For Gabriele, Vanessa and Anne

Preface

Comme quelqu'un pourroit dire de moy que j'ay seulement faict icy
un amas de fleurs estrangeres, n'y ayant fourny du mien que le filet à les lier.

"Essais", Livre III, Chapitre XIII
Michel de Montaigne

Public Health is defined as health promotion by population related measures. This is in contrast to the aims of medicine with its diagnostics and therapy which focus on the individual patient's health. Approaches to Public Health are apparently developing at different speeds in the various countries of the world. But there is a common feeling that the improved health of most of our people can only be achieved if aspects of prevention and health promotion are considered and practiced more successfully than curing the subjects' symptoms and diseases.
For the Encyclopedia of Public Health I have selected editors for the following fields. These I consider to be relevant disciplines for dealing with Public Health (in alphabetical order):

1. Biostatistics
2. Dental Public Health
3. Disaster Aftermath
4. Epidemiology
5. Ethics
6. Family Health
7. Health Behavior
8. Health Care and Rehabilitation
9. Health Economics (Burden of Disease)
10. Health Information
11. Health Management
12. Health Policy
13. Health Promotion
14. Health Technology Assessment
15. Indigenous People's Health
16. Infectious (transmissible) Diseases
17. Migrant Health
18. Nutrition and Physical Activity
19. Occupational and Environmental Health
20. Prevention
21. Public Health Genetics
22. Public Health Law
23. Public Mental Health

I was pleased to recruit for these areas 23 Field Editors, each of whom wrote a synopsis of their area or expertise and who are collectively responsible for producing nearly 300 essays and around 2000 definitions. Maximum quality was ensured by Field Editors recruiting experts in their field to write the essays. Ultimately, 152 scientists from 17 countries became authors of this book. I am sincerely thankful to all of them for enabling us to finalize the Encyclopedia of Public Health in a very timely fashion.

Dresden, April 2008 Wilhelm Kirch

Acknowledgement

To my colleagues from Public Health in Dresden Dr. med. Natalie Schmitt, Dr. rer. medic. Christiane Hillger, Dr. med. dent. Ursula Schütte, Mrs. Grit Neumann, Mrs. Anja Zscheppang, Mrs. Christiane Hagedorn, Mrs. Jane Damerau, Mrs. Anna Klamar and Mrs. Claudia Schindler I am sincerely thankful for preparing the Index of the underlying Encyclopaedia of Public Health. Furthermore, I would like to thank for secretary assistance during the whole time of editing this Encyclopaedia Mrs. Simone Arras, Mrs. Beatrix Hörger and Mrs. Ines Kube from my Dresden Office.

Aboriginal

Synonyms

Native; Indigenous

Definition

Term is used to denote people inhabiting a region before settlers arrival, i. e. before colonization. Usually it is used for native people in Australia and Oceania.

Cross-References

► Indigenous Health Care Services
► Indigenous Health, South America

Aboriginal People

► Indigenous Health – Australooceaninan
► Indigenous Health, North America

Aborigines

► Indigenous Peoples

Abortion

Synonyms

Miscarriage; Pregnancy loss

Definition

Abortion refers to the spontaneous (miscarriage, stillbirth) or induced termination of a pregnancy with expulsion of the embryo or fetus. Abortion may be induced either medically or surgically. Unsafe abortions are a major cause of maternal deaths around the world. Legalization of abortion reduces significantly the number of unsafe abortions and consequently the case-fatality rates.

Abortive Plague

Synonyms

Mild course of plague; Mild course of Black Death

Definition

Abortive plague is a very mild infection with *Yersinia pestis*. The patients develop mild fever and a slight swelling of the lymph nodes. Nevertheless, abortive plague induces the building of antibodies. Thus the individual achieves immunity against the other forms of plague.

Absence From Workplace

► Absenteeism

Absenteeism

Synonyms

Absence from work; Absence from workplace

Definition

Absenteeism is a general term for habitual absence from a duty or obligation. In occupational health, it refers to nonattendance when expected to work, for any

reason at all, medical or otherwise. Absence from work is not really a medical phenomenon. It can be viewed as a "social" disease of workers that is symptomatic of underlying faults in their ► working environments, and it falls within the realm of occupational health. Sickness absence is a convenient term for absence from work attributed to sickness or injury and accepted as such by the employer or social security system. Sickness absence is a complex phenomenon and is not necessarily the same as the health status of the individual or sickness in a society. Some sickness absence and some absenteeism for other reasons may be regarded as objectively necessary and, therefore, acceptable and normal. Absenteeism becomes abnormal – in medical terms, "pathological" – when it is excessive. This may refer to workday loss or frequency of absence.

Absolute Liability in Tort

► Strict Liability

Absolute Risk

Definition

Absolute risk is the probability of an event in a population under study.

Cross-References

► Risk

Absorption

Definition

Absorption is the process of a (pharmacological) substance entering the body.

Accelometer

Definition

Measuring device for acceleration.

Accidents at Work

► Occupational Accidents

Accuracy

Synonyms

Preciseness; Precision

Definition

Accuracy refers to the closeness of the measured value and true value. In most cases the true value is not known. In practice best estimate of true value is marked as "reference", "criterion" or "gold standard". If best estimate of true value do not exist, then accuracy errors cannot be quantified. Accuracy is influenced by both ► precision and ► bias.

The gold standard in laboratory measurements is defined by the referent laboratory. In diagnostic tests the gold standard is the best criteria or standard on which to base a final diagnosis – true disease status (estimation of diagnostic accuracy is shown in the essay "► Measurement").

In statistical estimation, accuracy is the deviation of an estimate from the true population value (parameter value).

Acid Deposition

► Acid Rain

Acid Precipitation

► Acid Rain

Acid Rain

Synonyms

Ecosystem acidification; Acid deposition; Acid precipitation

Definition

Acid rain is a popular term for the effect that certain air pollutants, combined with atmospheric moisture, have on almost the entire ecosystem – soil, water resources, and pertaining flora and fauna in certain highly polluted areas of the world. It means that ecosystem acidification is a regional effect of air pollution, and the final consequence in a series of chemical reactions. It is nowadays one of the most serious environmental problems. Complex chemical processes include atmospheric precipitation of acid substances (acid rain), and consecutive chemical changes in soil components and water resources, often microbiologically induced. Adverse environmental consequences are often noticeable (e. g. damage to vegetation, especially in forestlands; and erosion of structures built of stone), but human health impairments, due to environmental degradation, are also possible. The main causes of ecosystem acidification are partly natural processes (e. g. volcano eruptions), but mainly anthropogenic influences during the 19th and 20th century (oil and coal combustion). Acid rain was described for the first time in Manchester (England) during 1852, and was a consequence of coal burning (high sulfur dioxide [SO_2] emissions). In the 20th century, acid rains in south Italy were the consequence of the volcanic activity of Vesuvius (hydrogen chloride (HCl) emission). Other important pollutants are nitrogen oxides (NO and NO_2), present worldwide in the air over highly polluted industrial and/or urban areas. These effects of acid rain have been reported mainly in highly industrialized regions of Western Europe, eastern parts of North America, and in southeast China, but also in some other areas of the world due to transboundary transport of pollutants.

Acquired Immunodeficiency Syndrome

- ► Acquiring Social Identity
- ► AIDS
- ► HIV-Infection and AIDS

Acquiring Social Identity

Synonyms

Socialization

Definition

The process of teaching an individual or a group of individuals about how to behave according to the norms and values of a group. This process may occur indirectly at a societal level through exposure to different media (e. g. books, film, television). It may also occur at the group, interpersonal level through interaction and modeling of the behavior of individuals in a person's everyday life (e. g. schoolmates, co-workers, friends, parents). It may also be achieved more directly through instructional media and teaching by persons in positions of power or authority (e. g. parents, teachers, employers).

Action Area

Active Noise Control

Synonyms

Noise cancellation; Active noise reduction; Antinoise

Definition

Active noise control is a method of ► noise reduction that analyzes the waveform of the background noise

using a computer, then generates a sound wave with the same amplitude and the opposite polarity to the original sound. These waves cancel out in a process called destructive interference, and the result is a reduction in the amplitude of the perceived noise. The first patent for an active noise control system was granted to inventor Paul Lueg in 1934, for describing how to cancel sinusoidal tones in ducts by phase-advancing the wave and canceling arbitrary sounds in the region around a loudspeaker by inverting the polarity. By the 1950s, systems were created to cancel the noise in airplane cockpits. Antinoise is used to reduce noise in working environments with earplugs, and bigger noise cancellation systems are used for engines or tunnels.

Active Noise Reduction

► Active Noise Control

Active Smoking

Definition

Active smoking refers to the voluntary inhalation of mainstream tobacco smoke (smoke inhaled directly from a cigarette).

Active Surveillance

Definition

In this context active surveillance means that department of health officials proactively call physicians' offices to ask if they have identified any cases of a particular disease; in this instance, the information required is detailed because the disease is often not well understood and the ► surveillance system provides a means of collecting information that may help identify its causes or risk factors. Active surveillance is more expensive than ► passive surveillance and it is typically reserved for relatively infrequent but important infections or events.

Activities of Daily Living

Definition

Activities of daily living (ADLs) are the most basic and fundamental functions of self-care, and they are used to describe the functional status or ► functional ability of a person, usually with reference to older people or people needing long-term care. There are several dimensions of ADLs and people are classified as independent or dependent on each of them. These functions are bathing, dressing, using the toilet, transferring in and out of beds or chairs, continence, and eating. As continence is more indicative of a physiological state than a function, it is often removed from the ADL measures. Another term, "instrumental activities of daily living" (IADLs), describes activities that are not necessary for fundamental functioning but needed for independence in the respective environment or community. This includes activities like cooking, cleaning, laundry, shopping, making and receiving telephone calls, driving or using public transportation, and taking medicines.

Activity

Definition

Execution of a task or action by an individual.

Activity-Based Bugdets

Definition

Activity-based budgets are a method of financing hospitals based on their specific level of activity. According to the specific functions of a hospital, activity related budgets are annually established to reimburse hospitals for the treatment of their patients. As ► prospective budgets activity-based budgets do not generally incorporate incentives for the hospital to spend less than the budget fixed before. Under the persisting financial constraints in the hospital sector, many countries during the last 20 years changed their financing method for hospitals towards ► per-case payments based on ► diagnosis related groups (DRGs).

Activity Limitations

► Impairment and Disability

Actors in Health Promotion

Acute Care Bed

Synonyms

Curative care bed

Definition

Acute care beds are beds in hospitals available for curable care for patients, where the principal clinical intent is to –

- manage labor (obstetric),
- cure non-mental illness,
- provide definitive treatment of injury,
- perform surgery,
- relieve symptoms or reduce severity of non-mental illness or injury,
- protect against exacerbation and/or complication of non-mental illness and/or injury that could threaten life or normal functions,
- perform diagnostic or therapeutic procedures.

Acute Health Effects

Definition

A health hazard may produce serious, immediate and direct effects. These are called acute effects. Some health effects result from short-term exposure to a high concentration of a health hazard. The illnesses, diseases and other conditions that can result from health hazards are often referred to collectively as health effects or adverse health effects.

Acute Intoxication

Definition

A condition that follows the administration of a psychoactive substance resulting in disturbances in level of consciousness, cognition, perception, affect or behavior, or other psycho-physiological functions and responses. The disturbances are directly related to the acute pharmacological effects of the substance and resolve with time, with complete recovery, except where tissue damage or other complications have arisen. Complications may include trauma, inhalation of vomitus, delirium (► delirium tremens), coma, convulsions, and other medical complications. The nature of these complications depends on the pharmacological class of substance and mode of administration.

Acute Life-Threatening Infections

Monika Korn
Klinik für Kinder und Jugendmedizin,
Friedrich Ebert Krankenhaus,
Neumünster, Germany
hkorn80663@aol.com

Synonyms

Highly dangerous infectious diseases; Infectious diseases with a critical course

Definition

Acute life-threatening infectious diseases are characterized by the fact that they can take a lethal course within a few hours or a couple of days. The pathogens or their toxins can cause a cardiocirculatory shock, a failure of the functions of the central nervous system, respiratory insufficiency or multiorganic failure.

Basic Characteristics

Reasons for Life-Threatening Courses of Infections

Whether an infectious disease takes a life-threatening course or not, depends on various factors. The sever-

ity of an infection is determined by the virulence of the pathogens and the organs or organic systems that are involved; deadly courses have to be feared in cases where impairment of vital functions or multiorganic failure occur. The development of serious infections is facilitated by a weakened immune status or underlying (chronic) disease. Further important aspects are the prophylactic and therapeutic possibilities. Avoidable severe or even deadly courses can occur due to a neglect of preventive measures, especially due to missing active vaccinations (► immunization, active). Other reasons for a treatable disease taking a lethal course can be a lack of effective drugs (due to a shortage of resources), or the late onset of therapy. The quick introduction of treatment is highly significant in cases of infections with toxin-building germs, like tetanus, ► anthrax infection and ► gas gangrene. If there is no therapy against a number of infecting organisms or their toxins one has to be prepared for a lethal outcome. ► Hemorrhagic fevers belong to this category of infectious disease.

Sepsis

A sepsis is an inflammatory reaction, which involves the whole organism (SIRS = systemic inflammatory response syndrome). Characteristic symptoms are bacteremia, tachycardia, abnormal rapid breathing (tachypnea), a changed body temperature (fever or hypothermia) as well as changes in white blood cell count (> 12/nl or < 4/nl). The various pathogens have typical places of entrance, like wounds, the respiratory, the urinary or the gastrointestinal tracts. From there they reach the circulatory system and spread into other organs. In 70–80% cases of sepsis, gram-negative bacteria are responsible, and in 20–30% gram-positive. Poisons (toxins), which are set free by the bacteria, play an important role in the course of the sepsis. During the destruction of gram-negative germs endotoxins are released, and in the case of gram-positive pathogens exotoxins are released. Staphylococci are responsible for the ► staphylococcal toxic-shock syndrome (TSS) and streptococci for the ► streptococcal toxic-shock syndrome (STSS). In sepsis, substances, which mediate inflammations (cytocines, interleukines), start a cascade process that leads to a condition of life-threatening shock. A complex impairment of immunological, endocrinological, cardiovascular and metabolic functions results. Uncontrollable cardiocirculatory problems (extreme decrease of blood pressure), serious coagulation defects (consumption coagulopathy, disseminated intravascular coagulation = DIC) and organic failure of the lungs and kidneys are responsible for the lethal course of septic shock. Besides combined antibiotic treatment, surgical interventions (drainage of abscesses, removal of necrotic material) as well as intensive care measures (intravenous substitution of volume deficits, cardiocirculatory therapy, application of oxygen, mechanical ventilation) may be required. A typical example of an infectious disease leading to septic shock is meningococcal sepsis, which is also known as ► Waterhouse-Friderichsen syndrome.

Encephalitis

Encephalitis is the inflammation of brain tissue. Most frequently, the pathogens reach the brain via the blood vessels (hematogenic); some germs can also get into the central nervous by nerve tracts. Besides fever and headache, impairment of central nervous functions, cerebral seizures, neurological failure (pareses), impaired consciousness or changes in behavior are all possible symptoms of encephalitis. Therapy depends on the pathogen responsible. Even if treatment is possible and the course of the infection is not lethal, encephalitis is always a serious condition. Neurological defects can persist, which is not only a severe burden for the patient and his relatives but also may lead to the need for costly follow-up treatments. An extremely dreaded infection is herpes-simplex encephalitis. Without treatment, it takes a lethal course in about 70% of cases. Prognosis depends on the level of consciousness at the onset of therapy. A lethality of 20–50% has to be assumed in cases of ► Japan encephalitis. The prognosis is also bad when encephalitis occurs as a complication of ► malaria or ► measles.

Meningitis

Meningitis is an inflammation of the membranes that envelop the central nervous system. Diagnosis is confirmed by an examination of cerebrospinal fluid. In general, the micro-organisms come from the nose-throat area and reach the meninges from the blood vessels. In most cases, the course of a viral meningitis is not harmful. Of the bacterial inflammations of the meninges 60–

70% occur in childhood. In newborns, impaired breathing is the most conspicuous symptom. In older babies, fever, vomiting and agitation predominate. From the age of one year, meningitis is characterized by fever, headache, vomiting and nuchal rigidity (meningism); cerebral seizures and an impairment of consciousness can appear. Bacterial meningitis demands antibiotic therapy; from the age of four weeks, ceftriaxone, a 3rd generation cephalosporine, is the preferred form of treatment. Even though a great number of pathogens can cause meningitis, after the seven weeks of age only three pathogens are of clinical relevance: *Neisseria meningitidis* (meningococci), *Streptococcus pneumoniae* (pneumococci) and *Haemophilis influenzae* type B (Hib). Pneumococci are responsible for 6–20% of meningitis deaths; meningococci or Hib cause less than 5%. Possible long-term effects are impaired hearing, impaired motor and neurophysiological development, cerebral seizures and pareses.

Tetanus

Tetanus is caused by *Clostridium tetani*, a toxin- and spore-building bacterium, which exists worldwide and is found in the soil. Usually, infection is due to dirty wounds. In newborn babies, the navel is the main route of entry. Following an incubation period of 3 days to 3 weeks, in newborns after a short interval, tetanus infection is primarily characterized by muscular spasms and increased muscle tonus. The mouth cannot be opened completely, and a characteristic facial expression results, called "risus sardonicus". The cardiac muscle is damaged. Furthermore, hyperactivity of the sympathic nervous system and impairment of carbohydrate metabolism develop. After the onset of the disease, only ► symptomatic therapy can be carried out. To avoid a further build up of toxins, excision of the wound has to be performed. Death is primarily due to respiratory insufficiency and cardiovascular complications. Although 57 countries are known to have a high risk of tetanus, 90% of all infections occur in only 27 of them. The highest incidence of tetanus is found in the Middle East (Iraq, Yemen), in Africa, South Asia (Afghanistan, Bangladesh, India, Nepal, Pakistan), East Asia and in the Pacific region (China, Indonesia, Cambodia). The risk of a tetanus infection is extremely high if non-immunized women give birth to children under insufficient hygienic circumstances (http://www.who.int/vaccines/en/neotetanus.shtml). Through wounds (for example, when cutting through the umbilical cord) bacteria can reach the blood circulation of mothers and newborn babies. Every year about 250 000 newbornes and 30 000 women die after birth due to a tetanus infection. In newborn babies the infection takes a lethal course in 70%. Thus it is responsible for 14% of deaths in newborns. Prognosis, depends on the onset interval; if this interval is less than 24 hours, lethality is 100%. However, tetanus lethality is also high when the disease occurs later in life. Depending on the incubation period, it is 25–60%. The most important prophylactic measure is active tetanus vaccination (► tetanus vaccination, active). Under certain circumstances, a passive tetanus vaccination (► tetanus vaccination, passive) or a ► simultaneous vaccination is indicated. To prevent tetanus, it is necessary to carry out births under good hygienic conditions.

Rabies

Rabies is a viral infection with a deadly course, which is transmitted by the bite of an infected animal or by contact with contagious spittle. Animals with suspected rabies, show abnormal behavior: thus pets can be aggressive, while wild animals appear tame and trusting. The average incubation time of rabies is 3–8 weeks; it is shorter in injuries near the head than in those distant from the head. Initially, the virus affects muscle cells and then later passes along the nerve tracts to the brain. Finally, it gets into the salivary glands. In humans the course of rabies shows three phases. At the onset of the disease there are nonspecific symptoms like fever and exhaustion, the area of the bite is very sensitive to pain. During the following acute neurological phase, fear and agitation appear as well as changes in the frame of mind (aggressions, depressions). As swallowing induces pharyngeal cramps, the patients become afraid of drinking. To avoid swallowing, they let the spittle flow out of their mouths. Even the perception of water – visually or acoustically – leads to agitation and cramps. This state, which is typical of rabies, is called hydrophobia (or aquaphobia, fear of water). During the final phase of the infection the cramps decrease and progressive pareses inevitably lead to death. As there is no chance of cure after the onset of the disease, therapy should begin immediately after the patient has been bitten by an animal sus-

pected of having rabies. An active (► rabies vaccination, active), and – if necessary – a passive rabies vaccination (► rabies vaccination, passive), is carried out. Persons at risk, like veterinarians and hunters, should receive an active rabies vaccination as a prophylactic measure. It has to be recommended to be careful with unknown and, particulary, free running animals especially, if the animal cannot be caught for examination. These precautionary measures should also be taken seriously by travelers in regions with a high incidence of rabies (http://www.cdc.gov/ncidod/dvrd/rabies/).

Acute and Post-Traumatic Stress Disorder (PTSD)

Definition

A post-traumatic stress disorder is the only ► anxiety disorder that, per definition, was caused by a traumatic event. Therefore, this diagnosis can only be made if the person has experienced a trauma and if there are symptoms from the symptom cluster triad: experience distressing recollections of the event (e. g. flashbacks or nightmares), avoidance (e. g. apathy, emotional detachment, avoidance of places or persons connected with the trauma) and hyperarousal (e. g. insomnia, irritability, hyper vigilance). The symptoms of an acute stress disorder begin during or shortly following the trauma. Persons suffering from PTSD can also show ► dissociation. If the symptoms and behavioral disturbances of the acute stress disorder persist for more than one month, and if these features are associated with functional impairment or significant distress to the sufferer, the diagnosis is changed to post-traumatic stress disorder. Post-traumatic stress disorder is further defined in DSM-IV as having three subforms: acute (<3 months' duration), chronic (≥ 3 months' duration), and delayed onset (symptoms began at least 6 months after exposure to the trauma).

Cross-References

► Anxiety Disorders

Acute Spasmodic Laryngitis

► Spasmodic Croup

Acute Stress Disorder

Definition

Acute psychological damage caused by stress.

Acute Stress Reaction

Definition

An acute ► stress reaction is a transient disorder that develops in an individual without any other apparent mental disorder in response to exceptional physical and mental stress. It usually subsides within hours or days. Individual vulnerability and coping capacity play a role in the occurrence and severity of acute stress reactions. The symptoms show a typically mixed and changing picture and include an initial state of "daze" with some constriction of the field of consciousness and narrowing of attention, inability to comprehend stimuli, and disorientation. This state may be followed either by further withdrawal from the surrounding situation or by agitation and over-activity (flight reaction or fugue). Autonomic signs of panic anxiety (tachycardia, sweating, flushing) are commonly present. The symptoms usually appear within minutes of the impact of the stressful stimulus or event, and disappear within two to three days (often within hours).

Cross-References

► Stress

Adaptation

Synonyms

Environmental tolerance

Definition

Environmental tolerance means a process by which an organism becomes tolerant to a new environment so that it continues to survive and reproduce. The species undergoing this evolutionary process gets progressively modified for a better survival and maintenance. The adaptive process entails structural and biochemical changes that may or may not be reversible. On a genetic basis, it is driven by natural selection in which ► alleles enhance survival and reproduction, the frequency of which increases from generation to generation. The ability of penguins to live in the harsh Antarctic environment is one of the classical examples of adaptation. These birds have solid bones, and packed, water-tight feathers to stay underwater, flipper-like wings to fly underwater and insulating blubber to keep them warm.

Cross-References

► Coping Mechanisms
► Vulnerability Concerns

Adaptive Capacity

Definition

Ability of a system to adjust to changes, moderate potential damages, take advantage of opportunities, or cope with adverse consequences.

Addiction

► Substance Related Disorders

Adequate Understanding

► Informed Consent

Adiposity

Synonyms

Obesity; Overweight

Definition

Adiposy is defined as weight more than 20% above what is considered normal according to standard age, height and weight tables. According to individual national studies, the prevalence of obesity in European countries ranges from 10 to 20% in men, and 10 to 25% in women.

Cross-References

► Obesity

Adivasi (Scheduled Tribes in India)

► Indigenous Health, Asian

Adjusted Rates

Definition

Adjusted rates are summary measures of the rate of morbidity or mortality in a population in which statistical procedures have been applied to remove the effect of differences in composition of the various populations. There are two methods for the adjustment of rates: the direct method and the indirect method. Direct and indirect refer to the source of the rates.

Cross-References

► Standardized Rate

Adjustment

► Standardization

Adjustment Disorders

Definition

States of subjective ► distress and emotional disturbance, usually interfering with social functioning and performance, arising in the period of adaptation to a significant life change or a stressful life event. The stressor may have affected the integrity of an individual's social network (bereavement, separation experiences) or the wider system of social supports and values (migration, refugee status), or represented a major developmental transition or crisis (going to school, becoming a parent, failure to attain a cherished personal goal, retirement). Individual predisposition or vulnerability plays an important role in the risk of occurrence and the shaping of the manifestations of adjustment disorders, but it is, nevertheless, assumed that the condition would not have arisen without the stressor. The manifestations vary and include depressed mood, anxiety or worry (or a mixture of these), a feeling of inability to cope, plan ahead, or continue in the present situation, as well as some degree of disability in the performance of the daily routine. Conduct disorders may be an associated feature, particularly in adolescents. The predominant feature may be a brief or prolonged depressive reaction, or a disturbance of other emotions and conduct.

Administration

► Management of Occupational Diseases

Administration Law

► Administrative Law and Public Health

Administrative Act

Synonyms

Administrative order; Administrative deed

Definition

The administrative act is a core legal tool of the state administration (i. e., the government and its administrative institutions). An administrative act is a physical act performed or a decision issued by the administration which is determined to regulate and resolve a specific case (e. g., to mitigate a public health risk). Such acts have direct legal effects vis-à-vis the addressee of the act. Administrative acts include, among others, public health agency decisions that order the isolation of a person, the closure of a business, the abatement of a nuisance or the grant as well as the revocation of a professional license.

Administrative Deed

► Administrative Act

Administrative Law and Public Health

ADEM KOYUNCU
Mayer Brown LLP, Cologne, Germany
akoyuncu@mayerbrown.com

Synonyms

Administration law; Regulatory law

Definition

Administrative law is the body of legal rules that govern the exercise of sovereign powers by the state administration. Administrative law governs the legal relationships between private subjects (individuals and private legal entities) and the state administration with respect to the exercise of sovereign powers. Administrative law provides the tools and procedures for administrative practice. It includes the creation and funding of administrative departments and regulatory agencies. Administrative law also governs the relationships between the state administration institutions. Administrative law is a part of ► public law.

Basic Characteristics

Public health law is a branch of administrative law (Jacobson et al. 2007; Gostin et al. 2007; Grad 1990). Public health practice is governed by the rules, procedures and principles of administrative law. As legal background, administrative law itself is a branch of public law.

The Branches of Law

When trying to subdivide the laws, in most jurisdictions, three main branches of law can be differentiated, i. e., ► private law, public law and ► criminal law (*See* Fig. 1). The three branches can be further subdivided into specific sub-fields. For example, private law includes the law of contracts as well as the law of torts or family law.

Public law encompasses the legal rules that govern the relationship between individuals (including private legal entities) and the state institutions. Therefore, public law includes the relationships between individuals and the legislative powers, the judiciary powers (i. e., the courts) and the executive powers (i. e., the government and administrative agencies). Accordingly, subdivisions of public law include constitutional law and court procedure laws as well as administrative law. The latter is of particular interest for the practice of public health, although the former subdivisions are also relevant.

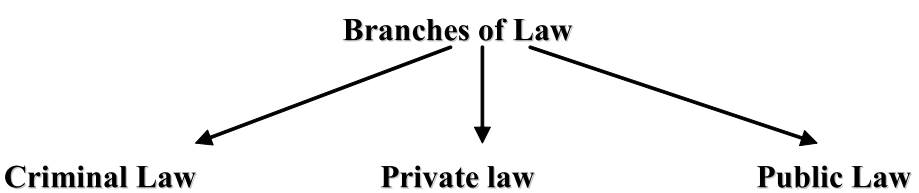
Administrative law is one field of public law; public health practice and public health law are also attributed to public law. The qualification of public health law as part of administrative law has consequences for public health practice because administrative law provides for specific principles, tools and decision-making procedures.

Actors and Means in Administrative Law

The protagonists of administrative law are the institutions of the state administration. These include the government and all administrative and regulatory agencies. Therefore, health departments and regulatory agencies as well as non-regulatory agencies fall in the scope of administrative law. The central actor of administrative law is the government. Thus, the government is probably the most important actor in public health policy and practice (*See* also Gostin et al. 2007).

The actors of administrative law are entitled to apply specific legal means. The governments may promulgate regulations that are legally binding. The legislator grants the government the power to issue regulations in order to specify general and abstract legal rules. As such, the government is commonly authorized in many laws to promulgate regulations to specify "the current state of the art". In addition to regulations (which are strong legal tools), governments may create standards and rules to specify technical or scientific terms and rules. Administrative laws also grant authority to the governments to create new administrative agencies and, in doing so, to create the necessary administrative infrastructure to exercise the state powers.

The *government* creates administrative agencies and delegates powers to them within the scope of their mission (Grad 1990). Consequently, agencies exercise state powers. Public health agencies belong to the old-



Administrative Law and Public Health, Figure 1 The Branches of Law

est administrative agencies in history (Parmet 2007). In the exercise of public powers, administrative agencies are provided with and bound to a certain set of legal tools:

- They may issue administrative orders (e. g., by ordering individuals to stay in hospital);
- They may perform physical acts (e. g., by destroying a dangerous object);
- They may enact ordinances (e. g., for zoning and planning purposes);
- They may set standards and make rules (e. g., specify the "state of the art");
- They may enter contracts governed by public law.

In addition to these means, *administrative agencies* in most jurisdictions are entitled to enforce compliance with their orders, including the use of coercion (administrative enforcement). The right to enforcement of its own orders by applying coercive measures is a characteristic of the exercise of state powers. In contrast, between individuals and private entities (in private law), no one is entitled to coercively enforce a right on his own. In private law, individuals must go to courts and take legal actions if they wish to enforce a private claim. Overall, public health law as a branch of administrative law has a powerful set of legal tools at its disposal. A health department may, for example, order the revocation of a license against a medical doctor and order the closure of his medical practice. If the doctor defies the order, the health department may effectuate the closure of the practice by using coercion. Similarly, if the health department orders the quarantine or isolation of certain persons, it is entitled to enforce these orders by coercively detaining the persons. Instruments of administrative enforcement are:

- Coercive enforcement penalties in case of non-compliance;
- Execution by substitution if the order addressee fails to comply; and
- Direct coercion to effectuate the ordered result.

Many practice areas of public health are specialized fields of administrative law. For example, the regulation of food, pharmaceuticals and chemicals, together with environmental law, occupational safety law and infectious diseases control laws are fields in the scope of special administrative law. Therefore, public health departments or health-related regulatory agencies are also entitled to order and enforce public health actions, and exercise extensive powers vis-à-vis individuals and private entities. Because of the reach and intensity of these powers and the possibility of severe intrusion of the rights of individuals, the administration has to respect specific principles and rules when exercising sovereign powers.

Principles and Rules of Administrative Law

The administration has to follow the *principle of legality*. The administration may only take measures and intrude personal rights if there is a legal basis allowing such actions. The administration is not allowed to act without the act being grounded in law. Particularly, this premise prohibits any kind of arbitrariness. In addition, the administration is not allowed to act *against* existing laws. This includes the administration's duty to respect the *principle of proportionality* (in German jurisdictions: *Grundsatz der Verhältnismäßigkeit*) between the combated threat and the personal and economic consequences of the selected administrative measures (*See* for U.S. law Gostin 2000, referring to the "Means/Ends-Test"). The European Court of Justice (i. e., the Supreme Court for the European Union that reviews community law matters) has acknowledged that the "principle of proportionality" is an element of primary European Community Law. Obviously, in all jurisdictions, the administration must perform a careful legal balancing of the conflicting rights before invading personal rights and interests. Further, the administration has to respect and must be consistent with the hierarchy of laws.

With respect to the administrative decision-making process, in most jurisdictions *specific administrative procedure rules* exist which are binding to administrative agencies (e. g., in the U.S. the "*Administrative Procedure Act*", or the German *Verwaltungsverfahrensgesetz*). These procedure laws impose duties in order to respect the individual's rights in the course of an administrative proceeding. Conversely, administrative procedure laws grant procedure rights to parties subject to administrative proceedings. These procedure rights intend to ensure the right to a "fair procedure" before an administrative order is issued. The administration's duty to guarantee a "fair procedure" includes, among others, the following measures, which must be observed before an order is released:

- Neutrality of the decision-making procedure with transparent and clear criteria;

- Exclusion of potentially partial persons (with conflicts of interests) from the proceedings.
- Prior notification to addressees (an individual or legal entity) of envisioned ► administrative acts (notification must be complete, timely and in writing);
- ► Hearing the addressees of administrative acts and allowing them to file objections, present their own facts and evidence and challenge the administrative findings;
- Allowing addressees access to the underlying proceeding records;
- Allowing representation before the administration by legal counsel;
- Providing addressees of administrative acts with reasons for decisions in writing.

When an administrative act is released, the administrative agency must provide the factual and legal justification for the particular order (decision reasons). Therein, the agency must evince that it has considered the individual case facts, including the hearing results and the evidence provided by the addressee. These procedural rules are designed to ensure that all state powers (sovereign powers) must be exercised with a high level of scrutiny.

In principle, the procedural requirements have to be met prior to all administrative orders issued by public health departments. However, in urgent cases or emergencies, administrative agencies or their officers are exceptionally relieved from some of the procedural obligations. In such cases, they may not be obliged to issue the order with reasons in writing. Notably, such alleviative emergency competencies are also granted by law.

In addition to these procedural requirements, administrative agencies have to follow *substantive decision-making rules*. These substantive requirements are particularly aimed at the protection of the rights of the addressees of administrative action. The discussion of these requirements would extend the scope of this essay (► legal balancing of conflicting rights).

A final but basic element of administrative procedure laws is the individual's *right to file opposition proceedings* against an administrative order at the next, higher level of the administration. This is an institutionalized inner-administrative control measure and a right of the affected individual to appeal the initial order within the administration at the superior administrative instance.

Administrative Courts and Judicial Review

Administrative law includes the individual's right to appeal administrative decisions in court. The guarantee of judicial review is a central element of democratic states. As all state powers derive from the people and as the powers are separated between the legislative, executive and judicial powers, the people have the right to challenge administrative decisions in court. This is one of the constitutional and human rights and is subject to the Universal Declaration of Human Rights of the United Nations.

Most jurisdictions provide for *specialized administrative courts*. Additionally, their proceedings are governed by specific administrative procedure laws in court, which are complementary to the criminal or civil procedure laws. Within the judicial review, courts review whether administrative decisions comply with procedural and substantive legal requirements. Among the formal aspects, courts assess whether the agency was competent and legally authorized to order the challenged action. If the agency lacked sufficient authority, the courts will reverse the challenged orders regardless of the desirability or ratio of the order.

The judicial review also comprises the administration's decision-making process, which particularly includes whether:

- The agency has interpreted the authorizing laws properly;
- The agency has gathered all relevant case facts;
- The agency has weighed the case facts appropriately (this is also why agencies have to provide reasons for administrative orders as they must enable the individual and the court to understand the administrative weighing, balancing and judgment);
- The agency has made a sound evaluation of the facts when assuming that the elements of the executed law are given (e. g., when determining the existence of a public health threat). As these decisions rely on specific expertise and particular case constellations at the time of the decision, courts regularly acknowledge that the agency officials have a scope of evaluation and judgment.
- The agency – when selecting a legal measure – has made appropriate use of its discretion (if there was room for discretion). Here, courts review the discretion use in light of the scope of the agency's mission and the public health threats at stake.

Overall, the judicial review has to assess whether the challenged administrative order complies with the underlying substantive and procedural laws. It is an integral part of administrative law and, as such, also part of public health law and public health practice.

Forms of Action Outside Administrative Law

Even though they are bound to administrative law, state agencies are allowed to involve private entities in the provision of public health services. For example, health departments may assign certain medical services to specialized doctors. In recent years, the importance of larger scale public-private cooperations is increasing, particularly in the realm of public health. In the practice of health promotion, the use of ► public-private partnerships to supply these services is increasing. Further examples of such public-private partnerships exist in the realm of health services and managed care (*See* Jacobson et al. 2007). The inclusion of private entities in the performance of administrative obligations does not absolve the administrative agency from its public responsibilities for the public's health. The agency has to ensure through pertinent contractual agreements that their private partners also provide the services with due care and respect for the personal rights and interests of the addressees of their services.

Adolescence

Definition

Adolescence is the time of growing up from childhood to adulthood or the period of life between puberty and maturity. The age span is defined differently, depending on the conceptualization of adolescence. The World Health Organization (WHO) defines adolescence as the period between the ages of 10 and 19 years. Adolescence is a transitional stage of development involving intense biological, social and psychological changes.

Adolescent Health and Development

ADALINE ZENOBIA MUYEED
Senior Technical Officer, Strategic Information, Family Health International, Arlington, VA, USA
amuyeed@jhsph.edu

Definition

Adolescence is defined as the period between childhood and adulthood when multiple developmental processes occur. These areas of development include physical growth, pubertal maturation, cognitive transitions, and psychosocial and social maturation. Early, middle, and late adolescence are defined in pediatrics by sub-categories of chronological age: early adolescence is characterized as ages 11–14; middle adolescence, ages 15–

17; and late adolescence as 18–21 years of age. However, young people between the ages of 10 and 24 years are considered, especially in light of the fact that the age at which young people assume adult roles is increasing globally. Although chronological age is an important indicator of adolescent development and provides an objective and practical measure, it does not account for individuals on different developmental trajectories in terms of physical, cognitive, and psychosocial maturation.

The notion of "adolescence", defined as an exploratory period between childhood and adulthood when young people typically have few responsibilities, has been said to be relevant mainly to advanced economies; young people (both men and women) in other parts of the world move directly from childhood to taking on adult roles. However, as compared with 20 years ago, there is evidence that a large number of young people (the total population of 10–24 year olds is estimated to have reached 1.5 billion worldwide by 2005) are now entering adolescence earlier and healthier, are more likely to stay in school longer, to postpone entry into the labor force, and to delay marriage and childbearing (National Research Council and Institute of Medicine 2005). A focus on adolescence is therefore gaining more attention worldwide. The need to help young people transition to successful adult roles such as work, citizenship, marriage, and parenthood is being advocated.

Basic Characteristics

Adolescent Development

Physical Growth and Maturation Adolescents experience rapid acceleration in physical growth (increase in height and weight; ► physical maturation), and pubertal and sexual maturation (► pubertal maturation), including further development of reproductive organs and development of secondary sexual characteristics (such as breast development in girls, genital development in boys, and pubic hair in both). Age at ► menarche is the most commonly reported indicator of sexual maturity in girls. Other physical manifestations include changes in body composition, and the quantity and distribution of fat and muscle. There are also changes in circulatory and respiratory systems which lead to increased strength and tolerance for exercise. The growth spurt occurs about 2 years earlier in girls compared with boys. These physiological changes occur between the ages of 9 and 16; however, there is inter-individual variation in the timing and tempo of these events (Steinberg 1993).

Cognitive Transitions From early adolescence onwards, adolescent thinking is characterized by increased knowledge, multi-dimensional thinking, and the ability for hypothetical reasoning (► cognitive development). Piaget described a shift from concrete to abstract thinking (such as the ability to see various sides of an issue and the perspective of others). The ability to think abstractly is made possible by cognitive advances that emerge between the ages of 11 and 20 years (Keating 1990). A liability of this developmental shift can be an overestimation of abilities.

Psychological and Social Transitions Adolescents grapple with issues of identity development, achievement, autonomy, intimacy, and sexuality during the adolescent period (► psychosocial development). The process of identity formation can take various paths (with a variable degree of exploration, seeking of alternatives, and sense of commitment), and some of these tend to be more adaptive than others. There are multiple domains of self-evaluation and self-description including scholastic and athletic achievement, and physical appearance, etc. The process of individuation, and increasing autonomy during this period, although culturally variable, can be the basis of potential conflict with authority figures, including parents. There is a line of research studying the effectiveness of different types of parenting style on teens, including democratic, autocratic and permissive styles, which allow a different degree of autonomy and negotiation. The choice and effectiveness of the various styles may be based on cultural preferences and social context.

Adolescence is a time of life when people expand their circle of significant others to include peers and other adults (► social transition). Young people also begin to navigate through social institutions such as school. Parents, guardians, teachers, classmates, and friends are important socializers. Social acceptance and integration become salient, and we see the development of friendships; in particular with larger ► peer groups and/or more intimate relations, such as in close friendships. There is a shift from same sex to opposite sex interest, and young people may begin dating, experience romantic relationships and become sexually active.

Adolescent Health and Development, Figure 1

Adolescent Health

Good physical and mental health, as well as the knowledge and means to sustain good habits, are key for healthy development in adolescents as many health compromising behaviors emerge during this period. It is known that the major causes of mortality and morbidity in youth are behavior related, and therefore can be prevented. In the United States, for example, youths between the ages of 15 and 25 are more likely to suffer from unintentional injuries (such as motor vehicle accidents, drowning and sports/recreational-related incidents), homicide, violent crimes, and suicide. Other health related problems that are prevalent in youth include alcohol use, tobacco use, illicit drug use, obesity/weight problems, eating disorders, teenage pregnancy and childbearing, and sexually transmitted infections, including HIV. There are regional variations in causes of death; for example, HIV/AIDS is the main cause of death in youth in Sub-Saharan Africa, whereas deaths from non-communicable diseases are more prevalent in other regions, as discussed earlier (National Research Council and Institute of Medicine 2005). Pregnancy and childbirth-related mortality and morbidity due to early childbirth (in Sub-Saharan Africa and South Asia) and abortion (in all developing regions) are substantial. Health compromising behaviors have a grave impact on individuals, societies and economies in the long-run.

Mental health illnesses pose a major burden of disability worldwide. In the US, mental and addictive disorders (including anxiety disorders, disruptive disorders, mood disorders, and substance use disorders) are prevalent in one out of five 9–17 year olds (USDHHS 1999). Mood disorders such as depression, for example, are known to be associated with academic, social, and behavioral problems (including suicide) during adolescence. Risk factors such as poverty, violence, and trauma, among others, contribute to mental illness in youth worldwide. There is a need to address the stigma associated with adolescent mental health. Global policies that will integrate mental health policy into the overall healthcare system and assess the global treatment gap are programmatic challenges are being advocated by the World Health Organization (WHO) (WHO 2005). It is important to promote preventive interventions, as they have been shown to cause sustained reduction of depression and feelings of hopelessness, but also aggressive and delinquent behavior, and alcohol, tobacco and drug use (WHO 2003).

Health Interventions

Steps can be taken to help young people navigate successfully through the multiple transitions and influences of adolescence, and remain healthy. Different approaches have been undertaken to understand and enable positive health and development in youth. These include developmental, ecological, and life cycle approaches, among others. Contemporary developmental theory and research stresses the dynamics of individual-context relations in understanding behavior and developmental change. Ecological approaches address the individual-level (such as timing of puberty, temperament, and age), micro-level (the immediate relationships such as parents, peer, and teachers), environmental (the home, school, and neighborhood), and broader macro-level influences and forces (such as cultural factors, poverty, political instability, and the media) that influence adolescent health and development for successful intervention. The life cycle approach requires the understanding that promoting and sustaining the health and development of youth begins in childhood, and continues throughout the life of individuals. It is useful to end with the WHO conceptual framework, which presents a wide array of enabling factors that begin early in life to promote healthy adolescent development. These fac-

tors include promotion of healthy behaviors, life-long learning and education during adolescence, preceded by good nutrition, a safe environment, and healthy development, beginning in childhood (The World Bank Group 2006).

Adoption Studies

Definition

The adoption studies approach is used to separate childhood rearing effects from genetic effects by studying the similarity of adopted children with their biological and foster parents. These studies are the most successful in populations where adoption records are systematically collected. The first step in this type of investigation is the identification of affected parents and control parents who have given up children for adoption. In the next stage, the frequency of disease in the children is then compared between the affected and control groups.

Advanced Reproductive Technologies

Definition

Advanced reproductive technologies are medical treatments or procedures designed to enhance a woman's fertility, such as in-vitro fertilization. Advanced reproductive technologies are commonly referred to as assisted reproductive technologies.

Cross-References

- ► Infertility

Adverse Drug Reaction

Synonyms

Side effect; Adverse effect; Adverse events

Definition

An adverse drug reaction (abbreviated ADR) is a term to describe the unwanted, negative consequences sometimes associated with the use of different medications. It includes a wide range of outcomes that can be toxic,

physical or psychological reactions to a drug. The reaction may be allergic, predictable or unpredictable. The scientific discipline that focuses on the study of ADRs is pharmacovigilance.

Cross-References

► Side Effect

Adverse Effect

Synonyms

Adverse events; Adverse outcome; Complication; Side effects

Definition

Adverse effects are harmful and undesired effects resulting from either medication or interventions like chemotherapy or surgery. Adverse effects that result from medication are called ► side effects when those effects are secondary to the main or therapeutic effect of the drug, sometimes due to unsuitable or incorrect dosage or procedure. Adverse effects from medical procedures may occur in the course of surgery, like infection, hemorrhage, inflammation, scarring, loss of function, or changes in local blood flow. Non-surgical procedures like high intensity radiotherapy might result in burned skin, for example. Adverse effects can cause reversible or irreversible changes.

Cross-References

► Adverse Drug Reaction
► Side Effect

Adverse Events

Definition

An adverse event (AE) is any adverse change in health or "side-effect" that occurs in a person during a clinical trial or within a pre-specified period after dosing of a drug is complete. Not every adverse event is causally related to the treatment being studied, but researchers must report all adverse events to the relevant regulatory authority in the country where the drug is to be registered. Adverse events categorized as "serious" (for example death, illness requiring hospitalization, events deemed life-threatening, etc.) must be reported to the regulatory authorities immediately, whereas minor adverse events are merely documented in the annual summary sent to the regulatory authority.

Cross-References

► Adverse Drug Reaction
► Adverse Effect
► Side Effect

Adverse Outcome

► Adverse Effect

Adverse Selection

Definition

Adverse selection refers to a situation in which individuals are able to purchase health insurance at a premium that is below actuarially fair premiums. Adverse selection occurs because of ► information asymmetries: consumers are better informed about their health status than health insurers are. The consequence of adverse selection of unregulated health insurance markets is market instability.

Advertising

Definition

Advertising in this context refers to "Direct to consumer advertising" about pharmaceuticals.

Advising

► Social/Emotional Support

Advocacy

Synonyms

Health advocacy; Public health advocacy; Health lobbying

Definition

Advocacy is the act of arguing or pleading in favor of an issue or an idea that is thought to enhance the well-being of another person, a group or a population. It involves campaigning for political, regulatory or organizational change on the local, district or national level. The goal of advocacy is to create conditions that are conducive to health. Since the determinants of health are multisectoral, advocacy, too, must extend well beyond the health sector. Advocacy for health and lobbying in the political arena should be an integral part of any health promotion effort. Key strategies are:

- Educating policy makers: e. g. by distributing fact sheets
- Creating advocacy coalitions: mobilizing support from colleagues, academics, institutions, groups
- Media advocacy: strategic use of media to advance the initiative, thereby enhancing visibility and credibility of the campaign
- Judicial advocacy: health professionals offer support in filing a lawsuit and take on the role of an expert witness
- Community advocacy: mobilizing the community to advocate for its own health concerns.

Advocacy for Health

Synonyms

Advocate

Definition

There are two possible roles, and thus definitions, in advocacy:

1. The act of directly representing or defending others; championing the rights of individuals or communities through direct intervention or through ► empowerment.
2. A combination of individual and social actions designed to gain political commitment, policy support, social acceptance and systems support for a particular health goal or programme.

Advocacy, particularly in the latter sense, is one of the three ► health promotion action strategies of the ► Ottawa charter and may be taken by and/or on behalf of individuals and groups. It can take many forms including the use of the mass media, the new information technologies, political lobbying and community mobilization to create coalitions of interest around defined issues. Health professionals have a major responsibility to act as advocates for health at all levels in society.

Advocate

Synonyms

Advocacy for health

Definition

Good health is a major resource for social, economic and personal development and an important dimension of quality of life. Political, economic, social, cultural, environmental, behavioral and biological factors can all favor health or be harmful to it. ► Health promotion action aims at making these conditions favorable through advocacy for health.

Affective Disorders

Uwe Ruhl
Institut für Psychologie, Universität Göttingen, Göttingen, Germany
uruhl@uni-goettingen.de

Definition

In affective disorders, the fundamental disturbance is a change in mood to depression (with or without associated anxiety) or to elation (► mania). The mood change is usually accompanied by a change in the overall level of activity; most of the other symptoms are either secondary to, or easily understood in the context of, the change in mood and activity. Most of these disorders tend to be recurrent (► recurrent depressive disorder) and the onset of individual episodes is often related to stressful events or situations.

Basic Characteristics

Introduction

Hippocrates was one of the first to use the term "melancholy", literally meaning "black bile", to describe depressive symptoms. Usually, sadness accompanies

tragic situations; for example, the death of a loved one or loss of employment. Everyone will experience such sad phases during their lifespan and everyone will experience other common symptoms of depressive disorders during times of stress; for example, problems with concentration, sleep disturbances, and changes in appetite. However, a depressive disorder differs both qualitatively (e. g., much more pervasive) and quantitatively (i. e., longer duration) from "normal" sadness or reactions to stress. Thus, actual definitions of depressive disorders (e. g. according to DSM-IV, ICD-10) define a severity threshold (depending upon a specific number of symptoms) and a minimum duration (2 weeks). Major depression is associated with female gender, lower social status, and stressful life events (e. g., hospitalization for a serious illness, pregnancy, death of a close relative, divorce). Depression can strike a person at any age (Cave: even small children!). Major Depressive Disorder (MDD) is very highly associated with potential morbidity and mortality (suicide, medical illness, disruption in interpersonal relationships, substance abuse, and lost work time).

► Dysthymia is a "chronic" form of depression. It is defined by its subsyndromal nature (i. e., fewer than the five persistent symptoms required to diagnose a major ► depressive episode are present) and a protracted duration of at least 2 years for adults. The symptoms of dysthymia alone do not meet the criteria for Major Depression and low mood is the primary symptom.

Patients with bipolar disorders (► bipolar affective disorder) suffer from depressive episodes and/or manic/hypomanic episodes (i. e., bipolar I and bipolar II disorders). A manic syndrome is defined as a period of unusual and extreme good mood or extreme irritability. Manic patients often show a decreased need to sleep and strong hyperactivity. Episodes of ► hypomania are typical. Bipolar disorders are associated with significant morbidity and mortality rates.

► Cyclothymia is also marked by manic and depressive states. Oscillation of high and low moods is typical. However, those phases are neither of sufficient intensity nor duration to merit a diagnosis of bipolar disorder or MDD.

Epidemiology

Depressive disorders are more common in women than in men (female/male ratio = 1.5–2/1). One year prevalence rates of depression in European countries are estimated between 1.9% (Netherlands and Great Britain; Bijl et al. 1998; Jenkins et al. 1997) and 8.3% (Germany Jacobi et al. 2004). Dysthymia affects about 2% of the adult population per year; women seem to be slightly more affected than men. The one year prevalence estimate of bipolar disorders in adults is 0.9% (Pini et al. 2005). Almost 2% of the adult population suffers from bipolar disorders (i. e., lifetime prevalence, Kessler et al. 1994). Because the costs in existing economic studies are based on a ► top-down approach (and depend on assumptions in terms of resource use), it is impossible to assess the exact economic burden. Depressive disorders have a high economic burden due to their high prevalence and their association with high disability in acute depressive phases (e. g., lost workdays, reduced working capacity). Unipolar major depression is one of the 10 leading diseases of the global disease burden (Lopez et al. 2006).

Pathophysiology/Etiology

The pathophysiology of MDD has not been clearly defined. Different studies have suggested a disturbance in CNS serotonin (i. e., 5-HT). Norepinephrine (NE) and dopamine (DA) are other important neurotransmitters for MDD ("monoamine hypothesis"). However, this hypothesis is not sufficient to explain the complex symptoms of depression. One problem is that many other neurotransmitter systems are altered in depressive disorders (e. g., GABA and acetylcholine). Another problem is that improvement of monoamine neurotransmission with medication and lifting of the clinical signs of depression do not prove that depression is actually caused by defective monoamine neurotransmission. Accordingly, in different studies, no objective biological markers exist that correspond definitively with the disease states of bipolar disorder (► bipolar affective disorder), ► dysthymia, and ► cyclothymia. Overall, the etiology of affective disorders is multimodal (e. g., biological factors, psychosocial factors, stressful life events) with a strong genetic component.

Consequences

The relationship between depressive disorders and comorbidity of other mental disorders (especially anxiety disorders, i. e. ► generalized anxiety disorders,

► panic, ► agoraphobia, and ► post-traumatic stress disorders) as well as physical illness is well established. Patients suffering from bipolar disorders frequently show comorbid anxiety disorders and substance use disorders. Accordingly, dysthymic disorders are associated with higher rates of comorbid substance abuse. Suicide is the most severe complication of major depression. Depressive disorders account for about 20 to 35% of all deaths by suicide (Angst et al. 1999). Men are much more likely to succeed in committing suicide than women (ratio about 4:1). However, women ► attempt suicide about four times more often than men.

Treatment

Antidepressant medication and/or cognitive-behavioral psychotherapy have the strongest evidence for the treatment of depressive disorders. In severe depressions (with or without psychotic symptoms), patients are mostly treated with antidepressants and cognitive-behavioral psychotherapy. Antidepressants should be changed if there is no clear effect (after an additional attempt of dose increase) within 4 to 6 weeks. Accordingly, revisions to a psychotherapeutic treatment plan should be considered, including the addition of antidepressant medication, if there is no symptomatic improvement within 3 or 4 months of therapy. Further, to reduce relapse rates, anti-depressive medication should be used routinely for at least 6 months after remission (i. e., continuation phase therapy). Cognitive-behavioral psychotherapy is also important for relapse prophylaxis. In recurrent depressive patients (► recurrent depressive disorder), either antidepressants or special medication for relapse prophylaxis and mood stabilization, respectively (e. g., lithium, valproate), may be used for years (i. e., maintenance phase therapy). Such maintenance pharmacotherapy is typically recommended for individuals with a history of three or more ► depressive episodes, chronic depression, or bipolar disorder.

Synonyms

Mitigation strategies

Definition

Various aspects of attitude towards risk after a disaster.

Basic Characteristics

Improvement of information about hazards is badly needed for raising awareness and enhancing the consultative process that leads to a hazard (► mitigation strategies). Only informed stakeholders can make rational decisions about the choice of strategy in an objective and rational cost-benefit framework. Informed citizens are likely to behave in a way that is compatible with disaster management activities.

Experience has demonstrated that repeated occurrence of a disaster in the same place within a relatively short time might enhance the positive learning effect. For example, there were two large floods on the Rhine, in December 1993 and January 1995. The maximum water levels in Cologne were of comparable magnitude (the second being actually even a little higher), but the values of the damage caused by each of the two floods differed largely. The damage in the second (higher) flood was considerably lower. Occurrence of the first flood raised awareness and triggered actions towards improvement of the flood preparedness system, based on the lessons learned. The first flood was still fresh in memory when the second flood occurred just a year later.

Misconceptions and myths about natural disasters and flood protection are deeply rooted in society – for the general public, politicians, and decision-makers alike. It is of utmost importance to dispel and rectify misconceptions and counter-productive "principles" that are held throughout political and social systems, such as the short-memory principle, where implementation is called the rule of hydro-illogical cycle with regards to floods and droughts. Flood (or drought) occurrence triggers high expenditures on flood (or drought) protection (► mitigation strategies). Yet, memory fades and, after some time without flood (or drought), the willingness to pay for costly preparedness systems drastically decreases. It is not easy to communicate this truth effectively to the electorate and decision-makers, whose term of office is short. A major natural disaster may not be likely to occur during decision-makers' terms of office.

Efficient actions aimed at raising awareness are of utmost importance for a disaster preparedness system (► mitigation strategies). There is a systemic lack of experience with a natural disaster of extreme dimensions. Among over 50 fatalities of the 1997 flood in Poland, many could have been avoided were the awareness better. Most flood fatalities in the US are related to vehicles whose drivers underestimate the danger and get trapped. Alone, car drivers obeying simple rules of conduct could help reduce the number of fatalities in many flood events.

The media may play an essential role in raising awareness and providing information. The ► risk perception is to a large extent determined by media coverage. In some cases, an atmosphere of risk is created and warmed up by the media (e. g. the impacts of the Three Mile Island accident, where the actual damage was low).

Risk perception involves the beliefs, attitudes, judgments, and feelings of individuals, as well as their wider social and cultural values and disposition towards hazards (being risk-prone, risk-neutral, or risk-averse). It also depends on age, gender, education, and past traumatic experiences.

In many areas, river levees (dikes) are the principal flood defenses. Existence of properly dimensioned and maintained levees, which adequately protect adjacent areas against small and medium floods, creates a misconception – an unjustified feeling of complete safety among the riparian population. When a dike breaks during an extreme flood, the damage may be higher than it would have been without a dike. The Netherlands, a country remembering the tragedy of coastal flooding in 1953 and which has a large part of the country located in depressions, below the mean sea level, has higher safety standards (flood protection design) than any other country in the world. Yet, even in the Netherlands, safety levels are now re-examined to account for global change effects. Building flood risk consciousness among the public and rectification of misconceptions, such as false feelings of absolute safety, is of paramount importance. No matter how high a flood design is, there is always a possibility that a greater flood will occur, inducing losses. Should dikes be designed to withstand a 100-year flood or a 500-year flood? The latter solution would give a better (but still incomplete) protection, but

is far more costly (prohibitively costly in most places, with the Netherlands being a notable exception as it is embarking on high safety standards with design values of 1250-, 4000-, and 10 000-year events for protection against river, large river, and coastal flooding). Water managers in a few countries, including the Netherlands, Australia, the UK, and the USA have begun to consider the implications of climate change explicitly in flood protection. Measures to cope with the increase of the design discharge for the Rhine in The Netherlands from 15 000 to 16 000 m^3/s must be implemented by 2015 and an increase in the design discharge to 18 000 m^3/s is planned in the longer term due to climate change.

Disaster risk communication is a difficult issue, especially communication of uncertainties, which requires assistance in understanding. When issuing warnings – communicated messages that a hazard is producing specific risks for a particular segment of the population – the response depends on the source, channel credibility, and past experience (relevance and accuracy of earlier warnings). People are likely to heed warnings if past warnings did not "cry wolf."

Age-Dependency Ratio

Definition

The age-dependency ratio is a summary measure of age composition in a population that incorporates specific assumptions about "productive" and "unproductive" groups. Age-dependency ratios represent the relative numbers of dependents to supporters in the population. The child dependency ratio compares the population of children (0–14 years) to the working age (15–64 years) population, while the aged dependency ratio compares those aged 65 years and over to the same working-age reference group. The total age-dependency ratio compares the combined youngest and oldest population to the intermediate working age group.

However, the use of chronological age alone for classifying individuals as "dependent" or "productive" assumes a uniformity of contribution in each age group which is unlikely to be accurate. For example, continued education may delay economic contribution for the intermediate group, and persons may continue to be economically productive past age 65. Where detailed data on employment and economic activity are lacking, age-dependency ratios are nonetheless a helpful estimate of economic dependency.

Agency Theory

Definition

Agency theory refers to a situation where one person (the agent) makes decisions on behalf of another person (the principal), usually because of asymmetry of information (► information symmetry). In ► health economics, agency theory is applied to the relationship between the physician (the agent) and the patient (the principal).

Agenda 21

Definition

Agenda 21 is a plan of action for the preservation of the Earth that was adopted at the UN conference on the environment and development at Rio de Janeiro in 1992. No fewer than 181 countries signed the document. Agenda 21 not only aims to solve environmental problems but also covers economic and social injustice in the world. Democracy, equality and the fight against poverty play an important role. It is a comprehensive blueprint of action to be taken globally, nationally and locally by organizations of the UN, governments, and major groups in every area in which humans impact on the environment. The number 21 refers to the 21st century.

Agent (of Disease)

Definition

A factor, such as a microorganism, chemical substance, or form of radiation, whose presence, excessive presence, or (in deficiency diseases) relative absence is essential for the occurrence of a disease.

Age-Specific Fertility Rate (ASFR)

Definition

Age-Specific Fertility Rate (ASFR) represents the annual number of births to women in a particular age group per 1000 women in that age group. It is used for comparisons in fertility behavior at different ages, ► fertility at different ages over time and fertility across countries or populations.

Aging and Health

Synonyms

Elderly and health; Health of the elderly; Older people and health

Definitions

Population aging, the demographic process by which older persons become a proportionally larger share of the total population, is associated with changing patterns of mortality, morbidity, and disability (UNPD 2002). In the older population different aspects of health have to be considered. ► Gerontology, the scientific study of the biological, psychological, and sociological phenomena associated with old age and aging, and ► geriatrics, the branch of medicine that focuses on health promotion and the prevention and treatment of disease and ► disability in later life, both deal with the well-being of older people.

Basic Characteristics

A gradual ► demographic transition – from patterns of high fertility and high mortality to patterns of lower fertility and later mortality – has been underway across the globe. Lower birth rates and growing longevity have led to an overall increase in both the absolute number and relative proportion of older people in the general population. By 2002, the population of individuals 60 years and over reached 626 million, or 10 percent of the total world population. Of these, nearly 70 million are among the oldest-old, aged 80 or over. The older population is projected to expand rapidly in the coming decades, more than tripling its current size and reaching 2 billion by 2050. The oldest-old population is expected to grow more than 5.5 times to reach 379 million by 2050. Decreasing fertility rates contribute to the prediction that older individuals will at that time constitute 21 percent of the total world population, twice their current proportion and equal to the number of predicted children. The proportion of the oldest-old will quadruple to 4 percent by the same year (UNPD 2003). Women constitute the majority of older people in most countries (Velkoff, Lawson 1998).

The demographic changes are linked with ► epidemiologic transitions, in particular a shift in the leading causes of death away from infectious, acute diseases in early life towards chronic and degenerative illness-

es in mid- and later life. Given the increase in total ► life expectancy, a number of gerontological theories addressing the implications of increased longevity for population health have emerged, each proposing different relationships between old-age mortality, morbidity, and disability, or limitations in performing activities of daily living. (For a review, see Agree, Freedman 1999) The theories range from the most pessimistic – in which delayed mortality is translated to increased years of life with disease and disability – to the most optimistic, in which morbidity and disability are compressed towards the end of life, increasing the healthy proportion of total life expectancy. More nuanced perspectives recognize the complexity, mutability, and inter-connectedness of the processes determining morbidity, disability, and mortality, and suggests a continuous dynamic relationship between them. International trends in mortality and disability outcomes are mixed, supporting a dynamic model of longevity and health in later life that is influenced by a multitude of biomedical, environmental, and social factors.

► Population aging is an aggregate mark of human success in reducing fertility, improving living conditions, and curbing risks of death through innovations in public health and medicine. However, insufficient preparedness for the needs of an aging population on the part of health and social service providers is a challenge confronting societies at all levels of development.

Geriatric Health

Aging populations have higher rates of chronic disease and ► disability, and the likelihood of having multiple co-morbidities rises significantly with age. In high and low-income countries alike, ischemic heart disease and cerebrovascular diseases are the leading causes of death. In more developed nations, cancers (lung, colon, rectum, stomach, and breast), chronic obstructive pulmonary diseases, diabetes mellitus, and Alzheimer's Disease and other dementias are also among the most prevalent causes of death. A range of chronic and adult-onset conditions including depression, hearing loss, alcohol-use disorders, osteoarthritis, schizophrenia, bipolar disorders, and chronic obstructive pulmonary diseases are among the leading causes of global disability (Murray et al. 2001). Chronic diseases may contribute to the gradual loss of senses such as sight and hearing, to impaired mobility, to increased risks of falls and fractures, and to disability in the performance of activities of daily living.

As ► senescence, or the slowing-down of physical systems that takes place as the body ages, progresses, a range of physical and mental capacities is weakened. Age-related mental illness, especially dementia, are particularly difficult to cope with for both patients and caregivers alike. Dementia is a condition of irreversible decline in cognition, functioning and behavior. Alzheimer's disease (AD) accounts for approximately 60–70% of dementia cases, with vascular dementia accounting for the majority of the rest. The prevalence of AD is estimated to be 8–15% in persons over 65. The primary risk factor for dementia is age, with the prevalence doubling for every 5-year age group after the age of 65 and reaching as high as 39 percent after age 90 (Jorm, Jolley 1998).

Chronic diseases exact a heavy burden on older adults due to associated long-term illness, diminished quality of life, and increased health care costs. Although the risk of disease and disability clearly increases with advancing age, poor health is not an inevitable consequence of aging. A healthy lifestyle (including regular physical activity, a nutritious diet, and avoidance of tobacco) is the recommended course for prevention. Screening for early detection is also recommended for those illnesses (e. g. some cancers, diabetes and its complications, etc.) for which a course of treatment is available.

Aging and Pharmacotherapy

Older people are particularly susceptible to the risks of medication use. Age-related loss of physiologic reserve leads to pharmacokinetic changes and increases inter-individual variability. The loss of renal function, for example, decreases the clearance of common drugs in older people, while the loss of lean body mass and fat mass leads to an altered volume of drug distribution.

Polypharmacy – the use of multiple (usually 5 or more) medications – is a common issue since geriatric patients frequently have multiple co-morbidities each treated with one or more medication. Furthermore, some medications bring about ► side effects that then lead to the prescription of additional drugs to treat the added symptoms. Polypharmacy increases the potential of drug interactions, adverse drug reactions, and the use of inappropriate medications, or drugs that should be

avoided in certain doses, disease states, or in combination with other drugs (Hanlon et al. 2001).

Care-Giving

Historically, older people in need of assistance received care from younger family members. However, previously high levels of mortality and fertility meant that the proportion of individuals reaching older ages was relatively small while a larger pool of children and relatives was available to share care-giving responsibilities. More recently, the proportion of the population at older ages has been expanding as the numbers of younger family members available to provide care has been shrinking.

Women – wives, daughters, daughters-in-law, nieces and granddaughters – have traditionally provided the bulk of family care-giving and continue to do so despite rising levels of labor force participation. Older people are as likely to provide care as they are to receive it, and in developing and developed countries alike, spouses are the main caregivers for both men and women. Because of the sex differential in longevity, however, women are more likely than men to find themselves without a spouse and to be living alone when they need care (Velkoff, Lawson 1998).

A relatively small proportion of older people – between 1 and 10 percent – reside in institutions in developed nations (Velkoff, Lawson 1998). There has been growing concern – though not much documentation – that as networks of family caregivers shrink the rate of institutionalization among older people may rise. Additional concerns about the quality and cost of institutional care are garnering attention in many countries.

Aging in Developing Nations

In developing nations a rapid ► demographic transition has outpaced economic development. Since 1980, developing countries have been home to a larger proportion of the world's population of persons aged 60 and above than their industrialized counterparts (Lloyd-Sherlock 2000). By 2000, 249 million people, or 59% of the world's 65 years of age and over population lived in developing countries (US Census Bureau 2001). According to demographic projections, by 2050, more than three-quarters of the world's older people will be living in developing countries. By 2050 developing countries will posses a similar age structure to today's more industrialized nations. Older people will then comprise over 30% of the population in East Asia, more than 20% of the population in Southern Asia and Latin America, and approximately 10% of the population in Africa (UNPD 2003).

Though they are among the most disadvantaged populations in developing nations, older people have not been prioritized by international aid agencies. Eighty percent of older people in developing countries have no regular incomes, and approximately 100 million older persons live on less than a dollar a day. Older people in developing regions are often excluded from economic development, healthcare and education programs due to age limits and discrimination and humanitarian agencies often fail to identify older people as a target in the planning and delivery of services in conflict areas (Help – Age International 2002). While incidence of chronic and age-related disease has been rising rapidly in developing nations, there is a lack of professionals in geriatric medicine, preventing older adults from receiving the health care they need (Keller et al. 2002).

Though norms of filial piety are still strong in many developing countries, changes in family structures and co-residence patterns are rendering traditional support networks more vulnerable. Recognizing the need for increased awareness and action on issues related to global aging, the Second World Assembly on Aging adopted the Madrid International Plan of Action in 2002. The Plan calls on governments, non-governmental organizations, and the international community to adopt the concept of "a society for all ages," to end age-based discrimination and abuse, and incorporate the concerns of older people into national and international economic and social development policies (United Nations Programme on Ageing, 2002). The formation of implementation and monitoring strategies for the Plan is now in progress.

Agoraphobia

Definition

The ancient term *agoraphobia* is translated from Greek as fear of an open marketplace. Accordingly to the International Classification of Disease of WHO (ICD-10), agoraphobia is characterized as the fear or avoidance of crowds, public places, traveling alone, etc. At least two symptoms of psycho-physiological agitation (e. g. tachycardia, fear of losing control) have to appear simultaneously. The psychological stress for persons suffering from agoraphobia is significant, especially as most realize that their safety-seeking behavior is exaggerated. Most people develop agoraphobia after the onset of ► panic disorder. Agoraphobia is best understood as an adverse behavioral outcome of repeated panic attacks and the subsequent worry, preoccupation, and avoidance.

Cross-References

► Anxiety Disorders

Agreement

Synonyms

Contract

Definition

Agreement for two measurement procedures is examined in the absence of a gold standard, and it refers to the closeness of two measured values, not to whether those values are correct or not. Inter-rater agreement (inter-rater reliability) for two or more raters is a measure of the closeness of the raters' decisions. When the result of measurement is binary data, the agreement is estimated by ► proportion of agreement or ► kappa coefficient, and in the case of continuous data agreement is estimated with ► Pearson's correlation coefficient (Pearson's r) or with intraclass correlation coefficient.

Cross-References

► Contract

AHRQ

Definition

The Agency for Healthcare Research and Quality (AHRQ) is the lead US Federal agency charged with improving the quality, safety, efficiency, and effectiveness of health care. As one of 12 agencies within the Department of Health and Human Services, AHRQ supports health services research that will improve the quality of health care and promote evidence-based decision making. Information from AHRQ's research helps

people to make more informed decisions and improve the quality of health care services. AHRQ was formerly known as the Agency for Health Care Policy and Research.

AIDS

Synonyms

Infection with the human immunodeficiency virus; Acquired immunodeficiency syndrome; HIV-infection; HIV/AIDS

Definition

HIV (human immunodeficiency virus) is a retrovirus that primarily infects vital components of the human immune system such as $CD4^+$ T cells (a subset of T cells), macrophages and dendritic cells. It impairs the body's ability to fight infection and certain cancers. HIV infection is diagnosable by antibody or antigen testing. Treatment aims to suppress HIV replication by combinations of drugs that inhibit HIV enzymes. Any of a list of illnesses that, when occurring in an HIV-infected person, leads to a diagnosis of AIDS, the most serious stage of HIV infection. AIDS is also diagnosed if an HIV-infected person has a CD4 count below 200 cells/mm^3, whether or not that person has an AIDS-defining condition. The Centers for Disease Control and Prevention (CDC) published a list of AIDS-defining conditions in 1993. The 26 conditions include candidiasis, cytomegalovirus disease, Kaposi's sarcoma, mycobacterium avium complex, pneumocystis carinii pneumonia, recurrent pneumonia, progressive multifocal leukoencephalopathy, pulmonary tuberculosis, invasive cervical cancer, and wasting syndrome.

AIDS-Defining Diseases

► AIDS-Defining Symptoms

AIDS-Defining Symptoms

Synonyms

AIDS-defining diseases; AIDS-defining illnesses; Opportunistic infections in AIDS

Definition

The term "AIDS-defining diseases" are the so-called opportunistic infections, which do not appear in immunocompetent individuals, and particular tumors. The tumors are Kaposi's sarcoma, a tumor of the connective tissue, and non-Hodgkin's malignant lymphoma. Opportunistic infections can be caused by viruses, bacteria, fungi or parasites. Typical AIDS-associated viral infections are cytomegalovirus and herpes infections. The bacterial infection, which most frequently occurs in connection with HIV-infection, is **tuberculosis** (► S. tuberculosis and other mycobacterioses). Fungal diseases, which have to be mentioned, are Candida-infections and cryptococcoses. A parasitic disease typical for AIDS is pneumonia caused by *Pneumocystis carinii*. In 1980 the so-called "wasting-syndrome" was identified; it is characterized by a loss of body weight of more than 10%, tiredness, persisting diarrhea and fever.

Ailment

Synonyms

Disease; Illness

Definition

Disease represents impairment of the normal state or functioning of the body as a whole or of any of its parts. Some diseases are acute, producing symptoms that last short period of time, for example, flu, pneumonia. There are also chronic disorders, such as, arthritis, hypertension, etc. that last for a long time. Diseases are usually classified according to cause. External factors that produce disease are infectious agents, including bacteria, viruses, fungi, but also disease may occur as a consequence of different chemical and physical agents such as drugs, poisons, radiation. Some diseases are inherited and some of them acquired due to environmental, infectious and various lifestyle factors. Also, many diseases are attributed to emotional disturbances. Most diseases occur as a result of an interaction between the body and the environment. In ancient times disease was ascribed to supernatural, spiritual, and humoral factors.

Air Quality and Pollution

ZORAN MARMUT
Institute of Hygiene and Medical Ecology, Faculty of Medicine, University of Belgrade, Belgrade, Serbia
zmarmut@eunet.yu

Definition

Air quality refers to the physical, chemical, and biological characteristics of air, both in outside space and in enclosed spaces, such as most industrial settings, other non-industrial working places, and residencies. Air pollution is the abnormal presence of various substances (gases, vapors or particles) in the air in sufficient concentrations such that accumulated substances lead to poor air quality and affect human health, living matter and other materials. These substances may be released into the air by natural processes or by human activities.

Basic Characteristics

Air is a mixture of gases, water vapor, solid and liquid airborne particles in a wide range of concentrations that range from essential for life to chemically inert. Some of them are even hazardous, but are normally present in low concentrations. Air is what constitutes Earth's atmosphere and it is present as an almost transparent, thin envelope around our planet. The atmosphere significantly determines the necessary conditions for various forms of life on Earth, and also shapes and modifies the subtle combination of environmental factors that we call climate.

The normal chemical composition of dry air in the troposphere is as follows: major gases are nitrogen and oxygen (78,09% and 20,94%, respectively, by volume); minor gases are argon (0,93%) and carbon dioxide (0,03%); and trace gases (the whole group totaling 0,01%) are neon, helium, methane, krypton, hydrogen, nitrogen oxides, ozone, ammonia, and sulfur dioxide. Water vapor content in the low atmosphere is highly variable, ranging from less than 1% to 5–6% by volume.

Air quality may range widely from quite good (satisfactory) to poor, in various degrees. Air quality is good when there is normal chemical composition of air without significant variations in physical (or physico-chemical, e. g. radiological) and biological characteristics. Air quality is poor and detrimental if air is odorous and stale, if physical parameters are out of optimal values, or if air is polluted by chemicals of various origin. The main physical characteristics of air that affect air quality are temperature, humidity, air velocity, and radiant heat. Biological origins of air quality deterioration include bacteria, viruses (humans are the main sources in indoor spaces), fungi (molds), insects (fleas and cockroaches), arthropods (e. g. ► house dust mites), mammals (e. g. home pets – their excreta, hair, dander or feathers), and plants (pollen grains). There are two

main groups of sources of air pollution – natural, and artificial or man-made sources.

Natural Sources of Air Pollution

Over the millennia it has been in existence, the atmosphere has been relatively balanced and stable in composition, being polluted mainly by natural processes. Like now, natural sources of pollution have been volcanic eruptions, forest wildfires, biochemical release of pollutants from soils and oceans, soil erosion, windstorms, lightning, and plant pollen release, etc. Natural sources are much stronger than artificial ones, but pollutants are usually diluted or widely dispersed over the whole atmosphere, often far from human habitation.

Artificial Sources of Air Pollution

During the last 150–300 years, which have seen agricultural and industrial revolutions, human technology has reached a point where it is disturbing the global balance of the atmosphere. Man has begun to pollute air in a much stronger manner than ever before. Pollution has been caused by an enormous output of harmful substances into the atmosphere, emitted from a variety of stationary or mobile sources. These artificial or man-made sources are usually situated inside human settlements or close to them; for this reason, they are much more threatening to human health than natural sources. The most important sources of pollution are: a) power and heat generation objects (e. g. fossil fuel power stations, domestic combustion appliances, and biomass burning); b) industrial objects (smelteries and foundries) and agricultural activities; c) transportation (motor vehicles with internal combustion); d) waste sites (the burning or spontaneous evaporation of pollutants out of dumps); and e) Other human activities producing gases, vapors or aerosols (fumigation, spraying, etc.).

Ambient or Outdoor Air Pollution

Major pollutants are slightly different throughout the world, depending on the predominance of pollution sources locally. However, the six major types are the organic pollutants carbon monoxide and hydrocarbons, and the inorganic pollutants nitrogen oxides, sulfur dioxide, particulates, and low ozone. ► Smog, a contraction of the words smoke and fog, is a common term used to indicate the presence of a mixture of multi-source pollutants in the air around large human settlements.

Indoor Air Pollution

Indoor space is the interior of each working or residential building in the commercial, public or private sectors, not including industrial working interiors or outdoor space. Indoor spaces are: a) private residences; b) non residential, commercial and public buildings, e. g. offices, libraries, cinemas, indoor market places, restaurants, hospitals, schools and indoor sport arenas, and c) transportation, e. g. the interior of private cars, buses, aircrafts and subways.

The indoor environment is now more significant for health considerations than the outdoor environment. Concerns about potential public health problems due to indoor air pollution are based on epidemiological evidence that urban residents spend approximately 90% of their time indoors. By such activity patterns, they have more exposure to harmful agents that exist indoors. The most important pollutants are nitrogen oxides, volatile organic compounds, formaldehyde, carbon monoxide, ozone, and ► suspended particles. If tobacco smoking is not restricted, a mixture of dangerous pollutants may be detected. Inside many indoor spaces, airborne allergens such as dust mites are present, and sometimes even the radioactive gas radon. Carbon dioxide is a marker of indoor air pollution rather than a specific pollutant.

Adverse Effects of Air Pollution

Enormous and continually increasing rates of outdoor air pollution may have significant consequences on the quality of air, human health and the whole environment. Local, regional and even global environmental effects are well known and scientifically proven. Considering local health effects, increased morbidity and mortality rates are reported among vulnerable population groups in highly polluted areas. Usually registered are: a) upper respiratory tract illnesses; b) lower respiratory tract illnesses (bronchitis, asthma and pneumonia); c) malignant diseases of the respiratory tract; d) ocular mucous membrane illnesses and complaints; and e) decreased resistance to common allergens. Effects on the local climate are also pronounced as climate characteristics change significantly over polluted areas.

Over certain regions of the Earth, air pollution induces ecosystem acidification and acid deposition (► acid rain), with both noticeable adverse environmental consequences (e. g. damage to vegetation), and human health impairments. Air pollution has also led to deterioration of the atmosphere on a global scale. The most important global consequences are ozone layer depletion in the stratosphere (ozone holes), and the greenhouse effect. As a consequence of ozone layer depletion, the amount of harmful short-wave ultraviolet reaching the Earth's surface has been enhanced. The ► greenhouse effect (global warming of the atmosphere) is mainly a result of carbon dioxide and methane being released into the atmosphere due to burning of fossil fuels and farming practices, respectively.

During the last decade of the 20th century, the US Environmental Protection Agency consistently ranked indoor air pollution among the top five risks for health impairments in general population groups. There is mounting evidence that exposure to polluted indoor air is the cause of excessive morbidity and mortality. The main health consequences of indoor air pollution are grouped into a) ► specific building- and home-related illnesses (SBRI), and b) ► chemical sensitivity syndromes.

Alcohol Abuse

► Alcoholism

Alcohol Consumption

GUNDULA BARSCH
Hochschule Merseburg, Merseburg, Germany
gundula.barsch@hs-merseburg.de

Definition

Different forms of alcohol have different functions: as part of cleaners, fuel, medicine, etc. Worldwide the substance ETHANOL is well known as a component of different alcoholic beverages. These beverages differ not only in taste, look and quantity of alcohol, but also within various populations the forms of usage are very different too. People use alcohol as a luxury, as part of their lifestyle; integrated into daily life, to cope with stressful situations for example. The general level of alcohol consumption of a population depends on socio-cultural factors, availability, production, trade, the distribution network and the regulations concerning sale. Therefore, throughout the world, there is a wide variation between countries and regions in forms and rates of alcohol consumption. For national health planning it is helpful to monitor trends of per capita production of beer, wine and spirits in different regions as well as per capita alcohol consumption of the population in general and in social groups in particular.

At the individual level alcohol consumption can be distinguished in three general forms: moderate drinking, heavy drinking and excessive drinking that is linked with dependence on alcohol. These different forms of alcohol consumption are integrated into individual daily lives, and misuse is connected with alcohol related problems. The terms "alcohol-related problems" and "alcohol problems" refer to the damaging consequences of alcohol consumption and the various adverse effects not only on the individual drinker but also on the family and society at large.

Trends in Rates of Alcohol Consumption

There have been considerable increases in average rates per capita alcohol consumption in recent years. Certain countries show a high rate of increase in per capita consumption of each category of alcoholic beverage. In considering the changing trends of consumption within a given population it is necessary to take account of changing demographic structures (► data collecting). For instance, in many developed countries the population is aging and the average consumption level is much lower than in developing countries with a younger population, and, whereas most females may not drink, the average consumption level of adult males may be four times that of the total population.

Although in alcohol-producing areas the dominant type of alcoholic beverage consumed is the type produced in that area and accounts for most of the increase in consumption, the use of additional beverage types also contributes significantly to the increase. In countries with traditional wine drinking, for instance, there has been a marked increase in consumption of beer and spirits, whereas in countries where beer was the preferred drink, the consumption of wine and spirit has become more general.

Socio-Cultural Factors

Socio-cultural factors are involved in both the causes and the consequences of moderate and heavy drinking. Such factors also determine whether or not the consequences of drinking are labeled as problems (► cultural beliefs). Among the factors that have been studied are the cultural beliefs about the value and symbolic functions of alcohol and the consequences of drinking, drinking contexts (such as use in rituals, functions, public and family occasions) and use of alcohol by different social and occupational groups.

Possible alcohol culture effects are:

- drinking is integrated into the community, not a banished or discredited conduct;
- drinking is an act of common life and not a private behavior;
- drinking is part of given rituals;
- drinking rules are made with common sense;
- drinking rules have a strong authority derived from common knowledge and shared experiences;
- drinking rules give rhythm (quality, quantity, frequency) and good order;
- drinking is not allowed everywhere and every time – given a place and special time, so it has a start and an end.
- drinking rules keep drinking in a frame and give orientation;
- drinking rules take no responsibility away but demand it from everyone.

That is why in any population where alcohol is socially acceptable there is a far higher percentage of moderate drinkers than of heavy drinkers.

When a positive alcohol culture prevails, alcohol consumption can be a beneficial experience within a supportive and protective environment; physical and mental health problems are minimized. With changing

socio-cultural conditions, resulting partly from the impact of opposing cultures, many forms of socio-cultural control seem to be breaking down: alternative customs are being followed, the limits of acceptable behavior and drinking are no longer clear and rapid increases in alcohol consumption are occurring in some population groups.

Socio-Demographic Groups

To understand the effects of alcohol consumption within a given population, consideration has to be given to specific socio-cultural situations and variations between population groups and the way social control is maintained and strengthened. The relaxation of cultural controls and emancipation of certain socio-demographic groups probably account in part for the increasing number of young people and women taking up drinking and often running the risk of suffering from the adverse effects of alcohol consumption and of causing alcohol problems.

To understand the dominant patterns of drinking, for instance in women and young people, it is necessary to have a look at the specific functions that alcohol consumption has in each of these socio-demographic groups. Drinking patterns in youth groups are not comparable with the drinking patterns in groups of adults, and the risks and alcohol-related problems are not the same.

Developmental factors affecting alcoholic consumption in youths:

- Special motives to start: come together, have fun together, feelings of social get-together.
- Special functions of drinking: access to peer-groups, bonding rituals, mimicking adult behavior, feeling male, feeling strong.
- The effects of strong drinking: often there is a standstill in developmental progress.

It is known that alcohol problems disappear as development progresses, so strong drinking is normally quit by the time youngsters grow to adulthood. Finally addiction seldom starts early in youth; that means help and support for young drinkers is more educational than therapeutic.

Alcohol Related Problems

Alcohol problems affect the health and development of individuals and nations and have political, economic and social implications. Alcohol problems may be the consequence of either acute episodes of heavy drinking or of prolonged drinking (▶ drug abuse). The development of alcohol problems can be viewed in the perspective of the public health model as complex interaction between the agent (ethanol), the host (drinker) and the environment (physical, mental and socio-cultural setting, the family and the general community).

Consequences of Acute Episodes of Heavy Drinking

- Short-term impairment of functioning and control, with aggressiveness and accident proneness
- Exposure to climatic conditions and physical disorders
- Arrest for drunkenness
- Alcohol poisoning

Consequences of Prolonged Heavy Drinking

- Increase risk of certain disorders, including liver cirrhosis, certain cancers, cardiovascular diseases and brain atrophy
- Aggravation of other physical disorders, e. g. malnutrition
- Prolonged impairment of functioning and control with increased proneness to accidents and impairment of working capacity
- Alcohol dependence syndrome
- Alcoholic psychosis
- Premature death
- Suicide

Possible Concomitants

Loss of friends, of family, of self-esteem, job, means of support and liberty.

Evidence is accumulating that a number of pathological conditions may however be related to the consumption of a small amount of alcohol, and may cause a much greater burden on the community than resulting from the alcohol dependence syndrome (costs of illness – utilities).

Preventing and Managing Alcohol Related Problems

If health is to be looked upon as an integral part of economic and social development measures to solve alcohol problems must be part of general health programs

and must be planned with the primary care approach in mind; responding to alcohol problems must be a joint responsibility of people and government.

Prevention

- Reducing the availability of alcohol beverages (control of distribution, price regulation)
- Reducing the demand for alcohol (information and education on alcohol and alcohol problems, inform about the upper "safe" level of daily consumption. Restrictions on advertising, moral and religious forces)
- Additional preventive measures (control measures focus on limiting the amounts of alcohol available to the drinker, educational measures concentrate on building up the host's resistance and reducing demand for alcohol, measures might be developed from consideration of links between the putative drinker and his environment).

Treatment

- Treatment and management of persons identified as being "alcoholics" and "heavy drinkers"
- Family support
- Management in occupational settings (initiated discussions with key personnel in a range of occupational settings to identify and reduce alcohol problems)
- Programs related to traffic safety (legislation regarding drinking and driving, high-risk drivers).

Alcohol Policies in a Health Context

A policy statement concerning alcohol availability and problems may be seen as an essential contribution to the formulation of national health policies, strategies and plans of action. It may be valuable to formulate at a high level the principles that should underlie the action to be taken and to establish priorities and strategies. The following have to be considered:

- Value of policy statement
- Focus on substance abuse or on alcohol problems
- Participation in policy development (range of participants, community involvement, coordinating bodies)
- Constraints on policy formulation and implementation
- Information needed for policy formulation
- Preparation to implement a national policy.

Alcoholism

Synonyms

Alcohol abuse; Alcohol dependency

Definition

Alcohol abuse and dependency are commonly called alcoholism. Alcohol intoxication can cause irritability, violent behavior, feelings of depression, and in rare instances hallucinations and delusions. Longer-term, escalating levels of alcohol consumption can produce tolerance as well as such intense adaptation of the body that cessation of use can precipitate a withdrawal syndrome usually marked by insomnia, evidence of hyperactivity of the autonomic nervous system, and feelings of anxiety.

Alexithymia

Synonyms

Emotional inarticulateness

Definition

This is a word that is frequently used in counseling and psychotherapeutic circles to denote the supposed inability of men to experience and/or express affect adequately. It literally means to be without words for desire. It is often used in an adjectival sense as in the assertion that men tend to be *alexithymic* in comparison to women. This usage seems to focus on an enduring state of a man or a trait of men rather than used to describe a particular response to a specific situation or circumstance. What might be more accurate is to stay that men, like women, can be at a loss for words at certain times and places. For most men, a tendency towards *alexithymia* might be more an indication of the lack of perceived safety than an accurate denotation of facility with language and self-awareness. Its use should be limited to those cases which actually warrant the use of the word in terms of individual diagnosis after observing the person in a wide rage of settings.

Allele

Synonyms

Allelomorph

Definition

Diploid organisms like humans carry two copies of each autosomal chromosome (paired homologous chromosomes) and thus, also two copies of every autosomal gene. One of the paired chromosomes (one of the two copies of a gene) of an individual is transmitted by the father, the other by the mother. The sequence (order of base pairs) of the two copies of a gene does not have to be completely identical due to normal variation (► polymorphisms) or ► mutations. Alleles are the different (alternative, non-identical) forms of a gene or DNA sequence at a specific genomic/chromosomal position (locus). An individual can only possess two alleles at each specific position on a pair of homologous chromosomes, but a group or population may contain a lot of different alleles at a certain locus.

Allelomorph

► Allele

Alliance

Synonyms

Partnership; Cooperation

Definition

An alliance for health promotion is a partnership between two or more parties that pursue a set of agreed upon goals in health promotion.

Allopathic Medicine

► Western Medicine

Alpha Error

Synonyms

Type I error

Definition

An alpha error is an error that results if a true null hypothesis is rejected or if a difference is concluded when no difference exists between comparison groups. In most research, it is desirable that the probability of making such an error is lower than 5%.

Cross-References

Alternative Hypothesis

Synonyms

Research hypothesis

Definition

The Alternative Hypothesis represents a statistical statement indicating the presence of an effect or a difference. It is the opposite of the null hypothesis. Since the statement of the research typically predicts an effect or difference, the researcher generally expects the alternative hypothesis to be supported based on rejection of the null hypothesis. It is represented by the notation H_A.

Alternative Medicine

Synonyms

Traditional medicine; Holistic medicine

Definition

Alternative medicine encompasses techniques of treatment and prevention of disease that are regarded by modern, Western medicine as scientifically unproven or unorthodox. Alternative medicine includes different therapies such as chiropractic, homeopathy, acupuncture, herbal medicine, massage therapy, aromatherapy, naturopathy and many others. Although many alternative therapies have been successfully used for a long time in the treatment of disease, the scientifically oriented modern medical establishment is often strongly opposed to the use of alternative medicine.

Altitude Sickness

Synonyms

Mountain sickness; Altitude illness

Definition

Altitude sickness is a medical condition caused by acute exposure to high altitudes. It usually occurs at altitudes of 2500–3000 m with the following symptoms: headaches, nausea, vomiting, fatigue, dizziness, insomnia, excitability, breathing difficulties, regurgitation, and peripheral edema (swelling of hands, feet, and face). Acute mountain sickness can progress to pulmonary edema or cerebral edema with high lethality. Altitude acclimatization is the prevention of altitude sickness; it is the process of adjusting to decreasing oxygen levels at higher elevations. In addition, acetazolamide and drinking large amounts of water are suggested. Injections of steroids are used in cases of pulmonary edema, and inflatable pressure vessels are used to relieve and evacuate severe mountain-sick persons.

Alveolar Bone

► Alveolar Process

Alveolar Process

Definition

The alveolar process is the thickened ridge of the jawbones that contains the teeth and the tooth sockets (alveoles) in which the ► roots of each tooth are held. The bone forming the alveoles is called alveolar bone.

Ambulant or Inpatient Service

Ambulatory Care

► Outpatient Care

Ambulatory Health Care

► Outpatient Health Care

Ambulatory Surgery

Synonyms

Outpatient surgery

Definition

Ambulatory surgery is surgery that does not require an overnight stay in a hospital and is therefore performed in an outpatient setting such as a physician's office or an ambulatory surgical center. Ambulatory surgery has become more popular in recent years for ► cost containment reasons, especially in the case of minor surgical procedures that where formerly performed in more costly hospital settings.

Amebiasis

Synonyms

Amebic dysentery; Infection with Entamoeba histolytica

Definition

Although *Entamoeba histolytica* is an intestinal parasite, which can be found worldwide, infections primarily occur in tropical regions. Contagious cysts are shed in the stool. After ingestion of fecally contaminated material – in most cases foodstuff – cysts develop into trophozoites in the bowel. Frequently, the infection is asymptomatic; in some cases symptoms like flatulence or mild diarrhea occur. When there is great number of amoeba, more serious symptoms can appear, like bloody diarrhea, abdominal cramps, fever and headache. In severe cases there might be a perforation of the intestinal wall and peritonitis. If the parasites reach the liver via the portal vein they can cause an abscess. This abscess can burst into the abdominal cavity, the chest cavity or the pericardial sack. *Entamoeba histolytica* can be detected in the stool. Treatment consists of metronidazole, tinidazole or diloxanide furoate administration; in intestinal perforation dihydroemetin is additionally administered. The most important means of prophylaxis of amebiasis is compliance with hygienic rules.

American Trypanosomiasis

Synonyms

Chagas disease

Definition

Chagas' disease is tropical parasitic disease typical for South and Central America caused by the parasite Trypanosoma cruzi. It usually affects children and young adults and is transmitted by the feces of infected insects, typically the assassin bug. Most of those infected have mild symptoms, such as fever and swelling and redness around the eyes, but from 10% to 30% develop chronic disease that may result in serious or fatal inflammation of the brain and heart tissues. There is no vaccine and no satisfactory treatment for chronic cases.

Cross-References

► Chagas Disease

Aminoglycoside Antibiotics

Synonyms

Aminoglycosides

Definition

Aminoglycoside antibiotics are bacteriostatic, that means they impede the bacteria's growth. This is achieved by a change in the permeability of the bacterial cell wall or disturbances of metabolism. The highest efficacy is seen for gram-negative germs. In comparison with other antibiotics, aminoglycosides have only a narrow therapeutic range. Overdose may result in damage to hearing, the organ of equilibrium or the kidneys (oto- and nephrotoxic side effects). Nevertheless, especially in a severe septic course of a disease, aminoglycosides are indispensable antibiotic therapy. Apart from local application as salves or drops (which can, for example be used for infections of the eyes), aminoglycosides can only be given parenterally.

Amnesic Syndrome

Definition

A syndrome associated with chronic prominent impairment of recent and remote memory. Immediate recall is usually preserved and recent memory is characteristically more disturbed than remote memory. Disturbances of time sense and ordering of events are usually evident, as are difficulties in learning new material. Confabulation may be marked but is not invariably present. Other cognitive functions are usually relatively well preserved and amnesic defects are out of proportion to other disturbances.

Analysis of Categorical Data

► Analysis of Frequencies

Analysis of Frequencies

GORAN TRAJKOVIĆ
School of Medicine, University of Pristina,
Kosovska Mitrovica, Serbia
goranty@yahoo.com

Synonyms

Analysis of categorical data; Categorical data analysis

Definition

Analysis of frequencies is applied on data obtained from individuals categorized into mutually exclusive categories according to one or more variable.

Basic Characteristics

Analysis of frequencies is applied in analysis of data originating from qualitative variables and in analysis of data originating from quantitative variables when such data are converted into grouped data. In the analysis of frequencies, several different procedures are applied depending on the aim of the study. ► Goodness-of–fit tests are applied when the aim is comparison of

sample frequencies against expected frequencies that are based on theory or previous research. ▶ Tests of homogeneity are applied when the aim is comparison of frequencies from different samples. ▶ Tests of independence are applied when the aim is to test association between two variables based on data given in the form of frequencies. A ▶ chi-square test is usually used for testing hypotheses in these situations. This test is used to evaluate the significance of differences between observed and expected frequencies. The formula for the chi-square test statistic is:

$$\chi^2 = \sum \frac{(O-E)^2}{E},$$

where O is the observed frequency and E is the expected frequency. Expected frequencies equate to a null hypothesis, by which we assume that the observed frequencies do not deviate significantly from the expected ones (Altman 1990). The value of the test statistic will follow the chi-square distribution with a specified number of degrees of freedom, and the null hypothesis is rejected when the chi-square statistic is equal to or higher than the critical value for the specified number of degrees of freedom and level of significance (usually 0.05 or 0.01).

Goodness of Fit Tests

The significance of differences between the frequencies of particular categories occurring in a sample and the expected frequencies can be assessed with the use of the chi-square ▶ goodness-of-fit test (McKillup 2006). In this test, expected frequencies are assessed based on previous research, theory, or the assumed statistical model of distribution of the observed variable. Data is presented in the form of a simple table (distribution by one variable). The number of degrees of freedom is $r-1$, where r is the number of categories or class intervals.

Assumptions for the application of the chi-square goodness-of-fit test are (Cochran 1952; Siegel 1956):

1. If the test includes only two categories ($r-2r=2$) of the variable under consideration, each expected frequency should be no less than 5;
2. For $r>2$, there should be no more than 20% of the expected frequencies that are less than 5; otherwise, neighboring categories should be merged.

Analysis of Frequencies, Table 1 Blood groups: chi-square goodness-of-fit test between observed frequencies and expected frequencies

Blood group	Observed frequencies (O)	Expected frequencies (E)	$\frac{(O-E)^2}{E}$
O	55	62.3	0.855
A	59	54.5	0.378
B	19	16.9	0.251
AB	7	6.3	0.078
Total	140	140.0	$\chi^2 = 1.562$

Example 1:

The aim of the study was to compare current and previous data on blood group frequency. Current data were obtained from a sample of 140 persons. Previous studies have shown that the relative frequencies of blood groups are as follows: group O – 44.5%, group A – 38.9%, group B – 12.1%, group AB – 4.5%. By multiplying these percentages (expressed as proportions) with sample sizes in the actual study, expected frequencies (E) were obtained. Thus, for example, the expected frequency of blood group A was 0.389 × 140 = 54.5. Observed and expected frequencies are presented in Table 1. The significance of differences between these frequencies was tested with the chi-square goodness-of-fit test. The number of degrees of freedom used was $r-1=4-1=3$.

The chi-square statistic was less than the critical value ($\chi_0^2 = 1.56 < \chi^3_{0.05,3} = 7.82$), *so it was concluded that blood group frequencies in the study described did not show any statistically significant difference from the expected.*

The chi-square goodness-of-fit test is also applied to check whether a certain mathematical model is suitable for studying a phenomenon. In this context, observed frequencies are compared with the frequencies expected based on an assumed model, such as normal, binomial, or Poisson distribution. The number of degrees of freedom is calculated as r–1, where r is the number of group or class intervals. If parameters of the statistical model are not known (e. g. arithmetic mean or parameters of binomial and Poisson distribution), but have to be assessed based on sample data, the number of degrees of freedom is reduced by the number of parameters assessed in that way. The null hypothesis states that the assumed model "fits" the data. If the val-

ue of the chi-square statistic is higher than the critical level, the null hypothesis is rejected and the alternative accepted, stating that the assumed model does not "fit" the data, and therefore it is not suitable for studying the phenomenon. Alternatives to the chi-square goodness-of-fit test are the ► Kolmogorov-Smirnov test or Lilliefors normality test.

Contingency Table Analysis

The significance of a difference between the observed and the expected frequencies, presented in the form of ► contingency table, can be assessed with the use of the chi-square ► test of homogeneity and the chi-square ► test of independence (LeBlanc 2004). The manner of calculation for these two tests in ► contingency table analysis is the same, the only difference being the concept and manner of sampling. Depending on the number of categories of tested variables, a contingency table can have different numbers of rows and columns. The smallest contingency table is 2×2, when the tested variables are dichotomous, that is, with only two categories each (e. g. yes-presence or no-absence of some characteristics). The frequencies need to be put into the table format given in Table 2:

The expected frequency for the given cell in the contingency table is calculated according to the formula:

$$\text{expected value of a cell} = (\text{row total}) \times (\text{column total})/(\text{table total}) .$$

The number of degrees of freedom is calculated as $df = (r-1)(c-1)$, where r is the number of rows in the contingency table (number of categories of the first variable), and c is the number of columns in the contingency table (number of categories of the second variable).

In the chi-square test of homogeneity, two or more samples are selected from the population according to one classification criterion. If the classification is dichotomous, there will be only two samples. Sample sizes, which are marginal frequencies under the classification criterion according to which the groups are formed, are controlled by the researcher. The null hypothesis states that populations are homogeneous regarding the proportions of categories of the second variable, or second classification criterion. If the null hypothesis is rejected, it is concluded that the above proportions are different in the observed populations.

Example 2:

In a prospective cohort study, there were two samples. The first group comprised 50 subjects from the smoking population, and the second group comprised 60 subjects from the non-smoking population. The incidence of acute respiratory infection during the three winter months was monitored. The null hypothesis stated that the populations of smokers and non-smokers are homogeneous regarding the proportion of persons suffering acute respiratory infections in winter. The results are shown in Table 3.

The percentage of persons who suffered from acute respiratory infection was 52% and 28%, in the groups of smokers and non-smokers, respectively. The chi-square statistic based on the data in Table 3 was 6.42. Since this value was higher than the critical value ($\chi^2_0 = 6.42 > \chi^3_{0.05,1} = 3.84$), the null hypothesis was rejected, and it was concluded that the proportion of persons suffering from acute respiratory infections during the winter period is larger in the smoking population.

The chi-square test of independence is used to test the independence of two variables i. e. to assess the significance of their association (hence the name, chi-square test of association). In this situation, the researcher has control over the total sample size, while marginal frequencies are random quantities. For all units of the random sample, categories of both variables are registered and frequencies are presented in a contingency table. Testing the independence of variables serves to assess if

Analysis of Frequencies, Table 2 General contingency table format

		Variable 2		
		Yes	No	Total
Variable 1	Yes	a	b	a+b
	No	c	d	c+d
	Total	a+c	b+d	a+b+c+d

a, b, c, d – observed frequencies

Analysis of Frequencies, Table 3 Smoking status and acute respiratory tract infection in prospective cohort study

		Acute respiratory tract infection		
		Yes	No	Total
Smoking	Yes	26	24	50
	No	17	43	60
	Total	43	67	110

Analysis of Frequencies, Table 4 Smoking status and acute respiratory tract infection in cross-sectional survey

		Acute respiratory tract infection		
		Yes	No	Total
Smoking	Yes	22	17	39
	No	16	35	51
	Total	38	52	90

the distribution of one variable is conditionally dependent on the distribution of the second variable. The null hypothesis states that the variables are independent. If the null hypothesis is rejected, it is concluded that the variables are dependent, i. e. that there is association between them.

Example 3:

In a cross-sectional study, a sample was formed of 90 subjects from the general population. Information on smoking status was obtained for every subject (smoker or non-smoker), as well as data on whether the subjects had suffered from acute respiratory infection during the previous winter. The null hypothesis stated that smoking status and suffering acute respiratory infection are independent variables, i. e. that there is no association between them. The results are shown in Table 4.
The chi-square statistic based on the data in Table 4 is 5.68. Since this value is higher than the critical value ($\chi_0^2 = 5.68 > \chi^3_{0.05,1} = 3.84$)*, the null hypothesis was rejected and it was concluded that smoking status and suffering from acute respiratory infection are dependent variables, i. e. that there is association between them.*

Same variables are analyzed in both ways, e. g. in both the second and third example – smoking status and suffering from acute respiratory infection – but with different aims and designs of studies. In the third example, the researcher only controlled total sample size, and did not have control over the selection of two samples from the two populations. It was therefore impossible to test the homogeneity of the populations, but it was possible to test the dependence of the two variables.
In 2×2 contingency tables, assumptions for applying the ► chi-square test are as follows (Cochran 1954; Siegel 1956):

1. When the total frequency in the contingency table is more than 40, the chi-square test can be applied if all the expected frequencies are ≥ 1.
2. When the total frequency in the contingency table is between 20 and 40, the chi-square test can be applied if all the expected frequencies are ≥ 5.
3. When the total frequency in the contingency table is less than 20, the test cannot be applied.

If these assumptions are not met, ► Fisher's exact test can be applied.
In contingency tables larger than 2×2, assumptions for applying the chi-square test are as follows (Cochran 1954; Siegel 1956):

1. None of the expected frequencies should be < 1.
2. No more than 20% of cells should have an expected frequency < 5.

If the above assumptions are not met, neighboring categories should be merged, thus reducing the number of rows or columns. Merging of neighboring categories can continue to the dimensions of the smallest table, which is 2×2.

Measures of Association in Contingency Tables

When the null hypothesis of independence of two variables is rejected, it is useful to have a measure of the strength of this dependence (association). Several measures of association can be calculated for data in contingency tables. Some of these coefficients and the manner of calculating them (Indrayan and Sarmukaddam 2000), using the example of the data in Table 4, are:

- Phi (φ) coefficient:

$$\phi = \sqrt{\frac{\chi^2}{N}} = \sqrt{\frac{5.68}{90}} = 0.25$$

- Contingency coefficient:

$$C = \sqrt{\frac{\chi^2/N}{1+\chi^2/N}} = \sqrt{\frac{5.68/90}{1+5.68/90}} = 0.24$$

  The contingency coefficient is not a good parallel with the correlation coefficient since its value never reaches 1 and depends on table dimensions.

- Cramer's V:

$$V = \sqrt{\frac{\chi^2/N}{\text{minimum}\,(r-1, c-1)}} = \sqrt{\frac{5.68/90}{1}} = 0.25$$

- Odds ratio:

$$\text{OR} = \frac{a \cdot d}{b \cdot c} = \frac{22 \cdot 35}{17 \cdot 16} = 2.83$$

Analysis of Frequencies from Paired Samples

When data originates from ▶ paired groups (matched samples or dependent samples), appropriate tests are McNemar's test (for two paired groups) and Cochran's Q test (for more than two paired groups).

Analysis of Relationship between Exposure to Risk Factor and Occurrence of Risk Event

In epidemiological studies, the result is often frequency of exposure to the ▶ risk factor or occurrence of the risk event (e. g. disease, injury, or death). Risk is defined as the proportion of the population at risk that was affected by the risk event during the observation. Relative risk is the ratio of risk of the group that is exposed to the risk factor and risk of the group that is not exposed. In cohort studies, risk and relative risk can be estimated directly (Katz 1997; Timmreck 2002). In Example 2, the cohort study, exposure to smoking as a risk factor was observed, and the occurrence of acute respiratory infection was a risk event. The risk of suffering from acute respiratory infection in the group that was exposed to smoking and the risk in the group that was not exposed was as follows:

$$\text{Risk}_{\text{exposed}} = a/(a+b) = 26/(26+24) = 0.52$$

$$\text{Risk}_{\text{unexposed}} = c/(c+d) = 17/(17+43) = 0.28$$

The **risk difference** (attributable risk) was:

$$\text{AR} = \text{Risk}_{\text{exposed}} - \text{Risk}_{\text{unexposed}} = 0.52 - 0.28 = 0.24$$

The **relative risk** (risk ratio) was:

$$\text{RR} = \text{Risk}_{\text{exposed}}/\text{Risk}_{\text{unexposed}} = 0.52/0.28 = 1.8$$

The risk of suffering from acute respiratory infection during the winter months is therefore 1.8 times higher in the group of smokers compared with the group of non-smokers.

The **attributable risk percent in the exposed** was:

$$\text{AR\%}_{\text{exposed}} = [(\text{Risk}_{\text{exposed}} - \text{Risk}_{\text{unexposed}})/\text{Risk}_{\text{exposed}}] = [(0.52 - 0.28)/0.52] = 0.46$$

In **case-control studies** and **cross-sectional studies**, it is not possible to calculate the relative risk directly, but it is possible to calculate the odds-ratio, which can be taken as an estimate of relative risk (Schechtman 2002).

Analysis of Frequencies, Table 5 Acute respiratory tract infection and smoking status in retrospective case-control study

		Smoking		
		Yes	No	Total
Acute respiratory tract infection	Yes	41	29	70
	No	30	50	80
	Total	71	79	150

Example 4:

In a retrospective case-control study, there were two samples of subjects, divided based on whether they had an acute respiratory infection in the previous three winter months. The first group consisted of 70 subjects who had an acute respiratory infection in the previous three winter months, and the other group consisted of 80 subjects who did not have an acute respiratory infection in the same period. Information regarding smoking status was then obtained from the subjects. The null hypothesis stated that populations of persons who had and those who did not have acute respiratory infections are homogeneous with regard to the proportion of smokers. The results are presented in Table 5.

The percent of smokers was 59% and 38% in the groups of people who had and who did not have acute respiratory infections, respectively. This difference was statistically significant ($\chi_0^2 = 6.65 > \chi^3_{0.05,1} = 3.84$). *The odds-ratio was* $\text{OR} = \frac{41 \cdot 50}{29 \cdot 30} = 2.36$ *(95% CI 1.22–4.54). The conclusion was that there is a significant statistical association between smoking and contracting acute respiratory infections during the winter months.*

ANCOVA

Synonyms

Covariance models

Definition

Models containing some quantitative and some qualitative explanatory variables, where the chief explanatory variables of interest are qualitative and the quantitative variables are introduced primarily to reduce the variance of the error terms. Analysis of covariance – ANCOVA – combines features of ANOVA and regression. It augments the ANOVA model containing the factor effects with one or more additional quantitative variables that are related to the response variable. The intention is to make the analysis more precise by reducing the variance of the error terms.

Ancylostomiasis

Synonyms

Infection with Ancylostoma Duodenale

Anemia

Synonyms

Deficiency of erythrocytes

Definition

Deficiency of erythrocytes refers to a reduction of red blood cells (erythrocytes) and/or dysfunction or decreased concentration of hemoglobin (the oxygen-carrying protein in the red blood cells) and/or decreased hematocrit (packed cell volume; volume percentage of red blood cells in the blood) resulting in reduced vitality. Causes of anemia may be in the production of red blood cells (hematopoiesis), the function of the cells, or an excessive destruction of red blood cells (hemolysis). Chronic and severe bleeding, pregnancy, infections, cancer and malnutrition may induce anemia. Signs and symptoms of anemia may be shock, fatigue, reduced vitality, dyspnea, tachycardia and angina pectoris.

Anesthesiology

Definition

Anesthesiology is the field of medicine specialized in the application of drugs and other agents that cause

insensibility to pain. It involves preoperative evaluation, intraoperative and postoperative care and supervision, and the management of the systems and personnel that are required to support the different activities. The subspecialties within anesthesiology include cardiothoracic anesthesiology, critical care, neuroanesthesia, obstetrical anesthesiology, pain management, pediatric anesthesiology, and ambulatory anesthesia.

Anitiviral Drugs

► Virustatics

Anopheles Mosquito

Synonyms

Malaria transmitting mosquito

Definition

There are about 400 species of the *Anopheles* mosquito, 60 of which transmit malaria. An infection is only caused by the females of the species as they feed on blood; males only sip nectar and fruit juice. *Anopheles* mosquitoes are primarily found in tropical and subtropical regions, where they live and breed near stagnant water. Mosquitoes cannot exist above an altitude of 2000–2500m. They are predominantly night-active and – most frequently – bite indoors between sundown and sunrise. To spread malaria, two blood meals within a specific timescale are necessary. On the first bite of an infected source, the mosquito takes up the plasmodia in the blood, which then develop inside the insect. With the second blood meal, plasmodia are transmitted to the human host.

Anorexia

► Eating Disorders

Anorexia nervosa

Definition

Persons suffering from anorexia nervosa show self-inflicted, substantial weight loss and retention of weight that is too low for their age (BMI $< 17.5\,kg/m^2$ in adults), or insufficient weight gain, accompanied by the conviction that one is overweight despite being underweight. Anorexia nervosa occurs most often at the age of 14.

Cross-References

► Eating Disorders

ANOVA

Synonyms

Analysis of variance

Definition

A test for significant differences between multiple means, achieved by comparing variances. It concerns a normally distributed response (outcome) variable and a single categorical explanatory (predictor) variable, which represents treatments or groups. The term analysis of variance refers not to the model but to the method of determining which effects are statistically significant. Major assumptions of ANOVA are the homogeneity of variances (it is assumed that the variances in the different groups of the design are similar) and normal distribution of the data within each treatment group.

Antagonism

Definition

Antagonism represents the situation in which the combined effect of two or more factors is smaller than predicted by the causal model being used. Antagonism is opposite of synergism.

Anthrax Infection

Synonyms

Infection with *Bacillus anthracis*

Definition

Anthrax is an infection with the spore- and toxin-building *Bacillus anthracis*. The disease primarily occurs in wild and domestic ruminants and is most frequent in warm countries. Anthrax can be transmitted to humans by direct contact with infected animals, breathing in of spores or ingestion of contaminated animal products. Incubation period ranges between a few hours and a couple of days. Without therapy or if treatment is induced too late, the course can be lethal within 2–3 days. Depending on the place of entrance, infection leads to skin anthrax, lung anthrax or gastrointestinal anthrax. Purulent vesicles develop on the skin and bloody swellings (hemorrhagic edema) are found in the inner organs. Surgical intervention is not allowed in cases of skin anthrax as the risk of spreading the toxins and causing sepsis increases. Lethality is assumed to be 5–20% in skin anthrax, 25–60% in gastrointestinal anthrax and > 90% in lung anthrax. Therapy should be carried through with gyrase inhibitors (ciprofloxacin); alternatives are penicillin G, tetracyclin, erythromycin and chloramphenicol. *Bacillus anthracis* has been used in biological warfare, for example, in 2001, letters were sent in the United States, which contained a powder contaminated with *Bacillus anthracis*. People who opened the letters were put at risk of breathing in the spores, being infected and dying of lung anthrax.

Antibiotic-Resistant Bacteria

Definition

Antimicrobial resistance (insensitivity) is the ability of a microorganism to prevent an antimicrobial (e. g., antibiotic) from working against it. Resistance to particular antibiotics can develop naturally. The use of an antibiotic for any infection, in any dose and over any time period forces bacteria to either adapt or die in a phenomenon known as “selective pressure”. The microbes that adapt and survive carry genes for resistance that can be transferred between individuals. When an antibiotic is given, it kills the sensitive bacteria but any resistant bacteria can survive and multiply. Microorganisms that are not killed or inhibited by an antibiotic are called “antibiotic resistant”. If a bacterium carries several resistance genes, it is called multiresistant.

Antibodies

Synonyms

Immune globulins; Immunoglobulins

Definition

Antibodies or immune globulins are proteins which react specifically against substances foreign to the organism. Their structure was described first in 1959 by G. Edelmann and R. Porter. From all immune globulins the types IgG, IgM, IgD, IgA and IgE can be differentiated. While IgD and IgE do not play a role in the defence of infectious diseases, IgA has an important function concerning non-specific defence mechanisms, particularly in viral infections. The immune globulins of the types G and M interact specifically with the different pathogens. As IgM is responsible for the primary immune response, it is the first immune globulin detected in the blood after contact with a pathogen. IgG is produced a little later. This type of immune globulin, which reacts very specifically against the antigen, becomes part of the immune memory. If there is a new contact with the same pathogen defence mechanisms are quickly available. In contrast to IgM antibodies, antibodies of the IgG type can pass through the placenta and thus protect the unborn baby in the womb from

a number of infectious diseases (see also ► nest protection).

Antimycotics

Synonyms

Drugs against mycoses; Drugs against fungal infections; Antimycotic therapy; Antimycotic therapeutics; Antifungal therapy; Antifungal therapeutics

Definition

Antimycotics are used to treat fungal infections of the skin and the mucous membranes and systemic mycoses. Several groups of substances with different effects are available. The polyen-antimycotics amphotericin B and nystatin are effective against dermatophytes and yeasts by influencing the synthesis of the fungal cell membrane. Substances, which belong to the group of azole antimycotics, are clotrimazole (against yeasts and cryptococcosis), ketoconazole (for local and systemic mycoses) as well as miconazole and fluconazole (both against yeasts and dermatophytes). Azole antimycotics influence different parts of the fungal metabolism. Flucytosine, which also interferes with metabolic processes of the fungus, is used parenterally in systemic yeast infections (candidiasis) and cryptococcosis.

Antimycotic Therapy

Antioxidants

Definition

There are natural antioxidants like vitamin C, vitamin E, carotinoids and artificial citrates. They are used in food, pharmaceuticals and in synthetic materials to avoid the oxidation (reaction with aerial oxygen or other oxidize chemicals) of sensitive molecules. Mostly they act as scavengers. Because natural antioxidants delay or advert the growth and development of many cells they possibly block the development of cancer. A lot of antioxidants which decrease the hazards of cancer are found in fruit and vegetables. And they also make aggressive oxygen particles harmless. It is supposed that a high intake of fresh fruit and vegetables has a protective effect against the development e. g. of cancer.

Anxiety Disorders

MICHAEL LINGEN
University of Göttingen, Göttingen, Germany
mlingen@gwdg.de

Synonyms

Panic disorder; Agoraphobia; Social phobia; Specific phobia; Simple phobia; General anxiety disorder (GAD); Obsessive-compulsive disorder (OCD); Acute and post-traumatic stress disorder (PTSD); Hypochondria; Health anxiety; Health phobia

Definition

Fear and anxiety are not primarily pathological, but ubiquitous phenomena necessary for life and survival. It is only in its extreme form that anxiety becomes problematic. Anxiety is a feeling of apprehension and fear characterized by physical symptoms such as palpitations, sweating, and feelings of stress. Anxiety disorders are a cover term for a variety of mental disorders in which severe anxiety is a salient symptom. Unlike the relatively mild, brief anxiety caused by a stressful event such as an exam or a business presentation, anxiety disorders are chronic, or can become chronic, or grow progressively worse if not treated, and are pathologically associated with other mental disorders.

Basic Characteristics

Epidemiology

Anxiety disorders rank among the most frequent psychological diseases. 1–2% of the total population are affected by an anxiety disorder in need of treatment. Epidemiological studies concluded that the lifetime prevalence of anxiety disorders is 14% (Regier 1998). The 12-month prevalence of anxiety disorders is 12.0%, ► specific phobias are most frequent (7.8%), followed by ► panic disorders (12-month prevalence: 2.3%; Wittchen and Jacobi 2005). The lifetime prevalence of panic disorders is estimated to be 3–5 percent (Faravelli et al. 2005). General anxiety disorder (GAD) shows a lifetime prevalence of 5% in adults (Ballenger et al. 2001). Prevalence rates of GAD are highest in middle-aged women (>45 years).

Aetiology

In a general model, anxieties can be explained as a consequence of a dysfunctional interpretation of events, which go hand in hand with a behavior that more and more strengthens the dysfunction (e. g. avoidance). According to this model, the ill-making interpretations are the result of individual, relatively stable convictions and doctrines. These are triggered by specific situations, physical reactions or thoughts that influence the (consequently very selective) processing and interpretation of information. Most patients, for example, over estimate dangers and underestimate their own capacity to deal with them. As soon as a perceived danger is assessed, a number of negative, automatic thoughts build up (e. g. self-doubt, sceptic predictions). This process of building up can be described as a vicious circle: signs of an assumed dysfunction enhance the perception of violability and influence the situational cognitions and the dysfunctional attempts to cope with it; these consist mainly in avoidance and safety-seeking behavior. Consequently, the person is convinced that only this behavior will avert the dreaded catastrophe. Experiencing that the catastrophe did not occur or perceiving that the situation could only be managed with this behavior, suppresses the development of functional assessments and behaviors. The term "safety-seeking behaviors" (Salkowskisk 1991) refers to every behavior used to avoid the dreaded event (e. g. diction or voice modulation of socially insecure people, always carrying a mobile phone or medication by people with panic disorders). Cognitive-behavioral therapy therefore stresses the need to modify this safety-seeking behavior; the behavioral-therapeutic approach also distinguishes between risk-factors (genetic precondition, life story), triggering or releasing factors (stages or events of life that were particularly stressful) and maintaining conditions (e. g. self-energizing processes based on self-evaluation and assessment of events as catastrophic, leading to avoidance).

From a psycho-dynamic point of view, in contrast, the symptoms of anxiety are seen as a result of inner conflicts or of deficits of the so-called self-structure, depending on the underlying concept. According to the conflict model, the psychological defense of unacceptable emotions (e. g. aggressive or egoistic impulses) leads to a massive inner conflict which in turn "is frightening" in the original sense. According to this model, people would rather suffer from anxiety than have a conflict with their consciences, an external authority or other images of themselves; they, however, are not aware of this inner conflict. The deficit model, on the other hand, assumes that the anxiety cannot be fought efficiently because of a weak ego, which then leads to increasingly strong appearances of anxiety in the form of symptoms. The continuous failure of psychological defenses in the face of increasingly trivial stimuli therefore leads to frequent and massive bouts of anxiety.

Consequences

In most anxiety disorders spontaneous remission is very rare. On the contrary, these disorders tend to become chronic at an early stage and sufferers have a high probability of developing a second anxiety disorder (up to 50%) or a depression (up to 50%). A common combination is anxiety disorder and substance abuse (up to 40%); this, however, in most cases, has to be regarded as an unsuccessful attempt by sufferers to treat their anxiety themselves. It is quite common that an anxiety disorder finds its expression in somatic symptoms (e. g. stomach ache) which are mistaken for symptoms of a physical disease and consequently wrongly treated. This in turn can lead to feelings of insecurity in the patient and in extreme cases result in a kind of vicious circle of increasing anxiety and increasing somatic symptoms.

Treatment

Until a few years ago, anxiety disorders had been regarded as difficult to treat. In recent years, however, newer and more effective therapeutic strategies have been developed. For all forms of anxiety disorders, psychotherapy is the method of choice. The benefit or lack of an additional treatment with medication is still under debate. The benefit of a pharmaco-therapy as an interim solution before the onset of psychotherapeutic measures is undisputed. A permanent therapy with medication (e. g. antidepressants, benzodiazepines), however, is not always appropriate, as it prevents the establishment of functional interpretations and coping strategies and is also probably not quite harmless because of potential addictions (as in the case of benzodiazepines). The general objective of psychotherapy for anxiety disorders is an adequate reduction of symptoms, a gener-

al psychological and physical improvement and, at the same time, an increase in the quality of life.

Behavioral-therapeutic measures for the treatment of anxiety disorders are based on the realization that anxieties are mainly influenced by learning processes, maintaining conditions (e. g. morbid gain in the form of social care) and distorted interpretations. Consequently, the specific therapeutic approach focuses on changing these conditions, e. g. confrontation with anxiety-eliciting stimulus, relaxation techniques, etc.

A decisive focus in which the psychoanalytical therapy differs from cognitive-behavioral approaches is the psychoanalytical handling of the therapeutic relationship with its specific interactions that are governed by the patient's unconscious conflicts. The objective is that these unconscious conflicts, which are inextricably linked to previous relationships, can be experienced and dealt with in the present relationship with the analyst.

Approximal Surfaces

Definition

The approximal surface of a tooth is the part of the crown that faces an adjacent tooth in the dental arch. Usually the approximal surfaces of the adjacent teeth touch punctiform (contact point), therefore forming a wedge-shaped interdental space that is difficult to reach for cleaning.

Aquinas, Thomas

Definition

Thomas Aquinas was born in Italy in 1225 and died in March 1274. He is known as one of the greatest philosophers and theologians in history. The Italian man belongs to the most important Catholic teachers; he is the principal agent of philosophy of the high middle age.

"Arising From Habit"

► Ethics and Religious Aspects

Aristoteles

Definition

A prominent advocate of philosophical reasoning. He was involved in the Natural Sciences and a very for-

ward thinker of the wider European world on religious history. He became involved in several other disciplines that he had formed himself and/or greatly influenced.

Arithmetical Skills Disorder

Synonyms

Specific developmental disorder of scholastic skills

Definition

The main feature is a specific and significant impairment in the development of arithmetical skills that is not solely accounted for by mental age, visual acuity problems, or inadequate schooling. During school age, emotional and behavioral problems are often associated with arithmetical skills disorder. Such disorders often continue into adolescence.

Artemether/Lumefantrine (Riamet®)

Definition

Lumefantrine is derived from the alkaloids of the bark of the South American cinchona tree (quinine and quinidine). Its effect results from the impairment of the metabolic processes in plasmodia. Artemether, which is extracted from *Artemisia annua* (Quinghasoso), impairs parasitic enzymes as well. The substances are effective against all forms of malaria, therapy is performed for three days. Side effects are headache, sleeplessness, dizziness and gastrointestinal symptoms.

Arthritis

Definition

Arthritis is a group of chronic conditions characterized by joint inflammation. It is one of the leading causes of disability in people older than 55 years. There are more than 100 types of arthritis, with osteoarthritis and rheumatoid arthritis among the most prominent. Although the various forms of arthritis are quite different from each other, they produce common symptoms which include sore, stiff, inflamed, and painful joints. There are different causes for arthritis; for some types theses are not even fully explored. Rheumatoid arthritis is an autoimmune disorder in which the immune system begins to act abnormally. Osteoarthritis occurs following trauma or infection of the joint, or as a result of aging. Usually, the first line of treatment is medication to reduce inflammation, swelling, and pain. The medication is often supported by physical therapy that might reduce the rate of deterioration of the joints. Surgery is only applied for the most severe cases.

Artifactual Association

► Spurious Association

Artificial Neural Network

Synonyms

Neural network

Definition

An analytic modeling technique modeled after the (hypothesized) processes of learning in the cognitive system and the neurological functions of the brain. It is capable of predicting new observations (on specific variables) from other observations (on the same or other variables) after executing a process of so-called learning from existing data. Artificial neural networks (ANN) are nonlinear and capable of modeling extremely complex functions by creating connections between processing elements – the computer equivalent of neurons. For example, the onset of a particular medical condition could be associated with a very complex (e. g., nonlinear and interactive) combination of changes on a subset of the variables being monitored (e. g., a combination of heart rate, levels of various substances in the blood, respiration rate). Neural networks have been used to recognize this predictive pattern so that the appropriate treatment can be prescribed. A distinction can be made between two different types of ANN – networks designed for supervised learning tasks (e. g., Multilayer Perceptron, Bayesian networks, Genetic algorithms) and networks primarily designed for unsupervised learning (Self Organizing Feature Map (SOFM, or Kohonen) networks).

Ascariasis

Synonyms

Ascaridosis; Roundworm infection

Definition

Roundworms are spread worldwide; in Africa more than 90% of the population is infected. Worm eggs can survive in the soil and stay contagious for a long time (up to years). People are infected by ingestion of contaminated foodstuff (containing worm eggs). A transmission by flies is also possible. In the intestines the eggs free their larvae. The larvae penetrate the intestinal wall, reach the liver via the portal vein and then get into the pulmonary circulation. Penetrating the alveolar wall, the larvae reach the bronchial system, the windpipe and then the pharynx. Here they are swallowed again and reach the intestines where they develop into adult worms. The females are 30–40cm long, the males 12–30cm. Shedding the eggs with the stool closes the developmental cycle. The larvae can cause inflammatory reactions in the various organs, moreover, ascariasis is responsible for general symptoms like a lack of appetite, stomach pain and nausea. In severe cases an ileus can develop, or worms can be vomited. The infection can be diagnosed by detection of worm eggs in the stool, or when worms are expelled with the feces. Ascariasis can be cured by pyrantel, mebendazole or albendazole.

Assessment of Work Ability

Synonyms

Fitness for work assessment

Definition

Assessment of work ability is an objective assessment of the health of employees in relation to their specific jobs, in order to ensure they can do the job and will not be a hazard to themselves or others. The assessment should always be conducted with reference to the specific job the worker holds or intends to hold. The reasons for assessment of work ability are numerous, such as the application or consideration for entry into employment and assignment to a specific job, the need to avoid diseases becoming chronic, return to work after sick leave, or assessment for social benefits.

Assessment of work ability must be specifically job-related, with judgments of fitness being based on the principle that the employees' state of health in relation to their individual jobs will not be hazardous to themselves or others. It is preferable that these activities should be undertaken by individuals who are specially trained or well experienced in occupational medicine.

Assessment of work ability, according to the definition of work ability, usually involves the measurement of activities related to personal care, mobility, sensory perception, communication, recreation, socializing, and intimacy. It is also related to mental and intellectual status, psychological distress, individual work environment, various occupational requirements, and even personal demographic characteristics. Assessment of work ability is a difficult task and probably cannot be performed by a single individual. Available methods that measure certain dimensions of work ability, such as functional capacity, physical performance components, or physical work performance, are generally considered

to be hardly sufficient measurements of the real work ability.

Occupational health service personne are in an excellent position to make an assessment of work ability as they have access to both medical and workplace data.

The work ability index (WAI), developed by the Finnish Institute of Occupational Health, is an instrument, with high validity, which can provide an integrated number useful for comparative longitudinal study and follow-up.

Assessment of Workplace Hazards

Synonyms

Workplace hazards measurements

Definition

Assessing health hazards involves the measurement of the concentration of potentially hazardous agents in the workplace to evaluate whether or not there is a risk of exposure (► workplace hazards).

Once a potential hazard has been recognized in the workplace, the next step is to assess it to determine if it is possible for a worker to be exposed and/or determine if exposure is at a harmful level. The exposure of workers to the agent must be evaluated to see if there is a risk of injury to their health. If so, a control will be needed.

Exposure means being in contact or exposed to a potentially hazardous agent for a determined period of time. Some agents can cause health effects even though the period of exposure is very short. Others are harmful only if exposure is for a prolonged or excessive period of time. In both cases, the higher the exposure level, the greater the potential for harm.

Assisted Living Facilities

Synonyms

Residential care facility; Personal care home; Domiciliary care facility; Adult foster care; Adult family homes

Definition

Assisted living facilities offer private rooms or apartments to people who are not able to live on their own but are still independent enough that they do not yet need the continuous care of a ► nursing home. The facilities offer meals, housekeeping assistance, assistance with ► activities of daily living, assistance with medication administration, social activities, and 24-hour support by trained staff. Usually, assisted living facilities have the mission of offering personal autonomy, independence, and privacy to often frail elderly people in order to provide homelike settings for them. Facilities that were built in the recent past are more likely to cater for the specific requirements of disabled people.

Association

Synonyms

Correlation; (Statistical) dependence; Relationship

Definition

An association is a statistical dependence between two or more events, characteristics, or other variables. An association is present if the probability of occurrence of an event or characteristic, or the quantity of a variable, depends upon the occurrence of one or more other events, the presence of one or more other characteristics, or the quantity of one or more other variables. The association between two variables is described as positive when the occurrence of higher values of a variable is associated with the occurrence of higher values of another variable. In a negative association, the occurrence of higher values of one variable is associated with lower values of the other variable.

Association Studies

Definition

The association studies approach is based on showing a higher or lower ► allele frequency among cases and controls, candidate genes presumed to include the disease-causing alleles are then studied. Although two types of genetic association studies are described (family- and population-based), the rationale is similar, ascertainment of mutation related to disease risk in genomic screening by identification chromosomal regions shared by patients.

Associative or Classical and Operant Conditioning

► Conditioning Model

Asymmetric Information

► Information Asymmetry

Asymmetry of Information

► Information Asymmetry

Atheism

Definition

The word Atheism is derived from the Greek adjective ‘atheas’ and when translated means ‘without God’. An atheist believes that the failings of the world can be found in the manner in which religious practices are conducted. It denies any presence of a god (or gods) and a transcendent power.

Atmospheric Condition

► Climate and Microclimate

Atovaquon + Proguanil (Malarone®)

Definition

Atovaquon interferes with the transport of electrons inside the plasmodia, proguanil impairs protein metabolism. The combination of both substances is effective against all forms of malaria. Treatment is carried out for three days. As water solubility of atovaquon is poor, it should be taken with a fatty meal to improve intestinal resorption. Side effects of the drugs are headache, cough and gastrointestinal symptoms (primarily vomiting and diarrhea).

Attention Deficit Disorder (ADD)

► Attention Deficit / Hyperactivity Disorder (ADHD)
► Hyperkinetic Disorder

Attention Deficit Hyperactivity Disorder (ADHD)

Synonyms

Hyperkinetic disorder

Definition

Accordingly to ICD-10, ADHD is characterized by an early onset (usually in the first five years of life), lack of persistence in activities that require cognitive involvement, and a tendency to move from one activity to another without completing any one, together with disorganized, ill-regulated, and excessive activity. Children with ADHD have difficulty paying attention to details and are easily distracted by other events that are occurring at the same time; they find it difficult and unpleasant to finish their schoolwork; they put off anything that requires a sustained mental effort; they are prone to make careless mistakes, and are disorganized, losing their school books and assignments; they appear not to listen when spoken to and often fail to follow through on tasks. The symptoms of hyperactivity may be apparent in very young preschoolers and are nearly always present before the age of 7. Such symptoms include fidgeting, squirming around when seated, and having to get up frequently to walk or run around. Several other abnormalities may be associated. Children with ADHD are often reckless and impulsive, prone to accidents, and find themselves in disciplinary trouble because of unthinking breaches of rules rather than deliberate defiance. Their relationships with adults are often socially disinhibited, with a lack of normal caution and reserve. They are unpopular with other children and may become isolated. Impairment of cognitive functions is common, and specific delays in motor and language development are disproportionately frequent. Secondary complications include dissocial behavior and low self-esteem.

Attention Deficit/Hyperactivity Syndrome (ADHS)

► Attention Deficit / Hyperactivity Disorder (ADHD)

Attributable Risk (AR)

Definition

Attributable risk (AR) is the proportion of the incidence of a disease in exposed individuals that is due to exposure. It is the incidence of a disease in the exposed population that would be eliminated if exposure were eliminated. It can be calculated as *rate difference* (the rate in the exposed group minus the rate in the unexposed group) or *risk difference* (the difference between the risks in the exposed and unexposed groups). When the level of risk in both exposed and unexposed groups is the same, the risk difference is 0. If an exposure is harmful (e. g., cigarette smoking), the risk difference is expected to be greater than 0. If an exposure is protective (e. g., vaccine), the risk difference will be less than 0.

The AR is sometimes referred to as attributable risk in exposed individuals because it is used to quantify the risk that can be attributed to exposure in the exposed group. The AR is the measure of association that is most relevant when making decisions for individuals.

Attributable risk percent (AR%) is the percent of the incidence of a disease that is due to exposure in exposed individuals. It is the percent of the incidence of a disease *in the exposed population* that would be eliminated if exposure were eliminated.

Attributable Risk Fraction

Definition

The attributable risk fraction is an epidemiological parameter. If there are several causes for the development of a health problem, the attributable risk fraction describes the percentage of the risk that is due to a certain risk factor, e. g. the percentage of risk for lung cancer caused by smoking.

Attributable Risk Proportion

Synonyms

► Population Attributable Risk (PAR)

Definition

The term "attributable risk" describes the proportion of disease that can be attributed to exposure to a ► risk factor (► hazard) that persons in a population have experienced. Population attributable risk (PAR) is the risk of a specified disease or other outcome of interest in a defined population that can be attributed to an exposure of interest. The PAR is the incidence rate of a condition in a specified population that is associated with or attributable to exposure to a specific risk factor (hazard).

The PAR in a total population is the proportion of the incidence or risk of a disease that can be attributed to exposure to a specific risk factor; this means the difference between the risk in the total population and the risk in the unexposed group.

The PAR in occupational health is the percentage of a given illness or outcome that could be prevented if the occupational factor causing or contributing to the illness or outcome was eliminated.

Atypical Anorexia nervosa

Definition

Atypical anorexia nervosa disorders are disorders that fulfill some of the features of ► anorexia nervosa but in which the overall clinical picture does not justify that diagnosis. For instance, one of the key symptoms, such as amenorrhoea or a marked dread of being fat, may be absent in the presence of obvious weight loss and weight-reducing behavior.

Cross-References

► Eating Disorders

Atypical Bulimia nervosa

Definition

Atypical bulimia nervosa disorders are disorders that fulfill some of the features of ► bulimia nervosa, but in which the overall clinical picture does not justify that diagnosis. For instance, there may be recurrent bouts of overeating and overuse of purgatives without significant weight change, or the typical overconcern about body shape and weight may be absent.

Cross-References

► Eating Disorders

Atypical Mycobacteria

► MOTT (Mycobacteria Other than Tuberculosis)

Audiogram

Definition

An audiogram is a graph showing hearing level as a function of frequency, as measured by an audiometer. The vertical lines on an audiogram represent pitch or frequency. The most important pitches for speech are 500–3000 Hz. The horizontal lines represent loudness or intensity. A reading of 0 dB on an audiogram denotes the hearing threshold level regarded as the normal audiometric standard at that frequency. Points below zero on the scale denote louder threshold levels, whereas those above, expressed in negative decibels with respect to the zero level, are less intense levels that, because of individual hearing differences, some people may normally hear. The softest sound a person is able to hear at each pitch is called the threshold and is recorded on the audiogram. Thresholds of 0–25 dB are considered normal (for adults).

Autochthonous

Synonyms

Endemic; Native; Indigenous

Definition

Endemic disease – the constant presence of a disease or infectious agent within a given geographic area or population group; may also refer to the usual prevalence of a given disease within such area or group.

Cross-References

► Native

Autochthonous Population

Synonyms

Natives; Original inhabitants

Definition

Autochthonous population is a general and more neutral term for natives or original inhabitants of a country or region. The term ‘autochthonous’ is used to avoid static ideas implied in terms like ‘native’ or ‘original’. The terms ‘allochthonous’ population and ‘immigrants’ can be seen as synonyms. The difference between autochthonous and allochthonous populations is not absolute – it is a relative one. The difference depends on both context and time, combined with a range of variables (e. g., ideas of origin, legal status, social inclusion and status, ethnic or racial background, religion) in a specific national or regional context.

Autologous

Definition

The term “autologous” refers to the source of cells or tissue for transplantation purposes. Cells are autologous

when obtained from the same patient who is treated. Hence, cells present the same surface molecules as the recipient tissue and are not rejected by the immune system. If cells are "allogeneic", they derive from a genetically different organism of the same species. Under this condition, immune responses have to be suppressed by appropriate medication. "Xenogeneic" transplantation deals with tissues or cells from individuals that do not belong to the same species. In humans, such experiments are performed using porcine heart valves. In contrast, "xenoplastic" grafts consist of synthetic substrates such as bone replacement materials.

Autonomy

Synonyms

Self-direction

Definition

Autonomy implies respect for the individual and that individual's personal rights. The essay "On Liberty", by the 19th century philosopher John Stuart Mill, strongly enunciated the autonomy principle. Mill states: "The only purpose for which power can be rightfully exercised over any member of the civilized Community, against his will, is to prevent harm to others. His own good, either physical or moral, is not sufficient warrant … In the part which merely concerns himself, his independence is, of right, absolute." This is an absolute principle in ► bioethics.

► Influenza and Avian Influenza

Bacille Calmette-Guérin (BCG) Vaccination

Synonyms

Bacille Calmette-Guérin immunization; Vaccination against tuberculosis (tbc); Immunization against tuberculosis (tbc)

Definition

Immunization against Bacille Calmette-Guérin (BCG) was developed in the 1930s, using a live, weakened strain of *Mycobacterium bovis*, which is similar to the germ causing tuberculosis in humans (*Mycobacterium tuberculosis*). While tuberculosis is no problem in many countries, and thus vaccination is not recommended there, it is highly prevalent in other areas of the world. In countries with high rates of tuberculosis, BCG vaccination should preferably be performed at time of birth as a single intradermal injection. After correct injection, an induration of the skin and afterwards a small scar develops at the needle site. The protection rate achieved by BCG vaccination is 70–80%. In all individuals older than six months, a tuberculin skin test (Mantoux test) should be carried through prior to BCG immunization to find out if the person has already come into contact with tuberculosis. In this test a small amount of tuberculin units is inoculated by an intradermal injection. The induration has to be measured by a trained person 48–72 hours after administration, with a red lump > 5 mm meaning a positive result. Contraindications for BCG vaccination are prior tuberculosis, acute illness with fever, generalized skin disease and immunodeficiency.

► Immunization, Active

Bacille Calmette-Guérin Immunization

► Bacille Calmette-Guérin (BCG) Vaccination

Background

► Environment

Background Meanings

Definition

Background meaning is a personally held, culturally derived, sense of reality which is taken for granted. It is often difficult for people to be aware of their meanings and values, but they are always present and give an approach to life and events which, in good faith, is thought to be the best.

Basic Immunization

Synonyms

Basic vaccination

Definition

In order to achieve immunity against one or several pathogens, it is necessary to administer a certain number of injections of the ► vaccine following a fixed procedure. The initial implementation of a course of vaccination is known as basic immunization. Subsequent vaccinations serve to boost the immune protection. Basic immunization is only complete when all of the vaccinations included in the procedure have been administered. However, in the case that the recommended time intervals have been exceeded, it is not necessary to restart the procedure or to repeat the single vaccinations. Each vaccination counts. Therefore in order to complete the basic immunization, it is only necessary to administer the missing vaccinations.

Basic Reproduction Rate

Definition

The basic reproduction rate characterizes the spread of an infectious disease. It is calculated as R_o = $\beta \times k \times D$. In this formula β is the risk of transmissions per contact (attack rate), k is the number of potentially infectious contacts of an individual in a certain time interval, and D is the duration of contagion of an infected person. When the basic reproduction rate is >1, a further spread of the disease has to be assumed.

Basic Rights

► Human Rights and Public Health

Bayes' Theorem

Bayes' Theorem allows new information to be used to update the conditional probability of an event, i. e., a formula for revising *a priori* probabilities after receiving new information. The revised probabilities are called *posterior* probabilities. The formula for Bayes' Theorem is as follows:

$$P(A_i/B) = \frac{P(A_i) * P(B/A_i)}{\sum_{i=1}^{k} P(A_i) * P(B/A_i)}.$$

For example, consider the probability that someone will develop an intestinal cancer in the next year. An estimate of this probability based on general population data would be *a priori* estimate; a revised (*posterior*) estimate would be based on both on the population data and the results of a specific test for this cancer. Let $A_1 =$ the event of a tumor being present, $A_2 =$ the event of a tumor not being present, and $B =$ the event of a positive screening test. If somebody has a tumor, the screening test has an 85% chance of detecting it, i. e., $P(B/A_1) = 0.85$. However, it also has a chance of falsely indicating that a tumor is present when there is no tumor, i. e., $P(B/A_2) = 0.10$. The probability of a person having a tumor is 0.02, i. e., $P(A_1) = 0.02$. If the screening test is positive, the probability of having a tumor is $\frac{0.02*0.85}{0.02*0.85+0.98*0.10} = \frac{0.017}{0.017+0.098} = 0.148$.

Bayesian Network

Definition

A probabilistic graphic model to generate hypothesis using joint probability distributions. This method is used in gene expression to group similar genes together for gene expression analysis (► serial analysis of gene expression).

Behavioral Patterns

MARTIN SIEPMANN
Forschungsverbund Public Health Sachsen-Sachsen Anhalt e. V., Medizinische Fakultät, Technische Universität, Dresden, Germany
martin.siepmann@tu-dresden.de

Definition

Behavioral patterns such as tobacco smoking, excess alcohol consumption, ► substance dependence, inappropriate nutrition, lack of ► physical activity, failure to use safety equipment including automobile seat belts, certain ► sexual practices, and failure to follow preventive guidelines and ► disease screening are all associated with elevated risk of disease or death. Causal conclusions have been strengthened, dose/response relationships have been clarified, the influence of many of these behaviors on overall public health has been quantified, and scientific guidelines have been formulated.

Basic Characteristics

Risk behaviors rarely occur in isolation, but cluster in patterns that in combination influence a person's risk of disease. Thus, a sedentary life-style in industrial societies connotes a pattern of mutually influencing behaviors such as taking little exercise, eating foods of poor nutritional value, consuming caloric drinks and possibly also smoking cigarettes. While these factors do not determine disease in an inevitable sense, they place the person at elevated risk of ► obesity, high blood pressure, and subsequently of cardiovascular disease as well as impairment of ► musculoskeletal health. Other unhealthful behavioral patterns include the connections among ► smoking behavior, malnutrition, and drug taking, and those among ► alcoholism, aggression, violence and ► suicide. Each of these patterns is reinforced by membership in a social milieu that brings similar people together, as well as by individual personal traits. Each pattern also trends to correspond to personal values and beliefs, which form the connection between behavior and culture.

Two general explanations have been suggested for unhealthy behavior. The first theorizes that some people are unaware about the harmful effects of substance abuse, smoking and obesity. An alternative explanation emphasizes that people engaging in unhealthy behaviors do not correctly weigh the health/lifestyle pros and contras regarding these behaviors (Wagner et al. 2005). It seems doubtful that the first explanation is reasonable. For example, virtually all women and most men recognize that lowering weight is desirable from a health perspective. While it is clear that obese people often differ in their energy metabolism from thin people, it is also obvious that some of the obesity in the developed countries results from eating foods considerably in excess of the amount that is known to be healthy. The attempt to control food intake by dieting is nearly universal at some point in the lifetime of women in the US and Northern Europe. Studies of incoming college freshmen women demonstrate that only 8–13% of women do not adhere to a diet (Krahn et al. 1992). With the median age of onset of dieting close to age 12, it is unlikely that the message is not getting to young women or is reaching them too late (Drewnowski and Hann 1999). Whether food preferences reflect dietary habits is an interesting issue. Data from epidemiological studies suggest that food consumption patterns show parallel influences of age, sex, health status, education, and income (Harnack et al. 1997). Generally, age influences both food preferences and food intake patterns in the direction of more healthful diets (Block and Subar 1992).

In the area of substance abuse, there is even more convincing data, documenting that knowledge is not the key problem. Studies of several school-based substance abuse prevention (► prevention and health promotion) programs found that these programs definitely increased student's knowledge regarding the health risk of these substances but, unfortunately had no effect or even increased the rate of substance abuse (Hansen 1992). Therefore, it appears unlikely that a simple lack of knowledge is what prevents people from avoiding harmful behavior.

Another area of research has examined the tendency to novelty seeking. For example, many adolescents begin smoking as novel behavior that seems to offer relief from thinking they are not as "with it" (Pomerleau et al. 1992). People who evidence early alcoholism are significantly higher on the dimension of novelty than are other individuals (Cloninger 1987). At the other end of the spectrum are those who are focused on avoiding harm (Harkness et al. 1995). Those high in novelty seeking and low in harm avoidance are thought to be most impulsive. People who are highly impulsive tend to be vulnerable to the short-term rewards offered by many high-risk behaviors (Newman and Wallace 1993). In a laboratory reward versus risk situation, highly impulsive people behave more quickly and give themselves less time to consider options. Behavioral intervention programs aim at introducing some delay in decision-making, so that the participants have some time to reflect on short-term benefits versus long-term-harm.

Behavior of Nutrition

Synonyms

Nutritional behavior; Eating habits

Definition

Patterns of action cover the conscious control of the choice and absorption of human ► nutrition. Nutritional behavior is the result of a process of psychological processing of all stimulus factors which lead to adoption or rejection. This process is for the most part learned behavior and is determined by a complex eating situation which is characterized by social determinants like food supply, preparation, classification and social arrangement.

Belmont Report

Definition

In the USA, the National Commission for the Protection of Human Subjects of Biomedical and Behavioral Research in their document known as the "*Belmont Report*", in 1979 underlined three basic principles to be used to generate specific rules and regulations in response to US research scandals: ► respect for persons, ► beneficence, and ► justice. Applications of the general principles to the conduct of research leads to consideration of the following requirements: ► informed consent, risk/benefit assessment, and the selection of subjects for research.

Beneficence

Definition

Beneficence goes back to the ► hippocratic oath (4th BC), which concerned the doctor-patient relationship, focusing on the physician's code of conduct. It stated: "I will use treatment to help the sick according to my ability and judgment." To the letter it means "doing good". In the modern connotation, it includes other aspects, like the physician's duty to refer to another health professional when needed, always keep updated with the latest discoveries and innovations in medical science, and so on.

Benefits

► Outcome

Berbers (Northern Africa, Tunisia, Algeria, Libya, Morroco)

Beta Error

Synonyms

Type II error

Definition

A beta error is an error that results if a false null hypothesis is not rejected or if a difference is not detected when a difference exists between comparison groups. This error can happen when the sample size is too small. Most studies aim to have less than 20% probability of such an error.

Between Subjects Design

► Unpaired Groups Design

Bias

ZORANA GLEDOVIĆ
Institute of Epidemiology, School of Medicine, University of Belgrade, Belgrade, Serbia
gledovic@sezampro.yu

Synonyms

Bias: Systematic error; Confounding: Bias due to confounding; Interaction: Effect modification

Definition

The important issues in deriving causal inferences are: bias, confounding and interaction.
"Bias can be defined as deviation of results or inferences from the truth, or processes leading to such deviation".
"Confounding is a situation in which the effects of two processes are not separated".
"Interaction is the interdependent operation of two or more causes to produce or prevent an effect" (Last 2001).

Basic Characteristics

The goal of an epidemiological study is ► accuracy in measurement. Epidemiological studies are prone to ► error. Errors can be either random or systematic.
Since the errors can never be eliminated, much attention is devoted to minimize them, and to assess their importance. The principles of study design emerge from consideration of approaches to reduce both types of errors. Random error is the divergence, due to chance alone, of an observation on a sample, from the true population value, leading to lack of ► precision in the measurement of an association. Sources of random error are: individual biological variation, sampling error and measurement error (Bhopal 2002). Random error can never be completely eliminated. The best way to reduce it is to increase the size of the study.

Validity

The validity of a study is usually separated into two components: internal validity and external validity.
Internal validity implies that the index and comparison groups are selected and compared in such a manner, that

observed differences between them on dependent variables under study may be attributed only to the hypothesized effect under consideration.

External validity concerns validity of the inferences as they pertain to people outside the study population. External validity depends on internal validity, which is its prerequisite, but it depends also on the results of other studies, theoretical knowledge of the disease process and related factors, and biological considerations.

Internal validity is the degree to which the results of an observation are correct for the particular group of people being studied. Internal validity can be threatened by all sources of systematic error (bias) but can be improved by good design of a study (Rothman and Greenland 1998).

There are three main types of biases: selection bias, information bias and confounding.

Selection Bias

Selection bias occurs when there is a systematic difference between characteristics of the people selected for a study and the characteristics of those who are not. There are a number of reasons for the occurrence of this type of bias. Common feature for all of them is that the relationship between the ► exposure and disease observed among those who participate in the study is different from that for the individuals who would have been eligible to participate but were unwilling or not selected by the investigator (Rothman and Greenland 1998).

Example: Selection bias can occur if investigators include hospital cases or cases under a physician's care and exclude those who die before admission to hospital because the course of their disease was severe, those with mild symptoms not requiring hospital care, cost of hospital treatment or other factors.

Information Bias

Information bias occurs whenever the study subjects are erroneously categorized with respect to either exposure or disease. The effect of this bias depends on whether this misclassification is differential or non-differential (Rothman and Greenland 1998).

Differential misclassification occurs when the proportion of subjects misclassified differ between the study groups. It can occur when there is any systematic difference in the soliciting, recording or interpreting of information from study participants.

Example: Mothers whose children have had or have died of leukemia are more likely than mothers of healthy children (control group in a ► case-control study) to remember details of diagnostic x-ray examinations to which these children were exposed in utero (recall bias).

The effect of differential misclassification is overestimation of an association even if it does not really exists, or underestimation or lack of an association when it really exists.

Non-differential misclassification occurs when inaccuracies in the categorization of subjects by exposure or disease are present in similar proportion in each of the study group. Such misclassification is often present because of inaccuracy of most measurements in biomedicine.

Non-differential misclassification almost always results in an underestimate of the true strength of the association. Some degree of this misclassification is present in almost all types of epidemiological studies and this bias may account for some apparent differences in the results of epidemiological studies (Hennekens and Buring 1987).

The control of potential biases must be accomplished by careful study design. Some of design features that can minimize potential biases are: carefully prepared ► questionnaire (close-ended questions), clearly written protocol, trained study personnel, the use of multiple sources of data whenever possible etc.

Confounding

The word confounding is derived from a Latin word meaning to mix up. The word's meaning in everyday language is to confuse or puzzle. Confounding mixes up causal and non-causal relationships.

Confounding is a major cause of bias in epidemiology, and the more difficult one to understand. The potential for it to occur is whenever the cardinal rule' compare like-with-like' is broken. This rule is perhaps never attained except in experimental research. Comparing like-with-like may be achieved in experimental studies where subjects can be randomly allocated to one group or another, a technique which employs the laws of chance to create comparable groups (Bhopal 2002).

Confounding is one of the most important problems in observational studies.

Example: In a study of mortality rates, investigators find that mortality rates in an English seaside resort are much higher than in a country as a whole. Why might this be so?

One possible explanation:

A holiday town attracts the elderly, so has a comparatively old population.

What is confounding factor in this example?

Age, which is associated with both living in a resort and with death.

The Control of Confounding

Several methods are available to control confounding, either through study design or during the analysis of the results (Hennekens and Buring 1987; Rothman and Greenland 1998)

The Control of Confounding in Study Design

► *Randomization* is applicable only in experimental studies. It is method which ensures that potential confounding variables are equally distributed among the groups being compared.

► *Restriction* is used to limit the study to people who have particular characteristics. For example, in a study on the effects of coffee on pancreatic cancer, participation in the study could be restricted to nonsmokers, thus removing any potential effect of confounding by cigarette smoking.

► *Matching* ensures that study participants are selected so that potential confounding variables are evenly distributed in the groups being compared. For example in a case-control study each patient with a disease can be matched with a control of the same sex and age group to ensure that confounding by sex and age does not occur.

Control of Confounding in the Analysis of Results

► *Stratification* involves the measurement of the strength of association in well-defined and homogeneous categories (strata) of the confounding variable. If the confounding variable is age, the association may be measured in 10-year age groups. Stratification is often limited by the size of the study and it cannot help to control many factors simultaneously. In this situation, *mathematical modeling* is required to estimate the strength of the associations while controlling for a number of confounding variables.

The multivariate modeling involves ► logistic model and analysis of covariance (Rothman and Greenland 1998).

Interaction

According to MacMahon interaction can be defined as follows: "When the ► incidence rate of disease in the presence of two or more risk factors differs from the incidence rate expected to result from their individual effects" (MacMahon 1972). The effect can be grater than that we would expect (positive interaction, ► synergism) or less than what we would expect (negative interaction, ► antagonism).

The problem is to determine what we would expect to result from the individual effects of the exposures.

In exploring the possibility of interaction, the first question is whether an association between exposure and a disease exists. If it exist, is it due to confounding? If it is causal, is it equally strong in each of the strata that are formed on the basis of some other variable? (Gordis 2004).

Example: If the association of smoking and lung cancer is equally strong in all strata formed on the basis of degree of urbanization, there is no interaction. But if the association is of different strength in different strata formed on the basis of age, there is interaction.

Conclusion

Biases reflect inadequacies in the design or conduct of a study and affect its validity. Because of that, biases need to be assessed and, if possible, eliminated, while confounding and interaction describe the reality of the relationships between certain factors and a certain outcome (Gordis 2004). Such relationships are particularly important in investigating the role of various factors in disease causation.

Binge-Eating Disorder

Definition

The term binge-eating disorder was introduced only in 1990 and involves regular bouts of ravenous eating, but without fulfilling the other criteria of anorexia or ► bulimia nervosa. Individuals suffering from binge-eating disorder eat large amounts of food and they eat much more rapidly than normal. ICD-10 classifies binge-eating disorder as an "other ► eating disorder not otherwise specified".

► Eating Disorders

Binomial Distribution

Binomial distribution is a discrete probability distribution of the number of successes in a binomial experiment. A binomial experiment consist of a fixed number of n independent Bernoulli trials, each of which has two outcomes, usually labeled "success" and "failure", and a constant probability of success from trial to trial. The term "independent trials" means that the outcome in one trial does not depend on the outcome of any other trial. "Success" in binomial experiment is typically used to designate the occurrence of an event of interest such as improvement, death and adverse effects.

Binomial distribution is denoted by $B(n, p)$, where n and p are called parameters of binomial distributions – n is the number of Bernoulli trials in binomial experiment and p is probability of success in one Bernoulli trial. Consequently, the probability of failure is 1-p. Probability (also called binomial probability) of x successes in a binomial experiment is given by the binomial formula:

$$P(X = x) = \frac{n!}{x!\,(n-x)!} p^x (1-p)^{n-x}.$$

In this formula $n!/(x!\,(n-x)!)$ is the binomial coefficient, which denotes the number of combinations that x successes can be drawn from n trials.

The mean of the binomial distribution is np, and variance is $np(1–p)$.

Bioactive Substances

Definition

Bioactive substances consist of secondary plant compounds, fiber and special products of fermentation like lactic acid. In general, it is a matter of nutritional contents that do not belong to nutriments.

Biocomputing

► Bioinformatics

Bioconcentration

Definition

Bioconcentration considers the uptake of substances from the non-living environment (soil), while the second stage, i. e. biomagnification, describes the uptake of such substances through the food chain. Both of these processes happen simultaneously during bioaccumulation. Some chemical contaminants have long half-lives,

but in other cases derivative chemicals are formed from decay of primary soil contaminants. Some toxic compounds may stay in a system for a much longer period of time, and if the input is greater than the rate of biotransformation or loss, produce bioaccumulation. For many fat-soluble and persistent chemicals, biomagnification is a dominant factor in the risk they pose; examples include DDT and lipid soluble poisons, including tetra-ethyl lead compounds (the lead in leaded petrol). These compounds are stored finally in the body's fat, and when the fatty tissues are used for energy, the compounds are released and cause acute poisoning. Another important example is the accumulation of Strontium 90, mistaken by mammalian and human bodies for calcium, and laid down in the bone tissue, where its radiation can cause long-term damage.

Bioengineering

► Biotechnology

Bioethics

Definition

Bioethics is a more inclusive term for ► ethics in clinical medicine. It is normative ethics applied to decision making and public policy in the domains of biology, medicine, and health care. It is also concerned with matters of basic scientific research and with the social applications of biological knowledge and biomedical technology. It is a new, broad field of study that has arisen largely during the last few decades, as new powers, new choices, and new dilemmas have been opened up by the biological revolution.

Synonyms

Computational biology; Biocomputing

Definition

Due the relative young age of the field, there have been many definitions produced. While bioinformatics purists emphasize the analysis of large-scale genomic and transcriptomic data, looser definitions define bioinformatics as any intersection of biology and computer science including analysis of scientific literature, epidemiological statistics, etc. Perhaps an inclusive definition can be proposed:

The application of computational, statistical, and mathematical methods to biological information to complement, aid, and expedite scientific discovery and enhance biological research. The three main aims include:

1) DATABASE: acquisition, gathering, storage, organization and management of large-scale data
2) ALGORITHM/TOOLS: development of algorithms and computational tools to analyze and classify the data
3) CONCLUSIONS/PREDICTIONS: process, abstract, and integrate the data to make conclusions and predictions

The data include and are not limited to nucleotide, proteomic, genomic, phylogenetic, chemical, structural, phenotypical, functional, ontological, and transcriptomic information.

Basic Characteristics

Since the development of protein sequencing by Sanger in 1955 and the Atlas of protein sequences by Margaret Dayhoff in 1965, there has been a revolution of high-throughput technologies that generate biological information on an increasingly large scale. In August 2005, the International Nucleotide Sequence Database Collaboration announced that the public collections of DNA and RNA sequences had exceeded 100 gigabases (or 100,000,000,000 bases, or "letters" of the genetic code), which represent both individual genes and partial and complete genomes of over 165,000 organisms. In response to this deluge of data, computer scientists and biologists collaborated in creating a new field of study named bioinformatics.

Bioinformatics of Genomes

Bioinformatics is driven by high-throughput technologies. In 1977, Fred Sanger introduced nucleotide/DNA sequencing technology (Sanger et al. 1977) and by 1980, the first complete gene sequence for an organism (FX174) was completed. In 1995, the first complete ► genome, H. influenze genome was completed. The draft of the human genome was reported in 2001 and completed in 2003. As of 2006, there are over 350 complete genomes with over 450 more in progress. Bioinformatics is thus necessary to organize and analyze all this data.

Currently, the major databases for genomic information include Genbank at NCBI, Ensembl at the European Bioinformatics Institute, DNA Data Bank of Japan at the National Institute of Genetics, and the UCSC Genome Browser at UC Santa Cruz.

There are many computational tools and algorithms that enabled the genomic revolution. Most notably, Jim Kent's GigAssembler (Kent 2001) program enabled the consolidation of sequence information from over ten labs to produce the draft human genome for the public effort. A computational problem central to sequence analysis is the alignment and comparison of sequences. The program was first solved by Needleman-Wunsch (Needleman 1970) and current implementations are based on ► multiple sequence alignment (MSA) algorithm suite named Clustal (Higgins, Sharp 1988). Another important problem has been the identification of similar sequences in whole genomic and databases searches. Current implementations that solve the problem include BLAST (Altschul et al. 1990), PSI-Blast (Altschul et al. 1997), and Blat (Kent 2002).

Bioinformatics of Transcriptomes

Besides large-scale sequencing, two other groups of technologies have revolutionized bioinformatics, namely transcriptomics (► transcriptome) and proteomics. In 1995, two independent technologies were developed to measure gene expression on a large-scale: ► serial analysis of gene expression (SAGE) (Velculescu et al. 1995) and microarray (Shena et al. 1995). By 1997, it was possible to measure the entire transcriptional profile of a complete Eukaryotic genome (Saccharomyces cerevisiae) on a microarray chip (DeRisi et al. 1997).

Consolidated databases of gene expression include Array Express repository at the EBI, Gene Expression Omnibus at NCBI, mouse Gene Expression Database at Jackson Laboratory, Sym Atlas with Novartis, and the Stanford Microarray Database.

A large set of different algorithms were developed to analyze these expression data.

Initial algorithms were based on clustering genes with similar gene expression together (► clustering algorithms) (Niehrs 1999) while programs incorporated later methods such as ► self organizing maps (Tamayo et al. 1999), ► bayesian networks (Friedman et al. 2000) and ► principal component analysis.

Bioinformatics of Proteomes

Since the development of protein sequencing in 1955 by Fred Sanger, protein research has greatly advanced. The study of proteomics relies on technologies such as two-dimensional gel electrophoresis and mass spectrometry to identify the entire constitution of proteins in an organism. The first ► proteome was published in 1995 by Wasinger for the smallest known self-replicating organism, Mycoplasma genitalium (Wasinger et al. 1995). Yeast-two hybrid technology allowed researchers to identify all the interactions between proteins. Furthermore, as more and more crystal structures were solved for the different proteins, in 1973, the Brookhaven Protein Databank was created to store the data.

The main databases for protein information include Pfam (Bateman et al. 2000), UCSC Proteome Browser (Hsu et al. 2004), Swiss-Prot, and UniProt (Wu et al. 2006) and many databases exist for specific proteins or post-translational modifications. The major structural genomics databases and classification schemes include Protein DataBank (PDB) at Brookhaven National Labs, Structural Classification of Proteins (SCOP) (Murzin et al. 1995), CATH (Pearl et al. 2005) Protein Structure Classification Database (UCL), and FSSP Database (Holm, Sander 1996).

The major question in proteomic bioinformatics is the in silico prediction of structure of proteins, also known as the ► protein folding problem. On all three levels of primary, secondary, and tertiary structure, numerous methods have been attempted such as comparative modeling, threading, energy minimization, and ab initio sequence methods. Various algorithms have also been developed to query structure databases for similar struc-

tures, such as DALI Server at EBI and Vector Alignment Search Tool (VAST) at NCBI.

Paradigm Shifts in Bioinformatics

In this post-genomic age, with the availability of large amounts of information on all levels, biological research is no longer confined to experimental methods based on single genes. Now, investigators have a wealth of information at their disposal. The new challenge is to consolidate, integrate, evaluate, and obtain data from established sources to generate hypotheses or produce a set of targets that can then be validated and investigated using experimental methods.

With more computation resources and more data available, researcher can now start to think of genes and proteins in relation to the vast network of interactions within the genome and think more in terms of pathways and systems. Just like biotechnological advances such as PCR, Western blots, and microarrays have revolutionized biology, future biological research will be intimately involved with bioinformatics databases, tools, and analyses.

Biological Terrorism

► Bioterrorism

Biomedical Research

Definition

Biomedical research refers to a class of activities designed to develop or contribute to generalizable knowledge in relation to health; it includes medical and behavioral studies pertaining to human health.

Biopiracy

Definition

Biopiracy refers to the appropriation, generally by means of patents, of indigenous biomedical knowledge by foreign entities (including corporations, universities and governments) without compensatory payment.
Biopiracy also refers to various forms of power imbalance between richer and poorer countries which arise out of poorer countries' tendencies towards high biodiversity and richer countries' tendencies towards needing or wanting the benefits of that high biodiversity. In 1992, the Convention on Biological Diversity (CBD) recognized the value of traditional knowledge in protecting species, ecosystems and landscapes, and incorporated regulations regarding access to it and its use. By 2006, 188 countries had ratified the Convention and agreed to be bound by its provisions, the largest number of nations to accede to any existing treaty (the United States is one of the few countries that has signed, but not ratified, the CBD).

Bioremediation

Definition

Bioremediation can be defined as any process that uses microorganisms, fungi, or their enzymes to return the contaminated soils to their original condition. Bioremediation may be employed against specific soil contaminants (such as degradation of chlorinated hydrocarbons by exogenous bacteria), or with a more general approach, like cleanup of oil spills by the addition of fertilizers (to facilitate the decomposition by indigenous bacteria). There are cost/efficiency advantages to bioremediation employed in areas that are inaccessible without excavation. Some examples of bioremediation technologies are bioventing, landfarming, composting, bioaugmentation, rhizofiltration, and biostimulation. Not all contaminants are easily treated by bioremediation; heavy metals such as cadmium and lead are not readily absorbed or captured by microorganisms. Genetic engineering creates organisms specifically designed for bioremediation like *Deinococcus radiodurans* (the most radio-resistant organism known), modified to consume and digest toluene and mercury from highly radioactive nuclear waste. However, the assimilation of metals such as mercury into the food chain may worsen matters in the whole biosphere.

Biostatistical Design

Definition

Biostatistical design is a unified approach to a common core of problems of statistical design that are central to many related fields in the biomedical sciences, in the health sciences, in the social sciences and in health services research led by three fundamental principles: 1) all problems occur in a system of interconnected processes, 2) variation exists in all processes, and 3) understanding and reducing variation are the keys of success. It covers at least the following elements: identification of the data to be collected (this includes the variables to be measured, their role in a study, ways of measurement, the number of experimental units, namely, the size of the study, and the way they were chosen and followed-up); the design of a comparison/relationship strategy; an appropriate analytic model for describing and processing data; and a list of questions to be answered throughout the study (What inferences does one hope to make from the study? What conclusions might one draw from the study? To what population(s) is/are the conclusion(s) applicable)?

Biostatistical Software

NIKOLA KOCEV
Institute for Medical Statistics and Informatics, School of Medicine, University of Belgrade, Belgrade, Serbia

Synonyms

Statistical software; Statistical packages

Definition

Biostatistics – is the application of statistics to the analysis of biological and ► medical data. Biostatistical software is a suite of computer programs specialized for statistical analysis of biological and medical data. It enables people to obtain the results of standard ► statistical procedures and statistical significance tests, without requiring low-level numerical programming. Most statistical packages also provide facilities for data management.

Basic Characteristics

Nowadays, very often, biostatistics uses general statistical packages, which include many procedures that are seldom used in the solution of biostatistical problems.
Statistical software used for biostatistics' problems should encompass routine procedures, such as: ► data entry and data management; summarizing information from data in tables and graphs and summary statistics; probability, probability distribution, randomization of patients, sufficient sample size to have adequate statistical power; for making inference from data: confidence intervals and hypothesis test; specifying α – type error I, β – type error II and ► power analysis; estimating and comparing mean or differences in mean; comparing three or more means (ANOVA); estimating and comparing proportions; associations and prediction; statistical methods (parametric and nonparametric) for analyzing survival data; statistical methods for multiple variables; evaluating diagnostic procedures, time series analysis, etc.
Bearing in mind that different statistical software's contain routine procedures more developed than other software's, we are frequently compelled to use more than one statistical package in the process of solving one particular biostatistics' problem. Also, given the moment in time that we are all living in, statistical software's tend to become rapidly outdated forcing software vendors to continually update and correct their product (often issuing patches or service releases that correct errors and bugs). Consequently, buyers – via vendor's web sites – can provide themselves with information regarding errors, bugs, macros and add-ons that extend the capability of the basic package. The same way, they are offered the possibility of a free 30-day trial of fully functional new version which enables them to test them with their own biostatistics' problems.
All in all, there are no ► data management packages available on the market which are designed and optimized for biostatics' softwares, nevertheless, each package comes with the data entry and data management options and it is their functionality that permits data adjustments for particular statistics' routine procedures and for connection with the existing database systems.

Statistical Software for Successful Biostatistics' Problem-Solving

For a successful biostatistics' problem-solving, it is possible to use one of the commercial packages, general public license packages, analysis packages with statistics add-ons, as well as some general purpose languages with statistics libraries. Consistent with that, some of the aforementioned are described later.

SAS/STAT® Software (www.sas.com)

From traditional analysis of variance and predictive modeling to exact methods and ► statistical visualization techniques, SAS/STAT software provides tools for both specialized and enterprizewide analytical needs.
Key features: analysis of variance, regression, categorical data analysis, multivariate analysis, survival analysis, psychometric analysis, cluster analysis, nonparametric analysis, survey data analysis, multiple imputation for missing values, study planning.
SAS/ETS contains popular forecasting methods such as regression analysis, trend extrapolation, exponential smoothing, Winter's method (additive and multiplicative), ARIMA (Box-Jenkins) and dynamic or transfer function models.

JMP
(http://www.jmp.com/)

SAS created the JMP desktop statistical discovery software, that uses a structured, problem-centered approach for exploring and analyzing data. The intelligent interface guides users to the adequate analyzes. JMP automatically displays graphs with statistics, enabling users to visualize and uncover data patterns.

BMDP
(http://www.statsol.ie/html/bmdp/bmdp_home.html)

BMDP has its roots as biomedical analysis packages from the late 1960s. It is a comprehensive library of statistical routines from simple data description to advanced multivariate analysis, and is backed by extensive documentation. Each individual BMDP subprogram is based on the most competitive algorithms available and has been rigorously field-tested. The BMDP package contains over 40 interrelated statistical programs. All of the programs share common instructions and convenience features to save time and effort.

SPSS
(www.spss.com)

Data Analysis with Comprehensive Statistics Software, statistical and ► data management package for analysts and researchers. SPSS for Windows is a modular, tightly integrated, full-featured product line for the analytical process – planning, data collecting, data access, data management and preparation, data analysis, reporting, and deployment. Using a combination of add-on modules and stand-alone software that work seamlessly with SPSS Base enhances the capabilities of this statistics software. The SPSS Programmability Extension™ enables analytic and application developers to extend the SPSS command syntax language to create procedures and applications – and perform even the most complex jobs – within SPSS.

StatSoft STATISTICA
(http://www.statsoft.com)

StatSoft's flagship product line is the STATISTICA suite of analytic software products. STATISTICA provides the most comprehensive array of data analysis, data management, data visualization, and data mining procedures. Its techniques include the widest selection of predictive modeling, clustering, classification, and exploratory techniques in one software platform. The STATISTICA Visual Basic language that can be used to write custom extensions.

NCSS and PASS
(Statistical & Power Analysis Software)
(www.ncss.com)

NCSS software provides a complete, easy-to-use collection of over 200 statistical and graphics tools to analyze and visualize data.
PASS (► power analysis and Sample Size) software is an easy-to-use research tool for determining the number of subjects that should be used in a study, performs power analysis and calculates sample sizes for over 150 statistical tests.

Mathematica, WOLFRAM RESEARCH
(http://www.wolfram.com/)

Mathematica's statistics capabilities are part of Mathematica's standard add-on packages. Like any statistics package, Mathematica provides a numerical and graphical toolset to illustrate, simulate, and find approximate numeric solutions to numerical problems.

Matlab
(http://www.mathworks.com/)

MATLAB® is a high-performance language for technical computing. It integrates computation, visualization, and programming in an easy-to-use environment where problems and solutions are expressed in familiar mathematical notation.
The Statistics Toolbox, for use with MATLAB®, is a collection of statistical tools built on the MATLAB numeric computing environment. The toolbox supports a wide range of common statistical tasks, from random number generation, to curve fitting, to design of experiments and statistical process control. The toolbox provides two categories of tools: Building-block probability and statistics functions and Graphical, interactive tools. The first category of tools is made up of functions that can be called up from the command line or from an individual's own applications. Many of these

functions are MATLAB M-files, series of MATLAB statements that implement specialized statistics algorithms.

R Project for Statistical Computing (http://www.r-project.org/)

R is a language and environment for statistical computing and graphics. It is a GNU project which is similar to the S language and environment which was developed at Bell Laboratories (formerly AT&T, now Lucent Technologies) by John Chambers and colleagues. R can be considered as a different implementation of S. There are some important differences, but much code written for S runs unaltered under R. R provides a broad variety of statistical (linear and nonlinear modeling, classical statistical tests, time-series analysis, classification, clustering, etc.) and graphical techniques, and is highly extensible. The S language is often the vehicle of choice for research in statistical methodology, and R provides an Open Source route to participation in that activity. R is available as Free Software under the terms of the Free Software Foundation's GNU General Public License in source code form.

Free Statistical Software (http://statpages.org/javasta2.html)

This page contains links to free software packages that can be downloaded and installed onto a computer for stand-alone (offline, non-Internet) computing. They are listed below, under the following general headings: General Packages: support a wide variety of statistical analyses; Subset Packages: deal with a specific area of analysis, or a limited set of tests; Curve Fitting and Modeling: to handle complex, nonlinear models and systems; Biostatistics and Epidemiology: especially useful in the life sciences; Surveys, Testing and Measurement: especially useful in the business and social sciences; Excel Spreadsheets and Add-ins: need a recent version of Excel; Programming Languages and Subroutine Libraries: customized for statistical calculations; need to learn the appropriate syntax; Scripts and Macros: for scriptable packages, like SAS, SPSS, R, etc.; Miscellaneous: do not fit into any of the other categories; Other Collections of Links to Free Software.

Biostatistics

JELENA MARINKOVIĆ
Medical Statistics and Informatics, School of Medicine and School of Public Health, University of Belgrade, Belgrade, Serbia
jmarinkovic@med.bg.ac.yu

Introduction

▶ Biostatistics is the application of ▶ statistics in health-related fields, including public health, medicine and biology, and the development of new tools to study these areas. Biostatistics constitutes the quantitative foundation for public health practice and research. It comprises the reasoning and methods for using ▶ data as evidence to address public health and biomedical questions.

Statistics itself has various definitions, but all definitions have as essential components that statistics is a science of generating information and knowledge through the collection, analysis and interpretation of data that are subject to ▶ random variation. It is a curious amalgam of mathematics, logic and judgment (Altman 1999). Statistics has its origins in three branches of human activity: first, the study of mathematics as applied to games of chance; second, the collection of data as part of the art of governing a country; and third, the study of errors in measurement, particularly in astronomy. At first, the connection between these very different fields was not obvious, however it came to be appreciated that data are governed to a certain extend by chance, that decisions have to be made in the face of

uncertainty and that errors in measurement have a random component (Senn 1997).

Biostatistics as a subject is very largely about data. However, data alone have little significance – to be meaningful, they must be placed in a context. Biostatistics works with data, yet its goals are: insight, discovery, exploitation, confirmation, explanation, ► prediction, control and decisions related to problems of human health and disease, Fig. 1. In order to achieve this, public health practitioners and researchers ought to implement ► statistical thinking following three fundamental principles: 1) all problems occur in a system of interconnected processes, 2) variation (► variability) exists in all processes, and 3) understanding and reducing variation are the keys of success. It involves an understanding of why and how information and knowledge are generated. This method of inquiry includes recognition and understanding of the entire statistical investigative process (from asking the questions to data collection, analysis selection, testing assumptions, etc.); understanding how models ► statistical model are used to simulate ► random phenomena and how the data are produced to estimate probabilities; recognition of how, when, and why existing inferential tools can be used; and at last, being able to understand and utilize the context of a problem to plan investigations and draw conclusions.

The domain of biostatistics includes: statistical aspects of public health and biomedical research design (how and why the data have been collected), descriptive statistics (description or summarization of a collection of data) and ► inferential statistics (the drawing of inferences about a pool of data when only a part of the data are observed). The latter can also be seen as the modeling of patterns in the data, in a way that accounts for randomness and uncertainty in the observations, to draw inferences about the process or ► population being studied.

This synopsis provides an overview of the field of biostatistics, setting a context for more specific articles – essays in this domain. It addresses: the history of biostatistics; key terms and concepts fundamental to the subject of biostatistics; building blocks of biostatistics – ► probability, measurement, research excellence and decision making; survey of biostatistical methods and its area of specialization; and the current scope of the field, which is increasingly fragmented into specific areas of inquiry. The other articles – essays, provide detailed reviews of different statistical methods and specifically focused areas of biostatistics.

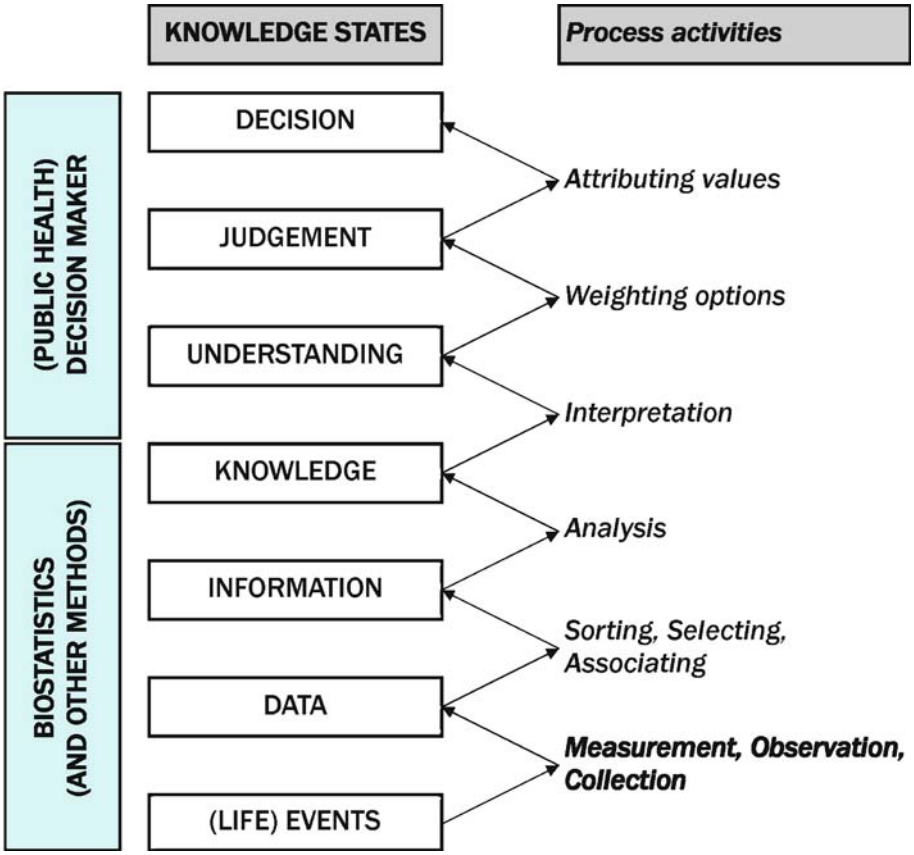
History of Biostatistics – the Origins, the Foundations and Important Contributors

The history of biostatistics, in its very large part, is the history of statistics as well.

The Rise of Modern Statistics

The beginnings of modern statistics are often dated to the early 20th century due to works of Karl Pearson (1857–1936) and Ronald Aylmer Fisher (1890–1962). Near the end of the 19th century, scientists began to gather a great amount of biological data. They faced obstacles because their data had so much variation, i. e. biological systems were so complex that a particular outcome had many causal factors. There were already a body of probability theory, however prevailing scientific wisdom supposed that this theory and actual data are separate entities and should not be combined (Chen 2003). Due to the work of Karl Pearson, this attitude was changed, and statistics was transformed from an empirical social science into a mathematical applied science. He transformed statistics from a descriptive to an inferential discipline.

Beside Pearson, another founder of modern statistics was Sir Ronald A. Fisher. He made numerous original contributions to almost every branch of statistics including, correlation, regression, significance tests, theory of estimation, analysis of variance, and multivariate analysis. Indeed many of these and other fields in statistics were originally developed by Fisher. Pearson who has been in a long dispute with Fisher (Johnson 1997) used large samples, which he measured and from which he tried to deduce correlations. Fisher, on the other hand, followed William Gosset (1876–1937) in an attempt to use small samples and, rather than deduce correlations, find the causes. In the course of developing statistical methods for design and analysis of the experiments, he proposed three fundamental principles – the essentiality of ► replication, ► randomization and the possibility of reducing errors by appropriate organization of experiments. For Fisher, statistical analysis and experimental design were merely two aspects of the same whole, and they accounted for all the logical requirements of the complete process of adding to natural knowledge by experimentation (Chen 2003).



Biostatistics, Figure 1

The new developments in statistical theory brought about by Fisher's work have also facilitated the emergence of the modern clinical trial. The first modern clinical trials were carried out by the Medical Research Council in the United Kingdom and their prime initiator was Austin Bradford Hill (1897–1991). The year 1946 marked the first clinical trial with a proper randomization on the use of streptomycin in the treatment of pulmonary tuberculosis. The core element was the random assignment of subjects to different therapeutic or preventive options. While randomization does not guarantee comparability of the study groups, it does eliminate the potential bias that may result from an investigator's preconceptions. Randomization makes it impossible to predict the assignment of the next person enrolled in the study. The trial involved patients from several centers, and they were randomized to two treatments – streptomycin plus bed-rest, or bed-rest alone. Disease endpoints were patient survival and radiological improvement evaluated independently (blindly and replicated) by two radiologists and a clinician. Both were significantly better on streptomycin. Hill's work set the trend for future clinical trials where both, the insight of physician and the statistical design of professional statisticians, were combined.

The emergence of the randomized clinical trials coincided with the change of definition about statistics as a discipline. Chernoff and Moses in 1959 said, "Years ago a statistician might have claimed that statistics deals with processing of data. Today's statistician will be more likely to say that statistics is concerned with the decision making in the face of uncertainty"(► decision making under uncertainty) (Chernoff 1959).

The Foundation of Statistics

The origins of statistics, however, can be traced back for centuries. Much of what we now call statistics has been known by other names since biblical times, and contributors to the field were not limited to mathematicians. Long before the birth of Christ, census counts were taken. Firstly, in order to register the number of people, then potential taxpayers, and lately to count disease events. The counting of disease events, representing the

idea of relative frequency, can be traced to John Graunt (1620–1674), who investigated in detail the bills of mortality in London, and William Petty (1623–1687), who proposed that a central statistical office be established and suggested what uses might be made of the data collected. Graunt introduced the notion of inference from a sample to an underlying population and described the calculations of life expectancy.

Late 17th Century

The origins of probability and statistics as sciences are usually found in the same period – the late 17th century – in the mathematical treatment of the systematic study of mortality data, as well as of games of chance. This period was the age of the scientific revolution and some of the leading scientists, Blaise Pascal (1623–1662), Christiaan Huygens (1629–1694) and Jakob Bernoulli (1654–1705), gave thought to probability influencing its further development. Much of the Pascal and Huygens' work into probability problems consisted of deriving mathematical laws in order to enumerate ways in which particular types of events may occur. One well known illustration of such a law, the binomial law, is given by Pascal's triangle. The last of them, Bernoulli, has been designated as a father of the quantification of uncertainty introducing a theory of probability in 1713. He demonstrated that because probabilities could be calculated for ratios of chance events (such as the fall of sets of dice), it can also be proved that the greater the number of experiments (or rolls of dice) the more closely the estimated ratios would come to the true ratio of their probabilities – law of large numbers which is central to the science of statistics.

18th Century

In the first half of the 18th century, probability established itself in physics, particularly astronomy, its most developed branch. The most enduring of these applications to astronomy dealt with the combination of observations. The resulting theory of errors was the most important predecessor of modern statistical inference, particularly of estimation theory. Abraham de Moivre (1667–1754) was the first to state the properties of the normal curve. Later the celebrated *Essay towards solving a Problem in the Doctrine of Chances* by Thomas Bayes (1702–1761), published in 1763, was the first attempt to use the theory of probability as an instrument of inductive reasoning; that is, for arguing from the particular to the general, or from the sample to the population. The work on conditional probability with applications to inverse probability defines the postulate of the celebrated ► Bayes' theorem.

Whereas Bayes excelled in logical penetration, Pierre-Simon Laplace (1749–1827) was unrivaled for his mastery of analytic technique. A direct result of Laplace's study of the distribution of the resultant of numerous independent causes was the recognition of the normal law of error and consequently – the ► central limit theorem. He viewed medical therapy as a domain for application of probability and assumed that the summary of therapeutic successes and failures from a group of patients could guide the future therapy (Chen 2003).

Carl Friedrich Gauss (1777–1855) was a younger contemporary of Laplace and undoubtedly a father of modern ► statistical reasoning. He approached the problem of statistical estimation in an empirical manner, raising the question of the estimation not only of probabilities, but also of other quantitative parameters, and finding solution through the method of maximum likelihood. Gauss, further, perfected the systematic fitting of regression formulae, simple and multiple, by the method of least squares, which, in the cases to which it is appropriate, is a particular example of the method of maximum likelihood. The contrasting figures of Laplace and Gauss dominated this period and work on the theory of errors had reached its climax.

Early 19th Century

The first census of population was taken in 1801, and the Statistical Society of London was established in 1834. This period saw the beginning of a philosophical literature on probability. The rise of statistical reasoning and thinking is connected to John Stuart Mill (1806–1873), who suggested these processes. In his view, if conclusions are found to accord with experience, a hypothesis is verified. Modern views have put this verification slightly differently: if the hypothesis is not contradicted, it remains a conjectured explanation of a relationship; if the hypothesis is contradicted, in even a single instance, it is rejected. This period also saw the beginning of the most glamorous branch of empirical time series analysis – the sunspot cycle.

Lambert Adolphe Jacques Quetelet (1796–1874) was the first to apply statistical analyzes to human biology, organize the first statistics conference, and had an extremely profound effect on the generations that followed. He studied the distribution of people's characteristics observed and, in parallel, the properties of the normal distribution curve – one of the central concepts in statistics. A prominent physician, Pierre Louis (1787–1872), following the ideas of Laplace, deemed that enumeration was synonymous with scientific reasoning. In his study of typhoid fever, for which the data had been collected between 1822 and 1827, Louis observed the difference in age, the duration of residency in Paris and the difference between the groups of patients who died and those who survived. More importantly, he studied the efficacy of bloodletting as a therapy for typhoid fever (Senn 1997). This study raised two crucial research questions – first being the insufficient sample size, and second one on choice of the control group.

Late 19th Century

A few important applied fields opened up in the second half of the 19th century. Probability found a major new application in physical science, in the theory of gases, which developed into statistical mechanics. Statistics entered the fields of psychology and economics, as well. The statistical study of heredity developed into the science of biometry and many of the advances in statistical theory were associated with this subject. Biostatistical reasoning and modeling were critical in the formation of the foundation theories of modern biology. After the rediscovery of Gregor Mendel's (1822–1884) work, the conceptual gaps in understanding between genetics and evolutionary Darwinism led to a vigorous debate between biometricians and Mendelians. The work of Pearson and Fisher (already described), and other biostatisticians helped bring together evolutionary biology and genetics into a consistent, coherent whole that could begin to be quantitatively modeled.

Methodological Controversies in the 20th Century

The 20th century is characterized by some major methodological battles. Firstly, there was a disagreement with regard to the preference for correlational large scale studies (Pearson) versus experimental small scale studies (Fisher). The field of experimental small scale studies witnesses the emergence of a second controversy: H_0 testing (Fisher) versus the inclusion of H_1 and the concept of Power (Jerzy Neyman (1894–1981) and Egon Pearson (1895–1980)). Thirdly, Charles Spearman's (1863–1945) belief in one general intelligence factor, which supposedly was the driving force behind the development of factor analysis, led to arguments, which have lasted for several decades, with Louis Thurstone (1887–1955) and others who gradually looked upon factor analysis as just a way of simplifying the data (Johnson 1997).

Biostatistical Methods in the 20th Century

Biostatistical methods expanded rapidly during the 20th century. Before the Second World War Andrei Kolmogorov (1903–1987) presented an axiomatic basis for probability and, together with Aleksandr Khinchin (1894–1959), developed a general theory of stochastic processes; Harold Hotelling (1895–1973) worked on principal component analysis, canonical correlation and discriminant analysis. The war generated research problems which led to Norbert Wiener's (1894–1964) work on prediction and Abraham Wald's (1902–1950) effort on sequential analysis. After the Second World War, non-parametric analysis boomed with the work of Frank Wilcoxon (1892–1965), William Kruskal (1919–2005), David Kendall (b. 1918) and John Tukey (1915–2000). The latter in 1977 presented an exploratory data analysis (EDA) as an antidote to the ritualized testing of hypotheses, instead of initially looking at the data. Sir David Cox's (b. 1924) 1972 paper on proportional-hazards regression ignited the fields of survival analysis and semiparametric inference. At the same time John Nelder (b. 1924) published a paper on generalized linear models. In 1976, Gene Glass (b. 1940) published his article on combining the results of multiple studies and named this approach meta-analysis. Bradley Efron (b. 1938) introduced bootstrap methods in 1976.

During the late 20th century, rapid improvements in computer support were essential to the growing role of empirical investigation and statistical inference. The changes following the introduction of computers have been much more radical than those following the use of mechanical calculating machines at the end of the 19th century. With the availability of computers traditional activities took less time and new activities became possible. Statistical tables and tables of random num-

bers first became significantly easier to generate and then they disappeared as their function was subsumed into statistical software packages. Significantly larger data sets could be assembled and analyzed and exhaustive data-mining became possible. Much more complex models and methods could be used and new methods have been designed with computer performance in mind. With the introduction of computer-based methods for generating pseudo random numbers, much more ambitious Monte-Carlo investigations (introduced by John von Neumann (1903–1957)) became possible. The Monte-Carlo experiment became a model of investigation on the finite sample behavior of statistical procedures.

Key Concepts and Terms Underlying the Subject of Biostatistics

Biostatistics depends on certain basic concepts that provide the necessary fundamentals for more specialized expertise in any area of statistical analysis. It is imperative to be clear about common terms used in this text as well. The selected topics illustrate the basic assumptions of most statistical methods and represent the components of one's general understanding of the "quantitative nature" of reality (Nisbett et al. 1987).

Data

In general, the term data refers to factual material used as a basis for discussion and decision making, while in biostatistics it refers to the material available for analysis and interpretation. By definition, data are facts, observations, realizations of one or more underlying ► variables recorded on one or more observational units.

Data are the results of taking measurements of certain characteristics or properties of observational units, which are of interest to us. By observational unit, we mean the source that imparts the value of the variable. It may be an individual item (e. g. an object, person or event) or it may be a collection of items (e. g. household, litter or set of symptoms). By measurement, we mean the assignment of numerals to these observational units according to a certain rule. Sources of public health data are numerous and diverse, but in practice five main sources are used: facts obtained in the course of research, certificates of vital and other health-related events, health surveys, medical records and unobtrusive data sources (e. g. economic statistics, police reports, insurance claims).

Data can be either categorical or numerical (otherwise known as qualitative or quantitative). Categorical data represent the simplest type of observation on an individual, which is the allocation of that individual to one of two or many possible categories (e. g. male/female, smoker/non-smoker, blood group, country of birth, social class, various staging systems of cancer, degree of pain). Numerical data arise either from counting processes (number of children in family, number of visits to health care institution, etc.) or through physical measurements (e. g. height, temperature, blood pressure). Since statistics deals with numerical data, we can artificially (codes/ranks) turn categorical data into numerical data. Still, they would be numerical in name only, because they do not share any or some of the properties of the numbers we deal with in ordinary arithmetic.

The terms data and information are used interchangeably in many contexts. This may lead to confusion. Definitely, there is a distinction between them. Data are physical representations of information. Through a context, data become transformed into information (i. e. when it becomes relevant to a specific decision problem). That context is a fusion of substantive knowledge of a topic, methodological approach to gathering the data and the statistics used to derive meaning.

Variation, Variability and Uncertainty

Biostatistics is very largely about variability (► variability, variation). Sometimes, it is the variability itself that is of prime interest, such as when describing the likely values of some measurement in a group of people. However, we are often more interested in detecting underlying trends which may be obscured by variability. The terms variability and variation are often used as synonymous in the literature. Precisely, the term variation refers to the differences that are actually present among the individuals in a population or a sample. It can be directly observed as a property of a collection of items. In contrast, variability is a term that describes the potential or the propensity to vary.

Sources of variation in public health and medical observations are true biological variation, temporal variation, measurement error and sampling error. True biological variation, which is inherent in natural populations,

refers to all those factors that tend to make one individual different from another (e. g. age, sex, race, genetic factors, diet, socioeconomic status and past medical history). Temporal variations refer to all those factors that produce variation in observations within an individual from one time to another (e. g. emotional state, circadian rhythms). Measurement error concerns all the factors that tend to produce differences with different measurements of the same phenomenon (e. g. observers, measuring instruments, technician errors, laboratory conditions). Sampling errors occur when estimates are derived from a sample rather than a census of the population. The sample used for a particular survey is only one of a large number of possible samples of the same size and design that could have been selected. Even if the same questionnaire and instructions were used, the estimates from each sample would differ from the others. This difference, termed sampling error, occurs by chance, and its variability is measured by the standard error associated with a particular survey.

The use of biostatistics is essential for making judicious decisions in the fields of public health and medicine. Due to variations, the outcomes of these decisions cannot be predicted exactly – they are always accompanied by an amount of uncertainty. The uncertainties can be measured, they can be assigned numbers and numbers can be interpreted. These numbers are called probabilities. It is thus necessary to be conversant with the proper techniques for dealing with such variations and uncertainties.

Although we related the concepts of variation, variability and uncertainty to human subjects, the similar considerations apply if one is studying variation from one country to another (for example in infant mortality rates), comparing characteristics of the groups of individuals, or looking at measurements of the same subject under different conditions.

Variable

A variable is any characteristic (property) of the observational unit with outcomes (data) that vary from one observation to the other. A variable may have a different value out of a specified set of values in different people, in different places or at different times. Some examples of variables include the height of adult females, the gender of preschool children, and IQ test score of patients seen in mental clinics. The variables are often referred to as random variables when the value of a particular outcome is determined by chance (i. e. by means of random sampling). To represent a particular random variable, statisticians generally use an upper case Roman letter, say X or Y. The particular value that this random variable represents in a specific case is often denoted by the corresponding lower case Roman letter, say x or y. Any characteristic that does not vary is a constant.

Each variable should be precisely defined, i. e. given a name (to know exactly what the variable is) and a description given of how it is measured – operational definition of a variable. The defined way of measurement in operational definition may produce different types of numbers, in the sense that some numbers are assigned different meanings and implications from others. There are four scale types, distinguished by the types of numbers produced by the measurement of a specific variable: nominal, ordinal, interval and ratio.

There are three main classifications of variables: 1) quantitative or qualitative; 2) continuous or discrete; and 3) independent or dependent variables. In the first classification – the quantitative (numerical) variable is one that can be measured in the typical, traditional, sense. For example, we can obtain measurements on height of adult females or values in mmHg of the variable systolic blood pressure. They can be measured either on an interval or on a ratio scale. Measurements made on quantitative variables convey the concept of amount. The qualitative (categorical) variable has values (attributes) that are intrinsically non-numerical, but can be put in a numerical form. For example, gender of preschool children or social class of citizens in a specific district. The latter can be ordered or ranked. Such variables are measured either on a nominal or on an ordinal scale.

The second classification comprises the distinction between a continuous and a discrete variable. Some variables (such as weight, height, reaction time) are measured on a continuous scale, meaning that there are an infinite number of possible values these variables can take. In contrast, discrete variables, such as the number of children in a household or their gender, can take only a limited number of values. Categorical variables are necessarily discrete ones, while numerical variables may be either continuous or discrete.

The third classification makes a distinction between an independent and a dependent variable. An independent variable is one whose changes relate (sometimes

cause) other variables to change in value. The independent variable is what researcher or nature manipulates – a treatment, a program, or a cause. Common types of independent variables, beside manipulated variables, are subject variables (e. g. age, gender). A dependent variable is the one that has its values affected by change in independent variable – effect or outcome. They are only measured or registered. All other variables that may affect the dependent variable are called covariates. Their relationship with the dependent variable, ideally, should be adjusted before the effects of the specified independent variables are examined. Common types of dependent variables are physiological measures (e. g. heart rate, blood pressure), self-reported measures (e. g. rating scales, opinion polls/questionnaires), behavioral measures (e. g. accuracy or speed of response, frequency of response), etc. A given research can use a single dependent variable, two or more separate dependent variables or a composite dependent variable (several measures combined into a single dependent variable). In modern statistics the terms independent and dependent are usually replaced by their statistical equivalents – explanatory and response variable.

Population and Sample

Population (or universe, or target population) is any finite (e. g. the babies born in Serbia in 2005) or hypothetical (e. g. the babies that will be born in Serbia in 2015) collection of observational units (persons, things, or measurement values) for which there is an interest at a particular time. In general, we are interested in different numerical characteristics of the population. We get them in the form of a ► parameter–information on statistical characteristics about populations. Sometimes, many populations are too large to measure (due to time and cost); others cannot be measured because they are partly conceptual. Thus, except for some data collected by a complete population census, we do not know the population parameters.

The best one can usually do is to select a subset of values from a population – sample, to make inferences about the population based on information contained in the sample. This is one of the major objectives of modern statistics. By definition, a sample is a collection of objects or individuals meant to represent a larger collection (the population). The population on which we are seeking information is called the target population. The population to be sampled is called the sample population. The sampling is a process of selecting a sample from a population.

The innovation made by statisticians was the recognition that if objects were selected randomly from a population of interest, those selected (the sample) would be representative of that population, and that measures of the error resulting from the use of the sample (e. g. rather than the population) could be computed. In other words, apart from random error, the information derived from the sample is expected to be the same had a complete census of the target population been carried out.

Parameter and Statistic

A parameter is a summary value (numerical quantity measuring some aspect of a population values) which in some way characterizes the nature of the population in the variable(s) under study. Often, it is a mathematical function of the population values of the variable(s) (e. g. the population mean, the population variance, the population proportion, the population correlation coefficient). Greek letters (μ, σ^2, π, ρ, respectively) represent parameters. The parameters are rarely known and they have to be estimated.

A ► statistic is a summary value (numerical quantity measuring some aspect of a sample values) calculated from the observations in a sample (e. g. the sample mean, the sample variance, the sample proportion, the sample correlation coefficient). Statistic is usually used as an estimator of some population parameter. They are represented by Roman letters ($\bar{x}$, s^2 or sd^2, p, r, respectively).

In general, if we use a statistic (sample information) to make an inference about a population parameter (in one of two ways: estimate its value, i. e. provide an point or interval estimate; or make decisions about its value, i. e. test a hypothesis about its value), we introduce an element of uncertainty into our inference. Consequently, it is important to report the reliability of each inference we make. Typically, this is accomplished by using a probability statement that gives us a high level of confidence that the inference is true. Reliability of the estimate is measured with confidence coefficient (in interval estimates), and the reliability of the hypothesis testing is measured by the probability of making an incorrect decision.

Statistical Model

Most statistical procedures are based on model assumptions – that is, one or more assumptions about a variable's distribution, or how data is selected, or about ► relationships between variables. A model is a representation, often in mathematical language, of the essential aspects of a system, situation, or process. A probability model is a mathematical model that incorporates an element of randomness. This contrasts with a deterministic model, in which reliable predictions are made only on account of observed variables. One of the most commonly used probability models is the normal, or Gaussian, probability distribution, of which there are many examples in biology, medicine, and public health. Variations in height, blood pressure, and attack rates in outbreaks of disease are examples of Gaussian distribution. Moreover, the distributions of many test statistics are normal or follow some form that can be derived from the normal distribution.

A statistical model is a simplified or idealized description of random phenomena, in probabilistic terms, that is a basis for inferences and predictions. The aim is to explain available data, thereby learning about the underlying processes that have formed these data sets. For example, a major contribution to our knowledge of public health comes from understanding trends in disease rates and/or examining relationships among different predictors of health. Biostatisticians accomplish these analyzes through the fitting of statistical models to data. The models can vary from a simple straight-line fit to models with a variety of nonlinear multiple predictors whose effects change over time.

In addition, worthy of note are three key steps associated with statistical model building. First, certain assumptions are made when a model is chosen, and it is important to attempt to verify that these are reasonable. An obvious common example is the assumption that the data have an approximately normal distribution, some form of which appears in most of the models used. Second, it is also important to consider how well the model fits the data. Goodness of fit (► goodness of fit test) refers to the procedures that assess how well a given model describes a particular collection of data. Third, the model that fits the data well should be capable of being utilized successfully when applied to new data. Model validation involves an assessment of how the fitted statistical model will perform in practice – that is, how successful it will be when applied to new or future data.

There are two principal aspects of the use of statistical models – exploratory and confirmatory. In the exploratory phase, models are used to describe various characteristics of the data that may be important for understanding it. Confirmatory use is the attachment of probabilities to the characteristics observed to assure that any conclusion drawn is not merely due to chance.

Biostatistical Design of Studies

Finally, some of the principles of ► biostatistical design are introduce. This is a reminder that statistics is not an end in itself, but a tool to be used in investigating the world around us (van Belle et al. 2004).

Biomedical and public health studies arise in many ways and the problems studied may be investigated in a variety of ways. There are several different schemes for classifying study designs: quantitative or qualitative studies; primary or integrative studies; experimental or observational studies; prospective or retrospective studies, cross-sectional or longitudinal studies; population or sample studies; studies with or without hypotheses; etc. Whatever the design of the study may be, it has to consider at least the following elements: identification of the data to be collected (this includes the variables to be measured, their role in a study, ways of measurement, the number of experimental units, namely, the size of the study, and the way they were chosen and followed-up); an appropriate analytic model for describing and processing data; and a list of questions to be answered throughout the study (What inferences does one hope to make from the study? What conclusions might one draw from the study? To what population(s) is/are the conclusion(s) applicable)? The remaining steps in study performance are: the study is carried out and the data are collected; the data are analyzed and conclusions and inferences are drawn; and the results are used (changing operating procedures, publishing results, and/or planning a subsequent study). The only step that lies outside the realm of statistics *per se* is the formulation of the problem to be studied. In all others, different statistical issues, previously mentioned in brief, are involved. Some of them are specifically related to certain types of studies, randomization, for example, while others are universal.

Building Blocks of Biostatistics

Probability

The mathematical foundation of statistics lies in the theory of probability, which is applied to problems of making inferences and decisions under uncertainty. Though statistics and probability theory are related, they do differ significantly. Probability theory is deductive; it is used for reasoning. Deductive reasoning is powerful in the manner that the conclusions drawn using deduction are guaranteed to be true when the premises are true. Statistical inference is inductive and it is used for learning. The power of inductive inference is the ability to draw general conclusions from observations, i. e. generalizing from the observed information in the sample to uncertain conclusions regarding the population. The conclusions made using inductive learning are not necessarily the true ones.

Probability Interpretations In statistics, there are two broad categories of probability interpretations. Frequentists assign probabilities only to events that are random, i. e. random variables, which are outcomes of actual or theoretical experiments. The relative frequency of occurrence of an experiment's outcome, when repeating the experiment, is a measure of the probability of that random event – frequency probability (informally statistical probability). On the other hand, there are several other interpretations classified as Bayesian probability. They assign probabilities to any proposition whatsoever as a way to represent its subjectivity, even when no random process or population is involved. Bayesian probability is named after Thomas Bayes, who proved a special case of what is now called ► Bayes' theorem. At the heart of Rev Thomas Bayes' paper titled *An essay towards solving a problem in the doctrine of chances* is a simple result that provides a way of combining *a priori* distribution for a parameter with the likelihood to provide *a posteriori* distribution for the parameter (Bayes 1763). Three interpretations can be given to prior distributions: as frequency distributions based on previous data, as objective representations of what is rationale to believe about a parameter, or as a subjective measure of what a particular individual actually believes to be true.

Likelihood The concept of likelihood is central to both the frequency and the Bayesian theory of inference. In general use, the word ► likelihood is a synonym for probability but in statistics, it has a more specific meaning – it is the probability of the observed data given the probability model, which gave rise to the data. Likelihood is used to compare different possible candidate values for the parameters of the model. The one with the greatest likelihood is considered to be more likely. Parameter values for which the probability of the observed data is greatest are most likely values, or maximum likelihood estimates. The ratio between likelihoods is used in hypothesis testing.

Odds In the groundwork for a way of measuring subjective probabilities, the concept of odds (and betting odds) is introduced. Odds are an alternative way to express the likelihood that an event (e. g. catching the flu) will occur. Probability would be the expected number of the flu patients divided by the total number of patients seen in primary health center. Odds would be the expected number of flu patients divided by the expected number of non-flu patients. Precisely, the odds that an event will occur against that it will not occur are given by the ratio of probability that it will occur to the probability that it will not occur. In a more complex situation when we have two instead of one event, the concept of odds ratio is introduced. It is capable of comparing odds of first with odds of second event occurring (e. g. the ratio of the odds of disease in exposed cohort divided by that in an unexposed cohort). The two, probability and odds of an event, can be converted from each other. They contain the same information, but express it differently.

Risk In biostatistics, the term risk is often mapped to the probability of some event, which is seen as undesirable (e. g. the probability that an individual without disease will develop disease over a defined age or time interval). The ratio of the risk of disease in an exposed cohort over a defined time interval to the risk of disease in an unexposed cohort over this same time interval is called relative risk. While the relative risk is mainly used to establish an association in etiological research, the attributable risk – probability of disease cases that can be attributed to exposure – has a public health interpretation as a measure of preventable disease.

Probability Sampling Statistical inference assumes that only if samples are properly selected, probabili-

ty methods can be used to estimate the error in the resulting statistic. For this reason, investigators must plan the sample size appropriate for their study prior to beginning research as well as a sampling method. The last may be classified as "probability sampling" (simple random, stratified, cluster, or systematic samples) and "non-probability sampling" (convenience, inverse or quota, judgment and purposive samples); or sampling with and without replacement. The sampling methods based on probability assure possibility of generalizations to the entire population. In summary, it is not only the sample-size but also the sampling method that are equally responsible for the power of the study.

Measurement

Measurement is the process of assigning numbers or other symbols to the specific characteristics of objects, persons or events in such a way that the relationships of the numbers or symbols reflect relationships of the attribute being measured (see essay ► measurement: accuracy and precision, reliability and validity). Because virtually all measurements involve errors, the problem of error is one of the central concerns of measurement theory. Understanding the nature and source of errors can help reduce their effect and prevent the drawing of incorrect conclusions. Among the various types of errors that must be taken into account are errors of observation (which include instrumental errors, personal errors, systematic errors, and random errors), errors of sampling, and indirect errors.
Measurement is the activity that produces the raw material that statistical methods analyze. If statistics is concerned with the connection between inference and data, and measurement theory is concerned with the connection between data and reality, then, both statistical and measurement theory are necessary to make inference about reality. Thus, the relationship between measurement and statistics is of a substantial importance.

Level of Measurement A particular way of assigning numbers or symbols to measure something is called a scale of measurement. The level of measurement of a variable is a classification proposed in order to describe the nature of information contained within numbers assigned to objects, therefore, within the variable. The most frequently used classification of measurement scales in statistics, even though subjected to many serious criticisms, is one defined by Stanley Smith Stevens in his article *On the theory of scales of measurement*, (Stevens 1946). An extremely important part of Stevens's contribution is the claim that "statistical manipulation that can legitimately be applied to empirical data depend upon the type of scale against which the data are ordered." Stevens's system includes four level of measurement: nominal, ordinal, interval and ratio. Each of them involves different properties (relations and operations) of the numbers or symbols that constitute the measurements as well as a set of permissible transformations.
The simplest of the scale types is the nominal scale, where the measurement of a variable involves the naming or categorization of possible values (attributes) of the variable (e. g. cause of death, gender, or blood type). The only relation pertinent is equivalence, i. e. a specific value of a variable either falls into a specific category, or it does not. Ordinal measurement involves rank ordering values of a variable (e. g. severity of condition, age group). Numbers assigned on an ordinal scale signify relationships between measurements but the distances between them do not have any meaning, i. e. the interval between values is not interpretable. The relations pertinent to this scale are those of equivalence and ordering (=, >, and <). Interval scales not only rank objects by the degree with which they possess a characteristic, but also indicate the exact distance between them (e. g. IQ, temperature in Celsius). For this scale, there is no absolute zero point. Arithmetic operations can be carried out, but cross-scale comparisons are questionable. Finally, in ratio measurement there is always an absolute zero that is meaningful (e. g. height, blood pressure). This scale involves all the above mathematical functions but also "/" and "x", (Polgar 1991).

Types of Measures Measurement is not limited to physical quantities and relations but can extend to the quantification of a magnitude of any kind – health, psychological and mental phenomena, for example. The difference can be attributed also to the unit of measurement (individual or population-level measures); purpose (descriptive, predictive, explanatory, and evaluative); according to their level of aggregation (aggregate, environmental, and global indexes, for example); instrument of measurement; standardization method applied (see essay ► standardization); type of numbers generated (absolute or relative); and to the dimensional-

ity of a measure (unidimensional or multidimensional). The adequacy of a measure is represented by its reliability and validity.

Research Excellence

Fixed vs. Sequential Sample Size Design The majority of studies have a fixed sample size, specified at the outset and determined by a formal sample size calculation. The importance of sample size calculation comes from the fact that the estimates will be sufficiently precise and the difference of interest is likely to be detected. These calculations rely on clearly defined study objectives, the study design, the main outcome, the planned analysis strategy, and determined statistical methods (see essay ► sample size determination). In sequential studies, enrollments continue until a stopping boundary (superiority or inferiority of treatment) is crossed. The last one, on average, requires a smaller sample size.

Primary vs. Integrative Studies The explosion of published primary research evidence, questionable sample sizes in primary studies and consequently a reliability of clinically important effects, a need for completeness of reliable evidences when judgment about a particular treatment should be made, gave rise to meta-analysis – systematic and quantitative review of the results of a set of individual studies, intended to integrate their findings and to provide an overall interpretation (see essay ► meta-analysis). More recently, the term systematic review has been introduced in order to refer to the whole process of qualitative and quantitative review, restricting the term meta-analysis to the quantitative aspects (see essay ► systematic reviews).

Individual-Level vs. Group-Level Studies A group-level or aggregate study focuses on the comparison of groups, rather than individuals, for example, health services, community based, and ecologic studies. The underlying reason for this focus is that individual-level data are missing on the joint distribution of at least two and perhaps all variables within each group (Kleinbaum et al. 1982). The distinctions between individual-level and group-level studies are probably best seen through the concepts of unit's level measurement and analysis.
The source of data used in studies typically involves direct observation of individuals (e. g. age, gender, and health status) but they may also involve observations of groups, organizations or places (e. g. type of health care system, ethnic group, and air pollution). These observations are then organized to measure specific variables in the study population: individual-level variables are properties of individuals, and group-level variables are properties of groups, organizations, or places.
The unit of analysis is the common level for which the data on all variables are reduced and analyzed. In an individual-level analysis, a value for each variable is assigned to every subject in the study and analyzed as such. It is possible, for one or more predictor variables to be group-level measures, e. g. exposure level. In that case, the average exposure level of each district might be assigned to every subject who is a resident of that district. In a completely group-level analysis, all variables (exposure, disease, and covariates) are group-level variables so that the unit of analysis is the group, e. g. district, workplace, health care facility, or demographic stratum. In a partially group-level analysis we have information on both, individual-level and group-level measurements.
There are various statistical methods capable of including both individual and group-level measures in the same analysis. Most frequently, the two multivariate analyzes are applied. The first one – contextual analysis is a simple extension of generalized linear modeling such as logistic regression. Its main limitation is that outcomes of individuals within the same groups are treated as independent, which is obviously not the case. The second one capable of handling this problem of within-group dependence is a statistical multilevel analysis – a special type of modeling technique that combines analysis conducted at two or more levels.

Randomized vs. Nonrandomized Trials Typically, in experimental studies a question of bias in the formation of the treatment groups is raised. The usual method for achieving similarity of treatment groups, as well as avoiding bias in the assignment process, is randomization. In the evaluation of nontherapeutic interventions, including educational programs or lifestyle modification, units of randomization are not individuals themselves, rather they are households or families, communities, classrooms, worksites and hospital wards – clusters of individuals. This characteristic then leads to cluster randomization in which clusters of individuals are randomized to different intervention groups.

The cluster randomization trials are characterized by between-cluster variation, i. e. the variation between observations in different clusters exceeds the variation within clusters. In order not to substantially decrease statistical efficiency, the attention should be on sample size determination, and methods for adjusting the effect of clustering.
In some circumstances, a non randomized trial with a historical control group might be considered. The difficulty to overcome is to show that the groups receiving new or standard treatment had comparable probabilities of favorable outcome.

Analysis "as Randomized" vs. "as Treated" Intention-to-treat analysis is an analysis that includes all randomized patients in the groups to which they were randomly assigned, regardless of what happened afterward. Treatment received analysis is an analysis that includes all patients according to the treatment actually given, (Petkova 2002). The gap between the two concepts is substantial. For now, intention-to-treat analysis is a widely used strategy for the analysis of comparative clinical trials in the definitive comparison of treatments. The treatment received analysis is used either as a secondary analysis to the intention-to-treat analysis, or for explanatory assessment of efficacy in subgroups defined by factors that could have differential response rate (e. g. compliance, age or gender).

Cross-Sectional vs. Longitudinal Studies Time is an important element of any research design, and makes one of the most fundamental distinctions in research design nomenclature: cross-sectional versus longitudinal studies. A cross-sectional study estimates the distribution of the quantity of interest (or joint distribution of several quantities) in a target population, at a certain single point in time. The primary use of this study is to determine the association between an outcome variable and some explanatory variables. Traditional statistical methods are those comprising model building efforts with one or more independent variables.
A longitudinal study is one that takes place over time – there are at least two (and often more) waves of measurement done on the same study units. A further distinction is made between two types of longitudinal designs: repeated measures and time series, based on the number of measurements over time made (20 is a conventionally used limit). In both types, the assumption of dependence between successive measurements should be taken into account. Statistical techniques used to analyze data from longitudinal studies include cross-sectional reduction of data or multivariate techniques.

Case-Control vs. Cohort Studies The goal of analysis in case-control studies is usually to identify risk factors that are related to the disease. As in other non randomized situations, the analysis must address the possibility of confounding and effect-modification by measured covariates. The most commonly used approach is a logistic regression, in which the dependent variable is the logarithm of the odds of disease. The independent variables could be discrete or continuous, regardless of distribution. When matched case-control studies are in question, a conditional logistic regression, which allows general matching schemes, arbitrary exposures, continuous or discrete confounders and effect-modifiers, is the optimal solution.
Cohort studies constitute a central epidemiological approach to the study of relationships between personal characteristics or exposures and the occurrence of health-related events. They involve a cohort of individuals moving forward in time and observing the occurrence of events of interest, over some follow-up period. Traditional approaches to the analysis of cohort studies include person-years analyzes of rare events, survival analysis for more general time-to-event data (see essay ► survival analysis), and longitudinal data analysis for repeated data (Breslow 1987).

Decision Making

Confidence Intervals vs. Hypotheses Testing There are advantages to considering analysis of trials in terms of confidence intervals rather than null hypothesis significance testing and its corresponding p value. The last one bears many critiques such as that null hypotheses cannot be proved – they can only be disproved (rejected). Moreover, failing to reject them does not mean that they are true. The misconceptions about p values are widespread and severe, too (Goodman 1999). In an attempt to address these problems the medical literature over the past decade has been moving away from tests of significance toward the use of confidence intervals – focusing on what the effect is, rather than on what the effect is not. Arguments for the use of confidence inter-

vals include: (a) they are easy to compute, requiring no more information than that required for a statistical test; (b) they provide a range of values within which the true effect is likely to lie; (c) they are just as useful as statistical significance tests for deciding whether an observed difference is due to chance or sampling variability; and (d) they facilitate the interpretation of results in terms of practical and useful clinical significance.

Statistical Significance vs. Clinical Significance Statistical significance refers to whether or not the value of a statistical test exceeds some prespecified level while clinical (in general a subject-matter) significance refers to the medical importance of a finding (see essay ► statistical vs. clinical significance). They often agree, but not always. In order to overcome this problem the studies are designed with appropriate power to detect clinically important differences in their outcomes.

Multiple Comparisons This term concerns the interpretation of the multitude of hypothesis tests that might be undertaken. The major sources of ► multiple comparisons are: multiple outcome measures (e. g. death, relapse, local and distance recurrence; morbidity outcomes), multiple treatment groups (e. g. two monotherapies and their combination in clinical trials; many geopolitical regions in ecologic studies), multiple items in a questionnaire measuring an exposure variable (e. g. some dietary questionnaires that have almost a 100 food items; quality of life questionnaires), repeated measurements over time of a specific outcome measure (e. g. viral suppression over time; creatinine clearance in dialyzed patient), and comparisons of outcome over subpopulations of subjects (e. g. subgroups defined by the values of some covariate – gender, age, race, stage of disease). Statistical analysis will give rise to many statistical tests with a high likelihood of finding many statistically significant test results purely by chance. The problem centers on the error rate that should be controlled either by multivariate global tests, adjusted marginal tests or by using summary measures.

Association, Correlation and Causal Relationship Association is a common form of dependence affecting changes in the mean values, or some other measures of level of response; association thus implies that the general level of one variable changes according to the value of another variable. Correlation expresses numerically the strength of association that might exist between two or more variables. A statistical association does not in itself provide direct evidence of a causal relationship among the variables concerned. One variable may fluctuate in relation to the other due to chance (coincidence) or both may be strongly affected by one or more confounding variables. Direct causal relationships, e. g. the relationship between vitamin C deficiency and scurvy, can rarely be proved without a randomized trial. In observational studies, causality can be established on non-statistical grounds. A causal connection probably does exist if we can establish that: there is a reasonable explanation of cause and effect; the connection happens under varying conditions; and potential confounding variables are ruled out.

Collinearity (Multicollinearity) Collinearity refers to a high level of correlation within the set of explanatory variables and is of special note in the regression modeling situation. The ► collinearity existence affects the independence of explanatory variables, and the precision of regression coefficients estimates, as well. With multicollinearity, the regression coefficient does not reflect any underlying effect of the variable on outcome, but rather a marginal effect that depends on what other variables are included in the model. The identification of collinearity can be done by computation of the variance inflation factor, by noting extremely large variance of the regression coefficient estimate, and by substantial difference between coefficient estimates from fitting simple and a multiple regression models.

Survey of Biostatistical Methods and its Areas of Specialization

Statistical methods can be used for different purposes. Firstly, to summarize or describe a collection of data – descriptive statistics (see essay ► descriptive statistics). Secondly, to draw inferences about the process or population being studied trying to reach conclusions that extend beyond the immediate data alone – inferential statistics (see essays ► confidence intervals and ► statistical tests). More precisely, inferential statistics is used to model patterns in the data, accounting for randomness and drawing inferences about the larger population. These inferences may take the form of answers to yes/no questions (hypothesis testing), estimates of numerical characteristics (estimation), descriptions of

association (correlation), or modeling of relationships and prediction of future observations (regression, and others). Nevertheless, before any data analysis the data should be carefully prepared (see essay ► data preparation). Data preparation involves developing and documenting data structure that integrates the various measures, data entry and coding, data screening, and data transformation and modification.

The use of multivariate statistical methods has developed substantially whatever the study design is in question. The difference between univariate, bivariate and multivariate statistics lies in the number of variables analyzed at a time, no matter if the aim of that analysis is to efficiently describe data or to make inferences upon them. Statistical methods most frequently used in terms of univariate statistics are: information on the value or range of a measured variable (e. g. mean, standard deviation, skewness, etc.), parameter estimation (confidence intervals), effect size calculation, and calculations of probability based on observed patterns found within one variable (t-test, analysis of variance, U test, etc.). When the bivariate statistics is in question, a numerical function describing the relationship between two variables (regression modeling) accompanied with calculation of probability based on observed patterns found between them (correlation coefficients or chi-square test) is typical. Methods applied in the multivariate statistics are a subject of particular essay – ► multivariate statistics, in this publication.

General implementation of biostatistical analysis techniques with emphasis on data application can be divided into categorical data analysis (see essay ► analysis of frequencies), ordinal data analysis and statistical analysis of continuous data. The amount of data being massed alone in all areas of biological sciences requires new thinking (how to think about very large data problems and how to think of stochastic processes) and new tools (statistical computing and software (see essay ► biostatistical software)).

With the increasing complexity of public health research, biostatistics and its areas of inquiry have become increasingly focused and specific. Areas of increased activity include epidemiological studies, clinical trials, health services assessments, basic laboratory research, biomedical imaging and most recently, genetics and genomics. The growing importance of investigations based on genetic and molecular data in the 90s, especially studies involving linkage analysis, segregation analysis, and research on polygenic inheritance of disease, require new study designs and new statistical methods for quantifying relationships at the molecular level. The other group of studies, mostly in molecular epidemiology, usually examines a classifiable genetic trait of an individual as either a risk factor or an effect-modifier for a disease outcome – the principles of study design and data analysis are similar to those encountered in epidemiological studies using other types of risk factors.

Finally, a word on the role of statistical science on public health policy issues is required. Policy issues in public health are becoming dominant in both internal and external affairs of many countries (e. g. worldwide AIDS epidemic, environmental threats, the outbreak of Sars, lifestyle risks, etc.). Many policy decisions facing these problems are based on quantitative information. The inputs to the decision makers are usually data, perhaps refined and integrated into quantitative models – models capable of predictions. This provides a chance for biostatisticians to expand their role, by not only being responsible for the collection, analysis and interpretation of data, but also by taking a greater leadership role in helping to make policy (Zelen 2006). This can be a major goal for the future of biostatistics.

Where to go?

The appearance of new concepts and methods, which are described below, creates further challenges for modern public health research and practice.

Statistical Learning Methods

During the past decades, there has been an explosion in computation and information technology. With these advances has come a vast amount of data in a variety of fields such as medicine, biology, public health, and financing. The challenge of understanding these data, the challenge of sorting through all of this data and separating out the consistent patterns from the noise, has led to the development of new tools in the field of statistics, and spawned new areas such as data mining, machine learning, and bioinformatics, (Hastie et al. 2001). The important ideas in these areas have a common conceptual framework – the concept of statistical learning from data, i. e. extracting knowledge from data. Statistical learning can be distinguished between supervised and unsupervised learning methods.

In supervised statistical learning methods, we are usually given an object with a set of variables – often called predictors, and a corresponding target – often called response or outcome values. The goal is to build a good model or predictive function capable of predicting the unknown, future target value, given input values. When the response is numeric, the learning problem is called "regression." When the response takes on a discrete set of *k* non-orderable categorical values, the learning problem is called "classification." There are many commonly used learning procedures including linear/logistic regression, discriminant analysis, generalized additive models, neural networks, kernel methods, decision trees, etc.

In contrast, in unsupervised learning, no outcome measurements are available. The aim here is to summarize or model the data in a way convenient for some objective. It is necessary to identify patterns in a given set of predictors and/or reduce the dimensionality of the predictor variables. In this case, there are no response variables and the technique of unsupervised learning is used to find and group data into similar sets of observations. Commonly used learning procedures are cluster analysis, principal components analysis, multidimensional scaling, self-organizing maps and the discovery of association rules.

Computationally Intensive Statistical Methods – Resampling Techniques

The continuing revolution in computing is having a dramatic influence on statistics. Modern computers and software make it possible to look at data graphically and numerically in ways previously inconceivable. Statistical study of very large and very complex data sets becomes feasible. But another impact of fast and cheap computing, and the only "great breakthrough" in statistics since 1970 as Kotz and Johnson stated, probably is less obvious – appearance of new methods that apply previously unthinkable amounts of computation to small sets of data in order to produce confidence intervals and tests of significance in settings that do not meet the conditions for the safe application of the usual methods of inference, (Kotz 1992). The bootstrap, permutation tests, and other resampling methods are part of this revolution.

Resampling refers to the use of the observed data (sample) or of a data generating mechanism (such as a die) to produce new hypothetical samples, the results of which can then be analyzed. Resampling repeated experimental trials on the computer enable the data (or a data-generating mechanism representing a hypothesis) to express their own properties, without difficult and misleading assumptions.

Resampling methods cover a variety of methods for computing summary statistics using: subsets of available data (jackknife), drawing randomly with replacement from a set of data points (bootstrapping), or switching labels on data points when performing significance tests (permutation test, also called exact test, randomization test, or re-randomization test), (Simon 1997). They require fewer assumptions than traditional methods and generally give more accurate answers (sometimes very much more accurate). Using such techniques, we can focus on reasoning and on understanding the data, not on complicated formulas and tables.

Frequentists vs. Bayesians

Most public health workers are surprised to learn that statistics is not monolithic. In fact, statistics as a discipline remains sharply divided even on the fundamental definition of "probability."

The logic of statistical inference presented previously is called the Neyman–Pearson approach, but it also might be termed classic, standard or frequentists' statistics. This approach assumes that the probability of an event is defined as the relative frequency of occurrence of the event in an infinite set of well defined random experiments.

Thus, frequentists believe that a population mean is real, but unknown, and unknowable, and can only be estimated from the data. Knowing the distribution for the sample mean one constructs a confidence interval, centered at the sample mean. Here the problem with logic starts. Either the true mean is in the interval or it is not. So the frequentist cannot say there is a 95% probability that the true mean is in this interval, because it is either already in, or it is not. That is because to a frequentist the true mean, being a single fixed value, does not have a distribution. However, the sample mean does. Thus, the frequentist must use a construct like "95% of similar intervals would contain the true mean, if each interval were constructed from a different random sample like this one." When would frequentist be

able to say, "There is a 95% probability that this interval contains the true mean"? – only after the performance of the interval estimate in repeated sampling (an infinite set of random experiments). Therefore, this would be helpful in the situation where one is performing a large number of 95% confidence intervals, but does not help the applied statistician who is interested in making an inference based only on a single dataset.

The main alternative approach to classic statistics – Bayesian approach, assign probabilities to any statement whatsoever (not only events as frequencionist do), even when no random process is involved, as a way to represent its subjective plausibility, (Carlin 2000). Bayesians also hold that Bayes' theorem can be used as the basis for a rule for updating beliefs in the light of new information – such updating is known as Bayesian inference. Bayes's Theorem begins with a statement of knowledge *prior* to performing the experiment usually in the form of a probability density. Now, it is desirable to improve this state of knowledge, and an experiment is designed and executed to do this. Bayes's Theorem is the mechanism used to update the state of knowledge to provide *a posterior* distribution. This *posterior* probability could be used as the starting *prior* probability for a second experiment. After successive iterations, it would be expected that the *posterior* probability would approach the truth.

Concerning the estimation problem illustrated before (as frequencionist see it), Bayesians have an altogether different world-view. They say that only the data are real. The population mean is an abstraction, and as such, some values are more believable than others based on the data and their prior beliefs. The Bayesian constructs a credible interval, centered near the sample mean, but tempered by "prior" beliefs concerning the mean. Now the Bayesian can say what the frequentist cannot: "There is a 95% probability that this interval contains the mean," when only a single dataset is in question.

Summary

The 20th century has seen a remarkable evolution of biostatistics, the quantitative science of public health and medicine. As the editors of the *New England Journal of Medicine* recently concluded, "Among the most important scientific developments of the 20th century is the explosive growth in statistical reasoning and methods for application to studies of human health" (Looking back on the millennium in medicine 2000). Examples include developments in epidemiological, environmental, spatial and imaging statistics, clinical trials, experimental design, survival analysis, meta-analysis, statistical computing and statistical genetics.

Substantive problems in public health and biomedical research, as well as in public health policy issues, have fueled the development of statistical methods, which in turn have improved our ability to draw valid inferences from data. Moreover, the appearance of new concepts and methods creates further challenges for modern public health.

Biotechnology

Synonyms

Bioengineering; Ergonomics; Genetic engineering

Definition

Biotechnology represents the use of biological processes through the exploitation and manipulation of living organisms or biological systems, in the development or manufacture of a product or in the technological solution to a problem. It is applied in pharmacology, medicine, agriculture, and many other fields. Example of biotechnology are techniques of genetic engineering.

Bioterrorism

Synonyms

Biological terrorism

Definition

Bioterrorism describes a form of terrorism that uses micro-organisms or toxic agents from living organisms to attack people, animals or plants for terrorist purposes. The difference between bioterrorism and conventional terrorism is mainly the duration from the time of attack to the time of the presentation of victims.

Bipolar Affective Disorder

Synonyms

Manic-depressive illness; Manic-depressive psychosis; Manic-depressive reaction

Definition

Bipolar affective disorders are characterized by two or more episodes in which the patient's mood and activity levels are significantly disturbed, this disturbance consisting on some occasions of an elevation of mood and increased energy and activity (► hypomania or ► mania) and on others of a lowering of mood and decreased energy and activity (depression). Repeated episodes of hypomania or mania only are classified as bipolar.

Bird Flu

► Avian Influenza

Birth Attendants

► Indigenous Health Care Services

Birth Control

► Contraception

Black Death Sepsis

► Plague Sepsis

Blame

► Fault

Blinding

Definition

Blinding or masking prevents conscious or subconscious biases in research. It is not inherent to randomized trials, but should be used whenever possible, as placebo effects are powerful. Blinding requires a placebo that cannot be distinguished from the treatment.

Bloodpoisoning

Synonyms

Septic infection; Systemic inflammatory reaction; Systemic inflammatory response syndrome (SIRS); Generalized infection

Cross-References

► Acute Life-Threatening Infections
► Sepsis

Bloodstream Infections

Synonyms

Sepsis; Bacteremia

Definition

Hospital bloodstream infections (BSI) constitute a serious health problem and are associated with high mortality. According to CDC definitions, a hospital BSI is defined as a patient with a clinically important blood culture positive for a bacterium or fungus that is obtained more than 48 hours after being admitted to the hospital. BSIs can be "laboratory confirmed BSI" or "clinical sepsis". BSIs can be further categorized as primary or secondary. Primary BSI occurs without any recognizable focus of infection elsewhere. Secondary BSIs are infections that develop subsequent to a hospital infection with the same microorganism at another body site. Vascular catheters account for most cases of hospital BSI.

Body Fluid Balance

Synonyms

Body fluid household; Equilibrium of body fluids; Fluid balance of the organism

Definition

The body fluid balance includes all the mechanisms that control and influence the excretion and retention of body fluids. The organism endeavors to reach an optimal amount of fluids inside and outside the cells and – at the same time – the optimal composition of these fluids. Besides intake and excretion of fluids the invisible loss of fluids also has to be taken into considered. Fluids are lost by breathing and over the skin, especially through the sweat. Larger amounts of fluids can be lost in diarrhea or vomiting and feverish conditions.

Body Fluid and Electrolyte Balance

Synonyms

Body fluid and electrolyte household; Equilibrium of body fluids and electrolytes; Fluid and electrolyte balance of the organism

Cross-References

► Therapy of Infectious Diseases

Body Function

Synonyms

Physiological function

Definition

The physiological or psychological functions of a body are defined as body functions. According to the WHO's International Classification of Functioning, Disability, and Health (ICF), body functions are categorized into different subfunctions. Mental functions, such as the functions of the brain, can be differentiated into global mental functions (consciousness, energy, drive) and specific mental functions (memory, language, calculation). Sensory functions include functions like seeing, hearing, tasting, etc., as well as the sensation of pain. Voice and speech functions produce sounds and speech. There are functions of the cardiovascular system (heart and blood vessels), the hematological and immunological systems (blood production and immunity), and respiratory systems (respiration and exercise tolerance), as well as functions of the digestive system (ingestion, digestion, and elimination), the metabolic system, and the endocrine system. The genitourinary functions refer to urination, and the reproductive functions include sexual and procreative functions. The neuromusculoskeletal and movement-related functions are responsible for movement and mobility, and include the functions of joints, bones, reflexes, and muscles. Finally, there are the functions of the skin and related structures, like nails and hair.

Body Lice

Synonyms

Clothing lice; Pediculosis vestibularis

Body Mass Index (BMI)

Definition

Body mass index is defined as the individual's body weight divided by the square of the individual's height (kg/m^2). The BMI is used for classifying underweight, overweight and obesity in adults. The BMI is a simple metric that relates weight and height. If an adult for example weighs 75kg and its height is 1.80m, the BMI will be 23.1. The cut-off points as defined by the WHO are <18.50 for underweight, 18.50–24.99 for normal range, 25.00–29.99 for overweight and ≥30 for obese. Those BMI values are age- and sex-independent in general, yet the BMI might not correspond to a similar degree of fatness in different populations. There are different health risks related with an increasing BMI, e. g. type 2 diabetes and cardiovascular disease.

Body Parts

Synonyms

Body Structures

Definition

Anatomical parts of the body such as organs, limbs and their components.

Body Structure

Synonyms

Body parts

Definition

Body structures describe the anatomic parts of the body like organs, limbs, and their components. Body structures are classified in the WHO's International Classification of Functioning, Disability, and Health (ICF). The structures of the nervous system include the structure of the brain, spinal cord, and related structures; the structure of the meninges; and the structure of the sympathetic and parasympathetic nervous systems. There are the structures of the eye (eye socket, eyeball, around eye), the ear (external ear, middle ear, inner ear), and the structures involved in voice and speech (nose, mouth, pharynx, larynx). The structure of the cardiovascular system includes the heart, arteries, veins, and capillaries. The structure of the immune system includes the lymphatic vessels, lymphatic nodes, thymus, spleen, and bone marrow. The structure of the respiratory system includes the trachea, lungs, thoracic cage, and muscles of respiration. The structures related to the digestive, metabolic, and endocrine systems comprise the salivary glands, esophagus, stomach, intestine, pancreas, liver, gall bladder and ducts, and endocrine glands. There are structures related to the genitourinary system (urinary system, pelvic floor), reproductive systems, and movement (head and neck region, shoulder region, upper extremity, pelvic region, lower extremity, and trunk). Skin and related structures cover the areas of skin, skin glands, nails, and hair.

Bone Marrow Cells

Definition

The bone marrow of adult human beings contains a heterogenous cell population. The adult cell pool mainly consists of osteoblasts, osteoclasts, fibroblasts and adipocytes. However, there are also undifferentiated cells: the hematopoietic stem cells (HSC) and the mesenchymal stem cells (MSC). The former have been recognized as stem cells more than 40 years ago and have been studied extensively in a clinical setting. Both HSC and MSC are investigated intensely with respect to the notion that any adult stem cell may be a bone marrow cell which has homed to a specific organ after circulating in the peripheral blood. Bone marrow cells (BMC) can be collected by apheresis or by puncturing the pelvic crest. They are often administrated to the organism without purification. Hence, it is not clear, whether HSC or MSC contribute to functional improvement of an organ following transplantation.

Bonesetter

Definition

Bonesetter is a person, usually not a licensed physician, who sets broken or dislocated bones.

Cross-References

► Indigenous Health Care Services

Bonfferoni Correction

Definition

This is a multiple comparison technique used to adjust the α error level.

Bootstrapping

Definition

Bootstrapping is a non-parametric technique to estimate the shape of distribution of a sample or estimate under conditions of ► uncertainty. The basic idea behind bootstrapping is a large number of repetitive computations. The empirically determined sample is regarded as the population from which repeated random samples of the same size are drawn with replacement. The bootstrap samples are analyzed and, by repeating the steps a large number of times, bootstrap confidence intervals are estimated. The bootstrapping technique is used increasingly often for health economic analyses, especially cost-effectiveness models.

Borderline Schizophrenia

► Schizotypal Disorder

BORG Scale / RPE Scores

Definition

Perceived perception of exertion.

Bottom-Up Approach (For Cost-Estimation)

Definition

In a bottom-up approach the costs are collected directly from patients suffering from a defined disease. The figures from those patients are extrapolated to represent the whole population by using national prevalence figures.

► BSE

Breakbone-Fever

► Dengue Fever

Breastfeeding

Synonyms

Nursing

Definition

Breastfeeding is the process of a woman feeding an infant or young child with milk from her breasts. It provides ideal food for the healthy growth and development of infants and also contributes to the health and well-being of mothers.

Bridges

Definition

Dental prosthetic means to replace missing teeth. Bridges (also referred to as fixed partial dentures) are normally anchored by crowns on teeth adjacent to the tooth gap. They cannot be taken out by the patient.

Bronchial Asthma

Synonyms

Bronchoconstriction

Definition

Asthma is a disease condition in man with airways inflammation and obstruction characterized by the presence of intermittent wheezing, chest tightness, shortness of breath, and cough. Exposure to certain allergens and different types of non-specific stimuli initiates a cascade of cellular activation events in the airways. A release of certain mediators into the air passages lead to alterations in the tone of airway smooth muscle, hypersecretion of mucus and damage to the airway epithelium. The magnitude of asthmatic attack varies within and between individuals. Asthma is the most common chronic pulmonary disease. It is relatively more common in children and occurs more frequently in boys than in girls.

The fundamental abnormality in asthma is increased responsiveness of airways to stimuli. This may include physiologic and pharmacologic factors such as histamine, and methacholine, exercise, air pollutants and allergens like penicillin, animal dander and wood dusts. Asthmatics commonly produce IgE antibodies in response to allergen exposure.

Bronchiolitis

Synonyms

Inflammation of bronchioli; Inflammation of small bronchi

Definition

Bronchiolitis is an inflammation of the peripheral bronchi and bronchioli, which causes ventilation problems. In babies, severe apneas have to be feared.

Cross-References

► Bronchoconstriction

Bronchoconstriction

Synonyms

Bronchial asthma

Definition

Asthma is a chronic condition in the airways of the lungs. It has two main components: (1) constriction, the tightening of the muscles surrounding the airways, and (2) inflammation, the swelling and irritation of the airways. Constriction and inflammation cause narrowing of the airways, which may result in symptoms such as wheezing, coughing, chest tightness, or shortness of breath. Furthermore, there is increasing evidence that, if left untreated, asthma can cause long-term loss of lung function.

Brucellosis

Synonyms

Infection with Brucella; Undulant fever; Malta fever; Bang's disease

Definition

Brucellosis, which is caused by bacteria, is spread worldwide, but it is most common in Mediterranean countries, Asia and Latin America. Cows, sheep and goats (in most cases by direct contact with small injuries of the skin or mucous membranes) are the main sources of infection. Transmission is also possible by contaminated milk or milk products. Following an incubation period of 1–3 weeks the disease starts with headache, rheumatic pain and a feeling of weakness. Later on, fever and gastrointestinal symptoms (nausea, vomiting, and diarrhea) develop. Moreover, cardiac arrhythmia and neurological symptoms are possible. Brucellosis is treated by antibiotic therapy.

Brundtland-Commission

Definition

The Brundtland Commission, formally the World Commission on Environment and Development (WCED), known by the name of its Chair Gro Harlem Brundtland, was convened by the United Nations in 1983. The commission was created to address growing concern "about the accelerating deterioration of the human environment and natural resources and the consequences of that deterioration for economic and social development." In establishing the commission, the UN General Assembly recognized that environmental problems were global in nature and determined that it was in the common interest of all nations to establish policies for sustainable development.

BSE

Synonyms

Bovine spongiforme encephalopathy; Mad cow disease

Definition

BSE is an infectious disease, which is caused by prions and was initially transmitted by the feeding of meat-and-bone meal to cows. In 1984, it appeared for the first time in Great Britain. The symptoms of BSE are similar to Creutzfeld–Jakob disease (CJD) in humans. The incubation period is very long, lasting 5–7 years. The disease starts with aggressive behavior and difficulties in coordination. Due to the death of nerve cells, the disease takes a lethal course within a couple of months. A quick test has been available since 1998, but up to now this test can only be carried out on the brain tissue of dead animals and humans. The highest concentration of prions is found in the brain, the bones, the eyes and the spleen. A transmission of BSE to humans is possible. In humans, BSE is characterized by psychiatric symptoms, like depressions and states of panic, followed later by neurological disorders. Dementia develops leading finally to death. Specific therapy or vaccination is not available.

Bubonic Plague

Synonyms

Infection with Yersinia pestis

Definition

Bubonic plague is caused by the bite of a rat flea which is infected with the bacterium *Yersinia pestis*. The onset of the disease is characterized by fever, headache, joint pain, malaise and muzziness. A swelling of the lymph nodes causes painful bubons at the neck, in the armpits and the groins. Due to hemorrhages, these bubons become black. After suppuration occurs within the bubons they rupture. Spreading of the bacteria into the skin causes subdermal bleedings and acral necroses. Without treatment, in 25–50% of cases, a hematogenic spread of germs leads to plague sepsis.

Buddhism

Definition

The religious teaching of Buddhism attracts some 350 to 500 million followers throughout the world. Its historical background dates to 500 BC in India.

Bulimia Nervosa

Synonyms

Eating Disorder

Definition

Bulimia nervosa is characterized by frequently occurring bouts of binge eating and a permanent preoccupation with food. Bouts of binge eating are followed by attempts to compensate the fattening effects of the food through various behaviors (emesis, abuse of laxatives, fasting). Repeated vomiting is likely to give rise to disturbances of body electrolytes and physical complications. There is often, but not always, a history of an earlier episode of ► anorexia nervosa, the interval ranging from a few months to several years. It occurs most often at the age of 18 to 20 years.

Burden of Disease

FRANZ HESSEL
Health Economics Outcomes Research, Sanofi-Aventis Pharma GmbH, Berlin, Germany
franz.hessel@sanofi-aventis.com

Synonyms

Burden of illness; Cost of illness

Definition

The term burden of disease generally describes the total, cumulative consequences of a defined disease or a range of harmful diseases with respect to disabilities in a community. These consequences include health, social aspects, and costs to society. The gap between an ideal situation, where everyone lives free of disease and disability, and the cumulated current health status, is defined as the burden of disease.
In the 1990s, the World Health Organization (► WHO), in co-operation with Harvard University and the World bank, developed a methodological concept to quantify the global burden of disease; this was based to a large extent on statistical measurement of the ► disability-adjusted life year (DALY). The DALY aggregates the time lost because of premature mortality and the time spent in a limited health state. Consequently, the DALYs for a defined disease or health condition are calculated as the sum of the years lost due to specific premature mortality and the years lost due to disability for incident cases of the health condition.

Basic Characteristics

The burden of illness or burden of disease approach used in public health and the epidemiological literature combines measurement of mortality and morbidity with respect to non-fatal outcomes such as quality of life aspects. With regards to these basic attributes,

burden of illness-concepts – and especially the DALY – include some key elements of utility-concepts, such as the QALY (► value, human life – utilities). However, due to the lack of foundation in economic theory, burden of illness is primarily seen as a descriptive epidemiologic concept, such as the regular burden of disease report of the US Center for Disease Control (Centers for Disease Control and Prevention 2004). Although it is possible to express the gain from the avoided loss of burden of disease relative to additional costs, this specific cost-outcome relation is very rarely found in the literature and is not regarded as a common health economic measure.

The most well-known and widespread concept following the burden of disease principle is the DALY (Homedes 1996). DALYs represent one key element in the WHO ranking of worldwide health care systems "The global burden of disease" (Mathers et al. 2003; Murray et al. 1997; Lopez et al. 2006). The first results of this project, for the year 1990, have been published, with regular updates and extension being carried out (Murray 2007; WHO 2007).

The cumulated disease-specific DALYs, aggregated according to the country-specific prevalence of the diseases and disabilities considered, reflect the burden of disease of a specific society or a specific country. The Global Burden of Disease concept of the WHO compares large numbers of low-, middle- and high-income countries with regard to their country-specific burden of disease. It offers mortality figures, which refer to the number of people who die and the causes of death. Thus, a comprehensive and consistent set of estimates of mortality and morbidity expressed by the single indicator DALY and differentiating by age, sex, and region, is given.

There are some specific aspects of the DALY concept, such as further time discounting and non-uniform age weights, which give less weight to years lived at a younger age. According to this concept, the death of an infant is equivalent to 33 DALYs and the death of a person between 5 and 20 years of age is about 36 DALYs. Consequently, the death of 100 infants in a society would be equivalent to 3,300 DALYs, which corresponds to 5,500 persons with blindness at an age of 50 years. The weight factors reflecting the severity of the disability or disease (e. g. the disability weight for blindness of 0.6) were originally defined by international experts. New concepts using health-related quality of life and utility concepts are currently being implemented.

In recent decades in most western industrial nations, a clear tendency regarding the burden of disease can be observed. There is an ageing of societies, with a decrease in mortality, accompanied by an increase in morbidity. The increase in morbidity is mainly due to an increase in the prevalence of chronic diseases and risk factors such as cardiovascular disorders, cancer, diabetes, and obesity. Mortality estimates are higher in low- and middle-income countries than in high-income countries. People in low- and middle-income countries die at a much younger age. In Africa, mortality is mainly cause by infectious diseases – mainly HIV/AIDS and malaria – which affect younger shares of the population compared with China, where the pattern of diseases is dominated by non-infectious diseases. The burden of disease in Africa is estimated to be more than four times higher than in high-income countries. The populations of Africa and India represent about one third of the population of the world, but the burden of disease in these two regions is nearly half of the total global burden of disease. Furthermore, the health inequities gap is widening in a considerable number of countries. The WHO Global Burden of Disease report from 2002 (Lopez 2006) reports three major trends: slowing down of gains and widening of health gaps; increasing complexity of the burden of disease; and globalization of adult health risks.

Although an improvement in health conditions and burden of disease has been observed in many low- and middle-income countries over the last decade, a large proportion of risk factors and diseases are still preventable, e. g. about one-fifth of the global burden of disease can be attributed to under-nutrition. In Africa about one-fifth of the burden of disease is attributed to unsafe sex leading to HIV and other sexually transmitted infections. Concerning high-income countries, tobacco consumption is the leading avoidable risk factor, accounting for 12 per cent of the burden of disease. Globally, about 42 per cent of the total burden of disease can be attributed to the leading 10 risk factors when joint effects are taken into consideration. The leading five risk factors are responsible for about one quarter of the total loss of healthy years of life. These figures demonstrate the enormous potential for improving mortality and morbidity by prevention and decrease of well-known risk factors. This underlines the importance of

research to develop cost-effective strategies for a relatively small number of risk factors to reduce a relatively large share of the global burden of disease (Mathers 2003; Murray 2007).

Business Intelligence Tools

Definition

Business intelligence tools are a type of software application designed for the analysis and presentation of data. Examples are different types of reporting software and online analytical data processing to support a management information system, and data mining to extract useful information from large amounts of data.

Caisson Disease

Synonyms

Decompression sickness; Diver's disease

Definition

Caisson disease is a medical condition related to sudden exposure to a reduction in the pressure surrounding the body. It can happen in many situations: in divers ascending from a dive, in workers coming out of a pressurized caisson or mine, or in pilots if the cabin pressurization system of an aircraft fails. This causes inert gases (mainly nitrogen), which are normally dissolved in body fluids and tissues, to come out of physical solution and form gas bubbles in blood and tissues. Symptoms include "the bends" (joint pain) in shoulders and knees, headache, visual disturbances, extreme fatigue, lack of strength, breathing difficulties ("the chokes"), and in some cases cardiovascular collapse, unconsciousness and paralysis. The only effective treatment is recompression, carried out in a recompression chamber, where the pressure is gradually decreased.

Calculus

Definition

Hardened ► dental plaque is called calculus. Hardening occurs if dental plaque is not being removed and accumulats in the absence of proper oral care resulting in the calcification of the plaque by the minerals of the salvia. Calculus can not be removed by rinsing or tooth brushing. Once formed, it should be removed by professional cleaning by a dentist or dental hygienist. Its rough surface provides an ideal medium for bacterial growth. Calculus can even extend into pockets created between the tooth and the gum.

Cancer

Synonyms

Malignant tumors; Neoplasms

Definition

Cancer is the general term for more than 100 different distinct diseases that can affect every part of the body. Cancer is defined by a rapid abnormal cell growth beyond usual boundaries that can affect adjoining parts of the body including other organs. This process is referred to as metastasis which is the major cause of death from cancer. Cancer is caused by changes in the genes responsible for cell growth and repair, driven by interaction between genetic host factors and external agents. These external agents can be categorized into physical carcinogens, chemical carcinogens and biological carcinogens. Prevention strategies play a vital role in reducing the burden of cancer as up to one third of all cases could be avoided by: changing tobacco and alcohol use, adjusting dietary and physical activity patterns or reducing exposure to sunlight, etc. Early detection and treatment of cancer is another key element in reducing the burden of cancer as it significantly improves the prognosis. When cancer is treated, the main objectives are curing, prolonging life and improving the quality of life of the patients affected. The common treatment methods are surgery, radiotherapy and chemotherapy.

Cancer Palliative Care

Synonyms

Palliative therapy in oncology; Symptomatic cancer palliation; Chemotherapy-effects and palliative care

Definition

Palliative care aims to improve the symptoms of patients with advanced incurable cancer who may undergo surgery, radiation therapy and/or chemotherapy, and symptomatic treatments and may suffer the unwanted effects of these therapies. The goal of cancer palliative care is to improve the quality of the remaining life. Palliative management usually is founded on a multimodality approach based on the advice of experts from various disciplines and careful coordination.

► Noma

Canonical Correlation Analysis

Definition

A canonical correlation analysis is a multivariate statistical technique that investigates the relationships between two (or more) sets of variables. In most applications, however, the two sets are not treated symmetrically; rather, one set is the predictor set, which is the set of independent variables, and the other set is the response set, which is the set of dependent variables. For example, one may want to study the relationship of various risk factors to the development of a group of symptoms; compute the (simultaneous) relationship between three measures of scholastic ability with five measures of success in school; or investigate the relationship between two predictors of social mobility based on interviews, with actual subsequent social mobility measured by four different indicators. The underlying principle is to develop two linear combinations (i. e., canonical variables) of variables in each set (both dependent and independent if such a distinction is made) that best explain the variation in the variables of the other set, i. e. such that the correlation between the composite variates is maximized.

Canons

► Ethical Principles

Capitation

Definition

In capitation-based payment systems, payment is made for individual patients. Physicians receive a specified sum of money for the care of individual patients for a specified period of time. Payment is independent of the extent of services individual patients require. Ideally, payments to physicians are risk-adjusted (► risk adjustment) for differences in morbidity of patients in order to reduce incentives for ► dumping. Physician income is determined by (risk-adjusted) capitation multiplied by the number of individual patients enrolled with the physician. There may be limits as to the maximum number of patients enrolled with one physician or decreasing capitation payments above a threshold of patients.

Capitation Payment

► Per Capita Payment

Carbohydrate Metabolism

Definition

Biochemical pathways to burn carbohydrates.

Cardiac Surgery

Definition

Cardiac surgery is surgery on the heart, in most cases applied to correct congenital heart disease or the complications of ischemic heart disease or valve problems, which can be caused by different causes e. g. endocarditis.

Cardiovascular Diseases

Definition

Cardiovascular disease is the general term for several ► chronic diseases concerning the heart and circulatory system. The major cardiovascular diseases (CVD) are coronary (or ischemic) heart disease (heart attack), cerebrovascular disease (stroke), hypertension (high blood pressure), heart failure and rheumatic heart disease. According to the WHO, CVD made up almost 17 million (19%) of total global deaths of which around 80% occurred in low and middle-income countries. It is expected that CVD will be the leading cause of death in developing countries by 2010. Several risk factors exist for CVD which can be categorized in unmodifiable factors (e. g. male, gender and heredity) and modifiable factors (e. g. cigarette smoking, high blood pressure, high blood cholesterol levels, physical inactivity, diabetes and obesity). It is estimated that more than 50% of the deaths and disabilities from heart disease and stroke could be avoided with effective prevention efforts targeted at reducing the modifiable risk factors.

Care

► Prevention, Tertiary

Caregiver

► Health Care Provider

Caregiver Burden

Definition

Caregiver burden refers to the stress experienced by family, professional and other providers when assisting others, especially individuals with disabling medical or psychiatric problems.

Caretaking

► Social/Emotional Support

Caries

► Dental Caries

Caries Decline

Definition

The term “caries decline” describes the decrease of dental caries prevalence in children and adolescents during the last two decades of the 20th century. Causes of this improvement of oral health are not quite clear and multi-causal. It is assumed that it probably can be traced back to, for example, fluoridation becoming widespread in public (toothpaste, water, salt) and improved dental hygiene among the public. This development was observed mainly in the Western world.

Caries Index

► DMFT-Index

Carlowitz, Hans Carl von

Definition

Hans Carl von Carlowitz was born on 24th December in 1645 in Oberrabenstein, near of Chemnitz (Saxony/Germany), and died on 3rd of March 1714 in Freiberg (Saxony/Germany). He was a mine captain and responsible for cameralistic accountancy. Carlowitz created the term sustained yield forestry and mentioned it in his publication about the economic cultivation of silvicultures (Sylvicultura oeconomica or ‘die haußwirtschaftliche Nachricht und Naturmäßige Anweisung zur wilden Baum-Zucht’) in 1713. Carlowitz is considered to be the creator of sustained yield forestry.

Case

Definition

In ► epidemiology, a case is a person in the population or study group identified as having a disease or disorder of interest.

Case Cohort Study

Definition

In a case-cohort study, cases are defined as those participants of the cohort who developed the disease of interest, but controls are identified before the cases develop. This means that controls are randomly chosen from all cohort participants regardless of whether they have the disease of interest or not, and that baseline data can be collected early in the study.

Case-cohort studies are very similar to nested case-control studies. The main difference between a nested case-control study and a case-cohort study is the way in which controls are chosen. Generally, the main advantage of case-cohort design over nested case-control design is that the same control group can be used for comparison with different case groups in a case-cohort study. The main disadvantages of the case-cohort design is that it requires a more complicated statistical analysis and it can be less efficient than a nested case-control study under some circumstances (e. g., in studies with long follow-up).

Case Control Studies

Definition

Studying infrequent events, such as death from cancer, using randomized clinical trials or other controlled prospective studies requires that large populations be tracked for long periods in order to observe disease development. Case-control studies use patients who already have a disease or other condition and look back to see if there are characteristics of these patients that differ from those who don't have the disease. The case-control study provides a much cheaper and quicker study of risk factors. If the evidence found is convincing enough, then resources can be allocated to more "credible" and comprehensive studies. The case-control study begins with the identification of an outcome or effect and a number of potential causative factors. A group of cases which exhibit the outcome under investigation is selected. A number of control subjects (or controls) who do not exhibit the outcome or effect under investigation are then chosen. These controls should match the cases as closely as possible with respect to the non-risk variables; this allows the proposed non-risk variables to be ignored in the analysis. Sometimes more than one control group is used. The case and control groups are then compared for the proposed causal factors, and statistical analysis is used to estimate the strength of association of each factor with the studied outcome.

Case-control studies are a valuable investigative tool, providing rapid results at low cost, but caution should be exercised unless results are confirmed by other, more robust evidence.

Cross-References

► Observational Studies

Case Finding

Definition

The identification of cases within routine systems of health care delivery, e. g. during a visit at the doctor's office for some related or unrelated cause. It may include special clinical or technical procedures in addition to the routine medical care of a patient. Case finding does *not* include a systematic invitation of the target population.

Case Reports

Synonyms

Case series

Definition

A case series describes characteristics of a number of patients with a given disease. No control group is involved.

Case series and case reports, since they do not use control groups, have no statistical validity.

Case Series

Synonyms

Case reports

Definition

A descriptive, observational study of a series of cases, typically describing the manifestations, clinical course, and prognosis of a condition, is called a case series. A case series provides weak empirical evidence because of the lack of comparability unless the findings are dramatically different from expectations. Case series are best used as a source of hypotheses for investigation by stronger study designs, leading some to suggest that the case series should be regarded as clinicians talking to researchers. Unfortunately, the case series is one of the most common study types in the clinical literature. Closely related to the case series is the case report, which provides only anecdotal evidence. It is a description of a single case, typically describing the manifestation, clinical course, and prognosis of that case. Due to the wide range of natural biologic variability in these aspects, a single case report provides little empirical evidence to the clinician. They only describe how others diagnosed and treated the condition, and what the clinical outcome was.

Case Studies

► Case Control Studies

Categorial Data

Definition

Categorial data are presented in a contigency table. It is a way of summarizing the relationship between variables. A contingency table usually shows frequencies for particular combinations of values of two discrete random variables X and Y, i. e., the joint frequency distributions of variables X and Y. Each cell in the table represents a mutually exclusive combination of X-Yvalues. The values in the rows of a contingency table are contingent upon (dependent upon) the values in the columns. Sometimes three-way (and more) contingency tables are used.

Categorical Data Analysis

► Analysis of Frequencies

Catheter

Definition

A catheter is a flexible tube for insertion into a body cavity, duct, or vessel, which creates a channel for the passage of fluid or the entry of a medical device.

Causal Factors

► Risk Factors and High Risk Groups

Causality

► Causation

Causation

Hristina Vlajinac
Institute of Epidemiology, School of Medicine, University of Belgrade, Belgrade, Serbia
kristiv@eunet.yu

Synonyms

Causality

Definition

A cause of a disease can be defined as an event, condition, or characteristic that plays an essential role in producing an occurrence of the disease (Rothman 1986). The most important aim of epidemiology is to identify the causes and the ► risk factors of a disease, and to improve public health by reducing or eliminating exposure to these factors.

Basic Characteristics

Epidemiological – Ecological Models

A disease is a result of the ► interaction of host factors and the environment. Several models have been developed in order to depict the ways in which these interactions influence the occurrence of the disease: the triangle, the wheel, and the web of causation.

The triangle – This model consists of three components, ► agent, host, and environment, which are in a kind of dynamic equilibrium. Change in any of these components will alter an existing equilibrium and increase or decrease the frequency of the disease. This model has been the most frequently applied to infectious diseases in which infectious organisms were separated from other environmental factors and identified as agents.

For diseases that have not been linked to specific agents, two other models have been developed.

The Wheel – In this model, the host, with its genetic make-up as its core, is presented as the hub of the wheel, surrounded with the environment, which is separated into biological, social and physical components. This separation is artificial since these three parts of the environment are closely interrelated with one another and with host factors.

The Web – The web model emphasizes the concept that effects never depend on single causes but develop as the result of causal chains, which make the web. Each link in the web is the result of antecedents, and breaking of the web at any level can prevent occurrence of the disease. This means that full knowledge of etiology is not needed for effective disease prevention and control. (Mausner, Kramer 1985; Bhopal 2002)

Search for Causal Relationship

There are two approaches to testing hypotheses about causes of disease, experimental and observational. Experimental study can establish the causal relationship of a factor with a disease more conclusively, but since experiments in epidemiology are performed on humans, for ethical reasons the effects of some possible causal factors cannot be investigated directly. Observational studies have therefore been providing the major contribution to the understanding of many diseases.

The first step in an investigation of causal relationship is to see whether there is an ► association between a disease and a postulated causal factor. If an association exists, it does not necessarily mean that it is a causal one. It can be: a) spurious (► spurious association), b) secondary (► secondary association), or c) causal. Before an association is assessed for the possibility that it is causal, other alternative explanations, such as chance, selection bias, information bias, and confounding, have to be excluded.

A Concept of Necessary and Sufficient Cause "A causal factor whose presence is required for the occurrence of the effect" (Last 2001), that is, without which the disease never develops, is the necessary cause. Sufficient cause is a "minimum set of conditions, factors or events needed to produce a given outcome; minimal implies that none of the conditions or events is superfluous" (Rothman 1986). A sufficient cause is not usually a single factor, but often comprises several components – component causes or contributing causes. A disease can have several sufficient causes and these may have one or more contributing causes in common.

Types of Causal Relationship A causal factor can be either necessary or sufficient, both, or neither:

1. Necessary and sufficient

A factor can be both necessary and sufficient, which means that the disease never develops without that factor, and that factor always produces the development of the disease. This type of causal relationship occurs rarely. For example, a person who has three copies of chromosome 21 instead of two will inevitably be mentally retarded – Down's syndrome (Bhopal 2002).

2. Necessary but not sufficient

The factor, although necessary, cannot produce the disease without the presence of some other factors, called component or contributory causes. For clinically manifest tuberculosis, in addition to the bacillus, which is the necessary cause, contributing causes such as poor nutritional and socio-economic conditions are needed.

3. Sufficient but not necessary

Although sufficient for producing the disease, the factor (usually more than one) is not necessary because there are some other factors that can also produce the disease. Either radiation exposure or benzene exposure can produce leukemia independently of each other (Gordis 2004).

4. Neither sufficient nor necessary

Smoking is a cause of lung cancer but not everyone who smokes develops this type of cancer and not everyone who develops lung cancer has smoked.

Guidelines for Causal Reasoning in Epidemiology Although epidemiologic evidence by itself is insufficient to establish causality, Bradford Hill (Hill, 1965) suggested that the following attributes (criteria) of an association be considered in assessment of the possibility that it is a causal one.

1. Strength of the association – The strength of association is measured by the relative risk (odds ratio), that is the ratio of disease rates for those exposed and those not exposed to the hypothesized causal factor. The stronger the association, the more likely it is that the relation is causal. However, it does not mean that a weak association cannot be judged to be a causal one. "The strength of an association is not a biologically consistent feature, but rather a characteristic that depends on the relative prevalence of other causes" (Rothman, 1986).
2. Dose-response relationship – A dose-response is established when, with increasing level of exposure ("dose" or duration), the risk of disease also increases. The absence of a dose-response relationship does not rule out the possibility of causal association since, for some causes, a threshold may exist and a disease may not develop unless a certain level of exposure is present.
3. Consistency of the association – A cause-effect relationship is supported when similar results are obtained in a number of studies performed in various populations or population groups, by different investigators, and with different methodology. The causal relationship might not be found in some studies because "the effect of a causal agent cannot occur unless the component causes act, or have already acted, to complete a sufficient cause" (Rothman 1986).
4. Temporality – Exposure to the postulated causal factor must precede the onset of disease by a period of time consistent with the proposed biologic mechanism (► induction, ► incubation, ► latency). In some diseases, especially chronic and those with a long period of latency, temporality cannot always be easy to establish. Although the only indispensable attribute among all Hill's conditions, a temporally correct association between two events does not necessarily mean that it is that of cause and effect. They could both be generated by the same factor.
5. Biologic plausibility – The existence of a cause-effect relationship is enhanced if it is coherent with the current body of biologic knowledge. This, of course, depends on the state of scientific information at a given time. An association that is biologically implausible at one time may eventually prove to be plausible.
6. Experimental evidence – Causal understanding can be greatly advanced by "in-vivo" and animal experiments, but data obtained in that way must be integrated with observations in the human population. Because of ethical reasons, experimental evidence is seldom from the human population. However, evidence for a causal relationship is supported if reduction or elimination of exposure to a certain factor (postulated causal factor) is related to decline of disease frequency.
7. Coherence – Coherence implies that a cause-effect interpretation of an association does not conflict with the generally known facts of the natural history and biology of the disease.
8. Specificity of the association – An association is specific when a certain exposure is associated with only one disease. Taking into account the multifactorial nature of disease and the fact that one factor can cause more than one disease, the specificity is the least important criterion to satisfy, and "should be probably deleted from the list" (Gordis 2004).

In making decisions about causation, the list of criteria presented above should be considered only as guidelines. If temporality is viewed as part of the definition of causation, "there is no necessary or sufficient criterion for determining whether an observed association is causal" (Rothman, Greenland 1998; Rothman, Greenland 2005). Decisions about causation must always remain a matter of judgment based on all available evidence "achievable through hypothesis generation and testing, with data interpreted using a logical framework of analysis, which draws on multidisciplinary perspectives" (Bhopal 2002).

Hill himself pointed out that these "viewpoints" cannot be used as criteria for causal inference, but can help to make a judgment, and to act on the premise that a causal relationship exists rather than awaiting further evidence: "All scientific work is incomplete – whether it be observational or experimental. All scientific work is liable to be upset or modified by advancing knowledge. That does not confer upon us a freedom to ignore the knowledge we already have, or to postpone the action that it appears to demand at a given time".

Most definitions are taken from the last edition of Last's Dictionary of Epidemiology (Last, 2001). We are much obliged to Professor Last for his kind consent.

Cause of Injury

Definition

The cause of injury is the route of the dangerous occurrence that led to ► occupational injury. It is important to recognize this in order to develop preventive measures. Quite often there are several causes leading to one ► occupational accident and it is not easy to identify it. In such complex cases, expert knowledge is needed to identify the most important causes. The success of preventing occupational accidents is directly dependent on the process of recognizing causes of an accident.

► Dental Caries

CD_4

Definition

CD_4 is a protein, which can be found on the surface of various cells, among others T-lymphocytes (T4-cells, helper T-cells). By binding to the CD_4-molecules, HI-viruses can pass into the cells. CD_4-test determines the amount of helper T-cells. The CD_4-value is reverse proportionally to the impairment of the immune system, this means, the lower the level is, the more immunodeficiency has progressed. Normal values for CD_4 are 600–1000 cells/pl.

In HIV-infections the graduation into the CD_4-helper status 1 to 3 depends on the CD_4-value: Status 1 means a value of 500 cells/pl, status 2 is reached when the value is 200–400 cells/pl, in status 3 CD_4-count is below 200 cells/pl.

Censored (Patient)

Definition

A patient is scored as censored if he or she did not suffer the outcome of interest. In survival analysis, patients who do not have an "► event" during a specified period are said to have censored observation. A *right-censoring* situation occurs when the terminal event is not observed; instead, it is only known that this event is at least later than a given point in time. Censored observations can arise in three ways: 1) the patient is known to be still alive when the trial analysis is carried out; 2) the

patient was known to be alive at some past follow-up, but the investigator has since lost trace of him; 3) the patient has died of some cause totally unrelated to the disease in the survival analysis.

Centers for Disease Control and Prevention (CDC)

Definition

The Centers for Disease Control and Prevention (CDC) was founded 60 years ago to help control malaria. Today it is the leading U.S. government agency of the Department of Health and Human Services for protecting the health and safety of the people of the U.S., with the following vision for the 21st century: "Healthy People in a Healthy World – Through Prevention". The CDC focuses national attention on prevention and control of infectious and chronic diseases, disabilities, injuries, and environmental health threats. It is headquartered in Atlanta, Georgia.

Central European Encephalitis (CEE)

► Tick-Borne Encephalitis (TBE)

Central Limit Theorem

Definition

The Central Limit Theorem is a statement about the characteristics of the sampling distribution of means of random samples from a given population. That is, it describes the characteristics of the distribution of values we would obtain if we were able to draw an infinite number of random samples of a given size from a given population and we calculated the mean of each sample. The Central Limit Theorem consists of three statements: 1) the mean of the sampling distribution of means is equal to the mean of the population from which the samples were drawn, 2) the variance of the sampling distribution of means is equal to the variance of the population from which the samples were drawn divided by the size of the samples and 3) if the original population is distributed normally, the sampling distribution of means will also be normal. If the original population is not normally distributed, the sampling distribution of means will increasingly approximate a normal distribution as sample size increases (i. e. when increasingly large samples are drawn).

C

Central Nervous System

Definition

The central nervous system (CNS) represents the largest part of the nervous system and consists of the brain and the spinal cord. The CNS and the ► peripheral nervous system (PNS) have a fundamental role in the control of behavior. The CNS acts as the main "processing center" for the entire nervous system and is responsible for the integration of all nervous activities.

Centre for Evidence-Based Medicine

Definition

The Centre for Evidence-Based Medicine was established in Oxford as the first of several centers in the UK whose broad aim is to promote evidence-based health care and to provide support and resources to anyone who wants to make use of them.

Centre for Reviews and Dissemination (CRD)

Definition

The Centre for Reviews and Dissemination (CRD) is the UK HTA agency and works closely with a number of other health, social research, and information organizations, as well as with international networks such as the Cochrane and Campbell Collaborations. It is a member of the International Network of Agencies for Health Technology Assessment (► INAHTA) and the Guidelines International Network (G-I-N). CRD has undertaken work for a number of different agencies including the National Institute for Clinical Excellence (NICE), the Home Office, the Social Care Institute for Excellence (SCIE), the Economic and Social Research Council (ESRC), the Health Technology Assessment Programme (HTA), and the Service Delivery & Organisation Programme (SDO).

Cephalosporins

Definition

Cephalosporins were first detected in *Cephalosporium acremonium* in 1945. They are quite similar to penicillin's. Like penicillin's, cephalosporins are bactericidal; they kill bacteria by interfering with the building of the bacterial cell wall. Three generations of cephalosporin have been developed. Cephalosporins act against both gram positive and gram negative germs. Their development from the first to the third generation saw an increased efficiency in their effect on gram negative organisms. Cephalosporin can be given orally or parenterally. Some of the drugs (like cefotaxime and ceftriaxone) penetrate well into the cerebrospinal fluid. Due to this quality they play an important role in the treatment of meningitis. Because of their similarity, an allergic reaction provoked by penicillin can also be provoked by cephalosporin. This phenomenon is called cross-allergy.

Cercarial Dermatitis

Synonyms

Dermatitis in schistomoniasis; Schistosome dermatitis; Swimmer's itch

Definition

From a few hours up to two days after cercaria, which are the larval form of schistosomas, have penetrated the skin, there appears strong itching and an exthematic reaction at the site of entry. These symptoms are called cercarial dermatitis or swimmer's itch. Usually, the dermatitis heals within two weeks.

Chagas Disease

Synonyms

American trypanosomiasis; Infection with trypanosoma cruzi

Definition

Chagas disease, which is found in Central and South America, is caused by the parasite *Trypanosoma cruzi*. It is transmitted by the bite of night-active predatory bugs. Up to 10% of the infections take a lethal course. Besides humans, the most common reservoirs of the parasite are armadillos; domestic animals (especially dogs and cats), which do not fall ill themselves, can also be infected. Chagas disease has 4 stages. At first, a local reaction appears at the site of the bite; 2–4 weeks later the acute phase occurs with non-specific symptoms, like fever stomach ache, diarrhea and edemas of the face and the feet. The acute phase is followed by a latency phase, which can last for years. The last stage is the chronic phase. In this phase, inflammations of the heart muscle can appear which might lead to heart insufficiency or cause a sudden cardiac death. Besides the heart muscle, nerve cells and the musculature of the intestines can be involved. An impairment of intestinal peristalsis leads to an abnormal dilatation of the colon (megacolon). Chagas disease can be treated with nifurtimox and benznidazole. Prophylactic measures are the use of insecticides and personal protective measures, like covering clothing and the use of mosquito nets.

Characteristic Property

Synonyms

Variable

Definition

A variable is any characteristic property of the observational unit with outcomes (data) that vary from one observation to the other. A variable may have a different value out of a specified set of values in different people,

in different places or at different times. Some examples of variables include the height of adult females, the gender of preschool children, and IQ test score of patients seen in psychiatric clinics. The variables are often referred to as random variables when the value of a particular outcome is determined by chance (i. e. by means of random sampling). Types of variables refer to the several different and important classifications of variables which are most essential to know in order to understand and appropriately use the most important and frequently used applied biostatistical methods. Three main classifications of variables are: 1) quantitative or qualitative; 2) continuous or discrete; and 3) independent or dependent variables.

Cross-References

► Cultural Determinants

Chemical Sensitivity Syndromes

Definition

Among the chemical sensitivity syndromes that are well described and usually reported are: (a) multiple chemical sensitivity syndrome or MCS, (b) sick building syndrome or SBS, (c) chronic fatigue syndrome, and (d) Gulf war syndrome. The first three are sometimes referred to as "syndromes in environmental medicine". Multiple chemical sensitivity syndrome is an acquired disorder presenting as recurring multiple and polysystemic subjective symptoms, such as fatigue, malaise, headache, asthenia, depression or irritability, gastrointestinal disorders, etc. In most cases, MCS appears as a response to very low doses of common environmental chemicals (one or more of them) that have a characteristic odor, and that do not cause harmful effects to the rest of the general population. These specific chemicals may be exhaust fumes, organic solvents, perfumes, air fresheners, paints, formaldehyde, cigarette smoke, or pesticides, etc. MCS should not be confused with sick building syndrome. As opposed to SBRI and MCS, sick building syndrome produces nonspecific and often unclear subjective complaints in a certain number of indoor space occupants but without a single known cause. Symptoms are difficult to confirm by laboratory tests and available medical examinations but they are benign, always reversible, and rapidly disappear or ameliorate once the individual leaves the "sick" building. The most frequent SBS symptoms are mucous membrane irritation (of the nose, eyes and throat), neurotoxic effects (e. g. headaches, lethargy, fatigue, and irritability), and even irritated skin, nausea, chest tightness, and coughing.

Chemical Substances

Synonyms

Chemical agents

Definition

Chemical substances in ► drinking water are inorganic and organic constituents including pesticides, disinfectant and disinfectant by-products present in water at levels which do not cause adverse effects on health.

Chemoprevention

Definition

Chemoprevention involves the administration of natural or synthetic substances to reduce the risk of developing cancer or to retard the development or progression of cancer. Chemoprevention is a relatively new approach to cancer prevention that has a precedence in cardiology, in which cholesterol-lowering, antihypertensive, and antiplatelet agents are administered to prevent coronary heart disease in high-risk individuals. Agents that are discussed to be chemopreventive include pharmaceuticals (e. g. anti-inflammatory drugs), vitamins, minerals or other chemicals. Diet may carry chemopreventive agents that could reduce the cancer risk. The concept of chemoprevention is based on epidemiologic and experimental evidence suggesting that specific compounds may influence carcinogenesis at various sites of the body, e. g. the gastrointestinal tract, lungs, breast, and prostate.

Chemoprophylaxis of Tuberculosis

Synonyms

Medicinal prophylaxis of tuberculosis; Medicinal prevention of tuberculosis

Definition

Prophylaxis of tuberculosis is recommended for certain groups of people. Chemoprophylaxis should be given to people who have had direct contact with shedders of tubercle bacilli, people <35 years of age with a positive tuberculin skin tests, HIV-positive individuals and other persons at risk. The latter are homeless persons, prisoners, inhabitants of nursing homes and immunocompromised patients (for example, patients on long-term steroid therapy). Newborn babies whose mothers suffer from tuberculosis should receive isoniazid for 3 months; in Asia they should additionally be treated with rifampin. At the age of 6 months, a tuberculin skin test should be performed.

Chemotherapy-Effects and Palliative Care

► Cancer Palliative Care

Cherry-Picking

► Preferred Risk Selection

Chicken Pox

Synonyms

Varicella

Definition

The highly contagious chicken pox is transmitted by droplets or direct contact, and the developing spots are the first manifestation of the ► varicella virus infection. After an incubation period of 8–21 days fever occurs and red itchy bumps appear in phases over several days. At the beginning there is a red papule which develops into a vesicle with an initially clear and afterwards cloudy fluid. The vesicle breaks and leaves a crust. The intensity of the exanthem can vary considerably. It has to be assumed that contagion lasts from one to two days prior to the appearance of the rash until five days after the last appearance of vesicles. Complications mainly concern immunocompromised persons. Superinfections of scratched vesicles, pneumonia and central nervous system effects (in most cases an inflammation of the cerebellum) have to be mentioned. If a severe infection is expected, a virustatic drug (aciclovir) can be administered. The varicella-zoster-virus remains dormant in sensomotor ganglia and can be reactivated later in life as shingles (herpes zoster). The most important preventative measure of chicken pox is active varicella-vaccination (► immunization, active).

Chiggers (Burrowing Fleas)

Synonyms

Chigoe; Harvest bug; Harvest mite; Jigger; Red bug

Definition

Chiggers represents parasites of the family *Trombiculidae*. Larves of this parasite live on insects, humans and other vertebrates. Its bite produces a wheal that is accompanied by severe itching.

Chigoe

► Chiggers (Burrowing Fleas)

Child Abuse

Definition

Child abuse refers to the physical, emotional and or sexual mistreatment of a child by a parent or guardian. Forms of child abuse include verbal insults, beating, neglect and sexual molestation.

Child Growth

► Child Health and Development

Child Health and Development

Ellen Meryl Schleicher
Accociaton of State and Territorial Health Officials (ASTHO), Bladensburg, MD, USA
eschleic@jhsph.edu

Synonyms

Child growth; Infant health; Maturation; Pediatrics; also ► Adolescent health

Definition

Child health covers improvements in well-being and development from birth to young adulthood. It spans the complete care of the child's physical, mental, and ► social health, both in the presence and the absence of disease. Healthy children are able to improve their abilities to interact with their physical, biological, and social environments.

Basic Characteristics

Nutrition

Nutrition is necessary for children's growth, development, metabolism, health, and well-being. Early nutrition has a powerful effect on cognitive development and growth, particularly in the first 2–3 years (National Research Council 2000). Breastfeeding for the first 6 months of age best supports healthy growth and development; breastfeeding is recommended for at least 12 months and thereafter at the discretion of the mother (Stang, Story 2003). Breast milk provides the correct balance of nutrients, enzymes, immunoglobulin, hormones, anti-infective and anti-inflammatory substances, and ► growth factors for the infant (Stang, Story 2003). Breast feeding is especially effective in developing countries where access to sanitized water is limited. Children above the age of two should follow a balanced diet as defined by the American Dietetic Association (Gerber 2005) or individual countries' health ministries. Children who do not follow a balanced diet are at risk for lifetime healthcare problems such as obesity, high blood pressure, cardiovascular diseases, and diabetes. Malnutrition affects nearly 250 million children worldwide; effects of undernourishment can last a lifetime including blindness, stunted growth, disability, and death (Blair et al. 2003).

Developed Countries and Chronic Diseases

In developed countries, child mortality and morbidity have fallen to the lowest levels in recorded history. In the past, infectious diseases were the top cause of death in children (Blair et al. 2003; National Research Council 2004). Improvements are attributable to vaccinations, better nutrition, water and sewage management, lowered ► fertility rate, and housing (Blair et al. 2003). Despite these advances, children are developing signs of chronic diseases typically not seen until adulthood. Diseases such as Type II diabetes, obesity, asthma, and cancer are on the rise. These diseases often disrupt daily life physically, emotionally, and socially. Lifestyle change has played a large role in the rise and earlier onset of childhood diseases. Social and physical factors are equally responsible. Children in these countries are more likely to eat prepackaged foods, high in sugar and fat, rather than more nutritious alternatives (Stang, Story 2003). Community layout, such as residential distance from schools and availability of parks, and increased television and video game use has lead to decreased walking and outdoor activity (National Research Council 2004). The consequences of these diseases play out over the lifespan, as unhealthy children typically grow up to be unhealthy adults.

Developing Countries and Acute Infections

Approximately 85 percent of the world's children live in developing countries (Blair et al. 2003). There, infectious diseases remain the primary cause of childhood death. Diarrheal diseases and respiratory infections, from sanitation deficiencies, pollution, and lack of access to healthcare, remain the top infectious burdens in developing countries (Blair et al. 2003). While vaccines have made progress in reducing acute illnesses, supply and access are typically limited in more rural communities. As a result, nearly 15 percent of deaths in developing countries are attributable to vaccine-preventable infectious diseases (Blair et al. 2003). Children are particularly at risk due to their exploratory natures, lack of previous exposure and immune resistance, contact with other children, and ► lung to body ratio (Blair et al. 2003; National Research Council

2004). Over 95 percent of the AIDS cases are in the developing world (Blair et al. 2003). While childhood HIV infection is declining due to prevention efforts in mother to child transmission, antiretroviral therapy and safe antenatal facilities remain expensive and inaccessible. Children are commonly left to head the household after losing their parents to the disease (Blair et al. 2003).

Mental Health

Emotional and behavioral problems during childhood are common. As high as 10 to 27 percent of children have an impairing mental health condition (Morris 2003; National Research Council 2004), such as depression, ► attention deficit hyperactivity disorder (ADHD), and conduct disorders. Mental illnesses and behavioral problems are linked with developmental delay. Children with mental illnesses have difficulty focusing, making friends, and learning in school (National Research Council 2000; Morris 2003). Without the help of comprehensive mental health services, cognitive, educational, and social delays may continue into adolescence and adulthood (Blair et al 2003; Morris 2003). However, symptoms of these illnesses are sometimes exhibited by normal children – making it crucial to determine the frequency and duration at diagnosis (Blair et al. 2003). In developed countries, the over-diagnosis and medication of children with mental illnesses, particularly ADHD, is a concern that has yet to be addressed in child health.

Social Environment

Family influences are imperative to children's health and well being. Not all children who enter school are ready to learn. Parental participation in children's lives can enhance or diminish the development of language and reading skills; developing these skills before school predicts scholastic achievement and family ties (National Research Council 2004). Likewise, violence in the home and community is associated with negative developmental outcomes. Firsthand experience with ► child abuse or ► child neglect, as well as witnessing violence at home and in the community, can lead to developmental delays, learning problems, anxiety, depression, and aggression (National Research Council 2000; Aday 2001; Rosquist, Krugman 2003).

Physical Environment

The physical environment exposes children to external conditions, usually preventable, that affect their health. While advancements have been made in the reduction of infectious diseases worldwide, relatively little has been done to reduce childhood injuries. Injuries represent a growing proportion of childhood deaths and the most common cause of physical disability (Blair et al. 2003; National Research Council 2004). Worldwide, auto accidents comprise the majority of childhood injuries (Bolton et al. 2003). In addition to causing accidents, cars and trucks emit carbon monoxide, carbon dioxide, and hydrocarbons, among other hazardous chemicals (National Research Council 2004). Children are also affected by other common air pollutants such as smoking, extermination agents, toxic paint, fumes from cleaning supplies, molds, and asbestos in old school buildings. Children who live in high traffic areas, near industrial parks, and/or are in contact with indoor pollutants, such as cigarette smoke, are particularly at risk for respiratory infections, allergies, and asthma (National Research Council 2004). Lead poisoning from lead pipes and paint cause neurological damage (National Research Council 2004). Contaminants in food, water, and immediate environment are particularly harmful to children. Children eat less diverse diets and consume more calories and water for their weight than adults, potentially exposing them to greater levels of pesticides, parasites, and pollutants in the water (National Research Council 2004). Natural disasters, such as hurricanes, tsunamis, mud slides and earth quakes, ruin crops, homes, and stability in their wake. Children are particularly at risk from malnutrition and infectious diseases that often follow environmental events (Blair et al. 2003).

Vulnerable Populations

Children of low socioeconomic status (SES), immigrants, and those in war torn countries are more likely to have poor health outcomes (Aday 2001; National Research Council 2004). Families with low SES are less likely to have available resources to purchase nutritional food, heating, adequate shelter, and healthcare for themselves and their families. In the United States, mortality from infectious diseases is over two times more common in the bottom ten percent than the top ten percent SES (National Research Council 2004). Parents

living in poverty are more likely to exhibit feelings of depression, anxiety, and low self esteem, possibly leading to an unstable home (Blair et al. 2003; National Research Council 2004). The children of refugees and undocumented immigrants face similar issues. Access to care in war torn countries is limited due to blocked road access, limited supplies, and unsafe conditions. The prevalence of depression and posttraumatic stress syndrome is especially high among child refugees fleeing from war-torn countries (Aday 2001). The children of undocumented immigrants tend to have poor health outcomes due to lack of social capital, community networks, and access to affordable healthcare (Aday 2001). Currently there are no comprehensive analysis regarding racial disparities and children's health (National Research Council 2004). The majority of the research has focused on adult health outcomes that are not applicable to youth. More studies must be done to confirm ► minority-status' effect on child health outcomes.

Conclusion

A healthy childhood is a critical determinant for health in adolescence and beyond. Children rapidly develop from birth through age five, building upon emotional, social, regulatory, and moral abilities (National Research Council 2000). While advances have been made in the reduction of childhood infectious diseases, chronic diseases commonly found in adults are beginning to present in children. Moreover, challenges lay ahead for developing countries still overwhelmed with infectious diseases and beginning to show signs of chronic disease as well.

Child Health Indicators of Life and Development (CHILD)

Definition

CHILD is a project funded by the European Commission that aims to seek a composite set of ► health indicators measuring all aspects of child health at the level of Member States. The proposed indicators of child health are divided into the following four groups: ► demographic indicators and ► socioeconomic indicators; indicators of child health status and well-being; health determinants, risk and protective factors; and indicators of child health systems and policy. Most of these indicators are available from civil registration data or hospital data. This project has also identified areas where further research is needed to identify new indicators, such as child abuse, childhood behavior disor-

ders, learning disorders, educational development, and family cohesion, etc.

Child Health Policy

► Family Health Policy

Childhood Autism

Definition

Childhood autism is a type of pervasive developmental disorder that is defined by: (a) the presence of abnormal or impaired development that is manifest before the age of three years, and (b) the characteristic type of abnormal functioning in all the three areas of psychopathology: reciprocal social interaction, communication, and restricted, stereotyped, repetitive behavior. In addition to these specific diagnostic features, a range of other nonspecific problems are common, such as phobias, sleeping and eating disturbances, temper tantrums, and (self-directed) aggression.

Chimaera

► Chimera

Chimera

Synonyms

Chimaera

Definition

A chimera is an organism which consists of cells that are not genetically identical. Chimeras can be produced by artificial fusion of two embryos after implantation of embryonic stem cells (ESC) into a blastocyst. If the implanted ESC replace the inner cell mass, the developing embryo consists only of ESC-derived cells. If they do not completely replace inner cell mass, the embryo is formed by ESC and embryoblast cells of the host blastocyst, resulting in a chimera. In the mid-80s, US scientists bred the "geep" – a chimera of a goat with a sheep.

► Podiatrists

Chi-Square Test

Definition

A test that is frequently used to detect significant relationships between two variables measured on nominal scales, or to determine whether a distribution differs significantly from expectations. Chi-square tests belong to the class of statistical inferential procedures known as nonparametric or distribution-free tests.

The chi-square test is a significance test based on chi-square distribution. A chi-square test is most commonly used as a ► test of homogeneity or a ► test of independence for ► contingency table analysis, and as a ► goodness-of-fit test for analysis of observed ► frequency distribution. Chi-square test statistic can be calculated as the sum of the squared differences between observed and expected frequencies, $\sum (O-E)^2/E$, where O is the observed frequency and E is the expected frequency. Statistic produced by this test follow a chi-squared distribution, with $(r-1)\ (c-1)$ degrees of freedom for a contingency table analysis and $r-1$ degrees of freedom for a goodness-of-fit test. In these formulas, r and c are the number of rows and columns, respectively, i. e. number of categories of variables.

Chlamydia trachomatis Infection

Synonyms

Non-gonococcal urethritis (NGU); Non-specific urethritis (NSU); Urethritis Waelsch; Waelsch's disease

Definition

Chlamydia are obligatory intracellular bacteria. The most important species is *Chlamydia trachomatis* with 15 serotypes, which are responsible for various diseases. The serotypes A–C cause endemic trachoma, which is primarily found in tropical regions and often leads to blindness. The serotypes D-L cause genital infections and conjunctivitis as well as neonatal infections. Lymphogranuloma venereum is due to an infection with the serotypes L1–L3. Worldwide, *Chlamydia* associated urogenital infections, which belong to the non-gonococcal urethritis (NGU) group, are very common. The incubation period lasts 1–3 weeks. In 75% of the women and 25% of the men, the infection is asymptomatic. Possible symptoms are vaginal discharge and – especially in men – painful micturition. A complication of the infection is adhesions in the urogenital tract, which can cause infertility in both sexes. *Chlamydia trachomatis* infection can be cured by doxycycline and erythromycin.

Cross-References

► Sexually Transmitted Diseases

Chloroquine (Resochin®, Aralen®)

Definition

Chloroquine is a derivative of the alkaloids quinine and quinidine, which can be extracted from the bark of the South American cinchona tree. Its effect results from the impairment of the metabolic processes in plasmodia. Chloroquine is the basis of treatment and prophylaxis in cases of infections with *Plasmodia ovale*, *P. vivax* and *P. malariae*. In general, it is tolerated well, and can also be administered during pregnancy and breast feeding. Treatment is carried through at 0, 6, 24 and 48 hours. Possible side effects are gastrointestinal symptoms and visual defects. When used for long-term prophylaxis, chloroquine can cause alterations of the cornea and the retina.

Cholera Immunization, Active

► Cholera Vaccination

Cholera Vaccination

Synonyms

Cholera immunization

Definition

The first dead cholera ► vaccine was developed as far back as in 1896. A modified version of this vaccine is still in use today, and can be given to patients from 6 months of age onward. However, the protective effect

of the cholera vaccination is only 50%, and side effects are frequent at 20–50%. For these reasons, the use of this vaccine is limited. Another possibility is an orally administered living vaccine, which is permitted for use from the age of 2 years, and which is given as a single dose. The contraindication for the living vaccine is immunosuppression.

Christianity

Definition

All Christians believe in God as the creator of all men and who, through Jesus Christ, provided us with rules and guidelines for a Christian way of life. The church is the main place of worship, with other centers available for believers to come together in order to share their faith and way of life.

Christian (Neighborly Love)

Definition

The preaching of God expresses the need for neighborly love in that the individual shall show love and passion toward their fellow being, similar to their acceptance of God.

Chromatid

► Chromosome

Chromosomal Mutation

► Mutation

Chromosome

Synonyms

Chromatid; Linkage group (in some species)

Definition

A chromosome is a single continuous strand of DNA which encodes genes as well as functional sequences (segments of DNA that may play structural or regulatory roles) and non-functional sequences, and also may included a complicated physical structure or arrangement of genetic materials. In prokaryotes (single-celled organisms), DNA is organized as a large circularized chromosome containing all relevant genes of the microorganism. It forms additional structure through supercoiling, which is a coiling or looping of the double-helical strand to relieve torsional stresses on the molecule. In eukaryotes (some single-celled organisms, all multicellular organisms), DNA is contained in chromosomes each composed of one enormously long single linear strand. Throughout the majority of the cell cycle in eukaryotes, DNA is linearized, bound to some proteins in a complex called chromatin and contained within a sac called the nucleus. However, during the cell cycle, the DNA contracts, binds with additional proteins, and is organized into a far more complex physical structure. DNA is always bound to a cluster of proteins called histones, around which it is wound to form a nucleosome. Multiple nucleosomes are said to look like 'beads on a string.' When cells divide, chromosomes contract to form an additional chromatin structure by binding with more proteins and forming a 'protein scaffold.' When cell division is complete and the chromosome is present within a new nuclear envelope, the protein scaffold dissociates, allowing the DNA to once again linearize. It should be noted that chromosomes have two regions with distinct features, the centromere and telomeres. When a chromosome is copied, it remains bound to its copy by a centrally-located tight collection of DNA called the centromere, which resembles the knot of a bowtie. The telomeres are the ends of a chromosome; they are often composed of highly repetitive sequences, which are used to preserve the ends of the chromosome from decay after repeated rounds of ► replication. It is also important to note that different species have different numbers of chromosomes, and chromosomes of varying length. For instance, the fruit fly *Drosophila melanogaster* has 8 chromosomes, while the common dog *Canis lupus*, has 78 chromosomes. In humans, somatic cells carry 46 chromosomes (2 copies of 22 different chromosomes and 2 sex chromosomes) while gametes carry 23 chro-

mosome (1 copy of 22 different chromosomes and 1 sex chromosome).

gernot.lenz@gmx.de

Definition

A chronic disease is a disease that lasts at least three months, it generally persists for a longer time and does not just disappear. Chronic diseases can typically not be prevented by vaccines or cured by medicine. The most observed chronic diseases in western industrialized countries are heart diseases, cancer and diabetes. Chronic diseases are costly for the health care systems and discussions on how to deal with these chronic conditions in the most efficient way, with respect to treatment and improvement in general health, are focused on giving up health damaging behavior.

Chronic diseases are characterized by a long latency period, a mixture of causal factors, a prolonged course of illness, a non-contiguous origin and functional impairment or disability. Chronic diseases are rarely completely cured. Typical examples of chronic diseases include ► cardiovascular diseases, ► cancer, ► chronic respiratory diseases, ► diabetes, and ► arthritis. Most of the chronic diseases are more common amongst elderly people. The global cost of these chronic conditions both in human and financial terms is tremendous. This is especially an issue for developing countries with limited economical strength. Going forward, public health has to face the challenge to reduce the burden, arrest or slow deterioration, and prevent disability from the chronic disease illnesses given the large chronic disease burden as well as the aging population.

Basic Characteristics

The Global Burden of Chronic Diseases

According to WHO out of the approximately 58 million deaths in 2005, about 35 million people or 60% died due to chronic diseases. This is double the number of the deaths due to infectious diseases, maternal and perinatal conditions and nutritional deficiencies combined. Around half of the people that died of chronic diseases were female. Almost 50% of the deaths were of people younger than 70 years and 80% of deaths came from low and middle income countries. When comparing the different chronic diseases, cardiovascular diseases are the main cause of death, accounting for 30% of all deaths in 2005. Cancer with 13% and chronic respiratory diseases with 7% are the other leading causes of death. According to the WHO, diabetes is only responsible for 2% of all deaths. This rather small percentage is driven by the fact that many patients live with diabetes for years and in many cases their official cause of death is recorded as cardiovascular disease or kidney failure. Chronic diseases are furthermore a crucial factor in the cause of disability.

The measurement of the burden of disease is often done by using the disability adjusted life years (or ► DALY) which was originally developed by the World Health Organization. DALY is increasingly used in the field of public health and health impact assessment. The DALY measurement quantifies the impact of premature death and disability on a population by combining mortality and morbidity statistics into a single, common metric. One DALY can be compared to one lost healthy year of life. Of the 725 million DALYs in 2005, almost 50% were caused by chronic diseases.

Causes of Chronic Diseases

The majority of chronic diseases can be explained by their modifiable risk factors in conjunction with the non-modifiable risk factors. The most relevant modifiable risk factors of chronic diseases, that are well-established in the medical scientific community and proven by various studies, are unhealthy diet/excessive energy intake, physical inactivity and tobacco use. This behavior often causes the intermediate risk factors like raised blood pressure, raised glucose levels, abnormal blood lipids, and overweight (► body mass index $\geq$25) and obesity (body mass index $\geq$30). The most important non-modifiable risk factors are age and heredity. There

are other risk factors that account for a smaller proportion of chronic disease like excessive alcohol use, infectious agents and environmental factors. Other causes that influence health in adult life are the conditions before birth and in early childhood. In most cases, these causes cannot be controlled by the person concerned as children cannot choose the environment in which they live. Each year there are at least 4.9 million people who die as a result of tobacco use, 1.9 million people who die as a result of physical inactivity, 2.7 million people who die as a result of low fruit and vegetable consumption, 2.6 million people who die as a result of being overweight or obese. Furthermore, there are 7.1 million people who die as a result of raised blood pressure and 4.4 million people who die as a result of raised total cholesterol levels.

Prevention of Chronic Disease

Just a small decrease in the average population levels of several risk factors can have a significant impact of the burden of chronic disease. Prevention strategies for chronic diseases should therefore aim at the whole population yet be combined with individual approaches where appropriate. There are several dimensions were prevention measures can be defined and applied. From a legal or regulatory point of view, those measures can be national and local legislation, regulations, ordinances, international laws and treaties and other legal frameworks. For example, laws have had a major impact on public health policy and practice like, for example, advertising bans for tobacco products. Although legislation and regulations are in place already, there is still potential to leverage them to more effectively reduce the burden of chronic disease. Another lever are tax and price interventions that can steer individuals towards the reduction of the consumption of tobacco and unhealthy foods or, on the other hand, can, through subsidies, promote healthy foods or physical activity. Other media for preventing chronic diseases are, for example, advocacy interventions that provide health education by means of communication methods (information campaigns, publications, web sites, press releases, lobbying and peer-to-peer communication).

Interventions can furthermore be community-based, school-based or occur at the workplace. Community programs aim at high-risk populations in schools, workplaces, recreation areas and other settings in the community. These programs usually include partnerships between community organizations, policy-makers, businesses, health providers and community residents. School-based interventions can be part of community programs and usually cover health policies, health education, supportive environments and health services. The programs themselves might, for example, include physical education or nutrition and food services (like providing only healthy drinks at vending machines). Workplace interventions can be driven by the community or by the employer or the workforce.

Medical screening is another important pillar of prevention. Screening tests are available for some chronic diseases like, for example, cardiovascular diseases or diabetes and, when medical screening is implemented effectively, it can prevent disability and death and improve the quality of life. Clinical prevention is aimed at people who are at risk of developing or who already live with a chronic disease and it is designed either to reduce the risk of disease onset or to reduce complications.

Conclusion

There existed, and in some countries still exists, a confusion and misunderstanding about the nature of chronic diseases, their prevalence, the people at risk, and the risk factors themselves. As a consequence, in the past, not enough focus and effort was put into progressing chronic disease treatment and prevention. This is changing with the realization that not only, as the population ages, more and more people are living long enough to develop chronic diseases, but also that, in today's socio-economic environments, more young people are developing chronic diseases. Futhermore, chronic diseases are the main cause of death in most countries and this fact has significant economic impact. Several examples of effective and cost-efficient intervention measures from different countries exist and these measures need to be applied on a global level to deal with the chronic disease threat and improve the quality and length of life for millions of people.

Chronic Effects

Definition

Symptoms of illnesses or diseases of long duration or frequent occurrence are called chronic effects. Chronic effects develop slowly, sometimes from repeated exposures to low concentrations of a health hazard. The time it takes for a health effect to develop after first exposure to a hazard is called the latency period.

Chronic Respiratory Diseases

Definition

Chronic respiratory diseases include disorders of the airways and other structures of the lung. Prolonged diseases and disorders of the respiratory systems in adults are present for months to years and although they are usually treatable, they are generally not curable. The most common chronic respiratory diseases are asthma, chronic obstructive pulmonary disease (COPD), respiratory allergies, occupational lung diseases and pulmonary hypertension. Around the world, there are hundreds of millions of people suffering from these diseases, for example about 300 million people in the world have asthma according to the WHO. Some risk factors for chronic respiratory diseases are preventable, particularly smoking, poor nutrition, frequent lower respiratory infections during childhood, and environmental air pollution (indoor, outdoor, and occupational). For a successful medical management of any chronic respiratory disease it is crucial to evaluate the patient as a whole and to assess the structure and function of the entire respiratory system.

CIOMS Report

Definition

CIOMS is the abbreviation for council for international organizations of medical sciences, a sub-organization of the World Health Organization (WHO). Concerning the reporting of adverse reactions the CIOMS reached agreement on a standard form report for reporting adverse reactions to the competent authorities which is widely used (Fig. 1).

Cis-Acting Gene

Definition

In ► gene therapy, genetic elements are transferred into a patient. If the transferred gene is integrated into the patient's chromosomal DNA (► deoxyribonucleic acid) it is termed *"cis-acting"*.

Claims Data Analysis

Definition

One important methodological approach in health economics is the analysis of large routine datasets. Claims data are collected by sickness funds, public health care payer's such as the National Health Service in the United Kingdom, or private insurance companies. Claims data analysis directly reflect the health care payers' expenses (► payer's perspective) in a routine care real life setting, but they also have the disadvantages associated with retrospective study designs, such as the danger of confounding.

Classification

Definition

In statistics classification is a procedure in which individual items are placed into groups based on quantitative information on one or more variables inherent in the items and based on a training set of previously labeled items. All classification methods are solving one of three related problems: to find a map of a feature space (which is typically a multi-dimensional vector space) to a set of labels, to consider classification as an estimation problem and to estimate the class-conditional probabilities and then use Bayes' rule to produce the class probability as in the second problem. Examples of classification algorithms include: linear classifiers (Fisher's lineardiscriminant,Logistic regression, NaiveBayesclassifier, Perceptron), quadratic classifiers, k-nearest neighbor, decision trees, neural networks, Bayesian networks, etc. Statistical classification algorithms are typically used in pattern recognition systems.

Classification and Prediction Statistical Methods

C

Synonyms

Multivariate statistical methods; Multivariate statistical analysis; Multivariate data analysis; Multivariable statistics

Definition

Classification and prediction statistical methods examines the simultaneous effect of multiple variables. Traditional classification of multivariate statistical methods is based on the concept of dependency between variables. If an interest centers on the association between two sets of variables, where one set is the realization of a dependent variable (or variables) and the other set is the realization of a number of independent variables, then the appropriate class of techniques would be those designated as dependence multivariate methods. If interest centers on the mutual association across all variables with no distinction made among variable types, one uses interdependence multivariate methods. Examples of dependence multivariate methods are ► multiple regression, ► discriminant analysis, logistic regression (► logistic regression analysis), ► proportional hazards regression (Cox's regression), ► loglinear analysis, ► canonical correlation analysis, multivariate analysis of variance and covariance, path analysis, and structural equation modeling. Examples of interdependence methods include ► principal component analysis, ► factor analysis, ► cluster analysis, multidimensional scaling, and correspondence analysis.

Client Interviews

Definition

Client interviews are the process of meeting with a client to gather information. Client interviews can have many purposes such as gaining an understanding of the client's business, discussing and addressing any client concerns or service related issues, and identifying and capitalizing on opportunities to generate additional business from the client. In contrast, client surveys are the process of assessing a client's satisfaction with the service they receive. The service provider, another member of the service provider's organization, or an outside consultant can conduct a client survey in writing, by telephone, or in person.

Climate Change

Synonyms

Global climate change

Definition

Climate change refers to the variation in the Earth's global climate or in regional climates over time. These changes may come from natural processes on the Earth, from changes of external factors (such as variations in solar radiation, the earth's orbit, and emission of greenhouse gases), or may be caused by human activities. The most important anthropogenic factors are CO_2 emissions from fossil fuel combustion, aerosols, land use, ozone depletion, and deforestation. The consequences of climate change on human health are related to changes in temperature, extreme ► weather conditions, air pollution (► air quality and pollution), shortages in water and food supply, changes in the biodiversity of vectors of infectious diseases, and increased risk of traumas, injuries, and related health effects (► climate and microclimate).

Climate and Microclimate

BRANKO JAKOVLJEVIĆ
Institute of Hygiene and Medical Ecology, Faculty of Medicine, University of Belgrade, Belgrade, Serbia
bra@beotel.yu

Synonyms

Weather; Atmospheric condition; Indoor climate

Definition

Weather is the condition of the atmosphere at a certain point of time or in a short period of time. It is characterized by several meteorological elements, such as temperature, air pressure, air velocity, and air humidity, and their interactions. On the other hand, *climate* can be understood as the average state of the atmosphere and the associated characteristics of the underlying land or water in a particular region, usually spanning at least several years. The term ► microclimate can be used to describe an atmospheric zone indoors or an indoor climate, i. e. the condition of the air in a certain closed space.

Basic Characteristics

Climate Elements and Human Health

Atmospheric Pressure Atmospheric pressure is the pressure above any area in the Earth's atmosphere and is caused by the weight of air. Atmospheric pressure at sea level equals 760 mmHg (101.3 kPa or 1 atm), and it decreases with increasing altitude, by approximately 10 kPa per kilometer for the first few kilometers above the surface. Effects on humans occur due to the decrease in partial pressure of oxygen and the subsequent decrease in oxygen concentration in the blood.
Healthy persons do not usually feel smaller changes of atmospheric pressure (± 2 kPa or ± 20 mbar), but some sensitive persons experience mood changes. Up to an altitude of 2500 m, most people do not experience any problems. ► Altitude sickness or mountain sickness usually occurs at altitudes of 2500 – 3000 m,

with the following symptoms: headaches, sleeplessness, excitability, breading difficulties, regurgitation, and peripheral edema. Pulmonary edema occurs in mountain climbers exposed to extreme physical efforts and has high lethality. At higher altitudes, physiological functions are highly suppressed and loss of consciousness occurs; over 7000 m, survival is impossible.

Within an occupational setting, there is one medical condition related to extreme change of atmospheric pressure – ► caisson disease or decompression sickness. It may occur among caisson workers, miners, or professional divers when coming to the surface from atmospheric overpressure to normal pressure. This causes inert gases (mainly nitrogen), which are normally dissolved in body fluids and tissues, to come out of physical solution and form gas bubbles in blood and tissues. Symptoms are "the bends" (joint pain) in shoulders and knees, headache, visual disturbances, extreme fatigue, lack of strength, breathing difficulties ("the chokes"), and in some cases cardiovascular collapse, unconsciousness, and paralysis.

Air Temperature Individuals have their own zone of comfort regarding air temperature, which is strongly dependent on air humidity. Unprotected exposure to extremely high or low temperatures leads to certain conditions and even irreversible consequences.

Thermal comfort is a feeling of satisfaction with the indoor climate, either in an occupational or living setting. In the state of thermal comfort, the process of thermoregulation is balanced. Thermal comfort depends on all indoor climate parameters – air temperature, humidity and velocity, and heat radiation, as well as on individual characteristics, intensity of physical activity, and clothing – all of these being especially important in an occupational setting. In order to achieve thermal comfort, recommended values of microclimate parameters in an occupational setting were established. Despite differences between various countries, the recommended indoor temperature range from 20 – 24°C in winter to 23 – 26°C in summer; relative air humidity should be 40 – 65% and indoor air velocity < 0.2 m/s in winter or < 0.3 m/s in summer.

Excessive exposure to heat leads to several emergency states: ► heat cramps (caused by loss of salt from heavy sweating), ► heat exhaustion, which is a disorder of the small venous blood flow in the peripheral circulation that is caused by dehydration; this can further progress to heat stroke, the most serious of the three. ► Hyperthermia (hyperpyrexia), also referred to as heat stroke or sunstroke, is an acute condition which occurs when the body produces or absorbs more heat than it can dissipate. The process of thermoregulation is inhibited, which can cause shock, brain damage, organ failure, and even death. Symptoms include confusion, headaches, and low blood pressure, leading to possible fainting or dizziness. The skin is pale or bluish, and the subject complains of chills and trembling. Some victims, especially young children, may suffer convulsions.

Exposure to cold leads to ► frostbites – damage to the skin and underlying tissues of peripheral parts of the body (fingers, nose, and ears) due to impairment of circulation. ► Hypothermia is a medical condition in which the victim's core body temperature has dropped significantly below normal and normal metabolism begins to be impaired. Symptoms include ataxia, confusion, cold skin, gray complexion, peripheral cyanosis, shivering, tremor, weakness, and rapid breathing and heart rate, which slow and weaken as temperature decreases, leading to death.

Air Humidity Humidity is the concentration of water vapor in the air. Air humidity is strongly but inversely correlated to air temperature – with an increase of temperature, humidity decreases. When air temperature equals 20°C, air can maximally contain 17.3 g/m^3 of water – air is said to be saturated with water, and relative air humidity is 100%. Humidity of 50% means that the air contains only half of the maximum possible quantity of water vapor at a certain temperature. An optimal relative humidity of 40 – 60% is recommended indoors, similar to German standards, 30 – 65%.

Humidity that is too high hinders the thermoregulation process due to cessation of evaporation. High air humidity in combination with high ambient temperature leads to heat stroke. At that moment, the pressure of water vapor in the air becomes similar to the pressure of sweat on the skin (around 40 mmHg), so that the sweat cannot be evaporated, and it streams down the body. This is a physiologically useless process, leading to severe dehydration, but can be impaired if exposed to higher air velocity. High indoor humidity also impairs air quality, such air is usually described as "stale", or "sultry", and it stimulates fungal infestation on walls, ceilings, and floors.

Humidity that is too low leads to drying of the mucosa, impairment of pulmonary clearance and increase of electrostatic charge of some artificial fibers and materials. High air temperature in combination with low air humidity leads to dehydration and heat exhaustion.

Air Velocity As previously mentioned, air velocity is an important microclimate parameter, since it has a great influence on convection – a process involved in thermoregulation. At an air temperature of 20°C, heat dissipation is performed predominantly by heat radiation (61%), and convection (26%), and least by evaporation (13%). With a temperature increase (i. e. 36°C), convection and radiation stop and thermoregulation is maintained by evaporation. The evaporation rate reduces after a few hours, probably due to some kind of exhaustion of sweat glands, but their reactivation is possible by cleaning the body, exposure to wind, or additional physical activity. Physiologically, the parts of the body most sensitive to air spreading are the neck and lower back.

When the air temperature is high, draught occurs at stronger air velocities. However, when the temperature is low, the air cools on the cold windows and flows down the walls and along the floor, so that draught occurs even at lower air velocities.

Global Climate Change and its Public Health Importance

Today, human activities have led to alterations of the world's climate. Change in world climate influences the functioning of many ecosystems and their member species, and likewise, a great impact on human health would be expected.

One of the most disastrous consequences of human activities is the "► greenhouse effect" – a global warming effect caused by uncontrollable emission of energy-trapping gases, such as carbon dioxide (mostly from fossil fuel combustion and forest burning), methane (from irrigated agriculture, animal husbandry, and oil extraction), nitrous oxide, and various human-made halocarbons. Natural sources of these gases have a minimal influence on the occurrence of the problem, since they have been overwhelmed by emissions from human activities.

It is already well known that the global temperature on the Earth has increased by 0.6 ± 0.2°C since the first systematic meteorological measurements in 1861. The sea level has increased by 10 – 20 cm in the last century, as has the temperature of the tropical oceans. Furthermore, the snow layers on the North Pole and mountain glacial ice have decreased by 10%, and the average duration of ice layers on lakes and rivers has decreased by 14 days. Other evidence of ► climate change includes the fact that rainfalls over the North Pole have decreased by 0.5 – 1% per decade, but on the other hand have increased in subtropics latitudes, leading to devastating droughts in Africa and Asia. In the Pacific Ocean, the long-lasting and intensive temperature abnormalities have resulted in the occurrence of El Niño events, with adverse consequences on agriculture, forests, many ecosystems, and human health.

Another important issue that is not part of global climate change is stratospheric ► ozone depletion. There are, however, several recently described interactions between ozone depletion and greenhouse gas-induced warming. It is well known that depletion of the ozone layer leads to an increase in UV radiation on Earth, and, consequently, there is a significant increase in the incidence of skin cancer (melanoma and other types). However, ultraviolet radiation exposure also causes immunosuppression that, in combination with other factors, could influence patterns of infectious disease, and the occurrence and progression of various autoimmune diseases. Finally, there is a wider, ecological, dimension to consider. Since ultraviolet radiation impairs the molecular chemistry of photosynthesis both on land (terrestrial plants) and at sea (phytoplankton), this could affect world food production, and thus contribute to nutritional and health problems in food-insecure populations.

Consequences on human health cannot be easily predicted, since climatic influences on health are modulated by interactions with other ecological processes, social conditions, and adaptive policies. However, it is expected that climate change will lead to several effects:

- Temperature-related illness and death – episodes of extreme heat already pose a health threat around the world, and the Centers for Disease Control and Prevention have reported an increase in heat-related mortality rates in recent years in the United States. The populations at risk of temperature-related deaths are residents of urban areas, the elderly, young children, the poor, and people who are bedridden, on

certain medications, or who have certain underlying medical conditions;

- Extreme ► weather related health effects – direct health impacts of extreme weather events such as hurricanes and floods are injuries and deaths, but indirect impacts occur as a consequence of changes in ecosystems and/or changes in public health infrastructures – such as the availability of food, safe drinking water, and other hygienic issues such as waste disposition, insect and rodent invasion, unavailability of medical help, etc.;
- Air pollution-related health effects – climate change affects exposure to air pollutants by affecting weather and pollution concentrations; affecting both natural sources and human-caused emissions; and changing the distribution and types of airborne allergens;
- Vector-borne and rodent-borne diseases – global warming will affect the abundance and distribution of disease vectors. Some vector populations may expand into new geographic areas, such as malaria, dengue, plague, and viruses causing encephalitic syndromes;
- Effects of food and water shortages – climate change will affect food systems in several ways – a direct effect will be lower crop production, due to changes in rainfall leading to drought or flooding, or warmer or cooler temperatures leading to changes in the length of growing season; an indirect effect will be changes in markets, food prices, and supply chain infrastructure.

The analysis and forecasts made by the World Health Organization suggest that climate change will bring some health benefits, such as lower cold-related mortality and greater crop yields in temperate zones, but these will be greatly outweighed by increased rates of infectious diseases and malnutrition concentrated in poorer populations in tropical/subtropical countries where the most sensitive climate-related health outcomes (diarrhea, malaria, and malnutrition) are already common and where vulnerability to climate effects is greater. This means that Africa, with the lowest emission of greenhouse gases, could suffer the greatest health impact.

It is, however, possible that our predictions are too much terrifying. One must take into consideration the possible adaptation of humans and other ecological systems, which will moderate harmful consequences. From the public health point of view, health impacts will be strongly influenced by local environmental conditions and socio-economic circumstances, as well as by social, institutional, technological, and behavioral adaptations taken to reduce the full range of threats to health.

Clinical Epidemiology

TATJANA PEKMEZOVIĆ
Institute of Epidemiology, School of Medicine, University of Belgrade, Belgrade, Serbia
pekmezovic@sezampro.yu

Definition

The term clinical epidemiology is derived from its two parent disciplines: clinical medicine and epidemiology. In general, it could be defined as the application of the logical and quantitative concepts and methods of epidemiology to the practice of clinical medicine (Fletcher et al. 1996). Sackett et al. state that clinical epidemiology is "a basic science of clinical medicine" (Sackett et al. 1991).

Basic Characteristics

The main objective of clinical epidemiology is to develop and apply methods of clinical observation that will lead to the making of correct decisions about the care of patients. Fletcher et al. pointed out that clinical medicine and epidemiology began together, and that the founders of epidemiology were mainly clinicians (Fletcher et al. 1996).

Scope of Clinical Epidemiology

There are many questions addressed by clinical epidemiology: Is the patient sick or well? How accurate are the tests used to diagnose disease? How does treatment change the course of disease? How much will care cost? Keeping in mind these questions, the main scope of clinical epidemiology comprises definitions of normality and abnormality, accuracy of diagnostic tests, prognosis, treatment results, prevention in clinical practice, cost analysis, etc. (Sackett et al. 1991).

The clinical events of primary interest in clinical epidemiology are the different health outcomes, known as the five Ds: disease, death, disability, discomfort, and dissatisfaction. They are the events that clinicians try to understand, predict, interpret and change (Fletcher et al. 1996).

Normality vs. Abnormality

The first priority in any clinical consultation is to determine whether the patient's symptoms, signs or diagnostic test results are normal or abnormal. This is necessary before further action can be taken. It would be easy if there were always a clear distinction between the frequency distributions of observations on normal and abnormal people. This is very rarely, except in genetic disorders, determined by a single dominant gene.
Three types of criteria have been used to help clinicians make practical decisions:

a) Normal as common (the criterion usually used in clinical practice is to consider frequently occurring values as normal and those occurring infrequently as abnormal).
b) Abnormality associated with disease (the criterion is based on the distribution of observations for both healthy and affected people, and attempts to define a cut-off point that clearly separates the two groups).
c) Abnormal as treatable (the criterion is based on evidence from randomized controlled trials, which indicate the level which treatment does more good than harm).

Accuracy of Diagnostic Tests

The first objective in a clinical situation is to diagnose disease, i. e. the purpose of diagnostic testing is to help in confirming possible diagnoses suggested by, for example, demographic characteristics and clinical symptoms. A disease may be either present or absent and a test result either positive or negative. In two of these combinations a test will have given correct answers (true positive and true negative). On the other hand, the test has been misleading if it is positive when the disease is absent (false positive) or negative when the disease present (false negative) (Fletcher et al. 1996).
Of particular importance are a test's sensitivity and specificity, as well as positive and negative predictive values. ► Sensitivity is defined as the proportion of

patients with the disease who have a positive test for the disease. ► Specificity is the proportion of patients without the disease who have a negative test. All diagnostic tests must be compared to a ► gold standard for the disease. It is an ideal test when both sensitivity and specificity are 100%. Some typical gold standards include blood culture for bacteremia, biopsy for tumors, etc. ► Positive predictive value is the probability of disease in a patient with abnormal test results. ► Negative predictive value is the probability of a patient not having a disease when the test result is negative. Predictive value of a test is determined by both sensitivity and specificity, as well as by prevalence of disease in population being tested (Mayer 2004).

Natural History and Prognosis

The term ► natural history refers to stages of a disease, which include pathological onset, presymptomatic stage (from the onset of pathological changes to the first appearance of symptoms or signs), and finally, the stage when disease is clinically obvious. In other words, natural history is the evolution of disease without medical and paramedical interventions. Detection and treatment at any stage can alter the natural history of the disease.
► Prognosis is the prediction of the course of disease and is expressed as probability that a particular event will occur in the future. Knowledge of the likely prognosis is helpful in determining the most useful treatment. Prognosis of disease can be express as case fatality ratio (for acute diseases), and survival rate (or probability) (for chronic diseases). Characteristics that relate to the likelihood of survival are referred to as favorable and unfavorable prognostic factors. (Greenberg et al. 2004).

Treatment

An important question in clinical epidemiology is how treatment changes the course of disease. Usually, the effects of treatment are less obvious and most interventions require research to establish their effects. In this situation randomized controlled trial is the method of choice for measuring efficacy and effectiveness. ► Efficacy addresses the extent to which the intervention produces its effect under ideal conditions. ► Effectiveness addresses the extent to which the intervention produces its intended effect in a real-word setting. Finally, ► efficiency reflects a situation in which resources used to provide a specific intervention of known efficacy and effectiveness are minimized (van Gijin, Vermeulen 2001).

Clinical Decision Making

Recently, methods for quantitative decision making have been introduced in medicine. The most commonly used strategies include decision analysis, cost effectiveness analysis, and cost benefit analysis. These methods explicitly define important factors in decision making and the consequences; probabilities are assigned to events and numbers to value judgments, such as quality of life.
In ► decision analysis, "one sets out alternative courses of action and then calculates which choice is likely to result in the most valued outcome, based on estimates of probability for each branch in the sequences of events and judgments about the relative value of the possible outcomes" (Fletcher et al. 1996). The basic steps in decision analysis are: a) creation of a decision tree, b) assignment of probabilities to chance nodes, c) assignment of utilities to the outcomes, d) calculation of the expected utilities, e) selection of choice, and f) sensitivity analysis.
A ► cost-effectiveness analysis is a method of evaluation in which cost (i. e. inputs) and consequences (i. e. outputs) of treatment or a health care program are systematically assessed, with the aim of assigning explicit values to new and existing technologies and health care programs and to improve resource allocation. In ► cost-benefit analysis, both cost and benefits of alternative options of action are expressed in terms of money (Gold et al. 1996).

Clinical Guideline

Synonyms

Clinical practice guideline; Medical guideline

Definition

A clinical guideline is a document to guide decisions in specific areas of health care. They briefly identify and summarize the most current data about prevention, diagnosis and therapy of particular diseases and define all relevant decision options with their respective health outcomes including a risk-benefit and cost analysis. By helping health professionals in deciding which treatment to use, guidelines aim to improve the quality of care delivered as well as to standardize medical care, to reduce risks and to enhance ► cost-efficiency. This approach to decision making by using clinical guidelines entered the medical world in 1990. In almost all developed health care systems clinical guidelines are produced at a national or international level by medical associations or governmental bodies, based on the current state of knowledge and clinical experience. Many countries have a clearinghouse for clinical guidelines that maintains a reference catalog of all the high quality guidelines published by the different organizations.

Clinical Informatics

Definition

Clinical informatics is a branch of ► medical informatics. Clinical informatics use the methods of medical informatics to support the management of patients using an interdisciplinary approach, including clinical and information sciences.

Clinical Information

► Medical Information

Clinical Knowledge

► Medical Knowledge

Clinical Pathways

Synonyms

Critical pathways; Integrated care pathways

Definition

Clinical pathways systematically plan and follow up an integrated care program focussed on patients. Clinical pathways have entered the medical world in the 1990s during the introduction of the concept of ► integrated health care. They are designed to provide a standard treatment protocol in postoperative management with the aim to enhance the quality of care and optimize the use of resources. The definition of clinical pathways includes explicit statements of the key elements of care based on evidence, best practice of a multidisciplinary care team and patient expectations.

Clinical Practice Guideline

► Clinical Guideline

Clinical Protocol

► Treatment Protocol

Clinical Relevance

► Statistical vs. Clinical Significance

Clinical Research

► Health Research
► Health Research and Indigenous Health

Clinical Studies

Synonyms

Clinical trials; Medical research

Definition

A clinical trial is a type of research which studies diagnostic, preventive or therapeutic measures in large groups of people, designed to demonstrate a specific generalizable response against a background of individual biological variation (for example, new vaccines and medicinal drugs, before being approved for general use, must be tested on human subjects).

Cross-References

► Clinical Trials

Clinical Trials

Synonyms

Clinical studies; Medical research

Definition

A clinical trial is a type of research study. The most commonly performed clinical trials evaluate new drugs, medical devices, biologicals or other interventions on patients in strictly scientifically controlled settings, and are required for regulatory authority approval of new therapies. Trials may be designed to assess the safety and efficacy of an experimental therapy, to assess whether the new intervention is better than standard therapy, or to compare the efficacy of two standard or marketed interventions. The trial objectives and design are usually documented in a clinical trial protocol.

Cross-References

► Clinical Studies

Clinical Trials, Register

Definition

In September 2004, the members of the International Committee of Medical Journal Editors (ICMJE) published a joint editorial aimed at promoting registration of all clinical trials. Since 2005, a trial can only be considered for publication if it has been registered before enrollment of the first patient. The purpose of a clinical trials registry is to promote the public good by ensuring that everyone can find key information about every clinical trial, and it has the principal aim of shaping medical decision-making.

Clonogenic

► Clonogenicity

Clonogenicity

Synonyms

Clonogenic

Definition

Clonogenicity refers to the stem cell's characteristic of self-renewal. By replicating itself, a single stem cell can give rise to a colony of genetically identical cells. The confirmation of a cell's clonogenicity is generally assumed to be the verification of its stemness. In this respect, clonogenicity is a cell's property and does not refer to artificial genetic or cloning manufacturing.

Clostridium botulinum Infection

Synonyms

Botulism; Botox-Infection

Definition

The anaerob, spore-building bacterium *Clostridium botulinum* produces a dangerous toxin called botulintoxin or just botulin. Only 0,1µg of botulin is lethal. *Clostridium botulinum* can be found in decayed food, most often in cans which appear blown out. Spores of the bacterium can also be present in honey. After ingestion these spores are activated in the bowel. As the spores can be very dangerous for babies, honey should not be fed during the first year of life. Due to the fact that botulism is an intoxication, the infection cannot be transmitted from one individual to another. The toxin leads to paralyses of muscles; if the course is severe and the cardiac muscle and the breathing muscles are concerned, the outcome may be lethal. As long as the toxin is circulating freely in the blood stream, it can be neutralized by antitoxins.

Clostridium perfringens Infection, Enteral

Synonyms

Food intoxication by *Clostridium perfringens*; Food poisoning by *Clostridium perfringens*; Enteritis necroticans

Definition

Clostridium perfringens is an anaerobic, spore-building bacterium, which can be present in the soil, in water, dust, food or in the intestines of humans and animals. Food at risk of contamination is heated meat, oysters and other seafood. *Clostridium perfringens* produces toxins (exotoxins) of the serotypes A, B, C, D and E. Serotype C causes food poisoning, which is also called enteritis necroticans. The symptoms are stomach ache, nausea, vomiting and diarrhea. In most cases the course of the intoxication is moderate, with the symptoms vanishing within 24–48 hours.

Clothing Lice

► Body lice

Cluster Analysis

Definition

A cluster analysis (CA) is a multivariate unsupervised learning statistical technique that divides units of observations into similar groups, i. e. determines a classification or taxonomy from multiple measures of a set of objects or subjects. In CA, as opposed to other classification techniques (e. g., ► discriminant analysis or ► logistic regression analysis), groups are not *a priori* defined. CA is an exploratory data analysis tool that aims to sort different objects or subjects into groups in a way that the degree of association between two objects is maximal if they belong to the same group and minimal otherwise. Given the above, CA can be used to discover structures in data without providing an explanation/interpretation. For example, the clustering of different signs and symptoms of diseases is done before a meaningful description of the differences between diseases is possible. Specific types of cluster analysis methods are Joining (Tree Clustering), Two-way Joining (Block Clustering), and K-means Clustering. The purpose of Tree Clustering is to join objects into successively larger clusters using some measure of similarity or distance. In Block Clustering, both cases and variables are joined together with the expectation that they both simultaneously contribute to the uncovering of meaningful patterns of clusters. The method of K-means Clustering, in contrast to the previous two methods, starts with a fixed number of (desired or hypothesized) *k* clusters, and its aim is to assign observations to those clusters so that the means across clusters (for all variables) are as different from each other as possible.

Cluster-Forming Cocci

► *Staphylococcus aureus*

Clustering Algorithms

Definition

An algorithm that groups genes that have similar expression profiles together and produces a cladogram for similarity. Often, genes that occur in the same clus-

ter are inferred to behave similarly, whether functionally or being controlled by similar processes.

Cochrane, Archibald

Definition

Professor Archibald Leman Cochrane (1908–1988) was born in Kirklands, Galashiels, Scotland. He qualified in 1938 at University College Hospital, London, and joined the Medical Research Council's Pneumoconiosis Unit at Llandough Hospital, a part of Cardiff University School of Medicine, in 1948. Here he began a series of studies on the health of the population of Rhondda Fach – studies which pioneered the use of randomized controlled trials (RCTs). His ideas eventually led to the development of the Cochrane Library database of systematic reviews, the establishment of the UK Cochrane Centre in Oxford, and the international Cochrane Collaboration.

Cochrane Central Register of Controlled Trials (CCTR or CENTRAL)

Definition

The CCTR (formerly Cochrane Controlled Trials Register) is a bibliographic database of definitive controlled trials. These controlled trials have been identified by the distinguished contributors to the Cochrane Collaboration. They and others, as part of an international effort to search the world's health care journals (and other sources of information) systematically, have combined results to create an unbiased source of data for systematic reviews. Because it has been shown that existing bibliographic databases are inadequate for the identification of all relevant studies, the Cochrane Collaboration embarked upon this formidable task in cooperation with the National Library of Medicine (NLM) in Washington, DC (USA) who produce MEDLINE, and Elsevier (Amsterdam, the Netherlands) who produce EMBASE. The CCTR contains over 300,000 bibliographic references to controlled trials in health care.

Cochrane Collaboration

Synonyms

Database of systematic reviews; Cochrane library

Definition

The Cochrane Collaboration is an international, independent, non-profit organization, dedicated to making up-to-date, accurate information about the effects of healthcare readily available worldwide. It produces and disseminates ► systematic reviews of healthcare interventions, and promotes the search for evidence in the form of clinical trials and other studies of interventions. The Cochrane Collaboration was founded in 1993 and named for the British epidemiologist, Professor Archibald Leman Cochrane.

Cochrane Database of Methodology Reviews (CDMR)

Definition

The broad intention of the CDMR is to include all published reports of empirical studies of methods used in reviews, as well as methodological studies that are directly relevant to reviews, such as empirical studies of the association between research methods and bias in randomized controlled trials. Details of ongoing methodological research are also included, together with books, conference proceedings, and special journal issues devoted to the topic of ► systematic reviews and ► meta-analysis.

Cochrane Database of Systematic Reviews

Definition

The Cochrane Database of Systematic Reviews includes the full text of the regularly updated systematic reviews of the effects of healthcare prepared by the Cochrane Collaboration. The reviews are presented in two forms: complete reviews (regularly updated Cochrane Reviews, prepared and maintained by Collaborative Review Groups) and Protocols (Protocols for reviews currently being prepared. Protocols are

the background, objectives, and methods of reviews in preparation). The database is produced by the Cochrane Collaboration – an international network of individuals and institutions committed to preparing, maintaining, and disseminating systematic reviews of the effects of health care. In pursuing its aims, the Cochrane Collaboration is guided by six principles: collaboration, building on people's existing enthusiasm and interests, minimizing duplication of effort, avoidance of bias, keeping up-to-date, and ensuring access.

Cochrane Library

Synonyms

Database of systematic reviews; Evidence based medicine database

Definition

The Cochrane Library consists of a regularly updated collection of EBM databases, including The Cochrane Database of Systematic Reviews – the major product of the Collaboration, which is published quarterly. Cochrane Review Groups are composed of healthcare professionals from around the world who share an interest in developing and maintaining systematic reviews relevant to a particular health area.

The major bibliographic databases cover less than half the world's literature and are biased towards English language publications. Of the evidence available in the major databases, only a fraction can be found by the average searcher. Textbooks, editorials, and reviews which have not been prepared systematically may be unreliable. Much evidence is unpublished, but unpublished evidence may be important. More easily accessible research reports tend to exaggerate the benefits of interventions. The Cochrane Library solves many of these problems and is published on a quarterly basis. Databases included in The Cochrane Library are The ► cochrane database of systematic reviews (as described above), The ► database of abstracts of reviews of effects, The ► cochrane central register of controlled trials (CENTRAL), The ► cochrane methodology register, The ► NHS economic evaluation database, The Health Technology Assessment Database and The ► cochrane database of methodology reviews (CDMR).

Cross-References

► Cochrane Collaboration

Cochrane Methodology Register

► Cochrane Database of Methodology Reviews (CDMR).

Cochrane Review Groups

Definition

Review Groups are composed of persons from around the world who share an interest in developing and maintaining systematic reviews relevant to a particular health area. Groups are coordinated by an editorial team who edit and assemble completed reviews into modules for inclusion in The Cochrane Library.

Cochran's Q Test

Definition

A nonparametric test examining change in a dichotomous variable across more than two observations.

Code of Conduct

Definition

The "Code of Conduct for medical and health web sites" is a voluntary code of conduct developed by an international organization, HON ("Health On the Net"). The owners of medical and health-related websites who sign this code are obliged to follow some basic guidelines for the distribution of reliable ► medical information.

Coded Data

Definition

An individual is given a number and all that individual's data is encoded under that number so that the individual cannot be recognized. Data are then collated, analyzed and reported on without the specific individual being

identified. Usually there is only one person who can link the code to the person to whom the data belongs. This system is used to keep a high level of ► confidentiality.

Code of Ethics

Definition

A code of ethics clarifies the ► ethical principles that are followed in a specific field. In this context we refer to the *Code of Ethics for Public Health*, formally adopted by the American Public Health Association in 2002. It is the first broadly accepted document of its kind. It lists the 12 principles of the ethical practice of public health, 11 values which inspired the principles, and includes some notes to better understand them. The code is not meant to provide clear solutions to convoluted ethical issues. It does, however, provide a list of values (► ethical values) and principles that should be considered in discussions and it makes clear to populations and communities the ideals of the public health institutions that serve them.

Coding Sheet

Definition

The coding sheet is used to collect information from the primary research reports. Information about primary research included on research synthesis coding sheets can be classified into seven categories: *1) Report identification*: in this part, the synthesist retrieves information concerning the background characteristics of the research report itself. *2) Setting of the study*: place were the study was conducted. *3) Subjects*: characteristics of the participants included in the primary research. *4) Methodology*: in this part, the synthesist retrieves information concerning study design used in the primary research. *5) Treatment characteristics*: the synthesist will need to describe carefully the details of how the independent variables were manipulated or measured. *6) Statistical outcomes or effect sizes*: relevant outcomes should be retrieved, which should be measured to determine ► effectiveness. *7) Coding process*: the coding sheet should be standardized to accommodate information about the main comparison of interest.

Co-Existing Diseases

Synonyms

Co-morbidities

Definition

Co-morbidities in medicine describe all other diseases or disorders of an individual suffering from one primary disease. Co-morbidities are in this sense all illnesses associated with the primary illness. Hypertension is for example a co-morbidity of many primary conditions such as diabetes, ischemic heart disease, and end-stage renal disease.

Cross-References

► Co-morbidity

Cognitive Development

Synonyms

Cognitive transition; Cognitive maturation

Definition

Cognitive development during childhood and adolescence includes the development of increased knowledge, multi-dimensional thinking, and the ability for hypothetical reasoning (in adolescents).

Cognitive Learning Theory

► Cognitive Social Learning
► Social Learning Theory

Cognitive Maturation

► Cognitive Development

Cognitive Pre-Testing

Definition

A cognitive pre-test is a qualitative research method used to improve the validity of survey questions before

field work. Cognitive pre-testing comprises different techniques to test the comprehensibility of questions designed to translate scientific concepts into the everyday language of the respondents. For this purpose, the respondents can be prompted to explain (by probing), circumscribe (by paraphrasing) or discuss (e. g. in focus groups) their interpretation of the questionnaire content. In contrast to standard pre-testing, cognitive pretests are not conducted under field conditions but in more or less experimental settings. The results lead to an improved wording of questions and thereby to more valid and/or precise measurements. In cross-cultural surveys (e. g. international or migrant surveys), cognitive pre-testing can also be applied to evaluate the translation of questionnaires from source to target languages.

Cognitive Social Learning

Synonyms

Cognitive learning theory

Definition

Cognitive social-learning theory proposes that reinforcements are not the sole determinants of behavior, but that behavior changes with observation of others. According to the cognitive social-learning theory, the most important prerequisite for behavior change is a person's sense of self-efficacy or the conviction that one is able successfully to execute the behavior required to produce the desired outcome.

Cross-References

► Social Learning Theory

Cognitive Transition

► Cognitive Development

Cohort

Definition

A cohort (from the Latin *cohors*, plural *cohorts;* large military unit) is a group of people from a given population who share a common characteristic or experience within a defined time period (e. g., are born, leave school, are exposed to a drug or a vaccine, etc.). For example, a group of people who were born in the year 1970 would form a birth cohort.
A prospective cohort study often tracks a cohort over an extended period of time.

Cohort Studies

Synonyms

Observational studies

Definition

A cohort study is a form of longitudinal study used in medicine and social science.
In medicine, a cohort study is usually undertaken to obtain additional evidence to refute or support the existence of an association between a suspected cause and disease. The cohorts are identified prior to the appearance of the disease under investigation. The study groups, so defined, are observed over a period of time to determine the frequency of disease among them. The main characteristic is that the study proceeds from cause to effect. A cohort is a group of people who share a common characteristic or experience within a defined time period (e. g. are born, lose their job, or are exposed to a drug or a vaccine, etc.).

Co-Insurance Rate

Definition

Co-insurance refers to the share of total medical spending which is borne by the beneficiary of health insurance. The higher the co-insurance rate, the lower the incentive problems due to ► moral hazard – and the higher the financial risk to the beneficiary of health insurance.

Collaborative Initiatives

► Governmental Regulations

Collective Bargaining Autonomy

► Tariff Autonomy

Collinearity

Definition

Collinearity is a high level of correlation within the set of explanatory variables and is of special note in the regression modeling situation. The collinearity (multicollinearity) existence affects the independence of explanatory variables, and the precision of regression coefficients estimates, as well. With multicollinearity, the regression coefficient does not reflect any underlying effect of the variable on outcome, but rather a marginal effect that depends on what other variables are included in the model. The identification of collinearity could be done by computation of the variance inflation factor, by noting extremely large variance of the regression coefficient estimate, and by substantial difference between coefficient estimates from fitting simple and a multiple regression models.

Colonization

Synonyms

Settlement

Definition

Colonization represents establishment of political control by one country over another. It also may be defined as a settlement in a new country, formed by certain ethnic group, which is either fully or partly subject to the state from which the settlers emigrated.

Colonization of Microorganisms

► Presence of Microorganisms

Combination Vaccination

Synonyms

Combined immunization; Combined vaccination

Definition

Immunization can be achieved by administering single ► vaccines – known as monovalent – or by a combination of different vaccines. Living vaccines may be administered simultaneously without compromising the success of the immunization. When living vaccines are given over time, it is necessary to adhere to minimum time intervals. The advantage of combined vaccinations – particularly in the case of basic immunization – is that the number of injections is kept to a minimum, which increases its acceptance by the public. The implementation of vaccination programs is greatly facilitated by the availability of combination vaccinations, especially in developing countries. The most common combination vaccinations are the measles-mumps-rubella (MMR) vaccine, the combination of diphtheria and tetanus vaccines (TD or Td), and the 6-fold combination of vaccines, most commonly administered to infants, against tetanus, diphtheria, polio, pertussis (whooping cough), *Haemophilus influenza* B and hepatitis B.

Commercial Regulation

► Legal Regulation of Professions, Businesses, and Products

Commitment

► Health Promotion Engagement
► Participation

Common Risk/Health Factor Approach

Definition

An approach that can be characterized by not being focused on a single disease but on the improvement

of health conditions for the whole population. A variety of common chronic diseases including oral diseases have risk and health factors in common. An example is smoking that affects heart disease, cancer and oral diseases. On the other hand, a healthy diet promotes both general and oral health.

Common Source Outbreak

Definition

This type of epidemic occurs when many people are suddenly exposed to the same source of infection, leading to a clear increase in the incidence of disease. The outbreak can be due to a point source, where people are exposed to the same source over a relatively brief period of time, so that all cases occur within one ► incubation period. This is the typical pattern of an outbreak of food poisoning. If the duration of exposure is prolonged (over a period of days, weeks, or longer), the epidemic is called a "continuous common source epidemic", and the epidemic curve will have a plateau instead of a peak.

Communal and Industrial Waste

GORICA SBUTEGA-MILOŠEVIĆ, JELENA ILIC
Institute of Hygiene and Medical Ecology, Faculty of Medicine, University of Belgrade, Belgrade, Serbia
sbutege@drenik.net, jelenil@yahoo.com

Synonyms

Waste management; Recycling; Composting; Disposal in landfills; Waste combustion; Rubbish; Trash; Garbage

Definition

Waste is something that is left over or that it is no longer needed, unwanted or undesired material which has lost its apparent value to its owner.

Waste is defined by the Environment Protection Act 1970 as any matter prescribed to be waste and any matter, whether liquid, solid, gaseous, or radioactive, which is discharged, emitted, or deposited in the environment in such volume or manner as to cause an alteration of the environment.

Basic Characteristics

Population growth, urbanization and industrialization result in the formation and accumulation of various types of wastes. Americans generate almost 208 million tons of solid waste each year. Today, each one of us generates about 4.3 pounds (2 kg) of waste per day. Although many different methods of disposing of garbage have been developed, there is really no absolutely safe way to do the job.

Waste can cause pollution and impact upon our environment if not properly managed. ► Disposing of waste that cannot be otherwise avoided, reused or recycled (► recycling) also represents a waste of resources, a lost opportunity and is a waste of money.

Now that the problem of illegal waste disposal, such as illegal dumping, is becoming more and more serious, the achievement of appropriate disposal is beyond the reach of a single local government.

As our social economic activities become more and more characterized by mass-production, mass-consumption and mass-disposal, the increased volume and diversification of wastes being disposed of raised the nation's concern about the burden they exert on the environment and the environmental ► pollution relating to landfill wastes.

Waste can be divided into many different types. The most common methods of classification is by their *physical, chemical* and *biological* characteristics. One important classification is by their *consistency*.

Solid wastes are waste materials that contain less than 70% water. This class includes such materials as household garbage, some industrial wastes, some mining wastes, and oilfield wastes such as drill cuttings.

Liquid wastes are usually wastewaters that contain less than 1% solids. Such wastes may contain high concentrations of dissolved salts and metals.

Sludge is a class of waste between liquid and solid. Such wastes usually contain between 3% and 25% solids, while the rest of the material is water dissolved materials.

Federal regulations classify wastes into three different categories. *Non-hazardous* are those that pose no immediate threat to human health and the environment.

Household garbage is included into this category. *Hazardous* wastes are of two types: those that have common hazardous properties such as ignitability or reactivity and those that contain liquid toxic components. The last type of waste is entitled *Special Wastes* and is very specific in nature. They are regulated by specific guidelines. Some examples would be ► radioactive wastes and ► medical wastes.

Commercial and institutional, or industrial, waste is often a significant portion of municipal solid waste, even in small cities and suburbs. In contrast to most residential waste, commercial material is usually collected by the private sector, and municipalities have been slow to target this area of recovery.

Across the country, many communities, businesses, and individuals have found creative ways to reduce and better manage Municipal Solid Waste (MSW) – more commonly known as trash or garbage – through a coordinated mix of practices that include source reduction, recycling (including ► composting), and disposal. The most environmentally sound management of MSW is achieved when these approaches are implemented according to the EPA's preferred order: source reduction first, recycling and composting second, and disposal in ► landfills or waste combustors last.

Nearly everything we do leaves behind some kind of waste. Households create ordinary garbage. Industrial and manufacturing processes create solid and hazardous waste. The Office of Solid Waste (OSW) regulates all this waste under the Resource Conservation and Recovery Act (RCRA).

RCRA's goals are to:

1. Protect us from the hazards of waste disposal
2. Conserve energy and natural resources by recycling and recovery
3. Reduce or eliminate waste, and
4. Clean up waste, which may have spilled, leaked, or been improperly disposed of.

Hazardous waste comes in many shapes and forms. Chemical, metal, and furniture manufacturing are some examples of processes that create hazardous waste. RCRA tightly regulates all hazardous waste from "cradle to grave." RCRA also controls garbage and industrial waste. Common garbage is municipal waste, which consists mainly of paper, yard trimmings, glass, and other materials. Industrial waste is process waste that comes from a broad range of operations. Some wastes are managed by other federal agencies or state laws. Examples of such wastes are animal waste, radioactive waste, and medical waste.

► Waste management has become a constant preoccupation, as it occurs throughout the living environment and affects public health. Households, business centers, industries, etc., are all confronted with waste problems. Many countries all over the world in their various departments of waste management and environmental protection prepare projects and ecological surveys on communal and industrial waste yards, report on their influence on the environment, work out methods of safe storage and transport of waste (including dangerous ones), and prepare feasibility studies for infrastructure investment.

Current laws direct polluters and municipalities on the proper methods of waste disposal. Responsible authorities are requested to set up management schemes adapted to given field conditions.

Communicable Diseases

Synonyms

Contagious diseases; Infectious diseases; Transmissible diseases

Definition

Communicable diseases are diseases caused by biological agents (e. g. bacterium, virus, parasite) that can be communicated from an infected person or animal to another person or animal, meaning that they can easily spread through direct or indirect contact. Direct contact means person-to-person or animal-to-person contact or close proximity. Indirect contact includes shared use of contaminated instruments or materials. Communicable diseases may be controlled through the use of protective measures against the many ways of transmission. These measures include isolation of patients with certain diseases, use of antisepsis, vaccination, safe water and food supply, sterile blood supply, waste disposal and education of the population.

Communicable Diseases Control Law

► Infectious Diseases Control Law

Communication

Synonyms

Transmission; Transfer; Expression; Contact

Definition

Communication represents the exchange of thoughts, messages, or information by speech, signals, writing, or behavior. The act of communicating may be direct and face-to-face (interpersonal communication) or indirect and at a distance, using technical means such as television, radio, cinema, books, newspapers, or magazines (mass communication). The aim may be to inform someone, or to warn, persuade, or give pleasure with immediate effect. Communication also may be used for long term purposes, such as the maintenance of cultural identity. Usually we think of communication as intentional process. However, it may occur unintentionally and be as important. For example, sweating may be a sign of embarrassment, fear, or simply being overheated. Interpretation depends on the context in which information is produced and received. The central role that communication plays in all human life is indicated by the fact that it is a major area of interest in psychology, sociology, anthropology, linguistics, and several other disciplines.

Communitarians

Definition

Different approaches guide public health stakeholders in dealing with ethical dilemmas. Communitarians are those who would stress social order and social connectedness where individuals are parts of a community. A basic question for communitarians is who decides what is good for that community. One view is that every community defines its own norms which should, then, be respected. Things become complex when we try to define “community”, since, at times, the term refers to the majority within a group, leaving behind the interests of the minority groups.

Community

Definition

A “community” may be a town or county in sparsely populated areas; or it may be a neighborhood, worksite, or school in more populous metropolitan areas. It can also apply to groups of people not sharing a specific geographic association, but sharing social, cultural,

political, or economic interests that link them together. Community represents, ideally, a level of collective decision making appropriate to the urgency and magnitude of a health-related issue, the cost and complexity of the solutions implied, the local culture and traditions of shared decision making, and the sensitivity and consequences of the actions required of people after the decision is made.

Community Based Rehabilitation

GERNOT LENZ
Forschungsverbund Public Health Sachsen-Sachsen Anhalt e. V., Medizinische Fakultät, Technische Universität, Dresden, Germany
gernot.lenz@gmx.de

Definition

According to a Joint Position Paper of the International Labour Organization, the United Nations Educational, Scientific and Cultural Organization and the World Health Organization, "Community based rehabilitation (CBR) is a strategy within general community development for the rehabilitation, equalization of opportunities and social inclusion of all people with disabilities. CBR is implemented through the combined efforts of people with disabilities themselves, their families, organizations and communities, and the relevant governmental and non-governmental health, education, vocational, social and other services." This is a multisectoral approach which comprises all governmental and non-governmental services that provide assistance to communities.

Basic Characteristics

Initiation of CRB

As stated by the WHO, there are about 600 million people in the world with disabilities of various types and degrees. It is estimated that 80% of those disabled people live in low income countries with the majority of the disabled people being poor. One of the greatest challenges of disabled people therefore is basic survival, especially for those who live in low-income countries and suffer severe and multiple disabilities. In consequence of the declaration of Alma-Ata in 1978, it was realized that there is a need for and benefit of an emphasis shift from primarily city-based institutions to the community. Although there already existed different forms of non-institutional rehabilitation, CBR gained its formal recognition and acceptance with the promotion by the World Health Organization and other UN agencies in the early eighties. CBR was promoted as a suitable method to rehabilitate disabled people living in rural areas in developing countries, who so far had had no access to the relevant services. The emphasis was on evolving a method that would provide wide coverage, at costs that were affordable to the governments of these countries.

CBR Evolution

In its early days, CBR was conceptualized primarily as a service delivery method with a medical focus, since WHO had recommended that it should be integrated into a primary health care system that was already well established in many developing countries. Early CBR programs therefore tended to focus on prevention of impairments and restoring functional ability in disabled individuals in order to fit them into their community. During the eighties and nineties the number of CBR programs in various developing countries grew significantly mainly funded by international donors. A large share of these programs were minor projects with only limited overall impact. Most of these micro projects, therefore, could not be replicated or grow into viable national programs. With the growing number of CBR programs, the way of conceptualizing those programs changed. Based on the realization that medical interventions alone did not complete the rehabilitation process, one of the first changes that was implemented was the shift from a mere medical focus to a more comprehensive approach. This resulted in CBR programs also addressing comprehensive interventions such as education, social rehabilitation and prevention (► prevention and health promotion). It was recognized that people with ► disability should have access to all services which are available to other people in the community, such as community health services, child health programs, social welfare and education. Besides the shift towards a comprehensive approach, it was furthermore realized that rehabilitation should not be limited to restoring the ► functional ability in an individual but instead addressing and changing community atti-

tudes and contextual factors. This was in line with the realization that CBR also should not exclusively focus on rehabilitation but include different issues related to disabled people's lives at all times. All those changes were reflected in the definition of CBR as published in the Joint Position Paper of WHO, ILO and UNESCO. A result of these changes is the growing number of organizations of people with disability in many developing countries that covered, for example, areas like service provision, information dissemination and advocacy. Several of those organizations have been lobbying with governments to push legislation to not only protect their rights but also effect changes in existing laws to prevent discrimination against disabled people.

The following points summarize the evolution of the CBR concept:

- As all communities are different due to socio-economic conditions, terrain, culture and political systems, there will never be one model of CBR that is applicable cross-nation wide.
- CBR is an integral part of the community development and aims at empowering the whole community. This approach is crucial for establishing successful and sustainable CBR programs.
- CBR has shifted its focus from ► medical rehabilitation towards a more comprehensive approach that covers multiple sectors. Another shift was the change from a focus on service delivery to managerial issues influencing both service effectiveness and service quality.
- CBR can be a means to enforce the human rights and equal opportunities of people with disabilities as stated in intentional legal instruments.

CBR Programs

CBR programs target primarily at the improvement of the quality of life of people with disabilities. Within the CBR program activities, one focus is put on working together with the community. This should result in positive attitudes towards people with disabilities and thus motivate community members to support and participate in CBR activities. It is important for the success of these programs, that people with disabilities are part of the programs from the start which includes both initial program design and subsequent implementation. It has to be ensured that disabled people involved in the CBR programs have distinct decision-making roles that highlight their importance for the program. It is highly recommended that CBR programs are as flexible as possible to ensure that they can successfully operate at the local level. These flexible, local programs ensure the involvement of the community and generate different program models that are appropriate for diverse situations. The components of a CBR program should include:

- Ways of creating a positive attitude towards people with disabilities to ensure equalization of opportunities within their own community.
- Provision of functional rehabilitation services to overcome or minimize the effects of the disabilities.
- Provision of education and training opportunities to enable people with disabilities to make the best use of the opportunities that occur in their lives.
- Ways of creating micro and macro income-generating opportunities including obtaining financial credit through existing systems, wherever possible.
- Provision of care facilities in the community where people with disabilities can get the assistance that they need.
- Ways of preventing the causes of disability.
- Processes that cogently manage, monitor and evaluate the effectiveness and efficiency of all CBR program components, both in the community and in the area of service delivery outside the community.

Today, ► disabled people's organizations (DPOs) increasingly take a substantial role in the development, implementation and evaluation of CBR programs. They aim at reaching more people with disabilities and being more active in representing them. In many countries, DPOs and organizations of parents of children with disabilities have been established and expanded. Their role includes educating all people with disabilities about their rights, advocating for action to ensure these rights, and working together with partners to exercise rights to access services and opportunities. One of the key tasks of DPOs is the identification of the needs of the disabled people, the communication of those needs and the development and promotion of appropriate measures to address those needs.

Conclusion

CBR has achieved much in the last decades, but challenges remain. In some countries, the multi-sector collaboration of health, education, social welfare and labor

is difficult to achieve. There will always be social groups within communities that may not work together easily. Community work itself often has a lower status which impacts on the career development of physical therapists and CBR workers. In settings where physical therapists are few, it may be hard to attain and develop core physical therapy skills compared to the potentially more diverse roles within CBR. As the evidence base for CBR is still weak arguing for funds may be compromised. These challenges have to be addressed in the upcoming years by the organizations involved to ensure the success and sustainability of community based rehabilitation programs.

Community Care

Gernot Lenz
Forschungsverbund Public Health Sachsen-Sachsen Anhalt e. V., Medizinische Fakultät, Technische Universität, Dresden, Germany
gernot.lenz@gmx.de

C

Synonyms

Home care; Informal care

Definition

There is no common definition of community care and the term has long been contested and used by different people in different ways at different points in time. In practice, the term community care (like its parent, community) has come to be used in several ways. In a broader view, community care can be defined as the blend of health and social services provided to individuals or families at home or in the community for the purpose of promoting, maintaining or restoring health or minimizing the effects of illness and disability and thus achieving maximum independence and control over their own lives. To ensure this, a wide range of services is crucial. The traditional main users of community care services are people that have a continuing need for care on a longer-term basis as a result of the effects of old age, mental illness, mental handicap or physical disability. Other potential users of community care are people that need extra help and support at some stage in their lives due to illness or temporary disability as well as people with drug and alcohol related disorders or those with progressive illnesses like multiple sclerosis. The spectrum of community care ranges from domiciliary support provided at home (if required supported by ► respite care and ► day care) through sheltered housing and group homes within the community with increasing levels of care. In the past, community care was always defined as ► informal care but this has changed with the blurring of boundaries between informal and paid care. Community care services have been promoted as an effective alternative to long-term institutional care as it may attain better outcomes at lower cost than institutional services and be preferred especially by older people. It has been one of the fastest growing segments in the health care industry in the US

and in many European Countries like the UK, where community care is explicit government policy.

Basic Characteristics

Housing and Community Care

Suitable good quality and affordable housing is essential to social care packages as it is one of the cornerstones of well being and thus an essential element of community care. Community care policy is based on the belief that most people prefer to live in ordinary housing than in institutions that often lack the capacity to be a home. The word home is rather complex and there is extensive literature on the term, e. g. responses to the question "what does home mean for you?": differ according to gender, class, ethnicity, country and age of respondents and ideas about home constantly change and evolve within a given society. Research suggests that many older people continue to retain a strong bond with the homes which they own or the accommodation they rent. Nevertheless, home can be associated with negative experiences as well, for example, house-repairs can be a major worry for elderly owners and people living in rented accommodation may experience harassment from landlords if they wish them to leave. There is also evidence that many older people manage to re-establish a sense of home when moving into good-quality sheltered housing as long as they tend to be self-contained units with some communal support facilities. However, willingness to move among elderly people does not extend to the more institutional environments like residential or nursing homes.

European Perspectives on Community Care

It can be observed that community care, especially for older people, has dramatically increased in most European countries as a preferred option to hospital and long-term care. This is primarily driven by the fact that the costs for long-term institutional care increases significantly amongst the elderly. Although several countries explicitly foster community care programs, there is still little information and research about the characteristics of older people enrolled in community care programs. In addition, there is no shared knowledge regarding models of efficient home care in Europe.

The exchange of information on good practice in individual member states is one of the central characteristics of EU social care policy. There are four different models of welfare regime within European Welfare States. The *rudimentary welfare state* is represented by the Latin Rim countries like Spain, Portugal or Greece. Welfare is provided by traditional institutions such as the church, family and private charity but only limited public welfare institutions and policies are available. The *residual welfare state* is mainly associated with the UK and is characterized by public services being contracted out to the independent sector with the state being a safety net and regulator instead of being a primary provider. The *institutional welfare state* is particularly linked to Germany where the focus is put on labor market solutions to social issues with those outside of the labor market often being dependent on local charity. The *modern welfare state*, as associated with Scandinavian countries, is characterized by a wide provision of good-quality publicly provided services with private and voluntary sectors being increasingly involved.

In all four models, there is an overall increased emphasis within community care on the non-state sector, with the possible exception of rudimentary welfare states. Given this information, it is still the family that has remained the main supporter of those needing care across the EU. Nevertheless, the role of the family in caring differs between the countries and systems. The spectrum ranges from systems where the family provides virtually all the support to systems where family care is an optional extra to state services. There is no trend towards a common pattern of provision of care by the family. A future scenario for all four models of welfare might be that the distinction between formal and informal care will be of less relevance since informal carers will receive training and become more professional. This might result in that they will even be paid for their work to some extent. There is a common understanding that there is still a need for better collaboration and cooperation between health services and community social services in all European countries. A coordinated community care has not been achieved yet. The difficulties appear to be less acute in countries applying the modern welfare state principle where coordination is assisted by the development of multidisciplinary teams, decentralization of service responsibility to small areas, common training programs and the conversion of nursing homes into health centers.

It can be concluded that there is still a high degree of diversity in approach to community care in countries

with different welfare traditions. The EU institutions should increasingly use this rich variety of community care approaches to evaluate a potential transferability.

Conclusion

The future challenge of community care, especially in many European countries, will be the generation of additional insights about the characteristics of the recipients of community care services and the organizations of services that produce the best outcomes for them and their informal carers. It is therefore necessary to conduct studies that compare the outcomes of different models of community care across countries. The development of evidence based on the structures, quantity and targeting of community care will then have major policy implications. This increased transparency will enable appropriate selection of the best elements of community care and will furthermore help to overcome the gap between acute care, institutional care and community care that still exists in many countries.

Community Health Management Information System (CHMIS)

Definition

The community health management information system is a type of ► health information system that links all community stakeholders—healthcare providers, consumers, providers, purchasers, payers, and researchers—in a given community. The purpose of this system is to provide better exchange of information across the community and thus enable better performance in the health sector.

Community Hospitals

Definition

Community hospitals are defined as local hospitals, units, or centers that provide an appropriate array of accessible health care facilities and resources to fulfill the needs of the people living in the respective community. Community hospitals normally offer ► inpatient beds, ► outpatient units, diagnostics, ► day care, minor injuries service, and other mainly primary care services. The medical care is mainly provided by ► general practitioners who consult ► secondary care specialists if necessary. The services provided may include rehabilitation, acute medical care, ► palliative care, terminal care, and ► respite care. Such services are offered by multidisciplinary teams.

Community Medicine

► Public Health

Community Psychiatry

Definition

Community psychiatry shows an approach to psychiatric care that reflects an inclusive public health perspective and recognizes the diverse settings and continuum of service needs of patients with mental disorders. Patients may be of any age, diagnosis, or economic circumstances. Community psychiatry is practice in any

mental health care setting that delivers a range of services to all patients in the community.

Community-Rated Premiums

Definition

In contrast to actuarially fair premiums, community-rated premiums are based on the utilization of a broad population in a specific region. Thus, community-rated premiums reflect average health risks instead of individual health risks.

Community Reinforcement Programs

Definition

Community reinforcement approach (CRA) in the context of substance dependence stands for a concept to utilise the natural social environment for maintaining positive treatment effects (e. g., alcohol abstinence). Social influence factors like the behaviour of family members, friends, employers, but also the work situation, can increase or decrease the risk for relapses, and therefore are systematically targeted in CRA. The CRA has good scientific evidence of effectiveness, but is rarely used by clinicians.

Commuting Accident

Definition

A commuting accident is an accident occurring on the usual route between a worker's residence and place of work or work-related training location, and vice versa, which results in personal injury or death. Also, an accident occurring on the usual route to the place where the worker usually takes his/her meal or remuneration (in both directions) is considered as a commuting accident.

Co-Morbidity

Synonyms

Co-existing diseases; Co-occurrence of disease

Definition

Co-morbidity is defined as co-occurrence of disease in the same individual. Co-morbidity describes the effect of all other diseases. A patient might have other than the primary disease of interest. Diseases usually co-exist as a result of the same risk or cause factors.

Company Doctor

Bogoljub Peruničić
Serbian Institute of Occupational Health, University of Belgrade, Belgrade, Serbia
perunb@eunet.yu

Synonyms

Company physician; Plant doctor; Plant physician; Occupational health doctor; Occupational physician

Definition

A company doctor is a person (or a medical service, or an ► occupational health care team) appointed by an employer, usually as a legal obligation, to take care of the health and welfare of company employees. The duties of company doctors are aimed at improving ► working conditions and ► working environments, preventing occupational health risks and consequently preventing injuries at work, occupational and work related diseases, protecting and promoting the health of employees, as well as providing advice, information and guidance to employers, employees and other stakeholders in the matters related to health in the workplace. The company doctor has two main clients with their own needs and demands and with divergent and sometimes conflicting interests – the employee and the company. Company doctors should perform their duties with full professional independence and according to the highest professional standards and ethical principles.

Basic Characteristics

History

Diseases arising from the working environment were recognized even in Hippocratic medicine (Hippocrates, c400 BC). Exceptionally precise descriptions of occupational diseases can be found in Ramazzini's book "De Morbis Artificum Diatriba", published in 1700 (Raffle et al. 1987). Probably the first company doctor in modern times was J.A. Scopoli (Goschfeld 2005). Scopoli was assigned as the physician in the mercury mine of Idria (Slovenia) to provide medical services to miners for sixteen years. Intensive socio-economic changes from the eighteenth century to the modern times, as well as establishment of a number of international bodies (International Labor Organization – ILO, Work Health Organization – WHO), stimulated and facilitated research in the field of ► workplace health and the development of ► occupational health and safety services (Stellman 1998). The ILO Occupational Safety and Health Convention No 155 (1981), and Occupational Health Service Convention No 161 (1985), with accompanying recommendations, No 164 and No 171 respectively, set a framework for core activities in the field of health and safety. Since that time the legislative basis for ► occupational health and safety in various countries, that naturally has a profound effect on practical arrangements of company doctors, started to bring about conformity. However, there are notable differences between countries and regions, even within the European Union, in spite of all directives and other regulations (Gericke et al. 2004).

However, there are common principles and issues within the ambit of the company doctor that are valid in all countries and cultures. The scope and practice of the company doctor have undergone important changes – from the complete curative activities or from the so called "compensation doctor" activities at the beginning of the twentieth century (Raffle et al. 1987) to the mostly preventive and health promotion activities of the modern occupational health service.

Main Goals and Practice

It should be underlined that there are considerable variations in the approaches and practices of company doctors over the world. This is influenced by many factors that include the level of socio-economical development and political system, as well as national tradition and culture. However, recent rapid globalization of national economies, technical, social and economic changes along with demographic changes have impacted on the duties and organization of the work of company doctors.

Today, in most countries, employers are forced by law to provide company doctor services for their employees, or to organize occupational health service. In some cases this obligation is strictly enforced by law, in others only partially with exemptions for companies of a certain size or operating in specified sectors, and sometimes it works only as a recommendation. The main goals of services provided by company doctors should be as follows: establishment and maintenance of safe and healthy working environment, protection and promotion of workers health and maintenance and promotion of employees' ► working capacity, as well as adoption of work and working environments to the workers.

To reach the above mentioned goals company doctors should undertake activities to:

1. assess ► occupational health needs of the company;
2. participate in ► workplace health risk assessment;
3. participate and conduct preventive and control activities in the workplace through ► surveillance of working environment (workplace visit, ► exposure assessments), by informing employers and employees about health hazards and risks arising from work;
4. conduct preventive activities oriented to employees by ► health surveillance (► pre-employment, ► pre-placement and ► periodical health examinations, health examinations after prolonged absence from work due to health reasons, health assessments after termination of work assignments); ► assessment of work ability and assessment of any health impairment which may be related to the job;
5. train and prepare ► first-aid services and to assess emergency preparedness for individual or serious accidents in the company;
6. conduct ► workplace health promotion activity;
7. provide (depending on national legislation and national health system organization) some curative services (diagnosis, treatment and rehabilitation of occupational and work-related diseases);
8. collect and keep relevant data related to employees' health;

9. provide information, education and advice to employers, employees and other stakeholders related to workplace health and safety issues;
10. communicate and cooperate with important external partners such as primary health care units, hospital-based specialized services, emergency units, social security and health insurance organizations, authorities, ► labor inspectorate; and
11. participate in professional associations and societies.

Organization and Competence

To carry out the above cited functions requires appropriate organization, facilities, financing and competence of company doctors, or ► occupational health care services. There are considerable differences in the models of organization of company doctors, depending on the size and economic power of companies. Large and international companies usually organize an ► in-plant health service that provides all preventive and mainly curative activities for their employees. Employers cover costs for all providing services, and treat company doctors as their employees. However, recently, large companies, and almost all medium size companies, have given up their in-plant health service organizations replacing them with public, private or hospital-based health services. These companies make contracts with occupational health service providers to take on the majority of company doctors' functions, and retain only a few doctors as employees, mainly for supervision and counseling activities. Medium- and small-sized companies frequently employ a full-time or part-time company doctor or get together and share occupational health services on a group basis. They cover all expenses of the provided services.

Besides the above mentioned models there are several other models of organization including a private or public health center with an ► occupational health unit, an out-patient clinic with an occupational health care service, or a social security organization ► occupational health department.

To reach the main goal, which is to cover all employees by competent and effective occupational health care services, some countries provide a social security subsidy that covers up to 50% of the costs of company doctor services, although the establishment of these services are the complete responsibility of the employers. In that way they successfully facilitate prevention of ► occupational health risks, promote workplace health and increase the investment of small- and medium-sized companies in employees' health.

The basic prerequisite of good and effective company doctor practice, in accordance with set standards and ethical principles, is appropriate education and gained competences (Palmer et al. 2002). In general, it is necessary that the company doctor be an ► occupational health physician – a medical doctor with postgraduate specialization in occupational medicine. An ► occupational medicine specialist may have to work within a well-defined and sometimes rigorously coded system of company rules requiring knowledge and abilities that are not always relevant to the medical domain (Franco 2001). At the same time company doctors are bound by two conflicting ideals – serving the medical needs of company employees whilst protecting the company's interests (Draper 2003).

Therefore, the quality control and evaluation of work practice of the company doctor should be a core strategy for determining the long-term success of ► occupational health care. Improvement in professional practice and cost limitation will inevitably influence both the present and future direction of the company doctor's activities.

Managed competition; Regulated competition

Definition

Due to a number of market failures, competition is rather severely restricted in health care markets. However, according to economic theory, competition is the principal mechanism by which to coordinate demand and supply and to obtain efficient market outcomes. Regulated competition models strive to overcome market failures in order to reap the benefits of competition in health care markets. This is achieved by establishing competitive pressure for health insurers and health care providers and by creating a set of regulatory mechanisms to prevent undesirable consequences of competition. Regulated competition is an attractive concept for designers of health care systems, and health care reforms in a number of countries have been based on it.

Basic Characteristics

Competition in Economic Theory

In economic theory, competition coordinates demand and supply in order to obtain efficient market outcomes. Efficiency has three important dimensions. First, ▶ pareto efficiency is equivalent to a situation where resources are allocated efficiently. Second, technical efficiency (▶ efficiency, technical) describes a situation where consumers are getting optimal value for money – either by reducing costs at a given quality or by improving quality at given costs. Third, dynamic efficiency (▶ efficiency, dynamic) refers to a high rate of technical innovation and the elimination of non-efficient producers.

Competition in health care markets is, however, usually severely restricted. The most important reasons for this are ▶ information asymmetries and agency problems (▶ agency theory) in the relationship between health care professionals and patients. Moreover, ▶ adverse selection problems lead to market failures in competitive health insurance markets.

Regulated Competition

▶ Regulated competition models aspire to overcome market failures in order to reap the benefits of competitive forces in health care markets – i. e. to improve the allocative, technical, and dynamic efficiency of

health care services. A comprehensive set of regulatory mechanisms is supposed to ensure that market failures are avoided. Regulated competition relies implicitly on three central assumptions with regard to the behavior of health insurers, health care providers, and consumers. First, insurers compete with each other via price and quality of health care services. Second, consumers have free choice between insurers and exercise their right to choose. Third, non-effective and/or non-efficient providers are induced to work more effectively and efficiently and to provide good quality or they are not contracted by insurers.

With the managed competition model in place, health insurers, providers of health care services, and consumers have incentives to behave as if they were in a perfectly competitive environment (Enthoven 1978; Enthoven 1988; Enthoven 1993). Price signals and competitive pressures are designed to let cost-conscious consumers, health insurers, and profit-seeking providers interact. In this concept, the so-called ► sponsor defines the ground rules for regulated competition, supplies consumers with information, and monitors the behavior of health insurers in order to prevent ► risk selection. Ideally, the sponsor collects premiums and distributes these premiums to individual health insurers on a risk-adjusted basis. Consumers are free to switch between health insurers periodically. Health insurers are free to contract selectively with health care providers or even to integrate with them.

Thus, health insurers are induced to monitor the quality of health care services as they compete for consumers. At the same time, health care providers are forced to increase technical efficiency as they compete for contracts with health insurers. Health insurers compete for consumers by offering an attractive ratio between price (premium) and quality of health care services. Competition is enhanced by free market access for providers and insurers. Effective competition policy makes sure that there is a high degree of competition in both the health insurer market and the health care provider market.

The attraction of regulated competition models is at least twofold. First, regulated competition strives to increase efficiency. At the same time, it maintains ► risk solidarity. Moreover, regulated competition reduces asymmetric information by providing additional information for consumers. Health insurers are supposed to act as an additional agent for consumers, which, in turn, is supposed to counteract agency problems in the physician-patient relationship (Schut and van Doorslaer 1999). Finally, adverse selection is counteracted by premium rate restrictions and the standardization of benefits. Second, the model shifts the responsibility for cost control from government to market actors to a large degree:

"... The competitive market would generate cost controls, but they would be private market controls based on individual and group judgments about cost versus value and not public controls based on arbitrary numerical standards, insensitive to the quality or the value of the services (Enthoven 1978, p. 715)."

The attraction of regulated competition models is reflected by the fact that health care reforms in a number of countries in the 1990s were based – explicitly or implicitly – on regulated competition approaches (► health systems reforms). It is rather peculiar that the regulated competition approach has been developed in the US but has never been put into place in the US. Most of the regulatory framework which is required by the regulated competition model is still missing in the US (Robinson 2003). A number of European health care systems – primarily the Dutch, German, and Swiss systems – show a number of key features of regulated competition models (Zweifel 2000; Greß et al. 2002; Schut and van de Ven 2005). However, the success of application of regulated competition has so far been limited in these countries. This is mostly due to the fact that health insurers lack instruments to induce providers to work more effectively and more efficiently. Moreover, risk selection is more profitable than managing care in Germany and Switzerland. Therefore, efficiency in the provision of health care services has not yet improved considerably as a consequence of the introduction of regulated competition (Greß 2006).

Complementary Medicine

Synonyms

Holistic medicine; Alternative medicine; Traditional medicine

Definition

Complementary medicine includes various procedures that differ form those recommended by orthodox medical science in the treatment of disease. There are more than 600 different approaches used and there is an evident increased demand for such techniques since individuals who have not been relieved of their complaints by orthodox methods have become more inclined to look elsewhere for treatment.

Complete Removable Dental Prosthesis

Synonyms

Complete denture; Denture

Definition

A removable dental prosthesis that replaces teeth in an edentate arch.

Complication

► Adverse Effect

Composite Filling

Definition

A direct intracoronal restoration made from a highly cross-linked polymeric material reinforced by a dispersion of filler particles bonded to the tooth by a coupling agent.

Composting

Synonyms

Solid-phase soil treatment; Ex situ treatment

Definition

Composting is a way of ► recycling. By composting organic material can be used as a soil amendment or as a medium to grow plants. The decomposition of plant remains and other once-living materials break down

into an earthy, dark, crumbly substance that is excellent for adding to houseplants or enriching garden soil. It is a way to recycle yard and kitchen wastes, and is a critical step in reducing the volume of garbage needlessly sent to ► landfills for disposal. Waste materials that are organic in nature, such as plant material, food scraps, and paper products, are increasingly being recycled. These materials are put through a composting and/or digestion system that controls the biological decomposing process of the organic matter and kills pathogens. The resulting stabilized organic material is then recycled as mulch or compost for agricultural or landscaping purposes.

Conception

Definition

A successful conception – the beginning point of a pregnancy – occurs when a fertilized egg implants in a woman's uterus. Conception is the culmination of two earlier steps, ovulation and fertilization. Women ovulate (release eggs) about 14 days into their menstrual cycle and fertilization by a male sperm must occur shortly thereafter, within about 24 hours. Consequently, practitioners typically estimate that a conception occurred two weeks after the start of the last menstrual period.

Conditional Probability

Definition

Conditional probability allows new information to be used to update the conditional probability of an event, i. e. a formula for revising *a priori* probabilities after receiving new information. The revised probabilities are called *posterior* probabilities. The formula for Bayes' Theorem is as follows: $P(A_i/B) = \frac{P(A_i)\cdot P(B/A_i)}{\sum_{i=1}^{k} P(A_i)*P(B/A_i)}$. For example, consider the probability that someone will develop an intestinal cancer in the next year. An estimate of this probability based on general population data would be *a priori* estimate; a revised (*posterior*) estimate would be based on both the population data and the results of a specific test for this cancer. Let A_1 = the event tumor present, A_2 = the event tumor not present and B = the event screening test positive. If somebody has a tumor the screening test has an 85% chance of detecting it, i. e. $P(B/A_1) = 0.85$. However, it also has a chance of falsely indicating tumor present when there is no tumor, i. e. $P(B/A_2) = 0.10$. The probability of person having a tumor is 0.02, i. e. $P(A_1) = 0.02$. If the screening test is positive, the probability of having tumor is $\frac{0.02\cdot 0.85}{0.02\cdot 0.85+0.98\cdot 0.10} = \frac{0.017}{0.017+0.098} = 0.148$.

Conditioning Model

Synonyms

Learning theory; Associative or classical and operant conditioning

Definition

Classical conditioning introduced concepts that have been particularly important in the design of health related interventions such as reinforcement. Although learn-

ing theory has been criticized for treating behavior in simplistic and mechanistic stimulus response systems, modern learning theory addresses complex components, including environmental cues and context, memory, expectancies, and underlying neurological processes related to learning. The concept of learning and conditioning provides support for preventive interventions that promote health-enhancing behaviors, as opposed to interventions designed to treat or change health-comprising behaviors.

Condom

Synonyms

Pariser; Durex; French letter; Rubber Johnny; Sheath; Wellington boot; Rubber; Raincoat

Definition

A condom is a cover which is rolled over the erect penis before sexual intercourse. It does not only prevent pregnancy but also protects against sexually transmitted diseases. The condom was invented in the 17th century and was made of sheep-gut. Initially, condoms were not too successful. On the one hand, they were not really reliable, and on the other hand, the government and the Catholic Church rejected contraception. The most decisive improvement concerning the security and reliability of condoms was the introduction of latex in the year 1843. Today, for people with latex allergy, latex-free condoms, which are made of polyurethane or polyethylene, are available. Instructions for use, in text and pictures, are found within the packaging. Successful use depends on acquiring the right size and using before the expiration date. If the condom is too small, it can tear or it can cause pain or impairment of blood circulation during sexual intercourse; if it is too large, it can slip off. Of course, in both cases, the preventive effect is lost.

► Sexually Transmitted Diseases

Conduct Disorders

Definition

Conduct disorders are characterized by a repetitive and persistent pattern of dissocial, aggressive, or defiant conduct. Such behavior should amount to major violations of age-appropriate social expectations (e. g., excessive levels of fighting or bullying, cruelty to other people or animals, severe destructiveness to property, fire-setting, stealing, repeated lying, truancy from school and running away from home, unusually frequent and severe temper tantrums, and disobedience). Conduct disorders are therefore more severe than ordinary childish mischief or adolescent rebelliousness and imply an enduring pattern of behavior (six months or longer).

Condyloma

Synonyms

Condyloma accuminata; Venereal warts; Genital warts; Infection with HPvirus; Infection with human papilloma virus

Definition

Genital warts are caused by the human papilloma virus (HPV). They are a very common and highly contagious sexually transmitted disease, which is spread worldwide. There are more than 80 different types of the virus. In most cases, infections are asymptomatic or only cause minor symptoms. The incubation period varies considerably, it lies between 4 weeks and several months. For local therapy, cytostatic agents or trichloroacetic acid can be used. Moreover, cryo-, electro- or lasertherapy or surgical removal are possible. A feared complication of an infection with HPV is the development of cervical cancer.

Since 2006, a HPV vaccine has been available that targets those HPV strains predominantly responsible for cervical cancer and genital warts. Vaccination is recommended for girls and young woman (between the age of 9 and 26 years), preferably prior to their first sexual intercourses.

Synonyms

Interval estimation

Definition

The confidence interval of sample statistics represents an expected range of values that encompasses the real population value of the investigated parameter for the assigned level of confidence or probability. The span itself is determined in order to include the real value of the observed statistic with the previously assigned probability. The defined probability is termed confidence level, while the determining points are confidence boundaries.

Basic Characteristics

In the majority of cases, medical research seeks to estimate an unknown population quantity or quality. For instance, when a random sample from the pool of all insured patients in a given insurance company is taken, the average in-hospital stay, number of days of sick leave, systolic blood pressure, levels of various blood or urine-analysis parameters, or the opinion of the treated on the quality of provided health care could be determined At the same time, the aim is to estimate the same values in the whole population, meaning in all the insured people with the same company.

A good estimate must be unbiased or lack a systematic error with a low sample-to-sample variability – meaning minimal variance (consequently, the mean and median of the population sample are unbiased estimates of the mean when the distribution of observations follows normal distribution, but the standard error of the median is 25% higher than the standard error of the mean).

► Estimation can be point or interval. A point estimate is a specific number and at the same time the best "guess" of the real value of the parameter in the population. Interval estimates, which contain a point estimate and variability of the estimate in another sample, are termed confidence intervals and their perimeters are confidence boundaries. The most commonly used are 95% confidence intervals (meaning that it can be claimed that the interval will contain the real value of the population parameter with a 0.95 probability) or 99% confidence intervals (meaning that it can be claimed that the interval will contain the real value of the population parameter with a 0.99 probability).

The principle behind the confidence interval construction is – as in hypotheses testing – the sample statistic distribution.

Equation

$$P(-1.96 \leq z \leq 1.96) = 0.95$$

shows that probability – the standard normal curve that lies between −1.96 and +1.96 – is 0.95; for any other normal distribution, any other critical value z can be replaced.

If the sample distribution of means is chosen, for instance (normal distribution with mean μ and standard deviation $\sigma/\sqrt{n}$ – ► standard error), the result is:

$$P(-1.96 \leq x - \mu/(\sigma/\sqrt{n}) \leq 1.96) = 0.95\,.$$

The previous equation can be also written as:

$$P(x - 1.96\sigma/\sqrt{n} \leq \mu \leq x + 1.96\sigma/\sqrt{n}) = 0.95\,.$$

Estimation shows a probable presentation of confidence intervals of the population mean. The perimeters of this interval (the left and right sides of the equation) are 95% confidence intervals and show the accuracy (the proximity of the given estimate to the real or actual population value) and precision (the probability of any other repeated measure, i. e. repeated procedure, estimating the same quantity). At the same time, precision represents half of the confidence intervals' width. It is always expressed either using the same units as the variable that is statistically estimated (i. e. 2 g to the left or to the right starting from the mean, the entire interval width is 4 g; 0.05 to the left and to the right from the proportion, the entire interval width is 0.1) or using a percentage of the estimate (i. e., 5% of the sample's mean).

Confidence intervals are interpreted in the function of repeating the same experiment and procedure estimation many times in a row. The obtained estimate means that in 19 out of 20 times that a procedure is repeated,

Confidence Interval, Table 1 Most common confidence intervals

Chosen descriptive statistics	Sample statistic (S)	Population parameter (P)	Lower border Confidence Interval $S - k_{1-\alpha/2}SE$	Upper border Confidence Interval $S + k_{1-\alpha/2}SE$
Mean; ($n \geq 30$) or known population variance	$\overline{x}$	μ	$\overline{x} - z_{1-\frac{\alpha}{2}} \times \frac{\sigma}{\sqrt{n}}$	$\overline{x} + z_{1-\frac{\alpha}{2}} \times \frac{\sigma}{\sqrt{n}}$

Difference between two means with unknown but similar population variances	$\overline{x}_1 - \overline{x}_2$	$\mu_1 - \mu_2$	$(\overline{x}_1 - \overline{x}_2) - t_{n_1+n_2-2;1-\frac{\alpha}{2}} \times \sqrt{SD^2\left(\frac{1}{n_1} + \frac{1}{n_2}\right)}$	$(\overline{x}_1 - \overline{x}_2) + t_{n_1+n_2-2;1-\frac{\alpha}{2}} \times \sqrt{SD^2\left(\frac{1}{n_1} + \frac{1}{n_2}\right)}$
Mean difference, known difference variance	d	δ	$d - z_{1-\frac{\alpha}{2}} \times \frac{\sigma_d}{\sqrt{n}}$	$d + z_{1-\frac{\alpha}{2}} \times \frac{\sigma_d}{\sqrt{n}}$
Mean difference, known difference variance	d	δ	$d - t_{n-1;1-\frac{\alpha}{2}} \times \frac{SD_d}{\sqrt{n}}$	$d + t_{n-1;1-\frac{\alpha}{2}} \times \frac{SD_d}{\sqrt{n}}$
Standard deviation	SD	σ	$\sqrt{\frac{(n-1)s^2}{\chi^2_{1-\alpha/2}}}$	$\sqrt{\frac{(n-1)s^2}{\chi^2_{\alpha/2}}}$
Variances ratio two Gaussian population	SD_1^2/SD_2^2	σ_1^2/σ_2^2	$\left(\frac{SD_1^2}{SD_2^2}\right) \times \left(\frac{1}{F_{\frac{\alpha}{2};DF_1;DF_2}}\right)$	$\left(\frac{SD_1^2}{SD_2^2}\right) \times \left(\frac{1}{F_{1-\frac{\alpha}{2};DF_1;DF_2}}\right)$
Number of favorable outcomes	X	$n\pi^*$	$\frac{x - n\pi - 1/2}{\sqrt{n\pi(1-\pi}}$	$\frac{x - n\pi + 1/2}{\sqrt{n\pi(1-\pi}}$
Proportion of success	$p = x/n$	π^*	$\frac{p - \pi - 1/(2n)}{\sqrt{\pi(1-\pi)/n}}$	$\frac{p - \pi + 1/(2n)}{\sqrt{\pi(1-\pi)/n}}$
Percentage of success	$100p$	$100\pi^*$	$\frac{100p - 100\pi - 100/(2n)}{100\sqrt{\pi(1-\pi)/n}}$	$\frac{100p - 100\pi + 100/(2n)}{100\sqrt{\pi(1-\pi)/n}}$
Difference between two proportions	$p_1 - p_2$	$\pi_1 - \pi_2$	$(p_1 - p_2) - z_{1-\frac{\alpha}{2}} \times \sqrt{\frac{p_1 q_q}{n_1} + \frac{p_2 q_2}{n_2}}$	$(p_1 - p_2) + z_{1-\frac{\alpha}{2}} \times \sqrt{\frac{p_1 q_q}{n_1} + \frac{p_2 q_2}{n_2}}$
Transformed Pearson correlation coefficient	$t_r = 0.5 \ln \frac{1+r}{1-r}$	ρ	$t_r - z_{1-\frac{\alpha}{2}} \times \sqrt{\frac{1}{n-3}}$	$t_r + z_{1-\frac{\alpha}{2}} \times \sqrt{\frac{1}{n-3}}$
Intercept	a	α	$a - t_{n-2;1-\frac{\alpha}{2}} \times SD_{yx}\sqrt{(1/n) + \frac{\overline{x}}{\Sigma(x-\overline{x})^2}}$	$a + t_{n-2;1-\frac{\alpha}{2}} \times SD_{yx}\sqrt{(1/n) + \frac{\overline{x}}{\Sigma(x-\overline{x})^2}}$
Slope of the regression line	b	β	$b - t_{n-2;1-\frac{\alpha}{2}} \times \sqrt{SD_{yx}^2/\Sigma(x-\overline{x})^2}$	$b + t_{n-2;1-\frac{\alpha}{2}} \times \sqrt{SD_{yx}^2/\Sigma(x-\overline{x})^2}$
Relative risk	RR		$RR^1 - z_{1-\frac{\alpha}{2}} \times \sqrt{x2}$	$RR^1 + z_{1-\frac{\alpha}{2}} \times \sqrt{x2}$
Odds ratio	OR		$OR^1 - z_{1-\frac{\alpha}{2}} \times \sqrt{x2}$	$OR^1 + z_{1-\frac{\alpha}{2}} \times \sqrt{x2}$

*normal distribution can be applied only if $n\pi \geq 5$ i $n(1-\pi) \geq 5$

the defined confidence perimeters will really contain the population's mean (1 in 20 times, they will not).
Confidence intervals can be constructed for any population parameter or their linear combination. Table 1 shows confidence intervals for calculation of estimates for most frequently used population parameters, based on known sample distributions. As shown in the footer, S is sample statistic; P, population parameter; SE, standard error; and $k_{1-\alpha/2}$, confidence coefficient.

Example

The researcher sought to determine values of diastolic pressure in one population. The average diastolic blood pressure in 65 people was 85 mm Hg. These 65 people were a random sample of a population with a standard deviation of diastolic blood pressure of 15 mm Hg. The mean value of diastolic blood pressure in a population was tested with a confidence level $(1 - \alpha)$ of 95% and 99%.
Using the previous formula, the 95% confidence level $(Z_{1-\alpha/2} = 1.96)$ is $81 \leq \mu \geq 89$ mm Hg, meaning the 99% confidence level $(Z_{1-\alpha/2} = 2.58)$ is $80 \leq \mu \geq 90$ mm Hg.

Confidentiality

Synonyms

Health data protection; Privacy; Secrecy

Definition

Confidentiality in this context refers to the code of conduct of a health worker. It originated in the ► hippocratic oath which stated: "Whatsoever I shall see or hear in the course of my profession … I will never divulge, holding such things to be holy secrets." It has evolved over the decades, and now modern clinical practice is not based on a person-to-person doctor–patient relationship, but often involves a multidisciplinary team. However, once the first health worker involved in the patient's consultation needs to pass on some information to other health professionals belonging to a different team, he would have to ask for a formal ► informed consent from the patient.

Cross-References

► Health Data
► Health Data Protection

Confirmed Case

Definition

In an outbreak, a case classified as confirmed must usually have laboratory verification.

Conflicts of Interests

Definition

A conflict of interest exists when an employee's financial or other interests interfere (or appear to interfere) with their obligation to act in the best interest of the University without improper bias. The mere appearance of a conflict may be as serious and potentially damaging

to public trust as an actual conflict. Therefore, potential conflicts must be disclosed, evaluated, and managed with the same thoroughness as actual conflicts.

Confounding: Bias Due to Confounding

► Bias, Confounding and Interaction

Confounding by Indication

Definition

Confounding by indication is a bias that occurs when the drug of interest is selectively used or not used by those who developed the outcome of interest; a causal relationship between the drug and its effect on disease outcome cannot be established. This situation frequently occurs when, within a study group, some of the patients with the given illness have other health problems requiring the prescription of several available treatments. It is not always possible to control for this type of confounding, although randomized control trials are considered as a method of choice for the assessment of drug-disease relationships in these circumstances.

Confounding and Interaction

Synonyms

One-sideness; Inclination; Favoritism; Bias

Definition

Bias is a deviation of a measurement from the "true" value. Bias can originate from many different sources, such as literature review bias, allocation bias, design bias, selection bias, data collection bias, analysis bias, interpretation bias, or publication bias. *Literature review bias* includes foreign language exclusion bias, literature search bias, one-sided reference bias, and rhetoric bias. *Allocation bias* is when there is a systematic difference between the experimental and control groups in a clinical trial. *Selection bias* is one part of design bias that occurs when studies included in a review are not a random sample of all relevant studies that fit the inclusion criteria. *Design bias* also includes sampling frame bias, nonrandom sampling bias, noncoverage bias, and noncomparability bias. *Data collection bias* refers to defects in measuring exposure or outcome that result in differential accuracy of information between groups. *Analysis bias* results from errors in analyzing the data. *Interpretation bias* includes conceptual bias, cognitive dissonance bias, correlation bias, and generalization bias. *Publication bias* is a form of selection bias where the publication of research depends on the nature and direction of the study findings. We can investigate publication bias by using a *funnel plot*: a graphical display of sample size plotted against effect size for the studies included in a systematic review. In the absence of bias, the plot will resemble a symmetrical inverted funnel. If there is bias, funnel plots will often be skewed and asymmetrical.

Bias is a term that relates to how far the average statistic lies from the parameter it is estimating, that is, the error which can arise when estimating a quantity. Errors arising by chance will cancel each other out in the long run, those from bias will not. Biases are the result of human choices, or any other factor other than the treatment that is being tested, that affect study results. Clinical trials use many methods to avoid bias, because biased results may not be correct. There are many forms of bias such as selection bias, measurement bias, recall bias, investigator bias, and confounding bias, etc.

► Congenital Gonorrhea

Congenital CMV

► Congenital Cytomegaly (CMV)

Congenital Cytomegalovirus Infection

► Congenital Cytomegaly (CMV)

Congenital Cytomegaly (CMV)

Synonyms

Congenital cytomegalovirus infection; Congenital CMV

Definition

Cytomegalovirus infection is the most common congenital infection. Primary infections during pregnancy are the cause of 10–15% of infections in the fetus. Directly after birth more than 90% of the newborn seem to be unaffected, but 5–15% develop impairments later on, like a loss of hearing or mental retardation. Babies, who are symptomatic at birth, can show a low birth weight, microcephaly and intracerebral calcifications. Moreover, pneumonia or chorioretinitis can be present. During the further course of the disease, impairments develop in 90% of the patients. The children show, for example, psychomental retardation. Severe congenital infections can be treated with ganciclovir. As benefits and risks of the therapy have to be weighed up, ganciclovir is only used in rare cases.

Congenital Drip

► Congenital Gonorrhea

Congenital Erythema infectiosum

Synonyms

Congenital parvo B 19 infection; Congenital fifth disease; Congenital slapped cheek syndrome

Definition

When there is a primary infection with parvo B19-virus during pregnancy, the highest risk for the unborn child is between the 13th and 30th week of gestation. Anemia and inflammation of the heart muscle (myocarditis) can result. In severe cases, hydrops fetalis can develop. The latter is characterized by an abnormal accumulation of serous fluids in the tissues and in the body cavities (generalized edema, ascites, pleural effusion). To treat a hydrops fetalis, an intrauterine transfusion may be necessary.

Congenital Fifth Disease

► Congenital Erythema Infectiosum

Congenital Gonogoccal Infection

► Congenital Gonorrhea

Congenital Gonorrhea

Synonyms

Congenital gonogoccal infection; Congenital clap; Congenital drip

Definition

If the woman's genitals are contaminated with gonococci, the child can be infected on its way through the birth canal. In earlier times, congenital gonnorhea was the most common reason for blindness in children. In 1881, Karl Sigismund Franz Credé introduced the application of a drop of silver nitrate into the eye of the newborn baby immediately after birth. Thanks to this procedure, pathogens are killed and an inflammation of the eyes is prevented. Crede's prophylaxis is still used today.

► Sexually Transmitted Diseases

Congenital Herpes simplex Infection

Definition

In primary infection with herpes genitalis (HSV 2) during pregnancy, there is a 30–50% risk of transmitting

the virus to the child on its way through the birth canal. By hematogenic spread the viruses reach the central nervous system of the newborn child and cause an encephalitis. The best therapeutics available are the virustatics aciclovir and vidarabin. Prognosis depends on the extent of the impairment of consciousness at the beginning of therapy; lethality reaches up to 50% and there is a high rate of neurological defects (60–75%) in the survivors.

Congenital Infection with Treponema pallidum

► Congenital Syphilis

Congenital Listeriosis

Synonyms

Congenital infection with *Listeria* monocytogenes

Definition

When a pregnant woman is infected with *Listeria*, the bacteria can pass through the placenta and reach the unborn child. Different organs of the fetus can be affected (liver, lungs, brain, skin). The child may also die in the womb with resultant stillbirth. Moreover, congenital listeriosis can lead to premature birth. If the woman's genitals are contaminated with *Listeria*, the child can be infected on its way through the birth canal. This being the case, the baby may develop listeriosis in the first weeks or months of life (► food safety and fecal-orally transmitted diseases).

► Infectious Diseases in Pediatrics

Congenital Lues

► Congenital Syphilis

Congenital Parvo B 19 Infection

► Congenital Erythema Infectiosum

Congenital Rubella Syndrome (CRS)

Synonyms

Gregg's syndrome

Definition

When a primary rubella infection takes place between the second and the sixth week of gestation, there is a high risk of congenital rubella syndrome (>60%) in the unborn child. The classical triad of anomalies of the heart, the eyes and the central nervous system is called Gregg's syndrome. Further characteristic findings in newborns are immaturity, microcephaly, pneumonia, blue-red efflorescences of the skin (blueberry muffins), decalcification of long bones (celery stalks) and low platelet counts (thrombocytopenia). The most common monosymptom is impaired hearing or deafness (80–90%). The diagnosis can be confirmed by detecting the virus by Polymerase chain reaction (PCR) or culture.

Congenital Slapped Cheek Syndrome

► Congenital Erythema Infectiosum

Congenital Syphilis

Synonyms

Congenital lues; Lues connata; Congenital infection with *Treponema pallidum*

Definition

During pregnancy, an intrauterine transmission of syphilis is possible. Congenital syphilis can cause abortion, stillbirth or premature birth. Moreover, the transmission of *Treponema* can lead to an infection of the unborn child with possible development of congenital anomalies. The disease can be symptomatic at the time of birth, but the development of the late stage lues is also possible after an interval of several years. In industrial nations, a routine test for syphilis is performed in all pregnant women.

► Sexually Transmitted Diseases

Congenital Varicella

Synonyms

Congenital chicken pox; Congenital varicella syndrome

Definition

When a primary varicella infection takes place between the 8th and 21st week of gestation, congenital varicella syndrome can be induced in the unborn child. This is characterized by skin defects, impairment of development of the muscular and skeletal systems as well as of the eyes and the central nervous system. Congentital varicella can show a severe course in newborn babies whose mothers fall ill from chicken pox between two days before and five days after delivery.

Congenital Varicella Syndrome

► Congenital Varicella

Conjunctivitis

Synonyms

Inflammation of conjuctiva

Definition

Conjunctivitis, inflammation or infection of the mucosal membrane that covers the eyeball and lines the eyelid. It may be caused by infections, foreign bodies, or chemicals. It results in a feeling of grittiness in the eyes, and is associated with stickiness of the eyelids and a discharge. The whites of the eyes are red and bloodshot. Conjunctivitis may also be associated with upper respiratory infection or with childhood diseases such as measles. Trachoma is a severe conjunctivitis that can cause loss of vision.

Consanguineal Marriage

Definition

The marriage between close relatives is called consanguineal marriage (consanguinity is the quality of being descendent from the same ancestor). In most cultures, marriages between close blood relatives are illegal. Most countries according to civil law accept marriages between cousins. Consanguineal marriages are presumed to be contributing to the often high incidence of congenital diseases (e. g. congenital metabolic diseases) amongst migrants.

Consensus Conference

Definition

The purpose of a Consensus Conference is to produce an informed debate on a limited subject presented in the form of a number of main questions, with the aim of evaluating available scientific information and advancing understanding of the issue in question. It normally consists of a two-day conference, during which experts from different disciplines and/or different schools make short presentations aimed at answering the questions previously defined by the scientific advisors. Prior to the conference, the jury, made up of non-experts in the field, is provided with background documentation about the presentations to be made by the experts. After attending the Conference, the jury meets up in order to prepare a Consensus statement on the issues raised. The Consensus text may then be published by the organizing societies.

Consequences

► Outcome

Consequentialism

► Utilitarianism

CONSORT-Statement

Definition

In response to overwhelming evidence and the consequences of poor-quality reporting of randomized controlled trials (RCTs), many medical journals and editorial groups have now endorsed the CONSORT (Consolidated Standards of Reporting Trials) statement. The

CONSORT statement, a checklist flow diagram first published in 1996 and revised 5 years later, is an effort to standardize, and thereby improve, published reports of RCTs. One of the additions to the 2001 revision was an item about reporting adverse events.

Constitution

Definition

The constitution is the basic and foundational legal document of a state. It derives from the people. Via the constitution, the people in the state set forth the state organization and structure and nominate the state organs. Constitutions arrange the legal system of a state. The constitutions assign powers to the state institutions and arrange the legal responsibilities, authorities, duties and the scope of the powers granted to the respective state institutions. Conversely, the constitution provides for the people's rights (constitutional or basic rights) and their legal status vis-à-vis the state and the political system. The exercise of all powers in a state must comply with the underlying constitution.

Consulter in Genetic Counseling

Synonyms

Propositus = client

Definition

Individual primarily seeking advice. ► Genetic counseling is open to individuals or families who are concerned about a disorder that may be hereditary.

Consumer

Synonyms

Patient

Definition

Consumer is a term used to describe a person who purchases or receives goods or services for personal needs or use and not for resale. In health care, patients and other users of health services are usually referred to as consumers.

Consumer Choice

STEFAN GREß
Health Services Research and Health Economics, Department of Health Sciences, University of Applied Sciences Fulda, Fulda, Germany
stefan.gress@pg.hs-fulda.de

C

Synonyms

Consumer sovereignty; Consumer theory

Definition

Consumer Choice refers to the economic axiom that ultimately consumers are the best judges of their own individual welfare. Due to several severe market failures, consumer choice plays only a limited role in health care markets. In health economics, consumer choice is primarily analyzed in the context of health insurance.

Basic Characteristics

Choice in Economics

In economics, consumer choice is an important prerequisite for competitive markets (Rice 2002; Folland et al. 2007). According to microeconomic economic theory, consumers seek to maximize their individual ► utility. The choice made by consumers is based on their individual preferences and on their individual budgets. If consumers are free to choose, the outcome of the competitive process will be efficient: nobody can be made better off without making somebody else worse off (► pare-to efficiency). As a consequence, the amount of goods and services that are produced and consumed is determined by the preferences of consumers. In the long run, supply adjusts to demand.

Consumer Choice in Health Care Markets

Consumer choice in health care markets is usually restricted severely. This is due to severe market failures on the demand side as well as on the supply side of health care markets. Most market failures originate from ► information asymmetries between individual consumers of health care services and the producers of health care services: patients are often unable to

make informed decisions because they do not have sufficient information to make good choices. Moreover, consumers in health care markets are often unable to determine the consequences of their consumption decisions. Furthermore, consumers often do not act rationally on health care markets; as a consequence, the consumer choice of individual patients is restricted in many countries. It is assumed that health care professionals – mostly physicians and nurses – are better informed than patients are and will help the patient to make informed decisions. However, health care professionals are not perfect agents of their patients (► agency theory). Moreover, health care professionals might have imperfect information as well.

Consumer Choice in Health Insurance Markets

Designers of health insurance schemes in many countries rely on competition as a means to stimulate innovation and – at least to some degree – to enhance consumer choice as a way to meet individual preferences (Laske-Aldershof et al. 2004). As a consequence, consumers who are shopping around for the lowest price and the best product – at least theoretically – will stimulate price competition and the development of new products (► competition, health care). The benefits of competing health insurers will be similar to the benefits of competition in other markets (Cutler and Zeckhauser 2000).

Unfortunately, health insurance is different. In contrast to other markets, some characteristics of the consumer of health insurance will most probably affect the price of the product. If health insurance calculates ► risk-related premiums, sick individuals will pay more for an identical product than healthy individuals will. Moreover, sick individuals prefer health insurers with generous benefits and low ► co-insurance rates. Since individuals also tend to have more information about their health status than the health insurers, the latter are unable to calculate actuarially fair premiums (► risk-related premiums). As a consequence, health insurers will charge some kind of average price. However, more generous health plans will attract a high share of sick individuals and less generous health plans will attract a high share of healthy individuals. As a result of this process of ► adverse selection, premiums of more generous health insurers will go up – which drives out the remaining healthy individuals – which in turn will increase premiums even further. The empirical evidence for adverse selection is rather strong and unambiguous (Cutler and Zeckhauser 2000; Geoffard 2006).

Adverse selection makes it extremely difficult – if not impossible – to reach market equilibrium, which leads to spreading of risk for both groups – sick individuals as well as healthy individuals. Moreover, health plans will have incentives to distort benefits in order to make themselves unattractive to sick individuals. What is more, they will face disincentives to develop product innovations that are likely to attract sick individuals. This outcome is rather undesirable from a societal point of view.

Designers of health insurance schemes in many countries strive to prevent the consequences of adverse selection. They do so by introducing mandatory coverage, standardizing benefits and premium rate restrictions. However, the trade-off between competition and selection remains an important issue in these health insurance schemes as well, because some kind of ► risk adjustment system will need to neutralize incentives for risk selection (van de Ven et al. 2003).

Risk selection (► preferred risk selection) in competitive health insurance markets with premium rate restrictions is undesirable from a societal point of view. Three adverse effects of incentives to select risks can be identified (van de Ven et al. 2004). First, health insurers face a disincentive to react to the preferences of bad risks. It is rational for health insurers to provide good service for profitable i. e. favorable risks. Moreover, it also rational for health insurers to provide bad service for unprofitable i. e. unfavorable risks since investments in preferred risk selection (“cream skimming”) have higher returns than investments in improving the efficiency of medical services. From a public health point of view, these disincentives are fatal, since unfavorable risks are usually patients that are chronically ill and need services that are better than average. Neither health insurers nor health care providers have incentives to gain a reputation for treating the chronically ill efficiently and effectively (van de Ven and Ellis 2000).

Second, if cream skimming is successful, it will eventually lead to market segmentation. Unfavorable risks (high-risk patients) will be enrollees of health insurers with high premiums. Conversely, favorable risks (low-risk patients) will be enrollees of health insurers with low premiums. This situation is not compatible with the idea of ► risk solidarity in ► social health insurance

since, in fact, it paves the way for risk-related premiums.

Third, preferred risk selection strategies that are highly rational from an individual health insurer point of view create welfare losses for society. Investments for the identification of favorable risks (e. g. information technology) and investments for the attraction of favorable risks and the deterrence of unfavorable risks (e. g. resources used for developing effective marketing strategies) do not create any societal gains. Therefore, resources spent on preferred risk selection represent a welfare loss (van de Ven and Ellis 2000). Moreover, preferred risk selection strategies may create an unstable market if some health insurers refrain from selecting risks. These funds may be forced to declare bankruptcy due to adverse selection of risks. This consequence also represents a welfare loss to society.

Consumer Confidentiality

Synonyms

Patient confidentiality

Definition

Patient confidentiality is the assurance that information about identifiable persons, the release of which would constitute an invasion of privacy for any individual, will not be disclosed without consent (except as allowed by law). Confidentiality refers to policies restricting access to personal data to those whom the patient agrees need access to them, except rarely in emergency and for the public good (i. e. to contain epidemics, to help solve crime etc.). In addition, other regulatory and institutional approval may be needed, such as consent from medical ethics committees or relevant national authorities.

Consumer Health Informatics

Definition

Consumer health informatics is the branch of ► medical informatics that analyzes consumers' need for information, studies and implements methods of making information accessible to consumers, and models and integrates consumers' preferences into medical information systems. The tasks of consumer health informatics include: educating consumers in how to use various information technologies, developing new methods for obtaining and using health information, estimating the effectiveness of information technologies, evaluating the quality of health information, and surveying the application of laws related to health information.

Consumer Privacy

Synonyms

Patient privacy

Definition

Patient privacy is the right and desire of a person to control the disclosure of personal health information.

Consumer Protection

KATARINA PAUNOVIĆ
Institute of Hygiene and Medical Ecology, School of Medicine, University of Belgrade, Belgrade, Serbia
paunkaya@net.yu

Synonyms

Patient protection; Consumer security

Definition

Consumer protection describes privacy, confidentiality and security measures that protect the personal health data of users of health services. Both the European Union (EU) and the US Government have recognized the need for protection of patients' health information, and have passed legislation giving consumers rights over their health information and setting limits on who can access it.

Basic Characteristics

Understanding Consumers' Concerns

The foundation of the traditional doctor–patient relationship is absolute confidence. Most people believe that they have a duty to share their personal medical information with their doctor, even with physicians not directly involved in their care, in exchange for better coordination of their medical treatment. This expectation is based on a principle of the Hippocratic Oath, established more than 2,000 years ago. However, in the electronic era we are witnessing a dramatic change in this relationship. Patients are being referred to as ► consumers, and as such, they are obliged to play a greater role in their own health care than in the past (Chhanabhai 2006). Consumers today feel that their health information should be private and protected, and they want to know who has access to personal information. There is increasing public concern over the potential for release of personal data, especially regarding computer-based systems. These concerns are based primarily on a lack of understanding of the privacy protection laws and regulations that exist, or on mistrust toward the health care system. Surveys show that patients are willing to put their health at risk by avoiding their regular doctor or asking their doctor to fudge a diagnosis, in order to protect their privacy (California HealthCare Foundation 2005).

Consumers can only be fully empowered when they are allowed to be full participants in the health care system. It is therefore advisable to inform them about their health care privacy rights (Chhanabhai 2006).

Privacy, Confidentiality and Security Concerns Regarding Health Information

Concerns over the privacy and security of electronic health information stem from inappropriate releases of information from individual organizations and/or the systemic flow of information throughout the health care and related industries (National Research Council 1997). In short, privacy refers to control over personal health information (► consumer privacy), confidentiality to the disclosure of health information (► consumer confidentiality), and security to policies implemented to maintain both privacy and confidentiality (► consumer security) (Rindfleisch 1997; Yasnoff 2003).

Several types of threats to the release of health information can be defined (National Research Council 1997):

Threat 1: Insiders who make "innocent" mistakes and cause accidental disclosures. This is the most common type of inappropriate release of health information. Examples include overheard conversations between care providers, test results given to people other than the patient, paper medical records left where passersby can see them, misaddressed e-mail or fax messages, and misfiled or misclassified data.

Threat 2: Insiders who abuse their data access privileges. Some health care providers with authorized access to health data willingly violate confidentiality. It is often by this means that potentially embarrassing health information (e. g. regarding psychiatric care episodes, substance abuse, physical abuse, abortions, HIV status, and sexually transmitted diseases)

about politicians, entertainers, sports figures, and other prominent people finds its way into the media.

Threat 3: Insiders who knowingly access unauthorized information for spite or for profit. This type of threat arises when an attacker with authorization to some part of the system but not to the desired data gains unauthorized access to data through technical or other means; for example, a billing clerk who exploits a system vulnerability to obtain access to data on a patient's medical condition.

Threat 4: Unauthorized physical intruders. In this case, the attacker has access to data, but has no authorization for use of the system or data. Examples include intruders who put on a lab coat and a fake badge, walk into a facility, and start using a workstation or asking employees for health information, or someone who maintains the information system exploiting their access rights for unauthorized purposes.

Threat 5: Vengeful intruders, such as vindictive patients, who mount attacks to access unauthorized information, damage systems, and disrupt operations. In this case, an attacker with no authorization breaks into a health information system from an external network. The aim may not necessarily be to extract patient records, but possibly to insert a computer virus in order to cause damage to the system.

Mechanisms of Protection of Health Information

There is a lot that can be done to prevent release of health information. Health care providers are most frequently responsible for inappropriate release of personal data, and are referred to as "internal agents". They abuse their privileges by accessing information for inappropriate reasons or uses, contravening the confidentiality policies that are essential for all health organizations, as mentioned above.

- Confidentiality policies must reinforce the ethical behavior of health care providers. Education of health care providers is of prime importance in order to ensure proper data collection and generation, and to avoid errors in data storage in the health information system. However, this is not enough and it may be appropriate to implement reminders and alerts for health care providers in order to avoid accidental or curiosity-driven disclosure of confidential information.
- Data systems must be protected against inappropriate access and release of information. Technical measures to protect systems include user authentication and authorization on every access, and audit trails which record the identities, times, and circumstances of access for all users accessing the information system. If such records are reviewed regularly, ethical users may think twice about abusing their privileges.
- System management precautions are crucial and include software management by using antivirus programs, firewall systems, encrypted contents, limit modes/protocols for access etc.

Once information is stored in the health information system, access of unsupervised secondary users must be prevented, and in such circumstances, ethical controls are absolutely inappropriate. Outsiders who are not authorized to use an information system or access its data, but who nevertheless attempt to access or manipulate data, or to render the system inoperable are called "external agents". Unauthorized secondary use of data can be controlled by technical measures such as denying access to unauthorized users, and installing adequate computer security software (antivirus, firewall, system backup, disconnection of users who repeatedly attack the system), which in turn must be supported by strict legal restraints (National Research Council 1997; Rindfleisch 1997; Yasnoff 2003).

Legislation on Consumer Protection

The basis for confidentiality policy in public health is "fair information practice", which was incorporated into the US Federal Privacy Act of 1974. "► fair information practice" dictates that confidential information collected by public health organizations should be relevant to public health, must have a written purpose, and may only be used strictly according to the stated purpose. Once information is in the system, measures must be taken to prevent loss, interception or misuse (alteration, destruction) of the information. Access to confidential information must be made on a "need-to-know" basis (only those who need to know it may be allowed to access it) and consent of the individual from whom the information is obtained is required before the use of their information. According to this practice, consumers are guaranteed the right to have access to information about themselves and the ability to correct

this information to the extent allowed by law (Yasnoff 2003).

The US Government has passed several federal laws to give consumers rights over their health information and set limits on who can access it (Department of Health and Human Services 2003). In short, consumers have the right to access their medical records, get a copy, and add corrections; they can also decide if they want to give permission before their health information can be used or shared for certain purposes. If a health care facility intends to use health information, either for health care purposes such as treatment, payment or administrative functions, or for non-health care purposes such as releasing information to financial institutions, interested parties such as life insurers, or for marketing purposes, consumers must be notified and receive a report on when and why their health information was shared. This protection extends to all types of personal health information, including oral communications and paper records that have not existed in electronic form.

The EU have also recognized the need for protection of patient health information, and issued the EU data protection directive (Directive 95/46/EC 1995), requiring all member countries to pass legislation enabling patients to have access to their medical records.

Consumer Protection in Research Area

The research area has become a dangerous zone regarding patient rights due to rising public concern about the privacy of individuals' personal information and because of the implementation of new legislative and regulatory frameworks for the conduct of research using such personal information. Epidemiologists are facing obstacles due to the complex and confusing rules regarding privacy, confidentiality, and consent (Centre for Health Services and Policy Research 2005; Walley 2006).

In general, patients are unwilling to have their personal information distributed other than for the purpose of clinical care and are very concerned when it comes to release of their health information. Studies suggest that the public does not support free access to their records by medical researchers, but want to be fully informed about information sharing, and consulted before their information is released (Whiddett et al. 2006). However, there is considerable debate over the circumstances when explicit consent is needed for the secondary use of personal information for research purposes. An important organization for the protection of patients' rights in clinical research is the ► ethics committee, a competent and independent group that should review all research proposals to assess the trade-off between the risk to individual privacy and the societal benefit of the research, and to ensure all possible steps are taken to maintain confidentiality. Researchers obtain consent from the ethical board and not directly from their patients, but must ensure protection of health data (Centre for Health Services and Policy Research 2005). (► ethics, aspects of public health research)

Consumer Protection and the Internet

Many consumers are using e-mail and the Internet to search for medical advice, whereby disclosure of personal information can occur without consumers' knowledge or consent. Furthermore, any electronic communication may lead to TGI (transaction generated information or access markers) that can make tracking of the origin (the patient) easy, violating privacy. Another problem is the quality of health information found on Internet sites (► e-health).

Consumer Health Informatics

Since patients are becoming active participants in health care, they are searching for all available health information in order to find help, advice, or to make more reasonable, informed choices regarding their health needs. ► Consumer health informatics empowers consumers by putting health information into their hands, including data on their own health. Consumer health informatics is the branch of medical informatics that analyzes consumers' need for information, studies and implements methods of making information accessible to consumers, and models and integrates consumers' preferences into medical information systems. Recognizing the use of and need for health information by those who need it the most – the consumers – the tasks of consumer health informatics are to educate the consumer and to encourage the use of various technologies (including telecommunication and network systems for consumers) to obtain information. Consumer health informatics must also play a proactive role in the development of methods for obtaining and using health information, studying the effectiveness of infor-

mation technologies, evaluating the quality of available health information, and surveying the application of laws related to health information (Eysenbach 2000).

Conclusion

Consumers are concerned about personal health information privacy, but are generally unaware of their privacy rights; both may lead to undesirable consequences. Consumers who are over-anxious about their privacy may put their health at risk by protecting their privacy too much, while those who are misinformed may take no action to protect their own information. The role of health professionals, policymakers and law enforcers is to educate consumers about existing regulations and protection, and to make every effort to preserve the trust they are given.

Consumer Safety

Synonyms

Patient safety

Definition

Patient safety is a patient's freedom from accidental injury during treatment. Ensuring patient safety involves the establishment of operational systems and processes that minimize the likelihood of errors and maximize the likelihood of intercepting them when they occur.

Consumer Security

Synonyms

Patient security

Definition

Security refers to the technical methods by which confidentiality is achieved. Patient security is a collection of policies, procedures, and safeguards that help maintain the integrity and availability of information systems and control access to their contents.

Contact

Definition

Contact is one of the most common modes of transmission of infectious diseases. It can be direct or indirect. Direct contact involves physical transfer of microorganisms to a susceptible host from an infected or colonized person. Direct contact includes large droplet spread of infectious agents. Other examples of direct contact transmission are kissing, shaking hands or other skin contact, sexual contact, and contact with soil. Indirect contact occurs when organisms from an infected host or other reservoir are transmitted to a susceptible host via a contaminated intermediate object. Indirect contact transmission may be airborne, vector-borne, or vehicle-borne.
Contact is the most important and frequent mode of transmission of hospital infections.

Cross-References

► Communication

Contact Tracing

Definition

Contact tracing consists in identifying, by taking the history of an individual affected by an infectious disease, all those people with whom the individual has been in contact and to whom the disease could have been transmitted. Of course, the meaning of "contact" depends on the disease and its transmission modality. Contact tracing is used in infectious disease control programs mainly to trace contacts during the ► incubation period and, therefore, with proper treatment full blown clinical symptoms are avoided.

Contagious Diseases

► Communicable Diseases

Contagious Diseases Acquired On Travels

► Tropical Diseases and Travel Medicine

Contagious Diseases Control Law

► Infectious Diseases Control Law

Contaminated Drinking Water

Synonyms

Polluted water; Water containing infectious agents; Water containing germs

Cross-References

► Water Quality and Waterborne Infectious Diseases

Contamination

► Pollution

Content Management

Definition

The term content management includes the systematic and structured production, generation, preparation, management, presentation, publication and utilization of ► information content.

Contingency Tables Analysis

Definition

Contingency tables analysis is a central branch of categorical data analysis, and is focused on the analysis of data represented as contingency tables. This sort of analysis includes hypothesis testing as well as estimation of model parameters, e. g. applying loglinear regression methods to fit loglinear models to the data. The major classes of questions addressed by contingency tables analysis are: (a) a hypothesis testing question of whether there is association among the variables or whether the variables are independent and (b) which model provides the best explanation for the data.

Contingent Valuation

Definition

Contingent valuation is the direct determination of the ► willingness to pay by measuring the stated preferences of individuals. Contingent valuation is a methodological approach to simulate a missing market through hypothetical survey questions. Contingent valuation is the most widespread approach to measure the outcome in cost-benefit analysis.

Cross-References

► Willingness-to-Pay Analyses

Continuity of Care

Synonyms

Continuum of care; Seamless care

Definition

Continuity of care relates to the degree to which several health care services are delivered coherently and which are consistent with the patient's medical need and personal context. Continuity of care may be threefold: Informational continuity means that information on past events and personal circumstances is used to deliver appropriate care for each patient. Management continuity describes the coherent approach to manage the patient's health conditions over time according to changing needs. Relational continuity refers to an ongoing therapeutic relationship between the patient and the provider of health care. According to the type of disease and care the definition of continuity may vary. Continuity in ► primary care for example implies a relationship between the general practitioner and the patient based on trust, loyalty and responsibility over time. In the context of ► chronic diseases continuity of care emphasizes the delivery and coordination of the different health care services in a coherent and efficient way over time.

Continuous Control

► Public Health Surveillance

Continuum of Care

► Continuity of Care

Contraception

Synonyms

Birth control

Definition

Contraception, also called birth control, is the deliberate prevention of pregnancy. Contraceptive methods are numerous and include barrier methods that physically prevent the man's sperm and the woman's egg from meeting, hormonal methods that prevent ovulation, and behavioral, such as abstinence around the time of ovulation. Contraception can be used both to limit family size and space births.

Contract

Synonyms

Agreement

Definition

A contract is a binding agreement between two or more parties. A contract can be concluded either in writing or orally. Contracts may also result from implied conduct of the parties without explicit documentation. They provide the contract parties with contractual claims and obligations vis-à-vis the other party. A contract can be concluded between private persons (i. e., individuals, companies) as well as between administrative agencies and private persons.

Controlling

► Evaluation, Models
► Standardization

Conventional Treatment

Synonyms

Orthodox medicine treatment; Western medicine treatment

Definition

Conventional treatment is defined as set of procedures and medicines aimed at treatment of different illnesses and prevention of complications.

Convergence of Systems

Definition

The basis of convergence theory is the hypothesis that industrial states with different forms of organization face comparable challenges and must accordingly develop similar solutions. The pressure of comparable problems, it is held, gives rise to similar requirements of adaptation and thereby results in an approximation of institutional, political and economic structures and strategies. A comparative study of health policies in the OECD member states concluded that "the most remarkable feature of the health care systems reform is the degree of emerging convergence". Transnational problems and trends in healthcare can be attributed to, for example, economic causes (mass unemployment or globalization), technical factors (innovative medical technology and consequent new treatment methods) and issues of population structure (demography and epidemiology).

► Co-morbidity

Cooperation

► Alliance

Coordination of Care

► Managed Care

Co-Payments

Synonyms

Direct payments; Out-of-pocket payments

Definition

Co-payments are payments by patients that occur directly with the purchase of a drug (e. g. prescription charge) or a medical service. According to the ► health insurance in place and the personal situation of the patient, there can be exemption from co-payments or not. In most developed health care systems exemptions are made for the young (generally people under 18) and people without sufficient revenues. Co-payments are either defined as a percentage of the price of a drug or medical service or as a fixed amount per prescription or medical service. The purpose of co-payments is to

strengthen individual responsibility for the use of medical services, but in most health care systems financing problems lead the health insurers to cut the provision of health care services and to open more and more services to co-payments.

Coping Mechanisms

Synonyms

Adaptation

Definition

Coping mechanisms are a set of behavioral and psychological strategies used to tolerate, reduce, or master stressful events. Two broad categories or coping mechanisms include active coping and avoidant coping. Active coping is characterized by problem solving through various plans and actions such as seeking information and support and/or thinking of the stressful event in a more adaptive way. Avoidant coping is characterized by the failure to address stressful events by participating in other activities (e. g., drug and alcohol use) and/or thinking of the stressful event in a less adaptive way. Active coping mechanisms are thought to be the "ideal" way in which to handle stressful events.

Core Legal Public Health Competencies

Definition

Core legal public health competencies encompass a set of individual law-specific skills and knowledge desirable for the practice of public health. These competencies serve as guides to the development of the ► workforce in public health – both for public health leaders (policy makers) who have specialized roles related to public health law, and for front-line staff who need a basic understanding of the role of law in protecting the public's health.

Core Public Health Competencies

Definition

The core public health competencies encompass the individual skills desirable for the delivery of ► essential public health services. The competencies are divided into the following eight domains: analytic assessment skills, basic public health sciences skills, cultural competency skills, communication skills, community dimensions of practice skills, financial planning and management skills, leadership and systems thinking skills, and policy development/program planning skills. Intended levels of mastery, and therefore learning objectives for public health workers within each competency, will differ depending upon their backgrounds and job duties.

Coronary Artery Disease

Definition

Coronary Artery Disease (CAD) is a condition of the coronary artery associated commonly with chest pain which may be dull and radiates to the arm, neck and jaw. It can be associated with shortness of breath, diaphoresis, and nausea or vomiting. This entire condition is referred to as angina pectoris. When chest pain occurs with exertion and is stable over a long period of time, it is called stable angina and when it occurs at rest, it is called unstable angina. If the chest pain persists for a long period of time without interruption, and an irreversible damage of cardiac cell has occurred, it is called myocardial infarction (MI). CAD is most commonly caused by deposition of atherosclerotic plaques in the walls of large coronary arteries leading to obstruction of epicardial vessels. Spasms of coronary arteries may occur due to release of mediators such as histamine. Inflammatory changes and rarely, congenital anomalies can also cause CAD.

► Ecological Study

Cost-Benefit Analysis

Definition

A cost-benefit analysis is an analytical procedure for determining the economic ► efficiency of intervention, expressed as the relationship between costs and outcomes, usually measured in monetary terms. In other words, both costs and benefits of alternative courses of intervention are expressed in the same units of value, i. e. money. The output of the analysis is a cost/benefit ratio. This type of analysis is useful mostly for guiding policy decisions. It also can be used for clinical decision making.

Cost-Consequence Analysis

Definition

Cost-consequence analysis is a form of health economic evaluation study in which all direct and indirect costs and a catalog of different outcomes of all alternatives are listed separately. No specific preference for one costing approach or one outcome measure (as is the case for cost-effectiveness analysis or cost-utility analysis) is made. Consequently, the result is not a definite cost-outcome ratio. The reader or the decision maker has to form their own opinion concerning the relative importance of costs and outcomes.

Cost Containment

Definition

Cost containment in health care involves a wide variety of strategies and measures to reduce overall health care expenditure, the growth rate of expenditure or certain costs of health care services. These measures include, for example, enhanced government regulation of the price of health care services through changes in the payment method of providers, co-payments, managed care programs, patient education, etc. The reasons for increased cost containment measures in health care are: the upward spiral of medical expenses in all health care systems due to medical progress and improvements in technology, the expansion of coverage by public health systems and aging populations in the industrial world with higher levels of ► chronic diseases and ► disability.

Cost of Disease

Synonyms

Burden of disease

Definition

Cost of disease refers to the cumulative effect of a broad range of disease consequences on a community, including the health, social, and economic costs to the individual and to society. It implies the impact of a health problem in an area measured by financial cost, mortality, morbidity, or other indicators. It is often quantified in terms of Disability-Adjusted Life Year (DALY), which combines the burden due to both death and disability into one index. This allows for the comparison of the disease burden due to various risk factors or diseases. It also makes it possible to predict the possible impact of health interventions.

Cost-Effectiveness

FRANZ HESSEL
Health Economics Outcomes Research,
Sanofi-Aventis Pharma GmbH, Berlin, Germany
franz.hessel@sanofi-aventis.com

Definition

A cost-effectiveness analysis is one type of analysis undertaken in health economic evaluation. It compares two or more health technologies by measuring the additional costs and the additional consequences of each alternative, and dividing the incremental costs by the incremental outcomes. The result of a cost-effectiveness analysis is the incremental cost-effectiveness ratio. The feature that distinguishes a cost-effectiveness analysis from other forms of economic evaluation, such as

a cost-utility or cost-benefit analysis, is that the outcomes of all alternatives are measured in identical natural units related to the specific clinical objective of the alternatives.

Basic Characteristics

The major methodological approaches of health economic analyses are cost-minimization analysis, cost-effectiveness analysis, cost-utility analysis, and cost-benefit analysis (Drummond et al. 2005; CADTH 2006). Cost-effectiveness analysis is the most prominent and wide-spread form of health economic evaluation study and is possibly the most important methodological approach in ► pharmacoeconomics. Although some authors describe cost-utility analysis as a special form of cost-effectiveness analysis, this essay follows the majority of the scientific literature on health economics, and the two forms of health economic evaluation are described separately in different chapters (Berger et al. 2003). For details on cost-utility analysis, refer to the description of utilities (► value, human life – utilities). The other methodological approaches of health economic evaluation and their common underlying principles are described in the chapter ► health economic evaluation.

Cost-effectiveness analysis was first described in the 1970s (Weinstein et al. 1977). Originally, cost-effectiveness analysis was conceived and designed as a methodological approach in the framework of ► medical decision analysis and is therefore not comparable to or an extension of clinical trials. The basic principle of medical decision analysis is to support health-care decision makers in making the best choices under conditions of conflicting objectives, ► uncertainty, and scarce resources. Unlike in clinical trials, which are more like a scientific experiment, a decision analytic cost-effectiveness analysis intends to give a conclusion based on the best available evidence in a real-life scenario. It is always, therefore, an estimation and can never express the complete scientific truth. Furthermore, it is always incomplete but cannot fail to reach a conclusion (Weinstein 2006).

Over the last decades, an increasing number of cost-effectiveness studies have been conducted and published worldwide. This rapid development made it necessary to establish some common methodological principles to allow comparison of the results of different cost-effectiveness studies. The US Panel on Cost-Effectiveness in Health and Medicine (Gold et al. 1996) recommended including a so-called reference case in every cost-effectiveness analysis, for which some standard approaches are prescribed (e. g. concerning the ► costing process, ► discounting, and ► sensitivity analysis).

In a cost-effectiveness analysis, one definite specific ► outcome measure must be selected for all alternatives. This outcome measure is typically the primary clinical outcome parameter for the disease or health state that is treated, e. g. number of events or complications avoided, degree of improvement of blood pressure, symptom-free time, or life years gained. For diagnostic procedures or screening programs, the outcome measure can also be a specific number such as the number of cases detected. Like for clinical trials, greater scientific evidence is associated with more definite final outcome measures, such as life years gained, rather than intermediate clinical measures or surrogate parameters, such as percent serum cholesterol reduction or reduction of HbA1c-level. If intermediate outcomes have to be used, it is important to demonstrate a causal link to hard endpoints from other studies.

The design of cost-effectiveness studies can be prospective and include collection of empirical clinical and cost data. The patients are randomized to the alternative programs and the cost and outcome data are collected over the follow-up period of the study. The selection of the patients, the choice of outcome, and cost parameter, as well as the setting, should ideally represent pragmatic real world effectiveness without the artificial framework and limitations of clinical trials. To demonstrate this difference, some authors also use the term cost-efficacy analysis. Due to the resource-consuming nature of randomized pragmatic health economic trials (► pragmatic trial), such a design can rarely be realized, although some reimbursement institutions increasingly proclaim their necessity for decision making in health care.

In the overwhelming majority of cost-effectiveness studies, the outcomes are taken from existing clinical trials. If the cost-effectiveness study is added onto part of a clinical trial focusing on clinical endpoints, the economic analysis is called a piggy-back study (► piggy-back analysis). The results of clinical trials focusing on efficacy and therefore usually having lower external validity can, to a certain extent, be adjusted (e. g. concerning compliance) to be more representative for the

real world. In modeling studies, the outcomes are usually taken from several clinical studies, meta-analyses, and systematic reviews; in cases of a total lack of valid data, expert statements may also be included. The costs are taken from different health care system specific sources (► costing process).

For a cost-effectiveness analysis, different perspectives can be chosen, reflecting the needs of the decision makers. The perspective that includes the most cost and outcome components is the societal perspective. From a ► societal perspective, all relevant direct (► direct cost) and ► indirect costs are included. More restricted and narrow perspectives are the ► perspective of the health care system, the ► payer's perspective, the institutional perspective (e. g. of a hospital), and the patient's perspective.

An essential element of cost-effectiveness analysis is the inclusion of sensitivity analyses and non-parametric statistical methods as ways to deal with uncertainty. Implementing specific ways to deal with the uncertainty that is an unavoidable consequence of the decision analytic approach of cost-effectiveness analysis, the assumed lack of internal validity is counteracted.

The result of a cost-effectiveness analysis is the ► incremental cost-effectiveness ratio (ICER). The estimated additional costs of a health care technology compared with an alternative are divided by the additional outcomes (for a more detailed description of the ICER, refer to the chapter about health economic evaluation). By this means, measures of cost-effectiveness, such as the costs per event avoided or the costs per live year gained, are constructed (Drummond et al. 2001).

Interpretation and Use of the Results of Cost-Effectiveness Analysis

Cost-effectiveness analysis is, by definition, comparative. If a choice between two new alternatives has to be made and one alternative shows better cost-effectiveness in a study comparing two new alternative options with the same standard alternative, a clear decision for the more cost-effective new alternative can be made. However, in most cases the situation is more complex because usually the question is whether it is good value for money to choose a new alternative at all, in other words, are the additional costs for the outcome gained acceptable? To answer this question it is necessary to set a more or less explicit ► threshold. The threshold is the amount of additional costs that is acceptable in order to gain a definite additional outcome.

There is no commonly agreed threshold for cost-effectiveness, although vague categories can be observed. Technologies with a cost-effectiveness of more than 50.000 USD or 50.000 EUR per life year gained are more likely to be classified as not cost-effective. A common source for a cost-effectiveness threshold is the decisions of the National Institute for Clinical Excellence (► NICE) in the United Kingdom. Most technologies with an ICER of less than 20.000 BPS were recommended for reimbursement and most technologies with an ICER above 30.000 BPS were not recommended (Rawlins et al. 2004).

The results of cost-effectiveness analyses are intended to support health care decision makers e. g. in defining the catalog of reimbursed items or setting appropriate prices for defined health care technologies. To answer these questions, not only two alternatives for a single health problem, but the whole catalog of reimbursed items have to be taken into consideration. Decisions about resource allocation in health care should certainly never be based on health economic measures such as cost-effectiveness or cost-utility alone, without taking ethical and medical aspects into consideration, but the results of cost-effectiveness analysis can give clear hints about the value for money of the use of a defined technology. If the same outcome measure and a comparable methodological framework, e. g. calculation of a reference case, are used, the cost-effectiveness of several different health care technologies can be compared. In so-called ► league-tables, technologies are listed according to their ICER (► incremental cost-effectiveness ratio). A league table listing can be used for setting priorities in health care resource allocation, either by supporting more cost-effective alternatives and limiting the use of less cost-effective alternatives or by setting an explicit or implicit threshold up to which technologies are reimbursed (Gerard et al. 1993).

Cost-Effectiveness Analysis

Synonyms

Costs for health gain analysis

Definition

In general, a cost-effectiveness analysis (CEA) compares the relative expenditures (costs) and outcomes (effects) of two or more options. In health care, the objective of a CEA is the comparison of costs and values of different health care interventions in creating better health and longer life. The CEA helps to evaluate if improved outcomes of an intervention justify the related expenditures compared with other options. These interventions can be new medical devices, procedures, diagnostic tests, or prescription drugs. This transparency about the costs and outcomes of comparative interventions is of high importance for public- and private-sector decision-making on how to use health care resources efficiently. The cost-effectiveness is calculated by determining the ratio of the cost of the intervention to the effect this action has on health. The costs are normally measured in monetary terms. On the outcome side, the measure applied depends on the intervention. Potential outcome indicators are the number of people cured of a disease or the number of symptom free days experienced. In the case of cost-utility analysis, the effects are measured in years of full health lived, which may be measured by ► QUALYs, for example.

Cross-References

► Costs for Health Gain

Cost-Effectiveness Calculation

Synonyms

Costs for Health Gain

Definition

A cost-effectiveness calculation is an analytical procedure for determining the ► efficiency of intervention in achieving a given outcome, in which the measurement of the outcome may be defined in any of several different ways. This analysis may be considered as using a schematic model – a branching tree – in which each of the branch points represents alternative possible pathways with different probabilities and independent outcomes. Each branch of the tree is associated with a given set of costs and health outcomes.

Cost-Effectiveness Ratio

Definition

The cost-effectiveness ratio (CER) is a calculation that summarizes the intervention's net cost and effectiveness. The three types of CER are: the average cost-effectiveness ratio (ACER), the marginal cost-effectiveness ratio (MCER), and the incremental cost-effectiveness ratio (ICER).

Cost-Efficiency

Definition

Cost-efficiency is a goal that has been integrated by policy makers into all modern health care systems to control the expansion of medical costs over time. It relates to maximizing the quality of a comparable unit of health care delivered or unit of health benefit achieved for a given unit of health care resources used. The implementation of this concept into the practice of health care provision is rather complex and involves difficult evaluation processes. The definition of health benefit and the quality of health care are always subject to great discussion. The attempt to create an objective basis for cost-efficient health care led more and more health care systems to apply ► clinical guidelines to measure ► health care quality and cost-efficiency.

Cost of Illness – Costing

FRANZ HESSEL
Health Economics Outcomes Research,
Sanofi-Aventis Pharma GmbH, Berlin, Germany
franz.hessel@sanofi-aventis.com

Synonyms

Burden of illness; Cost of disease

Definition

Cost of illness studies estimate the economic burden of a defined disease or health condition in a defined population. In cost of illness studies, the total economic impact of a disease or health condition is estimated by identification, measurement, and valuation of all direct (► direct cost) and indirect costs (► indirect cost). This form of study does not focus on a particular intervention and does not address any questions regarding treatment efficacy or efficiency. Therefore, cost of illness studies should not be categorized as economic evaluation.
Cost of illness studies usually adopt a ► societal perspective, measuring the financial burden incurred to different sectors of society such as the state or government, health insurers, and individuals.

Basic Characteristics

In this essay, cost of illness studies and the costing process itself are described. The calculation of costs in cost of illness studies is performed in a relatively detailed and comprehensive way. The description of the costing process is therefore combined with the description of cost of illness analysis, although the description of the costing process is also valid for other forms of health economic studies.

Cost of Illness Studies

In cost of illness studies, in which sector of the health care system the major expenses occur can be demonstrated in detail. The costing is usually differentiated at least into acute inpatient care, non-acute inpatient care such as rehabilitation clinic costs, ambulatory care by general practitioners or specialists, drugs, informal care, and ► indirect costs due to productivity loss. Different stages or grades of severity of a disease, gender, and age classes could also be calculated separately.
The costs of illness can be estimated by taking into account the costs of all patients with a defined health state in a specific limited time period (prevalence method) or by calculating the long-term costs of those patients whose illness is newly diagnosed during a specific limited time period (incidence method) (Akobundu et al. 2006; Berger et al. 2003; Drummond et al. 2005; Kobelt 2002).

Prevalence Based Studies

In cost of illness studies based on the prevalence of a disease, all costs for a defined patient population (e. g. patients with a specific disease) over a defined time period (e. g. one year) in a defined geographical area (e. g. a specific country or health care system) are estimated. Examples for prevalence based cost of illness

studies are the costs for treating all patients with diabetes mellitus type II in a given year in the USA, or the costs of dementia in the elderly in Germany over a defined time period. If data for several years are available, it is possible to describe the development over time and to give a prognosis of future costs.

Incidence Based Studies

In incidence-based cost of illness studies, it is attempted to estimate the lifetime costs for a patient with a defined disease from diagnosis to cure or death in chronic or life-threatening diseases, respectively. Incidence-based studies are more appropriate if the long-term costs of patients and the effect of a treatment or a preventive intervention on future costs are the focus of the study. For chronic diseases with a duration of many years, purely incidence-based approaches are more difficult to conduct and more resource-consuming compared with a prevalence-based approach. If a detailed prevalence-based cost of illness study is available which differentiates all relevant stages of the disease, the whole course of the disease and the long-time costs of illness can also be modeled based on prevalence-based data.

A special and more advanced form of cost of illness study is the estimation of the costs of a specific risk factor, such as tobacco smoking or alcohol abuse, which can lead to several different health problems or diseases, which themselves could also be caused by several other risk factors. Using the example of the costs of tobacco smoking, the various smoking-attributable risk fractions (► attributable risk fraction) of all relevant diseases that could be caused by smoking have to be estimated. In a further step, the lifetime costs have to be estimated for all these diseases and must individually be attributed to smoking according to the extent the risk factor is responsible for the disease.

Costs of illness studies create information about the amount of resources spent on the treatment of a disease. This information can be helpful in generating hypotheses for later ► health economic evaluation studies comparing different intervention strategies. Furthermore, the results can be used to set priorities for research activities for diseases with a larger potential of cost savings if more cost-effective alternatives would be preferred (CADTH 2006).

In situations of limited resources for health care, this information could be misunderstood as a signal to cut down resources primarily in the treatment of the most expensive diseases. However, ► rationing should be the second choice in ► resource allocation decisions. It should be taken into account that reducing the actual amount of money spent on a specific disease is certainly lowering the total outcome (► outcome measure) for the patients (assuming that healthcare interventions in this disease are doing more good than harm overall). A rational decision for more cost-effective alternatives not only considers the costs but also includes factors related to the medical benefit and can therefore produce more value for money in health care (Rice et al. 1994).

Costing Process

The costing with respect to the estimation of the costs is the main characteristic feature of all health economic studies. In cost of illness studies, the costing process is performed in the most detailed manner. Therefore, the description of the costing process is included in this chapter, although it is also valid for economic evaluation studies.

In general, all costs related to the use of a technology should be identified (► costing process: identification of relevant costs) and considered to be relevant. These costs are the monetary equivalent to resources such as goods or professionals' time. The resources are measured (► costing process: measurement of resources used) in quantifiable physical units, e. g. inpatient days or GP contacts, as detailed as necessary for the analysis, and should be differentiated into categories that are appropriate to the decision makers. In a further step, the measured resources are valued to express them in monetary units (Gold et al. 1996). For valuing (► costing process: valuation), standard reimbursement or pricing catalogs are mainly used (CCOHTA 1996). It has to be kept in mind that these charges are not necessarily identical to the ► opportunity costs according to the economic theory. With rare exceptions, the opportunity costs of health care resources can only be approximated assuming also that charges are the result of a societal process, like the price of any other good in a functioning economy.

Top-down or Bottom-up Approach

Different data sources can be used for estimation of the cost of an illness or the cost of a health care interven-

tion. Using a so-called bottom-up approach, the individual data from patients, patients' charts, epidemiological registries, or cohort studies can be aggregated to a population level. In a top-down approach, highly aggregated sources such as routinely collected national statistics or sickness fund databases can be used directly or can be disaggregated to a more detailed level. The choice of the costing approach depends on the availability and quality of the aggregated data and the level of detail that is necessary to achieve a valid estimation. Both approaches can be combined.

The major problem of retrospective analysis of large routine datasets (► claim's data analysis) is that, usually, not all pieces of information necessary to answer the study question, e. g. all health care sectors or comorbidity, are included in the original data set. On the other hand, a bottom-up data collection is limited to a smaller sample of patients, mainly for reasons of limited resources for the study, which makes it more complicated to ensure that the sample is unbiased and representative of the overall population.

Perspective

The perspective of an economic analysis of a health care technology describes the point of view that is taken. The choice of the perspective is a basic decision to be made for every analysis and can crucially affect the result of the calculation. It especially influences the determination of costs, but can also be relevant for outcomes.

From a ► societal perspective, all costs and benefits, including the productivity loss due to a health state, treatment, or diagnostic procedure, are taken into account (see also "Labor costs"). From the narrower perspective of a health insurance or sickness fund (often called ► payer's perspective), only their own expenses, expressed as reimbursement rates, in different sectors of the health care system are relevant. From the perspective of an institution like a hospital, only the costs for the institution itself, which are incurred during the inpatient stay, are considered. The most important perspectives are the societal, the payer's, and the institutional perspective. Further perspectives are the patient's perspective and the employer's perspective. According to most recommendations for economic evaluations in health care, a societal perspective should be taken at least in addition to other perspectives (Gold et al. 1996; Drummond et al. 2005; Canadian Agency for Drugs and Technologies in Health (CADTH) 2006).

Direct Costs

The costs related to the provision of the health care intervention itself, including all side effects and also all future consequences on health care diagnosis and treatment in different health care settings, are defined as direct medical costs (e. g. inpatient hospital treatment, ambulatory care, drugs, rehabilitation). In some diseases, direct non-medical costs e. g. for transportation or childcare during a medical intervention of the parent, can be incurred.

Indirect Costs

The so-called indirect costs express the loss of productivity to the national economy. Indirect costs can be due to decreased efficiency or total absence from work through an illness – for a limited number of days of absence or early retirement – or due to premature death. There are two ways of calculating the indirect costs: the ► human capital approach and the ► friction cost method. Both approaches are based on the assumption that the lost productivity can be valued by the achievable gross income of the employed population, thus giving the labor a defined value (► labor market).

The human capital approach is considered to be the simpler and more frequently used approach and is therefore recommended by a number of recommendations for economic evaluation studies, although it is also recommended that the friction cost approach should be calculated in an additional scenario, or at least that a sensitivity analysis using the friction cost method should be carried out (Gold et al. 1996).

Costing Process

Definition

Costs in health economic analysis are monetary units referring to resource used in the context of the provision of health care. The costing process is the measurement of the cost. Besides the general subdivision of costs (e. g. fixed cost, variable cost, total cost, marginal cost), ► direct costs and ► indirect costs are differentiated in health economic evaluation studies.

Costing Process: Identification of Relevant Costs

Definition

The first step in estimating the cost of a health care intervention (► labor market) is the identification of parts or consequences of the intervention that are responsible for any cost. Identification of the relevant cost components is determined by the perspective of the health economic analysis.

Costing Process: Measurement of Resources Use

Definition

The second step in estimating the cost of a health care intervention (► costing process) is the measurement of the natural units of health care (e. g. GP visits, inpatient days) that are connected with the identified relevant cost components. The measurement of resource use is mainly determined by the availability of data and the methodological approach of the analysis, e. g. bottom-up or top-down.

Costing Process: Valuation

Definition

The third step in estimating the cost of a health care intervention (► costing process) is valuation of the measured resource use in monetary units. For valuing, standardized costs per unit, e. g. GP visit, specific for a country or health care system and specific for the chosen perspective, are usually used.

Costs for Health Gain

Synonyms

Cost-Effectiveness

Definition

Health economic term which weighs the effectiveness of a health procedure, service or programme against its

expenses and potential savings. The consequences of an intervention are measured by natural or physical units, e. g. as infections averted, cases detected or years of life gained. It assumes that these consequences have value in themselves. It allows the comparison of the effectiveness of an intervention with respect to costs and with respect to a defined consequence, e. g. the costs in € per case detected, *without* making an attempt to compare the value of different consequences with each other.

Cox Proportional Hazards Model

► Cox Proportional Hazards Regression

Cox Proportional Hazards Regression

Synonyms

Cox proportional hazards model; Cox regression; Proportional hazard regression

Definition

The Cox or proportional hazards regression model is used to analyze survival or ► failure time data. The technique may also be used when survival is influenced by a large number of factors, some of which may be correlated, and the aim is to identify those features of the patient or the disease that are of independent prognostic significance. This model is a regression method for survival data, and provides an estimate of the ► hazard ratio and its confidence interval. The Cox proportional hazards model is an appealing analytic method that is powerful and flexible. The Cox model itself makes three assumptions: first, that the ratio of the hazards of two individuals is the same at all times; secondly, that the explanatory variables act multiplicatively on the hazard; and thirdly, that the failure times of individuals are independent.

Cox Regression

► Cox Proportional Hazards Regression

CPI (Community Periodontal Index)

Definition

Severity and degree of ► periodontal diseases (► gingivitis, ► periodontitis) in an individual (or in a section of a population) are assessed, according to a WHO-recommendation, by the CPI (Community Periodontal Index) taking as its basis the three features bleeding, dental calculus, and gingival sulcus. A special dental CPI-probe (WHO-probe) is used for the relevant examination. Periodontal diseases are classified into five degrees according to their severity ranging from 0 (healthy, inflammation-free gingiva and periodontium) to 4 (most severe form of periodontitis with loss of function of the teeth). Periodontal diseases of degree 1 may be cured by an improved domestic oral

hygiene, degree 2 and 3 must be looked after and treated by a dentist. Degree 4 require additional periodontal surgery.

Basis Characteristics

Background and Function

Criminal law is based on the state's penal power. In a constitutional state, only the state has the power to punish people. By enacting criminal law, the states have created a legal order for the people's coexistence in the community. Criminal law defines crimes and threatens everyone with penalties if found guilty of having committed such detrimental and forbidden acts. Criminal law protects the goods and legitimate interests of the community, which include life, health and safety of the people as well as compliance with existing laws.

The function of criminal law is – in contrast with those of most public health activities – not solely to prevent harm. Criminal law also pursues a repressive approach as it intends to uncover crimes and punish delinquents. In criminal law, both prevention and repression (i. e. punishment) are of the same rank. Criminal law pursues several objectives:

1. By threatening unlawful acts with penalties and enforcing penalties, criminal law has a deterrent effect on potential delinquents (general prevention).

2. Punishment, for example by imprisonment, protects the society from known offenders. The penalty also aims to deter the offender from future offences.
3. The punishment shall also educate the offender in order to promote lawful behavior and support his rehabilitation in society.
4. Finally, delinquents are also sentenced to penalties to retaliate them for their criminal offences (retaliation).

Pursuant to these objectives, criminal punishment has several functions, which complement each other (*See* also Tröndle and Fischer 2007; Lazzarini et al. 2007; Gostin 2000). Criminal law is regarded as the last resort (*ultima ratio*) to protect the legal order and the community as it is associated with personal sanctions.

Principles of Criminal Law

Two basic principles of criminal law are embodied in the Latin doctrines *nullum crimen sine lege* ("no crime without law") and *nulla poena sine lege* ("no penalty without law"). Thus, before a behavior can be classified and punished as criminal, the respective criminal offence must be defined by criminal laws so that each individual can determine whether a certain act is criminal or not.

Criminal laws codify crimes and define the elements of these crimes. These elements must be evidenced by the prosecutor to convince the judge or the jury that the accused has committed a crime. Typical crimes involving personal injuries include murder, battery and poisoning. Criminal offences against property rights include fraud, burglary, robbery, blackmail and corruption. In addition, in many other specialized fields of law certain acts are, on pain of penalties, forbidden and represent criminal offences. For example, environmental laws and occupational safety laws define specific criminal offences so that violations of these rules (which are primarily public health law offences) are at the same time crimes chargeable under criminal law.

For criminal punishment, the offender's act must have fulfilled the elements of the respective crime and they must have acted at fault (i. e., intent or negligence). Some criminal offences require that violators have acted with intent (e. g., murder) whereas others are fulfilled if the offense was committed involuntarily but negligently (e. g., negligent homicide). Additionally, the offender must have acted with personal criminal responsibility – a fundamental requirement of criminal law, which refers to the principle *nulla poena sine culpa* ("no penalty without responsibility"). Some persons lack criminal responsibility (e. g. children) or may have acted in a state of reduced or missing criminal responsibility, like mentally ill or drunk persons (Koyuncu 2000).

The practice of criminal law is governed by specific criminal procedure rules and specialized actors, which include the prosecutors who charge violators at court and criminal investigation departments. Criminal investigations are also governed by criminal procedure laws, which provide the actors with a flexible set of tools (e. g., searches, seizures, telephone surveillance). Criminal investigations are initiated if the prosecutors or police departments become aware of acts that fall under the scope of criminal law. Such awareness can result from any type of information, e. g., private complaints. In addition, if facts are unearthed in the course of public health investigations that indicate committed crimes, the public health agency will regularly involve the prosecutor's office. Then, the original public health investigation would lead into criminal investigations.

If criminal offences are charged before courts, specialized courts regularly handle such cases. In addition, the criminal law procedure rules differ from those that apply in civil litigation. For example, before criminal courts, the accused may claim the "benefit of the doubt" rule, which provides that when facts are in doubt, the court must assume the facts that would be beneficial to the accused person (*in dubio pro reo*).

If the court (or jury) finds that the offender was guilty, they will impose penalties depending on the crime, the gravity and all relevant case circumstances. The type and range of penalties for a crime is provided by law. Most criminal laws provide for monetary penalties and imprisonments; some allow death penalties. Crimes may also entail other sanctions imposed by criminal courts, such as a ban from professions, disciplinary sanctions, the forfeit of gain and the order to compensate the victim. Companies convicted of criminal offences may additionally be sanctioned by exclusion from public procurement contracts. In some jurisdictions, such companies are listed in public registers and are excluded from governmental assignments (*See* Grad 1990, for the U.S.).

Criminal Law and Public Health

Criminal law and public health practice have a number of points of contact. There, criminal law unfolds its various (direct and indirect) effects in the interest of the public's health:

- *First*, nearly all specialized fields of public health law define special crimes. In such cases, the public health offence simultaneously is a crime and may, in addition to administrative sanctions, lead to punishment of the violator under criminal law. Further, the potential of criminal punishment has a deterrent effect. Here, public health practice and criminal law proceed hand in hand. Against this background, investigations of the cause of public health issues may shift into criminal investigations.
- General criminal laws are also determined to protect individuals and the public from harm. When forbidding personal injuries, criminal law has behavior-influencing effects in the interest of the community's health. Here is a contact point between criminal law and public health based on an indirect effect. The effects are even bigger when addressed to particular persons close to the public's health: medical doctors, nurses and other health professionals particularly may be subject to prosecution because of patient injuries, and the awareness of criminal law risks has an additional deterrent effect. Criminal law also applies against employers who fail to provide their workers with appropriate workplace safety means. Public health officers may also be prosecuted if they fail to provide accurate services and negligently do not prevent a public health harm or inadequately violate personal rights.
- Criminal law also applies to individuals or companies causing harm to public health. Such cases involve persons with infectious diseases who disregard protection measures and transmit the infection to others. In this realm, a particular concern of criminal law is the intentional or negligent transmission of HIV by infected persons through unprotected intercourse (*See* Lazzarini et al. 2007 (for the U.S.); Tröndle and Fischer 2007; Wisuschil 1998 (for Germany)). These persons obviously pose a public health threat and simultaneously fulfill the elements of battery or at least negligent bodily injury. In a number of criminal proceedings, several such persons have been prosecuted and convicted.
- Criminal laws that penalize traffic offences (e. g., drunk driving) have contributed to the community's health and safety. Correspondingly, "motor vehicle safety" is among the ten great public health achievements of the 20th century, as published by the Centers for Disease Control and Prevention (CDC 1999).
- In the aftermath of the terrorist attacks in the U.S., "forensic epidemiology" emerged as a method that builds a new contact point between criminal law and public health. Forensic epidemiology is defined as "the use of epidemiologic methods as part of an ongoing criminal investigation of a health problem for which there is suspicion or evidence regarding possible intentional acts or criminal behavior as factors contributing to the health problem" (Lazzarini et al. 2007). The definition reveals that forensic epidemiology supports criminal investigations and, thus, is at the "intersection" between the practice of criminal law and public health (Goodman et al. 2003).
- Another intersection between criminal law and public health is formed by public health "standards" set by the administration. These standards often provide guidance for particular activities and, as such, describe the present "state of the art" for the pursuit of the respective activities. As negligence in criminal law must be determined based on the "state of the art", the public health standards can be used as evidence for the "state of the art". In summary, such standards regularly stand for "due care" (Koyuncu and Kamann 2007). Therefore, a breach of the standard may implicate a lack of the necessary "due care" when causing an injury. Disregard of a standard may also indicate an organizational failure, e. g., if an employer failed to provide the employees with the protective means prescribed in a standard for occupational safety (Koyuncu and Kamann 2007). Therefore, the interplay between these standards and criminal law is another relevant intersection between public health and criminal law.

There are substantial contact points between criminal law and public health law. To a certain extent, public health laws encompass criminal law rules. In addition, the interplay between criminal law and public health is based on several indirect effects of criminal law in the interest of the public's health.

Criminal Responsibility

Synonyms

Criminal capacity; Guilt

Definition

Criminal responsibility is defined as the capability of a person to be culpable for his acts under criminal law. Criminal responsibility requires that the person have the intellectual capacity to understand that his action is a criminal offence and the ability to control his actions. Criminal responsibility is the prerequisite for prosecution and the criminal punishment of a person. This is why children and many mentally ill persons or persons with certain blood alcohol levels are not, or only to a limited extent, criminally responsible.

Cripple Disease

- ► Polio
- ► Poliomyelitis

Critical Appraisal

Definition

Critical appraisal is one step in the process of evidence-based clinical practice. It is the process of systematically examining research evidence to assess its validity, results, and usefulness before using it to inform a decision. Together with skills in finding research evidence and changing practice as a result of research, critical appraisal is the route to closing the gap between research and practice and as such makes an essential contribution to improving healthcare quality. Critical appraisal allows us to make sense of research evidence.

Critical Pathways

- ► Clinical Pathways

Cross-Cultural Communication

Synonyms

Intercultural communication

Definition

Cross-cultural ► communication refers to network of information exchange, dealing with or comparing two or more cultures.

Cross-Cultural Psychiatry

► Social Psychiatry

Crossing-Over

► Recombination

Cross-Product Ratio

► Odds Ratio (OR)
► Relative Odds

Cross-Sector Efforts

Synonyms

Social regulation; Regulation

Definition

A legal restriction promulgated by government through official rulemaking processes. Regulations often represent attempts by government to modify prices, wages, pollution, industry practices, and standards of production for goods and services in the free market by limiting the discretion of individuals and companies to make decisions freely.

Cross-Sector Reallocation

► Governmental Regulations

Crown

Definition

With regard to the anatomical areas of the tooth, the crown is the visible part that extends in the mouth. The invisible part is the root of the tooth, which anchors the tooth in the jaw.
With regard to dental treatment, a crown is an artificial replacement that restores missing tooth structure by surrounding part or all of the remaining structure with a material such as cast metal, porcelain, or a combination of these materials.

Crude Birth Rate (CBR)

Definition

Crude birth rate (CBR) is calculated as the number of live births per 1000 population in a given year. It represents only a crude estimate of ► fertility – not all the population included in the denominator is exposed to the risk of ► pregnancy. CBR is not a good measure for comparing fertility across populations, as variations in age distribution of the populations being compared will affect the birth rate.

Crude Rate

Definition

The crude rate is a summary measure based on the total number of events (e. g. diseases, births, deaths) occurring in the total observed population over a given time. The standard reference period is one year. Because the size of population changes over a period of a year, the number of people in the population in the middle of the year (the mid-interval population) can be used as the denominator. Depending on the data available, this may be calculated as the average of the size of the population at the beginning and at the end of the one-year period, or estimated from census data. This rate should not be used for making comparisons between different populations when the age, race, and/or sex distributions of the populations are different.

Cryptosporidiasis

► Cryptosporidiosis

Cryptosporidiosis

Synonyms

Infection with cryptosporidia; Cryptosporidiasis

Definition

Cryptosporidia are single-cell eukaryotes, which are spread worldwide and which can be found in humans and in a couple of vertebrates. They are transmitted by contaminated water and food or as a smear infection. Young children (6–24 months) and immunocompromised persons face a special risk of cryptosporidiosis. Following an incubation period of 3–7 (up to 12) days diarrhea develops, which is accompanied by nausea, stomach ache and mild fever. The disease lasts for 7–14 days; in general, therapy can be restricted to the replacement of fluid losses. Severe courses are observed in immunodeficient persons. The most important means of prophylaxis of cryptosporidiasis is compliance with hygienic rules.

Cross-References

► Infection with Cryptosporidi

Cultural Awareness

Synonyms

Cultural identity

Definition

Cultural awareness is defined as recognition, acceptance and expression of cultural beliefs and system of values as part of cultural, social, ethnic and national identity.

Cross-References

► Cultural Identity

Cultural Beliefs

MASON DURIE
Mãori Research and Development, Massey University, Palmerston North, New Zealand
m.h.durie@massey.ac.nz

Definition

► Culture is essentially a convenient way of describing how members of a group understand each other and communicate that understanding. The nuances of meaning are generated by behavior as much as words and the interactions between members are often determined by shared values operating at an unconscious or 'taken for granted' level. ► Cultural beliefs are products of the world views held by collectives and underpin the ways in which members of the group view the human life-cycle, the environment, and the organization of society. Although the focus in this essay is on culture associated with particular ethnic groups who are indigenous, ethnic culture is only one cultural affiliation alongside others. Many groups have their own distinctive cultures – the elderly, the poor, professional groups, youth and the sick – and they have corresponding belief systems that arise from their particular circumstances. In this respect, a single individual, such as a young woman, may hold beliefs that are part of a universal culture (such as the culture of youth), and at the same time have cultural beliefs that are localized by ethnicity and indigeneity.

Basic Characteristics

Cultural Beliefs and Indigeneity

Indigenous peoples have experienced contact with other cultures and civilizations in vastly different ways, and have often suffered a range of unfortunate consequences including alienation from traditional lands and properties. But despite the adversity, a unifying characteristic has emerged. It is a sense of unity with the environment. Common to indigenous peoples is a world view that locates people within the context of the natural environment, rather than apart from the environment. 'We are the river, the river is us'. 'We are the land the land is us'. A bond with the land and the natural environment is the fundamental feature of indigeneity

and often land is an extension of ► tribal identity and personal ► identity.

Cultural Beliefs and Indigenous Knowledge

Arising from this close link between people and the environment are a number of cultural markers that are integral to indigenous cultural beliefs including the organization of indigenous knowledge, the categorization of life experiences, and the shaping of attitudes and patterns of thinking. The individual is a part of all creation and the idea that the world or creation exists for the purpose of human domination and exploitation is absent from indigenous world-views. A spiritual link between the physical and social environments also emphasizes the significance of resources as collective and intergenerational, and the importance of land for health and wellbeing. Similarly the basis for knowledge creation is the dynamic relationships that arise from the interaction of people with the environment, generations with each other, and social and physical relationships. Relationships form the substrate for indigenous knowledge. While it is often valued because of its traditional qualities, a creative and inventive capacity forms the core of an indigenous knowledge system and the emerging cultural beliefs. The perception of indigenous knowledge and culture as applicable only to the distant past misses the thrust for development that is part of the indigenous journey; the three most distinguishing features of indigenous knowledge are said to be that it is a product of a dynamic system, it is an integral part of the physical and social environment of communities, and it is a collective good.

Cultural Beliefs Around Birth and Death

For many indigenous peoples, birth is a celebrated event largely because it is a step towards survival of the tribe. Tribal cultures all over the world place high value on the wellbeing of future generations, partly because endurance has so often been threatened in the past – by harsh climates, natural catastrophes, inter-tribal warfare, ► colonization, and introduced diseases for which there was no natural immunity. Birth is important for the immediate family but there is also a strong belief that every child belongs to the wider network of extended family members and the community as a whole. That belief is often reflected in patterns of child-rearing and in later years can be manifest as a commitment to reciprocity, mutual benefits, and social inclusion. Some indigenous groups emphasize birth as an opportunity to reinforce the link with the natural environment by burying the new-born's placenta under a special tree or in another site that is of spiritual importance.

Indigenous beliefs about death and dying tend to be philosophical. Death is a normal part of the life cycle and even though grief may be unconstrained there is a sense of inevitability. As well, death represents a connection between present generations and generations who have long since died and may also be celebrated as an event that reinforces continuity with the natural environment, a reminder that human existence is contextualized by a wider environmental ethic.

Typically funeral rituals reflect cultural beliefs about spiritual links with ancestors and grief is openly expressed as elders offer farewell laments, encouraging the hovering spirit of the deceased to join deceased family members. A sense of union with the wider world of the departed is established, diminishing the impact of loss and establishing a place for the recently deceased within the realms of the departed. As a final tribute, children born around the time of death are often named for that person. Continuity has been restored to the family life cycle.

Cultural Beliefs and Health

Indigenous populations are likely to subscribe to values and attitudes that are distinctly different from the cultural experiences of western-trained clinicians. When confronted with poor health, for example, indigenous peoples may not accept conventional explanations nor differentiate between physical and mental disorders. Instead the event may be explained as a loss of balance between spiritual, mental, physical and family dimensions. Sometimes a health problem is seen as evidence of transgression against the social code, either by the individual or the family and can be manifest in a variety of ways. Physical disorders for example may not be regarded as bodily ailments but as reflections of mental processes, social circumstances and spiritual experiences. Similarly, mental disorders are deemed to have physical, as well as spiritual and family components.

The relative weightings attached to symptoms also have ► cultural determinants. Between cultures there are different symptom hierarchies and different interpretations of both severity and importance. A case in point is

depression. Patients in euro-centric cultures are more likely to complain about the emotional and psychological aspects of the illness while many indigenous populations are more worried about the physical aspects: lack of energy, debilitation, weight loss, abdominal pains, poor appetite, sensitivity to cold. In non-western cultures depression will not necessarily be regarded as a mental disorder but as a disorder of energy, or gastro-intestinal malfunction, or sleep disturbance. In any event, while depression may be a universal ailment, its presentation is largely colored by cultural beliefs and variations in the way symptoms are ranked.

Cultural Beliefs and Health Interventions

Clinical programs will be more readily accepted and outcomes will be improved when treatment process makes sense in cultural terms. Incorporating cultural beliefs and values into treatment and healing has been a goal in many countries since the early 1980s and at least four approaches have been used. First, there has been an increase in the utilization of traditional healing services, sometimes as an alternative to mainstream services though more often as a supplementary activity. Traditional healing incorporates a number of remedies largely based on the use of leaves, berries, bark, derived from native plants. They are usually dispensed by healers who also employ incantations, spiritual strengthening, and sometimes rituals to remove malevolent influences. Second, conventional health and medical services have increasingly added ethnic values and customary practices to treatment programs, creating a bicultural formula. Third, in respect of psychological therapies a number of ethnic centered techniques have been developed either independent of other processes or alongside them. Usually they aim to strengthen ► cultural identity. Fourth, indigenous health services have been established to provide more accessible services for their people by recognizing cultural beliefs and customs, employing indigenous health workers, and offering a mix of scientifically based treatments as well as traditional healing.

Cultural Beliefs and Human Diversity

Although cultural beliefs can shape perspectives on health and disease, it can be misleading to draw conclusions about an individual simply because of ethnicity or cultural affiliation. There may be similar histories, commonly held cultural views, and equivalent socio-economic living conditions, but no two human journeys are the same. Concluding that any condition can be explained entirely on the basis of cultural beliefs can be misleading. This does not mean that cultural beliefs are irrelevant but it does sound a note of caution about seeking explanations derived solely from cultural 'norms'. At the same time, the recognition of cultural beliefs as foundations for understanding health, provides a basis for engagement with families, communities, and populations so that interventions can be more effective and health planning can be an inclusive process.

Cultural Competence

Definition

In this context, cultural competence refers to public health professionals' recognition and understanding of the importance of culture in health-related activities and the history, beliefs, values (► ethical values), and practices of members of the communities they serve. Educational programs are at times needed in order to achieve or improve cultural competence.

Cultural Determinants

Synonyms

Cultural features; Characteristics

Definition

Cultural determinants represent features by which basic differentiation of cultures is possible. Cultural determinants include ethnicity, race, ► country of origin, language, non verbal communication, acculturation, gender, age, sexual orientation, values, behavior norms, rules, manners, social grouping and relationships, religious and spiritual beliefs, socioeconomic class and education.

Cultural Ethnicity

Synonyms

Ethnicity; Ethnic Identity

Definition

► Ethnic identity indicates identification with a particular group which is often descended from common ancestors. Members of the group share nationality, tribal affiliation, genealogy, religious faith, language, or cultural and traditional origins and are an identifiable minority within the larger ► nation-state. In Latin America for example it often refers to Indians and Africans, although perhaps everyone has some type of ethnic identity.

Cultural Preservation

Synonyms

Cultural protection

Definition

Cultural preservation refers to activities aimed at protecting ► cultural awareness, ► cultural identity, ► cul-

tural beliefs and cultural features from loss or disappearance.

Cultural Preservation and Protection

MASON DURIE
Māori Research and Development, Massey University, Palmerston North, New Zealand
m.h.durie@massey.ac.nz

Synonyms

Cultural sustainability

Definition

► Cultural preservation and protection is a major concern for indigenous peoples who have become minorities in their own lands. Dispossession of material resources such as land and forests has often been accompanied by loss of cultural resources including language, histories, art forms and intellectual knowledge. Retaining and safeguarding culture for future generations has therefore become an urgent matter especially in the face of globalization and the inevitable attrition of older generations who have served as the carriers of culture.

While the preservation and protection of indigenous culture is largely a function of indigenous peoples themselves, there are also implications for states and public agencies, including those within the health sector. Cultural restoration and transmission is not only justified for reasons of heritage, aesthetics and history, but also because cultural methodologies provide a basis for the acquisition and elaboration of knowledge, as well as creating platforms for the understanding and promotion of health, education, and justice.

Basic Characteristics

Sustaining Indigenous Knowledge

The manifestations of culture that are most obvious include the performing arts, visual arts and language. However, culture is underpinned by a knowledge base that provides a substrate for the parameters of culture including distinctiveness, consistency and cohesiveness. For indigenous peoples knowledge creation is bound into the dynamic relationships that arise from the interaction of people with the environment, generations with each other, and social and physical relationships. Relationships form a catalyst for the codification of indigenous knowledge which recognizes the interrelatedness of all things, draws on observations from the natural environment, and is imbued with an organic life force and spirituality. During contests for territory, much of the old knowledge was either lost or forced into a dormant mode. Although some knowledge has been lost forever, many countries have set out to reinvigorate indigenous methodologies and indigenous understandings of the natural world, not only to maintain a sense of tradition but also to provide parallel perspectives that have relevance to modern times – indigenous approaches to environmental management, health research, dispute resolution, psychological interventions and education.

The traditional knowledge resource is often valued because it has remained constant. However, many indigenous leaders consider that the notion of an unchanging body of knowledge is inconsistent with progress and threatens adaptation to changing environments and changing requirements. They argue that so called traditional knowledge actually developed in response to particular challenges and was subject to modification in light of new experiences and new discoveries. While values might have timeless relevance, knowledge is always changing; only in relatively recent times has 'old knowledge' been declared to be the only form of legitimate indigenous knowledge. Indigenous development did not stop with colonization and efforts to confine indigenous knowledge to a pre-colonial past do little to promote a climate of growth, development, and relevance.

Similar arguments have been heard in relationship to carving and art. Traditionalists maintain that carvers should follow established patterns in order to be true to form; there is a fear that departures from a classical tradition could betray the art. Contemporary indigenous artists, however, are more concerned with exploring new shapes, materials, and outlines, retaining elements of an older art form and perhaps continuing to follow an underlying cultural rhythm though not in a slavish way.

Language Revitalization

Dominated by the language of majorities, many indigenous languages have become extinct and many more

are under threat. Language revitalization has become a major exercise for indigenous populations including those in the USA, Canada, Australia, Wales, Ireland, the Nordic states, Taiwan, Spain, and New Zealand. A number of approaches have been helpful including the establishment of early childhood immersion centers where young (under six years) children are totally immersed in their native tongue. Introducing native languages into the wider school curriculum has also addressed some of the aspirations of indigenous peoples and has led to a new generation of school teachers who have additional language competencies. But particularly germane to indigenous youth has been the establishment of radio and television programs that broadcast in native languages using contemporary music, youthful models, topical issues, and sports commentaries as vehicles for the revitalization of language. Modern technologies have also assisted in the retention of language and other cultural resources. Despite some initial hesitancy, videos, DVDs and electronic archiving have found places in revitalization strategies.

Cultural preservation and protection is unlikely to occur if states are positively opposed to the recognition of cultural heritage or are simply disinterested. State support can occur through several avenues including the formal recognition of an indigenous language as an 'official' language, funding support for educational initiatives, and opportunities for indigenous languages to be seen and heard on public radio and television as well as in state publications and departments of state.

Heritage Protection

Frequently in the past cultural preservation and protection was regarded as the province of museums. However, museum curators are increasingly aware that an artefact, a museum exhibit, is not just a work of art or an historic relic, but an object that has a set of relationships with human beings; the value of the object cannot be separated from those associations. The tangible value resides in the object itself. But the intangible qualities come from the associations the object has with people. As a result, the object is imbued with spiritual meaning derived from the people who created it.

For that reason the value attaching to heritage, whether environmental heritage, sacred sites, artefacts, historic objects, or religious representations, cannot be adequately considered without also recognizing the associated human relationships. Heritage comes alive when the time-honored relationships with people are factored into the equation. In that respect heritage has a spiritual dimension which depends less on the beauty, aesthetics, or history of a site and more on notions of relationship and inter-dependence. It is relatively easy to appreciate the tangible. Indigenous peoples also have a way of also appreciating the intangible and their full involvement in the management and guardianship of national and local heritage sites, especially those that have special links to indigenous populations is crucial to their ongoing protection for future generations.

Culture and the Delivery of Health Programs

Although the significance of culture to health has long been recognized, the study of culture tended to be euro-centric, viewing ethnicities from the perspective of western philosophies, nomenclature and practices. Over the past two or three decades, however, the significance of culture to health and to the delivery of health services has been considered from ethno-centric perspectives. Indigenous peoples have emphasized the importance of their own explanations of behavior based on distinctive world-views, and have drawn attention to the different understandings that they bring to health and to health services. Indigenous health perspectives and access to indigenous networks have been important tools for health promotion and health education and have recognized that cultural expertise is a pre-requisite for effective engagement with communities. Often there has been collaboration between cultural advisors and health professionals and in some countries partnerships between medical practitioners and traditional healers have been formed.

The place of cultural approaches to healing alongside conventional medical practices has been a matter of some controversy. Because each approach is based on different bodies of knowledge and uses evidence in quite different ways, assumptions have been made that one is inherently superior to the other. However, cultural healing focuses on a spiritual element while modern health care focuses on corporeal dimensions. There is no reason why the two cannot be used in parallel provided that the criteria for best practice in one situation are not arbitrarily imposed on the other. The validation

of competence is one area where there is significance difference. Unlike processes for certifying health professionals, not all traditional healers undergo a formal accreditation process. Instead their reputations hinge on community acceptance and the use of methods consistent with the groups cultural values.

The wisdom held by cultural healers can have valuable benefits for indigenous populations, if not for wider audiences. As part of the process of cultural protection and preservation the health sector can assist by creating space where healers can enhance their skills and at the same time contribute to a cultural renaissance.

Cultural Protection

► Cultural Preservation

Cultural Relativism

Definition

Cultural relativism refers to the notion that because human, social and psychological characteristics are culturally produced, the diverse representation of these characteristics across human groups is relative to cultural variability. From this perspective, the moral values of different cultures cannot be compared. As a consequence, an outside critique on the basis of universal human standards – such as human rights – is not possible, because culturally different moral standards are all of equal worth. Thus, transcultural standards for the ethical assessment of cultural practices or human conduct are not objective or rationally valid, but always represent the imposition of one set of cultural values on another.

Cultural Sustainability

► Cultural Preservation and Protection

Cultural Universalism

Definition

Cultural universalism implies the existence of overarching principles (such as human rights) that are applicable cross-culturally and, therefore, could be used to determine the rightness or wrongness of specific cultural beliefs and practices.

Cultural Value

Synonyms

Cultural belief

Definition

Cultural value denotes values accepted by certain culture as true or real and as such as prominent feature

of social group. Cultural belief systems reflect our values and perspectives and at the same time can close our minds to accepting other ways of thinking and doing.

Culture

Synonyms

Civilization; Customs; Ethnology; Folklore; Lifestyle

Definition

Culture represents human behavior as integration pattern that includes thoughts, communications, actions, customs, beliefs, values and institutions of a race, ethnic, religious or social group.
Culture denotes way of life for an entire society and as such, it includes codes of manners, dress, language, religion, rituals, norms of behavior such as morality and law, and system of belief.
Culture influences behavior through customs such as use of or abstention from meat, alcohol, and tobacco; the practice of rituals such as circumcision; marital customs such as the prevailing age at which women marry; attitudes toward family size, childbearing, and child rearing; personal hygiene; disposal of the dead; and much else. People's values may be the most significant component of culture that affects behavior and through behavior, health.

► Culture

Cutoff Level

Definition

In order to separate persons who probably have disease from those who probably do not have disease, a cutoff level must be set. If the human characteristic of interest has a bimodal distribution (curve with two peaks), a cutoff level is relatively easy to set up. In general, most human characteristics, such as blood pressure, are distributed unimodally (curve with single peak). For these continuous variables, a cutoff level using statistical considerations and/or biological information can be chosen. Unfortunately, such data is not available for many human characteristics but a decision must be made to establish a cutoff level above which a test result is considered positive and below which a test result is considered negative. For any disease, the optimum level has to be selected depending on the consequences of missing a few positives if the cutoff level is set higher or falsely classifying more negatives as positive if the cutoff level is set lower.

Cycloid Personality

► Cyclothymia

Cyclothymia

Synonyms

Affective personality disorder; Cycloid personality; Cyclothymic personality

Definition

Individuals with cyclothymia show a persistent instability of mood involving numerous periods of depression and mild elation. None of those depressive and manic episodes is sufficiently severe or prolonged to justify a diagnosis of ► bipolar affective disorder or

► recurrent depressive disorder. Cyclothymia is frequently found in the relatives of patients with bipolar affective disorder. Some patients with cyclothymia eventually develop bipolar affective disorder.

Cyclothymic Personality

► Cyclothymia

Cysticercosis

Synonyms

Infection with larvae of the pork tapeworm

Definition

Cysticercosis is caused by the larvae of the pork tapeworm (*Taenia solium*). The symptoms vary depending upon which organs are involved. If the skin or the muscles are only involved, then only mild symptoms appear, whereas if the eyes are involved then visual defects or even blindness can result. An infection of the central nervous system can cause meningitis.

Cytomegaly (CMV)

Synonyms

Cytomegalovirus infection

Definition

The cytomegalovirus belongs to the herpes virus group. Most infections are asymptomatic. CMV is spread by saliva or other infectious body fluids. Symptoms of the infection can be similar to mononucleosis, like pharyngitis, swelling of lymph nodes and an enlargement of the liver (hepatomegaly). Premature infants can develop CMV sepsis with a lethality of 20% if they receive a CMV positive blood transfusion. For this reason, these patients should only receive blood conserves that are CMV-negative.

DAHTA

Definition

DAHTA is the German Agency for Health Technology Assessment (DAHTA@DIMDI) at the German Institute for Medical Documentation and Information (► DIMDI). DAHTA@DIMDI offers the benefits of electronic publication with the goal of publishing timely, current research results that are affordable, quality assured, and peer reviewed for health policy decision making. Thus, the Agency can offer interested parties a publication platform for the systematic evaluation of medical processes, Health Technology Assessment (HTA).

DALY

Synonyms

Disability adjusted life year

Definition

Disability adjusted life years (DALY) is a health gap measure developed by the World Health Organization. DALYs represent the sum of years of life lost due to premature mortality (YLL) in the population and the years lost due to disability (YLD) for incident cases of health condition. The DALY concept goes beyond the concept of potential years of life lost due to premature death (PYLL) as it considers equivalent years of healthy life lost in disability states or poor health. One DALY stands for one lost year of healthy life and the burden of disease measured by the gap between the current health status and the ideal status of a life free of disease and disability. The years of life lost (YLL) are calculated by multiplying the number of deaths by the standard life expectancy at the age at which death occurs. The years lost to disability (YLD) for a specific cause in a specific time period are calculated by multiplying the number of incident cases in that period by the average duration of the disease and a weight factor reflecting the severity of the disease on a scale from 0 (perfect health) to 1 (death).

Damages

Synonyms

Compensation

Definition

Damages are designed to compensate violations of personal or property rights resulting from actions or omissions of a person or organization that led to their liability under private law. Damage payments particularly result from tort liability and liabilities resulting from breaches of contracts. Most jurisdictions differentiate between compensatory (economic) damages, which are aimed at restoring the injured person/organization in kind, and damages for (noneconomic) pain and suffering. Some jurisdictions, particularly the USA, are additionally known for awarding so-called punitive damages.

Danger Defense Powers

► Police Powers

Daoism

Definition

Synonym: 'teaching the way'. A Chinese philosophical religion that attracts some 60 million followers and which is accepted as an authentic representation.

Data

Definition

In general, the term data refers to factual material used as a basis for discussion and decision making, while in biostatistics it refers to the material available for analysis and interpretation. By definition, data are facts, observations, realizations of one or more underlying variables recorded on one or more observational units. Data can be either categorical or numerical (otherwise known as qualitative or quantitative). Data are categorized according to the type of values used to quantify observations as discrete or continuous data. Data may be subdivided also according to the scale on which these data are measured (nominal, ordinal, interval, ratio) or by the process by which they were gathered (longitudinal data, time-series data, repeated measured data, paired data, cross-sectional data, etc.). Data are often thought of as statistical or quantitative, but they may take many other forms as well – such as transcripts of interviews or videotapes of social interactions. Non-quantitative data are often coded or translated into numbers to make them easier to analyze.

Data Access

Definition

Data access is access to collected and compiled data for the purposes of analysis and reporting. Data access can be allowed to different persons, depending on their nature: access to fundamental data for statistical analysis can be provided to statisticians, access to pre-interpreted data to provide decision support can be provided to health professionals, and access to presentations based on data can be provided to the public for educational purposes.

Data Accessibility

Definition

Data accessibility is a criterion of ► data quality, and is met when authorized health professionals are provided with the means to find, obtain, or make use of the data for various purposes. Considering the rising need to ensure confidentiality of ► patient data, access to patient data and other health information must be legally controlled.

Data Accuracy

Definition

Data accuracy is a criterion for ► data quality. Data are accurate if they meet characteristics proposed by "gold standards". This criterion includes data validity—the capability of a data item to measure what it is meant to; and reliability—the capability of a data item to measure what it is meant to when the measurement is repeated.

Data Acquisition

► Data Acquisition and Protection
► Data Collecting

Data Acquisition and Protection

PASQUALE DI MATTIA
CEFPAS – Centre for Training and Research in Public Health, Caltanissetta, Italy
lino-dm@libero.it

Synonyms

Data acquisition; Data collection; Data aggregation

Definition

Acquisition and use of health personal data are done in different ways. It is a necessary condition for the government to organize, within the reasonable limits of its resources, its most cost-effective health services, and its activities in ways that best prevent illness and disability,

and promote health among its population. "*Data protection*" refers to laws designed to protect the data of individuals or organizations from improper disclosure or use.

Basic Characteristics

Data Acquisition

Collection, aggregation and interpretation of personal data has become part of our computerized society. Personal data are regularly acquired from many sources, bringing about an increasing number and size of datasets. It is so even with health data, since collection, storage and dissemination of health information is partially automated. Each of the health *data acquisition* processes (surveillance, registries, evaluation, emergency data collection, comprehensive surveillance initiatives, secondary analysis of administrative data) requires high quality data in order to help provide more effective clinical care, to assess the quality and cost effectiveness of health services, to monitor fraud and abuse, to track and evaluate access to health services and patterns of morbidity and mortality, to research the ► social determinants, prevention (► prevention and health promotion), and treatment of diseases.

One of the main methods used in public health for health data acquisition is ► surveillance, which implies reporting to health authorities notifiable diseases. Surveillance history goes back to the seventeenth century, when Graunt analyzed London death records and drew inferences on the changing shape of mortality over a 70-year period. But it was not until the late 19th century that systematic reporting of infectious diseases began and continues to this day with many infectious diseases, like the sexually transmitted diseases and tuberculosis, being notifiable, thus allowing a society to monitor, plan and intervene to counteract any threats.

A surveillance system requires a physician to report certain diseases, when they are diagnosed, by filling out a form with information on the patient (name, age, sex, race and residential address), the diagnosed disease, the date of diagnosis, and the name of the reporting physician. This is called "► passive surveillance" in that the local health department relies on physicians to report. In some instances, a health department will proactively call physicians' offices to ask if they have identified any cases of a particular condition; in this instance, the information required is more detailed because the disease is often not well understood and the surveillance system is utilized as a means of collecting the information that may help identify its causes or risk factors. This "► active surveillance" is more expensive than passive surveillance and it is typically reserved for relatively infrequent but important infections or events. "► Sentinel surveillance" is a type of active surveillance in which a sample of physicians are contacted regularly to learn about any diagnosed cases of a particular disease.

Public health surveillance poses some ethical questions: when does the state have the right to require physicians and health care institutions to report, by name, those with certain conditions? Do such requirements violate the confidentiality that serves as a foundation of the clinical relationship? As for other fields of public health activities, the conflict is between individual ► privacy and ► confidentiality and the public good.

These ethical dilemmas become more prominent when surveillance is undertaken not only to track patterns of morbidity and mortality but also to initiate restrictive measures, e. g. compulsory treatment, and ► quarantine. The accepted practice of identifying individuals by name was questioned once HIV/AIDS came along since there was a strong social stigma attached to the condition. In examining the possibility of alternatives to the use of name based reporting, it was necessary to consider the appropriateness of earlier practices. It had to be evaluated whether or not the use of ► coded data, which imposed additional costs, was justified in the name of privacy, keeping in mind that data that relied on coded identifiers was less valuable than data that relied on name identifiers. In the USA it took almost 20 years for the Centres for Disease Control (CDC), in 1999, to reluctantly accept that coded data could be used in case reporting.

Data can be acquired systematically in a public health system through disease registries, program evaluations, and recorded emergency responses. A ► disease registry usually aims to collect information on every individual with a particular condition (for example a cancer registry would include information on the primary site and morphology of the cancer) within a given geographical area. In such circumstances diagnosing physicians are not required by law to report diagnoses to registries; instead, the registry personnel identify cases

through hospital record reviews. The purpose of a registry is to gather information that may advance the scientific understanding of a disease and provide ► incidence and ► prevalence data.

Data acquisition for disease registries poses critical ethical dilemmas when they include some behaviors or characteristics (injection drug use, some sexual practices, race, reproductive history, etc.) which may play a role in the ► etiology of the disease (therefore they need to be investigated) but are, at the same time, subject to social stigmatization. When case registries require ► informed consent for acquisition of personal data, then there is a high level of non-participation through selective non-enrollment of specific sub-population groups that affects the accurate recording of disease incidence, prevalence, trends in morbidity and mortality and even etiology. However, case registries that do not require consent raise important concerns about the issue of data protection.

When a public health program has been implemented, such as the promotion of the wearing of car seat belts or an anti-smoking campaign, data are often collected to evaluate the ► efficacy (whether the program can work in a single instance), ► effectiveness (whether the program works more generally in many settings), ► efficiency (whether the program is economical), and other characteristics of the program.

Public health programs are typically implemented in non-emergency situations. In an emergency, such as an acute disease outbreak, data may be collected on each case in order to guide the emergency response.

More and more datasets are in an electronic format which, on the positive side, facilitates record linking, but, on the negative side, requires the inclusion of names and other identifying information to make linkages both possible and accurate.

Data Protection

Electronic data collection contributes to a general mistrust of people about privacy protection, however, legal, ethical, and ► human rights principles provide some level of individual control over the circumstances in which their identifiable health data are acquired, used, disclosed, or stored. A new concept has developed from these arrangements of systematic surveillance and datasets: the "► data image". Each name entered in a database becomes the sum of all information available in all datasets linked to that name; to all those who have access to databases that name is actually the data image of the real person. The data image is essentially linked to the individual in a reflexive relationship: the individual contributes additional data to the data image, and the data image is used to form impressions and take decisions about the individual; incongruities can arise when the data image and not the actual patient becomes the basis for therapeutic decisions.

The concept of "data image" is motivating data protection advocates. In addition, public uncertainty about the dissemination and use of personal data has grown, and there have been calls for laws to be introduced to protect data and assure their appropriate use.

A very sensitive area where data acquisition and protection come into conflict is in the field of ► genetics. Surveillance data can determine:

- the population frequency of genetic variants that predispose people to specific diseases, both common and rare;
- the population frequency of morbidity and mortality associated with such diseases;
- the prevalence and effects of environmental factors known to interact with given genotypes to produce certain diseases.

At times, genetic interventions involve specific ethnic groups or individual conditions that may be objects of social stigmatization. In any case, genetic information is the most sensitive and personal data an individual possesses.

When registries or surveillance data are to be used for ► research purposes confidentiality becomes a very important issue; disclosure could harm the individual in various areas (psychological, employment, family, insurance, housing, and social). However, it appears to be more and more necessary for epidemiologists and researchers to have access to nominal data that has been collected without consent.

Health data acquisition and protection are strongly interlinked. On the one hand, the ability to share high quality data to accomplish the communal values or goals of public health practice is justified under the ethical theory of ► utilitarianism and the moral principle of ► paternalism; on the other hand, restricting access to health information and respecting the right to privacy has been assimilated into law under the ethical principle of confidentiality by producing legal norms for data protection.

"Guidelines for the protection of privacy and transborder data flows of personal data" is an official document on data protection issued by the Organization for Economic Co-operation and Development (OECD) in 1981. It defines some principles (► ethical principles) for data protection, including collection limitations, data quality, purpose specification, use limitations, security safeguards, openness, individual participation and accountability.

Several legislative measures on data protection have been taken since then in the USA, the EU, the UK and other countries.

However, the value of individual privacy regarding health information in public health practice is not absolute. Sharing identifiable health data may be justified when needed to promote communal good and uphold values (e. g. public health, human research), or when necessary to prevent harm to others (e. g. duty to warn requirements).

Advanced databases designs on the one hand, and transparent and strict guidelines on the use of databases by public health personnel subject to professional secrecy on the other hand, could provide possible solutions to the problems presented by the conflicts between the issue of health data acquisition and the issue of protection of privacy.

► Data Acquisition and Protection

Data Application

► Data Dissemination and Utilization

Data Authentication

► Data Verification

Database

Definition

A database is a structured repository for data, consisting of a collection of data and their associated data model (a schema by which data are organized), organized in a machine-readable format and usually stored on a computer system. The existence of a regular and formal

indexing structure permits rapid retrieval of individual elements of the database. A flat file database is organized like a card file, with many records (cards), each including one or more fields (data items). A relational database is organized as one or more related tables, each containing columns and rows.

Database of Abstracts of Reviews of Effects (DARE)

Definition

DARE contains summaries of systematic reviews that have met strict quality criteria. The reviews included are about the effects of interventions. Each summary also provides a critical commentary on the quality of the review. The database covers a broad range of health and social care topics and can be used for answering questions about the effects of interventions, as well as for developing guidelines and policy making.

Database Error Rate

Definition

Database error rate is a measure of data quality. It is defined as the number of errors divided by the total number of ► data. In practice, estimate of this rate can be obtained by counting the number of errors and dividing it by the total number of verified data, i. e. data sample size. The precision of the estimate of database error rate is associated with data sample size; increasing the sample size will raise the precision. An acceptable database error rate should be defined prior to the study beginning, and must be considerably below 1%. Finally, any decision about the error rate depends on the aims of the study. It is often defined at 0.1% level. Database error rate can be reduced through the process of ► data validation.

Databases, Full-Text

Definition

A full-text database is a compilation of documents or other information in the form of a database in which the complete text of each referenced document is available for online viewing, printing, or downloading. In addition to text documents, images are often included, such as graphs, maps, photos, and diagrams. A full-text database is searchable by keyword, phrase, or both. Important full-text databases in HTA are MEDLINE, EMBASE, and the Cochrane Library.

Database of Systematic Reviews

► Cochrane Collaboration
► Cochrane Library

Data Classification

Definition

Data classification is a critical function for increasing the efficiency of the system because it helps users in the retrieval of significant data. Computer programs can effectively order or sort data in different ways – in numerical or alphabetical order, or according to specific criteria: disease, gender, and age.

Data Coding

Definition

Data coding is the classification of data and assignment of a representation for that data, or the assignment of a specific code to a narrative statement of diagnoses and procedures.

Data Collecting

KATARINA PAUNOVIĆ
Institute of Hygiene and Medical Ecology, School of Medicine, University of Belgrade, Belgrade, Serbia
paunkaya@net.yu

Synonyms

Data acquisition; Data gathering; Data generation

Definition

Data collecting is the process of gathering data from various sources. Data acquisition includes both data collection and data generation that refers to the input of standard code formats.

Basic Characteristics

What Data are Collected?

Health data are important because they measure a wide range of health indicators for a community, provide comparisons for clinical studies, can be used to assess costs of health care and help identify needed prevention targets. They are also important for program planning and evaluation as they can be used to find a baseline against which to measure in the evaluation phase (► data, information, knowledge). (Allee et al. 2004)
Standard data elements collected in health care include: (Abdelhak et al. 1996; Smith 1996)

1. Patient characteristics: patient identifier, name, address, date of birth, gender, marital status;
2. Provider characteristics: unique hospital identifier, unique physician identifier, diagnostic and treatment information, admission date and status, admitting diagnosis code, condition code, diagnosis code, service date, service unit, description of service, principal and other diagnoses and procedures, date of procedure, emergency code;
3. Insurance/payment information: insurance number, insured name, relationship to insured, employer name and location, covered period of insurance, payer, total charges, non-covered charges, prior payments, amount due from patient, revenue codes, treatment authorization codes.
4. Secondary health care data: derived from the primary by statistical analysis – incidence and prevalence rates, mortality rates, vital statistics, registries for certain diseases.
5. Medical knowledge: the sources of medical knowledge can be medical textbooks or journals, the Internet or other colleagues, but the problem is to find data that can be adapted to the present medical situation.
6. Other data: other scientific, legal, political, social, ethical and public data obtained from various sources, which are relevant and important for decision-making.

In general, when patient data is collected, one must keep in mind that data can become information only if three aspects of the information are respected: the ► syntactic aspect, the ► semantic aspect and the ► pragmatic aspect, and if the content of the information is known (► health information).

Who Collects Data?

Data are not only collected by health professionals. Of course, physicians are in charge of collecting data such as patients' complaints, history of past illnesses, family and social information and results of physical examinations; therefore, they acquire data in several forms and decide what additional data should be collected. Nurses collect data from their care plans and during follow up of patients (observation, examination and history data in various forms). Other professionals involved in health care are responsible for the collection of specific data: laboratory personnel, radiology technicians and administrative personnel, who collect demographic and insurance data etc. (Dinca-Panaitescu 2003)

How are Data Collected?

The mode of data collection depends on its source. If people are involved (physicians, nurses, technicians, administrative workers or patients), data are collected manually, either on paper or entered into a computer (questionnaires or data collection forms), but if the medical device produces data (laboratory or medical apparatus, images, ECG readings etc.), data is collected automatically through built-in interfaces to computer systems.

Causes and Sources of Poor Data Collecting

Some causes and sources of poor data collection include the following: (van Bemmel 1997; WHO 2003)

- Poorly designed data collection forms with no logical sequence – health staff may find it difficult to use these forms or may collect data using other forms, such as previous versions of the forms that they find more appropriate.
- Inefficient staff, lack of training in interviewing patients and recording details, and lack of understanding of the need for accurate data collection. Although trained in procedures, staff may not collect all of the required information at the time of first

attendance due to lack of time, pressure of work, and lack of understanding of the consequences of such action.
- Lack of professional judgment by health care providers when recording data about a patient and his or her treatment. This refers to the possibility of absent-mindedly recording objectively false data.
- Delay in recording data – when data are not recorded at the point of contact with a patient the possibility of incurring errors increases dramatically.
- Data redundancy – the presence of a great amount of data impairs the physician's ability to find appropriate data to be used.
- Lack of understanding of data quality by health care professionals. Data collection must be understood to be the prime step for obtaining information that will be used in the process of decision-making regarding the patient's health or regarding the community as a whole. Professionals must recognize that all these actions serve only one purpose – obtaining high quality data (► data quality).

Data Verification

As data collection is highly dependent on humans, the data are often imperfect, and the collection process can be the origin of various errors. Validation of gathered data in the early phases of data processing reduces costs in the system ► data errors.

Typical errors in data collection include missing data (lost or miscoded data), inconsistent data (value out of range or false data), errors during measurements, and other sources of bias (incorrect answers from the patient, noise on biosignals, or errors in biochemical analyzes).

The process of ► data verification must be performed early in the process of data collection. It can be carried out manually, preferably by the person who knows the correct information, or automatically, when the software is designed to check for possible ► syntactic errors (errors in the format in which data is stored) and ► semantic errors (errors in the meaning of data).

Standards for Data Collecting

Standards (► data standards) that need to be established for optimal data collection have been proposed by the World Health Organization and the EUCOMP-project financed by the Commission of European Communities: (WHO 2003; van Mosseveld 2000)

- Standards regarding data collection – data must be collected in specific data forms, in a logical sequence, the process of data entry in the collection form must be as simple as possible, and each entry must be dated;
- Health professionals must be educated on the importance of timely and accurate documentation of patient care data; staff must be trained to control the validity of data, avoid mistakes, sign and date each entry, and avoid alterations or deletions of data;
- Standards and checks – data must be collected in standard forms, guidelines for the collection of data must be developed, a basic template for a data collection system that allows for input and basic analysis of the data must be developed. Routine checks on data for accuracy, validity, reliability, legibility, completeness and accessibility in both manual and computerized systems are advisable.

Conclusion

All health care activities involve gathering, analyzing and using data. Adequate and good quality data are the precursors of good quality health information that can be used for decision-making regarding the patient, as well as for research, national and international comparisons, and support to national health policies when appropriate. As it is the first step in providing information, data collection must meet the required quality standards and the requirements of the patient, health care provider, health care facility and government. It is important that all health care professionals and administrative staff understand the standards regarding data collection and apply them in their work.

Data Dissemination and Utilization

KATARINA PAUNOVIĆ
Institute of Hygiene and Medical Ecology, School of Medicine, University of Belgrade, Belgrade, Serbia
paunkaya@net.yu

Synonyms

Data dissemination:

Data sharing; Data exchange; Data distribution; Data transfer

Data utilization:

Data usage; Data application

Definition

Data dissemination is the process of transfer of data between users. In health care, data dissemination includes the distribution of general data and data from the patient's medical record. Data utilization refers to the application of information for decision-making in health care, statistical analysis, education, policy development and development of health care services, etc.

Basic Characteristics

Data Dissemination

Advances in information and communication technologies have made the global distribution of information and knowledge effortless and have made data available to multiple users the instant they are produced. More importantly, users have become more demanding in their need for information, requiring high quality data for producing new information or knowledge themselves (Edejer 2000).

Data to be distributed can be general – data that is not related to medical records or which originates

from books, journals, databases, collections or records, which are used for education; or case-oriented – data from the medical record, where the purpose is decision-making in patient care.

An important issue in the retrieval and distribution of data is security, referring both to access to data (► data access) and possible changes or damage to data.

Since the beginning of electronic data processing, users have invested effort to store information and to make it available again. The process of ► information retrieval can be performed by several techniques (Gardner 1997).

- Information retrieval systems based on the Boolean model (after George Boole, a 19th century English logician) are most widely used; relevant information is found by creating an expression consisting of the desired terms and operators with the meanings "AND", "OR", and "NOT". These information retrieval systems offer a list of all documents that contain the information of interest and show in which position. The Boolean system is fast, the principle is conceptually simple and it is easy for users to see why documents do or do not match the query. The disadvantages are that the user must learn the syntax for expressing queries, the all-or-none nature of the matching, the list of matching documents is too long, and the results are not ordered according to their relevance.
- Information retrieval systems based on the ranking model deal with documents as objects described by the value of properties related to the words they contain. The search is performed by creating a list of terms (without the need for operators), and the documents in the collection can be ranked in order of their similarity to it. These systems are computationally more demanding, but still commercially available. The only problem is short ambiguous terms, like "arms" – either a part of human body or a weapon, etc.

In many cases, information retrieval alone is not sufficient to find the requested document by search criteria. This is why documents contain the so-called "► metadata", or data about data, which, alongside the typical bibliographic information, contain key words related to the content of the document (Beier 2004).

Systems which involve information retrieval include Index Medicus, commercial interfaces to Medline (such as Ovid and SilverPlatter), and search engines for the ► World Wide Web, such as AltaVista or Lycos. Systems that do not involve information retrieval include age and sex registers, and most electronic medical records – these might rather be referred to as database systems.

Many studies have determined that the successful use of retrieval systems or computer systems in general depends on the operator's cognitive characteristics and general knowledge, rather than on age, gender or personality characteristics (Hersh et al. 2000).

Data Utilization

Generally speaking, the purpose of data is to create information (► data, information, knowledge). Data may be used for various purposes (► health information):

- Decision-making in health care, directly related to the patient or population that the data were obtained from;
- Statistical analysis and computation of health indicators for national or international comparisons;
- Education of health professionals and performance of scientific surveys;
- Public policy development and funding of health care services, etc.

Information can be used only if it is useful, which is determined as proportional to the relevance and validity of the information, but inversely related to the work involved to access the information (Smith 1996). The relevance of any information is based on the frequency of exposure to the problem being addressed and the type of evidence being presented. The validity of the information is the likelihood of it being true, and the work to access the information is the time and effort that must be spent extracting the information. The ideal information source will be directly relevant, contain valid information, and accessible with a minimal amount of work.

Dissemination of Information on the Internet

The ► Internet is a mode of ► communication that crosses the boundaries of all countries, and it is estimated that almost every sixth to seventh person worldwide is using it. Regarding health issues, health consumers are using the Internet to find information on diseases, healthy lifestyles, nutrition, fitness, and pharmaceuticals.

Health information on the Internet ranges from personal accounts of illnesses, virtual communities that support people with specific health problems and e-mail communication between physicians and patients, to journal articles, fact sheets and press releases from leading health organizations. The Internet is increasingly being used for health care delivery, not only in terms of telemedicine for remote diagnosis, but also for health promotion and education interventions (Powell 2003).

Nevertheless, the Internet is having a profound impact on health and health care. It has the potential to improve the effectiveness and efficiency of health care delivery, empower and educate consumers, support decision-making, enable interaction between consumers and professionals, support the training and revalidation of professionals, and reduce inequalities in health. On the other hand, a wide range of false information can be found on the Internet, created and represented by individuals, commercial organizations or research groups. The impact of the distribution of poor health information on the public is still unclear, but the quality of information has become a prime concern (► e-health) (Eysenbach et al. 2002).

Criteria for determining quality can be made by applying standards for all data quality. Information must be accurate and true, complete, relevant, adequately presented so that consumers can understand it, and, most of all, the privacy of the user must be protected (► data quality) (Calabretta 2002; Purcell 2002).

Several organizations have developed criteria to guide and evaluate health-related website content. The Health on the Net Foundation has published the ► Code of Conduct to help standardize the reliability of medical and health information available on the Internet (HON 1997). The eight basic principles that medical and health websites must fulfill are outlined below:

1. **Authority** requires a clear and fair statement to distinguish whether the medical or health advice on the site is given by medical professionals or by non-medically qualified individuals or organizations;
2. **Complementarity** means that the information is designed to support, not replace, the patient-physician relationship;
3. **Confidentiality** of data relating to individual patients and visitors is guaranteed;
4. **Attribution to clear references** means that source data must be supported with a html link to that data;
5. **Justifiability** requires support for any claims relating to the benefits/performance of a specific treatment, commercial product or service;
6. **Transparency of authorship** is assured by providing contact addresses of authors so that visitors can seek further information;
7. **Transparency of sponsorship** is assured by identifying commercial and non-commercial organizations that have contributed funding, services or material for the site;
8. **Honesty in advertising and editorial policy** refers to avoiding confusion for the visitors by distinguishing between original material, and that created for advertising on the website.

Problems related to access to information on the Internet could be due to:

- Retrieval of inaccurate and irrelevant information – consumers are concerned about the quality of health information. The best way to overcome this problem is to search sites run by government agencies, medical journals, or evidence-based groups.
- Language barrier – since most Internet postings are in English, it is important that local intermediaries read, translate, and convert the information into content that is relevant to the local context.
- Literacy barrier – refers to barriers in the use of new technologies. An initial passive behavior of consumers can easily be transformed into active participation with adequate training (Edejer 2000).

Conclusion

Information can be used for various purposes. The implementation of new communication technologies, such as the Internet, has increased the dissemination and application of information worldwide. Beneficial consequences are expected for health professionals, who will have increased access to evidence, policy and guidelines, and training and professional development; health consumers, who will be provided with good health information; and health systems, which will benefit from research and implementation of evidence-based health policies.

Data Distribution

► Data Dissemination and Utilization

Data Entry

Definition

Data entry is the process of entering data into a computerized database or spreadsheet. Data entry can be performed by an individual typing at a keyboard or by a machine entering data electronically.

Data Errors

Synonyms

Incorrect data

Definition

Data errors are incorrect results produced during data collection. Typical errors in data collection (► data collecting) include missing data (lost or miscoded data), inconsistent data (value out of range, false data), and errors during measurements (incorrect answers from the patient, noise on biosignals, or errors in biochemical analyzes).

Data Exchange

► Data Dissemination and Utilization

Data Gathering

► Data Collecting

Data Generation

► Data Collecting

Data Image

Definition

Data image refers to the sum of all information 74/100,000 available in all datasets linked to a spe-

cific name; to all those who have access to databases that name is actually the data image of the real person. The data image is linked to the individual in a reflexive relationship: the individual contributes additional data to the data image each time more personal information is given through any electronic database, and the data image is used to gain more knowledge about the individual; one of the contradictions is that the data image and not the person becomes the basis for some decisions. The concept of "data image" and the public uncertainty about the dissemination and use of personal data are motivating the call for laws to protect data and assure their appropriate use.

Data, Information, Knowledge

KATARINA PAUNOVIĆ
Institute of Hygiene and Medical Ecology, School of Medicine, University of Belgrade, Belgrade, Serbia
paunkaya@net.yu

Definition

Data are measurements of some characteristics of either a person or a thing. In the information system, data are given facts from which others may be inferred, a message that does not evolve, the carrier of information. In isolation, i. e. without context and analysis, data have little meaning.

Information is data organized into meaningful unions, data placed in context with relevance, purpose and meaning. Unlike data, information has various purposes in creating knowledge, decision making and guiding further actions.

Knowledge is the collection of all that is known; the awareness or familiarity gained by experience, a person's range of information, a theoretical or practical understanding of a subject, language etc. In an information system, knowledge is the application of information by the use of rules.

Wisdom is far beyond the accumulation of knowledge; it is the union of experience and knowledge with the power of applying them. Wisdom is the ability to think and act utilizing knowledge, experience, common sense and insight (The Knowledge College 2001; Lumpkin 2003).

Basic Characteristics

Data – Origin of Information

The starting points for health care information are data and the collection of data. In the context of health care, data refers to ► patient data. There are two types of data – primary data and secondary data: (Abdelhak et al. 1996)

- ► Primary patient data are obtained from the original data source – all documentation in the patient's health record, as well as hospital reports, daily ward census etc. Primary data are usually detailed, poorly structured, incomplete and inaccurate.
- ► Secondary patient data are derived from primary data – disease and procedure indexes, health care statistics, disease registries. Secondary data are created in a highly standardized way, making information derived from them comparable to other sources.

In order to interpret data – to make sense of the facts and use them – the data items need to be organized. Once organized, data become information. The process of data collection, storage, coding, transmission utilization and presentation is discussed in other sections.

Creation of Information

The process of producing ► medical information is very complicated and demands various skills from the physician. The physician must apply clinical knowledge and skills to acquire the relevant data from the patient. This data is recorded as a medical history. Then, before taking action, the physician collects relevant data from other medical sources, such as textbooks, the internet or other physicians, and compares them to the data stored in the patient's record. By using all the above-mentioned knowledge sources, the physician interprets the given facts, organizes them, structures them and creates information (Wyatt 2005).

The information generated in this way is highly dependant on its context for three reasons: (Berg 2004)

1. Data are produced for a purpose, and their specificity is directly tailored to that purpose. For example, when a patient's health state is stable and all signs are normal, a physician need record only vital functions. Failing to record all functions cannot be interpreted as incompetence or negligence because it will be deduced that empty fields imply that the patient's signs are normal in those fields.

2. Information is not a simple aggregation of isolated facts, but a mutual interaction and elaboration of data from various sources. This process depends on a specific situation or context, and evolves over time. For example, two patients who were treated with the same antihypertensive drug were found to have the same blood pressure 130/90 mmHg. Taking the contexts into consideration (e. g. different sex, or age or medical history) a physician will create different types of information and probably take different actions in the two cases (cease the therapy, continue with therapy, replace therapy, demand weight control or restrict sodium intake etc.).
3. Physicians assess the adequacy of medical information in the light of the credibility of its source. For example, medical information obtained from an experienced senior resident is usually considered more reliable than that generated by an inexperienced physician; or the results obtained from one laboratory are considered more specific than those obtained from another, simply because one is equipped with modern, highly specific technology and the other is not.

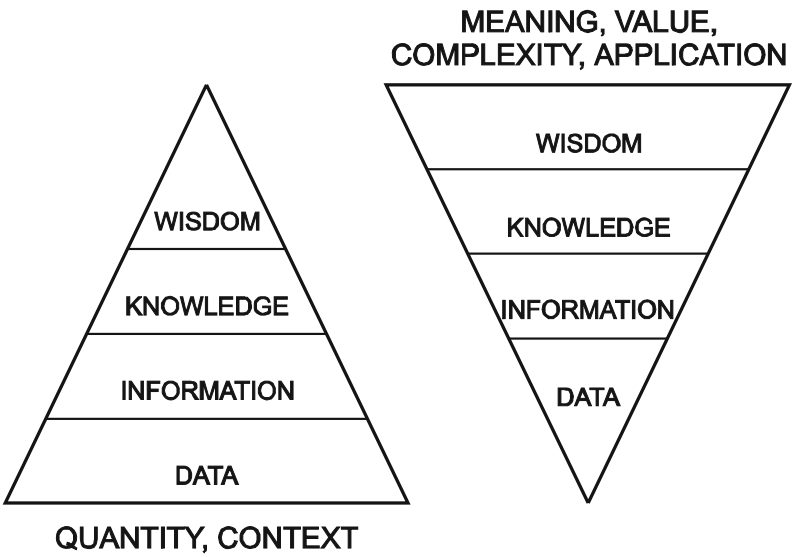
Thus information must not be used for other purposes outwith its context. This is formulated as the **"First Law of Medical Informatics"** (► law of medical informatics, ► medical informatics, ► health information). Two **"laws" of medical information** support this law:

1. The first "law": "The further information has to be able to circulate, the more work is required to disentangle the information from the context of its production." The disentangling of the information from its primary context requires work. Information that was understandable within its direct context of production has to be "made" transportable, understandable and recognizable outside of the conditions of its production.
2. Since work is required to make data suitable for accumulation, the second "law" is: "The more active the accumulation will be (sic), the more work needs to be invested." This "work" usually includes data storage (on paper, on a film or in a computer), data coding or structuring, or breaking down into simple elements, analyzing or modeling; all performed by health care professionals in order to make information usable for other purposes (Berg 2004).

Access to Information

Users of health information are facing some challenges regarding the access to health information in the development, maintenance and use of population-based health and health services (Centre for Health Services and Policy Research 2005). The proposed dimensions of information access are:

1. **Availability** is the relationship of volume and type of existing information resources to volume and types of information needs (as in economy, relationship between supply and demand). When looking for information, the user must: find out if the data or information exists in the first place, where it is stored, recognize the format in which it is stored and recognize its adequacy for use in research etc.
2. **Accessibility** is the relationship between the location of information supply and the location of users. This means that users must take into account: the means by which they obtain information (by internet, in the bookstore, in the library, by e-mail), the "physical convenience" of the data and the need to have license to access data. Furthermore, users' time and costs in obtaining information must be taken into consideration (e. g. price of a book, access by internet, specific software, time needed to obtain it, etc.).
3. **Accommodation** is the relationship between the manner in which the supply resources are organized to accept users and the users' ability to accommodate to these factors and the users' perception of their appropriateness. This refers to the appropriateness of the policies or procedures needed to access data, such as the requirement for identification of the user, the requirement to pay for information and time-limited access, etc.
4. **Affordability** refers to the relationship of prices of services to users' ability to pay. This is a pure question on information costs. Some users recommend that all public data should be free of charge, but in some situations, a certain cost for information seems reasonable. Information costs are especially high for data captured by health professionals in the structured, coded representation. The implementation of technologies such as the electronic health record has decreased the work of data technicians in updating and structuring data records and consequently decreased the costs of information.



Data, Information, Knowledge, Figure 1
Process of creation: data-information-knowledge-wisdom

5. **Acceptability** is the relationship of clients' attitudes about providers and providers' attitudes about clients. This raises the essential question of information privacy and security and consumers' protection from the misuse of medical information. The conflict may occur if a health care provider wants to use patients' health data for research, publishing or commercial purposes without patients' consent, or in spite of their disapproval (► consumer protection).
6. **Adequacy** is the suitability of data for users' needs. This is a question of data quality. Users require that data quality should be a priority. Standardization of data collection and processing, training of personnel, education of data users, the development of better data documentation, and the introduction of information technologies such as telephone-assisted surveys and electronic health records would all greatly improve ► data quality.

Knowledge

Human knowledge is a collection of individual theories elicited from scientific observations. In health care, knowledge refers to ► medical knowledge. The process of creating knowledge, from data organized into information, is sometimes referred to as the "Data-Information-Knowledge Ladder" (The Knowledge College 2001) or "Knowledge Spectrum" (Pantazi 2004), however, in the "Data-to-Wisdom-Continuum" (Godbout 1999) a further step is taken to the creation of wisdom. This process is represented on Fig. 1.

The process of creation has two dimensions: one refers to the quantity and context, the other to meaning, value, complexity and application. As represented in Fig. 1, during the process of creation, the dimension of quantity and context is constantly decreasing, while the level of complexity, meaning, application and purpose is increasing.

The creation starts from data – plain, simple facts, recordings or transactions or events gathered from observations and measurements. As such, data does not carry meaning, has little value and is understandable only in connection to the context of its production. Data is a means of processing transactions, and it is therefore only the raw material for the production of information. A large quantity of data, with many connections and interrelations, is needed to produce information. Information is less connected to its context, and is certainly more generally applicable than data. The purpose of information is to enable decision making, and it becomes further refined through communication and utilization (Sender 2004).

Information becomes knowledge when an individual (or a group of people) accept it as being a proper understanding of what is true and a valid interpretation of reality (Godbout 1999). Finally, combining knowledge and experience, by getting a deep insight into reality, one developes the ability to discern or judge what is true, right, or lasting, which is wisdom. Knowledge

enables one to identify boundaries and directions while wisdom enables one to offer advice. Unlike data and information originating from complex reality, knowledge and wisdom transcend reality and cross to the level of abstraction.

There are various classifications of knowledge. Knowledge is traditionally categorized into implicit and explicit (Hussain 2004; Pantazi 2004; Sender 2004).

► Implicit knowledge is the cumulative store of experiences, insights, expertise, know-how, trade secrets, understanding and learning. It also integrates wishes and hopes with views, opinions and ideologies. Sometimes referred to as embedded knowledge, it is unstructured and intangible and is thus hard to codify.

► Explicit knowledge is the abstract, symbolic type of knowledge presented explicitly in documents such as textbooks or guidelines, procedural guides, reports, strategies etc. It may be applied to both specific and generic problems and relies on an explicit reasoning mechanisms. It forms the base of a given value system. Since knowledge is a product of the human brain, all knowledge is originally individual. **Individual knowledge** can match solutions to problems in a personal, unique context. **General knowledge**, however, is the explicit, abstract, propositional type of knowledge, suitably applicable to context-independent, generic problems. General knowledge is more difficult to use in specific contexts because of the gap between the general knowledge itself and a particular application context.

The globalization of the digital world has led to an increasing complexity in the **management of health information** (► Health Information Management) and ► knowledge management. In the global economy, where capital is mobile, technology spreads quickly and goods are produced at lower costs, the most important resource becomes the knowledge. This knowledge-based economy will affect culture; social and economic dynamics, social classes and social problems, and changes in health systems and health services are to be expected.

Conclusion

Data, information and knowledge form a complex continuum, a dynamic state of interactions where data become information, information is used to create knowledge, and knowledge is applied to gather new data. These interrelations are of prime importance in health, because they are the bases of everything that health professionals think, learn and do.

Data Legibility

Definition

Data legibility is a criterion of ► data quality that refers to appropriate representation of data such that it improves the readability and understanding of data. This can be applied to all forms of data—written text, standard coding, standard images, and biosignals, etc.

Data Management

Synonyms

Data preparation

Definition

Data preparation for analysis precedes data description (► descriptive statistics) and statistical estimation and hypothesis testing (inferential statistics). Data preparation consists of several phases. The first phase of data preparation is developing and documenting the database structure. This phase includes the choice of ► variable order, unique identification of each unit of observation in the research, choice between numeric and alphanumeric codes for variables measured on nominal or ordinal levels, determination of the number of digit places for numerical variables, and codes for missing values. The second phase of data preparation consists of data entry and ► data validation. The purpose of data validation is the reduction of errors that may occur during data entry into a computer. The third phase of data preparation is data screening, where ► missing data and ► outliers (unusual values) are detected. The last phase of data preparation is ► data recoding and/or data ► transformation (► data preparation).

Data Management Packages

Definition

Data management packages software facilitates development of data processing systems with user-convenient interfaces. Facilities offered by these packages include data creation, manipulation, processing, organization, query processing and report generation.

Data Mining

Definition

Data mining, also called Knowledge-Discovery in Databases, is the process of automatically searching large volumes of data for patterns such as association rules. It is a fairly recent topic in computer science but applies many older computational techniques from statistics, information retrieval, machine learning, and pattern recognition. Although data mining is a relatively new term, the technology is not. For a long time companies have used powerful computers to sift through volumes of data such as supermarket scanner data, and produce market research reports. Continuous innovations in computer processing power, disk storage, and statistical software are dramatically increasing the accuracy and usefulness of such analysis.

Data Preparation

Goran Trajković
Medical Statistics and Informatics,
School of Medicine, University of Pristina,
Kosovska Mitrovica, Serbia
goranty@yahoo.com

Synonyms

Data management; Data quality assurance

Definition

Data preparation for analysis includes developing and documenting a database structure, entering data into the database and ► data validation, data screening and eventual recoding and/or transformation of data.

Basic Characteristics

Development and Documentation of a Database Structure

Data preparation for analysis precedes data description (descriptive statistics) and statistical estimation and hypothesis testing (inferential statistics). The first phase of data preparation for analysis includes development and documentation of the database structure.

The database, either in hard copy or in electronic form, is configurated into a matrix record, where in each new line data referring to a new unit of observation are recorded, and in each column data about a new variable in the research are set. Thus, the dimensions of such a matrix depend on the number of units of observations and their characteristics that are the subject of the research (Eric-Marinkovic et al. 2001).

The fist decision to make on the database structure is related to the choice of variable order. The unique identification of each unit of observation in the research (ID) is presented before any other variables. For that purpose, a unique numeric identification (personal identification number, ordinal number of entry in database, etc.) is usually used rather then an alphanumeric identification, such as name and date of birth, as this kind of identification is not necessarily unique. The unique identification is usually followed by demographic and socioeconomic variables, such as gender, age, economic status, profession, marital status, area where he/she lives, etc. Next are variables that are not of direct interest to the research (confounding variables, extraneous variables), and variables that are of direct interest to the research (factors and outcome variables).

The second decision refers to the choice between two existing ways of coding for variables measured on nominal or ordinal levels of measurement. This is a matter of choice between numeric and alphanumeric codes. Thus, for example, gender can be coded with M and F or 1 and 2, where 1 is code for males and 2 for females.

The third decision refers to the determination of the number of digit places that each variable will take in the database, depending on the accuracy with which the variable values are measured.

The fourth decision refers to the code that will be used for the missing values. The most commonly used is an empty field, dot (.) or some other value that is otherwise impossible as a variable value (–9999, for example).

The research database is followed by a codex that contains information about variable order and names, variable description, measurement units and level of measurement. Apart from the above, for categorical variables the information on the number of category and categories codes are included in the codex.

Data Entry into the Database and Data Validation

The second phase of data preparation entails the entry of data into the computer and ► data validation. Errors may occur during the process of data acquisition and final date entry. The errors might be the result of faulty reading or faulty copying of the original data, typing mistakes during data entry, or caused by a fault in the electronic equipment that is being used for automatic data acquisition and entry into the database.

Before carrying out any statistical analysis and drawing conclusions it is important to quantify the quality of the data and identify any sources of error. The data quality can be measured by the ► database error rate. Data quality evaluation is relevant to all variables, or group of variables, that crucially form the base on which final conclusions are drawn (Fong 2001). It is very hard to obtain absolutely correct data for the database. This is not necessary as high-quality data are just as effective a base on which to draw conclusions as are perfect data (Rasmussen 2000). There is no defined acceptable quality level for data, and thus a "fairly good" level can be considered appropriate.

The ► database error rate can be reduced through the process of ► data validation. There are several data validation procedures. One of them is visual inspection of printed or computer screen data. Higher consistency and lower error rate can be achieved by using such validation (Chow 2003). Thus alphanumeric characters (for example, data referring to a person's name only uses letters) are checked by the simple data validation method of visual inspection. Logical methods are also used, for example, checking that data lies within a certain range (number of teeth range from 0 to 32), or identifying data showing conflicting variables (a male has given birth).

Double data entry is another validation procedure. It is useful if errors occur frequently because of typing mistakes. It is possible to apply two types of double data entry: (a) two people separately carry out the same data entry, while a third person checks their entries and identifies possible differences, and (b) one person

carries out data entry in a first pass, and another person does the same in a second pass and at the same time identifies/corrects possible differences (Prokscha 2006). After the second entry, data quality in the resulting database is in inverse proportion to the probability that two people make the same mistake in the same field, so the error rate in the database can be very low (McFadden 1998). Instead of double data entry the following can be applied: (a) single data entry with extensive data check, or (b) the process of optical character recognition (OCR) in the first pass repeated, maybe several times, in later passes (Chow 2003). As double data entry is a drain on human resources, one alternative is to have data entry carried out by only one person with the quality of the work being checked by random data sampling of the database.

Any change made during the data validation procedure must be recorded and documented, along with the new data, the time of change, and the identity of the person who performed the change and the reason for the change (Chow 2003).

Data Screening

The third phase of data preparation is data screening, in which ► missing data and ► outliers (unusual values) are identified.

The analysis of missing data will show missing value patterns that appear in the database and identify their frequency as well as variable pairs that have the appearance of missing values. Proper treatment of missing values is important for all statistical analysis. The researcher must assume that missing values can influence the results of analysis and conclusions, and that the problem is not a resultant reduced sample size but the possibility of bias in the remaining data.

When data is missing completely at random, the ► missing data is independent from the value of that or some other variable. For example, information about a person's age is not dependent on that person's age, gender or education.

Sometimes missing data are not completely random, as they are dependent on some variable value. In that case they can be marked as data missing at random if their distribution is random after controlling for the variable on which their appearance is dependent (Allison 2002; Little and Rubin 2002). For example, a person's age is dependent on gender, but the data on gender is missing completely at random; this is a case of age data missing at random.

Non–ignorable missingness exists when missing data are not distributed at random, and when their appearance cannot be predicted according to a given model.

The treatment of ► missing data embraces several procedures. One procedure is deletion – casewise or pairwise deletion. Another is mean substitution – replacement by the arithmetic mean of the related variable. This procedure is not recommended since it reduces variations and it has influence on the value of correlation and regression coefficients. Multiple regression is another method of missing data treatment, where prediction of missing values is reached on the bases of existing data and their relation with other variables. A variation of this method is the adding of a random component to the values that are predicted from a regression model. This method is known as stochastic substitution (Afifi et al. 2004).

Some procedures of ► data reduction such as frequency distribution, analysis of minimum and maximum and variability range, are an integral part of data screening and enables detection of unusual values – ► outliers. As a general rule, if outliers are the result of error, such data must be corrected. A problem occurs when it is unclear whether outliers have wrong values – the values are unusually large or small, but not impossible. In such cases, the decision on eliminating outliers from further analysis must be taken carefully.

Data Recoding and Transformation

► Data recoding and ► data transformation are the last phase of data preparation. ► Data recoding involves missing values replacement, continuous data conversion into categories or combining categories of qualitative variables to reduce the overall number of categories. Identification of values with small frequencies can allow researchers to drop and/or combine certain values of category data. If a researcher decides to convert certain variables and recode data, a new variable can be introduced into the database by this combination process. This prevents the loss of the original information.

Many statistical tests include assumptions about normal distribution and/or equality of variance in the examined population. In order to achieve a normal distribution or a realization of some other assumption, ► data

transformation is often applied, which involves converting observed values to another scale. In this way characteristics of distribution and the influence of outliners is altered (Eric-Marinkovic et al. 2001). The most common transformations are logarithmic, square root, reciprocal, square and logistic (Petrie and Sabin 2005).

Synonyms

Data processing; Data computation; Data storage; Data reposition; Data recording

Definitions

Data processing is the process of data management, which enables creation of valid, useful information from the collected data. Data processing includes classification, computation, coding and updating.
Data storage refers to keeping data in the best suitable format and in the best available medium. Documents containing health data are referred to as records.

Basic Characteristics

Crude, unprocessed, direct data collected from patients are not always represented in a way that enables information production. Once data are collected, they must be managed through classification, coding, computation and updating. ► Data classification is a critical function for increasing the efficiency of the system because it helps users in the retrieval of significant data. Computer programs can effectively order or sort data in different ways – in numerical or alphabetical order, or according to specific criteria: disease, gender, and age. ► Data computation is the application of mathematical or statistical models for the transformation of primary data, and analysis, synthesis or evaluation of secondary data. ► Data coding is the classification of data and assignment of a representation for that data. Data update refers to changing of old data and generating new data in terms of new knowledge (► data updating, ► health data management) (Van Bemmel 1997; WHO 2003).

Data Standards

Since data are used to create information that is needed for a variety of functions of health institutions, the quality of data is of prime importance, implying that, among other criteria, data must be understandable. In order to satisfy quality demands, data must be standardized. A standardized approach is needed in the whole process of data management, from data collecting, data analyzing and data verifying, to data representing and exchanging, and communication and usage of information (Jernigan 2003).
The components of data standards are: vocabulary, format and information architecture. *Vocabulary* refers to the coded terms used to represent data that are being exchanged or stored – one can use either a local vocabulary (a specific set of terms) or a universal vocabulary

(a nationally recognized set of terms). Health staff find it easier to use local codes because they are more easily updated or changed, but they are not suitable for sharing information with others who are not familiar with the codes. Universal codes are useful for communication and data sharing, but training of staff is required and the codes may not be adaptable for representation of all information on a local level.

Format is the order and structure of data for the purpose of storing or messaging (► information design). There are two ways in which data can be stored: in a ► database format, in which data are structured according to their similarity or their affiliation to the same group; and in an electronic record format, in which data can be accessed from various places and from different viewpoints.

► Information architecture is the designated infrastructure for supporting data exchange – software, hardware, resources, staff needed for communication, data security, confidentiality requirements, and policy and regulatory requirements (Jernigan 2003).

Paper-Based Patient Record

Patient ► records contain data on patients' health status, stored in the formats in which they are collected (as text, numbers, images, biosignals and codes) (Van Bemmel 1997). The functions of health records are to document patient care, provide communication among health care team members, provide a medico-legal archival record of what has happened to the patient, and enable research.

Traditionally used ► paper-based patient records can not support all the needs of modern medicine. At the time they were created (in the 19th century), they were used as a reminder of patient details, but were inefficient in obtaining relevant information since they contained little information, and they did not serve to aid communication between health providers, like they do nowadays (Shortliffe 1999).

Generally speaking, paper-based records are the base point of health management in many countries, and have many advantages. They are fast for current practice activities, portable, unbreakable, allow great freedom for health professionals in writing data and entering various types of data, and are easy to use, retrieve and scan. However, paper-based medical records are being criticized for being vulnerable to error; data can be lost, incomplete, illegible, or sometimes duplicated because they are chronologically oriented and consequently it is difficult to retrieve data and carry out research, etc (Van Bemmel 1997; Grimson 2000).

In today's health care, most organizations in the developed world are moving to computer-based medical records.

D

Electronic Patient/Health Record

Electronic patient, health or medical records are terms that are used as synonyms. More strictly speaking, ► electronic patient record describes the medical record of periodic medical care, provided mainly by one institution, whereas ► electronic health record describes a longitudinal (lifetime) record of a patient's health and health care.

The advantages of the electronic health record over its paper-based counterpart are that it is always available, information can be retrieved almost instantaneously and transferred to a great distance, and it supports customized views for different specialists (physicians, nurses, pharmacists, and administrative staff). It allows providers to access health information from a variety of locations and to share that information more easily with other potential users. Multiple users may access the information simultaneously. The storage itself does not require much space, and records can be retained for a much longer time. The primary benefit of using electronic records is improved security, since access is limited to authorized and authenticated users, and can also be restricted to just one portion of the record that is important for the user. In principle, the electronic record can also be linked to evidence-based, best-practice guidelines, and literature databases, pharmaceutical information and other databases of health knowledge, to provide decision support.

Contrary to the chronological arrangement or time-orientation of paper records, electronic records offer various types of organization and presentation of data; by problem – data are time-oriented, but further grouped based on problem (e. g. acute bronchitis – problem 1, shortness of breath – problem 2, etc.), or by source of data – within each source (visits or laboratory tests), data are organized chronologically.

Electronic health information can be manipulated by computer-based tools so that knowledge about standards of care can be used to generate alerts, warnings,

and suggestions. These types of capabilities are known variously as real-time quality assurance, decision support systems, critiquing engines, and event monitors (Van Bemmel 1997; Grimson 2000; National Research Council 1997).

Electronic health records enhance productivity of health care professionals, increase patient satisfaction with health services, and facilitate clinical, epidemiological and health administration research (Canadian Institute of Health Information 2006).

Finally, cost-benefit studies show that the implementation of an ► electronic medical record system in primary care results in a positive financial return on the investment to the health care organization. Benefits are primarily due to savings in drug expenditures, improved utilization of radiology tests, better capture of charges, and decreased billing errors (Wang et al. 2003).

The disadvantages of electronic health records include considerable start-up costs, primarily for hardware, software, and their upgrade. Personnel also need to be well trained to use the records appropriately, but the question remains, who will enter data? Furthermore, who will have access to the data for verification, update, change or dissemination and how will this be achieved? More information technology staff would be needed for system maintenance. In order to be useful, the record must also provide simple mechanisms for displaying the required data, analyzing them, and sharing them among different kinds of individuals (including secondary users of the record who are not involved in direct patient care).

Challenges for the implementation of electronic ► health records include:

- Standards for implementation, and policies on consumer protection
- Technological developments – less expensive technology that is simpler and more accepted for use
- Integration of existing electronic data sources, e. g. laboratory systems, pharmacy systems, and physician dictation systems
- Data-related problems: collection, processing, coding, and access, etc.
- Changes in the work of health care providers, training, and responsibility for data quality
- Social acceptance. (Dinca-Panaitescu 2003; McDonald 1997)

Conclusion

The 20th century has been characterized by a revolution in the provision of health care services. Advances in medical science and management have created an entirely new system of health care. Health data are used for various purposes; they are no longer treated as the sole property of a health care facility, and they are transferred through the health information system and used by public health departments, governments, researchers, the media, and commercial organizations. Information technology can and must be implemented in health care, bearing in mind that its purpose is to serve, sustain and support health activities, rather than to create obstacles to them, and deteriorate the health system like an unwanted intruder.

Data Quality

KATARINA PAUNOVIĆ
Institute of Hygiene and Medical Ecology, School of Medicine, University of Belgrade, Belgrade, Serbia
paunkaya@net.yu

Definition

Quality can be defined as the ability to achieve desirable objectives using legitimate means (Donabedian 1988). Quality in general terms refers to achievement of excellence in the objective. Data quality is therefore a characteristic that describes data of excellence. The quality of data depends on its use and on the criteria being applied to it.

Basic Characteristics

Data are collected throughout health systems—by professionals in primary care, in hospitals, by public health departments, by community, and by state. Within this larger context, data are collected from multiple data sources and stored in databases. From this stored data, useful information is generated for organizational decision-making. Since data are used for various purposes, generally related to health promotion, disease prevention, or both, the quality of the data is crucial, not only for use in patient care, but also for monitoring the performance of the health service. Data collected and presented must be accurate, complete, reliable, legible, and accessible to authorized users if they are to meet the requirements of the patient, doctor and other health professionals, health care facility, legal authorities, and the state, province and national government health authorities (WHO 2003). The responsibility for ensuring data quality rests on health professionals.

Criteria for Data Quality

Data quality is a relative concept, because it depends on the use of the data. Data with quality considered appropriate for one use may not possess sufficient quality for another use as the quality of an object depends on the criteria being applied to it. Several criteria have been suggested to define quality in patient data (Iezzoni 1997; WHO 2003; Wyatt 2005; Canadian Institute for Health Information 2005).

1. **Accuracy**—data should be accurate when compared with a gold standard source of data (► data accuracy). Technically, accuracy includes:
   a. validity—the capability of a data item to measure what it is meant to. For example, codes used to classify diseases and procedures must conform to predetermined standards (it is impossible to use a diagnostic code that does not exist), all parameters must be within an acceptable value range (weight can not be equal to 100 kg for a 10 year old), and must be expressed with an adequate national or internationally accepted measurement unit.
   b. reliability—the capability of a data item to measure what it is meant to when the measurement is repeated. In other words, the diagnosis recorded on the front sheet of the hospital medical record must be consistent with the diagnosis recorded in the progress notes and other relevant parts of the medical record.
2. **Completeness**—defined as the percentage of data missing at a given point (► data completeness). In the process of decision making, it is essential that

all required data are present, but this is often difficult to achieve without access to multiple sources of information. For example, a medical record must contain all data identifying the patient, all data from all attending doctors, all nursing notes, and all of these data must be dated and signed.

3. **Timeliness**—refers to the delay from the event the data describes to its availability for use on the information system (► data timeliness). Timeliness is of prime importance for decision making; if data are not timely, all other criteria are useless. This means that all data must be documented as an event occurs, e. g. the operative report must be written immediately following surgery; and physician's orders, specialist reports, laboratory results, etc. must be documented and authenticated immediately, or usually within 24 hours.
4. **Relevance**—data relevance is measured by the impact of specific data on the decisions or actions of the user (► data relevance). Collecting irrelevant data contributes to information overload, which in turn complicates the processes of creation of information and decision making. For example, recording the birth weight of an 80-year old patient is usually irrelevant, and of no or little use in health care.
5. **Legibility/Appropriate representation**—defined as a degree of structuring and coding of items (► data legibility). This means that data should be concise, readable and understandable. This does not only apply to written text, which must be readable in terms of semantics, it also applies to the use of standardized abbreviations and avoidance of undecipherable codes or symbols.
6. **Accessibility**—data should be available to authorized persons when and where it is needed for patient care and for all other official purposes (► data accessibility). The difficult question is who should have access to patient health data? Many health providers, including researchers, administrative workers, insurance agencies, and public health, etc. claim to have the right to access information for various purposes. However, access to information must be controlled because disclosure of private information may cause social embarrassment, or limit the patient's opportunity to get a job. Patients are becoming more aware of the need to protect their data, and therefore access is now governed by consumer protection laws (► consumer protection).
7. **Usefulness**—information should be pertinent and useful (► data usefulness): this is usually defined as:
   a. inclusion of relevant details—data should be detailed enough to support decisions. This is highly dependent on the purpose and confidentiality of the information;
   b. inclusion of relevant context—data should also include enough detail on the context to support appropriate interpretation of the data.
8. **Confidentiality and security**—data should be confidential and secure (► consumer protection).

The above-mentioned criteria or dimensions may be further grouped into four categories: intrinsic data quality, accessibility, contextual data quality, and representational data quality (Strong 1997).

The **intrinsic** category refers to the accuracy, objectivity, believability and reputation of data. It is independent of the context in which data is produced and used. If data are observed as dysfunctional, without known cause, then the quality of the data is diminished because it can not be trusted. Furthermore, during evaluation of the accuracy of data, the sources of poor quality become evident and get the reputation of being less accurate, less reliable, or having little value for use.

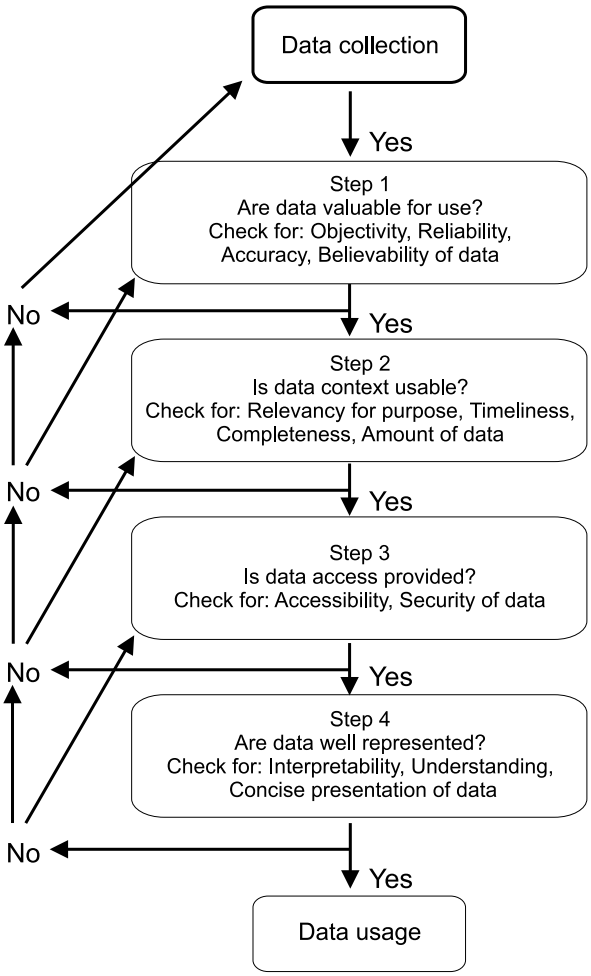
Accessibility problems are related to technical accessibility, data characteristics that may interfere with accessibility, and security for access.

Contextual data quality refers to the dimensions that define whether the data match the context of their production and use: relevancy, timeliness, completeness, and amount of data. If data are missing (incomplete), inadequately defined, measured, or aggregated, they can not be appropriately used.

Several dimensions—interpretability, ease of understanding, concise representation and consistent representation—define **representational data quality**. All dimensions are needed in order to ensure that the meaning of the data has not been lost in the communication process. The process of obtaining data quality is represented in Fig. 1.

Routine Data Quality Monitoring

The two most important monitoring procedures for inpatients, which have been undertaken for many years, are quantitative and qualitative analysis of medical records (WHO 2003; Green 2005).



Data Quality, Figure 1 Stepwise process of obtaining high quality data

1. Quantitative analysis of medical records
   To evaluate the quality of documentation, and subsequently patient care, the medical record must be complete. In a quantitative analysis, medical records should be reviewed to check that all documentation has been included. In some instances, a reviewer of medical records can complete the "deficiency form", indicating what data are missing (if all necessary reports are present, completely documented, and authenticated by the physician responsible). According to this deficiency form, all physicians involved in patient care can easily be instructed what corrections to make in a given medical record.
2. Qualitative analysis of medical records
   In a qualitative analysis of medical records, information pertaining to patient care is reviewed for accuracy, validity and timeliness. This means that medical records are reviewed to ensure that all clinically pertinent data have been accurately recorded and were recorded on time, and to ensure that the diagnosis and treatment recorded on the front sheet are supported by documentation in the body of the medical record.

D

Problems Related to Data Quality

Ensuring quality is much more difficult for data than manufactured goods. In theory, everybody agrees that quality is important, but in practice few people list it as a top priority. The problem of ensuring data quality is exacerbated by the multiplicity of potential problems with data and by the constant possibility that the integrity of data will be compromised. Similarly, sometimes it is difficult to determine the nature of data inadequacies, especially in multi-user environments, because users may have differing data quality requirements.
Data quality can be hampered by a number of issues, including the following (Kumar Tayi 1998; van Mosseveld 2000; WHO 2003).

- Lack of uniformity of data—the quality of data must be assessed early in the processes of data collection, storage, analysis, and distribution, using strict predetermined standards and uniform data sets. Lack of uniformity may be the consequence of poorly designed data collection forms, a poorly defined method for data coding, using non-standardized statistical methods for data analysis, or representing data in a non-standardized form. Another problem could arise from the fact that sometimes multiple medical records on one patient exist, which also limits the overall collection of meaningful data about an individual patient. Finally, errors occurring during the process of data collection and lack of data verification cause great data discrepancies and poor quality.
- Limited education of professionals—if the staff are unaware of the need for accuracy and completeness of data, then quality is threatened. Furthermore, some physicians may find it difficult to record data in a clear and concise manner, often using non-standard abbreviations, or are so oppressed by clinical work that they do not want to put any more effort into something that they do not find important.

- Limitations to information transfer from different parts of the facility—sometimes information transferred from one unit to another may be missing important data, such as the patient's name or medical record number. Such errors make it difficult to ensure that all data are filed in that patient's medical record. The transfer of information from one department to another or from a hospital to a clinic is also connected with problems in timeliness, loss of data in part or in whole during transmission, and especially with security and privacy.

The problems related to data quality suggest establishing a consensus about data content, and standards for data collection, coding, storage, transmission, and use, may be beneficial. In order to achieve this, an in-depth investigation on quality problems must be performed and areas to be targeted clearly defined.

Conclusion

Achievement of high quality health data is not an easy task within health services. When coupled with many other obstacles, such as an atmosphere of hard work, stress and anxiety, the need for obtaining quality may seem like another burden on the shoulders of health professionals. However, once accepted, it becomes obvious that the advantages of quality data overcome the time and work invested in its achievement. Health systems, public health, and other stakeholders in health also rely on comparable health data because they enable an adequate insight into the current situation in the system, as well as pose constraints for future investments and improvements.

Data Quality Assurance

► Data Preparation

Data Recoding

Definition

Data recoding is an important step in ► data preparation. Data recoding involves the modification of data depending on analytical aims. This may include procedures such as ► missing values replacement, conversion of a continuous ► variable into a categorical variable (e. g. dichotomization based on cut-off values), recoding a categorical variable (e. g. collapsing the categories of categorical variable into a smaller number of logical categories), conversion of the original text format into a numerical format, combining two or more variables to create a new variable, or modification of negatively worded scale items. Data recoding can use the same or a different variable. Recoding into the same variable involves replacing an old value with a recoded value with the consequent loss of the original values. Recoding into a different variable is done by creating a new variable but keeping the original data intact. Some operations include creating a new variable, such as combining of two or more variables or recoding categorical variables with more than two categories into a series of binary variables (dummy variables).

Data Recording

► Data Processing and Storage

Data Reduction

Definition

Data reduction has two meanings. Firstly, in univariate analysis, it is the process of reducing large masses of data to produce a few summary statistics. This process involves grouping data into tables, visualizing them in a ► graphical representation, and calculating statistics such as mean, ► standard deviation, quartile and correlation coefficient.
Secondly, in multivariate analysis, it is the process of reducing the dimensionality of multivariate data and simplifying its representation by principal components analysis or factor analysis.

Data Relevance

Definition

Data relevance is a measure of the impact of specific data on decisions or actions by the user. Collecting irrelevant data contributes to information "overload" and complicates decision-making in health care.

Data Reposition

► Data Processing and Storage

Data Sharing

► Data Dissemination and Utilization

Data Standards

Definition

Data standards are common terms and methods for sharing data and exchange of information, which are used uniformly. The World Health Organization has proposed standards for data collection: collection in specific data forms, in a logical sequence, as simple as possible; and with routine checks for ► data errors, in order to improve data quality. The responsibility for ensuring data quality in the process of data collection, management and use rests primarily on health professionals.

Data Storage

► Data Processing and Storage

Data Synthesis

Definition

Data synthesis is the computation of data in order to make sense of them and to use them for deriving conclusions, making suggestions and supporting decisions in health care.

Data Timeliness

Definition

Data timeliness is the time passed from the moment the event happened to when the data representing that event is available. The quality of data is improved if the event is documented by data at the moment it happens.

Data Transfer

► Data Dissemination and Utilization

Data Transformation

Definition

Data transformation is applied when there is a need to achieve a ► normal distribution or realize some other assumption about the distribution prior to carrying out certain statistical tests. Data transformation changes the scale of observed values. In this way characteristics of distribution and the influence of outliners is altered. The most common transformations are: (a) logarithmic transformation, which is applied in the presence of right skewed distributions, (b) square root transformation, for

data which follow Poisson distribution, (c) reciprocal, often applied when the standard deviation is proportional to the square of the mean, (d) square, when data are skewed to the left, (e) logistic transformation or logit, and (f) arc sine transformation applied for proportion.

Data Updating

Definition

Data update refers to change of old data and generation of new data by applying new experiences and knowledge.

Data Usage

► Data Dissemination and Utilization

Data Usefulness

Definition

Data usefulness is a criterion of ► data quality. This is met only if data contain relevant details and enough detail on the context of production to support decision-making in health care. The closest to this criterion is data relevance.

Data Validation

Definition

Data validation is a process which ensures the correctness of data, reduces ► database error rate and ensures an acceptable level of data quality. Data validation is the key to the quality of the database. It is carried out during or after a data entry and before any statistical analysis. Data validation checks out, for example, that the ► variable values within a range are possible, that there is consistency between data in the computer data file and the original data, that there are no ► missing values for variables which require completeness of data, and that there are uniqueness identifiers for data (e. g. identification number). There are several data validation procedures, such as visual inspection of printed or on screen data, program validation, logical methods and double data entry (► data preparation).

Data Verification

Synonyms

Data confirmation; Data authentication

Definition

Data verification is the process of proving that the data that were collected are correct. If performed on time and by trained professionals, data verification reduces costs in the system ► data errors.

Data Warehouse

Definition

A data warehouse is an integrated repository of data collected from various sources, with data available for integration and analysis. At the warehouse, data analysis can be performed quickly and efficiently since the information is directly available, regardless of the availability of the data sources. Furthermore, access to warehouse data does not tie up the information sources, and does not incur costs that may be associated with accessing data at the information sources. Furthermore, warehouse data is available even when the original information sources are inaccessible.

Day Care

Definition

Day care for adults includes programs, services and facilities that enable physically or mentally impaired adults to remain in their communities; otherwise they might require institutional ► long-term care or rehabilitation services. In general, day care programs are either based on the medical model or the social model. From a medical point of view, day care offers comprehensive medical, therapeutic and rehabilitation day treatment. Within the social model, day care comprises, as well as supervised activities, peer support, companionship and recreation. Both models are targeted at enabling older adults and patients with chronic conditions to remain independent as long as possible. Day care centers are facilities that provide activities for older people during the day to promote independence and enhance living skills.

Days Lost by Economic Activity

Definition

Days lost by economic activity are the number of days lost by cases of ► occupational injury with temporary incapacity for work. In cases of permanent disability for work, estimates of days lost are used instead of original data. Calculation of days lost by economic activities in most countries is based on the calendar days during which the injured ► worker was temporarily unable to work, excluding the day of the accident, up to a maximum of one year. In countries where the source of the statistics is an accident compensation scheme, calculation is based on workdays. Temporary absences from work of less than one day for medical treatment are not included.

Decision Analysis

Definition

Decision analysis is a theory of decision making under conditions of uncertainty, used for normative purposes. In clinical terms, decision analysis addresses the inevitable uncertainties in a clinical problem and combines these with preferences for health outcomes in a consistent framework that obeys the laws of probability calculus and the theory of subjective expected utility. The following basic steps are included in the decision analysis: defining and structuring the clinical problem in a decision tree, assigning probabilities to chance nodes, assessing utilities to outcomes, calculating the expected utilities, and selecting the choice and sensitivity analysis.

Decision Making

wolfgang.boecking@web.de, dtrojanus@gmx.net

Definition

Decision making in health policy describes the process of consultation of all groups involved in health policy related issues which leads to a legal framework generally applied on a national level. The main bodies responsible for health policy formation in all countries with developed healthcare systems are the government, the medical professionals' associations, the hospitals and the health insurance companies. The particular process of decision making as well as the degree to which the different ► stakeholders are involved vary from country to country.

Basis Characteristics

Key Factors of the Decision Making Process

As healthcare systems grow out of the historical, cultural and social context of each country, the decision making process established for health policy is also directly influenced by the national policy environment. Greenhalgh and Russel describe the decision making process in health policy as the "messy unfolding of collective action, achieved mostly through dialogue, argument, influence and conflict". Indeed, the interaction between the different actors within the decision making process are mainly influenced by the power they exercise. However, some key factors determining a fruitful health policy decision making process can be found across all developed healthcare systems:

- The government exercises leadership in setting out policy proposals and reform scenarios which ideally increase the public interest in participating in a debate process. This leadership role may be enhanced by the creation of a transparent and accountable policy making process through a national database for all stakeholders.
- The decision making process comprises a mechanism for reflecting the view of the different interest groups and particularly the view of the patients. Country examples demonstrate that the adoption of a corporatist approach privileging a patient-centered perspective rather than a competition of interest groups has a greater chance to lead to consensus.
- Health professionals, i.e. doctors, hospitals and other medical institutions are involved in the decision making process through their professional organizations. If they consider patients as consumers and collect information directly from the interaction with

their patients, they are able to effectively contribute to the decision making process with respect to the improvement of the content and administration of healthcare services.

To sum up, the national context and the power of the actors as well as the interaction between the actors are the key elements of the decision making process in health policy.

The Role of Research in Health Decision Making

In order to deepen the health policy process, there is a crucial need to involve academics that specialize in health policy research and are capable of objective and comprehensive analysis of medical care and health policy issues. However, the involvement of research in the decision making process evokes the question whether research contributes objective knowledge support or rather subjective decision support. Researchers are typically expected to provide research evidence for public policy benefit or harm. But on the other hand, researchers' ideas may also reflect their lifetime experience which is influenced by their professional or personal interest. Therefore, researchers may contribute to the decision making process on two levels. The actual policy making process in many countries shows, however, that academics are often not even mentioned by policy makers. Policy makers usually turn to special advisers from the political scene, think tanks, lobbyist and pressure groups as well as professional associations and the media.

Country Examples

The comparison of several national decision making processes regarding the adoption of healthcare reforms provides insight into the multitude of drafting and consensus formation processes underlying health policy making.

The United States Policy ideas are typically provided by government bodies, think tanks and other professional associations doing active lobbying. The American Medical Association (AMA), for example, promotes and advocates its policy positions in order to guide decision making and actions in American Health Policy. The core purpose of the AMA is "to promote the science and art of medicine and the betterment of public health". Policy statements are established to provide the information and guidance that physicians and others seek from the AMA about health care issues. The right to propose bills is restricted to members of the Congress, but the submission of bills may also occur across party lines. The information on health policy is shared through various medical databases that are publicly accessible. American health policy is shaped by the perception of health care as an engine for economic growth. Therefore, the simultaneous improvement of efficiency and quality are of major importance.

The United Kingdom The policy planning process is led by senior government figures and experts consulting political parties, think tanks, interest groups as well as academics for the promotion of ideas. The policy proposals are published as so – called Green Papers that are discussed in the various interest groups. The results of this consulting process are published in so – called White Papers which are then turned into bills that are amended and enacted by the Parliament. Information on health policy is shared through the release of official data on the ► National Health Service (NHS). However, due to the complex budgetary system of the NHS, data on cost is insufficiently available. Although industrial ► stakeholders such as pharmaceutical companies and private insurances are part of the health policy concept, there is little recognition of health policy as part of industrial policy.

Germany The decision making process in health care is led by the governing parties which determine policy proposals based on basic proposals of party members and the plans of the Ministry of Health. Bills are deliberated by the Bundestag and then special committees hear the opinion of the several interest groups. In the decentralized political system of Germany some topics such as hospital administration are under the authority of the Länder and require the approval of the Bundesrat. Information on health policy is available to the government and the related organizations via various databases. The political debate takes into account the different ideologies of the parties as well as other interests, e.g. patients, and can be therefore classified as a 'corporatist approach'. Although health policy is not seen as an instrument of industrial policy, there is an accepted need for limitation of the burden of insurance premiums on companies in order to promote domestic investment.

France Decision making is led by the administrative elite in the presidential, prime ministerial and cabinet offices. Legislation primarily comes from the administrational bodies and less from members of the parliament. The medical profession is organized into associations that influence the different areas of party politics. As the whole spectrum of opposing views is represented by interest groups, the power of the leading government figures is playing a major role in the decision making process. Information on health policy is shared via regional agencies and databases. The priority in French health policy is to contain medical costs and to improve quality. Therefore, health policy is not seen as an instrument of industrial policy.

Development of Decision Making

To complement the overview of different national decision making processes with regard to the development of a more global approach to decision making, the activity of the Society for Medical Decision Making (SMDM) based in the United States is worth being mentioned as an example for the future trend in decision making.

SMDM aims to improve ► health outcomes through proactive systematic approaches to clinical decision making and policy-formation in health care. The Society provides a scholarly forum connecting and educating researchers, health care providers, policy-makers, and the public.

The main goals are:

- To promote the use of systematic methods to deal with the uncertainties of health care decisions.
- To advance the scientific basis for and foster synergies between multiple areas relevant to medical decision making including for example decision analysis, predictive modeling, health outcome assessment, ► cost-efficiency analysis, ► evidence-based medicine (also ► evidence based medicine, in HTA).
- To develop and evaluate tools for shared decision-making with patients and the public.
- To develop and evaluate techniques for assisting clinicians' decision making under uncertainty.
- To foster and promote international exchange and synergies between health care decision making scholars from different countries.

To fulfill these goals, members come from a variety of countries and academic disciplines and work in hospitals, universities, corporations, foundations, and government agencies across the globe. Interdisciplinary scholarship and a global perspective on health care together with methodological excellence are major factors of the Society's work. In this sense, the Society promotes an integrated approach to health care decision making based on multiple perspectives and expertise from multiple disciplines.

Decision Making Process

Definition

Decision making is the cognitive process leading to the selection of a course of action among alternatives. Every decision-making process produces a final choice, which can be an action or an opinion. It begins when we need to do something but we do not know what. Therefore, decision making is a reasoning process which can be rational or irrational, and can be based on explicit assumptions or tacit assumptions. In healthcare, consensus decision-making is common. Consensus decision-making is a decision-making process that not only

seeks the agreement of most participants, but also aims to resolve or mitigate the objections of the minority in order to achieve the most agreeable decision. Consensus is usually defined as meaning both general agreement, and the process of getting to such an agreement. Consensus decision-making is thus concerned primarily with that process.

Decision Making Under Uncertainty

Definition

Decision making under uncertainty is a procedure for making logical decisions based on sample data. Due to variations, the outcomes of decisions cannot be predicted exactly – they are always accompanied by an amount of uncertainty. The uncertainties can be measured in terms of probabilities. For example, testing hypotheses is actually making a decision between two hypotheses H_0 and H_1. In decision-making, we can calculate two kinds of errors in decision (i. e., probabilities): accept H_1 when H_0 is correct (α, or accept H_0 when H_1 is correct (β).

Declaration of Helsinki

Definition

The Declaration of Helsinki was produced by the World Medical Association (WMA) as a statement of ethical principles for the guidance of physicians and other participants in medical research involving human subjects and identifiable human material or data. It is the first global statement on medical ethics.
The Declaration of Helsinki was adopted by the WMA 1964 in Helsinki, Finland. It has been modified over the years; the last change (clarification) was added in 2004 in Tokyo, Japan.

Decompression Sickness

► Caisson Disease

Deductible

Definition

A deductible is equivalent to the amount of health care expenditures for which the beneficiary is responsible before the insurer starts paying.

Deficiency of Erythrocytes

Synonyms

Anemia

Definition

Anemia is a decrease in the number of red blood cells, hematocrit (Hct), or hemoglobin (Hb) content, usually measured by a decrease in the amount of hemoglobin. Normal hemoglobin levels vary from 13.8 to 17.2 gm/dl (Male) respectively 12.1 to 15.1 gm/dl (Female). Anemia can result from blood loss and/or deficient erythropoiesis, and/or excessive hemolysis.

Definition of Public Health

NATALIE M. SCHMITT, JOCHEN SCHMITT
Forschungsverbund Public Health Sachsen-Sachsen Anhalt e. V., Medizinische Fakultät, Technische Universität, Dresden, Germany
Natalie.Schmitt@tu-dresden.de

Introduction

Public Health is an empiric and multidisciplinary field whose goal is to assure conditions in which people can be healthy. While medicine mainly focuses on treating illness in separate individuals, it is the central goal of public health activities to increase health at the population level. The ruling principle of public health is to deal with the health of the population in its totality. Health interventions on the population level include community hygiene, sanitation, health education, immunization, and promotion of nutrition. Public health covers preventive, curative, and rehabilitative actions. The success of public health depends on adhering to the basic rules of equity, partnerships, and social justice, as well

as the mobilization of local, national, and international resources.

In the preamble to the Constitution of the World Health Organization (WHO), *health* is defined as *"a state of complete physical, mental and social well-being and not merely the absence of disease or infirmity"*. This definition of health was adopted by the International Health Conference in June 1946, and entered into force on 7 April 1948 (UN 1946). The mission of public health includes both promotion of physical and mental health and prevention of disease, disease-produced decreased quality of life, injury, disability, and premature death.

Development of the Field of Public Health

Both the idea that many diseases are contagious and the concept of the environment having an impact on disease occurrence have their origins in antiquity (Tellnes 2004).

Up to three centuries ago, major parts of the population suffered from chronic pain, periodic famines, and epidemics of deadly infectious diseases. Major changes in human history often followed transformations in health. In developed countries, public health arose as a reaction to epidemic crises. The belief in the possibility of effective action as a prerequisite for public health emerged slowly. Supernatural ("Will of God") and natural (e. g. smallpox as a normal process of fermentation in the growing body) explanations of disease causation persisted tenaciously. The medieval Christian Latin culture, for example, mainly explained disease as punishment of sin.

For most of history, prevention of epidemic disease was intended to control disease among the masses primarily to protect the military and to assure the continuation of commerce. In contrast, protection of the health of individuals was not seen as an obligation (Hamlin 2004).

It has only been in early modern times that health and disease prevention have been regarded as part of broader issues of social welfare.

In the Middle Ages, two different theories concerning disease causation evolved. The germ theory competed with the widely accepted ancient miasma theory that promoted poisonous vapors as the major cause of illness. The miasma theory led to improvements in sanitation as it made the connection between dirtiness and disease. The germ theory refers to transferable microorganisms as the cause of illness and was supported by observations regarding microbiology (17th century). An intervention associated with the germ theory and already recorded in the Bible was the custom of isolating people with contagious diseases. Lepers, for example, were expelled from ecclesiastical and civil society. In addition, the germ theory seemed to be the scientific basis for the initiation of water sanitation by filtration of parts of the London water supply in 1829 as a consequence of cholera outbreaks. During this time, the era of epidemiology, the major discipline of public health began. The influence of John Snow's studies of cholera, especially his quantitative approach in analyzing the occurrence of a disease in a human population, was widespread; for example, only two years after publication of his report, all of the water companies in London had to filter their water by law. The collaboration between epidemiological science and public health policy and practice is still critically important today (Tellnes 2004).

Improvements in personal hygiene and environmental sanitation in the 18th and 19th centuries helped to prevent and control the spread of communicable diseases. Safe water supply and adequate sanitation facilities were particularly lacking in rural areas (Sein 2004). Social reforms and the hygienist movement in the 19th century provided the infrastructure necessary to achieve promised results in public health, e. g. in maternal and child health (Gunning-Schepers 2004).

Today, unfortunately, an estimated 1.7 million people still die annually from diseases linked to unsafe water, sanitation, and hygiene. Within this context, disease prevention requires constant efforts (WHO 2002).

Plague caused the first reported, widely fatal European epidemic, beginning in Athens in 430 BC. The wave of plague which spread across Europe from 1347 to 1351 was called the "Black Death". This disease, with case-fatality rates from 30% to almost 100%, returned to most European areas once every 20 years until the 17th century. High mortality disrupted society, interrupted commerce and industry, and challenged civil and ecclesiastical authorities. The impact of plague on all parts of society challenged the first institutional response to an epidemic in history and public health consequently emerged as a public authority. Preventive measures included the 40-day hold (quarantine) on ships coming from potentially infected places, isolation of victims and their families, as well as means of decontamination.

The public's health was monitored and prevention procedures were controlled and organized.

One of the greatest public health successes was the eradication of the smallpox virus. Inoculation against smallpox was introduced in Western Europe in 1721. At that time, smallpox accounted for 10% to 15% of childhood deaths. In 1796, Edward Jenner, a rural general practitioner, modified the technique of immunization. He observed that farm girls who milked cows never got infected with smallpox. Therefore, he supposed that the maids' contact with cowpox was responsible for the protection. This led to a historical experiment with tremendous public health impact: a young boy was first injected with cowpox pus and later exposed to smallpox virus. He did not fall ill – the experiment was successful. Jenner then introduced the term "vaccination", derived from "vacca", the Latin word for "cow". Soon afterwards, smallpox prevention became an increasing state concern. In the mid-19th century, implementation of mandatory vaccination in England and in the German Empire should have ensured universal vaccination against smallpox. However, vaccination had not yet been organized on an international level. Even a century after the discovery of smallpox vaccination, the disease continued to do mischief in the developing world, mainly because of the lack of methods of vaccine preservation. In the 1950s, millions of people worldwide still died because of smallpox infection. Consequently, the WHO aimed for the eradication of smallpox and launched a successful worldwide smallpox vaccination campaign. Intensified mass vaccination was the major strategy of the program, which also consisted of village-to-village searches for cases, providing rewards for reporting and educating people; this strategy was particularly applied in Asia. In Western and Central Africa, eradication was achieved by the surveillance-containment strategy, based on active case detection and mass vaccination only around cases.

The last naturally acquired human case of smallpox was reported in Somalia in 1977. Since then, the world has been free from natural transmission of smallpox. This is the most important public health achievement in the 20th century and resulted in wider acceptance of mass vaccination (Hamlin 2004; Sein 2004).

In modern times, international public health efforts also aimed at preventing the importation of epidemic diseases by trading ships. The first attempt to reach a consensus on international quarantine regulations was made at the First International Sanitary Conference in Paris in 1851. In 1907, the first international health office, called L'Office International d'Hygiène Publique (OIHP), was founded for the prevention and control of cholera, plague, and yellow fever epidemics. The League of Nations Health Organization, founded in 1923, undertook basic clinical and field research studies on medicine and public health and provided technical assistance, as well as international medical and public health education, to developing countries. After the Second World War, intergovernmental organizations like the United Nations were created. The World Health Organization (WHO) officially came into being in 1948 as a specialized agency of the United Nations. Since then, the WHO has been directing and coordinating international health work, providing advice on international health development, and adopting international regulations, conventions, and agreements (Sein 2004).

Public health's next mission was to regulate behavior and maintain a communal environment (Hamlin 2004). Preventive and curative interventions, i. e. drug treatment, especially antibiotic treatment, surgery, and rehabilitation, significantly improved the population's health in both developed and developing countries in the 20th century. Attention switched from environmental control to infectious disease monitoring, especially concerning tuberculosis and sexually transmitted diseases. Since the 1970s, public health departments have mainly focused on prevention of cardiovascular disease and cancer, which had become major causes of death in developed countries after the decline of infectious disease mortality (Gunning-Schepers 2004).

As health and economic development are mutually dependent, particularly citizens in developing countries frequently do not have access to a minimum level of health care. In many developing countries, total spending on health proportionate to the gross domestic product is still below 5 percent in addition, allocation of these limited funds is not efficient. In Western countries, health spending is about 8.5% of the gross domestic product on average. It has been shown that major improvements in health outcomes can be achieved while keeping spending at modest levels. Consistent development policies as well as programs for reaching the poor with the most effective and appropriate health interventions are critical in improving health in the population (Sein 2004).

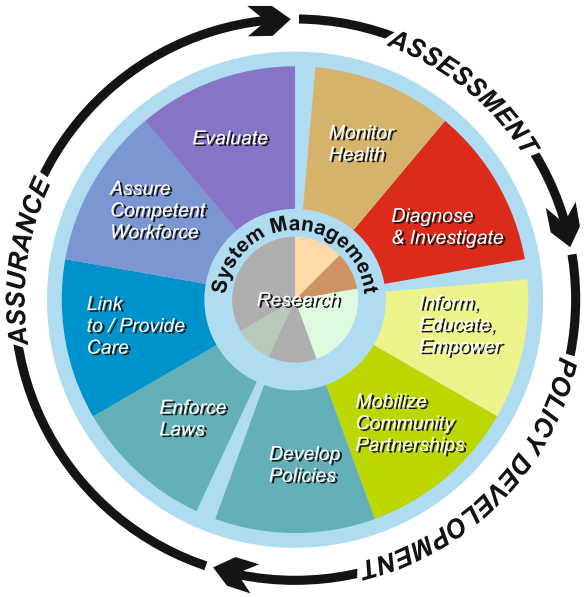
Key Concepts

Public health is a multidisciplinary field that combines and applies techniques from both social and natural science to assess the health state of a population, to promote health, and to prevent diseases. Additionally, public health policy is central for adequate reactions to current and predicted future health threats.

To define the core functions of public health, the Public Health Functions Steering Committee was established in the US in 1995. The Committee defined "*Healthy People in Healthy Communities*" as the public health vision, and its mission was to "*Promote Physical and Mental Health and Prevent Disease, Injury, and Disability*".

In order to accomplish these goals, the Committee listed the following ten "Essential Public Health Services" (USDHHS 1995) (Fig. 1):

1. Monitor health status to identify community health problems
2. Diagnose and investigate health problems and health hazards in the community
3. Inform, educate, and empower people about health issues
4. Mobilize community partnerships to identify and solve health problems
5. Develop policies and plans that support individual and community health efforts
6. Enforce laws and regulations that protect health and ensure safety
7. Link people to needed personal health services and assure the provision of health care when otherwise unavailable
8. Assure a competent public health and personal health care workforce
9. Evaluate effectiveness, accessibility, and quality of personal and population-based health services
10. Research for new insights and innovative solutions to health problems.



Definition of Public Health, Figure 1 Interdependence of Essential Public Health Services
SOURCE Public Health Functions Committee, Office of Disease Prevention and Health Promotion, U.S. Department of Health and Human Services, Washington, DC. http://www.health.gov/phfunctions/public.htm (accessed October 2nd 2006)
Nelson et al. 2002

These core functions are generally very well applicable to both national and international public health services, as they emphasize a proactive strategy for health protection and disease prevention with a focus on the community (Nelson et al. 2002).

Additional selected public health tasks / goals and corresponding subdisciplines of the field addressing these issues are listed in Table 1.

Priorities for research and expenditures should be set with regard to the magnitude of the problem and the effectiveness of available interventions, as well as potential social, legal, and ethical issues regarding public health problems and/or interventions.

While injuries were the leading cause of death in the 18th and 19th centuries, infections were the major health threats in the late 19th and early 20th centuries. Since then, chronic diseases have become more and more important (Yach et al. 2004). With about 12 million deaths, cardiovascular diseases (mainly ischemic heart disease and stroke) were the largest cause of death in the world in 2001, followed by lower respiratory infections (almost 4 million deaths attributable worldwide), HIV/AIDS (3 million), chronic obstructive pulmonary diseases (2.5 million), and perinatal conditions (2.4 million). Ischemic heart disease was the leading cause of death both in developing (proportionate mortality ratio 9.2%) and developed countries (proportionate mortality ratio 23.3%) (WHO 2003).

These leading causes of death share key behavioral risk factors like tobacco abuse, unhealthy diet, lack of physical activity, and alcohol abuse (WHO 2002). Addi-

Definition of Public Health, Table 1 Selected public health tasks / goals and subdisciplines of public health addressing these issues

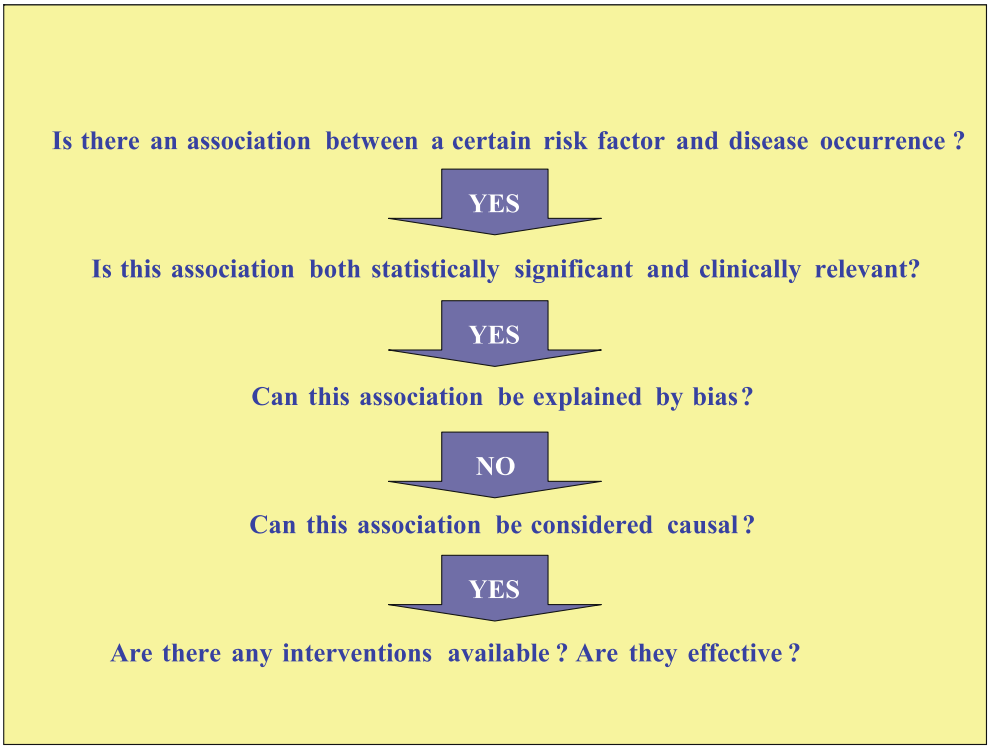
Public Health Task / Goal	Subdiscipline of Public Health
To identify risk factors for diseases	Epidemiology
To assure the accessibility of health services	Health Policy and Management
To educate people about health issues	Behavioral Sciences, Health Policy and Management
To protect people against environmental / occupational hazards	Environmental / Occupational Health, Health Policy and Management
To identify causal relationships between exposure and disease	Epidemiology
To monitor the health status in order to identify community health problems	Surveillance, Epidemiology
To evaluate the efficacy of medical treatments	Biostatistics, Evidence-Based Medicine
To evaluate the effectiveness, accessibility, and quality of health services	Health Services Research
To evaluate the efficiency of health care interventions	Health Economy
To encourage healthy behavior / lifestyle	Behavioral Sciences, Health Policy and Management
To investigate epidemics	Surveillance, Epidemiology
To overcome health inequalities	Health Policy and Management
To respond to disasters	Surveillance, Health Policy and Management

tional important examples of unhealthy behavioral and lifestyle factors that have a tremendous negative health impact on the population level are unsafe sex, illicit drug use, and unsafe injections within the health care system. Because of the increasing impact of behavioral factors, health promotion activities are becoming more and more important. Such activities typically seek to improve the population's health by inducing a shift towards healthier behavior and lifestyle patterns. In order to effectively reach the target population, health promotion activities often involve the community. In order to be successful, interventions to reinforce healthy behavior and to remove hindering behavioral factors need to apply a multilevel strategy including intrapersonal, interpersonal, organizational, societal, and political concerns. In designing such multilevel interventions, public health professionals frequently cooperate closely with social scientists.

The central public health activities, health promotion and disease prevention, are closely interrelated. It is important to distinguish three types of prevention: primary prevention aims to prevent disease occurrence, secondary prevention aims to detect diseases in an early (subclinical) stage in which curative treatment is still possible (e. g. screening programs), and tertiary prevention aims to limit disease complications and disability. Public health interventions typically apply to primary and secondary prevention strategies, while clinical medicine deals with tertiary prevention.

Frequently, there is uncertainty about the exact health risk of chemical, environmental, or other exposures. It is an important public health principle that in such cases the burden of proof of harmlessness should generally be shifted to the proponents of the activity. In face of uncertainty, preventive action as well as exploration of a wide range of alternatives to possibly harmful substances is suggested. In order to plan future health services it is essential to recognize that the current burden of disease reflects past exposure to risk factors, while the future burden will largely be determined by current exposures (Yach et al. 2004). This fact suggests that surveillance of both exposures and health outcomes on the population level are essential in order to detect and react to new health threats as early as possible. Additionally, surveillance of the health state of a population can also help to effectively identify health disparities. Surveillance of the health state may be accomplished by population-based surveys, population censuses, and vital registration systems. Ideally, data systems for public health surveillance should assess and process data in a timely manner, generate valid and reliable data that is comparable over time, and (only) collect all data that is really essential for the purpose of the system (Teutsch 2000).

Public health has evolved into a subdivision of medicine including disciplines of engineering and social sciences. Other non-medical factors which have been shown to influence public health are architecture, economic prosperity, religion, organization of labor, and political changes. Today people are preoccupied with health and expect health that may be translated into life, liberty, and the pursuit of happiness (Hamlin 2004).



Definition of Public Health, Figure 2 Hierarchy of Epidemiologic Research Questions. (Subsequent questions are only relevant if prior questions can be answered as indicated by the arrows)

Epidemiology is the most central public health discipline. Epidemiology studies the causes, distribution, and control of disease at the population level, and investigates disease outbreaks. When the distribution of disease occurrence is not uniform according to person, time, or place, hypotheses about causal relationships based on the agent-host-environment paradigm may be generated and tested. Epidemiologists employ a wide range of study designs and statistical methods with the purpose of revealing unbiased relationships between exposures and outcomes. After establishment of causal relationships, the effectiveness and efficiency of interventions and preventive measures can be assessed in subsequent studies (Szklo 2000; Gordis 2004) (Fig. 2).

Other public health disciplines include family health, maternal and child health, mental health, occupational and environmental health, biostatistics, molecular biology and microbiology, health policy and management, international health, health behavior and promotion, ethics, and health care services.

Public health genetics is among the most rapidly emerging disciplines. Due to the development of new DNA sequencing technologies, it is now possible to not only study effects of single genes, but the functions and interactions of all the genes in the genome. Therefore, genomic research and potential interventions from it are applicable not only to rare monogenetic disorders, but also to common disorders, which are typically caused by interactions of multiple genes and environmental factors (Guttmacher 2002). In key public health tasks and disciplines, such as prevention, risk assessment, epidemiology, and environmental health, issues related to genetics already play a central role and are likely to gain even more impact in the next decades.

Population Health Indicators and Measurement of Burden of Disease

Basic Indicators to Quantitatively Measure and Monitor the Health State of a Population over Time are:

- Life expectancy at birth,
- Crude / age-specific / age-adjusted mortality rate,

- Infant mortality ratio / neonatal mortality ratio, and
- Maternal mortality ratio.

Life expectancy at birth is the average number of years a newborn is expected to live if current mortality trends were to continue for the rest of his/her life (Haupt 2000).

Life expectancy at birth reflects the overall mortality level of a population. Until about 400 years ago, life expectancy at birth averaged between 20 and 30 years. In Western Europe, life expectancy averaged between 30 and 40 years until about 1850. Since then, there has been a sharp and sustained increase in life expectancy at birth. Life expectancy rapidly increased throughout the world in past centuries. However, there is a huge health gap between industrialized and developing countries, with life expectancies of about 35 to 50 years in most African countries compared with about 75 to 80 years in Europe, Japan, Australia, and other developed countries (WHO 2005). Differences in life expectancy between different ethnic groups within a country are good indicators for persistent health inequalities. In the US, for example, the average life expectancy at birth in 2003 was 72.8 years for African Americans compared with 78.0 years for Whites (Hoyert et al. 2005). Riskier behavior patterns and higher smoking rates in males, as well as wars, are some of the reasons why life expectancy at birth (and at any other age) is generally lower for men. Today, females in Japan, Australia, Canada, and some other countries have a life expectancy well over 80 years (Teutsch 2000).

The **crude mortality rate** (CDR; synonyms: crude death rate, total mortality rate) is the total number of deaths in a year / person-years lived in that year per 1000 population. The crude death rate measures the effect of mortality on population size. As a rule of thumb, a crude death rate of 10 implies that mortality is working to reduce population size by 1% per year. However, the crude death rate is very sensitive to age structure: populations with high proportions of elderly people tend to have high crude death rates, whereas young populations tend to have low crude death rates.

Age-specific mortality rates are very little affected by age distribution and are therefore very useful to monitor the health state of a population over time or to compare different populations in a longitudinal or cross-sectional setting.

In the context of comparison,**age-adjusted mortality rates** are particularly useful. Increasing age is a major cause of death. Thus, unadjusted mortality rates are likely to be confounded by age. Age standardization offers a more realistic view of other variables that might be causally related to mortality. When interpreting age-standardized mortality rates, one should bear in mind that the numbers do not necessarily represent the experience of any real population. The choice of the standard population is arbitrary. To be meaningful, it should be similar to the populations being compared (Teutsch 2000).

The **infant mortality ratio** (synonyms: infant mortality rate, infant death rate) is the number of children less than one year old who die in a year per 1000 live births during that year.

The **neonatal mortality ratio** (synonyms: neonatal mortality rate, neonatal death rate) is the number of deaths during the first 28 completed days of life per 1000 live births in a given year. Neonatal deaths account for a large proportion of child deaths. Mortality during the neonatal period is considered to be a good indicator of both maternal and newborn health and care. In developed countries, about two thirds of infant deaths occur in the first month after birth and are due mostly to health problems of the infant or the pregnancy, such as preterm delivery or birth defects. About one third of infant deaths occurs after the first month and is influenced greatly by social or environmental factors, such as exposure to cigarette smoke or problems with access to health care. Most European countries have infant mortality ratios < 5, indicating that the risk of death within the first year of life is below 0.5 percent. In contrast, more than 20 percent of all infants born in Angola, Congo, Niger, or other African countries die within their first year of life (WHO 2005). Whereas the infant mortality rate was between 5.7 and 5.8 in Whites and Hispanics, 13.8 out of 1000 children of African American mothers died within their first year of life in the US in 1998–2000. (NCHS, 2002)

The **maternal mortality ratio** (synonym: maternal mortality rate) is defined as the number of maternal deaths per 100,000 live births. Because the number of pregnancies is not regularly assessed in many developing countries, the number of live births is used as a denominator as a proxy for the population of pregnant women who are at risk of maternal death. The maternal mortality rate is a measure of the likelihood that a pregnant woman will die from maternal causes. Thus, the maternal mortality ratio is a good measure of

the quality of a health care system. High maternal mortality rates combined with high infant mortality rates usually reflect poor nutrition and medical care. According to the World Health Report (WHO 2005), Sierra Leone has the highest and Afghanistan the second highest maternal mortality ratio, with 2,000 and 1,900 maternal deaths per 100,000 live births, respectively. Rates < 5 were reported from Iceland and Ireland.

In addition to those direct (quantifiable) indicators of population health, decision makers in public health policy and management should also consider indirect indicators (surrogates) like childhood poverty, tobacco abuse, level of physical activity, trends in overweight and obesity, immunization rate, access to health care by socio economic position, suicide rate, etc. Critical appraisal of those factors and other indirect indicators of population health may be particularly valuable for anticipation of future needs.

Important Indicators to Quantify, Monitor, and Compare the Public Health Burden of Specific Diseases are:

- Disease-specific mortality rate,
- Years of potential life lost (YPLL),
- Health-related quality of life (HRQL) impact, and
- Disability adjusted life years (DALYs) / quality adjusted life years (QALYs)

The **disease-specific mortality rate** (synonyms: cause-specific mortality rate, cause-specific death rate) is the number of deaths attributable to a specific disease in a given population in a given year, usually expressed per 100,000 persons. The conditions with the highest disease-specific mortality rates are referred to as the leading causes of death. Comparisons of disease-specific mortality rates by geographical region, occupation, or time period, for example, may be useful in the identification of causal factors of these diseases and prompt preventive and/or political action. Confounding by age may be eliminated by applying age-standardized disease-specific mortality rates.

Disease-specific mortality rates do not contain information on the lifetime lost because of the condition of interest. However, for both individual and society this information is critically important, e. g. HIV/AIDS frequently affects young adults and their children, whereas most cancers manifest in older people. The indicator **years of potential life lost (YPLL)** (synonym: Years Life Lost (YLL)) accounts for the impact of premature mortality on a population. It is calculated as the sum of the differences between age 65 (sometimes average life expectancy is used instead) and the ages of death for those who died before that endpoint.

It has been recognized that not only mortality but also the level of morbidity caused by specific conditions is critically important for planning public health programs and services. **Health-related quality of life (HRQL)** is a multidimensional construct, including physical, mental, and social function, which measures the impact of a person's health status on that person's overall wellbeing. The concept of HRQL as a parameter of morbidity and disease severity allows the comparison of otherwise heterogeneous disorders. In health economy, the construct HRQL is also used to refer to the value of a health state. Usually, the state of perfect health (maximum HRQL) is assigned the value "1", whereas the value "0" corresponds to a health state judged equivalent to death (Gold et al. 1996).

As measurements of mortality and morbidity both only capture certain aspects of disease burden, so-called composite measures combining mortality and non-fatal outcomes were introduced in the early 1970s (Sullivan 1971). **Quality adjusted life years (QALYs)** and **disability adjusted life years (DALYs)** are the most widely used composite health outcome measures.

QALYs are calculated by integrating quality of life with length of life using a multiplicative formula. Thus, the QALY is a measure of health rather than ill-health. The QALY is the central outcome in health economic analyses, where the cost per QALY gained of different interventions is compared. Such cost-utility studies are increasingly used to assist health policy and management decisions (Haddix et al. 2003).

The DALY was developed to assess the global burden of diseases. It allows comparisons among different diseases and different populations. It is considered to be a simpler and more objective measure than the QALY, as it is concerned with the severity of disability rather than HRQL. As a measure of the health gap, the DALY combines years of healthy life lost from disability with those lost from premature death. Within the past decade, the DALY-approach has been used increasingly to aid health research prioritization (Gold et al. 1996; Haddix et al. 2003).

Table 2 lists a comparison of cause-specific mortality rates and DALYs lost due to selected conditions.

Definition of Public Health, Table 2 Comparison of mortality rates and burden of disease as measured by disability adjusted life years (DALYs) for selected conditions*

Condition	Mortality Rate		Disability Adjusted Life Years (DALYs)	
	n (000)	% total	n (000)	% total
Ischemic heart disease	7,181	12.7	58,725	4.0
Cerebrovascular disease	5,454	9.6	45,870	3.1
HIV/AIDS	2,866	5.1	88,429	6.0
Chronic obstructive pulmonary diseases	2,672	4.7	29,917	2.0
Tuberculosis	1,644	2.9	36,040	2.5
Road traffic accidents	1,194	2.1	37,719	2.6
Trachea/bronchus/lung cancers	1,213	2.1	11,258	0.8
Malaria	1,124	2.0	42,280	2.9
Diabetes mellitus	895	1.6	15,446	1.1
Measles	745	1.3	26,495	1.8
Breast cancer	479	0.8	6,317	0.4
Iron deficiency anemia	138	0.2	12,039	0.8
Unipolar depressive disorders	12	0.0	65,911	4.5
Migraine	0	0.0	7,565	0.5

* in WHO member states, estimates for 2001 (WHO 2002)

Although depression caused less than 0.1% of all deaths in 2001 it was a major cause of disability, accounting for 4.5 percent of the total burden of disease as measured in DALYs. On the other hand, ischemic heart disease caused 12.7 percent of all deaths in 2001, but was only responsible for 4.0 percent of the DALYs in the same year (Table 2) (WHO 2002).

Public Health in the 21st Century: New Challenges and Threats

In the past and present, health care systems have mainly focused on pathogenic (illness causing) factors in medical treatment. In the future, focus on health promotion, i. e. salutogenic (health causing) factors, needs to be emphasized as well (Tellnes 2004). Important future public health goals are to increase the duration of *healthy* life and to eliminate health disparities. Socioeconomic factors cause significant disparities in health outcomes. In the future, health policy interventions are needed to respond to those and other health disparities. Examples of public health policy interventions that should be prioritized in the near future include: improving access to education and job training; promoting healthier workplaces, homes, and cities; reducing threats posed by environmental hazards; and promoting social safety nets and other protections against impoverishment.

Threats Related to Tobacco Abuse

While the rate of smoking among adults has significantly decreased in the US, and bans on smoking in enclosed public places and at the workplace have recently been adopted in several European countries, the global impact of tobacco smoke on the population's health is still increasing. In the Western World, expanding workplace restrictions now protect the majority of adults, but homes remain the most important source of exposure for children. Involuntary exposure to secondhand smoke remains a serious public health hazard throughout the world, but particularly in China and India where the prevalence of smoking is still increasing.

The growing scientific evidence on the health risks of involuntary exposure to secondhand smoke even lead to the hypothesis that the lung cancer risk related to exposure to secondhand smoke in non-smokers is consistent with the dose-response relationship for active smokers. Global efforts against smoking need to be strengthened and focused towards countries in which the prevalence of smokers is skyrocketing. Many developing countries are not adequately prepared to tackle the burden of disease related to tobacco smoke, e. g. respiratory and cardiovascular disorders, malignancies, and sudden infant death syndrome. Sustained progress toward a society free of involuntary exposure to secondhand smoke should remain a public health priority (USDHHS 2006).

The HIV/AIDS Challenge

Since the explosive HIV epidemic in the 1980s, HIV/AIDS continues to be the most devastating disease worldwide. The HIV/AIDS epidemic creates a new challenge for societies and, in particular, for already disadvantaged families and children. Today, there is still a lack of knowledge on how to effectively provide services to affected families, how to best allo-

cate funds, and how to integrate family members into prevention programs. This devastating epidemic even reversed the progress in improving life expectancy over the past decades in many developing countries. Further declines in life expectancy are anticipated, especially in the most severely affected countries in Asia and sub-Saharan Africa. Reinforced national and international efforts in primary, secondary, and tertiary prevention are critical in order to defeat the pandemic.

Obesity Pandemic

Overweight and obesity are some of the most significant contributors to ill health. Globally, there are more than 1 billion overweight adults, 300 million of whom are obese. Obesity is prevalent in both developing and developed countries, affects children and adults alike, and is associated with significant mortality, morbidity, and economic costs. In some developing countries, under-nutrition remains a significant problem even while obesity is emerging.

In overweight and obese persons, the biological capacity to maintain energy balance is mainly overstrained by the lack of physical activity (spontaneous, at the workplace, or as part of leisure activities) and the over consumption of high-fat, energy-dense foods.

Chronic diseases resulting from obesity include cardiovascular diseases, cancer (especially hormonally related cancers and colon cancer), diabetes, and gallbladder disease. Less life-threatening conditions associated with obesity are musculoskeletal and skin problems, infertility, and respiratory difficulties. Public health action and societal changes are urgently required to stop the obesity epidemic and its medical burden (WHO 2002).

Mental Health

Worldwide, disability due to neuropsychiatric conditions is second only to infectious diseases. The significance of mental health in public health is increasing. Depression is the leading cause of disability in terms of years lost due to disability (YLD). Although depression can be reliably diagnosed and treated, only a small proportion of affected persons receive treatment. Major barriers to care may be the social stigma associated with mental disorders and the lack of resources. Acute psychiatric day hospitals may be an alternative to expensive inpatient treatment in times of raising health care costs and limited financial resources. Balancing community-based and hospital-based mental health care may improve patients' health outcomes, such as health-related quality of life. More uniform standards in the treatment of mentally ill persons need to be established (WHO 2002).

D

Demographic Challenge

A major future challenge to public health is related to the growing population of elderly people, combined with the epidemiologic transition in the leading causes of death from acute illness to chronic disease.

The world has experienced a gradual demographic transition from patterns of high fertility and mortality rates to low fertility and delayed mortality. By 1990, proportions of younger and older persons in developed countries were similar. For developing countries, age distribution is projected to have similar proportions by 2030. The largest increases in absolute numbers of older persons will occur in developing countries.

Developed countries in North America, Europe, and the Western Pacific have already undergone the epidemiologic transition in the leading causes of death from infectious disease and acute illness (HIV/AIDS, malaria, childhood diseases, diarrheal disease, respiratory infections, etc.) to chronic disease and degenerative illness (cardiovascular diseases, cancer, diabetes, respiratory disease, Alzheimer's disease, etc.). Other countries, particularly in Africa and Asia, are at different stages of progression (WHO 2002). Chronic diseases disproportionately affect older adults. The prevalence of Alzheimer's disease, for example, doubles every 5 years after age 65. In developed countries, health and long-term care spending is skyrocketing because of the rapid growth in the number of older persons, and the high health care cost per capita for elderly persons coupled with continued advances in medical technology and increased public expectations. The declining number of working taxpayers relative to the number of older individuals results in inadequate public resources and fewer adults available to provide informal care to older, disabled family members and friends. The demands associated with long-term care (nursing home and home health care) expenditures might pose the greatest challenge for both personal/family resources and public resources. However, medical and social costs will be less if public health interventions decrease disability

among older persons, helping them to live independently. Severe disability as a result of chronic conditions can be postponed through healthier lifestyles which need to be promoted in order to limit dramatically rising health care costs. Healthy behaviors must be supported throughout a person's lifetime, however, as behaviors that place persons at risk for disease often originate early in life.

Increases in the elderly population and chronic disease will place further strain on resources, particularly in countries where basic public health concerns such as control of infectious diseases and maternal/child health are yet to be fully addressed. In addition, in some developing countries population aging has occurred before these societies have reached the wealth necessary to build welfare states for supporting the elderly.

Summary

The multidisciplinary field of public health aims at increasing health and preventing disease and injury at the population level. Success in improving the population's health mainly depends on effective cooperation between epidemiology, a major discipline of public health, and public health policy and public health practice.

Early public health actions emerged as a response to fatal epidemics of diseases such as plague, cholera, leprosy, and smallpox, and were aimed mainly at isolating victims and their families. Improvements in personal hygiene and sanitation in the 18th and 19th centuries further reduced the burden of communicable disease. Steps in international public health efforts in terms of worldwide health promotion campaigns, such as the successful program for the eradication of smallpox, have only been taken since the 20th century.

Basic indicators to measure the health of the population are life expectancy at birth, mortality rate, infant and neonatal mortality ratio, and the maternal mortality ratio. Disease-specific mortality rate, years of potential life lost, health-related quality of life, and disability and quality adjusted life years are measures of the public health burden of different diseases.

In the 21st century, public health aims to increase the duration of healthy life, as well as eliminating health disparities. Threats related to tobacco abuse, obesity, and HIV/AIDS are persisting and increasing. Mental disorders represent a growing burden on population health. Today, depression is the leading cause of disability and is projected to be the 2nd leading contributor to the global burden of disease in the near future. A major future challenge to public health is related to the growing population of elderly people and the epidemiologic transition in the leading causes of death from infectious disease and acute illness to chronic disease and degenerative illness.

Degenerative Diseases

Synonyms

Chronic morbidity

Definition

Degenerative diseases are such diseases where the function or structure of the affected tissue or organ progressively deteriorates over time. This can be caused either by normal bodily wear or by lifestyle factors like exercise or eating habits. Degenerative diseases are often contrasted with infectious diseases. Examples of degenerative diseases are Alzheimer's disease, Osteoarthritis, Osteoporosis, and Parkinson's Disease.

Degrees of Freedom

Definition

Degrees of freedom (df) represents the number of values in a set of data that are free to vary after certain restrictions have been placed upon the data. In the simplest example of a 2×2 table, if the marginal totals are fixed, only one of the four cell frequencies is free to vary and the others will be dependent on this value not to alter the marginal totals. Thus, the df is only 1. Similarly, in a contingency table with r rows and c columns, the $df = (r-1)(c-1)$. In parametric tests, the idea is slightly different in that the n of data have n degrees of freedom before any statistical calculations are carried out. As soon as a parameter, such as the mean, is estimated, there is one less df than was initially present. This is why in most formulas the df is $(n-1)$. In the case of a two-sample t-test with n_1 and n_2 observations, both means are calculated. Thus, the $df = (n_1 + n_2 - 2)$. In linear regression, when the linear equation $y = \alpha g + \beta x$ is calculated, two parameters are estimated (the intercept and the slope). The number of df is then reduced by 2: $df = (n_1 + n_2 - 2)$.

Dehydration

► Heat Exhaustion

Deinstitutionalization

Definition

Deinstitutionalization is the practice of moving individuals with mental disorders (especially those with severe and persistent mental illness) from mental institutions into community-based or family-based environments.

Delhi Boil

► Leishmaniasis, Cutaneous

Delirium tremens

Synonyms

Alcohol induced delirium

Definition

A delirium is an organic cerebral syndrome characterized by concurrent disturbances of consciousness and attention, perception, thinking, memory, psychomotor behavior, emotion, and the sleep-wake schedule. Convulsions may also occur. The duration is variable and the degree of severity ranges from mild to very severe.

Delivery of Dental Care

SEBASTIAN ZILLER
Head of Dept. of Prevention and Health Promotion, German Dental Association, Berlin, Germany
s.ziller@bzaek.de

Synonyms

Provision of dental care/oral health care; Providing of dental care/oral health care

Definition

Dental care delivery is the process of providing oral health care. The most common way of providing oral health care is face-to-face delivery between care provider and patient. Oral health care is provided in dental practices, in universities, in hospitals, in multi-dentist centers or by public dental services. Dental care providers are dentists (dental practitioners, dental doctors) and dental auxiliaries (e. g. dental chairside assistants, dental nurses). Dentistry is practiced within the oral health care system of a country. The characteristics of a health care system have an important influence on the quality and structure of the delivery of dental care. Transparency of information is also a factor influencing the care delivery.

Basic Characteristics

Oral Health Care Systems of the EU

Dental Remuneration System in the EU An important item of oral health care delivery is the *dental remuneration system*, i. e. the means of paying dentists to deliver patient-oriented, adequate, and efficient care which also takes local needs into account. Funding conditions have a great influence on health care delivery, as they define who pays the costs and how dentists are compensated. The most significant differentiation in developed countries is the one between *salaried public health care* and *market-based health care* (as practiced in the US).

No matter whether paid ultimately by a government body, a sick fund or directly by the patient, *fee-for-service* (or fee-per-item) is the major form of payment for *private dental practitioners* all over Europe. The level of fees, how they are fixed and how much the patient pays, varies considerably.

The oral health care systems of the EU-countries can be divided into five broad categories (Widstrom and Eaton 1999):

1. The *Nordic system* (Denmark, Finland, Norway, Sweden) is characterized by a significant government involvement, a well-developed salaried service and a widespread use of clinical auxiliaries. A high proportion of dentists work in the public sector; some 30% in Denmark, 50% in Finland, 40% in Norway and more than half of the totality of the dental manpower in Sweden. Services are financed by taxes and organized within municipalities or counties. Dental care for children under 19 years is free and usually provided in municipal school clinics with a salaried staff. Adults use private or public dental services. The care is financed partly by the public health insurance and partly by payment in cash or by a private public insurance (Downer et al. 2006).
2. The *Bismarckian model*, valid in most central European countries (e. g. Germany, Austria, France, Belgium), is mostly financed by mandatory contributions of employees and/or employers who are paid in universal sickness insurances. In Germany, for example, there is a statutory health insurance system where health care depends on a membership in a state-approved sick fund (Tiemann et al. 2003). The majority (88.5%) of the German population are members of a sick fund which provides a legally prescribed standard package of oral health care that is managed jointly by the sick funds and the dentists' organizations. Most dentists (98%) have a contract with the statutory health insurance and work independently in their private practice. In principle, membership in a statutory sick fund entitles all

adults and children to receive oral care within the statutory health insurance system. In a normal year approximately 80% of the adults and 60–70% of children make use of the system (Kravitz and Treasure 2004). For more detailed information please look at the Encyclopedia-contribution "Health System in Dentistry" by David Klingenberger.

3. The *Beveridgian model* of a National Health Service is unique in the UK. It is mostly financed by the state and there is a state-delivery of health services and benefits.
4. The *Southern European model* is an oral health care system, predominantly private and without any government involvement; some public services are free of costs for children and also in emergency cases; a limited employment of clinical auxiliaries is allowed (e. g. in Spain).
5. Another group of countries has mixed systems with elements from the categories above (e. g. Ireland, the Netherlands) (Downer et al. 2006).

Dental Practice in the EU In the majority of the EU-countries dental care is mostly provided by *non-salaried, independent practitioners* established in their own dental surgeries (private -, liberal - or general practitioners). In most EU-countries, more than 83% of the practicing dentists have chosen this form of the dental practice (Table 1). Only in countries with a large, *salaried public dental service* is the liberal general practitioner of less importance and prevalence (e. g. in the Nordic countries). In addition to the general practitioners most countries have dentists who work in *public dental services*, *dental wards of hospitals*, *universities* or the A*rmed Forces*.

Both the countries with a developed *salaried public dental service* and the countries with *non-salaried practitioners* have a positive 12-year-old ► DMFT-index (caries index), i. e. generally low levels of dental caries. There is no discernible association between DMFT at 12 years and the provision of dental care. However, since the public dental services are usually orientated towards the provision of dental care to special groups, such as children, private practitioners are the major and often the only providers of care for the adult population in the EU (excluding the Nordic countries).

Dental Manpower Dental manpower provides oral health care and includes dentists and dental auxiliaries.

Delivery of Dental Care, Table 1 Percentage of oral health care provided in general/private practice in relation to economic data (► GNP) and to the caries index in selected EU-countries

Country	% of oral health care provided in general practice*	% of GNP spent on oral health care**	DMFT 12 years**
Sweden	44%	0.8%	1.1
Slovenia	50%	0.62%	1.8
Finland	54%	0.45%	1.2
Ireland	57%	0.33%	1.2

Luxembourg	99%	02%	3.0

Sources: * Kravitz and Treasure 2004; ** CAPP 2006 (last available data)

Dental care delivery is classified into primary, secondary and tertiary dental care. ► Primary dental care is provided by dentists or dental auxiliaries who have the first contact with a patient demanding dental treatment or care. ► Secondary dental care is provided by dental specialists. Specialist hospitals, clinics or regional centers provide ► tertiary dental care services.

In all countries, most oral health care is provided by *dentists*. The EU-Dental Directive gives a definition and description of the field of activities of a dentist. Dentists are generally capable of giving instructions on measures of prevention, diagnosing and treating anomalies and diseases affecting the teeth, mouth, jaws and

adjoining tissue (EU 2005). In 2003, the total number of registered dentists in the EU, including Romania, was about 365 000.

Orthodontics and Oral Surgery/Oral Maxillo-Facial Surgery are the two specialties which are grosso modo recognized formally in almost all of the 25 European countries. Many other specialties have national recognition to a varying extent. In most countries, patients may see *specialists* directly, without needing to go to a primary care dentist first, but in Sweden and the UK, for instance, a referral from a primary care dentist is absolutely necessary.

Dental Auxiliaries: In all countries, dentists have staff of different denominations, e. g. "dental surgery assistants", "dental nurses" or "dental chairside assistants", who may assist with chairside activities and tasks, including advising and motivating patients concerning prevention and therapeutic preventive measures. In some countries (e. g. Belgium, Portugal), most dentists work without any auxiliary assistance; in France and Poland less than one third of the dentists work with an assistant. In Germany, auxiliary staff can only work under the supervision of a dentist who is always responsible for the whole treatment of the patient. The range of auxiliaries is rather complex and include (with the relevant training) the Dental Chairside Assistant, the Specialized Dental Chairside Assistant, the Dental Administrative Assistant, the Dental Prophylaxis Assistant and the Dental Hygienist. These registered qualifications are co-ordinated by the German Dental Association (Bundeszahnärztekammer – BZÄK). Dental Technicians provide technical laboratory services for the dentists; however, in most countries they are entitled to repair dental appliances directly for patients, provided they do not need to take impressions or to do other interventions in the mouth of the patients.

Transparency

Transparency of information is also a factor defining a care delivery system. Information on practice conditions, treatment measures, quality standards, as well as on fees and tariffs have a great impact on patient choice and consequently on the motivation and therefore the incentive of the health professionals. Increased efficiency and improvement and transparency concerning the range of the services provided are necessary if a reliable and adequate health care for the whole population is to be assured. The quality of the patient–doctor relationship is dependent on the participants having mutual respect for each other and sharing knowledge and values which, in turn, promotes confidence, and relies on free access by patients to honest professional information about diseases, treatments and future prospects.

Conclusion

Permanent topics in the worldwide debate on public health policy are, on the one hand, medical, including social medicine and health care provision, and, on the other hand, economic. The delivery of dental care is an important factor in dental public health research because most countries are confronted with increasing expenditures in health care systems due to the increasing demands of aging populations and medico-technical progress. The level of dentistry practiced depends on the oral health care system of a country. The characteristics of a given health care system have a significant impact on the nature and structure of its dental care system. Although it is essential that the oral health care resources are allocated correctly and adequately, medical criteria should be of priority and in the forefront if a good health care system for all is to be guaranteed.

Delusion

Definition

A false belief based on incorrect inference about external reality that is firmly sustained despite what almost everybody else believes and despite what constitutes incontrovertible and obvious proof or evidence to the contrary.

Delusional Disorder

Definition

A disorder characterized by the development of either a single ► delusion or of a set of related delusions that are usually persistent and sometimes lifelong. The content of the delusion or delusions is very variable. Clear and persistent auditory ► hallucinations (voices), schizophrenic symptoms such as delusions of control and marked blunting of affect, and definite evidence of brain disease are all incompatible with this diagnosis.

Demand of Health Care

► Health Determinants, Economic

Demand Reduction

Definition

Demand reduction is a strategy to reduce the incidence of ► substance related disorders. It achieves to educate the population at risk (e. g. adolescents, drivers, pregnant women) to use substances adequately or to stay abstinent. Interventions include risk information, motivation enhancement and skills training.

Dementia

Definition

Criteria for dementia include demonstrable evidence of impairment in memory (according to ICD-10 a decline of memory as well) and either impairment in one other intellectual function (i. e., judgment, abstract thinking or higher cortical functions) or a personality change. These disturbances must be sufficient to interfere with work, social activities or relationships. There are several forms of dementia: vascular dementia occurs as a result of brain damage secondary to stroke. Other 'progressive' forms of dementia are associated with particular brain diseases such as Alzheimer's disease. Alzheimer's type dementia gradually and progressively compromises brain tissues, causing them to weaken and function erratically.

Dementia Praecox

► Psychotic Disorders

Democratization of Sport

Definition

The term Democratization of Sport means that societal and economic access barriers to sport participation become increasingly irrelevant and consequently every social group irrespective of parameters like age or sex is able to participate in sports activities.

Demographic Imperative

Definition

The term 'demographic imperative' refers to both the demographic changes and the corresponding pressure

on the Public Sector and Public Health. Demographic changes comprise different dimensions, e. g. rising life expectancy, aging work force, ongoing migration, increasing diversity. The Public Sector and Public Health are responsible for managing demographic and emerging social and health challenges in a proactive way. Moreover, the term 'demographic imperative' has the function to highlight the pressure on Public Sector and Public Health to respond with forward-looking and population-oriented strategies and to mirror the diversity of the population in the workforce in order to enhance the capability to fulfill the changing and diverse needs.

Demographic Indicators

Definition

Demographic characteristics related to health include measures of total population as well as the percentage of the total population by age group, gender, race and ethnicity; and the rate of change in population density over time, due to births, deaths, and migration patterns.

Demographic Perspectives on Family Health

Synonyms

Population trends and family health

Definition

Demography is the study of ► population change: entrances into and exits from populations through fertility, mortality, and migration, and the impact of these processes on the size, growth, and composition of populations (Preston et al. 2001). Family demographers investigate the processes of entrances and exits from families, as well as resultant changes in family composition. These population and family processes are deeply intertwined with family health.

Basic Characteristics

Introduction

Overall, children and adults are leading longer and healthier lives worldwide. Contributing factors include improvements in mortality (► mortality rate) and health, improved availability of ► family planning, and falling fertility levels. At the same, however, the HIV/AIDS epidemic, population aging and changing family structures are creating new challenges for societies and, in particular, for already disadvantaged families and children.

Changes in Mortality and Life Expectancy

In wealthy countries, life expectancy has now surpassed 75 years, increasing from 66 years in the early 1950s (UN 2005). Japan boasts the long average lifespan at 82 years. The fight against cardiovascular disease among adults and especially the elderly population has increased both the length and quality of life in most developed countries. Because mortality decline began in the early 20th and late 19th centuries, ► infant and child mortality and deaths to infectious disease were already low by mid-century. (Vallin, Meslé 2004)

In developing countries, the increase in life expectancy has been rapid by historical standards. In the *least developed countries* (including sub-Saharan Africa, Cambodia, Bangladesh), life expectancy has risen from 36 to 51 years over the past five decades. (UN 2005) Declining mortality was concentrated among infants and children, and occurred as a result of vaccination campaigns and other measures implemented to combat infectious disease. Yet, infectious diseases – largely eradicated elsewhere – remain a crucial contributor to mortality in these populations. The HIV/AIDS epidemic in Sub-Saharan Africa has slowed progress in child health; 17% percent of the children in this region die before their fifth birthday (UN 2005). *Less developed countries* (including population giants India and China), show the most rapid improvements in life expectancy over the latter half of the twentieth century: from 42 years to 66 years by 2000–2005 (UN 2005). Here most of the gains have come from the successful fight against infectious disease and, in particular, dramatic improvements in infant and child survival.

Despite this dramatic overall progress in life expectancy, new and re-emerging health threats have the potential to reverse this progress. Most devastating is the

HIV/AIDS epidemic. In Southern Africa, life expectancy fell to just 48 years by 2000–2005, a 14-year decline in a single decade, and further life expectancy declines are anticipated (UN 2005). The combination of HIV/AIDS and the existing tuberculosis (TB) epidemic has been particularly deadly. Mortality reversals have also occurred in Eastern Europe and the former Soviet Union, where male life expectancy has fallen to levels below many less developed countries. A deteriorating health system combined with the hardships of the transition to a market economy has hampered the fight against adult cardiovascular disease, alcohol- and tobacco-related mortality, and drug-resistant TB. The rapid spread of obesity and diabetes in developed and developing countries also has the potential to reduce life expectancy gains.

Fertility and Family Planning

The second major demographic trend of the twentieth century has been the dramatic decline in fertility rates throughout the world, from 5 children per woman in 1950–1955 to just 2.65 children by 2000–2005 (UN 2005). Remarkably, this worldwide decline in fertility has occurred at all levels of development and across a wide range of cultural settings. Fertility decline started first in Europe in the late 19th and early 20th centuries, and fell rapidly to replacement or below replacement levels (a total fertility rate of 2.1). According to the UN woman in the most developed countries now have, on average, just 1.6 children, down from 2.1 in the early 1970s. Fertility levels in less developed countries remained high through the early 1960s, but have been falling rapidly since then, from slightly more than 5 children per women in 1970–75 to around 2.5 children just 30 years later. Fertility levels in the least developed countries began to decline later and have fallen more slowly over the past 30 years, to 5 children per woman (UN 2005).

The expansion of ► family planning programs throughout the developing world has been credited, in part, for rapidly falling family sizes. The primary justification for international family planning efforts was the concern that rapid population growth would halt economic development and further improvements in living standards in developing countries. Additional program motivation developed from concerns about the health consequences of high fertility for women, infants and children – in particular, high rates of maternal mortality among women giving birth at young and older ages or who have many pregnancies (Seltzer 2002). Despite overall fertility declines, desired fertility and unwanted fertility (► desired and unwanted fertility) remain high in many poor countries and women continue to have limited access to family planning (Seltzer 2002; Bongaarts 2003).

In developed countries and increasingly in developing countries, policy concerns have shifted from preventing unwanted births to increasing fertility rates. Total fertility rates have fallen well below replacement levels throughout Europe and in parts of Asia. In many countries (notably Taiwan, Japan, Italy, Germany and throughout Eastern Europe), fertility levels have fallen to levels at or below 1.3 children per woman. Low fertility may create economic problems by hastening the process of population aging, and typically results from women having fewer children than they desire (Morgan 2003).

New Challenges for Families and Populations

The HIV/AIDS epidemic is today's most important population and family health crisis. More than 40 million people were living with HIV in 2005, and three million people died of HIV-related disease during the same year. Although two-thirds of the HIV-infected population lives in Sub-Saharan Africa, the number of people infected is increasing in all regions of the world (UNAIDS/WHO 2005). Because AIDS mortality typically strikes men and women of reproductive and working ages, the impact of HIV/AIDS extends far beyond the infected. Children are at risk of contracting the virus themselves (from infected mothers), and of becoming orphaned through the loss of their parents. Orphans experience high rates of poverty and receive less schooling, both of which can have life-long implications for health and well-being. The burden of caring for orphaned children and sick adults typically falls to the extended family, especially to grandparents who may expect or need assistance themselves. The vast scale of this epidemic, combined with its age-pattern of mortality, places enormous burdens on an often-impoverished extended family system.

Population aging poses an additional demographic challenge. Declining mortality and fertility rates

(► mortality rates) have shifted age distributions (► population age distribution) towards older ages in both wealthy and developing countries. The ► dependency ratio (the ratio of children and retirement-age adults to working-age adults) has increased as a result, and will continue to grow in the decades to come. Wealthy countries debate how to fund generous pension and health programs as there are fewer working-age adults to support the elderly. In developing countries, like Latin American and Caribbean nations, the problem is potentially more troubling. Population aging has occurred before these societies have accrued the wealth necessary to build welfare states that can support the elderly (Palloni et al. 2002). This responsibility falls instead to families. How societies and families will adjudicate between the needs of dependent children and the needs of the growing elderly population remains uncertain (Preston 1984).

These demographic challenges place new burdens on families at a time when rising rates of divorce and ► nonmarital fertility are changing and potentially weakening families. Children are increasingly living in single-parent families and, consequently, receiving less investment of parental time and money. These family structure changes may have lifelong impacts on children's health and well-being and appear to disproportionately impact already socio-economically disadvantaged children (McLanahan 2004).

Mortality and fertility declines have in most cases improved the quality of life for children and families. In all likelihood, improvement in family and child health will continue in the decades to come. However, as these new population challenges persist and others emerge, some children and families, the most disadvantaged, may be left behind.

Demographic Transition

Definition

Demographic transition theory describes ► population change over time as a change from high to low birth and death rates corresponding to the development of a country from a traditional, non-industrial to an industrialized economy. The demographic transition model was proposed in the first half of the twentieth century and is based largely on population changes in industrialized countries in Western Europe and North America. Starting from a pre-industrial state where birth and death rates are high and the population is relatively young, the model describes a decline in death rates due to improvements in food supply and sanitation, healthcare, technology, and education, which altogether increase life spans and reduce disease. Next, ► fertility rates decline due to increased access to contraception, education, economic development, urbanization, and other social and economic changes. In the last stage, fertility and ► mortality rates are low, and the population is older. The degree to which this multi-stage demographic

transition model can be applied to currently developing countries is still the subject of much debate.

Demography

Synonyms

Trends in population changes

Definition

Demography is science related to human population. Its primary aim is to ascertain the number of people in a given area, to determine what change that number represents from a previous census, to explain the change, and to estimate the future trends of population changes. Also, demography investigates in origins of population changes and its impact on many aspects of life including changes in health status, health needs and organization of ► health care services.

Dengue Fever

Synonyms

Dengue hemorrhagic fever (DHF); Dengue shock syndrome (DSS); Breakbone-fever; Dandy; Duengero; Ki denga pepo; Seven-day fever

Definition

Dengue fever is transmitted by mosquitoes, which are also day-active. It appears in the tropical and subtropical regions of Southeast Asia, South Pacific, Africa, Central and South America as well as in the Caribbean. Besides a mild course, Dengue hemorrhagic fever (DHF) or Dengue shock syndrome (DSS) can appear, lethality of which is 6–30%. Typical symptoms, the so-called "Dengue-Trias," are fever, a scarlatiniform rash and severe muscular and joint pain. A vaccination is not available.

Dental Caries

Synonyms

Caries; Tooth decay

Definition

Dental caries is a disease which – through interacting with food, ► dental plaque (biofilm) and microorganisms over a long period of time – leads to an irreversible destruction of the proper substance of the tooth, including dental enamel, dentin and tooth cement.

Bacteria are deposited in a biofilm on the enamel surface and produce acids from carbohydrates which are in the food. The consequence of this is that the minerals in the enamel surface are decayed. The dental enamel is demineralized and thus bacteria and their metabolic products may infiltrate more strongly into deeper dental membranes.

Many biological, socio-economical and behavioral factors have an impact on the disease process. In 2004, four out of five individuals worldwide suffered from dental caries. This means that 60–90% of all pupils, as well as most of the adult population, are affected by dental caries. Normally, the saliva is a perfect preventive agent thanks to its natural physiological rinsing activities. Adequate and good oral hygiene, the application and use of fluoride agents, a healthy diet and regular visits to a dental surgery are further means of preventing dental caries.

Dental Hygienist

Definition

Dental hygienists provide dental hygiene care for patients. Mostly, they work with dentists as part of the dental team. Education and training can be very different from country to country. The range of responsibilities varies considerably but focuses on teaching and counseling patients, plaque and calculus removal, and applying preventive materials such as fluorides and fissure sealants.

Dental Implants

Definition

A device made of alloplastic (foreign) material implanted into the jaw bone beneath the mucosal layer to support a fixed or removable dental prosthesis. Dental implants are often screw type or root-shaped and made from titanium.

Dental Plaque

Synonyms

Plaque; Bacterial plaque

Definition

Dental plaque is a biofilm, consisting of oral bacteria, extracellular polysaccharides, and proteins, that arises on the tooth surface. It is usually of a pale yellow to white color. If not removed regularly, dental plaque can lead to ► dental caries or ► periodontal inflammation, because those microorganisms nearest the tooth surface convert to anaerobic respiration and start producing acids. These acids lead to demineralization of the adjacent tooth surface, resulting in dental caries if the process persists and/or attack the gum and activate the body's immune response to infection. Plaque can become mineralized and form ► calculus.

Dental Public Health

Ursula Schütte, Michael Walter
Dental School, Department of Prosthetic Dentistry, University Hospital, University of Technology, Dresden, Germany

michael.walter@uniklinikum-dresden.de

Introduction

Dental Public Health is a branch of Public Health that focuses on dental and oral health. In contrast to clinical practice which operates at an individual level, Dental Public Health is concerned with promoting the oral health of the population by focusing action at a community level. So the terms "Community oral health", "community dentistry" are essentially synonymous for Dental Public health (Pine, 1997). The *science* of Dental Public Health is concerned with making a diagnosis of a population's oral health problem, establishing the causes and effects of those problems, and planning effective interventions. The *practice* of Dental Public Health is to create and use opportunities to implement effective solutions to population oral health and health care problems (Chappel et al., 1996). The American Dental Association gives a definition, which was adopted 1976 and is still generally current:
"Dental Public Health can be defined as the science and art of preventing and controlling dental diseases and promoting dental health through organized community efforts. It is that form of dental practice which serves the community as a patient rather than the individual. It is concerned with the dental health education of the public, with applied dental research, and with the administration of group dental care programs as well as the prevention and control of dental diseases on a community basis" (American Dental Association, 1976).
Dental Public Health is a broad subject which seeks to expand the focus and understanding of dental profession on the range of factors that influence oral health and the most effective means of preventing and treat-

ing oral health problems. It can considerably contribute to a better and broader understanding of oral diseases (► Outline of Dental Public Health). Even though, many dental professionals have difficulties in understanding and implementing the public health paradigm. In the United Kingdom and North America, dental public health has a long history whereas in other countries this field is still evolving and its potential has not yet been fully utilized. Like Public Health in general, dental public health has shifted from "Old" to "New" Public Health. The working fields of "Old" Public Health encompass prevention, oral health in high risk groups (e. g. institutionalized elderly or migrants), sociology, psychology, environmental health, and epidemiology. "New" Public Health additionally focuses on gaining basic and practice-oriented knowledge about the system and the practice of health care comprising health policy, health system research, economics, political and management sciences. Public Health mainly focuses on the prevention of widespread and socially important illnesses, so that caries and periodontal diseases as the most common of the chronic diseases clearly belong in this context. However, not only high prevalence rates but also their significant psychological and social impact underlines their considerable high public health relevance and high treatment costs their health economic weight.

Oral Health Related Quality of Life

Because the majority of oral diseases do not cause life-threatening conditions, oral health is often a low priority for individuals, policy makers, and public health specialists. In fact, oral diseases have a considerable impact on society and individuals (e. g. pain, limited functioning and appearance, high treatment costs). It influences how people grow, enjoy life, look, speak, chew, taste food and socialize, as well as their feelings of social well-being (Locker, 1997). Oral health is integral to general health. This relation is proven by evidence. Severe periodontal disease, for instance, can be influenced by diabetes or increases the risk of a cardiovascular disease. So, oral health affects people's life physically *and* on a psychosocial level, ranging between initial dental caries and effects on general health and quality of life (► oral health related quality of life).

Oral health means more than just having healthy teeth and thus has been more broadly defined as "the ability to chew and eat the full range of foods native to the diet, to speak clearly, to have a socially acceptable smile and dentofacial profile, to be comfortable and free from pain, and to have fresh breath" (Sheiham, 1997). All things considered, oral health is an important public health concern.

Health, one domain of well-being, is closely related to Quality of Life (QoL). QoL is a concept that brings together the multidimensional and widespread character of health status. QoL and not just survival became a core issue for Public Health. Since oral health is a part of general health, Oral Health-related Quality of Life (OHRQoL) as a subset of Health-related Quality of Life (HRQoL) has been established. OHRQoL, based on *self-ratings*, comprises the patients' perceptions of their illnesses, the resulting limitations to their daily activities, and assesses the success of the therapy after treatment from the patients' point of view.

In the past, the patients' subjective awareness regarding their health status has been an integral part of medical care and was not regarded as something independent. Studies have, however, revealed that in dentistry, objective diagnostic findings often differ from the patients' subjective views (Heydecke et al., 2003). Within the frame of health needs assessment as one part of health services research, a high objective need for dental treatment is often contrasted by considerably lower subjective need. Whereas, for instance, restorations after tooth loss in the posterior region are required from most professionals' point of view, leaving untreated open spaces in the premolar and molar regions is often accepted by patients of different age groups even in countries with highly developed oral health care systems. Furthermore, discrepancies between diagnostic findings and patients' health status have been recognized. This emphasizes that assessments of Oral Health Status should cover more than merely clinical-somatic components. Growing life expectancy underlines and promotes this trend, because therapies have to be found out which preserve or even enhance the patient's quality of life effectively in order to keep the patients well and fit over a long period of their life (reduction of morbidity).

As a consequence, measuring OHRQoL as an indicator of patient's well-being and the quality of health care services has become accepted as an explicit criterion of evaluation. It is an essential component within the assessment of outcomes of oral health care,

capturing the outcomes of public health programs. As a consequence, a number of OHRQoL measures have been developed to assess the functional, psychological, social and economic implications, recording the patient's own assessment of his health by using questionnaires. The best documented and most popular instrument for measuring OHRQoL is the Oral Health Impact Profile (OHIP), a questionnaire including 49 issues/questions (Slade and Spencer, 1994). A major advantage of this measure is that the statements were derived from a representative patient group, and were not conceived by dental research workers.

Oral Diseases and Their Prevalence in Different Age Groups

Oral diseases have afflicted the human race since the dawn of recorded history (Weinberger, 1948). The impact of oral diseases on both society and the individual is significant. Common effects are pain, discomfort, sleepless nights, limitation in eating function leading to pour nutrition, and time of school or work as a result of dental problems.

Oral diseases can affect all dentofacial and oral structures: the hard tissues including bone and teeth as well as mucosal, pulpal, periodontal and glandular soft tissues (► oral diseases). Within the possible oral diseases *dental caries* is one of the most frequent diseases in the world. It is a multifactorial localized destruction of the hard tooth tissue, caused by microorganisms (infectious disease). The principal factors leading to destruction are (1) time, (2) microorganisms in dental plaque (predominantly Streptococcus mutans), (3) host and teeth, and (4) substrate (principally sucrose). Caries lesions themselves seldom cause pain not until inflammatory complications. Chiefly responsible for the development of modern patterns of caries seem to be dietary changes that began during the eighteenth century, when principally refinement of foods and greater availability of sugar increased. For example, import duties on sugar in Britain relaxed in 1845 and were completely removed by 1875, a period during which the severity of caries greatly increased (Corbett and Moore, 1976).

Dental caries is still a major oral health problem in most industrialized countries, affecting 60–90% of schoolchildren and the vast majority of adults (Petersen, 2003). Worldwide differences exist in the incidence of caries, e. g. Eskimos and blacks have less experience with caries than people from developed countries. Due to changing living conditions, however, it is expected that the incidence of dental caries will increase in many developing countries, particularly as a result of a growing consumption of sugars.

For monitoring disease trends and enabling international comparisons, in their manual for oral health surveys the World Health Organization (WHO) suggests five age-groups as representative index ages: the 5-, 12-, 15-, 35–44-, and 65–74-aged (WHO, 1997). In order to describe the caries experience of these age-groups, in representative samples the prevalence of the *d*ecayed, *m*issing and *f*illed *t*eeth per individual are counted by the *DMF(T)*-Index (Klein et al., 1938; ► oral health in different age groups).

Looking at the oral health of different age groups, within the 12-year-old children, for instance, a substantial decline of dental caries levels can be recognized worldwide. In 2001 the global weighted mean DMFT value for this age group was reported to be 1.74 continuing to increase until today (global weighted mean DMFT = 1.61 in 2004). Although efforts have been made, there are still countries which suffer from a high rate of caries, and only 74% of the nations reached the formulated goal in 2004, representing 86% of the world population. In several developing countries even a trend toward higher levels of dental caries has been reported. The decreasing prevalence of caries within children (5 years, 12 years) does not continue in adolescents. The wide majority of adults are suffering from dental caries, but the increase of caries-prevalence is lower than at younger ages. Severity depends on many life circumstances and environmental factors and can be very different among individuals of the same population. For example, there is a tendency among elderly people with lower income to miss regular dental examinations and treatments and neglect regular oral hygiene. In addition to this they frequently consume much sugar and smoke and therefore suffer more often from dental caries. Dental caries seems to be closely associated with social and behavioral factors (► risk factors and high risk groups).

Throughout the world, losing teeth is still seen by many people as a natural consequence of aging. In many industrial countries the prevalence of edentulism is over 20% in people over 65 years of age. Whereas at younger ages dental caries is the main reason for the loss of teeth, in adulthood *periodontal diseases* (gingivitis, periodontitis) are predominantly responsi-

ble for extractions. Both, gingivitis and periodontitis result from bacterial infection and have been prevalent throughout human history. For assessing and recording the periodontal status, the WHO recommends the *C*ommunity *P*eriodontal *I*ndex (*CPI*-Index) (Ainamo et al., 1982). He uses three indicators (gingival bleeding, calculus and periodontal pockets) and comprises five codes. Code 0 is related to healthy conditions, Code 1 and 2 are signs for gingivitis, and code 3 and 4 is given in case of periodontitis (► oral health in different age groups).

Gingivitis is an inflammatory process of the gingiva in which the junctional epithelium remains attached to the tooth at its original level. In the young population, the frequency of gingivitis is nearly up to 100%. The prevalence increases from the primary dentition on and reaches highest scores in puberty. Beside the high prevalence of gingival inflammation (CPI-code 1 and 2 within nearly 100%), first signs of elevated probing depths could already be recorded in younger people. Only with a perfect personal oral hygiene it may be possible to diagnose a patient with no forms of gingivitis.

Periodontitis is a multifactorial process that on the one hand is a reaction on an untreated gingivitis although not every gingivitis stringently leads to periodontitis. On the other hand, there are individual dispositions that even make patients with a perfect oral hygiene suffer from aggressive loss of periodontal attachment. The expression of clinical disease is therefore a function of both bacterial infection and the host response to that infection, mediated by environmental factors like for example smoking and oral hygiene, genetic dispositions, professional periodontal-treatment, and much more (Burt, 2005). Periodontitis is characterized by clinical attachment loss (CAL) of the periodontal ligament and loss of bony support of the tooth. The kinds of periodontitis are mainly divided into an aggressive and a chronic form. Whereas early-onset periodontitis is infrequent, adult periodontitis is rather prevalent all over the world as well as gingival bleeding and calculus. But advanced disease with deep periodontal pockets (≥ 6 mm; Code 4), leading to severe loss of supporting periodontal tissues and tooth loss, affects only 10–15% of adults worldwide (Petersen,2003). It is well known that the destruction of the attachment apparatus can be reduced by continuous plaque and calculus removal. Within the last few years, the influence of periodontitis on other medical subjects has become a point of research. It is certain that periodontitis is a risk for bacteraemia. This is especially important for patients suffering from certain cardiac diseases who are at high risk of endocarditis. Not only an influence of diabetes with its risk factors on periodontitis but also the influence of periodontal diseases on progression of diabetes is discussed at the moment. It has been also linked to preterm birth and low birth weight.

Of all conditions that dental professionals see and treat, oral cancer is the only one that has life and death implications. Worldwide, the combination of tobacco use, heavy alcohol consumption and poor diet is responsible for 90% of all oral cancers (Johnson, 2001). It is high among men and the eighth most common cancer worldwide (Petersen, 2003). Carcinomas of the oral mucosa, tongue, and lip comprise 80% of all oral cancers on a global basis. Other affections counted among oral diseases are craniofacial anomalies, especially cleft lip and/or cleft palate, dentofacial anomalies like temporomandibular disorders or malocclusion and dental trauma (► oral diseases).

Management and Prevention of Oral Diseases

The management of oral diseases includes all the steps from examination to the diagnosis and treatment of these illnesses (► management of oral diseases). Since oral disorders can affect all oral and dentofacial structures, several treatment disciplines (specialties) exist due to the different types of diseases:

- *oral (and maxillofacial) surgery* (infections, maxillofacial trauma, oral cancer etc.)
- *Operative (or conservative) dentistry* (dental caries, dental trauma etc.)
- *Prosthodontics* (partial edentulism, temporomandibular disorders etc.)
- *Periodontology or periodontics* (gingivitis, periodontitis etc.)
- *Orthodontics* (dental misalignment, skeletal dysgnathy etc.)

Additionally, disciplines evolved focussing on certain age-groups: *Pediatric dentistry* centering on the provision of dental services to children, and *geriatric dentistry* concentrating on elderly and infirm patients.

The ultimate goal of treating oral diseases is the "restitutio ad integrum". This aim can only be achieved in fewest cases. Dentists primarily try to get a disease free state of the hard and soft tissues and in case of

restoration they aim at the longest possible survival of the treated tooth or the restoration respectively. The available methods of treatment have changed within the years. Looking for example at the management of dental caries, until the nineteenth century extraction of the affected tooth was the only useful treatment. Since then there has been a transition to restorative care in which the infected parts of the tooth are removed and replaced with an inert obdurating filling. During the latter half of the twentieth century technology enhanced. Badly destroyed teeth can now be restored with a range of adhesive tooth colored materials. Larger portions of dental hard tissues can be rehabilitated with full crowns. If single or multiple teeth are missing, the gap can be closed not only with removable dentures as in former times but also with fixed dental prostheses. Moreover, the missing units can be replaced by using an artificial tooth root replacement called dental implant which bear restorations as crowns and fixed or removable prostheses.

All these treatments provided by the dentists in fact improve or maintain a person's functional status and might reduce the social impact of dental caries on affected people but they do not help to avoid recurrence and therefore play a minor role in preventing. Hence, in the last centuries in dentistry a paradigm shift away from restorative to preventive medicine took place. Several studies pointed out that caries and periodontitis are avoidable to a high extent by using simple measures (► prevention of oral diseases). Due to the burden of oral diseases for the individual patient and the society, prevention of oral diseases is a prime objective for dental public health administrators. As in any area of public health, prevention can be approached through health education and health promotion, and through early case-finding and treatment. In general, successful caries prevention is based on (1) regular oral hygiene, (2) healthy food choice, (3) periodical consultation to a dentist, and (4) the use of fluorides. There are a number of well-tested and powerful methods of prevention at individual, professional and community levels. Measures at the individual level are regular oral hygiene, fluoride applications, healthy food choices and smoking cessation. Services delivered by dentists or auxiliaries include professional oral hygiene procedures, topical fluoride applications and fissure sealing. Caries prevention for groups can be offered in schools or Kindergartens and encompasses healthy food choices, the use of fluoridated salt, and oral health education. Community level measures are water fluoridation, all actions suitable to reduce common risk factors and all campaigns for healthy food choices. Improvements can be achieved, for example, by reducing the sugar intake to a maximum of 6–10% of food energy or four times daily and by improving nutrition in young children with regard to breast and bottle feeding. Establishing a safer environment by using seatbelts, child restraints, mouth protectors and helmets also reduces dental injuries.

Risk Factors and High Risk Groups

In order to clear up the etiology of the main oral diseases, for a long time research in dentistry was aimed at specific biological risk factors (bacterial or micro-structural causes). It is well known nowadays, that the immediate causes of the major diseases, caries and periodontal diseases, are diet (frequent intake of simple sugar), and plaque.

Current research in dentistry is more directed towards a wider risk concept including biological and psychosocial determinants, following the common risk factor approach (► risk factors and high risk groups). The Common Risk/Health Factor Approach aims at reducing risk and promoting health factors, no longer focusing on single diseases but rather aiming at an improvement of health conditions for the whole population. Risk factors are not necessarily causal. They include aspects of a person's condition (genetics), lifestyle or environment. Various combinations of risk factors lead to the disease. The more risk factors are involved in the disease process the more complex is the etiology of the disease. Subjects of high risk groups show more often such patterns of risk factor combinations which lead to an earlier disease onset and – in consequence – to a higher disease prevalence. However it is difficult to predict the disease in an individual subject using an isolated risk factor. Only a certain probability for the onset of a disease can be given if a risk factor is present. Ultimately, the use of a dentist's clinical judgment to identify people at risk of oral diseases has been shown to be as good as other selected methods because it includes not only aspects of the oral situation, but also aspects of lifestyle and environment (Kay, 1999).

Studies in dentistry exhibited that oral health is not only determined by diet and hygiene, but also by smoking, alcohol use, stress and trauma (Sheiham, 2000). This

core group of risk factors is common to many chronic diseases and injuries. Dietary excess, for instance, leads on one hand to chronic diseases such as obesity, cancer, and diabetes and on the other hand causes dental caries and periodontal diseases. Tobacco use, also a risk factor for cardiovascular and pulmonary diseases, has been estimated to account for over 90% of cancers in the oral cavity, and is associated with aggravated periodontal breakdown, poorer standards of oral hygiene and thus premature tooth loss (Petersen, 2003). These risk factors are common risk factors also found within the four most prominent non-communicable chronic diseases (NCDs): cardiovascular diseases, diabetes, cancer and chronic obstructive pulmonary diseases. Risk factors, related to lifestyle, are preventable. Lifestyle behaviors themselves are again problems related to social and cultural milieu rather than problems of the individual. Hence, adopting a collaborative approach is more rational than one that is disease specific.

Available data from population based studies show, that lifestyle problems as well as chronic (oral) diseases are more prevalent in disadvantaged and socially marginalized populations. Members of these social strata are characterized for example by an unhealthy and risky lifestyle, inability to change unhealthy behavior, bad oral hygiene, bad self-assessment of health, non-participation in prevention programs even if they are free of charge, and low social support. Periodontal diseases occur more often in smokers and in subjects with poor general health. Other specific risk groups for oral diseases are physically disabled and mentally handicapped subjects as well as immobile subjects show a higher risk for oral diseases.

The care of risk groups in dentistry should be directed to the change of their unhealthy and risky behavior. Therefore, it seems more useful to influence common risk factors for oral diseases related to lifestyle and environment. A major benefit of the common risk factor approach is the focus on improving health conditions for the whole population as well as for high risk groups, thereby reducing inequalities.

Social Inequalities in Dentistry

For a long time, the (oral) health status of the population has been mainly defined by the delivery and financing of medical care. But within the last centuries scientific surveys show that also in highly developed countries extensive social inequalities exist due to the state of health (► social inequalities in dentistry). Those groups of the population have the highest risk to fall ill or to die at an early age which have the lowest income, the lowest education level, the least possibilities to structure their lives, the lowest social assistance by small social networks (social support) and the lowest political influence – as an individual and also as a group. In short: lower socio-economic groups have poorer general and dental health and a shorter life than higher socio-economic groups.

Due to this finding science and politics are more and more interested in the fact that (oral) health reacts very seriously to social environmental influences, the so-called social determinants of oral health (SDOH). An extensive and recommendable paper on SDOH has been submitted by Marmot and Wilkinson (Marmot and Wilkinson, 1999). The most important SDOH with a lifelong impact on health are education and care in early life, social exclusion/inclusion, job security and working conditions, income inequality, stress, social support, general access to medical care, housing and food security, and physical environment.

Thus, the socio-economical conditions influence quite more the health status of the individuals than personal health behaviors and medical care. However, not only the objective strains of an individual are in the focus but also the individual possibilities and capacities to accept these strains and to deal with them (Sense of Coherence). Thus, the health strain per se is not important but the relationship of health strain and the individual resources to cope with them. In this context, the personal health behavior of an individual is influenced by this interaction and also by the kind of health care.

Many surveys on the prevalence of oral diseases amongst the population have been made worldwide. Dental caries is thereby the most carefully examined dental disease, in particular in the group of children and young adults. Studies show that caries, periodontitis and tooth loss had a significant association with a person's social status. Looking at caries for example in children and adolescents many surveys and studies point out that there is in fact a continual decrease of caries frequency (caries decline) since the 1970th, but – on the contrary – also a considerable imbalance of the caries prevalence (caries polarization). A high portion of dental caries occurs in a relatively small group of socially deprived people. The proportion of naturally

healthy dentition of children and young adults of the upper class is quite beyond the one of the social underclass. Caries in deprived portions of a population in children and adolescents might be accompanied by high prevalence rates of early onset type II diabetes, obesity and malnutrition. Caries polarization cannot only be observed in the group of children and young adults. This socio-medical problem indeed exists in all age groups and in different severity. The second major oral disease (periodontitis), too, shows clear stratum-specific differences with regard to its frequency in the population (Micheelis 2001.

For Dental Public Health these findings are of great significance with regard to prevention and care politics. The wider social determinants of health have of course also an impact on oral health as they have it on general health. All fields of politics, the explicit health policy, the primary and secondary prevention as well as the health promotion and the curative and rehabilitation fields are influenced by the interaction and correlation of the social situation and the health status. Therefore, politics, public health research, health care research and authorities of prevention and health care must deal with the social determinants of oral health (SDOH) in order to analyze the causes of health deficits of the society and to develop strategies for a structure of the social determinants orientated per se towards a better general and oral health. This should of course also include the aspect of social equality as the problem of social inequality is of priority importance for the society as a whole.

Oral Health Promotion

Tackling such health inequalities by health promotion has become a key policy objective. Health promotion, a core competency of (dental) public health, goes beyond health care. It is defined by the WHO as the process of enabling individuals and communities to increase control over the determinants of their health and thereby improve their health. The Ottawa Charter for Health Promotion, formulated during the first international conference on health promotion in Ottawa in 1986, announced five key action areas in this field: *1. Building healthy public policy, 2. Creating supporting environments, 3. Strengthening community action, 4. Developing personal skills, 5. Reorienting health services* (► oral health promotion). Promoting health can be achieved by three basic health promotion strategies: by advocacy for health, by enabling people to achieve their full health potential, and by mediating between the different interests in society in pursuit of health (WHO, 1986). (Oral) health promotion strategies can be orientated either towards the population as a whole or towards groups or individuals at risk of disease.

Factors, that have a significant influence on health, are numerous, interactive, and shaped by culture, economy and politics, which means that the fundamental determinants of oral health are socio-economic. Individuals have only a limited control over these determinants, but oral health promotion is a way to deal effectively with them. Oral health promotion uses techniques for multi-sectoral working and develops partnerships across agencies. Potential partners are not only doctors, paediatric nurses, pharmacists and midwives, but also teachers, parents, social workers, food producers, the advertising industry and local, national and international government (Daly et al., 2002).

Some say that health inequalities can only be addressed through a significant redistribution of income, e. g. by tax and benefit reform. But programmes can also aim directly at oral health, promoting equity of oral health outcomes by oral health education. Health education is defined as any educational activity aimed at achieving a health-related goal (WHO, 1984). It generally gives knowledge, develops skills, ensures understanding of health issues and promotes self-esteem in order to improve an individual's ability to choose a healthier lifestyle. In dentistry, health education has been adopted as the central thrust of prevention. But it is important to stress, that knowledge does not necessarily lead to behavior change. People can only transform new knowledge into action, if they are enabled to. Hence, their environment has to be changed. Nancy Milio formulated the core concept of health promotion: *Make the healthy choices easy choices* (Milio, 1981). So oral health education as a part of oral health promotion can only develop its full potential if it is supported by structural measures (legal, environmental, regulatory etc.).

Assessing the extent to which health promotion actions achieve a valued outcome is called health promotion evaluation. It is important as a means of developing effective interventions, for sharing and disseminating examples of good practice and for providing feedback to funding agencies, staff and participants. It is divid-

ed into *outcome* and *process evaluation*. Outcome evaluation looks for *what* an activity has achieved. Process evaluation wants to explain *how* outcomes have been achieved. Both quantitative methods and qualitative methods should be used.

Delivery of Dental Care

Dental care delivery is the process of providing oral health care, classified into *primary, secondary* and *tertiary care*. The most common way of providing oral health care is face-to-face delivery between care provider and patient. Dental care providers are mostly dentists (dental practitioners, dental doctors) and dental auxiliaries (e.g. dental chairside assistants, dental nurses). Dentists are generally capable to give instructions on prevention measures, to diagnose and to treat anomalies and diseases affecting the teeth, mouth, jaws and adjoining tissue. Dental auxiliaries may assist with chairside activities and tasks, including advice and motivation of patients concerning prevention and therapeutic preventive measures (► delivery of dental care).
Oral health care is provided in dental practices, in universities, in hospitals, in multi-dentist centers or by public dental services. Its organization is influenced by political, economic, social and technological factors, e. g. the characteristics of a health care system have an important influence on the quality and structure of the delivery of dental care. Information's on practice conditions, treatment measures, quality standards, as well as on fees and tariffs have also a great impact on the choice of the patients and consequently on the motivation and therefore the incentives of the health professionals (transparency). Another important item of oral health care delivery is the dental remuneration system. Funding conditions have a great influence on health care delivery, as they define who pays the costs and how dentists are compensated. No matter whether paid ultimately by a government body, a sick fund or directly by the patient, fee-for-service (or fee-per-item) is the major form of payment for private dental practitioners all over Europe, varying considerably within the countries. The most significant differentiation in developed countries is the one between salaried public health care and market-based health care (as practiced in the U.S.). In the majority of the EU-countries dental care is mostly provided by non-salaried, independent practitioners established in their own dental surgery (private-, liberal- or general practitioners). Only in countries with a large, salaried public dental service the liberal general practitioners are of less importance and prevalence (e. g. in the Nordic countries). In addition to the general practitioners in most countries there exist dentists who are working in public dental services, in dental wards of the hospitals, in universities or in the Armed Forces.
The delivery of dental care is an important factor in dental public health research because most countries are confronted with increasing expenditures in the health-care systems due to the process of demographic aging of the population, to the increasing demands and to the medico-technical progress.

Health System in Dentistry

Dentistry is practiced within the oral health (care) system of a country. Health systems have existed ever since people first attempted to protect their health and to treat diseases (► health system in dentistry). Organized health systems in the modern sense, however, are an institution of the last hundred or so years and universal cover is predominantly confined to industrialized countries.
In general the concept of health system subsumes all institutions and activities directed towards the provision and funding of health benefits to the population. Therefore, the "oral health system" is a combination of "organizations, flows of finance, workforce training and structure, laws, regulations and accepted practice which are aimed at improving the oral health of individuals and communities" (Anderson et al., 1998). Analysis reveals that the oral health system can be broken down into three components: (1) the oral health care system proper (the medical system), (2) the social, political and economic background to the oral health care system (health policy) and (3) patients' individual capabilities and attitude patterns (influenced by the oral health care system and the socioeconomic background). The objectives of the system are enshrined, for example, in the German Dental Association's "Oral Health Goals", which are in turn based on the World Health Organization's "Global Goals for Oral Health 2020". Compared with the health system as a whole, the oral health system exhibits certain particularities as "most oral care is provided as an outpatient service, and hospital oral health care is very limited" (Holst et al., 2002). Both the structure and organization of the system of oral

health care and the level of benefits provided depend on a state's specific "sociopolitical culture". Hence, existing national differences in the design of oral health systems are largely attributable to the historical and cultural particularities of the countries.

As decision-makers in countries of all levels of development, struggling to make appropriate choices to improve the performance of their health system, are faced with common problems, the interest in *comparative (oral) health systems research* has grown rapidly during the last two decades. Its central topics include studies of national health systems and reforms, differences and similarities in the macro-level structures of the health services, and the way in which various systemic changes and reforms enhance the quality, accessibility and cost-effectiveness of these services. An important aspect of comparative health systems research is international comparison of the *performance* of health systems – that is, the extent to which health goals (including oral health goals) are achieved and the resources required for this purpose.

The oral health care systems of the EU-countries are based on three different models (also see ► delivery of dental care):

1. The *Bismarck Model*, a government-regulated social insurance system, where oral health care is mainly financed through compulsory social insurance, with the option of voluntary private insurance.

2. The *Beveridge Model*, a government-organized and tax-financed national health system, where financing of oral health care used to be predominantly provided out of general and/or specific taxation, collected by central or regional government.

3. The *Semashko Model*, a mixed system of Bismarck [financing] and Beveridge [provision], in which oral health care is mainly financed by compulsory social insurance.

As a rule, these models are not applied in pure form; that is to say, a given national health system may perfectly well include individual features of a different model and thereby assume a hybrid configuration. Since all national health systems are faced with similar economic and demographic challenges and a concerted European health policy is proposed for the medium term (under the "Open Method of Coordination"), it is generally assumed that there will be a "convergence of systems".

Health Economics in Dentistry

Health economics is an independent branch of economics that is concerned both empirically and theoretically with the economic aspects of healthcare and more particularly with the production and distribution of scarce health goods (► health economics in dentistry). Health economics, then, is fundamentally a science not of minimization but of optimization. In the particular field of dentistry, the subdiscipline of "dental health economics" has hesitantly come into being and is still relatively undeveloped in the German-speaking countries as compared with the United States, the United Kingdom, the Netherlands and Scandinavia. According to the World Health Organization's standard definition, the function of health economics is "inter alia to quantify over time the resources used in health service delivery, their organization and their financing; the efficiency with which resources are allocated and used for health purposes; and the effect of preventive, curative, and rehabilitative health services on individual and national productivity" (World Health Organization, 1975). Health economics in the sphere of dental care is concerned in particular with (1) the allocation of resources to dental treatment, (2) the efficiency of dental service, (3) the distribution of health goods and services, and (4) the creation of value. The specific methods used in health economics are characterized by systematic comparison of the costs and benefits of given actions and the balancing of alternatives against each other.

Health-economic analysis can be applied at different levels. On the *micro-level*, sometimes referred to as "health services management", it concerns the actions of individual actors. The *meso-level* examines the actions of the intermediate actors in the health system. Finally, the *macro-level* is that of analysis of the characteristics of the system as a whole. "Health system analysis" is conducted from the macroeconomic point of view, and examines such issues as dental overprovision, underprovision and malprovision.

For practical purposes, perhaps the most important aspect of health-economic evaluation in the dental field is assessment of the costs and effects of different therapies and/or preventive strategies. The outcome parameters used are epidemiological data, such as the DMFT value for caries or the Community Periodontal Index (CPI) for periodontal status. To ensure that the results

of health-economic evaluation studies can be validly interpreted, minimum requirements as to methodology and transparency must be observed (Drummond, 2005). Within the systematization of types of health-economic evaluation, studies are divided into non-comparative studies (e. g. Cost of illness study (CIS)) and comparative studies (e. g. Cost effectiveness analysis (CEA).

Economic evaluations facilitate the choice of alternatives in dental practice in a situation of scarce resources. A strikingly large number of evaluation studies in the dental field are devoted to comparison of the costs of preventive strategies with their effectiveness (CEA). Preventive measures have a relatively long tradition in dentistry. A comparison of the economics of various prophylactic measures shows that all current measures of prophylaxis and tooth conservation are cost-effective and hence to be recommended in terms of health economics. Apart from vaccination, no other field of healthcare has such high efficiency as dental prophylaxis, and in particular fluoridation for the prevention of caries. With regard to the development of cost utility analysis (CUA) and cost benefit analysis (CBA), health-economic research is still in its infancy, as investigation of the benefits of dental measures is enormously more complex in terms of methodology than determination of their costs. The significance of health economics as an instrument of rational policy-making is likely to increase further in the future, as (oral) health is in economic terms a superior good, which means that the demand for it increases disproportionately as incomes in society as a whole rise.

Oral Health Policies

The WHO has described that a basic policy value is *equity*, which means that everyone should have a fair opportunity to attain his or her full health potential. Disadvantaged people experience much higher levels of oral disease than well-off people. A number of specific innovative approaches to reduce health inequalities have been employed in various European countries. Closely linked is the value of *solidarity*, meaning that everyone contributes to the health system according to his or her ability. A health policy that promotes solidarity is better able to counterbalance social inequities. Health policies include actions of both public and private organizations inside and outside the health system. They refer to what health agencies actually do, although their decisions or actions may not be intended or even recognized as policy. Taking part in policy development is an important task for oral health facilitators (▶ oral health policies).

Oral health policies are oral health-related formal statements, which set overall guidelines and outline future directions, or courses of action that affect institutions, organizations, services, funding arrangements, groups and individuals. On the international level, global oral health objectives have been presented. With regard to the content of oral health policies, the WHO proposes to address priority action areas like, for instance, supporting the widespread allocation of fluorides (particularly important in the light of a changing diet), improving the health of important target groups like school children, youth and elderly people, avoiding and discontinuing the use of all forms of tobacco, stimulating oral health research, supporting the development of oral health services that matches the needs of the country and much more. The targets relate to disease and disability indicators and have to be adapted by local authorities. The strategy is built around the twin goals of *improving* population health and *reducing* health inequalities.

A health-making policy deals effectively with the environments and ways of living. The concept of "healthy public policy" has been described as follows (Milio, 1981): Personal behavior patterns are not simply "free" choices about "lifestyle", isolated from the social and economic context. Lifestyles are patterns of choices made from the alternatives that are available to people according to their socio-economic circumstances and to the ease with which they are able to choose certain ones over others.

Choice options available to the population and to social groups do not simply "happen". Rather they are themselves the result of policy choices: governmental and corporate decisions concerning technology, income maintenance, taxation, health care and other services. These policies represent the scope of health-making policy. Policy, from this perspective, is *option-setting*. A health-making strategy eliminates those options that result in health-damaging situations, or increases the cost of those options. It provides new, easier opportunities, or reduces the costs of these options. This approach emphasizes neither prohibition nor prescription, but rather new opportunities for choice-making. Individuals and organizations that want to continue to choose health-damaging options would be able to do

so. However, they would pay higher costs than if they made health-promoting choices.

The process of health policy making refers to the way in which policies are initiated, formulated, negotiated, communicated, implemented and evaluated. Trying to influence oral health policy requires maintaining a strong oral health unit within health agencies. Opportunities for funding may arise in conjunction with key policy developments currently taking place. Oral health policies should explicitly relate to policies in the health and social sectors. Partners have to be found among policy makers, professionals, organizations, groups and the public. Interest groups (e. g. companies and for-profit-organizations) try to influence public policy on particular issues at various stages of the policy process. But also organizations registered as not-for-profit may not be independent.

Summary

Caries and periodontitis are among the most common diseases. The burden of oral diseases for the individual patient and the society is substantial; their sequelae with tooth loss on top affect all health dimensions. Dental diseases can be successfully treated and for their prevention an array of measures is available. Being widespread, preventable and of high impact upon the society and the individual, oral diseases meet the criteria of a public health problem. Therefore, the interdisciplinary field of Dental public health has been established focusing on oral health and oral and dental diseases. As in any area of public health, prevention can be approached through health education and health promotion, and through early case-finding and treatment.

Dental Restoration

Definition

In the narrow sense of the word, dental restorations comprise all means to restore single teeth or dental arches with fillings, crowns, bridges and implant-born crowns and bridges of any kind. Sometimes, also removable dentures are referred to as dental restorations.

Dental Sealant

Synonyms

Fissure sealing

Definition

A dental sealant is plastic material that is applied to the chewing surface (pits and fissures) of the ► molar teeth in order to prevent dental caries. The application of dental sealants is usually carried out in a dentist's office. The dentist or assistant first cleans and dries the tooth to be treated, then paints a thin layer of liquid plastic material on the pits and fissures of the tooth. After light curing, the plastic becomes a hard, thin layer covering the treated portions of the tooth. The approximal (sideward) tooth surfaces that are also very prone to caries are not accessible for sealants. When correctly applied, dental sealants are nearly 100% effective in preventing dental caries on treated tooth surfaces. Despite this, and the fact that dental sealants have been widely available since the early 1970s, it is estimated currently that fewer than 20% of the population have dental sealants.

Dental Treatment

► Management of Oral Diseases

Denture

► Complete Removable Dental Prosthesis

Denturist

Definition

A denturist is a non-dentist who provides treatment with removable dentures directly to patients. Many denturists have a dental technology background. Because intra-oral measures are conducted by non-medical professionals, denturists are only legally approved in some countries (e. g. some of the United States) whereas in others this approach is illegal.

2′-Deoxyribonucleic Acid

► Deoxyribonucleic Acid (DNA)

Deoxyribonucleic Acid (DNA)

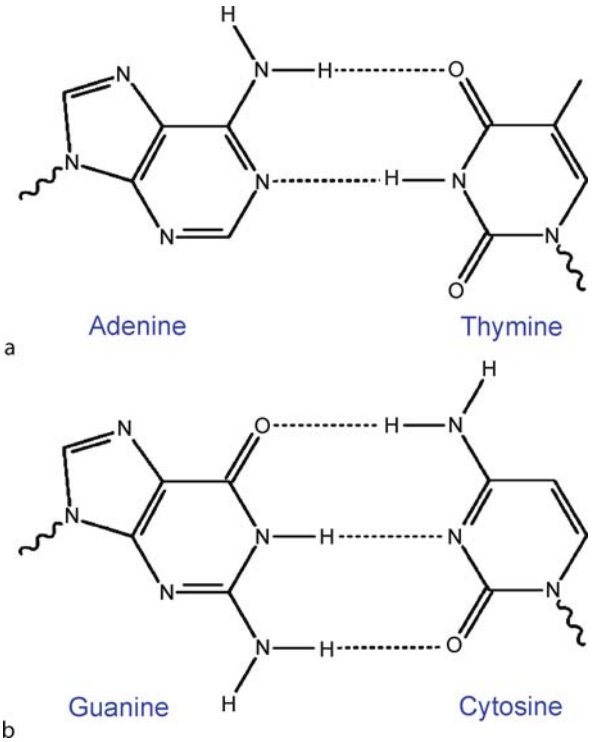
Synonyms

2′-Deoxyribonucleic acid

Definition

DNA is the molecule in which genetic information is primarily encoded in the genomes of most organ-

isms, including humans. It is a polymer which consists of subunits called 'deoxyribonucleotides' or just 'nucleotides,' and each subunit is made of a nitrogenous base (double-ringed purines Adenine (A) and Guanine (G), and single-ringed pyrimidines Thymine (T) and Cytosine (C)); a ringed five-carbon sugar, ribose, with a hydrogen (–H) instead of a hydroxyl group (–OH) bonded to the second carbon (2′ – hence, 2′-*deoxy*ribose), and a covalent bond between the first and fourth carbon; and phosphate groups ($-PO_4$) attached to the third (3′) and fifth (5′) carbon. In order to stabilize its structure, DNA aligns itself with a strand bearing a complementary sequence, as defined by the order of nucleotides on the strand; since A has an affinity for T, T for A, G for C, and C for G (Fig. 1), the sequence of the complementary strand always has the appropriate nucleic acid for weak bond formation. For proper orientation, the nucleotides of the complementary strand align with their 5′ and 3′ phosphate groups in the opposite direction of the 5′ and 3′ groups on the original strand, hence it is said that complementary DNA strands are 'anti-parallel'. For example, a section of sequence 5′-AGCTTA-3′ will align with a complementary sequence 5′-TAAGCT-3′. Two weakly-bonded nucleotides on complementary strands are often called a 'base pair', a term often used interchangeably with nucleotide. When DNA strands are copied in the process of ► replication, and when DNA is used as a template for the coding of an RNA transcript, both processes proceed by making base pairs with the template strand in the direction of the 3′ carbon; hence it is said that DNA is read 5′ to 3′. When complementary strands are first fully-bonded, the DNA relaxes into a coiled state as the most energetically ideal configuration; this right-handed coil of two strands is often called a double-helix and is the most common variant of DNA observed. Another important feature of the helical structure is that the distance between coil twists is asymmetrical- there is a major groove (18–19 angstroms between twists) and a minor groove (12–13 angstroms between twists), the existence of which is relevant to the binding of some proteins which interact with DNA. DNA is similar to ribonucleic acid (RNA), which is used for several functions in the cell. RNA differs from DNA in two ways: 1) there is no missing hydroxyl (–OH) group at the 2′ carbon – this allows degradative enzymes to recognize RNA so that transcripts are not overly abundant or repeatedly translated; and 2) instead of the nucleic acid Thymine (T), RNA incorporates Uracil (U), which differs in structure from Thymine by having one less methyl ($-CH_3$) group (Fig. 2).



Deoxyribonucleic Acid (DNA), Figure 1 Illustration of bond formation between nucleotides in a base pair

Dependence Syndrome

Definition

A cluster of behavioral, cognitive, and physiological phenomena that develop after repeated substance use and that typically include a strong desire to take the drug, difficulties in controlling its use, persisting in its use despite evidence of harmful consequences, a higher priority given to drug use than to other activities and obligations, negligence of social responsibilities, increased tolerance, and sometimes a physical ► withdrawal state. The dependence syndrome may be present for a specific psychoactive substance (e. g. tobacco, alcohol, or diazepam), for a class of substances (e. g. opioid drugs), or for a wider range of pharmacologically different psychoactive substances.

Dependency Ratio

Definition

The dependency ratio is the ratio of the economically dependent portion of the population to the productive part of the population. Children under the age of 15 and adults ages 65 and older are assumed to be economically dependent, while individuals 15–64 are considered to be productive or capable of working. A higher dependency ratio (the number of children or elderly is larger relative to the number of working-age adults) indicates that the productive population must carry a larger burden in order to provide for dependent children and the elderly.

Depressive disorder

Definition

Depression is a common mental disorder that presents with depressed mood, loss of interest or pleasure, feelings of guilt or low self-worth, disturbed sleep or appetite, low energy, and poor concentration. These problems can become chronic or recurrent and lead to substantial impairments in an individual's ability to take care of his or her everyday responsibilities. The term depression is often used to refer to any of several depressive disorders. Three are classified in the Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition (DSM-IV) by specific symptoms: major depressive disorder (major depression), dysthymia, and depressive disorder not otherwise specified. Two others are classified by etiology: depressive disorder due to a general physical condition and substance-induced depressive disorder.

Depressive Disorder

► Depression

Depressive Episode

Synonyms

Depressive reaction; Reactive depression; Psychogenic depression

Definition

Individuals suffering from depression show lowering of mood, reduction of energy, and decrease in activity. There are mild, moderate, or severe depressive episodes (with or without psychotic symptoms). Capacity for enjoyment, interest, and concentration is reduced in the depressed patient, and marked tiredness after even minimal effort is common. Sleep is usually disturbed and appetite diminished. Self-esteem and self-confidence are almost always reduced and, even in the mild form, some ideas of guilt or worthlessness are often present. The lowered mood varies little from day to day, is unresponsive to circumstances, and may be accompanied by so-called "somatic" symptoms, such as loss of interest and pleasurable feelings, waking in the morning several hours before the usual time, depression worst in the morning, marked psychomotor retardation, agitation, loss of appetite, weight loss, and loss of libido. According to ICD-10, depending upon the number and severity of the symptoms, a depressive episode may be specified as mild, moderate, or severe.

Depressive Neurosis

► Dysthymia

Depressive Personality Disorder

► Dysthymia

Depressive Reaction

► Depressive Episode

Dermatitis nodosa tropica

► Onchocerciasis

Dermatitis in Schistomoniasis

► Cercarial Dermatitis

Dermatology

Definition

Dermatology is the branch of medicine concerned with the diagnosis, treatment, and prevention of diseases of the skin, hair, nails, oral cavity, and genitals. It sometimes also includes cosmetic care and enhancement.

Synonym

Exploratory data analysis

Definition

Descriptive statistics is a group of statistical procedures used for organizing, numerical description, and tabular and graphical representation of a data set.

Basic Characteristics

Frequency Distribution

Data analysis usually begins by organizing and counting the data and placing frequencies into tables. It is often important to know the ► ratio of absolute ► frequency (x) of a unit of observation that possesses a certain specific characteristic (belonging to a specific category or class interval) and the total number of units of observation (n). This relative frequency is called ► proportion: $p = x/n$. Proportion can be expressed as a percentage: $p(\%) = x/n \cdot 100$. Proportions can be interpreted as the equivalent of ► probability, because one of the definitions of probability (empirical probability) is based on relative frequencies (Bowers 2002).

For qualitative variables the organization of data is by categories (e. g. for vaccination status data can be organized into the categories "vaccinated" and "non-vaccinated"). Frequencies of categories are obtained by counting the units of observation in every category. An example of a ► graphical representation of category frequencies is a pie chart, where every segment is proportional to the frequency of the category which it represents. Another method of representation is a bar chart, where the height of the bars are proportional to the frequencies of the categories.

Discrete quantitative variables are given specific numerical values, and continuous quantitative variables are given class intervals. ► Frequency ► distribution is thus obtained by counting. Absolute frequency distributions are actual frequencies, and a relative frequency distribution is obtained by dividing them by the total number of data (Horwitz, Ferleger 1980). Cumulative frequency distribution is obtained by adding the frequencies of single groups or class intervals. Cumulative absolute frequency distributions are actual frequencies, and cumulative a relative frequency distribution is obtained by dividing them by the total number of data.

Distribution frequencies can be presented as a tabular display or a graphical display. A frequency table contains the values of the variables in the first column (names of the categories, discrete numerical values or class intervals), and the remaining columns contain the frequencies and relative frequencies.

An appropriate ► graphical representation of a frequency distribution of discrete quantitative data is a bar chart, and a frequency distribution of continuous quantitative data can be represented in a histogram, frequency polygon, or stem-and-leaf plot (Krishnamurty et al. 1995).

Frequencies in Epidemiological Measurement

Frequencies in epidemiological measurement are defined as: (a) incidence – frequency of a new event (disease, injury, death) in a population during a defined period of time, (b) point prevalence – frequency of events in a population at a certain point in time, and (c) period prevalence – frequency of people in the population who have been affected by the event at any time over a specified period.

► Rate is a ► ratio of the frequency of events (numerator) and the population at risk (denominator). It is multiplied by a constant (100, 1000, 10000 or 100000), in order to avoid the fractioning of events and enabling easier interpretation and understanding of the rates. When the numerator is incidence, the result is the incidence rate, and when the numerator is prevalence the result is the prevalence rate.

Risk is estimated as the proportion of people who may be affected by a risk event within the observed period (Katz 1997), i. e. measure of ▶ probability of occurrence of a risk event (Bowers 2002). Rates can be used for risk estimate (Katz 1997).

Theoretical Probability Distribution

Summary ▶ measures of central tendency and ▶ measures of dispersion are usually calculated after obtaining the empirical frequency distribution. Which of these measures will be applied depends on which model of theoretical probability distribution is closest to the actual empirical distribution. The theoretical model of ▶ normal distribution is the one that is most often suitable for the analysis of empirical distributions. Normal distribution is graphically displayed as a bell-shaped curve, when the value of the variable is on the x-axis and the probability density of occurrence of these values is on the y-axis. Deviation of the empirical distribution from the theoretical normal distribution can be estimated by applying the analysis of skewness and kurtosis, and by applying statistical tests for testing the null hypothesis that the sample data came from a normal population. When the empirical distribution is close to the theoretical normal distribution, then the data are best summarized by parametric summary measures such as mean, ▶ variance and ▶ standard deviation. If the data are drawn from a non-normal distribution, then the non-parametric statistics such as median, mode, percentiles and range may be more suitable.
Other important theoretical distributions are ▶ binomial distribution and ▶ Poisson distribution.

Measures of Central Tendency

▶ Measures of central tendency are values around which the data tends to group. The measures of central tendency that are most commonly used are ▶ mean, ▶ median, mode and geometric mean.
▶ Mean is computed by dividing the sum of all values by the number of values: $\bar{x} = (\sum x)/n$.
▶ Median is equal to the numerical value of the central data in the sequence of data ordered from the smallest to the largest. When the number of data is even, the median is equal to the average of the two central values. Mode is the value with the highest frequency of occurrence in a set of data.

Geometric mean is the n-root of the product of n observations: $G = \sqrt[n]{x_1 \cdot x_2 \cdot \cdots \cdot x_n}$. It can also be expressed as the antilogarithm of the mean of the logarithms of every value: $G = \text{antiln}(\sum \ln x)/n$.

Example 1

For the example data 1, 7, 1, 5, 1, 3, and 6, mean equals

$$\bar{x} = \frac{1+7+1+5+1+3+6}{7} = 3.43\,.$$

By rearranging the data from the smallest to the largest, the following sequence is obtained: 1, 1, 1, 3, 5, 6, 7. The central data in the sequence is the fourth data ((7+1)/2=4). The fourth data has a value 3, and this is, at the same time, the value of the median.
The mode value equals 1, because this is the value that has the highest frequency of occurrence (it occurs three times).
Geometric mean equals:

$$G = \text{antiln}\frac{\ln 1 + \ln 7 + \ln 1 + \ln 5 + \ln 1 + \ln 3 + \ln 6}{7} = \text{antiln}0.92 = 2.51$$

Measures of Dispersion

▶ Measures of dispersion show a degree of ▶ variability (variation or dispersion) of values of the observed variable around the measures of central tendency. The measures of dispersion can be divided into the measures based on quantiles and the measures based on deviation of observations from the mean.

Measures of Dispersion Based on Quantiles Quantiles are values of the observed variable which divide the frequency distribution into groups that consist of equal proportions of the number of observations. The most frequently used ones are quartiles, deciles and percentiles. Quartiles divide the sample of data into four groups, each containing 25% of the observations, deciles into ten groups, each containing 10%, and percentiles into 100 groups containing 1%. The median is equal to the second quartile, fifth decile and fiftieth percentile.

Range is the Difference Between the Largest and the Smallest Value Interquartile range is the difference between the first and the third quartile, i. e. 25. and 75.

percentile, and it contains 50% of the central observations. Minimal and maximal value, the first and third quartile and median (second quartile) are graphically presented by using the box-and-whisker plot.
Interdecile range is the difference between the first and the ninth decile, i. e. 10. and 90. percentile, and it contains 80% of the central observations. Reference range is frequently used and it contains 95% of the central observations, i. e. when 2.5% of observations are excluded on each side of the frequency distribution (Petrie, Sabin 2005).

Measures of Dispersion Based on the Deviation of Observations from the Mean ▶ Variance is a mean square deviation from the mean, and its estimate based on the sample data is obtained using the formula:

$$s^2 = \frac{\sum (x_i - \bar{x})^2}{n-1} = \frac{\sum x^2 - n\bar{x}^2}{n-1}$$

where x_i is an individual value, $\bar{x}$ is the mean, n is the sample size, and $n - 1$ is the number of the degrees of freedom.
▶ Standard deviation is the square root of the variance, and therefore it is expressed in the same units of measurement as the original observations. Standard deviation is a base for calculating the ▶ z-score (standard score), which gives the deviation of an individual value from the mean expressed in standard deviations (De Muth 2006):

$$z = \frac{x_i - \bar{x}}{s},$$

where x_i is an individual observation, $\bar{x}$ is the mean, and s is a standard deviation.
Coefficient of variation is a relative measure of variation obtained by dividing the standard deviation by the mean and expressing this ▶ ratio as a percentage: $CV = s/\bar{x} \cdot 100$.

Example 2

On the basis of the sample data from example 1 an estimate of the population variance equals:

$$s^2 = \frac{1^2 + 7^2 + 1^2 + 5^2 + 1^2 + 3^2 + 6^2 - 7 \cdot 3.43^2}{7-1} = \frac{122 - 69.21}{6} = 6.62,$$

and standard deviation $s = \sqrt{6.62} = 2.57$. *Coefficient of variation equals* $CV = 2.57/3.43 \cdot 100 = 75\%$.
Deviation of the second observation (value 7) from the mean, expressed by z-scores equals:

$$z = \frac{7 - 3.43}{2.57} = 1.39.$$

D

Effect Size

▶ Effect size is a measure of the strength of the ▶ relationship between two variables. Effect size estimates make comparison of results between different studies easier because they have characteristics of standardized indices and are independent from the sample size (Abelson 1995; Hojat, Xu 2004). Depending on the type of data and the design of the research, they are calculated in different ways. The estimates of the effect size are most frequently calculated based on (a) difference between the means, (b) difference and ratio of proportions, and (c) ▶ measures of association.

Effect Size Based on the Difference Between the Means Standardized mean difference is most frequently calculated in one of the following ways: Glass's Δ, Hedge's g and Cohen's d. Glass's Δ is calculated as $\Delta = (\bar{x}_E - \bar{x}_C)/s_C$, where $\bar{x}_E$ and $\bar{x}_C$ are means of the experimental and control groups, and s_C is a standard deviation of the control group. Modifications of this metric are Hedge's g calculated as $g = (\bar{x}_E - \bar{x}_C)s$, and Cohen's d calculated as $d = (\bar{x}_E - \bar{x}_C)\sigma$, where denominators are pooled standard deviations (standard deviation of all data from both groups). For dependent samples in repeated measurement (pre-test post-test design) pre-test standard deviation can be used as denominator.

Effect Size Based on the Difference and Ratio of Proportions Effect sizes that can be calculated based on the difference and ratio of proportions are risk difference and ▶ relative risk (formulas and examples for these measures are given in the essay "Analysis of frequencies").

Effect Size Based on the Measures of Association Estimates of effect size used as ▶ measures of association are ▶ Pearson's correlation coefficient, phi (ϕ) coefficient, contingency coefficient and ▶ odds-ratio.

► Pearson's correlation coefficient (r) is a measure of the linear association of two variables. In correlation analysis and calculation of correlation coefficient it is not necessary to assume a ► relationship between the variables, in terms of independent and dependent variables, like in ► regression analysis. ► Graphical representation of the relation of data pairs using the scatter diagram precedes the calculation of correlation coefficient. The values of correlation coefficient vary from −1 to +1. Positive values indicate positive correlation, i. e. tendency of values of both variables to increase or decrease together. Values from –1 to 0 indicate negative correlation, i. e. tendency that the increase of value of one variable is associated with the decrease of value of the other variable and vice versa. Values close to 0 indicate low correlation, and those close to –1 or +1 indicate strong linear correlation of two variables. The value of correlation coefficient can be estimated by the formula:

$$r = \frac{n\sum xy - \sum x \sum y}{\sqrt{n\sum x^2 - \left(\sum x\right)^2}\sqrt{n\sum y^2 - \left(\sum y\right)^2}}$$

where x and y are the values of the variables whose correlation we are examining, and n is the sample size.

When data are presented in rank order or the data are from the ordinal scale of measurement, instead of Pearson's correlation coefficient we use Spearman's rank correlation coefficient or Kendall's tau (Kirkwood et al. 2003).

Two special cases of Pearson's correlation coefficient are: (a) point-biserial correlation coefficient – correlation coefficient where one variable is continuous and the other is dichotomous, and (b) biserial correlation coefficient – correlation coefficient where both variables are continuous, but one of them is artificially converted into a dichotomous variable.

Phi (ϕ) coefficient, contingency coefficient and ► odds-ratio formulas and examples of calculation are presented in the essay "Analysis of frequencies."

Interpretation of the Effect Size For easier interpretation, effect sizes can be classified as small, medium and large. For the standardized mean difference the value of 0.20 can be considered as small, 0.50 as medium, and 0.80 as large. When the correlation coefficient, phi (ϕ) coefficient, or contingency coefficient are observed as the effect size, the value of 0.10 can be considered as small, 0.30 as medium, and 0.50 as large (Cohen 1998).

Descriptive Studies

Definition

A study that aims to reveal patterns associated with a specific disease without an emphasis on pre-specified hypotheses is called a descriptive study. Sometimes these types of studies are called hypothesis generating studies (to contrast them with hypothesis testing studies). There are three general reasons that may lead to conduction of a descriptive study: to help in planning resource allocation, to identify areas for further research, and to provide informal diagnostic information. Generally, in a descriptive study, the emphasis is on estimation rather than testing. Some of the quantities that are estimated within a descriptive study are the prevalence of a disease, the natural history of a disease, the resources required to treat the disease, and attitudes and perceptions about the disease.

Desired and Unwanted Fertility

Synonyms

Wanted and unwanted fertility

Definition

Desired fertility is the ideal number of children a woman, man, or couple would have regardless of the number he or she already has. Any births in excess of desired fertility are considered unwanted fertility. Alternatively, unwanted fertility can be measured as the proportion of births in the past year that were unwanted. Unwanted childbearing is an important indicator of the need for ► family planning services in a community, particular when women who desire no additional children are not using contraceptive methods (► contraception).

Determinant of Disease

► Risk Factor

Determinants of Health

Definition

Determinants of health are ► health indicators that represent factors which either directly cause illness and disease, or are risk factors that affect the health status of populations and individuals. Determinants of health roughly include the social environment (cultural, political, policy, socioeconomic factors, economic systems, social capital, and community capacity, etc.), the physical environment (living and working conditions), person-related dimensions (such as genetic endowment and health behaviors), and access to health services.

Development Cycle of Plasmodia

► Development of Plasmodia

Development of Plasmodia

Synonyms

Development cycle of plasmodia

Definition

For their cycle of development plasmodia need two different hosts. In humans, which are intermediate hosts, plasmodia reproduce asexually. In the *Anopheles* mosquito, which is the final or definite host, the germs reach a mature stage and reproduce sexually. From the mosquito's stomach wall the plasmodia get into the salivary glands. Then – with the next bite – they are transmitted into the human blood vessels. After an intermediate stop in the liver the parasites affect the red blood cells. When an infected person is bitten the plasmodia are taken up by the mosquito. Thus the cycle of development is repeated.

DG SANCO

Definition

DG SANCO is the French acronym for the "Directorate General Santé et protection des consommateurs" – Directorate General for Health and Consumer Affairs. It depicts an administrative unit of the European Commission and is divided in the following 3 sections:

- Public Health
- Food safety
- Consumer Affairs

Diabetes

Synonyms

Diabetes mellitus

Definition

The word "diabetes" is borrowed from the Greek word meaning "a siphon". The 2nd century AD Greek physician, Aretus the Cappadocian, named the condition "diabetes". He explained that patients with it had polyuria and "passed water like a siphon". Diabetes mellitus is a group of metabolic diseases characterized by high blood sugar glucose levels, which result from defects in insulin secretion, or action, or both.

Diabetes mellitus

Synonyms

Group of chronic diseases with hyperglycemia

Definition

Diabetes Mellitus is a group of metabolic disorders in man. It occurs as diabetes mellitus type 1 (Juvenile onset type) and diabetes mellitus type 2 (Adult onset type). These conditions are characterized by high blood sugar levels and loss of glucose in the urine resulting from defects in insulin secretion, or action, or both. Normally, when blood glucose level rises, insulin is released from the pancreas to normalize the level of blood glucose. Generally, in diabetic patients, the release of insulin is absent, insufficient or the body cells are unable to use insulin efficiently thus leading to a rise in blood glucose.

In type 1 diabetes (insulin dependent diabetes, IDDM), there is an absolute lack of insulin secondary to an autoimmune destructive process occurring in the beta cells of the pancreas due to abnormal antibodies. The tendency to develop these abnormal antibodies is understood to be, in part, genetically inherited. Some viral infections or environmental toxins may also trigger the development of such abnormal antibodies. Type 1 diabetes accounting for only 10% of diabetic cases, tends to occur mainly in young individuals under 30 years of age. Occasionally, it occurs in older persons and is referred to as latent autoimmune diabetes mellitus (LADA). In type 2 diabetes (non-insulin dependent diabetes, NIDDM), there is insulin resistance and a steady decline of pancreatic beta cells affecting mainly the metabolism of muscle and fat tissues. Patients with this condition are normally over 30 years of age and produce an amount of insulin which is inadequate to meet the needs of the body. In a condition with insulin resistance or insensitivity of body cells to insulin, the pancreas may produce insulin that is greater than the normal amount usually required by the body. Type 2 diabetes accounts for about 90% of diabetic cases, and is frequently associated with clinical obesity.

In both types of diabetes, acute complications may consist of: a) severely elevated blood sugar level due to lack or insufficiency of insulin, b) abnormally low blood sugar level due to high amount of insulin or other blood sugar-lowering medication.

Chronic complications of diabetes include microvascular diseases involving the eyes (retinopathy), kidneys (nephropathy), nerves (neuropathy), and macrovascular diseases involving the heart and large blood vessels.

According to the World Health Organization, there are more than 180 million people worldwide with diabetes and in 2005 there were 1.1 million people who died from diabetes whereof 80% lived in low and middle-income countries. Of the affected people worldwide, 90% suffer from type 2 diabetes which is largely driven by excess body weight and physical inactivity and can therefore influenced by appropriate behavior and prevention measures.

Definition

Diagnosis Related Groups (DRGs) are a classification system for inpatient hospital services. Patients are grouped together "according to principal diagnosis, presence of a surgical procedure, age, presence or absence of significant ► co-morbidities or complications, and other relevant criteria" (U.S. Congress 1983). As all patients within the same DRG are expected to have similar hospital resource use, this classification system is also used to reimburse the cost of inpatient hospital care.

Basic Characteristics

History

DRGs were originally developed by the scientific team around R. B. Fetter in the late sixties at Yale University in the United States. As an instrument to control the provision of ► inpatient health care, DRGs relate the type of patient to the specific costs of treatment incurred. In 1983, in response to the persisting increase in the cost of hospital care, the U.S. Congress legislated a prospective ► per-case payment system for all patients under the ► Medicare program (i. e. U.S. state insurance program for people over 65) based on DRGs. Hospitals were paid a specific predetermined amount for each patient treated according to its DRG regardless of the actual cost of care provided.

In 1987, the State of New York introduces DRG-based payments for all non-Medicare patients. A revision of the Medicare DRGs including more information on hospital case types for the younger population has become necessary. With further regional expansion of the DRG system, replacements and refinements of the original Medicare DRG system took place. Several different more sophisticated DRG systems have been developed in the U.S.:

- Refined DRGs (RDRG): including a revision of the use of complications and co-morbidities.
- All-Patient DRGs (APDRG): extension of DRGs from Medicare population to all patients.
- Severity DRGs (SDRG): re-evaluation of the use of complications and co-morbidities for Medicare DRGs.
- All-Patient Refined DRGs (APRDRG): further refinement of all-patient DRGs adding subgroups and re-evaluating the use of complications and co-morbidities.
- International Refined DRGs (IRDRG): new classification system allowing international comparisons regardless of the specific coding system of the country.

Today, there are around 500 DRGs defined in the US which are updated annually in the CMS DRG Definitions Manual (i. e. Manual published by the Centers for Medicare and ► Medicaid Services (CMS) explaining history, design, classifications rules, application and updating procedures of the DRG system). The implementation of a DRG system in a hospital necessitates DRG ► grouper software which is provided by several IT companies who constantly update their software according to the new standard applied.

Further Developments

The regional expansion of DRGs led to a broader use besides ► reimbursement. Two major functions can be distinguished:

1. Evaluation of the utilization of hospital services: As DRGs demonstrate similar use of hospital resources, hospitals can be compared with each other and a prognosis for future hospital payments can be made.
2. Evaluation of the quality of care: Since all cases in a DRG are clinically similar, treatment protocols and other factors such as related conditions or demographic distribution can be analyzed. In addition, quality reviews can be established, critical pathways

D

can be designed and benchmarking between hospitals can take place (► health care quality).

DRGs in the Context of Hospital Financing Methods

Throughout the industrialized world, methods of financing hospitals have changed significantly over the past 20 years. There is a shift from ► prospective budgets towards ► per-case payments based on DRGs. Prospective budgets were mainly based on historical spending or the specific function of hospitals. They did generally not incorporate incentives to spend less than the fixed budget. Therefore, under the persisting financial constraints in the hospital sector, in several countries, governments changed the financing method and adopted per-case payments based on DRGs (► hospitals).

International Applications

In 2003, The Organization for Economic Cooperation and Development (OECD) counted 19 of its members having introduced DRG-based payments to control hospital reimbursement (Forgione et al. 2004). Most of the countries have adapted the original U.S. model to fulfill country-specific needs. According to the specific health system in the country, DRG-based systems have also be designed for planning, budget allocation and management of the hospital care provided.

Some country-examples highlight the various use of DRG systems:

- As payment systems: Nordic countries (Finland Norway, Sweden, Denmark), Portugal, Spain, Italy, Australia, Germany, Switzerland
- As a mechanism for budget allocation: France
- As a means to reduce the length of stay: Belgium, Ireland
- As a management system of hospital provision: UK

Positive and Negative Effects of DRG-Based Reimbursement Systems

Advantages of a DRG-based system are:

- Transparency: Due to a fixed amount of payment per DRG-based admission, the transparency and control of hospital financing and resource use is high, prognosis of future payments is possible, administrators and doctors have a clear basis of discussion.
- ► cost-efficiency: Fixed payments encourage hospitals to eliminate unnecessary services, to reduce the lengths of stay and to develop a competitive advantage in areas in which they are high-performers, as well as to reduce complications.

Potential negative effects are:

- The number of admissions and the use of hospital resources per admission determine the efficiency of the hospital. The DRG system induces efficiency incentives by setting a fixed payment rate per DRG. A rather low payment rate may lead hospitals to increase their number of admissions and reduce the adoption of new technologies of care. Patients are then discharged too early which produces either more costs in other health care sectors (cost-shifting) or patients are quickly re-admitted and the hospital claims the same DRG related payment twice. The cost-shifting to other health care sectors as outpatient home care or long-term facilities is particularly undermining the intention of cost-efficiency, because these other sectors are often inadequately resourced and qualified.
- Issue of true classification of the patient where hospitals classify as many cases as possible as severe. This problem is the so-called DRG ► up-coding used by hospitals in order to receive a higher ► reimbursement especially in the context of budgetary restrictions. However, this practice abuses the financing of hospitals and distorts ► health statistics. Facing substantial error rates in DRG coding (for example 20.8% in ► Medicare DRG coding in 1988), measures are being developed to motivate clinically correct coding via new reward systems for doctors.
- DRG-based classification systems in hospitals are focused on illness patterns and reward the hospital for the accurate treatment of that illness. All issues of disease prevention and health promotion that would help to reduce future costs of health are often left out.

Conclusion

The 20-years experience with DRG-based reimbursements in the U.S. as well as more recent experiences in other countries demonstrate a trend towards cost containment and the reduction of the length of stay. Nevertheless, the precise and careful implementation of the DRG system is an important condition to prevent neg-

ative effects such as the increase of admissions and the cost-shifting towards other sectors of health. The success of DRG system induced cost-efficiency depends after all on the notion of quality of care applied in the hospital.

Diet

Synonyms

Way of eating; Nutrition

Definition

Diet is defined as combination of food and drinks regularly consumed for nourishment. Usually "diet" implies restrictions in food or drink intake aimed at reducing body weight. Diet is influenced by climate, culture and tradition. Diets are rated in quality according to the balance of nutrients they provide and not solely on the type of food eaten or the amount of caloric intake. There are different types of diets such as low-calorie diet, low-fat diet, low-salt diet or hight-fibre diet.

Dietician

Synonyms

Nutritionist

Definition

A dietitian has expert knowledge in food and nutrition and helps to promote good health through proper diet. In medical care or rehabilitation, they often supervise the preparation and service of food, develop modified diets, and teach individuals and groups about good nutritional habits. Dieticians might also be involved in research where they examine, for example, the clinical aspect of nutrition for people with diseases or public aspects of nutrition on primary, secondary, and sometimes tertiary health prevention.

DIMDI

Definition

DIMDI, the German Institute for Medical Documentation and Information, is an institute of the Federal Ministry of Health (BMG). As a public institution, it aims to support all decision makers in health care from politics through hospitals, practitioners, and nursing, to the consumer. Therefore, open and freely acces-

sible modules are provided. Its scope ranges from an open process for identification and prioritization of topics for Health Technology Assessment (HTA) reports to a freely accessible information system covering HTA and related disciplines.

d Index

Definition

The *d* index measure of an ► effect size is appropriate when the means of two groups are being compared. The *d* index is typically used in association with the *t*-test. The formula for calculating the *d* index is:

$$d = \frac{X_1 - X_2}{(SD_1 + SD_2)/2}$$

X_1 and X_2 = the two group means
SD_1 and SD_2 = the average standard deviation of the two groups.
The *d* index expresses the distance between the two group means in terms of their common standard deviation. The *d* index is not only simple to compute but also scale-free.

Dioxins

Definition

Dioxins and PCBs are toxic long term chemical environmental polutants emerging from a number of industrial processes as well as from incineration of waste. They accumulate in milk and dairy products, meat, fish and moluscs. They cause chlor acne, toxic lesion on the liver, immunosupression. Long term exposure is manifested in endocrine and reproductive disorders. They can be found in human milk in people living in contaminated regions. Dioxins and PCBs are regulated in food and feed and traces of these compounds are found in many industrial products. PCBs are found in Baltic fish and threashold levels for herrings and salmon from the Baltic Sea are proposed for different age groups and pregnant women.

Diphtheria

Definition

Diphtheria is caused by the toxin producing *Corynebacterium diphteriae*. The infection, which is spread by saliva droplets, can take a life-threatening (lethal) course. Following an incubation period of 2–6 days, symptoms appear mainly in the nose-throat region. The most common localization of diphtheria is in the throat. The toxic effects lead to a robust inflammation with an intensive reddening and the development of a grey-white coating, afterwards the tissue becomes necrotic. The voice gets husky and difficulties in breathing can appear. Furthermore, there are general symptoms like fever, malaise, sore throat, headache, stomach ache and rheumatic pain. Dreaded complications are the generalized toxic effects, which cause myocarditis, paralyses and impaired functions of the liver and the kidneys. The effects of the toxin can be antagonized by an antitoxin, which should be used whenever somebody is suspected of having diphtheria. The bacterial production of toxins can be reduced by antibiotic therapy (penicillin, erythromycin). The most important preventative measure is active diphtheria-vaccination (► immunization, active).

Diphtheria Vaccination

Synonyms

Diphtheria immunization

Definition

Diphtheria toxoid has been available since 1925 and can be administered from the age of three months. ► Basic immunization is generally implemented three times as part of the 6-fold vaccination, or twice when no pertussis component is involved, at intervals of at least 4 weeks, followed by a further vaccination after 4–12 months. The first booster is given at 5–6 years of age. Further booster vaccinations should be given at intervals of 10 years, especially in the case of persons at risk, for example those employed in the health service or as public servants. For better tolerance, booster vaccinations for persons of 7 years of age or older are carried through with a reduced dose of diphtheria toxoid,

either alone (monovalent, "d") or in combination with the tetanus ► vaccine ("Td"). The clinical effectiveness of the diphtheria vaccine is more than 90%.

Direct Costs

Definition

In health economics, the term direct cost refers to all costs due to resource use that are completely attributable to the use of a health care intervention or illness. Direct costs can be split into direct medical costs and direct non-medical costs. Direct medical costs include the cost of a defined intervention and all follow-up costs for other medication and health care interventions in ambulatory, inpatient, and nursing care. All specialist and GP care, including emergency care, as well as rehabilitation and physiotherapy, is considered. Direct non-medical costs include e. g. transportation costs and additional paid caregiver time.

Directional Test

► One-Sided Test

Directly Observed Treatment

► DOTS

Direct Medical Costs

Definition

Cost for goods and services used in the prevention, diagnosis, treatment, and rehabilitation of the illness or disorder in question (e. g., cost for drugs, medical visits, hospitalization, diagnostic procedures).

Direct Non Medical Costs

Definition

Costs for all other resource use related to the disease of question (e. g., transportation costs, costs for social services but no medical cost).

Direct Payments

► Co-payments

Direct Standardization

Definition

Application of the stratum specific rates of each population to the number of individuals in the corresponding stratum in the standard population. This method yields an adjusted relative risk. The method is called "direct" because it uses the actual morbidity or mortality rates of the populations being compared.

Disability

Synonyms

Physical or mental impairment

Definition

Disability is an umbrella term for impairments, activity limitations or participation restrictions.

Disability is a physical or mental impairment that occurs at birth or later in life and is not curable. It substantially limits the condition or duration under which an average person in the population is able to perform a major life activity, such as walking, seeing, hearing, speaking, taking care of oneself, learning or working. The disability has not only a substantial but also a long term (at least 12 months) adverse effect on the person's ability to participate in the normal every-day life activities listed above.

According to the World Health Organization, disability is distinctive from functional impairment and handicap. While the term Impairment refers to any loss or abnormality of psychological, physiological, or anatomical structure or function, the term disability refers to any restriction or lack (resulting from an impairment) of ability to perform an activity in the manner or within the range considered normal for a human being. This definition reflects the idea that to a large extent, disability is a social construct. (More information about the WHO's definition and classification of disability can be found at http://www3.who.int/icf/icftemplate.cfm)

Disability Adjusted Life Years (DALYs)

Synonyms

Estimate of a population related gender of disease

Definition

Disability adjusted life years (DALYs) for a disease are "the sum of the years of life lost due to premature mortality (YLL) in the population and the years lost due to disability (YLD) for incident cases of the health condition. The DALY is a health gap measure that extends the concept of potential years of life lost due to premature death (PYLL) to include equivalent years of 'healthy' life lost in states of less than full health, broadly termed disability". "The DALY combines in one measure the time lived with disability and the time lost due to premature mortality. One DALY can be thought of as one lost year of 'healthy' life and the burden of disease as a measurement of the gap between current health status and an ideal situation where everyone lives into old age free of disease and disability". (World Health Organization, 2007. http://www.who.int/healthinfo/boddaly/en/index.html)

Traditionally, health liabilities were expressed using one measure: expected or average number of Years of Life Lost (YLL). This measure does not take the impact of disability into account, which can be expressed by Years Lived with Disability (YLD). DALY can be calculated by taking the sum of these two components, in a formula: DALY = YLL + YLD. Originally developed by the World Health Organization, it is becoming increasingly common in the field of occupational health. DALY can reveal very important things about a working population's health.

Disability Compensation

Definition

Disability compensation is a monetary benefit paid to employees with work-related disability (► Work-Related Diseases). It means that the disability is the result of an illness, disease or injury incurred or aggravated while the worker performed his/her working activities. This benefit is to compensate for a reduction in quality of life due to work-related disability and to provide compensation for average impairment in earnings capacity. The term "disability compensation" in occupational health sometimes refers to the compensations and benefits (financial and care support, devices, and modifications that help overcome or remove a disability, "positive discrimination", etc.) for significantly restricted or absent ability caused by or related to occupational or work-related impairments or disorders.

The term disability in a medical sense is often used to refer to individual functioning, including physical or sensory impairment, cognitive impairment, and mental disorders. In social models, the term disability focuses on the ability of a person to interact with his/her social environment, as a matter of full integration of individuals into society.

The physician's role in the disability compensation process depends on whether they are situated inside or outside the worker's compensation organization. If the physician is outside the organization, they will be involved in the medical treatment and rehabilitation of the injured or disabled worker and will also fulfill some of the regulatory requirements of the compensation system, including the filling of required medical reports on the worker's condition. Physicians who are part of the worker's compensation organization are usually involved in some aspect of claimant referral for examination or treatment and medical adjudication of disability.

Disabled People's Organizations

Synonyms

DPOs; Organizations of persons with disabilities

Definition

DPOs are involved in the development, implementation and evaluation of ► community based rehabilitation programs. These organizations already exist in many countries and often they are formed by parents of children with disabilities. The goal of DPOs is to address more people with disabilities and to actively represent them. The key roles of DPOs include the education and training of people with disabilities. Thus, disabled people and their families should get a detailed understanding of their rights and the role of DPOs in acting

as advocates to ensure that these rights are enforced. As disabled people in rural areas and in poor urban areas are not well represented in DPOs, there is an increasing need to encourage people in all areas and all socio-economic groups to form DPOs. There are two types of DPOs: cross-disability organizations and single-disability organizations. Cross-disability organizations represent people with any kind of disability, single-disability organizations represent individuals with a disability related to a specific impairment, e. g. seeing or hearing.

Disaster

Definition

A disaster is a serious disruption of the function of society, causing widespread human, material or environmental losses that exceed the ability of the affected society to cope using only its own resources.

Disaster Aftermath

ZBIGNIEW W. KUNDZEWICZ[1,2]

Introduction

A disaster (catastrophe) can be interpreted as event that causes great destruction/damage and human suffering. The term literally means – ill-starred event, i. e. misfortune, bad luck. A disastrous event may hit anywhere at any time. It may build up over time or strike suddenly. A notion of risk embraces a possibility (chance or degree of probability) of such an adverse event.

We are living with hazards and risks of natural and man-made disasters which may cause severe human and material damage. They may seriously, and in an adverse way, affect life, livelihood, and property, possibly resulting in permanent changes to human societies and the environment. Disasters may exacerbate vulnerable conditions and exceed individuals' and communities' means to survive and thrive. Even if in the 20th century the health care has become effective and the average length of life and health status have dramatically improved, disasters continue to cause adverse, and severe, health-related effects and may challenge the existing public health and health care systems. Therefore, priorities of basic public health programs include maintaining the expertise and the infrastructure to address large disasters, to respond rapidly to urgent needs. Modern societies are not prepared for extreme disasters, which are far beyond our planning and design assumptions. Despite developments in technology and high expenditures on disaster mitigation works, the occurrence of disasters and the severity of their impact, with accompanying hardship and material damage, have not decreased in general.

Hazards, Natural

Natural disasters are determined by the presence of destructive elements (e. g. volcanic lava, earthquake force, fire, snow, mud, heat, cold, strong wind, abundant water, or lack of water) in vulnerable places with a high damage potential. Since the dawn of civilization, natural disasters have jeopardized people and their settlements (▶ hazards, natural).

There are several generating mechanisms of natural disasters, such as: earthquake, volcano eruption, tsunami, storm, flood, drought, wild fire, landslide, avalanche, extreme heat wave, cold winter weather, blizzard, meteorite fall. The probability of occurrence of a severe disaster in each of these categories depends on the geographical location.

Disasters are getting more frequent in the more overpopulated world, with busy traffic. In many areas of the globe, natural disasters have recently become more destructive, causing material damage costing tens of billions of dollars as well as human damage with tens of thousands of fatalities annually. In particular, catastrophic weather events have exhibited a rapid upward trend: average annual material damage, in inflation-adjusted monetary units, increased tenfold between the 1950s and the 1990s. Many people, a large proportion of the human population, experience a traumatic disaster.

Material damage, caused by natural disasters, has been increasing over time, for a number of reasons, but

mainly due to an increase in exposure. For instance, humans have massively encroached flood-endangered areas by developing floodplains and coasts, and increasing damage potential by the build-up of populations and wealth in flood-prone areas. Urban squatting accompanies high vulnerability to flooding. Also, urbanization of many watersheds has adversely influenced flood hazard. Increase in the portion of impervious area (roofs, yards, roads, pavements, parking lots, etc.), reduction of storage, e. g. by the loss of natural inundation areas (lakes, wetlands, flood plains), deforestation and regulation of watercourses result in faster and higher maximum river flow (water level) generated by intensive precipitation. Nowadays, less extreme rain (compared with the past) may lead to a serious flooding disaster. In mountainous areas, developments extending into hilly slopes, are endangered with landslides and debris flows, triggered by intense rains.

There have been many large natural disasters, which caused immense human and economic damage. Nearly every week, natural disasters, occurring somewhere in the "global village", are reported by the media.

Many people have died of hunger caused by drought- and flood-related famines. For example, during, and after, the 1931 floods in China, the death toll was up to 3.7 million, according to some sources (conflicting estimates). Hundreds of thousands of fatalities were caused by cyclones (e. g. in the Bay of Bengal), tsunamis, and earthquakes. About 500,000 people drowned (and 100,000 were missing) during a coastal storm surge caused by the Bhola cyclone in East Pakistan and Bangladesh in November 1970, while another cyclone killed nearly 140,000 in Bangladesh in April 1991.

The tsunami disaster in December 2004, triggered by an earthquake (Richter magnitude 9.0 to 9.3) in the seabed off the Indonesian island of Sumatra, was unique in encompassing a very large area from Indonesia to Africa, including numerous resorts packed with foreign Christmas holiday tourists. The number of dead and missing has been evaluated at about 230,000 and the number of displaced at nearly 1.7 million. The height of tsunami waves reached 30 meters. The furthest recorded tsunami-caused death occurred in Port Elisabeth (South Africa), i. e. 8000 km away from the epicenter.

The Great Kantō earthquake devastated Tokyo (Japan) in September 1923, killing 100,000–150,000 people. A more recent, Tangshan earthquake in China (July 1976) caused the death toll of over 240,000. On 1 November 1755, an earthquake *cum* resultant fires devastated Lisbon, causing 15,000–40,000 fatalities.

Heat wave events are associated with marked short-term increases in mortality. In August 2003, a heat wave in Western and Central Europe caused between 27,000 and 40,000 excess deaths, while the death toll of a heat wave in the summer of 1980 in the United States was between 1250 and 10,000.

Tens of thousands of people were killed by single volcanic eruptions, such as the Nevado del Ruiz volcano in Armero, Colombia (November, 1985), with the death toll of 23,000–25,000. A large number of fatalities have been caused by landslides (e. g. 20,000 were killed in Peru in 1970), avalanches (10,000 fatalities in Tirol, Austria, in 1916) and blizzards, killing over 300 people in one day in November 1950 in the Eastern United States.

Disaster events, which cause highest economic losses, are not necessarily the main killers. The costliest ever disaster was Hurricane Katrina in the United States (August 2005), with – according to some estimates – up to 300 billion US $ in direct damage and 1 trillion US $ in total (i. e. including indirect) damage. Estimates of the death toll vary between 1,600 and 5,000. The material damage of the Kobe earthquake (Japan) in January 1995 was about 100 billion US $ (with over 5000 lives lost), while the material damage tag of the 1998 floods in China exceeded 30 billion US $ (and over 3600 fatalities).

According to some definitions, epidemics also belong in the category of natural disasters. It is estimated that in the 14th century, pest and famine killed 75 million people in Europe. In 1918–1919, the (pandemic) epidemic of Spanish flu killed 25–30 million. More recently, the widely-spread infectious disease HIV/AIDS considerably challenged the public health care systems, worldwide. However, epidemics are not considered in the present field material.

Analysis of data for individual destructive flood events worldwide led to a finding that, in general, the ratio of material losses to number of fatalities grows with the wealth level measured by the GNP per capita of a country. That is, more wealthy countries are more successful in saving lives, while material damages cannot be avoided.

Hazards, Technological

The active presence of the fast growing population has added new hazard dimensions in the ever more crowded world. It is estimated that 7–8% of people who have ever lived on Earth are living right now. A category of man-made disasters has emerged. Also, in many areas, people have become more vulnerable to some natural disasters (► hazards, technological).

Man-made disasters can be caused by accidents – unfortunate, undesirable, unplanned and unforeseen events; which may, or may not, result from carelessness or ignorance. Accidents trigger loss, injury, or death which may not be due to any fault or misconduct on the part of adversely affected people.

Man-made disasters can be classified into a number of categories, e. g. disasters related to human production activities: mining disasters, industrial disasters, chemical accidents, nuclear accidents. Numerous man-made disasters are related to transport, dam breaks, oil spills, explosion or fire disasters, and terrorist attacks. One special category of man-made disasters are wars, including the two World Wars in the 20th century, with a legacy of hundreds of millions of victims – dead and wounded, and immense human suffering. Mismanagement-related disasters constitute a special category. The enforcement of the communist system (collectivization of agriculture) is to be blamed, at least partly, for large famines in the ex-USSR that killed millions of people.

Many catastrophes are related to transport: ship or ferry, rail, car or bus, and plane disasters. The sinking of the Titanic in April 1912 caused over 1500 fatalities. In Poland, road traffic accidents during a single weekend may kill more people than floods over decades.

The terrorist attacks on 11 September 2001 were an "innovative" intentional mass killing. Passenger jets with many people onboard, fully fueled, were taken over by terrorists who crashed them against most important buildings with very high damage potential. The death toll of the terrorist attack on 9/11 exceeded 3000.

Man-made disasters in the 20th century, with considerable human health consequences, included the Bhopal disaster in 1984 (7000 fatalities), the mercury poisoning in Minamata, Japan, and the Itaiitai disease, due to cadmium poisoning, in Japan. Disasters in nuclear power plants – the Three Mile Island and Chernobyl accidents – were another category. Among the disastrous oil spills in the last decades were the catastrophes of Amoco Cadiz and Exxon Valdez, and, above all, the oil spill and oil fires generated by Saddam Hussein in Kuwait. One of the widely known man-made environmental catastrophes, resulting from mismanagement of water resources, has been the shrinking of the area and volume of the Aral Sea.

In China, a dam on the River Huang He was blown up in order to halt the Japanese invasion. The dam break caused several hundred thousand fatalities. A large mining disaster in Honkeiko (China) in 1942 caused 1549 fatalities, while explosions in Greece in 1856 killed about 4000 people. A large fire in Sandoz works in 1986 caused inflow of 30 tons of mercury pesticides into the Rhine, which devastated life in the river. In 1989, in Asha, Ufa, Bashkiria, USSR, over 500 people were killed by explosion and fire caused by leakage in a long distance pipeline and sparks from passing trains.

Physical, Environmental and Social Aspects of Disasters

The socio-economic consequences of a disaster are represented, in an aggregate way, by number of fatalities and the aggregate economic damage. Disasters kill and wound people, ruin their livelihoods and prospects, and destroy property. There is a lot of disaster-related suffering (e. g. due to loss of dear ones, disaster-related starvation, being wounded), morbidity, hardship, stress, and feelings of helplessness and humiliation. The accustomed sense of security disappears.

In the disaster aftermath, a new image of the community emerges. Municipalities, which functioned very well in normal conditions, may fail completely when disaster strikes. Urban areas in the developed world temporarily lose their modern infrastructure and are downgraded below the level of rural Third World communities.

Towns destroyed by an earthquake may turn into a sea of rubble, large dumping sites with disordered remnants of human infrastructure and belongings, and human bodies (or parts thereof). The landscape can be contaminated by floating fuel oil, animal carcasses, and other toxic debris.

Consequences of disasters can be divided into direct ones (caused directly by disasters) and indirect ones, which may occur over a longer period of time (e. g. even years after a nuclear accident). Detection of changes in time series of health-related indices and attribu-

tion of the changes (e. g. to a disastrous event) are very difficult. Even identification of "disaster-related deaths" (additional or excess deaths) in a region devastated by a disaster causes considerable methodological problems.

As a rule, after a major disaster, buildings are damaged (in some areas, nearly every home is destroyed e. g. totally ruined, or deprived of windows, roofs and walls) or rendered unsafe. Utilities are discontinued. There is no electricity or safe water, food supplies are spoiled, cars are disabled or destroyed. There is significant damage to the infrastructure including roads, railways, and bridges, health clinics and hospitals, schools and public buildings, levees, industrial installations, irrigation channels, affecting large cropland. There is vast damage to personal property. Some people's only remaining possessions are the clothes on their backs. Survivors leave their communities for the relative safety of displacement camps.

Since disasters ruin the domiciles of many of those evacuated, homelessness becomes a problem. Disasters paralyze social systems. Many businesses are damaged, and all are closed in the immediate aftermath. There is a loss of many jobs, some of which may disappear permanently. Yet, reconstruction creates an emerging opportunity for employment, economic growth, and better disaster preparedness.

Typical conveniences such as immediate repair of a downed power line, mail delivery, or a functioning public phone cell or an automatic teller machine become difficult to access. Some residents may endure without a roof or a cooked meal for months.

In some cases disasters may lead to mobilization of dangerous chemicals from storage or remobilization of chemicals already present in the environment, e. g. pesticides. Hazards may be greater when industrial or agricultural land adjoining residential land is affected. Increases in population density and accelerating industrial development in areas subject to natural disasters increase the probability of future disasters and the potential for massive human exposure to hazardous materials released during disasters (► physical, environmental and social aspects of disasters).

Human Health Aspects of Disasters

Even if disasters are not commonly perceived as public health events, they do clearly lead to the deterioration of human health over vast disaster-affected areas (► human health aspects of disasters).

Direct health-related impacts of disasters are: deaths, injuries, communicable diseases and mental health problems. Health effects may result from unsafe or unhealthy conditions (lack of safe drinking water, spoiled food supplies) following the disastrous event. Indirect effects arise through economic disruption, infrastructure damage and population displacement.

There are short-term health effects (injuries, stress associated with disaster) and long-term health consequences – psychiatric disorders, depression, anxiety, substance abuse, functional disabilities, domestic violence.

Life-threatening situations may arise, e. g. in elderly and lonely people with severe health problems who are trapped and abandoned in their homes.

Population displacement following disasters leads to increases in communicable diseases resulting from over-crowding, lack of clean water and shelter and poor nutritional status. Due to the very large number of people that may be affected, malnutrition and famine triggered by disastrous events may be among the most important consequences of a natural disaster, and may outnumber the direct fatalities.

In areas hit by a disaster with no evacuation warning, the hardship can be even more intense. Families spend nights huddled together in places they believe to be relatively "safe".

Disasters test the integrity of water supply systems and increase the risk of outbreaks of water-borne diseases. The impacts of disasters are particularly severe in less developed areas, featuring environmental degradation, and in communities lacking basic public infrastructure. Populations with poor sanitation infrastructure and a high burden of infectious disease, often experience increased rates of diarrhoeal diseases after disaster events. Post-disaster increases in cholera and typhoid have been reported. After some disasters in less developed countries, such as the 2004 tsunami, there was a fair possibility of the outbreak of diseases caused by polluted drinking water and risk of communicable diseases.

There has been vast evidence of disaster impacts on mental health. The prolonged impairment from common mental disorders (anxiety and depression) may be considerable. Depending on how much destruction and death they witness during a catastrophe, some survivors

suffer from post-traumatic stress disorder (PTSD), the same disorder that afflicts combat veterans. It is a psychological damage that develops after a traumatic experience and is almost always a delayed reaction to the trauma. Symptoms might appear soon after the event, but they might not surface until several months or even years have passed.

Among the symptoms of PTSD are vanished sense of security, fear of another calamity, hyper vigilance, fatigue, poor concentration, feeling nervous or tense, depression, anxiety/stress, and somatic experiences (sleep disturbances, appetite difficulties, etc.). They are expected reactions because of PTSD and the changed life circumstances in which many individuals find themselves. Dealing with joblessness, loss of a home, the inconvenience of extensive repairs, or radically transformed neighborhoods, people get into a state of shock and their rational thinking processes fail to function normally.

Those, who experience disasters, are prone to severe stress. Children suffer ongoing nightmares. They often cling to their parents and refuse to go to school. And those who do attend school after a traumatic event – even those who typically are well-behaved – develop discipline problems.

Health impacts of disasters also fall under the categories of medically unexplained physical symptoms (MUPS) and functional somatic syndromes (FSS).

Many survivors of a disaster have two life-changing experiences. First, they endure the trauma itself (e. g. seeing floodwaters sweep away their homes or watching gale-force winds destroy their neighborhoods, or witnessing a sudden death of their dear ones), which might undermine (even irreparably) their sense of security and their ability to cope with life's problems. Then, they may face ongoing disorder in their day-to-day lives.

Vulnerability Concerns

Disasters often happen in environments where distress is already present. Certain populations can be identified as being particularly at risk during disasters. Those unprepared for change have no economic resiliency, and lack a secure support system. Hence they are predisposed to a complicated recovery. Vulnerable groups include the elderly, those of lower socio-economic status, transients, and the unemployed (► vulnerability concerns).

Impacts of natural disasters are not evenly distributed, either in relation to income status, age, or gender. Poorer communities are more likely to live in flood-prone areas. Low-income and high-density populations in low-lying coastal regions experience a high burden from weather disasters.

Also the benefits of rescue and recovery aid are not evenly distributed. After a disaster in the south of the USA, when trailers were provided to hurricane victims, one had to be a head of household and to have provided the correct documentation in order to benefit. In an area where many live in extended family and shared rent situations and some are illiterate or speak only Spanish, a number of people were unable to benefit from or negotiate the available aid system.

In many disaster areas in the south of the USA low-income individuals are numerous, including a migrant worker population consisting predominantly of recently arrived Central American and Mexican citizens. There is also a high unemployment rate. Transients are attracted by the warm weather, which is also a factor explaining the area's high proportion of retirees. Many residents came from somewhere else – illegal immigrants, unskilled laborers, and elderly widows and widowers. Some areas in the south of the USA (e. g. Florida) have a disproportionate number of individuals with little or no support systems.

Many families are reluctant to evacuate and leave the remains of their homes (some being afraid of looting). Many do not have the money to move from their damaged apartments.

Disasters affect women and men differently. As shown by the 2004 Asian tsunami, male survivors outnumber females. The differences apply to exposure to risk, risk perception; preparedness behavior, warning communication and response (e. g. Muslim women staying at home in the absence of their husbands may ignore warnings); and ultimately to recovery and reconstruction. Gender interacts with race, income level, social class, and access to resources in the experience of disaster. Women are the providers of child care, which may put them at greater risk during and following a disaster. They may have limited mobility, restricted access to resources, and may be subject to social isolation.

Mitigation Strategies

Disaster mitigation can be defined in several ways, for instance as taking measures in advance of a hazardous event (emergency or disaster) which are aimed at preventing disasters from occurring or (more commonly) reducing the adverse effects of disasters on society and environment. This can be achieved by reducing the vulnerability of communities to the hazard, or by changing the environment in which hazards and communities interact.

A rigorous and systematic risk management process helps communities to identify the most cost-effective disaster mitigation strategy – a combination of measures for the range of risks which they face. The plan of action for disaster mitigation reflects priorities determined by the community and stakeholders.

In some countries, a national framework for mitigation exists for the whole country, with the goal of improving the disaster mitigation system and reducing adverse personal, social, economic and environmental impacts of disaster. The process of building the disaster mitigation strategy may include establishing land-use planning (zoning), taking into account hazards in the building codes, developing emergency preparedness systems, preparing and disseminating guidelines for natural hazards, and raising awareness. Cost-effect considerations are important, i. e. examining the costs of natural disasters, and the benefits of disaster mitigation.

If the occurrence of natural disasters is spatially restricted (e. g. in flood-prone areas), three ► mitigation strategies come about: protect, accommodate, or retreat. One may try to protect as far as feasible in the cost-benefit sense – it may not be financially feasible to offer a very expensive protection to a small community with low damage potential. Accommodating disasters means living with disasters rather than hopelessly trying to avoid them at very high cost. Finally, retreat can be interpreted as a permanent relocation of inhabitants of unsafe areas.

Important discussion of flood protection strategy dates back to the mid-19th century USA, when the Congress decided to embank the Mississippi river in a single channel isolated from its floodplain. This decision has largely influenced flood protection policy in the USA and elsewhere, leading to transformation of rivers and reduction of wetlands. In 1936, the US federal government assumed primary responsibility for flood damage reduction across the nation and over the next decades embarked on a multi-billion program of structural defenses. Yet, despite the dedicated long-term effort and high investments, the flood risk has not been eradicated, and never will be.

The process of building the flood preparedness system may include some, or all, of the following components:

- Flood risk assessment and mapping, conveying valuable spatial message. (Yet, in a number of cases, such maps, commissioned by authorities, have not been disseminated – due to the likely consequences for the property market, being unbearable to the ruling powers.)
- Rigorous implementation of zoning – land use management to limit the use of floodplains for the site of vulnerable elements (including human settlements, industrial infrastructure, etc.).
- Relocation of riparian inhabitants and structures out of the floodplain.
- Raising awareness of the floodplain communities.
- Building an effective and reliable flood forecasting and warning system.
- Engineering of structures in the floodplain to withstand flood forces (dikes, flood walls with opening barriers, dams, storm water drainage systems).
- Adaptation of building codes, e. g. building design to elevate floor levels, use of flood-resistant building materials (water resistant materials, waterproof seals, strong foundations), placement of storage and sleeping areas high off the ground.
- Development of system of flood insurance.
- Development of preparedness system for the case when the existing structural defenses (e. g. dikes) will not be able to restrain the flood waters, flood evacuation preparedness including identifying shelters, preparing boats and rescue equipment; emergency plans with clear division of competencies and responsibilities of agencies.
- Awareness raising, creating a flood preparedness culture.
- Watershed management, storing as much water as possible (according to "catch water where it falls" principle).

Mitigation of (preparedness system to) other natural disasters include essentially similar types of components as in the flood preparedness example above,

aimed at weakening the load and strengthening the system resistance.

In an earthquake preparedness system, it is necessary to improve the resistance of the system by seismic zoning. Land-use management should reduce development in geological areas known to amplify ground vibrations, e. g. alluvial soils, reclaimed land. Upgrading structural design is needed, by engineering of structures to withstand vibration forces; compliance with seismic building codes, enforcement of generally higher standards of construction; and adequately high design standards for important buildings; and strengthening of existing buildings (retrofitting).

In the gale-wind preparedness system, land-use management can improve protection from wind, e. g. by planting of windbreaks. One can considerably improve the system resistance by engineering structures to withstand wind forces; siting of buildings on leeward side of hillsides; adapting wind-load parameter in building codes; good quality construction of wind-resistant buildings; adequate securing of elements which could be blown away or cause damage; trimming of tree branches and cleaning of gutters. It is necessary to develop severe-weather forecasting and warning systems, to raise community risk awareness, and to provide safety shelters and evacuation plans.

Also a system for wild fire mitigation includes measures to constrain the wild fire (planting of fire-resistant vegetation and wild fire breaks) and to improve the system resistance. The latter category includes zoning (land use management to limit development in high wild fire risk areas); appropriate siting of structures (away from the top of slopes/ridges); building codes for fire hazards; fire resistant building materials; removing wild fire 'fuel' (rubbish, branches, leaf litter) from around house and gutters; secure storage of flammable materials (fuel, wood, paint). Development of a fire weather warning systems and improvement of community awareness of wild-fire risk is necessary. A fire evacuation plan should be in place, and sufficient water supply, hoses and protective clothing should be available.

Natural and man-made disasters can be considered in the sustainability context. On the one hand, they destroy human heritage and jeopardize sustainable development (whose one definition refers to "non-decreasing quality of life"). On the other hand, following the most common interpretation of sustainable development, one should not choose such disaster protection policies that could be rated by future generations as inappropriate options of defense. This is how several large structural flood defenses are often looked upon.

Definitely, changes leading to aggravating flood risk are perceived as negative. In some locations, people regret that levees have been built and low-lying areas developed. Now, the issue of river renaturalization may come about. Some large reservoirs, whose construction required inundation of large areas and/or displacement of a high number of people, do not match the principles of sustainable development. Studies on decommissioning reservoirs are being made and in a few cases decommissioning has taken place. When looking back into past developments, one often finds one-sided arguments supporting a decision on flood protection strategy, with important aspects ignored. This was, on the one hand, due to lack of knowledge and understanding and, on the other hand, due to the fact that value judgments have changed with time.

Disaster Response

► Disaster response includes strengthening of the protection measures (e. g. strengthening and heightening of levees), as relevant and necessary, and undertaking actions to reduce human and material damage. This includes providing assistance to affected people (with evacuation or without evacuation). Disaster response deals with a situation of active crisis involving numerous people, who present multiple survival needs, therein basic needs (safe water, housing/shelter, hygiene), and health and medical needs (medical attention, care of special medical conditions – diabetes, epilepsy, temporary hospitals and pharmacies). Also mental health needs attention, in particular, post-traumatic stress disorder (PTSD) and child and spouse abuse. In the disaster-affected environment, many of the normal helping agencies are not able to deliver services to their clients. Emergency assistance includes providing safe water, food, shelter, medical supplies, blood and blood products, first aid, clothing, fixed/mobile feeding stations, cleaning supplies, emergency transportation, home repairs, household items, etc.

If a forecasting-warning-response system is in place, it may be possible to evacuate people from endangered areas and relocate them to temporary shelters (e. g. in school buildings), where they should be taken care of

by rescue workers, who provide them with safe water, warm food, blankets and clothing, and psychological support, which may be necessary over a longer time. In displaced families (temporarily or permanently), children suffer the stress of having lost a home, a neighborhood, friends, a pet, and a way of life, being in a strange environment (possibly moving in with family members into overcrowded living quarters) and a new school. Some adults, who keep their jobs, may experience longer commutes to work with increasing fuel costs, repairs, and stress.

Disaster response includes a system to share relevant and reliable information, to dispel hysteria and rumor, and to offer support, counseling, and referrals to those in need, to inform, assist, and calm the public. The disaster-affected community seeks disaster information, becoming almost addicted to TV coverage of the disaster and its management. Local television and radio stations provide useful information on how to obtain food and water, rebuilding material, and medical assistance, etc. The media become daily human resource guides.

Schools reopen with improvised schedules and scarce instructional materials. Though possibly damaged, schools are indeed islands in a sea of confusion and turmoil, and symbols of hope for the community. The ringing of the school bell becomes an early, and welcome, sign of getting back to normal.

Disaster heightens awareness of many chronic but ignored problems, such as poverty, unemployment and homelessness, which may have been politically unpalatable. However, since a disaster leaves many middle-class people homeless, the definition of homelessness changes in public perceptions. The sight of families with small children with no place to go convinces many of the need for an organized response.

Recovery Strategies

► Recovery strategies should make it possible to gradually re-establish order and continuity, build life support systems, and livelihoods. This means much more than just rebuilding houses.

In the disaster aftermath, a decision has to be made as to whether the strategy of retreat is feasible and advantageous. In some disaster sites, wrecked houses are not leveled to the ground. By staying there, the memory of the disaster is kept alive. If destruction is beyond repair, then evacuees have no place to come back to. They permanently move away from the area and the area is abandoned. Some former housing complexes consist of roofless, derelict buildings and piles of unidentifiable wreckage. History provides well known cases of disappearing settlements after a disaster, e. g. after the eruption of Vesuvius which destroyed Stabies, Herculanum, and Pompei on 23 August 79.

After the 1755 Lisbon disaster, Marquis de Pombal led the recovery action based on the three principal tasks, formulated as follows: to take care of survivors, to bury the dead and to rebuild the city. In general, none of these tasks is easy in a post-disaster landscape.

Early responses to traumatic disaster events are focused on providing concrete help, food and drinking water, warmth, shelter, and medical assistance (*cum* psychological help) to survivors. Normal health care systems are not functioning, yet the needs can be very serious. In the case of the 2004 tsunami, it was necessary to rescue survivors, trying to care for millions of homeless, increasingly threatened by disease amid the rotting corpses. It was necessary to treat specific syndromes such as acute stress disorder, depression, and other anxiety disorders.

After the 2004 tsunami it was not easy to bury the dead. There were not enough body bags and there were not enough coffins and those available were too small for the bloated bodies of foreigners.

When the decision to rebuild is made, masses of refuse, composed of remains of human property have to be removed to landfills. The homeless family problem has to be addressed, e. g. by establishing a tent city (climate permitting), including day care, job counseling, and mental health assistance. Services, such as water, sanitation, electricity, gas, telephone, transportation, postal service, legal services have to be re-established. It is necessary to help people recover their livelihoods, e. g. via temporary employment, to secure money flow and financial support.

A post-disaster recovery creates a unique opportunity to build better. After a disaster, the building codes are carefully examined and strengthened and new housing is monitored and inspected far more stringently, and developers are more accountable. This is unlike before the disaster, when many areas may have experienced rapid, unplanned growth. Disasters unveil many cases of poor workmanship, use of cheap materials, and temporary fixes. Structures may not have met build-

ing codes (e. g. use of plastic straps attaching roofs to walls).

In the disaster aftermath, when the shelters close, the tent cities fold, the media spotlights turn off, and high-rank decision makers leave and go back to their time-consuming routine duties, continuation of assistance to disaster survivors is less spectacular, but badly needed. There may be little available housing for the displaced. Rents skyrocket, with landlords taking advantage of a scarce market. For a long time, a large number of inhabitants may live in substandard or even unsafe housing. The economic recovery can be sluggish. With many jobs lost and many small businesses destroyed or relocated, unemployment remains a critical concern. There is a need for long-term medical assistance, including mental health, and health monitoring.

The solidarity and altruism of individuals and groups has been crucial for recovery efforts. For instance, ad-hoc aid organizations are formed that do home repair for the uninsured and provide legal or medical advice. Joint initiatives arise to deal with the overwhelming task of moving toward recovery and becoming better prepared for the next disaster.

Emergency Preparedness

In general, much of responses to extreme disasters used to be a result of trial and error, and adhockery. The imminent stress and disorganization in the early aftermath makes it clear that adequate preparation before the disaster is critical.

Since a disaster protection system guaranteeing absolute safety is an illusion, a change of paradigm is needed. It is necessary to live with the awareness of the possibility of disasters and to accommodate them, rather than to try, in vain, to eradicate them. Extreme hazards, which exceed the design values assumed for building the preparedness system, may happen. Disaster mitigation systems do not provide a complete, 100%, safety. Hence, there is a need for plans of ► emergency preparedness for rare, but not impossible, events exceeding the planning/design conditions. Extreme hazards, which the existing state of preparedness cannot meet, can be realistic. For instance, a levee may protect riparian populations from a 50-year flood, so that no damage is involved when such an event occurs, however, a plan should be in place which could be used if a 1000-year flood arrives and the levee breaks.

Creating a culture of preparedness is needed for the entire nation. It must build a sense of shared responsibility among individuals, communities, the private sector, NGOs, faith-based groups, and federal, state, and local governments. Initiative and innovation must be recognized and rewarded at all levels. Individuals must play a central role in preparing themselves and their families for emergencies.

In France, emergency preparedness includes preparation of maps of the hazards, from which land-use regulations are issued; and plans for emergency and rescue.

Hurricane Katrina and the subsequent sustained flooding of New Orleans was a deadly reminder that the USA can and must do better in responding to emergencies. The disaster exposed significant flaws in the national preparedness for catastrophic events and the capacity to respond to them. The USA proved not to be as prepared as it should be at all levels: federal, state, local, community, and individual. The government felt obliged to re-examine how to address the full range of potential catastrophic events – both natural and man-made.

President Bush made clear that the federal US government would learn the lessons of Hurricane Katrina so that the nation can make the necessary changes to be "better prepared for any challenge of nature, or act of evil men, that could threaten people."

The emergency system preparedness should be in place prior to a disaster strike. Among the actions needed are such as the following ones, foreseen in the US as a part of lessons learnt from Katrina:

- ensuring that relevant federal, state, and local decision-makers are working together and in close proximity to one another in the event of a disaster;
- ensuring situational awareness by establishing rapid deployable communications;
- clear and non-ambiguous distribution of tasks and responsibilities; embedding a single point of contact to enhance coordination of military resources supporting the response;
- identifying and developing rosters of federal, state, and local government personnel who are prepared to assist in disaster relief;
- employing adequate technology to update and utilize the national emergency alert system in order to provide the public with advanced notification of and instruction for disasters and emergencies;

- enhancing the mechanism for providing federal funds to states for preparations upon warning of an imminent emergency;
- improving the delivery of assistance to disaster victims by streamlining registration, expediting eligibility decisions, tracking movements of displaced victims, and incorporating safeguards against fraud; and
- reviewing state evacuation plans and essential emergency services;
- checking if there are adequate help lines, offering information and advice in case of a disaster.

Advanced technologies must be leveraged to win the war on natural disasters. Advanced systems like infrared sensors, scanners can be mounted on helicopters and unmanned aerial vehicles and can help find trapped people. New radarscopes and sensors can be used on robots, which can sense a human being inside a building through 30 cm of concrete and 15 m beyond and can even sense breathing; after someone is discovered in the initial cleanup, the rescue teams can be called to the specific location.

Resiliency and backup services form a key part of disaster recovery. Network resiliency makes it possible to recover from a network failure or issue related to a disaster. A high availability network design is often the foundation for disaster recovery. Handling a crisis effectively could save lives and much money just as dealing with it ineffectively could do the opposite. And while a well managed crisis often enhances the organization's reputation, a poorly managed one can not only damage the reputation but also open the organization up to costly litigation.

Health Warning Systems

► Health warning systems, based on forecasting extreme weather and floods, help to protect life and health, and property and enhance the national economies. Some such systems have been in place, and others are being envisaged.

In the United States, excessive heat is the main weather-related killer, causing more fatalities in an average year than floods, strong winds (tornadoes and hurricanes), lightning, and winter events (storms and extreme cold spells). During an average summer, there are over a thousand excess deaths in the USA, which could be attributed to heat. If deaths by heart attacks, strokes or respiratory illness are above normal during a heat wave, they could be considered heat-related deaths, even if they may not be treated as such by a medical examiner. People living in cities with strong summer weather variability have the strongest weather-mortality relationship. They are not adapted to extremely hot weather, which is infrequent and occurs irregularly. The number of deaths reported during an intense hot spell is higher in such cities than in many tropical (hence always hot) cities. Early season heat waves can cause higher mortality, because people better acclimatize to the heat as the hot season continues.

There has been a considerable progress in the design and implementation of health warning systems in the USA, established to reduce effects of weather extremes as well as for the seasonal predictions of infectious diseases. Warning systems are being developed to permit urban health agencies and local meteorological offices to issue advice to the public if a dangerous heat wave is imminent. The National Weather Service (NWS) of the National Oceanic and Atmospheric Administration (NOAA) in the United States provides advance notice (with forecast capability of five days) of extreme heat events for the protection of life and health, based on a single heat index value derived from temperature and humidity. The excessive heat warning program started in Philadelphia and is currently functioning in 14 cities. A custom-made system is developed for each city, based on specific conditions of meteorology of each urban area, as well as urban structure and demography. The NWS is developing a plan to expand a heat/health warning system to each of over 70 large US municipalities, with population exceeding 500,000. The system initiated in Philadelphia is now becoming a worldwide model for heat forecasting and collaborative attempts to construct heat/health warning systems for vulnerable large cities around the world have been undertaken in three continents: North America, Europe, and Asia.

The situation which arose in France in August 2003 showed that the death toll of the heat wave was not foreseen and detected only belatedly; health authorities were overwhelmed by the influx of patients, retirees' houses had no space-cooling environment, and the number of deaths exceeded the working capacity of undertakers and crematoria. This lesson demonstrates the need for establishing health and environment surveillance, and heat wave forecasting and warning. Air conditioning in retirees' homes proved efficient (yet

very energy-consuming, hence contributing to enhancement of the greenhouse effect and global warming).

The World Meteorological Organization (WMO) develops a number of global products and services relevant to natural disaster management. For example, the WMO Tropical Cyclone Programme monitors all tropical cyclones around the globe from their early stages of formation, throughout their life time, providing information on their behavior, movement and changes in intensity, and on associated storm surges and floods. The WMO's Severe Weather Information Center project, carried out in collaboration with the Hong Kong Observatory, has the goal to develop a centralized source of official tropical cyclone warnings and information around the world.

Since deadly extreme heat events occur in many regions of the world, the World Meteorological Organization (WMO) is working with the World Health Organization (WHO) to develop guidelines that any country can use to set up and run heat/health warning systems. These systems will include monitoring and prediction of conditions leading to intense heat waves to be carried out by the national meteorological and hydrological services, communication between the meteorological and health sectors, and increasingly will include special measures for intervention (by the health and social service sectors), to inform and better protect the most vulnerable members of society.

Long-term forecasts, seasonal forecasts, e. g. based on El Niño-Southern Oscillations (ENSO), are being used in many regions, e. g. in drought warning, to improve preparedness and reduce disaster-caused human and material losses.

Aftermath Risk Awareness, Perception, Assessment and Communication

Improving information about hazards is badly needed for awareness raising and enhancing the consultative process, which leads to a hazard mitigation strategy. Only informed stakeholders can make rational decisions about the choice of strategy, in a cost-benefit framework. Aware citizens are likely to behave in a way that is compatible with disaster management activities.

Experience demonstrated that repeated occurrence of a disaster in the same place within a relatively short time may enhance the learning effect. For example, there were two large floods on the Rhine, in December 1993 and January 1995. The maximum water levels in Cologne were of comparable magnitude (the second being actually a little higher), but the values of the damage caused by each of the two floods largely differed; the damage in the second (higher) flood was considerably lower. Occurrence of the first flood raised awareness and triggered actions towards improvement of the flood preparedness system, based on the lessons learned.

Misconceptions and myths about natural disasters and flood protection are deeply rooted in society – the general public, politicians and decision-makers alike. It is of utmost importance to dispel and to rectify misconceptions and counter-productive "principles", valid throughout political and social systems, such as the rule of hydro-illogical cycle, holding for floods and droughts. Flood (drought) occurrence triggers high expenditures on flood (drought) protection. Yet, memory fades and, after some time without flood (drought), the willingness to pay for costly preparedness systems drastically decreases. It is not easy to effectively communicate this truth to the electorate and decision-makers whose term of office is short. A major disaster may not occur during their terms of office.

Efficient actions aimed at awareness raising are of vast importance for a disaster preparedness system. There is a systemic lack of experience with a catastrophic flood of extreme dimension. Over 50 fatalities occurred in the 1997 flood in Poland and many could have been avoided had there been better awareness. Most flood fatalities in the US are related to vehicles whose drivers underestimate the danger and get trapped in their cars. Obeying simple driving rules alone could help reduce the number of fatalities in many flood events.

Media may play an essential role in awareness raising and information. The risk perception is to a large extent framed by the media coverage. In some cases, risk atmosphere is created by the media (cf the Three Miles Island impacts, where the actual damage was low).

Risk perception involves one's beliefs, attitudes, judgments and feelings, as well as the wider social and cultural values and disposition towards hazards (being risk-prone, risk-neutral, or risk-averse). It depends on age, gender, education, and traumatic experience.

In many areas, river levees (dikes) are the principal flood defenses. Existence of properly dimensioned and maintained levees, which adequately protect adjacent

areas for small and medium floods, creates a misconception – an unjustified feeling of complete safety among the riparian population. When a dike breaks during an extreme flood, the damage may be higher than it would have been without a dike. The Netherlands, a large part of which is located below the mean sea level and remembers the tragedy of the coastal flooding of 1953, has higher safety standards (design flood) than any other country in the world. Yet, even in the Netherlands, safety levels have been re-examined to take into account the effects of global change. Building flood risk consciousness among the public and rectification of misconceptions, such as false feeling of absolute safety, is of paramount importance. No matter how high a design flood is, there is always a possibility that a greater flood could occur, inducing losses. Should dikes be designed to withstand a 100-year flood or a 500-year flood? The latter solution would give a better (but still incomplete) protection, being far more costly (prohibitively costly in most places, with the Netherlands being a notable exception, embarking on the high safety standards with design values of 1250-, 4000- and 10,000-year event for river, large river, and coastal protection).

Disaster risk communication is a difficult issue, especially communication of uncertainties, which requires assistance in understanding. When issuing warnings – communicated messages that a hazard is producing specific risks for a particular segment of population – the response depends on the source, channel credibility, and past experience (relevance and accuracy of earlier warnings). People are likely to heed warnings if past warnings did not "cry wolf" (aftermath risk awareness, perception, assessment and communication).

Disaster Management, International

Disaster management, especially in less developed countries, requires massive international assistance and the issue of disaster reduction has been one of articulated major human needs. The UN Millennium Summit, which adopted *UN Millennium Declaration* resolved "… to intensify cooperation to reduce the number and effects of natural and man-made disasters." The UN International Decade for Natural Disaster Reduction (IDNDR) was launched by the United Nations to enhance disaster preparedness. It provides a framework for international collaboration for strengthening preparedness skills and an institutional base. By the end of the decade, the UN International Strategy for Disaster Reduction (ISDR) aims at building disaster-resilient communities by promoting an increased awareness of the importance of disaster reduction as an integral component of sustainable development, with the goal of reducing human, social, economic and environmental losses due to natural hazards and related technological and environmental disasters.

While effective emergency management plays a vital role in avoiding loss of life and suffering, it generally fails to make the connection between the disaster risk and sustainable development. In recognition of this, the United Nations Development Programme (UNDP) has adopted a view that disasters are unresolved development problems that occur when risks go unmanaged. The mainstreaming of disaster reduction into development and post-disaster recovery has become an essential component of building a capacity for sustainable development. Ideally, disaster risk planning and preparation considerations should be factored into national and regional development programs and countries should take advantage of post-disaster recovery as unique opportunities to mitigate future risks and vulnerabilities in their countries. Mainstreaming disaster reduction in UNDP practice takes place in such areas as: poverty eradication and sustainable livelihoods; gender equality and the advancement of women; environmental and natural resources sustainability, and sound governance.

There are a number of agencies dealing with disaster management on the international scale, both IGOs (intergovernmental organizations, within the UN system) and NGOs (non-governmental organizations). Among the former are: UN Department of Humanitarian Affairs (DHA), UN Office for the Coordination of Humanitarian Affairs, United Nations Development Programme (UNDP), Food and Agriculture Organization (FAO), World Food Programme (WFP), World Health Organization (WHO), United Nations Children's Fund (UNICEF), and World Meteorological Organization (WMO). The UN High Commissioner for the Refugees (UNHCR) provides massive airlifts from UNHCR's global and regional stockpiles of life-saving supplies and operational capacity. There are several regional agencies, such as the Humanitarian Aid Office (ECHO – European Community Humanitarian Office) created to improve efficiency and give human-

itarian aid a higher profile. The Caribbean Disaster Emergency Response Agency is a regional inter-governmental agency responsible for disaster management in the region. It makes an immediate and coordinated response to any disastrous event, once a state requests such assistance. It secures, collates and channels comprehensive and reliable information on disasters affecting the region. It contributes to mitigating or eliminating as far as possible, the consequences of disasters, establishing and maintaining on a sustainable basis, adequate disaster response capabilities; and mobilizing and coordinating disaster relief.

Among the NGOs involved in disaster management, there are many organizations. Some are dedicated to the purpose of providing emergency medical and humanitarian aid, e. g. the International Federation of Red Cross and Red Crescent Societies (IFRC) or *Médicins sans frontiers*. Others act within a more general remit of assistance (e. g. ActionAid International). Also multiple national institutions, both governmental (e. g. development assistance agencies) and private contribute to disaster response, worldwide. Contributions of many agencies in raising disaster awareness and developing disaster preparedness material are numerous and very valuable.

After a disaster, agencies initiate fund raising and undertake immediate assistance efforts. An example of an ad-hoc coordinated activity is the United Nations' Inter-agency Earthquake Response Plan after the earthquake in Indonesia (27 May 2006). The UN Food and Agriculture Organization (FAO) mobilized resources to help farmers affected by a disaster in Indonesia, who had lost their productive assets and source of income, to quickly resume farming and livestock production activities. Early recovery of the agriculture sector is essential for quick and sustainable improvement of rural people's livelihoods.

The occurrence of a large disaster triggers international solidarity. After a large disaster, many international organizations and national organizations in many countries pledge emergency aid and send supplies, doctors and experts to devastated areas (► disaster management, international).

Disaster Management, National

On the national level, there is typically a central government department whose mandate is to lead the effort to prepare the nation for all hazards and effectively manage response and recovery efforts following any disaster. In some countries, a disaster management agency exists at the ministerial level (e. g. Ministry of Disaster Management in Sri Lanka, or Ministry of Emergency Situations in some independent countries born after the fall of the former Soviet Union). Often, such a government agency works in partnership with other organizations that are part of the nation's emergency management system (e. g. include state, regional, and local emergency management agencies). Among them are – civil defense units, army, police, and fire brigades. In some countries, problems exist of co-ordination of efforts, due to the existence of several agencies, whose responsibilities are not clearly straight cut; hence occasional problems in co-operation may occur. There are also many private disaster relief institutions (NGOs, charities related to churches).

In some countries and regions, active agencies play extremely valuable roles in disaster awareness raising and in contributing to the relief and recovery work. In a few countries, disaster risk assessment has become public and one can see an on-line hazard map for one's location.

The response to Hurricane Katrina, the most destructive (in terms of material damage) disaster on record worldwide, revealed several weaknesses in incident management, planning discipline, and field-level crisis leadership, in the most powerful country on the globe. Implementation of corrective actions was found necessary in many organizations (including the Federal Emergency Management Agency – FEMA), in order to ensure that the problems encountered during Hurricane Katrina will not occur again. The federal US government decided that the existing national preparedness system must be improved to minimize the impact of disasters on lives, health, property, and the economy.

Hurricane Katrina and its aftermath have provided the USA with the imperative to create a culture of preparedness, to design and build a unified and comprehensive, national preparedness system; preparing for and responding to natural and man-made disasters. Starting with a national, domestic, all-hazards preparedness goal, a robust preparedness system is being built that includes integrated plans, procedures, training, and capabilities at all levels of government. The system should integrate and synchronize the nation's policies, strategies, and plans across federal, state, and local gov-

ernments, as well as the private sector, non-governmental organizations (NGOs), faith-based groups, communities, and individual citizens, who share common goals and responsibilities. The objective of the system is to achieve and sustain risk-based target levels of capability to prevent, protect against, respond to, and recover from major natural disasters, terrorist incidents, and other emergencies.

The federal government has clearly articulated national preparedness goals and objectives and created the infrastructure for ensuring unity of effort. Among the elements of critical importance for a national preparedness systems are:

- building and integrating the federal government's operational capability for emergency preparedness and response;
- strengthening capacity to direct the national response effort while providing resources to responders in the field;
- ensuring unity of effort and eliminating delays in providing national assistance to disaster areas;
- strengthening disaster awareness, by education, exercises, and training programs; and
- ensuring that risk assessments, lessons learnt, and corrective action programs are institutionalized throughout the national government (► disaster management, national).

Prospects for the Future

The human and material damage caused by many disasters can be reduced if adequate measures are taken. Alone extension of the temporal horizon of forecasts, its penetration, and improvements in their accuracy and reliability, could save many lives and considerably reduce human suffering. Changes in the risk of natural disasters depend on the population and economic growth and the quality of the preparedness system.

However, human kind will never be free of natural disasters, generated by extreme geophysical (climatic, hydrological, seismological, volcanological) events and disasters caused by man. Potentially, the most disastrous event could be a collapse of a large man-made infrastructure object – a large dam break, jeopardizing people living downstream. In many areas, population density below large dams is high.

The September 11 tragedy unveiled the possibility of emergence of new man-made disasters – "innovative" and inhuman acts of violence, aimed at massive killing, where maximizing the number of anonymous fatalities is the terrorists' target. This was also the terrorists' objective behind the use of Sarin gas in the Tokyo subway, and the bombs in Madrid and London transportation systems.

Possible causes of hypothetical futural disasters are: a gigantic asteroid colliding with the planet Earth, megatsunami, and global climate change, which – in the long term – may severely, and adversely, affect life support systems in many areas. Climate change itself can indeed generate a disaster. Ultimate changes due to the finite Sun's lifetime are expected in the time scale of billions of years. Changes in solar activity and in parameters of the trajectory of Earth's movement around the Sun generate climate changes at a large time scale (e. g. many millennia – cf. glaciation periods). In the past, sudden climate change, e. g. induced by a fall of a large meteorite or strong volcanic eruption, caused severe effects, such as, possibly, the extinction of the dinosaurs, or "a year without summer" (1816), respectively.

There has been increasing evidence of the ongoing climate change, which is attributable to human activities, such as the rising emission of greenhouse gases (carbon dioxide, methane, nitrous oxide, etc.) leading to buildup of greenhouse gases in the atmosphere and enhancement of the greenhouse effect, and land-use changes (e. g. deforestation in tropical areas). The global climate system has been driven out of the stable natural variability mode. Global warming already has been observed and further, stronger, warming (by 1.1 to 6.4 °C by year 2100) is projected. All of the seven globally warmest years on record (since the beginning of global instrumental temperature observations, in 1860) have occurred since 1998. There have been ongoing changes in such variables as precipitation (growth in some areas, decrease in other areas of the globe), river flow, glacier extent, sea level. The area of the globe in very wet or very dry states has been increasing and the water cycle has accelerated, with extreme consequences. In many areas, increases in intense precipitation has been observed, which can be translated into increases in flood hazard. Even stronger changes are projected for the future.

Any regional increases in climate extremes (storms, floods, cyclones, droughts, etc.) associated with climate change would cause physical damage, popula-

tion displacement, and adverse effects on food production, freshwater availability and quality. Adverse health effects would increase, and in particular the risks of infectious disease epidemics in developing countries. Already at present, diarrhoeal diseases attributable to unsafe water and lack of basic sanitation cause almost 2 million deaths a year worldwide. Malnutrition affects every third human, dwarfing most other diseases. Increased risk of extreme events caused by climate change is likely to jeopardize the situation and exert adverse human health impact.

The 2003 European heat wave killed many thousands of people, showing that even developed countries may not be adequately prepared to cope with extreme heat. There were 10 days with temperatures over 35 °C in Paris and mortality in the time period from 1 to 20 August increased by 55%, as compared to earlier years. Occurrence of a heat wave as extreme as that in Europe in August 2003 would be unlikely in the absence of anthropogenic climate change. Hence, these excess deaths can be attributed directly to climate change. An increase in the frequency or intensity of heat waves in the future will increase the heat-caused risk of mortality and morbidity, particularly in the older age groups (sick people, isolated people), and among the urban poor (► prospects for the future).

Summary

Mankind is not free of natural and man-made disasters that have caused severe human and material damage, adversely affecting life, livelihood, and property. Despite developments in technology and high expenditures on disaster mitigation works, disasters do occur and the severity of their impacts and accompanying hardship and material damages is very high. Even if the health care has become effective and the average length of life and health status has dramatically improved, disasters continue to cause adverse, and severe, health-related effects, challenging the existing public health and health care systems. In brief, modern societies are not prepared for extreme disasters, which are far beyond planning and design assumptions. The present synopsis reviews components related to disaster aftermath.

Emergency management

Definition

Disaster management is a systematic process of using the body of policy, administrative decisions, organization, and operational skills and capacities to reduce the risk of natural or man-made disasters and their adverse effects. Disaster management can be realized at various levels – sub-national (local, regional), national, and international, and at various times – before, during, and after a disaster.

Basic Characteristics

International disaster management can be understood in two ways. On the one hand, it is management of international disasters affecting a number of countries, such as a tsunami, flood, drought, hurricane, epidemic, or war. On the other hand, the term describes international assistance to national (regional or local) disaster management (► disaster management, national).

Disasters devastate the lives, health, and livelihoods of millions of people every year. The vast majority of disaster-related deaths and adverse health effects occur in developing countries, where already fragile public services are further weakened. Disaster management, especially in less developed countries, requires massive international assistance. The United Nations (UN) Millennium Summit, during which the ► UN Millennium Declaration was adopted, resolved "... to intensify cooperation to reduce the number and effects of natural and man-made disasters" (United Nations 2000).

The 1990s were proclaimed the UN International Decade for Natural Disaster Reduction (IDNDR) by the UN. During the 1990s, the framework for international collaboration for strengthening preparedness skills and institutional bases was provided. The UN International Strategy for Disaster Reduction (ISDR) now promotes the building of disaster-resilient communities by increasing awareness of the importance of disaster reduction (► mitigation strategies) as an integral component of ► sustainable development, with the goal of reducing human, social, economic, and environmental losses (► physical, environmental and social aspects of disasters) due to natural hazards (► hazards, natural) and technological (► hazards, technological) and environmental disasters.

There are a number of agencies dealing with disaster management at the international scale, both intergovernmental organizations (IGOs; within the UN system) and non-governmental organizations (NGOs). Among the former are: UN Department of Humanitarian Affairs (DHA), UN Office for the Coordination of Humanitarian Affairs, United Nations Development Programme (UNDP), Food and Agriculture Organization (FAO), World Food Programme (WFP), World Health Organization (WHO), United Nations Children's Fund (UNICEF), and World Meteorological Organization (WMO). The UN High Commissioner for the Refugees (UNHCR) provides massive airlifts from UNHCR's global and regional stockpiles of life-saving supplies and operational capacity.

There are several regional agencies, such as the European Community Humanitarian Office (ECHO), cre-

ated to improve efficiency and give humanitarian aid a higher profile. The Caribbean Disaster Emergency Response Agency is a regional intergovernmental agency responsible for disaster management in the region. It makes an immediate and coordinated response to any disastrous event, once a state requests such assistance. It secures, collates, and channels comprehensive and reliable information on disasters affecting the region. It contributes to mitigating or eliminating the consequences of disasters as far as possible; establishing and maintaining adequate disaster response capabilities on a sustainable basis; and mobilizing and coordinating disaster relief.

Within the UN system, responsibility for disaster response rests with the Resident Coordinator within the affected country. However, in practice, an international response can be coordinated if requested by the affected country's government, by deploying a UN Disaster Assessment and Coordination (UNDAC) team from the UN Office for the Coordination of Humanitarian Affairs (UN-OCHA).

There are many NGOs involved in disaster management. Some are dedicated to the purpose of providing emergency medical and humanitarian aid, e. g. the International Federation of Red Cross and Red Crescent Societies (IFRC) or *Médicins sans frontiers*. Others act within the more general remit of assistance (e. g. ActionAid International). There are also multiple national institutions, both governmental (e. g. development assistance agencies) and private, that contribute to disaster response worldwide. The contributions of many agencies to raising disaster awareness and developing disaster preparedness material are numerous and very valuable.

The IFRC has played a pivotal role in responding to emergencies and reducing the impact of disasters around the world. The IFRC offers coordinated and focused responses to disasters by deploying emergency response units (ERUs), pre-trained teams of specialist volunteers (who already knew each other) and prepacked sets of standardized equipment ready for immediate use. Teams of experienced IFRC disaster managers (field assessment and coordination teams) are on standby to provide support after sudden major disasters. The deployment of ERUs speeds up the disaster response. ERUs are now a crucial part of the IFRC's disaster response and are part of the IFRC's integrated disaster management programming, which deals with emergency response, preparedness, and rehabilitation.

While effective disaster management plays a vital role in avoiding loss of life and suffering, it generally fails to make the connection between the disaster risk and sustainable development. In recognition of this, the UN Development Programme (UNDP) has adopted a view that disasters are unresolved development problems that occur when risks go unmanaged. The mainstreaming of disaster reduction into development and post-disaster recovery has become an essential component of building a capacity for sustainable development. Ideally, disaster risk planning and preparation considerations should be factored into national and regional development programs and countries should take advantage of post-disaster recovery as unique opportunities to mitigate future risks and vulnerabilities in their countries. Mainstreaming disaster reduction in UNDP practice takes place in such areas as poverty eradication and sustainable livelihoods; gender equality and the advancement of women; environmental and natural resources sustainability; and sound governance.

After a disaster, agencies initiate fundraising and undertake immediate assistance efforts. An example of an ad-hoc coordinated activity is the UN Inter-agency Earthquake Response Plan after the earthquake in Indonesia (27 May 2006). The UN Food and Agriculture Organization (FAO) mobilized resources to help farmers who had lost their productive assets and source of income due to the disaster in Indonesia, allowing them to resume farming and livestock production activities quickly. Early recovery of the agriculture sector is essential for quick and sustainable improvement of rural people's livelihoods.

Occurrence of a large disaster triggers international solidarity. After a large disaster, many international organizations and national organizations in many countries help affected societies to attain recovery.

Emergency management

Definition

Disaster management is a systematic process of using the body of policy, administrative decisions, organization, and operational skills and capacities to reduce risks of natural or man-made disasters and their adverse effects. Disaster management can be realized at various levels – sub-national (local, regional), national, and international, and at various times – before, during, and after a disaster.

Basic Characteristics

The responsibility for disaster (► hazards, natural; ► hazards, technological) management typically reflects the ► subsidiarity principle. It is attempted, as far as possible, to solve problems related to emergency at the lowest possible administration level of the place where the emergency occurs. The resources of the local authority (local government) are used first to manage a disaster occurring in a community. The response of local police, fire, and emergency medical services can be sufficient in the case of a smaller-scale emergency. Once it becomes clear that the resources of the local government are overwhelmed, the resources of the province are called upon (by the head of the local government, e. g. mayor) for additional help. When the resources of local and province governments are overwhelmed, the central government is called upon to help. Governors of the affected provinces may request a disaster declaration from a head of the central government (or a president) to ease the disaster management. In the case of a large disaster, foreign aid may be sought (► disaster management, international).

Disaster management is often considered a fundamental function of government at the national, provincial, regional, and local levels, and dedicated government agencies are established in many countries, reflecting the structure and functions of disaster management. On the national level, there is typically a central statutory authority for controlling any state of emergency declared by the central government. It is often a central government department whose mandate also involves leading efforts to prepare the nation for all hazards and effectively managing response and recovery efforts following any disaster that may occur. In some countries, a disaster management agency exists at the ministerial level (e. g. Ministry of Civil Defence and Emergency Management in New Zealand, Ministry of Disaster Management and Human Rights in Sri Lanka, and Ministry of Emergency Situations in some former Soviet republics). In the USA, the Federal Emergency Management Agency (FEMA) is the central, lead agency for disaster management. In some countries, the responsibility for governmental disaster management is placed with the institutions for civil defense.

Typically, provinces and local government bodies such as regional and city councils also have disaster management agencies to control local states of emergen-

cy. All these agencies defer to the central agency if a national state of disaster is declared. The central government agency works in partnership with these lower-level agencies and with other organizations that are part of the nation's disaster management system. Among them are civil defense units, the army, police, and fire brigades.

Disaster management deals with such issues as risk management, health planning and policies, management of health facilities, control of communicable disease, disaster medical services, psychological preparedness and response, and health information systems (including early warning, surveillance, and communication systems), among others.

In some countries and regions, active disaster management agencies play an extremely valuable role in raising disaster awareness in the society. In a few countries, disaster risk assessment has become public and individuals can see an on-line hazard map for their location.

The primary means of addressing disaster management is accomplished through relevant legislation. In some countries, such as the USA, there has been a long tradition of developing disaster management legislation. An early case of assisting people affected by a natural disaster through legislation was in response to the fire destroying New Hampshire (USA) over 200 years ago. In 1803, a Congressional Act was passed to provide financial assistance to the town. The Flood Control Act of 1934, which bestowed the responsibility for flood control upon the U.S. Army Corps of Engineers, the National Flood Insurance Act of 1968, and the Disaster Relief Act of 1974 were passed in the USA to address natural disasters. The current focus on terrorism was triggered by the attack on 11 September 2001. It is important that policies and legislation define the powers, duties, and functions of agencies involved in disaster management in an unambiguous way. There have been many examples when co-ordination of efforts led to problems due to existence of several agencies whose responsibilities were not clearly defined. Effective disaster management relies on the integration of emergency plans at all levels of government and active involvement of non-government bodies. Activities at each level affect the other levels of disaster management.

Chances of reduction of human losses and material damage and prospects of recovery (► recovery strategies) are greatly improved when survival plans are prepared beforehand (by local, provincial, and national governments, emergency services, and businesses), and geared to disasters (► hazards, natural; ► hazards, technological) that may occur in the area.

The response to Hurricane Katrina, the most destructive (in terms of material damage) disaster ever recorded worldwide, revealed several weaknesses in disaster management, planning discipline, and field-level crisis leadership in the most powerful country on the Globe. Thereafter, implementation of corrective actions was found necessary in many organizations (including FEMA), in order to ensure that the problems encountered during Hurricane Katrina are not likely to occur again. The federal US government decided that the existing national preparedness system must be improved to minimize the impact of disasters on lives, health, property, and the economy.

Hurricane Katrina and its aftermath have provided the USA with the imperative to create a culture of preparedness; to design and build a unified and comprehensive national preparedness system, preparing for and responding to natural and man-made disasters. Starting with a national, domestic, all-hazards preparedness goal, a robust preparedness system is being built that includes integrated plans, procedures, training, and capabilities at all levels of government. The system should integrate and synchronize the nation's policies, strategies, and plans across federal, state, and local governments, as well as the private sector, non-governmental organizations, faith-based groups, communities, and individual citizens, who share common goals and responsibilities. The objective of the system is to achieve and sustain risk-based target levels of capability to prevent, protect against, respond to, and recover from major emergencies.

Synonyms

Management damage reduction

Definition

Undertaking actions to reduce human and material damage caused by a disaster.

Basic Characteristics

The disaster response phase embraces the entirety of actions following the occurrence of the disaster, and is aimed at reduction of human and economic damage. Disaster response deals with a situation of active crisis, possibly involving numerous affected people in urgent need of assistance (► disaster management, national; ► disaster management, international). Search and rescue efforts after sudden disasters (such as earthquakes) start at an early stage in order to save lives. Depending on injuries, the ambient temperature, and victim's access to air and water, it is possible to survive for minutes, hours, or days. The chance of finding survivors decreases dramatically with time, particularly in the case of wounded people and cold weather.

People affected by a disaster present multiple survival needs, including basic needs (safe water, housing/shelter, hygiene), and health and medical needs (first aid, medical attention, care of special medical conditions such as diabetes and epilepsy, and temporary hospitals and pharmacies). Mental health also needs attention, particularly with regards to ► post-traumatic stress disorder (PTSD) and child and spouse abuse. Emergency assistance includes providing clothing, cleaning supplies, emergency transportation, home repairs, household items, etc. In the disaster-affected environment, the capacity of disaster management agencies is over-stretched and diminished by the disaster so that they are not able to deliver their usual services.

Some natural disasters can be forecast. If a forecasting-warning-response system is in place, it may be possible to evacuate people from endangered areas (at times, the number of evacuees can be very high). Families follow instructions and evacuate to friends, relatives, or to specially designated temporary evacuation shelters (e. g. school buildings, municipal arenas) on foot, by their own cars, or by means of transport delivered by rescue workers. They take an adequate amount of supplies, if possible. At evacuation shelters, they should be taken care of by rescue workers and provided with their basic requirements: safe water, warm food, blankets and clothing, and psychological support, which may be required over a longer time. In displaced families (temporarily or permanently), children suffer particularly from the stress of having lost a home, a neighborhood, friends, a pet, and a normal way of life, and being in a new, and unknown, environment (possibly moving in with family members into overcrowded temporary housing). The response can also take the shape of home confinement, i. e. a family may stay in their home for a long time (days) without outside support.

The disaster response plan should be well prepared and rehearsed in a disaster-free time. It should be developed as a part of the disaster preparedness plan. Improvisation in the time of emergency does not pay off and disables efficient coordination of rescue efforts.

Disaster response includes a system to share relevant and reliable information for several purposes: to dispel hysteria and rumor; to offer support, counseling, and referrals to those in need; and to inform, assist, and calm the interested public. Disaster-affected communities seek disaster information, becoming almost addict-

ed to media coverage of the disaster and its management. Local media (TV and radio stations and newspapers) provide a wealth of useful practical information on how to solve crucial everyday problems, such as obtaining medical assistance, food and water, rebuilding material, etc.

Schools may reopen with improvised schedules and without proper instructional materials. Though possibly damaged, schools buildings may play the role of save havens, islands in a sea of confusion and turmoil, and symbols of good hope for the community.

Disaster heightens awareness of many chronic but ignored problems, such as poverty, unemployment, and homelessness, which may have been politically unpalatable. However, since a disaster leaves many middle-class people homeless, the public perception of homelessness is likely to change positively. The sight of families with small children and no place to go convinces many of the need for an organized response.

The disaster response can be provided by national (► disaster management, national) and/or international agencies and organizations (► disaster management, international). If many organizations respond, effective coordination of disaster assistance is crucial. The disaster response includes the mobilization of the necessary emergency services and first responders in the area stricken by disaster, such as civil defense, fire brigades, police (if necessary and feasible – military units), dedicated Non-governmental organisations (NGO), and volunteers, driven by noble motives, who can help in the disaster response. However, non-coordinated actions of spontaneous and unaffiliated volunteers may be a hindrance to the disaster response and harm recovery efforts.

Discarding

► Disposing

Discounting

Definition

Discounting is defined as the adjustment of future values – whether costs or outcomes – to better reflect their present day value. The discount rate is the rate at which future values are adjusted. The rationale behind discounting is the observation that it is preferred to receive and consume something of value today rather than in the future. As there is no common standard discount rate, a rate of 3% or 5% is recommended for the base case analysis and a further sensitivity analysis with a rate between 0% and 10% should be conducted.

Discrete Event Simulation (DES)

Definition

In general, discrete event simulation describes the chronological sequence of events representing the operation steps of a system. In health economic ► modeling, discrete event simulation techniques are seen to be more flexible and, due to the consideration of individual patient experiences, more naturalistic than Markov models and decision tree analysis.

Discriminant Analysis

Synonyms

Discriminant function analysis; Linear discriminant function analysis

Definition

Discriminant analysis (DA) is one of a large class of methods for performing supervised classification. It uses a set of measured characteristics or attributes of subjects or objects to (a) put the observed units into one of two (or more) alternative groups *a priori* defined or (b) formulate differing classes or groups. Thus, the method can be used with two rather distinct objectives. The first is as a predictive tool with the aim of formulating a rule that will permit objects to be classified into one of several predefined classes. The second is to help understanding (i. e., explanation or description) with the aim of building a model that helps us understand the structure in data. For example, is it possible to predict which patient's breast cancer will have spread to the surrounding lymph nodes? In what way do those infants at high risk of dying from Respiratory Distress Syndrome differ from those at low risk when a set of variables that include sex, gestational age, birthweight, etc. are available? DA considers the classification procedure using the assumptions that a nominal outcome has two (or more) values, that independent variables are normally distributed and linearly related, and by applying Bayes' Theorem.

Discriminant Function Analysis

► Discriminant Analysis

Discrimination

Definition

Discrimination of mentally ill individuals is the treatment of a mentally ill person in a less favorable way compared with a person without mental illness but in the same circumstances.

Disdain

Synonyms

Scorn; Dislike; Aversion

Definition

Lack of respect accompanied by a feeling of intense dislike.

Disease

Definition

Disease refers to abnormalities in the structure and function of body organs and systems.

Disease Frequency

Synonyms

Morbidity

Definition

The term disease frequency usually refers to the rate of ► incidence of a disease. It reflects the rate of sickness as in specified community or group. It also may denote ► prevalence (the total number of cases in a particular population at a particular point in time) and incidence (the number of new cases in a particular population during a particular time interval) of a disease.

Cross-References

► Incidence
► Morbidity

Disease Frequency, Measures

Synonyms

Incidence rate in occupational medicine

Definition

In epidemiology (► epidemiology, aims and scopes), measures can be defined as a variety of parameters used to quantify the occurrence of health events in a population.

Basic Characteristics

To investigate distributions and determinants of health events, besides the number of ► cases, it is necessary to know the size of the ► population at risk and the time period during which the data were collected. There are three general tools used to relate the number of cases of disease or the outcome to the size of the population in which they occurred: ratio, proportion, and rate (Hennekens et al. 1987).

Ratio is any number divided by another without any specific relationship between the numerator and the denominator. The ratio may be expressed in the form *x*/*y* and is dimensionless. An example of a ratio is the ratio of male to female births.

Proportion is a type of ratio where the numerator is a part of the denominator. Proportions may be expressed as fractions, decimal numbers, or percentages. An example is the proportion of male deaths out of the total number of deaths (male deaths plus female deaths).

Rate is a special form of proportion because the denominator includes a measure of time. The rate expresses the probability or risk of a disease or outcome in a defined population over a specified period of time (Mausner, Kramer 1985; Bhopal 2002). Rates can range from zero to infinity. They can be crude (► crude rate), specific (► specific rate), or standardized (► standardized rate).

All measures refer to morbidity (illness) or mortality (death).

Measures of Morbidity

Presence of disease in a population or the probability (risk) of its occurrence can be measured using prevalence or incidence.

Prevalence indicates the number of existing cases of disease in the population at a specified point in time or over a specified period of time. Prevalence is measured as a proportion, so it must lie between zero and one. It provides an estimate of the probability that an individual will be ill at a particular point in time.

There are three types of prevalence, but when used without qualification it generally refers to point prevalence (Bhopal 2002).

Point prevalence comprises all affected persons that exist in the population at risk at a point in time. The numerator includes all new and pre-existing cases on a certain date. The denominator is the total population on that date.

Period prevalence combines the concept of incidence and point prevalence. It denotes the total number of cases that exist during a specified period of time, for instance a week, month, or longer time interval (a year or two). The numerator in the *period prevalence* is the number of cases at the beginning of a defined period (the point prevalence) and new or recurrent cases that occur during the period of interest. The denominator is the average population. Period prevalence is useful for studying episodic, recurrent diseases such as mental illness, migraine, low back pain, etc.

Lifetime prevalence is an extension of the idea of period prevalence, and includes all those who have had the disease at any time in their life. Lifetime prevalence is useful for investigating how common some diseases are.

Prevalence is based on both incidence and duration of disease.

Prevalence data are useful in describing the burden of a disease in a community (especially for long lasting infections, such as HIV), and in planning health resources such as facilities and personnel. Prevalence data are not helpful for studies of etiology of diseases.

Incidence is the number of new cases of disease or health conditions that develop in a population at risk within a specified period of time. Incidence expresses the probability or risk of illness in a population over a period of time. Incidence data can help in research on the etiology of disease. There are two specific types of incidence measure defined by the type of denominator: cumulative incidence and incidence rate or incidence density.

Cumulative incidence is the proportion of new cases of a disease during a specified period of time in the population at risk. The denominator is the size of the population at the start of the time period. The distinction between cumulative incidence and lifetime prevalence is that cumulative incidence permits the inclusion of any person who has developed the disease whereas lifetime prevalence tends to imply retrospective examination of individuals who are currently at a certain age.

Incidence rate expresses the probability or risk of illness in a population over a period of time, counting, as with the cumulative incidence, the number of new cases of a disease in that population. However, the denominator (called person-time of observation) consists of the sum of the different times that each individual was at risk of developing the disease. For example, a person at risk of disease followed for one year contributes one person-year of observation.

Attack rate is an alternative form of incidence, which is applied to a narrowly defined population observed for a limited time, such as during an ► epidemic (► outbreak).

Measures of Mortality

Measures of mortality are mortality rate and case-fatality rate.

Mortality (death) rate is a measure of the frequency of occurrence of death in a defined population during a specified period of time (for example, one year). It is calculated by dividing the number of deaths in the population during that period by the person-time of observation or by the average population (or the population at midyear). The number of persons in the population at midyear is used as an approximation because the population usually changes during the time period (Gordis 2004). The ► fetal mortality rate, the ► maternal mortality rate, and the ► infant mortality rate are commonly used as the indicators of the level of health in a community.

Case-fatality rate refers to the number of deaths from a particular disease, divided by all cases of that illness (Hennekens et al. 1987). Contrary to the mortality rate, where the denominator is the entire population at risk of dying, the denominator in the case-fatality rate represents only the individuals who already have the disease. This measure is usually expressed as a percentage or as a decimal. The case-fatality rate is a measure of the severity of a disease. In other words, what percentage of people diagnosed as having a certain disease die within a certain time after diagnosis (Gordis 2004).

Summary Measures of Population Health

Summary measures of population health are statistical measures relating to the burden of disease that combine information on mortality and morbidity (Murray, Lopez 1996).

Disability Adjusted Life Year (DALY) combines in one measure the time lost due to premature mortality and the time lived with disability. DALYs measure the gap between a population's actual health and some defined goal. They are calculated by taking the sum of the ► years of life lost due to premature mortality (YLL) in the population and the ► years lived with disability (YLD) for incident cases of the health condition. One DALY, for example, represents the loss of one year of equivalent full health (Murray et al. 2001).

A system of coordinated health care interventions and communications.

Disease Management Organizations (DMOs) (U.S.)

Definition

DMOs are providers of health care services for people suffering from typically chronic, high-cost and high-volume diseases covered by a disease management program. DMOs typically receive a prospective payment of care based on fixed prices combined with a performance bonus. They are generally required to report health outcomes of the patients as one of their primary goals is to improve the ► health status of the patients. The US Agency for Health Care Administration contracts for example with DMOs to provide health care services for ► medicaid patients enrolled in a ► primary care case management Program for ► chronic diseases such as AIDS, asthma or diabetes.

Disease Management Programs

wolfgang.boecking@web.de, dtrojanus@gmx.net

Definition

Disease management programs (DM programs) are coordinated health care intervention programs using interdisciplinary clinical teams, continuous analysis of relevant data, and cost-effective technology to improve the health status of patients with treatable chronic diseases (e. g. asthma, diabetes, etc.).
The design of a DM program involves typically a certain number of disease management activities. According to the Disease Management Association of America (DMAA), these activities comprise "population identification processes, evidence-based practice guidelines (also ► evidence based medicine, in HTA, ► evidence based medicine in Epidemiology); collaborative practice models, patient self-care management education as well as process and outcomes measurement".
In practice, the application and the design of DM programs varies from comprehensive patient care management programs including full medical service to limited medical assistance programs focusing on pharmaceutical services and administrative functions.

Basic Characteristics

History

► Chronic diseases necessitate generally a higher use of health care services, i. e. hospital care, doctor's visits and prescription of drugs. The increase in the number of people with chronic diseases and the rise in overall health care spending have led payers of health care (government, employers, insurances) to seek for measures to reduce their health care costs. Since 1990, disease management of chronic diseases has become increasingly popular in the United States because DM programs aim to enhance health conditions of chronically ill people while reducing the costs of health care by avoiding complications and unnecessary use of health care services. Traditionally it has been part of the comprehensive care that has been furnished by so called ► disease management organizations (DMOs). Today, there are many approaches of disease management used among the ► fee-for-service population and the approach is expanding worldwide.

Design Components of a DM Program

To design a successful DM program in terms of program implementation as well as cost and quality improvements, according to the DMMA six major activities have to be fulfilled:

1. Population identification processes:
   DM programs target costly chronic diseases or combination of diseases such as asthma, diabetes, congestive heart failure, coronary heart disease, etc. DM programs use demographic characteristics, utilization trends and medical cost components to identify individuals among the population who may enrol as

patients for a specific DM program. Once patients are identified by the most severe disease, ► co–morbidities need to be analyzed before enrolling in a specific DM program.

2. Evidence-based practice guidelines:
   Many DM programs develop practice guidelines for doctors based on clinical evidence to ensure that all patients receive the same medical treatment and lifestyle counseling about how to better live with their chronic conditions.
3. Collaborative practice models:
   To provide a comprehensive care management for the patients, DM programs use direct patient-physician contact with interdisciplinary teams including physicians, nurses, pharmacists, dieticians, respiratory therapists, and psychologists. The education of the individual to better manage its disease may lead health care providers to also work with support-service providers to fill in any gaps in the care team, such as the need for nutrition screening or patient monitoring at distance.
4. Patient self-management education:
   The patient's self-management education or treatment compliance education is an important factor in DM programs. It allows patients to receive better health care and ultimately leads to cost-savings. DM program enrollees may need additional support to stick to their medical regiment such as home visits, counseling, 24-hour call centers, etc.
5. Process and Outcomes measurement:
   DM programs need a system of quality measurement defining measurable goals for the process and the outcome of the program. Typically, DM programs measure the costs and use of all care components, the quality of care, the patient's and physician's satisfaction and changes in health status and well-being of the patient. These measures are defined prior to the beginning of the program and compared to a baseline or a control group at regular interval.
6. Routine reporting and feedback between patients, providers and health plans:
   Routine reporting and feedback between patients and members of the care team assure that patients are receiving the care they need and that they progress in managing their chronic disease. Reporting and feedback towards health plans helps to evaluate the overall impact and effectiveness of DM programs.

The components of effective disease management can take many forms in terms of the tools used, the techniques, and the latest advances.

Application of Disease Management Programs in the USA

DM programs are either applied by ► managed health care plans or by the government.

Managed health care plans have developed and implemented at least one or more DM programs. The most common programs concern the ► chronic diseases of diabetes, asthma and congestive heart failure. To provide services, managed health care plans typically contract with ► vendors or so called ► disease management organizations (DMOs). Some health care plans provide the necessary services on their own.

On the government level, since 1990 more than 20 states are engaged in developing and implementing ► medicaid DM programs for their primary case management and their ► fee-for-service population. Although DM programs have become increasingly popular, several differences between the state programs occur. Some states administer the DM programs on their own, others work with DMOs. Some states offer DM programs including the whole spectrum of necessary medical services and patient counseling, others focus on managing pharmaceutical services only. Some states build a medical care team around their DM programs, others contract with various professionals to fulfill the care management function in the DM programs. The use of performance indicators as for example cost savings, return on investment, secondary prevention activities, adherence to ► clinical guidelines or education of professionals and patients also varies from state to state.

International Applications

With the increasing need for cost containment in the health care systems of industrialized countries, the US approach of DM programs for chronic diseases has recently become popular in many other countries.

In Germany for example, the first initiatives of regional DM programs for breast cancer and diabetes became operational within the statutory health insurance funds in early 2003.

In the UK, the government introduced in January 2005 a model designed to help improve the care of people

with long term conditions. This model offers a personalized care plan for vulnerable people most at risk through improved care in primary and community settings.

Positive Effects and Potential Drawbacks of DM Programs in the USA

Positive effects of DM programs:

- Improves health outcomes: DM programs are based on a patient-centered approach which provides care by addressing psychological aspects, caregiver issues, and treatment of multiple diseases using evidence-based practice guidelines and evaluation of health outcomes.
- Patient satisfaction is generally high because DM programs support the physician-patient relationship by enhancing communication and facilitating feedback.
- Reduction of health care costs: The success of disease management programs in improving self-care practices can lead to the reduction of various health care services, including hospital admissions and emergency room visits. The ► medicare diabetes management program demonstrates among other examples that health care expenditures for certain populations with chronic conditions have decreased.

Potential drawbacks:

- As DM programs are still relatively new and cost-saving studies concentrate generally on a short period of time, the reduction of health care costs in the long run cannot yet be determined.
- The compliance of patients is a central element to assure success of a DM program. Patients are required to spend time and effort in order to improve their health care practices, but sometimes they feel oppressed by the health plans and lack motivation.
- Communication barriers between patients and providers pose challenges. Cultural differences, as well as language barriers, but also the lack of easy access to the provider can inhibit program outcomes.
- Patients may suffer from one or more chronic disease, making coordination of services or different DM programs necessary.
- As standards of care develop with innovation and technological progress over time, DM programs should be reviewed annually and revised as necessary based upon new treatments.
- There is a lack of common standards for measuring costs and clinical outcomes in order to evaluate nationwide the true impact of DM programs.

Conclusion

Although research on the impact of US disease management programs is somewhat limited, there has been some evidence that DM programs have improved the quality of care with limited cost savings. As people with chronic diseases tend to increase in number and to live longer, disease management efforts will certainly continue improving the effectiveness as well as the economic efficiency of DM programs. If the performance of DM programs increases, they may find a permanent home in the infrastructure of health care delivery not only in the USA but in all other well developed health care systems around the world.

Disease with Multiple Etiology

► Multifactorial Disease

Disease Outcome

Synonyms

Disease result

Definition

The outcome is the possible result that may stem from exposure to a causal factor, or from some intervention. To assess the results, investigators compare rates of disease, death, recovery, or another appropriate outcome. The outcome of interest is measured in the experimental and control group to evaluate efficacy.

Cross-References

► Outcome (Health Economics)

Disease Prevention

Synonyms

Health control; Health promotion; Healthy public policy

Definition

Health promotion comprises all activities to improve people's health and ultimately prevent diseases. These activities are a combination of educational and environmental support actions. They include the provision of information on health and well-being enabling individuals to increase control over their health situation. Health promotion moves beyond the traditional treatment of diseases and ► prevention by vaccination by concentrating its efforts on social, physical and economic factors that influence health including the promotion of physical fitness, healthy eating and living habits as well as early detection of health risks. Actions promoting health are taken at different levels in society: health and social policy at government level, school and community care centers at community level, and family and self at the individual level.

Cross-References

► Health Control
► Health Promotion
► Healthy Public Policy

Disease Registry

Definition

A disease registry aims to collect information on every individual with a particular condition (for example a cancer registry would include information on the primary site and morphology of the cancer) within a given geographical area. Diagnosing physicians are not required by law to report diagnoses to registries; instead, registry personnel identify cases through hospital records reviews. The purpose of a registry is to gather information that may advance the scientific understanding of a disease and to have incidence and prevalence data.

Disease Screening Practices

Synonyms

Preventive screening

Definition

Screening asymptomatic persons to detect preclinical disease has become an important part of public health. However, preclinical screening makes sense only if treatment initiated earlier in the disease process will reduce morbidity and mortality from the disease: there is no benefit in living with a diagnosis if a person's life or quality of life is not extended. The selection of appropriate tests for a given individual depends primarily on that person's age and sex. In addition, consideration of individual risk factors, such as lifestyle or family history, often is used to determine which tests are appropriate tests and how often testing should be performed. Screening for ► sexually transmitted diseases, hypertension, cervical cancer, colorectal cancer, breast cancer and prostate cancer are common examples.

Diseases with Multiple Etiology

Synonyms

Multifactorial disease

Definition

The term "disease with multiple etiology" is usually interchangeable with the term "multifactorial disease". Although, in some opinions, the terms are similar, they are not synonyms because a risk factor for disease development does not necessary mean it is the direct cause of a disease as determined by medical diagnosis or research.

Disinfectant

► Antiseptic

Disinfection

Definition

Disinfection is a process that eliminates many or all pathogenic microorganisms on inanimate objects or skin, but not necessarily bacterial spores. Bacteria grow attached to surfaces because of their insolubility in water. Disinfection reduces the number of bacteria to a level that is not harmful to health. In healthcare settings, disinfection is usually accomplished by the use of a liquid chemical or wet pasteurization. Antimicrobial agents that are applied during disinfection are called disinfectants.

Disinfection of Surfaces

► Antiseptic

Dislike

► Disdain

Disparity

► Health Disparities

Dispensaries

Definition

Dispensaries refer to a charitable or public facility where medicines are furnished and free or inexpensive medical advice is available.

Displaced Person

► Refugee

Displacement of Populations

Definition

Displacement of populations occurs when groups of people are forced to leave their homes or home regions. This phenomenon, known as forced migration, can be due to political or religious reasons, war, ► environmental degradation, or be development-induced. The latter is associated with the forcing of populations to leave their homelands, e. g. to make way for the construction of dams for hydro-electric power and irrigation purposes.

Disposal in Landfills

► Communal and Industrial Waste

Disposing

Synonyms

Throwing away; Dumping; Removal; Discarding

Definition

Help to keep your environment clean. Disposing is getting rid of potentially dangerous waste such as asbestos, pesticides, old electrical equipment, etc. Garbage should be placed in covered metallic containers that render the contents inaccessible to dogs and other animals and do not permit the breeding of flies. There are two general methods of refuse collection: the mixed system and the separate system. A garbage disposal or garburator is an electrically-powered device

installed under a kitchen sink. It shreds food waste into very small pieces so that they can be passed through the plumbing without clogging. Also called a food waste disposal.

Dissociation

Definition

Dissociation reflects a perceived detachment of the mind from the emotional state or even the body and it is a critical feature. Dissociation also is characterized by a sense of the world as a dreamlike or unreal place and may be accompanied by poor memory of the specific events, which, in severe form, is known as dissociative amnesia.

Distorted Thinking

► Psychotic Disorders

Distress

Definition

Distress is a negative form of ► stress with negative consequences. The resources of a distressed person are not adequate to cope with the challenges.

Distribution

Definition

Distribution is the dispersion or dissemination of (pharmacological) substances throughout the fluids and tissues of the body.

Diver's Disease

► Caisson Disease

Diviners

► Indigenous Health Care Services

DMF-Rate

► DMFT-Index

DMFT-Index

Synonyms

Caries index; DMF-rate

Definition

The DMFT-index describes the amount – the prevalence – of ► dental caries in an individual (so-called "caries load"). This index is used worldwide in epidemiological surveys to indicate the prevalence of dental caries in an individual. Thus, all **T**eeth or **S**urfaces respectively which are **D**ecayed, **M**issing and **F**illed due to dental caries are given a number. The sum of the three figures is the DMFT-value. It is used to get an estimate and idea of how much of the dentition has been affected by dental caries before the individual came for dental examination. For the primary dentition all indices are written with small initial letters (dmf-index). The caries prevalence increases during the lifetime of an individual. The DMFT-average of the 12-years-old children is 0.7 in Germany, making this German age group the top group worldwide (situation as per 2005).

DNA Chip

► DNA Microarray

DNA Microarray

Synonyms

Gene chip; Gene arrays; DNA chip

Definition

A DNA microarray is a solid surface onto which DNA (► deoxyribonucleic acid) molecules are arrayed at high density. DNA microarrays can be fabricated with short segments of DNA (oligos) or full length gene fragments (cDNA). DNA microarrays can be spotted mechanically onto a glass slide or may be synthesized *in situ.* DNA

microarrays provide a key tool to quantify transcript levels ► genome-wide.

DNA Transcription

► Transcription

DNA Variants

► Polymorphisms

Doctrine

► Ethical Principles

Domestic Mites

► House Dust Mites

Domestic Violence

► Intimate Partner Violence

Domiciliary Care Facility

► Assisted Living Facilities

Dominant Strategy

Definition

In ► health economic evaluation dominace describes a distinct situation. The strategy that is less costly and more effective is the dominant strategy and should be preferred. In extension to this situation of simple dominance, in a situation where two new alternatives are compared with the standard and both new alternatives show higher costs but also higher outcomes gained, the alternative with the better cost-outcome ratio is dominating. This situation is described as extended dominance.

Dose-Response Assessment

Definition

Dose-response (toxicity) assessment estimates how much of a substance does what kind of harm to humans. Dose-response assessment is the process of characterizing the relation between the dose of a ► hazard received, and the incidence of an adverse health effect in exposed populations. It determines whether the adverse effect increases with increasing exposure to the hazard. 'Dose' is commonly used to indicate the amount of a hazard while 'response' refers to the effect. The dose-response assessment is a second step in the ► risk assessment procedure. In this context, the dose-response assessment identifies the relationship between the exposure level and the magnitude of risk. In the toxicity assessment, uncertainties arise when the findings are extrapolated from animals to humans.

DOTS

Synonyms

Directly observed treatment; Short-course

Cross-References

► Tuberculosis and Other Mycobacterioses

► Water Quality and Waterborne Infectious Diseases

Dragon Worm Infection

► Dracunculiasis
► Guinea Worm Infection

Drinking Water

Synonyms

Potable water; Clean water; Safe water; Water free off germs; Non-contaminated water

Definition

Drinking water is freshwater. Its quality has to fulfill certain standards to be suitable for human consumption. Between industrial nations and developing countries there is a considerable difference in quality. In industrial nations the composition of drinking water is subject to particular regulations which set constituent standards. Drinking water should be odorless and colorless, the taste should be tempting and it should contain at least a minimum of minerals. Most frequently, drinking water stems from groundwater, which is supplied from springs or wells. Surface water from lakes or dams as well as water from rivers can be recycled as drinking water. Near coasts, water can be obtained from desalinized seawater.

Droplet

Definition

Droplets are generated from the source person during coughing, sneezing, or talking, and during the performance of certain procedures in hospitals, such as bronchoscopy. The transmission of infectious agents occurs when droplets containing microorganisms generated from the infected person are propelled through the air and deposited on the host's conjunctivae, nasal mucosa, or mouth. Droplets are large particles that cannot be transmitted beyond a radius of about 1 meter or less.

Drug

► Drug Law

Drug Abuse

GERD GLAESKE, FALK HOFFMANN
Health Economics, Health Policy and Outcome Research, Zentrum für Sozialpolitik, Universität Bremen, Bremen, Germany
gglaeske@zes.uni-bremen.de,
hoffmann@zes.uni-bremen.de

Synonyms

Medication abuse; Harmful use (of drugs); Hazardous use (of drugs)

Definition

Medication drug abuse can be defined as 'the consumption of a drug apart from medical needs', often 'apart from the licensed indication claim or in unnecessary quantities and duration'. However, the term is wide and used in varying meanings. Drug abuse is often referred to as the period before ► drug dependence. Drug dependence can be described as an ► adverse drug reaction, which has to be considered like other ► side effects. Drug dependence is a state of psychological or sometimes physical symptoms resulting from the interaction between a living organism and the chemicals of a drug. Drug dependence is characterized by behavioral and other responses that always include a compulsion to take the drug on a continuous or periodic basis in order to experience its psychological effects or sometimes to avoid the discomfort of its absence. The World Health Organization (WHO) is now using the term 'drug dependence' instead of 'drug addiction' or 'drug habituation' (WHO 1994).

Basic Characteristics

Substances Which May Lead to Abuse

The WHO has classified different groups of drugs that are prone to be abused and can be summarized as (for details see Poser and Poser 1996):

- Alcohol containing medications (e. g. cold or herbal remedies sometimes include up to 79 vol. %).
- ► Analgesics or antitussives (containing ► opioids (e. g. morphine, codeine) or over-the-counter analgesics with or without caffeine).
- ► Hypnotics and sedatives (containing barbiturates,

benzodiazepines, diphenhydramine and newer hypnotics such as zolpidem and zopiclone).
- ► Psychostimulants (containing amphetamines, anorectics, drugs containing ephedrine such as cold remedies).
- Other drug groups (containing laxatives, steroids, erythropoietin, antihistamines, anticholinergics (e. g. biperiden, atropine), beta-blockers, diuretics).

Therefore, abuse can occur with respect to psychotropic and non-psychotropic drugs (non-dependence-producing substances in terms of the WHO). The latter ones have no effects on the central nervous system (CNS). Because psychotropics are mentioned in several textbooks, we briefly discuss abuse of some non-psychotropic medications here. The chronic use of laxatives (e. g. bisacodyl, also strong herbal laxatives) leads to bowel habituation. Because of constipation due to liquid and electrolyte loss (especially potassium) more laxatives have to be taken and a vicious circle is started. The loss of electrolytes can also induce cardiac arrhythmia. The same holds for the abuse of diuretics (agents that promote the excretion of urine), e. g. by athletes, models, and people addicted to slimming who abuse dehydrating drugs for weight control and weight reduction. Steroids or erythropoietin may also be consumed by bodybuilders and sportsmen for doping purposes. Nose drops containing adrenergic alpha-agonists should only be taken for short-term. After 5–7 days of using such drugs they may dehydrate the nasal mucosa and, in the last stage, cause an atrophy of the nasal mucosa and a chronic rhinitis (drug induced cold) leading often to a continuing use (Rogers et al. 1984). Beta-blockers are reported to be abused as anxiolytic drugs by sportsmen and examination candidates. The misuse of over-the-counter analgesics, which were originally taken for headache, may result in drug-induced headache.

Epidemiology

As stated above, one has to distinguish between drug use, abuse, and dependence. Especially in the studies of medications such a distinction can be difficult. Although healthcare utilization data sets are increasingly available, their use for studying drug abuse is limited. To get information about the prevalence of such disorders, surveys should be carried out. However, due to different methodologies, drugs and classifications, estimated prevalences can vary in different countries or surveys. In the United States the National Survey on Drug Use and Health (NSDUH) has been conducted annually since 1971. Monitoring the Future (MTF), which started in 1975, is another annual study on adolescent drug use in America. Therefore, trends can be estimated from both surveys. Recent data of the NSDUH show that in 2004 an estimated 14.6 million Americans aged 12 years or older (6.1 percent of the population) used psychotherapeutics (defined as prescription-type analgesics, stimulants, hypnotics and sedatives but excluding ► over-the-counter drugs) non-medically during the past year. Analgesics (4.7 percent of the population), hypnotics and sedatives (2.4%), and stimulants (1.2%) were reported most frequently and some persons abused more than one of these drugs simultaneously. Respectively, an estimated 48 million persons aged 12 or older (20 percent of the population) had at least one non-medical use of psychotherapeutics in their lifetimes (Substance Abuse and Mental Health Services Administration 2005). Data of the Monitoring the Future survey suggest that the proportion of teenagers who used illicit drugs during the past year has dropped over the previous 15 years. But during the same period, the proportion of young people, using psychotherapeutics without medical supervision increased often because of the perception that these drugs were safe (Johnston et al., 2006). For Germany, however, repeated and representative survey data are rare. Only the German Epidemiological Survey on Substance Abuse (Epidemiologischer Suchtsurvey) fulfills these criteria. In 2003, the prevalence of problematic use of prescription drugs was 4.3% (Kraus and Augustin 2005).

Overall, data suggest that women are more likely to abuse drugs than men (especially analgesics, hypnotics and sedatives). With increasing age the prevalence of such disorders is on the rise (Kraus and Augustin 2005; Poser and Poser 1996). It is also suggested that health care professionals (e. g. doctors, nurses, pharmacists) may be at an increased risk of medication abuse. But the most important risk factor for drug abuse and dependence is a previously known dependency (e. g. alcoholism).

Consequences

The harmful consequences of drug abuse include not only dependence but traffic accidents, poor health and

disturbed patterns of behavior. But one should not forget that non-illicit drugs such as alcohol and tobacco may pose an even greater problem. The continuous abuse of psychotropic drugs may lead to drug dependence. Although initially a drug is often taken for medical purposes (e. g. headache, insomnia, common cold) several pathways can lead to abusive consumption. Dependence on psychotropis often occurs slowly and insidiously from drug abuse. Especially in benzodiazepines long-term use frequently does not result in dose increase. But psychological dependence, which is the craving for the drug in order to get the feeling of satisfaction, may occur in the long run. ► Withdrawal may result in physical disturbances, these symptoms are also seen in non-psychotropic drugs (e. g. laxatives, nose drops) (Poser and Poser 1996).

Because of their high rates of comorbidities, ► polypharmacy and changes in physiological functions and drug metabolism, older adults are at an increased risk for side effects of drugs and can have more adverse health consequences than younger persons. Furthermore, some drugs which may be abused (e. g. long-acting benzodiazepines, barbiturates) are considered to be inappropriate in the elderly because the risks outweigh the benefits.

Conclusion

A great number of medications are prone to be abused, not only prescription drugs but also those that can be obtained over the counter (see above). Pharmacies should, therefore, most carefully inform about drugs that can potentially be abused while doctors should, since many people visit different doctors to get more than one prescription (so called 'doctor hopping'), especially watch out for patients asking for these drugs. People who have had drug problems before should not be given drugs that may cause abuse or dependence. Health care professionals should continuously update information on drug abuse and potentially dangerous drugs. Drug abuse may lead to a vicious circle of needing more of a drug the more often it is taken. Drug abuse may, therefore, lead to drug dependence. But if not used for medical purposes, taking drugs may in this respect be compared to doping in sports. Drugs are, however, not for doping in everyday life. But they are sometimes used with wrong expectations, for example laxatives or diuretics have no lasting effects on body weight.

Generally, taking medications is socially more accepted than the use of alcohol or illicit drugs. Furthermore, subjects abusing drugs manage their everyday life without being conspicuous. But drug abuse and its general effects on public health should, therefore, not be underestimated. Especially the problem of abuse of non-psychotropics is frequently ignored in studies and in the public opinion. Even young people take analgesics and laxatives for the purpose of coping with apparently difficult situations (stress at school or at work, weight problems). Advertising also promotes the false conclusion that a pill exists for every indisposition ('a pill for every ill'). And even children are socialized with this behavior. It is, therefore, most important that schools should also provide the very young ones with information on the dangerous and destructive effects of drug abuse.

Drug Addiction

Synonyms

Drug dependence; Drug abuse; Substance abuse

Definition

Drug addiction represents habitual or chronic use of any chemical substance aimed at altering the state of the mind and body or at avoiding the pain and discomfort in its absence. Drug usage is compulsive despite the physical and/or psychological harm to the user and society. With the course of time, addicts need to increase the dose of the drug they are taking in order to feel the same effect. Addictive drugs include narcotics (e. g. heroin, cocaine), many types of sedative and tranquillizer, and nicotine. Psychological dependence is the subjective feeling that the user needs the drug to maintain a feeling of well being; physical dependence is characterized by tolerance (the need for increasingly larger doses in order to achieve the initial effect) and withdrawal symptoms when the user is abstinent. Nowadays, the term "substance abuse" is more often used than "drug addiction" because of the broad range of substances (including alcohol and inhalants) that can fit the addictive description.

Cross-References

Drug Law

PASQUALE DI MATTIA
CEFPAS - Centre for Training and Research in Public Health, Caltanissetta, Italy
lino-dm@libero.it

Synonyms

Drug; Medication; Medicament; Medicine; Remedy

Definition

Many sensitive ethical, financial and medical aspects are involved in the use of medicines; as a result, the law, based on consumer protection principles and on criteria relating to quality, safety and efficacy, has provided specific rules and regulations.

Basic Characteristics

From the beginnings of civilization people have been concerned about the quality and safety of foods and medicines. In 1202, King John of England proclaimed the first English food law, the Assize of Bread, which prohibited adulteration of bread with such ingredients as ground peas or beans. Regulation of food in the

United States dates from early colonial times. Federal controls over drug supply began with the inspection of imported drugs in 1848. The Food and Drug Administration (FDA) has been in place in the USA since 1930, though it was only with the "Food and Drug Administration Act" of 1988 that FDA was officially established as an agency of the Department of Health and Human Services with a Commissioner of Food and Drugs appointed by the President, with the advice and consent of the Senate; the Act broadly spelled out the responsibilities of the Secretary and the Commissioner for research, enforcement, education, and information.

One of the main factors which has influenced the new biomedical approach to diseases is the discovery of an incredible number of drugs, both, derived from nature and produced in laboratories. Most of the pharmaceutical industries are private, therefore, when dealing with drug issues a very important factor to be considered is the financial one; yes, there are obvious medical needs for new and better pharmaceutical products, yet the development of these products can take, and make, substantial amounts of money. As a consequence, ethical, medical, financial and social concerns are involved in all phases of drug use: from drug development, to pricing, to availability, to prescribing, to advertising. It is thus understandable why drugs are, of all consumer products, the most extensively regulated by law.

Developing a new drug involves investments of hundreds of millions of dollars, of which around 60 per cent is spent in ► clinical trials; the full development process takes 10–12 years. New medicines are selected from a range of many thousands of substances with the potential to treat the targeted condition. Fewer than one or two compounds in 10,000 tested actually make it through the process and are eventually authorized for use in patients. A potential new medicine may be rejected at various stages in the development process on safety, efficacy or quality grounds.

A new medicine arises from a series of pre-clinical tests, using techniques which identify potentially beneficial new compounds, like computer modeling, high-speed computer technology and tissue culture studies; it is then tested in a series of scientific studies using animals before any trials involving humans. In the search to understand, prevent and treat disease, clinical trials involving healthy volunteers and patients play an essential role. Their aim is to evaluate new medicines or a combination of medicines, as well as other types of therapies, to determine their potential benefits and safety.

Having decided clinical development is justified, clinical researchers will need to develop protocols for the necessary trials. A protocol is a study plan which is not only designed to answer specific research questions but also has the safety of participants in mind. Used as the basis for all clinical trials, protocols also determine:

- Who can participate.
- The schedule for tests, dosages and other details of the study.
- The trial duration.

Once the protocol has been established, a trial then needs physicians to carry out the study, always monitoring and caring for the patients involved.

A new medicine has to demonstrate its safety, quality and efficacy through a series of rigorous clinical trials in order to obtain a license (called a marketing authorization) and be available to the general public. Clinical trials consist of four phases: the first three occur before a license is granted and the last is conducted as a post-licensing phase. Each phase varies in size, character and focus:

1 *Phase 1* primarily determines how a medicine works in humans and helps to predict the dosage range for the medicine, and involves healthy volunteers.
2 *Phase 2* tests efficacy as well as safety among a small group of patients (100–300) with the condition for which the medicine has been developed.
3 *Phase 3* involves a much larger group (1000–5000) of patients which will help determine if the medicine can be considered both safe and effective.
4 *Phase 4* trials are conducted after a medicine has been granted a license. In these studies a medicine is prescribed in everyday health care environments which allows results to be gathered from a much larger group of participants. Safety is a major part of Phase 4 trials, which often involve several thousand patients so that more rare side effects, if any, may be detected.

Participants can only take part in a clinical trial on a voluntary basis. Additionally, these volunteers – whether they are healthy participants or patients – can only participate in clinical trials if they have given their ► informed consent and have confirmed that they have received and fully understood information about the trial. They are also free to withdraw from a trial at any time without prejudice to their continuing care.

Throughout the process, data is collected and recorded for analysis to evaluate patients' responses; however, only the investigators and their teams know the identities of the patients; the sponsoring company will only have patient code numbers to bring all the individual patient data together (► coded data). To make sure that data acquisition (► data acquisition and protection) will not contravene ► privacy and ► confidentiality, data protection (► data acquisition and protection) laws are applied.

Pharmaceutical physicians are essential members of the team working throughout the timespan of a therapeutic intervention, from the discovery research phase, through preclinical and clinical testing, licensing, launching, post-marketing studies and ► surveillance, any new formulation and new indications work, or through to its eventual demise on the grounds of lake of relative safety and ► efficacy or commercial non-viability. They should recognize their ethical responsibility to stand aside from product loyalty when assessing factors affecting the product itself. ► Ethical principles regulating physicians' activities are well outlined in various guidelines at national and international levels (► ethics, aspects of public health research), based on ► professional ethics, ► bioethics, etc.

► Ethical committees review and advise on whether proposals for research studies meet required ethical and scientific standards. These reviews are designed to protect people participating in studies. Many ethical and legal issues can be involved. A few examples are:

- the recruitment of subjects should be exempt from coercion, that is, subjects should not feel as though they cannot refuse to participate;
- involvement of ► vulnerable groups or individuals requires extra precautions;
- trials are increasingly conducted around the world, in order that greater numbers of patients and different ethnic groups can be included in a study; however, some more ethical considerations get added in ► international research, whereby we also have to deal with problems raised by the local culture (► ethics and culture) (language, beliefs, social values, relationship between individuals and communities) and by religious aspects, all components which may affect the meaning and the role of informed consent and autonomy, ► beneficence and ► non-maleficence, and of ► justice;
- most trials will make some sort of comparison between medicines or treatments; this means that in many clinical trials, while one group of patients will be given an experimental medicine or treatment, a control group is given either an existing standard treatment (comparator) for the illness or a ► placebo (a dose that looks like the medicine being tested but, in fact, contains no medical ingredients); placebos may be ethically justified when no adequate, proven prophylactic, diagnostic or therapeutic method exists, and the temporary withholding of an effective treatment would not expose the subjects to serious risk and there is no added risk of long-term harm.

Ethics committees are completely independent of industry and are at liberty to reject a clinical trial.

A great deal of detailed legislation now covers all industrially produced medicines, (including vaccines, toxins or serums and allergens, blood products, radiopharmaceuticals and medical devices) and some specific issues, such as animal and human research, self-medication, controlled substances, alternative medicines, orphan drugs, veterinary drugs, the manufacture of generic drugs, the use of contraceptives and abortive drugs, and the patenting of biologic materials.

Based on consumer protection principles, in addition to criteria relating to quality, safety and efficacy, legislation has also provided rules relating to:

- procedures for marketing authorization (time limits, giving of reasons, publication);
- manufacture (quality control and inspections concerning also the application of principles of good laboratory practice);
- labeling (packaging to include information relating to dose, ingredients, side effects);
- advertising of medicinal products.

Specifically on the last point, a very debated issue concerns laws on "Direct to consumer ► advertising" (DTCA). In general, the unnecessary use of drugs is one of the main problems in the field of health. Using unnecessary pharmaceuticals, not using necessary pharmaceuticals and using the necessary medication over the wrong period of time are examples of the inappropriate use of pharmaceuticals. It is stated that more than 50% of drugs are inappropriately prescribed, distributed or sold throughout the world, and that nearly half of this medication is then incorrectly used. In various countries, the ethical criteria suggested by the World

Health Organization in 1988, which emphasizes that prescribed drugs are not to be advertised to the public, still remains in effect. However, as the share of drug expenses have increased within the total health expenses of most countries, the institutions, employers and insurers who reimburse drug purchases have recently started to set limits on these expenses; restrictions on the prescriptions of physicians have been the easiest and the most frequently used method of imposing such limits. This situation is one of the important reasons which led drug companies to implement new advertisement strategies in terms of DTCA.

The Internet is an important factor in spreading knowledge about health issues to the public. For instance, 25% of information on the Internet in the USA is associated with health, and more than half of adults using the Internet make use of it to acquire information concerning health issues. Some of these Internet users, on the basis of gained knowledge, have later obtained certain drugs from their physicians. However, it is estimated that there are more than 300,000 Internet sites related to the sale of all kinds of pharmaceuticals. And, although drug companies would like to demonstrate responsible DTCA by claiming these sites are a form of educational activity, often they are actually more of a commercially, sale-based activity. In such cases, public-oriented drug advertisements play on the general public's poor knowledge and education in health; and these advertisements can have a significant effect on increasing unnecessary drug consumption, with consequent increasing drug expenditures and risk of adverse drug effects. Although these aspects are of importance in the developed countries, it is in the developing countries that their negative consequences have a major impact; not only do rising pharmaceutical costs drain health services in particular and the economy in general, but also records of side effects are often inadequate and insufficient.

It is the duty of public health institutions to counteract DTCA by providing adequate health education for the rational use of drugs.

For some decades, the wide range of the above-mentioned policies and laws have been felt mostly at nationwide levels, since drug approval policies are strictly linked to national health policies and the related budgets. Recently, more and more efforts have been made to standardize the most important drug laws worldwide. For example, The Food and Drug Administration (FDA) has been doing so in the USA, while as from 1994 the European Commission has established the European Medicines Evaluation Agency (EMEA) in an endeavor to harmonize member states' national drug policies.

At an international level, ► globalization has also influenced the drug market, calling for efforts to promote the standardization of drug approval policies and procedures. A very important step in this direction has been the work of the International Conference on Harmonization of Technical Requirements for the Registration of Pharmaceuticals for Human Use (ICH). The ICH, constituted by regulatory authorities and the representative pharmaceutical industry groups from Japan, Europe and the US, has set guidelines on the processes involved in clinical trials on medicines, based on the principles of good clinical practice (GCP). One of the aims of the Conference is to facilitate the mutual acceptance of data on clinical trials, thus reducing significantly the costs of drug development.

As a consequence, at this stage, all clinical trials must be performed in line with ICH GCP principles or they will be rejected by the regulators.

Drugs

Synonyms

Pharmaceutical products

Definition

Drugs are substances and mixes of substances that are developed to cure and improve the health status of ill people. Drugs are developed by researchers within the pharmaceutical industry and distributed through pharmacists and hospitals. According to their active ingredients drugs are classified into 'RX drugs' which are available only upon prescription and 'over the counter drugs' which can be purchased in pharmacies without any prescription. Over the counter drugs may in some countries also be purchased in supermarkets and drugstores. Each country regulates the dispensation of drugs, i. e. which drugs are available only with prescriptions and which ones are available over the counter. 'RX drugs' are in general reimbursed through health insurance but over the counter drugs have to be paid for by the patients. The reimbursement of drugs often includes a prescription charge which is a small part of ► co-payment by the patient depending on the specific contract of the health insurance.

Drug Safety Studies

Definition

Drug safety studies are designed to investigate the safety and efficiency of drugs. ► Observational studies, frequently used for this purpose, evaluate drug safety in a large number of patients in a real-world setting, where practice patterns, including off-label use, can be assessed. Such studies have a limited ability to determine causation, but they can detect signs that may suggest a safety concern. On the other hand, randomized controlled trials provide robust data on drug safety but may be subject to multiple sources of bias.

Drug Utilization Studies

Definition

Drug utilization studies are designed to improve rational drug use in populations and provide data for cost-benefit analysis. Various methodologies can be employed in drug utilization studies and numerous drug databases are available for drug utilization research. WHO defines drug utilization studies as involving marketing, distribution, prescription and use of drugs in a community, where special attention has been paid to medical, social and economic implications.

Dysfunctional Family

Definition

A family in which the relationships and/or communication is impaired such that the family cannot provide closeness and/or autonomy for its members. Often results in symptomatic behavior by one or more family members.

Dysfunction, Craniomandivular

Synonyms

Craniomandibular disorder

Definition

Dysfunction means deviations from normal function. In dentistry, common dysfunctions are related to the temporomandibular joint and the jaw muscles. Signs and symptoms for dysfunctions comprise, for instance, abnormalities during mouth opening, certain joint noises, tenderness of the temporomandibular joint or muscles on palpation, and parafunctional activities such as clenching or grinding.

Dysthymia

Synonyms

Depressive neurosis; Persistent anxiety depression; Depressive personality disorder; Neurotic depression

Definition

Dysthymia is a chronic depression of mood, lasting at least several years. However, this chronic depressive mood is not sufficiently severe, or individual ► depressive episodes are not sufficiently prolonged, to justify a diagnosis of severe, moderate, or mild ► recurrent depressive disorder.

Eating Disorders

MICHAEL LINGEN
University of Göttingen, Göttingen, Germany
mlingen@gwdg.de

Synonyms

Anorexia; Anorexia nervosa; Atypical anorexia nervosa; Bulimia; Bulimia nervosa; Atypical bulimia nervosa; Binge-eating disorder; Vomiting associated with other psychological disturbances; Psychogenic vomiting; Overeating associated with other psychological disturbances; Psychogenic overeating; Psychogenic loss of appetite; Pica in adults

Definition

We talk about an eating disorder if an abnormal eating behavior represents the main symptom of a psychological disorder. It is not just a "bad habit", but a disorder that is associated with severe psychosocial limitations (e. g. thoughts, feelings and activity focusing on food-related issues), increased mortality, physical complications (e. g. cardiovascular problems and renal insufficiency) and psychiatric symptoms like episodes of depression. An eating disorder is a complex compulsion to eat in a way that disturbs mental and physical health as well. The eating may be too limited (i. e. restricting) or excessive (i. e.compulsive, over-eating); it may include normal eating punctuated with episodes of purging or cycles of binging and purging. The three most common eating disorders are ► anorexia nervosa, ► bulimia nervosa, and binge eating disorder.

Basic Characteristics

History

Anorexia nervosa has been described in detail as early as in the 19th century and bulimia nervosa in 1978. The concept of binge eating disorders is relatively new, introduced to the classification systems only in 1990.

Anorexia Nervosa

According to the DSM-IV (Diagnostic and Statistical Manual of Mental Disorders, published by the American Psychiatric Association), the leading symptom of anorexia nervosa is a body weight of 85% of that expected or, according to ICD-10 (International Statistical Classification of Diseases and Related Health Problems) a ► body-mass-index (BMI = weight [kg]/height^2 [m^2]) at or below 17.5. Further characteristics are a distinct fear of weight gain despite being under-

weight, a distorted body image with regard to shape and weight or their disproportionate importance for the self-evaluation, as well as an amenorrhea. The disorder of the body scheme manifests itself in a distorted body perception in which one's own body is perceived as being not thin or even as too fat despite being underweight. This perception is accompanied by a disorder of visceral processes, so that hunger, satiety and the emotions associated with them can no longer be correctly identified. The aspired weight loss is mainly achieved by avoiding high-caloric food, self-induced vomiting, laxative and diuretics abuse and excessive exercise. The above-mentioned amenorrhea is mostly a consequence of weight loss or the ensuing reduced production of the hormone estrogen. Furthermore, the classification systems specify two types of anorexia nervosa, the restrictive type without active measures to reduce weight and the "purging" type which uses active methods to reduce weight.

Even though individual symptoms of an abnormal eating behavior, like restricted eating or bouts of binge eating, are frequent phenomena with women in adolescence or young adult women, the complete clinical picture of an anorexia nervosa is far more uncommon. The prevalence of anorexia nervosa for young women between 14 and 20 years of age range is, depending on the study, between 0.2 and 0.8%. The majority of these disorders is diagnosed before the age of 25. The ratio of women to men is 10 : 1. Though individual studies suggest an increase of eating disorders, there is also evidence to the contrary. Recent studies, however, accept an overall increase (Pawluck and Gorey 1998).

As with the majority of psychological disorders, eating disorders are assumed to have multiple causes. These could be complications during pregnancy and birth (e. g. genetic factors, gender, premature birth) as well as risk factors during childhood (e. g. early health problems, conflicts around eating and meals) or youth (e. g. early onset of puberty, diet behavior). The individual cause can usually be found within this framework, but not all of these factors have to play a role in an individual case. Apart from the predispositions and risk factors mentioned above, a comprehensive model will also have to consider familial, socio-cultural and biological factors.

In clinical practice, different elements of therapy are combined to treat anorexia nervosa. Even though nowadays there are a number of successful therapeutic approaches available, the prognosis for anorexia is still rather unfavorable. For mainly short-term results, behavior-therapy intervention to increase body weight and alter the distorted body perception has proved effective. For adolescence, a therapeutic method involving the family seems to be the method of choice. Medications can at best be used to stabilize a previously accomplished change and should be limited mainly to female patients with distinct symptoms of comorbidity.

Bulimia Nervosa and Binge Eating Disorder

► Bulimia nervosa is characterized by bouts of binge eating and counteracting behavior like vomiting or use of laxatives. During binge eating attacks, excessive quantities of food are consumed over a very short time. These binge eating episodes are accompanied by a feeling of lack of control, often preceded by feelings of tension, fear, boredom or loneliness. The bouts of binge eating can relieve these negative emotions short-term, but often generate feelings of shame, guilt and self-hatred. Self-induced vomiting is frequently used as a means of compensation. The use of laxatives is less frequent. As with anorexia nervosa, patients are preoccupied with weight, shape and food. The majority of patients with bulimia nervosa have a normal body weight; overall, the diagnoses describes a group of patients with normal weight or overweight with a high intensity of episodes of binge eating and compensating behavior.

Patients with binge eating disorders show bouts of binge eating, but lack a consistent compensating behavior. Most people with binge eating disorders are overweight and show a considerable amount of stress and psycho-social impairment. The patients suffer from their eating behavior, their weight and the failure of their purely dietetic approaches.

The prevalence of bulimia nervosa in western countries is estimated to be 1–2% for young women and 0.2% for young men. Studies regarding lifetime prevalence resulted in 1.1% for women and 0.1% for men. Even though some studies report a drastic increase also for bulimia nervosa, there is not sufficient evidence to indicate an increase in the number of cases (Fairburn and Beglin 1990; Garfinkel et al. 1995; Sullivan et al. 1998). The prevalence for binge eating disorders among adult women is 3% and 1% among men. Though eat-

ing disorders can be found in all cultures researched so far, bulimia nervosa is mainly found in western industrialized countries, and here mainly among competitive athletes, ballet dancers and people in the fashion business. Patients with bulimia nervosa and binge eating disorders often show a number of other disorders like depression, obsessive-compulsive disorders, anxiety disorders, substance abuse and personality disorders.

Models for the etiology of bulimia nervosa and binge eating disorders have to take into consideration similar elements as the models for the causes of anorexia nervosa; there is, however, the problem that the exact etiology factors for these eating disorders are unknown. The main risk factors seem to be an interaction between biological adjustment processes which are intensified by diets, cultural pressure on women to be thin, and a dysfunctional evaluation process regarding shape, body weight and nutrition, often in combination with a restrictive eating behavior and lack of physical activity.

The prognosis for the therapy of bulimia nervosa and binge eating disorders is more favorable than the one for anorexia nervosa. Psychological intervention is usually in line with cognitive behavioral therapy. Information about the disorder and its therapy, control of food-related behavior and behavior related to physical activity, identification and change of dysfunctional assumptions and evaluations of shape, body weight and nutrition are important elements. Drug treatment mainly involves selective serotonin re-uptake inhibitors (SSRIs) and tricyclic antidepressants. The use of SSRIs requires a higher dosage than for the treatment of depression, though, and the effect of a combined treatment with psychotherapy and medication is not superior to a solely cognitive-behavioral therapy.

EBM Literature Guides

Definition

The guideline-based approach to healthcare is a relatively recent one and originated in the United States in the 1990s. Guidelines are usually produced at national or international levels by medical associations or governmental bodies. A medical guideline (also called a clinical guideline, clinical practice guideline, or clinical protocol) is a document that has the aim of guiding decisions and criteria in specific areas of healthcare, as defined by an authoritative examination of current evidence. Clinical guidelines briefly identify, summarize,

and evaluate the best evidence and most current data about prevention, diagnosis, prognosis, therapy, etc.

Ebola Disease

► Ebola Hemorrhagic Fever
► Infection with Ebolavirus

Ebola Fever

► Ebola Hemorrhagic Fever
► Infection with Ebolavirus

Ebola Hemorrhagic Fever

Synonyms

Ebola disease; Ebola Fever; Infection with Ebolavirus

Definition

Ebola hemorrhagic fever is an acute viral illness caused by the Ebola virus which belongs to the Filovirus group. It is transmitted from person to person by direct contact or by drops through mucous membranes or indirectly by infected blood, secretions, semen and vomit. The reservoir of the infection is unknown and therefore it is difficult to evaluate the risk of transmission. Fatality rate is 50–80%. Symptoms are acute fever, diarrhea (often bloody), nausea, vomitting, headache, and, at a later stage, nosebleeds, conjuctival infection, dysphagia, and affection of central nervous system. The implementation of control measures may be difficult due to cultural reasons such as the custom of eating primate meat.

Echinococcosis

Synonyms

Hydatid disease; Infection with fox tapeworm; Infection with fox tenia; Infection with dog tapeworm; Infection with dog tenia; Infection with Echinococcus granulosus; Infection with Echinococcus alveolaris; Infection with Echinococcus multilocularis

Definition

Echinococcosis is caused by the ingestion of larvae of the dog tapeworm or the fox tapeworm. While the dog tapeworm (*Echinococcus granulosus*) is found worldwide, the fox tapeworm (*Echinococcus alveolaris* or *Echinococcus multilocularis*) is only present in the northern hemisphere. As humans are intermediate hosts, the larvae do not develop into adult worms, but stay at the larval stage. These larvae can settle in different organs. In infection with the dog tapeworm, the liver is concerned in 60–75%, settlement in the lungs, the brain, the kidneys and the spleen are possible. Due to the formation of fluid filled cavities (cysts), a feeling of pressure and pain is caused, in an infection of the lungs difficulties in breathing and cough occur. The fox tapeworm is predominantly found in the liver and the lung; the brain is seldom involved. Dense, knotty parasitic tumors develop, which cause pain and icterus in advanced stages of the infection. Without treatment, infection with the fox tapeworm often takes a lethal course. Treatment of echinococcosis is surgical intervention; in fox tapeworm infection an additional perioperative medicinal treatment is recommended. If an operation is not possible, long-term therapy with mebendazole is necessary. Prophylactic measures involve regular worming treatments of domestic animals. Moreover, contact with foxes and other wild animals should be avoided. Prior to the ingestion, wild berries and other free growing foodstuff should be washed thoroughly.

ECHTA

Definition

The ECHTA project (European Collaboration for Assessment of Health Interventions) – funded by DG V (Directorate General of the European Commission) – is coordinated by a research team at the SBU in Stockholm; all European HTA agencies participate in one of the working groups of the ECHTA project. It is the general aim of the ECHTA to strengthen coordination and cooperation of all kinds of HTA activities on the evaluation of health interventions. The main focus of ECHTA is to strengthen the structures of exchange of HTA knowledge.

Ecological Association

Definition

An association between a risk factor and a health outcome not at the level of individuals but of populations is called 'ecological'. For example, researchers in an ecological study may estimate the average salt consumption in a country and also obtain the average blood pressure of the population. If both are high, they have demonstrated an ecological association (i. e., one at population level) that may or may not hold at individual level – it could be that those individuals who consume the highest amount of salt also have the highest blood pressure, but the opposite could be the case as well. Only a study obtaining data for salt consumption and blood pressure at individual level could answer this question.

Ecological Health Promotion

Definition

The term 'ecological health promotion' refers to the close ties between human health and the environment as interdependent and mutually interacting systems. In contrast to 'ecological disease prevention', which aims at reducing and eliminating hazardous substances and pathogens from the environment, ecological health promotion tends to take a more positive stance by tapping into maintaining, restoring and strengthening the health-promoting resources in the environment. Accordingly, ecological health promotion comprises strategies and disciplines which contribute to promote and shape environmental and living conditions (e. g., in the context of ► environment-related health protection).

Ecological Study

Synonyms

Correlation study

Definition

An ecological study is a study in which data of average exposure and outcome for a population are compared with similar data for other populations in order to look for associations between the exposure and the outcome. Group-level study may also be the only way to study the effects of group-level constructs, such as laws (e. g., the impact of a seatbelt law) or services (availability of a suicide prevention hotline).

Ecological studies are fairly quick and easy to perform and they are useful for hypothesis generation. However, they do not allow causal conclusions to be drawn since the data are not associated with individual persons and are not good for hypothesis testing.

e-Commerce

Definition

e-Commerce describes the process of business transactions in health care. The goods that are sold this way refer to information, pharmaceuticals, and health services.

Economic Analysis in Toxic Substances Control

Synonyms

Economic benefits

Definition

In toxic substances control, an economic analysis of cost-benefit is required. In response to the escalating costs of hazardous waste cleanup and other consequences of pollution, the pollution prevention hierarchy was set out. As a rule, it is cheaper and smarter to reduce pollution at the source.

Prevention activities of pollution control save resources and contribute to the rationalization of medical care in the public health system. Benefits include:

- reduced incidence of unintentional, intentional, and occupational poisoning at the workplace, in the home, and in the outdoor and indoor environment
- early detection and elimination of unusually hazardous commercial products through regulatory measures, repackaging, or reformulation.

Economic Evaluation

► Health Determinants, Economic
► Health Economics in Dentistry

Economic Evaluation of Health

Definition

Economic evaluation of health is a "comparative analysis of alternative courses of action in terms of both their costs and consequences" (Drummond 2005). Such analyses can be set within the context of a randomized control trial or other health research study design, or can be undertaken through decision analysis modeling approaches.

Economic Growth

Definition

Economic growth is the increase in value of the goods and services produced by an economy. It is conventionally measured as the percent rate of increase in real gross domestic product (GDP). Growth is usually calculated in real terms, i. e. inflation-adjusted terms, in order to net out the effect of inflation on the price of the goods and services produced.

Economic Measures

DOREEN MCBRIDE[1], FRANZ HESSEL[2]
[1] Institute for Social Medicine, Epidemiology and Health Economics, Charité Universitätsmedizin Berlin, Berlin, Germany
[2] Health Economics Outcomes Research, Sanofi-Aventis Pharma GmbH, Germany, Berlin, Germany
doreen.mcbride@charite.de, franz.hessel@sanofi-aventis.com

Definition

Economic measures are the means by which health care costs and benefits are quantified and valued for use in economic evaluations. For the scientific analysis of economic aspects of health care programs, a number of specific measures are used. For economic evaluation studies, the cost and the outcome are measured. This essay gives a brief overview of the means by which costs and outcomes can be quantified.

Basic Characteristics

The purpose of economic evaluation of health care programs by programmatic decision-makers is to provide estimates of the relative merit or value of alternative measures in order to aid decision-makers in the distribution of assets to achieve objectives.
In conducting a health economic evaluation, the four main steps involve:

1. Quantifying the total costs of care incurred by the therapy, which provides the numerator in the cost/outcomes ratio
2. Quantifying outcomes of the therapy, which provides the denominator in the ratio
3. Assessing whether and by how much costs and outcomes differ
4. Comparing the magnitude of differences and outcomes in a ratio.

In this essay, the first two steps will be addressed by describing the means by which costs and outcomes can be quantified.

Quantifying Total Costs Incurred by the Therapy

There are three parts in quantifying the cost of care (► costing process). First, the costs to be included in the analysis must be identified through a probability tree of the therapeutic pathway that describes all relevant downstream events (CCOHTA 1996) (► costing process: identification of relevant resource use). Secondly, the resources used should be measured and quantified (► costing process: measurement of resource use). The

third aspect of quantifying the cost of care is establishing the unit costs of these resources (► costing process: valuing). These should be reported separately from the quantity of resource utilization, in order to establish the relevance of these factors to the setting.

Evaluating costs from a societal viewpoint, the main direct cost categories are those arising from the health care sector, resource use by the patient and family, social services costs, and spill-over costs on other sectors such as education. These are in addition to the indirect costs of lost time and productivity. Estimates of resource quantities should be based on data from real patients, collected either prospectively or retrospectively from medical records. Such sources provide accurate data on resource utilization with minimal burden to patients but require patient consent and/or patient questionnaires, which provide the highest level of detail possible, but are costly and subject to recall bias.

Quantification of Direct Costs

Direct health care costs (► direct cost) fall into three main domains: inpatient, outpatient, and other disease-related costs (Mittendorf 2003). Care must be taken to avoid overlapping and double-counting services such as diagnostic tests conducted during physician visits that are aggregated in the cost of the visit. Additionally, the cost of capital equipment purchased or used for the program or intervention should be discounted for depreciation.

To evaluate inpatient costs, the following utilization of resources should be documented: hospital facility costs, including surgery, physicians, nursing, and radiology, as well as overhead costs of the hospital; diagnostic measures; drugs; and rehabilitation and nursing home costs, as well as overhead costs of the hospital.

For the documentation of outpatient costs, the quantity of the following services can be included: physician visits (general practitioner and specialists), outpatient surgery, physiotherapy, occupational therapy, psychological counseling, drug expenses, diagnostic tests and therapeutic procedures, emergency room visits, and aids and devices.

Other disease-related costs can include transportation, such as ambulance services, taxi, and vehicle costs; home health care services, such as district nurse visits and community services; home remodeling; alternative medicine costs and out-of-pocket payments, including co-payments, and over-the-counter drugs; additional public transportation; disease-related payments not covered by insurance; and expenses incurred by relatives involved in caring for the patient.

Valuation of Direct Costs

Direct costs can be valued by three alternative costing methods, depending on how accurate or precise the cost estimates need to be within a given study: micro-costing, unit costing, and Gross costing. A major factor is the quantitative importance of each cost category in the evaluation, where a more detailed costing of the items which have the greatest impact on the study results is usually required.

Micro-costing (i. e. time and motion) provides very precise estimates and enables the detection of differences between various severity levels, but is costly. Unit costing also provides a precise estimate and enables the detection of small cost differences between groups but can be impractical if the individual cost data are overly burdensome to collect. Gross costing can be used when large differences in costs are expected. In this approach, cost estimates are more readily available and easier to apply than cost estimates of individual elements but subtle cost differences may not be detected.

The valuation of resource items is very dependent on the availability of local financial data. Nevertheless, general data sources for valuation are available, including patient bills, which render an accurate account of the patient's encounter with the health care system, and data from administrative databases, which provide real-world data for patients in clinical practice. These eliminate the need to collect resource utilization and cost data separately, but also contain charges that do not reflect the actual cost of the service given or are subject to various biases associated with who is treated.

Quantification and Valuation of Indirect Costs

The inclusion of ► indirect costs that are due to productivity loss is an essential part of costing in an economic evaluation from a societal perspective. Nevertheless, some methodological aspects remain controversial. For further details, refer to the essay about ► cost of illness and the costing process, where the different approaches for quantification of indirect costs are described (► human capital approach, ► friction cost method).

Discounting

Future costs are discounted to reflect the fact that individuals and society in general have a positive view of ► time preference. People prefer desirable consequences (such as benefits or delayed expenditures) to occur earlier and undesirable consequences (like costs) to occur later. Therefore, future costs are discounted to reflect the preference of having them occur in the future. The discounting of benefits remains controversial. On one hand, to maintain consistency in the evaluation, future benefits can be discounted to reflect the fact that they are worth less, simply because they occur in the future rather than the present. This also allows for consistency in the comparison of health care projects in the overall allocation of resources. On the other hand, discounting life-years in the future give less weight to future generations in favor of the present one. However, the argument for discounting has become increasingly strong and it is important that all studies use a common discount rate for comparability across studies, no matter how controversial the actual rate may be. Currently, a 3–3.5% discount rate for both costs and benefits is recommended (including an allowance for inflation) but variations of this rate (e. g. 0% to 5%) should be undertaken in sensitivity analyses, varying the rate for both costs and consequences.

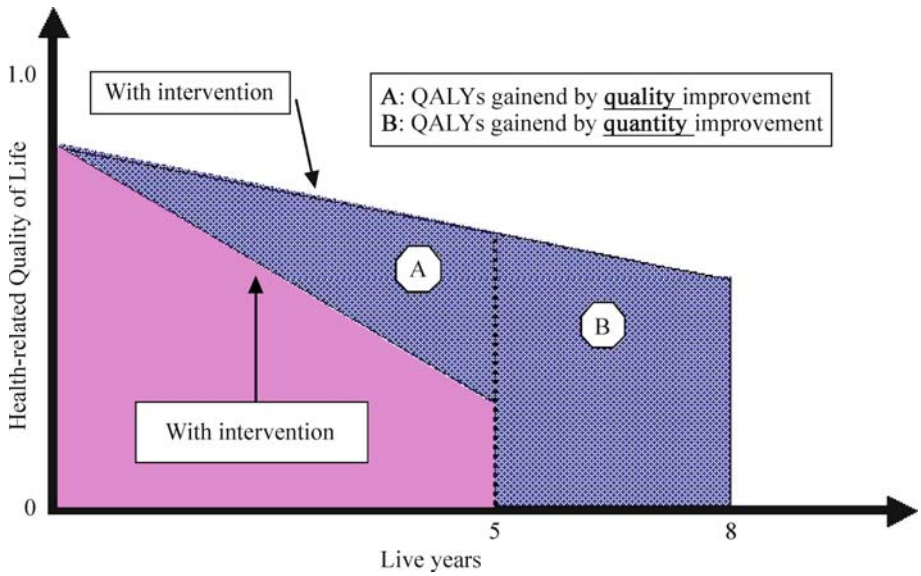
Quantifying Outcomes of the Therapy

Benefits can be defined in monetary terms or as clinical outcomes in natural units. Monetary outcomes, used in a cost-benefit analysis, include concepts such as resources saved by the intervention, the individual's ► willingness-to-pay (WTP) additional amounts for the program, or their willingness-to-accept (WTA) compensation for the removal of a program. Examples of clinical outcomes for use in cost-effectiveness analyzes include number of lives saved or adverse events avoided, or can be preference-based, with utility measurements of health-related quality of life (in a cost-utility analysis).

Quality-Adjusted Life Year

Cost-effectiveness analyzes require the selection of relative clinical outcomes. There is a wide variation in what can be selected, from events or cases averted, to changes in quality of life, to years of life gained. Examining only the years of life gained overlooks the effect that treatments may have on a person's quality of life. To overcome this deficiency, and in order to compare program across populations, diseases, and interventions, combining the duration of life with health-related quality of life into the single summary utility measure known as ► quality-adjusted life year (QALY) has become the method of choice in recent years.

Health state utilities, measured between 0 (death) and 1 (perfect health), are generated over the evaluation period either by specified generic questionnaires, such as the EQ5D, visual analogue scales, or the processes



Economic Measures, Figure 1
Quality-adjusted life years gained from an intervention (adapted from Drummond)

of ► time trade-off or ► standard gamble. Multiplied by the time in that health state, they are then summed to calculate the number of quality-adjusted life years. The difference between the QALY of one intervention and the QALY of another is the incremental benefit received by the intervention (Fig. 1). The number of QALYs gained can also be discounted to adjust for ► time preference.

Accurate quantification and valuation of economic indicators used in the economic evaluation of health care initiatives provide the basis for achieving an accurate appraisal of the value of such programs. Care should be taken to establish the appropriate perspective for the evaluation and to ensure that all costs and outcomes have been identified in the evaluation.

Economic Modeling

► Modeling

Economic Principle

► Minimum Principle

Economies of Scale

Synonyms

Increasing returns to scale

Definition

Economies of scale is a term often used by economists to describe the situation where the cost of producing a good or service decreases when the volume of goods or services produced increases. In other words, an equal percentage increase in all inputs results in a greater percentage increase in output. Economies of scale are especially relevant for industries with a high share of fixed costs. In service industries like the health care industry, fixed costs include costs for medical technology, core administrative functions, and expensive computer systems. Additional size advantages can result from volume discounting with suppliers.

Economies of Scope

Definition

Economies of scope are the benefits that arise from collectively producing multiple, often similar goods or services, instead of doing this separately. The tendency towards joint practices offering different medical specializations in many countries is driven by economies of scope. In the ► hospital sector, it often costs less to provide a range of services in one single hospital instead of having several hospitals offering a smaller range of services; for example, the emergency surgery unit and

treatment of heart attacks should be provided by one single institution instead of being offered separately.

Ecosystem Acidification

► Acid Rain

Ectopic Pregnancy

Synonyms

Heterotopic pregnancy

Definition

An ectopic pregnancy occurs if a fertilized egg implants and develops outside of the Corpus uteri. The most common site is within the Fallopian tube (95%), but implantation may also happen in the peritoneal cavity, the ovary, and the Cervix uteri. A ruptured ectopic pregnancy is a major cause of death in the first trimester of pregnancy. Symptoms of ectopic pregnancy are missed menses or an abnormal episode of bleeding and abdominal / pelvic pain. Early detection of ectopic pregnancy through recognition of symptoms, biochemical markers, and ultrasound technology prevent rupture and complications. Risk factors for the development of ectopic pregnancies are pelvic inflammatory disease and previous interventions in the genital tract: tubal surgery, reproductive techniques, intrauterine device. The recurrence rate is up to 50%.

Effect of an Intervention

► Effectiveness

Effectiveness

Synonyms

Effect of an intervention; Effect measured by impact and output

Definition

Effectiveness is a measure of the extent to which a specific intervention, procedure, regimen, or service, when deployed in the field in routine circumstances, does what it is intended to do for a specified population. It refers to the performance of an intervention in practice. Only a small number of clinical trials set out to answer questions of effectiveness. Assessment of community effectiveness of clinical interventions involves assessment of five components: ► efficacy, diagnostic accuracy, provider compliance, patient compliance, and coverage. Effectiveness is the performance of an intervention under conditions of routine service delivery within the target population. These conditions are frequently less ideal than the study of previous ► efficacy research conditions. The effectiveness may suffer e. g. from low acceptance in the target population, unspecific indications for its application or interference with the physical or social environment. Effectiveness relates to the question whether a health procedure, service or programme *does* work and to the actual usefulness to whom it is offered.

Effectiveness deals with the question "does offering a treatment or an intervention help under ordinary circumstances?", whereas efficacy asks the question "does receiving a treatment work under ideal conditions?". In other words, effectiveness is the capability of a medical intervention to produce an effect. However, it does not inform whether the effect is positive or negative, or compare the given effect to a standard. Contrary to efficiency, the focus of efficacy is the achievement as such, not the resources spent in achieving the desired effect. Therefore, what is effective is not necessarily efficacious, and what is efficacious is not necessarily efficient.

Effect Measured by Impact and Output

► Effectiveness

Effect Modifiers

Synonyms

Moderators of effect size

Definition

An effect modifier is a factor, such as age or disease severity, which alters the effectiveness of an interven-

tion. It is important that these effect modifiers be identified as they may explain apparent differences in the findings of the primary studies included in the meta-analysis. *Effect modification* means that the relation of the exposure and outcome is different depending on which stratum of the effect modifier we are in. Another series of possible "effect modifiers" in meta-analysis relate to study design. If the moderator proves to be significant, the meta-analyst should present an average effect size and confidence interval for each grouping of studies.

Effect Size

Synonyms

Treatment effect

Definition

The effect size is some specific non-zero value in the population. The larger this value, the greater the degree to which the phenomenon under study is manifested. It is convenient to use the phrase "effect size" to mean the degree to which the phenomen present in the population or degree to which the null hypothesis is false. Each effect size index is associated with a particular research design.

Efficacy

Definition

Efficacy is the net health benefits achievable under ideal conditions for carefully selected patients. It is a prerequisite for ► effectiveness and must be evaluated first. An efficacious treatment is one that does more good than harm to those who receive it. Efficacy of treatment can be estimated in randomized control trials.
The performance of an intervention under near ideal, e. g. study conditions. These positive conditions include a high compliance of study participants, a high adherence to the intervention, a standardized indication to begin with the intervention and the control of interferences with the environment. Efficacy relates to the question whether a health procedure, service or programme *can* work.

Efficacy is the ability to produce a desired amount of a desired effect. In a medical context it indicates that the therapeutic effect of a given intervention (e. g. intake of a medicine, an operation or a public health measure) is acceptable; for example, an efficacious vaccine has the ability to prevent a specific illness. In medicine, a distinction is often drawn between 'efficacy' and 'effectiveness'. Whereas efficacy may be shown in clinical trials, effectiveness is demonstrated in practice. The concept of 'self-efficacy' is an important one in the self-management of chronic diseases.

Efficiency

Synonyms

Most economical way of achieving a task

Definition

Efficiency is the capacity of intervention to produce maximum output for a given input. It measures the best possible result of a specific program against utilized resources. In other words, the most economical way of achieving a task.The approach is directed toward policy makers rather than clinicians and reflects several methodological developments. Efficiency is usually used to control increases in cost. This requires an understanding of patterns of treatment, volumes of services, and costs.

Efficiency, Dynamic

Definition

Allocative and technical efficiency refer to a static situation – i. e. efficiency at a given point in time. Dynamic efficiency refers to the development of innovations – increased efficiency of products and processes – over time.

Efficiency Postulate

► Minimum Principle

Efficiency, Technical

Definition

Technical efficiency describes a situation where producers use only those inputs that are technically necessary to attain a given output.

Egalitarianism

Definition

The underlying assumption of egalitarianism is that all persons are of equal moral worth and thus have basic political and civil rights. Egalitarians see equality as a basic value and associate justice necessarily with equality. In their conceptions of justice, some egalitarians favor equality of resources, some equality of opportunity and others equality of capabilities. As opposed to libertarians (► Liberalism and Libertarianism), egalitarians in general tend to strive for equal distribution of wealth within societies.

e-Government

Definition

E-Government refers to the implementation of communication and information technologies in the management of a community, region or state. The similarity with ► e-health is that e-government has the same aim – to provide all users with valuable information, at the right time, in the right place, and in an understandable and applicable form. In addition, one of the main aims of e-government is the improvement of e-Health in a community or state.

e-Health

BRANKO JAKOVLJEVIĆ
Faculty of Medicine, Institute of Hygiene and Medical Ecology, University of Belgrade, Belgrade, Serbia
bra@beotel.yu

Definition

E-Health is the use of the Internet or other electronic media by patients, health workers, and the public, to disseminate or provide access to health and lifestyle information or services. The implementation of e-Health should facilitate communication between population members, health professionals, health insurers and financers, policy providers, and other stakeholders. The primary aim of e-Health is to increase the quality of health services. e-Health encompasses telemedicine, telehealth, and teleconsultation, etc. (Wyatt 2005).

Basic Characteristics

The term e-Health is not easy to define. Revision of 51 definitions revealed a wide range of themes, including health, technology, and commerce, but no clear consensus about the meaning of the term could be identified (Oh et al. 2005). One of the widest definitions describes e-Health as the application of information and communication technologies across the whole range of functions that affect the health sector. e-Health tools do not refer only to Internet-based applications; they include health information networks, electronic health records, telemedicine services, personal wearable and portable communication systems, health portals, and many other information and communication technology-based tools assisting prevention, diagnosis, treatment, health monitoring, and lifestyle management (COM 2004).
The first incorporation of telecommunication systems into curative medicine was ► telemedicine, which is considered the origin of e-Health (Wootton 1996). Later, the concept of telemedicine expanded from the exclusively curative nature of medicine to the preventive fields of medicine, leading to the creation of the concept of ► telehealth (WHO 1997). Another term used synonymously to describe the application of communication technologies for all health-related services is ► health telematics (WHO 1998).

Benefits of e-Health

The implementation of e-Health offers advantages for the health system (► health systems) in several domains (Eysenbach 2001; COM 2004):

1. Benefits for the health sector: e-Health is expected to deliver significant improvements in access to

care, quality of care, and the efficiency and productivity of the health sector (► teleservices, ► telecare). e-Health tools support the aggregation, analysis, and storage of clinical data in all forms; information tools provide access to the latest findings; while communication tools enable collaboration between many different organizations and health professionals. Further progress in medical research, better management and diffusion of medical knowledge, and a shift towards evidence-based medicine are all supported by e-Health.

2. Benefits for health consumers: Both as patients and as healthy citizens, people can benefit from better personal health education and disease prevention. Health consumers today are actively involved in decisions related to their own health, rather than simply accepting knowledge that health professionals present to them, and are therefore proactively looking for information on their medical conditions. Teleconsulting (► teleconsultation) is another example of a method of seeking health information, second opinions, or advice from specialists using telecommunication systems. By making the knowledge base of medicine and personal electronic records accessible to consumers over the Internet, e-Health supports the development of therapy at a distance, i. e. ► teletherapy. All of these disciplines shift the midpoint of medicine from the health services toward the patient, which is known as patient-centered medicine.
3. Benefits for health professionals: e-Health tools and applications can provide fast and easy access to electronic health records at the point of need. They can support diagnosis by non-invasive imaging-based systems, and provide access to specialized resources for education and training. Examples include teleradiology, teledermatology and telepathology; all of which enable health professionals to transfer and access images anywhere.
4. Benefits for health authorities and health managers: Increasing efficiency in health care should lead to a decrease in health costs, by avoiding duplicative or unnecessary diagnostic or therapeutic interventions, through enhanced communication possibilities between health care establishments, and through patient involvement. e-Health systems can empower managers by spreading best practices, and helping to limit inefficient and inappropriate treatment.

Major Challenges for the Implementation of e-Health

The use of the ► Internet and other ► telecommunication strategies for the dissemination of health care and patient-related information is, however, facing some major challenges (Iakovidis 1998; Eng 2001; Podichetty 2003; COM 2004; Wyatt 2005). The proposed problems that need to be overcome in the future are:

- **Organizational issues** – common understanding, concerted efforts and long-term commitment of state authorities, health professionals, consumers, managers, and the community is needed. Only through concerted efforts by all can successful implementation be ensured, with benefits for all expected.
- **Financial issues** – the costs of implementation of a system are divided into investments and ongoing costs. To address this, a study on sustainability of the system must be performed at an early phase. Another question is the payment of health services provided by the system – whether by reimbursement, out of pocket, or insurance; together with the issue of paying health professionals for their services.
- **Technical issues** – in order to assure interoperability of e-Health systems, a thorough standardization of system components and services such as health information systems, health messages, electronic health record architecture, and patient identifying services is of prime importance. Furthermore, e-Health systems and services must be user-friendly, a quality highly dependent on the characteristics of the Internet connection. Practically, it will be difficult to provide similar standards in medical technology and equipment, especially in rural or low-income areas, and to enable interoperability of technology with future developments.
- **Education of professionals and patients** – the educative process should increase knowledge on the applications of the system, and enable judgment of the quality of the health information released on the Internet. This depends on the personal characteristics of the users (comfort using new technology, fears or doubts about technology effectiveness, and acceptance of the e-Health system, etc.) (► health education).
- **Ethical issues** – Security and confidentiality problems usually occur while transmitting information through the system. Sensitive topics include con-

fidentiality and protection of patient data, authentication and authorization of system users, secure transfer and storage of health data, and standards of data quality, etc. The ► e-Health Code of Ethics was developed by the Internet Healthcare Coalition in 2003 to ensure high quality of information on the Internet, protect users' privacy, and respect patients' rights to be informed and to decide if their personal data can be collected, used, or transferred (IHC 2003). The Health Insurance Portability and Accountability Act (HIPAA) has obliged health care providers who conduct financial and administrative transactions electronically to disclose how they use, store, and share health information; ensure patients have access to their medical records; and obtain patient consent before releasing patient information (► ethics, ► consumer protection).

- **Quality assurance** – one of the most important challenges for the e-Health system is quality assurance. Good quality e-Health services reduce delays in seeking appropriate health care, increase knowledge, reduce confusion on health-related issues among users, and promote improvements in consumers' health-related behavior. Criteria applied for quality assurance on the Internet are similar to general quality criteria, including accuracy, completeness, relevance, adequate presentation, usefulness, and privacy and confidentiality (► data quality). In addition to these, technical quality must be provided, referring to speed, browser compatibility, presence of search engines, design of the site, and disclosure of authorship and sponsorship, etc. (► data dissemination and utilization) (Eysenbach et al. 2002).
- **Access for all to e-Health** – the equal access of all groups of society to health services is an important goal in the public health policy field. e-Health can not reach some groups of society, such as isolated ethnic communities, immigrants, the homeless, the elderly, disabled persons, illiterates, the poor, and others who do not have access to computer technology. This phenomenon is referred to as the "digital divide" and is expected to persist even when new technologies become available.

Public e-Health

In the era of prevention, health promotion and evidence-based medicine, the Internet offers many possibilities for multidimensional communication. The Internet is not only a tool for the exchange of scientific information, but also a communication medium. In the field of public health, the Internet offers a chance to put health promotion and prevention onto a higher level, including allowing public access. Public health services can play an important role in providing the population with high quality, relevant and scientifically-based information on issues such as risk factors for non-communicable diseases, healthy life styles, and environmental issues, etc. (► public e-health).

The future applications of e-Health are not easily predictable. There are some indications that e-Health could be implemented in commercial services (► e-commerce), management in health care (► e-government), and the distribution of health receipts (► e-receipts) (Jähn 2004).

Conclusion

The benefits of e-Health for health professionals, health systems, and individual patients will come to light in the future since e-Health offers many opportunities for prevention, promotion, decision making, health care, disease management, and policy making. The issues of quantity, quality, access, equity, and security of information need to be clearly addressed in the future.

e-Health Code of Ethics

Definition

A group of about 100 international experts included in the Internet Healthcare Coalition developed the e-Health Code of Ethics in 2003. The Code obliges organizations and individuals who provide ► health information, health products, or ► health services on the ► Internet to uphold the following eight guiding principles: candor, honesty, quality, informed consent, privacy, professionalism in online health care, responsible partnering, and accountability.

Elderly

► Mental Health in Older Adults

Elderly and Health

► Aging and Health

Elderly Persons

Definition

In medical terminology, elderly persons are those over 50 years of age. With reference to social legislation, elderly and old people are defined by their entry into retirement. Further categories have been developed in accordance with the growing life expectancy. Such categories differentiate, for instance, between the very old (persons over 80 years of age) and the "young" old. This leads to a more accurate identification of the differing needs and demands manifested in elderly or old people and is therefore important for social and health care planning.

Elective Mutism

Definition

Elective mutism is characterized by a marked, emotionally determined selectivity in speaking, such that the child demonstrates a language competence in some situations but fails to speak in other (definable) situations. The disorder is usually associated with marked personality features involving ► social anxiety, withdrawal, sensitivity, or resistance.

Electroencephalogram

Definition

An electroencephalogram (EEG) is a test that measures and records the electrical activity of the brain. Electrodes attached to the head are connected by wires to a machine that amplifies and records the electrical activity inside the brain as a series of wavy lines drawn by a row of pens on a moving piece of paper, or as an image on the computer screen. There are several types of brain waves. Alpha waves have a frequency of 8 to 12 cycles per second and are present only in the waking state when the eyes are closed. Beta waves (13 to 30 cycles per second) are normally found when a person is alert or has taken high doses of certain medications. Delta waves (less than 3 cycles per second) and theta waves (4 to 7 cycles per second) are present only in children or during sleep. An EEG may be done to diagnose epilepsy, brain tumor, Parkinson's disease, inflammation, infection, bleeding, head injury, or sleep disorders, and to confirm or rule out brain death in a person who is in a coma.

Electronic Data Interchange

Definition

Electronic data interchange is the mutual exchange of routine information between businesses using standardized, machine-readable formats.

Electronic Health Record (EHR)

Synonyms

Electronic medical record (EMR)

Definition

In contrast to the traditional paper record, an electronic health record stores electronically all medical information of a patient's past and present ► health status and health care. It can serve the different users in the health care system to obtain quickly up-to-date information about an individual's health and to manage the whole history of a patient's health information. The use of EHR throughout the health care system implies that all providers of health care are equipped with computers and the software necessary to receive, transmit and store the relevant data on the electronic health record.
An electronic health record is a computer-based record system that includes the lifelong summary of a person's health episodes, assembled from summaries of individual electronic patient records and other relevant data. The electronic health record includes something that the ► electronic patient record neglected – the so called "wellness information" – innformation on the patient's state of health throughout their life. This system is accessible online from many separate, interoperable automated systems within an electronic network. Furthermore, the patient can also access and input some information into the system. The advantages of the electronic health record are availability, easy retrieval, access, and transfer of information for different specialists (physicians, nurses, pharmacists, and administrative staff). Electronic records offer many types of organization and presentation of data. The disadvantages of electronic health records are considerable start-up costs (hardware, software, and their upgrade), provision of adequate training for health professionals who use them, and employment of information technology staff for system maintenance.

Electronic Medical Record (EMR)

Definition

These two terms are sometimes used as synonyms. The electronic medical record is considered to be the ancestor of both the ► electronic health record and the ► electronic patient record. An electronic medical record is the digital documentation of each use of the health service by a single person. Therefore, one patient can have as many electronic medical records as the number of times different health services have been used (visits to general practitioner, dentist, and specialist, etc.).

Cross-References

► Electronic Health Record (EHR)

Electronic Patient Record (EPR)

Synonyms

Computer-based patient record

Definition

The electronic patient record (EPR) is a computer-based clinical data system designed to replace ► paper-based patient records. It includes a complete record of all the health-related information of a person, including data on dental and psychiatric visits. This means that the electronic patient record combines all of the existing electronic medical records of one patient. On the other hand, unlike electronic health records, the EPR is accessible from a single, automated provider-based system (e. g. a physician's or hospital's system), but data confidentiality and security must be provided.

Elimination

Definition

Elimination is the excretion of (pharmacological) substances from the body.

Embargo

Definition

Embargo is a legal term depicting an instrument attributed to the realm of trade law. Embargo describes import and export restrictions for products and goods from and to defined countries. An embargo may be limited to a defined group or category of products or limited to a specific country or area. Embargos are often used as a means of political sanctioning of certain countries. They can also be released based on health and safety reasons.

Embodied, Embodiment

Synonyms

Incarnate

Definition

Discussions about people can become quite abstract. People can be thought of as sharing universal characteristics without distinction or regard for the particulars of their lives and the histories of the other people with whom they share their living. The concept of embodiment seeks to redress this imbalance. It reminds us that there are environmentally conditioned physiological limitations that shape how people perceive and relate to their environments and others; they even shape our consciousness of ourselves. The term can help us avoid the other extreme of thinking that consciousness is *merely* the epiphenomenon of material processes. We might say that humans are embodied psychosocial beings who are more or less embedded in social structures that afford or deny a means of making a way through life and cultural systems that engender or destroy shared ways of making life meaningful in our particular environments. Others would extend embodiment to include a spiritual dimension as well.

Emergency Care

Definition

Emergency care is a medical service for the treatment of acute symptoms of illness or injury that are life threatening. Medical conditions requiring emergency care are generally sickness or injury of an advanced degree of severity in which urgent medical care is necessary to preserve the person's life or bodily functions. Emergency care is generally delivered in hospitals or specialized emergency ambulances.

Emergency Contraception

Synonyms

Post-coital contraception; Morning-after-pill" (colloquial)

Definition

By definition, emergency contraception (EC) does not constitute a termination of pregnancy (abortion). According to the moment in time within the menstrual cycle when the drug is taken, EC inhibits or delays

ovulation or tubal transportation of the sperm. The most common method is the intake of hormones within a few hours or up to 5 days after unprotected intercourse. Mechanical post-coital contraception comprises the insertion of an intrauterine device after unprotected intercourse. Availability of EC has the potential of preventing unwanted pregnancies. Making EC available is of particular importance in situations where sexual coercion and violence against women and girls, and as a result unwanted pregnancies, are common.

Synonyms

Hazard preparedness

Definition

Developing plans of action for the situation when the disaster strikes.

Basic Characteristics

In general, many of the responses to extreme disasters (► hazards, natural; ► hazards, technological) used to be based on trial and error, and adhockery. The imminent stress, disorganization, and chaotic developments in the early aftermath make it clear that adequate preparation before the disaster (i. e. anticipative, rather than reactive adaptation) is crucial.

Since a disaster protection system guaranteeing absolute safety is an illusion, a change of paradigm is needed. It is necessary to live with the awareness of the possibility of disasters and to accommodate them, rather than to try, in vain, to eradicate them. While trying to protect from floods up to some design magnitude, it should be borne in mind that extreme hazards may happen, which exceed the design values assumed for building the preparedness system. Disaster mitigation systems do not provide a complete, 100%, safety. Hence, there is a need for plans of emergency preparedness for rare, but not impossible, events exceeding the planning/design conditions. Extreme hazards, which the existing preparedness system cannot bear, are realistic. For instance, a levee system may protect a riparian population from a 50-year flood (► N-year event) in such a way that a flood of design magnitude is contained between levees, so that no damage is involved. However, a plan should be in place, which could be used if a 1000-year flood (► N-year event) arrives and the levee breaks, causing massive inundations of settlements.

Creating a culture of preparedness in the entire nation is needed. There must be a sense of shared responsibility among individuals, communities, the private sector, NGOs, faith-based groups, and authorities at all administrative levels. Individuals must play a central role in preparing themselves and their families for emergencies.

In contrast to disaster mitigation ► mitigation strategies which are aimed at preventing disasters from occurring, emergency preparedness results in developing detailed and robust plans of action for the situation when the disaster strikes. Common measures of preparedness include the proper maintenance and training of the emergency services, the development and testing of the system of the emergency warning and its dissemination, rehearsing an evacuation plan. The planning should include emergency shelters and detailed evacuation plans, equipment and supplies (a stockpile of supplies for sheltering purposes), warning devices, back-up life-line services (e. g. power, water, sewage). It is important to plan for the coordination of the agencies involved in emergency management, possibly in the form of an emergency operations center (EOC), with reliable external communications (including access to radio networks), to coordinate the activities in the response phase of the emergency.

Also members of the general public should be aware of the risk of disasters, and be prepared for them, so that they know what to do when disasters strike. In the USA, for the specific hazard of hurricanes and the likelihood of evacuation, the federal agency (Nation-

al Oceanic and Atmospheric Administration, NOAA) recommends preparation of a 'disaster bag' including, among other things, a flashlight with spare batteries; a battery-operated portable radio; a battery-operated NOAA weather radio; first aid kit; prescription medicines; cash and credit card(s); a cell phone with a fully charged spare battery; spare keys; a three-day supply of water; high energy non-perishable food; blankets or sleeping bags. Also special items for infants, the elderly or disabled family members; and a change of clothing should be included.

In France, emergency preparedness includes preparation of maps of the hazard areas, from which land-use regulations are issued; and plans for emergency and rescue. Preparation of flood risk maps and flood risk management plans are compulsory activities requested by the Floods Directive, being prepared by the European Union.

Hurricane Katrina and the subsequent sustained flooding of New Orleans was a deadly reminder that the USA can and must do better in responding to emergencies. The disaster exposed significant flaws in national preparedness for catastrophic events and the capacity to respond to them. The most powerful country in the world proved not to be as prepared as it should have been, at all levels: federal, state, local, community, and individual. The US government felt obliged to re-examine how to address the full range of potential catastrophic events – both natural and man-made.

President Bush made clear that the federal US government would learn the lessons of Hurricane Katrina so that the nation can make the necessary changes to be "better prepared for any challenge of nature, or act of evil men, that could threaten people."

The emergency system preparedness should be in place prior to disaster strikes. Among the actions needed are, for example, the following (foreseen in the US as a part of lessons learned from Katrina):

- ensuring that relevant federal, state, and local decision-makers are working together and in close proximity to one another in the event of a disaster;
- ensuring situational awareness by establishing rapid deployable communications;
- clear and non-ambiguous distribution of tasks and responsibilities; embedding a single point of contact to enhance coordination of military resources supporting the response;
- identifying and developing rosters of federal, state, and local government personnel who are prepared to assist in disaster relief;
- employing adequate technology to update and utilize the national emergency alert system in order to provide the public with advanced notification of and instruction for disasters and emergencies;
- enhancing the mechanism for providing federal funds to states for preparations upon warning of an imminent emergency;
- improving the delivery of assistance to disaster victims by streamlining registration, expediting eligibility decisions, tracking movements of displaced victims, and incorporating safeguards against fraud;
- reviewing state evacuation plans and essential emergency services; and
- checking if there are adequate helplines, offering information and advice in case of a disaster.

Initiative and innovation (therein advanced technologies) must be recognized and rewarded in emergency preparedness. Advanced systems like infrared sensors and scanners (e. g. mounted on helicopters) can help find trapped people. New technology developments, such as radarscopes and sensors can be used on robots, which could sense a living human inside a building (through 30cm of concrete and 15m beyond). After a living person is discovered and precisely located in the initial cleanup, a rescue team could be called to that specific location.

► Resiliency forms a key part of disaster recovery ► recovery strategies. Resiliency makes it possible to smoothly recover from a failure related to a disaster. A high availability network design is often the foundation for disaster recovery. Handling a crisis effectively could save lives and much money just as dealing with one ineffectively could do the opposite. And while a well managed crisis often enhances an institution's reputation of authority and leadership, a poorly managed one can damage both and open up costly litigation.

Employee

Synonyms

Worker; Agent

Definition

The employee is a person who works for an employer pursuant to the instructions and organizational control of the employer. The employee is legally dependent on the employer. He is entitled to claim wages as agreed in the underlying employment contract.

Employees Health

► Workplace Health

Employer

Synonyms

Principal

Definition

The employer is a person, company or any other legal entity that provides individuals (employees) with employment. The employer has the right to give instructions to his employees. On the other hand, he is obliged to pay their wages as agreed in the underlying employment contract.

Employment and Workers Safety Law

► Labor and Occupational Safety Law

Empowerment

Definition

In ► health promotion, empowerment is a process through which individuals and groups gain greater control over decisions and actions affecting their health. It may be a social, cultural, psychological or political process through which individuals and social groups are able to express their needs, present their concerns, devise strategies for involvement in decision-making, and achieve political, social and cultural action to meet those needs.

A distinction is made between individual and community empowerment. Individual empowerment refers primarily to the individual's ability to make decisions and have control over their personal life. Community empowerment involves individuals acting collectively to gain greater influence and control over the determinants of health and the quality of life in their community.

Enable

Synonyms

Enabling

Definition

Health promotion focuses on achieving ► equity in health. ► Health promotion action aims at reducing differences in current health status and ensuring equal opportunities and resources to enable all people to achieve their fullest health potential. This includes a secure foundation in a supportive environment, access to information, ► life skills and opportunities for making healthy choices. People cannot achieve their fullest health potential unless they are able to take control of those things which determine their health. This must apply equally to women and men.

Enablement/Enabling

Definition

Enabling is one of the three major ► health promotion action strategies laid down in the ► Ottawa charter (WHO 1986). In health promotion, enabling means taking action in partnership with individuals or groups to empower them, through the mobilization of human and material resources, to promote and protect their health. The emphasis in this definition on ► empowerment through partnership, and on the mobilization of resources draws attention to the important role of health workers and other health activists acting as a catalyst for health promotion action, for example by providing access to information on health, by facilitating the development of skills, and supporting access to the political processes which shape public policies affecting health.

Infection of brain tissue; Inflammation of brain tissue

Cross-References

► Acute Life-Threatening Infections

Endemic

Synonyms

Autochthonous; Indigenous

Definition

Endemic disease is defined as disease that is constantly present to a greater or lesser degree in people of a certain class or in people living in a particular location. It also refers to presence of an organism, plant, species, etc., "belonging","native to", or "prevalent in" a particular field, area, region, or environment.
In contrast to ► epidemics, endemic problems are distinguished by their consistently high levels over a long period of time.

Endemic Infectious Diseases

Synonyms

Endemics

Definition

The term "endemic" stems from the Greek and means "in people." Endemic diseases occur regularly in contained regions or populations and do not spread further. The cause of the disease, the pathogen, is permanently present in an endemic region. Endemics can appear wherever pathogens or their hosts depend on specific atmospheric conditions. Knowledge about where and how pathogens occur plays an important role in travel medicine. Examples of countries and their endemic diseases are: Japan encephalitis (see acute life-threatening infectious diseases), Tsutsugamushi fever (see tropical diseases/travelers diseases), West Nile fever (see tropical diseases/travelers diseases) and TBE (see tropical diseases/travelers diseases).

Endemics

► Endemic Infectious Diseases

Endocrine Disturbances

Synonyms

Endocrine system disease; Endocrinological dysbalance

Definition

Endocrine disturbances are about the glands and hormones of the body and their related disorders. In particular, it comprises pathological processes of the endocrine and diseases resulting from abnormal level of available hormones.

Endocrine System Disease

Engagement in Health Promotion

► Health Promotion Engagement

Enjoyment of Food

► Pleasant Taste

Enterobiasis

Synonyms

Infection with Enterobius vermicularis; Pinworm infection

Definition

Enterobiasis is the most common worm infection in moderate zones; in tropical regions it is rare. The eggs are ingested and in the intestines the larvae are set free and develop to adult worms. The female parasites are 8–13mm long, the male up to 5mm. At night the female worms move to the anal region to release their eggs causing severe itching. Due to scratching and afterwards touching the mouth, renewed self-infection can occur. Transmission can also occur from contact with contaminated dust or bed linen. Eggs can be detected using a sticky tape around the anus. Enterobiasis can be cured by pyrantel or pyrvinium. As the therapeutics only kill the adult worms but not the larvae, a second treatment is necessary after an interval of 2–3 weeks. Successful treatment depends on compliance with hygienic rules and simultaneous treatment of other family members may be necessary.

Environment

Synonyms

Milieu; Surroundings; Setting; Background; Scope

Definition

Environment may be defined as conditions and influences of the place of living. There are many different types of environment (for example, urban, rural, etc.). Also environment refers to the social and cultural forces

that shape the life of a person or a population. Physical environment describes the characteristics of a landscape (e. g. climate, geology) which have not been changed markedly by human impact, whereas the geographical environment includes the physical environment together with any human modifications (e. g. agricultural systems, industrialization, urbanization).

Environmental Contaminants

► Environmental Pollutants

Environmental Degradation

Definition

Environmental degradation relates to the deterioration of the environment, both in terms of quantity and quality. Quantity refers e. g. to the extinction of wildlife species and quality to air, water or land pollution. Environmental degradation has many forms and can occur naturally or through human processes. The loss of rain forests, air pollution and smog, ► ozone depletion, and the destruction of the marine environment are some of the main areas of concern at present. Pollution is occurring all over the world and the planet's oceans. Even in remote areas, the effects of marine degradation are obvious.

Environmental Engineering

Definition

Environmental engineering is the application of science and engineering principles to improve the environment (air, water, and/or land resources); to provide healthful water, air, and land for human habitation and for other organisms; and to remediate polluted sites. Negative environmental effects can be decreased and controlled through public education, conservation, regulations, and the application of good engineering practices. Many environmental standards are based in whole or in part on the best available technology.

Environmental Factors

Definition

The complete background of an individual's life.

Environmental Hazards

Definition

Environmental hazards are all kinds of environmental factors that adversely affect health or the ecological balance necessary to human health, safety and well-being. Environmental factors involve characteristics of the occupational or personal environment such as work safety and housing conditions, but also the global environment such as water, air and food. Environmental hazards are for example water contaminants, toxic chemicals, wastes, air pollution (► air quality and pollution), disease transmitters and ► radiation.

Cross-References

► Workplace Hazards

Environmental Health

Synonyms

Environmental hygiene

Definition

Environmental health is a medical discipline dealing with those aspects of human health and disease that are determined by physical, chemical, biological, social, and psychosocial factors in the environment. It also refers to the theory and practice of assessing and controlling factors in the environment that can potentially affect health. It strives to promote health and quality of life by preventing or controlling those diseases or deaths that result from interactions between people and their environment. Environmental health includes identification, evaluation, control, and prevention through education of all those factors in the total environment that exercise a detrimental effect on individual physical, mental, and social well being and development. It also implies continuous efforts to educate and prevent individuals from effecting the environment in such

a way that it becomes detrimental to their well being and development.

► Urban Environments

Environmental Health Determinants

► Health Determinants, Environmental

Environmental Health Indicators

Definition

Environmental health indicators are a set of parameters that directly influence health and quality of life. This category of indicators includes air and water quality, food safety, and exposure to environmental substances. In addition, home, workplace, or recreational conditions can also affect health and may result in premature disability or mortality.

Environmental Hygiene

► Environmental Health
► Urban Environments

Environmental Justice

Synonyms

Equity in the distribution of environmental hazards and resources

Definition

The environmental justice movement started in the USA during the 1980s as an initiative of African-American civil rights groups who protested against a disproportional clustering of hazardous waste dumps and industrial plants in the immediate vicinity of residential areas inhabited mainly by ethnic minorities and socio-economically weak groups. It therefore differs markedly from traditional supraregional environmental movements which seek to protect nature and the environment and whose members are mainly middle class. With its central mission – calling attention to the ethnic and social inequality and environmental justice in the immediate living space and eradicating this form of discrimination – the mainly locally oriented environmental justice movement has contributed significantly to politicizing environmental justice in the USA. The environmental justice movement has since spread across the world and, being particularly significant in the Third World, has now become an environmentalism of the poor.

Environmental Law and Public Health

ADEM KOYUNCU
Mayer Brown LLP, Cologne, Germany
akoyuncu@mayerbrown.com

Synonyms

Environment law

Definition

Environmental law stands for all legal rules that are aimed at the protection and development of the environment and its compartments as well as the protection of public health from harm, risks, and nuisances arising from the environment and the human-made interaction with the environment.

Basic Characteristics

The importance and perception of environmental law significantly increased in the final quarter of the 20th century. This is particularly the case for the laws that are designed to protect the environment. However, in the realm of public health, it was already understood that "disease and a poor environment went hand in hand" (Reynolds 1995). Indeed, public health laws traditionally and at an early point in time intended to improve the conditions the population lived in. Therefore, the reduction of health risks and nuisances arising from the environment were also the focus of early public health laws in the 14th and 15th century (Reynolds 1995; Coker and Martin 2006). For example, the importance of clean drinking water and sanitary conditions have long been recognized as important factors for healthy populations. The interrelation of public health and the envi-

ronment is much better understood today and a large number of laws govern specific aspects of this interrelation.

Environmental laws can be differentiated into two branches:

1. Environmental laws include "*environmental protection laws*" which consist of those legal rules that are aimed at the protection of the environment and its compartments as natural habitats. Their goals are the protection of the natural biological diversity and the protection of species (including herbal protection of species and animal protection);
2. Environmental laws also include "*environmental health laws*". Environmental health laws are legal rules that are aimed at the protection of human health from risks arising from the environment. This includes those "human-made" risks resulting from interactions between human beings and the environment (e. g., air and water pollution). Environmental health laws should be regarded as a distinct part of public health law. (Locke et al. 2007, with additional remarks).

In practice, these two distinct branches of environmental law have built their own infrastructure. There are regularly different agency units, some covering environment protection aspects and others covering environmental health aspects. Nevertheless, a relevant area of overlap exists so that to a certain extent both areas remain interwoven.

General Legal Remarks

Environmental health aspects have become one of the main pillars of contemporary public health practice. As the health risks resulting from the environment receive more and more policy attention, this correspondingly increases the awareness of the necessary and underlying environmental health laws. As there is a multitude of environmental health risks, public health actions to cope with them have a corresponding multitude of starting points. The safeguarding of public health from environmental health risks must combat, among others, health risks arising from air and water pollution and from the built environment as well as animal-caused health risks. Environmental health law has a broad scope. As the number of its practice areas will demonstrate below, the range of legal topics and issues is so multifaceted and complex that environmental law is indeed a "complex legal landscape" (Locke et al. 2007). In the following, a number of specific legal concerns related to the practice of environmental health are highlighted briefly.

Environmental health law is a cross-sectional subject that embraces legal provisions located in different areas. As such, environmental health law includes legal rules located in occupational safety laws as well as criminal law provisions that prohibit and sanction environmental crimes. Therefore, in the practice of environmental health, the competent authority for a particular issue may not be that easy to identify. This is particularly true as environmental law may be subject to federal legislation as well as state legislation so that federal and state authorities may be in conflict. The laws governing this field must set forth clear regulatory competencies and responsibilities. They also have to regulate interagency cooperation.

Because of the diversity of environmental health risks, the corresponding laws must provide the administration with sufficient authority and a broad range of legal means to combat the variety of risks. The agencies in charge of environmental health protection need powerful legal means, particularly as these agencies have to mitigate health risks that can affect large parts of the population. Therefore, the legal responsibility of the public health practitioner is enormous. On the other hand, his actions may affect the addressees (e. g., companies, individuals) severely, especially as some risk mitigation decisions are based only on preliminary assessments that can turn out to be incorrect in retrospect. In light of the personal and property rights affected by such public health actions, lawsuits and legal actions are not uncommon in the practice of environmental health law.

Structure and Practice Areas

Among the environmental laws, there is differentiation between rules for "general environmental law" and legal rules for "special environmental laws", which encompass the specialized legal fields of environmental law (Sparwasser et al. 2003):

- *General environmental laws* comprise the legal provisions, means, methods, and competencies that are relevant to all specialized environmental law practice areas. They may be regarded as umbrella provisions that apply to all fields of environmental law.

- *Special environmental laws* govern the legal means and practice of the different specialized practice areas of environmental law.

The specialized fields of environmental law cover a broad range of practice areas. They relate:

- To the protection of environmental compartments. As such, these provisions include air protection, land protection, water protection, and nature protection laws;
- To the sources of environmental and public health threats. These sources include hazardous activities, substances, or products. These legal provisions are not strictly linked with a particular environmental compartment. They include intromission protection laws, nuisance abatement laws, chemical laws, hazardous substances laws, nuclear energy laws, electronic equipment laws, construction materials laws, and waste and recycling laws (Sparwasser et al. 2003);
- To potential sanctions and recovery after the detection of environmental offenses. These provisions particularly form the body of environmental criminal law and environmental liability law.

The boundaries of these legal fields are not always clear-cut from other areas of public health law. Environmental law fields overlap and have numerous intersections with several other public health law fields (e. g., occupational safety laws, infectious diseases control laws, legal regulation of products and businesses). The instruments of environmental law are as diverse as the scope of this legal field.

General Legal Means

Environmental law has several legal avenues. In general terms, this field of law makes use of traditional tools of administrative law (e. g., administrative orders, injunctions). It also effectuates tools based on cooperative approaches. Therefore, the legal means and their mechanisms could be summarized as follows (Kloepfer 2004):

- Direct behavior influencing (e. g., by regulatory supervision, administrative orders);
- Indirect behavior influencing (e. g., by means of tax law, commerce law);
- Planning and zoning activities to create a healthy environment, including a healthy built environment (Perdue et al. 2003);
- Sovereign environmental protection activities conducted autonomously by the state and its administration;
- Information and education activities and state funded research;
- Legal means for promoting and funding cooperation between state and private institutions.

Besides these general techniques, the legal means of environmental law may be differentiated depending on the differing objectives of the field. Fundamentally, environmental law needs an administrative agency infrastructure. These agencies are created and funded by virtue of legal authorization. They must be granted with sufficient powers to be effective. Environmental law is an intensively regulated field. It contains numerous statutes, regulations, and ordinances, which govern various fields of this practice area (e. g., laws regulating industries or professions and laws governing water, chemicals, construction materials, food, drugs, cleaning and washing products, or waste). Administrative agencies play important roles in environmental law even though the legal means available to individuals and private organizations also contribute to the mitigation of environmental health risks.

Long-Term Legal Means

Environmental law must create a basis for a sustainable and healthy interaction between humans and the environment. This is a long-term objective. As environmental law particularly protects environmental compartments from harmful alterations, its tools must have a broader scope. Therefore, environmental law applies legal means vis-à-vis the general public like standards, technical rules, or thresholds for nuisances. This is accompanied by regulatory supervision, which includes surveillance, inspections, and reporting and notification obligations. Thus, environmental law imposes obligations on individuals and companies in the interest of the community's welfare. These are particularly directed towards companies operating potentially harmful plants or conducting risky activities.

For prevention purposes, environmental agencies are entitled to conduct their own research, e. g., with respect to environmental health risks or new technologies. The research results are used in advising the agency's addressees (e. g. industries, companies, individuals) so that they act with the best knowledge available. Agen-

cies also cooperate with their addressees to safeguard the public's health. In addition, they inform the public in order to influence behavior towards voluntary healthy behavior (health promotion). Through interplay with other legal fields, particularly tax and commerce law, environmental law may additionally provide incentives for healthier behavior.

Near-Term Legal Means

Environmental law also has to avert acute risks. Therefore, environmental agencies not only provide the industry with standards and thresholds but if they become aware of an acute risk (e. g., because of elevated levels of hazardous substances), they must react immediately and abate the risks. They may also inform and warn the public. Law must provide them with sufficient near-term means and corresponding legal authority to enforce their orders as such means may intrude personal and property rights (e. g., if an agency orders the closure of a business). If agencies detect violations, environmental law provides for immediate abatement and sanctions as well as remedies and penalties. Agencies may impose administrative fines or notify the prosecutor for criminal punishment if criminal offences are unearthed. These are all tools of indirect behavior influencing. Similarly, specific environmental crimes and liability rules are laid down in many jurisdictions.

Legal Means of Non-Governmental Actors

Apart from administrative agencies, individuals may also enforce a healthy environment and make use of a set of legal means, particularly if the agencies fail to react to mitigate risks in a timely manner. Here, individuals can have significant effects by means of private litigation (Locke et al. 2007). Individuals may litigate against the sources of the nuisances or pollution. They may also file lawsuits against the agencies in order to force them to take measures against a particular public health threat. Such individuals or non-governmental organizations may indeed be regarded as "private attorney generals" (Locke et al. 2007). In Germany, a city government was convicted by the Federal Administrative Court and forced to take appropriate public health measures to reduce air pollution caused by dangerous micro dust particles. This type of lawsuit, filed by private persons or public health advocacy organizations, is primarily intended to ensure and promote the public's health by urging the administration to take safeguarding action.

Overall, environmental law has a broad scope and encompasses a variety of legal means. Here, regulatory agencies play crucial roles. Individuals and private organizations are also relevant actors for the protection of the public's health from environmental risks.

E

Perspectives

Environmental health law faces new challenges and new threats. Particularly, climate change and its impact on the global environment is gaining importance. Therefore, the need for global legal initiatives and actions continuously emerge. The process of globalization and internationalization of environmental law is one of the major developments in recent years. Some of the contemporary environmental health risks can only be mitigated by a concerted international approach. Here, international laws will have to play their role.

In the future, environmental health laws will also have to handle new risk-profiles and new technologies with yet unknown risks. The administration will have to accompany these developments, conduct their own research, and inform the public accordingly. In addition, environmental health law will strengthen information, education, and health promotion activities. Such health promotion campaigns are already successfully used in other areas of public health (e. g., infectious diseases control, food safety). Environmental health law will continue to be a necessary but also highly complex branch of public health law.

Environmental Medicine

Definition

Environmental medicine as a part of modern medical research evolved from a variety of fields in medicine, above all toxicology, occupational medicine, environmental hygiene and the sub-disciplines water, soil, air and food hygiene as well as environmental ► epidemiology. Being interdisciplinary, environmental medicine draws on the know-how of a number of fields and occupations within medicine (e. g., the public health service, non- and paramedical professions) in dealing with the influence and effects of environmental factors on human health and well-being. Having developed along these lines, environmental medicine now runs on two tracks: the population-oriented preventive approach and the clinical, individual-oriented medical approach.

Responding to the increase in environment-related disorders, universities, public health services and state offices in Germany started opening environmental medicine clinics and counseling centers as early as the 1980s.

Environmental Pollutants

Synonyms

Environmental contaminants

Definition

Environmental pollutants are substances coming from mineral and fossil sources or are produced by humans. Pollutants can harm ecosystems, plants and animals and cause health problems in humans. Major air pollutants are carbon monoxide (CO), carbon dioxide(CO_2), chlorofluorocarbons (CFCs), lead, ozone (O_3), nitrogen oxide (NO_x), sulfur dioxide (SO_2), and volatile organic compounds (VOCs). Environmental pollutants are also found indoors. Other forms of pollution are water, soil and radioactive contamination.

Environmental Substainability

► Sustainable Development

Environmental Tobacco Smoke

► Passive Smoking

Environmental Tolerance

Synonyms

Adaptation

Definition

Adjustment in human systems in response to actual or expected stimuli/changes, in order to moderate potential damages, benefit from opportunities, or cope with consequences.

Environmental Toxins

Definition

Environmental toxins are any chemical in the environment that is poisonous to humans. While naturally occurring substances like aflatoxin can be toxic, the majority of the environmental toxins are man-made substances such as CFCs (chlorofluorocarbones), asbestos, carbon dioxides and nitrates. These and many other chemicals are or were once used in consumer products, manufacturing or other industrial uses, but escaped into the air, water or soil, where they can endanger entire communities. Exposure to environmental toxins can cause transient or irreversible damages, including cancer, birth defects, organ damage and blood disorders.

Environment-Related Health Protection

Definition

As a task which falls to states, cities and communes, environment-related health protection (ERHP) straddles health protection and environmental protection. Its focus is protecting human health from hazardous environmental factors. Formerly mostly reactive in nature, seeking to detect and eliminate existing health hazards (i. e., damage containment); ERHP has become increasingly proactive and prevention-oriented. Its main thrust now is educating the public through the media, assessing the effects of environmental factors from a public health perspective as well as encouraging and implementing measures for preventing health hazards and long-term effects (as by decreasing traffic immissions and ► noise pollution). Amongst others, the information and data required are provided by ► environment-related public health reporting services.

Preventive identification and analysis of potential health hazards through preventive measures (e. g., conducting health tolerance tests and taking ► health impact assessment surveys, public education campaigns in city districts) and using the environment as a health resource (e. g., green areas as health-promoting rest and recreation (R&R) areas) will play an increasingly greater part in ERHP. Likewise, ERHP will no longer be restricted to the environment and human health, and thus to the realm of public health, but henceforth requires interdisciplinary cooperation straddling different fields of research and activity.

Epidemic

Synonyms

Widespread Illness

Definition

The term "epidemic" stems from the Greek and means "upon people." An epidemic infectious disease is an outbreak of the disease in a given region or community in which masses of people are infected. Epidemics are restricted to a particular region and a certain period of time. Infections can appear simultaneously or subsequently.

Cross-References

► Widespread Illness

Epidemic Diseases

Definition

Epidemic diseases are diseases that spread rapidly and excessively among the population in one specific area due to easy transmission and insufficient protection. When the incidence of an epidemic disease extends beyond a country or continent, the disease is called pandemic. The contrary of epidemic or pandemic diseases are sporadic diseases occurring only as individual cases in separated geographic areas.

Epidemiologic Transition

Definition

The term epidemiologic transition describes the trajectory of changes in the pattern of disease and causes of death in a given country. In its original formulation by Omran, the epidemiologic transition referred to the process whereby the impact of natural disasters and the prevalence of infectious diseases declined and the prevalence of chronic and degenerative diseases increased in populations experiencing economic development. While initially thought to be a uniform and progressive process, the transition is now understood as a more complex and continuous transformation process with some diseases disappearing and others re-emerging across time and geographical settings.

Introduction

Definition

Defining epidemiology is difficult, primarily because it does not represent a body of knowledge, like some other disciplines (e. g. anatomy or pathology), nor does it target a specific organ system, like cardiology or nephrology. Epidemiology is a philosophical method of studying a very broad range of health problems within populations, and the basic science of public health. The term *epidemiology* originates from the Greek words *epi* (upon), *demos* (people), and *logos* (study of) (Friis and Sellers 1999).

There have been many definitions of epidemiology. In the past 60 years, the definition has broadened from concern with communicable disease epidemics to take in all phenomena related to health in populations.

Last's *Dictionary of Epidemiology* gives the definition that has been widely accepted. It defines epidemiology as "the study of the distribution and determinants of health related states or events in specified populations, and application of this study to control of health problems" (Last 2001).

Based on what has been done in the past, especially in the last century, epidemiology is the science and practice that describes and explains disease patterns in populations, and puts this knowledge to use to prevent and control disease and improve health. "The concept of populations is therefore fundamental to epidemiology. This embraces all aspects of epidemiology, including studies in general population, occupational populations, and the clinical populations. These populations experience exposures and health outcomes and to understand their etiologic relationships it is not sufficient to simply describe the occurrence (the distribution) of disease; epidemiologists also need to develop and test etiologic theories (which may involve population-level, individual-level or micro-level exposures) about the causes (the determinants) of these population patterns. Bearing all of these considerations in mind, the most appropriate definition of epidemiology is that it is the study of the distribution and determinants of disease in human populations" (Pearce 2004).

Historical Background

The historical antecedents of epidemiology began with Hippocrates, who implicated the environment as a factor in disease causation almost 2,400 years ago. He described the distribution of diseases by season, climate, age, and personal behavior – which is much the same perspective as modern epidemiologists have. John Graunt, a London businessman and one of the first "counters" of health events, compiled vital statistics in the mid-1660s. He provided statistical evidence for many theories on diseases, and also refuted many widespread ideas.

Well-known early epidemiologic experiments include Lind's trial of fresh fruit (oranges and lemons) against scurvy in 1747, and Jenner's experiments with cowpox vaccination in 1796. Lind found, almost 200 years before a cause of the disease was established, that ill sailors receiving oranges and lemons improved rapidly. Jenner showed that smallpox could be prevented by vaccinating with serum from the lesions of cowpox, taking the first steps that led to worldwide eradication of this disease by the late 1970s (Last 1998).

The birth of modern epidemiology occurred during the 19th century. Epidemic investigations prior to the mid-

dle of that century were mostly descriptive. The classic investigations on the transmission of cholera (John Snow), typhoid fever (William Budd), and puerperal fever (Ignaz Semmelweiss) led to understanding and the ability to reduce the spread of major infections. Pierre Charles Alexandre Louis (1787–1872) systematized the application of numerical thinking and championed its cause. His influence was widespread, primarily through his students. One of them, William Farr, pioneered the use of statistics in epidemiology. He set up a system for the routine collection of data on the number and causes of deaths and other vital statistics, and introduced the concepts of death rate, dose-response, herd immunity, and cohort effect. Together with William Guy and William Budd, he founded the Statistical Society in London in 1834 (Schoenbach 2003).

The relationship of epidemiology with war has been a reciprocal one. The U.S. Centers for Disease Control and Prevention (CDC) was born as the World War II Office of Malaria Control in War Areas, becoming the Communicable Disease Center in 1946, the Center for Disease Control in 1970, the Centers for Disease Control in 1980, and receiving its present name in 1992. The CDC's Epidemic Intelligence Service was established during the Korean War, in response to concern about importation of exotic diseases from Asia (Schoenbach 2003).

For more than half a century, since World War II to the present, epidemiology has expanded in a multiplicity of directions, penetrating the whole field of medicine and public health in a capillary manner. Many new departments have been created since the start of 1970s, when there were only a dozen schools of public health and few medical schools had epidemiologists among their faculties. The first textbook, of an introductory nature, appeared in 1960 (MacMahon et al. 1960), while we have several dozens today, for epidemiology generally and within specific subdomains.

The Aims and Scope of Epidemiology

As the basic science of public health, epidemiology has several aims (Gordis 2004):

- To identify the etiology or the causes and risk factors of a disease, and to improve public health by reducing or eliminating exposure to these factors.
- To determine the extent of disease found in the community.
- To study the natural history and prognosis of disease.
- To evaluate both existing and new preventive and therapeutic measures and modes of health care delivery.
- To provide the foundation for developing public policy and making regulatory decisions relating to environmental problems.

A prime purpose of epidemiology is the application of its findings in health promotion, health care, and health policy to improve the health of populations. Epidemiology is a population science. The focus on population distinguishes it from clinical research and the other medical sciences, which primarily study the individual (Bhopal 2002). However, epidemiology also has a big role in clinical medicine.

Epidemiologists have several roles in the process of policy making, including generating and interpreting data, presenting specific policy options and projecting the impact of each option, developing specific policy proposals, and evaluating the effects of policies after they have been implemented.

The scope of epidemiology has broadened with the discovery or invention of new applications and methods. This, and the changing pattern of diseases, has encouraged subdivisions of epidemiology. Nowadays there are many branches of epidemiology, like infectious disease epidemiology, cancer epidemiology, psychiatric epidemiology, cardiovascular disease epidemiology, public health epidemiology, spatial epidemiology, social epidemiology, clinical epidemiology, hospital epidemiology, nutritional epidemiology, pharmacoepidemiology, genetic epidemiology, behavioral epidemiology, molecular epidemiology, etc. ► epidemiology, aims and scopes.

Causation and Causal Inference

Epidemiology is the science that describes the relationship between the agent, the environment, and the host. Several *epidemiological – ecological models* have been developed in order to depict the ways in which these interactions influence the occurrence of disease: the triangle, the wheel, and the web of ► causation.

Establishing a cause and effect relationship between agent/exposure and disease is very important for public health, even though it is often difficult to do. If it

is determined that an exposure is associated with a disease, the next question is whether the observed association reflects a causal relationship. In 1840, Henle proposed postulates for causation that were expanded by Koch in the 1880s (Gordis 2004):

1. The organism is always found with the disease.
2. The organism is not found with any other disease, and
3. The organism, isolated from one who has the disease, and cultured through several generations, produces the disease in experimental animals.

These postulates were very useful for infectious diseases. However, they are not applicable for diseases that are not generally of infectious origin.

Although epidemiologic evidence by itself is insufficient to establish causality, Hill suggested that the following aspects of an association be considered in attempting to distinguish causal from non-causal associations (Hill 1965):

1. Strength of the association
2. Dose-response relationship
3. Consistency of the association
4. Temporal relationship
5. Biologic plausibility
6. Experimental evidence
7. Coherence
8. Specificity of the association

"Despite the popular view that these criteria should be used for causal inference, there is no necessary or sufficient criterion for determining whether an observed association is causal" (Rothman and Greenland 2005). The decision about causation must always remain a matter of judgments based on all available evidence.

Epidemiologic Measurement – Measures of Disease Frequency

Population health status has many dimensions, classifications, and measurements, as well as interactions between these, that pattern and trends often cannot be identified easily. Thus, the need for comprehensive population health measures and standardization of data collection is obvious and longstanding (Van der Maas 2002).

The prerequisite for any epidemiologic investigation is the ability to measure the occurrence of morbidity and mortality carefully and accurately, i. e. to quantify the occurrence of disease. Rates tell us how fast the disease is occurring in a population, and proportions tell us what fraction of the population is affected.

Measures of morbidity are incidence rate and prevalence, while measures of mortality are mortality rate and case fatality rate.

There are three general categories of rates: crude rates, specific rates, and adjusted rates. Although the crude rates are important and useful summary measures of the occurrence of disease, specific rates are more precise indicators of risk, especially if it is possible to construct rates specific to subsets of the population (e. g. age, sex, or race). To make comparisons across populations, adjusted rates may also be used.

In the last decade of the 20th century, a considerable effort has been put into the development of summary measures of population health (SMPH) that combine information on mortality and non-fatal health outcomes. In 1993, the Harvard School of Public Health in collaboration with The World Bank and the World Health Organization (WHO) assessed the global burden of disease (GBD). Aside from generating the most comprehensive and consistent set of estimates of mortality and morbidity by age, sex, and region ever produced, the GBD study also introduced a new metric – disability adjusted life year (DALY) – to quantify the burden of disease and to compare disease burden across a range of diseases, injuries, and risk factors. The use of DALY allows researchers to combine years of life lost from premature death (years of life lost – YLL) and years of "healthy" life lost because of illness and disabilities (years lived with disability – YLD) in a single indicator (Murray and Lopez 2002).

SMPH are a generalization of the concept of disease burden measurement. They include measures of the health gap (e. g. DALY) and measures of the health expectancy, for example, disability adjusted life expectancy (DALE).

SMPH have been proposed and developed as useful analytical tools for health policy-makers and analysts. The value of summary measures of population health as a tool for health policy and planning purposes has been increasingly recognized. ► disease frequency, measures.

Design Strategies in Epidemiologic Research

To determine whether an association exists between an exposure and a disease, different epidemiologic studies can be used. They can be divided into two broad groups – observational and experimental studies.

Observational Studies

In ► observational studies, the distribution of an exposure and/or an outcome is examined without any attempt by the investigator to influence them. The investigator only observes the natural course of events, with changes or differences in one characteristic being studied in relation to changes or differences in other characteristics, without intervention other than to record, classify, count, and statistically analyze results (Last 2001). Observational investigations include descriptive and analytic studies.

Descriptive studies are concerned with describing the distribution of disease, particularly in relation to person, place, and time. They can be used to determine the health status of the people in the community, to measure risks, generate hypotheses, etc. Descriptive data are primarily useful for the formulation of hypotheses about factors related to disease.

The first approach in determining whether an association exists might be to conduct a study of group characteristics, called an ecological study.

An ecological or ► correlation study is a study in which data of average exposure and outcome for a population are used to compare with similar data for other populations in order to look for associations between the exposure and the outcome.

The ► case report is the most basic type of descriptive study of individuals, consisting of a careful, detailed report of the profile of a single patient by one or more clinicians.

A ► case series describes characteristics of a number of patients with a given disease.

Postulated hypotheses can subsequently be tested using an analytic design. The common types of ► analytical studies are cohort, case-control, and cross-sectional.

In a ► cohort study, the investigator selects a group of exposed individuals and a group of nonexposed individuals and follows up both groups to compare the incidence of disease (or other outcome) in the two groups. The design may include more than two groups. There are two main types of cohort studies – prospective cohort study and retrospective or historical cohort study. The only difference between them is calendar time. In a prospective cohort design, exposure and nonexposure are ascertained as they occur during the study, the groups are then followed up for several years into the future, and outcome is measured. In a retrospective cohort design, exposure is determined from past records and outcome is ascertained at the time the study is begun (Gordis 2004).

In a ► case-control study, the investigator selects two groups – a group of individuals with a disease of interest (or other outcome variable), called cases, and, for purposes of comparison, a suitable group of people without that disease, called controls. The history of exposure to suspected risk factors is compared between "cases" and "controls" (Gordis 2004).

Nested case-control design combines elements of both cohort and case-control studies and offers a number of advantages.

A cross-sectional study is a study in which the prevalence of an exposure and/or an outcome is measured in a given population at a specific point in time. The data may be analyzed to look for an association between the exposure and the outcome (Gordis 2004).

Experimental Studies

In experimental (interventional) studies, conditions are under the direct control of the investigator (Last 2001). These studies are designed to test hypotheses by modifying an exposure within the study population.

► Experimental studies maintain the greatest control over the research setting. They ideally take the form of randomized controlled trials.

A ► randomized controlled trial (RTC) is an epidemiologic experiment in which subjects in a population are randomly allocated into groups, usually called *study* and *control* groups, to receive or not receive an experimental preventive or therapeutic procedure, maneuver, or intervention (Last 2001). The RTC is generally considered the "gold standard" of study designs. When hierarchies of study design are created to assess the strength of the available evidence supporting clinical and public health policy, RTC are always at the top of the list.

Studies in which the investigator does not have full control over the allocation of the exposure are called *quasi-experimental studies*.

An important consideration in any trial is the possible introduction of bias in the assessment of outcomes from the expectations of either the investigator or the participant. The best protection against this source of bias is a *double blind study* – neither the patient nor the physician knows whether the patient is receiving the treatment of interest or the control treatment.
Because of ethical reasons, allocation of exposures that are known to be hazardous is not possible. Such exposures can be assessed in experimental studies only indirectly, by attempts to eliminate them (Hennekens, Buring 1987; Gordis 2004).

Bias, Confounding and Interaction

Epidemiological studies are prone to error, because they usually study human populations in natural settings. Three important issues in deriving causal inferences are ► bias, confounding, and interaction.
Bias has been defined as any systematic error in the design, conduct, or analysis of an epidemiological study that results in a mistaken estimate of the association between exposure and risk of disease. There are a number of ways of categorizing the different types of bias. Biases reflect inadequacies in the design or conduct of the study and affect the validity of the findings. They need to be assessed and, if possible, eliminated. The types of bias encountered in epidemiologic studies are *selection bias* and *information bias*. While selection bias refers to any error that arises in the process of identifying the study populations, information bias includes any systematic error in the measurement of information on exposure or outcome (Hennekens, Buring 1987).
On the other hand, confounding and interaction describe the reality of the interrelationships between certain factors and a certain outcome.
Confounding is a major cause of bias in epidemiology, and one of the most important problems in observational studies. Confounding causes an error in the assessment of the association between a disease and a postulated causal factor.
Several methods are available to control confounding, either through study design or during analysis of the results. The control of confounding in study design includes randomization, restriction, and matching. Control of confounding in the analysis of results includes stratification and mathematical modeling (Gordis 2004).
Interaction (effect modification) is defined as the interdependent operation of two or more causes to produce or prevent an effect (Last 2001).The effect can be greater than expected (positive interaction, synergism) or less than expected (negative interaction, antagonism).

Prevention

A major goal of epidemiology is to assist in the prevention and control of disease and in promotion of health by identifying risk factors or etiologic factors for disease and the ways in which they can be modified (Beaglehole et al. 1997).
Prevention means actions aimed at eradicating, eliminating, or minimizing the impact of disease and disability, or if none of these is feasible, retarding the progress of disease and disability. The concept of prevention is best defined in the context of levels, traditionally called primary, secondary, and tertiary, and latterly including primordial prevention (Last 2001).
Primordial prevention aspires to establish and maintain conditions that minimize hazards to health, while primary prevention (► prevention, primary) aims to reduce the incidence of disease by controlling causes and risk factors. Primary prevention involves two strategies: population strategy (focuses on the whole population with the aim of reducing average risk), and individual strategy (focuses on people at high risk as a result of particular exposures).
Secondary prevention (► prevention, secondary) aims to reduce the prevalence of disease by shortening its duration through early diagnosis and treatment.
Tertiary prevention (► prevention, tertiary) aims to reduce the number and/or impact of complications.
Primary prevention denotes an action taken to prevent the development of a disease in a person who does not have the disease in question (e. g. immunization against certain diseases). Secondary prevention is the identification of people who have already developed a disease at an early stage of the disease's natural history (e. g. early detection of disease through screening and subsequent early treatment). The term early detection of disease means detecting a disease at an earlier stage than would usually occur in standard clinical practice. This denotes detecting disease at a presymptomatic stage, at which point the patient has no symptoms or signs of disease ► epidemiology, prevention.

Screening

According to the *US Commission on Chronic Illness*, ► screening is defined as "the presumptive identification of unrecognized disease or defect by the applications of tests, examinations or other procedures which can be applied rapidly". Screening tests sort out apparently well persons who probably have a disease from those who probably do not have a disease (Last 2001). The main aim of screening is to reverse, halt, or slow the progression of disease more effectively than would normally happen. Persons with positive findings must therefore be referred to their physicians for diagnosis and necessary treatment.

However, some purposes of screening are more controversial than trying to achieve a better outcome for individuals. It is also done to protect society, even though the individual may not benefit or might be harmed (e. g. screening potential immigrants for contagious disease at the port of entry; screening potential employees in the police, armed forces and airlines to select out unhealthy people) (Bhopal 2002).

A successful screening program will focus on a serious disease for which early diagnosis and effective treatment can reduce the risk of significant morbidity and mortality. A high-risk population for whom the test is acceptable must exist. The general principles that govern the introduction of screening programs include:

- the disease should be an important health problem;
- the disease should have a detectable preclinical phase;
- the natural history of the lesions identified by screening should be known;
- there should be an effective treatment for such lesions;
- the applied screening test should be acceptable for the target population and safe (Miller 2005).

In addition, a good screening test should be simple, rapid, and inexpensive (Friis, Sellers 1999).

Every screening program must to be evaluated, which involves consideration of two issues: feasibility and effectiveness of the proposed program (Hennekens, Buring 1987).

Investigation of Disease Outbreak

One of the most important roles of epidemiology is the investigation of disease outbreaks – epidemics – that occur suddenly and in a relatively limited geographic area. The emergence of a disease outbreak requires immediate action to determine the origin of the problem and to prevent further spread of the disease. ► Outbreak investigations also provide the opportunity to discover new etiological agents, to understand factors that promote the spread of the diseases, and at the same time to identify the weaknesses of existing prevention and health programs. Although there is no simple way to teach how to investigate a disease outbreak, there is an organized way of approaching and interpreting the data that assists in the solution of problems. According to Gregg, ten basic steps that are commonly used are the following (Gregg 2002):

1. Determine the existence of the epidemic
2. Confirm the diagnosis
3. Define a case and count cases
4. Orient the data in terms of time, place, and person
5. Determine who is at risk of becoming ill
6. Develop an hypothesis that explains the specific exposure that caused disease and test this hypothesis by appropriate statistical methods
7. Compare the hypothesis with the established facts
8. Plan a more systematic study
9. Prepare a written report
10. Execute control and prevention measures

Not all disease outbreaks warrant investigation. The decision to investigate an outbreak is typically based on the severity of illness, the number of affected persons, uncertainty about the pathogen, and the perceived need to control further spread of the disease.

Public Health Surveillance

► Public health surveillance (*epidemiologic surveillance* or *surveillance)* is a fundamental role of public health. It has been defined by the CDC as "the ongoing systematic collection, analysis, and interpretation of outcome-specific data for use in the planning, implementation, and evaluation of public health practice" closely integrated with the timely dissemination of these data to those who need to know. The term public health surveillance describes the scope (surveillance) and indicates the context in which it occurs (public health) (Thacker 2000).

Surveillance is distinguished from ► monitoring by the fact that it is continuous and ongoing, whereas monitoring is intermittent or episodic (Last 2001).

Surveillance is most frequently conducted for communicable diseases, but in recent years, it is increasingly being applied to other fields, such as primary care, noncommunicable diseases (e. g. cancer registers), environmental and occupational health, injuries, poisonings, and exposures or behaviors that predispose to disease.

Public health surveillance information is used to assess public health status, define public health priorities, detect epidemics, test hypotheses, evaluate programs, conduct research, etc.

Surveillance can be active, passive, or combined active/passive.

At the beginning of the 21st century, several activities have contributed to the evolution of public health surveillance. First, use of the computer has revolutionized the practice of public health surveillance. In developed countries, surveillance systems link all state health departments by computer for the routine collection, analysis, and dissemination of information on many conditions. The second field of renewed activity associated with surveillance, as a by-product of the use of computers, is the ability to make more effective use of sophisticated tools in order to detect changes in patterns of occurrence of health problems. In addition, more effective use of electronic media and all the other communication tools should facilitate the use of surveillance information for public health practice. Finally, surveillance needs to be used more consistently and thoughtfully by policymakers. Epidemiologists not only need to improve the quality of their analysis and interpretation, they also need to present surveillance information in its most useful form to the appropriate audience and in the necessary time frame (Teutsch, Churchill 2000).

Clinical Epidemiology

In the second half of the 20th century, accelerated development of ► clinical epidemiology followed by pharmacoepidemiology took place.

The term clinical epidemiology is derived from clinical medicine and epidemiology. It seeks to answer clinical questions and to guide clinical decision making with the best available evidence. Many of the methods used to answer these questions are epidemiologic methods.

There have been many definitions of clinical epidemiology. Fletcher and colleagues defined it as "the application of epidemiologic principles and methods to problems encountered in clinical medicine" (Fletcher et al. 1996). Clinical epidemiology had its origins in clinical practice and according to Sackett and colleagues, it is "a basic science for clinical medicine" and "science of the art of medicine" (Sackett et al. 1991).

Clinical epidemiology comprises many issues: abnormality versus normality (Is the patient sick or well?); diagnosis (How accurate are tests used to diagnose disease?); frequency (How often does a disease occur?); risk (What factors are associated with an increased risk of disease?); prognosis (What are the consequences of having a disease?); treatment (How does treatment change the course of disease?); prevention (Does an intervention, e. g. immunization, keep disease from arising? Does early detection and treatment improve the course of disease?); cause (What conditions lead to disease?); and cost (How much will care for an illness cost?) (Fletcher et al. 1996).

The clinical events of primary interest in clinical epidemiology that doctors try to understand, predict, interpret, and change when caring for patients, are the health outcomes known as the five Ds: death, disease, discomfort, disability, and dissatisfaction (Fletcher et al. 1996).

The purpose of clinical epidemiology is to ensure that clinicians' practice and decision-making is evidence-based. Clinical decision-making requires answering questions about diagnosis, therapy, prevention, and harm; providing estimates of prognosis; and obtaining unbiased and precise estimates of intervention effects. Clinicians should use the best evidence for clinical decision-making. Thus, clinical epidemiology and evidence-based medicine are closely linked: while clinical epidemiology grounds the clinical investigators' viewpoint, evidence-based medicine provides the framework for application of research findings in clinical practice (Schunemann, Guyatt 2005).

Evidence Based Medicine

► Evidence-Based Medicine (EBM) is a great beneficiary of epidemiology, and it is an important and relevant contribution to modern medicine. EBM is defined as "the conscientious, explicit, and judicious use of current best evidence in making decisions about the care of individual patients". The practice of EBM means integrating individual clinical expertise (the proficiency and judgment that individual clinicians acquire through clinical experience and clinical practice) with the best

available external clinical evidence (clinically relevant research on causation, prognosis, diagnostic tests, and treatment strategies) (Sackett et al. 1996).

The goal of EBM is to increase the likelihood of a better clinical outcome for an individual patient due to making better clinical decisions and doing so in a more efficient, cost-effective manner.

In order to apply EBM to the clinical problem of interest, the first step is to classify the problem as one of diagnosis, prognosis, therapy, harm, or another clinical and health care issue. The practice of EBM can then be divided into the following components: identifying a problem or area of uncertainty; converting information needs into answerable questions; selecting the most likely resources to search; searching and appraising the evidence found for its validity (closeness to truth) and usefulness (clinical applicability); acting on and appropriately applying the evidence; and evaluating the outcomes of the actions (Sackett, Rosenberg 1995).

Not all evidence is judged to be of equal value, that is, there are hierarchies of research design that are evaluated to have different strengths and different levels of value in the decision making process – the evidence pyramid.

Most clinicians do not have the time to read the literature in their own areas, to be up-to-date on new information, and to be able to critically appraise the literature and its validity and usefulness. Fortunately, there are readily available sources, like the *Cochrane Collaboration*, an international non-profit and independent organization that aims to help people make well-informed decisions about healthcare by preparing, maintaining, and promoting the accessibility of systematic reviews of the effects of healthcare interventions (The Cochrane Collaboration 2006).

Pharmacoepidemiology

One of the youngest scientific disciplines, ► pharmacoepidemiology, or drug epidemiology, has developed at the interface between clinical pharmacology and clinical epidemiology. It can be defined as the application of epidemiologic knowledge, methods, and reasoning to the study of the effects and uses of drugs in human populations (Porta-Sera, Hartzema 1997).

The main purpose of pharmacoepidemiology is to determine the impact of drugs upon the health of the population. It may be drug-oriented, emphasizing the safety and effectiveness of individual drugs or groups of drugs; or utilization-oriented, aiming to improve the quality of drug therapy. In the second instance, pharmacoepidemiology may focus on the drug (e. g., dose-effect), the prescriber (e. g., quality indices of the prescription), or the patient (e. g., selection of drug and dose vs. kidney function, drug metabolic phenotype/genotype, age, etc). Drug utilization research is thus an essential part of pharmacoepidemiology as it describes the extent, nature, and determinants of drug exposure. In common use, these two terms are sometimes used interchangeably. Since pharmacoepidemiological studies need to be large to study effectiveness and rare adverse effects, they are often conducted on existing databases that cover many exposed individuals. Among the examples of adverse and possible beneficial effects of drugs that have been revealed by systematic collection of data are the positive association between oral contraceptives and venous thrombotic episodes, and the negative associations between statins and dementia, and antibiotics and acute myocardial infarction. Pharmacoepidemiological studies may also provide useful information on patterns of drug utilization and pharmacoeconomic issues. Technology development has led to a considerable increase in the number of individual-based registers and databases, which may be of value in pharmacoepidemiological research, and the number of studies that are based on these data may be expected to increase.

A great challenge ahead is linkage of pharmacoepidemiological studies with the latest techniques of genetics, biochemistry, immunology, and molecular biology (Garbe, Suissa 2005).

Hospital Epidemiology

The disciplines of ► hospital epidemiology and infection control were born at the Vienna hospital, where, in 1847, Ignaz Semmelweiss decreased mortality from puerperal sepsis by instituting a disinfection procedure. Other luminaries followed and left their marks: Joseph Lister with his promotion of surgical antisepsis and asepsis, Florence Nightingale with observations on the deplorable conditions in hospitals that promoted the spread of infection, William Halsted with the introduction of rubber gloves during surgery, and Robert Koch who placed the germ theory on firm scientific ground (Mayhall 2004).

The field of hospital epidemiology is young and still growing. The challenges faced are getting more complex and multifaceted. The character of hospitals has changed. Patients are older and sicker, underlying diseases are more compromising, invasive diagnostic and therapeutic procedures are more common, and resources fail to keep up with demand for services. Antimicrobial resistance, often multiple, is increasing inexorably. Today, even more issues challenge and stimulate the hospital epidemiologists. As a consequence of the growing AIDS epidemic, employee safety from bloodborne pathogens and diseases has emerged as a major infection control issue.

The basic concepts of hospital epidemiology and infection control may not have changed radically from the time of Semmelweiss, yet the application of science and implementation of effective programs require knowledge in several disciplines including microbiology, infectious diseases, epidemiology, biostatistics, and the social sciences (Mayhall 2004).

Because of the illnesses, deaths, and added costs related to nosocomial infections, the field of infection control has grown in importance over the last 40 years.

Molecular Epidemiology

In recent years, developments in molecular biology were taken over by epidemiologists, and the use of biomarkers of exposure and effect has led to a boom of so-called molecular epidemiology (Ahrens et al. 2005). The basic premise of molecular epidemiology is that greater precision in estimation of exposure-disease associations can be made by using molecular biology in epidemiologic studies. This "discipline" (a method of measurement rather than a discipline) has already made many valuable contributions to biomedical and clinical science and has great promise for the future.

Genetic Epidemiology

A great improvement in understanding of the human genome led to the rapid progress of genetic epidemiology. Last's dictionary defines genetic epidemiology as a "science that deals with the etiology, distribution, and control of disease in groups of relatives, and with inherited causes of disease in populations. The study of the role of genetic factors and their interaction with environmental factors in the occurrence of disease in human populations" (Last 2001).

A popular textbook on genetic epidemiology defines it as a "discipline that seeks to unravel the role of genetic factors and their interactions with environmental factors in the etiology of diseases, using family and population study approaches" (Friis, Sellers 1999).

The terms *molecular* and *genetic* epidemiology are sometimes used interchangeably. These two fields overlap in some respects, but they differ in others. Genetic epidemiology is concerned with inherited factors that influence the risk of disease (it includes the identification of unknown genes); whereas molecular epidemiology uses molecular markers to establish exposure-disease associations (it evaluates the association of variation in a known gene with risk of disease).

Genetic epidemiology can be considered as a science designed to answer the following four questions:

- Does the disease cluster in families?
- Is the clustering a result of common environment and lifestyle, or similar risk factors?
- Are the risk factors for a disease within families consistent with Mendelian transmission of a major gene?
- Where is the chromosomal location of the putative gene?

The expected future scientific discoveries in the field of molecular and genetic epidemiology will not only improve our understanding of disease etiology, but may lead to better and more tailored approaches to primary and secondary prevention (e. g. screening for some diseases) (Friis, Sellers 1999). ► epidemiology, genetics.

Psychological, Behavioral, and Social Epidemiology

The field of social epidemiology is concerned with the influence of a person's position in the social structure on the development of disease. Behavioral epidemiology studies the role of behavioral factors in health. The term psychosocial epidemiology has been more broadly conceptualized as social, behavioral, and psychological factors (Friis, Sellers 1999).

Disaster Epidemiology

Epidemiologic methods can be used to measure and describe the adverse health effects of natural and human-caused disasters, and the factors that contribute to those effects. By identifying risk factors for specific outcomes such as death and injury, epidemiologists can help develop effective strategies to prevent future

disaster-related morbidity and mortality. In addition, they play an important role in establishing priorities for action by public health authorities, and in emphasizing the need for valid and timely data collection and analysis as the basis of immediate decision-making (Noji 1997).

The Feature of Epidemiology

In his essay "Epidemiology: Quo vadis?", Professor Olli S. Miettinen, one of the most influential epidemiologists of the 20th century, argues strongly that epidemiology has a 'central role in the production of the knowledge base for scientific medicine' and that epidemiologists have a crucial mission in this regard, proposing a 'larger and higher mission'. This 'meta-epidemiologic' mission places epidemiology centrally within medicine, and broadens its purpose into a number of clinical domains. He calls for a new activism on the part of epidemiologists, suggesting that they become 'agents of change' in challenging epidemiologists to face the future in non-epidemiologic environments (Miettinen 2004).

Where is epidemiology heading? In recent years, it has become an increasingly important approach in both public health and clinical practice. There are new challenges ahead for epidemiology and epidemiologists, some reflective of Miettinen's 'higher mission'. New technologies are 'pushing' biomedical research and medical practice, bringing the possibility of testing hypotheses at deeper biological levels in the population context. Research models and approaches are changing and becoming increasingly multidisciplinary. Public and funder expectations are high. If the past is a good predictor of the future, then epidemiology is well on track. The future is both challenging and promising (Samet 2004).

Summary

Epidemiology is the study of the distribution and determinants of health-related states in populations, and the application of this study to control of health problems. The concept of populations is fundamental to epidemiology. This embraces all aspects of epidemiology, including studies in the general population, occupational populations, and clinical populations. Epidemiology can identify the cause of a disease and the risk factors, determine the burden of disease in the community, describe the natural history of disease, predict disease trends, identify the health needs of a community, test the efficacy of intervention strategies, and evaluate intervention and public health programs.

Epidemiology has both the theoretical, and now increasingly, practical methodological tools to make it possible to examine the big questions of individual and population health. Epidemiological practice, uniquely in medicine, embodies the big-picture outlook of both community medicine and modern public health.

Epidemiologic methods are often the first scientific methods applied to a new health problem in order to define its pattern in the population and to develop hypotheses about its causes and methods of transmission. Epidemiological studies have apparently distinct designs but are unified by their common goal to understand the frequency and causes of disease, by their strategy of seeking associations between exposure to potential causes and diseases, by their utilization of the survey method, and by their basis in defined populations.

The scope of epidemiology has broadened with the discovery or invention of new applications and methods. This and the changing pattern of diseases have encouraged subdivisions of epidemiology. Nowadays there are many branches of epidemiology, like infectious disease epidemiology, cancer epidemiology, cardiovascular disease epidemiology, general epidemiology, epidemiology of aging, clinical epidemiology, hospital epidemiology, injury epidemiology, behavioral epidemiology, pharmacoepidemiology, genetic epidemiology, disaster epidemiology, etc.

In recent years, epidemiology has become an increasingly important approach in both public health and clinical practice. If the past is a good predictor of the future, then epidemiology is well on track. The future is both challenging and promising.

Definition

Epidemiology is defined as "the study of the distribution and determinants of health related states or events in specified populations, and application of this study to control of health problems. *Study* includes observation, surveillance, hypothesis-testing analytic research methods, and experiments. *Distribution* refers to analysis according to time, place, and classes of persons affected. *Determinants* are the physical, biologic, social, cultural, and behavioral factors influencing health. *Health-related states or events* include diseases and injuries, causes of death, behavior such as use of tobacco, reactions to preventive or therapeutic regiments, and provision and use of health services. *Specified populations* are those with identifiable characteristics, such as precisely known numbers. *Application to control* makes explicit the purpose of epidemiology – to promote, protect, and preserve good health" (Last 2001).

Basic Characteristics

Introduction

"Based on what it has done in the last 150 years, epidemiology is the science and practice which describes and explains disease patterns in populations, and puts this knowledge to use to prevent and control disease and improve health" (Bhopal 2002).

Epidemiology is primarily concerned with disease and health hazards in populations, not individuals. Patterns of disease in populations are results of multiplicative interactions between individuals, societies and environment. The science of epidemiology combines elements of biology, social science and ecology (Bhopal 2002). It is complemented by statistics, ► demography and philosophical theories. However, "epidemiology can not be reduced to a sub-division of one of the contributing sciences but it should be considered as a multidisciplinary science giving input to the applied field of public health" (Ahrens et al. 2005).

Aims of Epidemiology

The principal aim of epidemiology is to identify factors related to the ► occurrence of disease. Identification of these factors both causal (► causation) and ► risk factors, enable developing a rational basis for prevention (► epidemiology, prevention). This can be illustrated by investigation of an outbreak (► outbreak investigation) of food poisoning in order to determine which food was contaminated with the microorganisms or chemicals that caused the epidemic (► outbreak investigation), as well as by investigation of the relationship between various environmental factors and/or genetic factors with the occurrence of breast cancer.

Epidemiological investigations provide evidence which underline the critical processes of clinical practice, including diagnosis, prognostication, and selection of therapy. The practice of medicine depends on population data. "The physician applies a population-based probability model to the patient who is lying on the examining table" (Gordis 2004).

The epidemiology is a basic science of ► public health. Studying frequency and distribution of disease in a population, and the natural history of disease, as well as evaluating existing and new preventive and therapeutic measures and modes of healthcare delivery, epidemiology provides the foundation for developing healthcare policy and planning (Gordis 2004). For example; the Salk vaccine field trial (1954), which comprised nearly one million children, gave the basis for worldwide implementation of poliomyelitis vaccination programs for disease prevention; the community-intervention trials of fluoride supplementation in water (beginning during 1940s) have led to widespread primary prevention of dental caries; knowledge from Framingham Heart Study, initiated in 1949, and other similar epidemiological studies, has helped to stem the epidemic of cardiovascular mortality in majority of developed countries (Rothman, Greenland 1998).

Scope of Epidemiology

For many years epidemiology was considered to be restricted to the infectious diseases, which were the major health problem in the past. With changing pattern of population morbidity and mortality, the scope of epidemiology has been enlarging. "It is generally accepted that epidemiological studies can appropriately be applied to all diseases, conditions, and health related events, and it is concerned not only with epidemics, but also with interepidemic periods and with ► sporadic and ► endemic occurrence of disease" (Mausner 1985). "For more than half a century epidemiology, as an aggregate of knowledge with a methodological core, has expanded in a multiplicity of directions, penetrat-

ing in a capillary way the whole field of medicine and public health" (Saracci 2004).

The growing implementation of epidemiological methods in investigating health problems resulted in formulating of separate areas of epidemiology, defined according to disease groups (infection disease epidemiology, cardiovascular epidemiology, cancer epidemiology, neuroepidemiology and other) or according to group of factors, which relationship with diseases is investigated (social epidemiology, environmental epidemiology, nutritive epidemiology, reproductive epidemiology and other).

In the second half of the 20th century accelerated development of clinical epidemiology followed by pharmacoepidemiology, took place.

In recent years, developments in molecular biology were taken over by epidemiologists, and the use of biomarkers of exposure and effect has led to a boom of so-called molecular epidemiology. A great improvement in understanding of the human genome, led to the rapid progress of genetic epidemiology (Ahrens et al. 2005).

Most definitions are taken from the last edition of Last's Dictionary of Epidemiology (Last 2001). We are much obliged to Professor Last for his kind consent.

pekmezovic@sezampro.yu

Definition

Classic epidemiology is the study of the frequency and distribution of diseases in populations and the factors associated with their causation; the ultimate aim of such study is the prevention of disease. On the other hand, the techniques of molecular biology, e. g. DNA typing, are utilized in molecular epidemiological studies. Genetic epidemiology is an extension of molecular epidemiology, which evaluates the role of inherited factors in the cause of disease in families and in populations (Khoury et al. 1993). Thus, genetic epidemiology involves principles and methods from epidemiology, molecular biology and genetics.

Basic Characteristics

Genetic epidemiology was developed in the 1960s, as a "mixture" of population/statistical/mathematical genetics and classic/molecular epidemiology (Khoury et al. 1993). Gene–gene and, especially, gene–environment interactions are important in such epidemiological studies as genetic epidemiology aims to detect the pattern of inheritance of a particular disease by the localization of genes and the finding of markers associated with disease susceptibility.

Types of Genetic Epidemiological Studies

At any given point in time, the distribution of genetic traits in a population is a function of the combination of occurrence of mutation, forces that can alter allelic and genotypic frequencies, such as migration, selection, and drift due to population size. Thus, the measures of disease frequency can also be applied to

genetic traits using descriptive epidemiological studies. Study designs for examining associations include cohort, cross-sectional and case-control studies. The basic goal for all these studies is to examine the relationship between disease occurrence and the gene(s) of interest. Sometimes both cross-sectional and longitudinal components can be used in the same study (Bickeboller 2005).

The steps included in genetic epidemiological investigation of a disease are as follows: a) establishing that there is a genetic component to a disorder; b) establishing the relative size of that genetic effect in relation to other sources of variation in disease risk (environmental risk factors), and c) identifying the gene(s) responsible for genetic susceptibility. There are two essential types of genetic epidemiological studies in accordance with these steps,: family studies (segregation, linkage, association) and population studies (association). Additionally, genetic risk studies include family-based and twin/adoption studies (Khoury et al. 1993; Greenberg et al. 2004).

Clustering or familial aggregation of a disease is suggested when the ► recurrence risk among relatives of affected persons exceeds that among relatives of unaffected persons. Cohort and case-control studies are used most frequently to study and quantify a familial aggregation of disease (Neale and Cardon 1992).

► Twin studies provide a simple way to separate genetic from environmental factors, i. e. assess the relative importance of genetic and environmental factors by comparing monozygotic and dizygotic twins for concordance of disease. Greater concordance for disease among monozygotic twins as compared with dizygotic twins suggests genetically determined susceptibility (Neale and Cardon 1992). Similarly, ► adoption studies provide opportunities for separating genetic from environmental factors in a familial aggregation of disease; affected parents who have given up children for adoption and control parents who have given up children for adoption are identified and the frequency of disease in their children compared (Khoury et al. 1993).

► Segregation analysis is a complex statistical technique used to study the pattern of occurrence of disease within pedigrees and requires multigenerational family trees, preferably with more than one affected member. This type of genetic epidemiological study can suggest the likely mode of inheritance (autosomal dominant, autosomal recessive, or multifactorial), i. e. which mode of inheritance is most consistent with the pattern of disease occurrence seen within families (Bickeboller 2005).

Linkage studies (► linkage analysis) use parametric or nonparametric methods such as allele sharing methods (affected sibling-pairs method) with no assumptions about the mode of inheritance, penetrance or disease allele frequency. It is an indirect approach, that depends on a genetic linkage between the genetic marker and the disease susceptibility gene. Linkage studies provide information on crude chromosomal location (candidate regions) of the gene or genes associated with the phenotype of interest (Khoury 1998).

► Association studies may be family-based (transmission/disequilibrium test–TDT) or population-based. Alleles, haplotypes or evolutionary-based haplotype groups may be used in association studies. The studies can include nuclear families (index case and parents), affected relative pairs (sibs, cousins, and any two members of the family), extended pedigrees, twins (monozygotic and dizygotic) or unrelated population samples. "The aim of association studies is to show evidence for association and ► linkage disequilibrium in a population" (Bickeboller 2005).

Gene–Environment Interactions

The concept of genetic–environmental interaction is crucial in understanding the dynamics of health and disease (Ottman 2001). Five biologically plausible models account for the relationship between genotypes and environmental exposures, in term of their effects on disease risk. Under the model A, the genetic factor is the primary determinant of the disease, while the environmental factor has no effect by itself, but can modify the risk associated with the genetic factor. Model B specifies that the environmental factor is the primary determinant of the disease, while the genetic factor has no effect by itself, but can modify the risk associated with the environmental factor. In model C, the environmental factor exacerbates the effect of the genetic factor, but there is no effect of exposure in the low-risk genotype. In model D, both environmental and genetic factors are required to increase the risk of disease. Finally, in model E, both the genetic and environmental factors may increase or decrease the risk of disease by themselves, but the effect of each of these factors depends on the presence or absence of the other factor (Ottman 1990).

Genetic Epidemiology and Prevention

"Genetic epidemiology addresses the fundamental goals of preventive medicine and public health at the various levels of disease prevention" (Khoury et al. 1993). There are numerous methods for the prevention of genetic disorders, such as genetic counseling (primary prevention), genetic screening (secondary prevention), or for minimizing the effects of genetic diseases by preventing complications and deterioration (tertiary prevention). In line with these, the availability of genetic centers providing genetic counseling and prenatal diagnosis are essential for the prevention and management of many genetically determined diseases. Recently, special attention has been paid to family-centered prevention with the aim of predicting the risk of disease in relatives of individuals affected with inherited disorders.

Genetic epidemiology might be of great importance in ► public health surveillance, especially in fields of surveillance on teratogens, mutagens and carcinogens. In many developed countries, population-based surveillance systems for birth defects, including structural defects and chromosomal abnormalities, have been established with the aim of providing baseline information for prevention and research.

Epidemiology, Prevention

ZORANA GLEDOVIĆ
Institute of Epidemiology, School of Medicine, University of Belgrade, Belgrade, Serbia
gledovic@sezampro.yu

Definition

Prevention is defined as "actions aimed at eradicating, eliminating or minimizing the impact of disease and disability. The concept of prevention is best defined in the context of levels, traditionally called primary, secondary and tertiary prevention" (Last 2001).

Basic Characteristics

The goals of medicine are to promote health (► health promotion), to preserve health, to restore health when it is impaired and to minimize suffering and distress. The primary role of clinical medicine is to treat people who are sick. In population health we would prefer that people did not become ill. Epidemiology can play a central role in prevention by identifying ► causes of disease. In particular it provides quantitative measures of ► relative risk and ► absolute risk that help directly preventive action, and it plays a major role in evaluating whether preventive programs actually work in practice (Webb 2005).

Levels of Prevention

In discussing prevention it is helpful to distinguish levels of prevention customarily called *primary*, *secondary* and *tertiary* and later added *primordial* prevention. Between these levels there are no precise boundaries (Last 2001). All levels of prevention are important and complementary, although primordial and primary prevention most contribute to the health of the whole population.

Primordial Prevention

The aim of *primordial prevention* is to avoid the emergence and establishment of the social, economic and cultural patterns of living that are known to contribute to an elevated risk of disease. The target for primordial prevention is whole population (► target population) or selected groups. This level of prevention have been recognized the most recent as a result of increasing knowledge about the epidemiology of cardiovascular diseases. It is also needed in respect of the global effects of air pollution (the greenhouse effect, ozone-layer depletion) and health effects of urban smog (lung diseases). Effective primordial prevention often requires strong government regulatory action. The countries need to avoid the spread of unhealthy lifestyles before they become ingrained in society. The importance of primordial prevention, regrettably, has often been realized too late (Beaglehole and Bonita 1997).

Primary Prevention

The aim of *primary prevention* is to limit the incidence of disease by controlling causes and risk factors. Target for primary prevention may be the whole population, selected groups or healthy individuals. Primary prevention involves two strategies that are often complementary. It can focus on the whole population with the aim of reducing average risk (the population strategy), or on people at high risk as a result of particular exposures (individual strategy).

Population based approaches can be considered public health approaches, whereas high-risk approaches often require clinical action. In most situations, a combination of both approaches is needed (Gordis 2004).

The major advantage of the population strategy is that does not require identification of the high-risk groups, and main disadvantage is that it offers little benefit to individuals because their absolute risks of disease are quite low. For example, most people wear a car seatbelt while driving without being involved in a crash, while the widespread wearing of seat-belts has produced benefits to many societies. This phenomenon has been called the ► prevention paradox (Rose 1985).

Good examples of primary prevention are ► vaccination against infectious disease in children, use of condoms in the prevention of HIV infection, needle exchange system for intravenous drug users to prevent hepatitis B and HIV infection, and so on.

Secondary Prevention

Secondary prevention aims to cure patients and reduce the more serious consequences of disease through early diagnosis and treatment. It is directed at the period between onset of disease and the time of diagnosis, and aims to decrease the prevalence of disease. The two main requirements for a useful secondary prevention are a safe and accurate method of detection of the disease, preferably at a preclinical stage (► screening), and effective methods (► effectiveness) of intervention. Cervical cancer provides an example of the importance of secondary prevention and also illustrates the difficulties of assessing the value of prevention programs, because the mortality rates for cervical cancer were already decreasing before organized screening programs started. Many studies supported the values of such screening programs, and they are now widely applied in many countries. The example of secondary prevention that is widely used is blood pressure measurements and treatment of hypertension in middle-aged and elderly people (Beglehole and Bonita 1997).

Tertiary Prevention

Tertiary prevention is aimed at reducing the progress or complications of established disease and is an important aspect of therapeutic and rehabilitation medicine. It consists of measures intended to reduce impairments and disabilities. The rehabilitation of patients with strokes, injuries, blindness and so on is of great importance in enabling them to take part in daily social life (Beaglehole and Bonita 1997).

The importance of each level of prevention is inversely related to their range. From the public health point of view the greatest importance has been given to population approaches in primordial and primary prevention.

Choosing the Prevention Strategy

While the principle goal of ► public health should be primary prevention, for many diseases we do not have enough information to perform such program effectively. Even when we do have enough information, the barriers to implementation may be substantial (e. g. financial, cultural, ethical). For example, we know that ensuring everyone has access to clean water would prevent a large proportion of infectious diseases, but the practical and financial implications are enormous. Sim-

ilarly, by persuading people to stop smoking, stay out of the sun, exercise more and eat better we could prevent much chronic diseases, but changing behavior remains a major challenge.

The continuously changing patterns of mortality and morbidity over time indicate that great number of diseases are preventable. Epidemiology, by identifying causes of diseases, play central role in prevention. In addition to epidemiologists, in prevention are involved other medical doctors as well as sanitary engineers, chemists, sociologists, psychologists, economists and others.

The need for prevention is gaining acceptance in all countries as the limitations of modern medicine in curing disease become apparent and the costs of medical care escalate.

Epiglottitis

Synonyms

Supraglottitis; Inflammation of the epiglottis

Definition

Epiglottitis, which is caused by the bacterium *Haemophilus influenzae* type B (Hib), usually occurs in children at the age of 2–6 years. It is a disease with a dramatic course and a potentially lethal outcome. There is severe swelling of the epiglottis and the entrance of the larnyx; typical symptoms are: extreme deterioration, fever, sore throat, signs of respiratory distress, muffling or changes in the voice, difficulties in speaking and swallowing and salivation. An airway occlusion can lead to suffocation. The quick administration of antibiotic therapy (cephalosporines) is essential. Intensive care measures, like intubation or even an incision in the windpipe (tracheotomy) with subsequent mechanical ventilation, may be necessary. Luckily, since the introduction of the active Hib-vaccination (► immunization, active), the incidence of epiglottitis has declined rapidly.

Episodic Paroxysmal Anxiety

► Panic Disorder

Equality

Synonyms

Principle of equal treatment

Definition

Equality implies that all persons are equal to one another; they have the same rights and should have the same opportunities. It is the principle by which all persons or things under consideration are treated in the same way.

Equilibrium of Body Fluids and Electrolytes

► Body Fluid and Electrolyte Balance

Equity

Synonyms

Principle of fair treatment

Definition

Equity is defined as follows:

Equity means fairness. Equity in health means that people's needs guide the distribution of opportunities for well-being. The WHO global strategy of achieving "Health for All" is fundamentally directed towards achieving greater equity in health between and within populations, and between countries. This implies that all people have an equal opportunity to develop and maintain their health, through fair and just access to resources for health. Equity in health is not the same as equality in health status. Inequalities in health status between individuals and populations are inevitable consequences of genetic differences, of different social and economic conditions, or a result of personal lifestyle choices. Inequities occur as a consequence of differences in opportunity which result, for example in unequal access to health services, to nutritious food, adequate housing and so on. In such cases, inequalities in health status arise as a consequence of inequities in opportunities in life.

Equity in the Distribution of Environmental Hazards and Resources

► Environmental Justice

Equivalent Continuous Noise Level

Synonyms

Equivalent sound level; Equivalent sound pressure level

Definition

Equivalent continuous noise level (L_{eq}) is the continuous steady ► noise level that would have the same total acoustic energy as real fluctuating noise over the same interval of time. The mathematical definition of L_{eq} for an interval defined as occupying the period between two points in time, t_1 and t_2, is:

$$L_{eq} = 10 \log \left[\frac{1}{t_2 - t_1} \int_{t_1}^{t_2} \frac{p^2(t)}{p_0^2} \, dt \right]$$

In this definition, $p(t)$ is the time-varying sound pressure, and p_o is a reference pressure, taken as 20 μPa. L_{eq} has been adopted by the International Standard Organization for the measurement of community noise and assessment of hearing damage risk.

e-Receipt

Definition

A great change occurred with the emergence of paperless receipts when the Electronic Communications Act was published in Great Britain in 2000. Many European countries have since developed and locally tested electronic receipts or e-receipts. The proposed model of implementation is as follows: the physician should order a drug by entering specific data into the patient's record on the server, and the patient provides the pharmacist with a specific code that grants authorized access to the receipt on the server.

Ergonomics

SRĐAN BORJANOVIĆ
Institute of Occupational Health, Belgrade, Serbia
drsrle@sezampro.yu

Synonyms

Human factors; Human factors engineering; Human engineering

Definition

Ergonomics or "human factors" is a multidisciplinary, applied science that relates to the interaction, physical and behavioral, between the people and their work system, tool, task and environment. "Human factors" is a term used mainly in the United States. Variants include "human factors engineering", an extension of

an earlier phrase, and "human engineering". In Europe, Japan and the rest of the world, the term "ergonomics" is more prevalent. "► Human factors" is an umbrella term for several areas of research that include human performance, technology, design, and human-computer interaction. It is a field that deals with human abilities and characteristics which affect the design of equipment, systems, and jobs. Whereas ergonomics tends to focus on the anthropometrics and biomechanics for optimal human-machine interaction, human factors is more focused on the cognitive and perceptual factors.

Basic Characteristics

Overview

The limits of ergonomics itself are not entirely agreed. It crosses the boundaries of several scientific and professional disciplines and utilizes data, findings, and principles from all of them. Ergonomics draws on many disciplines in its study of humans and their environment, including anthropometry, biomechanics, kinesiology, work physiology, environmental medicine and psychology, as well as parts of engineering, industrial design, and operations research.

The terms ergonomics and human factors engineering are often used interchangeably. Initially ergonomics was more physiology and health and comfort oriented, while human factors engineering was more oriented to physical sciences. The focus of the study is the human interacting with the engineered environment. Human-factors engineers regard humans as an element in systems. A "► man-machine system" is the usual way of representing that relationship. A "man-machine system" means that the man and his machine have a reciprocal relationship with each other. A man is effectively a single channel device, although one that time shares. No matter how important it may be to match an individual ► operator to a machine, some of the most challenging and complex human problems arise in the design of large man-machine systems and in the integration of human operators into these systems. Examples of such large systems are modern airplanes, control rooms in industrial plants, air-traffic control rooms and artificial life support systems in space or in a nuclear submarine. With the adoption of a systems point of view, the scope of ergonomics has passed beyond the concern of individual worker and his machine or workplace to include consideration of the total work environment.

Ergonomists adapt the design of products and workplaces to human's sizes and shapes and their physical strengths and limitations. Ergonomists also consider the speed with which humans react and how they process information, and their capacities for dealing with psycho-physiological factors, such as stress and mental load. Knowing the complete picture of how humans interact with their environment, ergonomists develop the best possible design for products and systems. Ergonomists view human operators and the objects they use as one unit, and ergonomic design blends the best abilities of people and machines. An ergonomically sound system provides optimum performance because it takes advantage of the strengths and weaknesses of both its human and machine components. This has always been done intuitively by good designers, but systems ergonomics aims to ensure that this is done systematically. This involves a body of knowledge and techniques that are new and are not derived from the other sciences. The ergonomists work in teams which may involve a variety of other professions: design engineers, computer specialists, occupational health physicians, psychologists, health and safety practitioners, and specialists in human resources.

In the US human factors engineering was emphasized by the US military with concentration on human engineering and engineering psychology. The focus was on enhancing performance and reducing errors. Areas of interest for human factors specialists may include the following: workload, fatigue, situational awareness, user interface, learning and skill ability, training, vigilance, memory, human performance, information processing capacity, human reliability and errors, human-computer interaction, control and display design, stress, visualization of data, individual differences, aging, accessibility, safety, shift work, organization and work design, work in extreme environments including virtual environments, and decision making.

The term human factors engineering is used to designate equally a science, a technology, and a profession. As an intermediate science, among engineering, medicine and psychology, human-factors engineering is a collection of data and principles about human characteristics, capabilities, and limitations in relation to machines, jobs, and environments. As a technology, it refers to the design of machines, machine systems, work methods, and environments to take into account the safety, comfort, and productiveness of human users

and operators. As a profession, human-factors engineering includes a range of scientists and engineers from several disciplines that are concerned with individuals and small groups at work. In practice, human factors engineering is a problem solving process.

Domains

The International Ergonomic s Association (IEA) divides ergonomics broadly into three domains:
Physical ergonomics deals with the human body's responses to physical and physiological loads. Relevant topics include manual materials handling, workstation layout, job demands, and risk factors such as repetitive motions, force and awkward/static postures related with musculoskeletal disorders.
Cognitive ergonomics, also known as engineering psychology, concerns mental processes such as perception, attention, cognition, and memory storage and retrieval as they affect interactions among humans and other elements of a system. Relevant topics include mental workload, vigilance, decision making, skilled performance, human error, human-computer interaction, and training.
Organizational ergonomics is concerned with the optimization of socio-technical systems, including their organizational structures, policies, and processes. Relevant topics include shift work, scheduling, job design and restructuring, job satisfaction, motivational theory, supervision, and teamwork.

History

Although the terms "human factors" and "ergonomics" have only been widely known in recent times, the field's origin is in the design and use of aircrafts during World War II to improve aviation safety. World War II marked the advent of highly sophisticated machines and weapons, creating previously unseen cognitive demands on operators in terms of decision-making, attention, situational awareness and hand-eye coordination. The modern discipline of ergonomics was born in the United Kingdom on July 12, 1949, at an interdisciplinary meeting of the British Admiralty where the term ergonomics was officially proposed by Prof. Hugh Murrell. The term ergonomics came into use about 1950 when priorities of developing industry were taking over from the priorities of military. In United Kingdom, Ergonomics Society was formed in 1952, while in United States the Human Factors Society was founded in 1957, and renamed in 1992 as Human Factors and Ergonomics Society (HFES). Today, the ▶ International Ergonomics Association (IEA) is a federation of forty-two individual ergonomics organizations from around the world.

Application Examples

Ergonomists work to eliminate repetitive strain injuries, carpal tunnel syndrome and low back pain by designing workplaces without continuous repetitions of the same motions, like screwing or twisting items on an assembly line and without awkward postures, like banding or reaching. They design adjustable workbenches, desks, and chairs to comfortably accommodate workers of many different sizes. Ergonomically designed chairs distribute a person's body weight evenly to avoid back and neck strain. In recent years ergonomics have been associated more and more with computer products, such as ergonomic mice and keyboards. Specially curved computer keyboards enable typists to hold their wrists in a position that is less likely to cause a carpal tunnel syndrome. Human factors issues are also considered in a design of consumer products. Examples include cellular phones and other handheld devices. Some ergonomists practice in the area of job design, while cognitive ergonomists specialize in information design – the best way to present complex information. Ergonomists also design training simulations. Training for pilots and astronauts may include simulations developed by ergonomists. Quality of life for older and disabled people may also be enhanced by the ergonomic improvements in the built environment. Many ergonomists investigate the way control panel operators interpret information, their reaction speed, and how both of these factors are influenced by the stress of an emergency. Warning signals must be easy to interpret and control devices must be easy to use particularly in aircrafts, air traffic control rooms, and nuclear power plants, where quick accurate reactions are imperative to public safety. Number of accidents occurred due to disregarding of ergonomic design principles. A poorly designed control panel and human errors made during the night shift were factors during the near meltdown of the nuclear generating station at Three Mile Island, Pennsylvania, in 1979. Poorly designed aircraft cockpit was a factor in a crash of a China Airlines Air-

bus A300–600R during landing at Nagoya airport in 1994. The Presidential Commission on the space shuttle Challenger disaster determined that human error and poor judgment related to sleep loss and fatigue during early morning shift contributed to that incident (Scott 1994). The nuclear disaster in Chernobyl is attributable to plant designers not paying enough attention to human factors (Munipov 1998). The complexity of the reactor and the control panel outstripped the operator's ability to understand what is going on.

Error

Definition

Error could be considered as a false or mistaken result obtained in a study. Error can be either random or systematic. Random error is a part of variation in a measurement that has no apparent connection to any other measurement or variable, generally regarded as due to chance. Random error is often leading to lack of precision in the measurement of an association. Systematic error, often has a recognizable source, e. g., a faulty measuring instrument. It leads to results consistently wrong in a particular direction, and differ from the truth in a systematic way.

Error in Measurement

Synonyms

Measurement error

Definition

In all measurements some degree of uncertainty is present, and it can be expressed as error in measurement. Error is the difference between the measured value and the true value. The errors that occur in the measurement process are inherent, and can be reduced only by more adequate measuring. The errors can be classified into two categories: systematic and random errors (see essay Measurement). The measurement can be more adequate by identifying and minimizing error. Measurement adequacy subsumes various concepts such as ► accuracy, ► agreement, ► precision, ► reliability, validity.

Erythema infectiosum

Synonyms

Parvovirus B 19 infection; Fifth disease; Slapped cheek syndrome

Definition

Erythema infectiosum is caused by parvovirus B19, which was detected in 1974. The name "fifth deasease" stems from the 17th century practice of listing the rash-illnesses of childhood; erythema infectiosum was the fifth disease listed. Often the infection is either asymptomatic or presents with flu-like symptoms. The incubation period lasts 4–14 days. Contagion is highest between the first 4–10 days, that means even before symptoms develope. The typical rash is only seen in 15–20%; it starts in the face with bright red cheeks and then spreads over the upper arms, shoulders, thighs and buttocks. With the spots confluating and becoming pale in the center they look like a garland. Possible complications are joint pain and arthritis. As the viruses affect the red blood cells and their precursors in the bone marrow, anemia can result. A primary infection in pregnancy might be transmitted to the unborn child leading to an intrauterine infection of the baby (► congenital erythema infectiosum).

Erythema subitum

Synonyms

Exanthem subitum (ES); Roseola infantum; Infection with human herpesvirus 6; Pseudorubella

Definition

Exanthem subitum, which is spread by droplets, is caused by human herpesvirus 6 (HHV 6). It is most common in children between six months and three years of age. In most cases the disease takes a harmless course. It is followed by a lifelong immunity. After an incubation period of 5–15 days roseola infantum starts with high fever. The fever lasts for three days and then suddenly decreases. When body temperature returns to normal, a macular exanthem appears on the trunk, which spreads to the arms and legs. Usually, there is no rash on the face. In general, no therapy is necessary except for antipyretic measures.

Essential Public Health Services

Definition

Essential public health services are health services identified in "Public Health in America" that define the practice of public health. Ten services are listed: monitoring health status; diagnosing and investigating health problems; informing, educating, and empowering people; mobilizing community partnerships; developing policies and plans; enforcing laws and regulations; linking people to needed services; assuring a competent workforce; conducting evaluations; and conducting research.

Establishment of the Menses

► Menarche

Estimate of a Population Related Gender of Disease

► Disability Adjusted Life Years (DALYs)

Estimation

Definition

Estimation is concerned with inference about the numerical value of unknown population values from incomplete data such as a sample. If a single figure is calculated for each unknown parameter, the process is called point estimation. If an interval is calculated within which the parameter is likely, in some sense, to lie, the process is called interval estimation.

Ethical Absolutists

Definition

Different approaches guide public health stakeholders in dealing with ethical dilemmas. Ethical absolutists are those who do not see the point of an ethics discussion because they already know the right answer and do not wish to defend their values by giving reasons or to make themselves open to other views; usually their values are strongly based in a religious perspective.

Ethical Framework for Public Health Genetics

BRUCE JENNINGS
Center for Humans and Nature, New York, NY, USA
brucejennings@humansandnature.org

Definition

Public health genetics involves the application of genetics, genomics, and biotechnology to improve public health and to prevent disease. Genetics involves the analysis of DNA (► deoxyribonucleic acid), RNA, ► chromosomes, proteins and certain metabolites in order to understand heritable disease related ► genotypes, ► mutations, ► phenotypes, or karyotypes. Genomics studies the relationship between genetic factors and the environment, broadly defined to include all exogenous factors – chemical, physical, or social. Ethics involves the systematic analysis of moral principles, ideals, values, and standards of right and wrong, benefit and harm in human conduct and social policy.

Basic Characteristics

Until recently, medical genetics involved the study and treatment of rare disorders and the public health component of genetics was limited to newborn screening programs for the early detection and treatment of a small number of conditions such as phenylketonuria (PKU), Tay-Sachs, sickle cell anemia, and the thalassemias. Public health practice also extended into the area of health service delivery involving individual ► genetic testing and ► genetic counseling, although those areas have tended to be seen more as clinical practices rather than public health services. Both public health practice and the contemporary field of medical genetics inherently involve ethical questions, controversies, and issues. The intersection of public health and genetics is a domain that is particularly complex from an ethical perspective because potential conflicts between the rights and interests of individuals and the health and interests of society frequently arise.

A New Era of Public Health Genetics

In the 1990s The Human Genome Project and related genetic research moved the relevance of genetics for both clinical medicine and public health to a new level. It is now possible to identify genes (specific sequences of base pairs comprising the huge DNA molecule found curled in the nucleus of each cell of the body) associated with biochemical abnormalities that are in turn linked to symptomatic disease, dysfunction, and perhaps tendencies toward certain forms of behavior (Kitcher 1996).

The mapping and sequencing of the human genome (completed in 1994) has already begun to transform medical practice, and it promises both a better understanding of human biology and greatly increased insight into the causes and potential prevention and treatment of many very prevalent types of human disease. Effective ► gene therapy still lies years in the future. But the development of a vast array of new genetic tests, and less expensive testing methods, appears to offer a precise, objective approach to identifying who has or is at risk for certain diseases, thereby permitting earlier and better-targeted interventions, and hence may greatly enhance the knowledge base of public health beyond the level of epidemiological studies based on phenotype and the presence of symptomatic disease alone (Beskow et al. 2003). Genetic information may make it possible to develop more effective therapies or pharmaceuticals (► pharmacogenomics) for individuals or groups, including those socially defined as distinct racial groups. Data bases historically maintained by public health agencies may be important tools in new and advancing research in this field, and policies concerning the degree of public health involvement and cooperation in such research will have to be developed.

Unfortunately, this new knowledge and technology also threaten to create new forms of discrimination and domination (Duster 1990; Nelkin and Tancredi 1994). There are three principal reasons why the field of public health must exercise ethical caution as it adapts to and embraces the new knowledge base and technologies of genetics and genomics. First, the field of public health has been traditionally more oriented toward the values of population benefit and societal interests than it has to the rights and interests of individuals. Second, the history of public health involvement with matters of genetic and hereditary disease (► eugenics) is not a proud or ethically exemplary one (Kevles 1995). Third, the current state of public understanding of the significance of genetics is poor and due to misunderstanding about purported genetic determinism the danger exists of serious social stigma and discrimination against particular individuals or groups. On the other side of this coin is the potential for suspicion and loss of trust in public health authorities by such groups if public health is perceived as an instrument of such discrimination.

Individual Rights and the Public Interest

Public health and public health genetics are primarily concerned with population level knowledge and health. However, genetic information is inherently particular, unique and individuating. It is a mark of individual risk, potential, and even identity. It implicates the most intimate kinds of family and reproductive relationships and decisions. It has an impact not only on social stigma, but also personal self-esteem. In the areas of both surveillance and intervention, public health measures that are important on a population level may adversely affect the ► privacy and ► autonomy of individuals. And, in the case of the relationship between race and genetics, it may also adversely affect the self-perception and definition of communities.

For these reasons, public health genetics must resist the tendency to resort to legal "police powers" and coercive compliance measures in the areas of genetic screening, testing, and in the use of collected information. Public health should rely instead whenever possible on voluntary programs incorporating the requirement of individual ► informed consent and assuring the provision of adequate genetic counseling services. In the collection of genetic information personal identifiers should be carefully protected and confidentially (► confidentiality) maintained. Public health genetics poses very difficult balancing between the health of the society as a whole and the rights and protections of individuals and sub-groups within society.

The Ethical Legacy of Eugenics

Social science research has demonstrated that scientific knowledge is shaped by the worldviews and ethical values of the group(s) claiming that knowledge. Thus one can expect that the information that genetics appears to bring to medicine will reflect the cultural, religious, and historical perspectives and assumptions of those who apply this information in medical research, prevention, and treatment of disease. Because both health care practitioners and the lay public will view the findings of genetics through their pre-existing intellectual and experiential frameworks of health and illness, it is important to understand the prevailing views of medicine and disease in our society and the ethical tensions that they already embody.

Public health is not immune to social or racial prejudice (Paul 1995). It may mistake the individual who suffers from disease for a vector responsible for the spread of a disease. Its mission to rid society of disease, disability and other health burdens can be misconstrued as a mission of eliminating the genetic factors contributing to disease from the population (negative ► eugenics). It may also mistake its mission of promoting human health and welfare for the task of enhancing the traits and biological properties of individuals and populations (positive eugenics). Many of the methods and so-called public health programs of the past, such as forced sterilization and euthanasia, were crude and monstrous, almost unthinkable in today's climate. But this should not blind public health practitioners to the dangers of much more subtle methods and inducements (financial, social, and cultural) that might be associated with the goals of public health genetics in the future (Parens and Asch 2000). Here the safeguards of autonomy, freedom of choice, informed consent, and nondirective genetic counseling are important hallmarks of ethical public health programs. In addition, it is a public health responsibility to contribute to increasing the genetic literacy of the population and to increase the social acceptance and equal rights of those with various impairments and disabilities so that dangerous norms of "perfect functioning" or "perfect health" are offset by toleration and solidarity.

Partnership with Communities and Genetic Citizenship

The last consideration mentioned above underscores the importance of the role of public health agencies in working with local communities on educational and program efforts to incorporate the tools of genetics into accessible health programs without reproducing the prejudice and discrimination to which genetics is socially and culturally prone. Individuals confront public health genetics at two levels, as private consumers of genetic technologies and services and as public citizens concerned with just public health policy.

At the first level, the ethical practice of public health is concerned with providing equitable access to genetic services so that the new scientific and technological advances do not produce a multi-tiered system of genetic benefit for some and genetic disenfranchisement for others (Buchanan et al. 2000). Given the current distribution and internal incentives in the American system

of health insurance, this prospect of genetic inequality is very real.

Individuals are more than health care *consumers*; they are (and should be) health *citizens*. Public health should facilitate the involvement of community representatives and grassroots participants in the discussion, design, implementation, and evaluation of public health programs across the board, including those involving genetics.

Conclusion:
Guidelines for Public Health Genetics

Due to its particular ethical sensitivity and potential for injustice and the violation of individual rights, policies and programs in the area of public health genetics must be especially careful to adhere to ethical guidelines and benchmarks such as those developed by Childress, Faden, Garre, et al. (Childress 2002). Public health genetics programs must be:

- Effective (They must be reasonably likely to achieve appropriate goals.)
- Proportionate (The probable benefits of the program should outweigh it harms and risks.)
- Necessary (There must be no way to realize the goal without the program.)
- Flexible (The program should be the least restrictive option in terms of individuals rights, liberty and privacy.)
- Transparent (The program must be given a public, open justification.)

Ethical Imperialism

Definition

Ethical imperialism has been used to refer to the application of Western ethical standards, particularly in developing nations with different cultural norms.

Ethical Principles

PASQUALE DI MATTIA
CEFPAS – Centre for Training and Research in Public Health,
Caltanissetta, Italy
lino-dm@libero.it

Synonyms

Ethical rules; Canons; Standards; Doctrine

Definition

Ethical principles are part of a normative theory that justifies or defends moral rules and/or moral judgments; they are not dependent on one's subjective viewpoints. Ethical principles in public health practice refer to those general judgments that serve as a basic justification for the many particular ethical prescriptions and evaluations of public health activities.

Basic Characteristics

Definitions of public health vary widely. However, the field of public health is concerned with health promotion (► health promotion, ethical aspects) and disease prevention (► prevention and health promotion) throughout society, with a broad interest in a more equitable distribution of social and economic resources because social status, race, and wealth are important influences on the health of populations. Public health ethical issues were minimal when an attitude of ► paternalism ruled public health measures and was widely accepted by society. From the second half of the 20th century the authority of medicine and the paternalistic approach of physicians and public health officials has been questioned due to certain factors:

- the discovery of new treatments and new technologies enormously increasing the chances of cure along with the risk of causing harm;
- patients' knowledge in general and on medical issues in particular growing out of proportion;
- the place of the individual gaining more ground in society, and government policies and laws evolving to protecting the individual, on the bases of ► autonomy and ► human rights issues.

Consequently, codes of conduct for studies and research in medicine have been updated to meet this new reality and have been given the more inclusive term of "► bioethics". Bioethics' strong point of reference is the patient-centered approach, giving clinicians clear guidelines for their interaction with patients, based on four fundamental principles: ► beneficence (doing good), ► non-maleficence (not doing harm), autonomy (respect for the person and its rights), and ► justice (distributing benefits, risks and costs fairly).

Those four principles have also strongly influenced public health decisions in recent decades, based on the argument that, while directed to the whole population, public health activities affect individuals. Though public health practice should not overlook the rights, interests, and freedom of the individual, can the ethical principles and values (► ethical values) applied in bioethics (which follow the individualistic orientation) be used as a point of reference for public health interventions which look at the well being of the entire population?

Let us take the principle of non-maleficence. If the point of reference is a single person, it is (somehow) easy to understand what harm might be done to that individual and, as a consequence, measures taken to avoid it. But, in the case of a policy which targets the whole population, it becomes much more difficult (if not impossible) to identify all the factors which might cause harm to all the individuals within that population; even if some factors can objectively be identified, it may not be feasible to take precautions at an individual level when an intervention has to be carried out at the population level. As a conclusion, in public health the principle of non-maleficence can be understood as doing the least harm possible to the least possible number of people.

If we take the principle of justice things get very complicated. Different approaches define in different ways the concept of justice, which goes from the equal distribution of resources to the equal distribution of benefits.

Let us consider the principle of autonomy. The essay "On Liberty", by the 19th century philosopher John Stuart Mill clearly describes the ► autonomy principle. He states: "The only purpose for which power can be rightfully exercised over any member of the civilized Community, against his will, is to prevent harm to others. His own good, either physical or moral, is not sufficient warrant ... In the part which merely concerns himself, his independence is, of right, absolute."

This approach has deeply influenced bioethics and it is one of the roots of conflict in public health ethics between the concepts of common good and individual freedom and liberty. An example of this conflict is the issue of ► informed consent, which is an absolute requirement in clinical practice.

It is clear then that the ethical principles postulated in bioethics cannot be applied in public health practice just as they are.

There are other principles recognized as important in public health practice:

- the principle of ► equality: all people are equal;
- the principle of ► utility: actions and the use of resources should do the greatest good for the greatest number, but no one should be left out;

- the principle of ► stewardship: stakeholders should exercise social responsibility and good use of common resources.

It is not always easy and straightforward to get all the stakeholders involved in public health to agree on solutions to ethical dilemmas associated with some interventions. However, there are some tools which can help find a way forward and protect against some abuses.

A very good tool in the hands of public health workers and stakeholders involved in public health is the "► *Code of ethics for public health*", formally adopted by the American Public Health Association in 2002. It is the first broadly accepted document of its kind. It lists 12 principles for the ethical practice of public health, 11 values and beliefs which inspire the principles, and some notes to better understand them. Codes of ethics are not designed to provide clear solutions to convoluted ethical issues; that process requires deliberation and debate over the many factors relevant to a particular issue. It does, however, provide a list of values and principles that should be considered in any dispute.

The 12 principles for public health listed in the code are the following:

1. *Public health should address principally the fundamental causes of disease and requirements for health, aiming to prevent adverse health outcomes.* This principle gives priority not only to prevention of disease or promotion of health, but also to identifying the fundamental causes of disease. It acknowledges that public health is concerned with immediate causes and curative activities. For example, the treatment of curable infections is important to the prevention of transmission of infection to others.
2. *Public health should achieve community health in a way that respects the rights of individuals in the community*. This principle identifies the common need in public health practice to weigh the concerns of both the individual and the community. There is no ethical principle that can provide a solution to this perennial tension in public health practice. We can highlight, however, that the interest of the community is the primary interest in public health practice. Still, there remains the need to pay attention to the rights of individuals when exercising the police powers of public health.
3. *Public health policies, programs, and priorities should be developed and evaluated through processes that ensure an opportunity for input from community members*. The input process can be direct or representative. In either case, it involves processes that work to establish a consensus. Input from the community should not end once a policy or program is implemented. There remains a need for the community to evaluate whether the institution is implementing the program as planned and whether it is having the intended effect. The ability of the public to provide this input is critical in the development and maintenance of public trust in the institution.
4. *Public health should advocate and work for the empowerment of disenfranchised community members, aiming to ensure that the basic resources and conditions necessary for health are accessible to all*. While a society cannot provide resources for health at a level enjoyed by the wealthy, it can ensure a decent minimum standard of resources. The code cannot prescribe action when it comes to ensuring the health of those who are marginalized because of illegal behavior. It can only underscore the principle of ensuring the resources necessary for health to all. Each institution must decide for itself what risks it will take to achieve that.
5. *Public health should seek the information needed to implement effective policies and programs that protect and promote health.*
6. *Public health institutions should provide communities with the information needed for decisions on policies or programs and should obtain the community's consent for their implementation.* This statement is also the community-level corollary of the individual-level ethical principle of informed consent. Particularly when a program has not been duly developed and evaluated, the community should be informed of the potential risks and benefits, and implementation of the program should be premised on the consent of the community (though this principle does not specify how that consent should be obtained).
7. *Public health institutions should act in a timely manner on the information they have within the resources and the mandate given to them by the public.* Ability of public health institutions to act is conditional on available resources and opportunities, and by competing needs. Moreover, the ability to respond to urgent situations depends on having

established a mandate to do so through the democratic processes of Ethical Principle number three.

8. *Public health programs and policies should incorporate a variety of approaches that anticipate and respect diverse values, beliefs, and cultures in the community*. Public health programs should have built into them a flexibility that anticipates diversity in those needs and perspectives that might have a significant impact on the effectiveness of the program. Types of diversity, such as culture (► ethics and culture) and gender, were intentionally not mentioned. Any list would be arbitrary and inadequate.
9. *Public health programs and policies should be implemented in a manner that most enhances the physical and social environment.* This principle stems from the assumption that there is an interdependence among people, and between people and their physical environment. It is similar to the ethical principle from medicine, "do no harm," but it is worded in a positive way.
10. *Public health institutions should protect the confidentiality of information that can bring harm to an individual or community if made public. Exceptions must be justified on the basis of the high likelihood of significant harm to the individual or others.* This statement begs the question of which information needs to be protected and what the criteria are for making the information public. The aim of this statement is modest: to state explicitly the responsibility inherent to the "possession" of information. It is the complement of Ethical Principles 6 and 7, about acting on and sharing information.
11. *Public health institutions should ensure the professional competence of their employees.* The criteria for professional competence would have to be specified by individual professions, such as epidemiology and health education.
12. *Public health institutions and their employees should engage in collaborations and affiliations in ways that build the public's trust and the institution's effectiveness.* This statement underscores the collaborative nature of public health practice while also stating in a positive way the need to avoid any conflicts of interest that would undermine the trust of the public or the effectiveness of a program.

The "Code of Ethics for Public Health" is a very good tool; however, it is just a starting point, since it will need to be updated as society and medicine evolve; moreover, the process of globalization implies that many cultures come together in the same community, making it difficult to have one code of ethics which can be applied to all.

Ethical Relativists

Definition

Different approaches guide public health stakeholders in dealing with ethical dilemmas. Ethical relativists think that there are no universal standards of right and wrong; what is right for one person, or society, is not necessarily right for another person or society. For them having a reasoned discussion about ethics is questionable, since dialogue, persuasion, and agreement about ethics and values are impossible.

Ethical Rules

► Ethical Principles

Ethical Standards

► Ethical Values

Ethical Subjectivists

Definition

Different approaches guide public health stakeholders in dealing with ethical dilemmas. Ethical subjectivists believe that ethical values have no rational nor interpersonal basis; they are subjective and, therefore, will differ from one person to the next.

Ethical Values

Ethical standards

Definition

Value is given to what we choose as worthwhile or believe to have merit, in a general or broad sense, and that conforms to what is ethically right. Values should be freely and thoughtfully chosen; people should prize and promote them in order to further the human good (or the good of all beings). In this present context we refer to those values that assist decision-making in public health activities.

Basic Characteristics

Ethical values, to some extent, apply in virtually any decision-making situation: in families no less than in bureaucratic or legal settings. Ethical values influencing personal choices and actions can find their justification in religious faith, in the individual's consciousness or rationality and, more generally speaking, in the individual's culture (► ethics and culture). It is apparent that some values (like tolerance, veracity, ► respect for persons, human well being, freedom, empathy, altruism, partnership, citizenship, community) are taken to be good or desirable in themselves and transcend culture. On the other hand, the cultural context of a specific value may create very different meanings and result in different practices.

Public health ethics may be defined as the principles (► ethical principles) and values that help guide actions designed to promote health and prevent injury and disease in the population. It may be difficult to find a single set of values that relates to all public health professionals, because in public health many issues merge and many stakeholders get involved.

Public health ethics embraces issues of ► autonomy and coercion, of common good and individual freedom, of ► human rights and ► social justice, of research norms (► ethics, aspects of public health research), of cultural and behavioral changes and of multi-cultural values and environmental issues on a global scale.

Stakeholders involved in public health can be politicians, lawyers, different government departments, public representatives, social groups, each of them having their own values, which may be even supported by different types of political and moral theory.

Those who believe in ► liberalism, for example, would stress human rights and individual opportunities and would protect the individual from some abuses which have taken place in the past in the name of the common

good; they would justify opposing drug law restrictions, limits on abortion, motorcyclist's helmet requirements, and so on.

Those who follow a utilitarian approach would look at the consequences of a decision, specifically at their effect on the sum total of individual well being, or at the greatest happiness of the greatest number of people. ► Utilitarianism, however, by looking at the well being of the greatest number can lead to unfairness and to approaches which can conflict with society's views on moral conduct or even justify, in the name of the future benefits to the population, immoral actions as in the case of the Nazi experiments on humans and of the ► Willowbrook State School scandal.

► Communitarians would stress social order and social connectedness where individuals are parts of a community. A basic question for communitarians is who decides what is good for that community. One view is that every community defines its own norms which should, then, be respected. Things become complex when we try to define "community", since at times the term refers to the majority within the group, leaving behind the interests of the minority. ► Universalist communitarians, by contrast, believe in a single true form of good society and its associated virtues. They believe that certain behaviors and cultural patterns, can be justified by their health consequences (e. g. not smoking in public) or be regarded as rights (e. g. female literacy), and should be promoted in all societies, regardless of local cultural norms, as good in themselves, as part of a superior form of social organization. ► Globalization is bringing about new challenges to universal communitarians since other countries may have ideas which conflict with theirs (coexistence, tolerance, mutual learning, openness, dialogue and respect for differences which should exist among individuals and societies, being sources of mutual enrichment).

► Ethical subjectivists believe that ethical values have no rational nor interpersonal basis; they are subjective and, therefore, will differ from one person to the next; ► ethical relativists, closely related to the subjectivists, think that there are no universal standards of right and wrong; what is right for one person, or society, is not necessarily right for another person or society. For both, subjectivists and relativists, having a reasoned discussion about ethics is questionable, since dialogue, persuasion, and agreement about ethics and values are impossible.

At the other extreme are the ► ethical absolutists, who also do not see the point of an ethics discussion because they already know the right answer and do not wish to defend their values by giving reasons or to make themselves open to other views; usually their values are strongly based in a religious perspective. Even here globalization is bringing new challenges.

Each of these approaches, as we have seen, has some positive aspects. Though none of them can be used as an absolute point of departure for public health ethics, nonetheless, all of them influence in different ways, the many people involved in decision-making in public health practice. It is, therefore, not always easy and straightforward to get all stakeholders involved in public health practice to agree on solutions for the ethical dilemmas associated with some interventions. However, there are some tools which can help in finding a way forward and in protecting against some abuses.

A very good tool in the hands of workers and stakeholders involved in public health is the "► *Code of Ethics* for Public Health" formally adopted by the American Public Health Association in 2002. It is the first broadly accepted document of its kind. It lists 12 principles for the ethical practice of public health, 11 values which inspire the principles, and some notes to better understand them. Codes of ethics are not designed to provide clear solutions to convoluted ethical issues; that process requires deliberation and debate about the many factors relevant to a particular issue. A code does, however, provide a list of values and principles that should be considered in the discussion.

A code of ethics for public health clarifies the distinctive elements of public health and the ethical principles that follow from or respond to those distinct aspects. It makes clear to populations and communities the ideals of the public health institutions that serve them. A code of ethics thus serves as a guide for public health institutions and practitioners and as a standard to which they can be held accountable.

The values and beliefs listed in the code are the following:

Health

1. *Humans have a right to the resources necessary for health*. The Public Health Code of Ethics affirms Article 25 of the Universal Declaration of Human Rights, which states in part "Everyone has the right to a standard of living adequate for the health and well-being of himself and his family . . . "

Community

2. *Humans are inherently social and interdependent*. Humans look to each other for companionship in friendships, families, and communities; and rely upon one another for safety and survival.
   Positive relationships among individuals and positive collaborations among institutions are signs of a healthy community. The rightful concern for the physical individuality of humans and one's right to make decisions for oneself must be balanced against the fact that each person's actions affect other people.
3. *The effectiveness of institutions depends heavily on the public's trust*. Factors that contribute to trust in an institution include the following actions on the part of the institution: communication; truth telling; transparency (i. e. not concealing information); accountability; reliability; and reciprocity. One critical form of reciprocity and communication is listening to as well as speaking with the community.
4. *Collaboration is a key element to public health*. The public health infrastructure of a society is composed of a wide variety of agencies and professional disciplines. To be effective, they must work together well. Moreover, new collaborations will be needed to rise to new public health challenges.
5. *People and their physical environment are interdependent*. People depend upon the resources of their natural and constructed environments for life itself. A damaged or unbalanced natural environment, and a constructed environment of poor design or in poor condition, will have an adverse effect on the health of people. Conversely, people can have a profound effect on their natural environment through consumption of resources and generation of waste.
6. *Each person in a community should have an opportunity to contribute to public discourse*. Contributions to discourse may occur through a direct or a representative system of government. In the process of developing and evaluating policy, it is important to discern whether all who would like to contribute to the discussion have an opportunity to do so, even though expressing a concern does not mean that it will necessarily be addressed in the final policy.
7. *Identifying and promoting the fundamental requirements for health in a community are of primary concern to public health*. The way in which a society is structured is reflected in the health of a community. The primary concern of public health is with these underlying structural aspects. While some important public health programs are curative in nature, the field as a whole must never lose sight of underlying causes and prevention. Because fundamental social structures affect many aspects of health, addressing the fundamental causes rather than more proximal causes is more truly preventive.

Bases for Action

8. *Knowledge is important and powerful.* We are to seek to improve our understanding of health and the means of protecting it through research and the accumulation of knowledge. Once obtained, there is a moral obligation in some instances to share what is known. For example, active and informed participation in policy-making processes requires access to relevant information. In other instances, such as information provided in confidence, there is an obligation to protect information.
9. *Science is the basis for much of our public health knowledge*. The scientific method provides a relatively objective means of identifying the factors necessary for health in a population, and for evaluating policies and programs to protect and promote health. The full range of scientific tools, including both quantitative and qualitative methods, and collaboration among the sciences is needed.
10. *People are responsible to act on the basis of what they know*. Knowledge is not morally neutral and often demands action. Moreover, information is not to be gathered for idle interest. Public health should seek to translate available information into timely action. Often, the action required is research to fill in the gaps of what we do not know.
11. *Action is not based on information alone*. In many instances, action is required in the absence of all the information one would like. In other instances, policies are demanded by the fundamental value and dignity of each human being, even if implementing them is not calculated to be optimally efficient or cost-beneficial. In both of these situations, values inform the application of information or the action in the absence of information.

The code of ethics for public health practice is a very good tool; however, it is just a starting point, since it will need to be updated as society and medicine evolve; moreover, the process of globalization implies that many cultures come together in the same community, making it difficult to have one code of ethics to be applied to all.

E

Introduction

The modern approach to public health practice in the Western world, having as a goal the health of populations through health promotion and disease prevention, is only a few centuries old; however, its roots go much further back into the history of mankind:

- in very olden days, religions set rules to regulate behavior that specifically related to health, from types of food eaten, or alcohol drunk to the conduct of sexual relationships;
- in China around 1000 BC immunity from smallpox could be gained by inhaling the dried crusts that formed around lesions of infected individuals; also children were protected by inoculating a scratch on their forearms with the pus from a lesion;
- the Romans installed water supply and waste disposal systems;
- in the medieval period the practice of quarantine helped mitigate the effects of some infectious diseases;
- during the 14th century Black Death in Europe, dead bodies were removed and some areas of cities burned in an attempt to prevent the spread of disease.

The nineteenth century saw a very important stage in the foundation of modern public health:

- in England, between 1849 and 1854, before *Vibrio cholerae* was identified as the causative agent of cholera, John Snow observed an association between the distribution of cholera cases and house water supply systems, thus initiating the science of epidemiology;
- the discoveries of Koch and Pasteur completely changed the approach to infectious diseases, posing new challenges and putting new tools into the hands of public health officers.

From there on, because of the socio-economic and technological changes which have occurred in the Western world, the whole concept of public health practice has rapidly evolved, provoking even more challenges and ethical dilemmas.

Public Health

The 20th century saw very fast changes taking place; socio-economic, political, technological, medical and ethical transformations influenced both mankind and the environment. Public health practice was impacted by this general innovation and has since become more and more comprehensive. The processes of industrialization and urbanization brought new threats to health from food adulteration and contamination, pollution, occupational hazards, and pharmaceuticals. In the constant endeavor of preventing diseases and promoting health, after contributing to the great achievements in fighting infectious diseases through immunization and drugs (at least in the Western world), public health practice began to pay more attention to conditions such as cancer, heart disease, disability, aging, obesity, and diabetes.

Nowadays, thanks also to the development of epidemiology and biostatistics, public health practice deals with patterns of disease, and aims at identifying their causes; it establishes collective and institutional interventions to alleviate the risk or burden of diseases within the population (establishment of environmental regulations, immunization programs, regulations on use of tobacco, occupational health and safety standards, etc.); it embraces various programs for primary prevention (preventing a healthy person acquiring a certain disease), for secondary prevention (screening for a disease before it becomes clinically evident) and for tertiary prevention (preventing complications and providing rehabilitation).

The idea of health promotion continues to evolve, broadening its scope from influencing individual behaviors and risk factors to consideration of population-level issues such as inequality among population groups, levels of poverty, living environment and education standards (known as "social determinants of health"), in an endeavor to fairly distribute health benefits and disease burdens throughout society. Looking at the concept of social justice has been a major step forward in the recent evolution of public health practice: social status, race and wealth have been proven to have important influences on the health of individuals; at the same time, the increased costs of health care have brought along disparities in its distribution and accessibility within a specific population. Moreover, looked at globally, it cannot be ignored that the developing world is still devastated by preventable infectious diseases, malnutrition and poverty.

The "new public health" takes into consideration these health inequalities calling for population-based policies that improve the health of the whole population in an equitable way.

The evolution is still ongoing, as shown by the diversity of "public health" definitions:

- The Institute of Medicine in 1988, in its report on "The Future of Public Health", proposed one of the most influential contemporary definitions: "Public health is what we, as a society, do collectively to assure the conditions for people to be healthy." This definition emphasized the mutually shared obligation we all, as society, have, and reinforced the responsibility that governments and communities should take for health.
- The Associations of Schools of Public Health (ASPH) states that public health is: "The science and art of protecting and improving the health of communities through education, promotion of healthy lifestyles, and research for disease and injury prevention. Public health helps improve the health and well being of people in local communities and across our nation. Public health helps people who are less fortunate to achieve a healthier lifestyle."
- From a population health perspective, health has been defined as "the capacity of people to adapt to, respond to, or control life's challenges and changes" (Frankish et al, 1996).
- The European Public Health Association (EUPHA) in its "10 Statements on the Future of Public Health in Europe" states: "The term new public health is coming up. New public health defines health as an investment factor for a good Community life. It focuses on the behaviour of individuals in their present environment and the conditions of life that influence behaviour. Apart from the classic preventing disease, public health work is about promoting physical and mental health of individuals. This includes influencing living habits and living conditions, but also promoting self-esteem, human dignity and respect."

Public Health Ethics

Ethics, in general, is derived from philosophy. Some authors make no distinction between ethics and morals,

they are seen as the beliefs and standards which define the concepts of good and bad, right and wrong in a society; others distinguish the two concepts, and refer morality to individual behavior and ethics to social rules; others define ethics as the systematic study of morality: ethics, in other words, is the theory and morality is the practice.

More specifically, public health ethics may be defined as the principles and values that help guide actions designed to promote health and prevent injury and disease in the population. As a subject, it can be subdivided into a field of study (also called metaethics) and a field of practice (also called normative ethics).

Public health ethics, as a field of study, seeks to understand and clarify principles and values which influence decision making in public health practice. Whereas, public health ethics, as a field of practice, applies principles and values to public health activities; it helps to deal with ethical dilemmas, in order to come up with the best possible solution for a specific case. Public health ethics is also concerned with the ethical dimensions of public health as a specific profession (professional ethics).

Public health ethical issues were minimal when the paternalistic approach to public health measures was accepted (paternalism is the attempt to impose limitations upon someone or to require actions by someone for his or her own good; such impositions usually are justified with children because it is assumed that they are incapable of deciding on their own behalf, and with those who, because of cognitive limitations, cannot choose on their own behalf). As from the second half of the 20th century the authority of medicine and the paternalistic approach of physicians and public health officials started to be questioned due to certain factors:

- the discovery of new treatments and new technologies has enormously increased the chances of cure along with the risk of causing harm;
- patients' knowledge in general and on medical issues in particular has grown out of all proportion;
- the place of the individual has gained more ground in society, as have government policies and laws which have developed towards protecting the individual, being informed by autonomy and human rights issues.

Medical ethics has proportionally increased its body of study and research, in an effort to update its code to the new reality, which now includes problems like medicine and palliative medicine (► palliative care and hospice). As a result, the more inclusive term for ► ethics in clinical medicine is "bioethics". Bioethics has found a strong point of reference in the patient-centered approach. As a result, clinicians have clear guidelines for their interaction with patients, based on four principles: beneficence (doing good), non-maleficence (not doing harm), autonomy (respect for personal rights and the individual), and justice (distributing benefits, risks and costs fairly).

Those four principles have also strongly influenced public health decisions in the last few decades, based on the argument that, while directed to the whole population, public health activities interact with individuals. Although public health practice should not overlook the rights, interests, and freedom of the individual, it has to look at the well being of the entire population; therefore the ► ethical principles and values (► ethical values) applied in bioethics, which follow the individualistic orientation, cannot be used as a point of reference when dealing with and entire population.

Let us take the principle of non-maleficence (not doing harm). If the point of reference is an individual, it can be (somehow) easy to identify a possible harm and, as a consequence, be easy to avoid that harm. However, if the case is of a necessary intervention targeted at a whole population, there may well be individuals likely to be harmed by the intervention who are difficult (if not impossible) to identify and the harm, therefore, cannot be avoided. As a conclusion, in public health practice the principle of non-maleficence can be understood as doing the least harm possible to the least possible number of people.

If we take the principle of justice (distributing benefits, risks and costs fairly) things are very complicated. Different approaches define in different ways the concept of justice, which goes from equal distribution of resources to equal distribution of benefits.

The essay "On Liberty", by the 19th century philosopher John Stuart Mill clearly describes the autonomy principle. He states: "The only purpose for which power can be rightfully exercised over any member of the civilized Community, against his will, is to prevent harm to others. His own good, either physical or moral, is not sufficient warrant. He cannot rightfully be compelled to do or forbear because it will be better for him to do so, because it will make him happier, because in the opin-

ion of others to do so would be wise or even right. These are good reasons for remonstrating with him or reasoning with him or persuading him or entreating him but not for compelling or visiting him with any evil in case he does otherwise ... In the part which merely concerns himself, his independence is, of right, absolute."

This approach has deeply influenced bioethics and is one of the roots of the conflict in public health ethics between common good and individual freedom and liberty.

It is clear that public health ethics should find its own answers to dilemmas linked to the population-based perspective.

Public Health Ethical Dilemmas

Ethical issues in public health often pose genuine ethical "dilemmas" and, because there are many stakeholders involved, many different approaches may be required.

Everybody agrees that public health interventions have as a goal the well being of the whole population. Some of those interventions have to be compulsory and universal in order to be effective; for example, standards for public amenities (such as air and water quality, food safety and waste disposal, road and building safety) and regulations to safeguard the environment and individuals from damage caused by hundreds of chemicals, have to be imposed. Nevertheless, they are easily accepted by the people and their imposition is not seen as violating demands for individual consent and autonomy, partly because they are supported by officially proclaimed rights (e. g. the United Nations Commission on Human Rights made in 2001 proclaimed that everyone has the right to live in a world free from toxic pollution and environmental degradation), partly because they do not act directly on the individual's freedom and lifestyle, and partly because individuals cannot judge those standards by themselves.

Things change when public health interventions act directly on the individual's freedom. In those cases there would always be someone who disagrees with a certain policy and therefore will feel coerced. In public health ethics, one core question is whether the individual should be subordinated to the common good or whether the autonomy-focused and antipaternalistic approach in bioethics should also serve as a point of reference for public health activities. This dilemma involves most of the programs in the main fields of public health: from prevention (► ethics, aspects for prevention) of diseases to infectious disease control (► ethics, aspects of infectious disease control), from health promotion (► health promotion, ethical aspects) to research (► ethics, aspects of public health research).

In the past, infectious disease control programs included screening for the disease, surveillance and name-based reporting, contact tracing, treatment monitoring, isolation (the separation of individuals known to be infectious) and quarantine (the restriction of the activities of healthy individuals who have been exposed to a communicable disease). During the 20th-century, screening for the presence of disease, and at times occult infection, was a central feature of public health practice. Often such screening was imposed, as in the case of screening couples for venereal disease prior to marriage, screening children for entry into public schools, screening newborns for specific genetic conditions, and screening for tuberculosis in schools and workplaces.

A very typical example of coercion in infectious disease control programs is the isolation and quarantine applied in the name of the common good. In those cases, though the rights of the individual are overruled, the intervention is accepted because the course of the disease and the timeframe of the treatment are known. Things become more complex when isolation and quarantine are applied as interventions in cases where knowledge about the evolution and treatment of an infectious disease is lacking. A case which posed very dramatic dilemmas from many points of view, including an ethical one, was the worldwide threat of severe acute respiratory syndrome (SARS); because of the "unknown", governments took steps towards protecting public health which did not consider individual freedom, by using isolation and quarantine as a tool for controlling the spread of the disease. Dealing with infected cases was mostly accepted, but many queries were raised when dealing with only suspected cases or suspected exposure: the number of people put into isolation escalated very rapidly. A balance was reached once there was more knowledge about the course of the disease.

A supportive element for coercion in the SARS kind of intervention is that although individuals had no direct responsibility in contracting the disease, they presented a public health danger. Moreover, the "harm princi-

ple", which states that one person's freedom should not result in another person's harm (see the already mentioned "On Liberty" by John Stuart Mill), was supporting those interventions from the ethical point of view.

Things were different, from the very beginning, in the case of HIV/AIDS epidemics because of two of its main characteristics:

1. it presented as a lethal disease, with a latent period of incubation, during which the partner, the community in general, and even the individual infected, are not aware of the risk;
2. from the start HIV/AIDS was related to individual behaviors linked to a very strong social stigma.

Very soon a very dramatic ethical dilemma exploded: following the traditional name-based case reporting would have allowed public health officials to single out infected individuals and to counsel them in order to prevent further transmission, and would have permitted the monitoring of the incidence and prevalence of the infection; however, the antagonists of name-based reporting argued that social hostility and HIV-related hysteria could lead to changes in policy that would permit breaches in confidentiality with serious consequences for those appearing in the reports, in terms of losing their jobs, their housing and perhaps their liberty. How, then, to protect the individual freedom and privacy, and at the same time the partner or other community members from getting infected?

The already strong gay men organizations influenced the decision of public health policy makers on management of HIV/AIDS epidemics by framing the whole issue into the human rights perspective. From a public health perspective, then, the HIV/AIDS concern became a socio-political-moral-health issue. For the first time a new "exceptionalist" approach to an infectious disease epidemic was promoted, which rejected coercive measures that might "drive the epidemic underground" and focused on mass health education for behavioral changes, voluntary testing and counseling, following the principle that no public health policy which violated the rights of individuals could be effective in controlling the spread of HIV.

To this point we have focused on public health interventions designed to discover or monitor infectious diseases and prevent the spread of such conditions.

The "harm principle" has been the ethical point of reference also for other programs aiming at preventing some contagious diseases, as in the cases of compulsory vaccination. A child is vaccinated in order to avoid becoming infected and therefore infecting others not yet immunized. Vaccination for children for some infectious diseases is compulsory in many countries, bringing about a significant reduction in their incidence. In some states, however, exceptions are accepted for religious or philosophical reasons, which, true, involves a very small number of children, but, they pose the ethical question of whether parents have a right to place at risk, because of their beliefs, their children by failing to immunize them and therefore, place at risk those others who could be infected by them. With the falling-off of some of these infectious diseases, the problem of vaccine side effects comes to the fore: when many children are dying from a given disease a few cases of side effects is easy to accept but once there are few cases of the disease, side effects become more striking; as a result, parents are encouraged to refuse their children's immunization because of fear of harming their children. The ethical dilemma in these cases is sharpened by what is called "herd immunity": immunization involves both a direct benefit to the individual child as well as to those in the community who remain unimmunized and benefit from the immunization of the vast majority. An ethical principle which can help here is the one of justice, as fair distribution of risks and benefits.

Some countries are trying to replace compulsory vaccination for some diseases, which are now very rare, with an effective health education of parents; the conviction is that by showing them all risks (which are anyhow less and less) and all benefits of vaccination, the number of parents vaccinating their children would not drop.

Traditionally, the "harm principle" mentioned before, has been also used by governments in the field of health promotion to impose restrictions on individual autonomy and freedom; the paternalistic approach, which often inspired those activities, was considered universally accepted when the harm was obvious. Divergences arise when the harm to others which is to be prevented is not clear, or when health promotion activities interfere with individual privacy and freedom in the name of the common good. Some examples are taxes on cigarettes and alcohol, laws on motorcyclists' helmets, or even campaigns on lifestyle changes. After evidence of the health hazard of cigarette smoking was given, government interventions, like high taxes on cigarettes, were more accepted, both on the lines of protecting the

non smokers and discouraging adolescents from starting smoking; restrictions on smoking in public places was also accepted, knowing that harm occurs to passive smokers. Concerning regulations on motorcyclists' helmets one could say, quoting Mr Mills, that "over himself, over its own body and mind, the individual is sovereign"; however, "harm" can also be defined as the financial burden on society due to accidents and diseases which could have been avoided, and this justifies the application of the "harm principle" even in this case. After all, in a highly integrated society what action does anyone take that does not ultimately have an impact on society?

The issue of lifestyle changes takes us a step further. To what extent can the state regulate, restrict or prohibit behaviors that lead to premature morbidity and mortality? According to Mr Mills, "He cannot rightfully be compelled to do or forbear because it will be better for him to do so, because it will make him happier, because in the opinion of others to do so would be wise or even right." What role, if any, should government then play in urging citizens to give up their pleasurable butdamaging habits? Many people believe that a government should rarely exercise coercive powers either because they are ineffective or because they overrule the individual's autonomy, privacy, or liberty. In past decades, individual responsibility over health has often been subsumed under individual rights or demands to be guaranteed by government and delivered by public and private institutions. The evidence of the negative consequences of some private habits and lifestyles, both on the public and on the individual's health, has added to the idea that there is an obligation to preserve one's health for the common good. How should society determine whether to intervene to protect the public's health and safety when doing so will diminish a personal or economic interest and will undermine individual freedom and personal responsibility? And how can the state be prevented from taking power to remove more and more choice in the name of better population health?

A very important role in this dilemma is played by health education. The debate, in these cases, is whether health education, which preserves individual autonomy and avoids coercion, is enough, and whether health promotion campaigns and advertising are appropriate. Anyway, from the public health official's point of view, there could be justification for some paternalistic health promotion interventions: we are morally bound to prevent avoidable suffering and death regardless of its social costs.

The whole concept of health promotion was broadened by the World Health Organization (the ► United Nations specialized agency for health) at its first international conference on health promotion held in Ottawa in 1986. The Ottawa charter states that "Health promotion is the process of enabling people to increase control over, and to improve, their health. Therefore, health promotion is not just the responsibility of the health sector, but goes beyond healthy life-styles to well-being. The fundamental conditions and resources for health are peace, shelter, education, food, income, a stable eco-system, sustainable resources, social justice, and equity. Improvement in health requires a secure foundation in these basic prerequisites."

This new perspective has opened an on-going, challenging debate over its political and ethical implications.

An area of common interest for clinical medicine and public health is research: when research deals with humans it faces ethical concerns at the level of the personal behavior of the research team, and in the development, implementation, analysis, and dissemination of the study results. It is imperative, then, that researchers have to address issues like ► informed consent, individual right to privacy, to confidentiality, and to autonomy. The danger of breaching confidentiality increases in longitudinal studies, when data collection happens at different points in the life of the individual who, therefore, needs to be identified by the researcher. When identification is not essential for the research, then anonymous data are provided by changing the personal details of the participant with unidentified codes.

A much debated aspect of research, which requires extra precautions, is the involvement of vulnerable groups or individuals. By "vulnerable" we mean that they may be more than usually susceptible to exploitation in the process of research, either because they may be more likely to be pressured to participate, or to fail to understand the full implications of participation and may therefore be misled into participation. Types of vulnerability include: cognitive or communicative (e. g. mentally disabled persons, young children), institutional (e. g. imprisonment), deferential (i. e. cognitively able to consent but subject to the authority of someone else), medical (e. g. having a serious condition for which there is no satisfactory treatment), economic and social (e. g. members of undervalued social

groups). In these cases even the signed informed consent may not be meaningful. Some people believe that signing a consent form means that they are waiving their rights, including those to sue if something goes wrong, and that the primary purpose of a consent form is to protect doctors and hospitals from legal liability; in addition, the forms may be incomprehensible to them, it is therefore impossible to fully understand what they agree to. At times, to avoid these kinds of problems, vulnerable groups have been excluded from research, which protected them from the research-associated risks, but also meant that they were less likely to share in any benefits, both during the study and later when results were generalized to populations in which the interventions had not been studied. In addition, conditions more prevalent among, or disproportionately affecting, minority group members or women can simply go unstudied, and unintended harm may result from the failure to recognize specific group correlated factors.

To avoid the abuses of the past there are now some codes and guidelines which regulate research. Moreover, there are ► ethical committees to approve research protocols.

Different challenges are raised when research uses available health data in epidemiological studies. Acquisition and use of health data is a necessary condition for a government to organize, within the reasonable limits of its resources, its most cost-effective health services, and its activities in ways that best prevent illness and disability, and promote health among its population.

High quality data are needed to provide more effective clinical care, to assess the quality and cost effectiveness of health services, to monitor fraud and abuse, to track and evaluate access to health services and patterns of morbidity and mortality, to research the determinants, prevention, and treatment of diseases. Health ► data acquisition and protection are strictly interlinked, since the right to privacy and confidentiality has to be respected. Legal, ethical, and human rights principles support some levels of individual control over circumstances in which their identifiable health data are acquired, used, disclosed, or stored. One of the main methods used in public health for health data acquisition is surveillance. It implies reporting to health authorities not only notifiable diseases but also patients' names. It has been so with many infectious diseases, like sexually transmitted diseases and tuberculosis, in the effort to monitor, to plan and to intervene in such threats. Things changed with HIV/AIDS, mainly because, from the very beginning, a social stigma was attached to the condition. In the USA the debate on whether to disclose or not to disclose names lasted almost 20 years, until the Centres for Disease Control (CDC) in 1999 reluctantly accepted that there could be case reporting without using names. Data are also collected through registries, mainly hospital records, which can help to better understand specific conditions. In these cases, data acquisition is not strictly considered research. When those data are to be used for research purposes, the issue of confidentiality comes out very strongly, since, if disclosed, they carry the risk of bringing harm to the individual at different levels (psychological, employment, family, insurance, housing, and social).

In contrast to the obligation to keep some information confidential, researchers have also the responsibility of sharing results with the participants, because they helped contribute to the study, and with the community at large. Though research findings are typically presented as aggregated data that do not reveal the identities of the individual participants, nonetheless, they may also have some negative consequences on the community as a whole, which could be stigmatized if results are negative.

Data acquisition and protection come into conflict also when dealing with the field of genetics. At times, genetic interventions involve specific ethnic groups or individual conditions that may be the object of social stigmatization and therefore may bring harm to those involved. If a public health intervention based on genetic screening could bring some benefits to the individual and to the community, which would justify it, then the ethical question would be one of equitable access to services. As a consequence, in the case of public health genetics, all these three aspects should always be taken into consideration for any screening program: population benefit, individual interests and distributive justice. Additional ethical aspects have to be considered when research is done at an international level; then we also have to deal with issues raised by the local culture (► ethics and culture) (language, beliefs, social values, relationship between individual and community) and by religious attitudes (► ethics, religious aspects), all components which may vary considerably the meaning and the role of informed consent and autonomy, beneficence and non-maleficence, and of justice.

Different Approaches to Ethical Dilemmas in Public Health

Moral principles and values influencing personal choices and actions can find their justification in a personal religious faith or value system. This is not the case when we talk about ethics in public health practice, where many stakeholders are involved and many issues clash.

Politicians, lawyers, government departments, public representatives, social groups, etc. can all be stakeholders in public health and they can all have, at times, different ways of looking at things, different points of reference, and, therefore, different ethical perspectives. From a health economics point of view, for example, one may aim at attaining the best average level of health care services, while from a social justice point of view one may aim at achieving a situation in which there are the smallest feasible differences among individuals and groups.

Many issues have to be considered in public health ethics: issues of autonomy and coercion, of common good and individual freedom, of human rights and social justice, of research norms, of cultural and behavioral changes and of multi-cultural values and environmental issues on a global scale.

Moreover, in public health, several different types of political and moral theories overlap, converge, and contend with one another, including liberalism, utilitarianism and communitarianism, together eith widespread ethical subjectivism and relativism and ethical absolutism.

Liberalism stresses human rights and individual opportunities and protecting the individual from the abuses which have taken place in the past in the name of the common good. Human rights refer to a body of international law that originated in response to the egregious affronts to peace and human dignity committed during World War II. The main source of human rights law within the United Nations system is the International Bill of Human Rights comprising the United Nations Charter, the Universal Declaration of Human Rights, and two International Covenants of Human Rights. Human rights are also protected under regional systems, including those in American, Europe, and African countries. Human rights are often divided between those that protect civil and political rights on the one hand and economic, social, and cultural rights on the other, including the right to a standard of living adequate for the health and well being of the individual and of the family, including food, clothing, housing and medical care and necessary social services. (Considerable disagreement, however, exists as to whether "health" is a meaningful, identifiable, operational, and enforceable right, since this would suggests that states possess binding obligations to respect, defend, and promote that entitlement.)

Liberalism justifies opposing ► drug law restrictions, limits on abortion, motorcyclist's helmet requirements, and so on.

Utilitarianism looks at the consequences of a decision, specifically at the effect on the sum total of individual well being, or at the greatest happiness of the greatest number of people. However, dispute arises when trying to define well being, of which health, after all, is but one dimension. Subjective utilitarians assert that well being is best defined by each individual's personal experience, objective utilitarians want to centralize the assessment process and have a group of experts define an index that embodies the "rationally knowable" components of well being, and would rely on an expert-determined index of health status – like Quality-Adjusted Life Years (QALYs) or Disability-Adjusted Life Years (DALYs) – to measure the consequences of alternative decisions. The utilitarian approach is used by epidemiologists when studying risk factors, or by economists when conducting a cost-benefit analysis. It can be of some help when there are many factors or possibilities to be taken into consideration.

Utilitarianism, however, by looking at the well being of the greatest number, can lead to unfairness and to approaches which can conflict with society's views on moral conduct, or even justify, in the name of the future benefits to the population, immoral actions – as in the case of the Nazi experiments on humans and of the Willowbrook State School (a New York State institution for mentally defective children, all subjects from 1963 to 1966, were deliberately infected with the hepatitis virus; during the course of these studies, Willowbrook closed its doors to new inmates, claiming overcrowded conditions. However, the hepatitis program continued to admit new patients. Thus, in some cases, parents found that they were unable to admit their child to Willowbrook unless they agreed to his or her participation in the studies). History teaches us that often the happiness of the majority has been built at the expense

of the minority, or that, at times, the happiness of the most powerful group was achieved at the expense of the majority.

Communitarianism would stress social order and social connectedness where individuals are part of a community. It has a longer history than utilitarianism and liberalism. It goes back to a time when Greek philosophy guided thought in Europe and neo-Confucianism guided thought in Asia. A basic question for communitarians is who decides what is good for the community. One view is that every community defines its own norms which should, then, be respected. Things become complicated when we try to define "community", since at times the term refers solely to the majority group, ignoring the interests of any minority groups. Universalist communitarians, by contrast, believe in a single true form of good society and its associated virtues. They believe that certain behaviors and cultural patterns can be justified by their health consequences (e. g. not smoking in public) and that rights (e. g. female literacy) should be promoted in all societies, regardless of local cultural norms, because they are good in themselves, as part of a superior form of social organization. Globalization with the advent of new perspectives is bringing about new challenges to universal communitarians who now have to consider such things as coexistence, tolerance, mutual learning, openness, dialogue and respect of differences, which should exist among individuals and societies, being sources of mutual enrichment.

Ethical subjectivism considers that moral beliefs have no rational nor interpersonal bases; they are subjective and, therefore, will differ from one person to the next. Relativism, a closely related notion, states that there are no universal standards of right and wrong; what is right for one person, or society, is not necessarily right for another person or society. For both, subjectivists and relativists, having a reasoned discussion about ethics is questionable, since dialogue, persuasion, and agreement about ethics and values are impossible.

At the other extreme are the ethical absolutists, who also do not see the point of an ethics discussion because they already know the right answer and do not wish to defend their beliefs by giving reasons or making themselves open to other views; usually their beliefs are strongly based in a religious perspective. Even here globalization is bringing new challenges. However secure people may be in their own religious faiths and beliefs, or ethical perspectives, they still must live with others in a and pluralistic society where it is important to at least be open to other points of view and to communication with others.

Each of these approaches, as we have seen, has some positive aspects, though none of them can be used as an absolute point of departure for public health ethics.

Tools for Public Health Ethics

It is not always easy and straightforward to get all the stakeholders involved in public health to agree on solutions for the ethical dilemmas associated with some interventions. However, there are some tools which can be helpful in finding a way forward and in protecting against some abuses.

A very important tool is law. Though there is often debate on whether governments should intervene to protect the public's health and safety when doing so will diminish a personal freedom or economic interest, the fact remains that law is a primary means used by governments to bring about conditions for people to lead healthier and safer lives. Law creates goals for public health authorities, assigns their functions, and specifies the manner in which they may exercise their authority. Law is a tool in public health work which can influence the norms of healthy behavior, set and enforce health and safety standards in order to protect and promote the health, safety and general welfare of the population. Examples include: laws on the use of safety belts in cars and helmets for motorcyclists; smoking restrictions; licensing of people, institutions or businesses; inspection of institutions or businesses (checking for unsanitary conditions, impure products or unsafe environment); closing down a business, condemning a building, confiscating dangerous goods or fining for pollution.

In order to identify and respond to health threats laws have been made to make it mandatory to report some diseases, set up immunization programs, provide isolation and confinement in specific cases and treatment of particular diseases.

In some other instances, laws have assimilated ethical principles, as in the case of restrictions on access to health information and the maintenance of privacy.

In the case of working environment hazards, a lot has been done in the last few decades to protect workers, both, in terms of their right to know about hazards in

their workplace, and in terms of instigating occupational health and safety laws.

Ethical issues in occupational health, as for other public health fields, are a concern for many stakeholders: occupational health professionals (occupational health doctors and nurses, factory inspectors, occupational hygienists and psychologists, specialists in ergonomics, rehabilitation, working environments, accident prevention, and occupational health and safety researchers), workers, employers, and those who are supposed to denounce shortcomings, lawyers. As a consequence, the need for a code of ethics specific to this field of public health has become compulsory. The International Commission on Occupational Health has adopted the "*International Code of Ethics for Occupational Health Professionals*" which has become a point of reference. It covers issues on duties of occupational health professionals (which aim at protecting the life and health of workers, respecting human dignity and promoting the highest ethical principles in occupational health policies and programs), and on their obligations (which include integrity in professional conduct, impartiality, confidentiality, privacy).

Another very good tool in the hands of public health workers and stakeholders involved in public health is the "*Code of Ethics for Public Health*" formally adopted by the American Public Health Association in 2002. It is the first broadly accepted document of its kind. It lists 12 principles of ethical practice of public health, 14 values and beliefs which inspired the principles, and includes some notes to better understand them. It confirms that public health should address disease prevention and health promotion; affirms people's right to resources necessary for health; stresses the interdependence between people and their environment; emphasizes the importance of the public's trust in institutions; accents the need for collaboration among all stakeholders involved in public health; underlines the need for research; affirms community contribution to public discourse; demands distributive justice; asserts the duty of public health institutions to protect confidentiality; and to implement policies and programs in a way that respects diverse beliefs in the community, and so on.

The code of ethics for public health practice is a very good tool; however, it is just a starting point, since it will need to be updated as society and medicine evolve; moreover, the process of globalization implies that many cultures unite in one community, making it difficult to have one code of ethics to cover all eventualities.

Philosophers, policy makers and others first turned their attention to the ethical practice of research after the atrocities of medical experiments during World War II were revealed. Since then, much of the agenda in the field of ethics has been driven by the dilemmas presented by advances in medical technology and by research on human subjects. As a consequence, there are quite a number of guidelines on the ethical conduct of clinical research. Some of them were written in response to a specific event, and, therefore, they each focused on the instigating issue, emphasizing some specific aspects of research while leaving others out.

For instance, the "*Nuremberg Code*" was part of the judicial decision condemning the atrocities of the Nazi physicians and so focused on the need for consent, freedom from coercion and a favorable risk-benefit ratio.

The "*Declaration of Helsinki*" was developed to fill up the gaps in the Nuremberg Code, especially as related to physicians conducting research with patients, and so focuses on favorable risk-benefit ratio and independent review; the Declaration of Helsinki also emphasizes a distinction between therapeutic and non-therapeutic research that is rejected or not noted by other documents.

In the USA, the National Commission for the Protection of Human Subjects of Biomedical and Behavioral Research in their document known as the "*Belmont Report*", underlined three basic principles to be used to generate specific rules and regulations in response to US research scandals such as Tuskegee and Willowbrook; those principles are: respect for a person's autonomy (e. g. informed consent), beneficence (e. g. favorable risk-benefit ratio), and justice (e. g. to ensure that vulnerable populations are not targeted for risky research).

The Council of International Organizations of Medical Sciences (CIOMS) and the World Health Organization (WHO) prepared in 1991 a document addressing public health and epidemiological research ("*International Guidelines for Ethical Review of Epidemiological Studies*"), and in 1993 endorsed a revised "*International Guidelines for Biomedical Research Involving Human Subjects*". The CIOMS guidelines consist of a description of general ethical principles and fifteen recommendations with commentary addressing the application of ethical standards and the establishment of mechanisms

for ethical review of human subjects research in developing countries where local standards for scientific conduct may differ from those in Western industrialized nations.

In 2002, the Nuffield Council on Bioethics published the "*Ethics of Research Related to Healthcare in Developing Countries*". This document provides specific recommendations for ethical issues related to standards of care, informed consent, obligations of researchers to individuals and communities, and independent ethical review.

In 1991, the US Department of Health and Human Services (HHS) issued revised "*Regulations on Human Subjects Research*", which has come to be referred to as the Common Rule. According to the regulations, in order for people (or their legally authorized representatives) to give "legally effective informed consent," the researchers seeking participation must describe the research and its purposes, its foreseeable risks and expected benefits, possible compensation in case of injury, must disclose appropriate alternatives, and must state that confidentiality will be maintained and that participation is voluntary. Concerning research with children, the "Common Rule" gives detailed specifications, stating that research should not involve greater than minimal risk, other than when it could be of direct benefit to the individual subjects; or when the research involves greater than minimal risk and presents no prospect of direct benefit to individual subjects, then it should be directed to yielding generalizable knowledge which is of vital importance for the understanding or amelioration of the subjects' disorder or condition.

Other tools exist at international or national levels and some organizations and institutions have developed their own guidelines to help in dealing with ethical dilemmas within public health.

Conclusions

Privacy or surveillance? Liberty or isolation? Coercion or freedom? Autonomy or common good? It is difficult to find solutions to ethical dilemmas in public health that can be supported by everyone. How can the tension between conflicting values be broken?

The issue of public health ethics is just one facet of a more general step forward that each person and society as a whole are asked to make as mankind evolves. In the beginning, man was forced to accept some social obligations in order to remain within a social group or clan which provided survival security, since life outside the clan was not viable.

Greek philosophy brought a new understanding of man: it underlined the value of the individual but acknowledged the conflict created between his need to belong to a group and need to be recognized as an individual with specific characteristics. Aristotle, in particular, stated that the essence of a human being is not only his rationality but also his capability of relating to others, since man is naturally meant to live in a community.

Since then, a balance has been sought between these two characteristics. Unfortunately, history has shown how this tension has brought about very negative consequences: in the name of the common good some atrocities have been committed against individual freedom and dignity; in the name of individual rights society has been considered by some individuals as a system that frustrates fulfillment of needs and expectations causing them to opt out. By considering how both excesses have their limits and their pitfalls society is learning to value and respect the dignity of the individual, while the individual is discovering that society is not just for the reception of benefits, but is the right place to fully express and fulfill himself as a human being in a state of interdependence.

Interdependence is the complement of autonomy; an individual has a social role which, if carried out, prevents the development of an extreme individualistic perspective that is inconsistent with the true nature of human beings. We all understand that a society where individuals are free to do whatever they want would not last long. Many of the collective goals in society that benefit the whole community are achieved by sacrificing some degree of independence and freedom; maybe not every individual agrees with this social contract, but we all experience the collective benefits.

On the other hand, a public health perspective should aim at protecting individual rights and effectively eliciting the voluntary co-operation of individuals. Such efforts are desirable because, by reducing the necessity of invoking the coercive power of the state, they enhance the public's health without burdening privacy and liberty. One way of evoking voluntary co-operation is community consultation and community participation in decision making. If public health stakeholders were encouraged, or even required, to consult with members of the communities in which they conduct

interventions, their health services might better fit the actual needs of community members. If there is an inevitable clash between public health and civil liberties, then the situation must be open to public debate, the elements of the conflict should be made explicit, and rigorous, critical reasoning should be brought to bear on the relative benefits and burdens of a particular policy or intervention. Such consultation might help to restore trust and promote a collaborative relationship between service providers and members of the public. In many situations, the question is not whether to act, but how to act. Community consultation could reinforce the goals of the protection of well being and the promotion of self-determination. Playing a part in decisions does not guarantee to both parties that things will go the way each of them wants, but if the participatory process is genuine, the people who are affected by the decision will be less likely to feel abused or neglected by the policy makers and less resistant to those who carry out the policies; at the same time, it could help public health authorities to re-consider their approach, maybe trying ways that are more voluntary and less coercive.

At the dawn of the third millennium the development of new public health practice ethics can only be the result of the evolution of the relationship between the individual and the community. The individual should give up being totally self-interested and open up to the needs of the community, in order to be a "person", interdependent with other persons, and therefore part of a "people". The community, as a result, should create the proper conditions for the individual to be helped to grow into a person.

In this process the new public health has a vital role to play.

Summary

The modern approach of public health practice in the Western world, aimed at maintaining or improving the health of populations through health promotion and disease prevention, is only a few centuries old; however, its roots go much further back in the history of mankind. The 20th century has seen very fast changes: socio-economic, political, technological, medical and ethical changes. Public health practice has also been affected by these innovations and has became more and more comprehensive. The concepts of preventing diseases and promoting health have broadened and evolved to encompass even population-level issues such as social determinants of health and social justice. As the authority of medicine and the paternalistic approach of physicians and public health officials started to be questioned, bioethics updated its code applying four principles: beneficence, non-maleficence, autonomy and justice. These four principles have strongly influenced public health decisions over the last decades, following the argument that, while directed to the whole population, public health activities interact with individuals. Though public health should not overlook the rights, interests, and freedom of the individual, it is also true that public health looks at the well being of the entire population; therefore the principles and values applied in bioethics, which follow an individualistic orientation, cannot be used as a point of reference. Public health practice should find its own answers for ethical dilemmas linked to its population-based perspective. Many stakeholders are involved in public health, and each of them may have a different approach, particularly when interventions act directly on the individual's freedom, since in public health ethics one core question is whether the individual should be subordinated to the common good or whether the autonomy-focused and antipaternalistic approach should serve as a point of reference for public health activities. This dilemma is involved in most health programs: from prevention of diseases to infectious disease control, from health promotion to research. There are some points of reference which can help to find a way forward and to protect against some abuses; very important points of reference are laws, different codes of ethics (Code of Ethics for Occupational Health Professionals, Code of ethics for public health) and guidelines on ethical conduct of clinical research. However, the goals and strategies of the new public health in the third millennium call for a new public health ethics to respond to the new challenges, a new ethics where the individual and the community are not in tension but in relation.

Ethics, Aspects of Infectious Disease Control

PASQUALE DI MATTIA
CEFPAS–Centre for Training and Research in Public Health, Caltanissetta, Italy
lino-dm@libero.it

Definition

Strategies for infectious disease control programs have been traditionally based on the ▶ harm principle, on ▶ utilitarianism and on ▶ paternalism. In the last few decades, a strong influence on public health practices, has been the right of the individual to exercise full ▶ autonomy and self-determination. This has resulted in a tension between the concepts of individual freedom/privacy and common good, which has brought about new ethical challenges in the approach to infectious disease control.

Basic Characteristics

One of the main tasks of public health practice has been infectious disease control, which includes various methodologies: ▶ screening for the disease, surveillance and name-based reporting, ▶ contact tracing, ▶ treatment monitoring, ▶ isolation (the separation of individuals known to be infectious) and ▶ quarantine (the restriction of the activities of healthy individuals who have been exposed to a communicable disease).

During the 20th century, screening for the presence of disease and at times occult infection has been a central feature of public health practice. Often such screening was imposed, as in the case of screening couples for venereal diseases prior to marriage, screening children for entry into public schools, screening newborns for specific genetic conditions, screening for tuberculosis in schools and workplaces.

One of the main methods used in public health infectious disease control programs is ► surveillance. It implies reporting to health authorities notifiable diseases, including patients' names. It is used in many infectious diseases, like sexually transmitted diseases and tuberculosis, in an effort to monitor, plan and intervene.

A very typical example of the use of coercion in infectious diseases control programs is given by the isolation and quarantine applied in the name of the common good. In those cases, though the rights of the individual are overruled, the intervention is usually accepted when the course of the disease and the timeframe of the treatment are known. Things become more complex when isolation and quarantine are used to avoid infectiousness in cases where knowledge about the diseases and their treatments are lacking. A case which posed very dramatic dilemmas from many points of view, included the ethical one, was the world wide threat of severe acute respiratory syndrome (SARS); because of the "unknown", governments took steps, towards protecting the people's health, which did not consider individual freedom, using isolation and quarantine as a tool for controlling the spread of the disease. Although dealing with infected cases was mostly accepted, many queries were raised when it came to dealing with suspected cases or with individuals suspected of being exposed: the number of people put into isolation escalated very rapidly. Things became more balanced once more knowledge about the course of the disease was acquired.

What could have been a supportive element in the above-named interventions is that the individual had no direct responsibility in contracting the disease. Things drastically changed with the advent of HIV/AIDS. From the very beginning the HIV/AIDS epidemics posed new ethical dilemmas to public health institutions because it is a lethal, sexually transmitted disease, which has a latent period of incubation, during which the partner or the community in general, or even the very infected individual, are not aware of the danger; at the same time, from the onset HIV/AIDS was related to individual behaviors and bore a very strong social stigma.

Following the traditional name-based case reporting would have allowed public health officials to single out infected individuals and to counsel them in order to prevent further transmission, and would have permitted monitoring of the incidence and prevalence of the infection; the antagonists of name based reporting argued that social hostility and HIV-related hysteria could lead to changes in policy, that would permit breaches in confidentiality with serious consequences for those appearing in the reports, in terms of losing their jobs, their housing and perhaps their liberty. The already strong gay men organizations influenced the decision of public health policy makers on management of HIV/AIDS epidemics by framing the whole issue into the human rights perspective. From a public health perspective, then, the HIV/AIDS concern became a socio-political-moral-health issue. For the first time a new "exceptionalist" approach to an infectious disease epidemic was promoted, which rejected coercive measures that might "drive the epidemic underground" and focused on mass health education to bring about behavioral changes, voluntary testing and counseling, following the principle that no public health policy which violated the rights of individuals could be tolerated as a controlling method to prevent the spread of HIV.

The ethical implications of the debate concerned all aspects of infectious disease control strategies which interfere with one of the most important principles of biomedical ethics, the right of the individual to exercise his autonomy and freedom. How, then, to protect individual freedom and ► privacy, while protecting any partner or other community members from infection?

In the USA the debate between the two different approaches lasted almost 20 years, until the Centres for Disease Control (CDC) in 1999 reluctantly accepted that there could be case reporting without the use of names.

The "harm principle" has been the ethical point of reference for various programs aiming at preventing some contagious diseases, including immunization campaigns. Children should be vaccinated not only to prevent their own infection but also the infection of others not yet immunized. Vaccination of children for some infectious diseases has been compulsory in many countries, and has brought about a significant reduction in the incidence of these diseases. In some states exceptions are accepted for religious or philosophical reasons, which, true, involved a very small number of children, however, they pose the ethical question of whether parents have a right to place at risk not only their own children but others who could be infected by them.

With the falling-off of some of those infectious diseases, the problem of vaccine side effects comes to the fore: when many children are dying because of a certain disease, it is easy to accept that a few of them get some side effects; once there are few cases of the disease, then those who get the side effects become more evident; as a result, parents refuse to have their children immunized because of the fear of harming them. The ethical dilemma in these cases is sharpened by what is called "herd immunity": immunization involves both a direct benefit to the individual child as well as to those in the community who remain un-immunized and benefit from the immunization of the vast majority. An ethical principle which can help here is the one of ► justice, as fair distribution of risks and benefits.

Some countries are trying to replace compulsory vaccination for some diseases which are now very rare, with an effective health education of parents; the conviction is that by showing them all the risks (which are anyhow less and less) and all the benefits of vaccination, the number of parents vaccinating their children will not drop.

E

Definition

Disease prevention (► prevention and health promotion) is a strategy to protect health by reducing or avoiding risks of ill-health. To achieve this we can use different methods at different levels. At a personal level we act by avoiding illness (through vaccination, etc.) or by detecting illness at an early stage through screening; at the behavioral level we act by reducing/avoiding risks through information on health issues, health education, health counseling, health training and through social support; at the structural level we aim to reduce/avoid risks through protection of work and community environments. Each method presents some ethical issues because it interferes with individual freedom and behavior.

Basic Characteristics

In a constant endeavor to prevent diseases and promote health, after contributing to the great achievements in fighting infectious diseases through immunization and drugs (at least in the Western world), public health practice began to give more attention to specific conditions such as cancer, heart disease, disability, aging, obesity and diabetes. Nowadays, thanks also to the development of epidemiology and biostatistics, public health deals with patterns of disease, aiming at gaining some more understanding of their causes, and putting in place collective and institutional interventions to alleviate the risk or burden of disease at the general population level. Prevention of diseases and injuries has, therefore, become more broad in application. It embraces a number of aspects:

- interventions for primary prevention (aiming at preventing a healthy person getting a certain disease), ► prevention, primary;
- screenings for secondary prevention (aiming at diagnosing a disease before it becomes clinically evident), ► prevention, secondary;

- programs for tertiary prevention (to prevent complications and to rehabilitate), ► prevention, tertiary.

It is not always easy or straightforward to get all stakeholders in public health to agree on solutions because of the ethical dilemmas involved. However, there are some tools which can help in finding a way forward and in protecting against some abuses.

A very important tool, which has been used, especially for primary prevention interventions, is law. Together with creating a mission for public health authorities, assigning their functions, and specifying the manner in which they may exercise their authority, the legal system is a primary means used by government to bring about conditions for people to lead healthier and safer lives. Examples are laws on the use of car safety belts and helmets for motorcyclists, on smoking restrictions, on environmental regulations (to reduce health hazards in the living and working environment due to environmental pollution), on occupational health and safety standards, on regulating some activities by licensing people, institutions or businesses, on the inspection (checking for insanitary conditions, impure products or unsafe environments) or even the closing down a business, or condemning a building, or confiscating dangerous goods, or fining for pollution. Furthermore, in order to identify and respond to health threats, laws have been put in place to make it mandatory to report some diseases, instigate immunization programs, provide ► isolation and confinement for individuals suffering from specific diseases, and provide treatment for patients with particular diseases.

Though everybody agrees that public health should have as a goal the well being of the whole population, there is often debate on whether governments should intervene to protect the public's health and safety when doing so will diminish a personal freedom or economic interest. Some interventions have to be compulsory and universal in order to be effective; for example, standards for public amenities (such as air and water quality, food safety and waste disposal, road and building safety) and regulations to safeguard the environment against damage caused by hundreds of chemicals, have all been imposed. Nevertheless, they are easily accepted by the people and their imposition is not seen as violating demands for individual consent and ► autonomy, because of many factors:

- they are supported by officially proclaimed rights (e. g. the United Nations Commission on Human Rights made in 2001 proclaimed that everyone has the right to live in a world free from toxic pollution and environmental degradation);
- it is well-known at this stage that damage to human health can be caused by hundreds of chemicals, and, therefore;
- it is actually seen by many people as an ethical duty of all those directly involved in public health to safeguard both the environment and humans from them;
- they do not act directly on the individual's freedom and lifestyle;
- individuals cannot judge those standards for themselves.

Things change when public health interventions act directly on the individual's freedom. In these cases there is always someone who disagrees with a certain policy and therefore will feel coerced.

In the case of cigarette smoking, for example, government interventions (like high taxes on cigarettes), were more accepted (both on the basis of protecting non-smokers and discouraging adolescents from taking up smoking) only after evidence was provided that cigarette smoking was a health hazard; restrictions on smoking in public places were also accepted after scientific evidence proved that passive smoking caused harm. Anti-smoking campaigns emphasized not only the financial burden put on the whole community, but also underlined the life-saving benefits to the individual smokers themselves.

Concerning regulations on motorcyclists' helmets, some people objected, quoting Mr Mills, that "the only purpose for which power can be rightfully exercised over any member of the civilized Community, against his will, is to prevent harm to others … over himself, over its own body and mind, the individual is sovereign;" after all, the carelessness of the individual would just do harm to himself. Things changed when it became clear that "harm to others" could be construed as the financial burden on society, due to accidents and diseases which could have been prevented, and that this could justify the application by governments of the "► harm principle" whereby interventions could be put in place. However, from an ethical point of view, we ought to protect motorcyclists from the hazards of un-helmeted riding not just because they may impose costs on the community in the event of accidents or because they are too young to appreciate the

hazards entailed, but because we are morally bound to prevent avoidable suffering and death.

The "harm principle" has been the ethical point of reference also for other programs aiming at preventing some contagious diseases, as in cases of compulsory vaccination. Children should be vaccinated not only to prevent their own infection but also to avoid infecting other non-immunized children. In many countries vaccination for children for some infectious diseases has been made compulsory, and this has brought about a significant reduction in the incidence of these infections. Some states, however, have made exceptions due to accepted religious or philosophical reasons, which, true, involve only a very small number of children, but they pose the ethical question of whether parents have a right to place not only their own children but others at some risk. With the falling-off of some of these infectious diseases, the problem of vaccine side effects becomes more important: when many children are dying, it is easy to accept that a few will get some side effects, but, once there are few cases of the disease, then those who get the side effects become more of a concern; as a result, parents are more likely to refuse to have their children immunized because of the fear of harming them. The ethical dilemma in these cases is sharpened by what is called "► herd immunity": immunization involves both a direct benefit to the individual child as well as to those in the community who remain un-immunized and benefit from the immunization of the vast majority. An ethical principle which can help here is the one of ► justice, as fair distribution of risks and benefits. Some countries are trying to replace compulsory vaccination for some diseases, which are now very rare, with an effective health education of parents; the conviction is that by informing them about all the risks (which are anyhow less and less) and all the benefits of vaccination, the number of parents having their children vaccinated will not drop.

In the case of working environment hazards, a lot has been done in the last few decades to protect workers, both, in terms of the workers' right to know about hazards in their workplace, and in terms of occupational health (► occupational and environmental health) and safety laws. Ethical issues in occupational health, as for other public health fields, are a concern for many stakeholders: occupational health professionals (occupational health doctors and nurses, factory inspectors, occupational hygienists and psychologists, specialists in ergonomics, in rehabilitation, in the improvement of working environments, in accident prevention, occupational health and safety researchers), workers, employers, those who are suppose to denounce shortcomings, lawyers. Since it is not always easy to find a common perspective when looking at occupational health ethical dilemmas, the need for a code of ethics specific for this field of public health has become compulsory. The International Commission on Occupational Health has adopted the "*International Code of Ethics for Occupational Health Professionals*" which has become a point of reference. It covers issues on the duties of occupational health professionals (which aim at protecting the life and health of workers, respecting human dignity and promoting the highest ethical principles in occupational health policies and programs), and on their obligations (which include integrity in professional conduct, impartiality, confidentiality, privacy).

In the context of disease and risk prevention, a very important turning point has been the application of the ► precautionary principle, which implies that when an activity raises threats of harm to the environment or human health, precautionary measures should be taken even if some cause and effect relationships are not fully established scientifically. The precautionary principle is embodied in the very tradition of public health. A significant example was the control of cholera in the 19th century through improvement of public sanitation systems before scientific evidence could show any causal link between cholera and poor sanitation. The precautionary principle provides a starting point for the ethics of risk management.

One of the most sensitive aspects of disease prevention concerns ► genetics. Unlike public health interventions directed at the entire population, genetic interventions are at their core individually focused, requiring the collection of individual-specific data and often targeting individuals and groups at risk for genetic conditions; thus, by their misuse, they have the potential of causing or increasing social harms, especially when the targeted individuals or groups have been vulnerable in the past to discrimination or social stigmatization because of race or ethnicity. If a public health intervention based on genetic screening could bring some benefits to the individual and to the community, which would justify it, then the ethical question would be on equitable access to services. As a consequence, in the case of public health genetics, all these three aspects should always

be taken into consideration for any screening program: population benefit, individual interests and distributive justice. Genetic studies, due to their nature, pose ethical considerations on individual autonomy, ► privacy, and ► confidentiality; they can also bring about genetic discrimination: people with genetic defects, not all of which show up as dysfunctions, may be denied life insurance, health insurance, and access to schooling or to jobs (an employer could hire only those people whose genes indicate they are resistant to the health hazards of the work place, which is a cheaper alternative to making the work place safe for all). For these reasons, some critics maintain that few, if any, government-sponsored public health genetic interventions are appropriate. Only a few countries have introduced explicit legislation on genetic screening. In some countries, the focus for genetic screening programs has been on pregnant women and newborn children. ► Informed consent is not necessary for a newborn screening test, only for those disorders which are treatable. For those disorders for which newborn screening is available but the tests have not been validated or shown to have clinical utility, written parental informed consent is required prior to testing, even though requiring consent will likely lead to a decrease in both population and individual benefits because some infants will not be screened.

Prenatal screening, when provided, may be confined to conditions for which termination is offered. This approach involves all the ethical conflicts about pregnancy termination.

Primary prevention of genetic conditions includes the concept of "► eugenics", which can bring extreme pressure on people to make childbearing decisions on the basis of genetic information; mating between those with valued genes may be encouraged while mating between two people with dangerous recessive traits may be discouraged or even prohibited. Women carrying fetuses with genetic abnormalities may be encouraged to abort. As we have seen, in disease prevention activities, public health workers are dealing with the conflict between individual autonomy and common good. However, the principles (► ethical principles) included in the "► Code of ethics for public health" may help find a way forward.

Research; Investigation; Study; Exploration

Definition

The term "research" refers to a class of activities designed to develop or contribute to generalizable knowledge. Generalizable knowledge consists of theories, principles or relationships, or the accumulation of information on which they are based, that can be corroborated by accepted scientific methods of observation and inference. In the present context we refer to ► biomedical research to indicate its relation to health; it includes medical and behavioral studies pertaining to human health. Research ethics include both, the moral problems encountered in connection with scientific or other academic research (by the researcher, their subjects or their social environment) and the ► ethical principles which should be a guide when dealing with those problems.

Basic Characteristics

Research is an integral component of public health practice. Public health research includes the study of inanimate substances (such as water and air quality), biological processes not involving humans (e. g. the natural history of arthropods that are disease vectors) and questions that involve humans. There are ethical concerns in each of these types of research, but the majority involve research using human subjects.

Research involving human subjects include:

- studies of a physiological, biochemical or pathological process, or of the response to a specific intervention (whether physical, chemical or psychological) in healthy subjects or patients;
- ► clinical trials of diagnostic, preventive or therapeutic measures in larger groups of people, designed to demonstrate a specific generalizable response to these measures against a background of individual biological variation (for example, new vaccines and medicinal drugs, before being approved for general use, must be tested on human subjects);
- studies designed to determine the consequences for individuals and communities of specific preventive or therapeutic measures; and
- studies concerning human health-related behavior in a variety of circumstances and environments.

Most of ethical aspects in public health research involving humans are similar to those in clinical medical research (► ethics in clinical medicine), because both have to address issues like ► informed consent, individual right to ► privacy, to ► confidentiality, and to ► autonomy; other ethical facets involve matters of race and racism, appropriate study design and research hypotheses. Some more ethical considerations are involved in ► international research; then we also have to deal with problems raised by the local culture (► ethics and culture) (language, beliefs, social values, relationship between individual and community) and by religious aspects, all components which may vary considerably the meaning and the role of informed consent and autonomy, ► beneficence and ► non-maleficence, and of ► justice. While public health researchers should be sensitive to local customs, they are never authorized to conduct research without regard to potential risks and without attempts to seek individual consent from potential study participants. In particular, public health researchers working in international settings must avoid the exploitation of non-Western populations in research that would not be allowed in the investigators' home countries.

Ethical questions can occur at any time during the research process, from the design of the study to the recruitment of subjects, to the data acquisition (► data acquisition and protection) and publication. Just to give but few examples:

- the recruitment of subjects should be exempt from coercion, that is, subjects should not feel as though they cannot refuse to participate;
- in qualitative design, potential ethical conflicts exist in regard to how the researcher gains access to a group of patients, privacy may not be respected through the data collection process that mainly consists of observing or interviewing the subjects in their natural environment, and, furthermore, the concepts of relationship and power between researchers and participants are very prominent in qualitative designs;
- the danger of breaching confidentiality increases in ► longitudinal studies, when data collection happens at different points in the lifetime of the individual, who, therefore, needs to be identified by the researcher;
- issues surrounding randomized controlled clinical trials (RCT) offer a myriad of potential ethical

dilemmas, for example, in the conflict between the RCT and the therapeutic obligation;
- methods of data collection may raise ethical issues of confidentiality and anonymity of the research subjects if the method of data collection uses the Internet or email; the same ethical concerns are embedded in a method of mailed questionnaire imprinted with a code to retrace subjects that did or did not answer the questionnaire;
- researchers have the obligation to share the findings with the larger society; though research findings are typically presented as aggregated data that do not reveal the identities of the individual participants, they may also have some negative consequences on the community as a whole, which could be stigmatized if results are negative.

Let us look closer at some of the issues.

A much debated aspect of research, which requires extra precautions, is involvement of ► vulnerable groups or individuals. By "vulnerable" we mean that they may be more than usually susceptible to exploitation in the process of research, either because they may be more likely to be pressured to participate, or to fail to understand the full implications of participation and may therefore be misled into taking part. This principle would also apply to those who are extremely poor and therefore would find it very hard to turn down a reimbursement for a study procedure despite of being informed of the risks. In these cases even the signed informed consent may not be meaningful.

Furthermore, some people believe that signing a consent form means that they are waiving their rights, including those to sue if something goes wrong, and that the primary purpose of a consent form is to protect doctors and hospitals from legal liability; in addition, the forms may be incomprehensible to them, it is therefore impossible for them to fully understand what they have agreed to. At times, to avoid these kinds of problems, vulnerable groups have been excluded from research to protect them from the research-associated risks, but this also means that they are less likely to share in any benefits, both during the study or later when the results are generalized to other populations in which the interventions had not been studied. In addition, conditions more prevalent among, or disproportionately affecting, minority group members or women could simply go unstudied, and unintended harm could result from the failure to recognize specific group correlated factors.

Of course, in reality, a variety of individuals may be rendered vulnerable by virtue of various situational or persistent social factors. People who are sick or in pain, frightened, or overwhelmed by information or "bad news" may be vulnerable by virtue of these circumstances.

Those who lack the education, emotional maturity, or language and communication skills to understand and appreciate what is disclosed to them during an informed consent process may also be vulnerable to inappropriate pressure to participate (or, instead, to reject precipitously the option of research participation that might benefit them). Those who feel disempowered by virtue of the social roles they occupy, or who lack economic resources to investigate the proposed research or alternatives to it, may not feel free to refuse participation.

In the case of prisoners, researchers must take precautions to prevent the impression that participation or nonparticipation will in any way affect the duration of prisoners' incarcerations.

The process of informed consent can be improved by providing information, both written and spoken, in terms that can be easily understood, and by giving the participants time to make a decision about their participation in research, and to consult family members or make more inquiries about what they are being asked to do.

Parents of minors are required to give consent for their children to participate in a study. If children are old enough to understand the risks and benefits of participation, they are usually required to give their own consent in addition to the consent of their parents. However, there are limits to the level of risk to which parents can give consent.

Research involving human subjects may also make use of existing records, as in the case of ► surveillance or registries data (► disease registry). The use of these sources implies that data obtained from these records will remain confidential (► data acquisition and protection), since they carry the risk of causing harm to the individual at various levels (psychological, employment, family, social). However, in some countries, studies which involve no more than minimal risk to participants are freely reviewable, and some studies (e. g. surveys, observations, or studies of existing data) are exempt from informed consent requirements.

Significant ethical dilemmas arise when research concerns ► genetics. At times, genetic research affects specific ethnic groups or individuals suffering from certain conditions that may be subjected to social stigmatization and therefore may bring harm to those involved.

Research with human subjects should be carried out only by, or strictly supervised by, suitably qualified and experienced investigators and in accordance with a protocol that clearly states: the aim of the research; the reasons for involving human subjects; the nature and degree of any known risks to the subjects; the sources of recruitment of subjects; and the means proposed for ensuring that subjects' consent will be adequately informed and voluntary. The protocol should be scientifically and ethically appraised by ► ethical committees.

Different approaches to ethical dilemmas can influence researchers: ► utilitarianism may justify a research project on the basis that it will produce good consequences for the care of patients and be beneficial for the care of future patients, whereas a deontological ethical theory would judge the nature of the study as being right or wrong within itself regardless of its consequences.

Philosophers, policy makers and others turned their attention to the ethical practice of research on human subjects after the atrocities of medical experiments during World War II were revealed. As a consequence, there are quite a number of guidelines on the ethical conduct of clinical research. Some were written in response to a specific event and, by focusing on the instigating issue, only emphasize certain specific aspects of research while excluding others.

For instance, the "*Nuremberg Code*" arose from the judicial condemnation of the atrocities committed by Nazi physicians and so focused on the need for consent, freedom from coercion and a favorable risk-benefit ratio.

The "*Declaration of Helsinki*" was developed to fill gaps in the Nuremberg Code, especially in relation to physicians conducting research with patients, and so focused on the favorable risk-benefit ratio and independent review; the Declaration of Helsinki also emphasizes a distinction between therapeutic and non-therapeutic research rejected or not noted by other documents.

In the USA, the National Commission for the Protection of Human Subjects of Biomedical and Behavioral Research in their document known as the ► "*Belmont Report*", underlined three basic principles to be used to generate specific rules and regulations in response to US research scandals such as ► Tuskegee and ► Willowbrook State School; those principles are: respect for autonomy (e. g. informed consent), beneficence (e. g. favorable risk-benefit ratio), and justice (e. g. to ensure that vulnerable populations are not targeted for risky research).

► *Respect for persons* incorporates at least two fundamental ethical considerations, namely:

a) respect for autonomy, which requires that those who are capable of deliberation about their personal choices should be treated with respect for their capacity for self-determination; and

b) protection of persons with impaired or diminished autonomy, which requires that those who are dependent or vulnerable be afforded security against harm or abuse.

Beneficence refers to the ethical obligation to maximize benefits and to minimize harms. This principle gives rise to norms requiring that the risks of research be reasonable in the light of the expected benefits, that the research design be sound, and that the investigators be competent both to conduct the research and to safeguard the welfare of the research subjects. Beneficence further proscribes the deliberate infliction of harm on persons; this aspect of beneficence is sometimes expressed as a separate principle, *nonmaleficence* (do no harm).

Justice refers to the ethical obligation to treat each person in accordance with what is morally right and proper, to give each person what is due to him or her. In the ethics of research involving human subjects the principle refers primarily to distributive justice, which requires the equitable distribution of both the burdens and the benefits of participation in research.

The Council of International Organizations of Medical Sciences (CIOMS) and the World Health Organization (WHO) prepared in 1991 a document addressing public health and epidemiological research ("*International Guidelines for Ethical Review of Epidemiological Studies*"), and in 1993 endorsed a revised "*International Guidelines for Biomedical Research Involving Human Subjects*". The CIOMS guidelines consist of a description of general ethical principles and fifteen recommendations with commentary addressing the application of ethical standards and the establishment of mechanisms

for ethical review of human subjects research in developing countries where local standards for scientific conduct may differ from those applied in Western industrialized nations.

In 1991, the US Department of Health and Human Services (HHS) issued revised "*Regulations on human subjects research*", which has come to be referred to as the Common Rule. According to the regulations, in order for persons (or their legally authorized representatives) to give "legally effective informed consent," the researchers seeking participation must describe the research and its purposes, its foreseeable risks and expected benefits, possible compensation in case of injury, must disclose appropriate alternatives, and must give a statement about the maintenance of confidentiality and that participation is voluntary. About research with children, the "Common Rule," gets into detailed specifications, stating that research should not involve greater than minimal risk, otherwise it should present the prospect of direct benefit to the individual subjects; if research involves greater than minimal risk and no prospect of direct benefit to individual subjects, then it should likely yield generalizable knowledge about the subject's disorder or condition which is of vital importance for the understanding or amelioration of the subjects' disorder or condition.

In 2002, the Nuffield Council on Bioethics published the "*Ethics of Research Related to Healthcare in Developing Countries*". This document provides specific recommendations for ethical issues related to standards of care, informed consent, obligations of researchers to individuals and communities, and independent ethical review.

These are but few of the many relevant documents and guidelines concerning ethical aspects of research. Some of them are by international bodies, some are at national level. All guidelines are meant to smoothen the conflict between individual rights and the common good.

Generally, legal, ethical, and human rights principles strongly support the rights of people to control the circumstances in which their identifiable health data are acquired, used, disclosed, or stored. However, the value of individual privacy regarding health information is not absolute. Sharing identifiable health data may be justified where they are needed to promote communal good and communal values (e. g. public health, human research), or where it is necessary to prevent harm to others (e. g. duty to warn requirements). Particularly in the public health setting, the access, use, and disclosure of individual health data is needed to survey the population's health and protect against actual or potential threats to community health.

Community consultation has been proposed as a tool with multiple benefits for public health research and practice. It is suggested that if researchers and public health practitioners were encouraged, or even required, to consult with members of the communities in which they conduct research and offer interventions, their research questions and health services might better fit the actual needs of community members. Such consultation might help to restore trust and promote a collaborative relationship between researchers or service providers and members of the public. And, depending on the degree of influence that community members exerted (or were recognized to have), community consultation could reinforce the goals of the process of obtaining individual informed consent – namely, the protection of well being and the promotion of self-determination.

Ethics in biomedicine; Bioethics

Definition

Ethics in clinical medicine concerns principles (► ethical principles) and values (► ethical values) applied to decision making affecting the well being of the individual patient and to the personal relationship between the health worker and the patient.

Basic Characteristics

► Ethics, in general, is a discipline derived from philosophy. Some authors identify ethics with morals, as the beliefs and standards of good and bad, right and wrong, that people hold and should follow in a society; others refer morality to individual behavior and ethics to social rules; others define ethics as the systematic study of morality: ethics, in other words, is the theory and morality is the practice. Every profession has ethical dimensions, ► professional ethics, concerned with the ethical practice of the profession, such as the code of conduct for health professionals; doctors, indeed, cannot insulate their practice of medicine from their personal moral beliefs and, at the same time, cannot allow their personal morality to overrule their professional obligations (a typical example being the case of a woman requesting an abortion from a doctor who is personally against abortion on moral grounds).

Ethical concerns in medicine are as old as medicine itself. A universal basic code of conduct for physicians is known as the ► hippocratic oath, which originated in the fourth century before Christ, when the main task of the doctor was to cure using remedies known at that time, which rarely caused harm. The oath states: "I will use treatment to help the sick according to my ability and judgment, but I will never use it to injure or wrong them … And whatsoever I shall see or hear in the course of my profession … I will never divulge, holding such things to be holy secrets." Ethics consisted, therefore, of three, clear principles: ► beneficence, ► non-maleficence, ► confidentiality.

Ethical dilemmas in clinical medicine in the past were few at a time when the physician's paternalistic approach was acceptable. Nowadays, ► paternalism is seen in a very negative light and is very much criticized because it interferes with patient liberty and freedom. However, originally, it was regarded in a positive light; in a fatherly way, the doctor took decisions on behalf of patients and withheld information from them or their legal guardians as he considered best. A classic exam-

ple of the paternalistic approach is the case of a physician not revealing to a patient that he has cancer, thinking that in this way he leaves the patient with some hope, while, maybe, sharing the information with the patient's relative or friend. In other cases, the physician with a paternalistic approach may perceive his patients, due to their condition, as being in states of psychological and emotional instability which could have affects on their ability to make rational decisions, and so he will not allow them to exercise their rights to autonomy/freedom, because they might refuse treatment that could preserve their lives, prevent disability or ameliorate pain. Unfortunately, in the name of paternalism, some abuses have happened both in clinical practice and in research.

Since the second half of the 20th century the authority of medicine and the paternalistic approach of physicians has decreased because of certain factors:

- the discovery of new treatments and new technologies has enormously increased the chances of cure along with the risk of causing harm;
- the growth of patients' knowledge in general and on medical issues in particular has given them more power;
- the place of the individual has gained more ground in society, and government policies and laws, being informed by ► autonomy and ► human rights issues, have evolved towards protecting the individual.

At the same time:

- the increased costs of health care has brought along disparities in its distribution and accessibility within a specific population and among different populations;
- searching for a new code of conduct for health professionals has become more complex because, due to ► globalization, patients are of different nationalities and backgrounds, with varying cultural values;
- the old one-to-one doctor–patient relationship, based on patient trust and doctor beneficence, has deeply changed with the modern multidisciplinary approach to patient care.

As a consequence, medical ethics' body of study and research has increased; therefore, a more inclusive term for ethics in clinical medicine is "► bioethics". Bioethics has found a strong point of reference in the ► patient-centred approach and has given clinicians clear guidelines, which broaden the Hippocratic Oath rules and embody four basic principles: beneficence (doing good), non-maleficence (not doing harm), autonomy (respect for the person and individual rights), and ► justice (distributing benefits, risks and costs fairly).

In this evolution, the physician's duty to preserve confidentiality has become, in various states, a patient's right regulated by specific laws. However, exceptions to the right to confidentiality are found in infectious diseases control programs, which required some conditions to be reported to health authorities in order to protect the common good. An inconsistency to this form of state paternalism occurs in HIV/AIDS epidemics, where the patient's right to confidentiality has been enhanced.

The first two principles (beneficence and non-maleficence) in contemporary ethics have been enriched by other components. Non-maleficence, for example, implies that the doctor should continually improve his medical knowledge, or, if needed, should consult other specialists; beneficence now even includes health promotion (► health promotion, ethical aspects) and risks reduction, linked to the principle of utility, which requires that risks of harm should always be weighed against possible benefits, in order to maximize the latter and minimize the former.

The essay "On Liberty", by the 19th century philosopher John Stuart Mill, describes the principle of autonomy very clearly. He states: "The only purpose for which power can be rightfully exercised over any member of the civilized Community, against his will, is to prevent harm to others. His own good, either physical or moral, is not sufficient warrant. He cannot rightfully be compelled to do or forbear because it will be better for him to do so, because it will make him happier, because in the opinion of others to do so would be wise or even right. These are good reasons for remonstrating with him or reasoning with him or persuading him or entreating him but not for compelling or visiting him with any evil in case he does otherwise … In the part which merely concerns himself, his independence is, of right, absolute."

A very important and practical consequence of the principle of autonomy is the concept of ► informed consent, which has to be voluntarily given by a competent patient. It implies that:

- written permission should be given by patients when undergoing invasive procedures or when enrolling as subjects for medical research;
- for an adequate understanding of what is going to happen to them, proper and sufficient information

should be given to patients about certain treatments and their risks;
- transmission of medical personal records to another party should be only formally permitted.

Though they may sound straightforward points, this may not be so in daily practice. Should we give patients all the available information, taking the risk of confusing them, or should we just tell them what any reasonable person would like to know in such circumstances? Paternalism or patient autonomy? Both approaches can be justified or condemned when seen from differing theoretical points of view; it depends on the perspective and on the specific case. Neither can be the absolute answer when we take into account every day clinical realities. One way of solving the problem is to become involved in patients' lives in a way that enhances their personal growth and development without necessarily contravening their wishes. After all, there are many studies confirming the importance of the doctor–patient relationship and the therapeutic effects of all its dimensions. The key point is to look at patients as people, and how a course of action would affect all aspects of their lives as individuals.

The above-named four principles have also strongly influenced public health decisions in the last decades, based on the argument that, while directed to the whole population, public health activities impact on individuals. In particular, the principle of autonomy is at the root of the conflict in public health ► ethics between common good and individual freedom and liberty.

Though public health should not overlook the rights, interests, and freedom of the individual, it is also true that public health looks at the well being of the entire population; therefore the ethical principles and values applied in bioethics, which follow the individualistic orientation, cannot be used as an absolute point of reference.

If we just take the principle of autonomy, we can see how difficult it is to apply it in some public health interventions which have to be compulsory and universal in order to be effective. For example, standards for public amenities, such as air and water quality, food safety and waste disposal, road and building safety, have to be imposed. Because they are organizationally external to the health care system, their imposition is not seen as violating demands for individual consent and autonomy that have been so prevalent within medical ethics. By contrast, we can allow some variability in the standards to which consumer goods are produced. Yet here too we accept some compulsion in setting uniform safety standards, because we know that individuals cannot judge the safety of complex products for themselves. Only in marginal cases, where the effects of individual consumption are wholly on that individual, and where consumption is optional — high-tar cigarettes, safety helmets for cyclists — may we sometimes think it enough to warn and educate. Even in these cases there is constant debate as to whether health education and health promotion, which preserve individual autonomy and avoid compulsion (at least for adults) are enough.

It is clear that public health ethics should find their own answers to dilemmas linked to the population-based perspective.

Definition

According to the Glossary of the ► international conference of harmonization (ICH) ► harmonized tripartite guideline for ► good clinical practice E6 (1.27) an Independent Ethics Committee (IEC) is:

"An independent body (a review board or a committee, institutional, regional, national, or supranational), constituted of medical professionals and non-medical members, whose responsibility it is to ensure the protection of the rights, safety and well-being of human subjects involved in a trial and to provide public assurance of that protection, by, among other things, reviewing and approving/providing favorable opinion on, the trial protocol, the suitability of the investigator(s), facilities, and the methods and material to be used in obtaining and documenting informed consent of the trial subjects.

The legal status, composition, function, operations and regulatory requirements pertaining to Independent Ethics Committees may differ among countries, but should allow the Independent Ethics Committee to act in agreement with GCP as described in this guideline."

Basic Characteristics

History

The development of ethical standards leading to the development of ethical committees is strongly linked to German history in good and bad times. Apart from ethical standards from Greek and Roman history in medicine (nil nocere, Hippocratic oath), the earliest provisions concerning medical research ethics, in a modern sense, were regulated for the first-time in Germany by the Prussian Ministry of Education in 1900 as advice to the heads of hospitals (Minister der geistlichen, Unterrichts- und Medizinal-Angelegenheiten 1900/1). This document states, that only adults with full contractual capabilities giving informed consent are allowed to participate in medical research involving humans (► healthy subjects). However, therapeutic, diagnostic or prophylactic studies of ► patients were not covered by this legislation. In 1931, in new German legislation (Richtlinien für neuartige Heilbehandlungen und für die Vornahme wissenschaftlicher Versuche am Menschen, Reichsminister des Innern vom Februar 1931), the principles of informed consent were confirmed and expanded to patients being treated with new and not well-known treatments or participating in therapeutic, diagnostic or prophylactic studies. Furthermore, provisions for ► vulnerable populations (e. g. minors) were introduced in this legislation.

Unfortunately, this legislation did not prevent German physicians conducting cruel and, on the basis of this legislation, clearly illegal experimentation on humans, apart from other massive violations of human rights and genocide, during the time of the Nazi regime. These criminal offenses led to the Nürnberg Physician Trial 1946/7 which ended with the drawing up of the Nuremberg Code (Nuremberg Code 1949) (Fig. 1) by the 1st American Military Court of Justice concerning permissible experimentation on humans. This codex (listed below) reinforced the principle of informed consent (Weindling 2001), required a ► risk–benefit-evaluation, allowed the participants to terminate their participation during the trial should they so decide, and required prerequisites to limit potential harm or risks for the par-

Ethics Committee, EC, Figure 1 (on the facing page) The Nuremberg Code – reinventing the principles of the ethical conduct of clinical trials concerning human subjects after the Second World War.

The Nuremberg Code

From "Trials of War Criminals Before the Nuremberg Military Tribunals Under Control Council Law No. 10", Vol. 2, Nuremberg, October 1946 - April 1949. (Washington, DC: US Government Printing Office, 1949). pp 181-182.

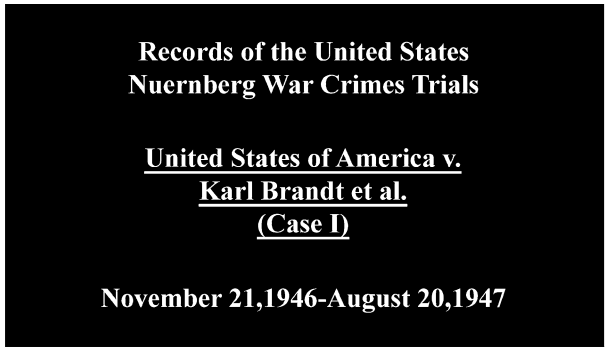
The great weight of the evidence before us is to the effect that certain types of medical experiments on human beings, when kept within reasonably well-defined bounds, conform to the ethics of the medical profession generally. The protagonists of the practice of human experimentation justify their views on the basis that such experiments yield results for the good of society that are unprocurable by other methods or means of study. All agree, however, that certain basic principles must be observed in order to satisfy moral, ethical and legal concepts.

1. The voluntary consent of the human subject is absolutely essential. This means that the person involved should have legal capacity to give consent; should be so situated as to be able to exercise free power of choice, without the intervention of any element of force, fraud, deceit, duress, overreaching, or other ulterior form of constraint or coercion; and should have sufficient knowledge and comprehension of the elements of the subject matter involved as to enable him to make an understanding and enlightened decision. This latter element requires that before the acceptance of an affirmative decision by the experimental subject there should be made known to him the nature, duration, and purpose of the experiment; the method and means by which it is to be conducted; all inconveniences and hazards reasonably to be expected; and the effects upon his health or person which may possibly come from his participation in the experiment.

   The duty and responsibility for ascertaining the quality of the consent rests upon each individual who initiates, directs or engages in the experiment. It is a personal duty and responsibility which may not be delegated to another with impunity.

2. The experiment should be such as to yield fruitful results for the good of society, unprocurable by other methods or means of study, and not random and unnecessary in nature.
3. The experiment should be so designed and based on the results of animal experimentation and a knowledge of the natural history of the disease or other problems under study that the anticipated results will justify the performance of the experiment.
4. The experiment should be so conducted as to avoid all unnecessary physical and mental suffering and injury.
5. No experiment should be conducted where there is an a priori reason to believe that death or disabling injury will occur; except perhaps, in those experiments where the experimental physicians also serve as subjects.
6. The degree of risk to be taken should never exceed that determined by the humanitarian importance of the problem to be solved by the experiment.
7. Proper preparations should be made and adequate facilities provided to protect the experimental subject against even remote possibilities of injury, disability, or death.
8. The experiment should be conducted only by scientifically qualified persons. The highest degree of skill and care should be required through all stages of the experiment of those who conduct or engage in the experiment.
9. During the course of the experiment the human subject should be at liberty to bring the experiment to an end if he has reached the physical or mental state where continuation of the experiment seems to him to be impossible.
10. During the course of the experiment the scientist in charge must be prepared to terminate the experiment at any stage, if he has probable cause to believe in the exercise of the good faith, superior skill and careful judgement required of him that a continuation of the experiment is likely to result in injury, disability, or death to the experimental subject.

a



b

The crimes charged in the Brandt case consisted largely of medical experiments performed on defenseless concentration camp inmates against their will; "euthanasia" carried out on the mentally defective, the physically sick, the aged, and ethnic and racial groups; and the murder of concentration camp inmates for the express purpose of collecting skulls and skeletons for the Anatomical Institute of the Reich University of Strassburg. The following medical experiments were conducted:

1. High altitude: to investigate effects of low pressure on persons.
2. Freezing: to test human resistance to extemely low temperatures.
3. Malaria: to develop controls over the recurring nature of the disease.
4. Mustard gas: part of a general research program in gas warfare.
5. Sulfanilamide: to test the efficacy of the drug in bone muscle and nerve regeneration and bone transplantation.
6. Seawater: to test methods of rendering seawater potable.
7. Epidemic jaundice: to develop an antitoxin against the disease.
8. Sterilization: to test techniques for preventing further propagation of the mentally and physically defective.
9. Typhus: to investigate the value of various vaccines.
10. Poison: to test the efficacy of certain poisons.
11. Incendiary bomb: to find better treatment for phosphorus burns.

The prosecution alleged and the judgment confirmed that these experiments were not isolated acts of individual doctors and scientists on their own responsibility but that they were the result of high-level policy and planning. They were carried out with particular brutality, often disregarding all established medical practice. Consequently, large numbers of the victims died in the course of or as a result of the experiments.

Ethics Committee, EC, Figure 2 Accusations in the Nuremberg physicians' trial

ticipants to the largest possible extent. Furthermore, the responsible person (principal investigator) was required to terminate trials if any unforeseen risks arose during the conduct of the investigation.

The prosecution alleged and the judgment confirmed that these experiments were not isolated acts of individual doctors and scientists on their own responsibility but that they were the result of high-level policy and

planning. They were carried out with particular brutality, often disregarding all established medical practice. Consequently, large numbers of the victims died in the course of or as a result of the experiments.

This German experience paved the way for the ► Declaration of Helsinki (World Medical Association 1964) and later the introduction of independent ethical committees.

Even though the exact provisions of ethics committees are regulated by national legislation, the duties and expectations of the work to be done (Parvizi et al. 2007) are agreed on globally – even though the answers to global imbalances in development are under discussion (Benatar 2002, Kirigia et al. 2005, Dhai 2005, Hyder et al. 2004) – and are fixed in international guidelines.

But, even today, discussion on ethical issues in research and how they should be integrated and handled evoke powerful emotions (Baer and Nelson 2006, Hueston et al. 2006) and will inevitably lead to further developments and adaptations by ethics committees.

Usually, independent ethics committees are responsible for ensuring the proper treatment of vulnerable subjects and upholding the rights and well being of individuals participating in clinical trials, whereas, regulatory authorities are responsible for ensuring that risks are minimized and safety guaranteed for participants before granting an IND (investigation of a new drug) permit.

The independent ethics committees and institutional review boards have to ensure the safety and rights of subjects participating in biomedical research. Furthermore, apart from these research-bound ethics committees, councils exist, which handle decisions of ethical relevance to individual patients in medically critical situations (e. g. termination of dialysis, artificial respiration, parenteral nutrition in critically ill patients).

Responsibilities of IEC

It is the responsibility of an independent ethics committee to ensure the safety, well being and the individual rights of all subjects participating in clinical trials. In addition, special attention should be drawn to the participation of vulnerable subjects (e. g. minors, pregnant women, people unable to give consent [e. g. in emergency situations, psychiatry], people unable to decide freely [e. g. military personnel, prisoners]) in clinical trials. If in these circumstances, prior consent of the subjects, or their legally acceptable representatives, is impossible, the ethics committee should determine if the documentation provided for this specific trial addresses all relevant ethical concerns and meets all applicable regulatory requirements for the specific trial.

The ethics committee has to obtain the documentation of the proposed study including, ► trial protocol with – if applicable – amendments, ► investigators brochure with additional safety information, written ► informed consent forms, including information regarding payments and/or other compensation offered to subjects for study participation together with proposed subject recruitment procedures, and documents concerning the qualification of the investigator who will be conducting the requested study. Also, the ethics committee may request any additional documents it deems necessary to fulfill its responsibilities.

The ethics committee should review this documentation within a reasonable timeframe and document its opinion concerning the proposed study, clearly describing the reviewed trial, the reviewed documents, modifications of the documents it required (e. g. additional information for the participating subjects) prior to its approval/opinion concerning the proposed study. The ethics committee should approve or disapprove or give a favorable or negative opinion on the proposed study and the qualifications of the investigator who shall be conducting the trial.

During the running of each trial, the ethics committee should conduct a continuing review at appropriate time intervals – depending on the degree of expected risk for participating subjects – with a minimum of once per year.

Composition of Ethics Committees (Minimal Requirements)

An independent ethics committee should consist of a reasonable number of members who have, as a board, the qualifications and experience to evaluate the scientific, medical and ethical aspects of the proposed investigation. Usually an ethics committee should include a minimum of five members with at least one member being independent of the institution and/or trial site proposed for the conduct of the trial. Furthermore, at least one member of the board has to be a layman/laywoman (i. e. someone who does not have specialized knowledge of the area of research).

Only the members of the ethics committee who are independent of the investigator and the sponsor of the proposed study should vote or provide opinion concerning trial related matter. A list of the ethics committee members and their qualifications has to be maintained for each meeting of the board.

Operations of Ethics Committees

An independent ethics committee should operate according to written ► standard operating procedures (SOPs) and has to maintain written records of its activities and minutes of its meetings. It has to comply with the guidelines concerning Good Clinical Practice (GCP) and with the applicable regulatory requirements for the location of operation.

An ethics committee should make its decisions, in adequate time, at an announced meeting at which at least a quorum (as stipulated in the applicable regulatory requirements and/or the written standard operating procedures) is present. Only those members involved in the review of the documentation and its discussion should vote, give their advice or provide their opinion.

Investigators involved in the research project may provide, either during the meeting or during the review process, information concerning all aspects of the study but they are not allowed to participate in the evaluation or voting, or express an opinion concerning their project.

Ethics committees may invite nonmember specialists, with expertise in special areas relevant to the trial, to give assistance, if such expertise cannot be supplied by members of the board.

The ethics committee must retain all relevant records for an appropriate period of time after the completion of a trial and, upon request, make them available to competent regulatory authorities.

The ethics committee should also provide, upon request, its written procedures, statutes and membership list to investigators, sponsors or competent regulatory authorities.

Statutes of Ethics Committees

Ethics committees should establish and or work according to the statutes and legal requirements. The statutes should include the composition of the board (names and qualifications of the members) and the authority to which the board is assigned, the time intervals between meetings and the procedures of notification prior to meetings, instructions on the conduct of the initial and continuing reviews of ongoing trials, and circumstances in which expedited review procedures might be used.

In addition, the statutes should state that no subject should be included in trials prior to a written approval or the obtaining of a favorable opinion for the concerned trial, and that deviations from or changes to the protocol should only be enforced after written approval from the ethics committee with an appropriate amendment to the documentation. Exceptions are only permissible to ensure the safety of the subjects participating in the trial when unforeseen hazards arise or for minor administrative changes to the trial (change of address, phone number, Monitor).

All investigators involved in a specific trial must report unforeseen hazards arising from the trial, changes in the risk–benefit evaluation, and serious and/or unexpected adverse drug reactions (► SAE, ► SUSAR – usually as ► CIOMS report) to the concerned ethics committee. Correspondingly, the ethics committee has to ensure that the investigators are informed whenever trial-related decisions are made, the reasons of such decisions and the procedures for appeal against such decisions.

Ethics and Culture

PASQUALE DI MATTIA
CEFPAS – Centre for Training and Research in Public Health, Caltanissetta, Italy
lino-dm@libero.it

Synonyms

Culture: customs; Lifestyle; Civilization

Definition

Culture is a system of shared beliefs, values, behaviors and practices common to a particular group or population that results from group experience interpreted in light of beliefs about the purpose and meaning of life. With regard to health and well being, culture includes:

- ideas about definitions and causes of health and illness;
- beliefs about how to protect and improve health; attitudes about when, how, and from whom to seek help;
- appropriate ways of expressing (or not expressing) symptoms or suffering.

Public health ► ethics include the principles (► ethical principles) and values (► ethical values) that help guide interventions within a specific population which has its own culture and ethics. The encounter between public health ethics and culture, often, generates some conflicts.

Basic Characteristics

Generally speaking, we are influenced by a kind of ► ethnocentrism: we consider that our own patterns for behavior are "normal", and we often describe people from another culture as "different", "strange", "weird", "primitive", revealing an underlying attitude in us that our own culture is superior, more advanced and preferable; it is not just different, but better. Actually, our own individual cultural codes and values are like glasses with distorting lenses: the things, events, and relationships we assume to be "out there" are, in fact, filtered by our own "cultural lenses". Cultural influences affect clinical medicine and public health practice. Much of medical practice is influenced by the predominant Western techno-medical culture; therefore, the health professionals must be careful not to impose their own cultural categories on others in a sort of "medical imperialistic" way. At the same time, from the patient's side, cultural factors usually surface as specific ethnomedical beliefs (assumptions, expectations, interpretations, attitudes) that concern the body, its normal functions, the self, the family and social network, causes and consequences of sickness, patho-physiology, help seeking activities and treatment choice, compliance, satisfaction, and many related issues. These beliefs may influence coping with sickness and response to care, because from them patients "learn" ways of being ill; as a consequence, while "► disease" can be catego-

rized as abnormalities in the structure and function of body organs and systems, "► illness" behaviors vary from culture to culture and from individual to individual, being influenced by the individual's experience of disease.

Though clinicians have guidelines for their interaction with the patients based on clear principles (► beneficence, ► non-maleficence, ► autonomy and ► justice), they still have to adapt those principles to the individual patient's culture. Let us take the example of ► informed consent, based on the principle of autonomy. For the consent to be "informed" it is important that what the informant (health worker, researcher, etc.) has said is actually understood by the recipient of the information. Things become more complex when a person lives in a culture where deference to authority figures or elders and non-individual decision-making is the cultural norm.

In research (► ethics, aspects of public health research), a major concern about obtaining informed consent is the ability of the potential study participant to truly understand the study and the risks and benefits that may be experienced; to understand this is to be truly informed. Other ethical aspects are encountered when research is done at the international level, or in a culture where studies are not common, or where Western scientific thinking is not dominant; here the local culture (language, beliefs, social values, relationship between individual and community) or religion, may vary considerably the meaning of the concepts of informed consent, autonomy, beneficence, non-maleficence, and justice. In such instances, researchers need to expend extra effort to gain an understanding of the culture and motivations of the study participants and how best to communicate with them about the study. The researchers also need to enable the potential study participants to understand the culture of the investigators, especially as it pertains to scientific inquiry.

The problem of balancing universal and local standards for ethical conduct in public health research is challenging for investigators facing the very real constraints of implementing a study in an area in which traditional customs may be in conflict with international ► guidelines and ► policies. These issues are particularly complex when public health research is implemented in areas known for human rights violations. Public and professional debates concerning health research in international settings often center around notions of cultural relativism and beliefs about cultural universalism. ► Cultural relativism refers to the notion that because human, social and psychological characteristics are culturally produced, the diverse representation of these characteristics across human groups is relative to cultural variability. From this perspective, the moral standards of different cultures cannot be rank ordered in terms of a common criterion of comparison; such standards are "incommensurable" with one another; as a consequence, neither internal critique of a malfunctioning culture nor outside critique on the basis of universal human standards – such as human rights – are possible; the only normative judgment that is possible is one that recognizes the equal worth of culturally different moral standards. Thus, transcultural standards for the ethical assessment of cultural practices or human conduct are not objective or rationally valid, but always represent the imposition of one set of cultural values on another. Indeed, the term ► ethical imperialism has been used to refer to the application of Western ethical standards particularly in developing nations with different cultural norms. Genocide, racism, violence against women and children, war crimes, and the like are highly problematic implications of cultural relativism.

► Cultural universalism implies the existence of overarching principles, such as notions of human rights, that are applicable cross-culturally and, therefore, could be used to determine the rightness or wrongness of specific cultural beliefs and practices. Some authors, from a perspective of autonomy, support basic ► human rights and their global applicability, while others consider notions of the "common good" as a foundation for human rights. In some cases it might be appropriate to consider cultural differences in the application of those principles.

Public health communication campaigns have been part of the strategy of health promotion (► health promotion, ethical aspects) and disease prevention (► prevention and health promotion). The production of messages to promote public health has used a wide range of communication strategies in order to achieve public health goals. Messages on how to improve health may not appear as ethically problematic, yet they may create subtle but real ethical dilemmas, especially when addressed to a multicultural population or to a population having a culture which is different from the Western one. This situation, which is very common in a multi-ethnic society like ours, poses the ques-

tion whether public health promotion messages should respect or indeed challenge cultural norms that appear to clash with Western values or even with human rights. There is no straightforward answer. The point is that things should not be taken for granted, and a culture sensitive ethical analysis should be applied to each phase of the communication activity, with imaginative thinking, open to different ethical approaches, because communication interventions that are sensitive to ethical and cultural concerns are more likely to be better executed and to be trusted by intended populations.

An integral constituent of the discipline of public health ethics is ► professional ethics which concerns the ethical dimensions of a specific profession. More and more, the professional ethics of different countries conform to universally accepted values. This may give the apparent impression that some values and ethical concerns transcend culture; "apparent" because while there may be common ethical concerns between cultures, the cultural context of the underlying values may create very different meanings and result in different practices. In the case of health professionals, for example, the values and ethical concerns embraced by members from different cultures make reference to competence, respect for the patient as a person (► respect for persons), responsibility (to the patient, family, physician and institution/employer), relationship and connection, the importance of the family, caring, good death, comfort, truth-telling, understanding the patient/situation, etc.; however, although these ethical concerns are common to various cultures, the related ► background meanings and consequent actions are often different between these cultures.

What then when cultures mix? In increasingly multi-ethnic populations, diversity has only highlighted the role of culture in defining health needs, appropriate services, and even, at the individual level, in influencing appropriate diagnosis and treatment. As a consequence, ► cultural competence and related education are recommended in order to improve public health professionals' recognition and understanding of the importance of culture in health-related activities and the history, beliefs, values, and practices of members of the specific communities they serve.

It is important to point out that as individuals, however secure we feel in our own cultures, we all live within a worldwide pluralistic society with people from diverse cultures. It is necessary to respect and, at least try to, understand the values of these different cultures, even if we do not share them; we must all learn to find some common ground and some shared ideas so that we can communicate with one another; the values of one single culture, religion or ethical perspective, cannot be just imposed on everyone, it is imperative that we find common acceptable values despite our diversities.

Ethics in End-Stage Disease

► Ethics in Palliative Medicine

Ethics and Hospice

► Ethics in Palliative Medicine

Ethics in Palliative Medicine

Synonyms

Ethics in end-stage disease; Ethics and hospice

Definition

From the ethical point of view patients with advanced chronic diseases should receive palliative care well before the point they are near to death (WHO, 2006). They should be supported with information, education and counseling about their diagnosis and the actual and future stages of their diseases. As patients with life-threatening diseases are now living longer and as they are getting more complex treatment, palliative caregivers have to develop new models of practice and a flexibility of attitude to be able to cater to individual needs. Thus, ethically, palliative medicine demands both physical and psychological support from the time of diagnosis of the incurable disease through to its terminal stage. The patient's autonomy and freedom of choice has to be respected. In palliative care the focus is directed to quality of life, which means there has to be good symptom control. In palliative medicine it is our **moral, legal and professional duty** to help patients achieve understanding, so that they have a clear idea of the options available and are able to give consent to examinations and therapies.

Ethics and Religious Aspects

URSULA WINKLER
Forschungsverbund Public Health Sachsen-Sachsen Anhalt e. V., Medizinische Fakultät, Technische Universität, Dresden, Germany
arzneimittelberatungsdienst@mailbox.tu-dresden.de

Synonyms

Meaning; "Arising from habit"; Morality

Definition

Ethics forms one of the main aspects of ► philosophy. It provides criteria for good and bad behavior and makes judgment on those motives with resulting consequences.

The principle of reason forms the main standpoint on which ethics, as a philosophical discipline, is based. It differs from the classical understanding of ► theological ethics in that it embraces the moral principles in God's Will and its belief in the prophecy used in God's name at the forefront.

A single definition of ► religion does not exist. It influences human thought and behavior. It also affects human values, which, due to varying cultures and their historical backgrounds, differ from one another.

Basic Characteristics

History

Ethics became a philosophical discipline under ► Aristoteles (384–322 BC) but ethics had been at the center of philosophical thinking since the time of ► Socrates (469–399 BC).

For Aristoteles, understanding of the term ethics required the scientific study of human customs and practices, and their moral standing and beliefs. He determined that ethics as a philosophical discipline should encompass the whole of human behavior, the meaning of which needed to be defined by utilizing philosophical terms to provide a normative value that, through this method, could be applied practically based on the detail provided.

General

Many of the earlier religions based well being and living together on specific ethical terms, their values of

which still exist today. This system included beliefs in what was right or wrong, good or bad, and how members of specific religions were to behave and conduct their affairs.

Through historical development, these beliefs are to be found in most other religions, which have similar principles with religious obligations. These should provide for a friendly relationship between various religions that share common goals and should have a positive influence on ► society and ► politics.

As in all worldly affairs, there is in religion a conflict between theoretical claims and their practical application. Whilst misunderstanding (misuse of political power) during the middle ages and earlier modern times was based on religious grounds by society, today there is an obvious trend away from this approach.

Sometimes, fundamentalism may lead to the formation of pseudo religious groups and their desire to carry out ► terrorist activities. These brutal actions (crusade, witch-hunt, and persecution of the Jews) and ► religious wars in the name of God have brought about the breakdown of religious ethical norms.

Ethics (Monotheism Religion)

The view of western society's philosophy with regard to ethics is based on the ► hebrew bible (old and ► new testament). ► Judaism and ► christianity share the same ethical terms with regards to their thoughts about the end of this life period. During their present life, believers obey rules decreed by God in order that they may receive, at some future time, a just reward for their endeavors.

Christian ethics are grounded in three virtues: Grace, Compassion, and ► forgiveness. All ► moral guidelines found in the New Testament follow one of these God-given instructions e. g. "Love thy neighbor as thy self." ► Augustine provided just two aspects of ethics, which became enriched through his philosophical renderings. Later, church principals took on those aspects. It was not until the middle ages that there came a strict separation between Ethical and Moral ► theological issues.

The earlier works by Aristoteles won favor in the deliberations of ► Albert Magnus and ► Thomas Aquinas. In his writings on the "Summa contra Gentiles", Thomas Aquinas treats the whole of the issue of ethics in a purely philosophical context. Even today, his works provide a never-ending source of information to philosophers and theologists of the Catholic faith.

Jewish ethics take on a middle stance between Jewish and traditional western philosophy. Similar to other forms of theology and religious ethics, the Jewish stance confines itself mainly to questions and answers regarding matters of a moral nature. The ethics of the Islamic faith deals strictly with the Commandments as laid down in the book of ► koran. The collective responsibility for good and bad is of the utmost importance.

The monotheistic religions have different beliefs concerning birth, death, and self-determination. For Christians, life begins with siring; i. e. within the moment that egg and spermatozoon unite. Death is a point in time that is determined by God himself; it cannot be determined by man without man becoming guilty.

In the Jewish religion, life begins with the first breath. This explains the position of Jewish scientists concerning stem cell research and its legality. Life's end is determined by God as it is in Christianity and the human being has no right to foil God's plans.

Muslims believe that the moment of insemination is the beginning of life, as Christians do. In contrast to Christianity and Jewry, ending your life in order to defend your religion is desired and will be rewarded in the afterlife by a thousand virgins.

Ethics (Asian Religion)

The religious faiths of ► buddhism, ► hinduism and perhaps ► daoism also demand their followers to base their activities on ethical principles; for example, the overcoming of hate, greed, untruth, or uncontrolled violence. The rules were formed on a worldly premise based on cosmological reasoning. Transgression of the rules was only marginally sanctioned by the religious community. In the main, such transgression would have a negative consequence for the individual at a later time.

Ethics (Early Modern Times)

Since the beginning of this period, questions on ► evolution or ethical matters no longer remained the domain of religion. They also became the responsibility of both the ► natural science and ► humanity bodies. This development (► secularization) occurred alongside the ► industrial revolution during which economic, social, and cultural changes and changes in the justice system were being undertaken.

The slogan "God is dead", made by ► Friedrich Nietzsche, resulted in the decline in ethical standards. This became evident in everyday life, in that individuals chose free expression on the premise that in the absence of God, everything is permitted.

In the late nineteenth century and during the whole of the twentieth century, Christianity within Europe lost its influence in social and political issues. There was a general decline in people attending churches, synagogues, and other forms of religious establishments. This trend was notable in England, France, and Germany alike. This occurred despite the fact that churches were in the public domain and available to all. However, since the beginning of the previous century and on a parallel with Fundamentalism, there has become a much deeper and knowledgeable involvement in church life, particularly by 'laymen' and groups of young people in search of the 'sin of life', seen through religious ► tradition or by choice in the development of newly formed religious groups. In part, but beyond the boundaries of Europe, religion is showing an increase in popularity. For example, China's religion has an estimated one million supporters, having been subjected to strict stately controls for centuries (► atheism).

Conclusion

Ethics is the contemplation of philosophical morals. The way in which we live is more important than the moral judgment made when dealing with our daily affairs, either good or bad. All ► christians should conduct themselves in the interest of their ► neighbor and not from the standpoint of seeking personal gain for later reward. Their conduct should reflect the need for brotherly love, without prejudice towards others. Does the bible provide the foundation for ethics today? The bible provides a source of information of both a spiritual nature and on matters associated with our everyday affairs. It reminds us constantly of the way we should live. In the bible, one finds the answers to the meaning of ethics; how we should deal with our affairs. This is independent of any individual spiritual needs. In the Ten Commandments, we find, through Jesus Christ, the method in which we should behave and conduct ourselves. These Commandments were formed by dedicated people who also demonstrated a form of 'spiritual love' towards their fellow men; therefore, they should not be seen as just an alphabetical list. According to ► Luther, the benefit to others is through the sinful manner in which we behave in our dealings with them.

Ethnic

Synonyms

Indigenous; Native; National; Traditional

Definition

Term refers to a member of a particular ► ethnic group, especially one who maintains the language or customs of the group.

Ethnic Affiliation

Synonyms

Ethnic association

Definition

Ethnic affiliation refers to individuals' assertions about their own group membership, and the character of that group as defined by its members. It focuses on how people develop their own feelings of ► ethnic identity.

Ethnic Association

► Ethnic Affiliation

Ethnic Group

Synonyms

Nation

Definition

An ethnic group is a segment of a population within a society whose members identify with each other and share common descent, attitudes and behavior, as well as cultural and physical characteristics, and who perceive themselves as a distinct group. Ethnic group may be considered as a cultural community. Recognition by others as well as specific name for the group contribute to definition.

Ethnic Identity

Lis Ellison-Loschmann, Neil Pearce
Centre for Public Health Research, Massey University Wellington Campus, Wellington, New Zealand
l.ellison-loschmann@massey.ac.nz, n.e.pearce@massey.ac.nz

Synonyms

Ethnicity; Cultural identity

Definition

► Ethnicity is a complex construct that involves biology, but may also involve history, cultural orientation and practice, language, religion, and "lifestyle", all of which may affect health.

Basic Characteristics

Ethnicity

► Ethnicity is a complex construct that involves biology, but may also involve history, cultural orientation and practice, language, religion, and "lifestyle", all of which may affect health (Durie 1995). It differs from the concept of "► race" which has been commonly defined in terms of biological differences between groups which

are assumed to be genetic (Pearce et al. 2004). However, human races are not and never were 'pure' (Templeton 1999), and broad 'continental' groupings of 'races' explain little in terms of the overall genetic variation of humanity. This is not to say that there are no genetic differences between "races", but very few differences have been found which directly relate to health (Cooper 2003). Those that have been demonstrated are usually not absolute; rather, they involve differences in the percentage of people that have particular gene types. Furthermore, most known genetic variants that are health-related are random mutations in sub-populations, or result from regional selection, and are not related to continental race (Cooper 2003).

The change from 'race' as a research variable to that of 'ethnicity' (Durie 1995) has been explained as being as much about a closer alignment with social reality through recognizing a person's right to self-identify (Robson and Reid 2001) as it is with realizing the limited scientific credibility of the term 'race' (Jenkins 1977). The strength of 'ethnic identity' as a social construct is in its ability to accommodate change – it reflects a fluidity in how people see themselves or are 'seen' which may change over time. However, it is also recognized that identity is not entirely self-constructed and that:

"Individual decisions about who we are and our lifestyle choices, while appearing to be unbounded and therefore, solely a consequence of agency, are, in reality, made within social constraints" (Karlsen and Nazroo 2002, p 4).

Social structures, internal and external factors, national (► nation) and international movements (► national identity), have all influenced the consideration of ethnicity as identity which has also come to have important connotations in terms of the political process of ► ethnic affiliation (Karlsen and Nazroo 2002). This has definitely been a feature of indigenous calls for self-determination and recognition of indigenous rights.

Ethnicity and Health

The fact that racial categorization based on genetic criteria is inaccurate and misleading (Schwartz 2001), does not change the historical reality of the effects of colonization on indigenous/First Nations peoples, nor the realities of indigenous health today. It does however change our interpretation of the causes of high mortality and morbidity in indigenous peoples, which primarily involve issues of ethnicity, rather than of race or genetics.

For example, the European colonization of the Pacific and the Americas after 1492 saw indigenous populations decimated by imported communicable diseases (Foliaki and Pearce 2003). In the Pacific indigenous people experienced high mortality from imported infectious diseases mainly when their land was taken, thus disrupting their economic base, food supply and social networks. When land was not taken in large amounts by European settlers the death rate was relatively low.

Access to health care is also of major importance for ► ethnic differences in health. A recent editorial (Ibrahim et al. 2003) argued that issues of access to care involve a complex mix of cultural factors and individual preferences of patients, characteristics and practices of health care professionals (e. g. racism, stereotyping, bias, discrimination, and lack of cultural safety), and the system of delivery of health care (e. g. composition of the workforce, location of facilities, costs of access) and involvement of different ► ethnic groups in shaping health policy and allocation of resources. It argued that "racial and ethnic disparities in health and health care are rooted in historic socioeconomic inequalities that persist today." Thus "race" may be more important in terms of the perceptions of health care workers, rather than in terms of the underlying disease aetiology.

Conclusions

In the past race has often been evoked as an explanation for health inequalities and in particular, as a reason for the greater incidence of disease and illness among ethnic minorities (or majorities in the case of colonial societies such as South Africa, Zimbabwe and Mexico). At its most basic and popular form it has been expressed as a kind of social-Darwinism. It was seen as inevitable that "weaker" races would die out following contact with "fitter more advanced" peoples. Assumptions about the importance of biological race as a risk factor for disease have in some instances been strengthened by the recent emphasis on genetic determinants of disease, despite the evidence that racial categorization based on genetic criteria is inaccurate and misleading. The concept of ethnicity avoids some of the most troubling and dangerous pitfalls of the use of the outdated

concept of race; in particular, "race" is a biologically-based concept, whereas the concept of "ethnicity" is much broader. This concept has increasing meaning in the international context particularly in terms of recognizing peoples right to self-identify. Barriers to health care may make an important contribution to ethnic differences in health in which the structure and delivery of health care and specific government policies play a crucial role.

Ethnicity

Synonyms

Ethnic identity; Cultural identity; Cultural ethnicity

Definition

Concept of ethnicity refers to a shared cultural identity that has a range of distinctive behavioral and possibly linguistic features, passed on through socialization from one generation to another. Focus is upon the connection to a perceived shared past and cultural traits (such as language, religion, etc.). This term may be confused with "► race". Many regard ethnicity as it is naturally determined. However, there are no distinct boundaries, cultural or geographic, that mark the limits of ► ethnic groups.

Cross-References

- ► Ethnic Identity

Ethnocentric Strategy

- ► Ethnocentrism

Ethnocentrism

Synonyms

Ethnocentric strategy

Definition

Ethnocentrism is a bias based on the assumption that one's own culture is superior to other cultures. Other cultures are seen as inferior and as sources of (all) problems. Ethnocentrism is a rather common pattern. The 'ethnocentric strategy' – even in migrant health care – combines two features. On the one hand, diversity is limited by restricting access, and, on the other hand, diversity is reduced by forced cultural assimilation. The idea of cultural superiority thereby ignores the possibilities to reflect one's own cultural assumptions and to manage cultural difference in a constructive way – based on a culture relativistic position and perspective. 'Ethnocentrism' is derived from the Greek term 'ethnos', which means people or culture (compare ► parochialism).

It also means considering that our own patterns for behavior are "normal", while describing people from another culture as "different", "strange", "weird", "primitive" – as already mentioned – it reveals an

underlying attitude in us that our own culture is superior, more advanced and preferable; it is not just different, but better.

Ethnology

► Culture

Ethnomedicine

► Indigenous Health Care Services

Etiological Factor

► Risk Factors and High Risk Groups

Etiology

Definition

The word etiology is derived from a Greek word which means "pertaining to causes". It is used in different fields. In medicine it refers to causes of a disease.

Eugenics

Definition

Eugenics is included among primary prevention measures (► prevention, primary). It applies to making childbearing decisions on the basis of genetic information. It can be also part of a pre-marriage counseling program.

EU Legislation and the Delivery of Services to Patients

Definition

The European Community has not yet adopted any specific legislation on health care delivery issues, but has developed a system for the coordination of national social security systems – regulations EC No. 1408/71 and 574/72. These regulations allow for reimbursement of costs for certain types of cross-border care. Patients can also obtain prior authorization to obtain medical treatment in another Member State. Many issues remain unsolved considering free movement of patients: the reimbursement of health care costs, authorization for care abroad, assurance of quality of health care and guarantees for medical devices, and legal liability across borders. The assurance of quality of health services is of prime importance, including clinical standards and protocols, accreditation of professionals to similar standards, and accreditation of health institutions.

EUnetHTA Project

Definition

The project "European Network for Health Technology Assessment", supported by the European Commission, was started in January 2006. In the project, 27 European countries are represented by 36 HTA institutions. EUnetHTA is the successor of the ► ECHTA/ECAHI project with a new, further-developed objective. The three-year-project should lay the basis for the systematic exchange of information in the European setting and there shall be a stable European network in excess of the project period.

EUPHA

Definition

The European Public Health Association (EUPHA) is an umbrella organization for public health associations in Europe. EUPHA was founded in 1992. EUPHA is an international, multidisciplinary, scientific organization, bringing together around 12 000 public health experts for professional exchange and collaboration throughout Europe. The organization encourage to a multidisciplinary approach to public health.

EUR-ASSESS

Definition

In the early 1990s, discussion between members of a group of European HTA agency heads culminated in a decision to submit an application to the EU's

BIOMED Programme DGXII for funding for a project aimed at promoting coordination of HTA in Europe. Following an unsuccessful bid in 1992, a successful application was made in 1993, which led to the project on Coordination and Development of Health Care Technology Assessment in Europe (EUR-ASSESS). The aims of EUR-ASSESS, funded between 1994 and 1997, were to improve methods of priority setting, to develop and formulate HTA methodologies, to ensure that effective dissemination strategies were being used throughout European agencies, and to improve decision making by stimulating wider use of technology assessments.

European Community Health Indicators (ECHI)

Definition

The general strategy and approach on ► health indicators – the European Community Health Indicators (ECHI) projects – is conducted under the Health Monitoring Programme of the European Commission. The ECHI-1 and ECHI-2 projects have developed a comprehensive list of indicators, including approximately 400 items/indicators by March 2003. The aim of the projects was to serve as a basis for the European health information and knowledge system. The information on health that should be collected includes health-related behavior of the population (e. g. data on lifestyles and other health determinants); diseases (e. g. incidence and ways to monitor chronic, major, and rare diseases); and health systems (e. g. indicators on access to care, on quality of the care provided, on human resources, and on financial viability of health care systems).

Eustress

Definition

Eustress is a healthy or positive form of ► stress. The demand and the available resources of the affected person are equivalent.

Euthanasia

Synonyms

Intentional killing; Medicide

Definition

Euthanasia is defined as the intentional killing by act or omission of a dependent human being for his or her alleged benefit. One has to differentiate:
Voluntary euthanasia: When the person killed has requested to be killed. **Non-voluntary euthanasia:** When the person killed made no request and gave no consent.
Involuntary euthanasia: When the person killed made an expressed wish to the contrary. **Assisted suicide:** Someone provides individuals with the information, guidance, and means to take their own lives with the intention that they will be used for this purpose. When it is a doctor who helps another person to kill themselves it is called "physician assisted suicide." **Euthanasia by action:** Intentionally causing a person's death by performing an action such as giving a lethal injection.
Euthanasia by omission: Intentionally causing death by not providing necessary and ordinary (usual and customary) care or food and water.
Justifications given for euthanasia are that no one should have to suffer unbearable pain, that one has the right to commit suicide and that people should not be forced to stay alive if they do not wish to do so (http://www.euthanasia.com/definitions.html).

Evaluation

Synonyms

Assessment

Definition

Evaluation is the systematic determination of merit, worth, and significance of something or someone. It is a process that involves assessing the relevance, effectiveness, and impact of activities in the light of their objectives. As defined by the American Evaluation Association, evaluation involves assessing the strengths and weaknesses of programs, policies, personnel, products, and organizations to improve their effectiveness. Evaluation is the systematic collection and analysis of data needed to make decisions. Process evaluations describe and assess program materials and activities, while outcome evaluations study the immediate or direct effects of the program on participants.

Evaluation of Infectiological Data

► Outbreak Management and Surveillance of Infectious Diseases

Evaluation, Models

ANDREAS FUCHS
Forschungsverbund Public Health Sachsen-Sachsen Anhalt e. V., Medizinische Fakultät, Technische Universität, Dresden, Germany
andreas.fuchs@tu-dresden.de

Synonyms

Assessment; Appraisal; Estimation; Quantification; Audit; Controlling; Revision

Definition

Evaluation has several distinguishing characteristics relating to focus, methodology, and function. Evaluation assesses the effectiveness of an ongoing program in achieving its objectives, relies on the standards of project design to distinguish a program's effects from those of other forces, and aims at program improvement through a modification of current operations. Evaluation with regard to health promotion evaluation is an assessment of the extent to which health promotion actions achieve a valued outcome (WHO 1998).

Basic Characteristics

General

Evaluation is based on the methodology of the social and economic sciences. By definition, evaluation is the systematic examination of benefit and value of objects, e. g. programs (► summative evaluation), projects, products (► summative evaluation), measures, organizations or political issues.

► Health promotion outcomes, conclusions or recommendations are also validated based on qualitative and quantitative empirical data. The term evaluation has its origin in Latin ("evaluare") and means "be strong." Evaluation elements play a significant role in ► quality assurance, ► quality management and objective assessment in the context of health promotion interventions. Evaluation aims at improving strategies as well as providing measurements to give assistance in reaching decision about the prolongation and course of projects. Furthermore, evaluation is directed towards measuring project outcomes.

In relation to health promotion, evaluation contributes to both the course of projects (implementation of empowerment or participation) and providing results at the end of projects. It is a basic element of ► quality assurance and contributes to the success of a health promotion intervention which means that evaluation is an essential part of each intervention. Surveillance of goal attainment, formulation of reachable and observable goals, and identification of target groups, documentation, legitimization and improvement in the course of projects are fundamental elements. Evaluation increases the understanding of the causes of success or failure of a project and validates intervention ideas. Planning of an intervention and evaluation of a project are closely and mutually connected.

In relation to health promotion intervention, the following main evaluation criteria are needed for measuring the outcome as well as the quality of a project:

- Criteria of acceptance – Did the intervention reach the target group and how was the behavior changed?
- Criteria of learning process – How do the participants understand the intervention and how do they reflect it?
- Criteria of transfer – How was the behavior influenced by the intervention?
- Criteria of outcome – How can the changes in health behavior of the participants be measured?

Evaluations of health promotion activities may be participatory, involving all those with a vested interest in the initiative; interdisciplinary, involving a variety of disciplinary perspectives; integrated, incorporated into all stages of the development and implementation of the health promotion initiative; and enhancing, helping build the capacity of individuals, communities, organizations and governments to address important health problems (WHO 1998).

Types of Evaluation Models

Evaluation is methodologically diverse using both qualitative and quantitative methods, including case studies, survey research, statistical analysis, and model building amongst others. It is estimated that more than 100

approaches of evaluation measures exist. In the following an overview of the most important evaluation types is provided.

The classification of evaluation types depends on their use in different stages of a project. Evaluation can be relevant for assessing context, (prerequisites), structure and process and outcome of a project (► formative evaluation, ► summative evaluation, ► transfer evaluation, ► impact evaluation). Evaluation measures can also be classified according to who evaluates the project, i. e. the initiators or external institutions. Great benefit can be derived from evaluating both the process and the results. Which process and outcome related evaluation measures are used depends on the type of methodology, organization models and the role of the ► evaluators in the research context. A range of well-known methods are used for obtaining data throughout the course of projects and assessing project outcomes by evaluation measures: for example, structured questioning, questionnaires, observations as well as analysis of project material are carried out, aided by systematic procedural methods and documentation.

In an evaluation, data are systematically organized and documented in order to reconstruct and review the project procedure and results. Internal and external data sources are available for this kind of evaluation measure. Internal evaluation involves implementation as well as observation and documentation of project activity. Close involvement with the project being examined can be an advantage in internal evaluation; the factors which are influencing the project's course are well known. However, closeness might also be detrimental as objective evaluation may be impaired. This disadvantage is eliminated in external evaluation and, hence, a higher legitimacy may be achieved for the evaluation outcomes if this method is adopted.

Further evaluation models are subdivided with regard to their experimental character. Experimental evaluation models evaluate the effect of an intervention by comparing the results of two groups in their achievement of a certain number of defined target variables; an experimental intervention group's results are compared with a non intervention group's results. The results measure the absolute effects between these two groups. Analysis includes comparison of data by the means of statistical testing procedures and comparison with regard to time. Aspects of confounder and bias have to be considered and improbabilities excluded using standardized measuring instruments. This action is also called goal attainment and describes rational and purposeful implementation of standardized instrumentation. In conclusion, the following basic questions have to be considered in the preparation of planning a health promotion project:

- Program attainment – Does the activity reach the target group?
- Participant satisfaction – Are participants satisfied with the activity?
- Program activities – Has the activity been successfully implemented?
- Performance of materials and other components – Are the materials and components of the activity of good quality?
- Ongoing quality improvement – What can be changed in order to improve the quality of the activity?

Evaluator

Definition

Specification of ► quality criteria, determination of quality standards, investigations empirical data and the decision on the quality of an intervention as well as acceptance of measures belong to the scope of evaluators' work.

Event

Synonyms

Event; Outcome; Dependent variable; Response

Definition

An event or outcome (typically the patient state at a given point in time) is chosen to be assessed to ascertain whether an intervention is effective. The endpoints should be sensitive to treatment effects and be clinically relevant. *The primary outcome variable* or *endpoint* is a measure capable of providing the best evidence directly related to the primary objective of the trial. It is important that the primary outcome variable be measured without bias in a reliable manner using validated instruments with adequate sensitivity to detect a real change in each patient's health status. A *surrogate endpoint* can be used in situations in which short-term measures of response to treatment may provide reliable indicators of long-term patient outcome. With responder or threshold analyses, we can re-express continuous or ordinal variables into categorical or dichotomous response variables. *Secondary outcomes* are either supportive measures to help interpret the primary results, or response variables related to secondary objectives or hypotheses. In recent years, clinical evaluation has included more complex experimental designs and used multiple response variables or *multiple endpoints*.

Evidence

Definition

In scientific research, evidence is accumulated through observations of phenomena that occur in the natural world, or which are created as experiments in a laboratory. *Scientific evidence* is evidence that serves to either support or counter a scientific theorem or hypothesis.

Evidence-Based

Definition

Diagnostic or therapeutic procedures are based on estimates of the risks of benefit and harm derived from population based high-quality research.

Evidence-Based Clinical Practice/Healthcare/Practice

► Evidence Based Medicine

Evidence Based Medicine

Synonyms

Evidence-based clinical practice/healthcare/practice

Definition

There are a number of definitions of Evidence-Based Medicine/Healthcare/Practice. According to the Centre for Evidence-Based Medicine (CEBM.net), the following definitions are among the most commonly cited:
Evidence-Based Medicine (EBM) according to the standard definition is "the conscientious, explicit, and judicious use of current best ► evidence in making decisions about the care of individual patients" (Sackett et al. 1996).
Evidence-Based Clinical Practice (EBCP) is "an approach to decision making in which the clinician uses the best evidence available, in consultation with

the patient, to decide upon the option which suits that patient best" (Muir 1997).

Evidence-Based Healthcare (EBHC) is "the conscientious, explicit, and judicious use of the current best evidence to make a decision about the care of patients" (Marwick 1997).

Evidence-Based Practice (EBP) is "an approach to health care wherein health professionals use the best evidence possible, i. e. the most appropriate information available, to make clinical decisions for individual patients" (McKibbon 1998).

Basic Characteristics

Responding to the limitations of traditional expert recommendations that act as a guide to clinical practice, evidence-based medicine has presented a ► paradigm shift in the way clinicians learn and practice medicine.

The practice of EBM calls for the integration of individual clinical expertise with the best available external evidence from systematic research. Individual clinical expertise is the proficiency and judgment that individual clinicians acquire through clinical experience and clinical practice. The best available external evidence is derived from clinically relevant research. Good doctors use both individual clinical expertise and the best available external evidence (Sackett et al 1996).

The concept of ► number needed to treat (NNT) has increasingly become part of EBM. NNT is a numerical indicator of the effectiveness of a therapy.

The purposes of EBM are as follows:

- Keeping skills up to date (EBM provides clinicians with the tools they need to find important new medical research quickly and easily.);
- Saving time (Computer indexes to the medical literature such as MEDLINE allow clinicians to do computer searches for the information they need quickly and easy.);
- Saving lives (A detailed and exact knowledge of the outcomes of different treatments, derived from research, can often save lives.);
- Supplementing clinical judgment (The computer only gives one of many elements that will enter into clinical decision – information about how other patients in similar situations have responded. It is up to the clinician to judge how applicable that information is to their patient and to decide on a course of action.).

History of EBM

Because of the scientific basis of medical research, evidence-based medical practice has been around for centuries. In the 1970s an astute British epidemiologist, Archie Cochrane, who is best known for his influential book 'Effectiveness and Efficiency: Random Reflection on Health Services', stressed the importance of using evidence from ► randomized clinical trials (RCTs), because these were likely to provide much more reliable information than other sources of evidence. His challenge led to the establishment of an international collaboration to develop the Oxford Database of Perinatal Trials in the 1980s. The explicit application of evidence, as EBM, to problem solving in clinical medicine began simultaneously in the late 1980s at McMaster University in Canada and at Oxford University in the United Kingdom. The term "evidence-based medicine" first appeared in the medical literature in 1992 in a paper published in JAMA by the Evidence-Based Medicine Working Group (Gyatt et al. 1992). In the same year, the Cochrane Centre in Oxford was opened, and in response to Archie Cochrane's call for systematic and up to date reviews of all healthcare related RCTs, the ► Cochrane Collaboration was developed in 1993 (Mayer 2004).

Steps in Practicing EBM

There are five steps in the process of EBM that practicing clinicians should take:

1. Convert the information need into answerable clinical questions – **PICO**, which stands for:
   Patient (population or clinical problem of interest);
   Intervention (exposure, test, or treatment);
   Comparison (what you think the intervention is better or worse than); and
   Outcome of interest (ideally, the one of interest to the patient).
2. Search the medical literature and find the best evidence with which to answer these questions.
3 Perform a ► critical appraisal of the evidence found for its validity (how close the evidence is to the truth) and its usefulness (how the results will help in caring for patient), by using one of eight published EBM guidelines (therapy, diagnostic testing, overview, prognosis, causation/harm, clinical measurement, quality of care, and economic evaluation) (► EBM Literature Guides).

4. Integrate the results of this appraisal with clinical expertise and apply the results in clinical practice, with an understanding of the patient context and values.
5. Evaluate (► evaluation) the performance after applying the evidence to practice.

In summary, evidence-based practice requires clinical expertise, common sense, understanding of the circumstances and values of the patient, and judicious application of the best available evidence.

Hierarchies of Evidence

The key idea of EBM is a "hierarchy of evidence". There are several published hierarchies for classification of research studies.

There are systems that grade studies by their overall quality, such as the following system developed by ► U.S. Preventive Services Task Force, which is the hierarchy that is the basis of the current grading scheme for clinical studies (Haris et al. 2001).

- Category I: Evidence from at least one properly designed randomized controlled trial.
- Category II-1: Evidence from well-designed controlled trials without randomization.
- Category II-2: Evidence from well-designed cohort or case-control analytic studies, preferably from more than one center or research group.
- Category II-3: Evidence from multiple times series with or without intervention or dramatic results in uncontrolled experiments such as the results of the introduction of penicillin treatment in the 1940s.
- Category III: Opinions of respected authorities, based on clinical experience, descriptive studies and case reports, or reports of expert committees.

Another classification scheme, developed at the ► Centre for Evidence-Based Medicine at Oxford University, uses levels A through D to designate the strength of the evidence, where Grade A is the strongest evidence and grade D the weakest. These levels of evidence are cataloged for articles regarding therapy or prevention, etiology or harm, prognosis, diagnosis, decisions, and economic analysis (Mayer 2004).

Criticism of EBM

Commonly cited limitations of EBM are as follows:

- Shortage of coherent, consistent scientific evidence;
- Difficulties in applying evidence to the care of individual patients;
- Barriers to the practice of high-quality medicine;
- The need to develop new skills;
- Limited time and resources; and
- Paucity of evidence that EBM "works".

The first three limitations outlined here are not unique to EBM but are universally encountered in the practice of medicine.

EBM, like other models of care, has limitations, and further innovation and study are required to resolve the issues raised by its critics. In particular, efforts need to be directed toward improving clinicians' access to evidence at the point of care; developing better methods of describing evidence to patients in order to facilitate shared decision-making; and conducting studies to test whether and how EBM affects the processes of care and patient outcomes (Straus and McAlister 2000).

Definition

Evidence-based medicine (EBM) applies scientific methods to medical practice. According to the father of EBM, ► Sackett, David: "Evidence-based medicine is the conscientious, explicit and judicious use of current best evidence in making decisions about the care of individual patients." In 2000, Sackett corrected his own definition to state that EBM is "the integration of best research evidence with clinical expertise and patient values", because he saw that there is some fear that evidence-based medicine will be hijacked and misused by purchasers and managers to cut the costs of health care.

Basic Characteristics

Overview

EBM uses techniques from science and ► statistics, such as various types of clinical and ► non-clinical trials, ► meta-analysis of scientific literature, and ► risk-benefit analysis, etc. It aims for the ideal that healthcare professionals should make "conscientious, explicit, and judicious use of current best evidence" in their everyday practice. Generally, there are two main areas of EBM. The first aim is to treat individual patients with acute or chronic pathologies by treatments supported by the most scientifically valid medical literature. Thus, medical practitioners would select treatment options for specific cases based on the best research available for each patient they treat. The second area is the systematic analysis of medical literature to evaluate the best studies on given topics. This process can be very human-centered or highly technical using computer programs and information techniques such as ► data mining.

History

Although testing medical interventions for ► efficacy and ► effectiveness has been carried out for many decades, it was only at the end of the 20th century that this effort evolved to impact on the fields of health care and policy. The work of Professor ► Cochrane, a Scottish epidemiologist, caused increasing acceptance of the concepts behind evidence-based practice. The explicit methodologies used to determine "best evidence" were mainly established by David Sackett. The term "evidence-based medicine" first appeared in the medical literature in 1992, in a paper by Guyatt et al.

Qualification of Evidence

In evidence-based medicine, different types of clinical evidence are categorized, compared to earlier approaches to systematize evidence, and ranked (see list below). This ranking refers to the grade of absence of various ► biases that beset medical research. The strongest evidence for therapeutic interventions is provided by randomized, double-blind, ► placebo-controlled trials involving a well defined, homogeneous patient population and medical condition. In contrast, cohort studies, case-control studies, case reports, and even expert opinions have lower scientific value. Practicing evidence-based medicine implies not only clinical expertise, but expertise in retrieving, interpreting, and applying the results of scientific studies, and in communicating the risks and benefits of different courses of action to patients or, in the context of health technology assessment, to policy makers.
The concept of ► number needed to treat (NNT) has increasingly become part of evidence-based medicine (McQuay and Moore 1997). The NNT is a numerical indicator of the effectiveness of a defined therapy. For example, an NNT of 10 means that if 10 patients were treated, only one would respond. Therapies with an NNT of 1 are the most effective as this means that every patient treated responds. However, an NNT of 20 to 40, or even more than 100, can still be considered as effective. The limit at which a therapy is considered as effective is the subject of political discussion

in the healthcare system. The opposite of the NNT is the ► number treated needlessly (NTN).

Many systems to stratify evidence by quality have been developed, all of them with only minor differences in the naming of the classes, i. e. I to IV, or A to D. In Europe, the system of rating available evidence that was published in 1996 by Hadorn et al. 1996 is widely used:

Ia at least one ► meta-analysis of properly designed randomized controlled trials
Ib at least one properly designed ► randomized controlled (clinical) trial
IIa at least one properly designed controlled trial without ► randomization
IIb quasi-experimental ► cohort-studies
III non-experimental ► case control studies
IV ► case series, expert opinions, ► consensus conferences, ► descriptive studies

Limitations of Available Evidence

It is recognized that, due to various reasons, not all evidence is made accessible by authors, and this can limit the effectiveness of any approach. Therefore, efforts to reduce ► publication bias and retrieval bias are required.

Failure to publish negative trials is the most obvious and important gap in the literature. Efforts to establish registers of clinical trials (► clinical trials, register) at the outset, with the obligation to pursue their results, are underway all over the world. In future, changes in publication methods, particularly related to the Internet, may reduce the difficulty of obtaining publication for a paper on a negative result of a trial. Treatment ► effectiveness reported from clinical studies is normally higher than that achieved in later routine clinical practice due to the closer patient monitoring during trials that leads to much higher compliance rates. More research is needed to identify the extent of the proven clinical outcome in everyday practice.

Criticism of Evidence-Based Medicine

Critics of EBM say lack of evidence and lack of benefit are not the same, and that EBM applies to populations, not necessarily to individuals. The knowledge gained from clinical research does not necessarily or directly answer the primary clinical question of what is best for the patient. Other critics suggest that proponents of evidence-based medicine discount the value of clinical experience.

Although evidence-based medicine is quickly becoming the standard for clinical practice and ► treatment guidelines, there are a lot of reasons why many current medical practices do not have a strong literature base supporting them. First, the types of trials considered to be "gold standard" (i. e. randomized double-blind placebo-controlled trials) are expensive, therefore funding sources play a role in what gets investigated. For example, public authorities tend to fund preventive medicine studies to improve public health as a whole, while pharmaceutical companies fund studies intended to demonstrate the ► efficacy and safety of their own, patent pended drugs. As a dramatic result, there are nearly no studies on old (generic) drugs conducted, with the consequence of limited evidence and, in the worst cases, exclusion of these substances from medical care. Second, in an increasing number of cases, conducting randomized controlled trials would be unethical, although ► observational studies are designed to address these problems to some degree. Third, certain patient groups have been under-researched, and as a result the literature is sparse in areas that do not allow for generalization. Fourth, the studies that are published in medical journals may not be representative of all the studies that are completed on a given topic (published and unpublished), or may be misleading due to conflicts of interest (i. e. ► publication bias). Thus, the extent of evidence available on particular therapies may not be adequately represented in the literature. Since a 2004 statement by the International Committee of Medical Journal Editors that they will refuse to publish clinical trial results if the given trial was not recorded publicly at its outset, this may become less of a problem. Additionally, the ► CONSORT-Statement (Consolidated Standards of Reporting Trials), published in 1996, is an approach that could improve the publication of evidence, rather than the quality of evidence itself.

Large randomized controlled trials are useful for examining discrete interventions for carefully defined medical conditions. The more complex the patient population, the conditions and the intervention, the more difficult it is to separate the treatment effect from random variation (► significance). A number of studies therefore obtain non-significant results, either because there is insufficient ► power to show a difference, or because the groups are not sufficiently balanced.

In some healthcare systems (such as Germany), evidence-based guidelines have been used as a basis for denying insurance coverage for some treatments that are believed by the physicians involved to be effective, but are not yet supported by published results from randomized controlled trials. A prominent example of the limitations of the EBM approach is that coverage for substitution of vitamin E in cystic fibrosis has been denied because nobody is funding a randomized controlled trial of this cheap, generic product.

Evidence Based Recommendations

E

ULF MAYWALD
Abteilung Ärzte/Apotheken, AOK Sachsen, Germany
ulf@maywald.com

Definition

The quality of evidence for a health intervention is usually categorized according to an ▶ evidence hierarchy. The strength of recommendation can be assessed using different scales; however, a consensus on the most appropriate scale does not currently exist.

Basic Characteristics

The identification of strong evidence for the ▶ effectiveness of an intervention does not necessarily lead to the formulation of strong recommendations for or against its implementation in the health care system.

Clinical Recommendations

Evidence of the effectiveness of health technology is only one part of the picture when considering recommendation. Clinical recommendations consider (for the most part) only the benefits and drawbacks of one or more specific interventions. Focusing exclusively on clinical recommendations, the evidence must be searched systematically to answer each part of the research question. Wherever possible the ▶ sensitivity, ▶ specificity, ▶ likelihood ratio (LR), and incremental ▶ cost-effectiveness ratio should be calculated.▶ Relative risk and ▶ odds ratios should be estimated for risk factors and co-morbidities.

Integrated Recommendations

Focusing only on the clinical aspects of a research question is often not appropriate. Other parts of the picture, such as the impact on organization of the system, resources available, responsiveness, and equity, also play a determinant role in the decision for or against

the introduction or implementation of a health intervention or technology. Even with strong evidence of health benefits from an intervention, recommendations from a health technology assessment (HTA) may be against its implementation. With consideration of other factors like cost and cost-effectiveness issues, the burden of disease, needs and priorities, barriers to implementation, features of the health care system, and cultural issues etc., implementation can appear to be improper in a given context.

Normally, health technology assessment explicitly considers such factors. However, for the assessment of these factors the highest place in the hierarchy of evidence is not taken by randomized controlled trials (RCTs), since such study design is not appropriate to answer relevant questions besides clinical efficacy. In addition, the epidemiological approach is not always the appropriate method in these cases. Therefore, evidence obtained with empirical, social, or political science methods needs to be considered in a HTA.

A consensus by the WHO Regional Office for Europe agreed a new definition of evidence in the context of HTAs: "findings from research and other knowledge that may serve as a useful basis for decision-making in public health and health care" (WHO Regional Office for Europe 2004). This emphasizes the prospective relevance and validity of different study designs and research forms. It also goes further, acknowledging the value of evidence obtained with methods that – within the scope of some scientific discourses – are not considered scientific.

Evidence Hierarchy

Definition

Not all evidence is judged to be of equal value. There are hierarchies of research design that are evaluated to have different strengths and different levels of value in the decision-making process.

The hierarchy of levels of evidence is briefly:

1.	A	Systematic reviews/ meta-analyses
	B	RCTs
	C	Experimental designs
2.	A	Cohort control studies
	B	Case-control studies
3.	A	Consensus conferences
	B	Expert opinions
	C	Observational studies
	D	Other types of study e. g. interview-based or local audit
	E	Quasi-experimental, qualitative designs
4.		Personal communications

Evolution

Definition

The beginning of the beginning and its continued state of existence.

Examination Survey

Definition

An examination survey is designed to collect data that are not well suited to be included in health interviews but are measured more reliably using medical methods. It may comprise the measurement of height and weight, drawing of blood and urine samples, tests of motor skills or medical interviews. The examinations are usually done by medical (or at least medically trained) personnel in the homes of the survey participants or in mobile field work units. Because of their rigorous standards, examination surveys provide the most objective data on the health status of a sampled population.

Exanthem Subitum (ES)

► Erythema subitum

Excessive Substance Use

► Substance Abuse

Exercise

Definition

Planned, structured and repetitive bodily movements, performed to improve or maintain one or more components of physical fitness. Exercise may be classified in one of two categories, anaerobic and aerobic, depending on where energy is derived from depending on intensity and duration.

Cross-References

► Physical Activity

Expansion of Morbidity

Definition

A hypothesis that assumes an increase in longevity will increase the number of years lived in bad health.

Experimental Studies

Sandra Šipetić Grujičić
Institute of Epidemiology, School of Medicine, University of Belgrade, Belgrade, Serbia
sandragru@ptt.yu

Synonyms

Intervention studies

Definition

Experimental study is "study in which conditions are under the direct control of the investigator" (Last 2001). It is employed to test the ► efficacy of a preventive or therapeutic measure.
Experimental studies can provide the strongest evidence about the existence of a cause-effect relationship.

Basic Characteristics

Types of Experimental Studies

There are two different types of experimental studies: *therapeutic* and *prevention studies* (Webb et al. 2005).
In *therapeutic studies* (*clinical trials*), different medicines or medical procedures for a given disease are compared in a clinical setting.
Trials that are conducted on healthy or apparently healthy individuals with the aim of preventing future morbidity or mortality are called *preventive studies*. Preventive studies include *community study*, in which the intervention is applied to groups, and *field study*, in which the intervention is applied to healthy individuals at usual or high risk of developing a disease.
Clinical and field studies ideally take the form of a *randomized controlled trial (RCT)*, in which the intervention is compared with a control and the allocation to experimental or control group is randomized. The RCT represents the "► gold standard" for epidemiologic research.

The Protocol

The aims and methods of the study should be described in detail in a protocol document. The protocol should also include a clear statement about the following: therapeutic or preventive measures to be used, the characteristics of the subjects to be recorded at the start of the study, assessment of endpoints (► outcome), entry criteria and treatment allocation, whether the total group is to be stratified, frequency of follow-up, the circumstances under which patients will be withdrawn from the study, times at which data from the study will be analyzed, strategy for the statistical analysis, and ethical aspects (Bhopal 2002).

Selection of Subjects

The first step in any study is to define the reference population suitable for the investigation, i. e. people with

disease for clinical trials or without disease for preventive trials.
In the next step, the experimental population in which the study is to be conducted is selected. Inclusion/exclusion criteria are used to identify appropriate subjects but not to reject people personally. It is essential to choose an experimental population that is sufficiently large, with a sufficient number of outcomes of interest within a reasonable period of time, and with a high rate of follow-up.
Then, subjects must be informed about the purposes of the trial, the study procedures, and the possible risks and benefits.
The last step is to divide the study population into two or more groups by simple or complex (block or stratified) randomization (Gordis 2004).

Randomization

Once subjects have been recruited and have signed an ► informed consent form, they are divided into experimental and control groups by random allocation, usually through the use of a table of random numbers or a computer-generated randomization list.
The main purpose of randomization is to create study groups that are comparable in every way except for the intervention. Randomization can only guarantee balance for large studies (Dawson, Trapp 2001).

Simple Randomization

Simple randomization is a method of random assignment in which every subject has an equal probability of being selected for the study groups (Gordis 2004).

Blocked Randomization

When the ► sample size is relatively small, block randomization is used to achieve balance between groups. In block randomization, subjects are first subdivided into homogeneous blocks that are the same size as the number of treatments, and then subjects from each block are randomly assigned to different treatment groups (Friedman, Schron 2002).

Stratified Randomization

If study groups are different in characteristics known to be related to outcome, then stratified randomization is used.

Stratified randomization means that participants are first divided into groups (strata) of similar characteristics (e. g. sex, age, etc.) and then randomized to treatment and control groups within each stratum. The groups are then bound to be comparable, at least for the factors that have been dealt with in this way (Gordis 2004).

Nonrandomized Experimental Studies

Nonrandomized experimental studies are studies that do not use randomized assignment. These studies are open to many sources of bias.

Parallel Designs

In parallel design, subjects are allocated to study or control groups and stay in the allocated group until the end of the study

Factorial Designs

In a factorial design, two or more interventions are carried out at the same time with minimal increase in cost (Gordis 2004).

Crossover Designs

The main advantage of crossover design is smaller sample size. In planned crossover, half of the subjects would receive the intervention followed by the control, and the other half the reverse. In such crossover, each subject serves as his or her own control. An unplanned crossover refers to a switch of subjects to different treatment conditions for various reasons.

Uncontrolled Experimental Studies

These are studies without a control group.

Experimental Studies with Historical (External) Control

In these studies, the experimental group is compared with patients who were exposed to the preexisting standard form of therapy (historical group) (Dawson, Trapp 2001).

Experimental Studies with Self-Control

In these studies, the same group of subjects is used for both the experimental and control group (Dawson, Trapp 2001).

Sample Size

An important step in designing a study is determining a sufficient ► sample size. Sometimes it would take too long to enroll the desired study group if the investigation were limited to one institution or one area. In this situation, the best solution is to set up a *multi-centric trial* (► multi-centric study).
Factors which are considered in the calculation of sample size for dichotomous outcome studies are event rate in the control group, expected benefit from the intervention, level of adherence to the groups, power to detect a real difference (► beta error), and α error (► alpha error) (Dawson, Trapp 2001).

Blinding (Asking)

Blinded studies prevent the introduction of ► placebo effect and ► observer bias in the assessment of outcomes, but ► open trials do not.
In a *single blind study*, only the participant is unaware of the administered treatment.
A *double blind study* is a trial in which the participant and the investigator do not know which individuals are in the experimental and control groups.
A *triple blind study* is a trial in which not only the participant and the investigator but also those responsible for data analysis do not know the group to which the participant has been assigned. In this type of study, the code is broken only after the entire study, including the analysis of data, is complete (Gordis 2004).

Placebo

When ► blinding is possible, it is usually accomplished by means of placebo. A placebo is an inactive treatment that is intended to be similar to the active treatment – in physical appearance, color, taste, odor, etc.
In therapeutic studies, the use of a placebo has caused ethical concerns. Comparison of a new treatment with an old treatment is often more appropriate. One way to avoid the use of placebo is to compare different doses or durations of a specific intervention (Fraceschi, Plummer 2005).

Adherence (Compliance) Bias

This bias (► bias, confounding and interaction) occurs when subjects do not comply with the assigned treatment. On one hand, subjects may stop taking the treatment assigned without admitting this to investigator. On the other hand, they may take the treatment assigned to the other group.
A variety of techniques (i. e. frequent contact, reminders, single-dose of medication, providing continuity of care, monitoring, etc.) to maintain good adherence are used to increase the statistical power of a study to detect any true effect of the study intervention (Friedman, Schron 2002).

Withdraw

Reasons why participants must be withdrawn from analysis are concomitant therapy usage, poor adherence to the protocol, poor quality or missing data, and loss to follow-up.

Outcome of Trials

When the ► outcome of a trial is dichotomous, such as being alive or dead, it is unlikely that patients will be misclassified. There is a need for explicitly stated criteria for all outcomes to be measured in a study (Gordis 2004).

Statistical Analysis

Various statistical analyses of follow-up data from intervention studies can be used. The risks of death or developing the disease or complication in each group can be calculated. The ► efficacy of an agent being tested can be expressed in terms of the rates of developing disease in the study and placebo groups (Fraceschi, Plummer 2005).

Ethical Issues

Many ethical issues arrive in the context of trials. It is well known that the benefits of participation in an experimental study must clearly outweigh any possible risks to the subject.
Another ethical problem is that experimental design requires that medication be withheld from people who might benefit from it. Because of this issue, experimental and control subjects are closely monitored to determine the outcome of an intervention. If the intervention produces improvement in the patients' condition, then it is given to members of the control groups as well (Friedman, Schron 2002).

Expert Dominance

Synonyms

Elitism; Technocracy

Definition

Expert dominance refers to a tendency for the expertise of the specialist to influence unduly the outcome of decision-making and policy development. There is a correct place for the salient influence of experts. However, as the expert becomes less likely to bear the full brunt of the consequences, it increasingly becomes a matter of allowing for other perspectives in the various processes. This is especially true of complex situations that preclude complete competence on the part of experts in various functional specialties. Additionally, due to the position that they occupy in a social structure, it can be the case that the expert gains undue political or social power. In such instances, they may exert influence beyond the circumscribed limits of their knowledge and skill. This can be observed easily when famous experts in one field are asked for their opinions in another field without reference to their actual abilities in that second field.

Explicit Knowledge

Definition

Explicit knowledge is the abstract, symbolic type of knowledge present in documentations of knowledge such as textbooks or guidelines, procedural guides, reports, strategies etc. It is applicable to both specific and generic problems and relies on explicit reasoning mechanisms. This type of knowledge can be communicated on paper or electronically, without person-to-person contact.

Exposure

Definition

Exposure could be defined as a contact with a source of a disease agent in such a manner that harmful effects of the agent may occur. It is the process by which an agent comes into contact with person in such a way that the person may develop the particular disease. Exposures may of course be beneficial rather than harmful, e. g., exposure to immunizing agents.

Exposure Assessment

Synonyms

Exposure quantification

Definition

Exposure assessment identifies specific agent(s), determines the route of exposure, and quantifies the amount and duration of exposure. Once a suspect substance is identified, scientists conduct studies to estimate the amount of the substance a particular population is exposed to. Exposure assessment is a third step in a ► risk assessment procedure. In the exposure assessment, uncertainties arise because it is difficult to measure the amount of a ► hazard over time, and how much is taken in by individuals.

Exposure assessment in occupational health means the estimation of workers' exposures on an individual or group level. Accurate exposure assessment is a great challenge in almost every occupational health setting. Over the years methods for occupational exposure assessment have been developed; modeling of occupational hygiene data, experts' exposure ratings, specific questionnaires. Biological markers may also provide valuable information for occupational exposure assessment. This process has become even more crucial, although many of the major occupational risk factors are now identified, proper knowledge is still needed on the effects of low level exposures present in complex workplace environments.

Exposure Levels

Definition

Evaluating exposure to toxic substances requires the calculation of exposure levels for comparison with standards in set by law or other guidelines. The data needed for these calculations comes from monitoring the presence of hazardous physical, chemical and biological agents in the workplace (► Workplace Hazards).

When an exposure level to a specific agent for a worker or group of workers has been determined, it can in some cases be compared with a standard or guideline to determine whether the exposure is within acceptable limits. There are many agents present in workplaces whose health effects are not fully understood. There are also many for which no legislated or recommended standard exists.

Exposure Quantification

► Exposure Assessment

Exposure to Stimuli

Definition

The nature and degree to which a system is exposed to stimuli.

Externality of Consumption

Definition

Externalities of consumption exist if one individual's consumption of a good or service has positive or negative consequences for the ► utility of another person. A positive externality increases the utility of the other individual – although he or she does not pay for it (e. g. immunization). A negative externality decreases the utility of the other individual (e. g. smoking).

External Motivation

► Extrinsic Motivation

Extra-Welfarism

Definition

Extra-welfarism acknowledges that a wide range of characteristics are relevant for individual welfare – not just the consumption of health care services and health in itself. It also refers to relative changes in consumption or work patterns as direct sources of ► utility or

disutility. In contrast to ► welfarism, extra-welfarism acknowledges the processes and transitions of life.

Extremely Low Birth Weight Infants

Definition

Extremely low birth weight infants are born weighing between 500 to 999 gm, measured within an hour of birth.

Extrinsic Motivation

Synonyms

External motivation

Definition

The desire or push to perform certain behavior based on the potential external rewards that may be received as a result.

Factor Analysis

Definition

Factor analysis (FA) is an advanced statistical method for examining the relationships between a set of variables without identifying a specific response variable. FA is based on a model that assumes that correlations between pairs of measured variables can be explained by the connections of the measured variables to a small number of non-measurable (latent) but meaningful variables, which are termed factors. The aims of FA are to (a) reduce the number of variables and (b) detect structure in the relationships between variables, i. e. to classify variables. For example, FA is often used in survey research to see if a long series of questions can be grouped into shorter sets of questions, each of which describes an aspect or factor of the phenomena being studied. A distinction can be made between two different types of FA – explanatory and confirmatory. Explanatory FA identifies relationships among variables that are often far from obvious in the original data. The purpose is to summarize and concisely describe the data by grouping correlated variables together. Confirmatory FA is a version of FA in which specific hypotheses about structure and relations between latent variables that underlie the data are tested. It is used to confirm the existence of these hypothetical constructs in a fresh set of data and has strong similarities to structural equation modeling.

Factors that Influence Health

► Health Determinants

Faculty of Medicine

► Medical School

Failure (Patient)

Definition

A patient is scored as a failure if he or she suffered the outcome of interest. If the patient failed, the length of follow-up is the time between diagnosis and failure. The sort of untoward ► events that could be studied include myocardial infarctions, leukemia relapses, strokes, metastatic developments, and death from one of a certain set of specified causes (ignoring deaths from other causes). In all of these cases, the design principles and statistical methods are virtually the same: the times at which each patient who suffers the event of interest does so are observed and analyzed.

Fair Information Practice

Definition

"Fair information practice" is a set of principles that define the responsibilities of an organization that holds confidential information about individuals. It was incorporated into the Federal Privacy Act of 1974 in the US. ► Consumers are guaranteed the right to have access to information about them and to correct this information to the extent allowed by law. According to this practice, confidential information collected by public health organizations should be relevant to public health, must have written consent from the patient who provided them, and may be used strictly according to the

stated purpose. Furthermore, the information in the system must not be lost, altered or destroyed, and access to information must be made on a "need-to-know" basis – i. e. allowed to a small number of health professionals who have adequate need for the information.

Family Composition

MARGARET M. WEDEN
RAND Corp., Santa Monica, CA, USA
mweden@rand.org

Synonyms

Family structure

Definition

Family composition discusses the role of ► family structure (e. g. single parent, married couple, married couple parents, kin co-residence); ► union formation (i. e. marriage, divorce and cohabitation); and ► marital quality on various health-related outcomes.

Basic Characteristics

► Family structure shapes the mental health, physical well-being and longevity of children, adolescents and adults. Major themes have typically been developed based on studies in industrialized countries. They address: 1) children's emotional and developmental well-being; 2) adolescent problem behaviors; and 3) the health and longevity of married couples.

Children's Emotional and Developmental Wellbeing

In both industrialized and industrializing nations, population-representative surveys strongly associate nonmarital childbearing with infant mortality, low birth weight, and delayed cognitive development. In industrialized nations, single parenthood (particularly when determined by divorce) is related to the highest levels of childhood emotional and behavioral problems (Dawson 1991).

Two mechanisms are most commonly used to explain the relationship between family composition and children's physical and mental health. First, there are differences in social and economic resources (► social resources) by family structure. Studies have found that economic factors such as poverty strongly mediate the relationship between non-martial childbearing, infant death, and low birth weight (Schor, Menagham 1995). Health insurance coverage often changes with changes in family structure (particularly divorce). Furthermore, in both the industrialized and industrializing nations, maternal education is a primary determinant of health utilization.

Secondly, family composition indirectly captures the psychosocial stress and disruption associated with divorce. Divorce is associated with increases in emotional distress, independent of changes in social and economic resources (Seltzer et al. 2005). The role of emotional distress appears to be strongest among the youngest children (i. e. preschool age), and to diminish within several years; however, it is noteworthy that studies of birth cohorts in the U.S. and the U.K. have observed differences in the mental health and social well-being of adults who experienced divorce as children (Seltzer et al. 2005). Current and emerging research uses information from birth cohorts in the U.S. and Europe to understand the role of family composition over the life course, and the mechanisms interrelating family dynamics with child and later-life well-being.

Adolescent Problem Behaviors

The research considering adolescent ► problem behaviors is closely linked with the research studying children's emotional well-being. In this context, not only is family structure considered in relationship to health, but also the correlates of family structure, such as the quality of the parent-child relationship. The literature in this area is commonly situated in an industrialized nation context. For example, a recent population-representative survey of U.S. high school students (ages 14–19 years) found that teenage smoking, drinking, weapon-

related violence, and sexual intercourse were all significantly more prevalent among students living in two-parent households than single parent households (Blum et al. 2000). Scholars are beginning to describe, however, how globalization and mass marketing are shaping changes in adolescent behavior and ► family formation patterns in industrializing countries (Lloyd 2005).

Adolescent problem behaviors, like child emotional problems, are related to family composition through differences in resources and psychosocial stress. In addition, differential access to adult role models provides an important mechanism linking dynamics in the family with adolescent well-being (Schor, Menagham 1995). Recently, the involvement of nonresident fathers has been found to mediate differences in family structure and adolescent behavioral outcomes (Carlson 2006).

Health and Longevity of Couples

In adulthood, family composition is related to the physical and mental health of men and women in complex ways. Marital status is associated with longer life, better physical and mental health, more health-promoting behavior, reduced health risk-taking and accidents, lower suicide, violence, homicide and even different immune regulation (Umberson 1992; Kiecoltglaser et al. 1993). However, there are also reciprocal relationships between health and family formation, which make causal inference particularly challenging (Lillard, Waite 1995; Rogers et al. 2000). Moreover, aspects of family composition such as marriage, kin co-residence, and family size may have both positive and negative influences on health, depending on factors such as the quality of relationships and the relative balance of family financial and emotional stressors to family resources (Rogers et al. 2000).

Family formation can influence the health of adults through pathways similar to those of children, involving differential resources and psychosocial stressors. For example, the role of financial resources has been identified as particularly important for women and not men in determining the positive relationship between longevity and marriage (Lillard, Waite 1995).

In addition, as active participants in the family formation process, adults (in contrast with children) are particularly influenced by aspects of partnership such as the degree of marital conflict, the extent of social monitoring and reinforcement, and even selection into and out of partnerships. The social support of a marital partner is independently associated with better medical outcomes following medical treatment associated with heart disease and cancer (Case et al. 1992). Similarly, spouses' contribution to monitoring and positively (or negatively) supporting each other's health behaviors is used to explain the differences in health and longevity upon divorce or widowhood (Umberson 1992).

New studies have begun to explore the quality of marital interactions. In controlled study settings, immune function has been shown to negatively correlate with marital conflict (Kiecoltglaser et al. 1993). Moreover, studies have highlighted how correlates of health (in particular attractiveness and poor health behaviors) may select individuals into and out of marriage in a manner which biases the positive relationship observed between marriage and longevity (Rogers et al. 2000).

Family Formation

Definition

The process of creating relationships between one's self and at least one other individual that allow the exchange of resources and responsibilities. Family formation follows from ► union formation and typically involves child rearing. The patterns of family formation, when studied at a population level, involve the intersecting changes in the timing and likelihood of such activities as parenthood, cohabitation, marriage, divorce, remarriage, and grandparent co-residence.

Family Health

NATALIE M. SCHMITT
Forschungsverbund Public Health Sachsen-Sachsen Anhalt e. V., Medizinische Fakultät, Technische Universität, Dresden, Germany
Natalie.Schmitt@tu-dresden.de

Introduction

The family is a private sphere of social life with intimacy and mutual interdependence. It offers a substantial means of insulation in the face of societal stress. Unfortunately, the private space of family life is also an arena of violence and abuse, especially to wives and children. Patriarchal domination still exists in most families and may be one cause of gender inequality in health. Civil law plays an interventionist role in supervising relationships, particularly concerning marriage and parenthood.

Health and illness have a great impact on families, and family has a powerful effect on health. Family health refers to the concept that each individual can affect the health of all other family members. This is evident for infectious diseases. However, any disease of a family member may have a negative social and psychological effect on individuals, especially children, regardless of whether or not they contract the disease themselves. Life-threatening and stigmatizing diseases such as ► HIV/AIDS may be particularly oppressive. On the other hand, social support from family members, e. g. through communication and cooperation, is health promoting. Marriage is the most influential family relationship on health for adults. It is important to consider that negative, critical family relationships have a stronger influence on health than positive, supportive relationships. In order to be highly effective, family health programs have to incorporate activities that promote behaviors directly related to physical health as well as improve communication within the family. In contrast to family therapy, which has been clearly demonstrated to improve family functioning and the emotional health of family members, there is much less evidence that family interventions can improve the physical health of family members (Campbell 2004).

Children with chronic illness and disabilities have to rely on family support to cope with their situation successfully. Vice versa, families have to balance the burden of the child's illness with other family needs. Both child and adult chronic illnesses can often dominate family life and affect relationships within the family. Family interventions for chronic childhood disorders may be effective in improving medical and psychosocial outcomes.

A growing number of the elderly must rely on family members for care. Family support and care giving may improve adherence to medical treatments, but exert a heavy toll on family members, who consequently show higher rates of mental illness and mortality compared with non-caregivers. Family support groups and intensive psychoeducational interventions that provide specific problem solving and coping skills may prevent increased morbidity in family caregivers. Family health

professionals should be part of health care teams and offer support for family members.

Unhealthy behaviors or risk factors tend to cluster within families: family members tend to share similar diets, engage in similar physical activities, and use or abuse drugs. The initiation and quantity of smoking, which remains the number one public health problem in much of the world, is influenced by whether and how much other family members smoke. The fact that partner support is important for smoking cessation greatly illustrates how family involvement may be important in the promotion of healthy lifestyles.

Family health may be divided into several subdisciplines: family demography, family health policy, gender differences in health, perinatal health, child health, adolescent health, women's health, men's health, reproductive health, and health of the elderly. Tobacco use and sexually transmitted diseases affect families to such a great extent that they both merit special consideration.

Family Composition

► Family composition shapes the mental and physical health and well-being of all family members, including children, adolescents, and married couples.

Infant mortality and delayed cognitive development in children seem to be strongly associated with nonmarital childbearing. The growing prevalence of childhood emotional and behavioral problems in developed countries may be the consequence of single parenthood, particularly when determined by divorce (Dawson 1991). Social and economic resources depend on the family structure, e. g. health insurance coverage often changes after divorce. Emotional problems in children and adolescent problem behavior are more prevalent in individuals experiencing psychosocial stress (e. g. due to divorce).

Maternal education is a primary determinant of health service utilization in children around the world. This highlights the importance of education not only for the mother's health but also as a proxy for the physical and mental well-being of her dependents. Not only does the family structure per se have an impact on health, well-being, and behavior of individuals, but also the quality of relationships within the family. The quality of relationships even determines whether factors like marriage or family size have a positive or negative influence on the health of adults.

In general, marriage is associated with better outcomes concerning physical and mental health; social, risk-taking, and health promoting behavior; and longevity. Married people of both sexes have death rates well below the rates of unmarried people. However, the relationship between family status and health of men and women is very complex. The degree of marital conflict, social support of a marital partner, and support of each other's health behavior are major determinants in this relationship. Of course, gender differences within the couple also interact with some correlates of health.

F

Demographic Perspectives on Family Health

Family demography is the study of changes in family composition due to entrances into and exits from families. Family demography is deeply intertwined with family health.

Despite the overall progress in life expectancy and health worldwide, new and re-emerging health threats have the potential to reverse this progress. Population aging and changing family structures create additional challenges for societies, in particular to already disadvantaged families and children ► demographic perspectives on family health.

In the developed world, infant and child mortality has been low since the middle of the 20th century. Prevention of cardiovascular disease, especially in the elderly population, has recently increased the length, but also the quality, of life. In developing countries, life expectancy has risen over recent decades. Vaccination and other means of prevention of infectious diseases have been especially effective in increasing infant and child survival. Unfortunately, the HIV epidemic has slowed progress in child health. Countries that are strongly affected by the HIV/AIDS epidemic, such as Southern Africa, countries in Eastern Europe, and the former Soviet Union, have seen mortality reversals. Conditions like obesity and diabetes have the potential to reduce life expectancy in many countries of the world.

Another major demographic trend of the 20th century is the considerable decline in fertility rates throughout the world, although desired fertility remains high in many poor countries, and many women continue to have limited access to family planning. Falling family sizes are partly due to family planning efforts, which have been developed to improve living standards in developing

countries and to reduce maternal and infant mortality. As total fertility rates have fallen well below replacement levels throughout Europe and in parts of Asia, and low fertility may cause economic and societal problems, policy concerns have shifted to increasing fertility rates in many countries.

The HIV/AIDS epidemic is today's most important family health crisis. Families have to compensate for loss of wages and organize care for sick adults. In addition, the burden of caring for orphaned children falls to the extended family, often grandparents, who are not in good health either.

Population aging poses an additional demographic challenge. Wealthy countries debate how to fund pension and health services for the elderly as there are fewer working-age adults to support the welfare state. In developing countries in Latin America and the Caribbean, welfare systems that can support the elderly have not yet been established. If societies cannot take care of the elderly, the responsibility falls instead to families. Moreover, rising rates of divorce and nonmarital fertility weaken families. Children raised in single-parent families are often socioeconomically disadvantaged. Divorce and single parenthood may have an impact on children's health and well-being for their whole life.

Gender Differences and Health

Women, on average, have lived longer but less healthy lives than men have in developed countries since the turn of the last century. Gender shapes differences in health behavior and health service utilization that are important for health, development, and longevity. Scientists are currently exploring complicated gene-environment interactions that are fundamental to the understanding of gender differences in health ► gender differences and health.

Smoking has been identified as the primary determinant of the convergence in mortality differentials between men and women in industrialized nations over the later part of the 20th century. At the beginning of the century, smokers were mainly male as tobacco was a luxury and it was not considered socially acceptable for women to smoke. Consequently, rates of smoking related deaths were much higher in men than in women. With relaxing of social norms, which began in the 1920s, and especially young women's increasing aspiration for independence outside of the home, the proportion of female smokers rose. Consistent with the trends in smoking, rates of cancer-related deaths began to increase among women over the later half of the 20th century. Due to current delays in smoking cessation among women compared with men, lung cancer mortality is still increasing in females but no longer in males in the US population (Pampel 2002).

All over the globe, men consistently show higher rates of accident and violence related mortality compared with women. There are even three times as many fatalities caused by road traffic injuries among men aged 15 to 44 years than among women in the same age category (WHO 2002c).

Differences in the social habits of men and women are related to higher mortality among men and higher morbidity among women. Changes in feminine social norms, especially concerning women's work outside the home, have been related to increased psychosocial stress, as women have to bear responsibilities both at home and at work. This increased psychosocial stress may explain the rise in women's morbidity. The feminine role of caregiver also hinders women from leaving abusive relationships in many cases. Physical and psychological violence against women is often legitimized by a woman's failure in a feminine social role and can be related to unsuccessful achievement of masculine social roles by men (Lorber 2005).

Child Health and Development

Child health includes developmental aspects from birth to young adulthood as well as children's physical, mental, and social health (► child health and development). Health in childhood is an important determinant of health in adolescence and adulthood. Malnutrition and its potential lifetime consequences on health (e. g. blindness, stunted growth) affects about 250 million children worldwide (Blair et al. 2003). Nutrition is necessary for children's metabolism, growth, development, health, and well-being. Nutrition during the first few years of life has a critical impact on cognitive development and growth (National Research Council 2000). Breastfeeding should be promoted, especially in the first 6 months of life, and even longer in developing countries where access to sanitized water is limited. Although the contents of breast milk depend on the mother's food supply and environment, nutrients

are mostly well balanced. Breastfeeding also provides fat and water-soluble vitamins, minerals, hormones, enzymes, and anti-infective and anti-inflammatory substances. Breastfeeding has negative effects for the child if the mother is HIV positive, drinks alcoholic beverages, or is or was exposed to pollutants such as DDT or PCB. Children are one of the subpopulations for which it is most important to follow a balanced diet in order to prevent chronic diseases such as diabetes and cardiovascular disease.

Children of low socioeconomic position, immigrants, refugees, and those living in war torn countries are most vulnerable due to lack of adequate nutrition, shelter, and healthcare. Parents' feelings of depression, anxiety, and low self-esteem, which are to a greater proportion present in poor than in wealthy families, increase children's risk of living in unstable homes (Blair et al. 2003). Children's social environment (e. g. parental participation, violence in the home and community, and abuse or neglect) is critically influential in the development of language, scholastic achievements, social behavior, and physical and mental health.

The physical environment has a great impact on child health. Efforts that have been made to prevent childhood injuries are far from sufficient. Injuries still represent the most common cause of physical disability. Motor vehicles are not only responsible for the majority of childhood injuries worldwide, but also emit hazardous chemicals. Children who live in high traffic areas, near industrial parks, and are in contact with indoor pollutants, such as cigarette smoke and asbestos, are particularly at risk of acute and chronic respiratory diseases. Lead poisoning from lead pipes and paint cause partially irreversible neurological damage. Contaminants and pollutants in food, water, and the immediate environment are particularly harmful to children as their diet is less diverse and their food and water consumption in relation to their body weight is higher than that of adults (Blair et al. 2003).

In developed countries, child mortality and morbidity are at their lowest levels in recorded history due to decreasing fertility rates and improvements in water supply, nutrition, housing conditions, and quality and acceptance of vaccinations. Prosperity also leads to lifestyle changes responsible for the dramatic rise in chronic conditions that have typically not been seen until adulthood: e. g. type II diabetes, obesity, joint disease, and headache. The consequences of these changes play out over the lifespan, as unhealthy children typically grow up to be unhealthy adults. Low quality nutrition (prepackaged food high in fat and sugar, etc.) and lack of physical exercise (less outdoor activity, and increased television and video game use) are equally responsible for these new aspects in child health (Blair et al. 2003).

Approximately 85 percent of the world's children live in developing countries, where infectious diseases – mostly diarrheal diseases and respiratory infections – remain the primary cause of childhood death. Progress in health care is limited to urban areas in most developing countries. While childhood HIV infections are declining due to prevention efforts in mother to child transmission, children are still commonly left to head the household after losing their parents to the disease (Blair et al. 2003).

Emotional and behavioral problems during childhood are common. Depression, attention deficit hyperactivity disorder (ADHD), and conduct disorders are linked with developmental delay (Morris 2003).

Adolescent Health and Development

Adolescence is the period in life in which physical growth, pubertal maturation, cognitive transitions, and psychological and social maturation happen. There is great variation in the paths of development within and across cultures. Physical growth, changes in body composition and physiology cause an increase in body strength on the way to adulthood. Sexual maturation physiologically leads to functionality of reproductive organs and development of secondary sexual characteristics. Adolescents may start becoming sexually active. Cognitive advances that emerge during adolescence include increased knowledge, multi-dimensional thinking, and the shift from concrete to abstract thinking. Social acceptance and integration in larger peer groups, as well as formation of close, intimate friendships, become salient. Moreover, adolescents deal with psychological transitions such as development of identity, autonomy, intimacy, and sexuality. The process of individuation and increasing autonomy can be the basis of potential conflict with authority figures. ► adolescent health and development.

Health compromising behaviors during adolescence may critically influence individuals, societies, and economies in the long term. Alcohol, tobacco, and drug

use, engagement in unprotected sexual intercourse, lack of physical exercise, and overcalorific nutrition often emerge in this period. Major causes of mortality and morbidity in adolescents are behavior related and therefore preventable: unintentional injuries (mostly from motor vehicle accidents), violence, homicide, suicide, teenage pregnancy, and sexually transmitted diseases.

Mental illness in youth causes a major burden of disability worldwide. Poverty, violence, and trauma contribute to mental illness. Mental, behavioral, and addictive disorders are associated with educational and social problems and should be prevented more aggressively. These conditions do not only affect individuals, but may have far reaching consequences on family life and the adolescent's future.

There are different approaches to help young people navigate successfully through the transitions of adolescence and enable positive health and development in youth. Interventions should take into account individual factors, immediate relationships, environmental influences concerning the school and neighborhood, for example, and societal forces, in order to be successful. Moreover, it is evident that healthy development and education on healthy behaviors that begins in childhood promotes and sustains health and development in adolescence and throughout the whole life.

Women's Health

► Women's health does not only imply pregnancy and reproductive health but also focuses on health issues across women's life-span and possible consequences arising from the multiple roles women frequently have to play (mother, wife, caregiver, worker, etc.). Women's health is significantly associated with not only biological differences between men and women, and women's reproductive role, but also with gender inequality in social, educational, cultural, and economic status. Several diseases are unique to women, more prevalent, or more serious in women. Risk factors and the effectiveness of interventions may also be different in women compared with men.

Women experience greater morbidity, but higher life expectancy compared with men. Particularly in older age, women have clear survival advantages (UN 2005). Infectious diseases like HIV/AIDS and malaria as well as maternal conditions are the leading causes of death for women worldwide. In developed countries, women's leading causes of death are cardiovascular disease and cancer. Being the most frequently diagnosed malignancy in women, breast cancer is one of the leading health concerns for women. Nevertheless, breast cancer mortality is still second to lung cancer mortality. Early detection of breast cancer through mammographic screening is able to reduce the burden of breast cancer in the female population and should be promoted worldwide.

Women are more vulnerable to infection with sexually transmitted agents, due to social inequalities between women and men concerning knowledge of STD prevention, influence on sexual relationships, and availability of health care services.

Cardiovascular disease shows different features in women compared with men. It occurs later in life, has higher case-fatality rates, and seems to be undertreated in women.

Another condition that greatly influences women's health-related quality of life is osteoporosis, a condition that significantly increases the risk of fractures which may be deadly, especially in older women. Prevention efforts have to begin in early life in order to be effective, as peak bone mass, which is critical for the risk of later osteoporosis, is mostly achieved during adolescence.

Reproductive health is the state of complete physical, mental, and social well-being in all matters relating to the reproductive system. Access to adequate healthcare services for pregnant women is a prerequisite for adherence to women's rights. Pregnancy and childbirth are major life events in which healthy behavior and a healthy environment, e. g. concerning exposure to smoking, alcohol, nutrition, physical activity, and positive relationships, are essential for the health of the mother and the newborn.

The decline in fertility rates worldwide is partly due to the development of contraceptive strategies. Contraceptive prevalence is 67% worldwide and is much higher in industrialized countries compared with the least developed countries. Unfortunately, there are still millions of women with unmet contraceptive needs in developing countries (UN 2005). The abortion rate is directly related to the prevalence of modern contraceptive methods and restrictiveness of abortion policies. Legalization of abortion reduces the number of illegal abortions, which are often conducted under unsafe conditions, and consequently decreases health risks for the mother.

Violence against women has a significant negative impact on women's health both directly and indirectly by reinforcement of social inequalities. Domestic violence, especially intimate partner violence, is the most important cause of homicide in women and a great burden to the female population worldwide.

Men's Health

► Men's health as a distinct area of critical intellectual and practical concern in the domain of public health has relatively recently been recognized in the Western World. Networks are only recently beginning to be formed across multiple sectors and disciplines (Hayes 2003). Regarding research, government policy, and programs, men's health remains a relatively minor area of concern. Existing efforts concentrate on men's reproductive health or men's engagement in anti-social and risk-taking behavior. Resources are often not assigned adequately to research on male conditions. Although the mortality rates are roughly equivalent in industrialized nations, research funding for the diagnosis and treatment of prostate cancer significantly lags that of breast cancer in women.

Men in general are considered to be incapable of experiencing and expressing emotions adequately or of engaging in appropriate self-care. These kinds of prejudices are popular and tenacious. In addition, Western societies often ignore the economic and political significance of the processes of socialization that prepare men to fight in wars or work in hazardous industries. Only recently, men have become less pathologized and men's health is taking a more positive primary health care and health promotion approach.

Increasing rates of workforce redundancy for men over 50 years of age, and decreased opportunities for nonconsumerist leisure options for males of all ages, necessitate public health interventions that create opportunities for men to maintain their social connections. Men's mental and physical health may benefit from maintained or increased social connectedness.

Life expectancy for males at birth is lower compared with women in various regions of the world. Globally, the leading causes of death for all males are related to cardiovascular disease (27%), non-respiratory infections and parasitic diseases (20%), malignant neoplasms or cancers (13%), followed by unintentional or intentional injuries (12%), respiratory infections, and other respiratory disease (WHO 2002b).

Prostate cancer is the most common noncutaneous human malignancy, and the second most lethal tumor among men. However, men tend to die with prostate cancer rather than because of it. Therefore, diagnosis leading to treatment of prostate cancer may not improve men's lifespan or health-related quality of life. As its natural history is often prolonged, survival benefits of early detection and local therapy in low-risk tumors are not easy to achieve. The large majority of prostate cancers are detected via prostate-specific antigen (PSA) screening. Discussion about the quality of screening methods is still ongoing. Appropriate disease management, particularly risk assessment, is necessary to avoid overtreatment for patients with indolent disease and to avoid undertreatment for those with aggressive prostate cancer. Even if prostate cancer screening is eventually demonstrated to provide benefit for asymptomatic persons, psychological and physical harms of treatment, including impotence and incontinence, must be taken into account. In general, men are more reluctant to accept screening compared with women; therefore, the usefulness of secondary prevention needs to be particularly emphasized.

Elderly and Health

Both the absolute number and relative proportion of older people in the general population are on the rise. By 2002, the population of individuals aged 60 years and over reached 626 million, or 10 percent of the total world population. By 2050, the older population is projected to be more than triple its current size. The majority of the elderly population is female in most of the world. In addition, it is projected that more than three-quarters of the world's older people will be living in developing countries by 2050 (UNPD 2003). Population aging is the result of the combination of reduced fertility and improved living conditions, together with successful innovations in public health and progress in medicine ► elderly and health.

Health in later life is influenced by various biomedical, environmental, and social factors. In general, physical and mental capacities weaken in older age. Aging populations have higher rates of chronic disease and disability. Chronic diseases may contribute to the gradual loss of quality of life and are a heavy burden to the

elderly as well as to the health care system. In the prevention of disabilities, a healthy lifestyle that includes regular physical and cognitive activity, a nutritious diet, and avoidance of tobacco is key. Societies need to prepare for the increasing health and social service needs of the elderly.

Changes in family structure and population aging result in decreasing availability of young family members who are able to provide care for the elderly in need. Around the globe, spouses are the main caregivers for both men and women, even in older age. Only a small percentage of older people live in institutions for long-term care. Community and home care services as well as the possibility of living in flat-sharing communities allow the elderly to remain in their own homes and reduce feelings of loneliness and reclusiveness.

Fertility

Reproduction is essential to the survival of societies as population size depends on survival, migration, and reproduction. ► Fertility describes the ability to conceive and produce a live birth. Human fertility is directly influenced by coital frequency, methods of birth control, sterility, lactational amenorrhea, and fetal loss. Endocrinological, nutritional, cultural, economic, and social factors have indirect effects on fertility. Natural fertilization is achieved when mature sperms penetrate the ovulated egg on its journey from the ovary to the uterus, and cell division begins in the fertilized egg. In this early stage, progress of the pregnancy depends on successful implantation of the embryo into the wall of the uterus where it develops into a fetus. To conceive a child naturally, the male and female reproductive organs must function without any abnormalities or disruptions.

Fertility rates are measured in terms of the number of live births per woman-year of exposure for a given period of time, usually one year. Fertility replacement is defined as the level at which a cohort of women has enough children on average to replace themselves and their partners in the population.

Over the last decades, global fertility levels have changed dramatically. Declines in fertility rates are visible in all regions of the world, although patterns of decline may vary across and within regions. Fertility decline first started in Europe in the late 19th and early 20th centuries. In the less and least developed countries, fertility decline began much later (1960s to 1970s). In North America, Europe, and East Asia, rates are below fertility replacement (see "► fertility", Fig. 1). This trend leads to fewer at-risk pregnancies and, consequently, to decreased mortality and morbidity in mothers and children.

There are several stages in the demographic transition from high to low fertility levels. The early stages show fertility declines among older childbearing-aged women, which typically exceed fertility reductions due to rising age at marriage among younger women. Delayed childbearing among women in their twenties and the growing proportion of women having none, or only one or two children, are responsible for further reduction of fertility toward below-replacement levels.

Contraception, abortion, poor nutrition, infectious diseases, and sexually transmitted infections are major factors influencing fertility. The latter factors are disproportionately present in developing countries, where ► HIV infection is an important reason for sub-fecundity in sub-Saharan Africa and malaria increases the risk of fetal loss in pregnant women.

Contraception is considered one of the major public health achievements of the last century. Worldwide, more than 60% of women of reproductive age who are married or in a union are using contraception. However, the proportion of women using contraception varies considerably across countries. Some of the most populous countries in the world, such as India, Pakistan, Nigeria, and much of sub-Saharan Africa, register low levels of use. Oral contraceptives and condoms are the most widely used methods in developed countries, and female sterilization and intrauterine devices (IUDs) in developing countries.

Pre-conceptional measures such as contraception help to assure that every pregnancy is intended. Worldwide, an estimated 38% of pregnancies occurring each year are unintended and approximately 60% of these end in an induced abortion (WHO 2005). Consequences of unsafe abortions account for 13% of maternal deaths and are therefore a major public health concern. Unsafe abortions should be entirely prevented. Research on fertility-regulating methods has led to the development of oral treatment regimens, such as mifepristone or misoprostol, which effectively terminate early pregnancies and seem to be safer compared with invasive abortion during the first weeks of gestation.

Infertility

► Infertility refers to the inability to produce a live birth, usually after one or two years of regular, unprotected sexual intercourse. In contrast, the terms infecundity and sterility describe the inability to become pregnant. Infertility is used in reference to any point in the fertility process, including the inability to conceive, become pregnant, carry a pregnancy to term, or produce a live birth. There are two types of infertility: primary infertility, which is the inability to produce any live birth, and secondary infertility, which is the inability to produce a live birth after the birth of a child.

Approximately 10% of couples are affected by infertility during their reproductive lives. Infertility is especially high in developing countries, with up to one-third of all couples trying to conceive without success in some countries in Central Africa. A baseline of 5% of all couples is estimated to be sterile, irrespective of nationality. Female factors, male factors, or conditions related to the couple as a whole can cause infertility. Male-factor conditions are present in at least half of all infertile couples. Non-preventable conditions leading to infertility including anatomical, genetic, hormonal, and immunological problems that prevent a successful pregnancy, are responsible for the core 5% of infertile couples and do not vary much across or within populations. Infections, environmental, and occupational factors are preventable causes of infertility that show significant variation around the world. Sexually transmitted infections (STIs) related to infertility include *Chlamydia*, gonorrhea, trichomoniasis, and syphilis. Prevention of asymptomatic STIs is difficult, as infection is often not detected until permanent damage, such as pelvic inflammatory disease and tubal occlusion, has occurred. Other infectious and parasitic diseases associated with increased risk of infertility include HIV infection, tuberculosis, schistosomiasis, and malaria. Women in developing countries face higher risks of nosocomial infections causing infertiliy than women living in industrialized countries. Permanent damage of the reproductive tract may be the result of postpartum infection, septic abortion, or infection following the insertion of an IUD. These conditions are mostly due to unhygienic practices in health care. The prevalence of harmful sexual initiation rites and subsequent complications varies significantly across countries, cultures, and religions. Preventable environmental exposure mostly affects sperm quality and quantity. Exposure to arsenic, aflatoxins, pesticides, and also consumption of tobacco and alcohol can cause infertility.

Infertility is a serious reproductive health problem that can have far-reaching effects on individuals and communities. In many cultures, infertility is highly stigmatized. It can result in discrimination, exclusion, ridicule, and even abuse. Even if childlessness is socially acceptable, infertile couples may still struggle with feelings of inadequacy, shame, and depression. Women usually carry the heaviest burden of the problem.

Helping individuals achieve their reproductive intentions will have profound effects on population health and societal well-being.

Worldwide, there has been a marked increase in the demand for infertility services, including advanced reproductive technologies. Assisted reproductive procedures are expensive, produce a higher number of multiple births, and result in at-risk pregnancies. Nevertheless, *In Vitro* Fertilization (IVF) is considered as one of the greatest achievements of reproductive medicine and extending assisted reproductive technology to the developing world is a global reproductive health priority (WHO 2002a). In cultures where traditional healers are commonly consulted, treatments can be painful, ineffective, and potentially harmful. Efforts to prevent infertility must be emphasized, as they are less expensive, more effective, and may avoid inappropriate treatment.

Perinatal Health

The external and the in-utero environment both influence birth outcomes. Pregnancy is a critical period for the health of the newborn as well as for long-term health and development of the infant. ► Perinatal health particularly covers preterm birth, low birth weight, intrauterine growth retardation of the fetus, and perinatal mortality.

Preterm birth occurs in approximately 10% of births, and continues to increase in most developed countries. It is associated with increased morbidity, and is the major cause of all perinatal mortality. As risk factors for preterm delivery are multiple and overlapping, advances in prevention have only been modest. Sociodemographic and biologic risk factors include maternal age, race and ethnicity, socioeconomic status, stress, drug abuse, family genetics, poor nutrition-

al status, multiple gestations, anatomic anomalies of the uterus, bleeding, and infection. Infants that survive preterm delivery are at higher risk of damage to the central nervous system. Timely detection of early labor is important to allow transport of mothers to qualified delivery facilities and initiate effective treatment such as antibiotic treatment of bacterial sexually transmitted diseases.

Fetuses that show intrauterine growth retardation are exposed to the same risks as babies born preterm. The growth restriction is caused by an inadequate supply of nutrients and/or limited oxygen supply to the fetus, which may be caused by fetal malformations or infections, maternal smoking, or inadequate nutrition. Early detection and management of fetuses experiencing growth restriction is crucial to determine optimal timing and method of delivery. Prevention strategies should continue to focus on prevention of smoking during pregnancy, maternal nutrition, and, in developing countries, malaria prophylaxis during pregnancy.

Low birth weight infants are born weighing 2500 grams or less. Low birth weight is the second leading cause of perinatal morbidity and mortality. Its incidence is much higher in developing countries. Any complication that limits oxygen and alters nutrient supply of the fetus may be a risk factor for low birth weight. These conditions include chronic hypertension in the mother, glucose metabolism and chronic cardiorespiratory disorders, maternal malnutrition, multiple pregnancies, infections, and anomalies in the fetus, placenta, or umbilical cord.

Ways to prevent low birth weight include improved access to adequate prenatal care to improve detection of small-for-date babies, identification of the causes of fetal growth restriction, and counselling mothers on risks associated with stress, smoking, alcohol and drug use, as well as inadequate nutrition during pregnancy.

Perinatal mortality includes stillbirths, fetal deaths after 20 weeks gestation, and mortality within the first 29 days after delivery. Almost 75% of deaths occur in the first week of life and the highest risk of mortality is in the first day of life. The main causes of neonatal deaths are preterm births (28%), infections (26%), asphyxia (23%), tetanus (7%), congenital abnormalities (7%), and diarrhea (3%) (Lawn et al. 2005). Maternal health and health care utilization are important determinants of neonatal health. The intrapartum period has the most significant impact on neonatal survival.

Sexually Transmitted Diseases (STDs) and Family Health

STDs are a broad category of infections that can be transmitted from person to person through sexual contact and from mother to child before or during birth. The Human Immunodeficiency Virus (HIV) can also be transmitted through breastfeeding. Sexual partners may be infected during the incubation period of the disease, i. e. before the occurrence of symptoms. Another barrier to effective prevention and treatment of STDs is the so-called "ping-pong effect", which describes the repeated reinfection of sexual partners with the same STD. That is why partner treatment is essential and public health professionals have to make assiduous efforts to convince patients of its necessity ► sexually transmitted diseases and family health.

Cesarean section delivery, in contrast to vaginal childbirth, can prevent most mother-to-child infections, e. g. with Herpes simplex II virus and *Chlamydia* bacteria; both of these infections can lead to serious health consequences for the child. Syphilis microbes, however, infect the fetus after the first three months of pregnancy. The existence, availability, and acceptance of high quality obstetric care services are critical for the primary prevention, early detection, and effective treatment of infections during pregnancy and delivery.

The prevalence of HIV infection has risen steadily since the 1980s and is still increasing. In 2005, the number of people living with HIV exceeded 40 million (United Nations Programme on HIV/AIDS 2005). As the mother is generally the main caregiver in the family, an HIV infection in her particularly has the greatest social and psychosocial impact on the family. Children living in poverty have even more difficulties coping with the mother's illness. It can be argued that HIV positive individuals may still be in good health and are still able to take care of the family. On the other hand, over 30% of HIV infected women show clinical levels of anxiety and depression, which are risk factors for poor parenting and poor family support in general. The mother-child relationship, in particular the quality of communication between the infected mother and her children concerning the disease, plays another major role in child adjustment. Children are at risk of contracting the virus themselves and of becoming orphaned through the loss of their parents. Orphans experience high rates of poverty and receive less schooling, both of which can have life-

long implications for health and well-being (Murphy et al. 2006).

To date, there is still a lack of knowledge about how to provide services more effectively to families affected by HIV infection, as the motivation and cooperation of several family members, as well as a substantial amount of resources, are necessary (Murphy et al. 2006).

Smoking and Family Health

Smoking of family members has negative consequences on the health and the financial welfare of the whole family.

Active but also passive smoking increases both female and male factor infertility. The likelihood of pregnancy complications such as ectopic pregnancy, low birth weight, and prenatal death is greatly increased in pregnant smokers. Even non-smoking women exposed to tobacco smoke during pregnancy have to be aware of their increased risk for complications. For example, secondhand tobacco smoke is causally associated with low birth weight and pre-term delivery. Smoking is the most important preventable cause of poor pregnancy outcome in developed countries ► smoking and family health.

The number of children and adolescents exposed to secondhand smoke in their homes is alarming: worldwide, almost 50% of middle-school students report such exposure. (Global Youth Tobacco Survey Collaborative Group, 2002) Unlike adults, who can choose whether to be in a smoky environment, babies have no choice and children have little choice. Maternal smoking is usually the largest source of tobacco smoke exposure for children because of the cumulative effect of pregnancy and close proximity to the mother during early life. The health of children of smoking parents is not only affected by secondhand smoke of their parents, but children of smokers are also more likely to take up the habit themselves. Maternal smoking, during and after pregnancy, is causally associated with Sudden Infant Death Syndrome (SIDS). Moreover, the frequency of bronchitis and pneumonia, as well as common respiratory symptoms like cough, is increased in children's first year of life if the parents smoke. Parental secondhand smoke during childhood years reduces children's maximum level of lung function, which may impair their whole life. In addition, studies have found a significant increase in childhood asthma and otitis media if the mother or both parents smoke (IARC 2004).

The non-smoking spouse also suffers from negative health consequences. Non-smoking women married to cigarette smokers have an estimated increase in the risk of lung cancer of 24%. Exposure to secondhand smoke is also associated with coronary heart disease and may play a role in the development of chronic respiratory symptoms and decrement in lung function (IARC 2004).

Active smoking is a major cause of lung cancer, heart disease, stroke, cancers other than lung, chronic bronchitis, peripheral vascular disease, and other circulatory disease. About half of individuals who start smoking as teenagers and continuously smoke are killed by tobacco in middle or old age. This excess burden of death falls particularly heavily upon individuals aged 45–64 years who are typically working and involved in raising children (WHO 2002b). Illness and death can therefore result in direct financial and emotional distress in families. Financial costs for families due to smoking include money spent on cigarettes, increased health care costs for the smoker as well as for his/her family members, and lost wages caused by illness.

In many countries, public health policies have successfully reduced exposure to secondhand smoke in the workplace. There is also an increased awareness of the negative health consequences due to secondhand smoke, resulting in voluntary bans in households. Unfortunately, homes remain a primary location of tobacco smoke exposure. Public education and intervention programs as well as stronger public smoking restrictions can further improve family health in the future.

Family Health Services

► Family health policies and the nature and budget of health care systems vary across countries and in some cases within countries across sub-national units. Family health services depend on the social, political, economic, and institutional situation in the country or region. In developed countries, attention paid to family health prevention programs, especially concerning maternal and child health, is on the rise. Reductions in infant mortality rates are mostly due to improvements in health services for postnatal care and immunizations (OECD 2005). Health policies often target the fact that

health problems are more likely and health-supporting resources are less likely to be found in poor families. Family health policies aim to improve access and quality of health care and health promoting services, protect the poor from financial risk concerning health care costs, and reduce socioeconomic disparities in health outcomes among population subgroups.

Summary

Family health is among the major disciplines in public health. Family health has never lost relevance, and attention paid to subdisciplines like maternal and child health is on the rise. In all likelihood, improvement in family and child health will continue in the decades to come. However, the challenge will be to avoid leaving disadvantaged families behind. Mortality and fertility declines have improved quality of life for children and families in most cases. Changing family structures, population aging, and the burden of caring for family members hit by the HIV/AIDS epidemic create challenging future public health issues.

University of Houston, Houston, TX, USA
erigby@uh.edu

Synonyms

Health care policy; Child health policy

Definition

Governmental programs, rules, and regulations affecting the public or private provision of health care, health insurance, and other health-related services to children and their parents. The focus, comprehensiveness and design of these policies vary across countries and in some cases within countries across sub-national units.

Basic Characteristics

Family health policy is a general term capturing a range of actions taken by government to affect the amount, type, nature or cost of health care and health-promoting services received by children and their parents. These policies may involve a range of policy tools, such as: the public provision of health care services; subsidizing health care costs for some populations (► health subsidies); the regulation of health care services provided either publicly or privately; incentives for health care providers to provide particular types of care or work in certain locations; financing of public information campaigns to promote healthy behaviors; and the establishment of outreach efforts focused on particular communities or health problems. Since countries, and even sub-national units, set their own policies, the precise definition of family health policy – and the services associated with it – varies across countries. Often these policy choices are shaped by the social, political, economic, and institutional context in the country – with the design of health policies usually mirroring other ► social welfare policy provisions in the country.

Public Role in Health Care

The size and nature of the overall health care systems varies a great deal across countries. According to the Organization for Economic Cooperation and Development (OECD 2005), among advanced industrial countries, the percent of gross domestic product spent on health ranges from approximately six percent in Korea and the Slovak Republic to more than eleven percent in Germany, Switzerland, and the United States. Also varying is each country's proportion of these health expenditures that are public rather than private. In Korea, Mexico and the United States the majority of health expenditures are private (65 percent, 57 percent, and 57 percent respectively). In contrast, public expenditures paid through government programs and policies cover the majority of health care costs in the other 27 OECD countries with the government paying 80 percent or more in the Czech Republic, Iceland, Japan, Luxembourg, Norway, Slovak Republic, Sweden, and the United Kingdom. For the majority of OECD countries these public health care costs are due to publicly-financed health insurance coverage or direct public financing of care. Through these health care policies, in most advanced industrialized countries access to good quality physician services is ensured at relatively low and sometimes no cost. However, even within these ► publicly-financed health systems, access to specialist care still tends to be skewed by income – with lower-income people having less access (Doorslaer et al. 2004). In fact, equity in health care is a primary policy issue in OECD countries, along with questions of the effectiveness of spending and cost containment.

Even larger gaps by economic resources are seen when comparing rich and poor nations. In fact, the OECD countries account for less than 20 percent of the world's population but are responsible for almost 90 percent of the world's health spending (WHO 2003). In middle-income countries between three and seven percent of national income is spent on health, while only one to three percent of gross domestic product is spent on health in the poorest countries. In these countries, due to the low overall income and wealth, this amounts to per capita spending of approximately two to five U.S. dollars (versus between $75 and $550 in middle-income countries and $1,000 to $4,000 in high-income countries; WHO 2003). Among non-OECD countries, there is tremendous variation in the proportion of health

expenditures that are public versus private. More than 75 percent of the health costs are borne by private parties in: Armenia, Azerbaijan, Brundi, Cambodia, Congo, Georgia, Guinea, India, Myanimar, and Taijkistan, while public spending covers over 75 percent of the health costs in more than twenty other low- and middle-income countries (WHO 2006).

Promoting Public Health and Prevention

All OECD countries are seeing rising health care costs that are putting pressures on public budgets. In response, additional attention has been shifted to preventing health problems through investment in ► public health programs. On average, only three percent of health expenditures are devoted to prevention – although this varies from less than one percent of health expenditures in Luxembourg and Italy to more than five percent in the Netherlands and Canada. Countries are experiencing success in reducing some health problems and their associated costs. Much of this attention has been paid to maternal and child health issues. A notable example is the problem of infant mortality. All OECD countries have seen reductions in infant mortality rates in recent decades. This has been credited to overall improvements in economic and social conditions, as well as improvements in health services for post-natal care and immunizations (OECD 2005).

General public health interventions are particularly critical in developing countries where preventable and treatable diseases take an enormous toll on the world's poorest people (Carr 2004). For example, in Africa, infectious and parasitic diseases accounted for more than half of all deaths in 2001, compared with 2 percent of deaths in Europe (WHO 2002). An estimated 1.7 million people die annually from diseases linked to unsafe water, sanitation, and hygiene (WHO 2002). Government policies to improve these conditions or to provide community-based education on how to reduce illness within this context have great potential to promote health.

Addressing Health Disparities Among Families

A key finding in research on maternal and child health is the persistent relationship between income and health status – with health problems more likely and health-supporting resources less likely to be found among poor families, as well as the poor more generally (► health disparities). This pattern is found within both rich and poor countries and is often the target of health policies. Carr (2004) classified these policy approaches into three categories: health-service approaches, health-financing approaches, and socioeconomic approaches. Health-service approaches reform the health care delivery system to improve access and quality of health care. Examples of a health-service approach to reduce disparity are targeting health care services toward the most disadvantaged, ► governmental regulations or purchasing of services, and the development of ► public-private partnerships. Health-financing approaches can provide governmental services free of charge or subsidize the health care costs of low-income families. Similarly, ► risk sharing plans or insurance can protect the poor from financial risk. Socioeconomic family policies typically focus on sectors outside of health as a response to the substantial socio-economic disparities in health outcomes. Examples of policy interventions are: improving access to education and job training; promoting healthier workplaces, homes, and cities; reducing threats posed by environmental hazards; and promoting social safety nets and other protections against impoverishment.

Conclusion

Family health policies can be defined broadly to capture the range of governmental actions affecting access to and the nature of health-promoting services. These actions can be focused in the health sector, on other sectors, or on ► cross-sector efforts. Great variation is seen among countries in the size of their health budget, the importance of public versus private expenditures, the focus on preventive care, and the nature of policy interventions used to promote better overall health, as well as decreasing disparities among population sub-groups.

Family Interventions for Physical Health

THOMAS L. CAMPBELL
Department of Family Medicine, School of Medicine and Dentistry, University of Rochester, Rochester, NY, USA
Tom_Campbell@urmc.rochester.edu

Definition

A field of inquiry and clinical practice that uses systems theory to understand the interactions between families or family variables and health processes and outcomes. Of particular interest are the impact of health and illness on families and how families can influence physical health.

Basic Characteristics

Research has demonstrated that families influence physical health, including both morbidity and mortality (Kiecolt-Glaser, Newton, 2001) and that social support, particularly from the family, is health promoting. Four broad conclusions can be made from this research (Campbell 2004):

- Families have a powerful effect on health, equal to traditional medical risk factors, such as smoking.
- Emotional support is the most important and influential type of support provided by families.
- For adults, marriage is the most influential family relationship on health.
- Negative, critical, or hostile family relationships have a stronger influence on health than positive or supportive relationships.

While this observational research is robust in its findings, research on family interventions is less definitive, yet critical for the advancement of the field. While ▶ family therapy has been clearly demonstrated to improve family functioning and the emotional health of family members, there is much less evidence that family interventions can improve the physical health of family members.

Childhood Chronic Illness

Patterson (1991) has identified nine aspects of family process which have been consistently associated with good outcomes in children with chronic illness and disabilities: 1) balancing the illness with other family needs, 2) maintaining clear boundaries, 3) developing communication competence, 4) attributing positive meaning to the situation, 5) maintaining family flexibility, 6) maintaining family cohesiveness, 7) engaging active coping efforts, 8) maintaining social supports, and 9) developing collaborative relationships with professionals. Many of these attributes have been targeted by family interventions for pediatric illnesses.

Mendenhall (2002) identified twelve randomized controlled trials (RCTs) of family interventions for insulin dependent diabetes mellitus, ten of which used hemoglobin A1C as an outcome measure, an excellent measure of chronic blood sugar control. Seven of ten studies demonstrated a significant improvement in diabetic control with a family intervention. A Cochrane review of three RCTs of family therapy to improve asthma control in children, concluded "There is some indication that family therapy may be a useful adjunct to medication for children with asthma." (Panton, Barley 2002) Similar results have been found for children with cystic fibrosis.

Adult Chronic Illness

Despite the evidence that adult chronic illnesses tend to dominate family life and affect marriage, few studies have examined the impact of couple interventions for chronic illness in adults. Several studies have shown that involving spouses of newly diagnosed adult diabet-

ics in diabetes education programs improves diabetic control. However, studies of spouse involvement in cardiac rehabilitation programs have shown mixed results with only some of the studies demonstrating improved physical outcomes. Twenty years ago, Morisky and colleagues (1983) demonstrated that educating and involving the spouses of low income patients with poorly controlled hypertension improved treatment adherence and lowered blood pressure and overall mortality. The study has never been repeated, but has resulted in broad recommendations that families be utilized as a support for adherence to medical treatments.

Chronic Disease in the Elderly

With the aging of the population, the rising incidence of disabling conditions in the elderly, and fewer resources for ► professional care-giving, a growing number of older individuals must rely on family members for care. Such care-giving exerts a heavy toll on family members. Family caregivers have much higher rates of depression and overall mortality than age matched controls. A number of effective interventions for the caregivers of patients with dementia have been developed and tested.

An excellent example of an effective, family ► psychoeducational intervention for family caregivers of Alzheimer Disease (AD) patients has been developed and tested by Mittelman and colleagues (1996). These families attended individual and group instructional and problem-solving sessions where they learned how to manage many of the troublesome behaviors of patients with AD. They also attended an ongoing ► family support group and could access a crisis intervention service to help them with urgent problems. In Mittelman's study, the caregivers who received the intervention were less depressed and physically healthier than those that did not, and AD patients were able to remain at home for almost a year longer than in the control group. The savings in nursing home costs were several times the cost of the interventions.

Sorensen and colleagues (Sorensen et al. 2002) conducted a meta-analysis of 78 caregiver intervention studies representing six different types of interventions for different illnesses. They found a significant improvement across all six outcome variables ► caregiver burden, depression, subjective well-being, perceived caregiver satisfaction, ability/knowledge and patient symptoms). The effects were the smallest for caregivers of dementia patients and most consistent with the psychoeducational interventions. Group interventions had smaller improvements than individual interventions.

These studies of family interventions for family caregivers suggest that providing education and support for family caregivers is necessary, but not sufficient to reduce their burden and improve their emotional health. Family caregivers need more intensive interventions that include skills training and assistance with problem solving. Similar interventions for caregivers of patients who have suffered strokes have improved outcomes.

Prevention of Chronic Disease

Over one-third of all deaths in the United States can be directly attributable to unhealthy behaviors, particularly smoking, lack of exercise, poor nutrition and alcohol abuse. These behaviors account for much of morbidity from chronic illnesses, such as heart disease, cancer, diabetes and stroke. Health habits usually develop, are maintained, and are changed within the context of the family. Unhealthy behaviors or risk factors tend to cluster within families, since family members tend to share similar diets, physical activities, and use or abuse of unhealthy substances, such as smoking.

Several large trials have shown that family interventions can promote healthy lifestyles and improve cardiac risks within couples and families. In a meta-analysis of couple involvement in obesity treatment, Black et al. (1990) found a small, but significant improvement in weight loss for those individuals whose partners participated in treatment, but that the effect disappeared on long term (1–3 years) follow-up. Studies of childhood obesity are more encouraging. Parental involvement in these weight reduction programs show clear superiority over individual treatments.

Smoking remains the number one public health problem in much of the world and is strongly influenced by the family. The initiation of smoking is influenced by whether other family members smoke. Smokers tend to marry other smokers, to smoke the same number of cigarettes, and to quit at the same time. Smokers married to non- smokers or to supportive partners are more likely to quit. Nine randomized controlled trials involving over 1700 subjects have examined the impact of partner support in smoking cessation. These

studies add a social support intervention to a traditional smoking cessation program which include nicotine replacement, behavioral therapy, and relapse prevention. The results have been disappointing, and a meta-analysis found no overall impact of partner support on smoking cessation (Park et al. 2002). In most of these studies, the amount of partner support reported by the smokers continued to predict successful smoking cessation, but few of the interventions had any impact on the level of partner support. These results suggest that partner support is important for smoking cessation, but that it is difficult to increase levels of support.

Conclusions

Effective family interventions have been developed and tested for some physical disorders and there are promising ones for others. Family interventions have not been developed or tested for many chronic physical illnesses. Family psychoeducation which provides both specific problem solving and coping skills is the most effective type of family intervention. It has wide appeal and applicability to numerous disorders. There are too few studies of ► family therapy for physical disorders to comment on its effectiveness, although family therapy is likely to be directed to a much more limited group of ► dysfunctional families.

Family interventions are most effective at each end of the life cycle when medical care is provided by family caregivers. The most successful family interventions have been in the treatment of family caregivers of dementia patients. These interventions have saved money as well as improved outcomes. Family interventions for childhood disorders, especially diabetes and asthma, are effective in improving medical as well as psychosocial outcomes. Family involvement for health promotion and disease prevention programs offers great promise.

This research suggests that family professionals have an important, but unmet role in the research and treatment of physical illness. Very few of these studies have been designed by family researchers, and much more research is needed. Family professionals should be a part of health care teams, offering support and interventions for family members. The field of families and health is a promising one with multiple research and clinical opportunities for family professionals.

Family Medicine

Synonyms

Family practice

Definition

Family medicine is concerned with the provision of continuing and comprehensive health care for the individual and family. Family medicine integrates the biological, clinical, and behavioral sciences and it comprises all ages, sexes, and organ systems and every disease entity.

Family Physician

► General Practitioner

Family Planning

Definition

Family planning is the deliberate effort by couples or by individuals to plan reproduction and family building prior to ► conception. These efforts include decisions about desired family size, the timing or spacing of births, and whether to adopt or to give birth naturally. Methods of family planning include those designed to prevent pregnancy, as well as those designed to assist reproduction. Family planning programs assist couples and individuals achieve their family planning goals.

Family Practice

► Family Medicine

Family Structure

Definition

The structure of relationships between persons living in the same household who recognize themselves as a single, inter-connected unit. The structure may include biological relationships determined by shared genes (e. g. biological mother and child) as well as non-biological relationships (e. g. husband and wife, or stepbrother and stepsister). The composition of these relationships denotes the family structure and it may range in complexity from a single-parent household to a multi-generational family with adopted and fostered children.

Family Support Group

Definition

Family support group refers to an organized group of families which share similar medical, psychiatric or other problems and meet regularly to provide emotional and/or instrumental support for each other. Family support groups may be led by a professional or lay person.

Family Therapy

Definition

Family therapy is a form of psychotherapy where the focus is on the family and the goal is to improve family relationships. Family therapy is often used when an individual's symptomatic behavior (e. g. eating disorder) is thought to result from family dysfunction ► dysfunctional family).

Family Tree

Synonyms

Pedigree

Definition

Drawing of the family history over at least three generations by use of clear and consistent symbols to document genetic information.

Family Violence

► Intimate Partner Violence

Fatal Occupational Accident

Definition

A fatal occupational accident is defined as an accident which leads to the death of a victim within one year of the accident. The limit of one year after the accident is accepted in a number of countries but there is a huge variation among countries in this field. Some countries use the term only for occupational fatalities before

contact with the medical service. For those resulting in death of the victim after contact with the medical service, they use the term "occupational accident with fatal outcome" which is quite similar to the original definition of fatal ► occupational accident. Therefore, to avoid misclassification in international data comparisons, one must check the exact meaning of fatal occupational accident in the countries compared.

Fault

Synonyms

Blame

Definition

Fault is a legal term under private liability law. It applies under contract liability as well as under tort law liability. It indicates whether a person is responsible under private law for a certain act or omission and its respective results. If a person acted at fault, the outcome of his doing is attributable to him under private liability law. Fault has several potential manifestations. The term includes "intentional acts and omissions" as well as involuntary "negligent acts and omissions".

Fault-Based Liability

Synonyms

Fault liability

Definition

The term indicates a particular type of liability under private law. For most liabilities under private law, a person must have acted at fault. Liability under tort law and contract liability are to the largest part fault-based liabilities. ► Fault.

Fault Liability

► Fault-Based Liability

Favoritism

Synonyms

Discrimination

Definition

Favoritism refers to unfair treatment of a person or group on the basis of some kind of prejudice.

Cross-References

► Confounding and Interaction
► Prejudice

F

Febrile Seizures

Synonyms

Febrile convulsions

Definition

Febrile seizures are cerebral convulsions, which appear in connection with a febrile illness, in most cases during a rapid rise of body temperature. Of all children between the ages of six months and five years 2.5–4% develop febrile convulsions at least once; the recurrence risk is about 30%. Usually, febrile seizures are characterized by a loss of consciousness and tonic-clonic movements of the extremities. In general, the prognosis is very good, febrile seizures only rarely develop into epilepsy (about 1% in the absence of further risk factors like complicated seizures or a positive family history for epilepsy). Therapeutic measures include the administration of antipyretics (for example paracetamol or ibuprofen) and diazepam as an anticonvulsant drug. The risk of recurrence can be reduced by the use of diazepam in cases of febrile illness.

Fecal-Orally Transmitted Diseases

Synonyms

Smear infections; Infections by contaminated food; Food-Borne infections

Cross-References

► Food-Safety and Fecal-Orally Transmitted Infectious Diseases

Fecundability

Synonyms

Monthly chance of pregnancy

Definition

Fecundability represents the probability that a woman will conceive during a menstrual cycle. It can either refer to an individual (measured over time) or to a population (measured as the number of conceptions occurring in one month).

Fecundity

Synonyms

Fertility

Definition

Fecundity represents the physiological capacity to conceive.

Fee-for-Service

Synonyms

FFS

Definition

Physician income in fee-for-service systems is determined by the number of services multiplied by the price of services.

Cross-References

► Indemnity Insurance Plan

Fee-for-Service Indemnity Health Insurance

Definition

Fee-for-service indemnity health insurance refers to conventional private health insurance in the US, although this type of health insurance can be found in other countries as well. Fee-for-service indemnity health insurers place few restrictions on the choice of providers and, maybe more importantly, remunerate physicians by paying a fee for service.

Fee-for-Service Payment

Definition

Fee-for-service payment is a payment method of physicians in which they receive their income according to fixed fees per service. Each health care service provided corresponds to a specific payment by the health insurance. The fees per service are subject to negotiation between the insurance companies and the physicians. The payment system of physicians is seen as a mechanism to achieve policy objectives such as controlling health care cost or improving ► health care quality. Under the fee-for-service payment physicians may have the tendency to provide more services than needed to improve their income. For cost containment reasons, insurances try to keep the fee per service as low as possible.

Fee-for-Service Population

Definition

Fee-for-service population in healthcare describes the part of population that pays physicians on a fee-for-service basis for the delivery of health care services. Demand for these health care services is individually driven by the advent of a generally acute disease. In contrast to the fee-for-service population there is the part of the population receiving health care services according to disease management programs or other managed care arrangements. In these cases health care services are delivered by a form of managed care organizations (► health maintenance organizations, ► disease management organizations) that coordinates and controls health care services with their own provider network.

Feeling of Itchiness

► Itching

Female

► Sex/Gender

Female-Factor Infertility

Definition

Female-factor infertility is the kind of infertility in which the cause or causes can be attributed to the female partner. Most often female-factor infertility is a result of ovulation disorders or the conditions of the fallopian tubes, uterus, or cervix.

Cross-References

► Infertility

Female Genital Cutting

► Female Genital Mutilation

Female Genital Mutilation

Synonyms

Female genital cutting

Definition

Female genital mutilation comprises all procedures involving excision or tissue removal of any part of the female genitalia for cultural, religious or other non-medical reasons. The most common type of female genital mutilation is excision of the clitoris and the labia minora, accounting for up to 80% of all cases; the most extreme form is infibulation (excision of part or all of the external genitalia and stitching/narrowing of the vaginal opening), which constitutes about 15% of all procedures. Immediate complications are severe pain, shock, hemorrhage and infections. Long-term consequences include keloid scar formation, urinary incontinence, dyspareunia, cysts, abscesses and childbirth complications.

Fertility

ANDREEA A. CREANGA, AMY O. TSUI
Population, Family and Reproductive Health, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, USA
acreanga@jhsph.edu, atsui@jhsph.edu

Synonyms

Fecundity

Definition

Fertility is the ability to conceive and produce a live birth. The term, initially applied to females, increasingly refers to males also, as reproductive mechanisms of both men and women become better understood. Human fertility is influenced by a wide range of factors. Direct influences include coital frequency, birth control practice, voluntary and involuntary fetal loss, lactational amenorrhea, and primary and secondary sterility. All other factors, such as endocrinological, nutritional, cultural, economic, or social – work indirectly through these proximal influences. Fertility rates are measured in terms of the number of live births per woman-year of exposure for a given period of time, usually one year. Variation in the quantity and timing of births has been the subject of extensive study, and the consequences of reproductive patterns are linked to many public health concerns.

Basic Characteristics

Physiology

The process of natural fertilization is achieved when the male and female reproductive organs are functioning without any abnormalities or disruptions. To conceive a child, a woman must release a mature egg from one of

her ovaries through a process called ovulation, and her male partner must ejaculate millions of mature, motile sperm. A woman is most likely to be fertile 10 to 14 days after the start of the menstrual cycle. A sperm must reach and penetrate the egg as it travels from the ovary to the uterus. Once the egg has been fertilized, cell division begins; the embryo drifts down the fallopian tube, reaches the uterus and anchors itself to the wall of the uterus where it develops into a fetus.

Measurement

The expanded availability of census, survey and vital registration data since the 1970s has improved the accuracy and availability of multiple fertility measures. The most commonly used one, the ► total fertility rate (TFR), is defined as the average number of live births a woman would have if she were subject to, throughout her reproductive life, age-specific fertility rates observed in a given year. The ► age-specific fertility rate (ASFR) is the annual number of births to women in a particular age group per 1000 women in that age group. The TFR is the sum of the ASFRs over reproductive ages. ► Fertility replacement is defined as the level at which a cohort of women on average have only enough children to replace themselves and their partner in the population – for example, a TFR of 2.1 children replaces the couple with some allowance for early child loss.

While TFR estimates are not affected by a population's age structure, they can appear to change more quickly when calculated for different periods than when calculated for specific age cohorts. This is because a birth cohort's actual fertility rates usually change more slowly than those prevailing at different points in time which are then applied synthetically to derive the period TFR. Examples of measures of the timing of fertility include mean ages at first and last birth and average birth interval length.

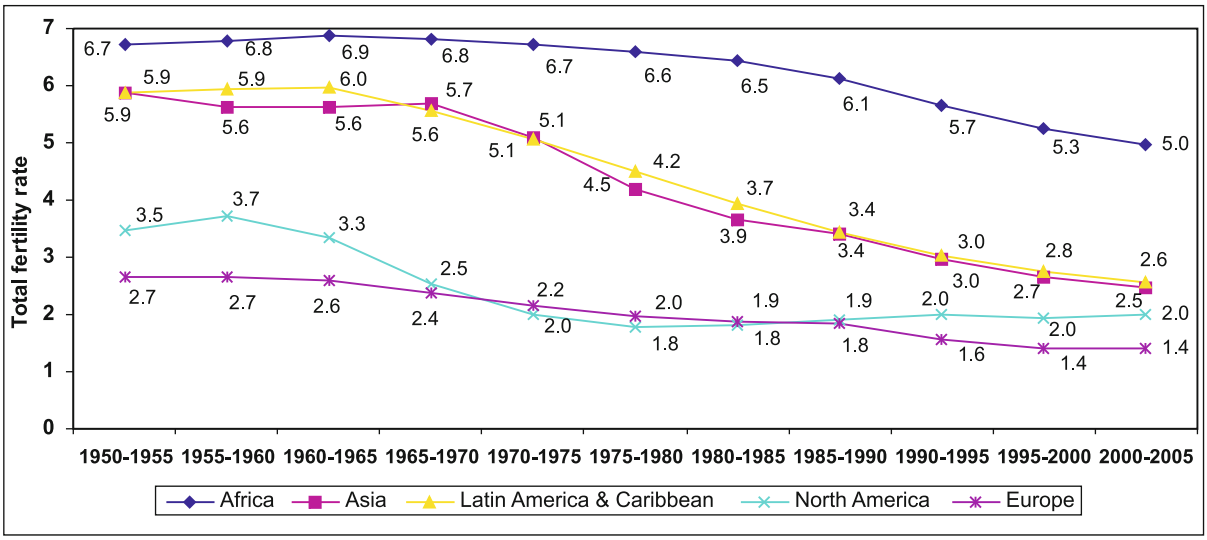
Levels and Trends

Reproduction is essential to the survival of societies, and over the past half century global fertility levels have changed dramatically. The declines visible in all regions of the world historically began as far back as 300 years ago for Europe, in the 1960s for some Asian countries and as recently as the 1990s for a few sub-Saharan African countries. Most countries in this latter region have yet to experience a fertility transition, and several have plateaued unexpectedly. Figure 1 illustrates the trends in fertility since 1950, at which time North American and European TFR levels were already below an average of 3 children per woman. Over the past decade, below replacement fertility in these regions and East Asia has continued to decline slowly, from 1.8 children per woman in 1985–1990 to 1.6 children per woman in 1995–2000. The average TFR for less developed regions as a whole declined from 6.0 in 1950–55 to 3.1 children per woman in 1995–2000. These average declines conceal large differences across regions (UN 2003). Striking is the correspondent pattern of fertility declines for Asia and the Latin American regions, with their very different socio-cultural settings.

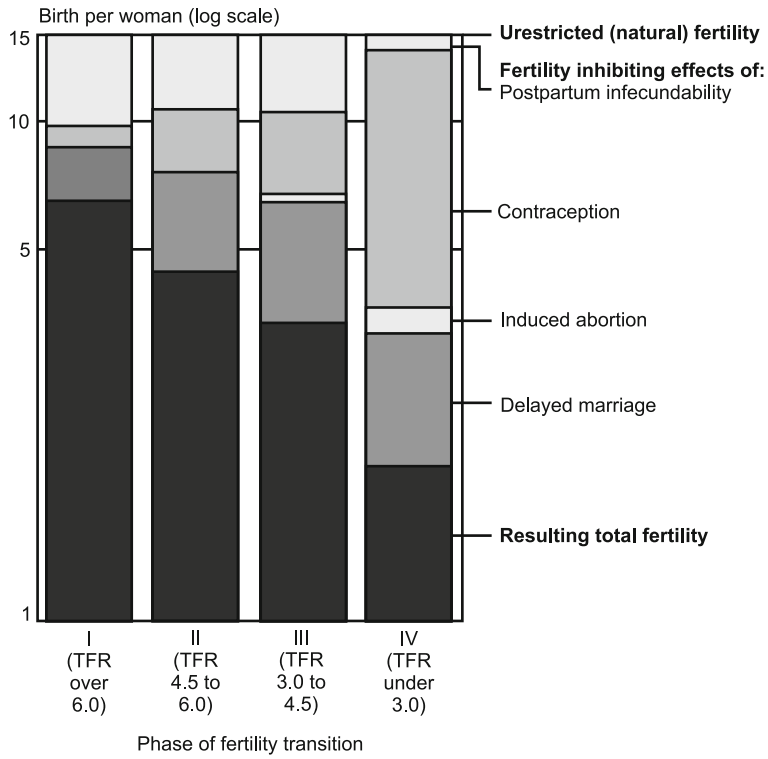
During the early stages of the transition, fertility tends to decline first among older childbearing aged women, lowering the mean age of childbearing. This drop tends to offset and exceed fertility reductions due to rising age at marriage among younger women. Several African countries serve as exceptions to this pattern, with fertility declines equally distributed across the prime childbearing ages (UN 2003). The shift toward below-replacement levels reflect delayed childbearing among women in their twenties (a tempo effect) and an increased proportion of women limiting childbearing at parities 1 and 2 (a quantum effect). The reproductive and child health consequences of the fertility transition are substantial, with fewer at-risk pregnancies resulting in maternal and child mortality and women spending less of their reproductive years pregnant. Some researchers wonder if the increased menstrual cycling of low-parity (► parity) females does not also raise the risk of some reproductive cancers, e. g., ovarian and uterine.

Factors Influencing Fertility

Bongaarts (1982) observed that as countries pass through the demographic transition from high to low fertility and mortality levels, four "proximate determinants" of fertility account for most of the difference between natural and observed reproduction – proportion of women married, contraception, induced abortion, and postpartum infecundability (► fecundability) due to breastfeeding. In this framework the relative importance of these factors varies with the phase of the fertility transition (see Fig. 2). It is through these direct



Fertility, Figure 1 Fertility levels in major world regions, 1950–2005. *Source:* UN Population Division (2005) World Population Prospects: The 2004 Revision



Fertility, Figure 2 Conceptual model of the changing contribution of contraception and other proximate determinants to fertility decline. *Source:* Bongaarts J (1982)

or proximate factors that external forces – industrialization, poverty, education, urbanization and other social changes – indirectly influence fertility.

► Contraception, as a means of fertility regulation, is considered one of the major public health achievements of the last century. Of the estimated 6.2 billion people living on the planet, approximately one billion are women aged 15 to 49 who are married or in union and more than three-fifths (61%) of these women are using contraception. Contraceptive use has risen historically in much of the developing world. It is already at ceiling levels of 80% in some countries and it will continue to

rise in many others. However, the pattern is uneven geographically, and a few of the most populous countries, such as India, Pakistan, and Nigeria and much of the sub-Saharan Africa, register low levels of use. A large majority (approximately 90%) of women using contraception rely on modern methods, with oral contraceptives and condoms being the most widely used methods in developed countries and female sterilization and intra-uterine devices (IUDs) in developing countries.

While abortion is not a method of contraception, whether it is a means of family planning is a matter of social definition. Worldwide an estimated 38% of pregnancies occurring each year are unintended, and approximately 60% of these end in an induced abortion (WHO 2005). Unsafe abortions, which are entirely preventable, account for 13% of maternal deaths. Abortion levels and trends are challenging to assess in settings where the procedure is not legal or carries a heavy social stigma. Research on fertility-regulating methods has also led to the development of treatment regimens, such as mifepristone or misoprostol, in the form of pills that terminate early pregnancies but, in the case of the latter, also manage postpartum hemorrhage during delivery. Because every ► pregnancy carries some mortality risk for the mother and fetus, pre-conceptional measures such as contraception assure that every pregnancy is intended, while access to adequate obstetric services ensures that every birth is safe. These are essential for good reproductive and public health.

The threat of reproductive impairment and loss from exposure to poor nutrition, infectious disease and sexually transmitted infections, especially HIV/AIDS, is disproportionately present in the developing world. In high HIV prevalence countries in sub-Saharan Africa, infected women become sub-fecund often at young ages and pregnant women affected by malaria show higher rates of fetal loss.

Infertility in the developed world has a different face of treatment. In Vitro Fertilization (IVF) is heralded as one of the greatest achievements of reproductive medicine. Still there are many aspects of IVF that have been both praised and criticized, and its legal, ethical and social repercussions have generated major debate and controversy. The capabilities of assisted reproduction are exemplified by the 2005 case of a 66-year-old Romanian woman, who after undergoing fertility treatment for almost ten years before being artificially inseminated, gave birth to a baby girl by caesarean section (BBC 2005). Today extending assisted reproductive technology to the approximately 80 million individuals in the developing world affected by infertility is a global reproductive health priority (WHO 2002).

Conclusion

Over the past decades, fertility trends in developing and developed regions of the world have changed dramatically. Low-fertility industrialized countries have adopted pro-natalist policies, while higher fertility developing countries have implemented anti-natalist policies. The specter of rapidly aging and even declining populations have brought forth contentious debates about international immigration policies in much of Europe.

Effective contraception has separated coitus from conception, enabling individuals to enjoy the former with minimal risk of the latter. Advances in reproductive medicine also have assisted persons with reproductive impairments or without lifetime partners to fulfill their desires for biologic parenting. Thus, contra-ception and pro-ception planning have entered the repertoire of mainstream reproductive behavior in many countries.

Small differences in fertility have large ramifications for the world's population. Projections show that a small difference in average family size – 2.5 vs. 2.0 children – in 2000 can translate into a difference of 1.7 billion additional people in the world's population by 2050 (PRB 2004). Aggregate population size depends intrinsically on individual decisions governing reproduction, survival and migration. Helping individuals achieve their reproductive intentions will have profound effects on overall fertility, population health, and societal wellbeing.

Fertility Rate

Definition

Fertility rate is defined as the total number of live births in an area to the female reproductive population of that area. It is typically expressed per 1,000 women of reproductive age, 15–44 years.

Fertility Replacement

Definition

Fertility replacement is defined as the level at which a cohort of women on average have only enough children to replace themselves and their partner in the population. For example, a TFR of 2.1 children replaces the couple with some allowance for early child loss. Replacement level fertility is said to have been reached when NRR=1.0 (► net reproduction rate (NRR)).

Fetal Death

► Intrauterine Mortality

Fetal Mortality

Synonyms

Still births or fetal death

Definition

Fetal mortality is defined as a still birth or death after 20 weeks gestation.

Cross-References

► Intrauterine Mortality

Fetal Mortality Rate

Synonyms

Stillbirth rate; Fetal death rate

Definition

Fetal mortality rate is the number of fetal deaths (death after the 20th or 28th week of gestation) per one thousand of the total number of births (live births plus fetal deaths) in the same year. This rate is considered a good measure of the quality of health care in a country or a medical facility. Fetal mortality rate is higher in certain ethnic groups and among mothers with health problems during pregnancy. It can be decreased by good prenatal care.

Fever

Synonyms

Elevated body temperature

Definition

Fever is an elevation of the body temperature, which is caused by an increase in the heat regulatory set-point (which is located in the thermoregulatory center in the

hypothalamus). Fevers can be classified as: sub febrile temperatures from 37.5–38.0 °C; moderate fever up to 38.9 °C; and high (septic) fever above 39 °C. Fever can develop for a number of reasons, like infections, destruction of cells or immune reactions. In fevers, biochemical reactions run faster, increasing the effectiveness of the defense mechanisms. The cause of the fever influences its course. Fevers can be classified as sustained or continuous, intermittent (daily temperature elevation that returns to normal), remittent (daily fever that returns to a baseline which lies above normal), undulating (wave-like) and recurrent or relapsing fever. Relapsing fever is characterized by short periods of fever interrupted by several days free from fever.

► Therapy of Infectious Diseases

Fever Attacks in Malaria

Synonyms

Course of fever in malaria; Temperature curve in malaria

Definition

In malarial infections, the duration of a fever attack depends upon the type of infecting plasmodia species; *Plasmodia ovale*, *P. vivax* and *P. malariae* 8–12 hours, *Plasmodium tropica* 16–36 hours, sometimes even longer. During the fever-free interval the asexual reproduction of the plasmodia takes place. The release into the circulatory system induces the next fever attack. Due to a synchronization of the reproduction, a characteristic rhythm of fever attacks is found during the course of the disease – except for infections with *Plasmodium tropica*, which do not synchronize their development. The fever-free interval lasts 48 hours in case of infection with *Plasmodia ovale* and *P. vivax*, and 72 hours for *Plasmodium malariae*. Due to the lack of synchronization there is no characteristic temperature curve in infections with *Plasmodium tropica*.

First-Aid Services

Synonyms

First aid at work

Definition

First aid is the immediate care given to victims of accidents before trained medical workers arrive. Its goal is to stop and, if possible, reverse harm. It involves rapid and simple measures such as clearing the air passageway, applying pressure to bleeding wounds or dousing chemical burns to eyes or skin. The critical factors which shape first aid facilities in a workplace are work-specific risk and availability of definitive medical care. First aid is a fluid concept not only in *what* (how long, how complex) must be done, but in *who* can do it.

First aid is a part of the total health care for workers. First aid and emergency treatment in cases of accident and indisposition of workers at the workplace are listed as an important part of the functions of the occupational health services in the ILO Occupational Health Services Convention and related Recommendation.

Different institutions may be involved in the organization of first aid and providing assistance following an accident or illness at work include the following: the occupational health service of the enterprise itself, other occupational health entities and, other institutions which may provide services, such as ambulance services, public emergency and rescue services, hospitals, clinics and health centers, both public and private; private physicians, poison centers, civil defense, fire departments and police. According to OHS legislation first aid provision is employer responsibility.

In some branches of the economy, like underground mining, there are rescue squads usually staffed by specially trained employees and emergency technicians

that provide first-aid services in confined spaces, mines, etc.

Fisher LSD

Synonyms

Least squares method; Post hoc test; Multiple comparisons

Definition

A method of fitting a straight line or curve based on minimization of the sum of squared differences (residuals) between the predicted and the observed points.

Fisher's Exact Test

Definition

This test is applied in 2×2 ► contingency tables analysis when the sample size is too small to use the ► chi-square test (see essay Analysis of frequencies). The test has no formal test statistic and critical value, and directly computes the probability of observed data. Calculation of probabilities in this test is based on hypergeometric distribution. The test procedure consists of calculating the sum of exact hypergeometric probabilities associated with the observed table frequencies and all the more extreme table frequencies under the null hypothesis. If this sum of probabilities is equal to or less than the specified significance level, the null hypothesis is rejected and it is concluded that there is a significant relationship between the two dichotomous variables. If the sum of probabilities is greater than the specified significance level, the null hypothesis cannot be rejected.

Fisher's Test

Definition

An exact significance test to analyze 2×2 tables for any sample size. It is a misconception that it is suitable only for small sample sizes. This arises from the demanding computational procedure for large samples, which is no longer an issue. It is the only test for a 2×2 table when an expected number in any cell is smaller than 5.

Fissure Sealing

► Dental Sealant

Fitness

► Physical Activity

Fitness for Work

Synonyms

Work capacity; Work ability

Definition

Fitness for work is an individual's capacity to do the work tasks he/she is required to do. This includes the ability to maintain physiological equilibrium when working at these tasks. To meet this requirement certain functional, anatomical, psychological, educational, and social characteristics are necessary to fulfill the demands of a specific job performance. Work ability cannot be measured only by the actions of a worker as factors related to the community, environment, organization and management of the work determine how a person is coping.

Evaluating workplace capacity involves assessing the ability of the body's biological features to meet the specific demands of a job. The evaluation of the fitness for work is a continual, dynamic, and permanent process,

and includes measuring workers' capacities to work at specific workplaces without endangering their health.

Food Allergies

Definition

A food allergy is an allergic reaction to a particular food. Many different foods can cause allergic reactions. Most commonly they are triggered by certain nuts, peanuts, shellfish, fish, milk, eggs, wheat, and soybeans. Additives such as, monosodium glutamate, metabisulfite, tartrazine can cause allergy. Allergic reactions to foods may be severe and sometimes include an anaphylactic reaction. Allergies may start during infancy. They are most common among children whose parents have food allergies, allergic rhinitis, or allergic asthma. Food allergies are sometimes blamed for such disorders as hyperactivity in children, chronic fatigue, arthritis, poor athletic performance, and depression. Food intolerance differs from a food allergy in that it does not involve the immune system. Instead it involves a reaction in the digestive tract that results in digestive upset.

Food-Borne Diseases

► Food Safety

Food-Borne Infections

► Fecal-Orally Transmitted Diseases

Food Decay

Synonyms

Food rot; Food spoiling; Food going bad

Definition

Besides the influence of air, water and light, microorganisms play an important role in food decay. Germs like bacteria and fungi do not only rot food, they can also cause diseases when the contaminated food is eaten. If food is improperly stored or kept too long, chemical changes of the contained fats take place inducing an unpleasant smell or taste. Furthermore, food qualitiy is influenced by the effect of enzymes, which are still active in the foodstuff. Microorganisms, which make food rot, are bacteria, yeasts and molds. When food goes bad, not only is there a change in taste but sometimes poisonous substances, toxins, are produced.

Food Hygiene

► Food Safety

Food Safety

GORDANA RISTIC
University of Belgrade, Faculty of Medicine, Institute of Hygiene and Medical Ecology, Belgrade, Serbia
risticg@eunet.yu

Synonyms

Food hygiene; Foodborne diseases; Foodstuffs safety

Definition

Food safety presents a major health problem in the world. There are more than 250 food-borne diseases registered. Serious outbreaks of food-borne disease have been documented on every continent every year, illustrating the public health and social significance of this problem. Food-borne diseases may affect all levels of the population, but the most susceptible are children, pregnant women, the elderly, and those with chronic diseases. Modern farming methods, globalization of the food trade and the higher accessibility of food produce a challenge for food safety and the prevention of the spread of food contaminants worldwide. Food safety programs are focusing on the farm-to-table approach as an effective means of reducing food-borne hazards. ► hazards may emerge from microbiological, chemical or physical contamination of food. Health significance of these hazards is estimated through ► risk assessment method, and thus hazards are regulated, controlled and kept under surveillance.

F

Basic Characteristics

Microbiological Hazards

Food-borne diseases caused by microorganisms present a major health issue. The most frequent infections are caused by *Escherichia coli, Salmonella, Campylobacter jejuni, Listeria monocytogenes*, parasites like *cryptosporidium, cryptospora, trematodes* and viruses. According to WHO data almost 1.8 million children die each year in developing countries (excluding China) from diarrhoeal disease caused by microbes which are present in food and water. In the USA each year some 100 million cases are attributed to food-borne illnesses, resulting in 325 000 hospitalizations and about 5000 deaths. Health experts estimate that the yearly cost of all food-borne diseases in the USA is 5 to 6 billion dollars in direct medical expenses and lost productivity. Infections with the bacteria *Salmonella* alone account for $ 1 billion yearly in direct and indirect medical costs (NIH 2005).

Five most frequent food-borne diseases are:

- Botulism
- Campylobacteriosis
- *E. coli* infection
- Salmonellosis
- Shigellosis

Botulism is a disease caused by *Bacillus botulinum*, an agent emerging from soil. The most common sources are canned meat and vegetables and the production of toxin can be regulated by controlling the acid pH of food.

Campylobacteriosis is an infectious disease caused by *Campylobacter* bacteria. *Campylobacter jejuni*, *C. fetus*, and *C. coli* are the types that usually cause campylobacteriosis in people. *C. jejuni* causes most cases of the illness. Infection can be caused by handling raw poultry, eating undercooked poultry, drinking nonchlorinated water or raw milk, or handling infected animal or human feces. Most frequently, poultry and

cattle waste are the sources of the bacteria, but feces from puppies, kittens, and birds also may be contaminated.

Escherichia coli* infection** is caused by different strains of ***E. coli bacteria. Harmless strains of *E. coli* can be found widely in nature, including the intestinal tracts of humans and warm-blooded animals. Disease-causing strains, however, are a frequent cause of both intestinal and urinary-genital tract infections. Several different strains of harmful *E. coli* can cause diarrheal disease. A particularly dangerous type is called enterohemorrhagic *E. coli*, or EHEC. EHEC often causes bloody diarrhea and can lead to kidney failure in children or people with weakened immune systems.

In 1982, scientists identified the first dangerous strain in the United States. The type of harmful *E. coli* most commonly found in this country is named O157:H7, which refers to chemical compounds found on the bacterium's surface. This type produces one or more related, powerful toxins which can severely damage the lining of the intestines. This strain is now found worldwide and present one of the most toxic bacterial sources to be found in food and water.

Salmonellosis, is usually provoked by *Salmonella typhimurium* and *S. enteritidis*. *Salmonella* bacteria can be found in food products such as raw poultry, eggs, and beef, and sometimes on unwashed fruit. Food prepared on surfaces that previously were in contact with raw meat or meat products can, in turn, become contaminated with the bacteria. This is called cross-contamination.

With the spread of organic farming new cases are recorded from eating raw alfalfa sprouts grown in contaminated soil. Salmonella infection frequently occurs after handling pets.

Shigellosis, also called bacillary dysentery, is an infectious disease caused by *Shigella* bacteria. Four main types of *Shigella* cause infection: *Shigella dysenteriae*, *S. flexneri*, *S. boydii*, and *S. sonnei.* It is commonly transmitted by food service workers who are sick or infected, but have no symptoms, and who do not properly wash their hands after using the toilet.

Listeria monocyotogenes is a bacterium that can cause a serious infection in humans called listeriosis. Food-borne illness caused by *L. monocytogenes* in pregnant women can result in miscarriage, fetal death, and severe illness or death of a newborn infant. Others at risk for severe illness or death are older adults and those with weakened immune systems. Listeriosis is now attributed to ready-to-eat foods and deli products.

Food-borne Viruses

Diarrhea can be caused by viruses present in food and water such as: caliciviruses, rotavirus, astrovirus, and hepatitis A virus. Norwalk virus (a particular calicivirus) caused a number of outbreaks of food poisoning at buffets and caterings. Current studies are trying to produce new vaccines including edible vaccines against Norwalk virus and hepatitis. Recently, inactivated vaccine for hepatitis A virus infection has been developed.

Prions. Mad Cow Disease is the commonly used name for Bovine Spongiform Encephalopathy (BSE), a slowly progressive, degenerative, fatal disease affecting the central nervous system of adult cattle. The exact cause of BSE is not known but it is generally accepted by the scientific community that the likely cause is infectious forms of a type of protein, prions, normally found in animals cause BSE. In cattle with BSE, these abnormal prions initially occur in the small intestines and tonsils, and are found in central nervous tissues, such as the brain and spinal cord, and other tissues of infected animals experiencing later stages of the disease. There is a disease similar to BSE called Creutzfeldt–Jacob Disease (CJD) that is found in people. A variant form of CJD (vCJD) is believed to be caused by eating contaminated beef products from BSE-affected cattle. To date, there have been 155 confirmed and probable cases of vCJD worldwide.

Chemical Hazards

Chemicals are a significant source of food-borne diseases, but it is sometimes difficult to link them to particular food. Chemicals include: natural toxicants such as ► mycotoxins and marine toxins, environmental contaminants such as mercury, lead, radionuclides and ► dioxins, but, also, naturally occurring chemicals in plants, such as glycoalkaloides in potatoes. Migration from packaging material has, also, been investigated and Acrylamide as a chemical compound that migrates is widely studied. Food additives and nutrients such as vitamins and minerals, pesticides and veterinary drug residues are used deliberately in order to increase food supply, but assurance that they are safe must be obtained prior to their use. Chemical contaminants may affect health through single use, but most commonly

they act after long-term exposure. Risk assessment must be performed in order to assess the potential for causing diseases after exposure to chemicals in food and water.

New Technologies

Genetic engineering, irradiation of food, ohmic heating and modified atmosphere packaging are used to increase agricultural production, extend shelf life or make food safer. Potential for causing ► food allergies should be carefully examined, as well as other possible changes. Food produced from or using ► genetically modified organisms (GMO) must be proven to be equivalent to conventionally produced food in terms of nutritional value and safety.

Control of Food Safety

Control over food safety must be performed through the whole food chain. It combines ► good agricultural practices (GAP) in basic production of food commodities, with ► good manufacturing practices (GMP) and ► standard sanitary operating procedures (SSOP) in food processing premises. The best way of controlling hazards in food production proved to be ► hazard analysis and critical control point (HACCP) – a preventive approach to identification and control of all possible hazards to be found in production of a certain foodstuff.

Conclusion

Access to safe food is one of the basic human rights. In spite of this, food-borne diseases still present major health problem both in developing and industrialized countries. Contaminants may be naturally occurring, but due to new agricultural techniques and demands for certain qualities and extended shelf-life of products, new pathogens are discovered along with classic ones. A holistic approach to food safety requires control of potential hazards throughout the food chain and this preventative approach should be fostered instead of the classic method of spot checking and analyzing of final products.

Food-Safety and Fecal-Orally Transmitted Infectious Diseases

Monika Korn
Klinik für Kinder– und Jugendmedizin,
Friedrich Ebert Krankenhaus GmbH,
Neumünster, Germany
hkorn80663@aol.com

Synonyms

Smear infections; Infections by contaminated food

Definition

In fecal-oral infections germs, which had been expelled with the feces of an animal or another human being, are swallowed. Most frequently, the pathogens are transmitted by contaminated foodstuff or polluted water; transmission is also possible by close contact with a chronic carrier of the organisms or by self-infection (re-infection).

Transmission of Diseases by Foodstuff

Humans feed on animal and vegetable products. Thus they are omnivores. To be suitable as a foodstuff, a product has to be edible. From edible food one has to distinguish substances, which are inedible but do not cause any harm and those, the ingestion of which is harmful or even toxic. A foodstuff, which in general is edible, not only can become unpalatable through ► food decay, but also can become damaging to one's health if eaten. Moreover, the ingestion of particular products can be dangerous for certain groups of persons, for example, due to their age (in case of babies) or due to underlying diseases. In the case of poisonous substances in foodstuff (toxins), two forms are identified: toxin-building microorganisms – like *Clostridium botulinum* (► *Clostridium botulinum* infection) or ► molds – where the toxin is already present in the foodstuff at the moment of ingestion, and microorganisms which set free toxins in the intestines – like *Salmonellae* or *Clostridium perfringens* (► *Clostridium perfringens* infection, enteral). A number of pathogens can be transmitted by foodstuff. These pathogens can be viruses, bacteria, ► protozoa or ► parasites (particularly worms). The germs, which had been shed with human or animal excrements (feces), are taken up orally with the food and lead to a fecal-oral infection, which – in most cases – manifests in the gastrointestinal tract. Gastrointestinal diseases with diarrhea are very common in childhood; worldwide, they are the cause of death in about 2 million children under the age of five years. Foodstuff can be contaminated by pathogens in different ways. To begin with, the meat and other products can come from an already infected animal. Food can also come into contact with fecal germs from fertilizers or water used in the growing process, or by washing with contaminated water in the production process. Moreover, persons, who shed pathogens with their stool – either in an acute phase of the disease or as ► permanent shedders – can transmit pathogens to food because of poor personal hygiene. Transmission of pathogens onto foodstuff is also possible by insects, especially flies, which have come into contact with feces. Due to the close contact with each other and the disregard of hygienic rules, young children face a special risk of fecal-orally transmitted infectious diseases and this age-group tends to suffer repeated self-infections (re-infections).

Prophylaxis of Fecal-Oral Infections

Different microorganisms play an important role in food decay. As diseases can be caused after ingestion, rotten food should not be eaten. The shelf life of foodstuff can be lengthened by various means of preservation (► preservation of food). In general, hygienic rules should be followed when dealing with food, like washing the hands with water and soap before preparing a meal. "Cook it, boil it, peel it, or forget it" – this phrase is of decisive significance in developing countries. Travelers especially should follow this recommendation. Boiling and frying kills pathogens; but one has to make sure that sufficient temperatures are also reached in the center of the foods. Pathogens, which are present in milk, can be killed by ► pasteurization; young children should not drink raw milk. Only washing foods like fruits or vegetables may not be sufficient; on the contrary, if contaminated water is used, germs can even be transmitted by this procedure. Pathogens on the surface can be eliminated by peeling. Regarding the storage of food, one should pay attention to avoiding the transmission of germs onto other foods (salad, other vegetables, fruits). Minced meat should be used immediately, in case of frozen meat the melting water should be disgarded. To avoid spreading fecal germs, hands should be washed with water and soap after using the toilet, and even a disinfection of the hands may be necessary. The same hygienic rules have to be followed after contact with possibly contaminated objects (e. g. diapers) or surfaces. In the case of a professional dealing with foodstuffs, strict hygienic instructions have to be kept to avoid infections. On the one hand, these regulations serve to protect the employ-

ees; on the other hand, they are important for the security of the consumers. At a work place where there is a risk of transmission of infectious diseases, protective clothing, hygienic regulations and measures of disinfection, as well as the prohibition of the consumption of food, can help to minimize the staff's risk of infection. According to special regulations within the industrialized countries, people with confirmed or assumed fecal-orally infectious diseases are not allowed to work in the production, treatment or distribution of foodstuffs, or where there is an open contact with the food. Further regulations concern work in communal services and special sectors of the health care system. Fecal-orally transmitted infectious diseases have to be reported to the responsible public health institutions.

Viral Gastrointestinal Infections

The most important viral pathogens, which cause infections of the gastrointestinal tract, are rotaviruses, Noro-(Norwalk-) viruses and adenoviruses. The most typical symptoms are stomach ache, vomiting and diarrhea, fever and malaise can also be present. The amount of fluid loss (dehydration) determines the severity of the disease. As antibiotics are not effective in viral infections, therapy is restricted to a re-establishment of the ► body fluid balance. In mild cases, this can be achieved by the administration of an ► oral rehydration solution; in severe forms, parenteral fluid therapy may be necessary. Worldwide, rotaviruses are the most common reasons for gastrointestinal infections in children between the age of 3 and 24 months. The hygienic status does not play any role as the incidence of the infection is the same in developing and in industrial countries. Rotaviruses are highly contagious and outside the macroorganism the virus can survive on objects and surfaces. After oral intake, the virus becomes adherent to the mucous membranes of the intestines. As intestinal cells are destroyed diarrhea results. Lethal cases of the disease primarily occur on the Indian subcontinent, in African countries and in South America. Due to the high incidence of rotavirus diseases, the health care systems of industrial nations face considerable costs. The most effective means of prevention is active ► rotavirus vaccination. Like the rotavirus, the Noro-(Norwalk-) virus, which was first detected in 1972, is spread worldwide. Infection primarily concerns young children and older people. In most cases, the virus is transmitted by fish and seafood. After an incubation period, from a few hours to a couple of days, the characteristic symptom of sudden onset of diarrhea occurs. In general, the gastrointestinal symptoms lasts for 2–3 days. Although severe cases are possible, a deadly outcome is very rare. Unfortunately, vaccination against Norovirus is not available. Depending on the serotype, adenoviruses cause different clinical pictures. The serotypes 1, 2, 5, 6, 40 and 41 are responsible for gastrointestinal symptoms. Most frequently, children between the age of 6 months and 5 years are concerned, the incubation period lasting 2–10 days. Severe cases are rare and the infection is self-limiting. Vaccination against adenoviruses is not available.

Hepatitis A

The worldwide spread hepatitis A virus (HAV) causes an inflammation of the liver, which frequently is asymptomatic. The incubation period lasts 2–9 weeks. Every year there are about 2 million new cases, which, fortunately, leave the infected patients with lifelong immunity. In general, transmission takes place by the ingestion of contaminated foodstuff (most commonly oysters, other seafood or crawfish) and drinking water; infection can also be transmitted as a smear infection, during sexual intercourse or by blood transfusions. In warm countries with an insufficient hygienic status, there is a high risk of infection. Typical symptoms of hepatitis A-infection are malaise, headache, rheumatic pains, stomach ache and jaundice (icterus); sometimes there is a strong itching. The urine is dark-colored, while the stool becomes light-colored. Diagnosis is confirmed serologically by the detection of antibodies. Two weeks before and 1–2 weeks after the onset of the disease or the icterus, the infected person is assumed to be contagious. Usually, the symptoms disappear within 2–3 weeks, chronic courses or deadly outcomes are rare. As medicinal therapy is not possible, treatment is reduced to measures like confinement to bed and a carbohydrate-enriched and low-fat diet. The most effective prophylactic measure is the active hepatitis A vaccination (► hepatitis A immunization, active).

Campylobacter Infections

Besides *Salmonellae*, *Campylobacter* (*C. jejuni*, *C. coli*, *C. lari*) are the most common causes of bacterial gastrointestinal infectious diseases. Ingestion of more

than 500 pathogens gives rise to infection. The germs, which are found in the intestines of animals, predominantly poultry, can get into the meat during slaughtering. The infection cannot only be transmitted by poultry, but also by minced meat, unpasteurized milk, or contaminated drinking water. Moreover, transmission is possible by direct contact with infected animals. If bacteria are shed in the feces, foodstuff or inshore waters can be contaminated. Thus, an infection can also appear after bathing in polluted water. Following an incubation period of 2–5 (1–10) days, diarrhea, fever, headache and rheumatic pains appear. Most frequently, it is children under the age of five years who are affected but people who have a close contact with animals face an increased risk of infection.

Infection with *Salmonellae* / Salmonellosis

Among others, diseases which are caused by *Salmonellae*, are typhoid (► typhoid fever), ► paratyphoid and salmonella enteritis. The latter is primarily caused by *Salmonella enteritidis* and *Salmonella typhimurium*. The sources of infection lie in farm animals, wild animals, sea-birds and fish. As for *S. enteritidis*, most frequently the infection is transmitted by poultry, eggs, mussels and fish. *S. typhimurium* can primarily be found in products of cattle, calves and pigs. Following an incubation period of 5–72 hours, watery, often slimy and sometimes bloody, diarrhea occurs along with stomach ache, vomiting and fever. The pathogens are detected in the stool. In general, therapy is restricted to the substitution of fluid losses. Usually, antibiotics are not administered as their administration lengthens the interval of germ shedding.

Enterohemorrhagic Escherichia Coli Infection (EHEC)

Escherichia coli (*E. coli*) bacteria are part of the natural intestinal flora. Therefore, coli bacteria are used as so-called indicator-germs to check for pollution of drinking water and foodstuff by fecal pathogens. Different strains of *E. coli* can cause intestinal diseases (enteritis infectiosa), which are characterized by diarrhea. One of these strains are enterohemorrhagic *E. coli* (EHEC), which can produce cellular toxins (shigatoxin or verotoxin). EHEC, which were detected in 1977, are resistant against environmental influences (low pH-value, drying out, high salt concentration); furthermore, they and highly contagious. EHEC 0157 can cause an infection even if as little as 100 germs are ingested. Natural reservoirs of EHEC are found in the intestines of cattle, sheep and goats. Infections are primarily caused by the ingestion of foodstuff of animal origin; but transmission can also take place by polluted drinking water or vegetables which were contaminated by dung. Moreover, transmission is either possible directly from an animal to a human or from one human to another (by the hands), or indirectly by contaminated objects or surfaces. The incubation period lasts a few days and contagiosity 5–20 days. A severe complication is the occurrence of ► hemolytic uremic syndrome (HUS). Usually, no antibiotic therapy is performed in EHEC-infections as the interval of germ shedding would be lengthened and the building of toxins would be stimulated.

Yersinia Infection / Yersiniosis

Yersinia are transmitted by contaminated foodstuff or direct contact with infected animals (primarily pigs, cats and dogs), their feces or other contagious body fluids. The incubation period is 1–14 days and bacteria can be detected in the stool. *Yersinia enterocolitica* causes an acute enteritis with watery, often slimy and sometimes bloody diarrhea. Moreover, stomach ache, vomiting and fever are present. Diarrhea can last up to 20 days, with an average of 9 days. After diarrhea has stopped, bacteria can still be shed in the stool for several weeks. *Yersinia pseudotuberculosis* causes an inflammation of the mesenterial lymph nodes (lymphadenitis mesenterialis), which can imitate the symptoms of acute appendicitis. Reactive arthritis is a complication, which occurs with a frequency of 1–3%, and primarily involves the joints of the lower extremities. In general, therapy of yersiniosis is restricted to the substitution of fluid losses, but antibiotics are administered in septic cases. Effective drugs are cotrimoxazole, 3rd generation cephalosporines and aminoglycosides.

Infection with *Listeria* / Listeriosis

Listeria – named after the British surgeon Jopeph Lister – are gram-positive rods, which can be present in the intestines of humans and animals; they are shed with the stool and can be found anywhere in the environment. The strain, which is pathogenic for humans, is *Listeria monocytogenes*. The transmission of the bacteria takes place through the ingestion of food of animal origin. It

has to be considered that the germs can survive even low temperatures (in the refrigerator). Often, the infection is asymptomatic. After an incubation period of up to 8 weeks, fever and diarrhea can appear. Severe forms of the infection are primarily observed in young children and immunocompromized people. They are characterized by a septic course and an inflammation of the meninges or the brain (meningitis, encephalitis); lethality reaches 30%. Infection during pregnancy or birth can cause a ► congenital listeriosis. Infections with *Listeria* are treated with antibiotics.

Foodstuffs Safety

► Food Safety

Food Typical for Certain Culture

► Traditional Food

Forgiving

Definition

The Christian religion provides forgiveness, through the will of God, for the individual who may have committed a sin. The individual should first admit the sin (repent) and seek forgiveness. In general, this will be accepted in the belief that the individual would refrain from committing further sin.

Formal Channels

Definition

Formal channels of communications have explicit rules that primary researchers must follow to enter information into such channels. They place restrictions on the kind or quality of information that is admitted to the system. The five major formal channels are professional conferences, paper presentations, personal journal libraries, electronic journals, and research report reference lists.

Formation of the Soil

► Pedogenesis

Formative Evaluation

Synonyms

Process evaluation

Definition

Formative evaluation is also called as process evaluation and it is conducted while measures are in progress. The role of formative evaluation is to discover deficiencies or successes in the intermediate version of the program. Process evaluation provides a continuous assessment of projects and their organization.

Free-Rider Behavior

Definition

The term free-rider behavior refers to the behavior of individuals who consume specific goods without contributing to the costs of provision of the specific goods.

French Letter

► Condom

Frequency

Definition

Frequency is the number of times a certain value of an observation occurs. This number is also called count or frequency count. Dividing the frequencies by the total number of observations results in relative frequencies, which is equivalent to empirical ► probability. For qualitative variables, frequencies are given for a specific category, for discrete quantitative variables for specific numerical value, and for the continuous quantitative variables frequencies are given for class intervals (class frequency). ► Frequency distribution summarizes these counts in tabular or graphical format.

Frequency Based Analyses of Selection

Definition

These make use of models to predict the expected distribution of ► allele frequencies for a locus under conditions of strict neutrality in a panmictic (non segregated) population of constant size. Natural selection can cause deviations between the predicted and observed allele frequencies by selecting for or against particular allele(s). Frequency based tests for selection include: The Hardy Weinberg equation, Tajima's D test, Fu and Li's D and F tests, the McDonald and Kreitman test, the Ewen Watterson test on observed homozygousity, Fay and Wu's H statistic and Weir and Cockram's FST.

Frequency of Death

► Mortality

Frequency Distribution

Definition

A frequency distribution describes the frequencies or counts of observations when the values of a variable are ordered according to their magnitudes. A grouped frequency distribution is a frequency distribution when the values of the variable are grouped into class intervals.

A relative frequency distribution is obtained by dividing the frequency distribution by the total number of data. A cumulative frequency distribution is obtained by the successive adding of the frequencies of single groups or class intervals. A cumulative relative frequency distribution is obtained by dividing the cumulative frequency distribution by a total number of data. Distribution of frequencies can be presented by a frequency table or by graphical representation. The frequency table contains the values of the variables in the first column (names of the categories, discrete numerical values or class intervals), and in the remaining columns it contains frequencies and relative frequencies. Appropriate graphical representation for frequency distribution of discrete quantitative data is a bar chart, and for frequency distribution of continuous quantitative data a histogram, frequency polygon, and/or stem-and-leaf plot.

Cross-References

► Descriptive Statistics

Frequency Rate

Definition

The frequency rate is the number of new cases of injury during the calendar year divided by the total number of hours worked by ► workers in the examined group during the year, and multiplied by 1,000,000. The frequency rate is similar to the ► incidence rate, the numerator is the same and the only differences are in the denominator and constant. One might assume that the frequency rate is a bit more precise than the incidence rate due to the fact that the frequency rate denominator comprises number of workers as well as of number of hours worked.

$$F = \frac{NC}{H} \times 1.000.000$$

F = Frequency rate
NC = Number of new cases of injury during the calendar year
H = Total number of hours worked by workers in the examined group during the year

Frequency Weighting

Definition

Sound level meters may use four different filters, A, B, C, or D, in order to weigh sound pressure levels as a function of frequency. Sound pressure levels in the weighted scales are expressed in decibel units with an associated letter indicating the weighing circuit, for example, dB (A). The A-weighting curve is most widely used in the community setting as it correlates very well with the frequency response characteristics of the human auditory system for pure tones. This reduces the low frequency response and some of the high frequencies, whereas the mid-frequency range is emphasized. The D-weighting curve is used for the measurement of single event aircraft noise. Another weighting, which is useful in estimating attenuated noise when personal hearing protectors are used is the C-weighting network. B-filters are used to match the auditory system response curves at moderate loudness levels.

Friction Cost Method

Definition

The friction cost method is a method to estimate the ► indirect cost due to productivity loss. The friction period is the time until another worker from the pool of unemployed has fully replaced the individual who is absent due to an illness. The value of the indirect cost is approximated by the value of an average individual's future earning over the friction period. The friction cost method reflects the true cost of productivity loss for employers. Over a long-term perspective, the friction cost method estimates lower indirect costs compared with the human capital approach.

Friedman Test

Definition

This non-parametric test is an extension of the Wilcoxon matched pairs signed ranks test, and is concerned with more than two time periods of data collection or conditions and groups of three or more matched subjects.

F

Frostbites

Synonyms

Congelatio

Definition

Frostbite is an acute damage to the skin and underlying tissues of peripheral parts of the body (fingers, nose, and ears) caused by extreme cold. Frostbite is distinguishable by the hard, pale, and cold quality of the skin. The area is likely to lack sensitivity to touch, although there may be an aching pain. As the area thaws, the flesh becomes red and very painful. If only the skin and underlying tissues are damaged, recovery may be complete. However, if blood vessels are affected, the damage is permanent and gangrene can follow, which may require amputation of the affected part.

Fugitive

► Refugee

Functional Ability

Synonyms

Functional limitation; Functional capability

Definition

Functional ability is the actual or potential capacity of an individual to perform the activities and tasks that can be normally expected. A given function integrates biological, psychological and social domains. It becomes increasingly important to measure the functional ability of an individual, especially related to ► long term care, because functional ability is a key factor in determining the individual's quality of life and it correlates to physical and mental health. The need for long-term care or rehabilitation services, including eligibility for funding, is often measured by the individual's ability to perform different functional activities. Especially in older people, measurement of functional ability is commonly either done by assessing the ability to perform "activities of daily living" (ADLs) or by measuring the ability to perform "instrumental activities of daily living" (IADLs). The measurement is done by questioning the individual or by observing the individual carry out an activity (e. g. getting up from a chair).

Functional Capability

► Functional Ability

Functional Food

Definition

Functional food means food which is enriched with added ingredients. Therefore, these products are enhanced with a positive effect to their original nutritional value (nutrient content and taste value) concerning preservation and advancement of health, physical capability or well being.

Functional Limitation

► Functional Ability

Functional Somatic Syndromes (FSS)

Definition

Group of disorders involving alterations in mind-brain-body interactions.

Functioning

Definition

Umbrella term encompassing all body functions, activities and participation.

Functions of Public Health

Definition

Public health is defined as the organization and analysis of ► medical knowledge in such form that is applicable

to health related issues by society. Three core functions of public health are: 1. surveillance of the health status of the population, assessment of quality of health services provided, and analysis of disease and injury patterns in a population, 2. policy development in the health sector and specific intervention projects, and 3. assurance that interventions are performed in an adequate way and for an adequate population.

Fundamentals of Genetics

► Genetic Principles and Genetic Variations

Fusion Inhibitors

Synonyms

Drugs to treat AIDS; AIDS-therapeutics; Anti-HIV medications; Antiretroviral medications

Definition

Enfuvirtide (T-20, Fuzeon) was introduced as the first fusion inhibitor at the beginning of 2003. It works by blocking the cells' viral uptake. Disadvantages of fusion inhibitors are their production difficulties, high costs and the fact that they have to be administered subcutaneously.

Gangrenous Stomatitis

► Noma

Garbage

► Communal and Industrial Waste

Garbage Management

► Waste Management

Gas Gangrene

Synonyms

Infection with *Clostridia*

Definition

Gas gangrene is a serious wound infection, which is caused by toxins of different species of *Clostridia* (in 60–80% by *Clostridium perfringens*). Without treatment, the course is lethal within 48 hours. *Clostridia* is found in the soil, water, dust, foodstuffs and in the intestines of humans and animals. In earlier times, gas gangrene was a common infection in theaters of war. Nowadays, it still is a frequent infection in tropical regions, but it has become rare in industrial nations. Incubation period ranges between a few hours and 3 days. The first signs of an infection are sudden, severe pain in the wound and swelling. In the absence of oxygen (in an anaerobic milieu), gas is produced in the tissue causing a crackling sound. Brown, bloody or amber-colored fluid with a bad, sweetish smell is secreted from the wound. With the destruction of tissue and the spread of toxins, failure of the liver, kidneys and the cardiocirculatory system occurs. If therapy starts immediately, lethality can be reduced to 15–50%. Treatment consists of two components. On the one hand, antibiotics (penicillin, cephalosporines, chloramphenicol and erythromycin) are effective. On the other hand, surgical intervention is necessary to make the wound aerobic; necrotic tissue removed, the wound left open (no surgical suture).

Gastrointesitnal Disorders

► Gastrointestinal Problems

Gastrointestinal Problems

Synonyms

Gastrointesitnal disorders

Definition

A gastrointestinal disorder comprises symptoms arising in the mid or lower gastrointestinal tract that are not attributable to anatomic or biochemical defects. The symptoms include abdominal pain, early satiety, nausea, bloating, distention, and various symptoms of disordered defecation. The three most common functional bowel disorders are irritable bowel syndrome (IBS), constipation, and functional dyspepsia.

GAVI, Global Alliance for Vaccines and Immunization

Definition

The Global Alliance for Vaccines and Immunization (GAVI) was founded in 1999. The aim of GAVI is to reach 30–40 million children in the developing countries in order to carry out the necessary vaccinations. Governments, non governmental organizations, UNICEF, the World Bank Group, the WHO, the Bill-and-Melinda-Gates-Foundation, the International Federation of Pharmaceutical Manufactures Association (IFPMA) and research and technical health institutes are partners of GAVI.

GDP

► Gross Domestic Product

Gender

Definition

A social characteristic that differentiates people on the basis of socially constructed, individually internalized and individually externalized attributes. These attributes range from appearance to beliefs and behavior. Gender is often considered a continuous outcome, whereby individuals locate themselves (and are located by others) on a continuum from a more female to a more masculine presentation of themselves. However, it is most commonly operationalized as a dichotomous outcome (i. e. male or female).

Gender Differences and Health

MARGARET M. WEDEN
RAND Corp., Santa Monica, CA, USA
mweden@rand.org

Synonyms

Sex differences and health

Definition

Researchers use ► gender to refer to the social construction of what it means to be a man or a woman in a specific culture (e. g. the roles, responsibilities, and norms about acceptable behavior for men and for women). Typically, ► sex is used to refer to the biological differences determined by whether a person carries an X or a Y chromosome. For example, studies that highlight the role of gender might examine why women, on average, have lived longer but less healthy lives than men in every industrialized nation since the turn of the century. Studies that highlight the role of sex might examine why an event such as preterm loss and infant mortality are higher when the infant is male than female, or why breast-cancer is higher in women than men.

Basic Characteristics

Gender and Health Behavior

Studies exploring gender differences in health and longevity have focused on the role of gender in shaping differences in health behavior, risk taking, and medical care utilization among men and women. Cigarette smoking is an excellent example of how gender shapes differences in health behavior important for health and longevity (Chapman Walsh et al. 1995). Throughout the later half of the twentieth century, cigarette smoking was the primary cause of mortality in the U.S. and U.K. At the beginning of the century, the rates of smoking-related deaths (especially lung cancer) were much higher for men compared to women. These higher rates of cancer are consistent with the changes in patterns of smoking among men and women. During the early part of the twentieth century, tobacco was a luxury that was not considered socially acceptable for women to smoke. Beginning in 1920s and continuing through to World War II, ► gender norms about appropriate behavior for men and women began to relax, and cigarette smoking became a symbol for many young women of their new independence outside of the home. Consistent with the trends in smoking, rates of cancer-related deaths began to increase among women over the later half of the twentieth century. Current delays in smoking cessation among women compared to men further underscore the inter-relationships between gender, health behavior, and environmental context, particularly as they relate to differences in stressful working conditions (Weden et al 2006). As a result of these trends in

cigarette smoking and cancer-related mortality, smoking has been identified as the primary determinant of the convergence in mortality differentials between men and women in industrialized countries over the latter part of the twentieth century (Pampel 2002).

Gender, Risk-Taking, and Unintended Injury

In contrast with the changes in gender norms which have shaped health behavior patterns over the last century, differences in gender norms about risk-taking and social protection appear to consistently predispose men to higher rates of accident and violence-related mortality. Globally, in nearly every period for which data is available, accident and violence-related deaths are higher among men than women (Preston 1976; WHO, 2002). Unintended injury is the primary cause of mortality in the ages 15–44, and road traffic injuries account for the largest sex differentials in this figure, with almost three times as many fatalities among men as women (WHO 2002). Differences in the ► socialization of men and women have been associated with the greater risks men take while driving (e. g. speeding, driving recklessly, driving under the influence of alcohol) that predispose them to traffic accidents (Waldron 1990). Similarly differences in the social acceptance of men's exposure to risks outside of the home (e. g. hazardous work) have been related to the higher rates of male mortality in these arenas (Waldron 1990).

Gender Socialization and Health

The differences in socialization of men and women (e. g. about appropriate roles, responsibilities, and behavior; ► gender inequality) that has been related to higher mortality among men has also been related to the greater degree of poor health among women (Lorber 2005). For example, uneven changes in feminine and masculine social norms over time have been associated with increases in poor health among women. Researchers describe how the loosening of social norms about women's work outside of the home in industrialized countries can be related to increases in psychosocial stress as women balance responsibilities at home and at work (► work-life balance) (Hoschchild 1989; Lorber 2005). Globally, researchers describe how physical and psychological violence against women is often legitimized by a woman's failure in a feminine social role (e. g. "good wife"), how battery can be related to unsuccessful attempts by men to achieve masculine social roles, and how difficult it can be for women to leave abusive relationships in light of socialization into the feminine role of caregiver (Lorber 2005). ► Sexism poses particular risks for women's reproductive health when norms legitimize male access to and control of women as sexual objects (Fugate Woods 1996).

Emerging Research

Historically, research on gender and health has considered, and discounted, biological aspects of male-female differences in isolation from the social constructions of femininity and masculinity. Recent research suggests that observed differences in longevity between men and women may involve complicated interactions between genes, biology and the social environment (Carey 1997). As scientists continue to explore gene-environment interactions, these relationships are emerging as a new area of research fundamental to the understanding of gender differences in human development, health and longevity.

Gender Inequality

Synonyms

Gender difference

Definition

Gender inequality refers to differences in the distribution of rewards and/or exposures and risks on the basis of ► gender. These rewards, exposures and risks may be material, psychological, or social in nature. It is important to distinguish inequality from inequity. Inequality simply denotes a difference, whereas inequity denotes a difference that is morally or ethically unjust. In light of the fact that gender inequality specifies that there is a difference between groups according to a characteristic that is socially constructed, gender inequality is often considered an undesirable outcome that is synonymous with gender inequity.

Gender Norms

Definition

These are expectations shared by a group, at a given point in time, that reflect a commonly accepted set of activities and ways of presenting oneself as either a man or a woman. Adherence to the set of expectations (i. e. male or female) that are consistent with how a social group perceives a given individual is achieved through various mechanisms of social control, including ► social stigma and positive social sanctioning.

Gene Arrays

► DNA Microarray

Gene Chip

► DNA Microarray

General Anxiety Disorder (GAD)

Definition

A person with a general ► anxiety disorder suffers from chronic ($\geq$ 6 months' duration), permanent anxiety or worry, accompanied by multiple associated symptoms triggered by activating the central nervous system. These symptoms include muscle tension, easy fatiguability, poor concentration, insomnia, restlessness, and irritability. The person is unable to control these feelings which extend to all areas of life (e. g. work, personal finance, relationships). Sufferers experience these worries and the constant, high-level tension that comes with it as excessive, but still realistic. In Diagnostic and Statistical Manual of Mental Disorders-IV (DSM-IV) an essential feature of generalized anxiety disorder is that the anxiety and worry cannot be attributable to the more focal distress of ► panic disorder, ► social phobia, ► obsessive-compulsive disorder, or other conditions.

Cross-References

► Anxiety Disorders

General Assembly

► United Nations General Assembly

General Fertility Rate (GFR)

Definition

General fertility rate (GFR) is the number of live births per 1000 women ages 15–19 in a given year. It can be calculated using the vital registration system for births

or may be estimated from national censuses or survey data using the child-woman ratio when birth statistics are not available. GFR relates births to the age-sex group at risk of giving births and it is a more refined measure than the ► crude birth rate (CBR) to compare ► fertility across populations – it approximately equals four times the CBR.

General and Generalized Linear Model

Definition

This is a specific model formulation which relates a response variable, Y, to a set of explanatory variables, X_1, X_2, …, X_k. The basic relationship is written as: $y = \beta_0 + \beta_1 x_1 + \ldots + \beta_k x_k + e$, where y is the observed value of Y corresponding to an observed set of values for the explanatory variables, x_1, x_2, …, x_k and the βs are regression coefficients, which are usually to be estimated. It is further assumed that: $E(Y) = \beta_0 + \beta_1 x_1 + \ldots + \beta_k x_k$ and therefore, that $E(e) = 0$. Many standard statistical models fall into the class of general linear models. These include the models used in linear regression (simple), ► multiple linear regression, analysis of variance, and analysis of covariance. The general linear model is a special case of a generalized linear model (GLM), a term used to refer to a regression model that relates a function of the mean of a response variable to a linear function of explanatory variables. Beside Gaussian linear regression, they include logistic regression (► logistic regression analysis) and loglinear models (► loglinear analysis) for count data. The GLM modeling scheme can be summarized as having three components, a random component, a systematic component and a function, which links the two. Within one paradigm, there are both an integrated conceptual framework and an emphasis on the explicit analysis of data through a model-building approach, allowing the estimation of the size of effects, predictions of the response variable, and the construction of confidence intervals.

Generalized Infection

► Bloodpoisoning

General Physician

► General Practitioner

General Practice

► Primary Care

General Practitioner

Synonyms

Family doctor; Family physician; General physician; Primary care physician

Definition

A General Practitioner (GP) is the first point of contact for health related services that are non-emergency cases and thus provides ► primary care. They are supposed to cover and coordinate all the basic medical care needs of the population and often act as gatekeeper to authorize referrals of the patient to ► secondary care providers like specialists or hospitals. The GP treats acute and chronic diseases and has an important role in providing ► prevention and ► health education for all ages and both sexes.

Generic Drugs

► Generics

Generic Instrument

Definition

Generic instruments for the measurement of health-related quality of life are instruments that measure general aspects of health and quality of life. They do not capture disease specific aspects. Generic instruments allow the comparison of health care interventions for different health problems and different sectors of the health care system, such as preventive interventions, acute care, and emergency care.

Generics

Synonyms

Generic drugs

Definition

Generics are ► drugs that are developed after the patent protection for a drug has expired. They include exactly the same active ingredients and dosage as the original drug. As they can be developed without any research and development, the prices of generic drugs are much lower than the original drugs. In the context of cost containment, generics are often prescribed to lower the cost of drugs.

Gene Therapy

PAOLA LEONE, CHRISTOPHER JANSON
UMDNJ / RWJ Medical School,
Cell & Gene Therapy Center,
Cooper University Hospital,
Camden, New Jersey, USA
leonepa@umdnj.edu, jansoncg@umdnj.edu

Definition

Gene therapy refers to the clinical application of different gene transfer technologies. The practice of gene therapy involves the transfer of one or more genes or nucleic acid elements to a patient in order to counteract a naturally occurring deficiency in gene function. The vehicle which is used to introduce the genetic element of interest to human cells is called the gene ► vector, which may be either a viral vector or a non-viral vector. This genetic element is known as a ► *trans*-acting gene or transgene if non-integrating, and a ► *cis*-acting gene if it integrates into the chromosomal DNA.

Introduction

Traditionally, genetic defects amenable to gene therapy have been single in nature (i. e., the single gene / single protein model of Beadle & Tatum), but complex genetic diseases are also subject to gene therapy. For example, early work in gene transfer involved the transfer of a gene to correct defects in adenosine deaminase (ADA) or interkeukin-2 receptor gamma chain (X-SCID) in patients suffering from these inherited forms of immune deficiency (Hacien-Bey-Abina et al. 2002). Results of early gene therapy experiments have been mixed, with some reconstitution of the defects in patients but also the possibility of untoward insertional effects such as malignancy (Hacien-Bey-Abina et al. 2003). Despite the lack of definitive results in early human gene therapy experiments which began in the 1990's, clinical trials are currently underway for a variety of different conditions, which include cancer and neurological disorders such as Canavan disease (Janson et al. 2001) and Parkinson's disease, as well as diverse inherited metabolic diseases. As more genes are correlated with human diseases, the challenge of gene therapy will be to find the optimal tools to introduce disease-modifying genes, either singly or in combination, and to attain adequate levels of long-term gene expression in a tissue or cell-specific manner. The study of population genetics is also critical to the future of gene therapy, because detailed gene-mapping and functional genomics will be required to determine the best genetic targets for clinical applications. There are significant public health implications for human gene therapy, since many common diseases are known to have a genetic component which may be modified or treated by gene transfer. The theoretical study of gene function and regulation as well as the more practical study of gene transfer technologies thus encompasses the future of this exciting field of clinical practice.

Basic Characteristics

Following the discovery of the rudimentary structure of DNA in the 1950's, it took nearly three decades for the promise of gene therapy to be realized. The modern era of gene therapy began with the discovery of recombinant DNA in the 1970's, which raised the theoretical possibility of replacing defective DNA through splicing with restriction endonuclease enzymes. Studying SV40 virus, Paul Berg discovered that DNA could be specifically spliced and reintroduced to another organism (Jackson et al. 1972). Herbert Boyer and Stanley Cohen expanded upon this work through the use of bacterial plasmids to shuttle DNA between species (Morrow et al. 1974). Later, Richard Mulligan made human gene therapy possible when he modified a SV40 virus to express a bacterial gene in mammalian cells (Mulligan

and Berg 1980) and also developed a murine retrovirus ► vector to express genes in mammalian hematopoietic cells (Williams et al. 1984). In parallel, other investigators such as Philip Felgner have developed nonviral, liposomal systems for stable delivery of genes to mammalian cells. In summary, rapid progress in technical issues surrounding gene manipulation occurred from 1970–1990, which was the foundation for further work in vector design and gene targeting experiments.

Population genetics is the study of genetic variation in human populations. A variety of mathematical tools are informing the discovery of genes and their function (Haines and Pericak-Vance 1998). It appears likely that functional genomics, or the study of gene function on a large scale, will contribute to the ultimate success of gene therapy through the provision of new material for study, and will also be informed by gene transfer technology (Janson and During 2001). At this time, population level studies of genes continue to find new targets for cancer, mental disorders, and many medically important complex diseases such as Alzheimer's and diabetes. Gene therapy has much to contribute to public health as the role of genes are elucidated and gene delivery techniques are further refined.

Genetically Modified Microorganisms

► Genetically Modified Organisms (GMO)

Genetically Modified Organisms (GMO)

Synonyms

Genetically modified microorganisms

Definition

GMO are bacteria, yeasts or filamentous fungi in which the genetic material has been changed through modern biotechnology in a way that does not occur naturally by multiplication and/or natural recombination. The introduction of foods produced with the aid of GMOs into the food supply brings potentially new issues of ► food safety. The safety assessment should involve: the characterization of the genetic modification, including deletion or insertion of DNA sequences, characterization of recipient microorganisms, the ultimate donor organism, the vector(s) used in the construction of the GMO, the construct and the GMO itself, natural habitat, history of use, gene transfer, genetic stability, pathogenic potential, characterization and verification of the expected protein expression product of the novel DNA, composition of the food containing the GMO, safety and nutritional assessment (including potential toxicity and nutritional aspects).

Genetic Counseling

Constanze Walldorf
Institute of Human Genetics, University of Bonn, Bonn, Germany
c.walldorf@uni-bonn.de

Definition

Genetic counseling deals with problems associated with the fear of a disorder that may be hereditary. This type of counseling helps an individual or a family understand medical and genetic information, consider different options and make decisions best suited to the given individual situation.

It is an interactive process providing information in a manner which is accessible to the person seeking advice. There are many different aspects involved (diagnostic, nature of the disorder, measures available for prevention and treatment, estimation of ► recurrence risks, communicative role, psychosocial issues and support).

Through genetic counseling responsible application of genetic knowledge in clinical practice can be guaranteed.

The ► consulter (propositus) is the individual primarily seeking advice. Genetic counseling is open to individuals and families worried about a disorder that may be hereditary.

The *index patient* is the individual through whom the family is ascertained. The *proband*, generally, is an affected individual.

The *genetic counselor* is a health professional with specialized education and experience in the areas of medical genetics and counseling. In Germany most genetic counselors are medical specialists in human genetics. In other countries counselors also enter the field from a variety of disciplines such as biology, psychology and social work.

Basic Characteristics

Aim and Basic Principles of Genetic Counseling

Genetic counseling aims to benefit the individual and the family. The consulter is enabled to make individual life decisions and consider aspects of family planning based on being well informed.

Counseling and genetic analyses are voluntary. The consulter should be informed in advance about the aims and course of action of the genetic counseling. Agreement (usually in written form) is necessary. There is a guarantee from the counselor of privacy, confidentiality and duty to inform patient.

► Non-directiveness is a central tenet of genetic counseling. Genetic counseling should ensure that individuals have the information that will enable them to make their own decisions. The importance of non-directiveness lies in allowing the individuals involved to make decisions right for their own particular situations. The counselor is required to respect the autonomy of the client.

Common Reasons for Genetic Counseling

As genetics has become increasingly relevant to all areas of medicine, the context in which genetic counseling occurs has expanded. Common reasons for genetic counseling are the following:

- possible genetic disorder in a child, a parent or a relative (child or other relative with inborn malformation or illness that is or might be heritable);
- advanced parental age;
- consanguinity;
- multiple pregnancy loss;
- stillbirth;
- infertility;
- distinctive features diagnosed before birth;
- possible mutagenic and teratogenic exposure.

Contents and Course of a Genetic Counseling Session

The personal concern and the specific disorder set the stage for the dialogue in genetic counseling.

The personal conversation in genetic counseling usually takes at least 30 minutes but can take up to 90 minutes or more. Often a second meeting is offered.

A counseling session usually consists of the following:

- contracting: listen to the ► consulter's goals and personal questions;
- collecting and interpreting the medical history and medical records. Genetic counseling is based upon a thorough patient's and family history and evaluating medical records;
- collecting genetic information by drawing up the ► family tree (pedigree) over at least three genera-

Genetic Counseling, Table 1 Showing main symbols used in constructing family trees

	unaffected male, female
	gender unknown
	affected male, female
	three healthy males
	deceased (affected)
	no children
	consulter / propositus (affected)
	consanguineous marriage
	parentage uncertain
	abortion
	non-identical twins
	monozygotic twins
	heterozygote (in autosomal recessive disease)
	heterozygote (in X-linked disease)

tions. The use of clear and consistent symbols (see Table 1) allows genetic information to be set out clearly. Of note are years of birth, age and cause of death, illnesses or other distinctive features. In each generation all individuals, whether alive or deceased, are noted – stillbirths and abortions are important as well;

- performing a physical examination if relevant;
- making a diagnosis as exact as possible: a clear diagnosis is the essential basis for accurate genetic counseling. Often additional information is needed;
- describing and explaining the specific disorder: etiology, clinical symptoms, prognosis, therapy/prevention, diagnostic options and their limitations;
- offering further support (e. g. patients' support group);
- explaining the genetic basis of the disorder and specific risk assessment;
- discussing genetic testing options;
- helping the consulter to reach the decision which is right in the given individual situation. Considering personal, familial, religious and psychosocial aspects;
- helping the consulter to deal with existing problems or problems arising from genetic testing;
- explaining general genetic risks;
- writing a letter summarizing the main points of the consultation. The letter is written in easy-to-understand language and is addressed to the consulter and, if the consulter requests, to the attending physicians.

G

Estimation of Genetic Risks in Genetic Counseling

In order to provide precise genetic advice it is essential to have an accurate diagnosis. It is one of the main tasks of the counselor to make this basis as firm as possible. However, genetic risks are rarely absolute, mostly one works in terms of probabilities or odds. Risk estimates may be based on different sorts of information.

For single-gene-disorders, following Mendelian rules of inheritance, a theoretical risk can be given. A 'prior' genetic risk, based usually on Mendelian inheritance, may be modified by 'conditional' information. Such modifying information may drastically alter the risk estimate (e. g. several unaffected brothers and CK-level in a possible carrier of Duchenne muscular dystrophy or age of a so far unaffected person at risk for Huntington's disease).

Theoretical predictions are not possible in multifactorial disorders. But for most of the more common non-Mendelian and chromosomal disorders empiric risk estimates are available.

This empiric risk estimate is based on observed data from many families in the same situation. Most empiric risks really fall into the category of composite risks. Due to heterogeneity of a disorder it can be impossible to distinguish to which group a special case belongs, so an intermediate risk will be given.

The results of special investigations may greatly alter the risk estimates (e. g. alpha-fetoprotein in amniotic fluid, carrier detection, linked DNA markers). The results of these investigations require combination with the prior genetic risk along with other modifying information.

Genetic Diagnostics and Genetic Counseling

In clinical medicine diagnostics is performed to clarify existing symptoms. Partly this is the case in genetic diagnostics as well (diagnostic testing). But partly genetic diagnostics is performed in persons at risk free of any symptoms or physical discomfort (e. g. predictive testing, heterozygosity testing). Here the impact of information and its consequences is far reaching. Therefore this kind of genetic diagnostics should be embedded by genetic counseling to safeguard informed consent and understanding of consequences.

Facing the results of genetic testing without genetic counseling has its risks; especially before prenatal and predictive genetic testing the person being analyzed must be informed in detail about the nature, power and possible consequences of the analysis. In the context of severe or untreatable disorders psychological support is recommended. After the genetic test the result has to be interpreted and consequences have to be explained. The person to be analyzed should know from the beginning that they can withdraw at any time.

International guidelines for predictive genetic testing have been drawn up (e. g. Huntington's disease). Requirements are: genetic counseling, full age, time to consider of at least four weeks between counseling and taking of the blood sample, involvement of psychological support and written informed consent.

In principle, predictive testing in children is to be considered critically and should only be performed when direct consequences concerning prevention or therapy will result.

Synonyms

Statistical genetics; Epidemiological genetics Population genetics

Definition

Genetic epidemiology is a branch of science which deals with the "etiology, distribution, and control of disease in relatives and with inherited causes of disease in populations" (Morton 1982). Genetic Epidemiology is an interdisciplinary field which seeks to understand both genetic and environmental influences and how they interact in causing various diseases and disease related traits in humans.

Basic Characteristics

Genetic Epidemiology, a relatively recent branch of science, deals with studies of how genetic and environmental effects act together in producing various human diseases and disease related traits. One cannot study genes except as they are expressed in certain environments, and one cannot study environmental influences except as they affect people with certain genotypes. Indeed, the same gene(s) may express differently in different environments, and the effect of the same environment may vary by the person's ► genotype, which is known as *gene-environment interaction*. Genetic Epidemiology is thus an interdisciplinary field which arose at the interface of ► population genetics and ► epidemiology.

Genetic epidemiological studies are usually carried out in relatively large samples of individuals/families from select populations and, therefore, the population history and dynamics are relevant. Population dynamics alter the frequency and distribution of both genetic and environmental factors, and thus, also the disease/trait of interest. Certain population characteristics can be exploited for the purpose of finding genetic determinants of disease because the history has affected the genomic structure in a way that specific genotypes associated with disease can be identified more easily in certain populations.

Although "genetic epidemiology" and "statistical genetics" are often used as synonyms, the former is broader and includes the latter. Whereas statistical genetics largely deals with the statistical issues surrounding the analysis of genetic data, genetic epidemiology also deals with (or should deal with) the underlying biology and the distribution of the etiologic determinants in different populations, thus enabling an assessment of the population impact of causal elements. These differences are less relevant as long as biology is integrated into the science.

History

Up until the 1970's, etiologic studies of human disease were carried out largely in terms of unmeasured latent genotypes through statistical analysis of family data. Investigations pertaining to the genetic basis of human diseases have been confined to simple Mendelian diseases (► mendelian traits) which, for the most part, either did not involve environmental effects or the effects were simple. Thus, standard methods of genetics were enough for analysis of those data. Pioneering contributions of a number of epidemiological studies such as the Framingham Heart Study have demonstrated the importance of the environment in understanding the disease susceptibility. As emphasis shifted from simple Mendelian diseases to complex disorders such as coronary heart disease (► coronary artery disease), hypertension, and diabetes (► diabetes mellitus), to name a few, population geneticists faced new challenges because familial effects were no longer entirely genetic. Realization that complex disorders were caused by the interplay between genetic and environmental influences paved the way for what is now called *Genetic Epidemiology*. It was first introduced by Neel and Schull (Neel, Schull 1954) as "Epidemiological Genetics".

In a volume edited by Neel, Shaw, and Schull (Neel et al. 1965), Thomas Francis remarked: "So when the human geneticist turns to disease and disorder in the population as his basis of genetic analysis, he is promptly in epidemiology. And when he asserts the concept of multiple factors to produce an effect, he is in full cry epidemiologically. Conversely, where the epidemiologist seeks explanation for familial or other group aggregation of health or disease, he is immediately involved in genetic problems". By the late 1970's, the new field has made considerable progress in terms of developing new statistical methods necessary for analysis of ► multifactorial traits (Morton 1978). The growth of genetic epidemiology has been quite rapid and explosive ever since, culminating in a series of books and edited volumes (Morton et al. 1983; Ott 1991; Thomas 2004; Rao, Province 2001).

Genetic Epidemiology is Unique

Genetic epidemiology, which is derived from population genetics and epidemiology, is unique. It differs from population genetics because of its preoccupation with human disease. It differs from epidemiology because of its emphasis on familial causes of disease. Whereas genetics treats the environment as noise and epidemiology traditionally treated genes as unnecessary and unfamiliar complication, genetic epidemiology treats both as legitimate contributors to disease. Genetic epidemiology also differs from evolutionary genetics because the former deals with microevolution of human diseases while the latter deals with macro level evolution (distant past or distant future).

Methods of Genetic Epidemiology

Genetic epidemiological investigations of complex diseases use an array of methods of data analysis (see Table 1). These generally include: familial aggregation and heritability which quantify the magnitude of transmission within families; segregation analysis which examines how alleles at a gene segregate from parents to children; linkage analysis which examines whether a trait locus and a genetic marker co-segregate within families; and association analysis which tests if the trait locus and the genetic marker co-occur in individuals. More recent methods include simultaneous considera-

Genetic Epidemiology, Table 1 Standard and evolving methods for genetic epidemiological data analysis

Method	Brief description
Familial resemblance & heritability	Heritability quantifies the percent variance in a phenotype due to genetic (familial) factors
Segregation analysis and major genes	Evaluates how genes segregate from parents to children
Linkage analysis (co-segregation in families)	Examines whether a marker and a trait locus co-segregate in families
Assiciation analysis (co- occurrence in individuals)	Examines whether a trait locus and the genetic marker co-occur in individuals
Linkage disequilibrium (LD) mapping	Linear mapping of markers and trait loci based on pair-wise marker-marker and marker-trait locus correlations
Haplotype analysis	Simultaneous analysis of allelic combinations at a set of closely linked genes
Bayesian Network Analysis	Bayesian analysis of the interrelationships among a given set of variables (usually phenotypes, attributes, and genetic markers)
Pathway-based studies & systems biology	Analysis of multiple genetic markers by integrating pathway-based biological information

tion of multiple genetic polymorphisms (► haplotype analysis) and preferential co-aggregation of a particular trait allele with a particular marker allele (linkage disequilibrium).

Principles of genetics; Fundamentals of genetics; Genetic polymorphisms

Definition

Genetic principles are the rules or standards governing the biological phenomenon of heredity, the transmission of characteristics from parents to offspring via information encoded biochemically using DNA, in units called genes. Genetic variations are portions of genetic information at the same genomic site across individuals that can differ between persons, with the size of the differing portions ranging from small single-nucleotide changes to differences extending across entire chromosomes.

Basic Characteristics

History

The transmission of biological information from parents to offspring that encode physiological features has been recognized since early recorded history. As long as 4,000 years ago, farmers in various parts of the world employed strategies of selective breeding of crops and animals in order to enhance desirable traits, such as crop resistance to an adverse climate and animal size and speed. Hereditary transmission of certain diseases in humans had also been observed, such as hemophilia, noted by the second century C.E. The first formal research on the genetic transmission of traits was initiated in the 1850s by Gregor Mendel, a monk living in the Czech town of Brno, who examined the patterns of transmission of observable traits in sweet peas, and characterized modes of inheritance (► mendelian modes of inheritance) for traits as a product of the transmission of ► alleles from parent to offspring (Mendel 1866), even before this terminology existed and before the biological process of reproduction had been characterized. It was not until the twentieth century that experiments by Avery, MacLeod and McCarty (Avery et al. 1944) characterized ► deoxyribonucleic acid (DNA) as the medium in which genetic information is encoded. Subsequent work by Francis Crick and James Watson (Watson and Crick 1953), who along with Maurice Wilkins were awarded the Nobel Prize in 1962, and with the help of Rosalind Franklin, determined the molecular structure of the encoding molecule DNA. Rapid advances in genetics beginning in the early 1970s resulted in the development of recombinant DNA technologies to study DNA functionality and eventually to characterize the structure and variation of the full library of a given organism's DNA, its genome. In humans, the Human Genome Project (HGP) was initiated in 1986 to map the human genome to the nucleotide or base-pair level, and attained 99% completion by 2003 (The National Human Genome Sequencing Consortium 2003) with revisions to the sequence still on-going. To the present, the HGP has sequenced approximately three billion base pairs and identified approximately 30,000 genes. Newer initiatives arising from the success of the HGP include the International HapMap Project (The International HapMap Consortium 2003); an effort to identify DNA sequence variants and common patterns of variation throughout the genome, which as of March 2006 has identified approximately six million ► single nucleotide polymorphisms (SNPs) (http://www.hapmap.org/).

The Structure of DNA

Individual units, or nucleotides, of the molecule encoding genetic information, DNA, consist of one of four nucleobases [Adenine (A), Cytosine (C), Thymine (T), or Guanine (G)] bound to a molecule of the sugar 2′-deoxyribose. These nucleotides are in turn bound to one another by covalent bonds between phosphate groups attached to the 5′ and 3′ positions of the ribose sugar backbone, and form a strand, going from 5′ to 3′. Each nucleic acid has a weak affinity for another nucleic acid (A for T, G for C, and vice versa), and aligns with another strand which has a 'reverse complement' of the sequence of the first strand. This double-strand relaxes to a low-energy state wherein the DNA coils and forms a 'double-helix.' Both double-strandedness and a helical structure serve to protect DNA from natural and enzyme-driven degradation.

The Molecular Superstructure of Genetics

Genetic information encoded in DNA strands comprise large sections of functional nucleotide sequences (such as genes and special sites for protein binding) and non-functional sequences. Long continuous DNA strands made up of these kinds of sequences and including hundreds to thousands of genes are referred to as ► chromosomes. In most bacteria, genes are encoded on one

large circular chromosome found in the cellular cytoplasm. In some bacteria and other single-celled organisms, as well as all multi-cellular organisms, genes are encoded on long, linear chromosomes, of which there may be multiple kinds encoding different genes, as well as multiple copies of the same chromosome, and these chromosomes are localized to the interior of a cellular organelle called the nucleus. The linear chromosomes of higher organisms also are part of additional structures. At certain times, the DNA strand is wrapped around a spherical bead-like protein complex composed of proteins called histones, which serve to pack DNA densely in a form called chromatin. Chromatin, in turn, is made up of loops that tightly coil all DNA into a dense structure when duplicated chromosomes are being segregating to new cells during a cellular process called ► replication. In humans, the observation of genomic DNA in a chromatin state has revealed that there are 22 unique autosomal chromosomes of which most cells possess two copies or 'homologues', and two sex chromosomes of which most cells possess either two copies of the X chromosome in females, and one copy each of an X and Y chromosome in males; because these cells have two homologues of each chromosome, they are said to be 'diploid.' This does not apply to reproductive (or 'germ') cells, eggs and sperm, which have only one copy of each unique autosomal chromosome and one copy of a sex chromosome, and because they have only one copy are said to be 'haploid.'

Genetics in the Cell Cycle: Mitosis and Meiosis

Each cell in which DNA is found undergoes a cellular cycle of DNA and cell duplication. In non-reproductive, or 'somatic' cells, the cell cycle consists of four separate phases: G_1, S, G_2, and M. G_1, the first growth phase, is a phase during which the cell readies itself to synthesize new DNA. During this period, a cell can enter a non-dividing or quiescent state called, G_0. S, the synthesis phase, is marked by the duplication of DNA via the process of replication. G_2, the second growth phase, is a preparation stage for cell division. These three phases are collectively called interphase, and account for 90% of the time spent in the reproductive cycle. M is the fourth phase and is called ► mitosis, a multi-step process by which the single, diploid somatic cell divides into two diploid daughter cells (46 chromosomes → 46 chromosomes). In germ cells, the cell cycle differs primarily in the M phase, which in this case is called ► meiosis. In contrast to mitosis, the first phase of meiosis witnesses an exchange of DNA sequence along the arms of homologous chromosomes through a process called ► recombination. Additionally, meiosis has two sets of cell division, a first meiotic division, whereby a diploid cell gives rise to two diploid daughter cells (46 chromosomes → 46 chromosomes), and a second meiotic division, where the two diploid daughters each produce two haploid daughter cells with only one copy of each homologous chromosome in each cell (46 chromosomes → 23 chromosomes).

DNA Activity over the Cell Cycle

During both mitosis and meiosis, DNA is tightly packed in its chromatin structure to facilitate transport to the nuclei of daughter cells. However, during interphase, DNA is unwound and spread throughout the nucleus, and is engaged in a number of biochemical processes, including ► transcription. During transcription, DNA is unwound from a double-helical state, and the open strand is used as a template for the construction of a single-stranded ribonucleic acid (RNA) molecular transcript. The sequence of the transcript serves multiple functions including (a) containing binding sites for transport of the transcript from the cell nucleus to the cytoplasm for protein production, and (b) a coding sequence for the ordering of amino acids into polypeptide chains that compose proteins. The process by which an RNA transcript brought to the cytoplasm is fed into a cellular organelle called a ribosome and used as a template sequence for the ordering of amino acids in constructing a polypeptide chain is called ► translation.

The Roles of Genetic Variations

The scheme by which cells use DNA to encode RNA, and RNA to encode proteins is called the Central Dogma of Molecular Genetics. The ordering of this scheme also helps to demonstrate how features encoded by genetics are manifested. Minute changes or errors in any of the processes with which DNA is involved may thus alter the types of protein products produced by cells, their functionality, or even the amounts in which they are produced. Changes to the DNA sequence of the genome that can occur include large-scale alterations

such as chromosomal abnormalities, but more commonly include small-scale alterations such as ► polymorphisms and ► mutations.

Chromosomal Abnormalities

Chromosomal abnormalities include both variations in the number of chromosomes as well as variations in the structure of transmitted chromosomes. Although normal human somatic cells are diploid, carrying 46 chromosomes or one copy of maternally – and paternally – contributed homologues ($n = 23$), failures in nuclear division can result in multiple complements of the full set of chromosomes ($3n$, $4n$). These mutations are uniformly lethal. More commonly, aneuploidy occurs where cells carry an extra copy or copies of a chromosome ($2n + 1$, $2n + 2$), or are missing a maternal or paternal homologue of one chromosome ($2n - 1$). Some potential causes include non-disjunction, the failure of chromosomes to separate during normal cell division processes, or anaphase lagging, the loss of chromosomes during cell division. These chromosomal number abnormalities affect all genes on the affected chromosomes, and thus can lead to multi-symptom syndromes, such as Down's syndrome, also called Trisomy-21 due to the possession of an extra copy of chromosome 21, in which affected persons typically have cognitive impairments and some abnormal physiological features, such as a tendency to ear infection. Other chromosomal abnormalities can include chromosomal rearrangements such as translocations, large-scale insertions and deletions, or inversions of chromosomal arms; these changes can result in errors of recombination whereby chromosomal arms exchanging DNA are incorrectly reconnected. In the case of some a translocations and inversions, there may be minimal or no effects on genetically-driven features if all of the misplaced or unordered genetic material is still present in the nucleus.

Polymorphisms and Mutations

Smaller-scale variations include local changes to the genomic sequence such as polymorphisms and mutations. Polymorphisms include common variants of particular segments of DNA and can vary in length from tens of nucleotides to a single nucleotide. ► Short tandem repeats (STRs) consist of small sets of nucleotides (usually two or three) repeated in several adjacent copies. Errors in the replication of DNA cause variation to arise by changing the number of short sequence repeats, so that the length of STRs may vary from individual to individual. This can potentially effect on proteins encoded from a DNA template as a varying number of repeats may affect the frame in which DNA coding is read when RNA is processed in translation. ► Single nucleotide polymorphisms (SNPs) are variations where a single nucleotide in the genome may differ from individual to individual. The effects of these polymorphisms may be nil, may alter protein functionality, or may directly change the sequence of encoded proteins. Single changes in the nucleic acid at a particular position may have effects on the single amino acid encoded, or no effects at all, whereas SNP insertion/deletion polymorphisms may shift the entire sequence of amino acids encoded by the DNA radically by changing the frame of reference in which the coding information is read. ► Mutations are another form of variation and may take several forms similar to the polymorphisms described above. Mutations identify changes in otherwise non-variant or differently-varying DNA within recent genetic history – a mutation can occur in a recent generation and be passed down to an individual, or can occur in the lifetime of an individual. Somatic cell mutations, due to errors in replication or DNA alterations by external stimuli, can be lethal and preclude transmission by affecting individuals' reproductive health; similarly, germline transmissions may affect a person's offspring without affecting the person themselves. However, as approximately 95% of DNA is noncoding, mutations at most points in the genome are unlikely to have any effect. Mutations are by nature infrequent, and can often be redefined to be polymorphisms if they achieve sufficient frequency in the population.

Conclusions

Genetic principles follow from the Central Dogma of Genetics – that DNA encodes RNA, which in turn encodes protein. Hence, several features exist in organisms to preserve and use DNA, and these also relate to several ways in which DNA can be altered to induce changes or differences between organisms of the same species. These differences in the genetic code between organisms of the same species can be characterized as genetic variations, of which there are several kinds,

including mutations, SNPs, and large-scale chromosomal abnormalities.

Genetics

Definition

Genetics is the study of heredity and how individual characteristics are transmitted by genes from parents to children.

Genetic Screening

Definition

Programs that identify persons within a subpopulation who may be at a higher risk for a genetic disease or condition.

Genetic Susceptibility

YOSEPH A. MENGESHA, CLARKE G. TANKERSLEY
School of Public Health,
Department of Environmental Health Sciences,
Johns Hopkins University, Baltimore, MD, USA
ctankers@jhsph.edu

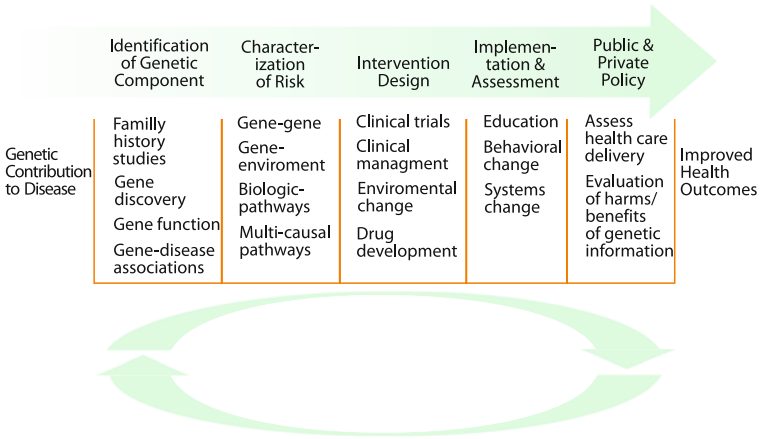
Definition

Genetic ► susceptibility is a condition in which changes in the genetic composition of organisms increase or decrease irritability to environmental factors like extreme temperature, high altitude, radiation, chemicals, air/water pollutants, occupational dusts, etc.

Basic Characteristics

Life, be it with or without ill-health, owes its existence to genes and their coincidental alterations. It is these genetic variations that have made evolution and life possible. Life forms continue to exist by virtue of steady streams of genetic novelties, which facilitate each organism's ► adaptation to extremes in environmental conditions. Adaptations originate from specific genetic determinants interacting with each novel environment. These genetic determinants may lead to favorable adaptation, or adverse consequences that in turn lead to less favorable disease processes. The latter circumstance is genetic susceptibility.

Gene mutations attract scientific attention immensely when their effects occur in the form of congenital diseases or disease susceptibilities, arising from deleterious genetic factors that are variants in nuclear and/or mitochondrial genomic sequences among individuals or populations. Genetic variations, depending on molecular dose, lead to the increase or decrease in susceptibility, which may be important particularly in chronic low-level exposures to environmental factors like air/water pollutants or radiation. With this in mind, researchers use genetic tools and strategies to identify individual susceptibility to environmental assaults. In brief, the essence of gene-gene and gene-environment interactions leading to various degrees of susceptibility patterns are illustrated by the following two flow charts; that is, general (Fig. 1) and specific (Fig. 2) flow charts entailing mechanisms that can raise public awareness and interest in disease susceptibility.



Genetic Susceptibility, Figure 1 Pathway illustrating translation of scientific findings into public health practices (Harrison et al. 2005). Permission to use this flow chart was obtained from Dr Karen Edwards, University of Washington and Editorial Assistant Sasha Ruiz, CDC

G

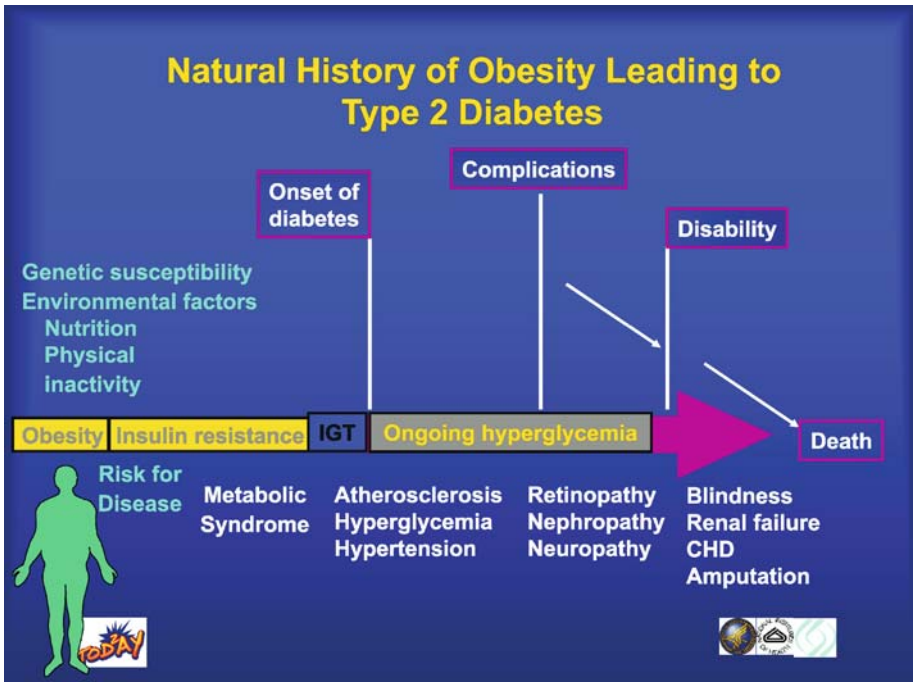
Changes Inducing Susceptibility to Disease

The identification of susceptibility genes is frequently complex, due to the contribution of multiple genetic factors; some have major effects and others have modulatory effects. For example, the genetic basis of type 2 diabetes (► diabetes mellitus) is quite a complex disease, which may evolve into different phenotypic outcomes of the disease. Atherosclerosis and retinopathy, for instance, are complications of type 2 diabetes that arise from different susceptibility genes. Environmental factors, such as nutrition and physical inactivity, contribute to the disease complexity and adverse consequences, like obesity and insulin resistance.

The development of diseases may depend more on one susceptibility gene than on another. In contrast, disease susceptibility may lead from an accumulation of environmental exposures in the face of a suite of genetic factors. Genomic variants inducing disease susceptibility are time-dependent determinants, being influenced by both acute and chronic environmental exposures. Classical examples with established genetic variants are acute lymphocytic leukemia and chronic lymphocytic leukemia. As an illustration, dioxin exposure has been suspected in leading to both acute and chronic leukemic processes (Bertazzi et al. 2001). When genetic variations are implicated, they may have originated from genetic alterations, such as deletion, insertion, inversion, duplication, substitution, and translocation. Any one of these disorders may be traced to several different genes and may account for acute and chronic disease conditions.

To date, more than 4.000 diseases caused by genetic variants are identified, and the majority of disease phenotypes arise when the gene is dominant (Bartoshesky 2004). This means that genetic changes may be: 1) Neutral, i. e., the change will have no effect on protein function or gene expression probably because the genes have low-penetrance; 2) Negative, i. e., there is a change in protein function or gene expression leading to an adverse health outcome; or, 3) Positive, i. e., there is a change in protein function or gene expression that is beneficial to the health of the individual. Genetic defects may be inherited often leading to a potential family history of disease. Alternatively, genetic defects can be coincidental arising from cells that are aging or are exposed to environmental factors such as diet, radiation, chemicals and some toxic pollutants. When cells fail to reverse or repair mutational changes, they develop susceptibility leading to diseases like cancers, diabetes, hypertension, and atherosclerosis. For example, lung emphysema from cigarette smoking, toxic effects from pesticide exposure and lead toxicity appear to be influenced by genetic susceptibility.

Industrialized societies appear to encounter greater number of chronic diseases that have multi-factorial origin. Gene-environment interactions constitute the primary cause for the development of common disease processes like chronic heart failure or skin cancer. Other environmental factors contributing to susceptibility diseases include diet, socio-economic status, age and gender. Susceptibility could also be induced by metabolism, and excretion or biotransformation of toxicants. In many susceptibility studies, it is noted that the number of genes involved in the biotransformation of toxicants and the cellular defense against toxicant-induced damage is growing.



Genetic Susceptibility, Figure 2 Adapted from "A Review Lecture on Type 2 Diabetes" by Dr. Jane L. Lynch, University of Texas. Permission to use this chart was obtained from Dr. Francine Kaufman, Children Hospital Los Angeles, CA, The Center for Diabetes, Endocrinology and Metabolism

Biological markers commonly signal events in specific biological systems. These markers fall into three categories: markers of ► exposure, markers of effect, and markers of ► susceptibility (Suk et al. 1987). Markers of susceptibility are now being used in the assessment of risk factors among individuals and populations. This assessment supplements epidemiological studies that can enhance early disease identification and prevention among the general population. Susceptibility differences in individuals, ethnic groups or populations confer either sensitivity or resistance to diseases. According to Suk et al. (1987), there are three categories of susceptibility markers expressing mainly individual variations:

1. Chemical alterations by enzymes leading to an increase or decrease in the ability of the chemical to interact with DNA, RNA or proteins.
2. Genetic differences of cellular capacity to repair DNA damage secondary to environmental insult.
3. Pre-existing hereditary defects that could be confined to one amino acid of a gene and increase the risk of chronic diseases like cancer.

Testing for genetic susceptibility through the use of DNA has now emerged to be an important tool for early warning and prevention of diseases. The need for such tests is, therefore, considered indispensable by laboratories, service providers, biotechnology firms, and scientists working in genetics. The assumption that it is possible to "fix" disease by "fixing" genes has become a plausible proposition.

Molecular Basis of Genetic Susceptibility

Hypotheses related to human evolution have been tested fairly accurately on molecular genetics of nuclear DNA, with 3×10^8 base pairs (inherited from both parents), and on mitochondrial DNA, with 16,569 base pairs (maternally inherited). However, the proportional density of base pairs involved in the process of gene expression is much greater for mitochondrial DNA than for nuclear DNA. The inheritance of variants in mitochondrial DNA is apparently the reason why some debilitating diseases of the nervous system pass from mother to offspring. Mitochondrial and nuclear DNA evolve independently with the rate of evolution being more rapid in mitochondrial than in nuclear DNA (Vawter and Brown 1986). Mitochondrial DNA is more sensitive to oxidative damage (e. g. resulting from increased exposure to radiation) compared with nuclear DNA (Morales et al. 1998). A primary source of biological aging is thought to result from damage in mitochondrial DNA leading to a decline in oxidative phosphorylation. Mitochondrial DNA levels are also significantly reduced in HIV-infected patients with hyperlactemia that is symptomat-

ic and nucleoside-related (Cote et al. 2002). In summary, mitochondrial DNA may be more susceptible to environmental insults than nuclear DNA.

It is occasionally observed that some diseases have common genetic determinants. For example, individuals with increased risk for Alzheimer's and ► coronary artery diseases have a common Apolipoprotein E epsilon-4 (APO E-e4) genotype (Rienzo and Hudson 2005). Likewise, many cancer-related genetic changes occur in the p53 tumor-suppressor gene, a mutant gene probably arising from exposure to carcinogens (Harris 1994). This genetic change is associated with a variety of tumors, and encodes a pleiotropic nuclear phosphoprotein that is involved in cell cycle control, DNA repair/synthesis and cell differentiation.

Negative mutations reflect molecular alterations in genes which can lead to diseases, given a specific environment exposure. Lung Cancer predisposition involves numerous genes and susceptibility loci that frequently require environmental exposure to cigarette smoke or air pollutants (Kiyohara et al. 2002). With respect to breast cancer, Ponder (2001) indicates that 13–40 susceptibility alleles account for all of the observed familial risks, including BRCA1 and BRCA2. Genetic susceptibility to ► asthma is attributable to multiple genes interacting with one another and the environment. Present findings indicate that genes near a major locus on chromosome 5q regulating serum cytokine levels lead to susceptibility to asthma (Hoffjan and Ober 2002). Asthmatic patients with this specific genetic susceptibility are more sensitive to the effects of common air pollutants, like ozone. Coronary Artery Disease (CAD) is caused by a complex series of factors consisting of genetic predisposition and environmental triggers. Most of these factors have their own genetic basis that may confer either susceptibility or protection to CAD. Many of the candidate genes implicated for CAD are associated with the regulation of low-density lipoproteins (LDL) and high-density lipoproteins (HDL). Susceptibility genes associated with CAD have been recently described (Watkins and Farrall 2006), and include CD14, toll-like receptor 4 (TLR4), and lymphotoxin-α 4H (LTA4H). Hypertension is attributable to a complex series of genetic susceptibility factors that appear to differ with respect to ethnic origin and the regulation of sodium homeostasis (Doris 2002). Type 1 diabetes is attributable to the sharing of alleles at susceptibility loci on chromosome 6 and at a minimum of 11 other loci on 9 different chromosomes (Todd 1995). Type 2 diabetes is a strongly familial condition associated with genetic and environmental factors. One susceptibility gene for type 2 diabetes is now identified to be HNF4a. HNF4a is understood to serve as a master switch for controlling many genes that function in the pancreas and liver (Touchette 2004).

In summary, the fact that individuals differ remarkably in their genetic susceptibility to diseases is epitomized by lung cancer. Although a majority of lung cancers are caused by tobacco, only a small fraction of all smokers develop lung cancer. According to Spitz et al (2003), one of the cellular processes explaining this inter-individual difference in risk is DNA repair capacity. In the future, early genetic susceptibility testing will serve as a major public health tool to avoid diseases and dramatically prevent morbidity and mortality.

Definition

The term molecular genetic analysis encompasses all procedures to examine variations (► mutations, ► polymorphisms) of DNA (► deoxyribonucleic acid) or RNA, respectively. In the field of medical genetics, molecular genetic diagnostics (MGD) is performed to identify disease-causing (pathogenic) mutations which are transmitted through the germline (eggs, sperm) to the next generation (germline mutations) as opposed to somatic, non inherited alterations. At present, MGD is particularly relevant in the group of monogenic diseases (hereditary disorders). These diseases are rare, follow Mendelian inheritance (autosomal-dominant, autosomal-recessive, X-chromosomal) and are each caused by highly-penetrant mutations in a single gene (Table 1). MGD can only be performed if the underlying (affected) gene has been identified. To date, around 4000 monogenic ► phenotypes caused by mutations in around 2000 different genes are known. In the near future, it is expected that the genetic etiology of any monogenic disorder can be clarified. Comprehensive and updated descriptions of monogenic disorders are provided by GenTests/GeneReviews (www.geneclinics.org).

The major applications of MGD include diagnostic testing, ► heterozygosity testing, prenatal diagnosis and predictive testing. Due to the nature of genetic disorders MGD can be performed on any accessible body fluid or tissue; the most common specimen is whole blood, while amniocytes or chorionic villus samples are collected for prenatal diagnostics. MGD represents an important part of clinical medicine; usually, it is performed in affected individuals or in persons at increased risk due to family history (family-based approach). More relevant to public health, but controversially discussed, are genetic screening programs of an entire population or a certain (ethnic) risk groups not related to a family history (population-based approach).

Basic Characteristics

Diagnostic Testing

Diagnostic testing is performed on symptomatic patients for diagnostic confirmation or differential diagnosis and is thus similar to other areas of medical diagnostics. Diagnostic testing is of special importance in (monogenic) phenotypes characterized by genetic ► heterogeneity (e. g. neuromuscular diseases) or unspecific symptoms (e. g. mental retardation). The spectrum of MGD for heritable disorders currently offered in Europe is available via the Internet (www.eddnal.com).

Heterozygote Testing (Carrier Testing)

Autosomal-recessive disorders manifest in the homozygote or the compound-heterozygous state and are more frequently observed in consanguineous couples. Heterozygous ► mutation carriers are clinically unaffected, but can transmit the mutation to their children. Heterozygote testing is defined as the examination

Genetic Testing, Table 1 Selected monogenic disorders, the corresponding gene, penetrance, and age at onset

Monogenic Disease	Gene	Penetrance*	Age at onset (years)
Cystic Fibrosis (CF)	*CFTR*	variable**	1
Duchenne Muscular Dystrophy (DMD)	*DMD*	~ 100%	early childhood
Hemochromatosis	*HFE*	1–2% (?)	30–60
Polycystic Kidney Disease, Autosomal-Dominant	*PKD1, PKD2*	> 50%	> 20
Spinal Muscular Atrophy (SMA)	*SMN1*	> 95%	birth – > 30
Familial Adenomatous Polyposis (FAP)	*APC*	~ 100%	> 10
Hereditary Non-Polyposis Colon Cancer (HNPCC)	*MLH1, MSH2, MSH6*	70–80%	> 25
Hereditary Ovarian Cancer	*BRCA1, BRCA2*	30–40%	> 25
Hereditary Breast Cancer	*BRCA1, BRCA2*	40–80%	> 25
Huntington Disease (HD)	*HD*	~ 100%	40–50
Myotonic Dystrophy Type 1 (DM1)	*DMPK*	~ 100%	10–30
Spinocerebellar Ataxia Type 1 (SCA1)	*ATXN1*	~ 100%	5–65

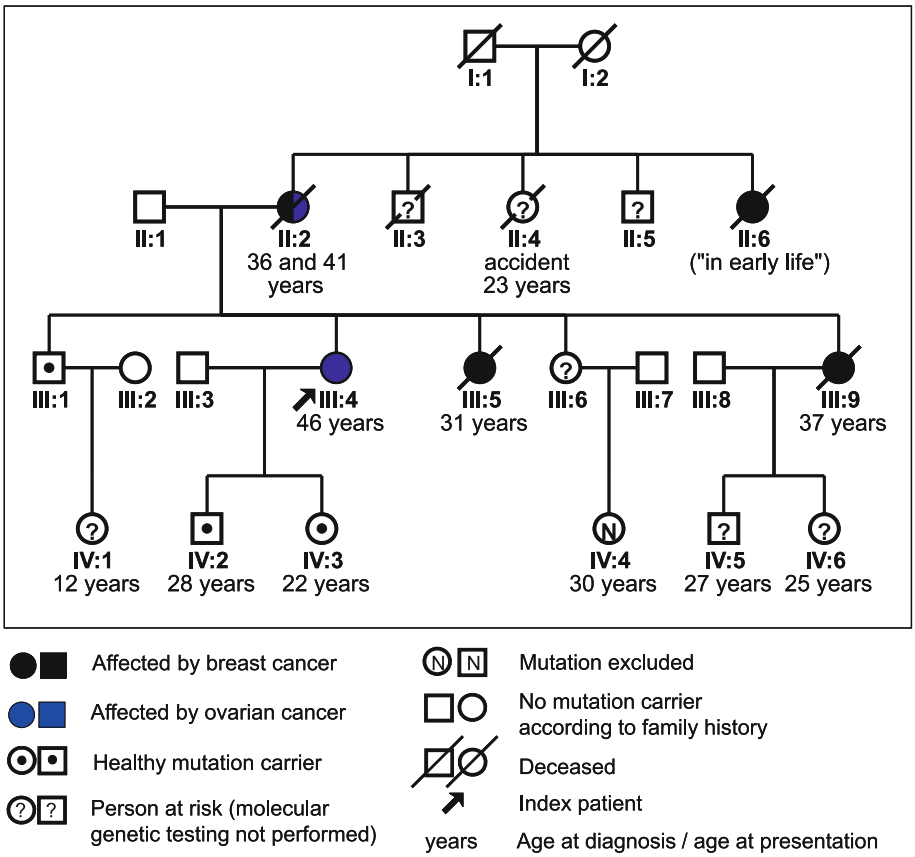
* Lifetime risk in untreated mutation carriers
** Dependent on genotype and clinical manifestation in the family

of healthy individuals for autosomal-recessive or X-chromosomal-recessive mutations in the heterozygote state. It is often requested because of a positive family history for an early-onset, severe, and non- or insufficiently treatable recessive disorder, such as cystic fibrosis or spinal muscular atrophy. Usually, a couple may wish to know what the chances are of their future children being affected by the condition that has previously affected other family members. Due to the mode of inheritance the recurrence risk is high (25%) in siblings of an affected person, but decreases rapidly in more distantly related relatives. It is advisable to primarily identify the disease-causing mutations in the affected person, otherwise a—generally slight—recurrence risk may remain in future children, even if the test results are negative, due to the incomplete mutation detection rate in most diseases. Assessment and communication of recurrence risks and their consequences are an important aspect of genetic counseling.

Predictive Testing

Predictive testing is defined as the examination of a presently healthy person for mutations that predispose to the development of a certain disease in future life. Although of great importance, it is not restricted to genetic analysis, as some other parameters also contain predictive information (e. g. HIV status, blood pressure, cholesterol level). Predictive genetic testing is primarily applied to healthy relatives (persons at risk) of patients affected by adult- or late-childhood-onset autosomal-dominant disorders (Table 1). To allow clear risk assessments, in most conditions, identification of the disease-causing mutation in an affected relative is required prior to genetic testing of persons at risk. If the known mutation is excluded the examined individual has no increased risk for the disease in question, otherwise the risk might be substantially elevated (Table 1, Fig. 1). However, the interpretation of a positive test result depends on the ► penetrance of the mutation and coexisting risk factors, it does not allow accurate prediction of age at onset or course of the disease. Therapeutic and prophylactic decisions must consider not only the genetic data, but also any other relevant findings in a patient.

Predictive DNA testing is the latest and most problematic molecular genetic application. It has opened a new area of medical diagnostics and offers tremendous service to many patients and their families, providing information and choices for their own lives and the life of their offspring. On the other side, there are numerous ethical and psychosocial issues that can arise since knowledge of an increased disease risk touches on sensitive private areas such as family planning. Predictive test results can relieve of a burden, but might also be accompanied by significant psychosocial distress.



Genetic Testing, Figure 1
Predictive testing exemplified in hereditary breast and ovarian cancer. Due to familial accumulation of cancer of a defined tumor spectrum (breast cancer, ovarian cancer) together with early age at onset, this family is highly suspicious for hereditary breast and ovarian cancer. All first-degree related females of an affected individual are persons at risk and should be admitted to an intense surveillance program. In the only affected female still alive (III:4), a pathogenic germline mutation in the *BRCA1* gene was identified, i. e. diagnosis of hereditary breast and ovarian cancer was confirmed by MGD. Thereupon, some of the persons at risk underwent predictive testing: in IV:4, the mutation was excluded, she no longer requires intensive surveillance, whereas IV:2 and IV:3 have to continue. Predictive testing has not yet been offered to IV:1 due to her young age

Every person has the right to know his or her genetic constitution, but also the right to ignore this information. Positive test results carry risks of stigmatization, discrimination, anxiety and depression. Important issues include the individual's right for genetic privacy from third parties (employers, insurers, the state) and communication of potentially relevant genetic information to relatives. In untreatable late-onset neurodegenerative disorders (e. g. Huntington's disease), many at-risk individuals opt not to be tested, preferring to live in a state of uncertainty.

To assure appropriate ordering for MGD, counseling and communication of test results, in Western societies, predictive genetic testing has been the area most stringently subject to standardized protocols, as paradigmatically developed for Huntington's disease. Voluntariness, specified informed consent, time for consideration, and strict confidentiality are prudent for predictive testing, which must be accompanied by pre- and post-test non-directive genetic counseling and psychosocial support services. These issues have been addressed in various ways by professional organizations in practice guidelines and recommendations.

Predictive genetic testing of children is controversially discussed. It is regarded appropriate for early-onset disorders that require surveillance or therapy in the near future (in particular, in a few familial cancer syndromes). It should not be offered in the context of late-onset (untreatable) conditions, as it prevents children from making their own decisions later on in life and thus interferes with the child's future autonomy and respect for confidentiality. This perspective is at least shared by professionals in Western countries but is not always accepted in other, less individualistic, societies.

Prevention

Predictive testing is of increasing importance to characterize certain risk groups who subsequently can be sub-

ject to specialized surveillance programs. In this context, hereditary tumor predisposition syndromes, such as hereditary non-polyposis colon cancer (HNPCC), familial adenomatous polyposis (FAP) or hereditary breast and ovarian cancer, are of outstanding relevance, since, on the one hand, the risk of developing cancer is high in carriers and, on the other hand, treatment of early tumor stages has proven to be very successful. Thus, surveillance procedures, like frequently performed colonoscopies or mammographies, are often very effective. Due to predictive testing, surveillance examinations can be restricted to mutation carriers with the high risk, while individuals at population-risk can avoid unnecessary investigations.

Prenatal Diagnostics (PD)

To detect abnormal growth and fetal malformations, prenatal ultrasound is routinely performed during pregnancy. The most common reason for invasive PD (amniocentesis, chorion villus sample) are age-related chromosomal aberrations such as trisomy 21 (Down syndrome). Non-invasive screening tests, like the First-Trimester-Screening, were introduced to avoid invasive procedures in case of negative results. MGD opened the field of PD for single-gene disorders: In principle, every monogenic disease that can be diagnosed by MGD postnatally can be tested prenatally as well. Usually, prenatal MGD is requested in case of a positive family history with respect to a severe, early-onset and untreatable condition, leading to termination of affected pregnancies. However, in some conditions, prenatal therapy can be offered. Normally, prenatal MGD is only reasonable if the parental ► mutation(s) of the disease in question have been identified.

The increasing application of (invasive) PD changed the perception of pregnancy by the parents and requires cumulative decisions regarding the appropriate spectrum of diagnostics and the consequences in case of conspicuous results. The increase of reproductive choices is accompanied by psychosocial stress and altered reproductive behavior. In particular, explanation of risk figures as well as interpretation of false positive and false negative test results is challenging. The conditions and the consequences of PD should be discussed with the parents prior to testing.

Preimplantation Genetic Diagnostics (PGD) involves single-cell genetic analysis performed on blastomere biopsy of embryos produced by in vitro fertilization (IVF). Due to technical complexity and costs, the procedure is restricted to a few specialized centers. Although discussed controversially in ethical respects, it has been successfully applied in pregnancies at risk for severe monogenic disorders such as cystic fibrosis, thalassemia and others (www.eshre.com).

Population-Based Screening

In the context of public health, population-based screening for genetic predispositions is of particular relevance. In Western societies, screening programs offered to large groups are considered to be justified only if therapeutic, prophylactic or reproductive consequences will follow from the results. Population-based approaches can be applied with two different intentions: 1. Screening to identify unaffected (healthy) carrier couples of (early-onset) recessive disorders (► heterozygosity testing) to offer prenatal diagnostics (reproductive population screening); 2. Screening to identify (as yet) healthy ► mutation carriers for severe (late-onset) monogenic diseases early in life so that preventive strategies or treatment can be initiated before irreversible organ damage occurs (predictive testing). Predictive population screening offers the chance of identifying at-risk individuals in the absence of any conspicuous family history. Whether or not a screening program is reasonable depends on several parameters, such as the heterozygote frequency in the population, the ► penetrance of the mutations, the ► predictive values, and the availability of a cost-effective, simple and valid test method.

Several heterozygote (carrier) screening programs for autosomal-recessive disorders have been successfully implemented in populations with a high carrier frequency: In some Mediterranean countries (Sardinia, Cyprus), thalassemia carrier screening is offered to couples since the health care system has been unable to guarantee appropriate therapy for the numerous affected individuals. In Israel, screening for population-specific severe metabolic disorders, such as Tay–Sachs disease, is widely accepted. The same is true for cystic fibrosis carrier screening in the United States. To date, the German Medical Association has refused population-based heterozygote screening because of several unsolved problems coming along with this procedure (see below).

The first and presumably most successful predictive screening program to be introduced for genetic disease is the newborn screening for some severe remediable autosomal-recessive disorders such as phenylketonuria. However, as with some other disorders (e. g. Tay–Sachs disease), biochemical testing is still preferred because it is more sensitive in case of mutational heterogeneity and more cost-effective than MGD.

Hereditary hemochromatosis is a late-onset monogenic disorder that serves as a particularly important model for preventive screening strategies relevant to public health. Untreated, hemochromatosis results in the accumulation of excess iron stores which lead to organ damage and life threatening complications. Periodic phlebotomy is a simple and effective preventive treatment that normalizes life expectancy if started in time. Thus, early identification of at-risk individuals through genetic screening is considered a major chronic disease prevention opportunity. However, epidemologic studies indicate low penetrance even for the hot-spot mutation in the HFE gene (low predictive value). Consequently, most of the individuals tested positive will be anxious due the genetic information, but may never develop any symptom of the disease. Especially due to this uncertainty regarding penetrance as well as the limited capacities for genetic counseling, universal population screening has not been generally recommended, so far.

Other predictive, often only regionally introduced, (newborn) screening programs include sickle cell disease, cystic fibrosis, Duchenne muscular dystrophy, or α-1-antitrypsin deficiency. These approaches are aimed to avoid unnecessary investigations and hospitalizations through early diagnosis, as well as costs and parental anxiety associated with having an ill but undiagnosed child. Some of these conditions may hopefully be influenced by early therapeutic or prophylactic intervention. However, the context of population screening for genetic disease is different from that of genetic counseling as a response to pre-existing family concerns, which has important ethical implications for professional practice in this area. All recommendations relevant to heterozygote, prenatal, or predictive testing in a family-based setting are by far more difficult to realize in a population screening program. Problems may arise particularly regarding appropriate information and counseling, informed consent, psychological support, and nondirective decision making. Established screening programs are vulnerable to routinization possibly resulting in a directive or even actively promoted procedure; thus, consent for entry into a screening program is often not based on careful considerations. The rate of uptake is critically dependent upon the way in which testing is made available, and the influence of structural and social factors on individual decision making about genetic tests is well known. Being identified as a carrier may have potential benefits (ability to make informed reproductive decisions, prophylactic therapy, clear diagnosis) and disadvantages (emotional impact, burden of future reproductive decisions, stigmatization in personal relationships, effects on an individual's sense of well-being and development). Against this background the question as to which of these tests should be made available as population screening must be carefully balanced.

To date, genetic testing usually includes only one or a few genes. However, the development and implementation of high-throughput technologies will allow comprehensive screening in the near future. From a technical point of view it is already possible to design assays for the detection of all known human mutations responsible for hundreds of diseases. Such methods can be introduced as predictive or prenatal population screening. However, only some of the diagnoses will have preventive consequences. The obvious ethical concerns in such scenarios have to be discussed.

Common Complex Disorders

In Western countries, most of the common disorders are caused by a multifactorial (complex) etiology (Table 2), i. e. they manifest by means of interactions between genetic predispositions and environmental factors. Due to their frequency and morbidity, the laborious treatment and corresponding health-care costs, these disorders are in the spotlight of preventive considerations and are extraordinarily relevant to public health. The search for underlying susceptibility ► alleles ('risk genes') has become one of the most active areas of biomedical research.

The most common predisposing genetic variants are ► single nucleotide polymorphisms (SNPs). However, only a statistical correlation exists between a certain SNP (genetic variant) and the ► phenotype. Usually, each of the underlying variants of a complex disorder is of low ► penetrance, contributing only little to disease manifestation (relative risk 1–5-fold). Research in

Genetic Testing, Table 2 Selected complex (multifactorial) disorders and the corresponding genes, in which risk associated variants (SNPs) have been described (not complete)

Complex Disease	Risk Associated Genes
Obesity	*GAD2, POMC, ACDC, ADRA, LEP, UCP, APOE, TGF-ß-1, ENPP1*
Cardiovascular Disease	*F2, ITGB3, GNB3, ACE, PDE4D, GPIIIa, MTHFR, AGT, AGTR1, ECE1, ADD1*
Type II Diabetes Mellitus	*CAPN10, HNF4A, NEUROD1, GLUT, IRS1, GPD2, TCF7L2*
Asthma	*ADAM33, GPRA, PHF11, DPP10, HNMT, AAA1*
Crohn's Disease	*CARD15/NOD2, SLC22A4, SLC22A5, DLG5*
Psoriasis	*CDSN, CMRF35H, RAPTOR, RUNX, HLA-B, HLA-C, OCT3*
Schizophrenia	*DAOA, NRG1, DTNBP1, SYN2, COMT*

complex traits is challenged by the difficulty in identifying susceptibility genes of modest effect, the large scale of the required family studies, and the extensive interactions between the different predisposing alleles at DNA, RNA or protein level and with the outside environment. Thus, our understanding of the genetic basis of complex diseases is still in its infancy and use of the data for prevention and treatment will require much more time than previously thought. Although identification of certain risk profiles in the future may contribute to an individual risk calculation in addition to traditional risk factors, to date, MGD in complex disorders is not reasonable in routine clinical practice. Despite these limitations, testing for SNP-based 'risk profiles' (e. g. for osteoporosis, cardiovascular disease, 'anti-aging'), associated with the hope of specific preventive options, is increasingly offered to the general public by commercial laboratories, particularly via the Internet. This trend should be seen very critically, as, apart from the lack of indications and low or absent ► predictive values of these analyses, professional quality standards of risk communication and counseling are often not guaranteed, leading to confusion, false reassurance or unnecessary anxiety.

One of the most promising fields is pharmacogenetics. Identification of genetic variants affecting the metabolism and impact of certain drugs may explain individual reactions and adverse effects. Although still at the early stages of their application in routine clinical practice, genotyping (► genotype) of relevant variants in pathways of drug metabolism may lead to an individualized drug therapy and drug design, increasing desired drug effects and avoiding complications. For example, screening for an activity-decreasing allele of the DPD gene is already recommended prior to chemotherapy with 5-fluorouracil to avoid severe side effects in carriers of the variant.

Conclusions and Perspective

MGD has increasing relevance for medical diagnostics and the prediction of individual or population-based disease risks. Virtually every patient undergoing diagnosis or treatment in the coming decades will be involved in some sort of molecular genetic procedure. However, MGD differs from conventional clinical laboratory analyses and genetic testing in other disease types (e. g. infectious diseases) in important ways. Therefore, specialized knowledge of human genetics is essential for appropriate interpretation and communication of results. A clear indication is required for any genetic test. The psychosocial and ethical implications of MGD vary substantially depending on the reason for testing: In particular, prenatal and predictive diagnostic procedures should be accompanied by genetic counseling as part of helping patients to understand and come to terms with possible implications. To date, MGD has limited clinical relevance for complex genetic disorders, although rapidly increasing knowledge on the underlying genetic factors and high-throughput, automated technologies (e. g. microarrays) allows ever more comprehensive genetic analysis. However, as the technical aspects of DNA tests have become easier, their interpretation becomes more complex and their limitations must also be kept in mind. In the future, MGD will not be restricted to medical genetics but will involve all areas of medicine (genetic or molecular medicine) and might play a major role in preventive strategies. The associated ethical and psychosocial issues will be challenging and will require new ways of risk communication and counseling.

Genome

Definition

The complete set of hereditary information contained in the DNA of an organism. This includes the full primary nucleotide sequence information for all the ► chromosomes, including introns, exons, coding, and noncoding sequences.

Genomics

► Transcriptomics

Genotype

Synonyms

Genetic constitution

Definition

The genetic content at a given locus (unit of genetic information). In diploid organisms like humans, the genotype is the combination of the two ► alleles of a certain gene or genomic/chromosomal position (locus) in an individual. More generally, the genotype describes the genetic constitution of an individual as a whole.

Genuine

► Native

Geographic Information System (GIS)

Definition

The geographic information system is a branch of ► health information system and ► public health information system developed for the capture, storage,

manipulation, analysis, and visualization of geographic data in public health. It provides analysis of spatial and temporal relationships between disease and the population. GIS software has been used in many ecological studies of disease, such as assessment of childhood leukemia in areas with different radon levels, clustering of respiratory cancer cases in areas with a steel foundry, and socioeconomic gradients in infant mortality. The GIS is a very useful tool for public health planning and surveillance purposes at local or national health departments.

Geomedicine

Synonyms

Medical geology

Definition

Geomedicine encompasses investigation of broader relationships between the natural geologic environment and the health or occurrence of disease in humans, animals, and plants living in the environment. Deficiency or anomalous distribution of trace elements is manifested as health problems in the form of enzootic or/and endemic geochemical disease. Living organisms that consume water and food grown in such areas can acquire various forms of disorders. In the beginning of the 20th century, only the importance of iron was known; however, in the following 20 years, Cu, Zn and Co were added as important trace elements. There are numerous examples of geographic variations in disease occurrence that may arise from geologic factors. The identification of a single significant geochemical characteristic from the dozens that vary simultaneously is complicated as the presence or abundance of one element modifies the effect of another.

Georemediation

Synonyms

Soil remediation; Soil cleanup

Definition

Remediation of soil uses principles of geology, physics, chemistry, and biology to degrade, attenuate, isolate, or remove soil contaminants in order to restore soil values and functions. There are two main strategies for soil remediation: *in situ* georemediation involves treating the contaminated soil at the site, while *ex situ* involves the removal of the contaminated material to be treated elsewhere. Examples of particular procedures are soil excavation and removal to a disposal site away from sensitive ecosystem contact, aeration of soils at the contaminated site (with risk of air pollution), extraction of groundwater or soil vapor with an active electromechanical system, and containment of the soil contaminants (by capping or paving over in place). Combined techniques used with bioremediation include landfarming, biostimulation, and bioaugmentation of soil biota with available microflora. The process of georemediation can be monitored indirectly by measuring the Oxidation Reduction Potential, or redox, in soil, together with pH, temperature, oxygen content, electron acceptor/donor concentrations, and concentration of breakdown products (e. g. carbon dioxide).

Geriatric Chaplain

► Hospice Chaplains

Geriatrics

Synonyms

Geriatric medicine

Definition

Geriatrics is the branch of clinical medicine focusing on health promotion among older people and the prevention and treatment of disease and ► disability in later life. Older people frequently have multiple co-morbidities and their presentation of symptoms is often different than the reaction of younger people to the same disease or condition.

Geriatricians are primary care physicians who are specially trained to detect and address the health concerns and care needs of older adults. In addition to general practitioners, professionals in the fields of nursing, social work, psychology, psychiatry, pharmacology, and physical and occupational therapy, among others, may specialize in geriatric care. Common areas

of concern in geriatrics include: complications due to co-morbidities and multiple medications, dementia and memory loss, delirium, frailty, incontinence, falls, and disabilities limiting the performance of activities of daily living.

German Measles

► Rubella

German Measles Immune Globulin

► Rubella-Vaccination, Passive

German Measles Immune Prophylaxis

Germs That Cause Malaria

► Plasmodia

Gerontology

Definition

Gerontology is a multi-disciplinary field encompassing the scientific study of aging and the application of knowledge in the design and implementation of programs that promote the well-being of older people. Researchers in gerontology use the methods of biomedical and social sciences to understand the biological, psychological, and sociological phenomena associated with old age in individuals and in populations. Gerontologists specialize in the study of aging within fields including: biology, demography, epidemiology, health services research and administration, nursing, psychology, and sociology, among others. Applied gerontologists work directly with older persons in programs providing health and social services and engage in education, communication, and advocacy with and on behalf of the older population.

Note that gerontology, the study of aging, should be differentiated from ► geriatrics, the branch of clinical medicine focusing specifically on the medical needs of older people.

Gestation

► Pregnancy

Gestational Diabetes

Synonyms

Diabetes mellitus that begins during pregnancy

Definition

Gestational diabetes is defined as carbohydrate intolerance of variable severity with onset or first recognition during pregnancy. It can develop in overweight, hyperinsulinemic, insulin-resistant women or in relatively thin insulin-deficient women. Diabetes during pregnancy increases fetal and maternal morbidity and mortality. Women with gestational diabetes are at risk of developing diabetes later in life. Without treatment gestational diabetes is a risk factor for eclampsia, fetal death (► intrauterine mortality), macrosomia, fetal hypoglycemia, and the development of ► obesity and diabetes in childhood and adolescence. Gestational diabetes should be prevented by changes in diet, increases in physical activity, and – if the foregoing are not successful – insulin replacement therapy.

Giardiasis

Synonyms

Infection with Giardia lamblia

Cross-References

► Lambliasis
► Zoonotic and Parasitic Infections

Gingivitis

Definition

Gingiva is the fibrous investing tissue, covered by epithelium, which immediately surrounds a tooth and

is contiguous with its periodontal membrane and with the mucosal tissues of the mouth. Gingivitis is a form of ► periodontal disease, an inflammation and infection that destroys the tissues that support the teeth, including the gingiva (gums), the periodontal ligaments, and the tooth sockets (alveolar bone). Gingivitis is caused by the long-term effects of plaque deposits. Plaque is a biofilm that develops on the exposed portions of the teeth, consisting of bacteria, mucus, and food debris.

Global Climate Change

► Climate Change

Global Health Policy

WOLFGANG BÖCKING[1], DIANA TROJANUS[2]
[1] Allianz SE Sustainability Program, München, Germany
[2] Forschungsverbund Public Health Sachsen-Sachsen Anhalt e. V., Medizinische Fakultät, Technische Universität, Dresden, Germany
wolfgang.boecking@web.de, dtrojanus@gmx.net

Definition

Global health policy refers to a concept of health policy beyond national borders, thus being much broader than traditional health policy assuring only national health. The term "global" refers to the fact that health problems are no longer coming only from one's own country but also across borders and that the common understanding of the multiple health determinants has expanded. Global health policy is calling for health strategies that take the effects of globalization and global ► decision making into account. Lee and Collin define global health as an "issue when the determinants circumvent, undermine or are oblivious to the territorial boundaries of states and thus beyond the capacity of individual countries to address through domestic institutions." In this sense, global health policy addresses various global health risk by setting concrete ► health targets that are based on outcomes (e. g. child mortality rates) and processes (e. g. initiatives to eliminate certain diseases). The actors in global health policy are international organizations such as the United Nations, the World Health Organization, a grouping of national governments (e. g. European Union) following global health targets and a number of private corporations, foundations and non-governmental organizations with global reach.

Basis Characteristics

Development of the Notion of Global Health Policy

Global health policy is mainly concerned with health risks that can be characterized as 'global'. They include traditional infectious diseases such as tuberculosis and new emerging diseases with typically pandemic character such as HIV/AIDS and avian flu as well as chronic diseases which are traditionally of the wealthier societies but are slowly becoming also a burden for poorer countries. Other risks to health are environmental factors such as pollution, natural disasters, economic and social situation as well as war causing food insecurity and malnutrition, preventable morbidity and premature death. Especially the control of pandemic diseases is a major concern among the global community as all nations are vulnerable because of the potentially large economic and social impact. As these diseases may be aggravated by the constant increase of cross-border flows of people, goods and services, global action in addition to existing national protection programs is needed to control such pandemic diseases. The process of globalization is leading to the internationalization of health risks and strengthens the interdependence between countries. Therefore, global health policy requires cooperation and coordination of ideas and policy projects in order to protect and improve health as a global public good.

There is a wide variety of interlocutors engaged in global health policy: The United Nations (UN), the World Health Organization (WHO) as well as the World bank are playing a vital role in defining global health policy goals and in financing and administering policies to achieve these goals. But also international non-governmental organizations (NGOs) as well as other private corporations or donors are financing and realizing health activities around the world.

Global Health Targets of the World Health Organization (WHO)

Numerous governments in the Member States of the WHO European Region and in OECD countries utilize ► health targets as an instrument and guidance

for policy formulation and implementation. The WHO launched a strategy in 1977 called "Health for All by the Year 2000" to set global targets and to form a global vision of health amongst the member states. In May 1998, WHO adopted a resolution to continue global efforts under the "New Global Health for All" policy and formulated 10 global health targets that can be divided into three subgroups.

1. Four ► health outcome targets concentrating on health equity, survival, the reverse of the global trends of five major pandemics (tuberculosis, HIV/AIDS, malaria, diseases related to tobacco, and violence or trauma) and the elimination of certain diseases before 2020.
2. Two targets on determinants of health: the improved access to water, sanitation, food and shelter and measures to promote health enhancing lifestyles and to weaken health damaging ones through a combination of regulatory, educational, economic and community-based programs.
3. Four targets on health policies and sustainable health systems focusing on the implementation of national "Health for All"-consistent policies, on the improved access to health care, on the implementation of a global and national health information and surveillance system and on research for health.

This framework is a guideline for all member states. It has to be mentioned that member states implement and adjust these targets according to their own economic and social situation. The degree to which a country has already developed its own health system plays a major role in the relevance of the different goals stated by WHO.

Millennium Goals of the United Nations

In the year 2000, at the Millennium Summit the member states of the United Nations adopted the UN Millennium Declaration, committing their nations to a new global partnership to reduce extreme poverty and setting out a series of time-bound targets, with a deadline of 2015, that have become known as the eight Millennium Development Goals. Five of them are directly linked to global health:

- Eradicate extreme poverty and hunger
- Reduce child mortality
- Improve maternal health
- Combat HIV/AIDS, malaria and other diseases
- Ensure environmental sustainability

On the basis of these goals, the UN publishes every year a report summarizing global action that has been taken in order to achieve these goals.

Opportunities and Risks of Global Health Policy

Because of the numerous actors in global health policy there are on the one hand a multitude of opportunities to realize global health goals, but on the other hand, there are many risks or problems inherent to such an undefined policy approach.

Key success factors for a large-scale health policy are clearly the following:

- Leadership: Political leadership on a national and international level is crucial to the achievement of global health policy goals not only in the poorer but also in the richer countries.
- Science: Scientific tools are needed to effectively treat and prevent diseases on the best available cost basis.
- Money: Sufficient sums of money over a long period of time are the basis to realize global health policy measures.
- Implementation: Good management of the policy programs as well as evaluation of programs on the ground necessary to use resources efficiently with regard to the results.

On the basis of the stated success factors, there are two main questions surrounding the effectiveness of global health policy:

1 Does the global community have the right institutions and systems to effectively achieve global health goals?
2 How can the private sector be more effectively engaged?

With respect to the role of research in global health it is estimated that less than 10% of research funds are spent on the diseases that account for 90% of the global burden of disease. Furthermore, research should always be an important part of the policy process providing evidence, laying out options for policy problems and measuring the effects of decisions. Unfortunately, policy ► decision making is often independent from research.

Since 2000, there is a considerable rise in the allocation of financial resources toward global health with the emergence of new private foundations and programs spending money for specific diseases. Neverthe-

less, the results are still disappointing as donors often fund projects on the basis of effort and not on the basis of results.

To sum up, global health policy making is complicated because of the proliferation of actors and institutions whose respective functions and purposes are both highly varied and often unstable. They operate in a confused and often contested domain. Some actors are present 'in the field' and while others will act temporarily on one specific issue. There is definitely a lack of relationship and cooperation with each other.

Example: Global Health Activities in the European Union

Europe's contribution to global health policy has been emphasized at the European Health Forum in October 2004 "Global Health, Global Healing". European Foundations working with the European Foundation Centre (EFC) have taken a range of initiatives with international and academic organizations attributing 5% of their spending outside Europe on global and development issues concerned by the UN Millennium Development Goals. The main strategic issues relating to global health are the following:

- Health and foreign policy: Europe's major role in preventing conflicts and assisting in post-war situations has to be strengthened.
- Health and sustainable development: Environmental changes as well as demographic changes in the European society need the collaboration of all actors which could be guided by the EFC.
- Health and economics: As global health issues such as pandemics could substantially affect the economic situation of the countries, the impact of industrial and research policy on health has to be assessed and clarified.
- Health and governance: The challenge of global health policy is to bridge the gap between the aspirations of the numerous actors and donors in this field and the actual results. The European Union could play an important role in the architecture of effective health governance.

Globalization

Synonyms

Increasing worldwide interdependence

Definition

Globalization is the process of increasing interconnections and linkages, within societies and across geographic areas, due to improved communication and expanded world trade. It limits the differentiation wrought by human cultural evolution, and homogenizes health practices, diets and lifestyles.

Globalization means an intensification of the processes of interaction involving institutional, social, political and economic dimensions that became a pervasive force for change in the last 2 decades of the 20th century. Social and institutional dimensions include the spread of education, literacy, scientific and technical expertise, democratic practice, civil and human rights, spread by free and open media and by capacity building in low-income countries. Economic and political dimensions of globalization include improvements for all society through privatization, de-regulation, flexible

labor marker, and free trade. However, these dimensions of globalization have a mixed impact on social well-being and population health; beneficial in industrialized countries, but producing enormous inequalities across the world in developing countries and often within each country.

Globalization is the process of increasing economic, political, and social interdependence, and global integration, that occur as capital, traded goods, people, concepts, images, ideas, and values diffuse across national boundaries. The benefits of globalization include the expansion of global markets, international savings, and technology transfers to many countries, which corresponds with increased human development, and supports the physical infrastructure, and microeconomic and macroeconomic policies. The effects of globalization on health are not easily predictable because they are mediated by income growth and distribution, economic instability, availability of health and social services, health policies, etc. For example, many African and Asian countries still have a high infant mortality rate (a key indicator of overall health), despite the implementation of highly efficient public health activities (e. g. vaccination programs).

Global Solar UV Index

► UV Index

Global Trade in Health Services

Definition

The impact of globalization on ► health services manifests in global trade in health services. It includes global cross-border delivery of health services, especially through electronic communication (► telehealth); movement of health professionals for the best education, employment or career opportunities; and the movement of patients from one country to another in order to get health services of the highest quality. The trade in health services is regulated by the General Agreement on Trade in Services (GATS), constituted by the World Trade Organization. The expected long-term consequence of these trends is improvement of ► health systems. This will be a result of the flow of financial resources, changes in health determinants and disease priorities, reorientation of health policies, and overall performance of health systems.

Global Warming

Synonyms

Greenhouse effect

Definition

The greenhouse effect is the process in which the absorption of infrared radiation by an atmosphere warms a planet. The effect occurs naturally to keep Earth's surface warm. However, the anthropogenic greenhouse effect results from gases, especially CO_2 emitted from human activities – such as fossil fuel burning, cement production and tropical deforestation. Elevated CO_2 levels increase global mean temperature by absorbing infrared radiation in the troposphere. Other greenhouse gases are methane, water vapor, ozone, nitrous oxide and halocarbons. The consequences of greenhouse effect are the increase of global temperature on the Earth, increase of sea levels; the melting of snow and ice layers on the North Pole, temperature abnormalities in the Pacific Ocean, resulting in El Niño events. Adverse consequences on agriculture, ecosystems and human health are expected. This in conclusion the greenhouse effect is the Absorption of infrared radiation emitted by the Earth's surface by the ► greenhouse gases in the atmosphere, trapping the heat within the surface-troposphere system and warming the Earth's surface.

Cross-References

► Greenhouse Effect
► Prospects for the Future

GNP (Gross National Product)

Synonyms

Gross National Income (GNI)

Definition

Indicators of national income and output are used in economics to estimate the value of goods and services produced in a political national economy. The GNP as

such is an indicator for the impact of the net product of a country and it is often used as a measurement to assess people's welfare. It is calculated according to the so-called national (domestic) concept. The GNP is the sum of the value of the income of all nationals during a specific period (1 year) drawn from work (employee's salary) and capital (company and assets' income) plus production and import fees, minus financial aids. Thus, the GNP is – within the economical overall calculation – an indicator expressed in money for the income of the nationals of a political national economy.

The relationship between Gross National Product (GNP) and Gross Domestic Product (GDP) – the indicator for the economic performance of a country – is as follows:

GNP = GDP + foreign income of nationals
– domestic income of foreigners.

Goitre

Synonyms

Struma; Thyreomegaly

Definition

Goitre is defined as enlargement of the thyrod gland that may be associated with changed function of the thyroid that can result from under-production or over-production of hormone or from a deficiency of iodine in the diet.

Gold Standard

Definition

We can calculate the sensitivity and specificity of ► screening tests only by comparing the results obtained by the screening test with results derived from some gold standard. A gold standard is an external source of truth regarding the disease status of each individual in the population. Sometimes this truth may be the result of another test that has been in use, which is very often a more invasive test (tissue biopsy, or cardiac catheterization). If the results from the screening test are the same as the results from the gold standard then the screening test would be 100% sensitive and 100% specific.

Good Agricultural Practices (GAP)

Definition

Good Agricultural Practices are applied on farms and they define elements for development of good management practices in production of fruit and vegetables. These practices are approved by major retailers and regulators worldwide. Farmers should be able to: maintain the consumers' trust in and expectations about the safety and quality of food, minimize undesirable effects on the environment whilst preserving nature and wildlife, reduce use of fertilizers, enhance the efficient use of natural resources, and have a responsible attitude towards health and safety of workers. GAP respects the preventative approach to ► food safety and helps maintain the required traits of raw material. GAP is a voluntary standard but it is being more and more accepted by regulators. Together with standards in food production it helps maintain the required level of food safety.

Good Clinical Practice (GCP)

Definition

Good clinical practice, when applied to pharmaceutical clinical trials, defines the most desirable way of running trials. Like good manufacturing practice (GMP, defines state of the art production of pharmaceuticals, conceived by the Pharmaceutical Inspection Convention and Pharmaceutical Inspection Co-operation Scheme [PIC/S]) and good laboratory practice (GLP, defines state of the art preclinical and analytical testing of pharmaceuticals, implemented by the Organization for Economic Co-operation and Development [OECD]), it regulates the general principles of developing and/or handling pharmaceuticals in any scientific area of interest. All these systems are regulated or handled by international organizations thereby providing a global framework for developing new pharmaceuticals.

Good Hygienic Practice

► Standard Sanitary Operating Procedures (SSOP)

Good Manufacturing Practices (GMP)

Definition

Good Manufacturing Practices describe methods, equipment, facilities, and controls for producing processed food. As the minimum sanitary and processing requirements for producing safe and wholesome food, they are an important part of regulatory control over the safety of the food supply. Many of the microbiological ► food safety problems can potentially be addressed through GMPs such as: proper employee hygiene, adequate training, and effective cleaning and sanitizing of the manufacturing equipment and environment. Rules for construction and maintenance of facilities and equipment, handling of water to be used in food production, storing of food, additives, cleansing utensils and materials are addressed through GMP practices. Chemical food safety problems are addressed by following good manufacturing practices, such as pest control and proper storage and use of chemicals.

Goodness of Fit Test

Definition

A goodness of fit test is a statistical test to determine whether there is a significant difference between the observed frequency distribution and a theoretical probability distribution (such as normal, binomial, poisson, etc.) that is hypothesized to describe the observed distribution. Various goodness-of-fit summary statistics can be computed for continuous and categorical dependent variables. Goodness of fit statistics for regression problems (for continuous variables) include mean square error, mean absolute error, mean relative squared error, and Pearson product moment correlation. Goodness of fit statistics for classification problems (for categorical variables) include Pearson Chi-square, G-square (maximum likelihood Chi-square), and Percent disagreement (misclassification rate).

Governmental Health Care

► Publicly-Financed Health Systems

Governmental Regulations

Synonyms

Collaborative initiatives; Cross-sector reallocation

Definition

Planning, funding, or service delivery strategies that engage key stakeholders across a range of governmental and private sectors. These efforts are often initiated to bridge the operations of distinct policy sectors whose actions have consequences for shared social goals – such as health maximization. These efforts may focus on linking units within the health care sector, linking the health care sector with other social service sectors, and/or linking seemingly unrelated policy sectors such as agriculture, education, fisheries and tourism.

Government Liability

► State Liability

Granuloma Inguinale

Synonyms

Donavanosis; Granuloma venereum

Definition

Granuloma inguinale, which can be found in tropical and subtropical regions, is caused by *Calymmatobacterium granulomatosis*. The incubation period lasts 1–12 weeks. The disease is characterized by small, painless nodules, which appear in the genital region. During the course of the disease these nodules ulcerate and slowly enlarge. A hematogenic spreading of the germs into the liver and the bones is possible. To avoid larger destruction of tissue, antibiotic therapy should be introduced quickly. The duration of treatment should be three weeks. Trimethoprim-sulfamethoxazole, azithromycin, erythromycin, gyrase inhibitors or doxycycline are effective drugs.

Graphical Representation

Definition

A graphical representation is a visual display of data and statistical results. It is often more effective than presenting data in tabular form. There are many different types of graphical representation and which is used depends on the nature of the data and the type of statistical results. An appropriate graphical representation of category frequencies is a pie chart, where each slice represent a different category and slice angles are proportional to the frequencies of the categories. Another graphical method used for category frequencies is a bar chart, where each bar represents a different category and the heights of the bars are proportional to the frequencies of the categories. Suitable graphical representation of frequency distribution of discrete quantitative data is also a bar chart, while for frequency distribution of continuous quantitative data convenient graphs are a histogram, frequency polygon, and/or stem-and-leaf plot. Suitable graphical representation of relationships between two variables is a scatter diagram (scatterplot). Other frequently used types of graphical representation are (a) line graphs for longitudinal data, (b) survival plots for cumulative probability of survival over time, (c) error bar for displaying central tendency, mean or median, and variability such as quartiles, standard errors or standard deviations, and (d) box-and-whisker plot for displaying minimal and maximal values, interquartile range and median.

Synonyms

Gravidness; Pregnancy

Definition

Gravidity represents the number of pregnancies a woman has had whether or not they produce a ► live birth.

Gravidness

► Gravidity

Greenhouse Effect

Synonyms

Global warming

Definition

The greenhouse effect is a term for the chain of events caused mainly by the accumulation of certain gases (greenhouse gases) in the low atmosphere (troposphere). Permanent increases in the concentration of these gases in the atmosphere may be responsible for the remarkable changes of climate on Earth (► climate and microclimate). Greenhouse gases influence the ways that temperature is balanced on Earth and, due to increased absorption of radiation in the infrared spectrum, air temperature increases as it would inside a greenhouse. This means that these gases trap the infrared radiation, or heat, which is given off by the Earth's surface after receiving it from the sun, inside the troposphere. If humans continue to increase the concentration of these gases in the atmosphere it will inevitably lead to global warming of our planet to a dangerous degree as a final consequence of that process. Major gases responsible for global warming are carbon dioxide and methane, which are released into the troposphere by the burning of fossil fuels and farming practices, respectively. Besides water vapor, other greenhouse gases are nitrous oxides (NO_x), chlorofluorocarbones (CFC-11 and CFC-12), methyl chloroform, carbon tetrachloride, ozone, and even carbon monoxide. The main effects of greenhouse gas accumulation on the climate are as follows:

a) Increased mean air temperature, especially at high latitudes and near the poles,
b) Extreme weather disturbances – e. g. floods,
c) Increased air pollution in large human settlements (as a feedback effect), although the greenhouse effect is also a consequence of air pollution,
d) Increased annual global rainfall,
e) Increased incidence of vector borne diseases – malaria, leishmaniasis, tick-borne encephalitis, Lyme disease, and even dengue,

f) Seasonal changes – short cold seasons and long warm ones,
g) Unequal changes in plant growth – weeds may increase their growth but crops may not,
h) Thermal expansion of the oceans, and possible polar ice cover melting, leading to a substantial rise in sea level, and
i) Various adverse effects, unpredictable at present, on the whole society.

Possible adverse effects on human health are also difficult to predict but, unquestionably, urban thermal stress would claim many lives (Recently, an increased incidence of heat-related deaths have been registered in London, Belgium and Athens). Among several possible ways of dealing with the problem, the most obvious way is reducing the production of greenhouse gases, which means reducing the rate at which fossil fuels are burnt.

Cross-References

► Prospects for the Future

Greenhouse Gases

Definition

Gaseous constituents of the atmosphere that absorb and emit infrared radiation, responsible for the ► greenhouse effect. The primary greenhouse gases are: water vapor, carbon dioxide, methane, nitrous oxide, and ozone.

Grippe

► Influenza and Avian Influenza

Gross Domestic Product

Synonyms

GDP

Definition

Gross domestic product is the total market value of all the goods and services produced within a country during a specified period of time.

Gross National Income (GNI)

► GNP (Gross National Product)

Gross Reproduction Rate (GRR)

Definition

Gross reproduction rate (GRR) is the average number of daughters that would be born to a woman during her lifetime if she passed through her child-bearing years conforming to the ► age-specific fertility rates (ASFR) of a given year. GRR is measured exactly like TFR except that it counts only daughters and measures "reproduction" – a woman reproducing herself in the next generation by having a daughter. Like TFR, GRR assumes that the hypothetical cohort of women passes from birth through their reproductive life without experiencing mortality. This assumption is satisfactory when one wants to compare levels of ► fertility and/or gross reproduction across populations and over time. However, for a more realistic assessment of the reproductive potential of a population, taking into account mortality, one needs to calculate the ► net reproduction rate (NRR) (► total fertility rate (TFR)).

Ground Water

Definition

Groundwater is freshwater, which can be found in natural cavities below the ground surface (in soil pore spaces and in fractures of geologic formations). It results from seeping precipitations (rain, snow water). The different layers of soil, through which the water passes, work as a filter system. When pollution is not too severe, this natural filter makes the groundwater free from harmful substances and pathogenic germs. Groundwater is a part of the water circulation; it occurs as springs, ponds or other surface waters. More than 80% of the drinking water comes from groundwater.

Group of Chronic Diseases with Hyperglycemia

► Diabetes mellitus

Grouper Software

Definition

Grouper software is an information technology software that is used to group medical records for inpatient care into ► diagnosis related groups (DRGs). The software needs health professionals to enter basic information on the diagnoses, therapeutic procedures, age, sex and the presence of ► co-morbidities to determine automatically the relevant DRGs.

Group Identity

► Social Identity

Growth Factor

Definition

Growth factor is a substance that stimulates and regulates the growth, division, organization, maturation and maintenance of cells and tissues.

Guidance Sheets

► Risk Management and Communication

Guidelines

Definition

Guidelines are published as an official document which gives an evidence based orientation on how to act in a specific situation. It is used to make actions more predictable and to assure a certain quality standard. Guidelines change according to new knowledge and best evidence and they are not compulsory.

Guilt

► Criminal Responsibility

Guinea Worm Infection

Synonyms

Dracunculiasis; Medina worm infection; Serpent worm infection; Dragon worm infection

Cross-References

► Water Quality and Waterborne Infectious Diseases

HACCP-Concept

Synonyms

Hazard analysis and critical control point (HACCP)

Definition

Microbiological, chemical and physical deficiencies in the fabrication, processing and distribution of food are ascertained and dangers are minimized in advance. Therefore, operating procedures have to be analyzed and documented. Thereby the delivery of food to the consumer is more transparent. To achieve ► food safety, the EU order (no. 852/2004) declares that all participants who are involved in food fabrication but also in processing and trade are obligated to self-control.

Haematopoietic Stem Cells

► Hematopoietic Stem Cells

Haemophilus influenza B (Hib) Vaccination

Synonyms

Haemophilus influenza B immunization

Definition

The ► vaccine against Hib was introduced in 1974 in Finland and the United States, and its effectiveness was improved over the following years. In the Federal Republic of Germany, the Hib vaccine has been authorized since 1990. Its rate of protection (90%) and its tolerance are good. From the third month of age, immunization is generally implemented three times as part of the 6-fold vaccination, or twice when no pertussis component is involved, at intervals of at least 4 weeks, followed by a further vaccination after 4–12 months. When vaccination begins after the first year of life, a single inoculation is sufficient to achieve an adequate immune response. Depending on the vaccine administered, the line is drawn between 14 and 18 months of age. Contraindications for the Hib vaccine are acute illness with fever, and a known severe allergic reaction to components of the vaccines or the carrier protein.

Haemopoietic Stem Cells

► Hematopoietic Stem Cells

Hallucination

Definition

Seeing objects or persons (i. e., visual hallucinations) or hearing voices (i. e. auditory hallucinations) when nothing or nobody is actually there.

Hamlet

Synonyms

Village; Small settlement

Definition

Hamlet is defined as a community of people smaller than a village. It may also refer to a settlement smaller than a town.

Hand Hygiene

Definition

Hand hygiene is the most important and basic means of reducing the spread of infections in healthcare settings. Hand hygiene is a general term that applies to hand washing (with plain soap and water), antiseptic hand washing (with water and soap or other detergents containing an antiseptic agent), application of an alcohol-based hand rub (alcohol-containing preparation applied to the hands to reduce the number of viable microorganisms), or surgical hand hygiene/antisepsis (an antiseptic hand wash or antiseptic hand rub undertaken by surgical personnel preoperatively). When healthcare personnel have hands that are visibly dirty, contaminated, or soiled, they should wash with soap and water. Hand rubs should be used when hands are not visibly soiled, to reduce bacterial counts. Hand hygiene is indicated before patient contact, and when donning gloves for the insertion of catheters or other invasive devices that do not require surgery. Hand hygiene is also indicated after any activity or contact that contaminates the hands, including following the removal of gloves.

Handicap

Definition

A handicap is a disadvantage for a given individual, resulting from an impairment or disability, that limits or prevents the fulfillment of a role that is normal, depending on age, sex, social and cultural factors, for that individual.

Cross-References

► Disability
► Impairment and Disability

Hand Surgery

Definition

Hand surgery is the field of medicine that consists of the investigation, preservation, and restoration by medical, surgical, and rehabilitative means of all structures of the upper extremity directly affecting the form and function of the hand and wrist.

Hansen's Disease

► Leprosy

Hanta Fever

Synonyms

Hemorrhagic fever with renal syndrome (HFRS); Nephropathia epidemica (NE); Korean hemorrhagic fever (KHF)

Definition

Hantaviruses are found in rodents, especially in mice and rats. The infection can be transmitted by breathing in contagious particles of feces or by ingestion of contaminated foodstuff. Hantavirus infections appear in Europe, Asia, Africa, North and South America, with the courses of the infection often being milder in Europe. One third of the infections are asymptomatic but in 20–30% a severe form has to be expected, with renal failure, shock and possible death. A vaccine is not available. The most important prophylactic measures are compliance to hygienic rules concerning food (► food safety and fecal-orally transmitted diseases) and the avoidance of contact with rodents.

Haplotype

Definition

A certain combination of ► alleles at a given set of linked genes.

Haplotype Structure

Definition

Haplotype refers to a set of ► alleles that are co-propagated, whether in an entire haploid ► genome or in a designated segment of that genome (such as a particular region of a chromatid). The independent segregation of ► chromosomes together with recombination between sister chromatids during meiosis will

tend to randomize the arrangement of alleles within the genome. Within a population the non random association of alleles at two or more loci is referred to as linkage disequilibrium and is measured by the indices D, D' and r^2.

Hard Tooth Structure

► Hard Tooth Tissue

Hard Tooth Tissue

Synonyms

Hard tooth structure

Definition

Hard tooth tissue comprises the firm substances of the tooth, including dental enamel, dentin, and tooth cement.

Harmful Substance Use

► Substance Abuse

Harmful Use

Definition

A pattern of psychoactive substance use that is causing damage to health. The damage may be physical (as in cases of hepatitis from the self-administration of injected psychoactive substances) or mental (e. g. episodes of depressive disorder secondary to heavy consumption of alcohol). Harmful use and abuse of substances are conceptualized as potential precursors for dependence.

Harmful Use (of Drugs)

► Drug Abuse

Harm Principle

Definition

The harm principle states that one person's freedom should not result in another person's harm (see the "On Liberty" by John Stuart Mill). It has been followed by institutions as an ► ethical principle when applying measures which have overruled the individual ► autonomy and freedom in the name of the common good.

Harvest Bug

► Chiggers (Burrowing Fleas)

Harvest Mite

► Chiggers (Burrowing Fleas)

Hazard

► Source of Potential Harm

Hazard Analysis and Critical Control Points (HACCP)

Definition

The HACCP is a science based and systematic system which identifies specific hazards and measures for their control to ensure the safety of food production and processing. It is used also in catering and retailing. HACCP is a tool to assess hazards and establish control systems that focus on prevention rather than relying mainly on end-product testing. Any HACCP system is capable of accommodating change such as advances in equipment design, processing procedures or technological developments. HACCP can be applied throughout the food chain. The application of HACCP systems can aid inspection by regulatory authorities and promote international trade by increasing confidence in ► food safety.

Cross-References

► HACCP-Concept

Hazard Identification

Definition

Hazard identification evaluates the weight of evidence for adverse effects in humans based on assessment of all available data on health impact and mode of action. It aims to determine the probability that an individual receiving a specific dose of the contaminant (chemical, ► radiation, ► noise, etc.) will develop an adverse effect. This is done, for chemical hazards, by drawing from the results of toxicology, epidemiology and animal studies. For other kinds of ► hazard, engineering or other disciplines are involved. Hazard identification is a first step in the ► risk assessment procedure.

Hazard Information

► Risk Management and Communication

Hazard Management

► Risk Management and Communication

Hazardous Use (of Drugs)

► Drug Abuse

Hazard Preparedness

► Emergency Preparedness

Hazard Ratio

Definition

The hazard ratio is an estimate of the ratio of the hazard rate in the treated versus the control group or between two differently treated groups. In a clinical trial where disease resolution is the endpoint, the hazard ratio indicates the relative likelihood of disease resolution in treated versus control subjects at any given point in time. The hazard ratio, which is derived from the Cox proportional hazards model, provides a statistical test of treatment efficacy and an estimate of relative risk of ► events of interest to clinicians. The hazard ratio may be used for purposes of statistical hypothesis testing and as one indication of amount of benefit (an increase in the odds of healing), but other measures must also be applied to understand the full importance of the study.

Hazard Reduction

► Risk Management and Communication

Hazards

Synonyms

Source of potential harm

Definition

Hazards are biological, chemical or physical agents in, or condition of, food with the potential to cause an adverse health effect. Hazard analysis is the process of collecting and evaluating information on hazards and conditions leading to their presence to decide which are significant for ► food safety and therefore should be addressed in the HACCP plan. Hazards should be minimized to the lowest possible level by the introduction of preventive measures which are applied at a number of control points. Control points which are the most important for the control of hazards and where hazards should be eliminated or lowered as much as possible are called Critical Control Points (► hazard analysis and critical control points (HACCP)). Preventive actions taken at critical control points must be documented as they form part of the documentation of the HACCP system.

Hazards, Natural

Risk of natural disasters

Definition

Natural hazard – the possibility of occurrence of a potentially damaging natural event.

Basic Characteristics

There are a set of fundamental notions germane to natural hazard, risk, and disaster. Natural hazards can be defined as the possibility of occurrence of a potentially damaging natural event in a given area. Often, the above definition is rendered more quantitative by interpreting the possibility as a probability, or chance of occurrence, of a damaging event within a specified period of time, which can be expressed in per cent. The notion of risk contains the above concept of hazard and the notion of loss/damage/harm to human health (► human health aspects of disasters), property, or the environment. Natural disasters are consequences of a combination of natural hazards and human damage potential and vulnerability (► vulnerability concerns); an earthquake over a desert does not result in a natural disaster because the damage potential is not present.

Natural disasters are determined by the presence of destructive element (e. g. volcanic lava, earthquake force, fire, snow, mud, cold, strong wind, abundant water, or lack of needed water) in vulnerable places with high damage potential. Since the dawn of civilization, natural disasters have jeopardized people and their settlements.

There are several generating mechanisms of natural disasters, such as earthquake, volcano eruption, tsunami, storm, flood, drought, wild fire, landslide, avalanche, extreme heat wave, cold winter weather, blizzard, and meteorite fall. The probability of occurrence of a severe disaster in each of these categories depends on the geographical location.

Disasters are getting more frequent in the more overpopulated world, with busy traffic. In many areas of the world, natural disasters have recently become more destructive, causing material damage of tens of billions of Euros as well as human damage of tens of thousands of fatalities, annually. In particular, catastrophic weather events have exhibited a rapid upward trend: the average annual material damage, in inflation-adjusted monetary units, increased tenfold between the 1950s and the 1990s. A large proportion of the human population is exposed to a traumatic disaster in their lifetime.

Material damage, caused by natural disasters, has been increasing with time for a number of reasons, especially due to increasing ► exposure. For instance, humans have been massively encroaching flood-endangered areas, developing floodplains and coasts, and increasing damage potential by accumulation of population and wealth in flood-prone areas. High vulnerability to flooding accompanies urban squatting. Furthermore, urbanization has adversely influenced the flood hazard in many watersheds. Increase in the amount of impervious areas (roofs, yards, roads, pavements, parking lots, etc), reduction of storage, e. g. by the loss of natural inundation areas (lakes, wetlands, flood plains), deforestation, and regulation of watercourses result in faster and higher maximum river flow (water level) generated by intensive precipitation. Nowadays, less extreme rain (compared with the past) is needed to lead to a serious flooding disaster. In mountainous areas, development extends to hilly slopes, which are endangered by landslide and debris flows triggered by intense rains.

There have been many large natural disasters that have caused immense human and economic damage. Nearly every week, natural disasters occurring somewhere in the "global village" are reported by the media.

Many people have died of hunger caused by drought- and flood-related famines. For example, during and after the 1931 floods in China, the death toll was up to 3.7 million according to some sources (conflicting estimates). Hundreds of thousands of fatalities have been caused by cyclones (e. g. in the Bay of Bengal), tsunamis, and earthquakes. About 500,000 people drowned (and 100,000 went missing) during a coastal storm surge caused by the Bhola cyclone in East Pakistan and Bangladesh in November 1970, while another cyclone killed nearly 140,000 in Bangladesh in April 1991.

The tsunami disaster in December 2004, triggered by an earthquake (Richter magnitude 9.0 to 9.3) in the seabed off the Indonesian island of Sumatra, was unique in encompassing a very large area from Indonesia to

Africa, including numerous resorts packed with foreign Christmas holiday tourists. The number of dead and missing is evaluated as about 230,000, while the number of displaced was nearly 1.7 million. The height of the tsunami waves reached 30 meters. The furthest recorded tsunami-caused death occurred in Port Elisabeth (South Africa), i. e. 8000 km away from the epicenter.

The Great Kantō earthquake devastated Tokyo (Japan) in September 1923, killing 100,000–150,000 people. A more recent Tangshan earthquake in China (July 1976) caused a death toll of over 240,000. On 1 November 1755, an earthquake *cum* resultant fires devastated Lisbon, causing 15,000–40,000 fatalities.

Heat wave events are associated with marked short-term increases in mortality. In August 2003, a heat wave in Western and Central Europe caused between 27,000 and 40,000 excess deaths, while the death toll of a heat wave in the summer of 1980 in the United States (US) was between 1250 and 10,000.

Tens of thousands of people have been killed by single volcanic eruptions, such as the Nevado del Ruiz volcano in Armero, Colombia (November, 1985), with a death toll of 23,000–25,000. A large number of fatalities have been caused by landslides (e. g., 20,000 were killed in Peru in 1970), avalanches (10,000 fatalities in Tirol, Austria, in 1916), and blizzards, with over 300 people killed in one day in November 1950 in the Eastern US.

Disaster events that cause the highest economic losses are not necessarily the main killers. The most costly disaster ever was Hurricane Katrina in the US (August 2005), with – according to some estimates – up to 300 billion US $ in direct damage and 1 trillion US $ in total (i. e. including indirect) damage. Estimates of the death toll vary between 1,600 and 5,000 people. The material damage of the Kobe earthquake (Japan) in January 1995 was about 100 billion US $ (with over 5000 lives lost), while the material damage tag of the 1998 floods in China exceeded 30 billion US $ (and over 3600 fatalities).

According to some definitions, epidemics also belong to the category of natural disasters. It is estimated that in the 14th century, pests and famine killed 75 million people in Europe. In 1918–1919, the (pandemic) epidemic of Spanish flu killed 25–30 million. A more recent, and widely spread, infectious disease is HIV/AIDS, which has considerably challenged public health care systems worldwide. However, epidemics are not considered in the present field material.

Analysis of data for individual destructive flood events worldwide has led to the finding that, in general, the ratio of material losses to number of fatalities grows with the wealth level measured by the GNP per capita of a country. That is, more wealthy countries are more successful in saving lives, while material damages cannot be avoided.

Synonyms

Technological risk

Definition

Technological hazard – the possibility of occurrence of a potentially damaging event resulting from application of technology.

Basic Characteristics

The active presence of the rapidly growing population has added new hazard dimensions to the increasingly more crowded world. It is estimated that 7–8% of people who have ever lived on Earth are living right now. A category of disasters that are man-caused has emerged. Furthermore, in many areas, people have become more vulnerable (► vulnerability concerns) to some natural disasters (► hazards, natural).

Man-made disasters can be caused by accidents – unfortunate, undesirable, unplanned, and unforeseen events; which may, or may not, result from carelessness or ignorance. Accidents trigger loss, injury, or death, which are not necessarily due to any fault or misconduct on the part of adversely affected persons.

A technological hazard can be understood as the possibility of occurrence of a potentially damaging event in a given area, resulting from application of technology and capable of harming people, property, or the environment. The above definition can be rendered more quantitative by interpreting the possibility as a probability or chance within a specified period of time, which can be expressed in per cent. The notion of risk includes the above concept of technological hazard and the notion of loss/damage/harm to human health, property, or the environment. Technological hazards may lead to technological accidents when failure or loss occurring through the application of technology, as above, actually occurs.

Man-caused disasters can be classified into a number of categories. Many disasters have been related to human production activities: mining disasters, industrial disasters, chemical accidents, explosion or fire disasters, and nuclear accidents. Numerous man-caused disasters have been related to transport, oil spills, infrastructure failure – e. g. dam breaks, and terrorist attacks. One special category of man-caused disasters is war, which includes the two World Wars in the 20th century, with a legacy of greater than a hundred million victims – dead and wounded – and immense human suffering. Mismanagement-related disasters constitute a special category. The enforcement of the communist system (collectivization of agriculture) can be blamed, at least partly, for large famines in the ex-USSR, killing millions of people.

Technological disasters can be related to objects whose functioning involves the possibility of major hazards, such as chemical plants and nuclear, coal, and oil power production plants, etc.

Chemical accidents are related to introduction of an undesirable substance into the environment. Undesirable contact with noxious substances may cause adverse changes in the physical, chemical, or biological characteristics of the air, water, or land that can harmfully affect properties or the environment, adversely affecting health, survival, or activities of humans or other living organisms. Noxious substances accidentally released into the environment can cause acute or chronic disease or injury to the human body. For instance, heavy metals interfere with the respiration, metabolism, and growth of organisms.

Man-caused environmental disasters may also be linked to refuse, which poses a hazard to the environment or to human health when improperly handled; and can include carcinogenic (adversely transforming cells to replicate and form a malignant tumor), mutagenic, teratogenic, or phytotoxic wastes; wastes harmful to aquatic species; or poisonous wastes.

Nuclear hazard refers to danger to human health or the environment related to harmful effects of ionizing energy. This hazard is connected to the functioning of nuclear power plants or use, storage, and transportation of radioactive materials. In a nuclear power plant, a nuclear disaster may result from a rapid reaction of atomic nuclei, yielding high temperatures and the release of potentially dangerous levels of radioactive materials into the environment. In such an incident, the steel and/or concrete containment chamber that encloses a nuclear reactor may fail and radionuclides could escape into the environment, causing harm to human health and the environment.

A specific class of technological hazards is biohazards, which are related to the possibility of damage via personal, laboratory, and environmental exposure to potentially infectious agents, including applications of genetic techniques in the manufacturing process or in environmental management capable of harming persons, property, or natural resources. Biohazards must be contained in order to reduce the potential exposure of the laboratory workers, people outside of the lab-

oratory, and the environment to potentially infectious agents.

There have been man-caused disasters in the 20th century that have had considerable human health consequences. They include the Bhopal disasterin 1984 (7 thousand fatalities), mercury poisoning in Minamata, Japan, and Itai-itai disease, due to cadmium poisoning, in Japan. Disasters in nuclear power plants – the Three Mile Island and, in particular, Chernobyl accidents – are another category. Among the disastrous oil spills in the last decades were the catastrophes of the tanker ships Amoco Cadiz and Exxon Valdez, and, above all, the oil fires generated by the order of Saddam Hussein in Kuwait during the Gulf War. One of the most widely known man-caused environmental catastrophes, resulting from acute mismanagement of water resources, is the shrinking of the area and the volume of the Aral Sea.

Many catastrophes are related to the movement or collision of vessels, vehicles, or persons along a land, water, air, or space route – ship or ferry, rail, car or bus, and plane or spacecraft disasters. The sinking of the RMS Titanic in April 1912 caused over 1500 fatalities. In Poland, road traffic accidents during a single weekend may kill more people than floods do over decades. Transport disasters are particularly dangerous to the environment when transported goods create hazards (e. g. toxic, ignitable, corrosive, or reactive products or by-products of technological processes).

The terrorist attacks on 11 September 2001 were examples of "innovative" intentional mass killing. Passenger jets with many people on board, fully fuelled, were taken over by terrorists who crashed them against some of the most important buildings in the USA, with very high damage potential. The death toll of the terrorist attack on 9/11 exceeded 3000.

In China, a dam on the River Huang He was blown up in order to stop the Japanese invasion during the World War II. The dam break caused several hundred thousand fatalities. A large mining disaster in Honkeiko (China) in 1942 caused 1549 fatalities, while explosions in Greece in 1856 killed about 4000 people. A large fire in Sandoz works in 1986 caused the inflow of 30 tons of mercury pesticides into the Rhine, which devastated life in the river. In 1989, in Asha, Ufa, and Bashkiria, USSR, over 500 people were killed by explosions and fire caused by leakage in a long distance pipeline and sparks from passing trains.

Healing

Synonyms

Treatment; Cure

Definition

Healing is defined as any method by which an illness or injury is cured; specifically, the use of a technique which is not recognized within orthodox medicine and involves no form of physical therapy or manipulation. Sometimes prayer, visualization, meditation, or other methods are used by the patient, healer, or both to help focus beneficial thoughts and energy onto the illness.

Although touch may be used to transmit healing energies, some healers claim to be able to treat their patients from a distance. Controlled studies have shown the beneficial effects of positive thoughts and healing energies directed at bacteria, plants, cancer cells, and even animals such as mice.

Health

Synonyms

Well-being; Wellness

Definition

The preamble to the Constitution of the World Health Organization in 1946 defined health as "A state of complete physical, mental and social wellbeing and not merely the absence of disease or infirmity". In 1984, this definition was revised and following definition was proposed that condensed to "The extent to which an individual or a group is able to realize aspirations and satisfy needs, and to change or cope with the environment; health is a resource for everyday life, not the objective of living; it is a positive concept, emphasizing social and personal resources as well as physical capabilities". This implies that individuals, families, and communities have some control over many determinants of their health. An alternative definition describes health as "A sustainable state of equilibrium of harmony between humans and their physical, biological and social environments that enables them to coexist indefinitely and to lead a socially and economically productive life."

Health Action Plan

► Health Strategy

Health-Adverse Life Styles

Definition

A health-related, i. e. health-adverse or health-promoting lifestyle, is defined as a collective pattern of behaviors with relevance to health that are based on routine choices people make about food, exercise, drugs, hygiene, safety, relaxation, and so on. This pattern is structured by specific needs, social norms, and constraints. Lifestyles are largely acquired through socialization, and they vary according to culture and social class. Importantly, a health-adverse Western lifestyle characterized by physical inactivity, unhealthy diet, smoking and alcohol consumption, among others, has been adopted more readily by less educated people, accounting for a relevant part of the social gradient of morbidity and mortality.

Health Advocacy

► Advocacy

Health for All

Definition

In 1977, the ► world health assembly decided that the major social goal of governments and WHO should be the attainment by all people of the world by the year 2000 of a level of health that would permit them to lead a socially and economically productive life. In 1981, the Assembly unanimously adopted a Global Strategy for "Health for All" by the Year 2000. Health for All means that resources for health are evenly distributed and that essential health care is accessible to everyone. It also means that health begins in several settings (at home, in schools, and at the workplace) and that people use better approaches for preventing illness and alleviating unavoidable disease and disability. Health for All means that people recognize that ill-health is not inevitable and that they can shape their own lives and the lives of their families, free from the avoidable burden of disease. Although it has been interpreted differently by each country in the light of its social and economic characteristics, the health status and morbidity patterns of its population, and the state of development of its health system, it has provided an aspirational goal, based on the concept of ► equity in health.

Health Anxiety

► Anxiety Disorders
► Hypochondria

Health Behavior

MARTIN SIEPMANN
Forschungsverbund Public Health Sachsen-Sachsen Anhalt e. V., Medizinische Fakultät, Technische Universität, Dresden, Germany
martin.siepmann@tu-dresden.de

Introduction

Health can be negatively defined as the absence of disease and injury, sometimes as a normative judgment referring to the average state of most people, and sometimes as a positive concept of well-being. Disability may be distinct form health or, together with health, represent different points on a continuum. From a medical perspective, people are healthy if they are uninjured and free of disease, but a person with risk factors for disease might be considered unhealthy. Health-related behavior is one of the most important elements in people's health and well being. Its has grown as nutrition and sanitation have improved and medicine has advanced. Diseases that were once incurable and fatal can now be prevented or successfully treated, and health behavior has become an important component of public health. The improvement of health behavior is central to public health activities.

► Behavioral patterns play a role in the leading causes of death, including chronic diseases such as heart disease, cancer and stroke. The most common behavioral contributors to mortality or death include the use of alcohol, tobacco, and motor vehicles, diet and activity patterns, sexual behavior and illicit use of drugs. Behaviors such as these contribute to almost half of the deaths in the United States and Northern Europe (McGinnis, Foege 1993) Those who are physically fit and have healthy habits are less likely to develop disability or die prematurely from chronic disease. People with high-quality personal relationships and supportive social networks tend to be more resistant to disease and to recover more quickly than those with poorer social relationships. Several epidemiological studies demonstrate that supportive social relationships reduce the risk of death form cardiovascular disease (Berkman 1995). The magnitude of the effect of social isolation on the risk of cardiovascular disease is comparable to that of elevated serum cholesterol or mild hypertension. Positive psychological states are associated with better coping with severe stress attendant to acquired immune deficiency syndrome (AIDS), cancer or arthritis (Folkmann 1997). Frankl (1992) demonstrated that a sense of purpose in life was associated with a greater likelihood of surviving Nazi concentration camps and psychological recovery from that experience.

A rising interest in preventing disability and death through changes in health behavior has emerged the 80th of the past century; particularly changes in lifestyle habits and participation in screening programs have been focused on. Much of this interest has been stimulated by the change in disease patterns from infectious to chronic diseases as leading causes of death, combined with the aging of the population, rapidly escalating health care costs and data linking individual behaviors to increases risk of morbidity and mortality.

Although there is more information about what constitutes healthy behavior and risk factors than ever before, this information has not always led to healthier behaviors. There have been some positive changes, however. Between 1988 and 1994, the average daily intake of dietary fat in the United States dropped from 36 per cent to 34 per cent of total calories; seat belt use increased from 42 per cent to 67 per cent; and the number of women over the age of forty who had breast examinations and mammographies doubled. Cigarette smoking has decreased among men by as much as 50 per cent in some countries. Unfortunately, during this same period, the number of obese adults rose, sexual activity among adolescents increased, more teenage girls began smoking, and the incidence of HIV (human immunodeficiency virus)/AIDS reached epidemic proportions.

Concepts of Health Behavior

Although the concept of positive health is clearly important, it presents several challenges. First, it is not clear whether positive health is incorporated into other definitions of health-particularly those that include both current function and prognosis. Most of the evidence supporting positive health per se is associated with better outcomes for those with healthy bodies, high-quality personal relationships, a sense of purpose, and high self-regard. Like people who refrain from smoking cigarettes or who have low serum cholesterol, those with positive psychological attributes could stay healthy longer than other people do or adapt better to health challenges.

Second, assessing positive health is difficult. Across cultures, socioeconomic status, and ethnic groups, people rate restrictions in activities associated with health conditions as less desirable than not having such restrictions (Patrick et al. 1985). The requirement to use a wheelchair is consistently rated as less desirable than is being able to walk freely. Such consensus is not evident, however, for attributes associated with good health. For example, there is much greater variability in ratings for the desirability of having a spouse, of participating in community activities, or of other aspects of social affiliation. There is considerable agreement regarding desirable aspects of physical functioning but there is little agreement regarding social components. There is also a difficulty with the definition of positive health. Current approaches regard optimal health as the condition of having no limitations on activity and being free of symptoms. The way in which positive and negative components interact to produce a given health status has not yet been described. There are many questions about health related behavior, or health behavior that are not yet well understood.

Health behavior encompasses a large field of study that cuts across various fields, including psychology, education, sociology, public health, epidemiology and anthropology. In the broadest sense health behavior refers to the actions of individuals, groups and organizations as well as their determinants, correlates and consequences, of these actions which include social change, policy development and implementation, improved scoping skills and enhanced quality of life. This is close to the concept introduced by David Gochman (1997) which includes not only observable, overt actions but also the mental events and emotional states that can be reported and measured. Gochman defined health behavior as those personal attributes such as beliefs, expectations, motives, values, perceptions and other cognitive elements; personality characteristics including affective and emotional states and traits; and overt ► behavioral patterns, actions and habits that relate to health maintenance, to health restoration and to health improvement. Interestingly, this concept of health behavior emphasizes the actions and the health of individuals. By contrast, a public health perspective is concerned with individuals as part of a larger community. These perspectives are interrelated, as the behaviors of individuals determine many of the social conditions that affect all people's health.

Categories of Health Behavior

Gochman's definition of health behavior is consistent with the concept of specific categories of overt health behavior proposed by Kasl and Cobb (1996). Kasl and Cobb define three categories of health behavior:

1. Preventive health behavior involves any activity undertaken by individuals who believe themselves to be healthy for the purpose of preventing or detecting illness in a asymptomatic state. This may include wearing a helmet when riding a bicycle, using seat belts, or wearing a condom during sexual activity.
2. Illness behavior is any activity undertaken by individual who perceive themselves to be ill for the purpose of defining their state of health, and discovering a suitable remedy.
3. Sick-role behavior involves any activity undertaken by those who consider themselves to be ill for the purpose of getting well. It includes receiving treatment from medical providers and involves a range of dependent behaviors, and leads to some degree of exemption from one's daily duties.

The classic categories and definitions have been well established. However, there is some degree of overlap between them and there are also several categories of behavior that need specific definitions.

Behavior versus lifestyle. Health behavior can be something that is done once, or something that is done periodically – i. e. getting immunization or a flu shot. It can also be something that one does only to oneself, i. e. putting on sun screen, or a behavior that affects others, like putting up a shade cover in order to protect children in a playground from the sun. Other health behaviors are actions that are performed over a long period of time, such as eating a healthful diet, getting regular physical activity, and avoiding tobacco use. These latter types of behavior are sustained patterns of complex behavior that are named lifestyle behaviors. A composite of various healthful behaviors is often referred to as health lifestyle.

Self-care behavior. Self care behavior, a key concept in health promotion, involves taking actions to improve or preserve one's health. Self-care is often thought of in terms as prevention or self-treatment of definable health problems. Examples of self-care behaviors include seeking information (i. e. searching in the internet, attending classes, joining a self-help group), exercising, consulting a doctor regularly, getting more rest,

lifestyle changes, monitoring vital signs, and seeking advice through lay and alternative networks (Wagner and co-workers 2005). An important feature of self-care behavior is that it involves active participation in the health care process. Studies report that 80 to 95% of all health problems are managed at home through self-care and that most people who consult a physician have tried to treat themselves before seeking medical advice (Dean 1986). The seriousness of the health problem and the extent and type of disability, including its affect on daily activities, are the best determinants of whether an individual uses self-care practices or seeks help from a professional. In one study of older persons Norburn and co-workers (1995) observed that race, gender, education, place of residence, and socioeconomic status did not significantly influence self-care behavior. Persons with chronic health conditions often become more knowledgeable about their conditions than the average health care professional, and they frequently participate in group or community self-care educational and support programs.

Health care utilization behavior. Health care utilization behavior is a continuum that ranges from using preventive services, such as getting immunization or early detection and screening tests, to elective surgery or involuntary hospitalization after an injury. The study of trends in health care utilization provides important information on this behavior and may spotlight areas that may warrant future in-depth studies because of potential disparities in access to, or quality of, care. Health care utilization also has evolved as the population's need for care has changed over time. Some factors that influence health care utilization behavior include aging, sociodemographic population shifts, and changes in the prevalence and incidence of different diseases. As the prevalence of chronic conditions increases, for example, residential and community-based health-related services have emerged that are designed to minimize loss of function and to keep people out of institutional settings. New and emerging technologies, including drugs, devices, procedures, tests and imaging machinery have changed patterns of care and sites were care is provided. Multiple forces determine how much health care people use, the types of health care they use, and the timing of that care. Some forces encourage more utilization; others deter it. For example, antibiotics and public health initiatives have dramatically reduced the need for people to receive health care for many infectious diseases, even though overuse can also increase antibiotic resistant strains. Aging is associated with increased health care utilization (Mathers 1999).

Dietary behavior. Recent years have seen an epidemic in obesity in the United States and European countries (Mokdad et al. 1999, Prugger, Keil 2007). Although genetic factors are important diet contributes significantly to maintenance of appropriate body weight. The contribution of inactivity and detrimental dietary patterns has been ranked as the second leading factor contributing to mortality in the United States (McGinnis, Foege 1993). Studies show that dietary factors are associated with 4 of the 10 leading causes of death, including coronary heart disease, stroke, some forms of cancer and non-insulin dependent diabetes mellitus (CDC 1997, USDHHS 2000). Recommendations for healthful dietary behavior include limiting consumption of high-fat foods, having a high intake of fruit and vegetables, increasing fibre, and controlling calorie intake to prevent obesity. Although most American and Europeans know about the health consequences of unhealthful diets, many of the public health goals for dietary behavior have not been met. Dietary behaviors play a role in preventing or managing disease when they are sustained over the long term. Behavioral considerations are key to any attempts to promote healthful dietary behavior. Several core issues about dietary behavior have been recognized. First, most diet-related risk factors are asymptomatic and do not present immediate or dramatic symptoms. Second, health-enhancing dietary changes require qualitative change, not just changes in the amount of food consumed. Third, both the act of making changes and self-monitoring dietary behaviors require knowledge about foods. Thus, information acquisition and processing may be more complex for dietary change than for other changes in health behavior i. e. smoking and exercise.

Substance-use behavior. Substance-use behavior focuses on the use of both licit and illicit mood-altering substances. This category of substances, typically referred to as drugs includes tobacco, alcohol, marijuana, cocaine, heroin, amphetamine-derivates and prescription medications taken improperly. Substance abuse which occurs when substance use behavior is at an extreme and harmful level is often associated with addiction. There is widespread agreement in the public health and medical communities that both cigarette-

smoking and alcohol consumption are the biggest external (non-genetic) contributors to death in the United States: tobacco-related diseases account for more than 400,000 deaths amongst adults per year and approximately 100,000 deaths are related to alcohol consumption in each year (CDC 1995, USDHHS 2000). Compared with other threats to human health, alcohol causes the widest variety of injures (Rose 1992). By the first grade, or earlier, children show temperament and behavior traits that are predictors of their inclination to use and abuse alcohol and drugs in their teenage and adult years. Brook (1992) and Hops (1990) have identified not only childhood risk factors and behaviors that predict drug and alcohol abuse potential but also protective factors that may shield children from influences to use drugs.

Sexual behavior. Sexual relationships and practices are complex to investigate, but their study is important because infectious disease has always been a possible outcome of sexual relationships, as has unwanted pregnancy. Both are crucial public health issues. Concern about AIDS has been an important motivation for recent studies of sexual behaviors, including a large survey of sexual behaviors and attitudes (Laumann 1994). Most of the issues that arise in relating sexual behavior to risk of infection with the human immunodeficiency virus (HIV) pertain to many other, more common, sexually transmitted infections such as human papilloma virus, gonorrhoea, chlamydia, and genital herpes, which vary in the severity of their consequences. By contrast, HIV has made unsafe sex a matter of life and death. Behavioral means for prevention of sexually transmitted infections include delaying the onset of sexual activity, limiting the number of partners, abstaining from sex with people not known to be infection free, and using effective barrier contraception. Community-focused interventions also are useful in reducing sexually transmitted infections. Such interventions generally aim to change behavioral norms. Mass media campaigns have used reinforcing messages to increase knowledge about HIV infection and ways to prevent it. Because only a small percentage of adolescents receive any prevention information from parents, and because for most teenagers schools are the main source of information about sexually transmitted infections, school-based interventions can be significant in motivating young people to modify their behaviors (American Social Health Association 1996).

Models of Health Behavior

The best way to design programs to achieve positive changes in health behavior is to explore why people behave as they do and what might motivate them to change. Theories of health behavior (► health behavior, theories) can be useful during the various stages of planning, implementing, and evaluating interventions. Growing evidence suggests that effective programs to change individual health behavior require a multifaceted approach to helping people adopt, change and maintain behaviors. For example, strategies for establishing healthy eating habits in children and adolescents might be quite ineffective for changing maladaptive eating behaviors – that is, when they are used to substitute one pattern for another – in the same population (Jeffrey and co-workers 2000). Similarly maintaining a particular behavior over time might require different strategies than will establishing that behavior in the first place. Models of behavior change have been developed to guide strategies to promote healthy behaviors and facilitate effective adaptation to and coping with illness. The stages of change model concern an individual's readiness to change unhealthful behaviors. Its basic premise is that behavior change is a process and not an event, and that individuals are at varying levels of motivation, or readiness to change. This means that people at different points in the process of change can benefit from different programs for change, and the programs work best if matched to their stage of readiness.

Social relationships can be described by three aspects. First, social integration refers to basic quantitative features of social relationships such as the number of active relationships and frequency of contacts. Second, mostly conceptualized very close to integration, social networks can be defined as person-centered webs of social relationships; characteristics of such networks are elaborate measures such as their reciprocity, intensity, complexity, and density. Finally, a third aspect of social relationships has been termed functional or relational content, thus essentially referring to their quality. Three specific sub-dimensions in terms of different kinds of social processes are distinguished: regulation and control, demands and conflicts, and support. As noted, particularly the latter has been a focus in research on health and health behavior. Establishing a closer link with basic behavioral science promises to provide important directions for the continued development of
