ► bioremediation (by natural plants and micro-organisms stimulated with additional nutrients).

Somatization Disorder

Definition

The main features of somatization disorders are multiple, recurrent, and frequently changing physical symptoms of at least two years duration. Most patients have a long and complicated history of contact with both primary and specialist medical care services, during which many negative investigations or fruitless exploratory operations may have been carried out. Symptoms may refer to any part or system of the body. The course of the disorder is chronic and fluctuating, and is often associated with disruption of social, interpersonal, and family behavior.

Somatoform Autonomic Dysfunction

Definition

Symptoms are presented by the patient as if they were due to a physical disorder of a system or organ that is largely or completely under autonomic innervation and control, i. e. the cardiovascular, gastrointestinal, respiratory, and urogenital systems. The symptoms are usually of two types, neither of which indicates a physical disorder of the organ or system concerned. First, there are complaints based upon objective signs of autonomic arousal, such as palpitations, sweating, flushing, tremor, and expression of fear and distress about the possibility of a physical disorder. Second, there are subjective complaints of a nonspecific or changing nature such as fleeting aches and pains, sensations of burning, heaviness, tightness, and feelings of being bloated or distended, which are referred by the patient to a specific organ or system.

Somatoform Disorders

Uwe Ruhl
Institut für Psychologie, Universität Göttingen, Göttingen, Germany
uruhl@uni-goettingen.de

Definition

Somatoform disorders refers to the preoccupation with multiple physical complaints suggestive of a somatic disease (together with persistent requests for medical investigations) for which a clear physical etiology and an adequate medical explanation cannot be found. Those physical symptoms are repeated in spite of negative findings and reassurances by medical doctors that the symptoms have no physical basis. If any physical disorders are present, they do not explain the nature and extent of the symptoms or the distress and preoccupation of the patient. Symptoms of somatoform disorders may include frequent headaches, back pain, abdominal cramping, and pelvic pain (► somatoform autonomic dysfunction). Other symptoms include pain in the joints, legs and arms, or chest, or abdominal pain. Somatoform disorder may also present with gastrointestinal problems, such as nausea, bloating, vomiting, diarrhea, and food intolerance. Somatoform disorders are divided into ► somatization disorder, pain disorder (► persistent somatoform pain disorder), conversion disorder, hypochondriasis (► hypochondriacal disorder), and body dysmorphic disorder. Other syndromes may not reach the diagnostic threshold for somatization disorder but may be clinically significant.

Basic Characteristics

Introduction/Etiology

Somatoform disorders account for a high proportion of consultations in primary care. A large variety of etiological hypotheses of somatoform disorders have been proposed, ranging from somatization as a somatic expression of psychological distress to biological

abnormalities. A heightened awareness of normal body sensations may be paired with a cognitive bias to interpret any physical symptoms as an indicator of medical illness. However, with current research methods no single mechanism can be shown to cause somatoform symptoms. It is obvious that many different pathways exist, and etiological factors interact in a very complex way. Those etiological factors are, for example, biological factors, unconscious intrapsychic conflicts, sexual abuse, and conversion. This situation is not different from almost all other mental disorders.

Epidemiology

Somatoform disorders are among the most prevalent forms of mental disorders. Whereas pain disorders (► persistent somatoform pain disorder) start mostly in childhood and early adolescence, dissociative disorders and conversion disorders seem to develop predominantly in the second decade of life. ► Somatization disorder is the most severe form of somatoform disorders. The prevalence of somatization disorders is between 1.1% (Italy; Favarelli et al. 2004) and 2.1% (Norway; Kringlen et al. 2001). Other forms of somatoform disorders (e. g., pain disorder, conversion disorder) show higher prevalence rates than somatization. It is estimated that the 12-month prevalence of somatoform disorders in European countries is 11%. Women are twice more likely to be affected than men (15.0% versus 7.1%) (Wittchen and Jacobi 2005). Accordingly, the estimated number of subjects suffering from somatoform disorders within 12 months in the general EU population is 18.9 million people.

Consequences

Somatoform disorders are frequently associated with other mental disorders. Patients with pain disorders very often show comorbid major depression (OR 4.34, 95%CI [2.33–8.08]), panic disorders (OR 8.55, 95%CI [3.29–22.20]), and posttraumatic stress disorder (OR 4.54, 95%CI [1.23–16.67]). Conversion disorders and dissociative disorders are strongly associated with eating disorders (Lieb et al. 2000). Somatization disorder patients show impaired quality of life and higher levels of emotional distress. Patients with somatoform disorders show increased rates of healthcare utilization and disability days (Ladwig et al. 2001).

Treatment

Treatment of patients suffering from somatoform disorders is often difficult, as patients do not accept that their symptoms are due to mental factors. Patients have relevant, real medical complaints; hence, a psychological origin of those complaints is similar to the allegation that they only imagine their problems. Patients may become angry or irritated with their doctors when they cannot determine the (physical) cause and correlate for their problems. Another difficulty that doctors may face is that people with somatization disorder, like everyone else, will develop new (comorbid) physical diseases at some point. Therefore, every new symptom is a challenge for a medical professional to know how far to investigate. Many people with a somatoform disorder also have other mental health problems and comorbid mental disorders, such as depression, anxiety, or substance abuse. These may be partly a result of having distressing physical symptoms. Treatment of these other mental health problems may improve the situation. In contrast to other mental disorders, somatoform disorders mostly need an interdisciplinary treatment, and treatment concepts may have a clear focus on the patients' somatic complaints (and not the psychological problems). If patients with somatoform disorders can be convinced that mental factors may contribute to, or cause, their physical symptoms then those patients may accept a psychiatric and/or psychotherapeutic treatment. Talking treatments may help patients to understand the reasons behind their symptoms, and aims to change any false beliefs that they may have and teach them how to identify and deal with emotional issues. A psychopharmacological treatment (e. g., antidepressants) can be indicated as well.

Sound

Definition

Sound is a form of mechanical energy produced by vibration of a gaseous, liquid, or solid elastic medium. It is transferred away from the source by a series of pressure changes referred to as sound waves. If these pressure changes are of higher magnitude than 20 µPa and in the frequency range from 16 Hz to 20 kHz, they will evoke physiological responses in the human ear and auditory pathways. Sound waves pass through the outer ear and set the eardrum into vibration. Three small bones in the middle ear, the hammer, anvil and stirrup, transfer the vibration of the eardrum to the liquid-filled cochlea – a part of the inner ear. Liquid disturbance distorts the basilar membrane in the cochlea; this is registered by extremely sensitive hair cells and transformed into nerve impulses that are transmitted to the brain through auditory pathways. Psychologically, sound is a mental event evoked by nerve impulses in the auditory brain.

Source of Infection

Definition

The source of an infectious agent is the person, animal, substance, or object from which the host acquires the infection. When a person or animal is the source, they may be sick, convalescent, or long-term carriers of the infection.

Source of Injury

Definition

The source of injury is identification of the object, substance, or bodily motion which directly caused an ► occupational injury. For example, if the worker lost a finger by cutting it with a saw, the saw is the source of injury. There is a direct relationship between the source and the nature of the injury. In contrast to the cause of injury, the source is always obvious. National and international agencies have developed different classifications of injury sources in order to enhance statistical analysis.

Source of Potential Harm

Synonyms

Hazard

Definition

In the context of ► risk assessment a hazard is a source of potential harm. Risk assessment estimates the risk to humans of a specified hazard, based on the availability of exposure data.

Spasmodic Croup

Synonyms

Acute spasmodic laryngitis; Pseudo-croup; Stenosing laryngotracheitis

Definition

Stenosing laryngotracheitis or pseudo-croup is a disease, which is primarily seen in babies and small children; in children of school age it is very rare. A viral infection of the respiratory tract causes a swelling of the mucous membranes in the subglottic area (in the region of the vocal chord). Pseudo-croup usually occurs at night and is characterized by hoarseness, barking cough and loud, noisy breathing (inspiratory stridor). In more severe cases children have difficulties in breathing (dyspnea) and show jugular or thoracal retractions. The parents, who are often very excited, have to be calmed. The prognosis in stenosing laryngotracheitis is excellent. After administering prednisolone (rectally), supplying fresh air and, if necessary, epinephrine inhalation the symptoms soon decrease and – in most cases – vanish within a few hours.

Specialized Health Services

► Secondary Care

Specific Building- and Home-Related Illnesses

Synonyms

SBRI

Definition

Specific building-related illnesses (SBRI) are specific, well-defined human illnesses (medical entities with objective physical signs and laboratory findings) caused by indoor environmental factors that can be identified, measured, and quantified, inside certain indoor spaces. Wide scientific interest in indoor air quality is now quite understandable because of (a) a variety of indoor environmental contaminants and problems; (b) an increasing amount of time spent indoors; and (c) numerous adverse health consequences. Environmental contaminants cause SBRI through five major mechanisms, which will be described in detail (1–5): (1) Immunologically induced inflammation (e. g. hypersensitivity pneumonitis, humidifier fever, asthma, and urticaria, etc.). Hypersensitivity pneumonitis or allergic alveolitis (HP/AA) presents as pneumonia with pulmonary infiltrates, gradually progressing to pulmonary fibrosis. Antigens of fungi, bacteria and insects, associated with very small suspended particles, are the main cause of HP. (2) Infections (e. g. Legionnaire's disease, Pontiac fever, influenza, the common cold, rubella, varicella). Legionnaire's disease is a severe form of pneumonia caused by *Legionella pneumophila*, a ubiquitous bacterium with transmission almost exclusively by the airborne route from contaminated water sources (e. g. cooling towers, humidifiers, whirlpools, and even showerheads). (3) Irritation is a third mechanism that can lead to SBRI. Even low concentrations of common irritants induce ill effects due to high acidity, desiccation, or through skin and mucous membrane stimulation. (4) Intoxication by a low level of air contaminants is another mechanism that can cause SBRI, and the main toxins in buildings are pesticide residues, combustion by-products, and mycotoxins. (5) Cancerogenesis (e. g. due to radon or asbestos) may be also included in the mechanisms of SBRI induction, though the latent period between cause and disease appearance is usually much longer than for the other four mechanisms (► Radon).

Specific Categories

Definition

Specific rates pertain to some homogeneous subgroup of the population such as an age, gender, race, or ethnic group. For example, gender-specific rates provide separate estimates of rates for males and females in the population. Age-specific rates refer to the number of events occurring in each specified age category. These rates are calculated to show how a risk factor, occurrence of death, or incidence of a disease change with age, sex, etc.

Specific Developmental Disorder of Scholastic Skills

► Arithmetical Skills Disorder
► Reading and/or Spelling Disorder

Specificity

Definition

The specificity is the operating characteristic of a diagnostic test that measures the ability of a test to exclude the presence of a disease (or condition) when it is not present. In contrast to sensitivity, specificity is the proportion of non-diseased patients for whom there is a negative test, expressed as: [true negatives ÷ (true negatives + false positives)].

Cross-References

► Screening

Specific Phobia

Synonyms

Simple phobia

Definition

A specific phobia is diagnosed if a person fears clearly defined objects (e. g. spiders, dogs, snakes) or situations (e. g. exams, heights, injections). It is important to distinguish between the fear triggered by the actual confrontation with the phobic stimulus and the fear that occurs when thinking about this stimulus. This so-called fear of fear adds to the problem. Exposure to the object of the phobia, either in real life or via imagination or video, invariably elicits intense anxiety, which may include a situationally bound panic attack. Adults generally recognize that this intense fear is irrational. Nevertheless, they typically avoid the phobic stimulus or endure exposure with great difficulty.

Cross-References

► Anxiety Disorders

Specific Rates

Definition

Specific rates refer to a particular subgroup of the population defined. For example, the rate can be evaluated in terms of race, age, or some other subgroup, or may be specific to some single cause of death or illness. Specific rates can be used to correct factors that may influence crude rates. Age-specific disease incidence rates evaluate the occurrence of disease in proportion to a specified age group. Age-specific Death Rates are also referred to as age-specific mortality rates. This is a rate that evaluates the number of deaths in a specified age population against the total number of persons within that age population for a particular time period.

Spectrum of Activity

► Spectrum of Efficiency

Spectrum of Efficiency

Synonyms

Spectrum of activity; Range of efficiency; Range of activity

Definition

The spectrum of efficiency includes the entirety of microorganisms sensitive for an antibiotic drug. It can be supposed that germs with similar characteristics can be treated with the same antibiotic. One of the criteria to distinguish between different bacteria is the way they react on Gram's stain. Bacteria, which accept the dye, appear blue when they are looked at under the microscope. They are called gram positive. In gram negative germs the dye is washed out, after a second coloring with another dye they appear to be red under the microscope.

Speech and Language Developmental Disorders

Synonyms

Language retardation

Definition

Children acquire language at different rates. Determination of when the normal process is so much delayed as

to constitute a disorder is arbitrary. Language retardation is not directly attributable to neurological or speech mechanism abnormalities, sensory impairments, mental retardation, or environmental factors. Specific developmental disorders of speech and language are often followed by associated problems, such as difficulties in reading and spelling (► reading and/or spelling disorder), abnormalities in interpersonal relationships, and emotional and behavioral disorders during school age.

Speech Therapy

Synonyms

Logopaedics; Phoniatrics

Definition

Speech therapy aims to treat speech, communication, and swallowing disorders. The specific therapeutic approach depends on the disorder. Potential practices include physical exercises to strengthen the muscles used in speech, speech drills to improve clarity, and sound production practice to improve articulation.

Spinal Cord Injury

Definition

Spinal cord injuries usually involve a sudden, traumatic blow to the spine that fractures or dislocates vertebrae. The damage starts as soon as the injury occurs, and displaced bone fragments, disc material, or ligaments bruise or tear into spinal cord tissue. In most cases, the spinal cord is not completely severed but the injury usually causes fractures and compression of the vertebrae. This then results in crushed and destroyed axons, which are extensions of nerve cells that carry signals up and down the spinal cord between the brain and the rest of the body. Depending on the extent of the damage, the prognosis may range from almost complete recovery to complete paralysis. The latter might include respiratory complications for severe cases, and they may require help with breathing and respiratory support. Aggressive treatment and rehabilitation can reduce the damage to the nervous system and in some cases even restore limited abilities.

Spiritual

Synonyms

Immaterial; Religious

Definition

Spiritual concerns with matters of the spirit or soul, involves notions and explanations of the overall nature of humankind. It also includes emotional experience. Spirituality may involve perceiving life as higher, more complex or more integrated with one's world view; as contrasted with the merely sensual. An important distinction exists between spirituality in ► religion and spirituality as opposed to religion. In recent years, however, spirituality is less dogmatic, more open to new ideas and myriad influences, and more pluralistic than the doctrinal faiths of established religions. Religion can not be identified with spirituality, it may only be one of the ways to express ones spirituality. Spirituality, according to most adherents of the idea, forms an essential part of an individual's holistic health and well being. Science takes as its basis empirical observations, and thus generally regards any appeal to the unseen, unmeasurable spirit as either beyond the purview of science, or as a pseudoscience.

Synonyms

Interest groups

Definition

In the last decades of the 20th century, the meaning of 'stakeholder' has evolved from the old concept in law of a person holding money or property to a person or organization having an interest or 'stake' in a project or entity. In this broader sense, stakeholders are defined as "individuals or organizations who stand to gain or lose from the success or failure of a system" (Nuseibeh, Easterbrook 2000).

In the area of Health Policy and Health Care, stakeholders are any governmental entity, organization, company or individual that has a stake or may be impacted by a given health care system or health policy approach to provision, benefits or regulation of health care in a country. In the Unites States, according to the American Agency of Healthcare Research and Quality "stakeholders include patients, providers, and policymakers, as well as health care scientists, clinical practice organizations, quality improvement groups, and purchasers of ► health care plans" (United States Department of Health & Human Services 2006).

Basic Characteristics

Description of Stakeholders

Stakeholders can be categorized in providers, beneficiaries, payers and decision makers. Providers of health care or ► medical devices are doctors, ► hospitals, laboratories, pharmaceutical companies, and in some countries the governmental agencies as public providers of health services. Beneficiaries of health care are the patients. Payers of health care are health insurances, individuals, employers and in some countries the gov-

ernment. The government is the decision maker and sets the regulatory framework for providers, payers and beneficiaries of health care. In the context of national health policy and health care, each stakeholder plays a different role according to the category he belongs to.

Government The government acts mainly as a decision maker to set the rules for a health care system that fulfills the values and ideals of the country (i. e. liberal market economy; social market economy; communism). Within the defined framework the government may regulate volume and quality of the health care services, be responsible for legislation on health care financing, corporate negotiations, major professional regulations and public health measures such as prevention and health promotion. In countries like the UK with a national health service, the government acts not only as a decision maker but also as a payer and provider of health care services (► public health services).

Doctors Doctors are providers of ► outpatient health care based in independent doctors' practices or medical centers or ► inpatient health care based in hospitals. They need to pass a specific university examination and be registered to practice. According to the existing health care system and the particular educational background, the payment of doctors varies from ► fee-for-service payment to a ► per capita payment or a monthly salary.

Hospitals ► Hospitals provide inpatient health care on a public or private basis. Hospitals either provide necessary health care for all kinds of diseases or specialize in a given medical area. The hospital sector is in most countries strongly regulated by government laws.

Health Insurances Health insurance companies are payers of health care for individuals in case of sickness or injury. Among other types of financing health care (for example taxation and direct payments), the insurance principle is employed in many countries in various forms. The organization of health insurances, their membership and funding mechanisms as well as their scope of financing varies from country to country.

Pharmaceutical Industry The pharmaceutical industry provides ► drugs and ► medical devices for the patients. Drugs are either delivered to the patient through pharmacies or directly through hospitals. The pharmaceutical industry invests regularly in research and development in order to meet continuous need for new pharmaceuticals while working as for-profit organizations.

Patients Patients are individuals who benefit from health care services. They also play a role as payers if they contribute to a health insurance or a tax-based health care system or if they spend money directly or as co-payers for health services.

Stakeholder Analysis

The stakeholder approach is a theory with the premise that firms which are managed to satisfy all stakeholders in an optimal way do better than firms which only maximize the profits or interests of the firm's shareholders. There is an increasing amount of management literature which deals with the identification of organizational key stakeholders, the analysis of their influence on the decision making process and ways to manage them (Freeman 1984; Post et al. 2002).

In the area of public health policy the stakeholder analysis has also become increasingly popular during the last decade.

Stakeholder analysis can be used to generate knowledge about the roles, relationships, behavior and interests of the stakeholders – individuals, groups, organizations – and how they influence the decision making process. This information is a necessary step to develop strategies for managing these stakeholders to facilitate the implementation of specific decisions or organizational objectives within the context of existing policy. The stakeholder approach may result in higher public health care performance if the value of health care is appraised collectively by the stakeholders of a health care organization and all stakeholders have the best available evidence on which to make decisions about health care and services. However, it cannot be ignored that stakeholders in the area of health policy have cooperative and competitive interests and that policy development is a complex process taking place in a continuously changing context. Therefore, the utility of stakehold-

er analysis for predicting future policy developments is limited.

Interaction and Conflicts

Analyzing the different stakeholder interests in quality of care may serve as an example to demonstrate that the interaction between stakeholders in a health system leads inevitably to conflicts.

Providers tend to view quality in a technical sense meaning accuracy of diagnosis, appropriateness of therapy and the resulting health outcome. Payers focus on cost-effectiveness and patients as the beneficiaries demand compassion, skill and clear communication. This leads to the following two types of conflicts:

a) conflict of interest between providers and payers of health care:
   - In order to provide the best service, providers tend to use the most accurate and newest tests and treatments which are also likely the most expensive.
   - Payers prefer a clear, evidence based, diagnostic plan which will provide accurate diagnosis and treatment with the fewest visits and least number of tests.

b) conflict of interest between patients and payers of health care:
   - Patients expect the payers (insurance companies, employers and the government) to offer a wide variety of options for health coverage that can be customized to their specific needs. They look to the employer to fund the majority of the cost of health insurance with the least out-of-pocket cost to themselves.
   - Payers want to maintain or lower their cost contribution. They want the patient to seek only needed care, follow providers' instructions, and recover quickly. Patients should also seek to reduce their health risk behaviors through, for example, diet, exercise and smoking cessation.

Stakeholders in the Context of Rising Health Care Costs and Limited Resources

The rising costs of health care due to technological progress and demographic aging has been a challenge to the majority of countries with developed health care systems. "Collaborative arrangements among stakeholders" in the health care system have been suggested as a way to improve health care performance and to contain health care costs (Young DW et al. 2001). In this context, a number of measures aiming to reduce medical expenses have affected and are continuing to affect all stakeholders:

Government:
- As a decision maker: regulation of financial framework
- As payer and provider: increase of resources to cover growth in health care cost

Health insurers:
- Increase in insurance fees to cover growing medical need
- Restriction of benefit packages

Hospitals:
- Limitation in numbers
- Budget control
- Manpower control
- Introduction of ▶ treatment protocols
- Performance management: reduction in the lengths of stay

Doctors:
- Controls on entry to medical education
- Change of payment method (from payment per item of service to ▶ capitation payment)
- Change in the relative value-scale under fee-for-service systems
- Influencing prescribing behavior by the promotion of the use of ▶ generics

Pharmaceutical industry:
- Direct or indirect control of prices and profits
- Price approval for reimbursement
- Control of the use of expensive equipment

Patients:
- Co-payments that may concern ▶ drugs, dentistry charges, spectacles and charges for visits to doctors, laboratory test
- Higher contributions for health insurances

Standard Deviation

Definition

Standard deviation is the square root of the ► variance, and therefore it is expressed in the same units of measurement as the original observations. The formula for sample standard deviation is:

$$s = \sqrt{\frac{\sum (x_i - \bar{x})^2}{n-1}} = \sqrt{\frac{\sum x^2 - n\bar{x}^2}{n-1}}$$

where x_i is an individual value, $\bar{x}$ is the mean, n is the sample size, and $n - 1$ is the number of the degrees of freedom.

Standard deviation is the most commonly used ► measure of the dispersion. Standard deviation is a base for calculating the ► z-score (standard score). When the standard deviation is divided by the mean and this ratio is expressed as a percentage it is the coefficient of variation, which is a relative measure of variation and independent of the units of measurement.

When the empirical distribution is nearly normal then the interval of one standard deviation above and below the mean includes approximately 68% of all observations. The interval of two standard deviations above and below the mean, includes approximately 95% of all observations, and the interval of three standard deviations above and below the mean includes almost all observations (99.7%).

Standard Error

Definition

The standard error (SE) or as it is commonly called, the standard error of the mean (SEM), is a measure of the extent to which the sample mean deviates from the true but unknown population mean. It is the standard deviation (SD) of the random sampling distribution of means (i. e., means of multiple samples from the same population). As such, it measures the precision of the statistic as an estimate of a population. The (estimated) SE/SEM is dependent on the sample size. It is inversely related to the square root of the sample size.

Standard Gamble

Definition

Standard gamble is a method to measure individual preferences for health outcomes under the condition of uncertainty. Standard gamble is the methodological approach for estimating utilities that is most based on utility theory. The preference is expressed by choosing between two alternatives. The outcome of one alternative would be received with certainty. The outcome of the second alternative would be received with a certain probability and would not be received with the inverse probability. The probability is varied until the individual is indifferent between the two choices. The utility is derived from the indifference probability.

Standardization

NATASA MILIC
Institute for Medical Statistics and Health Research, Faculty of Medcine, University of Belgrade, Belgrade, Serbia
nika4@eunet.yu

Synonyms

Adjustment; Controlling; Stratified analysis

Definition

Statistical method for deriving measures that are comparable across populations that differ in age and other demographic variables. Standardization methods are used to adjust for the effects of age and sex, and possibly other factors, in the comparison of disease rates between two or more populations.

Basic Characteristics

One of the most frequently occurring problems in epidemiology and vital statistics is comparison of the ► rate for some events, characteristics across different populations, or for the same population over the time. If the populations were similar with respect to factors associated with the event under study – factors such as age, sex, race, or marital status – there would be no problem in comparing the ► overall rates (total or crude rates) as they stand.

If the populations are not similarly constituted, however, direct comparison of the overall rates may be misleading.

History

Standardization methods have a long history, and rank among the earliest statistical tools developed. Keiding has traced their origins to eighteenth century actuarial mathematicians, though they were re-invented a century later by Neison and Farr. These two eminent men recognized that comparisons of crude death rates were not sufficient for examining mortality patterns over time or between geographical areas. They also showed that the average age at death was not an appropriate index for assessing differences in mortality.

Reasons for Standardization

Bearing in mind that there is no substitute for examining the ► specific rates themselves, there are some reasons for considering standardization:

1. A single summary index for a population is more easily compared with other summary indices than are entire schedules of specific rates.
2. If some strata are comprised of small numbers of people, the associated specific rates may be too imprecise and unreliable for use in detailed comparisons.
3. For small populations, or for some groups of especial interest, specific rates may not exist. This may be the case for selected occupational groups and populations from geographic areas especially demarcated for a single study. In such cases, only the total number of events (e. g., deaths) may be available and not their subdivision by strata.

Direct Standardization

► Direct standardization may be applied only when the schedule of specific rates for the given population is available. The data necessary for its implementation are:

1. The schedule of specific rates for the population being studied, say $c_1, \ldots, c_i$.
2. The distribution across the various strata for a selected standard population, say $p_{S1}, \ldots, p_{Si}$.

The direct adjusted rate is then simply

$$C_{\text{direct}} = \sum c_i p_{Si}$$

The term "direct" refers to working directly with the specific rates of the population being studied, in distinction to what has to be done in the method of ► indirect standardization.

Indirect Standardization

The second and third reasons given for standardization, the unreliability and possibly even the unavailability of some specific rates, lead to another method of standardization, the so-called indirect method. The data necessary for its implementation are:

1. The crude rate for the population being studied, say c.
2. The distribution across the various strata for that population, say $p_1, \ldots, p_i$.

3. The schedule of specific rates for a selected ► standard population, say $c_{S1}, \ldots, c_{Si}$.
4 The crude rate for the standard population, say c_S.

The first calculation in indirect standardization is of the overall rate that would be obtained if the schedule of specific rates for the standard population were applied to the given population. It is

$$c' = \sum c_{Si} p_i$$

The indirect adjusted rate is then

$$c_{\text{indirect}} = c_S \times c/c'$$

that is, the crude rate for the standard population, c_S, multiplied by the ratio of the actual crude rate for the given population, c, relative to the crude rate, c', that would exist if the given population were subject to the standard population's schedule of rates.

Standardized Mortality Ratio (SMR)

When deaths are the subject of the study, the indirectly standardized ratio is widely known as the ► standardized mortality ratio (SMR). The SMR, like other forms of standardization is used to create summary mortality statistics that can be used to compare populations with differing distributions of individuals in age, gender, and race categories. Sometimes, only one age will be categorized and single gender and racial groups studied. For example, an age-adjusted SMR for white males could be created.

Example

Comparing neonatal mortality rates in two hypothetical hospital groups in a region: one group is comprised of tertiary care hospitals with neonatal intensive care units; the other is comprised of community hospitals that appropriately transfer the majority of high-risk pregnant women for delivery at a tertiary center. The birthweight distribution in the two groups is considered a potential confounder since the tertiary care hospitals by definition serve higher risk pregnant women than the community hospitals do and birthweight is also known to be the major predictor of neonatal mortality. All live births in the state is used as the standard population.

The crude relative risk of neonatal death (not accounting for the birthweight distribution) when the two hospital groups are compared is 1 (5.8/5.8). Standardizing by birthweight will help determine if this relationship is a fair reflection of the neonatal mortality experience in the two hospital groups.

Standardization, Table 1 Hospital Group A: Community Hospitals

Birthweight Strata	Deaths	Births	% of Total	Stratum Specific Rate per 1000	Crude Rate per 1000
< 1500	61	200	1	305.0	
150–2500	19	850	4	22.3	
> 2500	37	18950	95	2.0	
	117	20000	100		5.8

Standardization, Table 2 Hospital Group B: Tertiary Care Hospitals

Birthweight Strata	Deaths	Births	% of Total	Stratum Specific Rate per 1000	Crude Rate per 1000
< 1500	79	400	2	195.0	
1500–2500	18	1450	7	12.4	
> 2500	20	18150	91	1.0	
	117	20000	100		5.8

Standardization, Table 3 Standard Population: All Live Births in the State

Birthweight Strata	Deaths	Births	% of Total	Stratum Specific Rate per 1000	Crude Rate per 1000
< 500	1217	5000	1	243.4	
1500–2500	480	34000	7	14.1	
> 2500	424	461000	92	1.0	
	2121	500000	100		4.2

► Direct standardization applies the stratum specific rates of each population to the number of individuals in the corresponding stratum in the standard population. This method yields an adjusted relative risk. The method is called "direct" because it uses the actual morbidity or mortality rates of the populations being compared.

Directly standardized relative risk is calculated as follows:

Adjusted Rate for the Community Hospitals:

$$= (5000 \times 305.0 + 34000 \times 22.3 + 461000 \times 2.0)/500000 = 6.4$$

Adjusted Rate for the Tertiary Care Hospitals:

$$=(5000 \times 195.0 + 34000 \times 14.1 + 461000 \times 1.0)/ 500000 = 3.8$$

Crude relative risk $= 5.8/5.8 = 1$

Standardized relative risk $= 6.4/3.8 = 1.7$

In the process of calculating an adjusted relative risk, it is necessary to calculate what appear to be ► adjusted rates for each population. They do not reflect the real mortality risk in the two hospital groups. They are byproducts of the standardization procedure and should not be used as stand-alone measures. The adjusted relative risk of 1.7 shows that the community hospitals have elevated neonatal mortality compared with tertiary care centers even though the adjusted relative risk was 1. Without adjustment, the better survival of neonates born in the tertiary care centers was masked due to the disparity in the birthweight distribution.

► Indirect standardization applies the stratum specific rates of the standard population to the number of individuals in the corresponding stratum in each of the populations being compared. This method is called "indirect" because it does not use the actual morbidity and mortality rates of the populations being compared. This method yields standardized morbidity or mortality ratios (SMRs), one for each population being compared.

SMRs are calculated as follows:

For the Community Hospitals:

$$\text{SMR} = (117/20000 \times 1000)/ ((200 \times 243.4 + 850 \times 14.1 + 18950 \times 1.0)/20000) = 5.8/4.0 = 1.4$$

For the Tertiary Care Hospitals:

$$\text{SMR} = (117/20000 \times 1000)/ ((400 \times 243.4 + 1450 \times 14.1 + 18150 \times 1.0)/20000) = 5.8/6.8 = 0.9$$

With indirect standardization, each SMR is itself an adjusted relative risk; the numerator is the observed crude rate in a population and the denominator is its expected rate given the mortality experience in the standard population. An SMR $>$ 1 indicates higher rates than expected and an SMR $<$ 1 indicates lower rates than expected. The two SMRs in this example lead to the same conclusion as the adjusted relative risk values – after accounting for birthweight, the community hospitals have higher neonatal mortality than the tertiary care centers.

Discussion of Methods

Over the years, many methods of standardization have been proposed. No single method has emerged on top and a variety of methods are in use. Direct and indirect standardization are undoubtedly the most popular, but other methods such as the Proportional Method have to be employed in certain circumstances. The Proportional Method is a method analogous to SMR and which calculates the ► proportional mortality ratio (PMR). In each age group, the population size is replaced by the number of all-cause death. Thus, the rates are replaced by the proportions of all deaths due to the cause of interest. Increasingly, mortality rates are being modeled using regression techniques. Many methods of estimating standard errors and deriving confidence intervals are also in widespread use.

As a final note, we must be aware that in any standardization procedure we lose something. Much of the debate about which methods to use is due to the fact that no standardized measure can replace analysis of the age-specific rates themselves.

Standardized Mortality Ratio (SMR)

Definition

Indirectly standardized ratio when deaths have been studied. With indirect standardization, each SMR is itself an adjusted relative risk; the numerator is the observed crude rate in a population and the denominator is its expected rate given the mortality experience in the standard population. An SMR > 1 indicates higher rates than expected and an SMR < 1 indicates lower rates than expected.

Standardized Rate

Synonyms

Adjusted rates

Definition

Standardized rates are a summary type of rate that account for the difference between populations. Age and sex are variables for which adjustment is most often required, but it is possible to apply adjustment procedures for other variables such as occupation, socioeconomic status, marital status, etc. As adjusted rates are not true population-based rates, they do not accurately measure the health status of a population. However, they can be compared across populations because the problem of different age, sex, etc. patterns has been removed. There are two methods of standardization: direct and indirect. They are equally applicable to incidence and mortality rates, and prevalence.

Standard Operating Procedures

Definition

Standard operating procedures (SOP) are formal documents which describe the procedures that have to be followed to accomplish repetitive standard tasks. Usually in regulated areas (e. g. by current guidelines and regulations on GCP) like clinical trials, laboratory or animal or in-vitro experimentation all repetitive standard activities undertaken have to be described in SOPs.

Standard Population

Definition

A specific population whose age (and sex) distribution is used in the calculation of standardized rates. For example, in trying to summarize age-specific rates for geographic regions within a country, the national population could be used as a standard. When examining rates for a variety of countries, a world population or population of the appropriate continent would be suitable standards. However, different choices of standard population can give rise to different results. Thus, identifying a suitable standard is a prerequisite for applying standardization methods.

Standards

► Ethical Principles

Standard Sanitary Operating Procedures (SSOP)

Synonyms

Good Hygienic Practice

Definition

Procedures which include good employee hygiene – proper hand washing, clothing, prevention of transition of bacteria, viruses and parasites from food handlers to food – are called SSOP. SSOPs are written procedures designed to achieve and maintain an effective sanitary condition in the facility: practicing and monitoring effective handwashing and gloving for safe hands,

restricting eating, smoking, and drinking in food preparation areas, using hair restraints, wearing clean uniforms, and restricting the wearing of jewelry. SSOPs are prerequisites to HACCP and all food producing, selling and serving facilities must employ good SSOP programs. SSOPs are designed to generate and maintain an environment to enable HACCP to concentrate on issues related to ► food safety.

Standby Therapy of Malaria

► Self-Therapy of Malaria

Staphylococcal Toxic-Shock Syndrome (TSS)

Synonyms

Toxic-shock syndrome; Tampon disease

Definition

Staphylococcal toxic-shock syndrome is the life-threatening result of a staphylococcal infection. It first occurred in the 1980s. As it was associated with the use of tampons, for some time it has also been called "tampon disease". After an improvement in the quality of the tampons, the incidence of tampon associated TSS has rapidly declined. Nevertheless, due to the release of toxins, a septic course can occur in other forms of a generalized staphylococcal infection. In most cases, TSS appears in formerly healthy persons between the age of 20 and 50 years. In children younger than 5 years, particularly in newborn babies, staphylococcal scalded skin syndrome (SSSS) is found. It is characterized by bright red patches of skin, which peel away in jagged sheets.

Staphylococcus aureus

Synonyms

Cluster-forming cocci

Definition

Staphylococcus aureus (Staph. aureus) is a gram-positive bacterium, which often grows as clusters. As it is quite insensitive to drying out, it can survive on objects and surfaces for a long period of time. Staphylococci can be a part of the natural skin flora, they are especially found in the groin and the front parts of the nose. Their colonization of the skin or the mucous membranes presents no threat of infection and thus cannot be an indication for antibiotic therapy. However, when staphylococci penetrate deeper into the tissue they can cause severe purulent infections. They cause, besides furuncles, wound infections, abscesses, pneumonia, osteomyelitis, endocarditis and sepsis.

State

► Country

Stated Preference Analyses

► Willingness-to-Pay Analyses

Stateless Person

Definition

The term "stateless person" designates a person who is not considered being a national by any state. This definition has been provided by the Convention Relating to the Status of Stateless Persons of 28 September 1954. The term "stateless person" does not apply to persons who are receiving protection or assistance from organs or agencies of the United Nations other than the United Nations High Commissioner for Refugees; neither does it apply to persons who have committed a crime against humanity or international humanitarian law. The convention details that contracting states shall apply to stateless persons lawfully staying in their territory the same treatment with respect to public ► relief and assistance as is applied to their nationals, and that they shall not expel a stateless person.

State Liability

Synonyms

Liability of public authorities; Government liability

Definition

State liability is the state's obligation to compensate and pay damages to any individuals or other legal entities (e. g., companies) for harm to their personal or property rights caused by or attributable to the state. State liability is a fault-based liability. For state liability, a violation of public duties by the state institutions or their officials or private actors authorized to provide public services must have led to the harm/infringement. State liability can apply if public health agencies negligently fail to react adequately to health threats or disproportionately encroach personal or economic rights. In many jurisdictions, the state is privileged by certain exemptions from liability.

Statistic

Definition

A statistic is a summary value (numerical quantity measuring some aspect of a sample values) calculated from the observations in a sample (e. g. the sample mean, the sample variance, the sample proportion, the sample correlation coefficient). Statistic is usually used as an estimator of some population parameter. They are represented by Roman letters ($\bar{x}$, s^2 or sd^2, p, r, respectively). In general, if we use a statistic (sample information) to make an inference about a population parameter (in one of two ways: estimate its value, i. e. provide a point or interval estimate; or make decisions about its value, i. e. test a hypothesis about its value), we introduce an element of uncertainty into our inference. Consequently, it is important to report the reliability of each inference we make. Typically, this is accomplished by using a probability statement that gives us a high level of confidence that the inference is true. Reliability of the estimate is measured with confidence coefficient (in interval estimates), and the reliability of the hypothesis testing is measured by the probability of making an incorrect decision.

Statistical Analysis

Definition

Statistical analysis is the use of statistical tests to strengthen effects (with respect to data) observed in studies. Statistical tests are mathematical formulas (or functions) used to determine if the difference in outcomes of a treatment and control group are great enough to conclude that the difference is statistically significant. Statistical tests generate a value that is associated with a particular P value. The choice of a test depends upon the conditions of a study, e. g. what type of outcome variable was used, whether or not the patients were randomly selected from a larger population, and whether it can be assumed that the outcome values of the population have a normal distribution or other type of distribution.

Statistical Literacy

Definition

Statistical literacy involves understanding and using the basic language and tools of statistics: knowing what statistical terms mean, understanding the use of statistical symbols, and recognizing and being able to interpret representations of data.

Statistical Method

► Statistical Procedure

Statistical Model

Definition

A statistical model is a simplified or idealized description of random phenomena, in probabilistic terms, that is a basis for inferences and predictions. The aim is to explain available data, thereby learning about the underlying processes that have formed these data sets. Most

frequently used statistical models are regression models that describe the variation in one (or more) variable(s) when one or more variable(s) vary, i. e. a model of relationships between some covariates (predictors) and an outcome. There are two principal aspects of the use of statistical models – exploratory and confirmatory. In the exploratory phase, models are used to describe various characteristics of the data that may be important for understanding it. Confirmatory use is the attachment of probabilities to the characteristics observed to assure that a conclusion is not merely due to chance. Statistical models are built through three key steps: 1) certain assumptions are made when we fit a model; 2) consideration of how well the model fits the data and 3) model validation that involves an assessment of how the fitted statistical model will perform in practice – that is, how successful it will be when applied to new or future data.

Statistical Power

Definition

Statistical power represents the likelihood of rejecting a false null hypothesis. It is determined by subtracting the value beta from 1 (i. e., power $= 1 - \beta$).

Statistical Power Analysis

► Power Analysis

Statistical Procedure

Synonyms

Statistical method

Definition

Statistical procedure is a method of analyzing or representing statistical data; a procedure for calculating a statistic. Parametric and nonparametric are two broad classifications of statistical procedures. Parametric tests are based on assumptions about the distribution of the underlying population from which the sample was taken. The most common parametric assumption is that data are approximately normally distributed. Nonparametric tests do not rely on assumptions about the shape or parameters of the underlying population distribution.

Statistical Reasoning

Definition

Statistical reasoning is the way people reason with statistical ideas and make sense of statistical information. Statistical reasoning may involve connecting one concept to another (e. g. center and spread) or may combine ideas about data and chance. Reasoning means understanding and being able to explain statistical processes, and being able to fully interpret statistical results.

Inferential statistical tests

Definition

A statistical test is a procedure for deciding whether an assertion (e. g. a hypothesis) about a quantitative feature of a population is true or false. We test a hypothesis of this sort by drawing a random sample from the population in question and calculating an appropriate statistic on its items. If, in doing so, we obtain a value of the statistic that would occur rarely when the hypothesis is true; we would have reason to reject the hypothesis. The choice of the statistical test depends on the research

aim, research plan, statistical model, and the variables' measurements procedure, its power and efficiency.

Basic Characteristics

Once collection of the data for a study is complete, the next step in the hypothesis testing procedure is to evaluate data using an appropriate ► inferential statistical test. The decision on whether to accept or reject the null hypothesis is based on contrasting the observed outcome of an experiment with the outcome expected if, in fact, the null hypothesis is true. This decision is made by using the appropriate statistical test.

The choice of the statistical test depends on:

- the criteria based on which the statistical test will be chosen (kind and type)
- the optimal choice in cases when alternative statistical tests are an option for the same research design (and consequently, the research question); this depends on the power and efficacy of the statistical test.

First of the many criteria is the research question, i. e. the previously chosen study plan:

a) Are difference(s), similarities of distributions, or correlations to be tested that fully determine the kind of the statistical test to be used?
b) What is the number of available or necessary samples (1, 2, or more)?
c) What is the sample relation (paired or unpaired samples) (► unpaired groups design; ► paired groups design)?
d) Which descriptive statistical measures – if existing or needed at all – that have differences, similarities, or tested relations will be used that partially determine the choice of statistical test and its test statistics?

The second criterion is related to defining the statistical model (determination of the nature of the population used to derive the sample and the way the sample will be chosen), as well as the variable(s) in stake measurements procedures (one of the four measurements' scales). This criterion, together with the previous one, then fully determines the type of the statistical test to be used and its test statistics.

An inferential statistical test is essentially an equation describing a set of mathematical operations that are to be performed on data obtained in a study. The end result of conducting such a test is a final value which is designated as the ► test statistic. A test statistic is evaluated in reference to a sampling distribution, which is a theoretical probability distribution of all the possible values the test statistic can assume if an infinite number of studies were to be conducted employing a sample size equal to that used in the study being evaluated. The probabilities in a sampling distribution are based on the assumption that each of the samples is randomly drawn from the population it represents.

Scientific convention has established that in order to declare a difference statistically significant, there can be no more than a 5% likelihood that the difference is due to chance. If a researcher believes that 5% is too high a value, they may elect to employ a 1% likelihood before concluding that a difference is significant. The notation $p > 0.05$ is employed to indicate that the result of an experiment is not significant. This notation indicates that there is an above 5% likelihood that an observed difference or effect could be due to chance. On the other hand, the notation $p < 0.05$ indicates that the outcome of a study is significant at the 0.05 level. This indicates that there is less than a 5% likelihood that an obtained difference or effect could be due to chance. The notation $p < 0.01$ indicates a significant result at the 0.01 level (i. e., there is less than a 1% likelihood that the difference is due to chance).

Parametric Versus Nonparametric Inferential Statistical Tests

Inferential statistical procedures are categorized as being **parametric** or ► nonparametric tests. According to some sources, ► parametric tests are distinguished from nonparametric tests on the grounds that parametric tests make specific assumptions regarding one or more of the population parameters that characterize the underlying distribution(s) for which the test is employed. The same sources describe nonparametric tests as providing no such assumptions about the population parameters. Basically, nonparametric tests are really not assumption free, and bearing this in mind, some sources suggest that it might be more appropriate to use the expression "assumption freer" rather than nonparametric.

As a general rule, inferential statistical tests that evaluate categorical/nominal data and ordinal/rank-order data are categorized as nonparametric tests, while those tests that evaluate interval data or ratio data are cat-

egorized as parametric tests. Although the suitability of employing the level of measurement as a criterion has been debated, its usage provides a reasonably simple and straightforward schema for categorization that facilitates the decision-making process for selecting an appropriate statistical test.

There is general agreement among most researchers that as long as there is no reason to believe that one or more of the assumptions of a parametric test have been violated, when the level of measurement for a set of data is interval or ratio, the data should be evaluated with the appropriate parametric test.

In the final analysis, the debate concerning whether a parametric or nonparametric test should be employed for a specific experimental design turns out to be of little consequence in most instances. The reason for this is that when a parametric test and its nonparametric analog are employed to evaluate the same set of data, they generally lead to identical or similar conclusions. In those instances where the two types of test yield conflicting results, the importance of adequate choice of a suitable test depends on the sample size.

Selection of the Appropriate Statistical Procedure

Test-statistic choice – i. e. choosing an adequate statistical test – can be shown as a function of the research aim and measurements' characteristic (chosen measurements' scales) as follows (Table 1):

Example

In two random samples, the lowest hearing frequency that a human ear can hear was measured. The first sample consisted of 24 men, below 30 years, and the mean frequency they heard was $x_1 = 18.83$ Hz with a variance $SD_1{}^2 = 58.8$. The second sample consisted of 17 men, over 30 years, and the mean frequency they heard was $x_2 = 15.94$ Hz with a variance $SD_1{}^2 = 100.81$. Is there a difference in sound perception of low frequency sounds between men below and over 30 years?

To test the significance of the difference of arithmetic mean, the t-test for two independent samples can be used:

$$t = (x_1 - x_2) / \sqrt{(n_1 SD_1{}^2 + n_2 SD_2{}^2)} / (n_1 + n_2 - 2) \times (n_1 + n_2)(n_1 \times n_2)$$

The calculated value of the t-test, $t = 1.02$, is lower than the critical value $t_{(0.05;30)} = 2.75$, so there is no reason to reject the null hypothesis. There is no difference in

Statistical Tests, Table 1 Selecting a statistical test

Goal	Type of Data: Measurement (from Gaussian Population)	Rank, Score, or Measurement (from Non- Gaussian Population)	Binomial (Two Possible Outcomes)

Statistical Thinking

Definition

Statistical thinking involves an understanding of why and how statistical investigations are conducted. This includes recognizing and understanding the entire investigative process (from question posing to data collection to choosing analyzes to testing assumptions, etc.), understanding how models are used to simulate random phenomena, understanding how data are produced to estimate probabilities, recognizing how, when, and why existing inferential tools can be used, and being able to understand and utilize the context of a problem to plan and evaluate investigations and to draw conclusions.

Statistical Visualization Techniques

Definition

Statistical visualization techniques is a method of analyzing or representing statistical data. Sophisticated techniques to display a two dimensional image of more complex phenomena, for instance, a three dimensional image – specialized statistical plots. Relevant functions accept grouping variables for the simultaneous visualization of different data groups. Interactive features allow you to explore data sets and experiment with different data models. Due to the powerful graphic interface in modern computers, visualization techniques have become more and more popular for data exploration. As a preliminary investigation, visualization is a greatly useful tool to lead to further statistical analysis and modeling.

Statistical vs. Clinical Significance

NATASA MILIC
Institute for Medical Statistics and Health Research, Faculty of Medcine, University of Belgrade, Belgrade, Serbia
nika4@eunet.yu

Synonyms

p value; Significance probability; Clinical relevance; Size of effect

Definition

Statistical methods enable estimation of probabilities of noted or of a higher degree of connection between independent and dependent variables in comparison to null hypotheses. Based on the estimate, on a sample of a given size, statistical significance of the results can be established. Usually, the level of statistical value is expressed as a *p* value. The obtained statistical significance – i. e., the fact that the obtained result is probably not the consequence of coincidence – does not mean that the result is either important or of interest.

Basic Characteristics

The ► *p* value is probably the most ubiquitous statistical index found in the applied sciences literature, and is particularly widely used in biomedical research. It is also fair to state that the misunderstanding and misuse of this index is equally widespread. To understand the meaning of *p* value and statistical significance, the process of testing the hypothesis must be previously understood.

Hypothesis testing is a process of statistical deduction of whether the results of the research depict only coincidence or the real effect at the given level of probability. Testing hypotheses presents articulation of the research question in the form of a ► null hypothesis (H_0) and an ► alternative hypothesis (H_A). The null hypothesis is an assumption that there is no difference between assumed and hypothetical value and the parameter is non-existing, while the alternative hypothesis states that a difference is present. It should be taken into account that – by convention – when treatment effects are tested, the null hypothesis is defined as an assumption that the effects are equal (i. e. that the difference between them is zero). However, the frame of hypothesis testing is much wider. It allows any difference – not just the null one – to be defined as the null hypothesis.

The result of hypothesis testing can be in the form of the ► two-sided test: the null hypothesis will be rejected disregarding whether the assumed value is above or below the real parameter's value; or the ► one-sided test: the sample value is a priori expected to be either below or above the population value. For example, two-sided testing would include $H_0: \mu = 21$ points and $H_A: \mu \neq 21$ points, while one-sided testing would include $H_A: \mu < 21$ points and $H_A: \mu > 21$ points (where μ is population mean).

In the process of testing a hypothesis, selection of an adequate statistical test is made for the given hypotheses, considering the fact that each test statistic has variability of distribution.

The next step comprises choosing the level of significance of the statistical test; the α value or probability of inappropriate rejection of the null hypothesis when it is actually true. As it is not a desired option, it should be small – usually 0.05. The other concept related to significance is the *p*-value, which is the probability of obtaining a result equal to or greater than the observed one if the null hypothesis is correct. Some interpret the *p*-value as a probability that the obtained result is only the consequence of coincidence. The *p*-value is obtained after application of the statistical test and if it is less than the α value, the null hypothesis is rejected.

Then, the value that the test statistic must have in order to be considered significant is determined. This value is an important value, a borderline value, or a critical value of the test statistic. Establishing a critical value is a simple procedure where every test statistic has its distribution (its distribution is divided into a surface that determines that the hypothesis is accepted and the remainder, which determines its rejection). These surfaces are determined by the chosen α value.

The next stage is test statistic calculation, followed by statistical decision making or forming a statistical conclusion; determining whether the observed value of the test statistic is above or below the critical value of the statistic, i. e. to which of the two surfaces it belongs. Four outcomes are possible in terms of conclusion accuracy.

The wrong conclusion means that the results say there are no correlations or differences when there actually are and *vice versa*, meaning that it is claimed a difference or correlation exists when it does not. The first situation represents a bigger problem because, colloquially, it is a bigger issue to find a needle in a haystack or note a signal in the presence of noise than to see things that are not actually there. The signal is the relationship the researcher is trying to find, while the noise denotes all the factors making it impossible to see things clearly. The sources of the noise can be: low liability of the measurements or measures (wrong questions, or bad instrument design or recording), accidental events in the research neighborhood (everything that disturbs the investigator or the investigated), or accidental heterogeneity of the subjects. All these are compiled in ► sta-

Statistical vs. Clinical Significance, Table 1 Statistical decision making

	In reality	
Our conclusion	**Null hypothesis is correct (no correlation, no difference, no fit, theory is wrong)**	**Null hypothesis is wrong (there is a correlation, there is a difference, there is a fit, theory is correct)**
We accept the null hypothesis	$1 - \alpha$ (most often 0.95)	β (most often 0.20)
	Confidence level	Type 2 error
	A chance to say that there is no correlation, difference, or effect when one does not actually exist	A chance to say that there is no correlation, difference or effect when there actually is
	A chance to not confirm the theory in a correct manner	A chance that the theory is not confirmed when it is actually true
	95 times out of 100 when there is no effect, it will be found that there is none	20 times out of 100, when there is an effect, it will not be recognized
We reject the null hypothesis	α (most often 0.05)	$1 - \beta$ (most often 0.80)
	Type 1 error	power
	Level of significance	Chance that there is a correlation, difference, or effect when one actually does exist
	A chance to say that a correlation, difference, or effect exists when it actually does not	A chance to confirm the theory in a correct manner
	5 times out of 100 when there is no effect, it will be stated that there is none	80 times out of 100, when there is an effect, it will be confirmed

tistical power. Determining the validity of the conclusion is achieved by good statistical power (at least 0.80), which, in turn, is achieved with good sample size and/or lowering the level of significance and/or changing – i. e., enlarging – the size of effect.

Once discovered and shown, a statistically significant difference still does not mean that the difference is relevant to research or health or clinically relevant. The importance of calculating sample size prior to data collection lies in the necessity that statistically confirmed research results are also relevant to research. Therefore, besides statistical significance, it is necessary to evaluate the clinical significance (size effect), i. e., the size of the difference or correlation observed within the data, as well as the social and clinical significance of the "effective" factor. The size of the effect identified by research shows the real size of differences observed among the groups or the strength of relationship among the variables. It is important to emphasize that although statistical significance might be reached, the size of the effect might be clinically insignificant.

Research significance according to statistical significance can be depicted using the results of the research which reached statistical significance, but also by asking the reasonable question "so, what?" if the proven difference between the factor categories is low and vice versa, if results of the research showed no statistical significance but it is clear to the researcher that an important difference does exist.

For example, focusing on the following two situations:

a) Statistically significant difference – "so, what?"

Number of subjects N_A	Blood pressure Drug A Mean pressure	Number of subjects N_A	Blood pressure Drug B Mean pressure
500	130.4 mmHg	500	130.5 mmHg
	$p < 0.01$		

b) Clinically important difference – statistically non-significant

Number of subjects N_A	Blood pressure Drug A Mean pressure	Number of subjects N_A	Blood pressure Drug B Mean pressure
10	125.4 mmHg	10	151.6 mmHg
	$p > 0.05$		

Both results (statistically significant difference of 0.1 mmHg = 130.5 – 130.4 and statistically non-significant difference of 26.2 mmHg = 151.6 – 125.4) are the consequence of lack of understanding regarding an adequate number of subjects, which means the size of

effect is not defined or poorly defined. This means that the important difference the research should confirm, if one exists (and it is shown with an appropriate formulation of the alternative hypothesis), is not confirmed.
Usually, these three values: ► Type I errors, ► Type II errors, and the size of effect, define the power of the research to discover possible differences; i. e., the power implies:

1. defining the effect size, i. e., the size of the difference needed to be discovered (clinically significant difference that should not be ignored)
2. the choice of probability that is needed to confirm the difference if it is present – the power of the method – difference between 1 and the probability of Type II error ($1 - \beta$)
3. the decision of risk size that the researcher is willing to take in declaring its presence – when a difference does not actually exist – the level of significance – the probability of Type I error – α value.

Statistics

Definition

Statistics is a mathematical science pertaining to the collection, analysis, interpretation or explanation, and presentation of data. It is applicable to a wide variety of academic disciplines.
Statistics is a science of generating information and knowledge through the collection, analysis and interpretation of data that are subject to random variation. Statistics has its origins in three branches of human activity: first, the study of mathematics as applied to games of chance; second, the collection of data as part of the art of governing a country; and third, the study of errors in measurement, particularly in astronomy. At first, the connection between these very different fields was not obvious, however it came to be appreciated that data are governed to a certain extent by chance, that decisions have to be made in the face of uncertainty and that errors in measurement have a random component.

Statistics in Health-Related Fields

Synonyms

Biostatistics

Definition

Biostatistics is the application of statistics in health-related fields, including public health, medicine and biology, and the development of new tools to study these areas. Biostatistics constitutes the quantitative foundation for public health practice and research. It comprises the reasoning and methods for using data as evidence to address public health and biomedical questions. The domain of biostatistics includes: statistical aspects of public health and biomedical research design (how and why the data have been collected), descriptive statistics (description or summarization of a collection of data) and inferential statistics (the drawing of inferences about a pool of data when only a part of the data are observed). The latter can also be seen as the modeling of patterns in the data, in a way that accounts for randomness and uncertainty in the observations, to draw inferences about the process or population being studied.

Statutory Health Insurance

Definition

Statutory health insurance is a form of sickness insurance organized by the government. To prevent an illness from becoming a financial risk, statutory health insurance funds cover members and their families in the event of illness. As a community based on solidarity, the statutory health insurance system has the task not only of restoring the health of insured persons, but also of providing measures for maintaining and improving health. For the most part, statutory health insurance finances itself mainly through the contributions of employees and employers. The amount of the contribution depends on the individual income of the insured person.

Stem Cell Research and Therapy

Susanne Proksch, Ursula Ravens
Institute of Pharmacology and Toxicology, Medical Faculty, University of Technology, Dresden, Germany
susanne_proschk@web.de,
ravens@rcs.urz.tu-dresden.de

Definition

Stem Cell Research consists of the investigation of different types of stem cells and their origin, as well as the characterization of their in vivo and in vitro properties. Stem Cell Therapy, on the other hand, deals with the application of stem cells in a clinical setting in order to regenerate injured tissues or, in more general terms, to improve a pathological condition.

Basic Characteristics

Classification

Stem Cells are defined by
(1) their capacity for long-term self-renewal
and
(2) their multilineage potential.
These properties allow them to self-replicate for indefinite periods without loss of proliferation capacity after any cell division, and yet to give rise to many different cell types.

Embryonic Stem Cells

Embryonic stem cells (ESC) are derived from the inner cell mass of ► pre-implantory blastocysts. ESC are clonogenic (► clonogenicity) and able to give rise to differentiated cell types of the three primary embryonic germ layers (endoderm, mesoderm, ectoderm) (Kirschstein and Skirboll 2001). Hence, they are considered to be omnipotent (► omnipotency). In vitro, spontaneous differentiation occurs when feeder layers or leukemia inhibitory factor (LIF) are removed from the growth medium, resulting in aggregation of suspended ESC to embryoid bodies (EB) (Dimmeler and Zeiher 2005). Differentiation into a particular cell lineage, e. g. cardiomyocytes, can be enhanced by modifiying culture techniques and adding defined growth factors or cytokines (Wobus et al. 1991).
Embryonic germ cells (EGC) with ES cell-like properties are derived from primordial germ cells. They can only be isolated from fetal tissue which raises ethical concerns besides limiting their availability. Few EGC data from animal experiments have been reported, yet it is generally assumed that compared to ESC their range of potential fates is rather limited (Chapman et al. 1999).
ESC are ► immune privileged, and their most promising use is transplantation therapy. In addition, ESC provide new insights into genetic, molecular and cellular events during early development. They represent a useful model to test candidate therapeutic drugs, extending information of animal model testing. ESC can be injected into blastocysts generating ► chimeras or even replacing inner cell mass, forming a new embryo. If administered without in vitro pre-commitment, they hold the risk of giving rise to tumours like ► teratomas.

Adult Stem Cells

Adult Stem Cells (ASC) are a heterogenous population of cells that reside in mature organs. It has been known for a long time, that any tissue contains progenitor cells which maintain its integrity and replace lost cells (Kirschstein and Skirboll 2001). ASC are able to give rise to different cell types by generating progenitor cells which are already committed to a specific cell lineage. Depending on the tissue of their origin, ASC vary in their morphology and characteristics. In general, they are localized at a special site within the tissue, termed a "niche", that is created by supporting cells and extracellular environment. Although they can cross the boundaries of germ layer derivation, ASC are supposed to have limited ► plasticity compared to ESC. ASC may originate from undifferentiated remnants of ESC-like cells in development, or they may represent ► bone marrow cells of peripheral blood after homing to the particular organ.

As an ► autologous cell source, ASC can be obtained from the same patient who is to be treated. Potential therapeutic use of ASC is mainly limited by their scarcity. Only 1 of 10,000 to 15,000 cells in bone marrow is a ► hematopoietic stem cell (HSC), which is probably the most studied cell type among ASC. Many tissues were shown to contain ASC, e. g. brain, heart, peripheral blood, dental pulp, liver, epithelia and skeletal muscle. Even adult germ cells were recently reported to be pluripotent (► multipotency) (Guan et al. 2006). The ability of ASC of preventing senescence and their capacity for self-renewal seem to be limited in comparison to ESC.

Stem Cell Biology

The capacity of self-renewal and the multilineage potential are encoded by a shared set of genes, including for instance the Pou5f1-gene. This gene encodes the transcription factor Oct-4, the expression of which is required for the maintenance of self-renewal and pluripotency (Kirschstein and Skirboll 2001). Another important mechanism is the LIF-STAT3 pathway. By binding to its receptor, LIF activates the latent transcription factor STAT3 necessary for continued proliferation (Marshak et al. 2001). Thus, when the balance between the various signaling pathways is shifted, cells are diverted from proliferation to differentiation. In vitro experiments try to mimic biological conditions and to induce certain differentiation processes by adding adequate growth factors or cytokines.

In general, cell fate between continued proliferation and the beginning of differentiation is surveyed at several checkpoints during the cell cycle, that are under the control of genes, paracrine factors or cell-cell interactions. In this respect stem cells resemble tumour cells which can return to an undifferentiated proliferating stage by skipping these cell cycle check points (Kirschstein and Skirboll 2001).

Stem Cell Research

ESC can be obtained from a 4–5 days old embryo, whereas EGC are collected from the gonadal ridge of aborted fetuses at a later stage of development. ASC, however, can be enzymatically isolated from tissue biopsies of adult individuals.

Therapeutic stem cell administration requires pre-commitment in vitro in order to avoid the risk of tumour formation. Depending on which cell lineage is required, specific culturing protocols have to be used (Wobus et al. 1991). Differentiation can be verified by evaluation of mRNA and protein expression using RT-PCR, Western blot, immunofluorescence or histological stainings, as well as by functional tests such as electrophysiological measurements or enzymatic assays. Further cell culture protocols aim to build three-dimensional tissue patches used in transplantation (Zimmermann et al. 2006).

Any stem cell population to be used for therapeutic purposes should be characterized by its surface marker profile in order to ensure sufficient enrichment and to prevent contamination with unwanted cells. The techniques for cell sorting include centrifugation, magnetic bead labelling, FACS analysis, mechanical filtration or the transfer of a neomycin resistance gene.

Therapeutical Applications

Stem cell therapies have been used experimentally and clinically to improve the function of several organs (Kirschstein and Skirboll 2001; Balana et al. 2003; Dimmeler and Zeiher 2005). However, it is not clear, whether the benefit is due to (trans)differentiation, angiogenesis or paracrine factors.

Residing stem cells can be induced to proliferate and to differentiate. This procedure offers biological safety and few ethical restrictions. Isolated stem cells can be

applied either directly by implantation into an injured area, or by injection into a blood vessel supplying the organ. Tissue used in transplantation therapy can also be engineered in vitro, as an example cardiomyocytes embedded in a collagen substrate that can be stitched onto an infarction scar in order to support the myocardium during systolic contraction (Zimmermann et al. 2006).

All of these methods require to solve 2 basic problems: 1) to find a suitable cell source and 2) to prevent immune response. ► Therapeutic cloning may provide a solution because it involves the transfer of the nucleus from a somatic cell into an unfertilized oocyte (Balana et al. 2003). Cell replacement therapy with genetically modified cells could overcome the immune response and regulate specific protein expression often associated with disease.

Up to now, only few therapies have been tested in clinical trials, but the results appear to be promising. Obviously, autoimmune disorders may be treated with blood cells, including T- and B-lymphocytes derived from HSC. Stem cell replacement has been shown to yield reestablishment of tolerance in T-cells (Kirschstein and Skirboll 2001), thereby decreasing the likelihood of disease reoccurrence. After mobilization of HSC from bone marrow to peripheral blood, cells are harvested repeatedly and returned after elimination of the mature immune cells. Subsequently, HSC differentiate and restore immune-competent cells.

New findings and increasing knowledge about ASC in differentiated tissues raise hope of amending defects so far incurable. In the central nervous system, therapies are heading to cell implantation and stimulation of the endogenous repair with growth factors and hormones. Human trials with fetal tissue transplants to replace the lost dopamine-releasing neurons in Parkinson's Disease, however, were so far disappointing because patients did not show significant benefit in quality of life.

Ethical Considerations and Legislation

Stem cell research provokes intensive public discussion and ethical concerns. Although stem cell research and therapy pursue sophisticated aims, there is no unanimous position with respect to ethical issues. Researchers and their financial supporters should look at the problem from both conflicting sides (Hug 2006) in order to act responsibly. Human life must be basically unviolable, and there is no general notion regarding gradual differences in human identity starting from conception, development, birth and maturation into adulthood. Human ESC are able to develop into individual human beings. Nevertheless, a blastocyst does not yet fulfill characteristics associated with personhood, like physiology, psychology, emotions and intellectual properties. A blastocyst is able to divide and give rise to two individuals. An arbitrary definition of what makes a human being is the gain of conscience and self-awareness. However, loss of these properties in old-age and disease does not implicate loss of human dignity. Therefore, also an embryo at the very beginning of its existence should be equally protected as more developed fetuses or adults.

Stem cell research is well funded. To find a consensus for the experimental handling of stem cells, governments enacted certain laws and guidelines. In Germany, similar to Ireland, Austria, Switzerland, Norway, Italy and Luxembourg, the "law of protection of embryos" (since 2002) is rather restrictive, prohibiting or limiting the production and import of embryonic stem cells (Dimmeler and Zeiher 2005). For research and therapeutic purposes, ASC are to be preferred to ESC also with respect to funding (DFG 1999).

Other countries permit investigations that do not provide an advantage for the embryo itself, but for society in general (France, Denmark, Sweden). Finland, Greece, Great Britain, Netherlands and Spain only restrict the usage of cells beyond the 14-day embryonic stage (Dimmeler and Zeiher 2005). The European Union, in general, prohibits the production of human embryos for research purposes. The United States of America also do not support research with embryos produced for this purpose, but experimentation with ESC lines or ESC isolated before 2001 is legal.

Definition

Stereotypes are beliefs. They represent notions of groups of persons. Recalling stereotypes does not implicate the agreement that those stereotypes are valid.

Sterility

- ▶ Infertility

Sterilization

Synonyms

Sterilization; Asepsis; Complete elimination of germs; Removal of viable microorganisms

Definition

Sterilization is a method of killing or eliminating any microorganisms, no matter if they are pathogenic or not. Asepsis is achieved when the number of germs is reduced by a factor of 10^{-6}, that means, only one in one million microorganisms survives. Mechanical sterilization is performed by the use of filters. Physical sterilization methods include dry heat, wet heat (steam) and radiation (UV-light, accelerated electrons, X-rays or gamma radiation). For heat-sensitive-items chemical sterilization might be suitable. Fractional sterilization, or tyndallization, is a procedure in which organisms are destroyed by exposure to heat for a definite period on each of several days – incubation periods between the intervals of exposure bring about a reactivation of the spores so that they can be eliminated by the next heat exposure.

Sterilization is the process that destroys all forms of microbial life, including bacterial spores, on inanimate surfaces. Sterilization is required for medical devices penetrating an already sterile part of the body, as well as for all parenteral fluids and medications. In healthcare settings, sterilization is usually accomplished by the use of physical (wet or dry sterilization) or chemical (ethylene oxide gas, hydrogen peroxide gas, or liquid chemicals) means.

Stigma of Mental Disorders

ISABEL HACH
Klinik für Psychiatrie und Psychotherapie,
Klinikum Nürnberg-Nord, Nürnberg, Germany
isabel.hach@klinikum-nuernberg.de

Synonyms

Labeling of mental disorders

Definitions

Stigma means a mark or sign of shame, disgrace or disapproval, of being shunned or rejected by others. ► Public stigma is the reaction of the general population for example towards people with mental illness. Three different public stigma components can be distinguished: ► prejudice, ► discrimination, and ► stereotypes.

Basic Characteristics

Introduction

For centuries, mental disorders have been associated with stigma and shame. Stigma is a part of culture, and there are different levels of stigma towards mental illness in different populations. Individuals may view people with mental illness in a negative stereotyped manner. People who have identities that society values negatively are said to be stigmatized. Stigma is a reality for people with a mental illness, and they report that how others judge them is one of their greatest barriers to a normal life. Usually, mental illness is not seen like other illnesses such as heart disease and cancer. Due to inaccuracies and misunderstandings, people have been led to believe that an individual with a mental illness has a weak character or might be dangerous. Those misconceptions could be shown by media analyses of print and film. The media often stress a history of mental illness in the backgrounds of people who commit crimes of violence. The Royal College of Psychiatrists (http://www.rcpsych.ac.uk) carried out a survey of about 1,700 people's attitudes towards the six most common mental disorders (Anxiety disorders, Depression, Schizophrenia, Alzheimer's disease and dementia, Anorexia nervosa and Bulimia nervosa, and Substance use disorders; 1999). They showed, for example, that about 75% of people rate drug addicts as dangerous while about 70% think schizophrenics are a threat and 65% believe persons with alcohol dependence are a danger, 16% of people believe depression cannot be treated, compared with 15% for schizophrenia, 14% for panic attacks, 12% for drug addiction, 11% for alcoholism and 10% for eating disorders. The Royal College of Psychiatrists (RCP) found out that many people still think it is difficult to communicate with people with mental illness. However, the survey had also positive signs, for example, it showed that over half of the people questioned had personal experience of mental illness and the public was mostly accurate when predicting the outcome of mental illness (exception: anorexia nervosa). In a German telephone-survey more than 7,000 people were asked about their knowledge in regard with schizophrenia and individuals suffering from schizophrenia, respectively. The results indicated that about one third of the interviewees were able to name causes of schizophrenia. More than 75% believed that people with schizophrenia often or very often needed prescription drugs to control their symptoms. Last, the major part of the interviewees (81.1%) believed that most people would pass over the job application of a former mental patient in favor of another applicant. Stigmatization can create a vicious circle of ► discrimination leading to social isolation, drug abuse, unemployment, and institutionalization, all factors that further decrease the chances of recovery and reintegration into society.

Public Stigma, Self-Stigma of Mental Illness and Effects of Labeling

Most individuals have stigmatizing attitudes about mental illness and people suffering from mental disorders, respectively. Studies suggest that even health care

professionals show stigmatizing views about mental illness. The effect of labeling of mental disorders has been discussed controversially. Labeling might have positive effects because if the mental disorder is seen as an illness, the privileges of the patient role might be granted and patients will not be held responsible for their illness. Labeling can introduce positive consequences through treatment. By contrast, through labeling the negative stereotype and stigmatization of the mentally ill could be triggered as well. Stigma not only causes individuals with mental disorders to feel isolated and unhappy, but may also prevent them receiving effective help and treatment (e. g., Goffman 1963). Angermeyer and Matschinger (2003) showed that labeling has, especially in people with schizophrenia, negative consequences. Labeling in those cases was positive correlated with the endorsement of the belief that individuals suffering from schizophrenia were dangerous (i. e., increase of fear and social distance). In the same study, labeling had no effect on those attitudinal components with major depression.

Moreover, individuals suffering from mental disorders might be also diminished by ► self-stigma and low self-esteem, or they might be angry because of the ► prejudice and stigma they have experienced by the public. Hence, self-stigma often is paradoxically associated with both low self-esteem and righteous anger. ► Self-stigma seems to be a quite complex and still not well known phenomenon.

Prevention of Stigmatization

Understanding the dimensions of mental illness stigma is one of the first steps to prevent stigmatization. However, there is no simple or single remedy to eliminate the stigma associated with mental illness. According to Corrigan and Watson (2002), change strategies for stigma have three approaches: protest, education, and contact.

- Protest is a reactive strategy that attempts to diminish stereotypes and negative attitudes about individuals with mental illness.
- Education programs provide information about mental disorders with the goal that the public makes more informed decisions about mental illnesses. Educational and training programs can improve knowledge of mental illness and modify negative attitudes in the general population as well as in specific target groups, such as those employed in mental health care (e. g. "Open The Doors"; Gaebel and Baumann 2003). Broader knowledge may redress public fears. In addition, to providing information about the nature, causes, and treatment of mental disorders, interventions should place special emphasis on achieving a more positive media portrayal of people with mental illness and on promoting personal contact with them. Information on the disorder and on the factors underlying its stigmatization should reach relatives, friends, colleagues, and superiors, as well as physicians, therapists and nursing staff.
- As research has shown, there is an inverse relationship between having contact with a person suffering from mental illness and endorsing psychiatric stigma. Hence, opportunities for the public to meet individuals with (severe) mental may reduce stigma.

Overall approaches to the reduction of stigma involve programs of advocacy, public education, and contact with persons with mental illness through schools and other societal institutions. The determination of causes and effective treatments for mental disorders is also an effective way to eliminate stigma. There is little knowledge, how long the effects of an anti-stigma intervention are maintained over time. The associations between social structures and the maintenance of stigma need to be investigated to plan effective intervention programs. Over the past 15 years, attitude research towards people suffering from mental disorders made considerable progress (Angermeyer and Dietrich 2006). However, to provide an empirical basis for evidence-based interventions to reduce stigmatization, there is still more research needed.

Stimulants

► Psychostimulants

Stratification

Definition

Stratification is a technique to control confounding in the analysis of a study that involves the evaluation of the association within homogeneous categories or strata of the confounding variable. If for example sex is a potential confounder, an estimate of the association between the exposure and the disease would be calculated for men and for women separately.

To examine the possible association between urban atmospheric pollution and lung cancer, the population may be divided into strata according to smoking status, because smoking is known as risk factor for lung cancer. The association between air pollution and cancer can then be estimated separately within each stratum.

Stratified Analysis

Definition

A stratified analysis (also referred to as contingency analysis) is a tabular or graphic representation of a research outcome differentiated by demographic, social or other relevant parameters (e. g. age, sex, class, migration status). When carrying out a stratified analysis, the researcher assumes that the outcome of his research is not independent of the stratification variables but rather varies systematically across their properties. Frequently, the associations examined are bivariate but a stratified analysis may also include more than one stratification variable simultaneously (e. g. sex *and* age). Furthermore, it can pursue a systematic multivariate research strategy of sequenced tabulations. The associations observed in stratified contingency tables can be assessed by calculating association and significance measures.

Cross-References

► Standardization

Stratosphere

Definition

Earth's atmosphere is usually divided into four layers that are, in order of increasing elevation, the troposphere, the stratosphere, the mesosphere, and the thermosphere (or ionosphere). The stratosphere is the atmospheric layer from about 16 km above Earth's surface near the equator (about 9 km near the poles), up to 50 km. One of the main characteristics of the stratosphere is the presence of ozone gas, which has its highest density at about 20 to 25 km above the Earth. Shortwave solar ultraviolet radiation is effectively absorbed by this ozone layer in the stratosphere, protecting all life forms on Earth against this harmful radiation (ozone shield). During the second half of the 20th century, considerable deterioration in the ozone layer has been observed, known as ozone holes. Air temperature increases with altitude in this layer, due to high absorption of UV ► radiation by stratospheric ozone. However, on the top level (upper boundary) of the stratosphere, the temperature value is almost the same as the average air temperature on the Earth's surface (15 °C). Finally, inside the stratosphere there is now a considerable collection of radioactive dust produced by numerous detonations of nuclear devices during the second half of the 20th century.

Streptococcal Toxic-Shock Syndrome (STSS)

Synonyms

Toxic strep syndrome

Definition

In cases of soft tissue injuries (also after insect bites), varicella infections or following a blunt trauma (muscle hematoma) there can be a superinfection by streptococci. When toxins are set free, a phlegmon, a myositis or a necrotizing fasciitis can be result. In the case of necrotizing fasciitis, parts of the skin and the subcutis become necrotic. A quick surgical intervention is necessary. Lethality is about 30%. Similar to toxic-shock syndrome, toxic strep syndrome most frequently occurs in formerly healthy persons between the age of 20 and 50.

Stress

Michael Lingen
University of Göttingen, Göttingen, Germany
mlingen@gwdg.de

Synonyms

Stress factors; Stress-related disorders; Acute stress reaction; Reaction to severe stress

Definition

Stress can be seen as a pattern of specific and unspecific reactions of a person to events which disturb the person's homeostasis (equilibrium) and call for, or even overextend, the person's ability to cope. These events comprise a range of external (e. g. a traffic accident, an argument) and internal conditions (e. g. an illness, worry, boredom), which are all called "stressors" and demand adaptation. Whether and to what extent an event is experienced as a stressor depends on the person's perception and evaluation of the event and the (perceived and deployed) ability to cope with it.

Basic Characteristics

History and Models

It is characteristic of stress that a (critical) event has multiple effects on a person's life and perception. Hans Selye first used the term "stress" approximately 50 years ago to describe a state of tension of the body which is necessary to mobilize the body's defenses. In his biological-medical theory of stress, Selye (1974) assumed that stress would lead to a disorganization of behavior which would make a complex process of readaptation necessary. According to this theory, stress is an unspecific reaction of the organism to any kind of demand. According to Selye, the stress reaction as such consists of three phases: an alarm state, a resistance state and an exhaustion state. In a situation of danger, the body switches to vegetative processes, because rationally assessing the situation and reacting to it could be dangerously slow. An external stimulus (a noise, a fast movement, a change of light intensity, etc.) puts the body in an alarm state. Adrenaline (epinephrine) and other hormones are released, blood pressure and blood glucose level are raised. In order to increase the reaction speed, the cognitive processes stored in the cerebrum are switched off for a brief moment in favor of the fast reaction processes stored in the brain stem. When the dangerous situation has been dealt with successfully, the stress hormones will be broken down and exhaustion sets in. The body has to regenerate. Seyle describes here a normal and rather positive process. The program described was of vital importance for human beings in a time when they were still threatened by wild animals. Today, this mechanism is often triggered when fight or flight is either useless or even wrong. Problems therefore often occur when the stressor appears repeatedly at short intervals or over a longer period of time: this leads to adaption. After the alarm state described above, the body falls into a kind of shock during which the stress hormones have to be either broken down or countered by other hormones. If the stress persists, however, the body switches to the state that Selye called resistance state during which the body is in a permanent state of alert. This means that the stress hormones are not broken down. If the influence of the stressors is still not reduced or stopped, the exhaustion state sets in. The body slows down all systems. Metabolism, immune functions, etc. are slowed down, the need for sleep increases, the organism falls ill and can sustain lasting damage or even die.

Another important differentiation was also introduced by Selye (1986), that of "▶ eustress" and "▶ distress". The loss of balance is called eustress when the person experiences an equivalence of demand and available resources. This so-called "positive" stress is seen as a challenge the person can cope with. Distress, on the other hand, describes psychic states or processes in which, at least temporarily, the relation between

demand and resources is disturbed in favor of the demand.

A newer definition, by Richard Lazarus (1974; 1993), assumes that it is not the stimulus causing the stress that is of importance, but the individual's reaction to it. The decisive question, therefore, is: "Can I cope with the situation with the resources available to me?" Accordingly, Lazarus sees stress as a transactional process, that is a process of interaction between a person and the environment that starts with the appraisal of an event and one's possibilities of coping with it. In the first place, the primary appraisal, people assesses whether the situation is relevant to their goals and wishes. Secondly, the secondary appraisal, people check whether the available resources are sufficient to cope with the situation. If that is not the case, the result will be stress. The coping strategy or adaptive reaction depends on the situation as such as well as on the personality and cognitive structures of the individual (e. g. attack, flight, search for alternatives, re-evaluation). The next step is the reappraisal, as the inner and/or outer conditions have been changed as a result of the coping strategy. Stress, according to this model, is not a static condition, but a dynamic process which occurs in a constant and reciprocal interaction (= transaction) between an individual and the environment.

The process of successful or failed adaptation depends on a number of other factors. The intensity of the stress reaction and the way the stress is dealt with largely depend on the evaluation and appraisal process with regard to controllability and attribution of causes. The coping process as such is further modified by personality factors, coping tendencies and coping styles and variables of social support. Depending on further circumstances, these personality and social features can reduce or intensify the stress reduction.

Stress may result in psychological disorders: an ► acute stress reaction is the consequence of an exceptionally stressful life event. Whereas, an ► adjustment disorder is the result of a significant life change leading to continued unpleasant circumstances. The mental disorder category "*reaction to severe stress and adjustment disorders"* (International Classification of Disease: ICD-10) differs from others in that it includes disorders identifiable on the basis of not only symptoms and course but also on the existence of one or other of two causative influences. The disorders of this category are thought to arise always as a direct consequence of acute severe stress or continued trauma (i. e. maladaptive responses). According to ICD-10, there are four stress-related mental disorders: reaction to severe stress, adjustment disorder, acute stress reaction, and ► post-traumatic stress disorder.

Stress Research

Stress Research and Life Event Research, whose methods and subjects match to a large extent, share a basic principle, namely that a person is in interactional exchange with the environment. A Life Event is an event which leads to a disorganization of behavior and a psychological disorder. According to Holmes and Rahe (1967), decisive events during a person's life, e. g. death of one's partner or a serious illness, represent particular strains which make a substantial reorientation necessary and can lead to illness or psychological disorder. But also smaller events like moving house or changing jobs, trouble with the boss, a holiday or taking out a loan can be a (stressful) burden and make an adaptation necessary. Most of the time, it is not the critical life events, but insignificant troubles and worries, the so-called "daily hassles", that are perceived as chronic stress events (e. g. noise, pressure of time). This is based on the assumption that a person's health is not so much affected by the few, important life-changing events but by continuous daily hassles and everyday mishaps. The respective diagnostic findings suggest that it is their frequency and their anticipated unavoidability which makes these daily hassles the greater danger to a person's health because, contrary to the more infrequent life events, they often occur many times over a long period of time. If a person thus experiences chronically stressful living conditions, a single, insignificant event can be the last straw if the person is sufficiently vulnerable.

Another characteristic that the Stress Research has in common with Life Event Research is its non-specificity: an analysis of the effects of stress or life events does not usually determine any specific kinds of psychological disorders or reactions that could be expected as a result of a critical life event or stress experience (e. g. depression, schizophrenia, high blood pressure, coronary heart disease, etc.).

From the earlier works about adaptation syndrome (Selye 1936) to the Life Event Research, a common, central model is used according to which stress is seen

as an organism's reaction to stressors that are, in a manner of speaking, objective. Efforts were made to make these stressors objective for research-methodological reasons; firstly by measuring physical influences on the organism (noise, light, etc.), and later by estimating the narrowness of the social living space. Psycho-diagnostically, efforts prevail to render stressors objective by operationalizing critical life events and daily hassles and worries. A number of event-checklists, ratings, questionnaires and interviews have been developed for this purpose (e. g. the *Life Events and Difficulties Schedule*, Brown and Harris (1989) or the *Daily Hassles- and Daily Uplifts-Scales* by Lazarus and Folkman (1989)).

Coping with Stress

Apart from investigating the causes and effects of stress, a major focus of research has always been the question of coping strategies. Here, an individual's ability to deal with stress plays a major role. Lazarus distinguishes between two kinds of coping with stress, the problem-oriented coping and the emotions-regulating coping. In problem-oriented coping, a person tries to change, overcome or adapt to a problematic situation by a targeted search for information and ensuing action (or inaction). Strategies belonging to this group are clarifying talks, changes in time management, delegating tasks, etc. In emotions-regulating coping, also called "intrapsychological coping", on the other hand, people try to either reduce the emotional agitation caused by the stress (e. g. by using relaxation techniques, positive self-instruction or reassessment of the situation) or increase their resilience without dealing with the cause of the stress.

► Stress

Stress at Work

► Job-Related Stress

Strict Liability

Synonyms

Liability without fault; Absolute liability in tort

Definition

The term indicates a particular form of liability under private law. In contrast to most private law liabilities, no fault is required to become liable under strict liability schemes. To claim damages under strict liability, a claimant does not have to prove that the tortfeasor acted at fault when causing the harm. Strict liability is an important liability subtype under tort law. It is imposed as a deviation from fault-liability in fields of activities that are inevitably associated with potential risks. Product liability is a typical area of strict liability.

Strongyloidiasis

Synonyms

Infection with Strongylodes stercoralis

Definition

Strongyloidiasis is caused by an infestation of the 1.8–3.2mm long roundworm *Strongyloides stercoralis*. After ingestion the worm settles in the upper part of the small intestine. The symptoms are malaise and diarrhea, which can sometimes be bloody.

Struma

► Goitre

Student's t-Test

Definition

A parametric test for the significance between means (two independent sample t-test or paired samples t-test) or between a mean and a hypothesized value (one-sample t-test). T-tests generally require the data to be normally distributed and from populations having equal variability unless samples sizes are approximately equal.

Study

► Ethics, Aspects of Public Health Research

Study Protocol

Synonyms

► Investigational Protocol

Definition

A protocol is a study plan which is legally required for answering all specific research questions. Having the safety of participants as one of the focal points of reference, a protocol also determines:

- Who can participate.
- The schedule for tests, dosages and other details of the study.
- The study duration.

Sub-Acute Care

► Short-Term Rehabilitation

Subsidiarity Principle

Definition

The subsidiarity principle involves ensuring that decisions are made as closely as possible to the citizen, i. e. at the lowest possible administration level. Only when tasks cannot be performed effectively at a lower level are they dealt with at a higher level.

Subsidy

► Health Subsidies

Subspecies

► Race

Substance Abuse

Synonyms

Harmful substance use; Excessive substance use

Definition

Substance abuse is the excessive use of a substance, especially alcohol or a drug. The DSM-IV (Diagnostic and Statistical Manual of Mental Disorders issued by the American Psychiatric Association 2000) definition is as follows:

"A maladaptive pattern of substance use leading to clinically significant impairment or distress, as manifested by one (or more) of the following, occurring within a 12-month period:

- Recurrent substance use resulting in a failure to fulfil major role obligations at work, school, or home (e. g. repeated absences or poor work performance related to substance use; substance-related absences, suspensions or expulsions from school; neglect of children or household)
- Recurrent substance use in situations in which it is physically hazardous (e. g. driving an automobile or operating a machine when impaired by substance use)
- Recurrent substance-related legal problems (e. g. arrests for substance-related disorderly conduct)
- Continued substance use despite having persistent or recurrent social or interpersonal problems caused or exacerbated by the effects of the substance (e. g. arguments with spouse about consequences of ► intoxication, physical fights)

The symptoms have never met the criteria for ► substance dependence for this class of substance."

Substance Dependence

Synonyms

Drug dependence; Drug addiction

Definition

In 1964, the World Health Organization concluded that the term drug addiction is no longer a scientific term and recommended substitution with the term drug dependence. The concept of substance dependence has had many officially recognized and commonly used meanings over the decades. Two concepts have been used to define aspects of dependence: behavioral and physical. In behavioral dependence, substance-seeking activities and related evidence of pathological use patterns are emphasized, whereas physical dependence refers to the physiological effects of multiple episodes of substance use.

Substance dependence is according to the diagnostic criteria for in DSM IV (American Psychiatric Association 2000, p. 197) characterized by "a maladaptive pattern of alcohol or substance use leading to clinically significant impairment or distress, as manifested by 3 or more of the following, occurring at any time in the same 12-month period:"

(1) tolerance (need for increased amounts of the substance to achieve the same desired effects);
(2) withdrawal (unpleasant somatic and cognitive effects after reduction or termination of use);
(3) loss of control on duration and amount of use;
(4) persistent, but unsuccessful efforts to control further use;
(5) spending a lot of time for acquisition and use;
(6) neglect of social and occupational activities; and
(7) continued use despite negative consequences.

[2] TIFT Institut für Therapieforschung, München, Germany
buehringer@psychologie.tu-dresden.de

Synonyms

Addiction; Drug dependence; Substance use disorders; Substance abuse; Substance dependence

Definition

"The Substance-Related Disorders include disorders related to the taking of a drug of abuse (including alcohol), to the side effects of a medication and to toxin exposure" (American Psychiatric Association 2000, p. 191). These substances have psychoactive properties which affect the central nervous system and impair perception, cognition, emotions and behavior. They can be grouped according to their profile of either predominantly sedating, stimulating or hallucinogenic effects: e. g., alcohol, cannabis, opioids, amphetamines, nicotine and hallucinogens. Substance related disorders are divided in two groups: (1) ► substance use disorders (SUD) with ► substance dependence and ► substance abuse as long-term negative consequences. Persons involved usually have lost their control on onset, duration and amount of substance use, despite significant negative consequences. (2) ► Substance induced disorderscover ► intoxication and withdrawal as major syndromes, but also more rare complications like delirium, dementia and amnesia.

Basic Characteristics

History

Marks of use and abuse of substances can be found in all periods of human history; heavy daily alcohol use was normal in the Middle Ages. The disease concept for alcohol abuse came up at the end of the 18th century, first inebriate asylums around 1870. Not before the beginning of the 20th century the modern understanding as a complex biopsychosocial disorder was developed. Over centuries and still today we have a controversial discussion on the relevance of individual responsibility for onset and cessation of use disorders: dependence as a "lack of willpower" or "lack of competences", as "vice" or "disease" (Valverde 1998).

Epidemiology

Prevalence figures for SUD vary extremely between world regions, based on cultural and religious traditions (e. g. low alcohol use in Islamic countries) and public access regulations (e. g. degree of prohibition, enforcement policy, store opening hours, taxation). In Europe about 3.4% of the adult population (men: 5.6%; woman: 1.3%) meet criteria for alcohol *dependence*, 0.3% for dependence on illicit drugs (Wittchen and Jacobi 2005). Inclusion of substance *abuse* will roughly double these figures. Worldwide about 76 million have a diagnosed alcohol use disorder (WHO 2004). Prevalence for tobacco use disorders vary around 20–60%, with a decline in most Western countries and very high figures in developing areas (worldwide about 1.3 billion smokers; Shafey, Dolwick and Guindon 2003).

Consequences

► Intoxication as the major acute impairment after heavy alcohol and drug use episodes increases the risk for (1) work and road accidents and (2) violence, (3) in severe cases even for fatal consequences (e. g. apnoea after heroin use). Long-term consequences for most substances occur on the somatic (e. g. various kinds of cancer and cardiovascular diseases, HIV and hepatitis after intravenous drug use), mental (depression) and social level (loss of work and social contacts, family problems). Alcohol attributable "► disability adjusted life years lost" (DALYS), combining premature death and life years in disability, account for 3–14% of all disease related DALYS (depending on sex and the country developing status). The corresponding figures for tobacco are 1–17%, for illicit drugs 0.2–2% (WHO 2004, Table 17). Annual costs of alcohol use disorders in Europe amount to 57 billion or about 24% of all mental disorders (Andlin-Sobocki, Jönsson, Wittchen and Olesen, 2005). Often forgotten are health and social consequences for victims, e. g. newborn of substance using mothers (alcohol-embryopathy), family members (rapes) and road casualities.

Classification

Diagnostic criteria for ► substance dependence in DSM IV (American Psychiatric Association 2000, p. 197) are (1) tolerance (need for increased amounts of the substance to achieve the same desired effects), (2) withdrawal (unpleasant somatic and cognitive effects after reduction or termination of use), (3) loss of control on duration and amount of use, (4) persistent, but unsuccessful efforts to control further use, (5) spending a lot of time for acquisition and use, (6) neglect of social and occupational activities and (7) continued use despite negative consequences. ► Substance abuse is defined as a maladaptive pattern of use leading to clinically significant impairment or distress like: failure to fulfil major social obligations, use in hazardous situations (e. g. driving), legal and other social problems, but without meeting the criteria for dependence.

Screening and Diagnostic Instruments

A broad range of established population ► screening instruments like the Alcohol Use Disorder Identification Test (AUDIT) or the Fagerström Test for Nicotine Dependence (FTND) are available in many languages (Babor, Sciamanna and Pronk 2004; McPherson and Hersch 2000). On the clinical level severe cases of SUD (with obvious somatic symptoms and social problems) can be identified without sophisticated diagnostic instruments. But many cases in medical and social services are not diagnosed, as these patients (1) did not yet recognize early signs of their problems or (2) try to hide their behavior. Alcohol related biological markers like y-GT, AST, ALT, MCV and CDT (Allen, Litten, Strid and Sillanaukee 2001), markers for drug use in urine, hair and other body material (Dolan, Rouen and Kimber 2004) as well as the standardized Composite International Interview – Substance Abuse Module (CIDI-SAM, Robins et al. 1990) are tools for clinical identification. Instruments are also available for detailed diagnostic purposes and for treatment planning like the Addiction Severity Index (ASI; McLellan et al. 1992). Important: The assessment of highly prevalent comorbid mental disorders is essential for treatment purposes.

Aetiology

SUD emerge as a complex interplay of person, drug and environment specific conditions which increase or decrease the probability for onset, continuation or cessation of such problems. Early vulnerability factors (e. g. family genetics, perinatal and adverse childhood complications, affect lability, personality traits like impulsivity and mental disorders) determine a general neuropsychopathological liability and interact with more proximal risk factors like availability of drugs, peer group behavior, social support network and negative life events. But little is known (1) about the underlying processes of change from first use to progression, early cessation or development of severe disorders, (2) about mechanisms for cessation or continued us after the same exposition to the effects of a drug (e. g. experimental smoking) and (3) about the time specifity of increased risk for SUD (e. g. nicotine and illicit drugs: adolescence and early adulthood; West 2006).

Prevention

Two distinct strategies to reduce the incidence of substance related disorders are available: (1) ► supply reduction aims to restrict the availability of substances by prohibition, taxation, store opening hours or minimum drinking age and strict law enforcement of all regulations. (2) ► Demand reduction achieves to educate the population at risk (e. g. adolescents, drivers, pregnant women) to use substances adequately or to stay abstinent. Interventions include risk information, motivation enhancement and skills training. Recent meta-analysis seem to demonstrate superior effects for supply reduction (Babor et al. 2003, for alcohol use disorders).

Treatment

(1) Lack of motivation for change, (2) high relapse rates after interventions (Tims, Leukefeld and Platt 2001) and – for long-term alcohol, cocaine and heroin use – (3) severely impaired health status and social functioning, are major challenges for treatment. Many try for decades to overcome their dependence, some never will reach that goal; but many stop their SUD without formal treatment (Klingemann and Sobell 2001). Pharmacological "► maintenance therapies" for heroin and nicotine are available to at least reduce the negative effects of long-term use. Further effective interventions are cognitive behavior therapies (CBT) and ► community reinforcement programs. Treatment abstinence rates vary between 20/25% for heroin and nicotine and 40/50% for alcohol use disorders (for reviews and

guidelines see Fiore et al. 2000; Berglund, Thelander and Jonsson 2003; Miller and Wilbourne 2002; Strain and Stitzer 2005).

Substance Use Disorders

ISABEL HACH
Klinik für Psychiatrie und Psychotherapie,
Klinikum Nürnberg-Nord, Nürnberg, Germany
isabel.hach@klinikum-nuernberg.de

Synonyms

Drug abuse; Substance dependence

Definition

Substance use disorders (SUD) are a subgroup of the *Substance related disorders*. The use or abuse of psychoactive substances (e. g., alcohol, nicotine, cannabinoids, opioids, amphetamines, cocaine, hallucinogens, sedatives or hypnotics) results in significant adverse consequences. The group SUD compromises substance abuse and substance dependence. The clinical states that may occur, though not necessarily with all psychoactive substances, include ► acute intoxication, ► harmful use, ► dependence syndrome, withdrawal syndrome (state), ► withdrawal state with delirium

(► delirium tremens), ► psychotic disorder, late-onset psychotic disorder (► residual and late-onset psychotic disorder), and ► amnesic syndrome.

Basic Characteristics

Prevalence and Costs of Substance Use Disorders

Substance abuse accounts for one of the major disease groups in Europe within mental health in terms of prevalence (e. g. European estimate (point prevalence) of alcohol dependence: 3.7%; European estimate (point prevalence) of illicit drug dependence: 0.6% (Rehm et al. 2005; nicotine dependence point prevalence rates are between 5.5% (Portugal) and 12.7% (Slovakia)). Substance abuse disorders show a high public health relevance, but overall there is not sufficient information on the prevalence of these disorders (the biggest gap exists for EU admission countries), and existing studies are plagged with methodical differences. Bergmann and Horch estimated the total costs of alcohol dependence per patient per year as 11,984€ . Their study takes cost of crime-related outcomes into account (Bergmann and Horch 2002). Healy et al. (1998) carried out a bottom-up study in 1075 patients, and they took both opioid and cannabinoid dependence into account (direct healthcare costs, costs of crime-related outcome). The costs per patient with drug dependence are estimated to 18,064€ per year. Last, the estimated costs per patient with nicotine dependence were estimated to about 850€ per year (direct and indirect healthcare costs) (Rasmussen et al. 2000; Ruff et al. 2000).

Treatment of Substance Use Disorders

Patients suffering from substance dependence who achieve sustained abstinence have the best long-term outcomes. A reduction of the substance use only to a "controlled" level (i. e., substance use without apparent functional consequences) is unrealistic for most patients. In all substance use disorders a multimodal treatment approach is typically required, since patients suffering from substance abuse are functionally and clinically heterogeneous. There are different treatment settings that have to be considered depending on the patient's constitution (e. g., hospitalization for individuals with a drug overdose or with co-occuring severe medical conditions; outpatient treatment for patients with stabil medical conditions). Medical detoxification is only the first stage of addiction treatment and by itself does little to change long-term drug use. Medical detoxification safely manages the acute physical symptoms of withdrawal associated with stopping drug use. While detoxification alone is rarely sufficient to help addicts achieve long-term abstinence, for some individuals it is a strongly indicated precursor to effective drug addiction treatment.

To be effective, treatment must address the individual's drug use and any associated medical, psychological, social, vocational, and legal problems. Treatment needs to be readily available. Because individuals who are addicted to drugs may be uncertain about entering treatment, taking advantage of opportunities when they are ready for treatment is crucial. Potential treatment applicants can be lost if treatment is not immediately available or is not readily accessible. Pharmacological treatmant may be used for patients with intoxication states, to decrease withdrawl symptoms (i. e., substitution of an agonist) or to promote abstinence (e. g., disulfiram in patients suffering from alcohol abuse). Methadone and levo-alpha-acetylmethadol (LAAM) are effective in helping individuals addicted to heroin or other opiates stabilize their lives and reduce their illicit drug use. There are also controlled trials with prescribed heroin in addicted patients. The findings of those recent studies support the hypothesis that prescribed heroin could be safely delivered. Also, in physical health, HIV risk behavior, street heroin use, and days involved in crime, heroin plus methadone was more efficacious than methadone alone (e. g., March et al. 2006). Naltrexone is also an effective medication for some opiate addicts and some patients with co-occurring alcohol dependence. For persons addicted to nicotine, a nicotine replacement product (such as patches or gum) or an oral medication (such as bupropion) can be an effective component of treatment. An individual's treatment and services plan must be assessed continually and modified as necessary to ensure that the plan meets the person's changing needs. A patient may require varying combinations of services and treatment components during the course of treatment and recovery. Remaining in treatment for an adequate period of time is critical for treatment effectiveness. The appropriate duration for an individual depends on his or her problems and needs. Research indicates that for most patients, the threshold of significant improvement

is reached at about 3 months in treatment. After this threshold is reached, additional treatment can produce further progress toward recovery. Because people often leave treatment prematurely, programs should include strategies to engage and keep patients in treatment. Counseling (individual and/or group) and other behavioral therapies are critical components of effective treatment for addiction. In therapy, patients address issues of motivation, build skills to resist drug use, replace drug-using activities with constructive and rewarding nondrug-using activities, and improve problem-solving abilities. Behavioral therapy also facilitates interpersonal relationships and the individual's ability to function in the family and community. Treatment does not need to be voluntary to be effective, but strong motivation can facilitate the treatment process. Sanctions or enticements in the family, employment setting, or criminal justice system can increase significantly both treatment entry and retention rates and the success of drug treatment interventions.

Addicted or drug-abusing individuals with coexisting mental disorders (e. g. ► psychotic disorders) should have both disorders treated in an integrated way. Because addictive disorders and mental disorders often occur in the same individual, patients presenting for either condition should be assessed and treated for the co-occurrence of the other type of disorder. Treatment programs should provide assessment for HIV/AIDS, hepatitis B and C, tuberculosis and other infectious diseases, and counseling to help patients modify or change behaviors that place themselves or others at risk of infection. Counseling can help patients avoid high-risk behavior. Counseling also can help people who are already infected manage their illness. Recovery from drug addiction can be a long-term process and frequently requires multiple episodes of treatment. Objective monitoring of a patient's possible drug and alcohol abuse might be helpful in preventing a relapse. Monitoring also can provide early evidence of drug use so that the patient's treatment plan can be adjusted. As with other chronic illnesses, relapses to drug use can occur during or after successful treatment episodes. Addicted individuals may require prolonged treatment and multiple episodes of treatment to achieve long-term abstinence and fully restored functioning. Participation in self-help support programs during and following treatment often is helpful in maintaining abstinence.

Even occasional use of drugs can inadvertently lead to addiction. For this reason, most prevention programmes are primary prevention programmes (in adolescents or young adults) with the aim to prevent the onset of substance use, and also to reduce the transition from experimental use (first use) to addiction.

Sudden Infant Death Syndrome (SIDS)

Synonyms

Cot death ; Crib death

Definition

SIDS refers to the unexpected death of a seemingly healthy infant under the age of one while asleep. The cause of SIDS is still unknown. Autopsies do not show any explainable cause of death. Risk factors for SIDS include prone sleeping position, soft bedding, exposure to secondhand smoke, prematurity, multiple birth babies, and the wintertime.

Suicide

Synonyms

Intentionally killing oneself

Definition

Suicide has occurred since the beginning of recorded history, with attitudes toward it varying from condemnation to tolerance, depending on the time and the culture. Today, suicide is viewed as neither a random nor a pointless act in developed countries. Suicide is often associated with unfulfilled needs, feelings of hopelessness and helplessness, ambivalent conflicts between survival and unbearable stress, a narrowing of perceived options, and a need for escape. Risk factors may include: psychiatric disorder, previous suicide attempt, coincident drug use and mental disorder, family history of suicide, impulsive or aggressive behavior, loss of significant relationships, loss of job, physical illness and lack of access to mental health treatment.

Summary Measures of Population Health

Synonyms

Health indexes

Definition

Summary measures of population health are health indexes derived from other ► indicators to represent the health of a particular population. They are widely used for comparisons of health status between populations or of the population at different points in time, identifying and quantifying overall health inequalities within populations, identifying priorities for health service delivery, research and development, and analyzing the benefits of health interventions. Summary measures should be comprehensible and practicable to calculate, and should preferably be linear aggregates of the other measures of health events. Ideally, they must reflect the changes of health status of the population, i. e. if the state of health of a given population worsens then a summary measure should get worse, or if mortality or morbidity rates decrease, a summary measure should improve. The most widely used summary health indexes are: disability-adjusted life years (DALY), quality-adjusted life years (QALY), healthy life expectancy (HALE), and years of potential life lost (YPLL), etc.

Summative Evaluation

Synonyms

Outcome evaluation; Product evaluation; Program evaluation

Definition

Product evaluation is carried out after completion of a measure or intervention. The result of this evaluation is often addressed to external an audience or decision maker. It summarizes the program's performance, validity and outcomes in comparison to alternative programs by using quantitative methods.
The systematic collection of information about the activities, characteristics, and outcomes of programs to make judgments about the program, improve program effectiveness, and/or inform decisions about future program development.

Superior Good

Synonyms

Positive income elasticity

Definition

Microeconomic household theory distinguishes between goods for which demand rises with increasing income levels (superior goods) and those for which demand falls as incomes go up (inferior goods). Whereas staple foods are as a rule inferior goods, medical goods and services are generally regarded as superior goods, whose social valuation tends to increase with time. The effect of an increase in incomes on the demand for specific goods can be analyzed by means of the "income elasticity of demand". In the case of absolutely superior goods, the income elasticity exceeds zero – that is, the demand for the good increases absolutely. If the income elasticity is greater than 1, the relative share of household income accounted for by the good also increases; for this reason the term "relatively superior goods" is also used. The characterization of health goods as relatively superior is confirmed macroeconomically by the phenomenon whereby the proportion of the economy accounted for by health spending increases with the general level of prosperity of a society. A knowledge of specific income elasticities is very important for estimating the market potential of medical and dental goods and services.

Supernutrition

► Overnutrition

Supplier-Induced Demand

Synonyms

Supply-side moral hazard

Definition

Supplier-induced demand is the change in demand of health care services that is associated with the discretionary power of health care professionals – most importantly physicians – over their patients. Additional health care services provided as a consequence of supplier-induced demand are in the self-interest of health care professionals rather than in the interest of their patients.

Supply Reduction

Definition

Supply reduction is a strategy to reduce the incidence of ► substance related disorders. It aims to restrict the availability of substances by prohibition, taxation, store opening hours or minimum drinking age and strict law enforcement of all regulations.

Supply-Side Moral Hazard

► Supplier-Induced Demand

Supporting Measures

► Humanitarian Relief Operations

Suppressive Therapy of Malaria

► Malaria Chemoprophylaxis

Supraglottitis

► Epiglottitis

Surface Water

Definition

Surface water are rivers, lakes and ponds which are mostly used as water sources in cases when there are no other safe sources of water available.

Surgical Site Infections

Definition

Surgical site infections (SSI) are a major source of morbidity and mortality for patients undergoing operative procedures. According to the CDC (► Centers for Disease Control and Prevention) definitions, these infections are classified into incisional, organ, and other organs and spaces manipulated during an operation.

These definitions should be followed universally for ► surveillance, ► prevention, and control of surgical site infections. The risk of developing an SSI is affected by the degree of microbial contamination of the operative site. Infections may be caused by endogenous sources (e. g., bacteria on the patient's skin) or exogenous sources (e. g., personnel, the environment, or materials used for surgery). Most SSIs are caused by the patient's own bacterial flora. The pathogens isolated from infections differ, primarily depending on the type of surgical procedure.

Surroundings

► Environment

Surveillance

► Public Health Surveillance

Surveillance Methodology

Synonyms

Watching over

Definition

It is a methodology used for monitoring something. In health it is applied to monitor health related issues. One way of doing so is to get information from physicians about specific conditions; depending on the process put in place, there can be passive, active or ► sentinel surveillance.

Surveillance of Transmissible Diseases

► Outbreak Management and Surveillance of Infectious Diseases

Surveillance of Working Environment

Definition

Surveillance of the working environment is a generic term which includes the identification and evaluation of environmental factors which may affect workers' health. It covers assessments of sanitary and occupational hygiene conditions, factors in the organization of work which may pose risks to the health of workers, collective and personal protective equipment, exposure of workers to hazardous agents and control systems designed to eliminate and reduce them. From the standpoint of workers' health, the surveillance of the working environment may focus on, but not be limited to, ergonomics, accident and disease prevention, occupational hygiene in the workplace, work organization, and psycho-social factors in the workplace.

Surveys (Statistical)

Definition

Surveys are used to collect quantitative information about items in a population. Surveys of human populations and institutions are common in political polling, healthcare, social science, and marketing research. A survey may focus on opinions or factual information, depending on its purpose, and many surveys involve administering questions to individuals. When the questions are administered by a researcher, the survey is called a structured interview or a researcher-administered survey. When the questions are administered by the respondent, the survey is referred to as a questionnaire or a self-administered survey. The questions are usually structured and standardized. The structure is intended to reduce bias and to ensure reliability, generalizability, and validity.

Survival

► Life Expectancy

Survival Analysis

Biljana Miličič
School of Dentistry, University of Belgrade, Belgrade, Serbia
bmilicic@eunet.yu

S

Synonyms

Survival analysis; Time-to-event analysis

Definition

Survival analysis is the study of distribution of life times, i. e. the times from an initiating ► event to some terminal event. Clinical trials commonly record the length of time from study entry to a disease endpoint for a treatment and control group. Time to event analysis provides a method of including patients who fail to complete the trial or do not reach the study end-point (censored data) by making comparisons between the numbers of survivors in each group at multiple points in time.

Basic Characteristics

If the outcome is an "► event" that may happen over time, then the trial is frequently called a survival trial. Survival analysis must be applied to any clinical trial that is concerned with the prevention of some untoward "event" (or "endpoint") that may eventually affect some or all of the patients. If these events may not occur for some time after starting treatment, it is worth looking at the times at which the events occur as well as counting patients. The sort of untoward events that could be studied in such a clinical trial include myocardial infarctions, leukemia relapses, strokes, metastatic developments, death from one of a certain set of specified causes (ignoring deaths from other causes), transplant rejection episodes, and so on. In each of these studies, it is usually possible to do a more informative analysis than a simple tabulation of the numbers of patients on each treatment who suffered the event of interest. Whether this event is death, local solid tumor recurrence, or something else, the design principles and statistical methods are virtually the same: the times at which each patient who suffers the event of interest does so are observed and analyzed.

With a survival-type event, an important consideration is whether one is interested in comparing the times to an event or only the proportions surviving at a specified time. If the follow-up is "long enough", crude survival can be used if the follow up on every patient treated meets both of two criteria. First, every patient must have been treated an adequate number of years before the analysis. Second, at the time of analysis the patient must be known to either have suffered the outcome of interest or must be known to be alive and without the outcome. What constitutes an adequate number of years varies according to the disease being studied.

These conditions are rarely met. Commonly, some patients die of unrelated causes or are lost to follow-up. If even a single patient has died of unrelated causes before an adequate number of years have passed since treatment then it is no longer appropriate to use crude survival. When absolute survival analysis (number alive divided by number treated) is no longer possible, estimated survival analysis must be performed.

In this situation, each patient has a different length of follow-up. It is difficult to assign meaning to the term "proportion surviving" without specifying a fixed period of observation common to all patients. One can estimate the probability of surviving when patients have differential lengths of follow-up using a life table or the ► Kaplan–Meier method.

Every patient is followed until failure occurs or the patient is ► censored. Patients who suffer the outcome of interest are scored as ► failures. Patients who do not suffer the outcome of interest are scored as censored. If the patient failed, the length of follow-up is the time between diagnosis and failure. If the patient is censored, the length of follow-up is the time between diagnosis and last follow-up visit.

"Actuarial" Life Table Analysis

► Life table analysis involves stratifying patients by length of follow-up. Within each time stratum, a probability of failing is computed as the number at risk at the beginning of the interval. For each time stratum, the probability of surviving is one probability minus the probability of failing. The estimated probability of surviving to a particular time is the product of the probability of surviving each of the preceding time strata.

It may be noted that the life table estimate of the chance of surviving any particular number of days from randomization is thus the product of the life table estimate up to the previous day and the observed survival rate for the particular day.

The Kaplan–Meier (or Product Limit) Method

The ► Kaplan–Meier method is used to recalculate the percentage of survivors at each death time. The key to understanding how it is possible to derive estimates of

survival percentages using incomplete follow-up information lies in the very obvious statement that in order to survive a whole year, the patient has to survive each of the 365 individual days comprising it. The chance of surviving one year is therefore

$$S_{365} = C_1 \times C_2 \times C_3 \times \ldots \times C_{364} \times C_{365}$$

C_1 is the chance of surviving the first day,
C_2 is the chance of surviving the second day having already survived day one,
C_3 is the chance of surviving the third day having already survived days one and two,
And so on to …
C_{364} is the chance of surviving day 364 having already survived days one to 363, and
C_{365} is the chance of surviving day 365 having already survived days one to 364.
We do not know the value of any of these individual Cs but we could estimate any particular one of them, C_{365}, for example, by calculating what proportion of patients who are at risk on day 365 actually survived it. This is termed observed survival. The individual probabilities (Ps) would be 1, but nevertheless the quantity obtained by multiplying them together provides the best mathematically possible estimate of S_{365}, the Kaplan–Meier chance of surviving one year. It should be noted that if we have already estimated S_{365}, then the estimate of S_{366} is just P_{366} times it. In practice, we do not need to perform calculations on days on which no deaths occurred because on those days $P = 1$ and the estimate of S will be unchanged. Very often in survival analysis, we report ► median survival time. Median survival time is the time at which 50% of cases are resolved.

Standard Errors of Survival Percentages The percentages in the Kaplan–Meier method are subject to sampling variation and if the number of patients is small, this variation can be appreciable. Furthermore, if a life-table method is used, the sampling variation becomes progressively larger as the survival percentages at later times are based on fewer and fewer patients. Knowledge of the sampling variation is important, since it is a measure of the range of survival percentages that are likely to be encountered if the study could be repeated under identical circumstances with different groups of patients.
For a survival percentage, S_t, calculated using the Kaplan–Meier method, the standard error (SE) is the square root of the variance, which is found from the expression:

$$SE_{(S_t)} = \sqrt{\sum \frac{d_i}{r_i(r_i - d_i)}} \quad \text{where}$$

d_i = number of deaths on day i
r_i = number at risk on day i.
We have seen that the percentage of survivors is recalculated at each death time so that when plotted on the ► Kaplan–Meier survival plot, the curve takes on a characteristic appearance of horizontal and vertical lines.

The Logrank Test

This involves counting the number of deaths observed in each group, O, and comparing it with E, the extent of exposure to risk of death in that group. The general definition is that the extent of exposure to risk of death among a subgroup of patients on a particular day is the total number of deaths on that day in the whole study population, multiplied by the proportion of patients at risk on the particular day that are in the subgroup of interest. The ► logrank test comparing treatment A with treatment B during a certain period involves:

1. Counting the total number of group A deaths observed during that period, calling this O_A;
2. Counting the total number of group B deaths observed during that period, calling this O_B;
3. Calculating the extents of exposure of the A patients to risk during each day of the period, adding them all up to get the total extent of exposure to risk of death suffered by the A patients during this period, calling this E_A;
4. Deriving similarly the total extent of exposure to risk of death suffered by the B patients during this period, calling this E_B;
5. Comparing O_A with E_A and O_B with E_B, to see if there are any marked discrepancies.

This method can be instantly generalized for the comparison of several groups of patients with each other: for each group, the extent of exposure to risk of death on a particular day is still the proportion who are in that group on that day multiplied by the number of deaths on that day. The total exposure in one group over an extended period is the sum of the separate exposures in that group on the separate days comprising the period. In any one period, the sum of all the Os will equal the

sum of all the Es. For example, if we were comparing four groups, A, B, C, and D, $O_A + O_B + O_C + O_D$ should equal $E_A + E_B + E_C + E_D$ at the end of the analysis.

Logrank significance levels or p-values may be estimated by comparing the sum of $\frac{(O-E)^2}{E}$ with an appropriate chi square distribution. We can calculate $\frac{(O-E)^2}{E}$ for each group and add up the results, one term from each group. The sum of all the $\frac{(O-E)^2}{E}$ calculations is termed $\chi 2$. If the symbol k denotes the number of groups being compared with each other, this has $\chi 2$ distribution with $df = k - 1$.

Cox Proportional Hazards Regression

The ► cox proportional hazards regression model is used to analyze survival or failure time data. The technique may also be used when survival is influenced by a large number of factors, some of which may be correlated, and the aim is to identify those features of the patient or the disease that are of independent prognostic significance. This model is a regression method for survival data and provides an estimate of the hazard ratio and its confidence interval. The ► hazard ratio is an estimate of the ratio of the hazard rate in the treated versus the control group or between two different treated groups. In a clinical trial where disease resolution is the endpoint, the hazard ratio indicates the relative likelihood of disease resolution in treated versus control subjects at any given point in time.

The Cox proportional hazards model is an appealing analytic method. The hazard ratio, which is derived from this model, provides a statistical test of treatment efficacy and an estimate of relative risk of ► events of interest to clinicians. The hazard ratio may be used for purposes of statistical hypothesis testing and as one indication of the amount of benefit (an increase in the odds of healing), but other measures must also be applied to understand the full importance of the study.

Example

Consider a randomized trial of two treatments A and B, where the outcome is survival time from treatment.

Survival Analysis, Table 1 Illustration of calculations for logrank test and Kaplan–Meier survival curve in a clinical trial of 16 patients (Campbell MJ, Machin D (ed) (1999) Medical Statistics: A Commonsense Approach. John Wiley&Sons Ltd, New York)

i	Order survival time t_i	Treatment	Total number at risk n_i	Number of events at time $t_i - d_i$	Probability of survival in t_{i-1}, t_i $\frac{1-d_i}{n_i}$	Cumulative survival probability	Number at risk in A n_{Ai}	Expected number of events in A e_{Ai}
0	0	-	16	0	1	1	8	0
1	21	A	16	1	0.94	0.94	8	0.5
2	33+	A	15	0	1	0.94	7	0
3	42	B	14	1	0.93	0.87	6	0.43
4	55	A	13	1	0.92	0.8	6	0.46
5	69	A	12	1	0.92	0.74	5	0.42
6	100+	B	11	0	1	0.74	4	0
7	130	A	10	2	0.8	0.59	4	0.8
8	130	A						
9	210	B	8	1	0.875	0.52	2	0.25
10	250+	B	7	0	1	0.52		See not 9 in text
11	290+	A	6	0	1	0.52		
12	310+	A	5	0	1	0.52		
13	365+	B	4	0	1	0.52		
14	365+	B						
15	365+	B						
16	365+	B						

+ = alive

Some patients will be lost to follow-up, or will only have been observed for short periods of time and so their observations are censored.

Kaplan–Meier Survival

Order the survival times for both groups combined. Censored observations usually follow death times of the same value.

1. The number at risk (n_i) is the number of patients alive immediately before an event at time t_i.
2. An event is death. A censored observation has no associated event.
3. Calculate the probability of survival from t_{i-1} to t_i as $\frac{1-d_i}{n_i}$.
4. Calculate the cumulative survival probability of surviving from 0 up to t_i as follows:

$$\left(\frac{1-d_i}{n_i}\right) \times \left(\frac{1-d_{i-1}}{n_{i-1}}\right) \times \ldots \times \left(\frac{1-d_1}{n_1}\right).$$

5. Note that a censored observation at time t_i reduces the number at risk by one but does not change the cumulative survival probability at time t_i.

The Logrank Test

6. Under the null hypothesis, the expected number of events at time t_i is

$$e_{Ai} = \frac{(d_{Ai} n_{Ai})}{n_i}.$$

7. The expected number of events should not be calculated beyond the last event (at time 210 days in this example).
8. The total number of events expected for treatment A, assuming the null hypothesis of no difference between treatments, is $E_A = \Sigma e_{Ai}$.
9. The number expected for treatment B is $E_B = \Sigma d_i - E_A$.
10. Calculate $X^2 = \frac{(O_A - E_A)^2}{E_A} + = \frac{(O_B - E_B)^2}{E_B}$.

This has χ^2 distribution with $df = 1$. This gives $p = 0.1$.

SUSAR

Definition

Abbreviation for suspected unexpected serious adverse reaction, in the US: SADR = suspected adverse drug reaction. An Adverse reaction is considered as unexpected if the nature, seriousness, severity or outcome of the reaction(s) is not consistent with the reference information for the investigational medical product (IMP). For "non-authorized" drugs or devices the reference document is the investigators brochure (IB), in all other cases the summary of product characteristics (SPC).

All suspected adverse reactions that occur within the concerned trial and are related to an investigational medicinal product (the tested investigational medicinal products *and* comparators) which occur in the concerned trial, and that are both unexpected and serious

("SUSAR") are subject to expedited reporting to the competent authorities. If such a reaction is included into the IB or SPC it becomes part of the body of knowledge and is thereby no longer unexpected and needs thereby no longer expedited reporting.

Susceptibility

Definition

Susceptibility is the degree of response or sensitivity to a given disease like microbial disease or malignancy. It is tested in various ways. One classical example of a susceptibility testing is the mixing of a minimal amount of a drug with micro-organisms to see if inhibition of growth or death of the micro-organisms occurs. It is tested genetically by making use of biomarkers that can identify predisposition to risk factors. Susceptibility markers may be genetic traits, pre-existing diseases, differences in metabolism, variation in immunoglobulin levels, etc.

Generally, susceptibility is described in a variety of fields including:

- ► Occupational and Environmental Health
- Pharmacology
- Medical diagnostics and Therapy
- ► Radiation biology
- Toxicology and ► epidemiology.

Cross-References

► Individual Susceptibility
► Vulnerability Concerns

Suspended Particles

Synonyms

Airborne particles ; Particulate matter (PM); Suspended particulate matter (SPM)

Definition

Suspended particles are any small bits of solid material or liquid that can become airborne. If they are of sufficiently small diameter to maintain stability in air or any other gas then they form an aerosol (particulate phase of aerosol). Solid particles are either nonviable, such as dust, fumes and smoke, or viable, such as microorganisms; liquid particles are mist and fog. Airborne suspended particles can range from less than 0.005 µm (e. g. small molecules) to 100 µm in diameter. Larger and even visible dust particles in the range up to 1000 µm tend to deposit very quickly. Respirable particles are those in the range of 0.005–10 µm but only those in the range of 0.1–10 µm are of larger interest because inhaled particles less than 0.1 µm can be easily exhaled. Sampling techniques and suitable devices that allow separation of airborne particles such as fine respirable particles less than 2.5 µm ($PM_{2.5}$) and large respirable particles less than 10 µm (PM_{10}) have now been introduced. Fine particles are emitted during various burning processes (motor vehicles and industry), while large particles are emitted particularly in mining, the construction industry, and during fires and windstorms. Having a small diameter and larger total surface relative to weight, fine particles are very harmful; they can penetrate lungs much deeper and can exist in air for weeks and even months. Suspended particles are among the most harmful air pollutants and health consequences of their inhalation include bronchitis, asthma, chronic obstructive pulmonary disease, and decreased lung functions. Some particles are even carcinogenic (e. g. asbestos, tobacco smoke, and silica crystalline, etc.). Finally, dangerous chemical substances, either gases or liquids, are often adsorbed on the surface of particles – e. g. some of polycyclic aromatic hydrocarbons (benzo[a]pyren) or sulfur-dioxide; these increase the harmful effects. Children are the most at risk in the general population because they inhale air deeper into their lungs than adults do, they spend more time outside, and they are more physically active (during activity breathing is deep and frequent).

Suspended Particulate Matter (SPM)

Synonyms

Sustainable development

Definition

Sustainable development is defined in the WHO Health Promotion Glossary as follows: as the development that meets the needs of the present without compromising the ability of future generations to meet their own needs.

Basic Characteristics

Sustainable development contains within it two key concepts: the concept of "needs", in particular the essential needs of the world's poor, to which overriding priority should be given; and the idea of limitations imposed by the state of technology and social organization on the environment's ability to meet present and the future needs (Brundtland Commission, 1987). Sustainable development does not focus solely on environmental issues. More broadly, sustainable development policies encompass three general policy areas: economic, environmental and social. It incorporates many elements, and all sectors, including the health sector, which must contribute to its achievement.

The term sustainability is derived from the field of forestry and was first mentioned by ► Hans Carl von Carlowitz in the context of Sustained Yield Forestry. During the 1980s the idea of sustainability was fundamentally embraced by the ecological movement at a time when environmental pollution had become an issue of increasing importance. The term was also introduced into political debate by the ► Brundtland-Commission in 1987. This commission stated that the term sustainable development should not be restricted to the field of forestry, as Carlowitz mentioned, but should be a matter of general concern for the whole of society. The concept of sustainability contains the following three aspects:

- Ecological sustainability
- Economic sustainability
- Social sustainability.

The concept of ecological sustainability has appeared frequently in official documents over the last 15 years, e. g. in the Convention on the Climate and the Kyoto Protocol. Sustainability opposes the wasting and short term plundering of resources, and promotes the respectful and responsible treatment of human resources with consideration given to future developments and generations.

Occasionally, ecological and economic sustainability may be at odds. For instance, a further population growth is counterproductive since it would increase the usage of resources and be detrimental to ecological sustainability. Whereas, from the economic point of view, a further population growth is desired in order to counteract the demographic imbalance brought about by an aging population. Thus the concept of sustainability has become a discussion theme of enormous importance to many scientific disciplines.

The term sustainability, over time, has acquired positive connotations and is frequently used as a synonym for eco friendly or spoken of in terms of success or innovation.

In the context of health promotion (► health promotion, actors; ► health promotion, fields of action; ► health promotion, models; ► evaluation, models) and disease prevention, the sustaining of health is linked to the development of a healthy environment and support for individual health-conscious decisions. The current health program of WHO, "Health 21," is supported by the program of sustainable development set out in ► Agenda 21.

The promotion of healthy lifestyles is closely related to environmental issues, and environmental issues, as laid out in Agenda 21, are closely linked to the concept of sustainability. However, a definition of sustainability has not been specified in any health promotion literature to date (Lawrence 2004). More evaluation is needed to assess the sustainability of health promotion projects with regard to their long term effects; health promotion intervention can be classified as sustainable if its aims are achieved by the end of a given project and if the processes developed in the intervention continue to have lasting effects. At best, each health promotion project should have sustainable effects, not only effects during the project's course.

Therefore, implementation of sustainability in health promotion interventions depicts also a part of ► quality assurance and evaluation (► evaluation, models) in projects. Sustainability of projects can be achieved through their ability to stimulate replication of successful health promotion projects. The use of the media can enhance the public's awareness of these projects and stimulate the social acceptance of health promot-

ing ideas. This leads to a continuation of the process of a health promotion intervention.

When planning a health promotion project, various essential factors, necessary for the implementation and sustainability of the project, have to be considered. This kind of sustainability can be assured through implementing the following structure and elements:

- Dissemination of the techniques of health promotion (empowerment, measures of equal opportunities, organizational development, management of projects).
- Development of networks, e, g. help desks and consistent patient counseling services (consumer protection and self help organizations, public health service institutions, coordination centers, various associations, societies and trusts).
- Services for special ► target groups (employees, families, day release for organizational development in companies) and establishment of educational seminars using new Medias.

The success of health promotion projects that have the above structures and elements established can be measured by comparing them with projects that do not have such structures and elements.

Sustainable Development

Synonyms

Environmental substainability

Definition

Development where the present generation fulfils its need without compromising the ability of future generations to meet their needs.

Sustainable development is a strategy to meet the needs of the present world population without causing adverse effects on health and on the environment, and without depleting or endangering the global resource base, hence without compromising the ability of future generations to meet their needs, as was defined at the Rio Summit. It is a concept proposed in opposition to the accelerating deterioration of the human environment and natural resources and the consequences of that deterioration for economic and social development. It is meant as a degree of development that meets the needs of the present without compromising the ability of future generations to meet their own needs. Four aspects are considered: environmental sustainability, economic sustainability, social sustainability and political sustainability. Sustainable development represents both a goal and a process. As a goal, sustainable development implies development which equitably meets the needs of today's and future generations. As a process, it means setting policies in such a way that they take into account not only economic factors but environmental and social factors as well.

Sustainable development describes the process of modification of the environment that remains ecologically in balance, so sufficient resources can be used without degrading the environment or irreversibility damaging the ecosystem, which remains intact and can continue indefinitely.

Cross-References

► Sustainability

Sweat House

► Sweat Lodge

Sweat Lodge

Synonyms

Sweat house

Definition

Any of various permanent or portable structures typically heated by fire or by pouring water over hot stones and used by certain Native American peoples to induce sweating, as for medicinal, spiritual, or social purposes.

Swimmer's Itch

► Cercarial Dermatitis

Symptomatic Cancer Palliation

► Cancer Palliative Care

Symptomatic Therapy

Synonyms

Treatment of the symptoms of a disease

Cross-References

► Therapy of Infectious Diseases

Symptom Relief in Palliative Medicine

Synonyms

Improvement by symptomatic therapy

Definition

Symptomatic treatment is defined as a medical therapy that only affects symptoms. It does not influence the cause or etiology of a disease. It is usually directed at reducing signs and symptoms in order to improve the quality of life of the individual patient. Typical symptomatic treatments are: a) Analgesics, for pain; b) Anti-inflammatory agents, for arthritis; c) Antitussives, for cough; d) Antihistamines, for allergy; e) Brain shunts, to alleviate hydrocephalus; f) Laxatives, for obstipation, etc. Symptomatic treatment itself may cause adverse effects, and may not be devoid of iatrogenic consequences such as allergic reactions, gastrointestinal bleeding, central nervous effects (nausea, dizziness, headache, etc.).

Synergism

Definition

Synergism is a situation in which the combined effect of two or more factors is greater than the sum of their solitary effects. It would be assumed that any joint effect that is more than additive as synergistic.
Antagonism, the opposite of synergism, occurs if there are persons who will get the disease when exposed to one of the factors alone, but not when exposed to both. Under these definitions two factors may act synergistically in some persons and antagonistically in others.

Syntactic Aspect of Data/Information

Definition

The syntactic aspect refers to the format of the carrier of information – its language, type of image, or biosignal. This format or structure is known as the syntax for the description, storage, or transmission of messages.

Syntactic Errors

Definition

A syntactic error is a type of ► data error referring to the format in which data is stored.

Syphilis

Synonyms

Venereal disease

Definition

Syphilis is a chronic sexually transmitted disease caused by *Treponema pallidum*. Primary lesion devel-

ops on the genitals or anus. Several weeks later generalized infection occurs, with fever and rash. Afterwards the infection may be dormant for years. Nodules form in skin and mucous membranes and cause ulcers. Both cardiovascular and nervous system become affected. If untreated it may be fatal. It is more common in undeveloped countries with poor sanitation and hygienic habits.

Systematic Literature Review

Definition

A systematic review is a literature review focused on a single question, and which tries to identify, appraise, select, and synthesize all high quality research evidence relevant to that question. These reviews help overcome the problems associated with large numbers of published research studies and variations in quality between studies. Unlike the traditional approach to reviewing literature, they utilize the same principles and rigor that is expected of primary research. As the name suggests, they are systematic in their approach and use methods that are pre-planned and documented in a systematic review protocol.

Systematic Reviews

Biljana Miličič
School of Dentistry, University of Belgrade, Belgrade, Serbia

Synonyms

Research review; Integrative research review; Research synthesis

Definition

Systematic reviews locate, appraise, and synthesize evidence from scientific studies in order to provide informative, empirical answers to scientific research questions.

Basic Characteristics

The Problem Formulation Stage

All empirical work must begin with careful consideration of the research problem. Systematic reviews are a scientific tool that can be used to summarize, appraise, and communicate the results and implications of otherwise unmanageable quantities of research. The choice of topics in research synthesis is influenced by the interest of researchers and social conditions that surround them. The research synthesist should undertake literature searches with the broadest possible conceptual definition in mind. They should begin with a few central operations but remain open to the possibility that other relevant operations will be discovered in the literature. More often than not, the cumulative results of studies are much more complex than the results of any single study. The synthesist's capacity for uncovering variables that explain why results differ in different studies and ability to generate notions that explain these higher-order relations are the most creative and challenging aspects of the research synthesis process. Both primary researchers and research synthesists must choose a conceptual definition and degree of breadth for their problem variables. Both must decide how likely it is that an event represents an instance of the variable of the interest. To complement conceptual broadness, synthesists should be thorough in their attention to the distinctions in study characteristics. Any suggestion that a difference in study results is associated with a distinction in study characteristics should receive some testing by synthesist, if only in preliminary analysis.

The next step is to construct a ► coding sheet. The coding sheet is used to collect information from the primary research. Information that should be included on the coding sheet is:

1. Report identification: This includes the authors of the report, the source of the report, when the report was published, and what information channel led to the report's discovery.
2. Setting of study: The place where the study was conducted. It should be noted whether the setting

and participants of the primary studies would reduce generalizability.

3. Subjects: Characteristics of the participants included in the primary research. Any restrictions placed by the primary researchers on who could participate in the study should be identified.
4. Methodology : In this part, the synthesist retrieves information concerning study design used in the primary research.
5. Treatment characteristics: The synthesist will need to describe carefully the details of how the independent variables were manipulated or measured. Equally important are characteristics of how control or comparison groups were treated. Differences in any of these variables among studies would be prime candidates for being the causes of differences in study outcomes.
6. Statistical outcomes or effect sizes: The synthesist retrieves the relevant outcomes, which should be measured to determine ► effectiveness. This may include factors such as characteristics of the patients and settings, choice of measurement of outcomes, or difference in the nature or delivery of interventions, all of which influence the estimates of effectiveness of the intervention under investigation. It is important that these ► "effect modifiers" are identified as they may explain apparent differences in the findings of the primary studies. Another series of possible "effect modifiers" relate to study design. The existence of differences between studies in these factors will have implications in the analysis of the results. If quantitative synthesis or meta-analysis of results is envisioned, the synthesist will also need to record more precise information on the statistical outcomes of studies.
7. Coding process: The coding sheet will be standardized to accommodate information about the main comparisons of interest. A general coding sheet will never capture the unique aspects of all studies; perfection is never achieved. The synthesist can view these occurrences as failures or as targets of opportunity, highlighting the diversity of research in their topics.

The Literature Search Stage

Literature search is a vital component of any systematic review. The aim of the search is to provide as comprehensive a list as possible of primary studies, both published and unpublished, which may fit the inclusion criteria and hence be suitable for inclusion in the review. As the precision of the estimate of ► effectiveness depends on the volume of information obtained, it is important that the search for primary studies is extensive. We can group search channels under the following headings:

► Informal Channels These channels of communication are distinguished by a lack of explicit rules governing the contact between the primary researcher and the literature searcher, without restrictions on the kinds of information that can be exchanged. The five principal forms of informal communications are personal contacts, solicitation letters, traditional invisible colleges, electronic invisible colleges, and the World Wide Web.

► Formal Channels These channels of communication have explicit rules that primary researchers must follow to enter information into channels. The major formal channels are:

1. Professional conference paper presentations. The selection criteria for meeting presentations is usually not as strict as that required for journal publication. An advantage of papers given at meetings is that they are more likely to be current than journal articles because the researcher may present a paper before a publishable manuscript has been written.
2. Personal journal libraries. Journals published in paper form are the traditional link between the primary researcher and the research synthesist. There would be some serious ► bias in a search based on personal libraries as the only or major source of research. Given that personal libraries are likely to include journals in the same network, it would not be surprising to find some bias associated with network membership. The appeal of using a personal journal library as a source of information lies in its accessibility. The existence of ► bias against non-significant results and confirmatory bias mean that peer-reviewed journal articles should not be used as the sole source of information for a research synthesist, unless the synthesist can convincingly argue that these biases do not exist in the specific topic area.
3. Electronic journals (e-journals). Two characteristics of e-journals are a source of bias. First, many electronic journals do not use peer-review proce-

dures. The synthesist must therefore assess both the methodological rigor of studies in the e-journal and the likelihood of publication bias. Second, e-journals have much shorter publication lags.

4. Research report reference lists. This route involves synthesists examining the research reports they have already acquired to see if they contain references to studies still unknown. It should not be used as a sole means of finding studies but they are generally a productive source of relevant research.

► Secondary Channels Secondary channels provide information about primary research documents and some even contain the documents. The major secondary channels are bibliographies, research registers, and reference databases, including citation indexes.

Recall of a database search depends on the search strategy that was used. Searches with high recall may have low precision, but the same conclusion may be reached with sources of information that are not identical. Synthesists should be explicit about how studies were gathered, including information on the reference database searched, for what years, and with what search terms. The synthesist should also present indices of potential retrieval bias if they are available. They should summarize the same characteristics of individuals used in separate studies.

The Data Evaluation Stage

Data evaluation requires the investigator to establish criteria for judging the adequacy of the procedures used to gather the data. The researcher must examine all the potential errors or irrelevancies that might have influenced each data point and then determine whether these influences are substantial and whether the data should be dropped from the inquiry.

Approaches to Categorizing Research Methods The synthesist must decide what methodological characteristics of studies need to be coded. This decision will depend on the nature of the question under scrutiny and the types of associated research. In the past, research synthesists have employed two approaches to coding to help them capture differences between good and bad studies.

1. The threats-to-validity approach requires the synthesist to make judgments about threats to validity (► validity, study) that exist in the study. There are two broad classes of validity threats in this approach; threats to internal validity related to the direct correspondence between the experimental treatment and the experimental effects and threats to external validity related to the generalizability of research results. Later, the notions of construct validity and statistical conclusion validity were added to this approach.
2. The methods-description approach to study evaluation requires the synthesist to code exhaustively the objective characteristics of each study's methods as they are described in the primary research.
3. The mixed-criteria approach is the optimal strategy for categorizing studies and appears to be a mix of two a posteriori approaches. It does not remove all problems from study evaluation, it is another step toward explicit, objective decision making in an area previously rife with subjective and arbitrary judgments.

Problems in Data Retrieval There are three problems:

1. Problems in library retrieval involve the inability of libraries to ensure that all documents of potential relevance are available to the synthesist.
2. Incomplete and erroneous research reports involve the incomplete or careless reporting of data by primary researchers. Reports can be missing information on *statistical outcomes*, preventing the meta-analyst from estimating the magnitude of the difference between two groups, the relationship between two groups, or the relationship between two variables. Primary research can be missing information on *study characteristics*, preventing the meta-analyst from determining if study outcomes were related to how the study was conducted.
3. Unreliability in coding study results involves the less-than-perfect information processing skills of the people who retrieve information from studies.

Identifying Independent Comparisons Important decisions must be made during the data evaluation stage involving how to identify independent comparisons or estimates of relationship strength. A single study may contain multiple tests of the same comparison or relation because more than one measure of the same construct might be employed and each measure analyzed separately or because different samples of people might

be used in the same study and their data analyzed separately. Several alternatives can be suggested regarding the proper ► unit of analysis in research syntheses: laboratories, studies, samples, comparisons, shifting unit of analysis, and statistical adjustment.

The Data Analysis Stage

In this stage, the researcher orders, categorizes, and summarizes data. These aims can be achieved through a narrative overview, sometimes complemented by the use of formal statistics techniques.

Qualitative Overview A broad ► qualitative overview is necessary to assess the overall evidence and the influence of various factors on the likely ► effectiveness. Key elements of the qualitative approach for assessing effectiveness include consideration of the following characteristics: people who were part of the study, intervention delivered, setting where the technology was applied, and other modifying factors such as personal skills, environmental factors that may influence compliance, and nature of the outcome measures used, their relative importance and robustness, and their comparability. The total number of research reports, studies, and independent samples that contributed to the tests of comparison or relationships (descriptive statistics) should be detailed. Effect size estimates should be calculated if these studies contained the necessary data but the effect sizes should not be combined statistically. The synthesist should give the total number of effect sizes that were positive and statistically significant, positive but non-significant, negative and significant, and negative but non-significant.

A narrative synthesis is unlikely to report an estimate of the average effect of the treatment but, in some circumstances, it may be able to conclude quite reliably whether or not the treatment appears to be beneficial or harmful and indicate the possible range of effect size.

Very often synthesists have faced problems when considering the variation between the results of different studies. Synthesists may find distributions of results for studies sharing particular procedural characteristics but varying on many other characteristics. Due to this, synthesists have to use quantitative synthesizing techniques in many circumstances.

The Interpretation and Presentation Stage

Systematic research reports are divided into four basic sections: introduction, methods, results, and discussion; this division highlights the types of information that need to be presented in order for readers to evaluate adequately the validity and utility of the synthesis.

The *introduction section* must contextualize the problem under consideration. It should include a general description of any prior synthesis, the controversies these syntheses have created or left unresolved, and which of these will be the focus of the new synthesis effort.

The *Methods section* involves details of the literature search, such as criteria for including studies, methods used in primary research, determination of independent findings, details of study coding, statistical procedures, and conventions.

The *results section* involves results or a qualitative overview including ► descriptive statistics, vote counts, and combined significance levels. Overall effect size should be included and should begin with a description of the range, average, and median effect size and a 95% confidence interval around the estimate of central tendency. The results of the overall test for homogeneity of the entire set of related effects should also be presented here. Analyses of influences on effect size should describe the results of analyses meant to uncover study characteristics that moderated the size of the effect. The synthesist should devote a subsection to interaction effects found in single studies.

The *discussion section* should contain at least five components. First, the synthesist should present a summary of the major results of the synthesis. Second, they should describe the magnitude of the important effect sizes found in the synthesis and interpret their substantive meaning. Third, the synthesist should examine the results in relation to the predictions and other prior assertions made about relationships. Fourth, an assessment of the generality of any findings should be included, especially with regard to limiting conditions. Fifth, new questions raised by the outcomes of the synthesis and old questions left unresolved because of ambiguous synthesis results or a lack of prior primary research should be discussed.

Example In our research synthesis (assembly of primary studies and synthesis of information from them for a doctoral dissertation), we want to evaluate the efficacy of selective decontamination of the digestive tract (SDD) as a prophylactic method against nosocomial infections. SDD has become both the most criticized

and, paradoxically, the best-evaluated intervention in intensive care medicine. Controversies center upon four issues: the effect of SDD on infection morbidity; the impact on mortality; the emergence of resistant bacteria; and cost-effectiveness. We searched the MEDLINE database for the years 1992 to 2005 using the following key words: selective decontamination of the digestive tract and intensive care units. We also reviewed the reference lists of all available review articles and primary studies to identify references in the computerized searches. We used the following criteria to select studies for inclusion: population included adults in an ICU; intervention (SDD) defined as use of oropharyngeal and/or nasogastric nonabsorbable antibiotics, with or without systematic antibiotics; outcomes-mortality; nosocomial infections; length of mechanical ventilation and ICU stay; resistance; and costs. The methodological quality of the primary studies was evaluated using a scoring system as a product mix criteria approach. A total of 5964 patients was included in the 25 randomized trials. Descriptive statistics and combined significance levels were used to determine the effect of treatment on mortality or the appearance or disappearance of disease, as well as overall relative risk.

We found that SDD reduces the total number of nosocomial infections, pneumonia rates, bacteremia, tracheobronchitis, urinary infection, and intrabdominal infection. Mortality was significantly reduced with the use of SDD. The length of mechanical ventilation and ICU stay were not different in the group of patients treated with SDD versus the group of patients not treated with SDD. There was no difference in emergence of resistance between the two groups. In our meta-analysis, no difference in cost between the SDD-treated and control groups was identified. These data suggest that the use of SDD should be limited to those populations in whom infection contributes notably to adverse outcome. Additional studies are required to further define appropriate indications and limitations of this preventive strategy.

Target Group

ANDREAS FUCHS
Forschungsverbund Public Health Sachsen-Sachsen Anhalt e. V., Medizinische Fakultät, Technische Universität, Dresden, Germany
andreas.fuchs@mailbox.tu-dresden.de

Definition

In the field of health promotion and disease prevention, a target group is a group of individuals with identical characteristics who are the objective of a health promotion or diseases prevention intervention.

Basic Characteristics

The term target group is borrowed from communication science and advertising and describes a group of individuals who are the objective of advertising and marketing measures. In addition, a target group shares designated characteristics or properties. Target groups are important elements of all ► health education and information measures in health promotion and disease prevention. A clear and well thought-out definition of the group which is the objective of an intervention is an important condition for formulating realistic objectives for reaching these objectives as well as for reaching the group itself. Strategies and measures have to correspond to the ► lifestyles of target groups if lasting individual or structural changes are to be achieved. If interventions are planned for a particular setting it is best to consult the stakeholders in that ► setting (Health Promotion Switzerland).

Target group orientated work is regarded as standard in health promotion activities and ensures ► sustainability of an intervention for changing ► health risk associated lifestyles and ► health determinants. A lack of target orientation is associated with an undifferentiated and inefficient appeal to all and sundry.

In order to evaluate the attainability of target groups, projects have to be structured to fit the characteristics of the participants, recipients and their social culture. The following criteria may be acquired:

- Social demographic determinants: income, education, marital status, residence, native language, etc.
- Characteristic lifestyle and habits.
- Number of people in the target group.
- Social attributes (social situation, lifestyle).
- Values and attitudes.
- Compliance (willingness to cooperate adherence into the brackets) and
- ► Motivation
- Definition and selection rules for delimiting target groups (FCHE 1999).

The following are examples of typical target groups:

- Health education campaign about the risks and hazards of smoking (target group: smokers).

Target Group, Table 1 Summary of certain characteristics of target groups

Characteristic of the target group	Examples
Sex	male, female
Age	children, adolescents, pensioner
Marital status	single, married, widowed
Lifestyle	degree of health conscious
Educational background	secondary modern school, primary school, A-level, master degree
Vocational training	employee, worker
Residence	rural vs. urban region
Health risks	alcohol consumption, non physical activity habits, smoking

- Health education campaign about sexually transmitted diseases (target group: adolescents with health risk related sexual behavior).
- Health promotion and disease prevention interventions in migrant population (target group: migrants).

The number of different characteristics possible show that a detailed definition should consider more than one social demographic determinant. A detailed description of the target group helps to make concrete the objectives of the health promotion activity and reduce the number of people who need to be targeted by the intervention. In planning a health promotion intervention, whether aimed at specific individuals or the general population, it is necessary that the defined target group has the correct balance of complexity and commonality. For this reason, it is helpful that representatives of the target group are involved in the planning phase as their interests, needs and wishes can be taken into consideration and inserted into the structure of the intervention; questionnaires and other research methods can be utilized to this end. In order to increase the efficiency of an intervention, widespread involvement is of considerable importance in reaching a definition of an appropriate target group.

The efficacy and efficiency of an intervention in the field of health promotion and disease prevention in a given population depends on the comprehensive and exact definition of the chosen representative target group. It is, therefore, important to avoid using only one ► risk factor as a defining factor of a target group since this will only reflect an incomplete picture of the target population and defeat the purpose of a general approach to health education (Lehmann, Sabo 2003).

► Evaluation and ► quality assurance of health promotion and disease prevention interventions will always look at the way target groups have been determined. The definition of target groups is one of the most important factors in health promotion that determine whether the planned measures will or will not reach the intended target population (Ovretveit 1998).

Target Population

Definition

Target population is the collection of individuals, items, measurements, etc., about which inferences are desired. The term is sometimes used to indicate the population from which a sample is drawn and sometimes to denote any "reference" population about which inferences are required.

Tariff Autonomy

Synonyms

Collective bargaining autonomy

Definition

Tariff autonomy denotes the right and freedom of employers and employees to build unions for safeguarding their respective interests, collective bargaining of wages and collective agreements (tariff agreements) and to create a body of autonomous collective bargaining law.

Taxonomy of Data/Variables

► Level of Measurement

TB

► Tuberculosis and Other Mycobacterioses

Tbc

► Morbus Koch (Koch's Disease)

TBE Immune Globulin

► TBE (Tick-borne Encephalitis)-Vaccination, Passive

TBE Immune Prophylaxis

► TBE (Tick-borne Encephalitis)-Vaccination, Passive

TBE Immunization, Active

Synonyms

TBE immunization, active; CEE vaccination, active; CEE immunization, active

Cross-References

► Immunization, Active

TBE (Tick-borne Encephalitis)-Vaccination, Passive

Synonyms

Application of TBE immune globulin; TBE immune prophylaxis

Definition

The administration of TBE-immune globulin as pre-exposure prophylaxis can be carried out directly before traveling into an endemic area. The protective effects start immediately and last for four weeks. As a post exposure prophylaxis passive TBE-vaccination is seldom performed.

Technological Risk

► Hazards, Technological

Technology Assessment

Definition

Health care technology assessment is a multidisciplinary field of ► policy analysis. It studies the medical, social, ethical, and economic implications of the development, diffusion, and use of technologies. In general, technology assessment is based on the conviction that new developments within, and discoveries by, the scientific community are relevant for the world at large rather than just for the scientific experts themselves, and that technological progress can never be free of ethical implications.

Telecare

Definition

Telecare describes health care at a distance. Telecare is a branch of ► telemedicine where the patient is located in the community (for example, their own home).

Telecommunication

Definition

Telecommunication is the process of exchange of information between users (human or automated) using electronic media.

Telecommunication Systems

► Telemedicine

Teleconsultation

Synonyms

Teleconsulting

Definition

Teleconsultation literally means consultation at a distance. It refers to clinical consultations carried out using a telemedical service.

Teleconsulting

► Teleconsultation

Telehealth

Definition

Telehealth is the process of integration of ► telecommunication systems into the practice of protecting and promoting health. The meaning and use of telehealth is more complex than ► telemedicine. Unlike telemedicine, where telecommunications are used for clinical purposes only, telehealth applies telecommunication technologies and electronic information to support long-distance clinical health care, patient and professional health-related education, or public health and health administration.

Telematics Platform

Definition

The term 'telematics platform' describes the participation of all stakeholders and users in health care: patients, health professionals, providers of health services (primary health care centers, hospitals, pharmacies, laboratories, and emergency units), professional organizations (nurses or physicians unions, etc), insurance companies, social services, the ministry of health, and the media. The role of this platform is to provide communication and support between all health users in order to ensure quality of health data.

Telemedicine

Synonyms

Telepreventive medicine; Telecommunication systems

Definition

Telemedicine describes the use of telecommunications technology, such as audio and video, for different kinds of health care services. It includes medical consultation, diagnosis, therapeutic services and treatment when the provider and patient are separated by distance. Telemedicine is also used to deliver medical information for education purposes, follow-up services and remote monitoring of patients. The advantages of telemedicine are improved provision of health care services, especially in isolated locations, and easier access for people with ► chronic diseases needing ► continuity of care.

Telemedicine literally means delivery of medicine at a distance. It refers to the delivery of health care services between geographically separated individuals, using ► telecommunication systems e. g. wire, radio, optical, or electromagnetic channels, transmitting voice, data and video. Telemedicine can be simultaneous (for example, telephone or videoconference), or store and forward (for example, an email with an attached image). Telemedicine facilitates medical diagnosis, patient care, and distance learning. Some medical disciplines have already implemented telecommunication methods into delivery of their services: telepreventive medicine, teleepidemioliogy, teledermatology,

teleoncology, telepathology, telepsychiatry, teleradiology, telecardiosurgery, and teleophthalmology, etc.

Telepreventive Medicine

► Telemedicine

Telescopic Crown, Double Crown

Definition

An (secondary) artificial crown constructed to fit over a (primary) coping. The secondary coping is often integrated into a (partial) removable dental prosthesis in order to retain it.

Teleservices

Definition

The term teleservices refers to health services that are provided by the use of ► health telematics and ► telemedicine. These services include clinical observation of chronic patients in their homes – ► telecare or telemonitoring. Other services provided at a distance are ► teletherapy, ► teleconsultation, and telerescue, etc.

Teletherapy

Definition

Teletherapy is a branch of ► telemedicine that provides therapeutic services for patients in a home setting. Examples are language teachers for speech training of patients after strokes, and home trainers for cardiology patients.

Temperature Curve in Malaria

► Fever Attacks in Malaria

Teratoma

Definition

A teratoma is a benign tumour consisting of cells from the three embryonic germ layers. The malignant variant is the teratocarcinoma. If ESC are implanted into an organ without in vitro pre-commitment, there is a risk of teratoma or teratocarcinoma formation. In adults, teratomas arise spontaneously, and preferentially in the testis or ovaries. Morphologically, teratomas consist of cystic structures with predominance of epidermal cells.

Terminal Care

► Palliative Care

Terminal Disease Stadium

► End Stage Disease

Terrorism

Definition

The vicious attacks carried out by politically motivated terrorists groups to strike fear and cause distraction amongst the people with the sole intention of bringing about a political change.

Tertiary Care

Definition

Tertiary care comprises medical services provided in specialized hospitals or medical centers equipped with specific diagnostic or therapeutic facilities usually not available in general local hospitals. This includes, for example, centers for organ transplants, specialist cancer treatment, trauma, burn treatment, etc. Patients are referred from primary or ► secondary care settings to the tertiary care facilities for special investigation or treatment.

Tertiary Dental Care

Definition

Tertiary dental care services are provided by specialist hospitals, universities or regional centers equipped with diagnostic and treatment facilities which are not generally available in local hospitals. Here often dentists work together in a cross-disciplinary way with other medical specialist groups in multi-professional teams. Tertiary dental care includes trauma centers, burn treatment centers, oro-maxillo-facial surgery, organ transplants, radiation oncology, etc.

Tertiary Guidelines

Definition

A guideline is a statement or other indication of policy or procedure by which to determine a course of action. In medicine, tertiary healthcare is specialized consultative care, usually on referral from primary or secondary medical care personnel. It is provided by specialists working in a centre (i. e. a hospital) that has personnel and facilities for special investigation and treatment. Consequently, tertiary guidelines are guidelines for the healthcare professionals employed in tertiary care.

Test of Homogeneity, Chi-Square

Definition

A test of homogeneity compares the proportions of responses from two or more populations with regards to a dichotomous variable (e. g., male/female, yes/no) or variable with more than two outcome categories. The chi-square test of homogeneity is the nonparametric test used in a situation where the dependent variable is categorical. Data can be presented using a ► contingency table in which populations and categories of the variable are the row and column labels. The null hypothesis states that all populations are homogeneous regarding the proportions of categories of categorical variable. If the null hypothesis is rejected, it is concluded that the above proportions are different in the observed populations. The chi-square test of homogeneity statistic is computed in exactly the same manner as chi-square ► test of independence statistic. The difference between these two tests consists of stating the null hypothesis, the underlying logic, and the sampling procedures.

Test of Independence, Chi-Square

Definition

A test of independence evaluates the existence of association between two categorical variables (e. g., gender and smoking status). Data for these two variables are observed for each ► unit of analysis. Data can be presented using a ► contingency table in which the two categorical variables are the row and column labels. The null hypothesis states that the variables are independent (uncorrelated, unrelated); if the null hypothesis is rejected, it is concluded that there is an association between the variables (dependent or correlated variables). The chi-square test of independence statistic is computed in exactly the same manner as chi-square ► test of homogeneity statistic.

Several measures of association can be calculated for data in contingency tables, such as phi coefficient, contingency coefficient, and Cramer's V (see essay Analysis of frequencies). These measures are interpreted like the ► Pearson's correlation coefficient.

Test Statistic

Definition

The end result (final value) of conducting a statistical test. A test statistic is evaluated in reference to a sampling distribution, which is a theoretical probability distribution of all the possible values the test statistic can assume if an infinite number of studies were to be conducted employing a sample size equal to that used in the study being evaluated. The probabilities in a sampling distribution are based on the assumption that each of the samples is randomly drawn from the population it represents.

Tetanus

Synonyms

Tetanus Vaccination

Synonyms

Tetanus immunization

Definition

Tetanus vaccination, which was introduced in 1927, can be administered from three months of age. For active inoculation leading to basic immunization, 2 ► vaccines (or 3 in the case of concomitant pertussis vaccination) with inactivated toxins are necessary at intervals of at least four weeks, plus a further vaccination after 4–12 months. In general, the first booster is given at the age of 5–6 years. Further boosters should follow over the whole lifetime at intervals of 10 years. The vaccine can be administered alone (monovalent) or in combination with other vaccines, especially diphtheria toxoid. Tetanus vaccination leads to 99% disease protection. Vaccinations are also possible during pregnancy. Passive tetanus vaccination with tetanus immunoglobulins is implemented immediately following injury if medical history is not available or if immunization has either not taken place or is incomplete. In such cases, simultaneous immunization is implemented, meaning passive immunization together with active vaccination.

Tetanus Vaccination, Active

Synonyms

Tetanus immunization, active

Cross-References

► Immunization, Active

Tetanus-Vaccination, Passive

Synonyms

Application of tetanus immune globulin; Tetanus immune prophylaxis

Definition

In most cases, tetanus immune globulin is given simultaneously with active vaccination in acute injuries when the status of immunization is not known or when there is no completed basic immunization. For tetanus immune prophylaxis human tetanus immune globulin (HTIG) is used.

Therapeutic Cloning

Definition

In reproductive medicine, cloning refers to transferring the nucleus of an adult somatic cell to an unfertilized, non-nucleated oocyte. Under this condition, formerly silenced genes of the terminally differentiated somatic cell-DNA are re-activated. When the oocyte becomes diploid, it starts to proliferate thereby producing a clone of genetically identical cells. This artificial blastocyst is able to develop and give rise to an embryo. If implanted into an uterus, the embryo can develop into a fully differentiated organism. The first cloned mammal was the Scottish sheep Dolly, which did not grow old. Since DNA-containing mitochondria of the oocyte are not replaced by the donor's mitochondria, the resulting clone is genetically not completely identical to the donor.

Therapy of Infectious Diseases

Monika Korn
Klinik für Kinder- und Jugendmedizin,
Friedrich-Ebert-Krankenhaus GmbH,
Neumünster, Germany
hkorn80663@aol.com

Synonyms

Treatment of infectious diseases; Therapeutics for infectious diseases; Therapeutic measures for infectious diseases

Definition

The therapy of infectious diseases summarizes all measures, which are carried out to help the individual to overcome the disease. On the one hand, drugs can be given which eliminate or at least moderate the effects of the disease, on the other hand, general measures can be taken to support the healing process or prevent complications.

Basic Characteristics

Approaches of Therapy/Kinds of Therapy

The treatment of diseases can be differentiated into symptomatic and causal types of therapy. A symptomatic therapy is not directed against the cause of a disease but aims at its effects on the organism. A causal therapy combats the disease-causing agent itself. Which kind of treatment is used depends on several factors. To begin with, the strength of therapy should be correlated to the severity of the disease. The circumstances of the medical care system have to be considered – including the personnel situation and the

availability of therapeutics. The latter might be the limiting factors, particularly in the developing countries.

Symptomatic Therapy

The symptoms of pathogenic infection can vary; ► fever, interference with the ► body fluid balance or even the failure of organic functions. In the following these different factors are described in more detailed. Some infectious diseases are accompanied by ► itching, which can be moderated by antihistamines.

Fever

Very often, infectious diseases are accompanied by fever. A physical reduction of fever can be achieved by cooling. On the one hand, bathing in slightly warm water can cool the whole body; on the other hand, cooling can be applied locally. Compresses around the legs, a well-known household remedy, are only useful in warm extremities as temperature drop over the skin can only take place when the skin's blood vessels are widened. It is much more effective to cool more central parts of the body, like the chest, the area of the kidneys or the inguinal region. As the body proportions of a child are different from those of an adult, cooling of the head can be an effective measure particularly in young children. An elevated body temperature can be reduced by different drugs called analgesics-antipyretics (or ► non-steroidal anti-inflammatory drugs (NSAIDs)). As the name already makes clear, these drugs are not only used to reduce fever but are also effective against pain; they are widely used for this purpose.

Electrolyte and Fluid Balance of the Organism

Loss of body fluid is another symptom of an infectious disease. Particularly, in gastrointestinal infections with diarrhea and vomiting extreme deficits of body fluids may result. Often, the problem is not only the loss of fluid volume but also an imbalance of ► serum electrolytes, especially sodium and potassium. If an individual is not able to ingest enough food and the resorption by the bowel wall is insufficient, malnutrition results. Starving leads to reserves being used up and – due to acidic metabolic products – systemic acidosis. In a mild or moderate case of diarrhea the administration of an oral ► rehydration solution (ORS) may be sufficient to stabilize the metabolic situation. When the loss of fluids is progressive parenteral fluid replacement becomes necessary. If acidosis is severe, compensation with sodium bicarbonate ($NHCO_3$) may be needed.

Intensive-Care Therapy of Infectious Diseases

When an infectious disease takes a severe course, intensive care measures may be necessary. These measures consist of intubations, mechanical ventilation and a number of other procedures. In sepsis the administration of plasma proteins (fresh frozen plasma = FFP) or thrombocyte concentrates may be required; in anemia blood transfusion may be necessary. A patient suffering from tetanus usually has to be sedated and may require mechanical ventilation. (It is also important with tetanus to avoid visual and acoustic stimuli.) For all immobile patients regular changes of the posture are essential for the prevention of bedsores. Physical therapeutic measures, like breathing exercises or percussion (knocking massage) of the chest may help to prevent pulmonary complications like pneumonia.

Causal Therapy

A causal therapy is directed specifically against a specific pathogen. Its aim is to kill or at least weaken the pathogens and thus enable the patient's own defense mechanisms to overcome the infection. Pathogens can belong to different groups: bacteria, viruses, prions, fungi or parasites.

Antibiotic Therapy

Antibiotics are used to combat bacterial infections. The history of antibiotic treatment goes back to the discovery of ► penicillin by the British bacteriologist Alexander Fleming in the year 1928/1929. As a drug penicillin was used for the first time in 1939. Antibiotics are metabolic products of bacteria, fungi, algae and higher plants or synthetic or partly synthetic copies of these metabolic products. This kind of drug is able to act specifically against microorganisms by either killing them (bactericidal antibiotics) or impeding their growth (bacteriostatic antibiotics). Since the introduction of penicillin a great number of antibiotics with different spectra of efficiency (► spectrum of efficiency) have been discovered or developed. Besides penicillin there are, for example,

► cephalosporins, macrolides (► macrolide antibiotics) and aminoglycosides (► aminoglycoside antibiotics). An antibiotic substance is not effective against every kind of bacteria and, due to the characteristics of certain pathogens, a number of ► resistances have evolved. For some infectious diseases a combination of antibiotics is advisable to achieve the optimum effect. A side effect of all systemic antibiotic treatments is diarrhea. This is due to the drugs not only fighting against the pathogens but also the natural intestinal flora. Further side effects, which have to be mentioned, are the possible impairment of organic functions (for example ototoxic or nephrotoxic effects) and allergic reactions.

Virustatic Therapy

While most viral infections can only be treated symptomatically, specific virustatic agents (► virustatics) are available. These virustatics have to kill viruses or at least impede their growth without causing damage to the normal cells of the macroorganism. In 1977, aciclovir was licensed as the first specific antiviral drug. It is directed against infections caused by the herpes-simplex or varicella virus. Other virustatic drugs are available, for example for treatment and prophylaxis of ► influenza-A infection or severe courses of cytomegaly infection. Today, antiviral therapy plays a very important role in the treatment of ► AIDS, the HI-virus infection.

Antimycotic Therapy

Fungal infections can appear as a local infection, concerning the skin or the mucous membranes, or as a systemic mycosis, which affects organs, organ systems or the whole organism. A variety of antimycotic agents (► antimycotics) are available. Yeasts (like *Candida* species) belong to the natural microorganisms of the human intestines. They only become pathogenic when the balance between microorganism and macroorganism is disturbed. Such a disturbance may be due to antibiotic therapy or treatment with steroids. In comparison with other pathogens, especially bacteria and viruses, fungal infections only play a minor role in severe diseases.

Therapy of Parasitic and Zoonotic Infections

A number of parasites cause diseases in humans, such as protozoa (for example *Plasmodium*, which cause ► malaria), worms (helminthes), lice and mites. The ► parasitic and zoonotic infections are described elsewhere as well as the treatment and prophylaxis of malaria. Drugs to treat worm infections (anthelminthic agents) belong to various groups of substances. They kill the worm by interference with different metabolic

Therapy of Infectious Diseases, Table 1 Therapeutics of parasitic infections (Gorbach et al. 2004; Frölich and Kirch 2006)

Parasite/disease	Therapeutics
Ascariasis (*Ascaris lumbricoides*)	Pyrantel, mebendazole
Beef tapeworm (*Taenia saginata*)	Praziquantel, niclosamide, mebendazole
Pork tapeworm (*Taenia solium*), cysticercosis	Praziquantel, niclosamide, mebendazole
Pinworm, enterobiasis (*Enterobius vermicularis*)	Pyrantel, mebendazole, pyrvinium
Hymenolepiasis (*Hymenolepsis nana*)	Praziquantel, niclosamide, mebendazole
Broad fish tapeworm (*Diphyllobothrium latum*)	Praziquantel, niclosamide, mebendazole
Hookworm (*Ankylostoma duodenale*)	Pyrantel, mebendazole
Whipworm, trichuriasis (*Trichuris trichiura*)	Pyrantel, mebendazole
Strongyloides	Ivermectin, mebendazole, albendazole
Onchocerciasis (*Onchocercus volvulus*)	Ivermectin, suramin
Schistosomiasis	Praziquantel
Liver fluke, fascioliasis (*Fasciola hepatica*)	Praziquantel
Lung fluke, (*Paragonimus westermani*)	Praziquantel
Head lice	Malathion, pyrethrum, permethrin
Pubic lice	Malathion, pyrethrum
Body lice	Pyrethrum
Mite, scabies (*Sarcoptes scabiei*)	Malathion, lindane, benzylbenzoat
Chagas disease (*Trypanosoma brucei*)	Nifurtimox, benznidazole
Sleeping sickness (*Trypanosoma gambiense*)	Pentamidine, erflornithine, suramin
Leishmaniasis	Pentamidine
Pneumocystis pneumonia (*Pneumocystis jiroveci*)	Pentamidine

processes. Among the anthelminthic drugs are pyrantel, praziquantel, mebendazole, niclosamide and ivermectin; their indications are shown in Table 1. Drugs against mites and lice are only suitable for external use as these substances are neurotoxic. As long as these drugs are used correctly and on intact skin, only a little amount of their substance is resorbed and the drug is tolerated well; but if they are applied on inflamed parts of the skin resorption is much higher and neurotoxic effects may occur. If they reach the systemic circulation, the drugs may cause side effects in the central nervous system, like tiredness or dizziness or even seizures. Mites are treated with lindane, malathion and benzylbenzoat. Lice can be treated with malathion, pyrethrum and permethrin; the advantage of permethrin is that it only has to be used the once.

Tick-Borne Encephalitis (TBE)

Synonyms

Central European encephalitis (CEE)

Definition

The TBE-virus can be found in small vertebrates, primarily in mouse-like rodents, which do not fall ill themselves, and in ticks. The virus is transmitted to humans by tick bite. Ten to thirty percent of the infections are symptomatic and take a biphasic course. During the first phase there are flu-like symptoms with fever, headache, vomiting and dizziness. After a symptom free interval there is a reoccurrence of fever. Later, the patients develop central nervous system symptoms, like tonic-clonic seizures, neurological impairment, apathy and coma. Frequently, the severe courses of TBE-infection show long-term damage or even have a lethal outcome. As a specific therapy is not available, the most important prophylactic measure is the active TBE vaccination (► immunization, active).

Cross-References

► Zoonotic and Parasitic Infections

Tick-Borne Encephalitis (TBE) Vaccination

Synonyms

TBE immunization

Definition

The vaccination containing inactivated TBE viruses is recommended for residence in certain regions: among others, for parts of Germany, Austria, Hungary, the Czech Republic and Slovakia. The TBE ► vaccine has been administered in Austria since 1974. Vaccination should preferably begin in autumn. Between 3 weeks and 3 months following the first inoculation, a second one should be given. The protective effect starts to be present a few days after the second dose. A third vaccination is given 9–12 months after the second, and a fourth 3–5 years after the third. Booster shots should be given at intervals of 3–5 years, as long as the patient

is still at risk of infection. Contraindications for the FSME vaccine are acute illness with fever, and a known severe allergic reaction to components of the vaccine.

Time-to-Event Analysis

► Survival Analysis

Time-to-Event Curve

► Kaplan–Meier Survival Plot

Time Horizon

Definition

The time horizon of a health economic study describes the time to a fixed point of time in the future that will be the endpoint to the estimation of costs and outcomes. The time horizon can be seen as the equivalent to the follow-up time in a clinical trial. The time horizon in economic evaluation studies should be as long as any differences in costs or outcomes between the alternatives can occur.

Timeliness of a Surveillance System

Definition

The timeliness of a surveillance system reflects the delay between steps in a system. It can best be assessed by the ability of the surveillance system to allow appropriate public health action. The need for timeliness (rapid reporting to a surveillance system) depends on the urgency of the problem under surveillance and the nature of the public health response. Computer technology integrated into surveillance systems may promote timeliness of reporting.

Time Preference

Definition

A preference to receive benefits today, rather than in the future, and to incur costs in the future, rather than in the present.

Time Series Analysis

Synonyms

Time series modelling

Definition

Time series analysis comprises a broad spectrum of exploratory and hypothesis testing methods that have two main goals: (a) identifying the nature of the phenomenon represented by the sequence of observations, and (b) forecasting (predicting future values of the time series variable). Both of these goals require that the pattern of observed time series data is identified and formally described. A time series is a sequence of observations made over time. For example, annual infant mortality rate, weekly admissions to an emergency center, or daily carbon monoxide concentration. Time series analysis accounts for the fact that data points taken over time may have an internal structure (such as autocorrelation, trend, or seasonal variation) that should be accounted for. Three broad classes of models for time series data (that depend linearly on previous data points) of practical importance are the autoregressive (AR) models, the integrated (I) models, and the moving average (MA) models. Time series analysis tools include: consideration of autocorrelation and the spectral density function, performing a Fourier transformation to investigate the series in the frequency domain, use of a filter to remove noise, use of a time-frequency analysis technique, use of ► artificial neural networks, and chaotic analysis.

Time Series Modelling

► Time Series Analysis

Time Trade-Off

Definition

Time trade-off is a method to measure individual preferences for health outcomes and to estimate utility. Individuals are asked to choose between two alternative health care interventions. The outcome of one alternative would be less preferable, received with certainty,

and last unchanged for the remaining lifetime. The second alternative would lead to perfect health but also to a decreased life expectancy. The remaining duration of life in the second alternative is varied until the individual is indifferent between the two choices. The utility is derived from the lost lifetime and the improved health state.

TNO

Definition

Nederlandse Organisatie voor Toegepast Natuurwetenschappelijk Onderzoek or TNO (The Netherlands Organization for Applied Scientific Research) is a non-profit organization in the Netherlands that focuses on applied science. It is a knowledge organization for companies, government bodies, and public organizations. The daily work of TNO is to develop and apply knowledge. The organization also provides contract research and specialist consultancy as well as granting licenses for patents and specialist software. TNO tests and certifies products and services, and issues an independent evaluation of quality.

Tobacco Consumption

MARTINA PÖTSCHKE-LANGER
Deutsches Krebsforschungszentrum,
WHO-Kollaborationszentrum für Tabakkontrolle,
Heidelberg, Germany
m.poetschke-langer@dkfz-heidelberg.de

Synonyms

Smoking; Cigarette smoking

Definition

Tobacco consumption is the use of tobacco products in different forms such as cigarettes, cigars, pipes, waterpipes or smokeless tobacco products. Cigarettes and tobacco products containing tobacco are highly engineered so as to create and maintain dependence. Many of the compounds they contain and the smoke they produce are pharmacological active, toxic, mutagenic, carcinogenic and tobacco dependence is separately classified as a disorder in major international classification of diseases.

Basic Characteristics

Levels and Trends

Currently more than one billion of people around the world are using tobacco products. The World Health Organization considers the tobacco epidemic as a global problem with serious consequences for public health worldwide. Assuming constant tobacco use is prevalent, WHO projects that from 2000 to 2025 the number of smokers will arise approximately from 1.2 billion to more than 1.7 billion and the annual number of death which is currently estimated about 5 millions will double in 20 years to 10 millions. (World Health Organization Tobacco Free Initiative 2004). The international community is concerned about the worldwide health, social, economic and environmental consequences of tobacco consumption and exposure of tobacco smoke. The increase in the worldwide consumption and production of cigarettes and other tobacco products, particularly in developing countries, as well as the burden this places on families, on the poor and on national health systems led to the agreement of UN member states to establish the first health convention in the history of mankind, the Framework Convention on Tobacco Control (World Health Organization 2003). Most of today's smokers are male and most live in developing countries. Nearly a third (300 million) live in China. The highest rates of tobacco use are found in Cambodia, Djibuti, Indonesia, Myanmar, Papua-Neuginea and Viet Nam. Trends in both developed and developing countries show that smoking rates among males are slowly declining. Better educated males are tending to give up smoking, so tobacco use is becoming a habit of poorer less educated males. If smoking remains prevalent, it is estimated that the number of males smoking worldwide will rise from one billion in 2000 to 1.4

billion in 2025. Among females, the tobacco epidemic started later. In developed countries it is estimated that 22% of females smoke tobacco and in developing countries 9% smoke tobacco, totaling about 230 million females worldwide. Cigarette smoking among females is declining in many developed countries, but this trend is not found in all developed countries: In several southern, central and eastern European countries, cigarette smoking is either still increasing among females or has not shown any decline. As social traditions change and incomes increase the number of females smoking could double to 460 million by 2030. It is well known that the greatest public health challenge in primary prevention (► prevention, primary) in the next 30 years will be the prevention of a rise in the level of smoking amongst girls and women in developing countries, especially in Asia.

WHO Framework Convention on Tobacco Control

The idea of an international instrument for tobacco control was initiated with the adoption of a resolution of the World Health Assembly in May 1995 (WHA 48.11) requesting WHO to develop an international convention on tobacco control together with member states. It took an ongoing process spread over several years for the convention to be negotiated. Finally on 21 May 2003 the 56th World Health Assembly unanimously adopted the WHO Framework Convention on Tobacco Control and the convention was opened for signature to member states. Up to August 2007 168 countries have signed and 148 countries have ratified the convention.

Individual and Economic Costs of Tobacco Consumption

Scientific evidence has unequivocally established that tobacco consumption and exposure to tobacco smoke causes death, diseases and disability, and that there is a time lag between the exposure to smoking, or other uses of tobacco products, and the onset of tobacco related diseases. Tobacco consumption is deathly in any form as WHO noted on World No Tobacco Day 2006 (World Health Organization 2006). Among the leading diseases that are caused by tobacco are cardiovascular diseases, chronic obstructive lung diseases, cancer in different sites, the most deadly being lung cancer. Premature death costs a smoker an average of 10 years of his life (Doll et al. 2004). The costs to individuals and their families include also the loss of money spent on buying tobacco, the loss of income through illness and premature death, the cost of illness or death of family members exposed to passive smoke in the home, the cost of the time spent by other family members looking after smokers or taking them to hospital, which may sometimes be measured in days in developing countries, health care costs induced by tobacco related illnesses, higher health insurance premiums, miscellaneous costs such as increased fire risk.

The economic burden of tobacco use on governments and societies is huge: Governments often have to bear the burden of caring for chronically sick and terminally ill smokers and providing for their spouses and children in the event of social incapacity or premature death. In countries where tobacco is not grown or is insufficient to meet national demand, the importation of cigarettes could lead to a net loss of foreign currency. Tobacco growing countries have a loss of agrarian areas that could otherwise be used to grow food. Companies have higher costs for employers due to absence from work, decreased productivity, higher accident rates and higher insurance premiums: Absence from work is often higher among smokers due to illness. In addition, cleaning and maintenance cost rise for buildings where smoking is permitted. Also the environmental costs are huge: Rainforests are destroyed because of tobacco growing and tobacco curing so that tobacco is contributing to deforestation worldwide (Geist 1999).

The Role of the Tobacco Industry

With the setting up of a unique data base, former secret tobacco industry documents are now publicly available (the result of the Master Settlement Agreement (MSA) between the tobacco companies and 46 United States territories and states) and information is now obtainable about the industry's formerly secret tactics and plans to deter effective measures to control tobacco use (British American Tobacco Documents Archive 2006; Legacy Tobacco Document Library 2006; Tobacco Documents Online 2006). For decades the tobacco industry has been acting on national as well as international levels against effective interventions to reduce tobacco consumption. The globalization of tobacco manufacturing, trade, marketing and industry influence poses a major threat to public health worldwide. WHO characterizes the tobacco industry as a "global force" that considers

the world as "its operating market by planning, developing and marketing its products on a global scale" (Yach, Bettcher 2000). Ensuring and increasing the profits are the main aims of the tobacco industry. The industry uses a variety of strategies to buy influence and power and penetrate markets so that their aims will be reached. To break this trend governments and public health authorities have to consider effective tobacco control intervention.

Effective Tobacco Control Strategies

The World Bank (World Bank 1999) and World Health Organization Tobacco Free Initiative (World Health Organization Tobacco Free Initiative 2004) have identified effective strategies to combat the tobacco epidemic on national and global levels. These strategies are summarized and recommended in WHO Framework Convention on Tobacco Control (World Health Organization 2003). Previously, governments and public health planners tended to leave tobacco control in the hands of medical practitioners. Although the role of health professionals is vital, it is well known that the medical model alone is not enough. Tobacco control requires a comprehensive approach, using a strategic mix of policies, legislation and program interventions and the involvement of other partners in society. In *low- and middle-income countries*, price measures are the most cost-effective way of reducing consumption, especially among young people, followed by non-price measures such as comprehensive bans on tobacco advertising and promotion, bans on smoking in public places including work places and the hospitality industry, strong warning labels on packages, information and research. Pharmaceutical products are relatively more expensive. In *high income countries*, price increases are still the most cost-effective measure, followed by pharmaceutical assistance with quitting and non-price measures. Governments and legislators are duty bound to increase the prices of tobacco and tobacco products, primarily through taxes on tobacco. The following non-price measures are effective interventions that reduce demand: Comprehensive bans on tobacco product advertising and promotion, legislation to prohibit smoking in public places and work places, use of prominent, strongly worded and pictural health warnings on cigarette packages, information and advocacy campaigns as well as cessation programs to assist those who want to quit smoking. As interventions that reduce supply the following strategies are effective: Control of smuggling, restricting access of minors to tobacco, crop substitution for tobacco farms and elimination of government subsidies for tobacco farming.

Conclusion

Tobacco consumption led during the last century to a tobacco epidemic as a global problem with serious consequences for public health. The international health community is concerned about the devastating worldwide health, social, economic and environmental consequences of tobacco consumption and exposure to tobacco smoke. WHO and member states established the Framework Convention on Tobacco Control as answer to the tobacco epidemic. International cooperation and the participation of all countries in an effective, appropriate and comprehensive international response on the way and the implementation of successful tobacco demand reduction strategies are in process.

Tort

Definition

Tort is a term of civil law and, here, it means a wrongful, unlawful and harmful act of a person or a legal entity (i. e., the tortfeasor) which causes an injury of life, body, health, property or other protected right of another person or legal entity.

Tortfeasor

Synonyms

Offender

Definition

Any person, company, other organization or legal entity, including state institutions, who has committed a tort. Tortfeasors are subject to liability under tort law. ► Tort.

Tort Law and Public Health

ADEM KOYUNCU
Mayer Brown LLP,
Cologne, Germany
akoyuncu@mayerbrown.com

Synonyms

Torts law; Law of torts; Law of delict

Definition

Tort law is one of the fields of private law. It encompasses the legal rules that attribute legal responsibility and compensation duties (liability) for damages resulting from torts. The term tort describes a wrongful, unlawful act injuring or affecting life, body, health, property or other protected right of another person. Tort law provides the prerequisites and limits of liability of tortfeasors and the extent of their obligation to compensate claimants. Main forms of tort liability are fault-based liability, strict liability and state liability.

Basis Characteristics

Background and Function

Tort law is one of the fields of private law with the highest practical relevance. The term tort law is mainly used in common-law countries, whereas the term "law of delict" prevails in civil law countries (*See* in Germany, where the respective part of private law is known as "*Deliktsrecht*" (translation: "Delicts Law") or "*Unerlaubte Handlungen*", which translates as "Unlawful Acts").

► Tort is a term of private law. Here, it means a wrongful, unlawful and harmful act of a person or a legal entity (i. e., the tortfeasor), which causes an injury of life, body, health, property or other right of another person or legal entity. Therefore, to classify an act as a "regular tort", the harmful act must have been unlawful and committed with fault (i. e., intentionally or negligently). These acts can regularly – but not always – also be classified as criminal acts and may be punishable under criminal law. Thus, tort litigation (a civil lawsuit) may be complementary to a criminal prosecution. However, tort liability is also possible without fault if the harm falls under the scope of so-called strict liability.

Tort liability must not be confused with liability under contract law. Tort law is not part of contract law. A tort leads to a statutory and not contractual legal relationship between the tortfeasor and the injured. This legal relationship determines the liability of the tortfeasor and his duty to pay ► damages to the injured person. Therefore, a person may have a tort liability together with a contractual liability if the tort additionally represents a breach of a contract.

Tort law as part of private law is not aimed at criminal punishment. Tort law has the objective of attributing responsibility for tortious acts and providing compensation to the injured subjects. The award of damages to compensate those injured by torts is one main goal of tort law. Correspondingly, tort law – like criminal law – has a retrospective perspective on tortious acts, whereas in public health law the *ex ante* prevention of harm is the primary goal. As a secondary objective, tort law is determined to protect community interests and persons from tortious acts. Thus, a court may release injunctive orders against tortfeasors based on tort law to omit the tortious act for the future. Affected persons may file a motion or ask for (preliminary) injunctions at court, based on tort law, to achieve relief from a tortious act (e. g., a nuisance). In such constellations, tort law can be used as a preventive public health tool. Finally, tort law protects the interests of the injured persons by convicting tortfeasors and awarding damage payments so that a financial restitution is achieved.

Principles of Tort Law

Tort law provisions define the legal elements of tortious acts. A regular type of liability under tort law is ► fault-based liability. However, tort law also encompasses ► strict liability and ► state liability as well as employer's liability, among others. Tort law as a general part of private law applies to everybody tortiously causing damage regardless of whether it is an individual causing a traffic accident, a medical doctor held liable for medical malpractice or a product manufacturer liable for injuring consumers by placing defective or extraordinary dangerous products on the market. Tort law is very far-reaching, which is one of the reasons for its practical relevance.

As a classic example of a fault-based liability, the central delicts law provision of German private law (§ 823 of the German Civil Code) can be cited, particularly as the provision is representative for tort provisions in some other jurisdictions (McClurg et al. 2007). § 823 of the German Civil Code provides in its first subsection: *"Anyone who unlawfully injures the life, body, health, liberty, property or any other right of another, either wilfully or negligently, is liable to such other person to compensate for any such damages resulting therefrom"* (translation by the author).

As such, in the realm of public health, fault-based liability also applies to medical doctors and hospitals injuring patients. The core elements of a "regular tort" (fault-based liability) are the causation of harm by a faulted and unlawful act. ► Fault includes wilful or negligent acts. Negligence plays the major role in the practice of tort litigation. Most tort claims are based on negligence. The tortfeasor must have acted without due care and in breach of a duty of care leading to the injury.

In addition to fault-based liability, strict liability plays an important role in tort law. Under strict liability, a claimant does not need to prove that the ► tortfeasor acted at fault when causing the harm. Strict liability is a liability scheme without fault. Product liability is a typical area of strict liability. As strict liability is regardless of fault, it provides a substantial enhance-

ment for claimants. Strict liability is grounded in the idea that a company that places dangerous products on the market must be responsible for harm resulting from the use of these products even if a fault is not proven. As the marketing of many products is inevitably linked with consumer risks, the legal system only allows such product marketing if the manufacturer accepts his fault-independent liability for the risks resulting therefrom (Koyuncu 2004). In many jurisdictions, environmental liability is also subject to strict liability. In Germany, car drivers' liability is also governed by strict liability.

State liability is also relevant for public health. This liability scheme applies to injuries caused by public health practitioners or administrative agencies and is fault-based. It may apply, if, for example, public health agencies negligently fail to react adequately to safeguard the public's health from a threat; an injured person may claim damages from the agency due to a breach of the agency's duty of care. Therefore, deficiencies in providing public health services may result in state liability of the agency. The same is true in cases of disproportionate and excessive public health actions unduly impacting personal or economic rights and interests.

Compensations in Tort Law

Tort law dictates the conditions, type and amount of damages, i. e. *compensation or other payments* resulting from tort liability. The possible compensation elements vary throughout jurisdictions. However, a general and widely accepted objective and principle of tort law is that the tortfeasor has to pay damages in order to make the injured person "whole again". This means that he has to pay damages "to restore the person, as nearly as possible, to the position" the claimant "would have been in but for the tortious conduct" (McClurg et al. 2007). Where possible, the tortfeasor has to "make whole" (restitution in kind) and restore or otherwise "make up" by paying compensation.

In addition to the economic compensatory damages, noneconomic *damages for pain and suffering* play an important role in tort law. In the common-law jurisdictions, particularly in the U.S. and the United Kingdom, so-called punitive damages are also relevant for the practice of tort law. Tort cases can also result in a court order to the tortfeasors to stop the tortious conduct. Such injunctive relief may be combined with damage payments. In some jurisdictions, e. g., the U.S., consequences of torts can include civil penalties and sanctions with a remedial nature like cleanup costs and liens on property (Grad 1990).

Practical Aspects of Tort Law

Tort law cases are handled by specialized civil law courts, which complement the court system, together with administrative and criminal law courts. Tort cases are private actions between private parties. Civil lawsuits are governed by civil procedure laws. These prescribe the way the case is handled at court as well as the rules for evidence and involvement of witnesses or experts. One important element of civil lawsuits is the *burden of proof*. The party bearing the burden of proof must provide the court/jury with the necessary facts to substantiate its assertions. If it fails to provide these facts, the case will very likely be lost. In civil lawsuits, there is no rule similar to the criminal procedure "benefit of doubt" rule (*in dubio pro reo*). In civil lawsuits, each party must provide the facts that are necessary to substantiate their legal assertions. Because of these procedural burden-of-proof rules, it is not surprising that the outcomes of civil lawsuits differ from those of criminal proceedings even if both were initiated because of the same act.

In most jurisdictions, many tort cases are finalized with consensual settlements between the parties. In entering a settlement, both parties agree on a compromise in order to find a consensual solution without waiting until the final court decision. Finally, there are relevant differences between procedural rules of civil lawsuits throughout jurisdictions. Among others, parties in the U.S. are entitled to file class actions. The discussion of these differences would extend the scope of this essay. Andrew McClurg and his co-authors (McClurg et al. 2007) discuss many of the relevant differences in practical tort litigation (e. g., procedure rules, juries, expert witnesses, damages, court and attorney fees).

Tort Law and Public Health

Tort law and public health have several intersections. With respect to their objectives, both fields are to a considerable extent consistent (Gostin and Jacobson 2006). The following points of contact between tort and public health law are highlighted in brief:

- Public health laws may – even though they are part of administrative law – provide compensation in cases of violations. Thus, they may include elements of tort laws. Several other intersections between tort law and public health law are – similar to the intersections between criminal law and public health – based on various indirect effects and interrelations between both legal fields. Overall, tort law has enhanced the level of protection in many public health fields.
- There may be a direct interaction between tort law and public health. This is the case where public health laws set forth compensations to infringed persons if they were harmed due to a violation of rules that protect public health. Then, the compensation is based on the applicable public health laws and not on tort law. Here, the public health laws form the legal basis for the claims.
- Another type of direct interaction between tort and public health law exists in jurisdictions (e. g., in Germany) where the compensation is based on general tort law but where the injury was due to a violation of (protective) public health laws (e. g., damages due to violations of occupational safety rules or infectious diseases control laws). In these cases, public health laws are not the basis of the claim. The basis of the claim remains in the general tort law. However, the applicability of tort law rules are linked with the violation of the public health law rules.
- Tort law also applies to public health officers and (in the manifestation as state liability) administrative agencies if they have violated their public health obligations. Individuals may claim damages from the agency or their officers asserting that they have failed to provide appropriate public health services.
- Tort law has increased the protection level in many public health fields. Tort law adjudication has developed particular rules and doctrines for the interaction between patients and medical doctors (e. g., informed consent rules). This has significantly promoted patient autonomy and empowerment. Similarly, product liability litigation has increased the awareness of consumer safety aspects and – in addition to deterrence – the courts have developed manufacturer obligations with respect to product marketing, instruction and consumer information, as well as good construction quality assurance duties (McClurg et al. 2007). Particularly, the tobacco industry has been subject to extensive tort litigation, which influenced this industry and its marketing in the interest of the public's health (Pamet and Daynard 2000; Gostin 2000; Teret 1986). Asbestos litigation is an example of occupational safety related litigation. As a consequence of the increased attention obesity is receiving as a public health issue, in the recent past individuals have filed lawsuits against fast food companies (e. g., Pelman v. McDonald's Corporation, U.S. District Court, S.D. New York, 2003. 237 F.Supp.2d 512). Such "obesity litigation" and similar forms of litigation are also intersections between tort law and public health.
- As already noted, tort law (comparable to criminal law) has a deterrent and protective effect in the interest of the public's health. This conclusion is supported by the author's own experience as a practicing medical doctor as well as a lawyer providing legal counsel to companies and medical doctors on consumer/patient safety aspects. The potential damage payments for injuring consumers/patients through non-compliance have significant impact on the decision-making process of these actors. Tort law and its potential consequences have a behavior-influencing effect in favor of legal and public health compliance.
- Public health standards set by the government and the administration also form an intersection between tort law and public health. Such standards regularly describe the present "state of the art" for the pursuit of the activities governed by the standard (e. g., occupational safety standards). As negligence in tort law is determined by the owed duty and standard of care, which are also influenced by the "state of the art", such standards have relevance as they reflect the state of the art. Public health standards can therefore provide evidence for a negligent act as they define the tortfeasor's "duty of care" and "standard of care" (Koyuncu and Kamann 2007). In this respect, public health law standards influence the outcome of tort claims.
- A violation of public health laws and standards may also affect civil lawsuits by influencing the civil procedure rules. As demonstrated above, in civil lawsuits, burden-of-proof rules exist. Under consideration of certain facts, the burden of proof shifts from one party to the other. A shifted burden of proof is regularly decisive for the lawsuit. A violation of pub-

lic health laws and standards may be able to shift the burden of proof and, then, decide the case in favor of the claimant. This is an additional incentive for all potential tortfeasors to act in regulatory compliance with public health laws.

In summary, tort law and public health are interrelated in the interest of the public's health. The mechanisms of tort law have deterrent and preventive effects in favor of the population's health and influence the behavior of individuals and companies accordingly. Further, compliance or non-compliance with standards and rules of public health law influence the outcome of tort cases. Therefore, tort law is indeed an important component of public health law and public health practice (Reynolds 1995). The higher the tort liability risks and damages in a country are, the more important tort law is. Tort law has to be viewed as an indirect type of regulation in order to ensure and promote the public's health. As an indirect form of regulation, tort litigation is a potent tool with "enormous potential for improving the public health" (Gostin and Jacobson 2006).

Public health law is interwoven with tort and criminal law as well as with other legal fields like tax law, commerce law, social law or constitutional law. All intersections either directly protect the population's health or have indirect effects that safeguard and promote the population's health. This additionally supports the conclusion that the establishment and pursuit of a public health system is probably the central objective of the society. As demonstrated, law supports this overarching purpose in manifold ways with substantial impact.

Total Fertility Rate (TFR)

Definition

Total fertility rate (TFR) is the most commonly used fertility measure and the best single measure to compare ► fertility across populations. The TFR is defined as the average number of live births a woman would have if she were subject to, throughout her reproductive life, ► age-specific fertility rates (ASFR) observed in a given year. The TFR is the sum of the ASFRs over reproductive ages. It is a synthetic measure of fertility that is independent of the age structure of a population.

Toxicogenomics

REBECCA C. FRY, LEONA D. SAMSON
Center for Environmental Health Sciences,
Massachusetts Institute of Technology,
Cambridge, MA, USA
rfry@MIT.EDU, lsamson@MIT.EDU

Definition

Toxicogenomics aims to identify and understand every gene product that influences the biological effects of environmental stressors and toxicants. It combines gene, transcript, protein and metabolite profiling with conventional toxicology to investigate gene-environment interactions that influence toxic biological endpoints, and that might therefore be involved in disease causation. Toxicogenomics aims to provide a global, system-wide view of the genetic and biochemical machinery that protects cells, tissues and animals against toxic exposure (Aardema and MacGregor 2002; Waters and Fostel 2004).

Basic Characteristics

Beginnings of Toxicogenomics

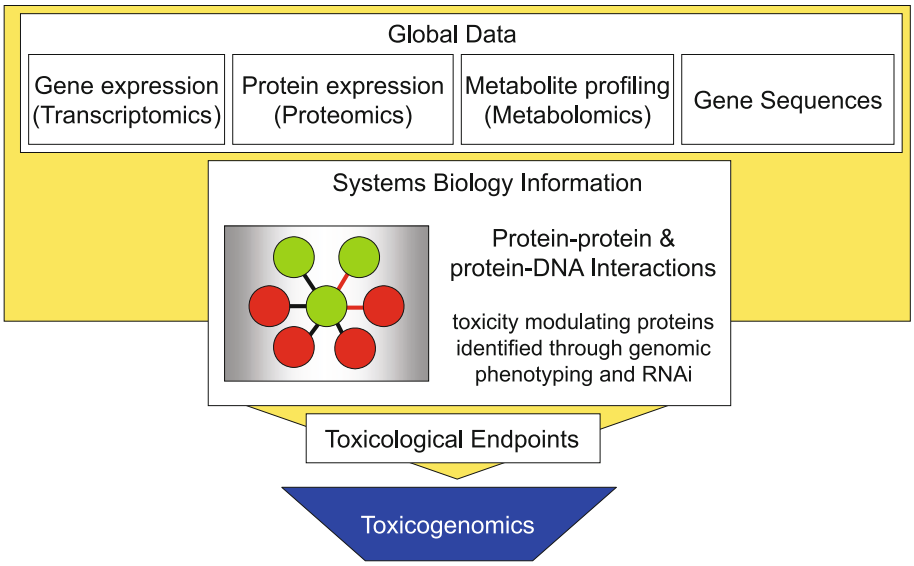
The foundation of toxicogenomics is in the field of toxicology, the study of toxic substances. In the past decade, advances in biotechnology and high-throughput genomic technologies have revolutionized all of the biological sciences and toxicology is no exception. Exemplary of these technologies is the ► DNA microarray, a solid surface onto which DNA molecules are arrayed at high density, enabling the monitoring of thousands of nucleic acids simultaneously. DNA microarrays enable detection of genome-wide transcriptional responses by measuring mRNA changes in organisms exposed to environmental agents and by detecting polymorphic variants in DNA (Aardema and MacGregor 2002; Hamadeh 2004). Also integral to the field of toxicogenomics has been sequencing of numerous organisms plus the associated gene and protein annotation. These data are instrumental in the application of gene-expression analysis to understanding the modes-of-action of toxic agents and other environmental stressors on biological systems. Together, these technological developments have been catalytic in the emergence of the field of toxicogenomics. The three overarching goals of the toxicogenomics field are: 1) to understand the relationship between environmental stress and human disease susceptibility, 2) to identify markers of disease and exposure to toxic substances, and 3) to elucidate the molecular mechanisms of toxicity (Waters and Fostel 2004).

Evolution of Toxicogenomics

The field has evolved from early gene expression studies involving the focused response of a biological system to a particular agent, towards more global investigations that integrate several different fields with toxicology and pathology. New families of technologies now enable global analysis of virtually all cellular molecules and these are termed "-omics" technologies. They are compiled from ► transcriptomics (the aggregate study of all mRNA transcript levels), ► proteomics (the aggregate study of all protein products) and metabonomics (► metabolomics, the aggregate study of metabolites). These multiple forms of complex data streams are integrated with information including gene sequences (single nucleotide polymorphic variants), protein-protein/protein-DNA interactions and toxicity modulating proteins (identified through genomic phenotyping of global gene deletion sets or through RNAi). Merging all of these datasets with endpoints of toxicological responses and histopathological data generate toxicogenomic data that can be mined to yield such information as toxicity biomarkers, disease causation, and mechanisms of toxicity (Fig. 1) (Waters and Fostel 2004; Fry et al. 2005; Merrick and Madenspacher 2005).

Applications of Toxicogenomics to Human Population Studies

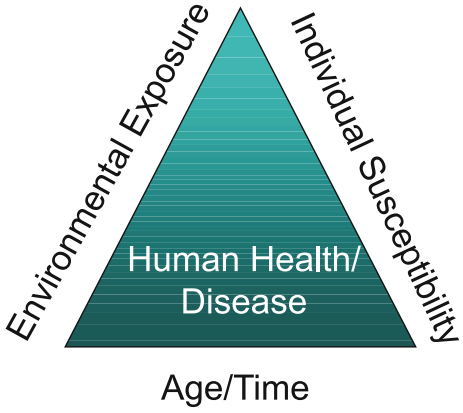
A major application of toxicogenomics will be the prediction of human susceptibility to disease. Prediction of human health risks from toxicant exposures is complicated by the diverse properties of toxic agents, the dose and time-specific response that influence the relationship between exposure and disease, and the genetic variation of human populations (Waters et al. 2003). Genetic differences between individuals can determine the relative sensitivities to environmental agents with some disease susceptibilities caused by a single inherited trait and other disease susceptibilities caused by multiple traits (Waters et al. 2003). No doubt, it is the



Toxicogenomics, Figure 1 Toxicogenomics combines global data from gene sequences (SNPs), transcript, protein and metabolite profiling and systems biology information with conventional toxicology

interaction between genetics and the environment that ultimately results in disease (Fig. 2).

Sequence differences (polymorphisms or mutations) also contribute to inter-individual differences in responses to drug treatment, the study of which is termed ► pharmacogenetics. Applications of toxicogenomics currently exist in the arena of drug discovery to identify safer drugs in a quicker, more cost-effective manner. Toxicogenomics has the potential to better identify and assess adverse reactions of new drug candidates (Yang et al. 2004). Toxicogenomics could contribute to early and reliable prediction of the toxic nature of compounds, avoiding extensive animal costs and time-consuming pre-clinical trials (Luhe et al. 2005). To date, various class prediction methods have successfully been used to identify genes that distinguish toxicological classes of agents (Maggioli et al. 2006).



Toxicogenomics, Figure 2 Interactions between environmental exposures and genetic variability ultimately influence disease status

The Future of Toxicogenomics

The evolution of truly ► predictive toxicology, where information from exposure to an agent in one species could be used to predict the impact of human exposure to that agent, will require the development of extensive knowledge-based databases. These databases must effectively integrate high quality genomic data with toxicological endpoint data. The power of such knowledge-based databases will depend on the quality of deposited data and recent work has highlighted the importance of improved methodologies in laboratory practice to obtain high quality genomics data (Bammler et al. 2005).

Moving forward in toxicogenomics, a systems approach will be required where the perturbation by toxicant and stressor, the molecular expression and conventional toxicological parameters are integrated. The further integration of global datasets built from genetic, proteomic and metabolomic data with frameworks established by genetic, protein-protein and protein-

DNA interactions will allow for sophisticated network modeling. Currently, global scale information of molecular interactions has been identified under non-perturbed conditions. In the future, structures of networks including protein-protein, protein-DNA and transcriptional regulatory mechanisms will need to be determined under a variety of different conditions to better understand cellular responses to stress (Fry et al. 2005). Combining the various -omics technologies (proteomics, toxicogenomics, and metabonomics) and integrating basal and toxicant- induced responses will increase our global understanding of cellular mechanisms of toxicity and disease generation.

Toxicology

Definition

Toxicology is the study of poisons (toxic effects of substances), their nature, harmful effects on humans, animals and plants and possible ways of their detection as well as their treatment. Toxicology is a multidisciplinary science involving medical and biological sciences to determine the relationship of the harmful effects to exposure and the mechanisms of action. Historically, progress in toxicology had served hunting and warfare and led to a better human adaptation to the environment. Today, toxicology emphasizes the detection and prevention of harmful effects of chemical or physical substances.

- ► Pollution

Toxoplasmosis

Synonyms

Infection with Toxoplama gondii

Definition

For the parasite *Toxoplasma gondii* humans are only intermediate hosts; the natural hosts are cats and catlike beasts of prey. Infectious oocytes are shed in cat feces and taken up by direct contact or contaminated food. The incubation period last 1–3 weeks. The infection, which is asymptomatic in more than 90%, induces a lifelong immunity. Possible symptoms are malaise, fever, headache, rheumatic pain and swelling of neck lymph nodes. In immunocompromised persons inflammation is usually localized to the brain, but other organs can also be affected. A primary infection during pregnancy leads to disease in 50% of the unborn children. The risk is highest between the 12th and the 27th week of gestation. An infection in early pregnancy may lead to a stillbirth or severe damage to various organs, especially the brain. Transmission in the last trimester has less extreme effects; nevertheless, up to 50% of the children may develop long-term damage with mental retar-

dation. Toxoplasmosis in pregnancy as well as congenital and symptomatic toxoplasmosis require an immediate antibiotic therapy.

Trace Elements

Synonyms

Microminerals

Definition

Trace elements are needed in minute amounts. They act as catalytic or structural components of larger molecules. Marginal or severe trace element imbalances can be considered as risk factors for several diseases that are of public health importance. The same element can have quite different effects depending on the concentration in which it occurs in soil or water, or that is finally consumed. Benefits only increase up to a point, after which harmful effects may be derived from consuming higher levels. The best-documented example of a dose-dependent relationship between trace element intake and health is the effect of fluorine in reducing the incidence and severity of dental caries. When 2–8 times the normal dose of fluoride is consumed, teeth may become mottled with dark spots, and when the amount exceeds 20–40 times the normal dose, it may trigger bone sclerosis and calcification of ligaments. Iodine is necessary to the proper functioning of the thyroid gland; however, a lack of iodine leads to thyroid enlargement, known as goiter. For half a century, it has been common practice to prevent endemic goiter by iodizing table salt. Zinc-deficiency symptoms can take many forms, including dwarfism, dermatitis, loss of taste sensitivity, and delay in the rate at which wounds heal. Lack of selenium has been shown to cause abnormalities in many plants and animals. Selenium deficiency in the form of cardiomyopathy in humans has been documented in the Keshan region of southeastern China. On the other hand, selenium toxicity is reflected in many impairments in animals and humans, like the development of cancer, malformation of nails and hair, and other symptoms.

Trade Agreements

Definition

Trade agreements refer to the international trade of goods or services, usually aiming to reduce so called 'barriers to trade'. Such barriers can be governmental restrictions, quotas and tariffs, but also control measures maintained by business organizations or professional bodies. There are different free trade areas around the world, e.g. the European Economic Area or the Free Trade Area of the Americas. The World Trade Organisation (WTO), which has 150 member countries, established the WTO Agreement in 1995 as a progressive instrument. It includes the General Agreement on Trade in Services (GATS), which also concerns health and social services. On a sector-by-sector basis, member countries can decide to liberalize trade to certain degrees (mode 1–4). This may range from purchasing services produced on another member country's territory, to the presence of natural persons providing services on the territory of the receiving country.

Tradition

Definition

The continuation of known practices in discussion, convincing of faith, and the giving of ones self.

Traditional Food

Synonyms

Food typical for certain cultures

Definition

Traditional food is defined as food conforming to or in accord with tradition. It refers to food specific to a certain region, culture, race or nation. It is usually food that is easily available, e. g. grown or cultivated for purposes of nourishment, or according to experience or belief, used for prevention or treatment of various ailments in specific populations. For example, rice is traditional food in the far East, olive oil is traditional food in the Mediterranean, etc.

Traditional Healers

► Indigenous Health Care Services

Traditional Knowledge

Synonyms

Indigenous knowledge; Local knowledge; Inherited knowledge

Definition

Traditional knowledge generally refers to the traditions and practices of certain regional, indigenous, or local communities. Traditional knowledge includes the wisdom, knowledge, and teachings of these communities. In many cases, traditional knowledge has been orally passed for generations from person to person. Some forms of traditional knowledge are expressed through stories, legends, folklore, rituals, songs, and even laws. Traditional knowledge distinguishes one community from another and may be considered as the community's identity that reflects its interests.

Traditional knowledge is often perceived very differently by indigenous and local communities themselves. Western society has separated secular from spiritual knowledge. This is generally not the case for indigenous and local communities. Indigenous people say that their knowledge is holistic and an integral part of their lands and resources. While traditional knowledge may be acquired from a teacher, and improved through experience, it ultimately may be derived through direct communication with the spirit world.

Cross-References

► Indigenous Knowledge

Traditional Medicine

Synonyms

Alternative medicine; Holistic medicine

Definition

Traditional medicine refers to medical knowledge systems, which developed over centuries within various societies before the era of modern medicine. It includes herbal medicine, Ayurvedic medicine, acupuncture, traditional Chinese medicine and other different medical practices all over the globe.

Traditional medicine is defined by WHO as "the medicine that refers to health practices, approaches, knowledge and beliefs incorporating plant, animal and mineral based medicines, spiritual therapies, manual techniques and exercises, applied singularly or in combination to treat, diagnose and prevent illnesses or maintain well-being."

Traditional medicine is widely used in Africa, Asia and Latin America as part of primary health care. For example, in Africa almost 80% of the population uses traditional medicine as primary health care. In industrialized countries, the term "traditional medicine" is very often confused with the term "alternative medicine."

Trans-Acting Gene

Synonyms

Transgene

Definition

In ► gene therapy, genetic elements are transferred into a patient. If the transferred gene is *not* integrated into the patient's chromosomal DNA (► deoxyribonucleic acid) it is termed "*trans-acting*".

Transcription

Synonyms

DNA transcription

Definition

Transcription is the process by which information contained in DNA within a gene is copied into a functional transcript made of RNA, to be used later as a template for the assembly of polypeptide chains leading to proteins. There are four central components to the process of transcription which are: 1) promoter recognition, 2) initiation, 3) elongation and 4) termination. A fifth component independent of transcription that prepares a transcript to be used as a template for the coding of proteins is post-transcriptional processing. The process of initiation begins after the enzyme RNA polymerase identifies a sequence in a gene from 20 to 200 bases in length and called a promoter, which is upstream (5′) of the transcription start site. After the polymerase binds to the promoter, it opens and separates (or 'denatures') the DNA into two separate strands in order to make the single strand which will be used as a template accessible. At a specific start site (identified as +1), transcription begins with the binding of a ribonucleotide complementary to the DNA nucleotides at +1. The RNA polymerase then moves along the template DNA strand, adding complementary ribonucleotides to the growing RNA strand in a 5′ to 3′ direction. When the RNA polymerase reaches a specific termination sequence, the RNA polymerase is unbound from the template strand and the single-stranded RNA transcript is released, allowing the separated DNA strands to rebind (or 'renature'). The released RNA transcript then undergoes post-transcriptional processing in order to be prepared for use by the ribosome to create polypeptide chains. The RNA transcript, also called a messenger RNA, or mRNA, is capped with a molecule called 7-methyl-guanosine cap at its 5′ end. At the 3′ end of the molecule, a length of as many as 200 adenosine nucleotides commonly called a poly-A tail is attached. The final step of mRNA post-transcriptional is RNA splicing: the removal and disposal of intermediate sequences of RNA which will not be used in polypeptide coding. The removed sequences are called introns, while the remaining sequences, which are ligated to form the mRNA transcript which will be translated, are called exons. This post-transcriptional splicing takes places in a protein complex in the nucleus called the spliceosome. From this point, the modified mRNA transcript is now ready for transport to the cytoplasm and the beginning of ► translation.

Transcriptome

Definition

The still frame capture of the complete set of transcripts (mRNA) for one or a group of cells for one time point under a specific condition. Due the fluctuating nature of gene expression, there are many possible transcriptomes the same cell or group of cells. This is used to monitor while genes are copied into mRNA for eventual translation in the cell.

Transcriptomics

Genomics; cDNA microarray hybridization and analysis

Definition

Transcriptomics is the collective study of all mRNA products from a ► genome. Using the high-throughput technology of ► DNA microarrays, messenger RNA samples are amplified, labeled and detected using automated image processing. The value of the expression intensity of a single transcript can be compared relative to other transcripts and to other samples resulting in gene expression profiles.

Transition Country

Definition

Transition countries are countries emerging from a socialist-type command economy towards market-based economy, covering a wider range of countries in Central and Eastern Europe, as well as countries outside of Europe such as China. Transition refers not only to economy-related issues, but also to other aspects of life such as culture, health care services, education, etc.

Translation

Synonyms

mRNA translation

Definition

Translation is the process by which an mRNA script is used as a template to identify specific amino acids and to link the amino acids in a polypeptide chain, which will subsequently be processed to form functional proteins (Fig. 1). The process of translation is composed of three processes: 1) initiation, 2) elongation and 3) termination. Elongation begins when an mRNA transcript, which has been transported to the cytoplasm is bound and encased by the two subunits (in eukaryotes, the 60S and smaller 40S subunits) of the ribosome. The ribosome is bound to the transcript by proteins called initiation factors (IFs) at the site of the first three nucleotide of the transcript which read AUG. At this site, a short RNA-based carrier molecule that is used to transport amino acids, called a transfer RNA or tRNA, binds to the AUG with a complementary RNA sequence of UAC. tRNAs are bound to the mRNA transcript only if they possess the correct complementary sequence; the three nucleotides to which a tRNA is bound is called a codon, whereas the three tRNA nucleotides used to complement the mRNAs codon is called an anti-codon. Because this tRNA is attached to an amino acid (in this case, the amino acid Methionine), it is called an aminoacyl-tRNA. After the first Methionine-carrying aminoacyl-tRNA has bound to the first AUG, the next three ribonucleotides (in other words, the next codon) in

the mRNA transcript binds to another aminoacyl-tRNA with the corresponding complementary RNA sequence. With the assistance of proteins called elongation factors (EFs), the process of elongation begins, whereby the first aminoacyl-tRNA carrying methionine has the bond to its amino acid broken, and that methionine is bonded via a 'peptide' bond to the amino acid attached to the tRNA matching the second codon. The mRNA transcript shifts down one codon, and the first tRNA, now devoid of an amino acid is released. The second amino acid moves into the position of the former first tRNA, the third codon is read, and an aminoacyl-tRNA is matched to it. The amino acid chain is bound to the new amino acid on the third tRNA, and so the process proceeds, first matching codons with anticodons of the appropriate aminoacyl-tRNAs, then releasing used tRNAS, while elongating a chain of amino acids called a polypeptide chain. Each codon, with four possible bases (U, C, A, G) and ($4^3 =$) 64 possible combinations, binds to a unique tRNA; however, as there are only 20 different amino acids, different tRNAs, usually sharing the same first and second nucleotide in the anti-codon, are attached to the same amino acid variant (Table 1). Because multiple codons can encode the same amino acid, the RNA is said to be 'degenerate'. The elongation process ceases and termination begins when one of three codons, UAA, UAG, or UGA is read. These three nucleotide sequences do not have corresponding aminoacyl-tRNAs, and as a result, the unoccupied codon is bound to a termination factor (TF), which releases the polypeptide chains once the last amino acid is bound, and triggers the disassembly of the ribosome from around the mRNA transcript. The mRNA transcript is eventually degraded, and the resulting polypeptide chain undergoes post-translational processing, where the chain is folded and other bonds and superstructures are formed in order to construct a functional protein.

Transmissible Diseases

Synonyms

Infectious diseases; Communicable diseases

Definition

Communicable diseases are illnesses caused by microorganisms and transmitted from an infected person or animal to another person or animal. They may be transmitted directly through contact, or indirectly through contaminated food or water, or may be introduced into the body by animal or insect carriers. There are also human disease carriers: healthy persons who may be immune to microorganisms they carry, but represent source of transmission. For some infective organisms specific circumstances are required for their transmission, for example sexual contact in syphilis and gonorrhea, injury in the presence of infected soil or dirt in tetanus, infected transfusion blood or medical instruments in serum hepatitis.

Cross-References

Transplant Surgery

Definition

Transplant surgery addresses the removal of an organ, tissue, or blood product from a donor and surgical placement or infusion into a recipient. It is usually the ultimate treatment option for diseases or conditions where other medical treatments have not resulted in improvements but have caused organ failure or injury.

Transtheoretical Model

Synonyms

Stages of Change Theory

Definition

The Transtheoretical Model (TTM), also called Stages-of-Change-Theory, differentiates phases through which people, groups, or organizations go when changing – both for eliminating an old and for adopting a new behavior or condition. This theory provides a time dimension for the change process. The TTM of intentional behavior change describes change as a process that unfolds over time and progresses through six stages: precontemplation (not ready to take action); contemplation (getting ready); preparation (ready); action (overt change); maintenance (sustained change); and termination (no risk of relapse). In addition to these temporal stages, the transtheoretical model encompasses the concepts of decision criteria, self-efficacy, and change processes. The transtheoretical has been influential in research on smoking and has been extended to other health risk behaviors.

Trash

► Communal and Industrial Waste

Traumatic Brain Injury

Synonyms

Intracranial injury; Head injury

Definition

Traumatic brain injury (TBI) is a brain damage caused by a sudden trauma. The leading causes of death from TBI are injuries related to firearms (among persons aged 20–74), motor vehicles (among persons up to 19 years of age), and falls (among persons aged 75 and older).The parts of the brain that might be damaged include the cerebral hemispheres, cerebellum, and brain stem. Depending on the extent of the damage to the brain, the symptoms may range from mild to severe and the outcome may be complete recovery, permanent disability, or death. The abnormal states of consciousness that may result from a TBI are stupor, coma, persistent vegetative state, minimally conscious state, locked-in syndrome, and brain death.

Treatment Guidelines

Definition

A guideline is a statement or other indication of policy or procedure by which to determine a course of action. A medical guideline is a document with the aim of guiding decisions and criteria in specific areas of healthcare, as defined by an authoritative examination of current evidence (► evidence-based medicine). Guidelines usually include summarized consensus statements but, unlike these, they also address practical issues. Clinical guidelines briefly identify, summarize, and evaluate the best evidence and most current data about prevention, diagnosis, prognosis, therapy, risk/benefit, and cost-effectiveness. They then define the most important questions related to clinical practice and identify all possible decision options and their outcomes. Thus, they integrate the identified decision points and respective courses of action for the clinical judgment and experience of practitioners. Many guidelines place the treatment alternatives into classes to help providers in deciding which treatment to use.

Treatment of Infectious Diseases

► Therapy of Infectious Diseases

Treatment of Leprosy

Synonyms

Therapy of leprosy; Therapy of infections with mycobacterium leprae; Therapy of Hansen disease

Definition

There are two forms of leprosy, the paucibacillary (with a small amount of bacteria) and the multibacillary. In the case of paucibacillary leprosy, rifampin and dapsone are given for 6 months; if there is a break in therapy, the treatment should be recommenced where it broke off within a time interval of 6–9 months. Additional to rifampin and dapsone, multibacillary forms are treated with clofazimine; treatment should last for at least 2 years.

Treatment Monitoring

Definition

Treatment monitoring is implemented as part of ► infectious diseases control programs. It entails that the patient's treatment should be monitored, to make sure that an individual takes and carefully follows the prescription. The most typical example nowadays is the so called "DOTS" (Direct Observation of Treatment-Short course) for TB patients, which requires that the patient should be seen taking the tablets.

Treatment Options

► Management of Oral Diseases

Treatment Protocol

Synonyms

Clinical protocol; Medical guideline

Definition

A treatment protocol in health care represents a plan for a course of medical treatment. It aims to ensure the safety, efficiency and efficacy of a therapeutic intervention (medical guideline for further explanations).

Treatment of the Symptoms of a Disease

► Symptomatic Therapy

Trematodes

Synonyms

Infection with flukes

Definition

The symptoms, which are caused by various species of trematodes, depend on which organs are affected. Most frequently, flukes settle in the liver. There is a feeling of discomfort in the upper region of the abdomen due to swelling of the liver (hepatomegaly); hepatitis, inflammation of the gallbladder or the bile ducts or occlusions of the bile ducts can also occur. The liver trematodes involved are: the liver fluke (*Fasciola hepatica*), which is spread worldwide, the cat liver fluke (*Opisthorchis felineus*, causing ophisthorchiasis), which can be found in Russia, and the Chinese liver fluke (*Clonorchis sinensis*). Fasciolopsiasis is caused by the large intestinal fluke, which is predominantly found in Eastern Asia. The infection leads to abdominal symptoms like colicky pain, meteorism, nausea, vomiting, obstipation and diarrhea. Lung flukes are found in Eastern and Southeast Asia, tropical West Africa and Central and South America. These germs cause paragonimiasis, which is characterized by fever, cough, sputum production and chest pain.

Trial Protocol

Definition

The trial protocol is a planning document that has to be written prior to all trials or experiments involving human subjects, human materials or data. It has to describe the study design, including the choice of control groups (active comparator and/or placebo), all planned procedures/treatments (including dosage, timing and – if applicable – blinding), the criteria to be included or excluded (including prior and concomitant therapies, treatment compliance, necessary safety measures), the human subjects or materials or data involved in the described procedures and how they will be assigned to the treatment groups and the determination of the necessary sample size, the efficacy and safety variables to be evaluated, the primary and secondary endpoints as well as the statistical and analytical methods to be used to evaluate the data. Additionally, a risk–benefit evaluation of the planned project and a description of the quality assurance applied to the project data has to be included in the trial protocol.
The trial protocol is a major part of the documentation required to be evaluated by the competent authorities and ethics committees.

Tribal Characteristics

► Tribal Identity

Tribal Identity

Synonyms

Tribal characteristics

Definition

Tribal identity relates to characteristics of a tribe. The tribe builds its identity on the positive image of the collective self that is essential for the prosperity of the tribe. Tribe members are taught that their tribe is the smartest, the strongest, the most honest, etc.

Tribe

► Nation

Trich

► Trichomoniasis

Trichinellosis

► Trichinosis

Trichiniasis

► Trichinosis

Trichinosis

Synonyms

Trichiniasis; Trichinellosis; Infection with Trichinella nematodes

Definition

When insufficiently heated pork meat, contaminated with *Trichinella* larvae, is eaten, trichinosis can occur. In the intestines the larvae develop into adults (0.5 to 4mm in size), which release larvae into the mucous membrane of the bowel. The larvae then penetrate the intestinal wall, spread throughout the whole body and reach the muscles. The muscles concerned most frequently are the diaphragm and the muscles of the chest, the arms and the legs. Besides aching and swelling of the musculature, edema of the face and the eyelids can appear. Trismus (characterized by an impairment of the muscles responsible for breathing, chewing and swallowing) occurs. Possible complications are neurological symptoms, meningitis, encephalitis and cardio-circulatory failure. Inspections of meat are carried out in the food processing industry to avoid trichiniasis and, prior to consumption, meat should be sufficiently cooked.

Trichomoniasis

Synonyms

Infection with Trichomonas vaginalis; Trich; Ping pong disease

Definition

Trichomoniasis, which is caused by the flagellate protozoon *Trichomonas vaginalis*, is spread worldwide and primarily involves women. The risk of infection is about 70% in each case of unprotected sexual intercourse. Infections are asymptomatic in 50% of cases. The incubation period lasts 4–20 days. Detection of the pathogen is by culture. The main symptoms of the infection are vaginal discharge, itching, an inflammation of the urethra (urethritis) and painful micturition. Trichomoniasis can be treated with metronidazole.

Cross-References

► Sexually Transmitted Diseases

Trichuriasis

Synonyms

Infection with Trichuris trichiura; Whipworm infection

Definition

The whipworm, which is up to 5cm long, settles in the cecum and in other parts of the upper colon. Symptoms appear when there are more than 500 worms. These symptoms are abdominal pain, diarrhea and bleeding. The latter can cause anemia.

Tropical Diseases

Synonyms

Friedrich-Ebert-Krankenhaus GmbH,
Neumünster, Germany
hkorn80663@aol.com

Synonyms

Infectious diseases typical for tropical regions; Infectious diseases acquired on journeys; Contagious diseases acquired on travels; Travelers diseases

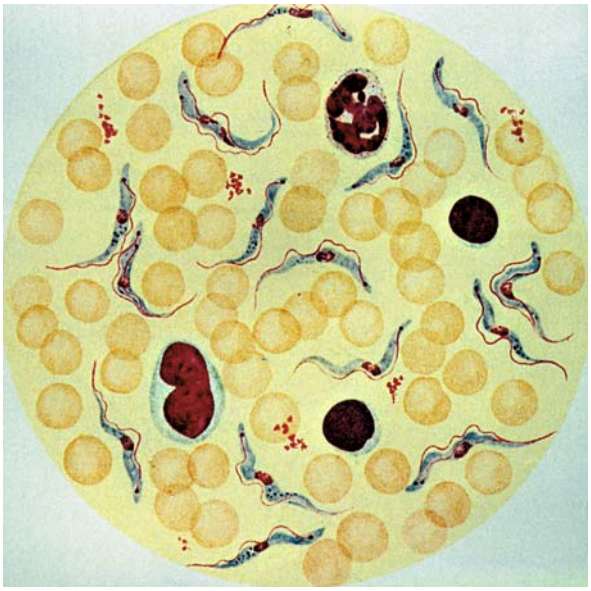
Definition

Tropical diseases are infectious diseases, which predominantly or exclusively appear in tropical or subtropical regions, due to the living conditions of the pathogens or their transmitters. With the increase in vacation travel of the populations of industrial countries, travel medicine has become a special medical subject. It aims at the registration of characteristics of different countries or regions – especially aspects of infection, in order to give recommendations to travelers concerning prophylactic and therapeutic measures. Moreover, travel medicine specialists can carry out, or at least support, diagnostic measures for, and therapy of, traveler's diseases.

Basic Characteristics

Characteristics and Transmitters of Tropical and Travelers Diseases

Pathogens can be spread worldwide or only be present in particular areas. Moreover, the virulence of one and the same germ can show regional variability. The spreading of microorganisms depends on different factors. On the one hand, the characteristics of the germ itself play a decisive role; on the other hand, the modes of transmission are important. If a pathogen is specialized to a particular host, it can only exist in the biosphere of that host. Some of the disease-transmitting insects are exclusively or predominantly found in tropical or subtropical regions. Among such insects are various mosquito species that, for example, transmit ► malaria, ► yellow fever, ► onchocerciasis, ► Japanese encephalitis or ► West Nile fever. Particular mites, which live in Southeast Asia and Northeast Australia, transmit Tsutsugamushi fever, predatory bugs, which are found in Central and South America, are responsible for Chagas disease. Tsetse flies transmit sleeping sickness (Fig. 1), which appears in Africa. Some mites live in the moderate climatic zone. Diseases, which are transmitted by these parasites, thus are primarily found in Europe, like ► tick-borne encephalitis (TBE) and ► Lyme borreliosis (LB). Parasitic infections, which are restricted to tropical regions, are – among others – bilharziasis (► schistosomiasis) and ► Guinea worm infection. A warm climate and bad hygienic conditions facilitate reproduction and spreading of many pathogens. Thus, several diseases primarily occur in warmer regions, like hepatitis A and typhoid or paratyphoid (typhoid fever). The number of cases of salmonellosis increases by 5–10% with every increase of surroundings temperature by 5°C. Climatic changes can cause a modification of the regional pathogens. Due to global warming, one has to fear a further spreading of germs, which up to now are only found in tropical regions.



Tropical Diseases and Travel Medicine, Figure 1 *Trypanosoma brucei rhodesiense* in blood slide with blue colored cytoplasma, red colored cell nucleus and undulating membrane; leucocytes; Giemsa stain; magnified 1100:1 (from Grönert and Koenig 1968) (Source: Lentze MJ, Schaub J, Schulte FJ, Spranger J (2002) Pädiatrie, Grundlagen und Praxis, 2nd edn. Springer, Berlin, p 823, Fig. 101.4)

Recommendations in Travel Medicine

Among the populations of industrial nations, there is a distinctive travel urge, and long-distance journeys have become very popular. Journeying in a number of countries involves great risk of contracting particular infectious diseases. To avoid unnecessary risks, it is essential for a traveler to be aware of necessary protective measures. Besides the family doctor, physicians, who are specialized in travel medicine, and institutions (like tropical institutes or public health departments), the internet provides plenty of information, which is useful for travelers (http://www.thirdworldtraveller.com/Disease/diseases_TropSAmer.html, http://www.cdc.gov/travel, http://dtg.org/). Recommended vaccinations, especially protection against tetanus, do not

only reflect the interests of the traveler, but are often a condition of entry to various countries; some countries demand a certificate of yellow fever vaccination (► yellow fever vaccination, active). Depending on the situation at the time of the journey, a TBE-vaccination (TBE-vaccination, active) may be recommended when traveling into endemic regions. As repeated vaccinations are necessary to achieve protection, sufficient time should set aside for completion of the immunization program. A great number of diseases are transmitted by the ingestion of contaminated food or polluted drinking water. Due to an accelerated reproduction rate of germs at higher temperatures, the risk of infection is greater in warm regions. Thus, a consistent compliance to hygienic rules is very important (► water quality and waterborne infectious diseases, ► food safety and fecal-orally transmitted diseases). Particular fecal-orally transmitted infectious diseases can be prevented by immunization: active hepatitis A-vaccination (► hepatitis A-vaccination, active) as well as an active typhoid-/paratyphoid vaccination (► typhoid fever/paratyphoid vaccination, active) is available. Tourists should be informed about further risks of infection in tropical and subtropical regions. When bathing in stagnant waters, infections with schistosomes (*Bilharzia*) (► schistosomiasis) or the Guinea worm can be transmitted. Several infectious diseases are transmitted by insects, especially mosquitoes. Thus, prophylactic measures, prophylaxis of insect bites, are of absolute importance. With regard to malaria, there are recommendations for chemoprophylaxis and therapy in the various endemic countries. If unexplained symptoms occur after a stay in a foreign country, particularly following a journey to tropical or subtropical regions, it is very important to inform the physician of that journey; thus tropical diseases can be taken into consideration, a diagnosis made more quickly and therapy started earlier. In this connection, cooperation with a specialized institute or laboratory might be necessary to allow the necessary diagnostic procedures to be carried out.

Hemorrhagic Fevers

Hemorrhagic fevers are infectious diseases that are accompanied by internal bleeding. By international agreement, they are named after the place of their first detection. Infections, which belong to this group of hemorrhagic fevers, are ► yellow fever, ► Ebola fever, ► Dengue fever, ► Lassa fever, ► Marburg fever and ► Hanta fever. The viruses causing hemorrhagic fever belong to four virus families: filoviruses, arenaviruses, flaviviruses and bunyaviruses. The infection is a zoonosis as, in general, it is transmitted from animals to humans. The main hosts are rodents and mosquitoes. Some of the hemorrhagic fevers can also be transmitted from one human to another. The pathogens are spread worldwide, but they are primarily found in Africa, South America and Southeast Asia. As they are easily transmitted and have high virulence, the viruses are very dangerous. Diagnostic measures have to be carried out in high security laboratories. Frequently, in developing countries, these measures, which are very expensive, are not available at all or cannot be performed in time. Thus a spread of the disease is easily possible. The average incubation time of hemorrhagic fevers is one week; in Ebola it ranges between 2 and 21 days. Characteristic symptoms are high fever, aching muscles and bones, joint pain, edema and an impairment of the function of the liver and the kidneys. Disruption of blood coagulation leads to internal bleeding. Possible neurological complications are pareses and cerebral seizures; moreover, shock and cardiocirculatory failure can occur. Lethality depends on the pathogen involved; in Ebola it can reach up to 80%. Quick therapy can considerably improve prognosis. Except for yellow fever, no vaccinations are available to prevent hemorrhagic fevers. Thus, prophylactic measures are of great significance. The best means of prevention is compliance to hygienic rules (► food safety and ► fecal-orally transmitted diseases), avoidance of contact with rodents (especially rats and mice) and prophylactic measures against insect bites. Furthermore, regulations concerning quarantine have to be followed. In hospitals contaminated material has to be disposed of properly, medical staff – and, if necessary, also relatives of the patient – have to wear protective clothing (gowns, glasses, gloves, mouth-nose mask). Careless behavior concerning contact with infected persons, even their dead bodies, is very dangerous; during funeral ceremonies pathogens have been transmitted by close contact with the corpse.

Black Plague (Black Death)

Black Death is a disease which has been feared since ancient times, and which had an important influence

on the history of mankind. Plague is mentioned in the Bible in the book of Exodus as one of the 10 calamities God inflicted on Egypt. There are numerous representations of the disease in art and literature. Disastrous plague epidemics repeatedly occurred, and they are especially well-known from the Middle Ages. Today, plague is primarily found in parts of Southeast Asia, Iran, Congo, Tanzania and Madagascar as well as in the tropical regions of Central and South America. Four forms of plague can be differentiated: ► bubonic plague, ► plague sepsis, ► lung plague and ► abortive plague. The disease is caused by the bacterium *Yersinia pestis*; in general, it is transmitted by the bite of an infected rat flea, the incubation period ranges between a few hours and 7 days. Lung plague can also be transmitted from one individual to another by droplets. Therapy consists of the administration of antibiotics, with streptomycin, chloramphenicol or tetracyclines + sulfonamides being effective. An immunization is possible, but due to various reasons, it is hardly ever indicated: disease protection rate is not sufficient, the vaccine is not tolerated well, immunity only lasts for 3–6 months, and the overall risk of infection is low. Important prophylactic measures include improving hygienic conditions and rat extermination. *Yersinia pestis* has been considered as of use in biological warfare.

Leishmaniasis

Leishmaniasis is caused by different flagellate protozoa of the genus *Leishmania* (Fig. 2). It is transmitted by sand flies. Various vertebrates can serve as hosts, primarily dogs, foxes and small rodents. Leishmaniae have not been found beyond the 45th degree of latitude or 800m altitude. Except for Australia, they have a worldwide spread and cause about 12 million cases of disease each year. Due to global warming, an increasing incidence has to be feared. The incubation period of leishmaniasis varies considerably; it ranges from one week to several months or even years. The most dangerous form is visceral leishmaniasis (► leishmaniasis, visceral) or "kala-azar" (Hindi for "black water fever"), which – without treatment – takes a lethal course. Further forms of the infection are cutaneous (leishmaniasis, cutaneous) (Fig. 3) and mucocutaneous leishmaniasis (► leishmaniasis, mucocutaneous). The strains of leishmaniae cannot be distinguished morphologically; differentiation requires immunological or molecular biological methods. Prophylactic measures to avoid leishmania infection include the use of repellents (N-diethyl-m-toluamide, DEET) and permethrin-impregnated mosquito nets.

Tsutsugamushi Fever

Synonyms

Infection with Rickettsia tsutsugamushi; Scrub typhus

Definition

Tsutsugamushi fever is caused by the bacterium *Rickettsia tsutsgamushi*, which is found in Central, East and Southeast Asia as well as in Northeast Australia, India, Pakistan and Oceania. The infection is transmitted by mites that live on low growing plants and in rice fields. Following an incubation period of 7–30 days, the infection starts with fever, headache and joint pain. Later a generalized rash develops. In severe cases, myocarditis or encephalitis can occur, the outcome might be lethal. Treatment consists of antibiotic administration, with tetracyclines and chloramphenicol being effective. The only prophylactic measure is to wear covering clothes to avoid mite bites.

Tuberculin Skin Test

Synonyms

Mendel–Mantoux test

Definition

The tuberculin skin test or Mendel–Mantoux test was developed by Felix Mendel (in Germany) and Charles Mantoux (in France) in 1909. By means of the test, immunologic reactions are checked to reveal a prior contact with tubercle bacilli. For the test 0.1ml (5 units) of purified tuberculin are injected intradermally at the inner side of the forearm near the wrist. After a time interval of 72 hours, the reaction is judged by a skilled person. An induration of >5mm means a positive result, or >15mm in the case of a prior BCG vaccination, respectively. Falsely negative results are possible if the tuberculosis infection is recent, there is an infection with another mycobacteria or virus, or if only 6–8 weeks has elapsed since active vaccination. If a person cannot show an adequate immune response due to AIDS or other forms of immunodeficiency, the tuberculin test can be negative as well.

Synonyms

TB; Mycobacterium tuberculosis complex; Consumption; Phtisis ($\pi\eta\tau\iota\sigma\iota\sigma$); King's evil; White plague; Wasting disease; Scrofula, Pott's disease

Definition

Tuberculosis (TB) is responsible for the most infectious diseases deaths worldwide. It is caused by mycobacteria and is most frequently transmitted by droplets. Tuberculosis primarily occurs under conditions of poor socioeconomic status, poor health or a compromised immunity.

Basic Characteristics

History

Tuberculosis is a very old disease. Remnants of skeletons from India and America, dated to 2000 BC, and Egyptian mummies from 3000–2400 BC, show evidence of tuberculosis. In 460 BC, the Greek physician Hippocrates described tuberculosis as the disease with the widest spread. The Greek term "phthisis" means consumption. In 1839, Johann Lukas Schönlein made clear that a variety of described symptoms were manifestations of the same disease. It was observed that there was a connection between insufficient nutrition and bad living conditions and the occurrence of TB. Due to this observation, tuberculosis sanatoria were founded (the first in Poland in 1859). With tuberculosis being understood as an infectious disease, the patients were isolated; furthermore, avoidance of contact with contagious sputum was recommended. To improve surveillance, tuberculosis became a notifiable disease in most of the European countries in 1880. In 1882, the German bacteriologist Robert Koch discovered that TB was caused by ► Mycobacterium tuberculosis. The technique of X-ray, invented at the end of the 19th century, became an important diagnostic measure. With the recognition that tuberculosis in cattle was similar to the disease in humans, untreated milk was identified as a source of infection. ► Pasteurization of milk considerably reduced the incidence of intestinal tuberculosis. The development of the ► tuberculin skin test, by Felix Mendel (in Germany) and Charles Mantoux (in France) in 1909, allowed people who had been in prior contact with the tubercle bacilli to be identified. In 1921, a vaccination against tuberculosis, the ► bacille clamette–guérin (BCG) vaccination, was introduced. By 1943, the first effective antibiotics against mycobacteria (streptomycin, PAC, conteben and neoteben) became available.

Significance of Tuberculosis (TB)

Since ancient times, tuberculosis has been of great significance for mankind. Without treatment, 50–60% patients die within 2–5 years. Due to their close contact living conditions in mass camps, tuberculosis was a common disease in soldiers of municipal armies during the 19th and 20th centuries. In the year 1815, tuberculosis was the cause of a quarter of all deaths; at the beginning of the 20th century every sixth person in France died from TB. The social relevance of tuberculosis was underlined by its representation in the arts, as in "Lady of the Camellias" by Alexandre Dumas and in "La Traviata" by Guiseppe Verdi. With the improvement of socioeconomic conditions in industrial countries (better living situations, improved hygienic standards and better nutrition), a decline of TB incidence was observed by the beginning of the 20th century. However, since the 1980s tuberculosis has gained significance again. On the one hand, multiresistant strains have developed; on the other hand, a dramatic increase in the incidence of tuberculosis has occurred along with the increased incidence of AIDS and the immunocompromised status of those infected with HIV. In 1993, the WHO declared tuberculosis a global emergency. TB has the highest worldwide mortality. Today, 95% of the disease appears in Asia, the South Pacific region and Africa. In the Western World, where the incidence of TB, once classified as low, has gained significance due to migration movements from countries with high TB-incidence. Worldwide, 8–9 million new TB-infections and 2 million deaths have to be expected every year. In new infections, 45% of the organisms can be detected in the sputum of infected people and TB has to be classified as highly contagious. One third of the world population is assumed to be infected with tuberculosis; 5–10% of these are expected to develop an active TB at sometime. With people between the age of 15 and 45 years being the most frequently involved, a great socioeconomic problem arises as this is the age-group with the highest productivity.

Classification and Different Forms of Tuberculosis

The term *Mycobacterium tuberculosis* complex summarizes infections that are caused by the mycobacteria *M. tuberculosis*, *M. bovis* and *M. africanum*. Other mycobacteria, except for *Mycobacterium leprae* (see below), are called ► MOTT (mycobacteria other than tuberculosis). Tuberculosis can be divided into ► primary complex of tuberculosis (when a person is first infected) and ► post primary tuberculosis (a fresh infection in a person who has had an earlier attack). Tuberculosis can also be classified as pulmonary and extrapulmonary. With a percentage of 85%, TB manifestation in the lungs is the most frequent form. Lymph node TB generally appears at the neck and in the armpits. In skin tuberculosis, there are small wounds, tears and warty, purulent efflorescences. Other organs that can be affected are: the intestines, the kidneys, the urinary tract, the meninges, the liver and the eyes. Moreover, the knees or other joints as well as bones, especially the spinal column, can be involved. Miliary tuberculosis is characterized by many small foci that can be spread over various organs. Tuberculosis can appear as open or closed. In closed tuberculosis, the pathogens are encapsulated and do not come into contact with the outside world. The open form of TB occurs when pathogens are present in the respiratory or the urinary tract and thus can be expelled by coughing or passed in the urine.

Transmission of TB

Tuberculosis can be transmitted from animals to humans; TB belongs to the zoonotic infections. Transmission from human to human occurs most frequently by droplets. The only contagious form is open tuberculosis. In this connection, is has to be mentioned that infection cannot only take place due to a breathing in of infectious droplets, but also by germ-containing dust particles or dried contagious secretions. Moreover, transmission is possible by ingestion (milk) or through the skin as a so-called inoculation tuberculosis. Other extrapulmonary forms of TB in general are caused by hematogenic spread of the pathogens.

Symptoms of Tuberculosis

In closed TB, the symptoms are nonspecific (tiredness, lack of appetite, loss of weight and swollen lymph nodes) and specific (a mild fever that occurs in the afternoon). Typical symptoms are: night sweats and a permanent little cough without much sputum. In open tuberculosis, cough persists for more than 3 weeks, with the cough causing chest pain; shortness of breath (dyspnea) can occur. The sputum of infected persons consists

of a yellow-greenish mucus and, in cases of lung damage, blood.

Diagnostics of TB

Diagnosis of tuberculosis can be done microscopically on direct preparation or by a culture of bronchial secretions (sputum) or gastric juice. The disadvantage of a culture is that the pathogens grow slowly, detection taking 4–6 weeks. However, fluid cultures with modern methods take 1–2 weeks. A direct identification can be done through PCR (polymerase chain reaction) or other molecular biological methods. Differentiation of species is achieved by gene probes. Diagnostic measures include X-ray and computed tomography (CT) of the lungs. X-ray of the chest shows round foci of calcification; in CT a moth-eaten pattern is seen.

Therapy of Tuberculosis (TB)

In earlier times, surgical intervention consisted of artificial collapse of the lung (pneumothorax) or the removal of parts of the lung (lobectomy) and, besides drugs and stays in health resorts, was the mainstay of treatment. Today, surgery is only resorted to in cases of resistant disease, which cannot be cured medicinally. Improving living conditions (hygiene, nutrition) still has an important supporting function regarding TB convalescence. As for medicinal treatment, uncomplicated and multiresistant tuberculosis (► medicinal treatment of uncomplicated tuberculosis; ► medicinal treatment of multiresistant tuberculosis) have to be considered separately. Therapy in uncomplicated TB lasts for 6 months; complicated TB 9 months, unless it coexists with HIV-infection when it can last up to 12 months; and multiresistant TB for 21–24 months. The medications have to be taken once daily. If the drugs are effective against the pathogen, the patient is no longer contagious after a therapy interval of 2 weeks.

Problems in TB-Therapy

The fight against tuberculosis proves to be extremely difficult. When there are increases in total populations, large refugee movements, regions of impoverishment with poor living conditions, insufficient nutrition, and lack of hygiene and medical care, the incidence of TB increases. Another complicating factor is the increasing spread of AIDS. As treatment of TB is long-lasting, a great deal of tolerance is required from patients. Despite having tuberculosis, many patients do not feel very ill. That is why they often do not see the need for consistent long-term therapy, especially when they lack any knowledge of the disease. This situation is most common in the developing countries, and elsewhere where there are difficult socioeconomic circumstances (homelessness, drug addiction). Due to ineffective therapy, there is a risk of resistant strains of mycobacteria developing. For various reasons, these resistant germs are a serious problem for a health care system. To begin with, therapy costs are much higher than those for standard therapeutics (about 100 fold); moreover, higher drug toxicity has to be expected. Last, but not least, the duration of treatment is much longer (21–24 months). Due to the longevity of the treatment, there is a high rate of dropout from therapy, resulting in a reduced healing rate and an increased mortality. To increase compliance with therapy, especially in the developing countries, observation of drug administration was established, the so-called DOTS (directly observed treatment, short-course)-strategy (http://www.who.int/tb/dots/en/).

Prevention of Tuberculosis (TB)

Besides isolation of infected persons and effective medical treatment, preventive measures, like good public health and conscientious surveillance, are of great significance. If control is neglected there is a risk of an increase in the incidence of TB. This was shown in the 1980s when there was a revival of tuberculosis in New York and in the 1990s a similar situation occurred in the former Soviet Union. In countries that are at high risk of tuberculosis, the BCG vaccination is a possible preventive measure. It has to be carried out quite early after birth. Unfortunately, the protective effect of the immunization is time-limited. Under certain circumstances, a ► chemoprophylaxis of tuberculosis can be indicated.

Leprosy

Leprosy is caused by *Mycobacterium leprae*. Like tuberculosis, it is a very old disease, which was already known in ancient times. The most famous historical description is found in the Bible (in the Old Testament). In antiquity, for fear of infection, people who fell sick with leprosy were isolated. However, the risk of infec-

tion is low as leprosy is only transmitted in long lasting close contact situations. Today, 75% of all cases of leprosy occur in South East Asia, primarily in India. Outbreaks of the disease increase in poor socioeconomic conditions (lack of nutrition, bad physical constitution, insufficient hygienic measures). Leprosy primarily involves the skin and the peripheral nervous system. Typical symptoms are a loss of hair, an impairment of sweat production and sensory disorders. Spots and nodules appear on the skin, indurations destroy the face and, later, other parts of the body. Due to damage of the nerve tracts, muscle weakness and muscular atrophy occur; eyelid closure disruption can lead to blindness. Due to the trophic impairment of the skin, even small injuries can cause abscesses and necroses, the enlargement of which can lead to mutilation of the extremities. People suffering from leprosy have always feared social isolation but, in 1984, WHO announced that antibiotic ► treatment of leprosy could cure the disease. Treatment lasts several months (http://dermatology.cdlib.org/92/reviews/leprosy/ishii.html).

In conclusion, tuberculosis is the infectious disease with the highest worldwide mortality. With the advent of AIDS, TB-incidence increased and the disease gained enormous significance. Poor socioeconomic conditions, a lack of knowledge and understanding of the disease, the necessity of long-term therapy and the development of multiresistant germs make the fight against tuberculosis – and against the other forms of mycobacterioses – very difficult.

Tuskegee

Definition

Tuskegee Study of Untreated Syphilis in the Negro Male, started in 1932. Its purpose was to record the natural history of syphilis in black males with the hope of justifying treatment programs. It was conducted without any ► informed consent and without explaining to the participants the real purpose of the study. Researchers told the men they were being treated for "bad blood," a local term used to describe several ailments, including syphilis, anemia, and fatigue. Although originally projected to last 6 months, the study actually went on for 40 years. Participants did not receive the proper treatment, even after the discovery of penicillin. For taking part in the study, the men received free medical exams, free meals, and burial insurance. It is referred to as one of the most shameful scandals against human dignity.

Twin Studies

Definition

Twin studies have been traditionally used to estimate the genetic contribution to disease development by comparison of monozygotic pairs, who share all their genes, with dizygotic twins, who share half their genes, using a concordance rate as a standard measure of similarity. Greater concordance rate in monozygotic twins compared to dizygotic twins favors genetic factors, while any discordance in monozygotic twins underline the role of environmental factors.

Two-Sided Test

Synonyms

Two-tailed test; Non-directional test

Definition

Test of statistical significance based on the assumption that the data are distributed at both sides of a central value.

Two-Tailed Test

Type I Error

Synonyms

Alpha error

Definition

A Type I error is an error when a true null hypothesis is rejected (i. e., it is concluded that a false alternative hypothesis is true). The likelihood of committing a Type I error is specified by the alpha (α) level a researcher employs in evaluating an experiment. The more concerned a researcher is about committing a Type I error, the lower the value of α the researcher should employ.

Cross-References

► Alpha Error

Type II Error

Synonyms

Beta error

Definition

A Type II error is when a false null hypothesis is retained (i. e., it is concluded that a true alternative hypothesis is false). The likelihood of committing a Type II error is represented by beta (β) and is inversely related to the likelihood of committing a Type I error.

Typhoid immunization; Enteric fever vaccination; Enteric fever immunization

Definition

The oral typhoid ► vaccine was developed between 1930 and 1943. It is administered in 3 doses at intervals of 48 hours, with a further dose given a year later if the risk of infection is still present. The vaccine is very well tolerated and provides a protection rate of 50–90%. A contraindication for the vaccination is immunodeficiency. As an alternative, a dead vaccine may be administered once parenterally. This vaccine is permitted after 2 years of age. Repeat vaccinations must be given after 3 years if the risk of infection is still present.

UK HTA Methodology Programme

Definition

The UK HTA Methodology Programme is a scientific program in the UK with the aim of promoting the identification, development, and use of appropriate research methods so that health and social care can be built on the best possible evidence base.

Ulcus molle

Synonyms

Chancroid; Chancroidal bubo; Inguinal bubo; Soft chancre; Simple chancre; Ducrey's chancre; Ducrey's disease

Definition

Ulcus molle, which is primarily found in tropical regions, is caused by the bacterium *Haemophilus ducreyi*. Following an incubation period of 3–7 days, a painful ulcer develops at the site of infection. Often, the disease spreads via the lymphatic vessels. Treatment consists of a single dose of azithromax orally or ceftriaxone intramuscularly. Possible alternatives are an oral erythromycin for a week or oral gyrase inhibitors for three days.

Uncertainty

Definition

With uncertainty, a condition is described in which the true value of a parameter is unknown because the knowledge or the methods for measurement are not perfect or not available. Uncertainty is distinct from variability, which describes known differences in a parameter. The uncertainty around the true value of a parameter in health economic analysis should be identified, measured, and described. Common instruments to describe uncertainty are deterministic and probabilistic ► sensitivity analysis.

Under-Five Mortality

Synonyms

Infant mortality; Child mortality

Definition

Infant and child mortality are deaths to children under age 1 and age 5. The infant ► mortality rate (IMR) is usually calculated by the number of deaths to infants under age one per thousand births in a given year. Despite its name, the IMR is not a rate; rather the

IMR approximates the probability of dying before age 1. Child mortality (often called under-five mortality) is measured as probability, or the proportion of children dying before their fifth birthday. Like the IMR, under-five mortality is often reported per-thousand births. Child mortality can be determined using mortality rates, where available, or indirectly based on census data. Although infant and child survivorship have greatly improved throughout the world, mortality remains high in many developing countries. In Africa, about 10 percent of all children born will die before their first birthday; by age 5 this proportion will exceed 17 percent.

Cross-References

Understanding of Good Health

Synonyms

Health literacy

Definition

Health literacy is defined in the context of Health Promotion by the WHO Heath Promotion Glossary as follows: Health literacy represents the cognitive and social skills that determine the motivation and ability of individuals to gain access to, understand, and use information in ways that promote and maintain good health. Health literacy is the degree to which individuals can obtain, process, and understand the basic health information and services they need to make appropriate health decisions. However, health literacy goes beyond the individual. It also depends upon the skills, preferences, and expectations of health information providers like doctors, nurses, administrators, home health workers, the media, and many others. Health literacy arises from a convergence of education, health services, and social and cultural factors.

Unintentional Injuries

Definition

WHO defines unintentional injuries as '… a bodily lesion at an organic level resulting from acute exposure to energy (this energy can be mechanical, thermal, electrical, chemical or radiant) interacting with the body in amounts that exceed the threshold of physiological tolerance. In some cases a injury results from an insufficiency of any of the vital elements (in drowing, strangulation or freezing). The time between exposure and the appearance of the injury is short.' In contrast, intentional injuries are caused by external violence or they are self-inflicted.

Union Formation

Definition

The process of forming a partnership with another individual through which there are socially recognized rights and responsibilities. In the context of family studies, these rights and responsibilities typically extend to issues of sexuality as well as social and economic resources (► social resources). In this context, a union may involve the partnership of a same sex or opposite couple. The formation process may involve a legal or political process such as marriage or a commitment ceremony. Cohabitation is typical in the union formation process; however, union formation may also occur among non-cohabiting couples.

Unit of Analysis

Definition

The decision regarding a unit of analysis should be based on statistical considerations and the nature of the particular problems under study. This decision must be made during the data evaluation stage. This includes identification of independent comparisons or estimates of relationship strength. The unit of analysis in research synthesis must be laboratories, studies, samples, or comparisons. *Laboratories as units*: in this case, the synthesist conducts a synthesis within a synthesis because a decision about how to synthesize results must first be made within laboratories and then between laboratories. *Studies as units*: if a single study contains information on more than one test of the same comparison, the synthesist can calculate the average results and use these to represent the study (median results can be used). *Samples as units*: this permits a single study to contribute more than one statistical test if the tests are carried out on separate samples of people. *Comparison as units*: in this case, identification of independent units of analysis uses the individual comparison. *Shifting unit of analysis*: this method permits each statistical test to be initially coded as if it were an independent event.

United Nations Organization; UN; UNO

Definition

The United Nations is an international organization with, as of 2007, 192 member states. It was founded on 24 October 1945 by 51 countries ratifying the United Nations Charter. The organization is made up of administrative bodies including the General Assembly, Security Council, Economic and Social Council, Trusteeship Council, Secretariat, and the International Court of Justice. It intends to maintain international peace and security, to develop friendly relations among nations, to cooperate in solving international economic, social, cultural and humanitarian problems and in promoting respect for human rights and fundamental freedoms as well as to be a center of harmonizing the actions of nations in attaining these goals. Several agencies, programs, and bodies strive to realize these purposes.

Basic Characteristics

Structure

The international organization consists currently of 192 member states, communicating in six official languages – Arabic, Chinese, English, French, Russian and

Spanish. It was founded in 1945 after the end of the Second World War hoping that it would solve future political problems among countries in a peaceful way. The constituting instrument of the United Nations is the ► United Nations charter which spells out the rights and duties of member states and establishes the organization's organs and procedures. The organization is made up of six principal organs – ► United Nations General Assembly, ► United Nations Security Council, Economic and Social Council, Trusteeship Council, ► International Court of Justice and Secretariat. The most important organ for deliberation is the General Assembly to which all members belong. The Security Council's main responsibility is the maintenance of international peace and security. It consists of five permanent members (China, France, Russia, the United Kingdom, and the United States) and ten rotating members that are voted by the General Assembly for two-year terms. However, the United Nations family additionally consists of several agencies, programs, and bodies. United Nations programs and funds, such as the ► United Nations Children's Fund (UNICEF) and the ► United Nations Development Programme (UNDP), as well as specialized agencies, such as the ► World Health Organization (WHO) and the ► United Nations Educational, Scientific and Cultural Organization (UNESCO), aim at supporting economic and social endeavor.

The headquarters of the organization is in New York City but its land and buildings are international territory. In addition, several offices exist all around the world. The organization is financed from contributions by the member states.

Purposes

According to the Charter, the United Nations aims at the maintenance of international peace and security, the development of friendly relations among nations, the cooperation in solving international economic, social, cultural, and humanitarian problems and in promoting respect for ► human rights and fundamental freedoms and at being the centre for harmonizing the actions of nations in achieving these tasks.

Achievements

Human Rights The creation of a comprehensive body of human rights law is one of the great achievements of the United Nations. By the adoption and proclamation of the Universal Declaration of Human Rights in 1948 a basis was established for a universal and internationally protected code of human rights. Numerous expansions led to improvements creating a broad range of internationally accepted rights. Actually, the United Nations still continues to strengthen and coordinate the protection and promotion of them around the world.

Humanitarian Action For the first time the United Nations coordinated ► humanitarian relief operations in Europe after the end of the Second World War. Today, they are a major provider of emergency relief and longer-term assistance. In 2002 alone, the Office for the Coordination of Humanitarian Affairs launched 24 inter-agency appeals collecting more than $ 4.2 billion to support 35 million people in 18 countries and regions. Leading institutions to deliver humanitarian assistance are the ► United Nations High Commissioner for Refugees (UNHCR), the ► World Food Programme (WFP), the United Nations Children's Fund (UNICEF), and the United Nations Development Programme (UNDP).

The United Nations High Commissioner for Refugees supports every year millions of ► refugees, asylum seekers, internally displaced persons, stateless persons, and others of concern. The agency endeavors to protect them and to resolve their problems. It assists these people in finding safe refuge in another state. By the end of 2005, 20.8 million people had received help.

The World Food Programme saves millions of lives. It supports victims of wars and natural disasters with relief and reconstructive operations. The program helps people who are unable to produce or obtain enough food for themselves and their families. The WFP food aid reached 96.7 million people in 82 countries in 2005.

The United Nations Children's Fund pays particular attention to children. It strives to ensure the protection of children's rights and to expand their opportunities to reach their full potential. In cooperation with other ► humanitarian agencies, such as the ► International Red Cross and Red Crescent Movement, the fund provides children with drinking water, food and medicine. It provides vaccinations for children and organizes the buildings of schools. In 2005 the fund carried out programs for children and their families in 157 countries, areas, and territories.

However, the United Nations do not only help immediately after disasters. In form of the United Nations Development Programme the organization also assists disaster-prone countries for extended periods. The program is mandated to fight poverty. It fosters security, economic growth, good governance, and respect for human rights hoping to reduce man-made disasters.

The work of the World Health Organization (WHO) for the delivery of humanitarian assistance is essential as well. It concentrates on the health needs of people in poverty and misery. The organization arranges and coordinates appropriate relief operations, including measures to combat disease, especially infectious disease, provisions of vaccinations, and appropriation of drugs and medical equipment. One of the achievements the WHO is most proud of is the eradication of smallpox in the late 1970s. The organization coordinated the campaign to eradicate the deadly disease between 1967 and 1979. For the first and, so far, only time a major infectious disease has been completely eliminated. At the moment, the WHO is trying to eradicate polio worldwide. So far the Global Polio Eradication Initiative has reduced the number of cases of polio by more than 99%. In 2005 there were just a few hundred cases reported.

International Peace and Security One of the primary purposes of the United Nations is to maintain international peace and security. Since its foundation, the organization has helped to end numerous conflicts. It promotes activities of prevention and peacemaking, peacekeeping, peace-building and disarmament. As of February 2007, there have been 61 peacekeeping operations since 1948. For the last years more conflicts have taken place within, rather than between, states. Confronted with this problem, the Security Council has established complex and innovative peacekeeping operations. However, faced with the immense problems within some countries, the UN were unable to establish any operations between the years 1995 to 1997. More recently, new missions have shown just how important the work of the United Nations is in solving conflicts peacefully.

Criticism

The achievements of the United Nations demonstrate that the organization has improved the lot of many people and that conflicts can be resolved peacefully through their work. However, there are things that need criticizing and improving.

The weak spot of the United Nations is its lack of inherent authority. Due to the structure of the Security Council, the organization is often unable to act in a clear and decisive way when confronted with a crisis. The five permanent members often use their veto power to avert condemnation and sanctions against themselves or their friendly nations. Thus, many a time no action can be agreed upon. This vetoing system of the permanent members gives them powerful privilege and, therefore, sometimes, objective decisions cannot be reached.

Conclusions

It is difficult to meet all demands made on a world organization. The facts show that the United Nations have achieved a lot; however, theoretically, even more could be achieved. In the past, some good intentions have failed against the forces of human nature; it appears that for the most part people try to get the best for themselves forgetting the needs of others. For instance,

every year people still die in the developing countries as a result of hunger or diseases that are not treated sufficiently, whereas, in the industrialized countries, surplus food is thrown away every day and drugs are produced in abundance. In the light of such circumstances, the idea that some day these problems will be solved and that all people will live in peace seems indeed unrealistic. However, like in the United Nations, it is important that efforts to solve these contradictions continue.

Additionally, the task of the United Nations to find acceptable solutions for all is complicated by the different opinions and views of the many nations involved. The organization will still be faced with huge challenges in the future. Therefore, new ideas, further improvements, and reforms are necessary to optimize the work of the United Nations and to realize the concept of a functioning world organization.

United Nations Charter

Synonyms

United nations organization charter; UN charter; UNO charter

Definition

The United Nations Charter is the constituting instrument of the United Nations appointing the rights and obligations of member states and establishing the organization's organs and procedures. It was signed at the United Nations Conference on International Organization in San Francisco on 26 June 1945 by 50 of the 51 original member states (Poland was not represented at the conference and signed it later) and came into force on 24 October 1945, after being ratified by China, France, the Soviet Union, the United Kingdom, the United States, and a majority of other signatories. By 2007 192 nations had ratified it.

United Nations Childrens' Fund

Synonyms

United nations international childrens' emergency fund; UNICEF

Definition

The United Nations Children's Fund is part of the United Nations family providing long-term humanitarian and developmental assistance to children. Among other things, it strives to achieve the immunization of all children against common childhood diseases and their proper nourishment. In addition, it works to prevent the spread of HIV/AIDS and it promotes girls' education.

Currently, the Fund supports children in 191 countries through country programs and National Committees.

United Nations Development Programme

Synonyms

UNDP

Definition

The United Nations Development Programme is the United Nations' global development network providing countries with knowledge, experience, and resources to help people build better lives. It fosters security, economic growth, good governance, and respect for human rights. Furthermore, the organization publishes an annual Human Development Report to measure and analyze developmental progress.

United Nations Educational, Scientific and Cultural Organization

Synonyms

UNESCO

Definition

The United Nations Educational, Scientific and Cultural Organization are a specialized agency of the United Nations founded on 16 November 1945. It promotes international cooperation in the fields of education, science, culture, and communication. It is financed by assessed contributions from its member states and voluntary contributions from donors.

United Nations General Assembly

Synonyms

United nations organization assembly; General assembly; UN general assembly; UNO general assembly

Definition

One of the six principal organs of the United Nations is the General Assembly. It is composed of representatives of all member states making it the most important organ for deliberation. Every member state has one vote. Decisions on important questions, such as those on peace and security, admission of new members and budgetary matters require a two-thirds majority. For decisions on other questions a simple majority is sufficient. The functions and powers of the organ are set out in the Charter of the United Nations. The General Assembly is empowered to make only non-binding recommendations. However, they initiated actions that have improved the situation of millions of people.

United Nations High Commissioner for Refugees

Synonyms

UNHCR

Definition

The United Nations High Commissioner for Refugees is an agency of the United Nations mandated to lead and coordinate international action to protect refugees and resolve problems of refugees worldwide. It supports everyone in seeking asylum and finding safe refuge in another county – with the option to return home voluntarily, integrate locally or to resettle in a third country.

United Nations Security Council

Synonyms

United nations organization security council; Security council; UN security council; UNO security council

Definition

The United Nations Security Council is one of the six principal organs of the United Nations charged with maintaining peace and security among nations. It is made up of 15 member states. Five of them, China, France, Russia, the United Kingdom, and the United States, have permanent seats. The ten temporary members are voted by the United Nations General Assembly for two-year terms. Decisions are made by an affirmative vote of at least nine of the 15 members. In addition, the permanent five hold veto power over substantive but not procedural resolutions. That means that decisions on substantive matters require the votes of all five permanent members. In contrast to the other organs which only make recommendations, the United Nations Security Council has the power to take decisions, which member states are obligated to act on under the Charter.

Universalist Communitarians

Definition

Different approaches guide public health stakeholders in dealing with ethical dilemmas. Universalist communitarians believe in a single true form of good society and its associated virtues. They believe that certain behaviors and cultural patterns, can be justified by their health consequences (e. g. not smoking in public) or regarded as rights (e. g. female literacy), and should be promoted in all societies, regardless of local cultural norms, as good in themselves, as part of a superior form of social organization.

Universal Prevention of Mental Disorders

Definition

Interventions that are targeted at the general public or to a whole population group that has not been identified on the basis of increased risk.

UN Millennium Declaration

Definition

International act adopted by 189 world leaders at the Millennium Summit in 2000. It contains plans of action to reach Millennium Development Goals.

Up-Coding

Synonyms

Up-charging

Definition

Up-coding describes the fraudulent medical practice of shifting a patient's ► Diagnosis Related Group to one that yields a greater ► reimbursement from the health insurance. This practice may also be used by other professional providers of health care as a method to maximize revenues for their health care services. An example of up-coding would be when physicians intentionally use a higher reimbursement rate code than the actual health status of the patient allows.

Urban Environments

GORICA SBUTEGA-MILOŠEVIĆ
Institute of Hygiene and Medical Ecology, Faculty of Medicine, University of Belgrade, Belgrade, Serbia
sbutege@drenik.net

Synonyms

Environmental hygiene; Environmental health; Housing

Definition

► Environmental health comprises those aspects of human health, including quality of life, that are determined by physical, chemical, biological, social, and psychosocial factors in the environment. It also refers to the theory and practice of assessing, correcting, controlling, and preventing those factors in the environment that potentially can adversely affect the health of present and future generations.

Environmental health, as used by the World Health Organization (WHO) Regional Office for Europe, includes both the direct pathological effects of chemicals, radiation, and some biological agents, and their effects (often indirect) on health and well-being of the broad physical, psychological, social, and aesthetic environment, which includes housing, urban development, land use, and transport.

Environmental hygiene is defined as practical prevention and control measures used to improve the basic environmental conditions affecting human health; for example, clean ► water supply, human and animal waste disposal, protection of food from contamination, and provision of healthy housing, all of which are concerned with the quality of the human environment.

Basic Characteristics

Housing culture is a group of characteristics which represent the housing of a family, group of people, or population.

The types of housing culture are: semirural, rural, semiurban, urban, and ultra-urban. Urban housing is characterized by high level technical equipment with a central connection to electrical and water supplies, as well as heating. It creates the necessity to make some sort of specialized equipment for watching children, food preparation, laundry, ironing, etc.

It is important to notice that proper housing is important for health and well-being of the individual or family. Living on higher floors or living in inappropriately constructed and ill-maintained buildings (for example with ► humidity walls > 3%) could seriously affect the health of inhabitants.

The need for hygienic housing conditions includes a requirement for 30 m^3 of fresh air per hour for adults. This means that the height of the flat should be 2.8 m, or at least 2.6 m. It is necessary to provide 16 m^2 of room per individual (6 m^2 for bedrooms, 6 m^2 for dining rooms, 1.5 m^2 for the kitchen, 1.5 m^2 for sanitary facilities and 1 m^2 for communications per tenant).

The maximum level of ► noise from sources in the building that is allowed in flats with closed windows is 35 dB(A) during the day and 30 dB(A) during the night. The flooring in bedrooms and dining rooms should be parquet, while kitchen, bathroom and supporting rooms should have terrazzo material flooring, which is a good isolator and easy to clean.

It is important to have good ► illumination, both natural and artificial, with a photo-coefficient (relation between the surface of window glass and the ground) between 1:6 and 1:8 in flats. The requested illumination of resi-

dential environments range from 50 to 600 lx, depending on the purpose of the room (the bedrooms and bathroom should be 50–60 lx, the library and workingrooms should be 300–600 lx).

The children's room must have enough space for children to play or learn if they are schoolchildren. Children of different sexes should also have separate rooms: if they are of the same sex, there should not be more than two children in the same room.

Another important aspect of environmental hygiene is climate control (► climate and microclimate). Many facilities use air-conditioning or similar control systems to maintain proper ventilation, humidity, and temperature control. In facilities without air-conditioning, windows that can open from the top and bottom provide cross ventilation. In addition to maintaining a healthy climate, good ventilation is necessary in controlling and eliminating disagreeable odors. In cases where airflow does not control odors, room fresheners should be used discretely. Objectionable odors such as bad breath or perspiration are best controlled by proper personal hygiene and clean clothing.

All rooms should correspond according to needs and purposes, sufficiently correlated to number, arrangements, structure, and equipment.

► Sick building syndrome is also important as a consequence of modern construction of buildings with inappropriate ventilation and/or lamination as well as noncritical use of synthetic materials in interior design. This syndrome is frequently connected with increased incidence of respiratory infections, cardiovascular diseases, and mental disorders.

Urbanization

Definition

Urbanization refers to the process by which urban areas increase over time in population density and/or size. It can be planned or unplanned. Planned urbanization occurs when the urban infrastructure (houses, schools, public parks, sustainable drainage systems, roads etc.) is installed before urbanization occurs. The infrastructure can be extended as the need arises. Unplanned urbanization leads to overcrowding, establishment of shanty-towns, and a breakdown of existing infrastructure. These factors, in turn, can aggravate poverty and health problems.

U

Ureaplasma urealyticum Infection

Definition

Ureaplasma urealyticum is a bacteria-like germ without a cell wall, which belongs to the group of mycoplasmas. The incubation period lasts 10–20 days. *Ureaplasma* is one of the germs causing non-specific urethritis (NGU). Furthermore, this pathogen can lead to prostatitis and an inflammation of the pelvis of the kidney. During pregnancy, chorioamnionitis can be caused. In neonates disseminated infections are possible with the development of pneumonia, meningitis and abscesses. Adhesions in the urogenital tract can cause infertility.

Infections with *Ureaplasma urealyticum* can be treated with macrolides, tetracyclines or clindamycin.

Urinary Infections

Definition

The urinary tract is the most common site of hospital infection, accounting for more than 40% of the total number reported by acute-care hospitals. The CDC (► Centers for Disease Control and Prevention) has developed a set of ► surveillance definitions that aim to distinguish hospital-acquired from community-acquired infections. Hospital urinary tract infections include symptomatic urinary tract infection, asymptomatic bacteriuria, and other infections of the urinary tract. Urinary catheterization is the most common risk factor for these infections. Hospital urinary tract infections are caused by a variety of pathogens, including *Escherichia coli, Klebsiella, proteus*, enterococcus, *Pseudomonas, Enterobacter, Serratia*, and *Candida*. The origin of these microorganisms is endogenous (the patient's flora) in two thirds of cases, but they can also be acquired by cross-contamination from other patients or hospital personnel or by exposure to contaminated solutions or non-sterile equipment.

Urology

Definition

Urology is the medical and surgical specialty that deals with the urinary system and male reproductive organs. Urologists use bladder catheters, cystoscopes (to view the inside of the bladder), and various diagnostic imaging techniques. They treat prostatic disorders, they perform vasectomies, and they surgically remove stones in the urinary tract as well as cancers of the kidneys, bladder, and testicles.

Utilitarianism

Synonyms

Rationing by exclusion; Consequentialism

Definition

Utilitarianism is a form of consequentialism. Proponents of utilitarianism appraise an action based on an analysis of its consequences. The criterion for appraisal is utility, implying the goal of maximizing the net-benefit for the highest number of people. Some utilitarians believe that wellbeing will best be achieved by following each individual's preferences, while other utilitarians favor planning for rational resource allocation. Utilitarianism is often accused of leading to unfairness because it does not offer any principle of justice beyond the basic idea that everyone's happiness counts equally. Health planning that is based on the principle of utilitarianism may lead to "rationing by exclusion" when health problems are neglected because they affect only a minority.

Different approaches guide public health stakeholders in dealing with ethical dilemmas. Those who follow an utilitarian approach would look at the consequences of a decision, specifically at its effect on the sum total of individual well-being, or at the greatest happiness of the greatest number of people.

Utility

Synonyms

Use of resources

Definition

Different approaches guide public health stakeholders in dealing with ethical dilemmas. The concept of utility implies that actions and the use of resources should do the greatest good for the greatest number of people.
Utility is equivalent to the satisfaction, happiness, or level of welfare of individual consumers. It is a function of various combinations of consumer goods. Utility is an important microeconomic concept because consumers are assumed to maximize individual utility by choosing between bundles of consumer goods within their individual budgetary constraints.

UVI

► UV Index

UV Index

Synonyms

Ultraviolet index; UVI; Global solar UV index

Definition

The UV index is a measure of the UV ► radiation level on the Earth's surface. A higher UVI numerical value means that a proportionally higher level of dangerous UV radiation reaches Earth's surface and, in other words, has a greater potential for damage to the skin and eye. The UVI was formulated on account of the ability of UV radiation to cause adverse health effects, such as erythema, in humans. A calculation for UVI was proposed in 1995 by the World Health Organization in collaboration with the World Meteorological Organization, the United Nations Environment Programme, and the International Non-Ionizing Radiation Committee of the International Radiation Protection Association. The value of the UV index may be in a range between zero (only at night time) and even up to 20 depending on Sun elevation, cloudiness, latitude, altitude, stratospheric ozone level, and ground UV reflection. UVI (and UV radiation level) always reaches a maximum around mid-day (solar noon) and, for example, in New Zealand the maximum summer value is about 12 (1 or 2 during the winter period), but in Northern latitudes rarely exceeds 8. In countries close to the equator and at high altitude, tropical sites, UVI can reach up to 20. UVI is an integral part of the weather forecast in newspapers, TV, and radio in many countries, allowing people a simple and useful way to plan everyday activities and personal protective measures. The most effective means of protection is staying out of the sun during the hours around solar noon, combined with appropriate clothing, broad hats, and sunglasses with UV filters and side panels. Five categories of UVI, their numerical values, and recommended protective measures are as follows: (a) *Low* (UVI range 0 to 2)—free exposure for the average person because danger is minimal; (b) *Moderate* (3 to 5)—some protective measures are needed such as appropriate clothing, hat, sunglasses, and sunscreen with an SPF of at least 15; (c) *High* (6 to 7)—sun exposure during the hours around midday should be minimized, and protective clothing, sunglasses, and sunscreen should be worn; (d) *Very high* UVI (8 to 10); and (e) *Extreme* UVI (11 and more)—extreme protective measures are needed, such as avoiding the Sun as much as possible.

Vaccination

Synonyms

Immunization

Definition

Vaccination refers to means of producing immunity against pathogens, such as viruses and bacteria, by the introduction of live, killed, or altered antigens that stimulate the body to produce antibodies against causative agent.

Vaccination is a protection of susceptible individuals from infectious diseases by administration of a living modified agent (measles), a suspension of inactivated microorganisms (whooping cough), inactivated toxin (tetanus) or by other various antigens prepared in specific procedures. The original use of the word was related to vaccination against smallpox. This was the first method of preventing a lethal disease by immunizing humans. It was introduced by Edward Jenner (1749–1823). This discovery led directly to the worldwide eradication of smallpox.

Immunization against 15 diseases is recommended for young children and adolescents: hepatitis B (HepB); diphtheria, tetanus, and pertussis, given together as DTaP; *Haemophilus influenzae b* (Hib); poliomyelitis (IPV); pneumococcal infections, including pneumonia, meningitis, and bacteremia (PCV and PPV); ► measles, mumps, and rubella, given together as MMR; chickenpox (varicella, Var); hepatitis A (HepA); ► influenza; and *Neisseria meningitidis* (meningococcal meningitis). Immunization against diseases such as yellow fever may be necessary before traveling to some countries.

Vaccination, Active

Synonyms

Immunization, active

Cross-References

► Immunization, Active

Vaccination Against Tuberculosis

► Bacille Calmette-Guérin (BCG) Vaccination

Vaccination, Passive

► Immunization, Passive

Vaccine

Definition

A vaccine is a dilution or suspension, which contains pathogens/antigens. It is introduced into the organism with the aim of making it unsusceptible to the disease in question – in other words, to immunize it. This is achieved through the build up of antibodies. One must distinguish between vaccines made from living or dead germs, from detoxified toxins (toxoid, anatoxin), or from antigen extracts. The latter contain immunologically potent subunits of the pathogen. Different vaccines can be combined. The most important vaccines, classified according to the type of vaccine, are:

1. Those made from living, weakened pathogens, i. e. pathogens which no longer cause illness, against:

yellow fever, polio, anthrax, plague, small pox, rabies and tuberculosis.
2. Those made from dead pathogens against: cholera, typhus fever, influenza, pertussis (whooping cough), polio, measles, rubella (German measles), typhus and paratyphoid fever.
3. Those made from detoxified (rendered harmless) pathogen toxins, against: diphtheria and tetanus.

Validity Measurement

Definition

Validity can be considered as the extent to which a measurement, test, or study measures what it purports to measure. Three major types of validity are content, criterion and construct validity. Content validity indicates whether the measuring instrument covers all areas under investigation. Criterion validity is empirically based, and relates to the correlation of the instrument with external criteria. Construct validity is applied when there is no adequate gold standard, existing instruments, criteria or other data against which results can be compared. The correlation coefficient between measures and criterion variable is sometimes referred to as validity coefficient. Construct validity assesses the existence of an association between a measure and other observed variables in a way that is consistent with the theory defined by the construct and its measurement.

Validity Study

Definition

The validity of a study is the degree to which the inference drawn from a study is justified. Internal validity is the degree to which the effect observed in a study can be attributed to the hypothesized effect under investigation. It is related to the direct correspondence between the experimental treatment and the experimental effects. Internal validity is usually highest in large randomized controlled trials, and decreases with decreasing scientific rigor. External validity (generalizability) is the degree to which the results of study hold true for situations other than those pertaining to the study, in particular in routine clinical practice. Construct validity refers to the possibility that the operations that are meant to represent a particular cause or effect construct can be constructed in terms of more than one construct. Statistical conclusion validity refers to the power and appropriateness of the data analysis technique.

Value, Human Life – Utilities

FRANZ HESSEL
Health Economics Outcomes Research,
Sanofi-Aventis Pharma GmbH, Berlin, Germany
franz.hessel@sanofi-aventis.com

Synonyms

Cost-utility analysis, preferences

Definition

The value of health gain or the value of human life can be expressed using the human capital approach, using a social preference approach, or by determination of the willingness to pay.
In health economics, utility is defined as a quantitative expression of individuals' preferences for (desirability of) a defined particular health state under conditions of uncertainty.

Basic Characteristics

Value of a Human Life

Discussions about the interpretation of the results of economic evaluation studies (► health economic evaluation) and the appropriate ► threshold value up to which a new health care technology should be reimbursed by public payers also opens the dispute about the value of a human life. There are three main approaches to estimate the value of health gain with respect to the value of human life.
The ► human capital approach (the human capital approach is also used to estimate indirect costs; see also ► labor market) estimates the maximum expected future earnings based on the average achievable gross income. Heavy criticism was made of the use of this measure for valuing a human life as it implies that the value of a human life is reduced to their productivity from a national economic point of view. This approach

discriminates against major parts of the population that do not work for payment such as children, housewives, the unemployed, the elderly, and people with chronic illnesses or disabilities. A second so-called social decisions approach uses decisions made in the public sector, like reimbursement decisions or legal acts. Values not necessarily measured directly and not necessarily from the health care sector are transferred to the health care system for the purpose of decision making by assuming a consistency and transferability. There are some major problems with transferring general findings ► resource allocation. The results are mainly useful for demonstrating inconsistencies in public decision making and creating hypotheses (Culyer 2005) rather than making resource allocation decisions in health care. The third approach is based on empirically created data on people's preferences. This can be done directly, by assessing the maximum amount an individual is willing to pay to acquire a defined good or to avoid a prospective loss (► willingness to pay). To estimate the value of a human life, the willingness to pay for a life year or a life-saving health care intervention can be determined directly or indirectly e. g. from surveys about the value placed by individuals on reduction of the risk of death due to a particular hazard. The third approach is currently regarded as the most appropriate as it reflects the individual preferences and uncertainty that is characteristic of such estimations (Culyer 2005).

Comparing the different approaches and the results of different studies using the same approach, an extremely wide variation is observed, from a few thousand EURO up to a few hundred thousand EURO. In surveys, a discrepancy between social valuations and decisions and individual preferences was demonstrated with regards to health changes (Gyrd-Hansen 2004). Currently, the methodological approaches are in an early stage of development and valid results will not be available for many years, if at all.

Health-Related Quality of Life

More abstractly, the value of a human life can also be described by the quality of the lifetime. Health-related quality of life is a theoretical construct combining a catalog of measures to evaluate the values, attitudes, perceived levels of satisfaction, and general wellbeing associated with specific health conditions or life as a whole from an individual's perspective. Health-related quality of life includes at least two of a number of dimensions, e. g. physical functioning, mental health, pain, cognitive functioning, etc. To create a measure for health-related quality of life, disease-specific or generic questionnaires are developed, tested, and validated according to the psychometric principles of test theory. To include health-related quality of life as an outcome measure in health economic evaluation studies, it is necessary to use an instrument that gives an index measure aggregating the different dimensions of health-related quality of life to a single number, usually the percentage of limitation compared with a perfect health state. The most common health-related quality of life instruments for health economic evaluation studies are the EQ-5D, the SF-6D, and the Health Utility Index (HUI). (Berger et al. 2003; Spilker 1996).

Utility Concept

In general, utilities are numbers or percentages that represent the strength of an individual's preference for defined health states under uncertainty. The utility scale give a utility of 0.0 for the worst possible health state, usually death, and a utility of 1.0 for complete perfect health. Utilities can be measured by direct techniques such as ► standard gamble or ► time trade-off. Another way to estimate utilities is to use health-related quality of life index instruments. In technical terms, only standard gamble involves ► uncertainty and therefore measures true utilities – the other methodological approaches measure values – but the term utility usually covers both preferences: utilities and values (Berger et al. 2003; Sculpher et al. 2005; Culyer 2005).

By far the most widespread and prominent utility measure is the quality-adjusted life year (► QALY). The other utility concepts of ► healthy years equivalent (=HYE) (Mehrez and Gafni 1991) and ► saved young live equivalent (SAVE) (Nord 1992) have not been implemented for practical use in decision making so far. The QALY is a generic measure of utility that combines both the quality and the quantity of life generated by health care interventions. A year spent in perfect health is, by definition, one QALY, and a year spent in less than perfect health with a lower health-related quality of life is worth less than one QALY, depending on the decrease of quality of life. Death or the poorest imaginable state of health is defined as "0". Aggregating the quality of life and the remaining lifetime, it has to be

taken into account that the quality of life fluctuates over time rather than remaining at a constant level. Therefore, either the quality of life has to be measured with ► generic instruments such as the EQ-5D, the health utility index, or the SF-6D repeatedly over time (the course between the point measures has to be estimated), or the quality of life over the total health state path is estimated at one time using techniques such as standard gamble or time trade-off (Dolan 2000).

There is a certain amount of controversial debate about the empirical robustness of the results of such measures and ethical implications of their possible use in resource allocation decisions. One central assumption of the concept is that a QALY is a QALY no matter if it is achieved mainly by improvement of quality of life or solely by an increased life expectancy, and no matter if it is achieved by saving the lives of a small number of children or a much larger number of elderly people. Furthermore, there are some practical constraints. It is certainly impossible to estimate the costs per QALY gained for all possible health care interventions at a time for a single health care system. However, it is feasible to use the QALY concept for a limited number of reimbursement decisions, as is current practice of the ► NICE in the UK.

Cost-Utility Analysis

Utilities offer a patient-orientated generic measure, which in theory allows comparison of the effects of all possible interventions influencing the health state. Cost-utility analysis can be seen as a special form of cost-effectiveness analysis in which the outcome measures are the units of utility gained. To use utilities as an outcome measure in health economic evaluations, the utilities of different health states have to be ranked on a ratio scale (Sculpher et al. 2005; Gold et al. 1996).

QALY League Table

One way of presenting the results of several cost-effectiveness or cost-utility analyses for decision makers is a ► league table. QALY league tables rank health technologies and interventions according to their relative cost-outcome ratio, starting with the lowest cost per QALY gained and ending with the most unfavorable cost per QALY ratio. In theory, league tables could be used by decision makers to allocate resources within a limited budget e. g. by reimbursing only technologies with costs per QALY gained below a defined threshold. There are major arguments for not making decisions about resource allocation in health care solely on the basis of league tables (Bleichrodt et al. 2004). The methodology can never be completely standardized and there are a number of factors that influence the absolute result of cost-effectiveness estimations, such as the measurement of utilities, the ► perspective taken, and methodological aspects of the ► costing process. The results of health economic evaluations can provide helpful additional pieces of information for the process of decision-making but decisions about allocation of health care resources have to be the result of a societal consensus and should never be made based on economic analyses alone.

Vancomycin

Definition

Vancomycin is an antibiotic, which is primarily used for infections with oxacillin-resistant staphylococci, enterococci, *Clostridium difficile* and *Corynebacterium jeikeium*. It safely can be given in the neonatal period. Only parenteral administration (as an infusion) is possible.

Variability

Synonyms

Variation

Definition

The degree to which the measurements of the same variable differ among each other.

The terms variability and variation are often used as synonymous in the literature. Precisely, the term variation refers to the differences that are actually present among the units (persons, objects) in a population or a sample. It can be directly observed as a property of a collection of items. In contrast, variability is a term that describes the potential or the propensity to vary. Variability thus belongs to the group of dispositional concepts, e. g. variability of a phenotypic trait describes its propensity to change in response to environmental and genetic influences. Covariation refers to the state that exists when two variables vary together.

Variable

Synonyms

Characteristic property

Definition

A variable is any characteristic (property) of the observational unit with outcomes (data) that vary from one observation to the other. A variable may have a different value out of a specified set of values in different people, in different places or at different times. Some examples of variables include the height of adult females, the gender of preschool children, and IQ test score of patients seen in mental clinics. The variables are often referred to as random variables when the value of a particular outcome is determined by chance (i. e. by means of random sampling). Types of variables refer to the several different and important classifications of variables that are most essential to know in order to understand and appropriately use the most important and frequently used applied biostatistical methods. Three main classifications of variables are: 1) quantitative or qualitative; 2) continuous or discrete; and 3) independent or dependent variables.

Variance

Definition

Variance is a mean square deviation from the mean. Estimation based on the sample data is obtained using the formula:

$$s^2 = \frac{\sum (x_i - \bar{x})^2}{n-1} = \frac{\sum x^2 - n\bar{x}^2}{n-1}$$

where x_i is an individual value, $\bar{x}$ is the mean, n is the sample size, and $n - 1$ is the number of the degrees of freedom. The formula for population variance, which is denoted as σ^2, is similar to the above but the denominator is n instead n–1. As the sample size increases the difference between these two values, sample and population variance, become minimal.

Variance is a matter of great importance in statistical theory. Variance reflects the dispersion of the values around the mean. Its value is always positive and can be zero only if all values are identical. The units

of measurement of the values of variance are different units from the original measured values. For example, if weight is measured in kilograms (kg), the variance units will be square kilograms (kg^2). In this sense then, the better measure of dispersion is the square root of variance – ► standard deviation, which is in the same units as the original values.

Varicella Immune Globulin

► Varicella Immunization, Passive

Varicella Immune Prophylaxis

► Varicella Immunization, Passive

Varicella Immunization

Synonyms

Application of varicella immune globulin; Varicella immune prophylaxis; Application of chickenpox immune globulin; Chickenpox immune prophylaxis

Definition

Following a contact with chickenpox the administration of varicella immune globulin is recommended for certain groups of people. These people are immunocompromized patients, extremely premature infants (less than 28 weeks of gestational age), premature infants whose mothers do not have any varicella immunity and newborn babies whose mothers become ill from chickenpox between five days before and two days after delivery.

Varicella Vaccination

Synonyms

Varicella immunization; Chicken pox vaccination; Chicken pox immunization

Definition

The varicella living ► vaccine was developed in 1970 in Japan. Its authorization in the United States took place in 1995. For patients between the ages of 11 months and 12 years, the vaccination is given as a single inoculation. For older children and adults, varicella immunization is recommended if the patient has not previously contracted the disease and if no vaccination has been carried out before. In these cases, the vaccine is administered twice, preferably at an interval of 4–8 weeks. The effectiveness in primarily healthy patients is 95–100%. In high-risk patients (e. g. patients with tumorous diseases), the success rate is much lower at 80–90%. Due to its damaging effect on the embryo, it must be taken into consideration that pregnant women may not be inoculated and that for four weeks following an inoculation, contraceptive methods must be practiced. Additional contraindications for the varicella vaccine are acute illness with fever, and a known severe allergic reaction to components of the vaccines or the carrier protein.

Variola

Synonyms

Smallpox

Definition

Variola is an acute infectious disease with high fever and successive stages of severe skin eruptions. The causative agent is a virus that may be airborne or spread by direct contact. It is common in childhood. After the incubation period of about two weeks, fever occurs with symptoms of respiratory infection followed by skin eruptions. Skin lesions become like blisters and pustular within a week. The lesions become open and a crust forms causing itching and pain. There is no specific treatment for smallpox. Antibiotic therapy may be administered to prevent secondary bacterial infections.

Vector

Synonyms

Gene vector; Transducing vector

Definition

The vehicle which is used to introduce the genetic element of interest to human cells is called the gene vector.

The gene vector may be either a viral vector or a non-viral vector.

Virus Load

Synonyms

Viral concentration

Definition

The virus load is a measure of the quantity of the HI-virus in one milliliter of blood. It is very high directly after infection – before antibodies have been built up – and in later stages of the infection. To detect the viral concentration, genomes (DNA-test) or genome equivalents (RNA) are measured. Controls of virus load during the course of the disease should always be performed with the same method. For modern tests the lowest level of detection is (20-)50 copies/ml. A low viral concentration is understood as a RNA-level < 1000 copies/ml, a high virus load means > 50.000 copies/ml. In HIV-infections viral concentration is an important value on which to base therapeutic decisions and control the therapy.

Virustatics

Synonyms

Antiviral therapy; Anitiviral drugs; Antiviral agents; Antiviral substances

Definition

Virustatics are drugs that can be used either for prophylaxis or therapy in some viral infections. The substances have to kill the viruses or at least impede their growth without causing damage to the human cells or their metabolic processes. They impede uptake of the virus into cells, influence intracellular replication or

viral release. In the treatment of AIDS, the very important enzyme, reverse transcriptase, is impeded by these antiviral agents.

Vital Statistics

Definition

Vital Statistics refer to all official information on births, deaths, marriages, divorces, fetal deaths and abortions within a population retained by a government. In most countries, vital statistics are published by the national ► health statistic centers dealing with a broader range of health related statistical information. Vital statistics are used as a basis for public health policy-making.

[1] Research Centre for Agricultural and Forest Environment, Polish Academy of Sciences, Poznań, Poland
[2] Potsdam Institute for Climate Impact Research, Potsdam, Germany
zkundze@man.poznan.pl, zbyszek@pik-potsdam.de

Synonyms

Susceptibility

Definition

Vulnerability is the degree to which a system is susceptible to, or unable to cope with, adverse changes. Vulnerability depends on three factors: exposure to changes (function of the character, magnitude, and rate of change to which a system is exposed), system sensitivity to these stimuli, and system adaptive capacity.

Basic Characteristics

Vulnerability is the degree to which a system is susceptible to, or unable to cope with, adverse changes. Vulnerability is a function of three factors: exposure to changes (function of the character, magnitude, and rate of change to which a system is exposed), system sensitivity to these stimuli, and system ► adaptive capacity. Prospects of ► adaptation to changes depend not only on the technical feasibility of certain adaptation measures but also the availability of required resources, the costs and side effects, implementability, perception, etc. Disasters, which involve violent changes, often happen in environments where distress is already present. Certain populations can be identified as being particularly at risk during disasters. Those who are unprepared for change, having neither the adaptive capacity nor economic resilience and lacking a secure support system, are predisposed to a complicated recovery. Vulnerable groups include the elderly and those of lower socio-economic status (unemployed, transients). Vulnerability concerns mean that suffering and dying is a function of poverty, underdevelopment, illiteracy, and lack of health care (► human health aspects of disasters).

Impacts of natural disasters (► hazards, natural) are not evenly distributed in relation to income status, age, or gender. Poorer communities are more likely to live in disaster-prone (e. g., flood-prone) areas. Low-income and high-density populations in low-lying coastal regions experience a high burden from weather disasters (► physical, environmental and social aspects of disasters).

Certain areas and groups of people in developed countries can also be vulnerable, as demonstrated by the European heat wave of summer 2003 and the hurricane Katrina disaster in 2005. In many disaster areas in the south of the USA, low-income individuals are numerous, including foreign migrant worker populations, and the unemployment rate is high. Many residents came from somewhere else (such as illegal immigrants), or are unskilled laborers or retirees, including elderly widows and widowers. Some areas in the south of the USA have a disproportionate number of individuals with little or no support system.

Many families are reluctant to evacuate and leave the remains of their homes (some being afraid of looting). Many do not have the money to move from their damaged apartments.

Disasters affect women and men differently. As shown by the 2004 Asian tsunami, male survivors outnumber females. The gender-related differences apply to exposure to risk, risk perception, preparedness behavior, warning communication and response (e. g. Muslim women staying at home in the absence of their husbands may ignore warnings), and ultimately to recovery and reconstruction. Gender interacts with race, income level, social class, and access to resources in the experience of disaster. Women are the providers of child care, which may put them at greater risk during and following a disaster. They may have limited mobility, restricted access to resources, and may be subject to social isolation.

Key vulnerabilities related to climate change merit particular attention because they endanger the lives or well-being of people or other valued attributes of climate-sensitive systems. Examples of vulnerable systems are low-lying islands or coastal cities and arid agricultural lands, where environmental refugees may occur. Some vulnerabilities of important systems are likely to be of high magnitude (interpreted as a scale – e. g., the area or number of people affected and intensity – the degree of damage caused in monetary and non-monetary measures), persistent and irreversible, expected to happen (relatively) soon, and with the potential to harm individuals, groups, and societies of low adaptation capacity.

Vulnerable Groups

Definition

In research, by "vulnerable" we mean that a person or a group may be more than usually susceptible to exploitation in the process of research, either because they are more likely to be pressured into participating, or because they fail to understand the full implications of participation and may therefore be misled into taking part. The principle would also apply to those who are extremely poor and therefore would find it very hard to turn down a reimbursement for a study procedure despite of being informed of the risks. In these cases even the signed ► informed consent may not be meaningful.

Vulnerable Populations

Definition

Vulnerable populations are groups of people in whom the informed consent procedures need to be reviewed and controlled; all measures should be taken to ensure that their participation in medical experiments is truly voluntary. These groups include prisoners and military personnel on the one hand, and relatives and other persons dependent on the investigator (like employees of the institution) on the other hand, and their voluntary participation and freedom to make decisions have to be questioned; people who are legally not able to give informed consent (or to do so in the usual way) like minors, emergency patients, people with mental incapacity or unsound mind, or patients unable to write or read have to be included in this group.

It has to be ensured that vulnerable populations participating in a clinical trial or medical experiment do so in their own best interests (e. g. being treated for a previously untreatable medical condition, or potentially benefiting from a new treatment) and that no major or unforeseeable risks are taken and that their personal will is respected to the highest possible extent.

Waste Management

Synonyms

Garbage management; Refuse management

Definition

Waste management is the collection, transport, processing (waste treatment), recycling or disposal of waste materials, usually ones produced by human activity, in an effort to reduce their effect on human health or local aesthetics or amenity. It is the process of dealing with waste. Waste management can involve solid, liquid or gaseous substances with different methods and fields of expertise for each. Managing municipal waste, industrial waste and commercial waste has traditionally consisted of collection, followed by disposal. Depending upon the type of waste and the area, a level of processing may follow collection. This processing may be to reduce the hazard of the waste, recover material for ► recycling, produce energy from the waste, or reduce it in volume for more efficient disposal.

Waterhouse-Friederichsen Syndrome

Synonyms

Waterhouse–Friderichsen syndrome; Meningococcal septicaemia; Septic course of meningococcal infection

Definition

The Waterhouse–Friederichsen syndrome is the septic course of a meningococcal infection, which is accompanied by a very high lethality (up to 95%). As the disease progresses an inappropriate acceleration of coagulation (DIC = disseminated intravascular coagulation) develops. DIC results in complex hemorrhagic disorders with micro thrombi in the blood vessels, hemorrhages into organs (especially the adrenal gland), widespread purpura of the skin, necroses and multiorgan failure. A profound shock develops. If Waterhouse–Friederichsen syndrome is not treated immediately, the outcome is fatal.

► Infectious Diseases in Pediatrics

Water Pollution

Synonyms

Water contamination

Definition

Water pollution results from an inflow of industrial and communal wastewater into water sources and soil. It is a man made contamination influencing water quality (► water quality and pollution).

Water Quality and Pollution

Tanja Knežević
Institute of Public Health "Dr Milan Jovanović-Batut", University of Belgrade, Belgrade, Serbia
tanja_nezevic@batut.org.yu

Synonyms

Water standard; Water contamination

Definition

The quality of water is a standard for water intended for human consumption and household purposes, which means water free from organisms and from concentrations of chemical substances that may be a hazard to health. The water is polluted in cases when concentration of toxic substances and the number of pathogenic organisms exceed recommended standards and may cause adverse effects to health.

Basic Characteristics

Water Sources

Depending on its origin, natural waters have their properties, by which they differ. Those differences are mainly the result of specific physical, chemical and biological processes they are subject to, merging of waters of different qualities, change in geological composition of soil, as well as of various hydro-meteorological conditions.

Based on their origin, there are the following types of natural water:

- Atmospheric (rain, snow, etc.).
- Surface water (oceans, seas, rivers, lakes, etc.).
- Ground water (springs, wells, etc.).

The main ► water sources for water supplies and domestic use are ground and ► surface water, and only exceptionally, in water-poor areas, precipitation water.

The quality of ground water depends on the aquifer from which the water is drawn for the purpose of water supply. The most frequent ground water sources for water supply are: springs and dug wells.

Surface-water as a water source includes rivers, lakes, as well as artificial accumulations.

The quality of surface-water varies, mainly depending on the kind and quantity of precipitation and erosion in the watershed, degree of industrial development in the watershed area, as well as on the quantity of effluent water and industrial wastewater outfalling into surface-waters.

Water Quality

Many parameters must be taken into consideration in the assessment of water quality, such as source protection, ► water treatment efficiency and reliability and protection of the distribution network. However, water quality is determined by microbiological characteristics and the guideline value for chemical parameters, which represents the concentration of constituent that does not result in any significant risk to the health of the consumer over a lifetime of consumption. Guideline values are usually established as national standards which are harmonized with recommended guideline values for ► drinking water quality defined by WHO and EU.

Microbiological Quality

The greatest risk from microbes in water is associated with consumption of drinking water that is contaminated with human and animal excreta, although other sources and routes of exposure may also be significant. The waterborne pathogens (► pathogen organisms) that can be found in the water supply are: bacteria, viruses, protozoa, helminths and free living organisms.

Water intended for drinking and other household purposes must not contain waterborne pathogens, and must be free of human enteroviruses to ensure a negligible risk of transmitting viral infection. Also the protozoa and helminths should not be present in drinking water.

The organisms most commonly used as indicators of ► water pollution are *E. coli* and a coliforms group as a whole. Some organisms grow in pipe water distribution systems (e. g. *Legionellae*), whereas other occur in source waters (guinea worm *Dracunculus medinensis*) and may cause outbreaks and individual cases.

Chemical Quality

► Chemical substances that can be found in drinking water are mainly divided into two groups—organic and inorganic, with a separate group of pesticide, disinfectant and disinfectant by-products.

Regarding their influence on health, chemical substances can be divided into the following groups:

- Beneficial-substances that, when introduced into organism, take part in many oxido-reductive and metabolic processes; those substances include iron, copper, manganese, zinc, magnesium, and other trace elements.
- Toxic—if the concentration of those substances exceeds recommended guideline values in drinking water; those substances are heavy metals (mercury, lead, cadmium, etc.) and many of organic substances.
- Carcinogenic, teratogenic and mutagenic substances.

Chemical pollution of drinking water can be a result of soil and streamflow pollution with wastewater, soil pollution with pesticides and artificial fertilizers, as well as pollution with detergents, used motor oil etc.

Water Pollution and Health Risk

The most common and widespread ► health risk associated with drinking water is contamination, either directly or indirectly, by human or animal excreta, particularly feces.

Persistence of pathogenic bacteria, viruses, protozoa and/or parasites in drinking water leads to sporadic or epidemic cases of infectious diseases. The most frequent ► water related diseases in many countries in the world are bacterial diarrhea, shigelosis and hepatitis A.

Acute intoxication with chemical toxic substances through drinking water is rare, due to the low concentrations of those substances in water, although a daily intake of those substances in water, food and air, over a long period of time, can result in adverse health effects.

Monitoring and Surveillance

The monitoring of drinking water ideally consists of two components:

- Continual quality control on a routine basis to ascertain that treatment and distribution comply with the given objectives and regulation;
- Periodic microbiological and public health ► surveillance of the entire water supply system from source to consumer.

The continual control function is an integral part of the responsibilities of the water supply agency through which the waterworks management ensures the satisfactory performance of the treatment processes, the quality of the product water and the absence of secondary contamination within the distribution network. An independent body should verify that the waterworks correctly fulfills its duties. The surveillance is usually the responsibility of the health authorities at local, regional and national levels.

Water Quality and Waterborne Infectious Diseases

MONIKA KORN
Friedrich-Ebert-Krankenhaus GmbH,
Neumünster, Germany
hkorn80663@aol.com

Synonyms

Infectious diseases due to polluted water; Infectious diseases due to contaminated water

Definition

Waterborne infectious diseases are due, mostly, to drinking polluted water. In some cases, germs can penetrate the intact skin of a person who comes into contact with the water in which the germs live.

Basic Characteristics

Significance of Water

Water is essential for life. It is also called the "gold of the 21st century". The United Nations General Assembly, in December 2003, proclaimed the years 2005 to 2015 as the International Decade for Action, "Water for Life" (http://www.un.org.waterforlifedecade/background.html).

Water covers 75% of the earth's surface. Of this, 97% is seawater and only 3% freshwater. Two percent of the 3% freshwater is ice, 0.9% is ► ground water and 0.1% is surface water. Most probably, a sufficient supply of ► drinking water is one of the decisive factors guaranteeing health and the avoidance of infectious diseases and epidemics. Due to the rising world population and an excessive consumption of water, the average amount of water available for each individual is steadily decreasing. These calculations are for the world as a whole, not individual regions. As the actual amount of water available varies considerably, there are a number of regions which suffer from extreme water shortage. To survive a human needs 2–3 liters of water daily. In the developing countries the access to water has great significance. In many regions, obtaining water takes a lot of time and shapes the whole day. In general, in the developing countries it is the girls who have to col-

lect the water for their families and, due to this, they often do not have enough time to go to school.

Water as a Transmitter of Infectious Diseases

Every year about 4 million children die due to diseases caused by polluted drinking water and bad hygienic standards. In relation to the total number of pathogens that exist, the number of germs causing waterborne infection is quite low. To survive in water, the germs have to be extremely resistant to environmental influences. Moreover, a certain concentration of pathogens is needed to cause a disease. Most of the germs are fecal in origin and they get into the drinking water by pollution from sewage plant drains, sewers or storm water overflows. The spread of pathogens is facilitated where there are no effluent disposal units or toilets. Diseases, belonging to the classic waterborne infections and which are primarily transmitted by polluted drinking water, are: cholera (*Vibrio cholerae*), typhoid (*Salmonella typhi*), paratyphoid (*Salmonella paratyphi*) and bacterial dysentery.

In stagnant waters in tropical or subtropical regions there is the risk of a transmission of the Guinea worm and *Bilharzia*. Legionellae are also found in water. These infections are described in more detail below. A number of these pathogens can be transmitted by contaminated water, but are more frequently transmitted in other ways, especially fecal-orally (see food-safety and fecal-orally transmitted infectious diseases). Examples of such infections are: gastrointestinal infections with rotaviruses (► rotavirus infection) and Norwalk virus (► Norwalk virus infection), ► protozoa infections, like ► amebic dysentery (*Entamoeba histolyticum*), ► giardiasis (*Giardia lamblia*), ► cryptosporidiosis (*Cryptosporidium parvum*) and ► poliomyelitis.

Prophylaxis for Waterborne Infectious Diseases

In industrial nations, people take clean drinking water for granted. Water for drinking has to satisfy high quality standards; it is strictly separated from waste-water. In general, in the developing countries, a sufficient amount of clean drinking water is not available. Worldwide, more than one billion people do not have access to clean water, more than one third of the total population has to live without latrines and effluent disposal systems. To avoid spreading diseases via drinking water, the water has to be kept free of pollutants and germs. Drinking water must not contain any human or animal excrements. If water is contaminated, it has to be treated before consumption. A great number of pathogens can be eliminated by filters (like gravel-packed filters or carbon filters). The filters have to be intact (they must not show any fissures or tears) and they have to be cleaned and renewed regularly. Moreover, pathogens can be killed by chemical treatment; chemicals, however, are only suitable for optically clear water. In households without piped water, the water should be boiled or disinfected by other means such as ► solar disinfection (sodis) (http://almashriq.hiof.no/lebanon/600/610/614/solar-water/unesco/35-46.html). The latter method has certain value in poor regions. Unfortunately, cooling is not a suitable method of sterilization as a number of germ types are not destroyed by freezing; poor quality drinking water should not be used to make ice cubes. Pathogens in water are not killed by alcohol either.

Education of the population is a very important factor in the prevention of waterborne diseases. People have to know that contaminated water is a source of danger, and they have to understand the significance of hygienic rules. The raising of health-consciousness has to involve the whole population. For instance, where *Bilharzia* (*Schistosoma*), the fluke causing schistosomiasis, is endemic in a tropical or subtropical region, it is recommended that people should not bathe in places of stagnant water. Prophylactic measures include the elimination of snails, which are the intermediate hosts of schistosomas; snail poisons are used and river bank vegetation removed.

Cholera

Cholera is caused by the bacterium *Vibrio cholerae*. In India, the disease has been known since the 6th century BC. By the beginning of the 19th century cholera was spread throughout Europe; after the year 1826, the boom in steam navigation led to a worldwide spread of the disease. Historically 7 cholera epidemics have been described. *Vibrio cholera* was detected by Filippo Pacini in 1854; Robert Koch succeeded in growing a pure culture in 1883. After the consumption of cholera contaminated water, an incubation period occurs which lasts from a few hours up to a couple of days. The bacteria release toxins which cause severe diarrhea with a great loss of fluids and electrolytes. Due

to the loss of fluids, muscular cramps result, primarily in the calves. The diarrhea, with so-called rice-water stools, has a sudden onset; without treatment 60% of patients die due to hypovolemic shock and renal failure. Therefore, the treatment of cholera is ► rehydration, the replacement of lost fluid, either orally or intravenously. If therapy is carried out quickly and sufficiently, lethality can be reduced to less than 1%. Cholera is classified as one of the ► quarantine diseases, with an isolation period of 5 days. Even when cholera has been successfully treated, the pathogens can still be shed in the stool for weeks or even months. The most important prophylactic measure is compliance to hygienic rules; an active cholera vaccination (► cholera vaccination, active) is available, but a protective effect is only reached in 60%.

Typhoid/Paratyphoid

Typhoid and paratyphoid, caused by *Salmonella typhi* and *Salmonella paratyphi*, appear after an incubation period of 1–3 weeks (*S. typhi*) or 1–10 days (*S. paratyphi*), respectively. The onset is characterized by exhaustion and stomach ache. After a few days, high fever appears (40–40.5°C), which – without treatment – lasts 2–3 weeks. During the second week of illness, obstipation and diarrhea occur. The most important complications are bleedings in the gastrointestinal tract, and possible perforation. Further complications are shock, affection of the central nervous system, myocarditis and paralytic ileus. The highest mortality is seen in babies. Besides the fecal-oral mode of transmission, the germs can also be transmitted as a smear infection, particularly in children. The infections are contagious from the first week and usually remain so for 2 (*S. paratyphi*) to 3 weeks (*S. typhi*); a further shedding of the germs for some months is possible. Infected persons or those, who are suspected of infection, should be isolated. Treatment consists of stabilization of the ► body fluid and electrolyte balance, and antibiotic therapy. Drugs most commonly used in infections with *S. typhi* or *S. paratyphi* are: chloramphenicol, ampicillin, trimethoprim-sulfamethoxazole and chinolones (gyrase inhibitors). The most significant prophylactic measure is compliance to hygienic rules. Travelers to regions at risk of infection can have a typhoid vaccination (► typhoid fever vaccination, active) (http://www.who.int/water_sanitation_health/diseases/typhoid/en/).

Bacterial Dysentery

Bacterial dysentery, caused by *Shigella dysenteriae*, requires ingestion of only 10 pathogens (in drinking water or food). Following an incubation period of 1–3 days, fever and diarrhea appear. In the beginning, diarrhea is watery, later it becomes bloody-slimy-purulent. The course of the disease can be very serious, extreme fluid loss can lead to circulatory failure. The pathogens can be detected in the stool. Although bacterial dysentery is spread worldwide, a warm climate and bad sanitary conditions facilitate the appearance of the disease. To shorten the course of dysentery and to break the chain of infection, besides the replacement of fluid loss, antibiotic therapy should be given. Chinolones are the drugs of choice.

Bilharziasis/Schistomoniasis

Bilharziasis (schistomoniasis) is a worm infection, which is primarily spread in tropical and subtropical regions. It is caused by the various species of *Schistosoma* (e. g. *S. mansoni*, *S. japonicum*, *S. haematobium*). Worldwide, 200–300 million people are infected and 600 million at risk of infection. For its development, the parasite needs particular water snails as intermediate hosts; humans are the definite or final hosts. From the eggs, expelled with the stool or urine into the water, larvae develop, which then penetrate snails. Inside the snails, the larvae further develop and reproduce; finally they are released into the water as cercaria (free swimming larvae). Humans are infected by a contact with this contaminated water. Cercaria can penetrate the intact skin. Via the blood and lymphatic vessels they reach the liver, where they develop into adult parasites. And via the great veins, schistosomas reach other organs. Besides the liver, the most frequently affected organs are the bladder, the intestines, the lungs and the brain. The first symptom in bilharziasis is ► cercarial dermatitis, during the further course of the disease, ► Katayama fever can occur. Without treatment, a chronic infection develops; the symptoms depend on the affected organ. In intestinal bilharziasis, stomach ache and diarrhea occur; an affection of the bladder is characterized by painful micturition and bloody urine. Possible complications are the development of bladder cancer, failure of the affected organ and the occurrence of fistulae in the intestines or the bladder. Diagnosis of schistosomiasis is confirmed by the detection of eggs in

the stool or the urine. The infection is treated with praziquantel, which is administered twice at a time interval of 4 hours.

Guinea Worm Infection/Dracunculiasis

The Guinea worm (or Medina worm), which is primarily found in Africa and Asia, releases its larvae into stagnant waters. These larvae are eaten by small freshwater crabs (*Hyallela azteca*), which thus act as intermediate hosts. If larvae of the Guinea worm are swallowed – either during swimming or with drinking water – they get into the human intestines, where they develop to 1m-long worms within a year. The adult parasites penetrate into the subcutaneous tissue; then they drill through the skin and release their larvae. In the skin, painful ulcers develop, which heal badly. In most cases, the feet and the legs are involved. Due to the pain, patients can hardly walk; thus children cannot go to school, adults are not able to work. Further possible symptoms of dracunculiasis are fever, shivering fits, nausea and exanthemas. Worldwide, about 50 million people are infected with the Guinea worm. The infection can be prevented by the use of nylon filters. Treatment consists of the manual extraction of the worm with supporting antibiotic therapy, niridazole or metronidazole. Administration of an anthelminthic is ineffective. The manual worm extraction with a step by step rolling up of the parasite is a very old method, described in Egypt in 1550 BC (Fig. 1). According to some, the animal seen winding around the caduceus (Asclepius's staff in the insignia of physicians), is not a snake, but a Guinea or Medina worm (http://www.cdc.gov/ncidod/dpd/parasites/dracunculiasis/factsht_dracunculiasis.htm).

Water Quality and Waterborne Infectious Diseases, Figure 1 Extraction of a Guinea worm (according to Granz W, Ziegler K (1976) Tropenkrankheiten. HJ. A. Barth, Leipzig). Internist, 47, 2006; 803

Legionellosis/Legionnaires Disease

Legionellosis, which is caused by *Legionella pneumophila*, first appeared in Philadelphia during the state convention of the American Legion in 1976, hence the name legionnaires disease. The infection, which is transmitted by droplets, is characterized by nausea, high fever and serious pneumonias. Without treatment, the course is lethal in 15–20%. Legionellae reproduce best in warm water (20–45°C), the pathogens die at temperatures above 60°C. Sources of infection are hot water supplies in private houses, hotels, homes, hospitals or sport facilities. Transmission especially takes place via shower heads, Jacuzzi baths and humidifiers. The initial treatment is intravenous administration of macrolides (erythromycin) or chinolones (gyrase inhibitors). When the patient is free of fever, a change to an oral administration of the antibiotics is possible. To prevent legionellosis, ultra filtration or thermic disinfection (heating over 70°C) should be used. To avoid a reproduction of legionellae, the water in reservoirs should be kept at temperatures of more than 60°C.

Water-Related Diseases

Synonyms

Water borne diseases

Definition

Water related diseases are diseases caused by microbial pathogens or toxic agents present in water manifested as a sporadic case or as an epidemic.

Water Sources

Synonyms

Water resources

Definition

Water sources are basically different categories of naturally occurring ground water, rainwater and surface water which, with appropriate water treatment, provide safe water for water supplies.

Water Standard

► Water Quality and Pollution

Water Supply

Synonyms

Water system

Definition

The water supply is the total amount of water available for human and other uses. This refers to the share of water abstraction which is supplied to users (excluding losses in storage, conveyance, and distribution). It is a process or activity by which water is provided for some use, e. g., to a home, factory, or business. The basic source of water is rainfall, which collects in rivers and lakes, under the ground, and in artificial reservoirs. A complete water supply system is often known as a waterworks. Sometimes the term is specifically applied to pumping stations, treatment stations, or storage facilities. Storage facilities are provided to reserve extra water for use when demand is high and, when necessary, to help maintain water pressure. Treatment stations are places in which water may be filtered to remove suspended impurities, aerated to remove dissolved gases, and disinfected with chlorine, ozone, ultraviolet light, or some other agent that kills harmful bacteria and microorganisms.

Water System

► Water Supply

Water Treatment

Definition

Water treatment is a process of physical and chemical removal of pollutants, removal of pathogens and biodegradable compounds in water as a barrier to contamination of the ► drinking water system.

Way of Eating

► Diet

Way of Life

► Lifestyle

Weather

Definition

Weather is the condition of the atmosphere at a certain point of time or in a short period of time. The principle parameters of weather are temperature, air pressure, air velocity, and air humidity, and their interactions.

Welfare

► Well Being

Welfare Culture

► Sociopolitical Culture

Welfarism

Definition

The term welfarism refers to the traditional microeconomic approach where social welfare is based on the sum of individual utilities, which in turn are determined by the goods and services consumed.

Well Being

Synonyms

Welfare; Wellness

Definition

Well-being can be describe as a state of being well, healthy, contented, etc. Well-being at work can be defined as a state of feeling well and a positive attitude towards work. It also implies that ► workers are able to experience personal growth and positive energy from their work. ► wellness

Well being denotes state of human existance in which basic needs are adequately met and satisfied. It also refers to ► health status, meaning not only absence of illness, but also quality of health.

There are many components to well-being. A large part is standard of living, the amount of money and access to goods and services that a person has; these numbers are fairly easily measured. Others like freedom, happiness, art, environmental health are even more difficult to measure.

Cross-References

Western Medicine

Synonyms

Allopathic medicine; Orthodox medicine

Definition

Western medicine refers to medicine practices that developed in western world since the early Renaissance period (around 1450) and that are still practiced by majority health care systems throughout the world. Western medicine is also called biomedicine, allopathic medicine or the Hippocratic tradition. It is opposed to various medical practices that have also developed in the Western world, primarily in terms of scientific basis.

Western Medicine Treatment

- ► Conventional Treatment

West Nile Fever

Synonyms

Infection with the West Nile Fever

Definition

West Nile fever, which appeared first in 1937, is transmitted by certain mosquitoes and is principally found in Uganda, Mozambique, Egypt, Israel, India and Indonesia. Since the end of the last century, infections have also been noticed in America and Europe. Wild living birds are the reservoir of the virus. Dead birds, primarily crows, are assumed to be the first sign of the appearance of West Nile fever. Most cases of the infection are asymptomatic or similar to a flu-like infection with fever, headache, joint pain and aching muscles. Possible complications are myocarditis and encephalitis, which especially appear in immunocompromised persons. These cases may also show a lethal outcome. A specific therapy is not available; the most important preventive measure is the prophylaxis of insect bites.

WHO

Definition

The World Health Organization (WHO) is a specialized agency of the United Nations (UN) that acts as a coordinating authority on international public health. Established on 7 April 1948, and headquartered in Geneva, Switzerland, the agency inherited the mandate and resources of its predecessor, the Health Organization, which had been an agency of the League of Nations.
The vision of the WHO is to improve the health status of all populations in the world to an extent where all human beings can live a socially and economically productive life. The main topics of the WHO are infectious diseases (such as HIV and malaria), smoking, and obesity. The WHO regularly collects data to estimate the worldwide burden of disease and the quality of health care systems.

WHO Global Influenza Program

► WHO Influenza Surveillance Program

WHO Influenza Surveillance Network

► WHO Influenza Surveillance Program

WHO Influenza Surveillance Program

Synonyms

WHO global influenza program; WHO influenza surveillance network

Definition

In 1946, the WHO established an influenza surveillance network. At present, 110 reference laboratories in 83 countries take part in the program. Additionally, there are 4 international reference centers: the Medical Research Centre in London (MRC, England), the Center for Disease Control in Atlanta (CDC, USA), the Commonwealth Serum Laboratories in Melbourne (CSL, Australia) and the National Institute of Infectious Diseases in Tokyo (NIID, Japan). These centers check the different influenza strains for their variants. The composition of the influenza vaccine is defined based on the most probable variants.

Cross-References

► Outbreak Management and Surveillance of Infectious Diseases

Whooping Cough

Synonyms

Pertussis; Infection with Bordetella pertussis

Definition

Pertussis is caused by *Bordetella pertussis*, a highly contagious bacterium, which is only found in humans and which produces various toxins. The infection is spread by droplets. After an incubation period of 7–14 (–20) days the first of three stages starts, the catarrhal stage. This stage, which last for 1–2 weeks, is characterized by flu-like symptoms and is highly contagious. The following paroxysmal stage presents with paroxysms of coughing, followed by an inspiratory "whooping" sound. During these coughing fits glutinous mucus is brought up and vomiting may also occur. The paroxysmal stage lasts for 4–6 weeks and is followed by the convalescent stage, in which the coughing fits slowly decrease. The most common complications are pneumonia and otits media but in some cases seizures and an encephalopathy can occur. By initiation of early antibiotic therapy with macrolides (erythromycin) for a period of 14 days, the course of the disease can be shortened or weakened. The best preventive measure is active pertussis-vaccination (► immunization, active). Unfortunately, neither natural infection nor active immunization can give lifelong immunity.

Widespread Epidemic

Synonyms

Pandemic

Definition

A widespread epidemic refers to an infection that is geographically widespread; occurring throughout a region or even throughout the world. For example, influenza pandemics are often global.

Widespread Illness

Synonyms

Epidemic

Definition

A widespread illness is defined as an outbreak of a contagious disease that spreads rapidly and widely. It is an occurrence of cases of a disease in excess of usual expectations for a particular population.

Several kinds of widespread illness can be distinguished. A *point-source epidemic* is one in which a group of people all fall ill as a result of a single exposure, typically to an agent in food they have all consumed. An example would be an outbreak of acute food

poisoning due to staphylococcal enterotoxin. A *common-vehicle epidemic* is due to an agent that is spread on an ongoing basis in a "vehicle" such as food, water, or air. Food-borne common-vehicle epidemics usually cause gastrointestinal disease, and are sometimes perpetuated by a carrier who is a foodhandler. *Vector-borne epidemics* are spread by insect vectors and include viruses such as dengue and viral encephalitis, which are transmitted by mosquitoes.

Wilcoxon Matched Pairs Signed Rank Test

Definition

A non-parametric test for comparing the distribution of a continuous variable between two dependent groups. It is analogous to the paired sample t-test, and can be used when the data are ordinal or not normally distributed.

Willingness

► Motivation

Willingness to Pay

Definition

In health economics, the willingness to pay (WTP) is defined as the maximum amount of money an individual is willing to pay to avoid or reduce a specific health problem or to gain a specific health benefit. Willingness to pay is used for cost-benefit analysis. It is measured either directly (► contingent valuation) or indirectly (► revealed preferences). The willingness to accept is the inverse approach of willingness to pay, in which an individual has to define the minimum amount of money that would be acceptable to lose a specific health care service.

Willingness-to-Pay Analyses

Synonyms

Contingent valuation; Hedonic pricing; Stated preference analyses

Definition

How can the value assigned by a patient to a medical benefit be assessed? One way of determining the value of a medical measure in terms of monetary units is the "willingness-to-pay" method, which seeks to determine the medical preferences of patients or of society by ascertaining the level of demand on the basis of hypothetical prices. Such an approach is appropriate mainly for establishing the value of goods whose prices are not determined freely by market conditions or are subject to regulation (e. g. by fixed scales of fees). However, one problem is that an individual's willingness to pay may vary greatly according to his or her state of health. A person who is ill will understandably place an appreciably higher value on a medical intervention than someone who is healthy. Accordingly a representative selection of interviewees is important in any willingness-to-pay analysis.

Willowbrook State School

Definition

Willowbrook State School is a New York State institution for mentally defective children. All subjects, from 1963 to 1966, were deliberately infected with the hepatitis virus; during the course of these studies, Willowbrook closed its doors to new inmates, on the grounds of overcrowding. However, the hepatitis program continued to admit new patients. Thus parents found that they were unable to admit their children to Willowbrook unless they agreed to them participating in the hepatitis studies. It is referred to as one of the most disgraceful scandals against human dignity.

Withdrawal

Synonyms

Withdrawal syndrome

Definition

Withdrawal can be described as a group of physiological and psychological symptoms of variable clustering and degree of severity which occur on cessation or

reduction of use of a drug that has been taken repeatedly, usually for a prolonged period or in high doses. A withdrawal syndrome is one of the indicators of ► (drug) dependence. However, onset, symptoms and course of withdrawal depend on the consumed substance and dose.

Withdrawal State

Definition

A group of symptoms of variable clustering and severity occurring on absolute or relative withdrawal of a psychoactive substance after persistent use of that substance. The onset and course of the withdrawal state are time-limited and are related to the type of psychoactive substance and dose being used immediately before cessation or reduction of use. Possible complications of a withdrawal state are convulsions.

Withdrawal Syndrome

► Paired Groups Design

Women's Health

NATALIE M. SCHMITT
Forschungsverbund Public Health Sachsen-Sachsen Anhalt e. V., Medizinische Fakultät, Technische Universität, Dresden, Germany
Natalie.Schmitt@tu-dresden.de

Synonyms

Health of the female population; Female health; Health of women

Definition

Historically, women's health implied only pregnancy and ► reproductive health. Today, however, in parts of the world, a woman's reproductive years comprise less than half of her life expectancy. Weisman's definition of 'women's health' considers this fact and refers to three features:

- Health is a product of cultural, social, and psychological factors *and* biology;
- It is important to consider and emphasize a life-span and multiple role perspective;
- The individual and society have to promote health and prevent disease in order to fulfill the concept of health beyond the absence of disease (Weisman 1998).

The focus on women's health is critical as there are diseases which are unique, more prevalent, or more serious in women. In some diseases risk factors and interventions are different for women compared to men. Moreover, changes in diseases over time and across the lifespan differ in the female and male populations.

Basic Characteristics

Female Morbidity and Mortality

Women experience greater morbidity than men although women's life expectancy is higher. Because over the lifetime of a population the proportion of women increases, women are at higher risk of experiencing age-related morbidity and are less likely to have a surviving spousal partner to rely on for assistance (Wang et al. 2004). The female adult ► mortality rate is lower than the male adult mortality rate in almost all countries in the world. Life expectancy at birth for females is at least 80 years in most Western European countries, Japan, the US, and Canada, but below 40 years in some African countries. In older ages women have a clear survival advantage compared to men (UN 2005).

The leading causes of death for women worldwide are HIV/AIDS, malaria, tuberculosis and maternal conditions (WHO 2004). Complications of pregnancy and childbirth are the leading cause of death and disability among women of reproductive age in less developed nations. Maternal mortality ratio, the number of maternal deaths per 100,000 live births, is estimated to be over 1500 in some African countries and Afghanistan and is under 10 in most Western European countries (UN 2005).

In developed countries, women's leading causes of death are cardiovascular disease and cancer. Women's rates of lung cancer mortality have skyrocketed since the 1980s. Breast cancer mortality is second to lung

cancer mortality, followed by colorectal cancer mortality. Breast cancer is the malignancy most often diagnosed in women and is, therefore, one of their leading health concerns. Its early detection through ► mammography should be promoted worldwide. Mammography screening, beginning at the age of 50 years, reduces the burden of breast cancer in the female population as diagnosis before the onset of symptoms results in a better prognosis. However, although the results of screening gradually improve as women get older, their risk of breast cancer increases with each passing decade.

► Sexually transmitted diseases (STDs) are a major burden for the female population. Compared to men, women are less likely to be treated as their disease is more often asymptomatic. Social inequalities between women and men concerning knowledge of STD prevention, influence on sexual relationships and availability of health care services make women more vulnerable to infection and chronic disease. Worldwide, ► HIV infection is increasing among women of childbearing age. HIV infection directly influences women's health and social life, may be decisive in family planning considerations and is a threat for the newborn.

Cardiovascular disease occurs later in life and is more deadly in women compared to men. Short- and long-term survival are lower in women than in men. Diagnosis of cardiovascular disease is difficult in women, as women often only show unspecific symptoms like nausea, anxiety, cold sweat and shortness of breath. Women's cardiovascular disease seems to be undertreated. In the prevention of cardiovascular disease levels of HDL and triglycerides may be more important in women than in men (Woodfield et al. 1997).

Worldwide, the prevalence of ► anemia is about 34% in women and almost 50% in pregnant women. Anemia in pregnancy causes fetal growth retardation and preterm birth and increases the risks in childbirth for the mother and the baby. Anemia may be due to nutritionally related iron deficiency, chronic diseases or menorrhagia prior to pregnancy (Wang et al. 2004).

► Osteoporosis is much more prevalent in women, particularly in postmenopausal women, than in men. In the US about 15% of women over the age of 50 years suffer from osteoporosis which increases the lifetime risk of fractures to about 40%. Prevention (adequate intake of calcium, physical activity) needs to begin during childhood as 95% of bone acquisition is completed by age 17 in girls and peak bone mass is critical for the risk of later osteoporosis. Hip fracture is the most devastating type of fracture leading to death (15%), placement of women into nursing homes (25%) and a decreased quality of life (USDHHS 2004).

Reproductive Health

Worldwide the average age of menarche has declined due to improved nutrition and sanitation. Mean age of menarche, the time of the first menstrual bleeding, is about 13 years. Mean ► menstrual cycle length is 28 ± 7 days, mean duration of menstrual flow is 2–6 days.

► Menopause, the final menstrual period, occurs on average at the age of 51 years. Postmenopausal health risks are heart disease and osteoporosis. The lack of estrogen greatly influences women's quality of life, e. g. in terms of vaginal discomfort and bladder symptoms. ► Hormone replacement therapy is effective in the treatment of menopausal symptoms, but increases women's risk of breast cancer and cardiovascular disease.

► Reproductive health is a state of complete physical, mental and social well-being in all matters relating to the reproductive system. Access to appropriate health care services that enable women to go safely through pregnancy and childbirth is requisite for adherence to women's rights. Pregnancy and childbirth are major life events in which healthy living is essential for the health of the mother and the newborn. Tobacco should be eliminated for the pregnant woman's environment, women should not drink alcohol while pregnant and should pay special attention to their nutrition during this period. Supplementation with folic acid before and during the first weeks of pregnancy significantly reduces the risk of ► neural tube defects in the baby. In addition, daily physical activity during pregnancy is highly recommended. Conditions such as ectopic pregnancy, ► gestational diabetes, hypertensive disorders (e. g. preeclampsia), severe bleeding and chronic ► anemia may be life-threatening to the pregnant woman.

Between under 5% (Sierra Leone) and over 80% (China, Switzerland, Spain and the United Kingdom) of married woman, or woman currently living in a union, aged 15 to 49 years use methods of contraception. Contraceptive prevalence is 67% worldwide, 32% in the least developed countries and 78% in industrialized countries. According to these numbers, fertility rates are much higher in developing countries, but have

declined worldwide due to the development of contraceptive strategies. In developing countries there are still millions of women – on average 19% of the married female population – with unmet contraceptive needs. China with its strict birth control policy and widespread family planning services is an exception. Contraceptives are available to about 90% of married Chinese women (Wang et al. 2004; UN 2005).

The abortion rate is directly related to the prevalence of modern contraceptive methods. More than 25% of the female population live in countries with most restrictive abortion policies, where abortion is not allowed at all or only permitted to save the mother's life. In contrast, 40% of women worldwide live in the 54 countries without restrictions as to reason, and abortions are carried out mostly within a gestational limit of 12 weeks. In other countries a woman's poor socioeconomic position or the risks to her physical or mental health by the pregnancy are acceptable grounds for abortion. Thirteen percent of maternal deaths are due to the complications of unsafe abortions. Legalization of abortion reduces the number of illegal abortions and decreases health risks for the mother. Ninety five percent of abortions conducted under unsafe conditions occur in developing countries, although the abortion rate is highest in Europe (about 50 abortions per 1000 women in reproductive age) (Wang et al. 2004; Center for reproductive rights 2005).

Violence Against Women

Family violence includes physically and emotionally harmful acts: assault or physical intimidation, sexual coercion, threats to harm, control and restraint of daily activities, social life or freedom and denial of access to resources. Violence against women has a significantly negative impact on women's health both directly and indirectly by reinforcement of social inequalities. Violence in areas of conflict affects both women and men, although men are more likely to be the perpetrators and victims in these situations. In addition, women risk violence from members of their own family resulting in injury, depression, or death. Domestic violence, especially ► intimate partner violence, is the most significant cause of homocide in women. Consequences of domestic violence or rape account for about 5% of women's disease burden in developed countries and 19% in developing countries. It is estimated that 25 to 50% of women worldwide experienced physical abuse from men, which is mostly long term (Wang et al. 2004).

The process of successfully ending abuse within intimate relationships is complex. Firstly, women have to recognize the abuse as a problem, be interested in change, and accept and utilize the support of caring others. Public health interventions targeted at women who endure violence have to consider the women's readiness to change and their helpseeking behavior in order to be effective.

Conclusion

Much of women's health risk is associated not only with biological differences between men and women and women's reproductive role but also with gender inequality in social, educational, cultural and economic status. In addition, women have lower access to health care, more often encounter high-risk sexual intercourse and violence. The International Conference on Population and Development (ICPD, Cairo, 1994) and the World Conferences on Women promote good women's health and reproductive health worldwide.

Workforce Planning

Definition

Workforce planning is a strategic activity of an organization, aiming to identify and forecast the workforce skills it needs to reach its goals, and to take appropriate measures to fill emerging gaps. It usually starts from an analysis of the organization's environment and its current workforce profile. Future developments are captured by forecasting on the basis of available quantitative data, and/or by developing different scenarios, which also take into account qualitative information. Critical elements then need to be identified and addressed in accordance with the organization's strategic goals.

Workforce in Public Health

Definition

The public health workforce is an integrated national system that involves the collaboration of health partners to provide a continuum of accessible learning opportunities for public health workers.

Working Capacity

Synonyms

Work capacity; Work ability; Fitness for work; Work capability

Definition

Working capacity in general describes the individual's capacity to do the work tasks he/she is required to do. This includes the ability of the body to maintain physiological equilibrium during work. To meet this requirement certain functional, anatomical, psychological, educational, and social characteristics of the worker are necessary to fulfill the demands of a specific job performance. However, working capacity cannot be assessed by targeting only the actions of a person; it requires consideration of the factors related to the work community, the work environment, and the organization and management of work.

Working Conditions

Synonyms

Workplace conditions; Working environment

Definition

The term working condition refers to a job, task, machinery, tools, layout, factory premises or working climate that covers the workplace environment. It also includes the workers' physical, social and mental workload, psychosocial and organizational contexts of job-tasks under which the job has to be performed or which might influence the work (or job tasks) or work environment.

Cross-References

► Working Environment

Working Environment

Synonyms

Work environment; Workplace environment; Environment at work

Definition

The working environment includes the surroundings, conditions, and influences at work and at the ► workplace that affect an employee. In occupational health, it refers to the physical (physical, biological, chemical, and ergonomic factors at work) and psychosocial (work organization, inter-individual relationships at work, work culture, job security, etc.) work environment. The working environment may be considered as part of a general environment, and there is an obvious inter-relationship between the working environment and the environment. The definition of working environment is essential for occupational health preventive actions that try to change the working environments that are harmful for health and support beneficial ones.

Working Population

Synonyms

Workforce

Definition

Working population may refer to the population employed in a specified occupation or to the total population of a country who are employed and looking for employment. The term on a country level usually covers all people between 15 and 65 years old.

Work Injury

► Occupational Injuries

Work Inspectorate

► Labor Inspectorate

Work-Life Balance

Definition

The extent of conflicting responsibilities and requirements at work and in one's personal life. Attention to the lack of a balance between work and home- or personal-life became particularly relevant to women during the later half of the twentieth century who attempted to strike a balance between ► gender norms about women's role in the household and changing opportunities for women in the workplace. More recently, this balance has gained further relevance for both men and women as changes in technology have offered greater flexibility in the structure of work while also eroding the distinction between work and personal life (e. g. the opportunity to telecommute or work non-standard work hours).

Work Overload

Definition

Work overload happens when job demands exceed an individual's ability to deal with them; i. e. exceed the time and resources available. Work overload represents the weight of hours, the sacrifice of time, and the sense of frustration with the inability to complete tasks in the time given. Long working hours, particularly at the expense of other parts of workers' lives, help to create overload. Added to long hours is the sense that there is too much to do in too little time.

Work overload may be seen as quantitative or qualitative. Quantitative overload is defined as having too much work to do in the time available. Quantitative overload is related to the amount of time available, whereas qualitative overload refers to the skill level of the employee, e. g. to the resources.

Work overload may lead to work-related stress (► job-related stress) – to harmful emotional and physical responses when requirements of a job do not match available individual characteristics and resources. The evidence suggests that a chronic work overload is closely related to burnout syndrome.

Workplace

Synonyms

Worksite

Definition

The workplace is a space where one or more workers perform their job tasks. The workplace also covers all places where workers need to be or to go by reason of their work. Another definition of worksite is that it is a physical area where workers need to be or to go due to their work which is under the control of an employer.

Workplace Conditions

► Job Task
► Working Conditions

Workplace Disability

► Occupational Disability

Workplace Environment

► Working Environment

Workplace Environmental Exposure

Synonyms

► Occupational Exposure

Definition

Workplace exposure is exposure to hazards arising *in* or *from* the workplace, and which could impair the health and well-being of workers. Workplace hazards could be

divided in: accident hazards (transport accidents, falls of persons or objects, stubs, cuts, burns, drowning, etc.), physical hazards (► noise, vibration, ionizing radiation, non-ionizing radiation, etc.), chemical hazards, biological hazards, ergonomic and social factors (mental or physical stress, lifting of weights, violence at workplace, burnout syndrome, etc.). Occupational exposure can be examined on industrial hygiene measurements that are carried out in the workplace.

Workplace Exposure

Synonyms

Occupational exposure; Exposure at work

Definition

Occupational exposure can be defined as the presence of a ► risk factor in the ► working environment external to the ► worker. ► Workplace exposures include physical conditions (e. g., structural insecurity or deficient lighting), physical stressors (e. g., lifting heavy weights or repetitive strain injuries), physical agents (e. g., ► noise, vibration, or ► radiation), chemicals (e. g., dusts or solvents), biological agents (e. g., bacteria or viruses), and psychosocial stressors (e. g., low control over job tasks or poor communication with workmates).

Apart from the nature of ► occupational exposure, it can also be characterized by the intensity, duration, and frequency of exposure. Occupational exposure can occur in different time-frames, such as short-term, long-term, and cumulative exposure. Although many occupational exposures may occur as environmental exposures for the general population, workers are usually exposed to higher levels, and are frequently the focus of research on health effects of these exposures and agents.

As occupational exposure does not only result from the presence of a harmful agent in the environment, it is sometimes defined as "the contact of an occupational chemical, physical, or biological agent with the outer boundary of an organism".

Workplace Factors

► Workplace Hazards

Workplace Hazards

JADRANKA MUSTAJBEGOVIĆ
School of Medicine, Andrija Stampar School of Public Health, University of Zagreb, Zagreb, Croatia
jmustajb@snz.hr

Synonyms

Occupational hazards; Workplace factors; Environmental hazards

Definition

Workplace hazards are any activity, situation or substance at the workplace that can cause harm.

Basic Characteristics

History

In the 19th century, the Industrial Revolution brought many safety problems and a higher level of public concern about these problems; the first factory inspections and first job safety laws were established. Social reformers and growing union power achieved, by 1900, minimal legislation to improve workplace health and safety in the most heavily industrialized states. This regulation and system of inspection were, however, inadequate. Those states that had some legislated protections rarely enforced them and focused largely on safety issues; little was done to protect workers from exposure to the growing number of chemicals in the workplace. After 1900, the rising tide of industrial accidents resulted in the passage of state workers' compensation laws so that by 1920 virtually all states had adopted this no-fault insurance program.

The International Labor Organization's Constitution calls for an improvement of working conditions. At the International Labor Conference in 1919, the year the International Labor Organization was founded and asked to "draw up a list of the principal processes to be considered unhealthy". Eventually an encyclopedia was substituted for the list. A comprehensive encyclopedia

was formulated to include analyzes of work; type of worker and working environments; the substances used at work and their related hazards; possible sources of disease and injury; methods of treatment and prevention; and existing protective legislation. The first edition was published in 1930. It covered specific industries, occupation and hazards; medicine and hygiene; and some social policy issues. More than half of the articles were devoted to various individual chemicals. The new, fourth edition, published in 1998, discusses specific industries and their associated hazards in detail.
After World War II, workers in the industrialized countries were able to gain better working conditions by exerting pressure on their national governments.
Occupational health and safety legislation in individual European countries experienced a great deal of flux after the formation of the European Union. The Single European Act establishing the EU was enacted in 1987. Article 118A of the Act addresses employment, working conditions, and occupational health and safety and provides a streamlined legislative process for the development of health and safety directives, and minimum health and safety standards. The EU directives have the force of law and set down general principles for the protection of workers.

Hazards Effects

Workplace hazards are divided into two broad categories: health hazards and safety hazards. Health hazards can cause occupational diseases, and safety hazards may cause injuries.

Health Hazards

A health hazard is something that has the potential to cause an adverse health effect. A potential health hazard exists when a person comes into contact with any agent, situation or condition that can cause harm to the body and result in an illness or a disease. There are five types of health hazard: chemical, physical, biological, ergonomic and stress hazards.
A health hazard may produce serious and immediate (► acute effects) effects or it may cause long-term (► chronic effects) problems which can be developed after a latency period. All or part of the body may be affected. Some health effects are local (► local health effects) while others are systemic (► systemic health effects).

Dealing with workplace hazards involves three key steps: recognition, assessment and control. Regulations require employers to have an ongoing system for the identification (► workplace hazards identification) of existing and potential risks to the health or safety of workers at the place of employment and the measures (► assessment of workplace hazards), including procedures to respond to an emergency, that will be taken to reduce, eliminate or control those risks (► workplace hazards control). The most effective method of identifying health hazards is through the systematic ► inspection of the workplace. The most accessible source of information about the health effects and other characteristics of suspected hazards is the material safety data sheet which by law must be available in the workplace. Evaluating exposure to toxic substances requires the calculation of ► exposure levels for comparison with standards set out by law or other guidelines.

Safety Hazards

Safety hazards may cause injury. They include: slipping/tripping, fire and explosion, moving parts of machinery, tools, and equipment, work at height, ejection of material, pressure systems, vehicles, lifting and other manual handling operations, materials falling from a height, rolling, shifting, or caving-in, unsafe use of explosives, workplace violence, hazards posed by working alone or in isolated workplaces. Injury caused by a safety hazard (such as a cut or fracture) is usually obvious. Safety hazards cause harm when workplace controls are not adequate.
The seriousness of the harm that could result from a hazard is often described as: catastrophic (death and/or permanent injury), critical (serious injury), marginal (minor injury) or negligible (no injury).

Workplace Hazards Control

Synonyms

Workplace hazards management

Definition

Controlling health hazards means protecting, limiting or preventing harmful exposure of workers to the hazard (► workplace hazards). Controls can be located at the source of the hazard, along the path between the source and the worker, or around the worker.

If a hazardous agent is found to be present in the workplace in concentrations that could cause health effects, it must be controlled. Control means eliminating the hazard or reducing it to a level that protects workers from adverse health effects. A control must:

- adequately control the hazard to eliminate the danger to the worker;
- protect all workers who are likely to be exposed;
- not create a new hazard in the workplace;
- not create an environmental hazard outside the workplace.

Workplace Hazards Identification

Synonyms

Recognition of workplace hazards

Definition

Recognizing hazards means identifying potential causes of adverse health effects (► workplace hazards) such as agents or workplace conditions that can cause adverse health effects if exposure or overexposure occurs. An understanding of the health effects of hazardous agents or conditions in the workplace is an essential part of determining whether workers are being exposed to health hazards. The first step in determining whether a health hazard exists in the workplace is to determine what chemical, physical or biological agents and stressors are present in the workplace. All hazardous materials present in the workplace must have an up-to-date material safety data sheet.

Workplace Health

Synonyms

Occupational health; Workers' health; Employees health

Definition

Since 1950, the International Labour Organization (ILO) and the World Health Organization (WHO) have had a common definition of occupational health. The definition was adopted by the Joint ILO/WHO Committee on Occupational Health at its First Session (1950): Occupational health is the highest degree of physical, mental and social well-being of workers in all occupations. It represents a dynamic equilibrium between the worker and his occupational environment. The definition was revised at its 12th Session (1995): 'Occupational health should aim at: the promotion and maintenance of the highest degree of physical, mental and social well-being of workers in all occupations; the prevention amongst workers of departures from health caused by their working conditions; the protection of workers in their employment from risks resulting from factors adverse to health; the placing and maintenance of the worker in an occupational environment adapted to his physiological and psychological capabilities; and, to summarize, the adaptation of work to man and of each man to his job.'

Workplace health means strategies, policies, programs, and practices found in the workplace that provide benefits that improve the total health of the individual and

the population – mental, physical, and psychosocial. It represents a dynamic equilibrium between the worker and his occupational environment.

Workplace Health Promotion

SRMENA KRSTEV
Serbian Institute of Occupational Health, University of Belgrade, Belgrade, Serbia
srmena@sbb.co.yu

Synonyms

Worksite health promotion

Definition

Workplace health promotion has been defined as the combined efforts of employers, employees and society, to improve the ► health and well-being of people at work, as was stated in the Luxembourg Declaration on Workplace Health Promotion in the European Union, 1997. Combination of improved work organization and work environment (► working environment), promotion of active participation and encouragement of personal development can reach the aim – healthy people in healthy organizations.

Basic Characteristics

Rationale

The starting point of health promotion in general is the Ottawa Charter from 1986. In the Ottawa Charter (WHO 1987), the World Health Organization emphasizes that health promotion is the process that enable individuals, groups or organizations to increase control over their health and to improve it. This Charter indicated the movement away from individually based health promotion towards the influence of the wider environmental settings in which the individual was placed. It expresses the hope that citizens in each country will take an active role in promoting their own health. Moreover, the prerequisites and prospects for health cannot be ensured by the health sector alone, it demands coordinated action by governments, health and other social and economic sectors, non-governmental and voluntary organizations, local authorities, industry and media. The concept has been further developed in the Bangkok Chapter (WHO 2005), in which the following has been pointed out:

- Strong intergovernmental agreement to increase health;
- Core responsibility of government on health promotion for all;
- Promotion of health as a key focus of communities and civil society; and
- Promotion of health as a requirement for good corporate practice.

Advantages of Health Promotion at the Workplace

This general health-promoting concept can also be applied to the ► workplace setting. Since the 1970s when the emphasis was on preventing illnesses and risk factors at work, or changing a particular lifestyle habit or behavior of individual workers, this approach has moved to a more interdisciplinary model addressing both individual ► risk factors and the broader organizational and environmental issues (Baranski et al. 2002). Workplace health promotion should involve both workers and management in their efforts to change the workplace into a health-promoting setting. Development of healthy work practice and promotion of health at work is one out of ten priority objectives proposed by the WHO Global Strategy on Occupational Health for All (WHO 1995).

The workplace is considered to be an important setting for health promotion activities for the following reasons (Zucconi et al. 2001):

- The adult population is already assembled and organized, and structures already exist for occupational health and health and safety requirements;
- Most adults spend much of their time at workplaces;
- Information and assistance to improve their ► wellness, not accessible through other channels, can be given to large numbers of the population at their workplaces;
- Participation rate is higher than elsewhere;
- Employers and employees have a common interest in promoting health at work;
- Health promotion programs at work can be profitable investments as they improve workers' health and ► fitness for work, thus leading towards greater effectiveness, competitiveness and productivity, and reducing turnover rates, mistakes at work, occupational accidents, absenteeism, etc.

Generally, the workplace setting includes many different types of organization involved in workplace health promotion, such as: large, medium-sized and small enterprises, public administration, health care services and welfare (e. g. hospital health promoting programs, Vienna Recommendations, 1997), schools, and the labor market and administration.

The main obstacle to workplace health promotion is a generalized lack of political awareness at all levels, particularly in middle-sized and small enterprises. The relevant legislation in each country should be implemented and enforced to facilitate enterprises to adopt health-conductive policies and practices. Health promotion must be understood not as a cost but as an investment in the prosperity of a nation and the increased quality of life of its citizens.

Program Structure

Program planning is based on the needs assessment at worksites. Needs assessment is usually based on questionnaires to obtain information on matters such as: self-reported health habits (e. g. smoking, physical activity, nutrition, alcohol consumption), other health risk (e. g. stress, hypertension, hypercholesterolemia, and diabetes), ► occupational hazards (chemicals, noise, stress, etc.), personal priorities for risk reduction and health improvement and willingness to participate in the program activities (Fielding 1998). Any program should be adequately promoted and planned according to the established needs at the workplace. Promotion materials, such as posters, brochures, pamphlets, articles in company publications, videos, films, etc., are a useful tool to call attention to the availability and desirability of participating in the program (Warshaw and Messlte 1998). Activities include clinical check-ups (mammography, flu immunization, etc.); health education on risk factors (smoking, weight control, fitness training, etc.); counseling and behavior modification in relation to weight control, nutrition changes, smoking cessation, fitness, etc.; skills to be developed for stress management, and pre-retirement planning, etc. At the end of the program both the participation rate and employee satisfaction and its outcomes to estimate individual and company achievements should be evaluated, and the need for improvements and possible expansion of the program should be identified, as well.

Integrated Occupational Health and Safety and Workplace Health Promotion

There is emerging evidence that coordinating and integrating ► occupational health and safety and workplace health promotion enhance workers' health (Sorensen and Barbeau 2006). The rational for this integrated approach is the evidence that exposure to occupational hazards and risk-related behavior increases workers' risk of disease, the effect being additive or even synergistic (e. g. smoking and asbestos). Further, workers who are at highest risk of exposure to hazardous working conditions are also those most likely to have risk-related behaviors. Integrating worksite health promotion and occupational health and safety may increase program participation and effectiveness for workers at ► high-risk workplaces, as well as benefiting the broader work organization and environment.

Workplace Health Promotion Activity

Definition

Workplace health promotion involves the combined efforts of employers, employees and society to improve the health and well-being of people at work. This can be achieved through a combination of improving the work organization and the working environment; promoting the active participation of employees in health activities and, encouraging personal development. Workplace health promotion activities are viewed as multi-faceted initiatives to improve health in the workplace based on comprehensive health promotion programs.

Expected benefits for workplace health promotion activities include decreased absenteeism, reduced cardiovascular risk, reduced health care claims, decreased turnover, decreased musculo-skeletal injuries, increased productivity, increased organizational effectiveness and the potential of a return on investment.

Amongst the different kinds of activities involved in workplace health promotion, two should be emphasized – the provision of a healthy workplace and advocacy. Promoting a healthy workplace recognizes that a healthy workforce is essential and integrates policies, systems and practices conducive to health at all levels of the organization. Advocacy is a key health promotion activity for overcoming major barriers to public health and occupational health. The barriers addressed by advocacy are poor living and working conditions, rather than individual or behavioral barriers.

Workplace Health Risk

► Occupational Health Risk

Workplace Health Risk Assessment

Synonyms

Health risk assessment at workplace

Definition

Workplace health risk assessment is a process of identification and evaluation of risks to the workers' health and safety arising from hazards in the workplace which can lead to the elimination or reduction of the risks or the application of control measures where necessary. In the context of occupational health, risk assessment is the process of quantifying the probability of a harmful effect to the health of individuals or populations from certain workplace activities. Occupational health risks also are directly related to physical, chemical and biological factors in the environment and related behaviors. In estimating the risks, three or more steps are involved, requiring the inputs of different disciplines.

The calculation of risk is based on the likelihood or probability of the harm being realized and the severity of the consequences. This can be expressed mathematically as a quantitative assessment or as a qualitative assessment – description of the circumstances by which the harm could arise.

The assessment should be recorded and reviewed periodically and whenever there is a significant change to work practices. The assessment should include practical recommendations to control the risk. The risk assessment provides the basis for planning and organization of work and to undertake actions for prevention.

Modern occupational safety and health legislation usually demands that a risk assessment should be carried out prior to an intervention.

Workplace Health and Safety

Synonyms

Occupational health and safety

Definition

Workplace health and safety is meant to provide work conditions that reduce or eliminate occupational injuries and work-related diseases and enable physical and psychosocial well-being. The protection of workers need not be considered simply as one of the costs of doing business, but as a critical factor necessary to the achievement of economic, environmental and social objectives which are an integral part of sustainable development. This means that the protection of workers should be seen and calculated as an investment with a potentially positive environmental, social and economic effects. The protection of workers cannot simply be seen as a matter of their workplace, but should take into account the inter-relationship between their work, general health, living conditions (water, sanitation, housing), transport, culture and so on. It also implies that action to improve occupational safety and health is a prerequisite for meeting the basic economic and social development perspectives in developing countries, and not simply a luxury to be reserved for the rich countries.

Workplace Stress

► Job-Related Stress

Work-Related Diseases

Bogoljub Peruničić
Serbian Institute of Occupational Health, University of Belgrade, Belgrade, Serbia
perunb@eunet.yu

Synonyms

Work-related illnesses; Work-related ill-health; Work-induced diseases; Occupational diseases in wider sense; Non-specific occupational diseases

Definition

The term "work-related diseases" includes a variety of ► multifactorial diseases and disorders in which work and the ► working environment contribute significantly to the cause, but are among numerous causative factors. These diseases are more prevalent among the ► working population than "specific" occupational diseases. They also occur among the general population, but work and ► working conditions need not be a risk factor in every case of each disease. Personal charac-

teristics of the working people and other environmental and sociocultural factors usually play a role as risk factors of these diseases (WHO 1985). Work-related diseases are of great importance to occupational health and public health due to their huge sociomedical and economic impact and the possibilities of their prevention or mitigation.

Basic Characteristics

Work-Relatedness

It is well known that work, as a well-adjusted and profitable human activity, can be an important factor in human health promotion. However, if work is accompanied by excess hazards, it may negatively affect the health of working people in several ways. *First*, specific physical, chemical, or biological exposures from the working environment and during the work performance can cause occupational disease. *Second*, the work may provoke onset of a diseases, or aggravate, accelerate, or deteriorate the course of an already existing disease of non-occupational origin. *Third*, work (performance and working environment) can be one of the numerous causes in a number of ► diseases with multiple etiologies.

The ► work-relatedness of diseases with multiple etiologies was stressed by the World Health Organization (WHO) in the 1970s and 1980s (WHO 1976; WHO 1985; WHO 1989). The WHO Expert Committee (1985) emphasized that "multifactorial work-related diseases are often more common than occupational diseases and therefore deserve adequate attention by health service infrastructure", and that "the new concept of work-relatedness is of substantial importance to health care workers in promoting the health of workers."

The term "work-related disease" defines neither the pathological mechanism nor the diagnostic criteria. For the time being, two pathogenic mechanisms that both operate and interact to varying extents and in various ways are being evaluated: (i) *direct*, physicochemical pathway and (ii) *indirect*, stress-mediated pathway. According to some authors, only work-related stress reactions (physiological, behavioral, emotional, and cognitive) and their long-term consequences (hypertension, affective disorders, alcohol dependence, and musculoskeletal disorders associated with ► absenteeism and loss of productivity) are considered as ► work-related ill-health.

The WHO Expert Committee defines work-related diseases of public significance as follows:

(a) Mental health disorders (e. g., behavioral responses and psychosomatic illness),
(b) Cardio-vascular disorders (e. g., hypertension, ischemic heart disease),
(c) Chronic non-specific respiratory diseases, and
(d) Musculoskeletal disorders (e. g., low back, shoulder, and neck pain).

Recently more attention has also been paid to ► occupational stress-mediated disorders and work-related cancers.

The WHO Expert Committee also listed occupational factors that contribute to the causation of work-related diseases, including physical hazards (e. g., noise, particulate matter), chemical hazards (including carcinogens), ergonomic hazards (e. g., lifting heavy loads, repetitive movements), and psychosocial hazards (e. g., ► work overload, ► work underload, ► shift work, long hours, insecure employment, ► job-related stress).

Epidemiology and Socio-Medical Importance

A high incidence of non-communicable ► diseases with multiple etiologies in the adult human population, including work-related diseases, has enormous social and economic implications. The incidence of work-related diseases is also an important indicator of the quality of the ► working environment. The direct costs of health care for affected individuals, production losses (resulting from absenteeism, disability, and premature death), financial costs (e. g., ► sick-leave, ► disability compensation), and social losses (family problems of diseased or deceased individuals, etc.) are enormous.

According to international data from the WHO and the ILO (WHO 2002; ILO 2004), 2.25 million people die every year from work-related accidents and diseases, among them 315,000 from work-related cancer. About 160 million workers suffer from work-related diseases; and in one third of these cases, illness causes the loss of four or more working days. The ILO has estimated that 4% of GDP is lost every year due to work-related diseases and injuries. Around 4% of total cancers, 10% of skin cancers, 10% of lung cancers, and 2% of leukemias are attributed to ► workplace exposure. Work-related diseases remain a leading cause of productive years lost, also including young workers.

Globally, 37% of all low back pain cases are attributable to occupational risk factors, the attributable fraction being higher among men (41%) than among women (32%). Work-related low back pain was estimated to cause the loss of 818,000 ► disability adjusted life years (DALY) annually.

The American Thoracic Society (ATS 2003) estimated the work-related burden of obstructive airway diseases (both asthma and chronic obstructive pulmonary disease) by ► population attributable risk, and found it to be 15%. The annual costs in the U.S. due to these diseases alone are estimated in a very conservative way to be nearly US$ 7 billion.

According to the survey on working conditions in the European Union (EuroFound 1997), the most common work-related health problems reported by the respondents were low back pain (30%), stress (28%), general fatigue (20%), muscular pain (17%), and headaches (13%).

Issues in Research and Prevention

A consensus on the definition of work-related diseases and particularly for its application in practice is still lacking on an international and national level. Some authors and agencies only consider occupational diseases that are compensated and have a direct causal relationship with workplace exposures as work-related diseases. Others, under the term "work-related disease" consider both classical occupational diseases and "other work-related diseases", like "a disease caused or aggravated by work". There are also opinions that "work-related diseases" can only be considered "multifactorial non-communicable diseases" partially caused by workplace exposure or work practice.

The terminological ambiguities of work-related diseases and their practical implications may be summarized as follows:

(a) There is no internationally recommended or accepted list of work-related diseases, such as the ILO List of Occupational Diseases (ILO 2002).

(b) This makes research and comparison of data on work-related diseases very difficult on a national level as well as on an international level, which may endanger some estimates on work-related disease frequency or their economic consequences.

(c) It is rather difficult to define a case of work-related disease, and to determine the magnitude of ► work-relatedness in each individual case of work-related disease. Variable diagnostic criteria and lack of standard definition of a case of work-related disease might have a significant impact on estimates.

To solve the above-mentioned difficulties, and to investigate and identify underlying pathogenic mechanisms, well-designed epidemiological studies play a leading role.

It is especially important to bear in mind that many work-related diseases can be prevented by addressing workplace exposure and individual lifestyle choices. As work-related diseases can result in adverse or fatal health outcomes, high health care costs, and reduced workplace productivity, their prevention should be the focus of both occupational and public health.

Work-Related Ill-Health

Synonyms

Workplace-related ill-health

Definition

Work-related ill health is any health condition caused by, or made worse by a job. This term, in the broadest sense of the word, encompasses all ► occupational injuries, ► occupational diseases, and ► work-related diseases. However, in some instances and in some national practices, work-related ill health has a narrower concept. It means occupational diseases and work-related diseases. Appropriate systematic registration, collection, and analysis of data on work-related ill-health allows insights into the prevalence of work-related ill-health and the costs that it may cause on a company or national level, and permits priorities in prevention to be set.

Cross-References

Work-Relatedness

Definition

Work-relatedness refers to the link between work (occupational risk factors) and specific health outcomes (► occupational diseases, ► occupational injuries, or work-related disorders) in a working population. Identification of the etiology of an occupational or ► work-related disease or injury implies an understanding of the etiology of the disorder, the circumstances of exposure, and the predisposing conditions of the patient. Identification of causation is a critical step in an occupational or work-related case because it may establish the patient's entitlement under workers' compensation if a disease or injury is occupational or work-related and may force correction of the problem, if it still exists, to prevent others from being exposed. The resolution of causation leads naturally to assessment of work-relatedness.

There are several sets of criteria for the determination of work-relatedness for different circumstances. The following set of questions is viewed as appropriate in deciding whether work is causative or a contributing factor to an employee illness: 1. Are the symptoms consistent with the diagnosis? 2. Are the signs consistent with the diagnosis? 3. Is the temporal relationship of exposure and disease clear? 4. Do fellow workers with similar exposure have similar problems? 5. Is workplace monitoring data available and indicative of suspected exposure? 6. Is the condition biologically plausible and confirmed? 7. Is there a lack of non-occupational exposure to the harmful agent?

Assessing work-relatedness is a difficult matter in many cases of chronic disease and in some contested workers' compensation cases. Many disorders that are known to have occupational causes may also occur for other reasons and for unknown causes. A given case may present with a history of multiple exposures over several jobs, each associated with a particular health outcome. This is particularly common in cases of asthma, hearing impairment, and musculoskeletal disorders.

Work Stress

► Job-Related Stress

Work Underload

Definition

Work underload occurs when work-related demands are too low so that they do not sufficiently challenge the individual, (e. g., monotonous work situations). Two kinds of work underload may be observed – quantitative and qualitative. Quantitative work underload is defined as having too little work to do in the time available, whereas qualitative overload refers to the skill level of the employee (e. g., high skill for very low-level demands). Work underload may be seen as a work-related stressor that can lead to work-related stress (► job-related stress).

World Court

► International Court of Justice

World Food Programme

Synonyms

WFP

Definition

The World Food Programme is a United Nations' agency combating global hunger. Its humanitarian and development projects are financed entirely by voluntary contributions. It works together with non-governmental organizations to deliver food in least developed and low-income countries where victims of natural disasters, refugees, displaced people, and the hungry poor face severe food shortages. Furthermore, its development activities promote the self-reliance of poor people and communities.

World Health Assembly

Definition

The World Health Assembly is the forum through which the ► World Health Organization (WHO) is governed by its 192 member states. It is the world's highest health policy setting body and is composed of health ministers from member states. The main tasks of the World Health Assembly are to approve the WHO program and the budget for the following biennium and to decide major policy questions.

World Health Organization

Synonyms

WHO

Definition

The World Health Organization is a specialized agency of the United Nations focusing on international public health. It arranges and coordinates appropriate relief operations, including measures to combat disease, especially infectious disease, provisions of vaccinations, and appropriation of drugs and medical equipment. Experts of the Organization develop health guidelines and standards and help countries to address public health issues.

Yates's Correction

Definition

The approximation of the Chi-square statistic in small 2×2 tables can be improved by reducing the absolute value of differences between expected and observed frequencies by 0.5 before squaring. The effect of this correction is to bring the distribution based on discontinuous frequencies nearer to the continuous Chi-squared distribution.

YAWS

Synonyms

Frambesia; Pian

Definition

Yaws is defined as an infectious, nonvenereal tropical disease, primarily of children, characterized by raspberrylike eruptions of the skin and caused by a spirochete, *Treponema pertenue*, that is closely related to the agent of syphilis. It is common in Africa.

Years of Life

► Life Expectancy
► Longevity

Years of Life Lost (YLL)

Definition

YLL is the mortality component of DALY (► Disability-Adjusted Life Years). It represents the number of years of life lost due to premature mortality in the population. YLL corresponds to the number of deaths multiplied by the average life expectancy at the age at which death occurs.

Years Lived with Disability (YLD)

Synonyms

Years lost due to disability (YLD)

Definition

YLD is the disability component of DALY. It represents the number of years of healthy life lost due to disability caused by the non-fatal experience of disease or injury in a population.
To estimate YLD for a particular cause in a particular time period, the number of incident cases in that period is multiplied by the average duration of the condition and a weight factor that reflects the average degree of disability caused by the condition.

Years Lost to Disability (YLD)

Synonyms

YLD; Disability adjusted life years

Definition

Disability-adjusted life year is a measure that expresses years of life lost to premature death and years lived with a disability of specified severity and duration. 1 DALY can be thought of one lost year of healthy life.

Yellow Fever

Definition

Yellow fever can only be transmitted by the bite of the yellow fever mosquito (*Aedes ägypti*), which is primarily found in the tropical regions of Africa, Central and South America. After an incubation period of 3–8 days, the infection starts with general symptoms, like fever, shivering fits, headache and joint pain. Nausea and vomiting can be present as well. The symptoms disappear within a few days. In about 15% of infected persons, a second phase follows, which is characterized by a new rise of body temperature, an icterus, a loss of proteins with the urine (proteinuria) and internal bleeding. These hemorrhages take a lethal course in about 50% of cases. The principal organs concerned are the liver, the brain, the muscles, the joints and the skin. As therapeutic possibilities are restricted to symptomatic measures, prophylaxis of insect bites plays an important role in the prevention of yellow fever. Moreover, an active yellow fever vaccination is available. Immunization is supervised by WHO and is only allowed to be performed in authorized institutions.

Yellow Fever Immunization, Active

► Yellow Fever Vaccination, Active

Yellow Fever Vaccination

Synonyms

Yellow fever immunization

Definition

In yellow fever vaccination, which was introduced in 1937, weakened viruses are administered. Only authorized institutions (like tropical institutes) are allowed to perform this immunization. The ► vaccine can be given to anyone from the age of 6 months. A single shot is sufficient, immunity starts about ten days after vaccination and lasts for ten years. According to the WHO, yellow fever immunization should be carried out routinely in all infants in the yellow fever belts of Africa and South America; travelers to these countries should be vaccinated as well. Contraindications for the yellow fever vaccine are immunodeficiency, acute illness with fever, a known severe allergic reaction to components of the vaccine and early pregnancy (up to the 12th week of gestation).

Zoonotic and Parasitic Infections

MONIKA KORN
Friedrich-Ebert-Krankenhaus GmbH,
Neumünster, Germany
hkorn80663@aol.com

Synonyms

Infectious diseases transmitted by animals; Infectious diseases due to leeches; Infectious diseases due to sponges

Definition

Zoonotic infections are communicable diseases that are naturally transmitted to humans by vertebrates. Transmission can take place directly, by foodstuffs or by animal vectors (ticks, mosquitoes, etc.). Parasites are living organisms that reside on other creatures where they feed and reproduce themselves. Diseases caused by parasites are called parasitoses.

Basic Characteristics

Transmission of Zoonoses

In 1958, zoonoses were defined by WHO as diseases that are naturally transmitted between vertebrates and humans. Parasites that carry infection, like ► head lice, ► pubic lice or ► body lice as well as ► scabies, are transmitted from one human to another. Worldwide, there are about 200 known zoonoses. Possible pathogens are viruses, bacteria, fungi, protozoa, worms and arthropods as well as prions (proteinaceous infectious particles). The latter are responsible for the transmission of bovine spongiform encephalopathy (► BSE). The spread of zoonotic infections is effected by an intensive contact between humans and animals. Besides an infection due to direct contact, transmission can take place by contaminated foodstuffs and drinking water or by other vectors, like mosquitoes, flies or ticks. Persons at high risk of contact infections are those who professionally deal with animals, like farmers, veterinarians or animal keepers, and employees in the meat processing industry. In the private sphere, ► toxoplasmosis, which is transmitted by cats, is a wide-spread infection. In regions where humans and animals live closely together, maybe even in the same room, there is a high risk of transmission of zoonoses that cause ► brucellosis, ► avian influenza and severe acute respiratory syndrome (► SARS); the latter infectious diseases of recent times are characterized by severe courses.

Characteristics of Parasitoses

Parasites are organisms that live in or on others and draw nourishment therefrom. The animal infested by a parasite is called a host. The effects of a parasite on a host can vary from hardly any impairment at all to weakening or damage or even death. Various parasites require different hosts for their cycles of development and some even require an intermediate host before infecting their final or definite host. In cases where sexual reproduction is part of the cycle, it, in general, only takes place in the final host. Micro- and macroparasites are classified according to their size. Viruses, bacteria, fungi and protozoa are microparasites. ► Trichomoniasis, ► leishmaniasis, ► amebiasis and ► cryptosporidiosis are caused by protozoa. Worms, lice, ticks, mites and fleas are macroparasites. While ectoparasites live on the surface of the host's body, endoparasites are found inside. The latter are divided into parasites that live

extracellularly, like *Giardia lamblia* (causing ► lambliasis), and those that live intracellulary, like plasmodia (causing ► malaria). While ecto- and endoparasites always stay on or inside their hosts, temporary parasites only come to the hosts for feeding. Temporary parasites are mosquitoes, flies, mites, ticks and predatory bugs. As the vectors are dependent on their biospheres, many of the infectious diseases transmitted by insects are only found in tropical or subtropical regions. Among others, so-called ► tropical diseases are: ► yellow fever, ► West Nile fever, ► Dengue fever, ► onchocerciasis, ► Japanese encephalitis, ► sleeping sickness and ► Chagas disease.

Prevention of Zoonoses and Parasitoses

To avoid zoonoses, compliance to hygienic rules is important when dealing with vertebrates. In animal keeping, cleanliness of sheds, stables and enclosures plays an important role. Contact with animals should not be too intense. This is of special significance for immunocompromised persons. As for pets, a regular deworming should be performed. Particular caution is necessary in dealing with unknown animals, especially free-running cats and dogs in vacation spots. Whenever animals show a strange behavior – unusually tame and trusting wild animals or unusually aggressive pets – they might be infected with ► rabies. Contact with animal spittle, or, especially, a bite, has to be avoided by all means. Dead (wild) animals should not be touched as they might be contagious. These rules should be taught to all children. Transmission of zoonotic and parasitic infections is a particular problem in developing countries (tropical/subtropical) as pathogens reproduce more quickly at warm temperatures and under poor hygienic conditions. However, the risk of fecal-orally transmitted (► fecal-orally transmitted infections) or ► waterborne infectious diseases must also be taken seriously in industrial nations. When dealing with foodstuffs – in both professional and private spheres – compliance to hygienic rules is the most important measure of prophylaxis. As for the zoonoses and parasitoses that are transmitted by vectors, there are different means of prevention. To begin with, insecticides can be used; moreover, the ► prophylaxis of insect bites has to be mentioned. ► Schistosomiasis can be avoided by refraining from bathing in stagnant tropical waters.

Infectious Diseases Transmitted by Ticks

Ticks (*Ixodes ricinus*) are small parasitic arachnids that feed on blood. They are found in moderate climatic zones and prefer a humid environment (soil, grasses, bushes and undergrowth). The period of greatest tick activity is in the muggy weather of spring and autumn. Ticks are responsible for viral ► tick-borne encephalitis (TBE) and for Lyme disease – ► Lyme borreliosis (LB) (Fig. 1), which is caused by the bacterium *Borrelia burgdorferi*. TBE-infected ticks are found in Europe in the bush- and woodland lying on the 7°C isotherm. Endemic regions are Russia, the Baltic countries, Poland, Austria, Czech Republic, Slovakia, Hungary, Slovenia, Croatia and parts of Germany and Sweden. Ticks, which are infected with *Borreliae*, are found in Middle Europe. A simultaneous presence of both pathogens in the same tick is possible. To avoid tick bites, it is recommended to wear covering clothing. As the risk of infection increases with the duration of the adhesion of the tick, the body should regularly be inspected for the arachnid. Ticks should be quickly removed, best by use of pincers. While bacterial Lyme borreliosis can be treated with antibiotics, no specific treatment is available for the viral TBE. As a preventive measure, the population of endemic regions and travelers can receive an active TBE vaccination (► TBE vaccination, active).

Zoonotic and Parasitic Infections, Figure 1 Erythema migrans in Lyme borreliosis. Lentze, Schaub, Schulte, Spranger (2002)

Worm Infections

Diseases due to worms (vermes) are spread worldwide. Most frequently, infection takes place by the ingestion of contagious worms in various stages of development (eggs, larvae, nymphs); food hygiene plays an important role in prevention. In ► schistosomiasis, ► strongyloidiasis and ► infections with *Ancylostoma duodenale*, larvae can actively penetrate the intact skin. Worms, which are of significance for humans, are divided into flatworms and roundworms (nematodes); tapeworms (cestodes) and flukes (► trematodes) are flatworms. Humans most frequently are the final hosts of cestodes; typically, there is an ► intestinal tapeworm infection. ► Cysticerciasis is an infection due to the infestation of larvae of the pork tapeworm. Humans are wrong intermediate hosts for the dog- and fox tapeworms; an infection with larvae causes ► echinococcosis. *Schistosoma* and other flukes belong to a species of ► trematodes. With more than 20 000 various species, nematodes show a great diversification. The most common worldwide infection with a roundworm is ► ascariasis (Fig. 2). Other infections with nematodes, which are significant for humans, are ► enterobiasis, ► trichuriasis, ► trichinosis, ► ankylostomiasis, ► strongyloidosis, ► dracunculiasis and ► onchocerciasis. Diagnoses of worm infestations are usually done through microscopic detection of eggs or larvae in the stool (Fig. 3); sometimes, worms, or parts of them, are visible in the stool with the naked eye. In ► trichinosis an increase of eosinophils in the white blood cell count (up to 89%) is diagnostic; in infestations by other worm species there is no obligatorily elevation in the number of eosinophils. Worm infestations are treated with ► anthelminthic therapy. Praziquantel is effective against tapeworms and schistosomes, mebendazole against roundworms, hookworm, threadworms and whipworms.

z-Score

The z-score is the deviation of an individual value from the mean measured in standard deviations:

$$z = \frac{x_i - \mu}{\sigma},$$

where x_i is an individual observation, μ is the population mean, and σ is a population standard deviation. The numerator value $x_i - \mu$ is called deviation score. The population standard deviation in the above formula usually is not known, and therefore may be estimated using sample data.

The z-score is dimensionless. It points out how far the observed value is located from the mean. For example, if a z-score is –3, then the observed value is located three standard deviations below the mean. The z-score is positive when the observed value is above the mean. z-Scores have a mean of zero and a standard deviation of one. It is informative when the empirical distribution is close to a normal distribution. In such cases, z-scores may be used to compare relative locations of values from distributions with different means or standard deviations. z-Scores may be transformed to scores with any mean and standard deviation, to avoid negative numbers or decimals. For example, if T-scores have a mean of 50 and a standard deviation of 10, then multiply the z-scores by 10 and add 50 to each score (z-scores × 10 + 50).
