health-related behavior interventions. One important example of a model that attempts to integrate individual psychological processes with contextual factors is Social-Action Theory. It views the person as influenced by environmental contexts or settings to which he or she brings a particular temperament and biological context. Thus, a person's capacity to practice healthy eating habits and to exercise is influenced by access to health-enhancing foods and safe places to exercise and by internal goal structures, self-efficacy beliefs, and problem-solving skills. In Social-Action Theory, biology and social environmental contexts determine the success of interventions to promote individual behavior change. Social-Action Theory specifies mediating mechanisms that link organizational structures to personal health. It provides a framework for multilevel approaches to health promotion and illness prevention. It offers a theoretical rationale for intervening in health policy and for creating environments that are conducive to self-protective choices. Social-Action Theory provides an approach for defining public health goals and modifiable social and personal influences that can be used to encourage individual health behavior change. It fosters interdisciplinary collaborations by incorporating and coordinating the perspectives of the biological, epidemiologic, social, and behavioral sciences. Like other models Social-Action Theory underscores the long-term nature of the process of altering health behavior, and of the need to make a detailed behavioral diagnosis for each person and to tailor interventions to match his or her current stage of readiness to change.

Summary

The impact of behavior on health is enormous. In the early eighties of the past century the US Department of Health and Human Services compared the estimated contributions of various determinants of mortality and morbidity on the ten leading causes of death in the US, showing that individual lifestyle accounted for more than 50 per cent of the overall contribution (Badura 1994). The European Commission (EC 1998) has reported that approximately 80 per cent of death among European citizens aged 35 to 64 are due to cancer, cardiovascular diseases, accidents and suicides, thus underlining the significance of behavioral factors known to be contributing to these diseases and causes of death. Given this epidemiological situation, health psychology understandably has a major focus on behaviors that lead or contribute to health and illness. Healthcare professionals, community leaders, and policy try to understand interactions between health and behavior and to make that knowledge useful to improve the health status of individuals and populations. Health and behavior are related in various ways, yet those interactions are neither simple nor straight-forward. Given the wide acknowledgment that cigarette smoking is linked to a variety of deadly diseases, for example, it has to be questioned for which reason people smoke. And given equally convincing evidence connecting excess weight with cardiovascular disease and other health problems it has to be questioned for which reasons so many people are far above their optimal weight. It is not clear whether such unhealthy behavior indicates a simple lack of willpower. It is still being under investigation how social environment influences these behaviors. It is not understood how stress makes people sick. The present synopsis reviews available information about links between health and behavior, about the influence of social environment on these behaviors, and about interventions to improve health by means of modifying behavior or personal relationships.

martin.siepmann@tu-dresden.de

Synonyms

Theories of health behavior; Models of behavior change

Definition

Models of behavior change have been developed to guide strategies to promote healthy behaviors and facilitate effective adaptation to and coping with illness. The corresponding theories focus on a range of factors influencing behavior determinants, including facts within an individual (such as thoughts, feelings and beliefs), factors in groups or relationships, and factors that exist in organizations and communities (such as structures, regulations, policies and laws). The concept of community itself has been defined repeatedly. Most of these definitions include two basic features: locality and quality, or structure and function. Structure refers to an area with geographic boundaries. Function describes shared values, norms, communication, and helping patterns. This function is also the major operating force in community psychology interventions.

Basic Characteristics

Many theories that have been developed in health psychology to explain health-related behaviors emphasize individual cognitions, thoughts or beliefs. These theories can be named social-cognition models (Conner and Normann 1998). Prominent examples are the ► health belief model (Rosenstock 1974), the theory of reasoned action (► reasoned action theory) (Ajzen and Fishbein 1980), the theory of planned behavior (► planned behavior theory), ► protection motivation theory (Conner and Normann 1996), ► health locus of control and self-efficacy theory (Sanders 1982). Other models include the model of health promotion behavior, the ► transtheoretical model of change, the model of conditioning (► conditioning model), the ► cognitive social learning theory, ► self-regulation, the theory of trying, the precaution adoption process model, the ► social action theory, and the health action process approach (Schwarzer 1996). Self-efficacy is a concept, which is most widely, acknowledged across these theories (O'Leary 1985). It has been applied to diverse areas such as school achievement, mental and physical health, career choice and socio-political change

(Wagner and Kirch 2006). Self-efficacy has become a key variable in clinical, educational, social, developmental, health and personality psychology. By means of the self-system, individuals exercise control over their thoughts, feelings and actions. Among the beliefs with which an individual evaluates the control over his/her actions and environment, self-efficacy beliefs are the most influential arbiter of activity. Self-efficacy is constructed on the basis of the four most influential sources: enactive attainment, vicarious experience, verbal persuasion and physiological as well as emotional factors. It plays a central role in the cognitive regulation of motivation, because people regulate the level and the distribution of effort they will expend in accordance with the effects they are expecting from their actions. While outcome expectancies refer to the perception of the possible consequences of one' s action, perceived self-efficacy pertains to personal action control (Bandura 1992). A person who believes in being able to cause an event can conduct a more active and self-determined life-course. Self-efficacy reflects the belief in being able to cope with challenges by means of adaptive action. It can also be regarded as an optimistic view of one's capacity to deal with stress. A low sense of self-efficacy is often associated with feelings of depression, anxiety and helplessness. People with low self-efficacy levels often have pessimistic thoughts about their accomplishments and personal development. In order to initiate and maintain health behaviors, it is necessary to believe that one has the capability to perform the required behavior. Therefore, the likelihood that people will adopt a valued health behavior (i. e. physical exercise) or quit a detrimental habit (i. e. smoking) depends on the level of self-efficacy.

Health Belief

► Oral Health Behavior

Health Belief Model

Definition

The Health Belief Model was developed in the 1950s in the U.S. Public Health Service. It is still used as an assessment tool to understand why persons participate in programs for the prevention or detection of diseases (e. g. being immunized against the flu). The original model encompassed five concepts; self-efficacy was added for modern applications. Perceived susceptibility is defined as the subjective opinion about the chances of contracting a condition; perceived severity is the subjective opinion of how serious a condition and its consequences might be if untreated. Perceived benefits means the opinion of the effectiveness of various available actions in reducing the problem, and perceived barriers are the potentially negative aspects of a health action, e. g. side effects or costs. Cues to action might be an environmental event or a bodily trigger. Self-efficacy is defined as the person's confidence in performing a particular behavior successfully.

Health of Boys and Men

► Men's Health

Health Campaigns

Synonyms

Health promotion; Prevention

Definition

Health campaigns refer to various activities aimed at promotion of healthy lifestyle and prevention of health risk factors such as smoking, poor diet habits, sedentary lifestyle, etc. They include activities such as preparation and dissemination of culturally appropriate health materials in native languages, inclusion of indigenous health practitioners in health promotion activities, and also promotion of mutual learning, capacity building and sharing information through workshops.

Health Care

Synonyms

Health maintenance; Health protection; Medical management; Preventive medicine; Medical services

Definition

Health care refers to the prevention, treatment, and management of illness and the protection of mental and physical ► well-being through the services provided by the medical nursing, and allied health professions. The organized provision of such services may constitute a ► health care system.

There are many ways of providing health care in the modern world. The most common way is face-to-face delivery, where care provider and patient meet personally. This is practice in general medicine in most countries. However, with modern telecommunications technology, it is becoming more common that practitioner and patient communicate over the phone, video conferencing, the internet, email, text messages, or any other form of non-face-to-face communication. The characteristics of a health care system have significant effect on the way medical care is delivered.

Cross-References

► Health Care Services

Health Care Access

Synonyms

Health care availability

Definition

Health care access refers to availability and accessibility of ► health care services in terms of proximity of health care services, infrastructure of ► health care delivery, number of ► health care professionals providing medical services, medical insurance. There is a vast discrepancy between access to health care and ► public health initiatives between developed nations and developing nations. In the developing world, many ► public health infrastructures are still forming. There may not be enough trained health workers or monetary resources to provide even a basic level of medical care and disease prevention. As a result, a large majority of disease and ► mortality in the developing world results from and contributes to extreme poverty.

Health Care Costs

STEFAN GREß
Health Services Research and Health Economics, Department of Health Sciences, University of Applied Sciences Fulda, Fulda, Germany
stefan.gress@pg.hs-fulda.de

Synonyms

Health care expenditures; Expenditures on health care

Definition

Health care costs are the sum of both public and private expenditures spent on health care services in a given country at a given time. The variation in health care costs between countries is substantial. The main drivers of health care costs are non-demographic factors such as national income, relative prices, and technology.

Basic Characteristics

Health Care Costs: International Comparisons

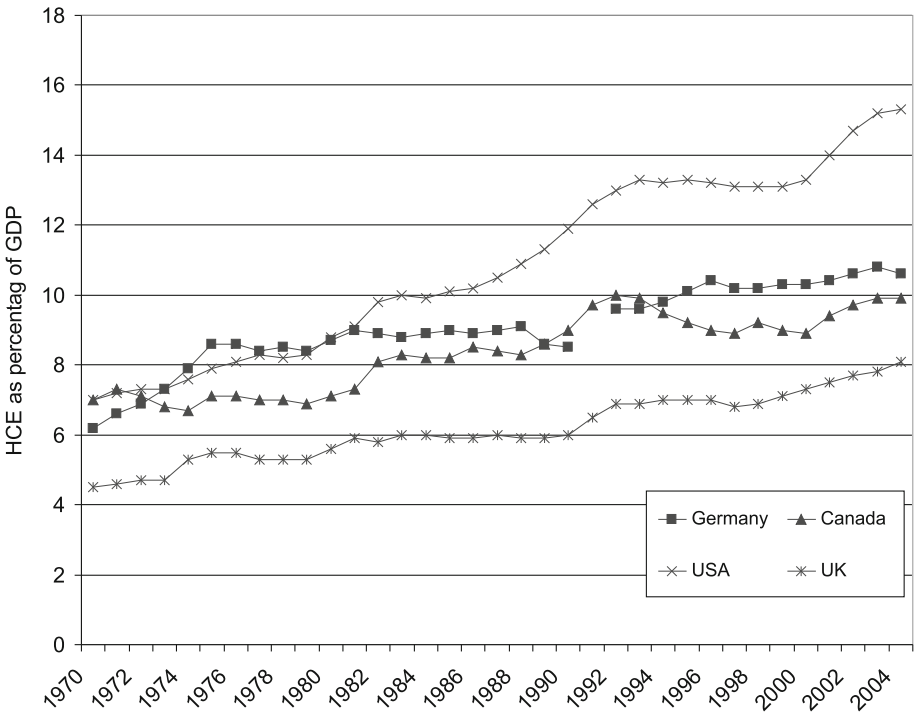
From a macroeconomic point of view, the sum of health care costs is the sum of both public (taxes, social insurance) and private (private insurance, out-of-pocket payments) expenditures spent on health care services in a given country at a given time. The Organizations for Economic Co-Operation and Development (OECD) has developed a methodology to standardize health care expenditures and to make them comparable across member countries (OECD 2005). Health care costs are either measured per capita in US$ PPP (► purchasing power parity) or as a share of ► gross domestic product. Figure 1 shows the development of health care expenditures as a share of GDP over time for four selected countries.

The variation in health care spending between countries is substantial and is mostly determined by the wealth of individual countries – measured in GDP per capita, the outliers being the United States (way below the regression line in the upper right hand quadrant), Luxemburg (way above the regression line in the upper right hand quadrant) (see Fig. 2). Moreover, differences in health care costs also originate from different approaches toward health care system design such as ► health financing and remuneration of health care providers (► regulatory mechanisms).

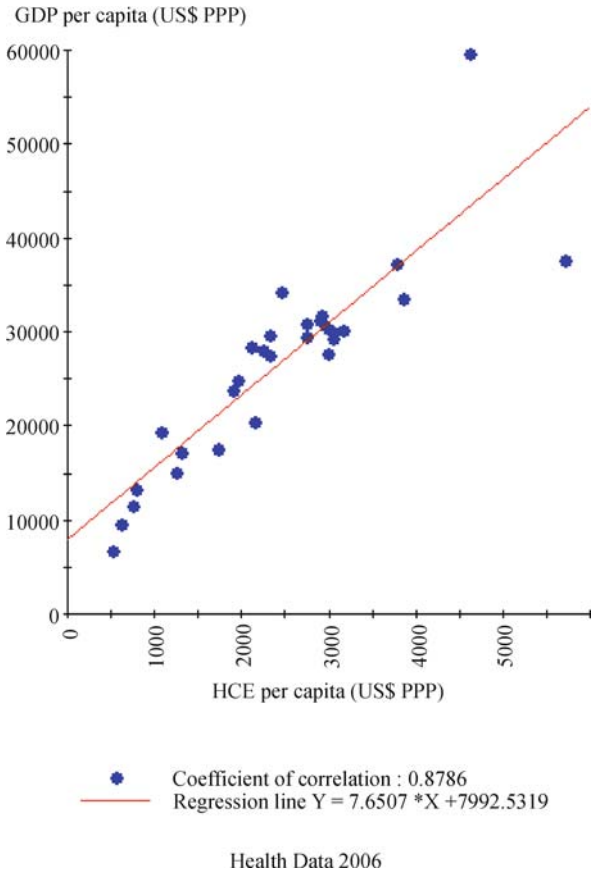
Drivers of Health Care Costs

Policy makers are concerned about the pressure that rising health care costs are putting on publicly financed health care systems. As a consequence, projections about the future trends of health care costs have been developed both nationally and internationally. In order to project future trends, the main drivers of health care costs need to be identified. These can be distinguished as demographic and non-demographic factors (OECD 2006).

Demographic factors originate from the tendency that population ageing – i. e. a rising share of older age groups in the population as a consequence of increased



Health Care Costs, Figure 1
Health care expenditures as a share of GDP in the United States, Canada, the United Kingdom and Germany 1970–2004. Source: OECD Health Data, October 2006



Health Care Costs, Figure 2 Health care expenditures per capita and gross domestic product per capita. Source: OECD Health Data, October 2006

life expectancy – will induce upward pressure on health care costs, since health care costs increase with age. This is true if an increase in longevity increases the number of years lived in bad health (► expansion of morbidity); however, there is at least one major factor that alleviates this tendency. Health care costs are concentrated at the end of life. If increased life expectancy means that more individuals live longer and die later, pressure on health care costs will be lower than expected (► compression of morbidity). In other words, if longevity gains translate into more years of► "healthy ageing", there is no reason to identify population ageing as a major driver of costs in health care (OECD 2006). As a consequence, projections which identify population ageing as a major driver of health care costs will overestimate the growth of health care costs (Stearns and Norton 2004). Empirical evidence on the question whether "healthy ageing" or "unhealthy ageing" is prevailing points to the hypothesis that non-demographic factors are the main drivers of health care costs. Several empirical studies have found that the impact of population ageing on health care costs is rather limited if proximity to death is controlled for – with the possible exception of long-term care, in which circumstance "unhealthy ageing" matters (Zweifel et al. 2004; Werblow et al. 2007).

Health Care Costs, Table 1 Decomposing growth of public health care spending, 1981–2002

	Health Spending	Age Effect	Income Effect	Residual
Canada	2.6	0.4	1.7	0.6
Germany	2.2	0.2	1.2	1.0
United Kingdom	3.4	0.2	2.3	1.0
United States	4.7	0.1	2.0	2.6

Source: (OECD 2006)

As a consequence of the rather weak link between population ageing and health care costs, other – non-demographic – factors need to be considered as the key drivers of health care costs. These factors include growth of national income, since health care costs tend to grow as national income goes up (see Fig. 2). However, even after controlling for demographic factors and growth of national income, a "residual" growth in health care costs remains. The residuum can mostly be explained by technology and a growth of relative prices (OECD 2006). Table 1 shows a decomposition of public spending growth per capita for selected OECD-countries.

Health Care Delivery

Definition

Medical care delivery
Health care delivery is aimed at prevention and treatment of disease through health care system. It is classified into primary, secondary and tertiary care.
Primary care medical services are provided by physicians or other health professionals who have the first contact with patient seeking treatment or care. It is organized in medical office's, nursing homes, schools, home visits. It also includes preventive care and health education.
Secondary care medical services are provided by medical specialists in their offices at clinics or hospitals. Patients are referred to them by primary ► health care provider who first diagnosed or treated patient.
Tertiary care medical services are provided by specialist hospitals or regional centers equipped with diagnostic and treatment facilities not generally available in secondary care medical services.

Health Care Differences

► Health Care Disparities

Health Care Disparities

Synonyms

Health care differences

Definition

Health disparities are defined as population-specific differences in the presence of illness, health outcomes or access to health care. Health disparities refer to gaps in the quality of health and health care across racial and ethnic groups. There is evidence for higher incidence of chronic diseases (such as diabetes, cardiovascular diseases, etc.), higher ► mortality and poorer health outcomes among minority populations (or indigenous populations in nation-states).

Health Care Profession

GERNOT LENZ
Forschungsverbund Public Health Sachsen-Sachsen Anhalt e. V., Medizinische Fakultät, Technische Universität, Dresden, Germany
gernot.lenz@gmx.de

Synonyms

Health care industry; Pharmaceutical industry; Health care education

Definition

The health care profession comprises all persons who provide services aiming at the preservation or improvement of the health of individuals or the treatment or care of individuals who are injured, sick or disabled. In a very broad definition, all individuals that participate in some way in the delivery of health care are part of the health care profession. The contemporary health care profession is more and more characterized by a group of highly trained professionals providing their services as an interdisciplinary team.

Basic Characteristics

Background

The health care industry is one of the world's largest industries with still significant growth rates. It consumes about 9% of the gross domestic product (GDP) of the OECD countries compared to nearly 7% in 1990 and 5% in 1970. Health care thus forms an enormous part of a country's economy. The United States has the highest share of health care costs related to GDP in the world with 15.3%. The USA is followed by Switzerland with 11.6%, France with 11.1% and Germany with 10.7% share of health care costs related to GDP. Per capita health spend in the OECD countries has in average increased by more than 80% in real terms between 1990 and 2005 compared to only 37% growth in GDP per capita.

Medical Profession

The medical profession holds the most important position within the health professions. The physician forms the central part of the medical profession. Whereas in the United States, the term physician is commonly used, other countries like the UK, Canada, Australia, Germany or Japan usually use the term doctor. In these countries, a physician often refers to specialists in ► internal medicine. In all developed countries, the studies of medicine are offered by a ► medical school belonging to a university. The entry-level medical education programs are tertiary-level courses that are often followed by a period of supervised practice before full registration is granted. Physicians need government permission to practice in most countries, which is known as licensing in the United States, approbation in Germany or registration in the UK.

The general practitioner (GP) or family physician (FP) is a physician who is mainly responsible for providing comprehensive health care to every individual seeking medical care which is summarized as primary care. The GP acts as a generalist and accepts every patient be it for the treatment of acute and chronic illnesses or the provision of preventive care and ► health education for all ages and both sexes. The medical specialists on the other hand limit access to their services based on age, sex and/or diagnosis. They specialize in a certain field of medicine and go through additional training. Usually general practitioners act as gatekeepers. They see the patient first and if necessary refer them to the respective specialist.

According to the OECD, the number of doctors in OECD countries has increased significantly by 35% between 1990 and 2005 to 2.8 million. This growth was predominantly driven by an up to nearly 50% growth of specialists compared to a 20% increase in general practitioners (GPs). In most OECD countries, there are now more specialists than general practitioners. With regard to income levels, the specialists earn more than the GPs in most OECD countries which is one reason for the greater increase of specialists in recent years. There are, furthermore, large variations when it comes to numbers of doctors per capita. As of 2005, in the OECD countries, this number ranges from around 4 doctors per 1000 population in Belgium, Italy, Spain and Switzerland to below 2 doctors in Mexico, Turkey and Korea. Overall, this ratio of practicing doctors per 1000 population has grown in almost all OECD countries between 1990 and 2005. However, this growth was lower than in the 15 years before, mainly driven by the introduction of cost-containment measures in many countries.

Nursing Profession

The nursing profession consists of people responsible for the treatment, safety, and recovery of acutely or chronically ill or injured people. Nurses also support the health maintenance of healthy individuals and the treatment of life-threatening emergencies. Nursing education and career structure differs widely throughout the world. In general, there are in most cases several different levels of nurses that are distinguished by increasing education, responsibility, skills and experience. Besides the clinical activities, nurses might also participate in medical and nursing research as well as the execution of non-clinical functions that are part of the health care delivery. The nursing profession forms the largest group of providers within the health care system and they are still predominantly female. The number of practicing nurses per 1000 population in the OECD countries again differs widely. The countries with the highest density of nurses are Ireland, the Netherlands and Norway with about 15 nurses per 1000 population compared to the countries like Mexico, Korean and Turkey with only about 2 nurses per 1000 population which is only slightly higher than the density of doctors in these countries.

Pharmaceutical Profession

The pharmaceutical industry in general has the two functions of research and development (R&D) and manufacturing. Most pharmaceutical companies are engaged in both functions, some specialize in either R&D or manufacturing. Most of the drug producers are large multinational companies that serve the three largest markets in the world, the United States, Europe, and Japan. Within the pharmaceutical industry, all different health care professions are found as the large drug manufacturers employ individuals with different educational backgrounds like medicine, pharmaceutics, chemistry, bio-chemistry, etc. Spending on pharmaceuticals and other medical non-durables accounts for a significant share of the total expenditure on health in most developed countries. For the OECD countries, this percentage ranges from around 9% in Norway, Denmark and Luxembourg to around 30% in the Slovak Republic, Poland and Hungary. In Germany, pharmaceutical expenditure accounts for 15% of total health expenditure compared to 12% in the United States.

The drugs prescribed by the physicians are distributed by pharmacists in pharmacies that might be either dedicated premises or part of a retail drugstore or chemist. The pharmacists furthermore provide advice on the selection, dosage, interactions and ► side effects of the medication. They also offer detailed information about ► over-the-counter drugs that do not require a prescription by a physician. Some pharmacist offer more and more public health related services: giving advice about diet and exercise, participating in health promotion campaigns, providing advice on complimentary medicine. As mentioned above, pharmacists increasingly pursue non-traditional pharmacy work. Some phar-

macists work as employees of pharmaceutical companies where they are engaged in research and development or marketing and sales or they work for health insurance companies where they develop pharmacy benefit packages and carry out cost-benefit analyses on certain drugs. Other pharmacists work for governmental institutions or pharmacy associations. Finally, pharmacists engage in academic work either as teachers or researchers.

Allied Health Professions

The term allied health profession is used to describe all those people who are not covered by the medical profession, the nursing profession and the pharmaceutical profession but still are part of the health care system and contribute to its function. Allied health professionals are characterized by a formal education and/or clinical training credited through an official certification, registration or licensure. They usually collaborate with physicians and/or other members of the health care system to support a high quality delivery of patient care, be it identification, prevention, or treatment of diseases, disabilities and disorders. There are numerous professions that are encapsulated in the allied health professions, e. g. electrocardiographic technicians, nutritionists and dieteticians, occupational therapists, kinesiotherapist, and speech therapists.

Conclusion

An increase in medical and health care expenditures can be observed on a global level. In many countries, this has resulted in shifting patients away from hospital treatment to outpatient treatment in physicians' private and group practices or ambulatory hospital settings. This is in line with an increasing demand for specifically trained specialist physicians as reflected in the significant growth rates of the last 15 years. Despite this trend, the general practitioner's role remains key to the health care system and some countries, like Germany, have even changed their legislation and increased incentives to prevent patients going directly to the more expensive specialists. This gate keeper role of the GP, already established in the Anglo-American countries, is expected to be further enforced in the future in other countries to mitigate against the growth of the direct use of specialists. The growing importance of public health related topics, especially prevention and care of the chronically ill, will further strengthen the role of the general practitioner as well as the demand for nursing and other services offered by the allied health professions.

Health Care Professionals

Synonyms

Persons providing medical treatment and care; Medical staff

Definition

▶ Health care professionals are people working in health sector providing health care in terms of preventive and curative services in different types of medical and even non-medical institutions.

Health Care Provider

Synonyms

Health professional; Caregiver

Definition

► Health care provider is defined as a person who helps in identifying or preventing or treating illness or disability. Health care providers are physicians, nurses, pharmacists, etc.

Healthcare Providers

Definition

Healthcare providers are persons who provide health care as part of their job responsibilities. In the purest sense, healthcare providers work for emergency medical services, hospitals, medical clinics, etc., but a child-care worker or employee who is required to provide emergency care in any business may be deemed a healthcare provider in his or her employment setting. Normally, a healthcare provider is a doctor, a nurse, or another trained member of a healthcare team.

Health Care Provision Indicators

Definition

Indicators of resources and provision of health care include several dimensions. Some refer to health workers, their education, employment, and performance. Others concentrate on health care itself, its availability, access, provision of health care on all levels of prevention (primary, secondary, tertiary), health expenditures, and medical technology. The utilization of health care is determined by rates of hospitalization, hospital beds, employment-to-bed ratio, and length of stay in hospital. The most difficult factor to estimate is the quality of health care, since it relies on many other parameters – health care, health professionals, and consumers, etc.

Health Care Quality

Definition

Health Care Quality has been defined by the American Institute of Medicine as "the degree to which health services for individuals and populations increase the likelihood of desired ► health outcomes and are consistent with current professional knowledge" (Lohr 1990). Donabedian proposed thirty years before to define quality in health care as three-fold: quality of health care structure, process-quality and quality of outcome (Donabedian 1966). The quality of the structure of health care relates to adequacy of the facilities, personnel, and policies to deliver medical care. Process quality is concerned about the appropriateness of diagnostic or therapeutic interventions. Outcome quality means the effectiveness and efficiency, i. e. the ► health status that people experience as well as the economic dimension of the health care provided.

Despite all efforts, the proposed definitions of health care quality remain rather vague and suggest that a definition of health care quality on an absolute level is impossible. Health care quality can only be defined with respect to a specific goal, for example with respect to standards, norms and criteria for process and outcome quality. In this case, the definition of health care quality depends on the dynamics of the environment caused for example by technical progress and has to be revised regularly. Another important factor is that the definition of quality relies on rather subjective than objective factors, because the health status of an individual depends mainly on its personal estimation.

Basic Characteristics

History of the Idea of Health Care Quality

The dimension of quality in health care has become increasingly popular in the industrialized world after the first important waves of ► cost containment in the health care sector during the 80s. Economic evaluation and ► rationing in health care have put enormous pressure on health care providers and a lowering of their quality of services has been observed. Although in former times, health care quality was taken for granted, today, more and more patients and health care authorities are concerned about the quality of health care.

As the idea of health care quality had entered the medical scene, health care professionals tried to make it more operational. Various measures of quality have been developed according to the general definitions.

Measures for health outcome were conclusively related to a process or a group of processes that can be modified to improve the outcome. Measures for the organizational quality were either connected to the processes or directly to the outcome in order to be reliable and valid quality measures.

The American Institute of Medicine described a few years later quality in health care as "patient-centered, timely, efficient, effective, safe and equitable, as well as coordinated, compassionate and innovative." Ultimately, health care quality does not mean under-utilizing care that could help people, using the wrong kind of care and overusing care that is not necessary.

Indicators of Quality

In order to assess and improve quality in health care, many countries have developed indicators of quality on a national level that may serve as a framework for all health care provider. Indicators of quality are criteria, standards, and other direct qualitative and quantitative measures used in determining the quality of health care.

In **Germany** for example, indicators of quality are defined along the three-fold definition of quality according to Donabedian.

Indicators for the organizational quality are:

- Education and training of doctors
- Continuing qualification and number of staff
- Equipment of the health care provider (doctors' offices, hospitals, laboratories)
- Access to doctors' offices and hospitals
- IT-infrastructure of the health care provider (doctors' offices, hospitals, laboratories)

Indicators for the process quality are:

- Diagnostic techniques
- Therapeutic measures and nursing
- Principal diagnosis of hospital admissions
- Co-operation between colleagues
- Communication with patients

Indicators for the quality of outcome are:

- Improvement of ► health status, healing of diseases
- ► Patient Satisfaction
- Level of blood pressure and blood sugar
- Change of behavior that influences health status
- Impact on ► morbidity

These indicators are interdependent as the existing organization and resources have an influence on the processes, and processes influence the quality of outcome.

In the **United States**, health care quality indicators have been developed by the Agency for Healthcare Research and Quality (► AHRQ) using a broader approach than the German classification above.

The quality indicators are a set of four modules each of which measures quality associated with processes of care that occurred in an outpatient or an inpatient setting.

1. Prevention Quality Indicators (PQIs) identify hospital admissions that could have been avoided, at least in part, through high-quality outpatient care.
2. Inpatient Quality Indicators (IQIs) reflect quality of care inside hospitals and include:
   - Inpatient ► mortality for medical conditions
   - Inpatient mortality for surgical procedures
   - Utilization of procedures for which there are questions of overuse, underuse, or misuse
   - Volume of procedures for which there is evidence that a higher volume of procedures may be associated with lower mortality
3. Patient Safety Indicators (PSIs) also reflect quality of care inside hospitals, but focus on potentially avoidable complications.
4. Paediatric Quality Indicators (PDIs) both reflect quality of care inside hospitals and identify potentially avoidable hospitalizations among children.

On an **international level**, the Organization for Economic Co-Operation and Development (OECD) has recently developed International Health Care Quality Indicators responding to the growing interest by health care policymakers and researchers in OECD countries in measuring and reporting the quality of medical care. These indicators serve to compare the quality of different countries with different health care systems.

According to the OECD, quality indicators means "indicators for the technical quality with which medical care is provided, i. e. measures of health outcome or health improvement attributable to medical care (changes in ► health status attributable to preventive or curative activity)" (Kelly, Hurst 2006).

The recommended indicators from the OECD Health Care Quality Indicators Project are:

- Breast cancer survival
- Mammography screening
- Cervical cancer survival
- Cervical cancer screening

- Colorectal cancer survival
- Incidence of vaccine preventable diseases
- Coverage for basic vaccination
- Asthma mortality rate
- AMI 30-day case fatality rate
- Stroke 30-day case fatality rate
- Waiting time for femur fracture surgery
- Influenza vaccination for adults over 65
- Smoking rates.

The comparison of OECD countries according to the health care quality indicators in this project has shown that no country is among the best countries on all indicators and no country is among the worst countries on all indicators. Most of the countries have one or more indicators on which they are high performers and some other indicators where they are low-performers. The differences across countries may depend on several factors, for example the country specific disease incidence or prevalence of risk factors (age, gender, etc.).

Quality Assurance and Quality Management

In the well developed health care systems throughout the world, ► stakeholders in health care are concerned with health care quality. Even if the notion of quality is subjective, health care professionals try to incorporate quality indicators in their daily work and the terms of quality assurance and quality management are part of the health care sector. On the provider level, quality of health care is maintained or improved by measures of quality assurance and by an overall quality management. Quality assurance (or quality assessment) in health care intends to assure or improve the quality of care in a defined medical setting or program. Quality assurance includes the evaluation of the quality of care (for example through quality indicators), the identification of deficiencies and the activities leading to assure or improve quality.

Quality management describes the whole spectrum of activities leading to the continuous improvement of quality. It encompasses the planning of quality measures including quality assurance, the implementation of these measures in the service delivery process, regular checking of the effectiveness of the measures and the follow-up actions to ensure continuous improvement of quality. The quality management approach also analyzes the different factors that influence the quality of the delivery of health care, such as the use of practice guidelines, ► clinical pathways or protocols, the motivation of health care personnel through recognition of professional accomplishment or payment policies.

Country Examples of Quality Assurance

In all countries with well developed health care systems, quality assurance has become increasingly important at least on the national health policy level. With respect to the structure, processes and outcome of health care provision various programs and measures have been developed by the governments. On a provider level, there is in some countries a lack of implementation and transparency of the quality assurance programs. The following country examples highlight the different approaches to implementing quality assurance in health care:

In the United States, there is a growing concern about health care quality since the publication of three reports detailing quality-of-care deficiencies in 1998. The Agency for Healthcare Research and Quality (AHRQ) provides an annual update on quality of health care using performance measures to monitor quality progress in the United States in the National Healthcare Quality Report since 2003. Many health care organizations have implemented their own quality management systems based on the national standards set by AHRQ.

In Denmark, a national strategy for continuous quality development was defined in 1993. According to this strategy, counties and municipalities had to include quality measures in their goals for ► health plans. In this context, compulsory practice guidelines were applied for the first time assuring certain standards of quality of care.

In the Netherlands, quality assurance is an important goal of the public health policy. However, the development and implementation of quality assurance is largely the responsibility of health care providers who regulate themselves. The government acts only as a controller of the quality systems by supporting certification activities of health care providers.

In other countries, specific measures of quality assurance are implemented with great success: In Finland for example, there are quality assurance programs for prevention in the sector of mother-child care. In Switzerland, prevention in the dentistry sector especially for children is excellent.

gernot.lenz@gmx.de

Introduction

Health care is defined as the prevention, treatment, and management of illness and the preservation of mental and physical well-being through the various services offered by the medical profession (physicians/doctors) and other professionals such as nurses, pharmacists, and therapists. The provision of those services constitutes a health care system, which is the response to the health problems of a society. The nature and format of health care delivery is strongly influenced by the respective health care system. The financing approach has the greatest influence within a health care system as it determines the payment and compensation structures for the health care provided. Public health is an important part of a health care system, with the objective of improving health, prolonging life, and improving the quality of life among whole populations through health promotion, disease prevention, and other forms of health intervention. Rather than individual health care that focuses on individual's illnesses and risk factors, public health serves the whole population with a focus on disease causes, means of disease prevention, and on processes and outcome of care.

There has been a wide array of different health care practices since the beginning of recorded history, of which medicine is the mainstream scientific tradition. It was developed in the Western world in around 1450 and is also called biomedicine, allopathic medicine, or Hippocratic tradition. Throughout the world, there are still several other health care practices separate from Western medicine. Health care practice combines science and art, with science and technology being the evidence base for many clinical problems for the general population. The application of this scientific knowledge combined with intuition and judgement to derive the correct individual diagnosis and corresponding treatment approach is the art of health care practice.

The health care industry is one of the major and fastest-growing industries worldwide and constitutes a key part of national economies. It covers over 10% of the gross domestic product (GDP) of most developed nations. For example, health care costs in 2005 for hospitals, doctors, nursing homes, diagnostic laboratories, pharmacies, medical device manufacturers, and other components of the health care system accounted for 15.3% of the GDP of the United States (US), the largest proportional expenditure of any country in the world. The 2005 average for the Organisation for Economic Co-operation and Development (OECD) countries was 9.0%, with the US, Switzerland (11.6%), and France (11.1%) having the top three highest proportional expenditures.

Health care addresses acute diseases as well as chronic diseases. Typically, acute care is delivered in high technology, intensive, institutional type settings such as hospitals or physician's practices. Acute care uses primarily medical care to fix or cure acute diseases or injuries. Chronic care is an array of integrated medical and non-medical services which take place in a variety of settings. The objective is to assist people with chronic conditions to live independent, full lives. Chronic care is a continuum of care that is required over a period of time for people who either never acquired or have lost functional abilities. Rehabilitation services are applied to both acute diseases and chronic conditions (diseases and disabilities), with a clear focus on the latter. In case of acute diseases, rehabilitation services are only used for a certain period of time ("subacute care") whereas for chronic conditions they are in most cases applied longer term. There is no temporal dividing line between acute and ► chronic disease as the difference in addressing the respective diseases is more attitudinal than temporal. Management of acute illness tends to focus on cause and cure while management of chronic disease tends to focus on limitation of effects, dealing with these effects, and maximizing patients' potential quality of life.

Profession

Although the physician ('doctor') holds the most important position within the ► health care profession, other professionals like nurses, therapists (e. g. occupational therapists, physiotherapists, and speech and language therapists), and pharmacists are also fundamental in offering their respective services. This is especially true for ► long-term care and rehabilitation, where the important role of interdisciplinary teams has become increasingly recognized in recent times.

The term physician is traditional and commonly used, especially in the US, whereas the term doctor is more common in other countries like the United Kingdom (UK); physician then often refers to specialists in internal medicine. The entry-level medical education programs in developed countries are tertiary-level courses offered by medical schools that usually belong to universities. After completion of the entry-level program, the graduated doctors often have to undertake a period of supervised practice prior to receiving full registration. The permission to practice must often be granted by government and is known as licensing in the US, registration in the UK, and approbation in Germany.

The general practitioner (GP) or family physician plays a vital role in many health care systems as he or she provides ► primary care by treating acute and chronic illnesses, provides preventive care, and offers health education for all ages and both sexes. GP is a common term in the UK and some other Commonwealth countries. A medical specialist is a physician who is specialized in a particular field of medicine. Medical specialists have to undertake additional training and internship to become sufficiently knowledgeable about a specific part of the human body. GPs usually see the patients first and refer them to the respective medical specialist if they cannot cure the illness or cannot identify the cause of the illness.

A nurse is – along with other health professionals – responsible for the treatment, safety, and recovery of acutely or chronically ill or injured people, health maintenance of the healthy, and treatment of life-threatening emergencies in various health care settings. Nurses might also be involved in medical and nursing research programs and they often offer a wide range of non-clinical services that are necessary for the delivery of health care. Although the structure of the nursing profession differs throughout the world, there are usually different levels of nursing practitioners depending on education, responsibility, and skills.

Pharmacists are drug therapy experts who optimize medication management to produce positive health outcomes. In a traditional view, pharmacists have primarily compounded and dispensed medications on the orders of physicians. In the recent past, the pharmacists' services have evolved towards clinical practice, medication review, and drug information. In some country legislation, those new roles have become mandated by law.

Distinct from the medical, pharmaceutical, and nursing professions, there are many other clinical healthcare professions, often summarized as allied health professions. They act as allies in the healthcare team and ensure that the healthcare system functions well. Titles and roles vary from country to country. Depending on the country and the local healthcare system, the following professions may be included: bioengineers, dental hygienists, diagnostic medical sonographers, electrocardiographic technicians, hemodialysis technicians, laboratory technicians, medical assistants, nutritionists & dietitians, occupational therapists, phlebotomists,

physical therapists, physician's assistants, radiographers, respiratory therapists, and speech therapists. Due to consistently increasing costs for health care, there has been a trend towards shifting patients away from expensive hospital treatment towards physician's practices and ambulatory clinics, resulting in an increased requirement for skilled health care delivery personnel. The allied health professionals increasingly have to adhere to national training and education standards, which is often reflected in diplomas and certified credentials that have to be accomplished.

Health Care Delivery

Health care delivery is the process of providing health care, with face-to-face delivery being the most common form. However, technological progress also allows for health care offerings in absentia by, for example, communication by phone or internet, video conferencing, emailing, text messaging, or any other form of non-face-to-face communication.

Health care provision can be differentiated into primary care, secondary care, and tertiary care. Primary care can be defined as "the provision of integrated, accessible health care services by clinicians who are accountable for addressing a large majority of personal health care needs, developing a sustained partnership with patients and practicing in the context of family and community" (Green et al. 2004). Primary care is provided by physicians specifically trained for and skilled in comprehensive first contact and continuing care for persons with any undiagnosed sign, symptom, or health condition not limited by origin of the problem, organ system involved, or diagnosis. Primary care includes diagnosis and treatment of acute and chronic illnesses in a variety of health care settings as well as health promotion, disease prevention, health maintenance, counseling, and patient education. A significant proportion of all medical visits can be treated by the primary care provider. The primary care physician – often a GP or family physician – usually collaborates with other health care professionals utilizing consultation or referral as appropriate. When it comes to ► medical specializations, the primary care physician usually covers family practice, internal medicine, pediatrics, and at times obstetrics and gynecology.

Secondary care services are medical services offered by specialized physicians in their offices, clinics, or hospitals. Patients are often referred by the primary care physician who treated the patient first and required the expertise or procedures offered by specialists. Tertiary care medical services are offered by specialist hospitals or regional centers that are equipped with diagnostic and treatment facilities that are not available at local hospitals, clinics, or practices. Patients are usually referred to tertiary care settings by primary or secondary care personnel. Examples of tertiary care services are specialist cancer care, neurosurgery, burns care, and plastic surgery.

There is differentiation between systems that are primary care led and those that are more hospital-based, also called pluralistic systems. To prevent excess utilization of expensive secondary care services, some primary care based countries like UK or The Netherlands have introduced a referral system with the GP in a gate-keeping role. Patients in those countries only have access to hospital inpatient and outpatient services by means of referral. In the US, also primary care led, however, there has been a trend toward self-referral by patients for these services, rather than referral by primary care providers. Countries such as Germany and France (mostly with a social security system) that maintain parallel access to GPs and medical specialists use other means to ration the use of health care services like co-payments and other financial disincentives.

Acute Illness

Acute care covers the treatment of an acute period of illness, the treatment of injuries related to an accident or other trauma, and recovery from surgery. It is provided in a physician's practice or in a hospital by specialized personnel utilizing complex and sophisticated technical equipment and materials. When considering acute care, it can be differentiated into ► outpatient care, ► inpatient care, and self medication/self care. Outpatient (or ambulatory) care includes all health care services that are provided to patients who do not require an institutional bed as inpatients during the time when services are offered. Inpatient care applies to a patient who is formally admitted to an institution for treatment and has to stay for at least one night in the hospital or other institution providing inpatient care.

Inpatient care primarily takes place in hospitals and is provided by physicians, nurses, and other health care

professionals. Some patients only attend the hospital for diagnosis and/or therapy without staying overnight (outpatients), while the majority is formally admitted and stays overnight or for several weeks or months (inpatients). Hospitals are differentiated from other health care facilities by their ability to admit and care for patients. The most common type of hospital is the general hospital, which offers a broad range of medical specializations including an emergency ward to treat patients with immediate threats to health. A general hospital is usually the primary regional health care facility offering a significant share of beds for intensive care and other specialized facilities. There are also specialized hospitals, which include trauma centers, children's hospitals, seniors' (geriatric) hospitals, and hospitals dealing with specific medical needs such as psychiatric problems or pulmonary diseases. Some hospitals are affiliated with universities for medical research and the training of medical personnel. Many hospitals are still non-profit, however there is an increasing trend towards for-profit institutions in many developed countries.

Following an acute illness or operation like e. g. a hip replacement, ► short term rehabilitation is often required, also called sub-acute care. Short-term rehabilitation is considered appropriate when there is reasonable medical expectation of a significant functional improvement within 60 days of initial treatment. The services are usually performed by interdisciplinary teams, often under the direction of a physician. According to the needs and wishes of the patient, the services are either provided in a residential setting, the physician's or therapist's practice, or the patients own home.

Besides consultation with physicians, individuals increasingly take actions to maintain good health or respond to illness on their own. Those actions are summarized as self care, which includes self medication in the form of individual initiation and management of treatment instead of prescription by a health care professional. The increasing pressure on worldwide health care budgets has encouraged more self care as a way of managing demand for health care services. Going forward, it is therefore likely that pharmacists become increasingly involved in managing minor illnesses. Examples of those symptoms and conditions for which the public already regularly treats itself are headache, dandruff, heartburn, migraine, colds, and acid stomach.

Chronic Diseases and Disabilities

Chronic conditions are health problems that require ongoing management over a period of years or decades. Considered from this perspective, ► chronic diseases like ischemic heart disease, cancer, stroke, arthritis, chronic obstructive pulmonary disease, dementia, and depression comprise an enormously broad range of what appear on the surface to be distinct health issues. There is furthermore considerable ► impairment and disability associated with trauma and infectious diseases like HIV/AIDS, tuberculosis, and malaria prevalent in less developed countries. Throughout the world, there are about six hundred million people who live with disabilities of various types, of which around 80% live in low-income countries. Most of these people are poor and have only limited or no access to basic health care and rehabilitation services and facilities. The number of people with disabilities is increasing due to war injuries, landmines, HIV/AIDS, malnutrition, chronic diseases, substance abuse, accidents, environmental damage, population growth, and medical advances that preserve and prolong life.

Chronic conditions and disabilities presently comprise the major health burden in developed countries, and trends for developing countries forecast a similar situation. Non-communicable conditions and mental disorders accounted for around 60% of total mortality in the world and almost 50% of the global burden of disease in 2000. This share will increase to 60% of the global disease burden by the year 2020, with heart disease, stroke, depression, and cancer as the largest contributors. In developing countries, chronic conditions including injuries and mental disorders are even expected to be responsible for almost 80% of disease. Low and middle-income countries are the biggest contributors to the increase in burden of disease from non-communicable conditions. In China or India alone for example, there are more deaths attributed to cardiovascular disease than in all other industrialized countries combined. This implies that health care costs become excessive when the national health care systems do not succeed at efficiently managing and addressing chronic diseases. The costs associated with chronic diseases greatly exceed expenses for medical treatment but affect society as a whole.

Most health care systems have not yet developed and adjusted towards better reflecting the increasing need

for chronic care. The health care is often fragmented and still focused on acute and emergent symptoms. Although the individual's health behavior and adherence to therapies is crucial to treat chronic conditions, the information and skills provided to the patients to optimize handling of these conditions is often not considered essential or comprehensive. This is reflected in the fact that many health care systems usually do not include a long-term, goal-oriented plan for patients with chronic conditions, and relevant and reliable medical information is not available across providers or over time. The organization of health care often lacks the use of existing community programs, which is a particular issue in low-resource settings that cannot be sufficiently served by the existing primary care setups. Although many chronic conditions are preventable, health care professionals still quite often fail to regard their interactions with patients as opportunities to inform, educate, and motivate them about health promotion and disease prevention strategies. This information would enable patients and their families to improve their health, to prevent or delay the onset of chronic conditions, and to prevent and reduce complications related to chronic conditions for patients that already suffer from a chronic disease. Prevention and health promotion should be part of every health care encounter but this is still far from clinical reality. ► Managed care – as exists in the US and is emerging in other countries like Switzerland – has the potential to provide a range of integrated services required by people with chronic conditions, although the managed care industry is just beginning to realize and respond to chronic care needs.

► Long-term care involves individuals with chronic diseases and disabled persons, often elderly members of society. Long-term care refers to a continuum of medical services, social services, and housing designed to support the needs of people living with chronic health problems or disabilities that affect their ability to perform everyday activities. The goals of long-term care are much more complicated and considerably more difficult to measure than the goals of acute medical care. While the primary goal of acute care is to return an individual to a previous functioning level, long-term care aims to prevent deterioration and promote social adjustment to stages of decline. Long-term care includes a broad range of services emphasizing medical as well as social services. While acute care is usually limited to specialty providers, the providers of long-term care are more wide-ranging. They include traditional medical providers such as physicians and hospitals, rehabilitation providers such as physiotherapists, formal community caregivers such as home care agencies, facility providers such as nursing homes and assisted living facilities, and informal caregivers such as friends or family members. It is common for long-term care to provide custodial and non-skilled care, like assisting with normal daily tasks like dressing, bathing, and using the bathroom. Long-term care can be differentiated into institutional care and non-institutional care like ► community care.

Institutional (or facility) care comprises nursing home care and several kinds of supportive housing. Nursing homes provide institutional care for people recovering from an acute illness or for those whose chronic needs require skilled nursing care and significant assistance with activities of daily living (ADL) such as bathing, toileting, or transferring. Supportive housing is designed to provide group living, assistance with daily personal care, and protective oversight for people with long-term care needs. The various types of supportive housing services differ from country to country.

Community care is especially prevalent in Anglo-American countries like the US or UK. It can be either formal care like home health care and hospices or informal care, meaning in-home care and support by friends and family. Home health care, also known as domiciliary care, is health care provided in the patient's home by health care professionals. Home health care differs from home care or custodial care. Home care is non-medical care provided by persons who are not nurses, doctors, or other licensed medical personnel. Home health care may involve a wide variety of medical and social services and providers, depending on the patient's needs.

Hospices provide supportive emotional and spiritual services to terminally ill patients and their families, in addition to medical services. These services usually involve an interdisciplinary team that includes a physician, a nurse or nurse's aide, a social worker, a member of the clergy, and volunteers. Team members provide medical services, social services, and respite care for the patient and their family. The modern hospice is a relatively recent concept that originated and gained momentum in the UK after the founding of St. Christopher's Hospice in 1967. Since its beginning, the hospice movement has grown dramatically. The first hos-

pice in the United States was established in 1974. Hospice care is one form of ► palliative care that still most often occurs in the dying person's home. Palliative care concentrates on reducing the severity of the symptoms of a disease or slows its progress rather than providing a cure. It aims at improving quality of life by reducing or eliminating pain and other physical symptoms, enabling the patient to ease or resolve psychological and spiritual problems, and supporting the partner and family. Palliative treatment methods may also be applied to patients that suffer from side effects of curative treatments like, for example, the nausea associated with chemotherapy. Although palliative care is by no means a new concept, only a few physicians have put much focus on it in the past. Traditionally, the predominant goal of the physician was to cure patients; putting more efforts into making the conditions for the patients more comfortable and increasing quality of life was often interpreted as giving up on them. The concept of accomplishing a good quality of life has gained importance in the recent past; however, there is still a way to go.

In all countries, informal care provided by the family has always been and still is the major source of provision of long-term care. This is true for care of older persons as well as for care of patients with chronic conditions. However, the heavy burden of care cannot be shouldered by families alone. Due to a wide range of social, economic, demographic, and epidemiological factors, family resources are dwindling. In addition, family caregivers need guidance, support, and skills to manage this often complex care. The growing demand for home care means that families that do not have sufficient know-how are often left to deal with the caregiving responsibility and effort on their own. Effective long-term policies are therefore a key challenge for many health care systems around the world. There is no single solution that covers all the national issues and countries are therefore evaluating several different approaches. Yet, they are still not shared appropriately and comprehensively to enable other countries to use the existing knowledge and establish long-term care as an integral part of their health and social systems.

Table 1 summarizes the characteristics of acute and chronic care.

Rehabilitation

With the increase in chronic diseases and disabilities, rehabilitation medicine has emerged and developed in the recent past. Rehabilitation services primarily address disabled and chronically ill persons; ► short-term rehabilitation also covers acute illnesses, as explained above. Rehabilitation is an active and dynamic process by which a disabled person is helped to acquire knowledge and skills in order to

Health Care and Rehabilitation, Table 1 Characteristics of acute care and chronic care

Characteristics	Acute care	Chronic care
Goals of care	Cure: Restore to previous level of functioning	Assistance and care: Maintain independent living Facilitate successful personal and social adjustment Minimize further deterioration of physical and mental health Prevent acute exacerbations of chronic conditions
Providers of care	Specially trained health care and human services professionals in institutions set up for acute care purposes	Multiple caregiver sources and settings, often includes network of relatives, friends, and community services along with hospital, home health care, and social service professionals
Scope of care	Primary care with specialist support if required	Broad scope of social, community, and personal services, as well as medical and rehabilitative care
Quality of care measures	Significant government investment in many developed countries in outcome measures and quality of care standards for most hospital-based acute conditions	Relatively few measures to assess quality of care
Care delivery setup	Typically occurs within one organization	Multiple organizations involved; collaboration required

maximize physical, psychological, and social function, thus promoting activity and participation. Rehabilitation approaches can aim at:

- reducing disability
- acquiring new skills and strategies that reduce the impact of the disability
- altering the physical and social environment to allow for easier functioning with the given disability.

The key benefits of rehabilitation are improved functional outcomes, reduced unnecessary complications, and better coordination and use of resources. One key element of rehabilitation is team work, which involves a wide array of different professionals. ► Rehabilitation teams can work in many different contexts like hospital based, mainly consisting of physicians, therapists, and nurses, or community based, involving local authority employees such as social workers and community occupational therapists. The rehabilitation team has to function as a coherent whole, allowing client-centered goals to be set and monitored. Thus, the team has to be outcome oriented instead of discipline oriented. The rehabilitation core team generally consists of a rehabilitation nurse, a clinical neuropsychologist, an occupational therapist, a psychotherapist, a speech and language therapist, and a rehabilitation physician.

As for health care, there are again different organizational models of ► rehabilitation delivery. There is no single way to develop a rehabilitation service and the physical base, team, structure, scope, and range of the services provided differs from community to community and from country to country. Inpatient rehabilitation takes place in the hospital in a dedicated rehabilitation unit that is usually able to deliver all standard post-acute inpatient rehabilitation. In the case of regional hospitals, the rehabilitation unit often consists of more specialized therapists, physicians, and nurses and will probably contain a more specialized range of equipment and assessment facilities. In many countries, those specialized services are also offered in specific inpatient rehabilitation clinics. Outpatient rehabilitation can be performed at the disabled person's home, in outpatient rehabilitation centers, or at the specialist therapist's office.

The delivery models described are primarily applicable to health systems in the Western World. A large part of the rest of the world, especially developing countries, has less than adequate rehabilitation resources and facilities. Thus, other models had to be developed to overcome those difficulties. The World Health Organization (WHO) initiated the concept of ► community based rehabilitation (CBR) as part of general community development efforts aiming at the rehabilitation, equalization of opportunities, and social inclusion of all people with disabilities. Its implementation is driven though the combined efforts of the people with disabilities, their families, organizations, communities, and the relevant governmental and non-governmental health, education, vocational, social, and other services. CBR has evolved in recent years towards putting more emphasis on human rights, ongoing actions to address inequalities and alleviate poverty, and expansion of the role and influence of Organizations of Persons with Disabilities (DPOs), which have been established and strengthened in many countries.

The objective of the WHO concept of an inclusive community is the adaptation of the structures and procedures of the community to facilitate the inclusion of people with disabilities. It focuses on all citizens and their entitlement to equal treatment, including those with disabilities, and thus benefits all people in the community, not just those with disabilities. A characteristic of CBR and similar programs is the involvement of the disabled people and their representatives. To enforce equal opportunities for people with disabilities, a common, multi-sectoral approach involving communities, DPOs, national policies, different government ministries, NGOs, and other stakeholders is necessary.

Summary

The development of health care in the last century has been characterized by increasing differentiation in the tasks of physicians, resulting in the development of a range of disciplines. On one hand, there are physicians with generalist tasks, mostly working outside the hospitals, who fulfill an important role in prevention and treatment of diseases in populations. On the other hand, there are specialists who are increasingly focused in narrow areas of health care, offering those services mostly in hospital settings and losing the connection to the community. The future society will be an aging one with the concurrent burden of degenerative diseases. The "Health for All" call made in 1978 at the WHO conference in Alma Ata which aimed at achieving this approach to health care has failed in many instances. This is partly driven by the fact that primary care still

needs to further improve and delineate its role in public health care to achieve health for all. The individualist, high-cost hospital-based care system will neither be affordable in the future, nor deal with the problems facing our society. An effective approach to address those newly emerging health problems requires changing the structure of the hospital-based health system towards a public health oriented, community-based structure, as has already been partly implemented in long-term care. Rehabilitation services have to be integrated within this approach given the increasing demand for those services by both disabled and chronically ill people, especially the elderly. This is especially true for developing and poorer countries where, for example, community based rehabilitation points towards the right direction. All of this implies that collaboration between public health and individual health care is required to bridge the gap between the two disciplines and achieve health for all people. The provision of a community-oriented health care system seems inevitable in many countries as the hospital-based health care system will not be able to solve the problems of health care in the future.

Health system

Definition

Health care systems are organizations where health services and health care are provided. They can be divided into three subgroups: state health services, social health security systems, and private health insurance systems. There is no overall accepted definition for health care systems. As an interdisciplinary field of research, health care systems aim at promoting and maintaining the population's health. Thus, they have contributed greatly to better health. How they act and are implemented depends on which services are provided and how the health care systems are organized.

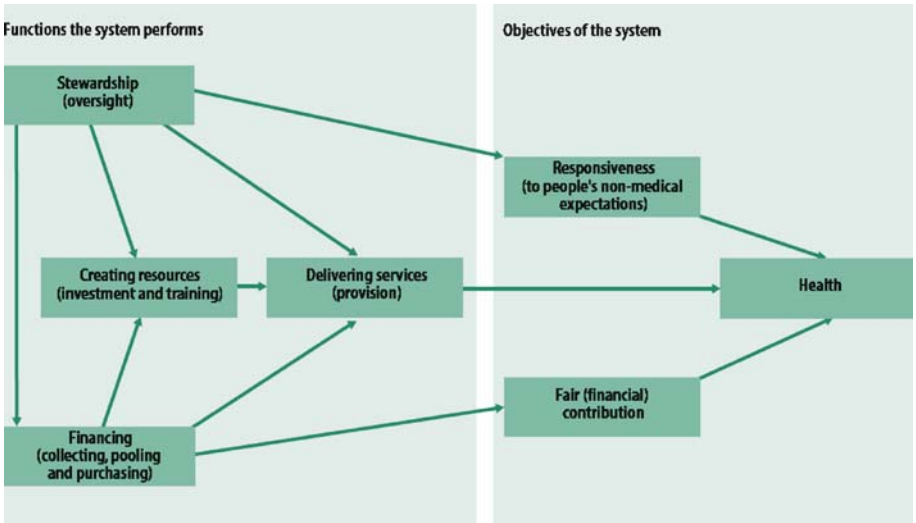
Basic Characteristics

Besides individual behavior and personal circumstances, an individual's health is also affected by health care systems, starting with care during pregnancy and delivery of a healthy baby and up to care of the elderly. As an interdisciplinary field of research, health care systems aim primarily to promote and maintain the population's health. Thus, the lives of most people are dependent on health systems. Intention and overall aims are to improve the well-being of the individual or population, minimize risk factors, and identify and treat diseases (Schwartz and Janus 2006). Health care systems are based in institutional structures, which differ from nation to nation. Financing of these systems is guaranteed by both public (e. g. taxes) and private funds (e. g. donations).

What are Health Systems?

As there are many influencing factors on health, such as nutrition, physical activity, social circumstances, workplaces, and so on, health care systems and the definition of a health care system often vary. This is not only the case on an international and national level but on a regional level too. There is no precise definition existing regarding what health care systems are – neither on a national nor on an international level. According to the definition from the World Health Organization (WHO), there is no specified frame regarding what a health care system stands for, where it starts, and where it ends. Finally, a health system is defined as "*... all the activities whose primary purpose is to promote, restore or maintain health.*" (WHO 2000). This statement includes both health activities that have a direct impact on the individual's health, as primary prevention and health promotion, and also covers activities with a secondary health-enhancing effect, like improving environmental safety. Although the definition of health care systems is not precisely given, these systems "*... today represent one of the largest sectors in the world economy*." (WHO 2000). Development started in 1883 when Germany enacted a law for the health of low-wage workers and thus started the first social insurance model. Many nations worldwide followed and adopted the law on a national level.

In general, health care systems are organizations from which health care is provided. These vary widely from one nation to another. If comparing the systems among different countries, the financing and management of the health care systems are appropriate aspects to compare. Funding can be public or private and control can be led by governmental or public bodies. Thus, health systems are mainly characterized by great dif-



Health Care Systems, Figure 1 Relations between functions and objectives of a health system (WHO 2000)

ferences in organization and funding. These differences often lead to diverse outcomes in health policies and, finally, health within the population itself. It follows that mistakes in investment in a health system have long-lasting consequences for all individuals and systems involved. Health system research therefore aims at developing tools for describing these differences and tries to improve circumstances for better health (WHO 2000).

Much preventable disease could have been prevented by a well-established health system that reaches the whole population and aims at promoting health and preventing diseases. Particularly deprived people are affected by unequal distribution. The intention is to compare health systems by looking at what they achieve and what they really do in terms of realizing their overall goals (Roemer 1991). Figure 1 gives an overview on how functions and objectives of health care systems are related to another.

Three fundamental objectives are recognized for health care systems – improving the health of the population they serve, responding to people's expectations, and providing financial protection against the costs of ill-health (WHO 2000). For implementing these on a national level, the impact of policy and its decisions is fundamental. Individual circumstances within each country lead to different implementation of these objectives. Resources differ and health problems within each country vary. Influences such as distribution of income and wealth or impact of climate constitute no real indicators.

Success in the overall frame of health systems covers the effective control of diseases (WHO 2000). The final aim is the protection and improvement of health of the population; inequalities have to be limited by fairness and without discrimination. Resources in health systems need to be raised appropriately.

Health systems in all nations have a great impact on the health of an individual. With their design, management, and financing they contribute to better health for all by affecting people's lives directly. After undergoing reforms in the past 100 years and concentrating on the extension of the social insurance system, health systems' focus is now on the promotion of primary health care.

A problem that still exists is the unequal distribution of resources within different international health care systems. Generally, they should integrate people's health needs and their expectations. Often, there exists an unbalance between these expectations and reality, particularly with regard to tariffs that people have to pay and the benefits they get in return. Misuse of the health system's power can lead to harm rather than to a well structured and organized system. Thus, the intention of health care systems is not implemented as it is supposed to be and preventable diseases occur that could have been avoided. These aspects lead to a high potential for improvement of health care systems and their funding, starting at the policy level.

An overall objective of health care systems is the health of the whole population from the beginning of their lives. Aiming at implementing this goal requires the

best management and financial distribution with respect to current improvements and political circumstances, influencing whether health care systems do their job effectively or not.

Finally, demographic changes and medical and technical improvements have to be taken into account. This aspect leads to increased expenditures in health care systems, and affects all nations (WHO 2000).

Policy's interest has to be to help health systems to use their own resources for achieving goals. Furthermore, policy-makers need to find out how health systems are structured and how they work. These findings are fundamental for understanding and, thus, for improvement of health care systems, giving support within their resources. On the other hand, it is not only the health care system that influences the individual's health. It is in the population's interest to pursue resolutely their rights and obligations, leading to them being better informed. People should be able to integrate their expectations in order to become an active part of the whole health care system. In addition, through comparisons of experiences from other nations, the individual health care systems can be adopted according to their specific cultural, historical, and social circumstances.

Health Care Teams in Palliative Care

Synonyms

Interdisciplinary palliative care groups; Multimodality hospice approach

Definition

In palliative medicine and hospice care transdisciplinary work is fundamental. Groups of physicians, nurses, social workers, physiotherapists, occupational and complimentary therapists, hospice chaplains, family members, housekeepers and volunteers provide the best chance for successful health care in patients with incurable illnesses. They support the critically ill patient medically on the one hand, and psychologically on the other hand. The caregivers are by themselves under severe emotional stress.

Health Care Utilization

► Health Determinants, Economic

Health Change

Synonyms

Health outcome

Definition

Health outcomes describe the change in the ► health status of an individual due to a clinical intervention or therapy. To measure health outcomes, health professionals establish a list of the end results of a particular health intervention according to the experience of the patients. It includes for example the change of the ability to function in everyday life and the general perception of well-being. The research of health outcomes that links the care patients receive to the outcomes they experience has become an important factor to monitor and improve the quality of health care (► health care quality).

Health Communication

Definition

Health communication is the art and technique of informing, influencing, and motivating individual, institutional, and public audiences about important health issues. The scope of health communication includes

disease prevention, health promotion, health care policy, and the business of health care, as well as enhancement of the quality of life and health of individuals within the community.

Health Control

Synonyms

Health promotion; Healthy public policy; Disease prevention

Definition

Health control includes the policies and processes that enable people to increase control over and improve their health, as is stated in the Ottawa Charter for Health Promotion (1986). These address the needs of the population as a whole in the context of their daily lives, rather than focusing on people at risk for specific diseases, and are directed toward action based on public policies on the determinants or causes of health. The main goal is a progress towards a healthier world.

Health promotion must become an integral part of domestic and foreign policy and international relations, including in a situation of war and conflict. To achieve this, it is necessary to promote dialog and cooperation among nation states, civil society and the private sector. An example of such a successful treaty to improve health of the population is the World Health Organization Framework Convention on Tobacco Control.

[2] Forschungsverbund Public Health Sachsen-Sachsen Anhalt e. V., Medizinische Fakultät, Technische Universität, Dresden, Germany
wolfgang.boecking@web.de, dtrojanus@gmx.net

Definition

Health data management comprises all activities relating to managing health data as a valuable resource. It encompasses acquiring, entering, processing, coding, outputting, retrieving and storing of data gathered in the different areas of health care, for example at the level of health care providers (physicians, hospitals, pharmacies and other health care facilities) and at the level of health care payers (health insurances, social insurances). Health data management also embraces the validation and control of data according to legal or professional requirements.

Basic Characteristics

Evolution of Health Data Management

As a result of the great progress in information and communication technologies over the last years, the landscape of health care delivery and medical data management has significantly changed. In contrast to former health data management through paper records that stored physically data where it has been produced, there are today more and more health care areas in which data are managed electronically. In many health care provider organizations, information technology plays an important role not only for document management, but also for administrative activities and clinical processes. Electronic data management allows improved physician's access to clinical data, the use of bar coding, computerized prescriptions and numerous software applications supporting health care providers in the ► reimbursement process via ► diagnosis related groups as well as in their quality assessments (► health care quality). With rising cost-consciousness in the health care sector, the need for information automation as well as for transparency of resource utilization

is increasing. As a result, information technology and computer science continue to have a great potential in the health care and medical world. Health care payers, for example, turn increasingly to ► business intelligence tools and analytical data processing systems to evaluate cost, utilization and effectiveness of health care services. The growing efforts towards Integrated Health Care (► integrated health care) led to further developments of ► telemedicine (or ► e-health applications) as an important tool to improve access to services for patients in more remote areas and to offer distance learning for health care professionals. Another popular development, electronic health or patient records are increasingly applied to centralize patients' information of the different services provided in one health care unit or across several health care units. Further developments head towards so-called "patient smart cards" loaded with clinical and demographic information. These developments require organizational, functional and scientific knowledge as well as ethical and legal standards for data quality, information security, access control and privacy.

Challenges: Standardization and Norms

Ethical aspects concerning the secure distribution of sensitive medical information, the balance between groups of patients' needs, expectations of health professionals and the health care industry's requirements are major challenges to the recent development of health data management.

In all countries with well developed health care systems, efforts on national and international levels to set norms for electronic health data management can be observed. Recommendations are formulated to:

- harmonize standards for data exchange, e. g. harmonization of formats, syntax, headers, links, etc.
- protect database access and patient identification, e. g. digital signature for health professionals, unique identification process for patients, etc.
- define the role for health data management and the electronic health record including long term preservation and a set of minimal functions
- evaluate conformity to existing norms and standards on an international level

In most countries governments are setting legal standards for health data management. In Europe, the European Committee for Standardization delivers proposals and recommendations on standards for health informatics and ► e-health (European Committee for Standardization 2005).

Electronic Health Records (EHR)

In all developed health care systems, the introduction, or broader application of, ► electronic health records is a highly discussed topic.

Definition EHR capture and manage the whole history of patient health information. They function as the physician's primary information resource during the delivery of care.

Advantages and Risks EHR enable doctors, administrators and patients to benefit from a rich and sophisticated informational environment. As individual medical records can be electronically linked and aggregated, they promise a more comprehensive and coordinated health care approach for patients. On a community or national level, EHR provide a previously impossible insight into the health of population groups and therefore offer new opportunities for epidemiological studies.

EHR support the monitoring and evaluation of the quality of care provided, the effectiveness of the health care organization's infrastructure and the utilization of practice guidelines (► infrastructure and service delivery). Electronic patient data facilitates the accountability in health care as ► resource allocation, ► reimbursements, ► health outcomes and risks (co-morbidities and side-effects) become transparent. From the epidemiological perspective, EHR offers the possibility to realize new comprehensive studies of population health, risk factors and disease burdens thanks to the provision of appropriately masked long term information on a much broader basis than former survey data. Furthermore, the various scientific research institutes will be able to exploit electronically available patient data in order to improve the overall information about the health care system.

However, electronically available patient records make access and distribution of data easier and could therefore threaten privacy and lead health insurers to discriminate against patients with high-risk disease profiles. The electronic management of health data could be vulnerable to unauthorized access and exploitation.

Conclusion

Despite the advantages of EHR, ethical standards have to be imposed externally on every organization dealing with personal health data in order to ensure respect for the well-being and dignity of patients and to protect their interests. As physicians have the obligation of confidentiality and, generally, patients own their own health records, it is they who decide to authorize physicians to disclose health data or not.

The future of EHR is a question of balance between the protection of individual ► privacy rights and the realization of public benefits from electronic health information. The use of EHR depends ultimately on successful de-identification to make health records anonymous and patients' consent authorizing health data disclosure.

Health Data Protection

Synonyms

Confidentiality

Definition

A subset of ► privacy that focuses on health data protections arising from a relationship of trust between individuals (e. g., relationships between physicians and patients, researchers and human subjects, genetic counselors and clients).

Health Determinants

Synonyms

Factors that influence health

Definition

The events and environmental factors that give rise to the immediate causal factors are often termed "determinants". Health determinants include physical, biological, behavioral, social, and cultural factors.

Among physical factors the most important ones are climate and geographical characteristics of a particular region.

Biological determinants may be inherited or acquired.

Social determinants of health are very complex. Perhaps the broadest social determinant of health is a country's level of social and economic development.

Cultural factors influence behavioral patterns that in turn may promote or endanger health.

Health Determinants, Economic

Health care access; Health care utilization; Medical outcomes; Economic evaluation; Health impact assessment; Demand of health care

Definition

Health status is influenced by a multitude of factors. The health status and the health-related quality of life of individuals, or a specific population, are fundamentally determined by the environment and the circumstances (health determinants) of a person, or a population. It can be further assumed that economic circumstances have a considerable influence on the environment. Ironically, not only has the economy an influence on health status but health status has an enormous influence on income and economic growth. Our health status and our ► health-related quality of life is dependent on where we live, the condition of our environment, our individual genetic make-up, our income and educational level and social status. It is obvious that health determinants have to be included in a health economic analysis. Besides genetic prerequisites (biology and genetic endowment), gender and culture it is clear that economic circumstances have an enormous influence on health and health-related quality of life.

- **Social and economic environment:** Health is dependent on income and social status. The bigger the differences between the rich and the poor, the larger the differences are in the health status of a society. Resources should be sufficiently available to guarantee the imbedding of the individual into social support networks and social environments.
- **Physical environment:** An environment which maintains health requires a corresponding infrastructure which maintains a healthy environment (water, air, traffic, and home) and healthy working conditions. Health services which provide prevention, diagnosis and therapy have to be available. Individuals and the society in which they live have to have sufficient financial resources to maintain the desired environment and provide the essential infrastructures.
- **Individual characteristics and behaviors:** People with a low standard of education and literacy tend to be less healthy. Inadequate working conditions, stress and little self-esteem have negative effects on health. People who have secure employment are healthier, particularly if they have control over their work environment and their job. Balanced nutritional habits, physical activity, personal health practices and coping skills have a positive effect too. The fundamentals of healthy living are formed in childhood. It is essential to support individuals and whole populations; sufficient personal financial resources have to be provided.

Basic Characteristics

Health and Economic Growth

The targets of a health care system are the maintenance, support and recovery of the population's health in its group-specific and regional sub-structures. Objectives for political action can be derived from the general and special factors which determine health status and the health-related quality of life. Health policy related decisions can be aligned to the scope of actions mentioned above. Health equals wealth: countries with a high level of health grow faster than countries with a low level of health. There is also a linkage between improved health and the escape from poverty. Health interventions are subject to political decision-making processes since financial and social resources have to be utilized. From the economic point of view, scarce resources need to be utilized optimally; thereby maximizing the benefit for the individual and/or the whole society, thus, the health sector makes an important contribution to the welfare of a society. Despite the constant regrets about increasing expenditures, a paradigm shift is presently taking place in the perception of the health and social sector.

Health can no longer be seen as a dependent variable of economic and social development but has to be recognized as a factor for ► economic growth. This was recognized by the WHO commission examining the interrelations among investments in health, economic growth and poverty reduction (WHO Commission on Macroeconomics and Health 2001). The report on "Macroeconomics and Health: investing in health for economic development" detects several key findings: A worldwide scaling up of health interventions for the low-income countries of $30 to $40 per person will require approximately $27 billion per year in donor grants by 2007 ($38 billion per year by 2015). Around $6 billion per year are currently provided. These investments would save up to eight millions lives and they would translate into hundreds of billions of dollars of increased income. So, besides the expense of maintaining health, which burdens the economic disbursements for social systems and the nation's competitiveness subject to financial plans, the contribution of health care

to economic growth and employment is documented. The health status of the population has a qualitative and quantitative influence on human resources of a society and therefore is an essential input factor for economic growth. The productivity of workers is improved by health (qualitative dimension) and by the reduction of illness the number of workers is increased (quantitative dimension). Also, the market for individual health services with its various products, services and facilities is itself an industry where enormous sales can be made and in which many people can find jobs. The demand for a higher quality of life and a best possible state of health is not just based on an ethical and moral sense of justice; health represents a productive resource and therefore is of social value and promotes the growth of a society as a whole.

International differences in life expectancy provide a cross-national challenge concerning the maintenance, re-establishment and promotion of health as well as the financing of health services. Health-related political targets, outlined above, are dependent on the economic power or the social wealth of a country. Based on extensive literature, there is an obvious link or interrelation between health and poverty. Moreover there is an interrelation between health expenditure, gross domestic product, education and life expectancy. Taking these indicators into account the various health determinants are important parameters in a country's economy.

Health Determinants and Evaluation

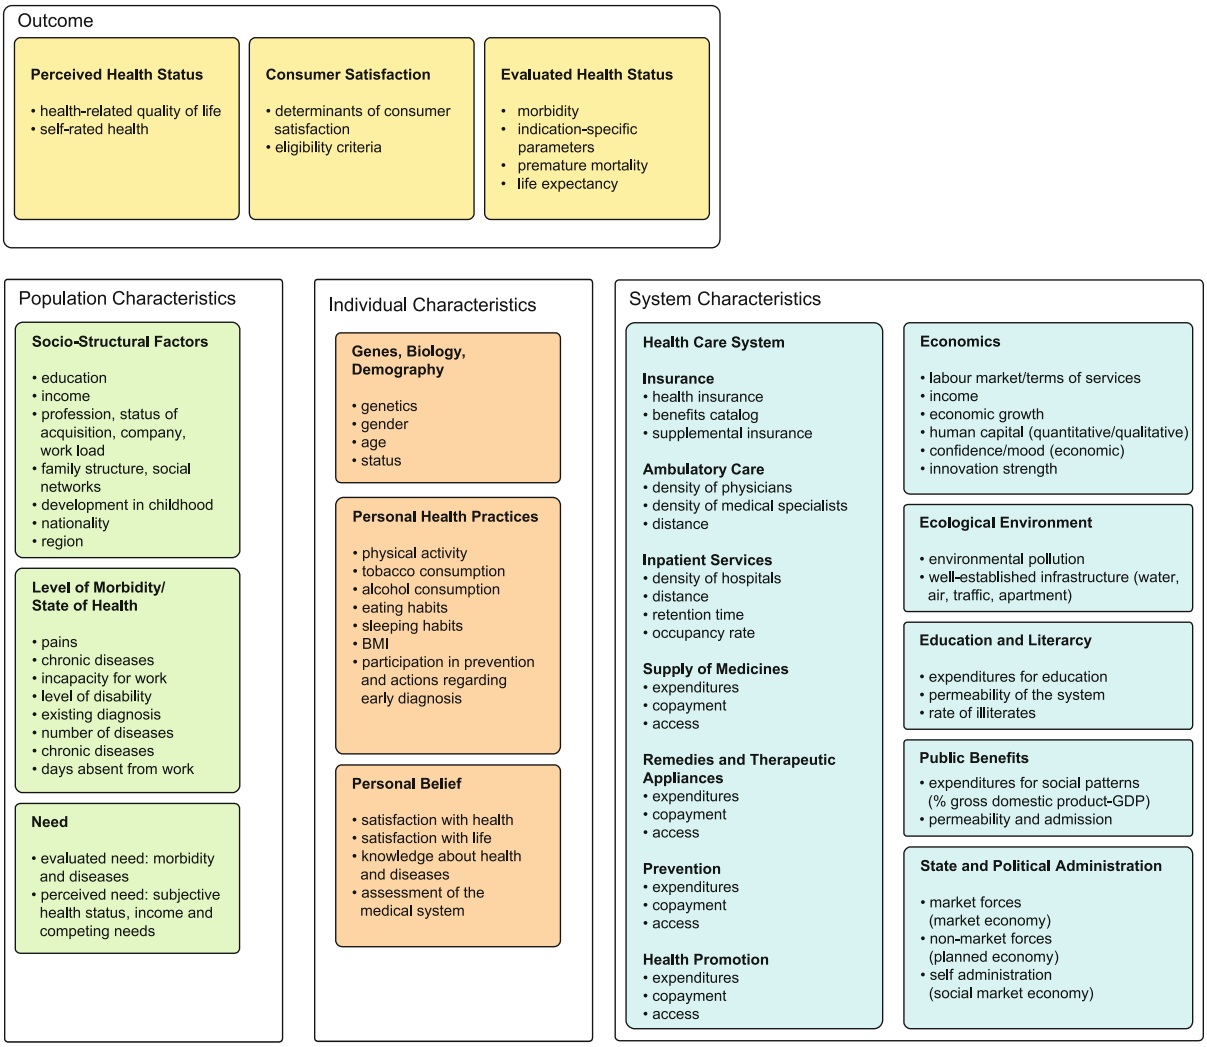
Measures of health promotion and health care interventions aim to affect health determinants. Intervention at both a governmental and a personal level are required. So, substantial environment, social environment and personnel resources need to be provided to promote changes in behavior – with the aim of increasing life expectancy and a health-related quality of life and reducing morbidity and early mortality. In terms of an optimal use of scarce health resources the achieved results (medical outcome and health-related quality of life) must be in relation to the used resources (input factors). Health economics play an important part in the evaluation of health and health care interventions and provide a set of techniques to assist decision making in the health care sector, to promote efficiency and ► equity. Making optimal decisions concerning the allocation of scarce resources can make a big difference in the degree to which health care systems continue to function; ultimately it can mean saving more lives and providing a better quality of life (social benefits). Health economics is about maximizing social benefits obtained from constrained health producing resources.

The ► health economic evaluation makes a comparison between alternative courses of action, therefore the existing options are evaluated in terms of both their costs and their benefits (Drummond 2005). On this basis a ► health impact assessment intends to identify the positive or negative impact, effectiveness, efficiency and eligibility of different populations. Due to complex causal pathways between interventions (projects, programs or political/social strategies) and a potential health impact at the individual or population-related level, a verification is often hardly possible. Numerous confounding factors do influence the outcome and impact (health status) so that the verification of an existing correlation between alternative action and changes of health status and a health-related quality of life is quite difficult (Andersen 1995; Sprangers and Schwartz 1999).

First the health determinants have to be registered and their influence or causal effect chain has to be described. Regarding the documentation of the results sources have to be made transparent and missing or incomplete information has to be pointed out. A comprehensive representation is based on qualitative and quantitative evidence. Therefore a model of demand and production of health-related products/services is required – including predisposing characteristics, enabling resource as well as need's influencing factors.

Demand and Health Care Utilization of Health Goods and Services

Due to the requirements mentioned above two theories out of economics and social sciences should be focused on in the following. Health economics deals with the claims and the production of medical care and health promotion. The supply and demand are described by models which explain the behavior of the interested people and contractors by economical decisions. Regarding the empirical revision of the assumption it has to be noted that the socio-scientific and health economic models are overlapping and develop into multivariate models. Socio-scientific and economic analysis



Health Determinants, Economic, Figure 1 Individual-, system- and production characteristics effecting health status

point out the behavior of individuals or whole populations by means of population-related and system-related characteristics. These can be completed by result-related characteristics of politics and production-related features.

One health economic model for estimating demands or claims on health goods and health services is the so-called Grossman Model (Grossman 1972). According to the basic models for the household productions Grossmann established a periodical model to present the demand for health. In 1986 Wagstaff developed a simplified presentation which is based on periodical presentations of Grossmann 1972 and also represents his three basic assumptions:

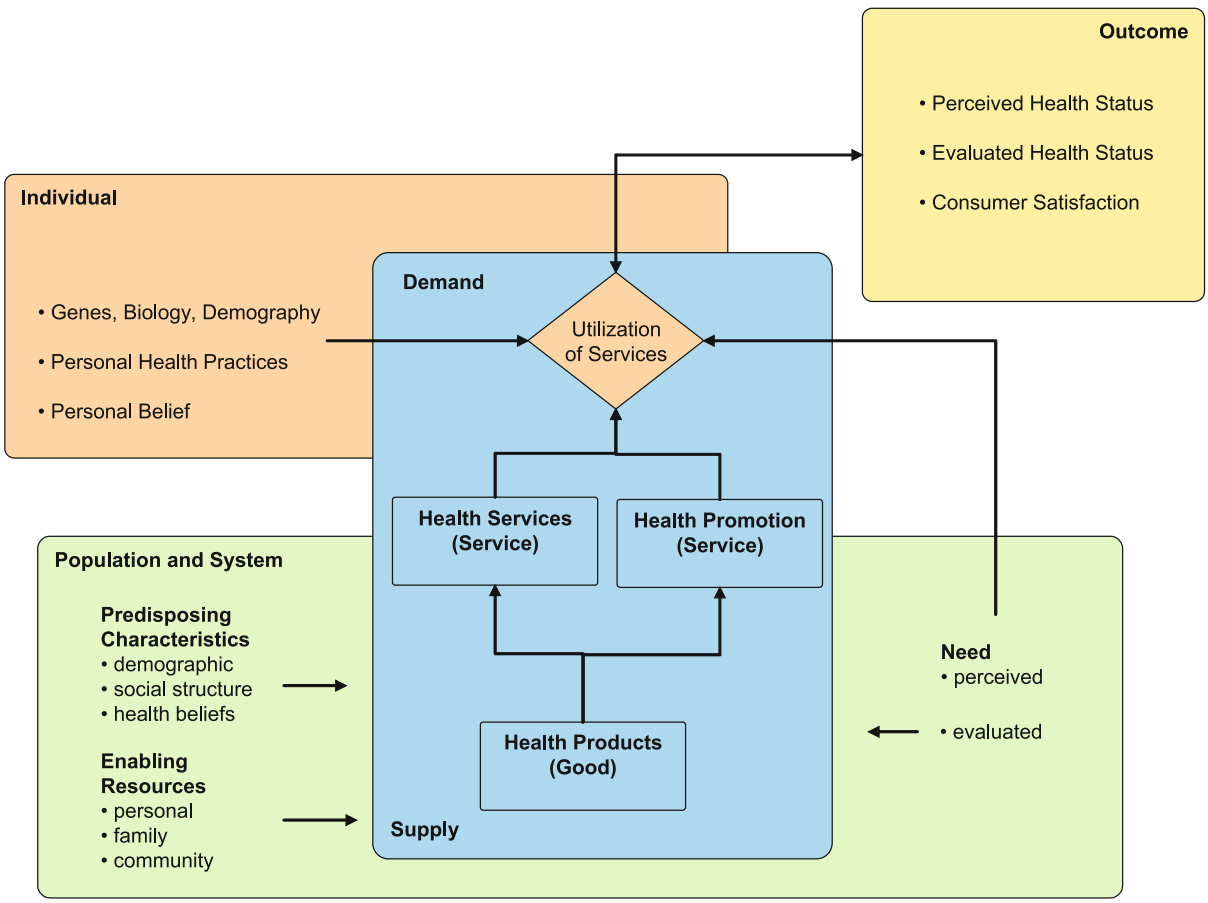
- Health is a human need besides other needs. With no doubt a good health status is the aim of every person; however, health is also competed with other needs. The satisfaction of these needs is competed with health: first by the consumption of scarce resources which could be used by health goods, on the other hand through the direct influence of health (smoking, alcohol etc.). The thesis, that health may be seen as the "uppermost commodity", can be questioned – often harmful behaviors are noticed. The capital stock of health depends on the claims of medical services and a deduction rate which is explicitly defined as a role of age (of capital stock of health) and the intensity of its use. With the help of the

deduction rate characteristics like health behavior or the education level can also be integrated into the model.

- The person's state of health is determined by the consumption of health goods or health services.
- In this model the demand for medical services is interpreted as a derived demand, i. e. the individual asks for health and not medical services. By the use of services (medical and custodial care or services of other professions in the field of cure) or the use of products (drugs, medical engineering, other means etc.) the health of the individual can be kept or restored completely or partly. The target regarding the consumption of health goods is the prolongation of life at simultaneous attention of the quality of life. The consumption of health goods or services takes place with exchange that is connected to costs. A connection between the earned income and the state of health can be established by ascribing an intensive and consumption use to a higher capital stock of health. There are only limited resources that are available for people interested in goods. Apart from an underlying health insurance, the basics of the model can be seen to be that the consumer of health services has to pay for it directly, i. e. he or she has to raise the amount for medical care, services or health products within the limited budget.

Some statements of the Grossman model have been disproved by the empirical evidence. According to the model the state of health and the demand for medical services have to be correlated positively, this has not been confirmed empirically.

Within the production of health services there is a distinction between the service level of the manufactoring of health products (level I: secondary sector) and the establishing of services (level II: tertiary sector).



Health Determinants, Economic, Figure 2 Synthesis of the determinants of the demands and the production of health

In economics, a service is the non-material equivalent of a commodity. The delivery of these services typically involves the following factors: service providers, equipment and physical facilities for service provision, the client and customer contact. During the provision of a health service a high degree of interaction between patient and service provider is required. The patient's cooperation is an additional component of the production (additional input factor). Therefore it is difficult to analyze behavior like utilization of health care services and the resulting outcomes.

A socio-scientific behavioral model was already published by Andersen at the beginning of 1970 (subsuming: Andersen 1995). This basic approach which was steadily developed over the years, contains a wide (potentially complete) spectrum of categories for subsuming of individual and social determinants which can influence the utilization of health services. The model is suitable for putting in an analytical order categories or determinants which can be consulted for the description, explanation and forecast of the utilization. The categories Predisposing Characteristics, Enabling Resources and Need are in the center of the model as magnitudes of influence on the demands of health services.

- **Predisposing Characteristics:** With this underlying item Andersen summarizes all features which indirectly affect the demands. These features include different areas like demography (age, gender), social structure (social status, education, etc.) and health beliefs (attitudes, values and knowledge related to health).
- **Enabling Resources:** These resources describe necessary conditions for the use of health services. It is distinguished between personal (income and the existence of health insurance and additional insurances) and community-related resources (the existence and the reachability of facilities at the habitation and working place).
- **Need:** Interestingly enough Andersen distinguishes between an affected person's need (according to the individual needs) and one by a professional sentence objectified need (subjective sentence of an expert).

Later the model was completed with the components *Outcomes* and *Environment*. Moreover Andersen and his co-workers completed the model with feedbacks of outcomes on ► population characteristics (population-related features) and on the health behavior. There are many international studies which base on the model of Andersen. The empirical explanatory power strength of Andersen's model is about 25% of the interindividual variance. The most important explanatory variable is the subjective assessment of own symptoms (Need) while other factors play a smaller role. Figure 2 gives a summary of the most important factors for the classification of the determinants related to health care utilization.

Definition

The emphasis which research and public discussion are increasingly placing on environment and health is an expression of the growing importance which long-term assurance and improvement of both living conditions and the environment have as indicators and determinants of human health and welfare. The World Health Organization (WHO 1998) uses the term 'environmental health' to include all physical, chemical, biological and psychosocial factors which can have a potentially harmful effect on the health of both the currently living as well as the future generations.

Basic Characteristics

Statement of the Problem

During the 20th century, environmental determinants of human health (e. g., ► workplace hazards and living conditions, health services) and individual lifestyles (Naidoo and Wills 2003) underwent a change in quality mainly in the industrialized nations. Advances in curative medicine and environmental hygiene, improved living and working conditions, socio-economic and technological progress as well as availability of health care structures have contributed significantly to increase the life expectancy and quality of life (Kistemann et al. 2002). Although the environmental conditions have improved greatly thanks to technological progress and legal regulations (e. g., threshold values), the current high level of health is subject to interference from a number of factors which arise from new or recurring questions about the relationship between people and their environment (EEA 2003).

According to estimates, a fourth to a third of the world's ► burden of disease is due to environment-related ► risk factors. The WHO-commissioned Environmental Burden of Disease Study showed that about a third of all health problems in Europe affecting children and adolescents (i. e., from birth to the age of 19) can be traced back to environmental agents (Valent et al. 2004). In children aged 0–5, up to 40% of the total burden of disease is due to environmental risks (EEA and WHO 2002).

The Importance of Multifactorial Determinants of Public Health

While most deaths in developing countries are caused by communicable ► infectious diseases associated with poverty, scarcity of water, sewage disposal and poor hygiene – e. g., malaria, cholera and tuberculosis (WBGU 2005) – the so-called 'modern health risks' predominate in the industrialized nations. These stem from changes in lifestyle, a technological environment and global environmental processes such as climate change which increasingly endanger human beings and the environment beyond the local and the national level (Kevekordes and Mersch-Sundermann 1999). Typically, changes in the illness pattern show a shift towards ► chronic diseases (e. g., cardiovascular or nutrition-dependent diseases, allergies, asthma). On the one hand, these are caused by individual, lifestyle-associated risk factors (e. g., smoking, ► nutrition), on the other hand they are clearly connected to environmental factors. An explicit, causal relationship between exposure and effect can rarely be shown. Using a rough classification, the following must therefore be distinguished:

- multifactorial environment-related diseases (e. g., allergies) (Behrendt et al. 1999);
- diseases where environment involvement is discussed and where environmental factors can act as triggers or co-factors (e. g., some types of cancer) (Nguyen 2002);
- environment-related functional syndromes (e. g., multiple chemical sensitivity [MCS]) where environmental factors are discussed as possible contributory causes (Wiesmüller and Hornberg 2002); and
- ► somatoform disorders (Bullinger 2002).

In addition to their influence on health-related quality of life, these problems also have a significant economic aspect for the public health system (e. g., the burden of disease which is caused by environmental pollution due to road traffic and accidents). The causes of these health problems are likely to be found in various areas of life and in the everyday physical and social environment. Evaluation and assessment of the relevant environmental determinants must therefore base on an understanding of the environment that transcends a strict scientific and technological definition.

The Environment as Seen from the Public Health Perspective

Public Health in the context of ► ecological health promotion and ► environment-related health protection requires a concept of the environment which comprises not only environmental toxins, but living conditions in general. The one-sided biomedical definition with emphasis on pathogenetic factors must be expanded to include the central dimensions of the social, economic and cultural environment (Schmidt-Denter 2002) in the various areas of life (e. g., housing and health; Fehr et al. 2005) where physical, chemical, biological and social factors interact. A comprehensive understanding of the environment depends on a broader definition including psychosocial and ecological aspects and integrating the often neglected potential and resources found in the environment to promote and safeguard human health.

The Effect of the Environment on Human Health: Environmental Factors as Both a Resource and a Health Risk

Since human beings and their environment constantly interact with each other, the influence on human health by environmental factors must be seen as natural and hence unavoidable. Environmental resources like water, soil, air, plants, animals, microorganisms, electromagnetic and other ► radiation can act in two ways: On the one hand, they can promote human health. Contact with nature is able to help relax, alleviate ► stress and generally contribute to the individual well-being (RMNO 2004). Green spaces in residential districts improve the quality of recreation in public areas and have a positive influence on human activities. They encourage ► physical activity, thus indirectly promoting healthier ► behavioral patterns and hence improving the health status (Maller et al. 2005). On the other hand, an artificially altered environment can endanger human health. Potential environment-related threats can stem from a number of factors; e. g., harmful substances can be taken up through various routes, including the gut, the airways and the skin. The main factors are chemical (e. g., gases, particles, fibers, heavy metals, organic compounds, pesticides, estrogens in the environment), biological (e. g., microbial contamination of food, indoors contamination by bacteria and mold) and physical (e. g., ► noise, radiation) (Seidel 1998). Important social determinants (► health determinants, social) (Neuser et al. 2002) include isolation, poverty and discrimination. Human health is affected mainly by these factors acting in combination – also depending on the intensity, degree and duration of exposure – in different areas of everyday life such as home, food, leisure, work, traffic in ► urban environments etc. (Fehr et al. 2005).

The Home and the Living Space as an Important Environmental Determinant of Human Health

The home and the living space is where human beings spend most of their time. The importance of its resources and limitations as environment-related determinants of human health was rediscovered and made a topic of public ► health policy only a few years ago (Jackson 2003). Social ► epidemiology and hygiene research in the 19th century focused on hygiene standards and basic infrastructure. Nowadays, emphasis is on challenges posed by the increasing volume of individual travel, intensified land development (construction) to the detriment of green and recreation areas, as well as growing social problems (Stronegger and Freidl 2004). The home and the living space, who are related in a variety of ways (Schmidt-Denter 2002), are particularly well suited to illustrate the close correlation between the environmental burden, the availability of environment-related public health resources, as well as social status. Since a lower income is associated with a clear disadvantage regarding quality of home (e. g., construction) and living space (e. g., traffic, nearby industries), differences in exposure to physical and chemical factors show a definite correlation with education, income and professional status. Accordingly, the less affluent population shows a greater clustering of health risks and problems (Bolte and Mielck 2004). Unlike the ► environmental justice movement in the USA, in Germany these social inequalities started being addressed and were made a subject of public health research only a few years ago. Considering the potential effects of a high exposure, especially for socially disadvantaged groups and areas, there is a pressing need for action, including ► risk assessment, ► integrated environment-related public health reporting and ► health impact assessment (HIA). Population-related preventive ► environmental medicine – including the basic disciplines environmental hygiene, environmen-

tal toxicology and environmental epidemiology (Kistemann et al. 2002) – is a vital part of public health.

Strategies and Approaches for Promoting Environment-Related Public Health

In view of the scarcity of data regarding the actual risk potential of environmental factors endangering human health; cause-effect relationships; specific groups at particular risk from environmental factors (e. g., children, migrants, pregnant women, the elderly and sick people); ► gender differences in exposure and health effects of environmental burdens; social and regional distribution patterns of environmental burdens; as well as possible (eventually late) health effects of chronic, ► low-level exposure, etc. (Meyer and Sauter 2000), environment-related determinants of human health must be approached with prevention in mind by minimizing the risks and making the most of environment-related public health resources. Keeping an ecological perspective of human health and disease, this requires a holistic view of the environmental media, health-promoting resources as well as environmental toxins and their health effects while taking into consideration populations in their entirety and their interaction with the environment (Fehr et al. 2005).

While ► prevention starts with specific diseases or rather disorders and emphasizes lowering of risks, ► health promotion follows a resource-oriented approach. Despite different perspectives and strategies, prevention and health promotion can complement each other effectively in practice (Altgeld and Kolip 2004). The existing approaches for ► health behavior prevention – e. g., preventing exposure, promoting environmentally sound consumer behavior – aim at disseminating behavior prevention in the people's immediate environment. This would open up the possibility of not limiting environmental awareness in health promotion projects to just preventing danger and reducing risks, but implementing it from a health-promoting angle both in particular ► settings and at the community level. There is great potential for integrated programs which have become established both at the national and the international level in the last few years. They form the basis for an integrated cooperation of health, urban development and the ► urban environment. The most important programs are the 'Local Agenda 21', the German 'Healthy Cities Network' and the Federal-Länder Program 'Socially Integrative City' (Trojan and Legewie 2001). Their special characteristic is to focus on environmental *and* human health determinants and engage in transregional cooperation in different technical fields which shape environmental and living conditions (e. g., urban planning, environmental medicine, social work).

Risk and protective factors of psychological health and well being

Definition

Health determinants follow a broad theoretical framework allowing the consideration of psychological, physical, biological, social and environmental protective and risk factors as well as the interplay of these factors affecting psychological health and general well

being. Psychological health is characterized by a continuum of health related conditions ranging from healthy states to ill conditions. Psychological health and its determinants represent a theoretical framework as well as an applied field for health psychology aiming at health promotion and prevention of illness as well as an approach to clinical treatment for established illness.

Basic Characteristics

Concept of Psychological Health

The definition of psychological or mental health has varied over time in terms of concept and complexity. A movement away from a definition of mental health as resistance to or absence of mental illness emphasizes the way a person felt about himself or herself, other people, and the world, particularly in reference to his or her own place in it, while special significance was attached to the person's feelings about earning a living and their responsibilities towards those who depend on them. This movement became known as positive mental health. In defining mental health, Ginsburg (1955) settled for simple criteria such as 'the ability to hold a job, have a family, keep out of trouble with the law, and enjoy the usual opportunities for pleasure'. A more complex definition is reflected by Jahoda (1958), who suggested six approaches to the concept. These approaches were based on:

1. self-concept and attitudes towards self, including accessibility of the self to consciousness for self-objectification, a correctness of self-report, self-acceptance, and a sense of personal identity;
2. self-actualization and positive growth motivation;
3. integration of personality, including the balancing of physic forces, a unifying outlook on life, and a capacity to withstand stress and tolerate anxiety;
4. autonomy, including a stable set of standards for one's actions and a capacity for relative independence from the social and physical environment;
5. perception of reality characterized by accuracy, freedom from need distortion and accurate empathy towards other people;
6. adaptation and environmental mastery, including the ability to love, to work, to play, to engage in interpersonal relationships, to meet situational requirements, to adjust, to solve problems.

Despite Jahoda's definition being criticized as an unreal expectation of universal bliss, it indicates the ideal of those who insist that mental health is more than absence of mental illness. In addition, this broad and complex definition is suitable for the concept of ▶ mental health promotion. Norman Sartorius, Director, Division of Mental Health, World Health Organization in Geneva states 'promotion of mental health means different things to different people. To some, it means the treatment of mental illness; to others, preventing the occurrence of mental disorders; and to still others, increasing the ability to overcome frustration, stress, and problems and enhancing resilience and resourcefulness' (Sartorius 1989).

Factors Influencing Psychological Well Being

Psychological well being is essentially a subjective construct, and people appear to derive an assessment of their own well being using both external (social and environmental) as well as internal (personal) indicators. Diener (1998) has contended that well being is related to inherited temperament in addition to factors such as person–environment fit, self-esteem, life tasks and goals and the sense of agency in the realization of these goals. This is consistent with the view that a strong sense of psychological well being may indicate an individual's perception of his mastery over life's challenges, especially in relation to that of others (Napholz 1994). A diminished sense of emotional well being may contribute to poorer health status by affecting health behavior and lifestyle as well as the level of risk awareness (Steptoe and Wardle 2001). This suggests that health and psychological well being are intimately related and also impact on socio-economic indicators such as employment since depression and the resultant low level of psychological well being has been shown to decrease the chances of obtaining and maintaining employment (Alexandre and French 2001).

Since life experience is an integral part of well being (Ryff and Heidrich 1997), the interpretation of these experiences in terms of the degree of satisfaction with life must also be important. Since subjective assessments are more influential in determining well being and life satisfaction than objective circumstances (Stedman 1996), it is clearly necessary to distinguish the internal determinants of well being from those that are predominantly social. In terms of public health and social policy, it is important to pay attention to people's perceptions of their own health, partly because of

the interactions between social relationships and physical and mental health. These interactions are even more significant when one considers how well being and satisfaction with life are inextricably linked to social and economic factors. In this larger context of social and economic development, Marsella et al. (1997) has suggested that success is meaningful only when it can be translated into personal well being and an acceptable degree of satisfaction with life. The other direction of this relationship also holds true; that sustainable social and economic development is most likely to occur when the members of a society have a sense of psychological well being and life satisfaction.

The Concept of Psychosomatic Medicine

The term *psychosomatic* emphasizes essential unity of the psyche and the soma, a combination rooted in ancient Greek medicine. Common disorders caused at least partly by psychological factors include childhood ► asthma (http://www.highbeam.com/doc/1E1-asthma.html), certain ► gastrointestinal problems, ► hypertension, ► endocrine disturbances, ► diabetes, and ► heart disease. In most psychosomatic conditions there is some interaction between psychological factors and physiological predisposition to the illness. Sigmund Freud, at the end of the 19th century, laid the scientific groundwork for psychosomatic study, with his theoretical formulations based on new methods of treating hysteria. His methods were reinforced by the psychobiology of the American psychiatrist Adolf Meyer and the research of the American physiologist W. B. Cannon on the physiological effects of acute emotion. The treatment of psychosomatic ailments may involve a medical regimen as well as some form of psychotherapy for the patient. In recent years, psychosomatic medicine has been subsumed under the broader field of behavioral medicine, which includes the study of a wider range of physical ailments. Understanding the psychological causes of various ailments is crucial: studies suggest that a large percentage of deaths are rooted in behavior. In the 1960s, concepts related to conditioning gained prominence, as researchers found that humans and animals could learn to control their autonomic nervous system responses, usually involved in psychosomatic complaints. Emerging from this research came the technique of biofeedback that provides individuals with information concerning their own physiological responses, which they may begin to alter through conscious techniques of control. The newest area of research related to psychosomatic medicine has been called ► psychoneuroimmunology, the study of the interactions of the endocrine system, central nervous system, and immune system. Researchers believe that studies of these biological systems can help to show how an individual becomes vulnerable to illness.

Definitions and Concepts of Prevention and Intervention

Two physicians, Hugh Leavell and E. Gurney Clark (1953) defined three levels of prevention that were applicable to all disorders and dysfunctions. The initial concept of prevention was rooted in a public health (community) perspective, and so pure prevention, specifically 'primary prevention', was aimed at groups and communities believed to be at increased risk for the development of a disorder or dysfunction. The standard epidemiological definitions of prevention appear in Table 1. Primary prevention reduces the prevalence of a disorder or dysfunction by reducing the number of new cases (incidence) that appear in a defined population. The goal of primary preventive interventions is to prevent the onset of a disease or disorder, thereby reducing its incidence (number of new cases occurring in a specific period of time). In essence, primary prevention may be dichotomized into two main endeavors: (1) actions designed to prevent the development of psychiatric disorders; (2) interventions designed to promote well being as an inoculant against dysfunction.

Secondary prevention reduces the prevalence of a disorder by reducing the duration of a disorder or dysfunction in individuals who have expressed signs and symptoms of that disorder. Secondary prevention is defined as early intervention and prompt treatment of the early signs and symptoms of an emerging illness or disorder, with the goal of reducing the prevalence (total num-

Health Determinants, Psychological, Table 1 Epidemiological definitions of prevention

Prevalence	= Incidence *x* duration
Incidence	= Prevalence/duration
Primary Prevention	Reduce prevalence by reducing incidence
Secondary Prevention	Reduce prevalence by reducing duration

H

ber of existing cases) of the condition by decreasing its duration. According to Cowen, there are two distinct pathways to secondary prevention:

1. identify prodromal signs of serious disorders early, so that prompt effective steps can be taken to divert dire psychological consequences;
2. identify signs of dysfunction as soon as possible in a person's life history and use the best available tools to short-circuit later, more serious problems.

Tertiary prevention is the reduction of the prevalence of residual defects or existing disability secondary to the presence of an illness or disorder (often of chronic nature and duration). Tertiary prevention refers to rehabilitative efforts to enable those with longstanding or chronic mental disorders or disabilities to function at their highest possible physiological and psychological level.

Any model for the prevention of psychiatric disorders must allow for many different types of interventions to co-exist in a comprehensive, coordinated, and collaborative program. The types of interventions that are currently being developed, implemented, and evaluated for the prevention of mental disorders and the promotion of mental health are quite broad (Tables 2 and 3), reflecting the multidimensional, multicausal, and multifactorial vies of psychiatric disorders and psychological health.

Socioeconomic influences; Social causation

Definition

The analysis of social determinants of health is concerned with how the health of populations is influenced by features of a society and its socioeconomic and sociocultural organization. To understand how the circumstances in which people live and work affect their health, descriptive and analytical knowledge is required, which is largely drawn from social epidemiology, sociology, and related public health disciplines. The largest variations in health between and within countries probably emerge from people's differential standing within in a societal hierarchy: the lower the individual's socioeconomic status, the poorer their health. Social determinants of health are explored both at the individual and aggregate level of data analysis.

Basic Characteristics

Levels and Trends

Throughout history, substantial differences in disease rates and mortality between and within countries existed, and continue to exist even in modern industrialized societies. In addition to a North-South gradient in health – with poorer health in less developed countries – an East-West gradient is observed, in particular between Central, Eastern, and Western Europe, where differences in life expectancy between e. g. men in Russia and Sweden are as high as 20 years.

The influence of ► social factors on health is not restricted to poverty and material deprivation despite their overwhelming impact in less developed countries. With the epidemiological transition from infectious to degenerative diseases as primary causes of mortality, ► health-adverse lifestyles have become major determinants. These lifestyles are shaped by specific cultural norms, economic incentives, and social pressures. A 'Western lifestyle', characterized by consumption of food rich in fat and calories, sedentary life, smoking, and alcohol consumption, among others, is being spread across the world, in particular across rapidly developing countries.

In recent decades, this 'wealthier' lifestyle has become more prevalent among lower socioeconomic groups. Hence, substantial social inequalities in health are observed, resulting in a social gradient: the lower a person's status (in terms of educational attainment, income, and occupational standing), the higher his or her risk of poor health. These differentials are substantial even in most advanced current societies, where mean life expectancy is shortened by five to six years among members of the lowest compared with the highest socioeconomic status groups (Mackenbach and Bakker 2002; Marmot and Wilkinson 2006).

Macrosocial and Microsocial Factors

Every human society is characterized by a set of social values, norms, and institutions that are instrumental for the survival and growth of its members. If these values and norms lose their validity and meaning or if patterns of social exchange become unpredictable and unstable, individuals tend to suffer from states of social anomie (lack of rules and orientations). A number of epidemiological investigations have explored adverse effects on health produced by sociocultural instability, by rapid social change, or by a high level of social anomie.

The majority of these studies found evidence of elevated risks of subsequent physical and mental illness (Berkman and Kawachi 2000). Thus, a stable social network and a particular quality of social exchange, termed social support, may act as protective resources in coping with stressful circumstances. Social support is defined as the experience of, or access to, social relationships that offer mutual understanding, trust, and solidarity, and that recurrently elicit positive emotions. Negative health effects result from social separation, social isolation, or exclusion. These microsocial conditions are reinforced by macrostructural patterns of

social disintegration and a shrinking social capital. Social capital describes reciprocal social exchange in neighborhood and community life, including solidarity and trust. As these conditions are more prevalent among lower socioeconomic groups, they aggravate the burden of disease in less privileged populations (Kawachi and Berkman 2003).

The Role of Work and Employment

Among the macrosocial and microsocial determinants of health, work and employment are of outstanding significance for several reasons. Having a job is a principal prerequisite for continuous income and, thus, for independence from traditional support systems (family, community welfare, etc.). Increasingly, the level of income determines a wide range of life chances. Furthermore, training for a job and achievement of occupational status are important goals of socialization. It is through education, job training, and status acquisition that personal growth and development are realized, that a core social identity outside the family is acquired, and that goal-directed activity in human life is shaped. At the same time, occupational settings produce the most pervasive continuous demands during one's lifetime, and exposure to harmful job conditions is an important determinant of disability and premature death in midlife.

People threatened by job loss, job instability, or downsizing, and people undergoing forced or downward mobility were shown to suffer from increased morbidity and mortality. With the advent of economic globalization and automatization, these conditions are likely to continue to impact on a substantial proportion of working populations. However, even within a stable work force, exposure to stressful work environments contributes to the burden of disease. These social determinants of health are not confined to physical adversity, but concern an adverse ► psychosocial work environment. A large body of evidence indicates that jobs characterized by high demands in combination with low control and employment conditions, defined by an imbalance between high efforts and low rewards in terms of money, esteem, or promotion prospects, adversely affect the health of working populations (Siegrist and Marmot 2006).

Life Course

Much of the social inequality in adult health is due to socially patterned environmental exposure in early life. Poor growth in utero, insecure attachment in early life, and early adversity (e. g. lone mothers, poverty) are more prevalent in deprived social groups and have long-term effects on health (Kuh and Ben Shlomo 2004).

Different developmental trajectories may aggravate the burden of disease later in life through increased vulnerability or accumulation of adversity. Adolescence is one such stage within the developmental trajectories with far reaching health effects, due to the fact that health adverse behaviors are acquired and reinforced during this period, particularly among socioeconomically and socioemotionally vulnerable groups. Exposure to adverse environments continues to affect health beyond working life as recent studies document a continuation of the social gradient of morbidity and mortality into early old age (McMunn et al. 2006).

Policy Implications

Despite the fact that a convincing body of scientific evidence on social determinants of health originates from observational studies rather than from randomized controlled trials, this evidence has direct policy implications at several levels. While it is difficult to target macrosocial levels of societal structures and processes, population health can clearly be improved by changing lifestyle-related behaviors and by modifying microsocial environments. Creating a nurturing environment for children, improving education and social skills, implementing health-promoting working conditions, and strengthening infrastructure and social capital in deprived neighborhoods and communities are examples of public health measures that aim to reduce social inequalities in health.

Conclusion

The world's population is experiencing substantial progress in life expectancy. Yet, adverse social conditions continue to affect health and to result in premature mortality. These conditions include poverty and social disintegration, unhealthy lifestyles, noxious and stressful working conditions, social exclusion from work and participation, and critical conditions during infancy, childhood, and adolescence. It seems unlikely that

these trends will be diminished in the near future. Moreover, pressures originating from population growth and poverty in developing parts of the world, new socioenvironmental risks, and man-made disasters may aggravate rather than moderate this burden. At the same time, with increasing awareness of public health evidence and increasing policy efforts, a sustainable and healthier future is still a realistic goal.

Economic evaluation of health care technologies

Definition

The term health economic evaluation describes the comparative assessment of costs and outcomes of alternative health care technologies or health strategies. The result of health economic evaluation studies is the incremental cost-outcome ratio (► incremental cost-effectiveness ratio), the relation of the estimated additional costs and the estimated additional outcome saved or lost by using an alternative health care technology.

Basic Characteristics

There are two main features of health economic evaluation. First, this kind of economic analysis evaluates the input and the output; the costs and the ► outcomes of health care technologies, respectively. The outcomes are sometimes also called benefits or consequences. The costs per one unit of a definite measure of outcome are defined as the cost-outcome ratio or cost-outcome relation, which expresses the value for money of a defined health care technology. Second, in health economic evaluations, the choice between two or more possible alternatives to improve a defined health problem has to be made. Therefore, health economic evaluations are by definition comparative. They compare at least two different alternatives and attempt to define an explicit set of criteria that may be useful for the decision that must be made in situations with scarce resources. If there is only one existing alternative or the costs or the outcomes of only one alternative are assessed, the study should not be described as a full economic evaluation, but only as a cost-, outcome-, or cost-outcome description (Berger et al. 2003; Drummond et al. 2005). Most economic evaluation studies compare two alternatives to solve a health problem in one defined medical indication. If generic outcome measures are used, it is also possible to compare health technologies used for

different indications and in different settings of health care from a theoretical and methodological point of view. Although in practice it is not yet fully implemented, in theory it is possible to evaluate a large number of possible diagnostic and therapeutic interventions – e. g. the whole catalog of reimbursed items of a sickness fund – and to list them according to their cost-outcome ratio in a league table. The most prominent representative is the QALY (► quality-adjusted life year) ► league table.

One key element of economic evaluations comparing alternative health care programs is the economic concept of "incremental change", which means that only the additional cost of an alternative is compared to the additional outcome gain. Consequently, in contrast to cost of illness studies, only the differences from one alternative to another (= increment) are considered and not the full range of all possible costs and outcomes. The main result of a health economic evaluation study is the incremental cost-outcome ratio (► incremental cost-effectiveness ratio), which expresses the additional costs per additional standardized outcome measure.

The results of economic evaluation studies are demonstrated graphically, in so-called cost-effectiveness planes, which show the incremental costs on the y-axis and the incremental outcome gain on the x-axis (Drummond et al. 2005; Drummond and McGuire 2001). The four quadrants of a cost-effectiveness plane illustrate the four possible relations of costs and outcomes comparing two alternative strategies e. g. a new technology and a standard treatment:

1. The new technology shows higher costs and a lower outcome (north-west quadrant)
2. The new technology shows lower costs and a better outcome (south-east quadrant)
3. The new technology shows lower costs and a lower outcome (south-west quadrant)
4. The new technology shows higher costs and a better outcome (north-east quadrant)

If the incremental cost-effectiveness is located in the north-west or the south-east quadrant, the decision for the less costly and more effective alternative can easily be made. One alternative shows a better outcome for lower costs and is the so-called ► dominant strategy. The decision for or against a new technology is more difficult if their incremental cost-effectiveness is located in the north-east quadrant. This is often the case for innovations because they tend to have an additional medical benefit combined with higher costs. In this case, the crucial question is what is the relation of the additional costs and the additional outcome? In other words, is it adequate value for money to use the new technology?

Establishment of an implicit or explicit ► threshold depends on the ability of the decision makers and the preferences of the society. So far, no official threshold has been established by decision makers, but implicit thresholds derived from reimbursement decisions of 50,000 EUR, 50,000 USD, or 30,000 BPS per life-year gained or per quality-adjusted life-year are discussed in the literature (Rawlins and Culyer 2004).

According to the type of outcome measure, four forms of full health economic evaluations can be differentiated (abbreviations in brackets) (Gold et al. 1996; Drummond et al. 2005; Kobelt 2002; CADTH 2006):

- Cost-minimization analysis (CMA)
- Cost-effectiveness analysis (CEA)
- Cost-utility analysis (CUA)
- Cost-benefit analysis (CBA)

For the description of cost-effectiveness analysis and cost-utility analysis, refer to the corresponding chapters: "► cost effectiveness" and "► value, human life – utilities". Some authors also use the term cost-consequence analysis for a type of study in which the costs and various outcomes are estimated without indicating the relative importance of the components listed; this approach leaves the reader or the decision maker to form their own view (► cost-consequence analysis) (Berger et al. 2003).

Cost-Minimization Analysis

In cost-minimization analyzes, it is assumed that all consequences of the compared alternatives are identical and that there is no additional benefit of the use of one or another of the alternative strategies. An example would be two drugs that lower the blood pressure with exactly the same side effects, quality of life, patient satisfaction, and interactions with other drugs. Consequently, making the assumption of identical outcomes, only the costs of the alternatives are compared.

This kind of health economic analysis is not usually recommended because, in most cases, it cannot be assumed that different alternatives show an identical outcome (Berger et al. 2003; Gold et al. 1996; Drummond et al. 2005; CADTH 2006). There is another sce-

nario in which cost-minimization analyzes can be chosen: if the aim is to demonstrate the dominance of one strategy. If a clear superiority of one alternative compared to another has been demonstrated in clinical studies and, in an additional cost-minimization analysis, the alternative with the better outcome also shows lower costs, there is a situation of dominance in which the decision is definitely made for the alternative with lower costs and better outcome.

Cost-Benefit Analysis

In cost-benefit analyzes, all costs and all outcomes are expressed in monetary units (e. g. EUR or $). The result is given as a net calculation of gain and loss (in contrast to CEA and CUA in which the results are expressed in cost-outcome ratios).

The costs of the intervention are measured. The outcomes and benefits for the patients are also expressed in monetary items using methods of valuation of the patients' observed or stated preferences. The most common approach is to determine the ► willingness-to-pay, meaning that individuals are asked to define the amount of money they would be willing to pay to avoid a certain health state or illness. Willingness-to-pay can be determined either directly by trained interviewers (► contingent valuation) or indirectly by drawing conclusions from the behavior of individuals (► revealed preferences).

The main advantage of cost-benefit analyzes is the generic approach. Due to the fact that no specific outcome measure has to be chosen, very heterogeneous technologies, with any kind of benefit that patients consider beneficial enough to attribute a certain amount of money to, can be compared. Cost-benefit studies are widespread outside the health care sector but, due to the ongoing methodological dispute over measuring and quantifying the medical benefit of health care in monetary terms, they are currently less common and less important for decision makers in health care resource allocation.

For the costing process, refer to the chapters about ► economic measures and ► cost of illness – costing.

Time Horizon

For economic evaluation studies, a time period that covers all relevant consequences of the intervention should be considered (Gold et al. 1996). This so-called ► time horizon is often longer than the follow-up period of clinical or epidemiological studies. This has two consequences: (1) it has to be acknowledged that, for economic evaluation studies, the standards of evidence-based medicine cannot be used in the same strict manner as is common with clinical trials. (2) the time exceeding the follow-up period of randomized clinical trials or epidemiological studies can only be estimated by ► modeling (Buxton et al. 1998).

Data Sources

In health economic analyzes, it is not usually possible to base the complete calculation on primary data individually collected from the included study population. Usually, the primary data of randomized controlled trials or epidemiological analyzes are combined with a number of different additional data sources such as administrative data from sickness funds, routine data sets from official statistics, and reimbursement catalogs or predefined package definitions e. g. from DRG catalogs or treatment guidelines (CADTH 2006). Also in contrast to clinical studies, data collection in health economic analyzes can not only follow the described bottom-up approach but can also use routinely collected large data sets, e. g. of sickness funds or health care organizations (► claims data analysis), as the basis of the analysis in a top-down approach. Following the framework of evidence-based medicine, these retrospective analyzes of routine data, which are quite commonly performed in the US, have less scientific evidence compared with randomized controlled studies (Sackett et al. 1996). However, to gain knowledge about real-life routine care, such studies offer clear advantages by avoiding strict patient selection and an artificial study-determined treatment setting.

Introduction

Health economics is the application of economic theory and economic methods to phenomena and problems associated with health (Culyer 2005). A comprehensive taxonomizing framework that systematically includes the various topics of health economics was developed by Alan Williams from the University of York. The "Williams' Schematic of Health Economics" (Culyer and Newhouse 2000) conceptualizes this definition (► health economics, concepts). Topics of health economics include – among others – the meaning and measurement of health status, the production of health and health services, the demand for health and health services, ► cost-effectiveness analysis, economic evaluation, health insurance, health care financing, equity problems, the organization of health care markets, methods of remuneration of physicians, performance management of health care organizations, and economics of comparative health systems (Culyer 2005; Jones 2006).

This synopsis of the field of health economics is divided into two main parts. The first part covers research topics of health economics which are summarized under the heading health care system design. This part includes topics such as methods of health care financing, problems of health insurance markets, regulatory mechanisms, and systems of provider remuneration. The second part of the synopsis covers topics that are related to the economic evaluation of health care technologies and interventions. These topics include costs of illness, and cost-effectiveness and cost-utility analyses, as well as the question whether the value of human life (► value, human life) can be reflected by these concepts. The bridge between the two parts is built by a summary of the ► burden of disease concept of the World Health Organization (WHO). This generic and mainly epidemiological approach should not be seen as an integral part of health economics, although there are clear implications for health economic topics such as health care financing and cost of illness.

Health Care System Design

Economic theory – more specifically neoclassical microeconomic theory – generally assumes that a competitive process of adjusting demand and supply of goods and services will lead to an optimal allocation of scarce resources. This process should be left alone by policy makers and public interventions. If it is not, economic incentives for the modification of supply and

demand will be disturbed and market forces will not be able to reach the allocative optimum.

However, health care systems around the world are heavily regulated – which is even the case for rather libertarian countries such as the US. The reasons for this rather extensive regulation are a number of severe market failures in health care markets. Health economics provides some important tools to analyze the origin of market failures and to develop solutions to deal with them. In this section, the most important market failures on the demand side as well as on the supply side of health care markets are summarized. Moreover, policy tools that have been designed to address them are discussed.

According to microeconomic theory, demand is the mechanism which drives a competitive economy (Rice 2002; Folland et al. 2007). Demand is the key: the amount of goods and services that is produced and consumed is determined by the preferences of consumers. In the long run, supply adjusts to demand. However, demand theory is based on a number of important assumptions. Specifically, the following assumptions need to be fulfilled (Rice 2002) (► consumer choice):

- Individuals are the best judges of their own welfare.
- Consumers have sufficient information to make good choices.
- Consumers need to know the results of their decisions.
- Individuals are rational.

Most of the time, these assumptions are not fulfilled in health care markets. Individual consumers usually lack the medical education needed to execute informed choices on treatment options. The outcome of medical interventions (or non-interventions) is not always clear for consumers of health care services. The rationality of consumers is disturbed by the often very personal consequences of consumption decisions. If the demand for health care services were unregulated and were left to the competitive process only, severe market failures would occur. The economic and medical results of these market failures – most importantly unequal access to health care services – are generally not acceptable to societal preferences. As a consequence, designers of health care systems usually restrict individual choice – e. g. by requiring mandatory coverage of health insurance.

In most microeconomic applications, supply plays a subsidiary role to demand. It is generally assumed that supply adjusts if consumers' preferences change. Again, supply theory is based on a number of crucial assumptions, most importantly that supply and demand are determined independently. Once more, this essential assumption is not fulfilled in most health care markets. Supply and demand of health care services are closely interlinked, which is clearly contradictory to the traditional microeconomic model. Health economics closely studies the question of whether health care providers – particularly physicians – act as perfect agents for their patients or whether physicians are able to induce demand for their services among patients (Rice 2002). Health economists generally agree that physicians – the suppliers – are able to induce demand for their services, at least to some degree. As a consequence, designers of health care systems have come up with a variety of policy measures to reduce incentives to induce demand.

Table 1 summarizes the dimensions of health care system design (► health systems). Policy makers around the world heavily regulate health care financing, demand, and supply as a consequence of market failures in health care markets which are not socially acceptable. The role of health economics in this process is twofold. It analyzes market failures themselves and develops possible instruments for solutions – e. g. justifying universality of access as a consequence of non-rational consumers. Moreover, health economics also analyzes problems that occur due to the introduction of solutions to the original problems – e. g. non-optimal consumption of medical services because of universal coverage. In the remainder of this section, the dimensions of health care system design and the role of health economics are discussed in more detail (► regulatory mechanisms).

Health Economics (Burden of Disease), Table 1 Dimensions of health care system design

Health care financing	Universality of access Tax-financing vs. financing by health insurance premiums Role of private health insurance Single payer vs. multiple payers
Regulation of demand	User charges Basket of health care services
Regulation of supply	Remuneration of physicians and hospitals

Source: Based on (Rice 2002)

The first dimension of health care system design is health care financing (► health financing). With the exception of the US, Organisation for Economic Co-operation and Development (OECD) countries strive for universality of access to health care services. Universality of access can be justified for allocative as well as for distributive reasons. On the one hand, consumers may be willing to buy health insurance but they are unable to buy it if premiums are risk-rated – which will lead to distributive consequences that are socially unacceptable in all OECD-countries outside the US. On the other hand, adverse selection may also result in non-optimal market outcomes. Adverse selection can occur if health insurers set their premiums in relation to the average health risk of a population and consumers have different probabilities of illness. In that case, consumers with low probabilities may refrain from taking out health insurance. They may even consume health care services without paying for them – e. g. if these services are paid for by welfare or social assistance (free-rider behavior). At the same time, consumers with high probabilities of illness will most probably seize the opportunity to take out health insurance eagerly. If this is the case, insurers need to cover clients who incur higher health care expenditures than expected and therefore insurers need to raise premiums, which in turn further decreases incentives for low-risk individuals to take out health insurance. Universality of access is achieved by tax-financing of health care in countries such as the United Kingdom, Canada, or Scandinavian countries. In these countries, residents are eligible to consume health care services that are financed out of general tax revenue. Another possibility to achieve universality of access is mandatory universal coverage by social health insurance. In countries such as the Netherlands, Switzerland, and – for part of the population – Germany, consumers are obliged to take out social health insurance. Premium rate restrictions apply to make sure that individuals with high health risks are able to afford health insurance premiums. The US stands out because consumers in the US are not required to take out health insurance.

Universality of access can be achieved in tax-financed health care systems as well as in health care financing systems that rely primarily on social health insurance premiums. However, there are other policy objectives that may determine the choice between tax-financing and financing by health insurance premiums – notably implications for the redistribution of income and implications for employment. Implications for the redistribution of income in social health insurance systems very much depend on the mode of premium calculation. In tax-financed national health systems, implications for the redistribution of income depend on the design of the tax system (Wagstaff and van Doorslaer 2000).

If health care financing systems contain a direct link between health care expenditures and labor costs, rising health care expenditures lead directly to rising labor costs. Moreover, if there is a direct link, rising health care expenditures increasingly drive a wedge between labor costs of the employer and net wages of the employee. As a consequence, microeconomic labor market theory generally assumes that incentives for the employee to work diminish. What is more, incentives for the employer to substitute capital for labor – or to substitute cheaper labor abroad for domestic labor – increase. Therefore, all other things being equal, employment goes down. The growth of health insurance premiums may consequently result in a drain on employment in employment-based health insurance schemes, such as in group-based private health insurance in the US or social health insurance in Germany (► labor market).

With the notable exception of the US, OECD countries do not rely on private health insurance as a predominant mode of health care financing (► health insurance markets). Private health insurance serves three distinct functions. The first is as an *alternative* to other social health insurance or public arrangements. The second function is to *supplement* basic health insurance or tax-financed health care, providing coverage for services not covered by the public arrangement or to cover the financial risks of co-payments and coinsurance. A third function of private insurance is to provide what can be termed *complementary or double-cover* coverage, in which consumers purchase additional private health insurance even though they have to participate in existing public schemes (Colombo and Tapay 2004).

Tax-financed systems, such as those in the United Kingdom, Canada, and Scandinavian countries, are non-competitive single payer systems. The term single payer system means that in any given region, only one payer organization – such as primary care trusts in the UK – is purchasing care on behalf of patients. In the 1990s, the UK government strived to introduce internal markets (► health systems reforms). The competitive

nature of the market was supposed to provide the necessary incentives for health care providers to improve efficiency and responsiveness of the system. Internal markets were replaced by primary care trusts which emphasize cooperation rather than competition (Oliver 2005). Social health insurance systems may also be non-competitive systems – as is the case in France. However, as a result of a number of health insurance reforms in the 1990s (► health systems reforms), several countries, such as Germany, the Netherlands, and Switzerland, introduced competitive multi-payer systems based on a regulative framework of regulated competition (► competition, health care). A key element of regulated competition is an effective method of risk adjustment in order to neutralize incentives for risk selection by competing health insurers (van de Ven et al. 2003). Consumer choice (► consumer choice) is another key element in increasing competitive pressure for health insurers. Consumer choice is less pronounced in the competitive multi-payer private health insurance market of group contracts for the non-elderly in the US. In most cases, employers purchase a number of options for employees and the employees' choice is limited to these options (Dowd and Feldman 2006).

As noted above, microeconomic theory strongly emphasizes demand as a driving force of competitive markets. This logic is also inherent in most theoretical models of health economics. However, in order to avoid market failures, demand for health insurance and health care services by individual consumers is heavily regulated in most OECD-countries. From an economic point of view, however, universal access to health insurance leads to over-consumption. The rationale behind this argument is quite straightforward: because the marginal price of health care services is lower than marginal utility – the price is zero if there is full coverage without user charges – consumption of health care increases. This effect is called ex-post moral hazard and is generally considered to result in a welfare loss to society. Ex-ante moral hazard refers to the effect that being insured has on behavior – notably, less effort for preventive activities. This theoretical argument has been confirmed empirically. In a unique natural experiment (RAND health insurance experiment), it has been shown that demand for health care services increases as coverage by health insurance goes up (Newhouse and Insurance Experiment Group 1993). Health economists usually suggest introducing user charges at least for health care services that are elastic in price – specifically non-urgent, elective health care services. As a consequence, patients will refrain from using health care services that provide a low marginal utility (Cutler and Zeckhauser 2000). However, the share of non-urgent elective health care services as a share of total health care expenditure is rather small (► health care costs). Moreover, due to severe information asymmetries, user charges may also deter consumers from using health care services that provide high marginal utility. The RAND health insurance experiment has also shown that consumers reduce consumption across all health care services if user charges are introduced, they do not differentiate between services which were considered to be highly or rarely effective (Lohr et al. 1986).

The problems of adverse selection and moral hazard are also important for the definition of the basket of health care services that are provided by health insurance. If the basket of health care services is not standardized – as is the case in most private health insurance schemes in the US and elsewhere – low risk individuals may find it attractive to choose a basket of health care services which provides only very basic coverage. At the same time, high-risk individuals will most probably choose maximum coverage – which results in adverse selection. If regulation mandates an extensive standardized basket for health care services in order to fight adverse selection, problems of over-consumption (moral hazard) will develop. As noted before, user charges will only solve this problem if consumers are able to identify health care services with low marginal utility – which is rather doubtful. Regulation usually attempts to solve this dilemma between adverse selection and moral hazard by the centralized assessment of marginal benefits of health care services. In fact, the economic evaluation of health care interventions, which is performed by the National Institute of Clinical Excellence in England and by other institutions in other countries, seeks to substitute the individual assessment of marginal costs and marginal utility with a collective assessment of marginal costs and marginal utility.

As noted before, traditional microeconomic theory does not put much emphasis on the supply of goods and services. Supply is supposed to adjust to changing preferences of consumers. However, it can also be argued that demand is not determined independently of supply. The suppliers of health care services – primarily physicians and hospitals – do not act as perfect agents of

their principal – the patient. As a consequence, health economics is concerned with the regulation of supply of health care services as well – more so than traditional microeconomic theory is concerned with producers. Health economics aims primarily to develop remuneration systems with the goal of making it advantageous for the physician to behave in a way that is in the patient's and the payer's best interest (► regulatory mechanisms). Traditionally, research was focused on fee-for-services payment systems – which contain incentives for over-utilization of health care services – and on capitation payment systems, which developed primarily in managed care organizations and contain incentives for under-utilization of health care services. Recently, research has been focused on "pay-for-performance" schemes. In these schemes, the remuneration of physicians and hospitals is linked to defined quality performance thresholds (Rice 2006).

Burden of Disease

The term ► burden of disease generally describes the total, cumulative consequences of a defined disease or a range of harmful diseases and their respective disabilities on a community. This approach combines measurement of mortality and morbidity with non-fatal outcomes, such as quality of life aspects. The gap between an ideal situation, where everyone lives free of disease and disability, and the cumulated current health status is defined as the burden of disease.

In the 1990s, the WHO, in co-operation with Harvard University and the Worldbank, developed a methodological concept to quantify the global burden of disease based on statistical measurement of the disability-adjusted life year (DALY). The DALY aggregates the time lost because of premature mortality and the time spent in a limited health state (Homedes 1996). Consequently, the DALYs for a defined disease or health condition are calculated as the sum of the years lost due to specific premature mortality and the years lost due to disability for incident cases of the health condition. Further time discounting and non-uniform age weights give less weight to years lived at a younger age.

The cumulated disease-specific DALYs aggregated according to the country-specific prevalence of the diseases and disabilities considered reflect the burden of disease of a specific society or a country. The Global Burden of Disease concept of the WHO compares a large number of low-, middle-, and high-income countries with regard to their country-specific burden of disease, and offers mortality figures, which refer to the number of people who die and the causes of death. Thus a comprehensive and consistent set of estimates of mortality and morbidity is given, expressed by the single indicator DALY and differentiating by age, sex, and region.

Economic Analyses of Defined Health Care Technologies and Interventions

This field of health economics is characterized by the intention to describe or investigate economic aspects of defined health conditions or the use of defined health care technologies. Health care technology in this case stands for all diagnostic, therapeutic, rehabilitative, or palliative procedures that influence the health of an individual. With relevant influence from medical sciences, the concepts can be subdivided into: (1) mainly descriptive studies with epidemiological elements and the intention to describe real-life health care settings, and (2) study designs derived from the methodological concepts of clinical studies, which focus on clearly defined medical interventions in often highly selected patient groups, typically not only giving an average measure for the costs and the medical outcome of patients but further aggregating the results to a more abstract ratio of the costs per a predefined outcome such as life-year gained. Examples of the first group of study designs are cost of illness studies, decision analytic health policy models, and budget impact analyses. Classic economic evaluation studies such as ► cost-effectiveness or cost-utility studies are examples of the second group (Gold et al. 1996; Drummond et al. 1997). Inclusion of costs distinguishes health economic analyses of defined health technologies from epidemiological or clinical studies. Costs refer not only the costs of the intervention but also the costs of all direct or indirect consequences of the use of the technology. There are some general aspects of the costing process (the measurement of costs) such as the perspective, approaches, sources of data, and the types of costs, which will be described before the different study designs are mentioned (Canadian Coordinating Office for Health Technology Assessment (CCOHTA) 1996; Canadian Agency for Drugs and Technologies in Health (CADTH) 2006).

Time Horizon and Modeling

For many diseases, the medical and economic consequences of a more successful therapy compared to a less successful alternative are relevant for a long period of time, often a patient's lifetime. In many cases, e. g. screening tests or other measures for primary or secondary prevention, the medical and economic benefits often occur a long time after the intervention. For economic evaluation studies, therefore, a time period that covers all relevant consequences of the intervention should be considered (Gold et al. 1996). This so-called time horizon for comparing health economic analyses is often longer than the limited follow-up period of clinical or epidemiological studies. This has two consequences: (1) it has to be acknowledged that the standards of evidence-based medicine cannot be used for economic evaluation studies in the same strict manner as is common with clinical trials; (2) the time exceeding the follow-up period of randomized clinical trials or epidemiological studies can often only be estimated by ► modeling. Widespread modeling techniques such as medical decision tree analysis, Markov models, or discrete event simulation are seen as standard methods for estimating the medical and economic consequences of many health technologies in the patient's lifetime, but it has to be assured that the studies are conducted and described transparently and with high methodological standards (Philips et al. 2004).

Perspective

The perspective of an economic analysis of a health care technology describes the point of view which is taken for the costing and, if relevant, for the outcome measurement. The choice of the perspective is a basic decision to be made for every analysis and can crucially affect the result of the calculation. It especially influences determination of the costs. From a societal perspective, all costs and benefits are taken into account, including productivity loss due to a health state, treatment, or diagnostic procedure. From the narrower perspective of a health insurance or sickness fund (often called the payer's perspective), only their own expenses, expressed as reimbursement rates in different sectors of the health care system, are relevant. From the perspective of an institution like a hospital, only the costs to the institution itself that are incurred during the inpatient stay are considered. The most important perspectives are the societal, the payer's, and the institutional perspective. According to most recommendations for economic evaluations in health care, a societal perspective should be considered at least in addition to other perspectives that have been chosen (Gold et al. 1996; Drummond et al. 1997; Canadian Agency for Drugs and Technologies in Health (CADTH) 2006).

Costing Process

In general, all costs related to the use of a technology should be identified and considered to be relevant. These costs are the monetary equivalent of resources such as goods or professionals' time. The resources are measured in quantifiable physical units e. g. inpatient days or GP contacts, as detailed as necessary for the analysis, and should be differentiated in categories that are appropriate to the decision makers. The measured resources are valued in a second step to express them in monetary units (Canadian Coordinating Office for Health Technology Assessment (CCOHTA) 1996; Gold et al. 1996). For valuing, mainly standard reimbursement or pricing catalogs are used. It has to be kept in mind that these charges are not necessarily identical to the costs according to the economic theory, which requires that the opportunity costs and the benefits that could have been derived from funding the next best alternative should be estimated. With rare exceptions in health economic analyses, the opportunity costs of health care resources can only be approximated using charges, assuming also that charges are the result of a societal process like the price of any other good in a functioning economy.

In health economic analyses, it is not usually possible to base the complete calculation on primary data collected individually from the study population included. Usually, the primary data of randomized controlled trials or epidemiological analyses are combined with a number of different additional data sources such as administrative data from sickness funds, routine data sets from official statistics, reimbursement catalogs, or predefined package definitions e. g. from DRG catalogs or treatment guidelines. Also, in contrast to clinical studies in health economic analyses, data can be collected by a top-down approach, using routinely collected large data sets e. g. of sickness funds or health care organizations as the basis of the analysis, as well as the described bottom-up approach. Following the

framework of evidence-based medicine, these retrospective analyses of routine data that are quite commonly performed in the US are considered a lower grade of scientific evidence compared with randomized controlled studies. However, to gain knowledge about real-life routine care, they offer clear advantages by avoiding strict patient selection and an artificial study-determined treatment setting.

Direct Costs

Direct medical costs are defined as the costs related to the provision of the health care intervention itself, including all side effects and all future consequences on health care diagnosis and treatment in different health care settings (e. g. inpatient hospital treatment, ambulatory care, drugs, rehabilitation). In some diseases, direct non-medical costs, e. g. for transportation or child care during a medical intervention of the parent, can also be incurred.

Indirect Costs

The so-called indirect costs incorporate the loss of productivity suffered by the national economy. Indirect costs can be due to decreased efficiency or total absence from work through illness – either for a limited number of days of absence or due to early retirement – or premature death.

There are two ways of calculating indirect costs: (1) the human capital approach and (2) the friction cost approach. Both approaches are based on the assumption that the lost productivity can be valued by the achievable gross income of the employed population, giving the labor a defined value (► labor market). Using the human capital approach, the entire period of absence from work due to illness is considered and valued by the achievable gross income. The human capital approach is based on economic theory and gives a maximum possible productivity loss (Sculpher 2001). The friction cost method more accurately estimates the actual loss of productivity in western industrialized countries. This method takes two main aspects of criticism against the human capital approach into consideration. First, some part of a short-term work absence, e. g. due to an influenza infection, is compensated for either by colleagues or by the employee when back at work. Second, in societies with a significant percentage of unemployed people, a large percentage of positions will be taken by a previously unemployed individual after a certain time, called the friction period (Koopmanschap et al. 1995). Using the friction cost method, only the shorter friction period is valued by the average achievable gross income.

The human capital approach is considered to be the simpler and more frequently used approach and is therefore recommended by a number of guidelines for economic evaluation studies, although it is also recommended that the friction cost approach in an additional scenario or at least a sensitivity analysis should also be calculated (Gold et al. 1996).

Cost of Illness Studies

The term ‘cost of illness’ has to be seen as separate from the ► burden of disease concept of the WHO. While the burden of disease concept is a generic approach, estimating the burden of all relevant diseases of a large number of populations, cost of illness studies are defined as analyses of the total costs due to one specific disease or health condition in one defined population.

In cost of illness studies, the total economic impact of a disease or health condition on society is estimated by identification, measurement, and valuation of all direct and indirect costs. This form of study does not focus on a particular intervention and does not address any questions regarding treatment efficacy or efficiency. Cost of illness studies usually adopt a societal perspective, measuring the financial burden incurred in different sectors of society such as the state or government, health insurers, and individuals.

The costs of illness can be estimated by taking into account the costs associated with all patients with a defined health state in a specific limited time period (prevalence method) or by calculating the long-time costs associated with those patients whose illness is newly diagnosed during a specific limited time period (incidence method).

Costs of illness calculations create information about the amount of resources spent on the treatment of a disease. This information can be helpful in generating hypotheses for health economic evaluation studies that compare different intervention strategies. Furthermore, the results can be used to set priorities for research activities regarding diseases with a larger potential of cost savings if more cost-effective alternatives would

be preferred. In situations where there are limited resources for health care, this information could be misunderstood as a signal to cut down resources primarily in the treatment of the most expensive diseases. A rational decision for more cost-effective alternatives should be prefered which not only considers the costs but also includes factors related to the medical benefit and therefore has the opportunity to produce more value for money in health care.

Economic Evaluation of Health Technologies

Economic evaluation studies are a systematic method of comparing two or more health technologies that can be used alternatively, by measuring the costs and the consequences (outcomes) of each alternative. As the outcome comparator, disease-specific measures such as time to relapse or events avoided, or generic measures such as life-years gained or utilities, can be chosen.

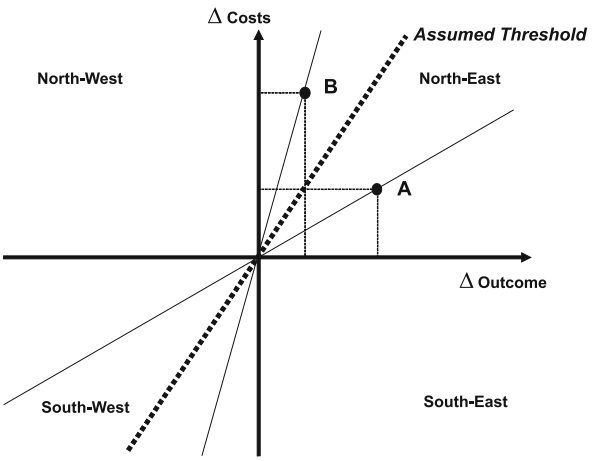
One key element of economic evaluations comparing alternative health care programs is the economic concept of "incremental change" which means that only the additional costs of an alternative are compared to the additional outcome gain. Consequently, in contrast to cost of illness studies, it is not necessary to calculate the full range of all possible costs and outcomes but only the difference (increment) between one program and an alternative.

The central result of a ► health economic evaluation study is the incremental cost-outcome ratio, expressing the additional costs per additional standardized outcome measure. Common examples are the costs per life-year gained or the costs per event avoided.

The results of economic evaluation studies are commonly demonstrated graphically in so-called ► cost-effectiveness planes showing the incremental costs on the y-axis and the incremental outcome gain on the x-axis (Black 1990; Drummond et al. 1997). The four quadrants of a cost-effectiveness plane illustrate the four possible relations of costs and outcome when comparing two alternative strategies e. g. a new technology and a standard treatment:

1. The new technology shows higher costs and a worse outcome (north-west quadrant)
2. The new technology shows lower costs and a better outcome (south-east quadrant)
3. The new technology shows lower costs and a worse outcome (south-west quadrant)
4. The new technology shows higher costs and a better outcome (north-east quadrant)

If the incremental cost-effectiveness is located in the north-west or the south-east quadrant, the dicision for identification of the less costly and more effective treatment is clear. One treatment shows a better outcome for lower costs and is dominant over the other. The decision for or against a new technology is more difficult if their incremental cost-effectiveness is located in the north-east quadrant. This is often the case for innovations because they tend to have an additional medical benefit connected with higher costs. In this case, the crucial question is: what is the relation of the additional costs and the additional outcome? In other words, is a new technology adequate value for money? Figure 1 shows a schematic cost-effectiveness plane. The use of the new technology B is responsible for higher additional costs and lower additional outcome compared with standard treatment than the new technology A. Technology A is more cost-effective than technology B. However, both new technologies are located in the north-east quadrant. Standard treatment is less effective but also less costly. The decision to use an implicit or explicit threshold depends on ability and the preferences of society. So far, no official threshold has been established by decision makers, but an implicit threshold of 50,000 EUR, 50,000 USD, or 30,000 BPS per life-year gained or per quality-adjusted life-year gained, derived from reimbursement decisions, is discussed in the literature (Rawlins and Culyer 2004).



Health Economics (Burden of Disease), Figure 1 Cost-effectiveness plane (adapted from Drummond et al. 1997)

Value of Human Life

Discussions about the interpretation of the results of economic evaluation studies and the legitimization of a threshold value up to which a new health care technology should be reimbursed by public payers also opens up the dispute about the value of a human life (► value, human life). Three main approaches should be considered. The human capital approach estimates the maximum expected future earnings of an individual based on the average achievable gross income. Heavy criticism was made of the use of this measure for valuing a human life and by doing so implying that the value of a human life is reduced to productivity from a national economic point of view. Furthermore, this approach discriminates major parts of the population who do not work for payment, such as children, housewives, the unemployed, old people, and people with chronic illnesses or disabilities. A second, so-called social decisions approach, uses decisions made in the public sector like reimbursement decisions or legal acts. The third approach is based on empirically created data on people's preferences. This can be done directly, by assessing the willingness to pay for a life year or a life-saving health care intervention, or indirectly, e. g. from surveys about the value placed by individuals on reduction of the risk of death due to a particular hazard. The third approach is currently regarded as the most appropriate as it reflects the individual preferences and uncertainty that is characteristic of such estimations.

Comparing the different approaches and also the results of different studies using the same approach, an extremely wide variation can be observed, from a few thousand € up to a few hundred thousand €. Currently, the methodological approaches are in an early stage of development and valid results will not be available for many years, if at all.

In the following chapters, the two main types of ► health economic evaluations, namely cost-effectiveness analysis and cost-utility analysis, are described. The third study type is the cost-benefit analysis (sometimes also misused as a generic term for economic evaluation). In cost-benefit studies, not only the costs but also the outcome is expressed in monetary units using valuations of the patients' observed or stated preferences. The most common approach is to determine the willingness-to-pay, meaning that individuals are asked to define the amount of money they would be willing to pay to avoid a certain health state or illness. Cost-benefit studies are widespread outside the health care sector but, due to the ongoing methodological dispute regarding the measurement and quantification of the medical benefit of health care in monetary terms, they are currently less common and less important for decision makers in health care resource allocation than other studies.

Cost-Effectiveness Analysis

The most common type of economic evaluation is the ► cost-effectiveness analysis. In this type of analysis, the outcome is expressed in adequate medical or epidemiological units e. g. life-years gained or number of events avoided, or specific measures like units of reduction of diastolic blood pressure (Gold et al. 1996; Drummond et al. 1997). The more specific the outcome measure is, the more difficult it is to use cost-effectiveness analyses to compare treatments for different diseases or whole health care programs. The advantage of cost-effectiveness studies is their ability to adopt the most relevant and clinically significant parameter and to compare treatment alternatives for a specific disease. The results are often more of a clinical nature. Therefore, they are often more easily accepted by the medical society than the more abstract results of cost-utility analyses. Cost-effectiveness studies can give useful information concerning the decision between a limited number of treatment alternatives for a clearly defined health problem. This is often the case for diseases where a standard treatment is already available, and the value for money of a new treatment alternative should be estimated based on the results of the first clinical efficacy studies. However, for use in the process of decision making for non-disease or non-indication specific allocation of health care resources, the results of cost-effectiveness studies are less useful. It is not possible to compare the costs per life-year gained of a life-saving intervention like heart surgery with the costs per case detected in a screening program, or the costs per exacerbation avoided in an educational program with COPD-patients.

Cost-Utility Analysis

Cost-utility analyses can be seen as a special form of cost-effectiveness analysis in which the outcome measures are the units of utility gained. In general, utili-

ties are numbers assigned to entities presumed to be the objects of patients' preferences, and thus the entities can be quantified and ranked. Utilities offer a patient-orientated generic measure which allows comparison of the effect of all possible interventions influencing the health state (Feeny et al. 1996).

By far the most widespread and prominent utility measure is the quality-adjusted life year (QALY). The QALY is a generic measure of utility that combines both the quality and the quantity of life generated by health care interventions. A year spent in perfect health is one QALY and a year spent in less than perfect health with a lower health-related quality of life is worth less than one QALY. Death or the poorest imaginable state of health is defined as "0". Aggregating the quality of life and the remaining lifetime, it has to be taken into account that the quality of life fluctuates over time. Quality of life must therefore be measured repeatedly over time (the course between the point measures has to be estimated) with generic instruments such as the EQ5D, the health utility index, or the SF-6D. Alternatively, the quality of life over the total health state path can also be estimated at one time using techniques such as standard gamble or time trade-off.

There is a certain amount of controversial debate about the theoretical foundation of the QALY, especially about its foundation in the welfare theory, as well as about the empirical robustness of the results and ethical implications of a possible use in resource allocation decisions.

League Table

One way of presenting the results of several cost-effectiveness or cost-utility analyses for decision makers is a league table. League tables rank health technologies and interventions according to their relative cost-outcome ratio, starting with the lowest cost per QALY gained (or the gain in another generic outcome measure) and ending with the most unfavorable cost per QALY ratio. In theory, league tables could be used by decision makers to allocate resources within a limited budget e. g. by only reimbursing technologies with costs per QALY gained below a defined threshold. There are major arguments for not making decisions about resource allocation in health care solely on the basis of league tables (Gerard and Mooney 1993; Bleichrodt et al. 2004), but in general the results of ► health economic evaluations can provide helpful additional pieces of information for the process of decision making. Decisions about allocation of health care resources have to be the result of a societal consensus and should never be made on the basis of economic analyses alone.

Summary

Health economics is defined as the application of economic theory and economic methods to phenomena and problems associated with health and health services. Topics of health economics include – among others – the meaning and measurement of health status, the production of health and health services, the demand for health and health services, ► cost-effectiveness analysis, economic evaluation, health insurance, health care financing, equity problems, the organization of health care markets, methods of remuneration of physicians, performance management of health care organizations, and economics of comparative health systems.

Health care systems cannot be regarded as a normally functioning market as this may lead to market failures such as inequity of access to health care services. As a consequence, competition in most health care systems is regulated in several directions. The main dimensions of health care system design are financing of health care and regulation of demand and supply. With regard to health care financing, three main principles, tax-financing, social health insurance, and private health insurance, can be distinguished. Key elements in regulating competition are risk adjustment and consumer choice. To decrease the moral hazard effects leading to increased demand in health care, regulative elements such as user charges can be implemented. An unnecessarily increased supply of health care should be regulated by remuneration systems that modify the incentives for hospitals and physicians.

In a situation of scarce resources available for health care, not all imaginable interventions can be reimbursed by third–party payers. As patients and health care professionals are mostly unable to assess the additional benefit of single health care technologies, collective assessments of the additional costs and the additional medical benefits or utilities are performed. In economic evaluation studies, the cost consequences, as well as the clinical efficacy of alternative interventions, are compared based on cost-outcome ratios. In cost-effec-

tiveness analyses, the chosen comparators are the costs per adequate clinical or epidemiological parameter such as the costs per life-year gained or the costs per event avoided. Utilities, the outcome measure of cost-utility analyses, aggregate the life-time gained by a defined intervention together with the patient's quality of life to a generic measure, which allows comparison of interventions for different indications and in different health care sectors. Key elements of economic evaluation studies of health care interventions are the choice of the perspective, the use of modeling techniques, and the choice of different cost components to consider for the costing process. More generic approaches to describe costs with respect to the effectiveness of health care systems as a whole are cost of illness studies and the burden of disease concept of the WHO.

Definition

The application of economic theory and economic methods to health poses some severe challenges. This is illustrated by a number of assumptions of economic theory and its application to phenomena and problems associated with health – such as externalities of consumption, the extension of traditional welfarist approaches, and agency problems.

Basic Characteristics

Health economics is the application of economic theory and economic methods to phenomena and problems associated with health (Culyer 2005). A comprehensive taxonomizing framework that systematically includes the various topics of health economics has been developed by Alan Williams from the University of York. The "Williams' Schematic of Health Economics" (Culyer and Newhouse 2000) conceptualizes this definition. However, the application of economic theory and economic methods to health poses some severe challenges. This is illustrated by a number of assumptions of economic theory and its application to phenomena and problems associated with health (Rice 2002).

Market Competition and Externalities

Market competition assumes that there are no negative externalities of consumption and no positive externalities of consumption. ► Externalities of consumption exist if one individual's consumption of a good or service has positive or negative consequences for the ► utility of another person. If externalities exist, a competitive market process will not lead to socially optimal outcomes. A positive externality increases the utility of another individual – although he or she does not pay for it. One classic example of a positive externality in health economics is immunization: the benefit of immunization is not restricted to those individuals who have been treated. However, in competitive markets, the direct beneficiary of the immunization will have to bear the full cost. As a consequence, individual consumers would buy too few immunizations. In order to overcome this market failure, governments may subsidize the purchase of immunizations, provide them for free, or make them mandatory. A negative externality decreases the utility of another individual. A classic example of a negative externality in health economics is smoking. Smoking by one individual decreases the utility of another individual. As a consequence, governments will either raise the price of smoking or restrict individual opportunities to smoke in the presence of non-smokers.

Demand Theory: Information Asymmetries and Extra-Welfarism

Economic demand theory assumes individuals are the best judges of their own welfare and consumers have sufficient information to make good choices. Moreover, demand theory also assumes consumers know the consequences of their decisions with reasonable certainty and that individuals are rational. Finally, demand theory assumes social welfare is based on the sum of individual utilities, which in turn are determined by the goods and services consumed (Rice 2002).

Most of the time, these assumptions are not fulfilled in health care markets. There are several examples that illustrate that regulation overrides the right of individuals to be the best judge of their own welfare – e. g. the obligation to wear a helmet while riding a motorcycle or the obligation to wear a safety belt while riding in a car. Moreover, individual consumers usually lack the medical education necessary to execute informed choices

on treatment options, which results in severe information asymmetries in the patient–physician relationship. The outcome of medical interventions (or non-interventions) is not always clear for consumers of health care services. The rationality of consumers is disturbed by the often very personal consequences of consumption decisions.

Finally, the "welfarist" approach of economic theory – social welfare is based on the sum of individual utilities, which in turn are determined by the goods and services consumed – is under close scrutiny in health economics (► welfarism). If the welfarist approach is applied to health, it means that health is a source of utility – both directly and indirectly – through the effects good health has on the individual's capacity to enjoy other goods and services. However, this approach is rather limited. Therefore, the concept of "► extra-welfarism" has been developed in health economics (Hurley 2000). Extra-welfarism acknowledges that a wider range of characteristics is relevant for individual welfare – not just the consumption of health care services and health in itself; it also refers to relative changes in consumption or work patterns as direct sources of utility or disutility. Extra-welfarism "*acknowledges the processes and transitions of life*" and "*makes no heroic assumptions about the ability of sick people to make rational utility-maximizing decisions on their own behalf*" (Culyer 2005: 127).

Supply Theory: Agency Problems

In most microeconomic applications, supply plays a subsidiary role to demand. Generally, it is assumed that supply adjusts if consumers' preferences change. Again, supply theory is based on a number of crucial assumptions, the most crucial being that supply and demand are determined independently. Once more, this essential assumption is not fulfilled in most health care markets. Supply and demand of health care services are closely interlinked, which is clearly contradictory to the traditional microeconomic model. Patients rely on health care professionals to reduce ► information asymmetries and to support them in order to make informed choices. This assumes that health care professionals act as perfect agents for their patients and refrain from pursuing self-interests that might be divergent from the interest of the patient. However, in practice, physicians are quadruple agents. They pursue the interest of the patient, their own self-interest, the interest of the third-party payer, and the interest of society as a whole (Rice 2006). Health economists generally agree that physicians – the suppliers – are able to induce demand for their services, at least to some degree. As a consequence, designers of health care systems have come up with a variety of policy measures to reduce incentives for ► supplier-induced demand (► regulatory mechanisms).

Medical economics; Economic evaluation; Health services management

Definition

Health economics is an independent branch of economics that is concerned both empirically and theoretically with the economic aspects of healthcare and more particularly with the production and distribution

of scarce health goods. The justification for a specifically economic consideration of the non-economic good represented by health is that many healthcare problems (a) are connected with economic phenomena and conditions, (b) can be described and quantified in economic categories, and (c) either can be solved by economic means or, in view of the ► scarcity of the resources required, call for a strategy based on economic considerations. In addition, of course, other, non-economic, approaches (e. g. evidence-based medicine/evidence-based dentistry, social medicine or social law) can be applied, the results of which can contribute on an interdisciplinary basis to analyses in the field of health economics.

History

The genesis of health economics as an economic discipline in its own right is closely bound up with the trend of healthcare costs and the consequent realization that not everything desirable in the field of health is affordable. In view of this somewhat gloomy state of affairs, health economics for a long time enjoyed a reputation as a "dismal science". Yet health economics is not a mere policy instrument for containing costs, but in fact an indispensable aid to rational policy-making.

In the particular field of dentistry, the subdiscipline of "dental health economics" has now come into being, albeit hesitantly. In 1973 the American economist Paul J. Feldstein published the first systematic consideration of health-economic issues in the dental field, *Financing Dental Care: an Economic Analysis* (Feldstein 1973). Dental health economics is still relatively undeveloped in the German-speaking countries as compared with the United States, the United Kingdom, the Netherlands and Scandinavia.

Basic Characteristics

The specific methods used in health economics are characterized by systematic comparison of the costs and benefits of given actions and the balancing of alternatives against each other. According to the World Health Organization's standard definition, the function of health economics is "inter alia to quantify over time the resources used in health service delivery, their organization and their financing; the efficiency with which resources are allocated and used for health purposes; and the effect of preventive, curative, and rehabilitative health services on individual and national productivity" (World Health Organization 1975).

Research Issues

Health economics in the sphere of dental care is concerned in particular with the analysis of issues in and aspects of the following fields:

- **Allocation**: Is the allocation of resources to dental treatment inadequate or excessive compared with those provided for other areas of demand such as nutrition or education? Within the field of dentistry, should more or less be spent on prevention relative to expenditure on curative treatment (Räbiger 1989)?
- **Efficiency**: Are dental services rendered at the lowest possible cost for a given quality of care (in accordance with the "► minimum principle"), or are as many dental services as possible at the highest possible quality rendered for a given level of resources? And how can economic incentives contribute to increased efficiency, for instance with regard to the remuneration of dentists (Tiemann, Klingenberger, Weber 2003)?
- **Distribution of health goods and services**: How are the benefits of the dental healthcare system distributed to different sections of the population? Is good-quality care received only by those who can afford the services, or is there an entitlement to good healthcare irrespective of income, age, etc.?
- **Creation of value**: What is the significance of the dental care sector as a factor of growth and value in the economy and as a source of income for those working in the sector?

Levels of Analysis

Health-economic analysis can be applied at different levels. On the *micro-level* it concerns the actions of individual actors (e. g. aspects of dentist-patient communication, or effective practice management), the emphasis being placed on microeconomic elements. This level is sometimes referred to as "health services management". The *meso-level* examines the actions of the intermediate actors in the health system (e. g. associations of statutory health insurance funds, or regional associations of statutory health insurance dentists). Owing to the German tradition of strong corporatist structures, "intermediate-level control" is comparatively important in this country (Tiemann, Klingenberger,

Weber 2003). Finally, the *macro-level* is that of analysis of the characteristics of the system as a whole. The macro-level arises by the aggregation of individual actors into collectives such as "the dental profession", or "patients". "Health system analysis" is conducted from the macroeconomic point of view, and examines such issues as dental overprovision, underprovision and malprovision (SVRKAiG 2002).

Methods of Health-Economic Evaluation

For practical purposes, perhaps the most important aspect of health-economic evaluation in the dental field is assessment of the costs and effects of different therapies and/or preventive strategies. These are examined from various points of view, such as that of the individual patient, that of the health insurance sector, that of the dental industry or indeed that of society as a whole. The outcome parameters used are epidemiological data, such as the DMFT value for caries or the Community Periodontal Index (CPI) for periodontal status. To ensure that the results of health-economic evaluation studies can be validly interpreted, minimum requirements as to methodology and transparency must be observed (Drummond 2005). The most common types of studies are enumerated in Table 1.

A strikingly large number of evaluation studies in the dental field are devoted to comparison of the costs of preventive strategies with their effectiveness (CEA). Preventive care concepts have a relatively long tradition in dentistry. The principal landmarks in the prevention of dental pathology in Germany are the placing of group-prophylactic measures for children on a statutory basis in 1989 and the introduction of the system of individual prophylaxis in the statutory health insurance scheme in 1991. A comparison of the economics of various prophylactic measures (Saekel 2002) shows that all current measures of prophylaxis and tooth conservation are cost-effective and hence to be recommended in terms of health economics (Table 2). Apart from vaccination, no other field of healthcare has such high efficiency as dental prophylaxis, and in particular fluoridation for the prevention of caries (Räbiger 1989).

Similar studies have been carried out for a number of dental prosthetic treatments (Kerschbaum 1997; Walter et al. 1999). The usual method of calculating the cost of the alternatives is "decision tree analysis". This is a methodological approach to the systematization of decision-making processes that uses what are known as transitional probabilities to predict the occurrence of various health-related states (e. g. secondary caries or tooth loss), sometimes extending over relatively long periods. In the case of long-term predictions, the costs of medical measures must be not only added together but also discounted. In the dental field, a long-term perspective is appropriate mainly in connection with the survival rates of restorations, prostheses and implants, and with the biomedical compatibility of various dental materials.

With regard to the development of cost utility analysis (CUA) and cost benefit analysis (CBA), health-economic research is still in its infancy, as investigation of the benefits of dental measures is enormously more complex in terms of methodology than determination of their costs. Owing to the relative non-availability of empirical data in the field of dental health-

Health Economics in Dentistry, Table 1 Systematization of types of health-economic evaluation

Non-comparative studies	
Cost of illness study (CIS)	Determination of the direct and indirect costs of an illness without consideration of effects.
Comparative studies	
Cost minimization analysis (CMA)	Determination of the costs of two or more alternative courses of action assuming equality of effects.
Cost effectiveness analysis (CEA)	Comparison of two or more alternative courses of action in terms of cost and effectiveness. This calls for a uniform effect dimension defined clinically or epidemiologically.
Cost utility analysis (CUA)	This combines different effect dimensions within the single effect dimension of "quality-adjusted life years" (► QALY), so that the relative value of therapies can be determined even where indications differ.
Cost benefit analysis (CBA)	This considers effects in terms of monetary units, thus providing a common dimension for costs and effects. The inputs and outputs of different courses of action can then be compared and balanced against each other.

Health Economics in Dentistry, Table 2 Economics of selected measures of prophylaxis and tooth conservation

Measure	Benefit : Cost (B/C)
Home use of fluoridated iodine salt	> 70
Group prophylaxis (age range 4–12 years)	5.1
Fissure sealing of permanent molars	2.3
Risk-based intensive prophylaxis as group prophylaxis	2.9
Risk-based intensive prophylaxis at the dental practice	1.2
Root canal treatment	16.7

care, ► willingness-to-pay analyses bear great difficulties. Yet research on the quality-of-life aspects of dental care has made significant progress with the development of the Oral Health Impact Profile (OHIP) for the determination of the benefit, or utility, of alternative dental treatments from the patient's point of view. There is now a validated German-language short form of the OHIP questionnaire with 14 items (John et al. 2006), which allows problem-free assessment of patients' oral-health-related quality of life at the dental practice or in appropriate studies.

Conclusion

The significance of health economics as an instrument of rational policy-making is likely to increase further in the future, as health – including oral health – is in economic terms a ► superior good, which means that the demand for it increases disproportionately as incomes in society as a whole rise. The fact that medicine is a growth market is evident from the proportion both of the labor force (1970: 2.9%; 2004: 10.6%) and of GDP accounted for by the healthcare sector: in 2005 health-related spending averaged 9% of gross domestic product in the OECD countries, compared with only just over 5% in 1970.

Health economics, then, is fundamentally a science not of minimization but of optimization. Economic evaluations facilitate the choice of alternatives in dental practice in a situation of scarce resources. It would therefore be negligent to eschew health-economic approaches to issues in the field of dentistry.

Definition

Health education is defined in the context on health promotion as follows: Health education comprises consciously constructed opportunities for learning that involve some form of communication designed to improve health literacy, including improving knowledge and developing life skills that are conducive to individual and community health (WHO 1998).

Basic Characteristics

Health education deals with mediating health information that influences social, economic, or environmental related determinants of healthy lifestyles, health promoting behavior, and use of health services. Health education aims primarily at learning experiences and the voluntary actions people can take, individually or collectively, for their own health, the health of others, or the common good of the community. Defining health education as any combination of learning experiences designed to facilitate voluntary actions conducive to health emphasizes the importance of multiple determinants of behavior (Green and Kreuter 1999).

In addition, health education comprises the development and strengthening of ► life skills. Health education plays a significant role in health promotion and is needed for implementation of ► intervention strategies of primary, , and ► tertiary prevention.

The regional European office of the ► world health organization (WHO) describes health education as strengthening knowledge and experiences of individuals on health and illness and the organism and its functions, as well as disease prevention. It emphasizes the strengthening of knowledge and experiences of individuals regarding the utilization of health services and understanding of their functions. The objective of these efforts is to give individuals the responsibility for their health and the ability to use the offerings of health care systems. Health education is a systematically planned activity, and can thus be distinguished from incidental learning experiences. Further, this description of health education draws attention to voluntary behavioral actions taken by an individual, group, or community with the full understanding and acceptance of the purposes of the action – either to achieve an intended health effect or to build capacity for health.

Furthermore, the idea of health education is based on principal human rights to gather complete information in the field of health and illness. Health education contributes to fostering the motivation, skills, and confidence necessary to take action to improve health (BzgA 2003). Health education paves the way for ► health literacy, which is understood as the concept of well-informed humans, giving them autonomy in their health-related behavior.

Actions on health education might be carried out by individuals, groups, or communities; or policymakers, employers, teachers, or organizations whose actions or practices control or influence determinants of health. Health education can be described in the following contexts:

- Health education in traditional context
- Health education
- Health counseling
- ► Peer Education.

Health Education in Traditional Context

Health education developed from the educational work in hygienic issues at the end of 19th century and at the beginning of the 20th century. This kind of education aimed to educate humans in important aspects of health and diseases, which was the objective of historical education in ► hygiene. It was directed to the whole population or parts of it. At that time, health education was mainly disease-related. It was realized through mass media in order to educate the population in essential aspects of health and medical conditions. Subsequently, this approach of health education was replaced by the following principles that were outlined by the WHO:

- Strengthening of knowledge and experience on health, diseases, and about the physiology of the human organism
- Strengthening of knowledge and experience in regard to the structure of health services and their utilization
- Increasing awareness about social and environmental factors and health determinants.

Further Developments in Health Education

The development of health education was shaped by methods of social medicine, public health, and psychology that are based on concepts of risk factors and the ► health belief model. This model is still used as an assessment tool to understand why persons participate in programs for the prevention or detection of

diseases. Modern methods of psychology were considered after it was revealed that positive effects in health education were not achieved by education using the "wagging finger". Traditional health education aimed at increasing participation in interventions such as early recognition measures of diseases and vaccination campaigns, reduction of risk factors of diseases and addiction, and improvement of physical and mental health. The meaning of isolated health education campaigns decreases since the knowledge and cognitive abilities do not change sustainable health risk behavior to the extent that is desirable. Complex approaches promise more success.

Since the beginning of the 1970s, the main focus of educational measures has been directed towards risk factors of chronic diseases like smoking habits, obesity, lack of physical activity, and mental balance as well as high blood pressure and high blood sugar. For individuals in these risk groups who suffer from chronic illness, measures are intended to motivate them towards more healthy living. This development was supported by the possibility of medical monitoring of risk factors (BzgA 2003).

Currently, modern health education is shaped by the concept of designing and strengthening ► life skills. The WHO demands the promotion of communication offerings that contribute to the improvement of health literacy. Health education contains more than dissemination of information and knowledge transfer on health issues. Competences in health topics that are achieved by health education support the aim of a health promoting lifestyle for individuals and therefore support the strengthening of community actions in health promotion.

Actions on health education might be carried out by individuals, groups, or communities; or policymakers, employers, teachers, or organizations whose actions or practices control or influence determinants of health.

General health education measures like ► mass media campaigns using methods of mass communication may be also carried out in an organized form in adult education centers or at night schools. This kind of health education is characterized through voluntary participation and participation related, social and self-determined learning and integrated educational concepts on health topics. Measures of health education are also offered by health insurers and other different educational institutions. In this context, it is also termed health training or health counseling. Such facilities also offer information on health and depict a special form of health education but the information is only given to individuals or a small group of individuals. It is orientated on individual circumstances and differs from traditional health education.

In addition, a special kind of health education uses the concept of peer education. Peer education in the sense of health promotion means learning and mediating information, behavior patterns, and ethical qualities on health through the participants of the education group themselves, especially in population groups of youths and adolescents. The approach of peer education is used widely in the United States and is part of the academic curricula. Positive experiences exist for the following topics: Primary prevention of smoking and substance and alcohol abuse; counseling and information on eating disorders; HIV prevention and prevention of unintentional pregnancy; and coping with stress.

Health care financing

Definition

Designers of health care financing systems—at least in high-income countries and with the notable exception of the US—rely on either social health insurance premiums or taxes as the primary source of health financing. Both provide a high degree of risk solidarity and comprehensive coverage. In contrast, private health insurance premiums and out-of-pocket payments are usually considered to be secondary sources of health care financing.

Basic Characteristics

Sources of Health Care Financing

Health care systems are financed by a variety of sources. The most basic source of health care financing is ► out-of pocket payment. Usually, out-of-pocket payments are a secondary source of health care financing, since health care expenditures are highly skewed and out-of-pocket payments do not provide any risk-spreading (► health insurance markets). The second source of health care financing is premium income from ► private health insurance. Private health insurance is characterized by ► risk-related premiums. Due to ► adverse selection in unregulated private health insurance markets, private health insurance premiums in most countries—with the notable exception of the US—do not serve as a primary source of health care financing (Colombo and Tapay 2004; Reinhardt et al. 2004). In most industrialized countries, the primary source of health care financing is either ► social health insurance premiums or taxes (for empirical information on the share of different sources of health care financing see ► health systems). In the remainder of this section, we will discuss the implications of private health insurance, social health insurance, and tax financing for risk solidarity and income solidarity.

Implications for Risk Solidarity

Societies in most industrialized countries place a high priority on *fairness or solidarity* as a policy objective in health care financing (Wagstaff and van Doorslaer 1992; Wagstaff and van Doorslaer 2000). Two dimensions of solidarity need to be distinguished (van de Ven and Ellis 2000). The most basic dimension of solidarity is ex-post ► risk solidarity between the healthy and the sick. This means that there is a limited redistribution of resources from the unexpectedly healthy towards the unexpectedly sick. Risk solidarity is limited to health risks that become apparent after establishing the insurance contract. Risks that had been visible before the contract are accounted for by higher health insurance premiums. If the regulator does not intervene, private health insurance therefore provides ex-post risk solidarity between the healthy and the sick only.

However, with the notable exception of the US, most high-income countries do not rely on private health insurance as a predominant mode of health care financing (Gottret and Schieber 2006). Instead, designers of health care financing systems prefer to implement modes of financing which provide an enhanced degree of solidarity and redistribution (Mossialos et al. 2002; Wasem et al. 2004). Both social health insurance and

a ► national health service that is based on tax funding provide ex-ante risk solidarity as well as ex-post risk solidarity between the healthy and the sick. Ex-ante solidarity between the expectedly healthy and the expectedly sick implies that health risks are covered at any time. In social health insurance, premium rate restrictions apply—health insurers have to refrain from charging higher premiums for high health risks. In tax-financed systems, tax payments are not related to health risks.

Although both tax-financed schemes and social health insurance schemes provide comprehensive risk solidarity between the healthy and the sick, there are important differences between the two modes of financing. In tax-financed health systems—such as the English National Health Service or Canadian Medicare—solidarity is based on residence. There are few opportunities to opt out of the system. Thus, comprehensive coverage—and therefore comprehensive risk solidarity between the healthy and the sick—is easy to obtain. In contrast, social health insurance systems restrict solidarity to the members of the risk pool. Compared to private health insurance contracts, membership to social health insurance is easy to obtain. However, if it is not mandatory to take out social health insurance for the entire population, selection problems will follow: good risks may try to opt out of the social insurance system. They either will take out private health insurance—if it is available—or may rely on the provision of public services in the case of need. As a consequence, fewer good risks will be in the risk pool to subsidize bad risks. An effective instrument to neutralize incentives for opportunistic ► free rider behavior is the obligation for the entire population to take out social health insurance (Rice 2002).

Implications for Income Solidarity

Comprehensive risk solidarity between the healthy and the sick is an indispensable property of social health insurance. Moreover, ► income solidarity—solidarity between the rich and the poor—may be a fundamental feature of social health insurance as well, but not necessarily so. If social health insurance calculates ► community-rated premiums, these premiums are independent of income. As a consequence, social health insurance in this case does not redistribute resources from the rich to the poor. What is more, the consequences of community-rated premiums are regressive: the higher the income, the smaller the share that is spent on social health insurance premiums. In most OECD-countries that use social health insurance as the predominant mode of health care financing, these consequences are not socially acceptable. Therefore, designers of health care financing systems either implement a system of tax-financed and needs-tested premium subsidies as a complement to community-rated premiums or use income-dependent premiums as the primary mode of financing.

In tax-financed national health systems, the implications for the redistribution of income depend on the design of the tax system. The consequences on the distribution of income can be progressive, regressive, or proportional. Direct taxes on income may be equivalent to social health insurance premiums in terms of income solidarity. Thus, the consequences of direct taxes on income distribution are proportional if the tax rate is uniform across all income categories and across all income groups. The consequences are progressive if the tax rate is not uniform across all income groups but goes up as income goes up. However, direct taxes are only one important component of general tax revenue. Indirect taxes on consumption are another component. The consequences of consumption taxes on income distribution are usually regressive: the higher the income, the smaller the share that is spent on indirect taxes. This is a consequence of the fact that low-income groups have a lower savings rate than high-income groups. A popular instrument to attenuate this regressive effect of indirect taxes is to exempt basic consumer goods from indirect taxes or to apply lower tax rates to these goods.

Health Goals

ANDREAS FUCHS
Forschungsverbund Public Health Sachsen-Sachsen Anhalt e. V., Medizinische Fakultät, Technische Universität, Dresden, Germany
andreas.fuchs@mailbox.tu-dresden.de

Definition

Health goals are general statements of intent and aspiration, intended to reflect the values of the community in general, and the health sector in particular, regarding a healthy society (WHO 1998).

Basic Characteristics

In General

Goal statements are clearly articulated, general statements that describe the future state of affairs and provide general direction, purpose or intent of what needs to be accomplished. In the context of health promotion, Nutbeam defines health goals as a summary of ► health outcomes which, in the light of existing knowledge and resources, a country or community might hope to achieve in a defined time period. On the basis of firm evidence, health goals are used for creating recommendations and a catalog of measures in special sectors and population groups. The involved participants commit to implement health goals in their field of authority. The implementation and sustainable development of health goals is applied in a long term process (WHO 1998).
Numerous countries have adopted an approach to setting health goals and ► health targets as a statement of direction and intent with regard to their investments for health. The World Health Organization (► WHO) has supported the development, and has promoted the use of health goals and targets at global and regional, national and local levels. One of the most known health goals is the general WHO statement "► health for all."
The prioritization of health risks and health problems formed the background for the development of health goals, related to citizens in general and patients in particular, in order to forward the political discussion about the advancement of health promotion, disease prevention and rehabilitation. Moreover, in order to achieve a high percentage of these health goals and energize both managers and suppliers of health promotion, available resources and funds should be used in a fast and efficient way.

Historical Development of Health Goals

In the 1970s health goals were developed from the reorientation of ► health policy with its new aims in health promotion and disease prevention. The World Health Assembly aimed at enabling the "Health for All" policy whereby every citizen would have the opportunity of leading a full productive and social life. This overall goal was adopted as the general strategy "Health for All" in 1979 and it has so continued (Declaration "Health for All in the 21st Century", adopted 1998). The global strategy "health for all" was followed by the European program with the title "Health for All 2000"

in 1984. It encompassed 38 health goals amongst other overall goals like "for a better health" or "for promoting healthy life styles." It was also agreed to measure the reaching of health goals regularly and to publish the results of this measurement. Therefore, 65 indicators were developed as standard measurements of achievement.

By 1991 health goals had undergone further development. After that the program was transferred to the health goal program, "Health for All in 21st Century – Health 21." An additional updating was carried out in 2005. The program does not provide explicit goals for any given region since the complex social economic and health conditions vary within the European Regions which make up the WHO. In this regard, it is necessary that each member state formulates its own concrete description of implementation and benefit of health goals at both national and regional levels. The priority goal of the WHO to reach health for all is supported by the following three fundamental aspects:

- Health as a one of the fundamental ► human rights.
- ► Equity in health and solidarity in action between countries, between groups of people within countries and between genders.
- ► Participation by and accountability of individuals, groups and communities and of institutions, organizations and sectors in health development.

The following four main strategies for action have been chosen to ensure health as fundamental human right:

- Multisectoral strategies to tackle the determinants of health, taking into account physical, economic, social, cultural, and gender perspectives and ensuring the use of ► health impact assessments.
- Health-outcome-driven programs and investments for health development and clinical care.
- Integrated family- and community-oriented primary health care, supported by a flexible and responsive hospital system.
- A participatory health development process that involves relevant partners for health, at all levels – home, school and worksite, local community and country – and that promotes joint decision-making, implementation and accountability.

On the basis of the mentioned principles of the WHO, the following 21 health goals depict the currently framework for health policy in the European region. These 21 health goals are regarded as standard for the assessment of progress in health situation improvements, preventive health care systems and the reduction of ► health risks and hazards (WHO 1999).

- Solidarity for health in the European region.
- Equity in health.
- A healthy start in life.
- Health of young people.
- ► Healthy Ageing
- Improving ► mental health.
- Reducing ► communicable diseases.
- Reducing noncommunicable diseases.
- Reducing injury from violence and accidents.
- A healthy and safe physical environment.
- Healthier living.
- Reducing harm from alcohol, drugs and tobacco abuse.
- ► Settings for health.
- Multisectoral responsibility for health.
- An integrated health sector.
- Managing for ► quality of care.
- Funding health services and allocating resources.
- Developing human resources for health.
- Research and knowledge for health.
- Mobilizing partners for health.
- Policies and strategies for health for all.

The 21 health goals of the program "Health for All" was taken into the health policies of almost all members of the European Union (WHO 1999). Numerous member states of the Organization for Economic Cooperation and Development (► OECD) adopted the idea of health targets and a large number of health goals were developed both at national and regional level. Since the beginning of the 1970s health goal programs have spread worldwide. For example, health goals were defined in Australia, Denmark, Finland, France, Great Britain, Ireland, Italy, Poland, New Zealand, United States and Sweden. Programs on the issues were also drafted at the regional level in many countries.

Health Impact Assessment (HIA)

Definition

Health impact assessment provides decision makers with information about how any policy, program or project may affect the health of people. HIA seeks to influence decision makers to improve the proposal. WHO supports the use of HIA because of its ability to influence policies, programs and/or projects. This provides a foundation for improved health and well being of people likely to be affected by such proposals (WHO Definition).

Health impact assessment (HIA) comprises detection and assessment of the impact a planned measure, project or program (e. g., expansion of an airport, street building) could have on the health of the population (e. g., ► noise, air pollution). In the context of ► prevention, HIA must aid the decision-making process by providing transparent and clear data on possible public health consequences for the various population groups as well as buildings and other structures involved. HIA can thus contribute to health being considered in other, not immediately health-related areas of politics such as municipal and residential planning.

In view of the different countries and bodies of law, implementation of HIA will be quite heterogeneous and not comparable between countries. Despite long-standing calls for implementing HIA alongside the legally mandated testing for potential environmental hazards. Currently, public health aspects are being incorporated in some countries only within the context of the legally mandated cooperation of the lower public health authorities in planning the course of environmental safety testing. One of the hurdles for implementing HIA is that environment-related aspects of health are not included in planning at the communal level, a lack of standards for implementing HIA, and no cooperation between the environmental and public health authorities.

Definition

Health indicators are quantitative or statistical measures or instruments used for the measurement of health status of an individual or defined group. They are variables that can be used to measure the changes in the level of health target achievement, or as indirect or partial measures of complex situations. ► Indicators can be numerical (rations, proportions, rates), or qualitative (existence or absence of an event). Health indicators

are divided into several main domains: demographic and socio-economic factors, indicators of health status, health determinants, indicators of health systems, and indicators of health policy, etc.

Basic Characteristics

Characteristics and Criteria for Design

Health indicators are constructed to measure health status (i. e. the occurrence of a disease or other health-related event) or a factor associated with health (i. e. health status or other risk factor) among a specified population. (Pan American Health Organization 2001) Furthermore, health indicators are markers of health-care system performance. They are used for ► health monitoring and ► health surveillance. Health indicators are selected and defined based on scientific principles and by their quality (► quality of health indicators). An ideal indicator must be: (PAHO 2001; European Commission 2001)

- Valid – effectively measures only what it attempts to measure, and it represents a true expression of the phenomena it is measuring;
- Reliable / objective – results of the measurement should be the same when the measurement is performed by other people or under similar circumstances;
- Sensitive – the indicator should have the capacity to measure changes of the phenomena of interest;
- Specific – it should reflect changes only of the situation/phenomenon it is related to, and not of similar or unrelated events;
- Measurable – data should be available or easy to obtain;
- Policy-relevant – the indicator should be capable of providing clear responses to key policy issues;
- Cost-effective – results of the use of an indicator should justify the investments in its implementation;
- Understandable – information users must be able to understand it and it should be easy to use and interpret by analysts.

Under the Health Monitoring Programme, the European Commission has proposed several strict criteria for the design of indicator sets:

1. Comprehensive and coherent – an indicator set should cover all domains of the public health field, but at the same time be consistent in structure, refer to the integrity of all data, and the values of all indicators within the set should be realistic and not contradictive.
2. Taking account of earlier work in the area of indicator selection and definition, an indicator set should follow rather than duplicate the previous efforts of international organizations, such as World Health Organization, in the establishment of good health indicators; furthermore, only standardized operational definitions, measurements, and calculation procedures should be used to guarantee the quality and comparability of the indicators.
3. Indicators should cover the priority areas that Member States of European Community currently pursue and meet the needs of Community Policies. Health indicators are expected to facilitate monitoring of health objectives and goals, strengthen the analytical capacities of health teams, and serve as a platform to promote the development of interconnected health information systems. (European Commission 2001)

Classification of Health Indicators

Various classifications of health indicators have been proposed. (OECD 2005; European Commission 2005; WHO 2005a; WHO 2006) Despite great advances in the development of indexes and complex health indicators, conventional health indicators, based on mortality and morbidity, are still being used as a base point of public health policies in practice (the so-called "pathologic" approach to health measurement). Introduction of methods oriented toward quantifying health rather than quantifying disease have led to the establishment of novel indicators, and turned the whole viewpoint toward a "generic" or positive approach to the measurement of health status. Based on various resources, health indicators can be summarized in the following groups.

Indicators of Health Status of the Population

1. Positive health indicators: low birth weight, low weight for age, low height for age, low weight for height, and low arm circumference for age;
2. Negative health indicators: perinatal mortality, infant mortality, maternal mortality, under 5 mortality, life expectancy, mortality rates by causes of death, incidence and prevalence rates (previously morbidity – HIV/AIDS incidence, cancer incidence,

prevalence of chronic illness, incidence of congenital anomalies, and incidence of communicable diseases), prevalence of long term disabilities, prevalence of injuries in road traffic accidents or at the workplace, average number of days lost due to illness per year for school, work, homemaking, and other social roles;
3. Perceived general health – satisfaction is measured as the proportion of the population aged 15 and over that report being dissatisfied with their social life; quality of life is measured as the proportion of the population that report perceiving themselves in fair or poor health (► health status indicators).

Demographic and Socioeconomic Indicators Related to Health

1. Indicators of population: rate of birth vs. death, internal migration rate (natural population growth per 1000 population), live births, crude birth rate, total deaths, crude death rate, abortion rate, total fertility rate, percentage annual increase or decrease in population, and median age of the population (► demographic indicators);
2. Indicators of socioeconomic development: national income per capita (in international dollars per capita), average annual growth of national income, gross national product, annual growth of gross national product; average income per working adult, and the allocation of income by geographical region or by profession group (► socioeconomic indicators; ► health determinants, social);
3. Employment and working conditions: total unemployment, total labor force, rate of unemployment of women, index of the dependence of the population, population by employment type, population by occupational class, and deaths due to work-related accidents;
4. Indicators of education: percentage of illiterate persons aged older than 10, percentage of primary, secondary or high school education, expenditures on education per student, average number of students per teacher, education attainment, and education enrolment;
5. Household conditions: total size of residence per person, rate of building, percentage of comfort apartments, and percentage of the population with a home connected to the water supply system;
6. Lifestyles and environmental indicators: average energy value of daily food intake, average content of macro nutrients, estimated consumption of fruits and vegetables (kg/capita/year), alcohol consumption (in liters of pure alcohol per capita), regular adult smokers aged 15 and over, first admissions to drug treatment centers, and average annual concentration of particulate matter $<10\mu$m (in $\mu g/m^3$). (► environmental health indicators; ► health determinants, environmental)

The indicators referring to the physical and social environment, genetics, and human behavior are also known as ► determinants of health.

Indicators of Health Policy

1. National health policy and strategy – the indicator is the adoption of national health policy and its implementation in the constitution and legislation of a state (► health policy indicators);
2. Allocation of resources in health – measured by the proportion of national income that is used for the funding of health protection of the population (total health expenditure as percentage of gross domestic product, or total expenditures on health in international dollars) (► health economics);
3. Health expenditure by sources of funds: social security, out-of-pocket payments, private insurance, or other private funds;
4. Community involvement – measured by its relation to decision making for health care and the presence of mechanisms to meet patients' health needs.
5. Presence of organizational setting and management process – measured by the existence of communication and cooperation between various departments and organizational units within the health service, as well as committees, expert groups, councils for health development, and non-governmental organizations.

Indicators of Health Care Provision

1. Provision of primary health care – can be estimated by provision of primary health care in a community (per total population), by immunization rate (percentage of the population immunized), provision of maternal, child and elderly health care (per total number of women, children and elderly, respectively), food and water supply, and health education

and promotion (► health care provision indicators; ► health care quality);
2. Availability of health care – number of people in the population divided by number of health workers or health institutions;
3. Accessibility of health care – percentage of people who will be using health services considering barriers – geographical, economical, and cultural, etc;
4. Utilization of health care: number of services per resident; rate of hospitalization; hospital beds per 100,000 population; number of nurses, physicians, or other health workers per 100,000 population; number of nurses and midwives per physician; in-patient care admissions per population; average length of stay in hospital (in days), discharge rated by diagnostic categories; and number of surgical procedures and transplantations, etc;
5. Health expenditures: total health expenditure (as percentage of gross national product or in international dollars per capita); expenditure on prevention and public health; expenditure on health administration and insurance; expenditure on medical services; expenditures on in-patient, out-patient and home care; and expenditure on pharmaceuticals, therapeutic appliances and medical goods;
6. Medical technology in health care: number of computed tomography scanners, magnetic resonance imaging units, and amount of radiation therapy equipment etc;
7. Education in health: number of health graduates, number of organizations and institutions to promote health, and implementation of health education in school activities;
8. Health workers' performance: availability (absence rates and waiting times), competence (prescribing practices, readmission rates, and rates of cross infection), responsiveness (patient satisfaction and assessment of responsiveness), and productivity (occupied beds, outpatient visits, and interventions delivered per worker or facility);
9. Quality of health care – can not easily be estimated; however, indicators include: accessibility of health care (physical access, availability, and affordability of health care), effectiveness of care, efficiency, acceptability, equity, continuity, qualifications of physicians, consumer satisfaction, and cost of care, etc. (Campbell 2000). (► health system indicators; ► health systems)

Summary Measures of Population Health

► Summary measures of population health combine information on mortality and non-fatal health outcomes to represent the health of a particular population in a single numerical index. Summary measures can be used for ► health reporting – comparing the health of different populations and monitoring changes in health status of the population over time. Such estimations are, in turn, used for the identification of priorities for health service delivery and planning, and research and development in the health sector. (Murray 2000; Mathers et al. 2004; WHO 2005b; Etches et al. 2006)

1. Disability-adjusted life years (DALY) is one of the indexes measuring the total economic burden of a disease. It refers to time lived with disability and time lost due to premature death and ill health in terms of the equivalent of the healthy years that did not happen, or the health debit. Simplified, it can be calculated as the sum of years of life lost due to premature death (YLL) and years of life with disability (YLD).
2. Healthy life expectancy (HALE) represents the number of healthy years people can expect to live under current conditions.
3. Potential years of life lost are estimated for every specific cause of death by adding estimated years of life up to 75 for every person who dies from birth until the age of 75. This indicator is important for the estimation of preterm mortality and is useful for assessing priorities in preventive activities in health.
4. Quality-adjusted life years (QALY) are an indicator of the quality of work of health service. This indicator summarizes the improvements in length and quality of life that occur as an outcome of health interventions or programs. Every year gained as a result of an intervention or program is standardized according to social value of the gain for that person. Good health is referred to as 1, whereas poor health causes a decrease in quality years of life of up to 0.5.
5. The physical quality of life index represents the combination of mortality rate of the newborn, lifetime expectancy for children aged one, and the rate of literacy in the population. (► health-related quality of life; ► health determinants, psychological)

Conclusions

The fact that environmental, socioeconomic, and early life conditions, together with individual actions and medical care, all interact to affect health has been known for a long time. Improvements in data collection, regular censuses, disease reporting, and statistical analysis have further helped to integrate information on the health status of the population. In turn, health professionals have been given a chance to act on several levels of prevention in order to improve conditions affecting health and health status itself.

paunkaya@net.yu

Introduction

This is an era of informatics where the quantity and quality of information is increasing exponentially – a phenomenon commonly referred to as "information explosion" or "information epidemic". As a consequence, users face the problem of managing the variety

of information they are covered by, known as the "information barrier", which in turn causes frustration named "informatics anxiety" (Greenes 1990).

Health information needs are universal. Health care professionals, health managers, statisticians, decision-makers within the health system, health insurance organizations, public health providers, and consumers – they all need health information. The ever-increasing amount of available information makes it even more important to manage the flow of knowledge. The multidisciplinary nature of public health disciplines makes it especially hard to capture useful updates without becoming overwhelmed by the diversity of information.

From Information to Informatics

Information is a result of the events taking place inside a material system; it is the output of a system of interest. The words information and data are used interchangeably in many contexts, which may lead to their confusion; however, they are not synonyms.

Data is the carrier of information, and is defined as given facts from which others may be inferred; it can also be described as a message that has not been developed with relation to its value in the specific situation. Data is further organized into meaningful unions, or accessed or interpreted to obtain specific information. **Information** is defined as data endowed with relevance, purpose, and meaning. It represents data that has been developed, and can therefore be valued by its capacity to increase our knowledge. Nevertheless, the process of creation does not stop there. **Knowledge** is developed from using or applying information. Knowledge is defined as the awareness or familiarity gained by experience, a person's range of information, a theoretical or practical understanding of a subject or language, etc., or the sum of what is known. **Wisdom** flows from the accumulated experience of applying and using knowledge, or as experience and knowledge together with the power of applying them. Obviously, the process of creation and transformation from data to wisdom is characterized by increasing interactions and complexity, supported by the human capability of understanding relations, patterns and principles on every level. This continuum is called the **Data, Information, Knowledge Ladder** (► data, information, knowledge) (The Knowledge College 2001). Today, many forms of human knowledge can be recorded and used in electronic information systems. Wisdom, however, remains essentially human at present.

Information, as well as energy and other natural reserves, has become one of the key resources available today. In order to fulfill this important role, information must be timely and correct, available at the moment of decision-making, acceptable, of adequate quality and quantity, at a fair price, easy to update, and of multiple uses.

Information can be observed from several **aspects** (Van Bemmel 1997):

- The syntactic aspect refers to the grammar or syntax used for the description, storage, or transmission of messages. The syntactic aspect of information is strongly related to the carrier of the information, that is, the specific language, type of image, or biosignal. The purely syntactic aspect of information is data.
- The semantic aspect of information refers to the meaning of the message, in terms of its significance for interpretation and decision-making. The meaning can often be derived only if we know the context of the message.
- The pragmatic aspect of the information refers to the value of the information, the media that carries it, the resolution and precision that it was written with, and the quantity in which it was produced, transferred, and received. From the perspective of human behavior, information was created with a certain purpose and a certain effect, such that a concrete action or state of mind occurs after we receive it.

Information can be created, transferred, stored, retrieved, accepted, copied, processed, and destroyed. But, in a digital world, written information must be coded before it can be transmitted over a digital system. The quantity of information transmitted by any message can be **measured**. The measurement of information is the measurement of the uncertainty of a situation. That measurement is called entropy. If entropy is large, then a large amount of information is required to clarify the situation. If entropy is small, then only a small amount of information is required for clarification. The unit of information is called a bit (binary digit), which represents the quantity of information needed to make a difference between two events with same probability. By reducing entropy per bit, coding can reduce transmission errors (uncertainties) due to the transmission medium.

Health care information is used for different **purposes**. The primary purposes are those directly linked to the work of professionals and patients; secondary purposes are in administration, management, education, research, etc. Information can be classified by the time of production, as periodical or non periodical; or by its material format, information can be in paper, electronic, or film format (signals, waves), etc.

Information is contextual by **nature**. This means that information can not be seen outside of the context of its production – without its context, information is often useless. For this reason, the use of primary medical information for secondary purposes without its context is associated with several problems such as misuse, inadequate coding and transfer, and waste or misinterpretation of valuable information. With its context, data can be used for advanced functions within health care, but not always. This has been translated into the First Law of Medical Informatics: "Data shall be used only for the purpose for which they were collected. If no purpose was defined prior to collection of the data, then the data should not be used." (Van der Lei 1991)

The scientific discipline that explores the structure and characteristics of information is called **informatics.** The name originates from the French phrase *information automatique*, defining the science of automatic processing of information. It is one of the youngest scientific disciplines but has the most dynamic and dramatic development, with important implications on the development of society and other sciences. Informatics encompasses analysis of the structure; properties and organization of information; information storage and retrieval; information system and database architecture and design; library science; project management; and organizational issues such as change management and business process reengineering.

Health care informatics is the science that addresses how best to use information to improve health care. Health informatics is an essential and pervasive element in all health care activity. It is the field where health, information and computer sciences, psychology, epidemiology, and engineering intersect, and proposes to improve the quality of patient care, increase productivity, and provide access to knowledge (Mullner 2006).

This field includes several areas: bioinformatics, medical informatics, public health informatics, and consumer health informatics, as well as clinical informatics, nursing informatics, imaging informatics, dental informatics, clinical research informatics, and pharmacy informatics. These specialties can be defined following a similar pattern: bioinformatics involves the use of informatics and computer science to solve biological problems; dental informatics investigates the application of informatics in dentistry; pharmacy informatics in pharmacy, nursing informatics in nursing, etc.

► Medical informatics is the scientific discipline that investigates the laws of creation, transfer, processing, and use of information, data and knowledge in order to solve medical problems, or more precisely it is a discipline related to cognitive tasks, tasks of processing of information and communication in medical practice, and education and research, including scientific methods and technology supporting these tasks (Hersh 2002).

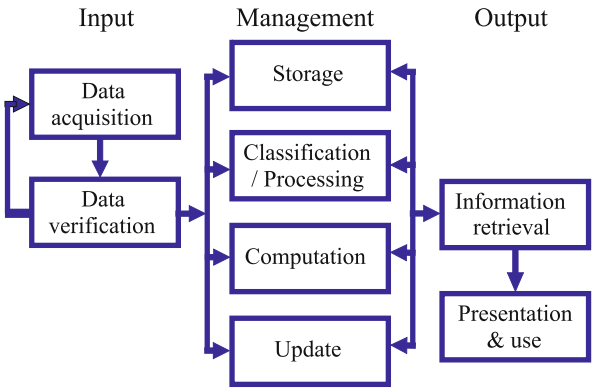
► Public health informatics is a scientific discipline that involves the systematic application of information, computer science, and technology to public health practice, research, and learning. Public health informatics is differentiated from other informatics specialties as its primary focus of concern is health prevention in populations or communities, rather than the health of specific individuals; thus, its health improvement strategy is oriented toward prevention rather than on treatment, and it has a wide range of interventions and operations within a governmental context (O'Carrol 2003).

► Consumer health informatics analyzes consumers' (i. e. patients') needs for information; studies and implements methods of making information accessible to consumers; and models and integrates consumers' preferences into medical information systems (Eysenbach 2000).

Evolution of Data into Information

All health care activities involve gathering, analyzing, and use of data. In the health information system, data usually, but not necessarily, follow a specific sequence (Fig. 1) (Dinca-Panaitescu 2003)

The main scope of **data acquisition** is to provide health professionals with information as a basis for further activities and a crucial tool in the process of decision-making. The physician can then apply his own knowledge on the specific condition or disease, and decide what intervention would be most suitable in that situation. Beside this obvious application, data are the basis of the whole process of decision-making in health care,



Health Information, Figure 1 Data in the Health Information System. Reproduced with the permission of Prof. Serban Dinca-Panaitescu

especially for health service planning and evaluation, and as indices of health service provision, usage, needs for health services, etc. Data acquisition includes data collection and data generation. The process of ► data collecting involves gathering data from various sources, whereas data generation refers to input of standard code formats.

Data can be divided into the following groups by the type of data collected and by the type of data source (Abdelhak 1996):

1. Administrative data – all data generated in an interaction between a patient and a provider in the health care delivery system: demographic, socioeconomic, legal, financial, and data from the provider.
2. Clinical data on a patient whether admitted to a health care facility or treated in a primary health care environment: main condition or principal diagnosis, medical history, physical examination and assessment, diagnostic tests, medications, operative procedures, and disposition.
3. Non-inpatient data – data collected for an emergency patient, outpatient, clinic, or aid post medical/health record: patient identification, history of presenting illness and physical findings, clinical observations, reports of tests and procedures performed, and the outcome of the visit.
4. Hospital census data – data on inpatients, emergency patients and ambulatory patient attendance that are collected daily by health care facilities and processed by the admission office staff: daily inpatient census, daily number of admissions, daily number of transfers in and out of wards, daily number of discharges, and deaths.
5. Secondary health care data collection – abstracted data from the daily inpatient census are used for: monthly and annual statistics such as the length of stay of inpatients and the inpatient occupancy rate; calculation of the gross and net death rates; autopsy rates; maternal, fetal, newborn and neonatal death rates; hospital infection rates; completion of morbidity statistics; vital statistics (births and deaths) for the production of national death and birth rates; and special registries related to patients with a specific diagnosis, condition or procedure (diabetes, HIV/AIDS, birth defects, infectious and contagious diseases, and organ transplants).

In collecting data, users are often faced with sometimes considerable anomalies in the data, such as incomplete or incorrect answers from the patient, noise on biosignals, or errors in biochemical analyzes. Information only exists to support decisions and actions; if it fails to do this, it is irrelevant noise. If the data are full of errors or incomplete, refer to past rather than present situations, or cannot be interpreted by the user then they are unlikely to help. More subtly, if useful data items are present but vital context is omitted (e. g. estrogen and progesterone levels present, but context, e. g. day of menstrual cycle, omitted), it is still hard to use the data.

The importance of ► data quality in the phase of data collection can not be underestimated. **Validation** of gathered data in the early phases of data processing reduces the cost of system data errors.

In order to reduce errors at the point of data entry, data should be entered as closely as possible to the information source, avoiding multiple independent points of unverified data entry, and the person doing the task should know the correct information. Furthermore, health professionals collecting and processing data should check for ► data errors, namely syntactic errors – are data presented in the right format and value; and semantic errors – are data possible and plausible.

It is often said that the quality of health care is measured by the quality of data in the medical record. In order to improve the quality of data, several steps can be taken (WHO 2003):

- An on-going quality assessment plan must be developed, supported both by managers and health staff;
- Staff responsible for quality control should be involved and deal with quality reports properly by

reading and acting upon recommendations in a timely manner;
- Performance indicators can be developed as a guide to monitor and evaluate the quality and appropriateness of care;
- Staff must be properly educated in order to clearly understand what quality means to the health institution, what is expected of them, and what benefit they get from high quality data;
- The data collection system needs to be simple and user-friendly;
- Quality activities need to focus on practice and not individual workers;
- Confidentiality needs to be maintained.

According to Fig. 1, once collected, data must be adequately managed. This management involves ► data processing and storage – classification, computation, coding, and eventual updates.

Most of the data collected in health care nowadays is **stored** as paper documentation. **Documentation/records** are defined as a group of techniques necessary for harmonized presentation, organization, and communication of the specific knowledge stored within (► record). The main purpose of documentation is to provide maximal accessibility and use of the information it contains (Van Bemmel 1997).

Medical documentation/medical records represent the notes of doctors and nurses about the patient's health status at the moment of contact with, and use of, the health service. It comprises anamnesis history, laboratory findings and results from other diagnostic procedures, and information on the applied therapies. The data within can be in various formats: textual format – natural language (medical history, consultation reports, and therapeutic protocols), numbers (measured variables, e. g., blood pressure, pH or temperature, and integer numbers e. g. heartbeats per minute, or number of hospital visits per month), images (radiography, CT scan, MNR scan, etc.), biosignals (ECG, EEG, etc.) and codes (diseases or drugs) (Van Bemmel 1997).

Stored data are usually organized chronologically as "time-oriented medical records". This structure of medical documentation means that users must go through all parts of the documentation in order to learn about a patient's current status or to find data they are interested in, which makes their use much more difficult. Computers can facilitate data collecting, storage and use, at least by enabling other types of data organization within a medical record, such as "sources-oriented medical records" and "problem-oriented medical records" (Van Bemmel 1997).

A collection of data is called a ► database. Data within a database are structured according to their similarity or affiliation with the same group. A file is a collection of records arranged in a database, which can be created, searched, updated, processed, reorganized, and destroyed. A special software system that enables manipulation of data is called a database management system. It is used for data storage, modification, retrieval, and control, as well as for data modeling on demand by the users. Using this system a user can access data easily and modify them for various purposes.

Paper records are physically stored in archives; in the computer, data are organized in files and directories, and physically stored in internal computer memory, or on external memory storage devices (magnetic, optical, and magneto-optical storage).

The rapid development of **electronic medical documentation** has enabled simultaneous access to documentation from various places (ambulance, hospital unit, and even operation theater), access to data from different viewpoints (by chronology, by organ systems, by medication, or by decisions made), highly structured data input, easy access to data, support to data analysis, and rapid electronic data exchange. A great challenge for electronic documentation is data stored in the format of free text that can not be coded, such as physician's observations on patient status, and which are sometimes more informative than coded, standardized information. This is why traditional paper documentation still has some advantages: it can be easily transported; data input is not highly structured enabling great freedom in writing data; medical staff need only basic education; it is a source for supporting patient care, research, and educating clinicians; it forms a basis for healthcare management and services; and it represents a legal report of medical actions (Van Bemmel 1997).

Crude, unprocessed, direct data collected from patients are not always represented in a way that enables information production. In order to generate information from data, we need data **processing**. This process is usually referred to as **coding/classification**. Medical records are coded to enable reporting, compiling, and comparing of health care data. Coding is defined as classifying data and assigning a representation for that data; it is the assignment of a specific code to a nar-

rative statement of diagnoses and procedures (WHO 2003). Data **computation** means mathematical or statistical analysis of the data (e. g. computation of Body Mass Index from body weight and height). Finally, we must bear in mind that health data are dynamic, that old values are changing, and new data are generated. Therefore, the process of data **update** must be performed regularly.

The final step in the evolution of data into information (Fig. 1) is ► data dissemination and utilization. Information does not exist without its users. **Users** of information are (WHO 2003):

- Physicians, nurses, and other health care professionals, who use information in the process of decision-making on the health status of patients and the population;
- Citizens – patients themselves, whose information forms the main part of their medical records;
- Health insurers, who require information to reimburse the health care facility for services rendered for every patient;
- Ministry of health, to review vital statistics and the incidence and prevalence of disease in a city, state, or country. The provision of accurate and reliable aggregate data is important for public policy development and funding of health care services;
- Legal representatives and courts, to protect the legal interests of the patient, physician and other health care professionals, the health care facility, and the public;
- Health educators and researchers, to analyze and interpret data to determine causes, prevention methods, and treatments for diseases, injuries, and disabilities;
- National governments who use the information to develop health care policy and provide and regulate funds;
- Media reporters, whose activities account for a considerable amount of the dissemination of information.

If useful information can not be retrieved then its acquisition can not be justified. ► Information retrieval systems are large, complex, heterogeneous, and loosely structured systems (such as journal articles, book sections, images, audio or video clips, and executable programs), in comparison to database systems that tend to be small and simple (birth dates, diagnostic codes, lab results, and drug prescriptions) (Gardner 1997).

Data and information can be **presented** in several forms: as tables, graphics, images, video, sounds, signals, etc. Creation of information from complete, correct and up-to-date data is not the last step in the evolution process described above. Once it evolves, information needs to be distributed, presented, and used. Furthermore, by synthesizing information from different sources to produce a concept or idea we create knowledge.

As mentioned above, we are living in an era in which the main world resource is knowledge, as expressed by Peter Drucker (2001): "In today's economy the most important resource is no longer labor, capital or land – it is knowledge" (The Knowledge College 2001).

The distribution of knowledge worldwide is enabled by the development of **communication technologies**. ► Communication represents the process of exchange of information, thus supporting contact between various users of information.

Although the most common type of communication in health care is mail, and in some countries the only type, this kind of communication is slow, and doesn't satisfy the need for accurate, up-to-date information. However, the flow of information is getting faster with the use of e-mail, electronic data interchange, and network technology. Advances in information and communication technologies make the global distribution of knowledge seem effortless. Technology, specifically the World Wide Web, enables information to be made available to multiple users the instant it is produced.

The process of delivery of health related services and information via telecommunication technologies is defined by the term ► telehealth (Wikipedia). In clinical medicine, telehealth technologies are used for the transmission of medical images for diagnosis (store or forward telehealth), transmission of medical data for diagnosis or disease management, exchange of live health services or education via videoconference (real-time telehealth), etc. Non-clinical uses of telehealth technologies include: distance education (continuing medical education, patient education, etc.), administrative uses such as meetings among telehealth networks, presentations, supervisions, and research.

The development of telehealth enables access to any knowledge, anytime and anywhere, speeds up the availability and spread of information, saves time, enables cooperation among colleagues and groups, and improves the quality of decisions.

► Telemedicine can be generally defined as "**medicine at a distance**" (Wootton 1996). Since telehealth is understood as the integration of telecommunication systems into the practice of protecting and promoting health, telemedicine is the incorporation of these systems into curative medicine.

The primary purpose of telemedicine is to enable access to specialized health services to people in distant and isolated places – teleconsulting (► teleconsultation). Teleconsulting has recently been used in surgery, for transmitting angiograms to vascular surgeons for consultation; and ophthalmology, for transmitting retinal images to the ophthalmologist using a retinal camera. Other examples of telemedicine include teleradiology – transmission of radiographic images to a radiologist for interpretation; telepathology – transmission of pathohistological samples for evaluation; teledermatology – transfer of images of pigmented skin lesions, including clinical and anamnestic data; and telepsychiatry – transmission of diagnostic and treatment information via audio-visual communication.

The terms ► e-Health and telemedicine are at times used interchangeably with telehealth. Like the terms "medicine" and "health care", telemedicine often refers only to the provision of clinical services, while the term telehealth can refer to both clinical and non-clinical services such as medical education, administration, and research. e-Health is used as a term that includes telehealth, electronic medical records, and other components of health information technologies.

e-Health is sometimes defined as "the use of the Internet or other electronic media by patients and the public to disseminate or provide access to health and lifestyle information or services" (Wyatt 2005). This differs from telemedicine, in which there is a health professional at one or both ends of the communication.

It appears that, in the United Kingdom, the development of e-Health has enabled better information to be available for patients and the public and better communication of patient information within the primary health care team, leading to fewer phone calls and appointments, and improved adherence to treatment (Wyatt 2005).

In the near future, e-Health implementation will be facing various challenges. Since e-Health provides simple, easy access to health information, support services, and goods, will it lead to the loss of the general practitioner's role as a mediator in health care? For example, a patient and specialist could email each other directly, or a patient could seek advice on the Internet rather than visit a physician; however, this risks possible exposure to false or incomplete information. Another issue might be the responsibility of the physicians to respond to patient emails promptly, raising questions concerning the moral or professional grounds of such responsibility and what sanctions would be enforced if this duty was neglected, as well as how the duty would be handled during holidays (Eng 2001).

Several societal issues will also need to be addressed: the quality of e-Health information and communication, privacy and confidentiality, clinical appropriateness, public policy, cost and financing, and resource distribution. Public services must clearly define the implications of these technologies for health care and public health systems in terms of quality, access, and cost, and must establish and adopt standards and guidelines for their appropriate use (Eng 2001).

There is a clear potential conflict of interest between patients, about whom information is collected, and health care providers, stakeholders, and society, who might benefit from access to information for commercial and purchasing reasons (Department of Health and Human Services 2000). ► Consumer protection measures will have to be undertaken in order to protect patient from commercial suppliers who can influence and even mislead them. The fact that patients have trouble accessing their medical information while that very information is being used for unregulated secondary uses has exacerbated worries about the confidentiality and proper use of medical records. Wyatt has proposed the term "e-Health nightmare" to describe a consumer's irrational fear of information technology and e-Health care. This fear, sometimes supported by the media, might even lead to the rejection of information technology advances in health care (Wyatt 2005).

Giving patients control over allowing permission to view their records – as well as over their creation, collection, annotation, modification, dissemination, use, and deletion – is key to ensuring patients' access to their own medical information while protecting their privacy. Patients have the right to understand and control their health information in several forms (Department of Health and Human Services 2000):

- Patient education on privacy protections. Health care providers are required to give patients a clear written

explanation of how they can use, keep, and disclose their health information.
- Ensuring patient access to their medical records. Patients must be able to see and get copies of their records, and request amendments. In addition, a history of most disclosures must be made accessible to patients.
- Receiving patient consent before information is released. Patient authorization to disclose information must meet specific requirements. Health care providers who see patients are required to obtain patient consent before sharing their information for treatment, payment, and health care operations purposes. In addition, specific patient consent must be sought and granted for non-routine uses and most non-health care purposes, such as releasing information to financial institutions and parties determining mortgages and other loans, or selling mailing lists to interested parties such as life insurers. Patients have the right to request restrictions on the use and disclosure of their information.
- Ensuring that consent is not coerced. Health care providers can not condition treatment on a patient's agreement to disclose health information for non-routine uses.
- Providing recourse if privacy protections are violated. People have the right to complain to a covered health care provider about violations of the provisions of this rule or the policies and procedures of the covered entity.

Health Information System

An information system is a technologically implemented medium for information recording, storing, and dissemination, as well as for drawing conclusions from such information. The ► health information system (HIS) is an information system for processing data, information, and knowledge in health care environments. The goal of a HIS is to use computers and communication equipment to collect, store, process, retrieve, and communicate patient care and administrative information for all hospital-affiliated activities, and to satisfy the functional requirements of all users. Therefore, a HIS has several functions (Van Bemmel 1997):
- support of day-to-day activities;
- support of the planning and organization of these day-to-day activities;
- support of the control and correction of planned activities and their costs, in view of agreements on medical and financial policies (management control);
- support of clinical research through use of the HIS database, which is particularly important for university hospitals.

Health information systems should address several domains (AbouZahr 2005):
- health determinants (socioeconomic, environmental, behavioral, and genetic factors), and the contextual and legal environments within which the health system operates;
- inputs to the health system and related processes, including policy and organization, health infrastructure, facilities and equipment, costs, and human and financial resources;
- the performance or outputs of the health system such as availability, quality, and use of health information and services;
- health outcomes (mortality, morbidity, disability, well-being, disease outbreaks, and health status);
- health inequities in determinants, coverage and use of services, and outcomes, including key stratifiers such as sex, socioeconomic status, ethnic group, and geographical location.

The classification of information systems is made by size, complexity level and fields of application (Van Bemmel 1997):
1. by size – systems can be local, institutional, regional, national, and international;
2. by structure – centralized or distributed;
3. by field of application: health information systems, medical research information systems, and medical education information systems.

Health information systems can be further divided into primary care information systems and hospital information systems, according to the levels of health care organization, and even further divided by subsystems into information systems of specific departments (radiology, laboratory, intensive care units, etc.)

A ► primary care information system has been developed in the Netherlands, Great Britain, and Scandinavian countries, where more than 80% of physicians use personal computers to communicate with colleagues and other levels of health care. Since primary health care is the point of first contact of the patient with the health care system, information systems on this lev-

el must fulfill the requirements for several tasks: electronic record keeping, organization of everyday administration, financial activities, reporting, statistics, and research.

The main purpose of the ► hospital information system is to support hospital activities on an operational, tactical, and strategic level. This system should enable more efficient use of limited resources in the health system, improvement in the quality of services offered by the health facility, support to research, and support to the undergraduate and postgraduate education of health professionals.

In order to satisfy these functions, hospital information systems must be equipped with electronic databases; applications for data access, retrieval, presentation and distribution; communication technologies; and terminals for data use. The future of these systems will be a detachment from isolated hospital information systems, moving toward "broad-spectrum" health information systems, created, accessed, and used by all providers of health services.

► Medical research information systems enable health professionals to stay up to date with current medical investigations. One of the well known databases of biomedical literature is Medline, updated by the National Medical Library of the USA. It indexes over 600 000 papers a year, published in medical journals. Intense flow and exchange of information in recent decades has resulted in the development of "evidence-based medicine". A new discipline, evidence-based medicine is based on systematic searches for evidence in medical investigations. As a consequence, the process of decision-making can not be based on intuition and the non-systematized clinical experience of a physician. Evidence-based medicine demands new skills from the physician who must be trained for efficient searching of medical literature and application of formal rules in the process of offering evidence based on critical evaluation of such literature.

► Medical education information systems provide easier learning and assimilation of knowledge from various fields of medicine and health care. They were enabled by the development and availability of multimedia (the Internet), and decrease in the price of computer technology (hardware and software) and printed publications (encyclopedias, dictionaries, handbooks, textbooks, and journals).

Advanced Applications of Health Information

Public health has been defined by the World Health Organization as "the art of applying science in the context of politics so as to reduce inequalities in health while ensuring the best health for the greatest number" (WHO 1998). Broadly speaking, the practice of public health may be defined as the organization and analysis of medical knowledge in such a way that it may be utilized by society for decision-making in health related questions.

► Public health departments play an important role in the collection and dissemination of national health statistics, which must be accurate, clear, concise, and understandable. The core activities of public health include (WHO 2003):

- collection, analysis, and dissemination of quality statistical information on the health status of the population, the availability of health services, and community-based immunization and health screening programs;
- development of public health policy at state, province and national level;
- development of quality assurance programs to monitor the collection of accurate and appropriate data and policy decisions;
- compilation and publication of statistics on the health of particular population groups, such as children (including infants and babies), women, indigenous people, and ethnic groups; and
- analysis of trends in mortality within the community and country.

Public health agencies are mandated to protect and improve the health of all people within their legal jurisdiction through surveillance of health trends, regulation, health promotion, and disease prevention. These highly information-dependent functions are generally performed in partnership with health care providers and organizations, which themselves depend on public health surveillance and guidance. Public health participation in health information exchange is likely to result in reduction of the costs and increase of the speed of health services.

Many countries have their own government agencies, usually Ministries of Health, which should respond to domestic health issues. In the United States, the frontline of public health initiatives is the Centers for Disease Control and Prevention in Atlanta.

The ten essential services developed by the National Public Health Performance Standards Program for the Centers for Disease Control and Prevention are (Centers for Disease Control and Prevention 2006):

1. Monitor health status to identify and solve community health problems,
2. Diagnose and investigate health problems and health hazards in the community,
3. Inform, educate, and empower people about health issues,
4. Mobilize community partnerships to identify and solve health problems,
5. Develop policies and plans that support individual and community health efforts,
6. Enforce laws and regulations that protect health and ensure safety,
7. Link people to needed personal health services and assure the provision of health care when otherwise unavailable,
8. Assure a competent public and personal health care workforce,
9. Evaluate effectiveness, accessibility, and quality of personal and population-based health services,
10. Research for new insights and innovative solutions to health problems.

Based on these essential services, this program identifies public health activities that should be undertaken in all communities.

Health protection is everything that a state or community, as well as social services, do in order to protect and improve the health of the population. The main task of the health system is to provide health services. The human, financial, information, and technical/material resources of a health system merge to provide health services. Ensuring equitable, universal access to health care – whether preventive, promotive or curative – is a key objective of health systems (WHO 2004).

► National Health Service delivery is usually divided into various levels of health protection. Generally, the classification of health protection is on three levels: the first level of health protection is primary prevention, referring to health promotion, protection, and prevention of disease; the second level is secondary prevention referring to early diagnostics and in-time treatment; and the third is tertiary prevention, related to rehabilitation after disease.

Activities and measures provided by the National Health Service according to the levels of health protection include:

1. On the level of health promotion and protection – general and personal hygiene, adequate food and water supply, physical activity, environmental protection, avoidance of risk behavior, and general and health education,
2. On the level of disease prevention – immunization, disinfection, pest eradication, occupational and environmental health prevention, and genetic counseling,
3. On the level of early diagnostics – screening and selective examinations,
4. On the level of disease treatment – pharmacological and surgical treatment, etc.,
5. On the level of rehabilitation – social integration, professional re-education, re-employment, and occupational therapy in hospitals.

The National Health System provides other important services specifically for vulnerable population subgroups:

1. For women during pregnancy and after childbirth – obligatory physical and ultrasound examinations during pregnancy, assisted childbirth in hospital units, medical examination after delivery, patronage visits, laboratory examinations, and genetic counseling;
2. For newborns and infants – systemic examinations in the 3rd, 6th, 9th and 12th month of life; screening for phenylketonuria and hip dislocation, and obligatory active immunization;
3. For young children – systemic examinations in the 2nd, 4th, and 6th year of life, and screening for hearing loss and eyesight impairment;
4. For school children – obligatory systemic examinations at the age of 7, 9, 11, 13, 15, and 17;
5. For students – systemic examination at enrollment, and reproductive health counseling;
6. For the elderly – patronage nurse visits, home care, and clubs for the elderly;
7. For disabled persons – prevention of injuries and accidents; prevention of stress and mental disorders; prevention of chronic degenerative disorders; early diagnosis and treatment of chronic diseases; rehabilitation, social integration, re-education, re-qualification, and employment; provision of orthopedic

facilities, physical therapy, psychological counseling, and social worker services; and special education of deaf, blind, and mentally retarded persons.

► Health indicators are instruments used for the measurement of health status. The World Health Organization has defined health indicators as "a construct of public health surveillance that defines a measure of health (i. e., the occurrence of a disease or other health-related event) or a factor associated with health (i. e., health status or other risk factor) among a specified population." (Pan American Health Organization 2001). In general terms, health indicators represent summary measures that capture relevant information on different health attributes and dimensions, and the performance of the health system. Taken together, these measures attempt to reflect and monitor the health status of a population. Most indicators are quantitative (represented by absolute or relative numbers), but there are also qualitative indicators (statements that something exists or not, or the gradations of an event – good, neutral, or bad, etc.). The Health Monitoring Programme under the European Commission has financed a project to establish a health indicator set with the primary purpose of measuring health status, its determinants, and the trends therein throughout the European Community (EC) in order to facilitate the planning, monitoring, and evaluation of EC programs and actions, and to provide member states with appropriate health information to make comparisons and support their national health policies (European Commission 2005).

Main categories for the ECHI (European Community Health Indicators) indicator set are (European Commission 2005):

1 **Demographic and socioeconomic factors:**
   - 1.1 Population: birth and death rates, net migration, total fertility rate, mother's age distribution, annual in(de-) crease of population in %, median age of population, etc.;
   - 1.2 Socioeconomic factors: national income per capita, total unemployment, total labor force, population by employment type, population by occupation, population by education, population in poverty, etc.

2 **Health status:**
   - 2.1 Mortality: life expectancy, infant mortality, perinatal mortality, mortality of children aged 1 to 5, specific mortality rates by causes of death;
   - 2.2 Morbidity: incidence and prevalence rates, disease-specific morbidity, prevalence of long term disability;
   - 2.3 Generic health status;
   - 2.4 Composite health status measures: Quality Adjusted Life Years (QALY); Disability Adjusted Life Years (DALY), Healthy Life Expectancy (HALE), Potential Years of Life Lost (YLL).

3 **Determinants of health:**
   - 3.1 Personal and biological factors: body mass index, blood pressure, breastfeeding;
   - 3.2 Health behaviors: regular smokers, total alcohol consumption, intake of fruit and vegetables, physical activity, use of illicit drugs;
   - 3.3 Living and working conditions: total size of residence per person, rate of building, percentage of comfort apartments, adequate food and water supply.

4 **Health systems:**
   - 4.1 Prevention, health protection and health promotion: immunization coverage, breast cancer screening, preventive activities, treatment of the most common diseases, provision of medicines;
   - 4.2 Health care resources: availability of health care – number in the population divided by number of health workers or health institutions;
   - 4.3 Health care utilization: number of services per resident; rate of hospitalization; hospital beds per 100000 population; physicians per 100000 population; number of nurses per 10000 population; number of health workers, nurses and midwives per physician; in-patient care admissions per 100 population; average length of stay in hospital;
   - 4.4 Health expenditures and financing: insurance coverage, expenditures on health;
   - 4.5 Health care quality/performance: end product of health service, consumer satisfaction.

The term ► international health service refers to all activities in the field of prevention, diagnosis, and treatment of diseases, requiring the combined discussion and actions of more than one country. The multifaceted nature of health and the multisectoral interactions that influence it have induced an increasing number of organizations to become active in the health field.

The need for international health cooperation has been recognized for years due to the fact that diseases are enhancing the borders of single countries, such as epi-

demic infective diseases and non-communicable diseases. Globally speaking, the health status of many populations has been significantly improved in the 20th century, following the improvement of socioeconomic standards, and technological and pharmacological developments in the field of health care. Still, the need for international cooperation exists due to occurrence of similar problems in some countries: poverty, malnutrition, infective diseases, and early death. Health services need international guidelines for diagnosis and treatment of diseases, standards for drug and medication registration and trade, and international regulations for quarantined diseases, etc.

International health services can be organized into several categories (Frenk 1997):

- Surveillance and control of diseases that represent a regional or global threat, including exchange of information about the incidence of epidemic diseases, provision of uniform regulations about quarantines, and uniform medical documentation;
- Promotion of research and technological developments related to problems of global importance, including establishment of mechanisms for exchange of information and experiences;
- Development of standards and norms for international certification and other global issues, such as standardization of vital statistics, trade with biological tissues, and hazardous drug registries, etc.;
- Assistance for health services in solving problems, including epidemics control, health service planning, and training of health staff;
- Advice to governments and health ministries related to international health issues such as malaria, AIDS, hemorrhagic fever; development of social medicine, improvement of living conditions, sanitation, nutrition, and water supply;
- Protection of international refugees.

Many international agencies, both governmental and nongovernmental organizations, are involved in international health services: the World Health Organization (WHO), the United Nations Children's Emergency Fund (UNICEF), the International Labor Organization (ILO), the United Nation's High Commissioner for Refugees (UNHCR), and the Council for the International Organizations of Medical Sciences (CIOMS), to name just a few.

The WHO is taking a proactive role in defining actions that will ensure tangible improvements in the health of populations. Since the first International Conference on Primary Health Care in Alma Ata in 1978, the WHO has been committed to the health movement "Health for All". The Regional Office for Europe adopted a long term European strategy "Health for All" in 1980, and expanded it in 1998 into a policy named "Health21 – health for all in the 21st century" (WHO 1998). The two main aims of this policy are to promote and protect people's health throughout their lives, and to reduce the incidence of the main diseases and injuries and alleviate the suffering they cause. Twenty-one targets for Health for All have been set, which spell out the needs of the European Region and suggest necessary actions to improve the situation. They are not meant as a prescriptive list, but together they make up the essence of the regional policy. They provide a framework for action for the region as a whole, and an inspiration for the construction of targets and development of health policies in the countries of the European Region.

From the outset, the WHO's closest collaboration has been with UNICEF. The role of UNICEF in health programs is to provide the required supplies and services in practically every field of interest to child health – e. g. the campaigns for BCG vaccination, the program for the supply of streptomycin and malaria projects, the projects on maternal and child health, nutrition, environmental sanitation, aid to hospitals, and milk hygiene, etc. The United Nations Educational, Scientific and Cultural Organization (UNESCO) is collaborating with the WHO on studies of education combined with community development, including studies of school health, health training for teachers, and teaching of social sciences (WHO 1998).

New partners on the health scene, both from the United Nations nongovernmental organizations, have brought new challenges to the WHO, which now has to maintain its role as the directing and coordinating authority in international health work. New challenges make it essential for the WHO to strengthen its leadership role in the new millennium.

Summary

Health informatics is a rapidly evolving discipline. The primary goal of health informatics is to solve scientific and practical problems. One of the greatest challenges is to simplify the process of data collection and creation, its transformation into useful information, and

finally the conversion of information into knowledge. A second task is to produce usable standards to represent data, information, and knowledge in such forms that enable their adequate application. Health informatics must provide good communication and interactions between users and the computer that would be free, informal, and safe at the same time. Since we do not fully understand the process of decision-making based on knowledge on one side and medical data on the other, the creation and modeling of knowledge represents both a scientific and a practical challenge. Implementation of hardware and software technology and the integration of existing systems is yet another challenge (Greenes 1998).

The main purpose of health informatics should be the improvement of health, addressing the needs of individuals, the population, health services and health professionals. This goal can be achieved in several ways: when applied in clinical practice, health informatics is used for the creation of electronic medical documentation, for monitoring devices that record vital signs, for image processing and analysis, for computer support to medical documents, and for hospital information systems.

Its application in health administration enables tracking of patients within the hospital, automated staff scheduling, cost analysis, managing materials and inventory, automatic billing for supplies, quality assurance, and outcome analysis.

Informatics supports the continuous education of health professionals, including web-based education, enables distance learning via teleconferencing, and supports the development of evidence-based medicine. Health informatics is also applied in research, analyzing the outcomes associated with treatments and procedures, performing quality assurance, and in the implementation of various treatment protocols, etc.

The use of valuable information improves health services, especially preventive services, and, furthermore, information provided to consumers guides their choice of health plans. With regards to clinical systems, informatics supports the process of decision-making for both healthcare providers and patients (O'Carroll 2003).

All in all, health informatics serves to improve health. The main cornerstone of this science is information, highly supported by computer technology that improves its flow, making it accessible, usable, and meaningful.

Health Information Management

Definition

Health information management is the job of handling the information requirements of a health care organization, including development, integration, evaluation and quality assurance of ► health information systems in health care.

Health Information System

Synonyms

Healthcare information system; Patient-care information system; Medical information system

Definition

A health information system (HIS) is an ► information system for processing data, information, and knowledge in health care environments. It can be defined as an integrated effort to collect, process, report, and use health information and knowledge to influence policy-making, program action, and research.

Basic Characteristics

Development of Health Information System

Branches of health information systems are ► primary care information systems (information systems supporting primary health care), ► hospital informa-

tion systems (information systems supporting clinical work), public health information systems, geographic information systems, ► medical research information systems, ► medical education information systems, ► medical management information systems, etc. (► health information).

To initiate the development of new information systems, the World Health Organization proposes the following steps: first of all, the organization must identify the goals, desired outcomes, and the functional requirements of the system needed for healthcare. The information management team must set the technical program of information requirements, specify the criteria of the information technology architecture, and determine how the information technology will be implemented. Furthermore, all key stakeholders must be included in the project in order to ensure that the system will meet all their needs. And finally, the team must commit to a long term project with appropriate budget funding (WHO 1993). However, during the process of development, the information management team is faced with a dilemma—whether it is better to use a home-grown information system that will be sustainable in the long run, or to apply a system already available on the market without any changes. This issue might be solved by considering the main characteristics of the systems available on the market, including their costs or applicability to the present needs, and if these requirements are not met, development of a new information system must be considered (Berg 2004).

Healthcare and health services are constantly changing. Paper-based medical documentation is being abandoned while computers and new technologies are being included in healthcare; therefore the need for functionality in using patient data or medical knowledge for decision making has become predominant. Furthermore, since patients' rights have been recognized and are now respected, a new challenge for health information systems is that they must switch orientation from the healthcare system toward the health ► consumers (Haux 2006).

Implementation of a Health Information System

In the process of implementation of a system, the Public Health Information Institute recommends some guidelines to be followed (Public Health Information Institute 2004):

1. Engagement of all work process experts—everyone affected by a health information system must participate in the program of developing a HIS—public health program experts, information technology experts, healthcare providers, administrators, policymakers, and the business community, as well as the people in the community.
2. Analyzing the logical principles of information systems—understanding the processes and defining system requirements before physical implementation are the most important steps in developing or acquiring any information system.
3. Assuring interoperability—exchange of health information between all users of the system: public health departments, medical care providers, hospitals, laboratories, pharmacies, community agencies, etc.
4. Management for accountability—analyzing the capability of the system to meet the requirements of all users, accounting for the requirements in financial resources and time needed to complete the project.

Successful implementation of a system has many dimensions: effectiveness, efficiency, organizational attitudes and commitment, worker satisfaction, and patient satisfaction, and must be understood as a dynamic process. When implementing a health information system, health professionals must keep in mind that:

- Implementation is not only the technical realization of the system—the technology will inevitably affect the distribution and content of work tasks (change the recording practices), change information flows, and alter the relationships between healthcare professionals and other staff (raising the question of access to data). Physicians may feel oppressed by the need to be more structural and precise in their work.
- Implementation should not be managed by the information technology department—it is important for all users to understand the system, and to express their needs for the design, implementation, and improvement of the system.
- Implementation can not be fully planned and controlled. Health services might change, the mode of data collection might change, and the needs of health professionals might change, and so a system must have the capacity to be redesigned and reengineered in order to survive for years (Berg 2004).

Evaluation of Health Information Systems

The process of evaluation should follow several steps, and each step must be carefully planned and accomplished (Ammenwerth et al. 2003; Wyatt 2003; Berg 2004):

1. Goal of the evaluation—the goal of the evaluation is comparison of the situation before and after implementation of the HIS.
2. Time of the evaluation—recommendations are that the general intention of the evaluation and the starting point should be decided early in the life cycle of information technology.
3. Domains to evaluate—the areas of evaluation should be restricted to aspects which can be measured with the available resources. A complete evaluation of all aspects of a system is usually not feasible. Systems include many domains: the technical performance of the system—compatibility with other systems, upgradeability, maintenance, adaptability, etc; the professional domain—the impact of the system on professional work, user-friendly applications, supporting professionals' needs, and making work easier; the organizational domain—impact on the work process and organization as a whole, impacts on organizational strategy and health services provided, adjustments of the organization needed for implementation, and unexpected negative effects; the economic domain—the costs of buying the system, training personnel, and maintenance, and the expected benefits; the ethical point of view—effect of the system on the doctor-patient relationship and decision making, and the data security issue; and the legal features—legal status of patient data.
4. Study approach of the evaluation—when issues to be evaluated are determined, and when all stakeholders agree on the goals of evaluation, then the evaluators should define the most appropriate design of the study, relevant study questions, and outcome variables in detail.
5. Analysis and reporting—data interpretation depends on the material collected. It is recommended that different reports are produced for different stakeholders, reflecting their needs and perspectives.
6. Recommendations for further actions—both positive and negative results must be published in order to stimulate improvements and further development.

Failure of Implementation of Health Information Systems

Defining failure or success of the information system may be difficult because failure may look like success from one perspective, and vice versa from another. When an information system is implemented and major goals are met without the occurrence of any undesirable outcome for a long time, then implementation of the system must be considered successful (Littlejohns 2003; Heeks 2006). Failure may be attributed to several reasons:

- Failure to include healthcare professionals in the process of design and implementation, so that the system does not meet all of their needs.
- Failure to recognize the need for quick implementation in the healthcare sector, where management and responsibilities are changing.
- Failure to take into account the social and professional cultures of health organizations, or failure to provide adequate training and education of healthcare professionals.
- Failure to motivate healthcare professionals to adapt to the system in the atmosphere of anxiety and time pressure they are in, especially if the system is difficult to operate.
- Failure to learn from previous mistakes, usually as a consequence of failure to grasp an "overall view" of healthcare interventions in terms of cost, effectiveness, professional satisfaction, etc. When only selected professionals (e. g. information technologists, economists, etc.) are assigned to develop an information system they may not be able to take an objective view of other aspects of the system. They may be able to comprehend only the positive aspect of the system, rather than its disadvantages or negative aspects; this phenomenon is referred to as "my baby" syndrome (Littlejohns 2003).

Public Health Information Systems

Public health is a discipline that has made dramatic advances in recent years. Thanks to developments in public health, many health problems can be analyzed and understood from the perspective of the population. Public health is in great need of information systems that can be used for continuous monitoring of public health events, planning and surveillance of public health programs, financing and management in public

health, and health research (► public health information system) (AbouZahr 2005).

Geographic Information System

A ► geographic information system (GIS) is computer software developed for the input, analysis, and use of geographic data in public health. In the field of public health, GIS systems have provided a means to analyze data from a much more sophisticated perspective. In addition to being able to assess disease of the population by location, these systems have provided the means to analyze spatial and temporal relationships between variables, allowed users to identify spatial patterns in data, and have provided the means to integrate databases on the basis of geography (Richards et al. 1999). An example of the use of a geographical information system is for the assessment of exposure to environmental health hazards. A main advantage in using a GIS for exposure assessment is the possibility of modeling exposure geographically, so that individual exposure may be estimated without the need for time-consuming and expensive measurements (Jarup 2004).

Community Health Management Information System

The need for integrating all health systems into one information network has resulted in the development of the ► community health management information system (CHMIS), an electronic network linking all community stakeholders—healthcare providers, consumers, providers, purchasers, payers, and researchers—in a given community. Its main purpose is for the aggregation and exchange of information across the community in order to assure better performance in the health sector (O'Carroll et al. 2003).

Conclusions

Health information systems are rapidly increasing in variety, size, complexity, and sophistication. Health information systems are not limited to ► hospital information systems, but are expanding to worldwide networks, whose users can be patients, healthcare professionals, system operators, administrators, or researchers. With an increasing pressure on health services, public health, and health policy makers to improve population health with limited financial resources, health information systems can provide strong support to their activities in primary health care, clinical work, research, and education.

Definition

Health insurance is a system of protection which provides financing of health care (hospital, physician or medical expenses and treatment) in case of sickness or injury. Among other types of financing health care (for example taxation and ► direct payments), the insurance principle is employed in many countries through various forms. The organization of health insurances, their membership and funding mechanisms as well as their scope of financing varies from country to country. However, two types of health insurance models are predominant: the social health insurance characterized by the presence of sickness funds receiving a contribution of their member's wages and the private health insurance receiving premiums according to the risk profile of the insured.

Basic Characteristics

Health Insurance in the Context of Health Policy

In a majority of countries around the world, policymakers are concerned by an issue of paramount importance: how to ensure that all people in a country have access to health care when they need it? There are three main options for policymakers to design a system of health care:

1. tax-based health care system:
   In tax-based health care systems, individuals contribute to the provision of health services through taxes on income, purchases, property, capital gains and a variety of other items and activities. These taxes are typically pooled across the whole population. The government is in charge of the provision of health care services, usually from a mix of public and private providers and allocates the existing resources to the different areas of health care. Examples for health care systems mainly based on taxation are the United Kingdom, Ireland, Spain and Portugal, Denmark, Sweden and Finland.
2. social health insurance system:
   In social health insurance systems, contributions from workers, the self-employed, enterprises and the government are pooled into a single or multiple sickness funds on a compulsory basis. These so-called statutory sickness funds are either run by the government or by independent non-profit organizations. They typically contract with a mix of public and private providers for the provision of a well defined health care benefit package. Examples of countries with a social health insurance system are Germany, France, the Netherlands and Belgium.
3. private health insurance system:
   In private health insurance systems, premiums are paid directly by individuals, employers or associations to insurance companies, which pool risks across their membership base. Private health insurance can be a complete substitute for social insurance, typically found in market-based systems such as the US. They can also supplement an existing social insurance system as it is the case in France, Belgium and the Netherlands. Private health insurance is in general voluntary in contrast to social insurance that tends to be compulsory. However, in some countries private insurance may also be compulsory for certain segments of the population (for example the formal, employed sector).

To reach universal coverage, many countries opt for a mix of tax-based and private insurance health care systems or a mix of social and private insurance, mostly together with ► direct payments or so-called ► co-payments for services that are not covered by the insurance.

Comparison of Social and Private Health Insurance

Social health insurances and private health insurances are the two main types of health financing systems that

see the idea of insurance as superior to the idea of general taxation.

However the two types differ in many aspects:

(a) Contributions: The social insurance is organized along the ► principle of solidarity as contributions represent a percentage of the income that is generally paid partly by the employee and partly by the employer. Children or unemployed family members are typically free of contribution. The system aims to balance the different economic situations of their members. The private health insurance calculates its contributions with respect to the individual risk situation of the insured according to the ► principle of equivalence. Children and other family members contribute individually. The economic situation of the insured is not taken into account.

(b) Provision of health care: The social insurance works on a 'payment in kind' or third party payer principle, i. e. the insured do not have to pay the received health care services as long as they stay in the negotiated framework and social insurance contracts with providers of health care. Private insurance always reimburses the patient's expenses or co-payments. Some private insurance companies contract also with their providers and pay them directly. The scope of the health care provisions is typically higher with private health insurances because the choice of doctors and hospitals is free.

(c) Organization: Social insurance is mostly organized by the presence of several social sickness funds being either governmental agencies or independent non-profit organizations. Private health insurances are private for-profit organizations or companies often providing a wide range of other insurances.

(d) Financing model: The social insurance is typically based on a pay-as-you-go system, which means that all money that is paid into the health insurance system by its members and their employers, is being spent in the same year. The contributions have to cover the benefits in the same period. Private health insurances are typically fully-funded systems which means that the individual premium of the insured is calculated to cover the potential risk of illness for this individual over the whole contract period. Therefore private health insurances are less sensitive to the ratio of contributors to beneficiaries.

Health Insurance in the Context of Rising Medical Expenses and Limited Resources

Health care expenses are rising in almost every country with a health care system of universal coverage due to three main factors:

1. ► medical progress and improvements in technology
2. expansion of coverage by public health systems
3. aging populations in the industrial world with higher levels of ► chronic diseases and ► disability

The funding for the upward spiral of medical expenses is limited in all health care systems: In tax-based health care systems governments are unable to continuously raise the taxes. In social insurance based systems the compulsory contribution has to stay bearable for employees and employers. Private insurance models depend on the willingness of the individual to spend for health care especially if the private insurance comes as a supplement to compulsory social insurance (e. g. France).

In the context of rising medical expenses and limited resources, health insurances are obliged to define a number of measures on the demand and the supply side aiming to reduce medical expenses if a growth in the contribution rate becomes unbearable for the insured.

Demand side measures:

- The benefit package is restricted by the health insurance.
- Patients are asked for ► co-payments that may concern drugs, dentistry charges, spectacles and charges for visits to doctors.
- Health insurance improves the cost-awareness of their members by giving incentives not to consume health care (e. g. premium rewards).

Supply side measures:

- Health insurance sets budgets for hospitals and doctors operating under direct contract.

Global Examples

In some high-income countries general taxation replaced social insurance and in most countries the role of voluntary private health insurance increased moderately. Only a few countries offer private health insurance as a substitute for compulsory social insurance

or a taxed-based health system. In the USA, Germany, Switzerland and the Netherlands, private health insurance is the primary coverage for certain population groups. In these countries, private insurances offer also additional services for those who want to supplement their compulsory social insurance scheme. Countries like France and Belgium offer private health insurance only as a complement to the existing social insurance in order to insure the co-payments.

Most of the low- and middle-income countries have health care systems with very low or incomplete coverage of the population. Some of them are interested in extending their existing health insurance for specific groups to eventually cover the entire population. To reach a higher level of health insurance coverage, some factors are very important: the socioeconomic and political context, the level of income, the structure of the economy, distribution of the population and the possible role the government can play in facilitating the transition to universal coverage.

Definition

Since the distribution of medical spending is highly skewed, health insurance is an important tool for spreading risks. This property of health insurance is considered to be of considerable value, both for individuals and for societies. This value is somewhat reduced by incentive problems of health insurance. Evidence on the health outcome of health insurance is surprisingly scarce. However, research from the US shows unambiguously that lack of health insurance leads to inferior health outcomes.

Basic Characteristics

The Value of Health Insurance

The value of health insurance is derived from the uncertainty and unpredictability of medical spending. Of any given population, only a very small fraction of individuals incurs a very large fraction of medical spending. The distribution of medical spending at any given time (and over time as well) is highly skewed. Although individuals have some information about their health status and their needs for medical spending, the exact amount is highly uncertain. As a consequence, health insurance is an important tool for spreading risks. This property of health insurance is highly valuable for individuals. Moreover, it is highly valuable from a societal perspective as well. In most developed industrial countries – with the notable exception of the US – comprehensive coverage against the financial risk of medical spending is highly valued by society. Moreover, comprehensive mandatory coverage avoids market failures such as ► adverse selection (► consumer choice).

However, the value of health insurance that is created by the spreading of medical risks is somewhat dimin-

ished by incentive problems caused by health insurance. There is a substantial body of literature in health economics which presumes that the existence of health insurance leads to overspending (Pauly 1968). Individuals with health insurance will use more medical services than they would if they were paying for these medical services themselves (► moral hazard). The term 'moral hazard' does not refer to some moral failure of individuals. It simply implies that individuals adapt their behavior to incentives set by health insurance: "the response of seeking more medical care with insurance than in its absence is a result not of moral perfidy, but of rational economic behavior" (Pauly 1968: 535). Economic analysis of the welfare implications of moral hazard actually led to the conclusion that moral hazard substantially reduces the value of health insurance and consumers might even incur a negative value from health insurance if the ► co-insurance rate is very low (Manning and Marquis 1996). This welfare loss occurs because, under health insurance, patients consume additional services that provide little benefit to them (Rice 2002).

A rather famous natural experiment has found that (higher) coverage of health insurance indeed leads to higher utilization rates of medical services. The RAND Insurance Experiment randomized about 6,000 individuals in six areas in the US into different insurance programs. The insurance programs differed by co-insurance rates – between 0 and 95 percent. Without co-insurance, total medical spending per capita was considerably higher than with some degree of co-insurance (Manning et al. 1987; Newhouse and Insurance Experiment Group 1993). However, the RAND Insurance Experiment also found that individuals are unable to distinguish between highly effective and less effective treatments (Lohr et al. 1986).

The design of health insurance involves a trade-off between spreading risk and appropriate incentives. More generous health insurance spreads risk more broadly but also leads to more overspending due to moral hazard. Several studies simulate optimal co-insurance rates, which range between 25 percent and 58 percent (Cutler and Zeckhauser 2000). From a societal point of view, these co-insurance rates are – at least outside the US – not acceptable. Therefore, most countries accept some degree of moral hazard in order to gain the benefits that are due to risk spreading: "Perhaps the most persuasive empirical evidence regarding the values of health insurance is purchased voluntarily, or provided to the citizens of democratic states. This evidence, represented by the high proportion of US consumers who are insured and the high proportion of developed democracies that have some form of national health insurance, suggests that the value of health insurance is overwhelmingly positive" (Nyman 2006: 102).

Health Insurance and Health Outcomes

It is quite evident that the health consequences of not having insurance at all can be quite dramatic. Research about the consequences of being uninsured in the US has shown consistently that individuals without health insurance receive fewer preventive and diagnostic services, tend to be more severely ill, and receive less therapeutic care. More importantly, having health insurance would decrease the mortality of the uninsured in the US significantly (Hadley 2003).

Evidence on the health consequences of different health insurance programs is scarce and rather ambiguous (Cutler and Zeckhauser 2000). The RAND Health Insurance Experiment has found some relationship between the level of co-insurance and health outcomes – although the findings were less dramatic and less conclusive than the relationship between the level of co-insurance and medical spending. Health outcomes did not differ across plans for most individuals. However, "health among the sick poor – approximately the most disadvantaged 6 percent of the population – was adversely affected … In particular, the poor who began the experiment with elevated blood pressure had their blood pressure lowered more on the free care plan than on the cost-sharing plans. The effect on predicted mortality rates – a fall of about 10 percent – was substantial for this group. In addition, free care marginally improved both near and far corrected vision … and increased the likelihood that a decayed tooth would be filled" (Newhouse and Insurance Experiment Group 1993: 339).

Evidence regarding the health outcomes of managed care insurance is also ambiguous. A review of the empirical literature comparing health outcomes of ► managed care health insurance and ► fee-for-service indemnity insurance did not find clear differences. About half of the studies found that managed care improves health outcome (quality of care) while the other half found that managed care has a negative impact on health outcomes (Miller and Luft 2002).

Indigenous health knowledge; Traditional medicine

Definition

Traditional health knowledge is a dynamic system of distinctive knowledge of health maintenance in indigenous communities developed over centuries through empirical observation, spiritual insight, and traditional teaching. It is used by the majority of the world indigenous population for its affordability, accessibility, cultural beliefs, and efficacy of treatment. Indigenous people have a holistic (► holistic medicine) view of health that takes into account physical, mental, spiritual, social, and ecological dimensions. The value and importance of ► traditional knowledge for public health needs are recognized and evaluated. Traditional knowledge should be protected from disappearance and misuse.

Basic Characteristics

General Description

Traditional health knowledge in general refers to the unique health care experience and practices of indigenous communities. These practices uphold the specific concept of health and disease in a certain community. Local wisdom has accumulated and developed over centuries through naturalistic trial-and-error or investigation, application, modification, and innovation by indigenous and local communities to meet the health needs of their people. Importantly, unlike many Western models of health (► Western medicine), indigenous people's notion of health is often not individu-

al but one that encompasses the health of the whole community and the health of the ecosystem in which they live (Stephens et al. 2005). The indigenous communities tend to accentuate the spiritual, cosmological, and ancestral connection to their knowledge. While this knowledge may be acquired from a teacher and improved through experience, it eventually may be derived through direct communication with the spirit world through dreams, intuition, and visions. Aboriginal knowledge is often conveyed in narrative or metaphorical language.

Traditional health knowledge is highly influenced by the culture and historical conditions within which it first evolved, and as such eludes a precise definition, often containing diverse characteristics and viewpoints. The World Health Organization has adopted a very general definition which describes ► traditional medicine as knowledge based on the theories, beliefs, and experiences indigenous to different cultures, either codified in writing or transmitted orally and used in the maintenance of health as well as the prevention, diagnosis, improvement, or treatment of physical and mental illness. Traditional medicine includes diverse health practices, approaches, knowledge, and beliefs incorporating plants, animals, and/or mineral based medicine, spiritual therapies, manual techniques, and exercises applied singularly or in combination (WHO 2002).

Because of the holistic view of health, indigenous peoples have pluralistic solutions to their health problems that take into account physical, mental, spiritual, social and ecological dimensions of health. Treatment is based in the belief that each individual has his own constitution and social circumstances; therefore, it is designed not only to address the symptoms but also to restore the state of equilibrium within oneself and the environment.

The vast majority of the world's indigenous peoples (about 70%) live in Asia. Two kinds of system in traditional medicine are described in this area. One is the highly developed academic system with rich experience in disease therapy and prevention with theoretical basis, research institutes and established literature. The examples are Chinese medicine or Ayurveda, Unani or Siddha medicine in India, which are already institutionalized. On the other hand, there is a large pool of simple systems practiced by traditional healers in small ethnic groups. However, they are often marginalized, and they lack the respect and recognition from authorities.

Use

The majority of the indigenous population use traditional medicine to meet their primary health care needs. The main reasons for this are *affordability, accessibility, and cultural beliefs*, which are determined by a range of social, economic, geographical, and cultural factors as well as by efficacy of treatment. In some rural areas of Africa the ratio of traditional healers to population is 1:200 in contrast to the availability of allopathic (► allopathic medicine) practitioners, for which the ratio is 1:20 000 or less (WHO 2002). Traditional healers play an important role in the community. Payment for treatment differs, but most healers consider their ability to heal as something given by God, and they cannot accept any money.

In the poor countries, traditional knowledge becomes the only source of health care for the indigenous population. For instance, in Peru, where over 40% of the total population is indigenous, modern health care in many rural areas is completely unavailable. However, the indigenous population still has intimate knowledge of their traditional medicine, which has a history going back at least two thousand years. Elder healers from high altitude villages of the Peruvian Andes and elder shamans and native healers from the Amazon jungle are often sought by poor families for health care and help in need. The role of traditional birth attendants is also extremely important as more than half of all births in rural areas take place in the mothers' own homes. Recently, traditional treatment of infectious diseases is sought even in cases with possible access to pharmaceutical drugs due to a rise in antibiotic resistant bacteria and increasing resistance of the malaria parasite to ► conventional treatment. A successful treatment of drug addictions was achieved by a combination of Western health knowledge and indigenous spiritual healing in the Takiwasi Rehabilitation Centre where the rate of full recovery is around 60%, which is much higher than the recovery rate in the West.

In the wealthy countries, where access to modern health care is available, cultural beliefs play the most important role in the use of traditional knowledge. For example, in Canada at the Withehorse General Hospital, the First Nations innovative program integrates traditional knowledge to ensure quality and culturally sensitive care. The Elders, highly respected for their knowledge and recognized by their communities, are involved in

all aspects of the program, and patients can choose to receive a traditional treatment in a special healing room. With the imposition of ► Western medicine came the criminalization of the practice of traditional Inuit midwifery, and expectant mothers are still evacuated thousands of miles to give birth in the hospital. However, this is linked to a decrease in birth weight or an increase of birthing complications, and currently there is an interest in the reintroduction of traditional midwifery and "bringing birth back to the community" (NAHO 2005).

In traditional Chinese medicine, as in aboriginal culture, there is no clear distinction between food and medicine. Indigenous peoples have extensive knowledge about the benefits of ► traditional food. A recent study suggests that when aboriginal people return to their traditional ► diet and lifestyle, they can actually begin to reverse the effects of Western problems such as diabetes, hypertension, and poor cardiovascular health (Milburn 2004).

WHO Initiatives

The first international symposium entitled "Traditional Medicine – Its Contribution to Human Health in the New Century" was convened in 1999 and since then many international institutions, universities, research institutes, and regional NGOs have organized workshops, seminars, and conducted research on traditional medicine. In 2002 the WHO elaborated "TM Strategy 2002–2005" concentrated on four main objectives: policy; safety, efficacy and quality; access and rational use of traditional medicine. By 2006 the WHO published over 25 reports on traditional medicine, among them a National Policy on Traditional Medicine and Regulation on Herbal Medicines and a Global Atlas of Traditional, ► complementary medicine and ► alternative medicine. The WHO established a network of the WHO collaborating centers for traditional medicine, of which there are currently nineteen.

Protection

Traditional health knowledge has to be protected for two main reasons:

- possibility of disappearing;
- threat of ► biopiracy.

Despite its importance, traditional health knowledge is rapidly being lost due to a reduced capacity of indigenous communities to conserve their knowledge for future generations. Among the reasons are, for instance, that the younger generation does not want to retain knowledge from the older generation (especially in areas where modern medicine is available) or indigenous knowledge is regarded as a secretive art, and it is not passed between herbalists and traditional healers.

Since the mid 1990s the interest in the potential of traditional knowledge especially for pharmaceutical product development has dramatically increased. The medicinal value of plants is very significant, and indigenous people have traditionally been the ultimate resource for retrieving this extensive range of knowledge for the purpose of application to modern medicine. So far, 25% of drugs used by modern medicine are derived from rainforests; nonetheless, fewer than 5% of tropical forest plant species have been examined (Butler 2005). This leaves great potential for discovery but also the potential for biopiracy – unauthorized patenting of genetic resources.

The protection of traditional knowledge, including traditional medical knowledge, arises under Article 8(j) of the Convention on Biological Diversity (1992) – an international treaty signed by 188 member states of the United Nations by 2006. The World Trade Organization (WTO) and the World Intellectual Property Organization (WIPO) play important roles in protection of traditional knowledge. One problem is that this knowledge, being community-owned and handed down through generations, clashes with international property rights, which view knowledge as owned by an individual or a company.

Both the disappearance and misuse of traditional knowledge could be protected through its systematic collection and documentation organized on a national or a community level.

Here are a few examples:

- In India the Traditional Knowledge Digital Library was developed and 36 000 ancient medicine formulations were translated from Sanskrit to many languages.
- The American Association of the Advancement of Science (AAAS) is working to create an international database of traditional plant knowledge.
- TRAMIL (Traditional Medicine in the Islanders) collected information on the Caribbean ethnomedicines through direct contact with individuals who rely largely on home remedies.

However, very few traditional systems have a fair level of documentation in place and some forms of traditional medicines have largely become extinct.

Conclusion

Considering the growing awareness of the value of traditional health knowledge, and of its importance for public health needs, there is need for significant investment of human and economic resources in the further enhancement of traditional medicine to ensure its efficacy and reliability and to improve delivery. Promoting awareness of the reality behind traditional health knowledge, its importance, the challenges for its promotion, and the need for protection of the populace against malpractice is a task that is being addressed by a number of international organizations.

Synonyms

Medical knowledge, modern

Definition

Western health knowledge is scientific medical information thoughtfully applied in the health care delivery system in a community. This is achieved through knowledge translation and knowledge transfer. Health knowledge translation is the adjustment of health information into a language accessible to a targeting population group. Knowledge transfer is accomplished after identifying data dissemination strategies that enable information to be shared effectively to meet the needs of different groups.

Basic Characteristics

Western Health Knowledge and Indigenous Health

Knowledge is "information combined with experience, context, interpretation, and reflection. It is a high-value form of information that is ready to apply to decision and actions" (Davenport et al. 1999). Health knowledge transferred into action serves as a tool for health promotion and improvement of people's lives.

Western health knowledge is based on solid evidence, efficacy, safety and rational use. It is developed through scientific research: identifying problem, making diagnosis, articulating treatment and raising effective responses. It means that clinical strategy in western medical care is based on the best available scientific evidence (► evidence based medicine). Medicine based on biomedical principles and practiced by holders of a medical degree (M.D.) or doctors of osteopathy degree (D.O.) and by their allied health professionals, such as physical therapists, dentists, psychologists and nurses is called conventional medicine (► conventional treatment), ► allopathic medicine, ► western medicine, mainstream medicine, orthodox medicine,

regular medicine or biomedicine (PAHO 2006). At all levels, modern medicine is an evolving medicine that is open to knowledge and advancement through conventional research.

In the 20th century science has led to dramatic improvements in health worldwide; for example, among public health successes is the global eradication of smallpox or the Framingham Heart Study delineating risk factors for cardiovascular diseases. In spite of these advances, health statuses within most indigenous groups remain poor.

Persistent existence of poor health knowledge, poor quality health service, shortage of professional health care staff and medication shortage are common in many of the remote locations in which indigenous peoples live.

The major health indicators show the significant inequities and the widening health gaps between countries and between the richer and poorer groups within countries. Most vulnerable population groups such as indigenous peoples have less access to health resources, get sicker and die earlier than people in more privileged social positions. Despite the diversity of indigenous people, it may be noted that they share common problems regarding health status and suffer from high child and maternal mortality, infectious diseases and malnutrition. In recent years, the incidence of chronic diseases (cancer, diabetes, obesity and cardiovascular disease), drug and alcohol addictions, sexually transmitted diseases and suicides have notably increased. Health is particularly poor for communities whose original ways of life were destroyed and replaced with a western lifestyle, inadequate housing, unemployment, and high rates of addictions.

Even in the wealthy nations, most studies show alarming health disadvantages for indigenous peoples. In Canada, tuberculosis is affecting Aboriginal Peoples at a rate six times that of the national average, and diabetes rates are as much as four times that of the mainstream population. The life expectancy for Inuit is on average 10 years less than the Canadian average (UN 2005). Pan American Health Organization experts noted that 40 percent of indigenous people in the Americas still lack access to conventional health care services (PAHO 2006).

Most illnesses, especially infectious diseases, are either preventable or to some extent treatable with a relatively small number of medicine. Combined with appropriate public health interventions, appropriately prescribed essential medicines and vaccines could, in principle, massively reduce the impact of disease of communities (UN 2005).

Biomedical discoveries (developing new interventions, drugs, vaccines, devices and other applications) cannot improve people's lives without research on how to apply these to diverse population groups. At present, there is overwhelming dominance of biomedical and clinical research compared to research into social determinants of health and health system research. The main contribution of research to health system is the translation of knowledge into action – using research to shape policies, health practices and public opinion (UN 2004).

Knowledge Translation, Transfer and its Use in the Indigenous Population

Health knowledge translation can be described as alteration or adjusting of health information into a language accessible to a targeting population group. Knowledge transfer can be accomplished after identifying data dissemination strategies that enable information to be shared effectively to meet the needs of different groups. Effective use/application of health knowledge enables to improve health service delivery.

Health knowledge translation and transfer to a variety of indigenous peoples (370 millions, in 70 countries, 5000 languages) are challenging because of their vast diversity including different levels of health literacy. Indigenous communities preserve at least in part their cultural, linguistic and social uniqueness that explains their sensitivity to accept different knowledge. Importantly, unlike many western models of health, indigenous people's notion of health is often not individual, but one that encompasses the health of the whole community and the health of the ecosystem in which they live. Because of this holistic view of health, indigenous peoples have pluralistic and holistic solutions to their health problems, with mix of traditional and allopathic medicine (Stephens et al. 2005). Western health knowledge translation activities have to account for this significant cultural differences including contrasting philosophy of what knowledge is. Biomedical health measures may not be compatible with local understanding of health and local ways of sharing knowledge. Therefore, indigenous communities often reject the imposed

modern health services only because they are misunderstood.

Barriers to uptake and use modern health knowledge are either specific to particular indigenous groups, or are commonly experienced by many such groups. They may exist in the:

- *cultural environment*: cultural belief about appropriate care; traditional beliefs and practices
- *social environment*: low literacy level, health behavior, influence of social trends, inappropriate influence of the media, distrust of western influence (may be related to previous adverse experience of innovation and exploitation), continual marginalization and discrimination, persistent poverty
- *political environment*: political corruption, different priorities
- *health care system:* lack of financial resources, inadequate human resources, lack of access to health care, failure to provide practitioners with access to appropriate information;
- *practitioners*: obsolete knowledge, poor practice organization, beliefs and attitudes
- *patients*: perceptions or cultural beliefs about appropriate care, health literacy

Regarding indigenous groups, any attempt to implement western health knowledge without community support may fail. After developing an appropriate message based on research knowledge it is essential to use credible messengers and proven approaches to transfer message. The message has to identify community beliefs and concerns. The effective way of conveying this knowledge to indigenous communities and establishing mutual understanding is facilitated for instance by:

- special events that bring together researchers, traditional healers and village elders (facilitate communication and bring mutual understanding)
- cultural brokers or indigenous health workers (they have trust of the community and serve as guides of incorporating culturally and linguistically competent health principles, values and practices).

In areas with Internet access e-learning technology assists to improve health knowledge.

Various international organizations, institutions, universities, or NGO's demonstrate the concern for improved health care access, health promotion and endorsement of health literacy of indigenous peoples.

WHO's regional offices play an important role for developing a comprehensive action plan to meet the goal of the Millennium Development Goals (MDG) and organizing activities for western health knowledge dissemination and its implementation in their respective regions.

A few examples:

PAHO (Pan American Health Organization) carried out several events, among them: "Health of indigenous peoples of Americas: Achievements and future directives" (December 2005 Nicaragua) or "The evaluation of the Health of the Indigenous Peoples Initiative within the framework of the International Decade of the Indigenous Peoples of the World", where only 5 of the 19 participating countries reported having scholarships specifically for indigenous students to pursue tertiary education. Most countries described the existence of local networks on malaria, children's health, maternal mortality, HIV/AIDS, and water and sanitation; however, coordination among different indigenous health networks and programs is limited (PAHO 2006).

The UNFPA (United Nations Population Fund) organized a project in Equator, Otavalo through local Jambi Huasi health clinic. Its services were upgraded to provide reproductive health education and information to women, men and adolescents and introduce a referral system for obstetric complications. The education is carried out in a culturally sensitive fashion, taking into account the special needs and concerns of Quechua-speaking natives. This way they are more receptive to the messages and services and, as a result, the contraceptive prevalence rate has climbed from 10 to 40 per cent. Both the infant and maternal mortality rates have fallen (UNFPA 2006).

"Health Unlimited", established in 1984, is the British charity that supports indigenous communities, and today they work in 15 countries across Africa, Asia and Latin America. 95% of their staff are indigenous people. The results of their work clearly illustrate that people can benefit from developing their skills as indigenous health workers and their ability to organize and take action to improve their health.

E-learning technology: "Health Academy", launched by the WHO, provides the general public with health information to create basic health knowledge; it promotes equality based on gender, nation, culture and education.

Conclusion

In conclusion, the appropriate and sensitive application of western health knowledge in indigenous population can undoubtedly advance the health of indigenous people. However, an intercultural approach and close cooperation with communities to develop mutual understanding is essential. The beneficial co-existence of traditional and modern medical system was already established in many cases.

Health Literacy

Synonyms

Understanding of good health

Definition

According to a definition of the American Medical Association, health literacy is the ability to obtain, process, and understand basic ► health information and services needed to make appropriate health decisions and follow instructions for treatment. Health literacy incorporates a range of skills: to read, comprehend, and analyze information; decode instructions, symbols, charts, and diagrams; weigh risks and benefits; and, ultimately, make decisions and take action.

Health literacy includes the capacity to understand instructions on prescription drug bottles, to interpret test results, to understand medical education brochures, to give patient history, to articulate health concerns and describe symptoms accurately, to analyze relative risks and benefits, to understand informed consent forms, and to negotiate complex health care systems. With the development of the world wide web as a source of health information, health literacy may also include the ability to search the Internet and assess the quality of websites.

Studies show that people from all ages, races, income and education levels are challenged by this problem. Limited health literacy has negative implications for ► health outcomes, ► health care quality, and ► health care costs. For example, low literacy adversely impacts cancer incidence, mortality, and quality of life. It also affects glycemic control in diabetes, or blood pressure control in patients with hypertension, etc. Poor health literacy proves to be a stronger predictor of a person's health than, for example, age, income, or education level.

Improving the health literacy is a core aim of ► health promotion. Health literacy activities include creating easy-to-read, culturally appropriate health information materials, advocating for readers with limited skills, or enhancing access to health services.

Health Lobbying

► Advocacy

Health Locus of Control

Definition

The locus of control construct emphasizes the importance of perceptions of control, including mastery, self-efficacy and personal competence. It overlaps with concepts that focus on the causes of events. Although locus of control beliefs to some extent are based on causal attributions, there is a clear conceptual distinction between locus of control beliefs and causal beliefs. Causal beliefs focus on the causes of past events, whereas locus of control beliefs focus on expectancies for future events. While causal attributions in response to serious illness such as cancer has been investigated in sufficient detail, there has been little work applying attributional theories to health behavior among healthy populations.

Health Maintenance

► Health Care

Health Maintenance Organizations (HMOs) (U.S.)

Definition

Health Maintenance Organizations (HMOs) are a type of managed care organizations providing ► health insurance coverage and health care services through a number of contracted hospitals, physicians and other health professionals. They have been introduced in the United States during the 1970s. Patients being insured by a HMO receive all necessary health care services including disease prevention from one specific provider group within defined contracts. Patients generally receive a primary care physician who coordinates all medical care and acts as a gatekeeper for specialty services. HMO-providers receive fixed amounts per person (capitation payment) and therefore have no incentives to deliver unnecessary care, focus on prevention rather than costly hospitalization.

Health Management

Introduction

While health policy focuses on defining health goals and creating the surroundings of a desired health system, health management focuses on achieving those goals. Since there is a broad variety of health goals which are partly competing against each other, such as reducing cost while improving the quality of health, health management deals primarily with the allocation of limited resources towards health oriented goals.

In any health care system, there are numerous ► stakeholders focusing on different health care related goals. The main stakeholders in health care are:

- Patients
- Inpatient health care providers: ► hospitals
- Outpatient health care providers: e. g. doctors, laboratories, etc.
- Health insurance companies
- Pharmaceutical industry
- Government

The variety of actors and goals in health care systems leads to a variety of health management practices being applied. Health management can further be defined as a systematic approach to optimize organization and processes in order to achieve predefined health related goals.

Patients

One of the primary targets of health management is to improve public health for individuals (patients) within a health system. This target includes, amongst various other targets, the improvement of a health-induced quality of life and a growing life expectancy. While life expectancy is easy to measure, it is much more difficult to measure the improvement in the quality of life. Various approaches have been made to find a method of measuring the quality of life. However, no comprehen-

sive system has been established on a global basis that has been consistently used by countries to manage the outcome of health care on a comparable basis (► health care quality).

Besides setting goals for health care and ► health insurance providers, and besides being a major source of funding for most health systems, patients also have significant control over health-related factors themselves. These areas can be categorized into preventative actions and compliance, which can have a strong impact on a patient's health status. In the preventative actions area, various measures of caution and 'healthy' life-style can be maintained (i. e. not smoking, exercising regularly, health-oriented diets) in order to manage one's personal health risk better. Compliance refers to how closely a patient follows instructions during and after a treatment or surgery. Various studies have shown that a lack of compliance, especially in the area of medication, can have a high impact on the recovery rate of a patient. In this sense, patients play a role in their own health management which is not neglectable.

But at present, only few health care systems educate their patients and apply incentives accordingly. Besides informing people about their ability to influence their health directly, a number of incentives could be institutionalized, such as health insurance tariffs that are linked to a person's manageable risks (as opposed to non manageable, chronic disease risks, such as allergies).

Instead, there are multi-layered conflicts that exist between patients and health insurance companies. On the one hand, health insurance companies need patients as customers to raise money for the insurance claims. In that regard, insurance companies need to appeal to the interest of the patients. On the other hand, those patients, i. e. customers, expect reimbursement for their insurance claims. They expect the payers to offer a wide variety of options for health coverage according to their individual needs. The payers, however, need to keep payments low, or they will face an increase in overall expenses, which leads to higher tariffs and, therefore, most likely fewer customers in the future. Ideally, payers want the patients to seek only needed care, follow providers' instructions, and recover quickly. If restrictions become too tight though, a patient may choose to change insurance providers.

The mentioned conflicts between patients and insurance companies are only an example of possible conflicts between patients and other stakeholders in a health care system. This demonstrates that health management has to deal constantly with opposing stakeholder goals and patient goals, although the overall goal remains the achievement of the best ► health outcome for the individual patient within the financial and organizational restrictions of the health care system.

Inpatient Health Care Providers: Hospitals

Hospitals are providers of inpatient health care on a public or private basis. They constitute an important part in every health care system with regard to the financial resources they need as well as to the medical impact they have. Hospitals are either providing necessary health care for all kinds of diseases or for specialized medical areas. As the hospital sector is vital to health management in any health care system, it is strongly regulated by government laws in most countries. The organization and structure of the hospital sector is therefore shaped by health policy guidelines. In order to constantly improve the health outcome of the delivered hospital services within restricted financial resources, health management measures constantly change.

A few examples of the main changes in hospital health management are:

Change of Payment Systems in Hospitals Towards Diagnosis Related Groups (DRGs) Traditionally hospitals have been financed by public or private financial resources on a basis of retrospective funding which means that the hospital owner allocates the financial resources according to the costs the hospital incurred the year before. Due to technical and medical improvements during the past decades, the hospital sector has particularly increased its need for financial resources leading hospital owners to shift from open-ended retrospective funding towards prospective budgets or per-case payments. Per-case payments are particularly popular in well developed health care systems. They are either based on contractual agreements between purchaser and provider or on ► diagnosis related groups (DRGs). Within the DRG system, patients are grouped together "according to principal diagnosis, presence of a surgical procedure, age, presence or absence of significant co-morbidities or complications, and other relevant criteria" (US Congress 1983). As all patients with-

in the same DRG are expected to have similar hospital resource use, DRGs are used to reimburse the cost of inpatient hospital care. Hospitals are paid a specific pre-determined amount for each patient treated according to its DRG regardless of the actual cost of care provided. This trend in the change of the financing method follows the overall need to reduce the continuously rising costs in the hospital sector (Mossialos 1999). The Organization for Economic Cooperation and Development (OECD) recently noted that 19 of its members had introduced DRG-based payments to control hospital reimbursement costs (Forgione et al. 2004). Most countries have adapted the original US model to fulfill their specific needs.

Besides using DRGs as a basis for reimbursement, some countries have designed DRG-based systems for planning, budget allocation and management of the hospital care provided. In France for example, DRGs are used to allocate budgets to hospitals: As DRGs demonstrate a similar use of hospital resources, hospitals can be compared with each other and an estimate for future hospital payments can be made. In Belgium and Ireland, DRGs are a means of reducing the length of stay and in the UK they are used as a system of management of hospital provision. DRGS may also be used to evaluate the quality of care: Since all cases in a DRG are clinically similar, treatment protocols and other factors, such as related conditions or demographic distribution, can be analyzed. In addition, quality reviews can be established, critical pathways can be designed and benchmarking between hospitals can take place.

Change of Disease Treatment With the change of disease patterns, such as the increasing advent of chronic diseases, the treatment methods are changing accordingly. There is a shift from distinctive operating hospital units towards multidisciplinary treatment, including the idea of a health care chain. These changes in disease management require not only a redesign of the processes of the health care delivery, such as the introduction of so-called disease management programs (► disease management programs), but also a redesign of organizational structures in hospitals.

Disease management programs became very popular in the United States during the 1990s as chronic diseases continued to be the major financial burden in the health care system. Enhancing health conditions of chronically ill people while reducing costs is the main concern of disease management programs. The key to success is to offer coordinated health intervention while avoiding complications and unnecessary health care services.

With regard to hospital management, many large hospitals of the early 20th century were divided into medical disciplines which delivered health services according to their own independent procedure. These rigid and very hierarchically organized hospital disciplines are slowly changing to integrate the idea of interdisciplinary cooperation and to participate in disease management programs.

Progress in Health Technology Health technology advancements in the hospital sector, such as diagnostic imaging, intravascular ultrasound and minimal invasive surgery, have led to a considerable reduction in the average length of stay of a patient. As a consequence hospitals have experienced an overall reduction in the number of their beds and a higher turnover in patients. Because administrative structures and procedures in hospitals needed to adapt, management techniques have become increasingly important. During the last decades there has been a boom in 'hospital management', attributing more importance to hospital administration than before.

Efforts to Improve Quality of Care Hospitals need to improve their quality of services in many areas (► health care quality). There is a lack of coordination between services, often an inappropriate use of resources with respect to the quality delivered and scarce maintenance of building and equipment as well as a lack of information among hospital staff on costs and outcome. Improvement in the quality programs necessitates changes in the organization and management of hospitals. The current trend is to consider hospitals as industrial companies which must be organized, managed and evaluated. In this sense, management functions and clinical activities have to be provided with a shared common goal of health care quality. Many initiatives aiming at the continuous improvement in health care quality have started: for example, the introduction of clinical guidelines, continuing medical education, disease management programs and standards for health technology assessment.

The continuous development of medical knowledge and improved treatment practices, together with the financial pressure of cost-containment and the rising expec-

tations in terms of quality of care, will inevitably lead to further changes in the organization and management of hospitals. The future challenges are two-fold:

1. to change the functional interaction between the levels of care incorporating the idea of a health care chain to provide effective and integrated health care to the patients, and
2. to change the reporting measures in order to make the effectiveness of health services transparent with regard to the patient's health quality.

Outpatient Health Care

Outpatient or ambulatory health care comprises health care services delivered outside the hospital in offices of physicians, dentists and other health care practitioners such as mental health specialists, physiotherapists, etc. Providers of outpatient health care operate in a national legal framework consisting of medical guidelines on the one hand and reimbursement methods on the other. The specific health infrastructure (► infrastructure and service delivery) of a country determines the health management measures applied in outpatient health care delivery. In the past decades health care delivered in the ambulatory or outpatient sector has become increasingly important as the inpatient sector faces more and more financial constraints. However, similar financial constraints, as already mentioned with regard to the hospital sector, are found within the outpatient health care sector and have led to numerous measures of cost-containment, initiated by the purchasers of health care services, i. e. health insurers or the government. Increasingly, controlling mechanisms and rationing measures have been developed.

With regard to doctors, many countries control entry to medical education and limit the number of independent doctors' offices that can be established. Their payment or reimbursement methods have also changed over the years. The payment per item of service method has, in some countries, been replaced by the so-called capitation payment whereby doctors receive a given amount per patient regardless of the individual medical situation of the patient. Other countries maintained the payment per item system but changed the relative value-scale in order to cut costs. Another important measure concerns prescribing behavior which is influenced, in many countries, by government guidelines promoting, for example, the use of generics.

With regard to the organization and processes of outpatient health care services, the development towards integrated health care (► integrated health care) leads to continuous changes in health management practices. In the field of prevention, long-term care and rehabilitation, which increasingly concern ambulatory services, integration is the key factor in the delivery of quality of care within financial constraints. To develop a more integrated approach to health care delivery some organizational changes are suggested as necessary:

- Ambulatory care has to be more flexible in order to link different levels of care, to improve access to adequate care and to improve the coordination between outpatient and inpatient health care.
- Telemedicine or ► e-Health applications have to be increasingly developed as a tool to improve access to services for patients in remote areas or with specific chronic diseases.
- The development of home health care on an ambulatory community level might be a cost-efficient and quality enhancing measure for the treatment of patients with diseases that are better suited to care at home than to long–term care in a facility.

Health Insurance

Health insurance companies are important stakeholders in the health management context as they are responsible for the payment of health services for individuals in case of sickness or injury. In countries with well developed health care systems there are three forms of health care financing:

1. Tax-based health care system, in which individuals contribute to the provision of health services through taxes that are typically pooled across the whole population. The government is in charge of the provision of health care services, usually from a mix of public and private providers and allocates the existing resources to the different areas of health care. Examples of health care systems mainly based on taxation are the United Kingdom, Ireland, Spain and Portugal, Denmark, Sweden and Finland.
2. Social health insurance system, in which contributions from workers, the self-employed, enterprises and the government are pooled into a single or multiple sickness fund on a compulsory basis. These so-called statutory sickness funds are either directed by the government or independent non-profit organiza-

tions. They typically contract with a mix of public and private providers for the provision of a well defined health care benefit package. Examples of countries with a social health insurance system are Germany, France, the Netherlands and Belgium.

3. Private health insurance system, in which premiums are paid directly by individuals, employers or associations to insurance companies pooling risks across their membership base. Private health insurance can be a complete substitute for social insurance; typicall of a market-based system such as the US. It can also supplement an existing social insurance system as is the case in France, Belgium and the Netherlands. Private health insurance systems are, in general, voluntary in contrast to social insurance systems that tend to be compulsory. However, in some countries, private insurance may also be compulsory for certain segments of the population.

Regardless of the specific form of health insurance, all face financial constraints due to medical progress and improvements in technology, expansion of coverage by public health systems and aging populations in the industrial world with higher levels of chronic diseases and disability. However, the funding for the upward spiral of medical expenses is in all health care systems limited: In tax-based health care systems governments are unable to continuously raise taxes. In social insurance based systems the compulsory contribution has to remain bearable for employees and employers. Private insurance models depend on individual willingness to spend money on health care, especially if the private insurance comes as a supplement to compulsory social insurance (e. g. France).

In this context health insurers are obliged to take measures affecting the balance of demand and supply aiming to reduce medical expenses if a growth in the contribution rate should become unbearable for the insured.

Demand side measures:

- The benefit package is restricted by the health insurance.
- Patients are asked for co-payments that may concern drugs, dentistry charges, spectacles and charges for visits to doctors.
- Health insurance improves the cost-awareness of their members by giving incentives not to consume health care (e. g. premium rewards).

Supply side measures:

- Health insurance sets budgets for hospitals and doctors under direct contract.
- Implementation of Disease Management Programs (► disease management programs) to improve care for chronically ill people while reducing costs through an automatic and streamlined care process.

Even if a growing insurance premium is not only in the interest of the health insurer but also in the interest of the patients, who are mostly contributors as well, there are still conflicts between patients and payers of health care that influence health management practices. On the one hand, patients expect payers to offer a wide variety of options for health coverage that can be customized to their specific needs. On the other hand, payers want to maintain or lower their cost contribution. They want the patient to seek only needed care, follow providers' instructions, and recover quickly. Patients should also seek to reduce their health risk behaviors through, for example, diet, exercise and smoking cessation.

Pharmaceutical Industry

As one of the completely private stakeholders in a health care system, the pharmaceutical industry comprises numerous private pharmaceutical companies who invest in research and development in order to meet the need for new pharmaceuticals or medical devices while working as for-profit organizations. Drugs are either delivered to the patient through pharmacies or directly through hospitals. Similar to the situation of ambulatory doctor's offices or hospitals, the pharmaceutical industry sector is highly regulated in all developed health care systems by government laws. These regulations mainly concern the process of research and development, the approval of drugs before commercialization is authorized, quality assurance in the production process and also the market price and reimbursements. In the context of medical cost containment, a number of measures have become very popular: the direct and indirect control of prices and profits by the government, the necessary price approval for reimbursement before a pharmaceutical product may be launched and the control of the use of expensive equipment in the inpatient sector. As a consequence the pharmaceutical industry tries to influence health policy decisions by lobbying through often nationwide associations. Representing an important part of the industry in the well developed countries, the power of these indus-

trial pharmaceutical associations is often considered as high.

Government

The government plays an important role in health management as it mainly acts as a decision maker to set the rules for the functioning of a health care system that fulfills the values and health policy ideals of the country. Within the regulatory framework the government may regulate volume and quality of the health care services, is responsible for legislation on health care financing, corporate negotiations, major professional regulations and public health measures such as prevention and health promotion. The government administration of health (e. g. Ministry of Health) formulates and administers the government policy in health, sets standards for the regulation and licensing of health care providers as well as for medical personnel in hospitals. Other governmental agencies that set public health standards are the Food and Drug Regulation Agencies and agencies regulating occupational health and safety in the workplace.

In most countries with well developed health care systems the government is in charge of a number of public health services (► public health services) which are focused on the health status of the whole population. Public health programs are typically provided by the ministry of health or other government agencies in order to promote, protect and improve public health. Programs encompass disease prevention measures, health education, immunization programs, control of communicable diseases, sanitary measures, and protection against environmental hazards.

In countries like the UK with a national health service (NHS), the government acts not only as a decision maker and provider of public health services but also as a payer and provider of individual health care services.

Health Management Worldwide

In 1998, many countries took a greater interest in improvement of health management, considering better management of their national health systems to be among their major needs and priorities. During this year, WHO Representatives' Offices in 16 countries managed WHO technical cooperation at country level and provided policy support to ministries of health on various aspects of health. Desk officers at the Regional Office continued to provide support for countries without WHO Representatives' Offices. In addition to serving as an interlocutor and focal point for contacts between WHO and its countries, the WHO Representatives play an important role in the implementation of the global health policy strategy 'Health for all', liaising with other UN agencies as well as bilateral donors and non-governmental organizations. The increasing reliance in recent years on extra-budgetary sources of income due to a combination of higher demands on WHO and lower regular budget resources in real terms underline the importance of the WHO Representatives' role in resource mobilization. Every effort is being made to make use of recent technological advances to establish communication links between WHO headquarters, its regional offices and country offices as well as countries to permit an efficient flow of information between all parties.

In most developing countries, health services are weak due to a lack of responsibility in the government, a lack of investment in health infrastructure to deliver health services as well as poor training and career structures for medical professionals. In order to respond adequately to national and regional expectations, needs and priorities, great efforts are being made by the Regional Office to provide necessary support to countries in the development and improvement of health management in the regions. This has been done through a variety of approaches including contractual services agreements, fellowships, national training activities, consultancy services and regional consultations, particularly on developing and expanding the use of the district team problem-solving (DTPS) technique.

Regional Office experts are regularly developing guidelines for restructuring the national health system, proposing possible reasons for restructuring, as well as mechanisms of restructuring, and the resources required to be made available for this process. The Regional Office collaborates with the Ministries of Health and develops a Quality Management Training Center for the countries they are in charge of. The center, which enjoys full support from policy-makers, is an innovative strategy to improve the quality of health care and health status through quality orientation, health system development and managerial capacity-building. The center focuses on the core health processes, problem solving and team work. The 12-month modular training program is action-oriented and product-oriented and fol-

lows a learning-by-doing approach designed to build on the knowledge and experience of the trainees.

The Regional Office continued its support to a number of countries in strengthening their planning capabilities at central and district levels. Efforts were made to promote strategic planning in ministries of health and to disseminate WHO literature on health futures. Support was provided through WHO collaborative programs to the national institutes of health management.

Summary

The overview of the different stakeholder activities within the well developed health care system has shown the wide spectrum of health management. In order to realize health policy goals, health management includes organizational strategies for the stakeholders, priority setting and cost-effectiveness analysis with regard to existing financial constraints and the implementation of a sound quality management.

Great effort has been made during the past decades in improving overall health management, new management techniques have been developed and promise to help bridge the gap between health care quality and existing financial constraints in the health sector. However, there are two main challenges for the success of health management in the future:

1. to manage the conflict of interest between the stakeholders in order to effectively apply health management practices, and
2. to deal with changing environment patterns of the health care systems, such as epidemiological and demographic changes.

As far as health management in developing countries is concerned, the organization, scope and quality of health standards and health services are still far behind the services provided in well developed industrial nations despite the WHO efforts over many years.

Health Outcomes

Synonyms

Health change

Definition

Health outcomes are defined as follows in the WHO Health promotion glossary:

A change in the health status of an individual, group or population which is attributable to a planned program or series of programs, regardless of whether such a program was intended to change health status. Such a definition emphasizes the outcome of planned interventions (as opposed, for example, to incidental exposure to risk), and that outcomes may be for individuals, groups or whole populations. Interventions may include government policies and consequent programs, laws and regulations, or health services and programs, including health promotion programs. It may also include the intended or unintended health outcomes of government policies in sectors other than health. Health outcomes will normally be assessed using health indicators. Health outcomes include morbidity and mortality; physical, social, and mental functioning; nutritional status; and quality of life.

Introduction

Health Policy combines the elements of formulating health related goals, choosing the approach, instruments and financing via a political ► decision making process, and evaluating the outcome. In 2006, there is no consistent process or standardized approach in place as to how those steps are applied in different countries and different health care systems. Instead, national health policy is based on several factors, such as the political system, history of health policy throughout past decades, and the power of the different ► stakeholders in the health care system. Those systems and their respective health policy processes can therefore differ widely.

Global Health Policy

When defining ► global health policy, it is necessary to define targets and goals of such a policy. Health targets are such instruments, which can facilitate the achievement of health policy. Health targets therefore represent a commitment of a system or legislative body to achieve specific pre-defined outcomes over a pre-defined period of time. Furthermore, they enable the monitoring and evaluation of progress towards those goals.

Health targets are based on outcomes and processes. They can be quantitative, such as immunization rates, or qualitative, such as the introduction of national health care programs and initiatives. To faciliate monitoring and management towards the achievement of health targets, they should ideally be specific, measurable, accurate, realistic and time–bound (SMART).

Targets set priorities and can be used to create high levels of commitment. They are the basis for follow-up and evaluation. Health targets can be applied nationally, internationally, or within systems on sub-national levels, such as public health care systems.

Numerous governments in the member states of the WHO European Region and in OECD countries utilize health targets as an instrument and guidance for policy formulation and implementation. Countries across the world have shown a persistent interest in health targets, with some countries having a long track record in formulating such targets. Those targets have been optimized and fine-tuned over the past decades, thus representing a second- or third-generation iteration of country- or system-specific health targets.

WHO states that "undoubtedly, health targets have stimulated the debate and contributed in various ways to the development of national and sub-national health policies. However, when it comes to implementation the track record of health targets is less clear and less perfect."

Global Health Targets

A "Health for All by the Year 2000" strategy was launched by WHO in 1977 to set global targets and to form a global vision amongst the member states. In May 1998, WHO adopted a resolution to continue global efforts under the "New Global Health for All" policy. Coinciding with the 50th anniversary of WHO and the appointments of a new director general, this is commonly viewed as an opportunity for the organization to unify global goals once again, focus on the ten most relevant goals, and to re-establish its role in achieving those goals. The 10 global ► health targets can be divided into three subgroups: four health outcome targets, two targets on determinants of health, and four targets on health policies and sustainable health systems. This framework is supposed to be implemented throughout all member states, which will have the opportunity to finetune and adjust their own targets within that framework. The 10 Global Health Targets are (van Herten and van de Water 1999):

Health Outcome **1)** Health equity: childhood stunting. By 2005, health equity indices will be used within and between countries as a basis for promoting and monitoring equity in health. Initially, equity will be assessed on the basis of a measure of child growth.

2) Survival: maternal mortality rates, child mortality rates, life expectancy. By 2020, the targets agreed at world conferences for maternal mortality rates (<100/100 000 live births), under 5 years or child mortality rates (<45/1000 live births), and life expectancy (>70 years) will be met.

3) Reverse global trends of five major pandemics: By 2020, the worldwide burden of disease will be reduced substantially. This will be achieved by implementing sound disease control programs aimed at reversing the current trends of increasing incidence and disability caused by tuberculosis, HIV/AIDS, malaria, diseases related to tobacco, and violence or trauma.

4) Eradicate and eliminate certain diseases: Measles will be eradicated by 2020. Lymphatic filariasis will be eliminated by the year 2020. The transmission of Chagas' disease will be interrupted by 2010. Leprosy will be eliminated by 2010, and trachoma will be eliminated by 2020. In addition, vitamin A and iodine deficiencies will be eliminated before 2020.

Determinants of Health **5)** Improve access to water, sanitation, food, and shelter: By 2020, all countries, through intersectoral action, will have made major progress in making available safe drinking water, adequate sanitation, and food and shelter in sufficient quantity and quality, and in managing risks to health from major environmental determinants, including chemical, biological, and physical agents.

6) Measures to promote help: By 2020, all countries will have introduced, and be actively managing and

monitoring, strategies that strengthen health enhancing lifestyles and weaken health damaging ones through a combination of regulatory, economic, educational, organizational, and community based programs.

Health Policies and Sustainable Health Systems

7) Develop, implement, and monitor national Health for All policies: By 2005, all member states will have operational mechanisms for developing, implementing, and monitoring policies that are consistent with the Health for All policy.

8) Improve access to comprehensive essential health care: By 2010, all people will have access throughout their lives to comprehensive, essential, quality health care, supported by essential public health functions.

9) Implement global and national health information and surveillance systems: By 2010, appropriate global and national health information, surveillance, and alert systems will be established.

10) Support research for health: By 2010, research policies and institutional mechanisms will be operational at global, regional, and country levels.

When reviewing those goals, it becomes apparent that individual goals have a different relevance for different countries. The development status of a country – developing country or developed country – plays a major role in the relevance of the different goals as stated by WHO. Van Herten and van de Water have analyzed those targets in 1999 (see Table 1).

Health Policy Analysis

Health policy analysis is the process of determining how to spend money or invest resources based on different alternatives that affect the health care system, public health system, or the health of the general public. Health policy analysis involves multiple steps:

a) identifying and defining a problem
b) identifying the ► stakeholders, i. e. who is affected by the problem (private healthcare providers , industry groups, medical device manufacturers, professional associations, industry and trade associations, advocacy groups, the government, and consumers)
c) identifying and comparing the potential impact of different alternatives on how to solve the problem
d) deciding between the alternatives
e) implementing the alternative of choice and evaluating the impact

Decision Making Process

The ► decision making process is largely dependent on national and regional specifics, such as type of government, historical processes and different levels of power of parties involved. The process aims to find a consensus on how – using which resources or instruments – a certain goal can be reached best, given restrictions such as financing, development levels, technical expertise, etc. The stakeholders involved include patients, governments, agencies, ► health insurance companies, medical doctors, health service providers, pharmaceutical companies, hospitals, private and public companies and different organizations representing various interest groups.

Those groups have historically been easy to differentiate. In recent years, however, there has been a trend towards integration of various tasks, which leads to an ► integrated health care approach. Such integrated concepts can help to bundle resources and thus can make healthcare more efficient by eliminating unhelpful boundaries. Moreover, the growing efforts towards integrated health care leads to further developments in the area of ► health data management. Thanks to the development of information technology in the medical area, transparency of resource utilization as well as the automation of information flows has increased. However, these developments also require decision making bodies and health policy makers to adjust their decision making process respectively.

Financing Health Care

According to WHO, there are five broad ways of revenue collection for health care financing:

1. general revenue (taxation)
2. social health insurance
3. voluntary or private health insurance
4. out-of-pocket payments
5. internal donations.

Within WHO, countries have selected different ways of collecting revenue. Globally, in 1998, the estimated health expenditure (after adjusting purchasing power) amounted to US$ 3.1 trillion or 7.9% of the global income. The average expenditure per capita was determined as US$ 503, ranging from US$ 82 in Africa to over US$ 2.000 in OECD countries. Nearly 30% of this global expenditure came from taxation, around 20–25% from out-of-pocket payments (OOP), and anoth-

? = questionable

er 20–25% from social ► health insurance contributions. The remaining 15% was accounted for by private insurance. Variation in the distribution between different sources of financing is wide; Asian and African countries have spent more from out-of-pocket financing than from government general revenue or social health insurance.

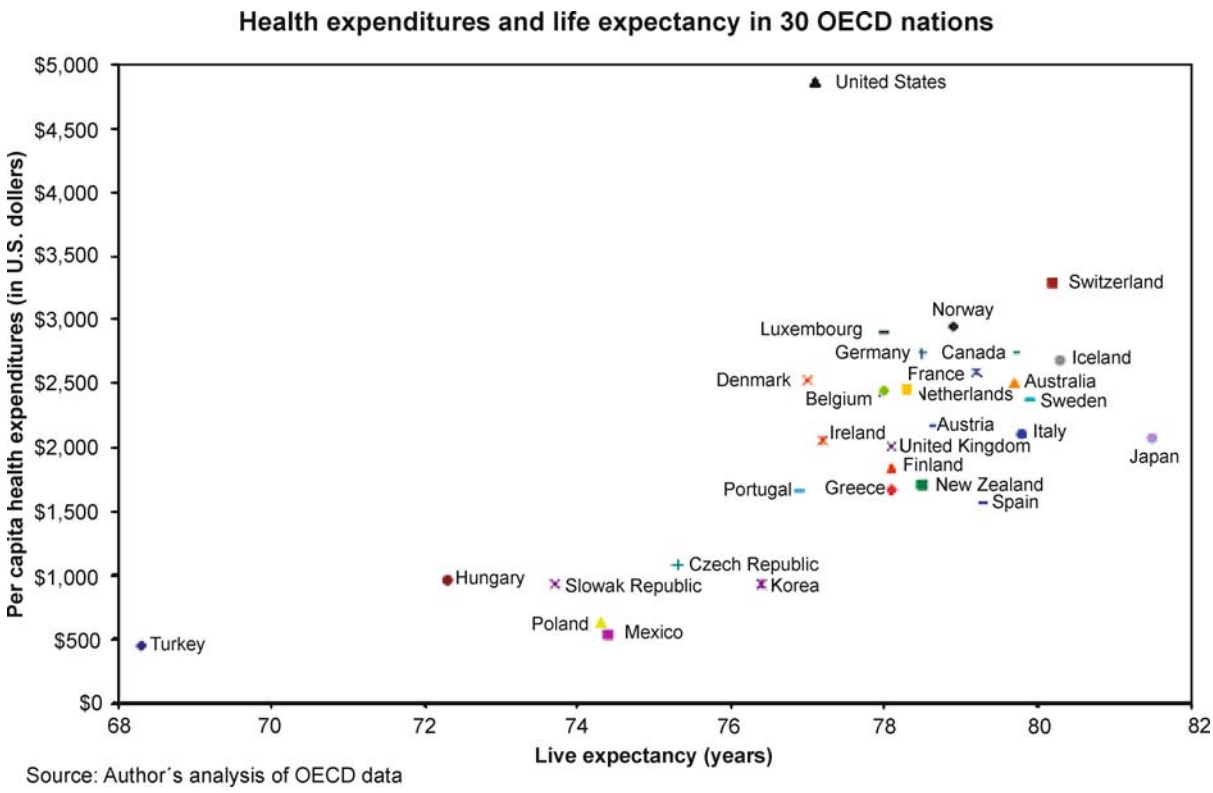
The Report of the WHO Commission on Macroeconomics and Health (WHO-CMH) recommended that countries should adopt an essential set of interventions with an average cost of US$ 30–40 per person. There is evidence to show that health systems which spend less than approximately US$ 60 per capita find it difficult to deliver a reasonable, minimum range of services.

The main source of financing across WHO – independent of the development state of a country – is from public general revenue, which is collected via taxes, health insurance contributions, and other methods. The levels vary, partly depend on the development state of a country. Moreover, the question remains what the optimum level of spending should be, how it should be collected, and what outcome should be achieved. An OECD study has demonstrated this challenge by comparing health expenditures and health expectancy in 30 OECD countries:

In 1981, a new indicator was proposed for the purpose of monitoring and evaluating of the global strategy for health for all by the year 2000: "the number of countries with at least 5% of GNP spent on health" (WHO 1999). While this indicator has never been formally adopted, the numerical level "5% of GNP spent on health" is commonly viewed as the WHO-recommended target.

According to WHO, "an appropriate percentage benchmark or target for health spending, like the fictitious target above, is extremely difficult to set. Research is under way to better define the minimum amounts of finance that countries should invest in order to optimally develop their health systems" (WHO 2005).

In a 2001 Report, WHO recommended that the low-income countries should increase their domestic spend-



Health Policy, Figure 1 Health expenditures and life expectancy in 30 OECD nations (Gould 2004)

ing on health by an additional 1% of GNP by 2007, and by an additional 2% by , linked to future trends of economic growth.

While many countries rely on general revenue for financing health care, others create or expand compulsory health insurance contributions, generally referred to as "social health insurance". These are usually based on pay-roll deductions, with additional contribution from the government in the form of general tax revenue. The World Bank in 1997 estimated that when a country's taxation is low (10% of GDP or lower), it would take 30% of government revenues to meet 3% of the GDP health expenditure target, through formal collective health financing channels. According to WHO "usually, poorer countries have widespread tax evasion among the rich and the middle class in informal sectors, thereby leading to low tax collections. They also rely heavily on taxation on international trade (exports and imports) and have the added limitation of broad-based taxes such as income tax or value-added tax."

A few countries have tried to add extra resources for health through earmarking a certain proportion of revenue collected from indirect taxation for health promotion and disease prevention. Some countries run state lottery services or other special revenue collection schemes, and earmark a certain proportion of collected funds for social services including health and education. Thailand recently enacted a legislation for a "Health Fund", which has specified a certain percentage of general revenue generated from taxes received from sale proceeds of tobacco and alcohol, being set aside for health promotion activities. With the adoption of the WHO Framework Convention on Tobacco Control (FCTC), an increasing number of countries are expected to use part of the revenue collected through a similar "sin-tax".

For inter-country comparisons, the level of health spending (like total health expenditure or per capita health expenditure as a percentage of GDP) may be useful. However, experience in some high- and middle-income countries has shown that more is not always better or always possible. Some developing countries with low investment in health could show outcomes comparable with those with high investment. What needs to be

seen is how efficiently and effectively countries spend their health resources according to their health needs. The output of effective spending according to health needs is reflected in the level of inequities in health outcome (WHO 2005).

Recent Trends and Developments

A WHO initiative was launched called "Health for All: the policy framework for the WHO European Region 2005 Update". According to WHO, "it answers the question of "Does tradition match the modern realities of policy-making?" In Europe, Health for All has proven to be visionary and inspirational. Is it also useful? Countries constantly face the need to make difficult choices and decisions that affect the functioning of their health systems. Can Health for All help them do so in a manner that ensures respect for human rights and for the values that lie at the heart of the European social consensus? The 2005 Health for All update proposes answers to some of these questions. Twenty-five years since the Health for All policy framework was first adopted in WHO's European Region, it is still seen by countries as valid, interesting and relevant. For some countries, Health for All served as a direct blueprint, in others it triggered the development of original, national Health for All policies, and many saw it as a basis for national target-setting, a source of ideas, a reference point or a general guideline in the area of values, health and human right and ethics. In the context of this broad usage of Health for All, the 2005 update should be seen exactly as what it is – an update, not a new policy. It reaffirms the European Region's 1998 HEALTH21 policy and is in the spirit of the global Health for All movement" (WHO 2005).

Since the update proposed an open-ended Health for All process, it provides a policy framework that can be developed further by the Health for All activities that countries decide to implement themselves. According to WHO, "It is hoped that the process will encourage the exchange of information, experiences and ideas inspired by the update and generated at the national and sub-national levels. Thus, the update will serve as a tool for promoting the ethical development of health policies and will be only one step in the continuing evolution and improvement of the regional Health for All policy" (WHO 2005).

Summary

Health policy does rarely exist on a global scale, but mostly depends on national specifics. Nevertheless, there are elements of health policy which can be applied globally. Therefore, WHO has formulated health goals, which naturally have different relevance for individual countries. Overall, within health policy, each decision making process is aimed at finding the most effective or efficient solution of specific health related goals, given different interests and levels of power of the stakeholders affected by the policy, and the ability to finance a potential outcome within a health care system.

Health Policy Indicators

Definition

Indicators of health policy are a subset of characteristics referring to the presence and implementation of national health policies and strategies, universal financial coverage, equitable distribution of resources, low cost sharing, comprehensive services, and family-oriented services. Some include indicators of social protection: social expenditure and community involvement.

Health Professional

► Health Care Provider

Health Promoting Hospitals

Definition

A health promoting hospital, as defined by WHO, does not only provide high quality comprehensive medical and nursing services, but also develops a corporate identity that embraces the aims of health promotion, develops a health promoting organizational structure and culture, including active, participatory roles for patients and all members of staff, develops itself into a health promoting physical environment and actively cooperates with its community.

Health Promoting Schools

Definition

A health promoting school can be characterized as a school constantly strengthening its capacity as a healthy setting for living, learning and working. It is defined by WHO as a place that takes all measures to foster health and learning, secures the health and education of officials, teachers, teachers' unions, students, parents, health providers and community leaders. Additionally, health promoting schools strive to provide a healthy environment and implement policies and practices that respect an individuals well being and dignity.

Health Promoting Workplace

Definition

A health promoting workplace (HPW) is a priority setting for health promotion. The concept of the HPW, as defined by WHO, is becoming increasingly relevant as more private and public organizations recognize that future success in a global marketplace can only be achieved with a healthy, qualified and motivated workforce. A HPW can ensure a flexible and dynamic balance between customer expectations and organizational targets on the one hand and employees' skills and health needs on the other, which can assist companies and work organizations to compete in the marketplace. For nations, the development of HPW will be a prerequisite for sustainable social and economic development.

Health Promotion

Synonyms

Healthy public policy; Health control; Disease prevention

Definition

Process of enabling individuals and communities to increase control over the determinants of health and thereby improve their health. Health promotion not only encompasses actions directed at strengthening the basic life skills and capacities of individuals, but also at influencing underlying social and economic conditions and physical environments which impact upon health.
The ► Ottawa Charter for Health Promotion (WHO 1986) identifies 3 basic strategies: ► advocacy, Enabling (► enablement) and Mediating (► mediation). Five areas of action support these strategies: building healthy/public policy, creating supportive environments for health, strengthening community action for health, developing personal skills for health and re-orienting health services ► prevention and health promotion

Cross-References

► Disease Prevention
► Health Campaigns
► Health Control
► Healthy Public Policy
► Public Health Law, Information and Communication

Actors in health promotion

Basic Characteristics

Background

The conception and implementation of the complex aim "health promotion" demands the collaborative work of many actors not only in the medical field but also many other fields and involves state or governmental and non governmental levels. Appropriate health promoting structures need to be in place to enable active intersectoral cooperation (► intersectoral cooperation) between different levels and all population groups.
Providing appropriate health promotion depends upon the cooperation of political decision makers at both national and international levels. Not only are regulations and laws required but also sustainable funding for continuous and long-term support is necessary along with flexible mediating and advising structures in health promotion. Those who devise and implement health promotion (the actors), at governmental as well as non governmental levels, come from the fields of education, welfare, health care and work.
For instance, at the European level, the European Union in 1986 passed a law assuring preventative health care and in 1993 the treaty of Maastricht contained health promotion as a central field of action of the European Community. The ► DG SANCO as part of the European Commission is responsible for the actions related to health promotion in the European Public Health Programme and it is the basis for the health policy in Europe.
The treaty of Maastricht anchored health promotion as a central field of action of the European Union. The DG SANCO of the European Commission runs the public health program which contains the following eight main topics amongst others:

- Health promotion.
- ► Health Information.
- ► AIDS and other ► transferable diseases.
- ► Cancer.
- ► Orphan Diseases
- Prevention of diseases.
- Environmental health.
- Prevention of addiction.

(Schwartz et al. 2002)

Principle Structure and Institutions Involved in Health Promotion and Disease Prevention

The national implementation of health promotion is strongly influenced by the structure and instruments of health policy devised by the politicians. Political activity can be subdivided in the following terms:

- ► Politics.

- ► Policy as well as ► policy networks.
- ► Polity.

Furthermore, political activity depends on the particular organization of the political authorities within any given state (e. g. central state or federal political system). In order to understand the structure and instruments of a country's health policy, one has to take into account the political organization of that country, remembering that health promotion actors are located on governmental as well as non-governmental levels. The principle structure depends also on the funding of health promotion and the legal framework. The financial funding for health promotion is significantly influenced by the implementation of one priority fields of action in health promotion: investment for health (Altgeld 2003).

Table 1 depicts an overview of several institutions that are possibly involved in health promotion and disease prevention activities.

Therefore, health promotion is strongly shaped by building up networks between the mentioned actors from different levels and representation bodies. These networks are often referred to an intersectoral cooperation, alliances, and partnerships or inter-organizational networks (► network) for health promotion. An ► alliance for health promotion is a partnership (► public private partnership) between two or more parties that pursue a set of agreed upon goals in health promotion. Building of alliances will often involve mediation between different partners and their aims such as the definition of common goals and ethical ground rules, joint action areas, and agreement on the form of cooperation. A partnership for health promotion is a voluntary agreement between two or more partners to work cooperatively towards a set of shared health outcomes. Such partnerships may form a part of intersectoral collaboration for health, or be based on alliances for health promotion. Such partnerships may be limited by the pursuit of a clearly defined goal – such as the successful development and introduction of legislation – or may be on-going, covering a broad range of issues and initiatives. Increasingly, health promotion involves a partnership between the public sector, civil society and the private sector.

Since the beginning of the 1990s, health promotion has been closely related to the development of networks. Important pioneering work on creating, developing and managing networks in the field of health promotion was published by the World Health Organization (► WHO). The WHO regional office in Europe encouraged the development of networks between local, regional, national, and international institutions as well as organizations. Many of these representative bodies in the field sought information from the key documents of the WHO on health promotion (WHO 1986).

The WHO provides these networks with a health policy framework for health promotion in the key documents "Health for All" and the "► Ottawa Charter on Health Promotion." The concept of interinstitutional and intersectoral collaboration and cooperation through network building was significantly promoted by the WHO. Currently, discussions concern not only a system of networks in health promotion but also the appropriate

Health Promotion Actors, Table 1 Actors and organization involved in health promotion activities at different levels

Level	Governmental institutions and other public bodies	Non governmental organizationsand private institutions/agencies
International	International policy institutions e. g. European Commission, DG Sanco	Representation bodies like ► INHPF, ► IUHPE, ► EUPHA
National	State or Federal Ministries of Health, Education, Welfare. Federal Centre for Health Education	National public health organizations, Federal association of consumer advice center, National contact center for self help groups, National societies of nutrition
Regional	Regional public health services	Regional federations on health promotion, Coordinating centers of self-help groups
Local	Local public health departments	Local activities of self-help groups Local health center Sport club Private trust and foundations

► setting of health promotion networks. It is considered that fostering networks enables the establishment of the necessary long term prerequisites of health promotion (Brößkamp-Stone 2002).

Successful health promotion and disease prevention requires a wide base of several institutions and state facilities, and ministries of health and state agencies for public health have to be involved. For instance, the American ► center of diseases control and prevention is one well known state public health institution in this field. Other issues of public health and prevention are also carried out by state ministries of consumer protection. The work of such state ministries is supported by subordinate departments in the following areas of work:

- Institutions for hygiene and transmissible diseases that aim at recognizing, preventing and fighting transmissible diseases.
- Public and state institutions for the protection of health and safety standards at work that aim at securing occupational safety and the prevention of work related health threats.
- Federal agencies for health education and health promotion.

Furthermore, various associations, foundations and scientific societies aim to strengthen and implement the goals of health promotion and disease prevention in order to improve knowledge about factors influencing the health of the population. These numerous organizations are derived, for example, from the following fields:

- Associations on nutrition.
- Associations on physical activity.
- Medical associations.
- Cancer associations, etc.

Health Promotion Engagement

Synonyms

Commitment; Involvment; Engagement in health promotion

Definition

Involvement of affected or concerned persons in the process of identifying problems and needs as well as in the process of planning, implementing and evaluating actions. People have to be at the center of ► health promotion action and decision-making processes for them to be effective.

Participation can assume different degrees of involvement and commitment. There is a distinction between

active and equal collective participation and more passive collective acceptance of expert-oriented measures. Participative engagement in the sense of ► empowerment positively affects health through fostering the awareness of being able to exert control over one's living conditions and through revealing and furthering new skills and abilities.

Health Promotion, Ethical Aspects

PASQUALE DI MATTIA
CEFPAS – Centre for Training and Research in Public Health, Caltanissetta, Italy
lino-dm@libero.it

Synonyms

Health improvement; Health enhancement

Definition

Health promotion, as one of the main goals of public health practice, is the process of enabling people to increase control over, and to improve, their health. In order to reach this goal, public health initiatives at times come into conflict with other ethical principles (e. g. individual ► autonomy, ► social justice), therefore public health promoters have to deal with ethical dilemmas at various levels.

Basic Characteristics

Health promotion is significantly playing a more important role in health care in general, and public health practice in particular. Health promotion, as one of the main aims of modern public health practice, initially only focused on the lifestyle changes that might impact on the prevention of such things as cancer, chronic degenerative diseases and metabolic disorders; then it evolved and broadened its viewpoint to improving the physical and mental health and well being of people in local communities, including influencing living habits and living conditions that affect behavior, and also promoting individual self-esteem, dignity and respect.

To reach a state of complete physical, mental and social well being, an individual or group must be able to identify and realize aspirations, satisfy needs, and change or cope with the environment. Health is a positive concept emphasizing the possession of social and personal resources, as well as physical capacities. From this perspective, health promotion is a strategy to promote health by strengthening personal resources. To achieve this different methods are utilized at different levels. At a personal level, through positive socialization in families and peer groups, health consciousness is heighten and a sense of coherence is created; at a behavioral level, through health information, health education, health counseling, health training and social support, resources are strengthened; at a structural level, through a healthy public policy, resources are further strengthened. Health promotion is, therefore, not just the responsibility of the health sector, but involves the adoption of personal healthy life-styles that lead to personal well being.

Debating health promotion at times evokes different perspectives. On the one hand, the idea of individual responsibility has been submerged by the concept that individual rights or demands should be guaranteed by the government and delivered by public and private institutions, and that, in order to improve public health, government bodies should take responsibility. On the another hand, governmental institutions stress the responsibility of individuals to keep themselves healthy; this approach, however, may be seen as an ideological strategy for relieving a government of the obligation to provide healthy conditions and health care services.

Nevertheless, there is an increasing agreement, among both the general population and health professionals, that a good deal of disease is self-inflicted, and is a product of imprudent behavior, as proven by the evidence that various personal habits and lifestyle choices (such as poor nutrition, smoking, alcohol and drug abuse, failure to wear seat belts, unsafe sexual practices) are major causes of morbidity and mortality.

Traditionally, the "► harm principle" has been used by governments to impose restrictions on individual autonomy and freedom; ► paternalism, which imposed restrictions on those who represented a risk to others, was considered universally acceptable when the harm being caused was obvious. Divergences arose when the harm being posed to others was unclear, or when health promotion activities interfered with individual privacy and freedom in the name of the common good. What is still open, then, is the ethical question of how far a government should go in regulating, restricting or prohibiting behaviors that bring about morbidity and mortality;

or even in protecting citizens from commercial influences that may encourage or sustain patterns of behavior that are dangerous to health. How do we reconcile personal freedom and good health? Personal choice and common good?

According to Mr Mills, "He (the individual) cannot rightfully be compelled to do or forbear because it will be better for him to do so, because it will make him happier, because in the opinion of others to do so would be wise or even right." What role, then, should government play in urging citizens to give up their pleasurable but damaging habits? Many people believe that government should rarely exercise coercive powers either because they are ineffective or because they overrule individual autonomy, ► privacy, or liberty. The evidence of the negative consequences of some private habits and lifestyles, both on the public and on the individual's health, has added to the idea that there is an obligation to preserve one's health. How should society determine whether to intervene to protect the public's health and safety when doing so will diminish a personal or economic interest and will undermine individual freedom and personal responsibility? And how can the state be prevented from taking power to remove more and more choice in the name of better public health? Anyhow, some paternalistic health promotion interventions are based on the position that the costs of risky behavior are a national and not an individual responsibility; moreover, public health officials may feel justified and morally bound to prevent avoidable suffering and death regardless of social costs.

A very important role in this dilemma is played by health education. Health communication campaigns are the most common form of intervention designed to promote healthy behavior. Though they discourage certain activities linked to morbidity and mortality and encourage the adoption of others, they provide information to the individual, thus enhancing his personal autonomy. They have been credited with helping raise awareness regarding risks from chronic illness or new infectious diseases. They have been a tremendous factor in helping to promote the adoption of recommended treatment regimens and helping de-stigmatize populations that suffer from new and old medical conditions.

The debate, in these cases, is whether health education, which preserves individual autonomy and avoids coercion, is enough, and whether health promotion campaigns and advertising, using a wide range communication strategies in order to produce messages to promote public health, are appropriate.

Messages about how to improve health may not appear as ethically problematic and they can be viewed as rather benign, compared to more coercive methods in public health that involve regulations and sanctions. Yet, they may create subtle but real ethical dilemmas which permeate all facets of the public health communication process, including the initial focus on a particular health issue, choice of target populations, design of message appeals and assessment of effectiveness. Just to give but few tips:

- Tailoring messages corresponds to the communication ethical stipulation of comprehensibility, which requires the provision of complete and culturally-appropriate messages to diverse populations. A drawback associated with disseminating messages tailored to particular populations is that groups that are not provided with culturally-specific messages may feel excluded or short-changed.
- Tailoring messages may present competing demands to provide complete and accurate information whilst presenting this information in a format that is appropriate for low-literacy audiences. Yet, for some, low literacy may be a source of embarrassment and they may want to distance themselves from materials that have an appearance of being designed for low-literacy populations. This poses the challenge of developing materials that are respectful and not condescending but effective in their format.
- When the intended populations for communication interventions are the young, additional ethical issues may emerge: parents may object to the dissemination of information or the implementation of activities on certain topics. Yet, their children would like to obtain this information and public health practitioners strongly believe it is essential to promote their health. Should the children be provided with the information, despite the objections of their parents? Can this be justified on the basis of the rights of children and the young? Can this be justified on the basis of preventing vulnerable populations from harm?
- Appeals to personal responsibility are common in public health messages. Linking responsibility messages to health outcomes raises several ethical issues: the first concerns conceptions of culpability. Implied in messages that make a causal link between

a person's behavior and their health, is an assumption that people's behavior can significantly affect their health and therefore they can be held responsible for detrimental health outcomes. Whereas such messages resonate with the notion of human agency, they may be ethically problematic because they do not take into consideration that individuals may have limited impact on social factors that affect their behavior. Linking health with personal responsibility may, by implication, characterize those who do not adopt recommended health related practices as weak of character and at fault. This can lead to the conclusion that people should be held morally, and perhaps legally, accountable for their behavior, thus exempting society from paying certain health care costs, or requiring certain individuals to pay higher premiums.

- Messages that scare people regarding the hazards of a potential disease, on the one hand raise their motivation to avoid contracting it, but on the other hand may present a negative image of those who have the disease, thus stigmatizing them. Once stereotypes and stigmas are established, they can result in individuals being feared, avoided, regarded as deviant, and even blamed for engaging in the immoral behaviors that must have elicited the 'punishment' of their affliction. In general, this type of social climate can be devastating to members of vulnerable populations who suffer from stigmatized medical conditions since it can result in the internalization of self-blame and the destruction of self-esteem.
- With a continuous barrage of health messages aimed to promote the health of the public, the public is inundated with messages on the importance of health. As good health increasingly signifies virtue, those who are unhealthy may be made to feel that they are unworthy, forgetting that pain and suffering are part of human life and give a precious contribution to human growth and development at the psychological and spiritual level.

The task of developing ethically-derived public health communication also needs to include consideration of issues of diversity and pluralism amidst mounting social and economic disparities within and across nations. Scrutinizing public health communication strategies for ethical concerns should become a routine, not only because any benevolent attempt to contribute to people's well-being needs to be ethical, but also because communication interventions that are sensitive to ethical concerns are more likely to be better executed and to be trusted by intended populations.

One of the ethical aspects of health promotion concerns ► nutrition. We talk about nutrition when addressing lifestyle changes in relation to increasing foods with protective factors and reducing those with disease-promoting properties. If we look at a restricted population or at a specific Western country, it could be relatively easy to give guidelines which could also include the concepts of "► sustainable development" and "justice". The perspective changes if, instead, we look at the worldwide population. Just to give an example. The most recent general dietary guidelines for a healthy diet from the American Heart Association recommend: 'Eat at least two servings of fish per week.' This recommendation is based on scientific evidence. In the USA, there are 280 million potential fish consumers. Adherence to this recommendation would require the preparation of 29 billion fish portions per year for this market. Extended to the whole world, this would require 642 billion annual servings. Even if one were to restrict the recommendation to adults, this would only reduce the projected consumption by approximately half. Global compliance with the USA American Heart Association recommendation for regular fish consumption would risk the fish supplies of the world, and the ecological balance of aquatic and marine habitats. This recommendation is pro-people, but strongly anti-environment.

A very important step forward in the concept of health promotion has been "The ► Ottawa Charter for Health Promotion", released at the First International Conference on Health Promotion held in Ottawa in 1986.

The charter broadens the approach to health by proclaiming that good health is a major resource for social, economic and personal development and an important dimension of quality of life, and that its fundamental conditions and resources are: peace, shelter, education, food, income, a stable eco-system, sustainable resources, social justice, and equity (known as "► social determinants of health").

In this approach, health promotion includes various areas of action:

- Build healthy public policy .
- Create supportive environments.
- Strengthen community action.
- Develop personal skills.
- Reorient health services.

As a consequence, improvement in health requires a secure foundation in these basic prerequisites and demands coordinated action by all concerned: by governments, by health and other social and economic sectors, by nongovernmental and voluntary organization, by local authorities, by industry and by the media. Health promotion strategies and programs should be adapted to the local needs and possibilities of individual countries and regions to take into account differing social, cultural and economic systems.

The Ottawa Charter has definitely opened up new paths for the future development of health promotion and public health in general.

Looking at social justice has been indeed a major step in the recent evolution of public health practice, which has focused, more than in the past, on reducing differences in current health status and ensuring equal opportunities and resources to enable all people to achieve their fullest health potential. One of the ethical issues is that the increased costs of health care have brought along disparities in distribution and accessibility within a specific population; moreover, if we look at the global level, it cannot be ignored that the developing world is still devastated by preventable infectious diseases, malnutrition and poverty.

There is still a long way to go, but health promotion aims and activities have already, as we have seen, taken up the challenge.

Action area

Definition

Action areas in health promotion were outlined in the ► Ottawa-Charta and support the implementation of the three basic strategies (► advocacy, ► enablement, and ► mediation) of health promotion mentioned in the Charta. The action areas are:

- Build healthy public policy
- Create supportive environments for health
- Strengthen community action for health
- Develop personal skills (life skills) and
- Re-orient health services.

The term "health promotion" was defined as an overall goal in the declaration "Health for all" that was made at the beginning of the 1980s in the last century. Aims, principles, and necessary terms of health promotion were summarized in the Ottawa-Charta on health promotion. According to the understanding of

the ► World Health Organization (WHO), health promotion describes the concepts of analyzing and increasing the resources and potential of health on all policy and social levels. This description led to the above-mentioned five important fields of action in health promotion that concretize the aims of it.

Health Promotion Action means to be active in the five fields described above, and is defined as follows by the WHO (WHO 1986):

Basic Characteristics

Healthy Public Policy (► Health Policy)

The development of healthy public policy was described by the WHO as a formal statement or procedure that is not limited to medical and social care. Moreover, health care has to be considered on all levels of political and social activities. A policy of health promotion is distinguished by mutually adding approaches in legislative rule-making that define regulations and incentives to enable the provision of health services and programs, and access to those services and programs. Further developments in healthy public policy initiatives will depend on them arising from a systematic process of building support for public health action that draws upon available evidence integrated with community preferences, political realities, and resource availability.

Supportive Environments for Health

The second field of action in health promotion is defined as creating supportive environments. The basis of action in this field is the close relation between human kind and the environment since a healthy environment has to be recognized as having a significant role producing health promoting living conditions. Protection of nature and the environment as well as sustainable development (► sustainability) dealing with resources is a prerequisite for implementing the strategies of health promotion. Creating supportive environments requires development of a stimulating and satisfying working and living condition (► living conditions). Direct political action is needed to develop and implement policies and regulations that help to create supportive environments. Economic action is also required, particularly in relation to fostering sustainable economic development and social action.

Community Action for Health

Strengthening community action is also a central matter in health promotion. It aims at establishing the development of community action of the population and supporting the capabilities of ► self-help groups and their activities in the sense of self-determination. Community action is also addressed through the ► participation of society in health issues and the health promotion-related work of each individual.

Develop Personal Skills

Developing personal skills is the process of supporting personality development and social competence through information and health-related education as well as the improvement of social competence. It aims at empowering (► empowerment) persons to increase their influence in health related behaviors and their everyday living conditions. In this context, it is aimed that individuals should get the possibility of a lifelong process of learning in order to attain the ► life skills that could be needed to deal with chronic disease or handicaps.

Re-orient Health Services

The term "re-orient ► health services" is understood as the development of a health care service by public health bodies that does not only concentrate on the process of recovery and rehabilitative issues but also on the improvement of health. It should also be considered that health is the result of a large number of health influencing determinants. This perspective leads to the identification of resources and their potential and specific strengths, which have to be supported by re-orientated health services.

The above-mentioned fields of action were confirmed as important and added to at the successor conferences of health promotion. In particular, all action areas were expressly established as effective measures for health promotion at the fourth conference of health promotion in Jakarta in 1997.

Further development of the concept of health promotion as defined by the WHO was significantly influenced by the conferences on health promotion held in Ottawa in 1986 and in Jakarta in 1997. The declaration of the conference of Jakarta focused on the following newer priorities (WHO 1997):

Promote Social Responsibility for Health

Social responsibility for health is reflected by the actions of decision makers in both the public and private sector to pursue policies and practices that promote and protect health (WHO 1997).

Increase Investments for Health Development

Investment for health refers to resources that are dedicated explicitly to the production of health and health gain. They may be invested by public and private agencies as well as by people as individuals and groups. Investment-for-health strategies are based on knowledge about the determinants of health and seek to gain political commitment to healthy public policies (WHO 1998).

Secure an Infrastructure for Health Promotion

Infrastructures for health promotion are understood as human and material resources, and organizational and administrative structures, policies, regulations, and incentives that facilitate an organized health promotion response to public health issues and challenges. Such infrastructures may be found in a diverse range of organizational structures, including primary health care; government, private sector, and nongovernmental organizations; and self-help organizations, as well as dedicated health promotion agencies and foundations (WHO 1998).

- Expand partnerships for health promotion
- Increase community capacity and empower the individual.

In summary, all of the above-mentioned fields of actions in health promotion are accepted as important for successful implementation of the strategies of health promotion. Mutual consent exists in the scientific community that health promotion activities are effective if the basic strategies are carried out in combination in order to achieve a high rate of participation of the target groups (► target group), to empower all actors, and to stimulate the building of networks and community action for health (Noack 2002).

Health promotion theories

Definition

Models or theories in health promotion are systematically built and validated constructs with clearly defined and interconnected concepts covering a wide range of

phenomena related to health behaviors or health conditions. For this essay, the terms "model" and "theory" are used interchangeably, since their application does not follow a stringent logic.

Basic Characteristics

Empirical Basis for Practical Theories

Models or theories in health promotion are – in contrast to those of disciplines like physics – not approximations to an accepted hypothesized "truth" but guiding schemes for the explanation or planned change of health-related human behaviors or conditions. What makes them models according to generally accepted concepts is the fact that they have been empirically tested and proven to be of generalizable, practical usefulness: their "truth" is the compilation of effectiveness by experiences from many studies (sometimes far more than 1000) in vastly different types of populations.

Historical Developments and Types of Models

The best-known and most often applied health promoting models have four different orientations: the first, from the 1930–1950s examine ► health behaviors and behavior changes by focusing solely on the individual and her/his characteristics. While these theories substantially contributed to the understanding of human health practices, the attention to and inclusion of the broader environmental and socio-economic context led to a second generation of theories that additionally focus on the influence and competence of a community or "setting" in which individuals live, work, play, or learn. These theories might include the individual as one focus of intervention, but they also address issues beyond the control of the individual, such as the increased availability of supporting devices (e. g. condoms free of charge or the implementation of a health center in the neighborhood).

A third group of theories clusters around *awareness raising* and *knowledge transmission through communication and action-motivation*. Here, the targets might be individuals, (risk) groups, communities, or even whole nations, addressed by mass communication campaigns (► mass media) or social marketing strategies (e. g. BZgA's HIV-prevention campaign "Mach's mit").

A fourth group of theories focuses on the *analysis of organizational structures* and structural change mechanisms and their health impact by means of general policy or "► healthy public policy" development (Nutbeam and Harris 2004).

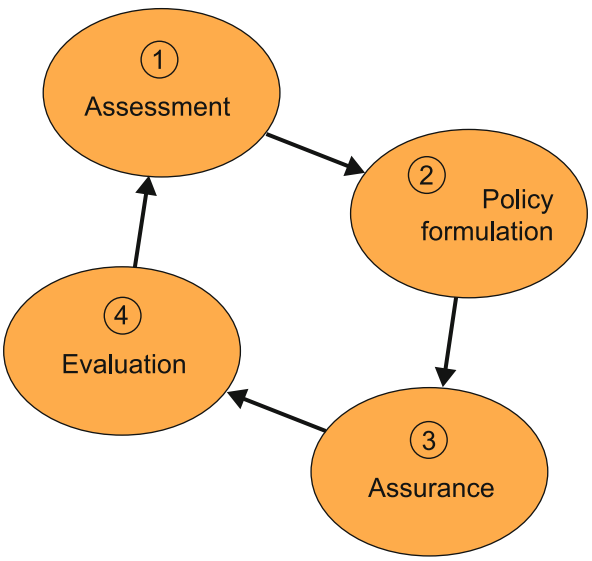
Many projects have successfully been conducted without theory – solely based on experience or intuition. However, the likelihood of success and ► effectiveness has been proven to be higher when the conceptualization is theory-led.

Usefulness of Models for Health Promotion

The use of models in health promotion can serve the purpose of helping to systematically plan, conduct, and evaluate health promotion interventions or programs. In modern public health practice, a mix of concepts from different models is usually employed and all major theories are checked for their applicability to a given project. One intervention model – the Pantheoretical Model – is a synergistic composition of concepts from theories of different disciplines like *education and training*, *persuasion*, *motivation,* and *facilitation* (McAlister et al. 1991; Seibt 2003a).

Models such as the Public Health Action Cycle (Fig. 1) remind practitioners to follow a systematic approach – from *assessment* to *policy and strategy formulation*, and from *implementation* to *evaluation* (Institute of Medicine 2003).

The ► precede–proceed health promotion planning model (Seibt 2003b; Green and Kreuter 2004) propos-



Health Promotion Models, Figure 1 The Public Health Action Cycle

es a clear understanding of the *social*, *epidemiological, behavioral, environmental, educational, organizational, administrative,* and *policy aspects* of a problem area during the needs assessment or planning stage; for evaluation, there is a distinction between ► process evaluation, ► impact evaluation, and ► outcome evaluation.

Selected Psycho-Social-Ecological Models

► Health education and prevention have developed towards health promotion along the following path: they started in the 1950s of the last century with context-free models, such as the ► health belief model where the individual is the sole target, and progressed to more recent theories such as the Social-Learning Theory or the Stages-of Change-Theory, which focus on the individual but also consider the individual's life style and their ecological and socioeconomic environment.

A short introduction to the three models mentioned is outlined here:

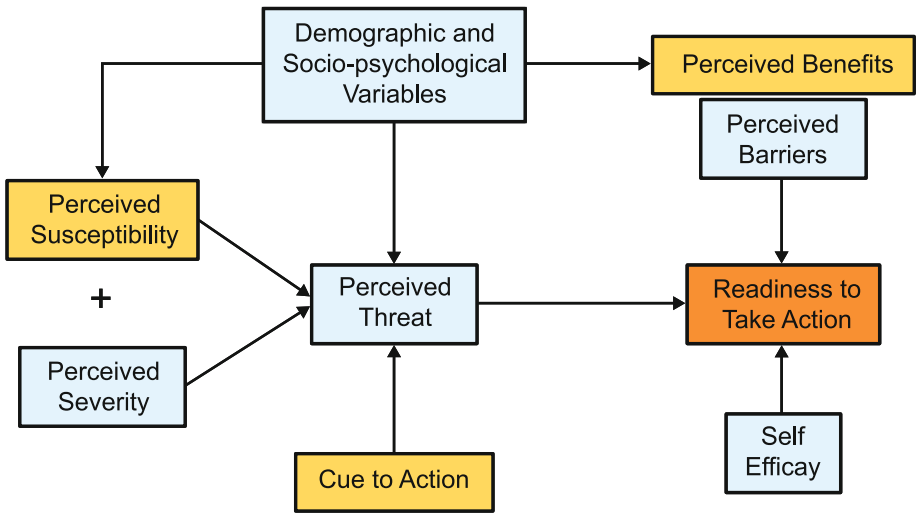
The Health Belief Model was developed in the 1950s by the U.S. Public Health Service. It is still used as an assessment tool to understand why persons participate in programs for the prevention or detection of diseases (e. g. being immunized against the flu). The original model encompassed five concepts; self-efficacy was added for modern applications (Fig. 2). Perceived *susceptibility* is defined as the subjective opinion about the chances of contracting a condition; perceived *severity* is the subjective opinion of how serious a condition and its consequences might be if untreated. Perceived *benefits* means the opinion of the effectiveness of various available actions in reducing the problem, and perceived *barriers* are the potentially negative aspects of a health action, e. g. side effects or costs. *Cues to action* might be an environmental event or a bodily trigger. *Self-efficacy* is defined as the person's confidence in performing a particular behavior successfully (Bandura 1986).

The model's empirically highest validated concepts are susceptibility and barriers, mostly used in combination with concepts of other models (Seibt 2003c).

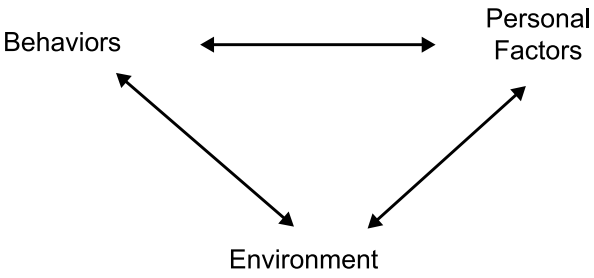
The ► social learning theory, also called Social Cognitive Theory, not only explains how people "learn" and maintain certain behavioral patterns, but also explicates factors influencing health behaviors and thereby provides the basis for intervention strategies for the promotion of behavioral change. Human behavior is explained in terms of a triadic, dynamic, and reciprocal model, in which behavior, personal factors (including cognitions), and environmental influences all interact (Fig. 3).

According to the theory, humans are not only able to learn from direct experience, but also by observing others and anticipatorily drawing conclusions for their own behavioral outcome; this type of vicarious learning enables them to build outcome expectations through cognitive processes, to acquire tactile and social skills through (imitative) training, and, amongst others, to develop self-efficacy expectations.

Social Learning Theory is widely used since its concepts are easy to operationalize for health promoting interventions: role models can be used to model pos-



Health Promotion Models, Figure 2 The Concepts of the Health Belief Model



Health Promotion Models, Figure 3 Scheme of the triadic, reciprocal interaction between the three determinants for human behavior according to the Social Learning Theory: Environment, Person, and Behavior (according to Bandura 1986)

itive outcomes, to correct misconceptions, to demonstrate self-reward, to reflect mastery, to point out opportunities, to signal social support, etc. (Seibt 2003d).

The Stages-of-Change-Theory, also called the ► transtheoretical model (TTM), differentiates phases through which people, groups, or organizations go when changing – both for eliminating an old and for adopting a new behavior or condition. This theory provides a time dimension for the change process.

The original Stages-of-Change-Theory distinguishes five phases:

In the first stage – *Precontemplation* – people have no awareness of the problem and no intention to take action; this stage is the most stable one. The second stage – *contemplation* – is defined as an intention to take action some time in the future, conceptualized as within the next 6 months for most individual problem behaviors. In this phase, there is recognition of a problem, and causes, effects, and solutions are reflected. However, there is no readiness yet to engage in any changes. In the third stage – *preparation* – the focus lies on the solution rather than the problem. There is an intention and a plan to test the new condition. It is an ambivalent stage with high awareness, anxiety, impatience, etc. Often, small changes have already taken place (e. g. a reduction in cigarette consumption per day). *Action* is the (fourth) stage in which individuals overtly modify their behavior or environment in order to overcome their problems. This phase requires considerable commitment of time and energy. *Maintenance* is the (fifth) stage in which people work to prevent relapse and consolidate the gains. For addictive behaviors, this stage often extends to an indeterminate period (e. g. former alcoholism).

A second dimension of the Stage-Theory is the specification of processes, by which people (or groups or organizations) move onto the next stages. In short, the progression through stages one to three involves cognitive, affective, and self-evaluative processes, while for stages three to five, social support, contracts, rewards, and environmental control mechanisms are important. In each stage, people can rush through, stay for long periods of time, or remain forever.

This theory allows differentiation between target populations and intervention methods in a stage-sensible way (Seibt 2003e). There is almost no public health problem behavior for which the theory has not yet been tested and used.

H

Other Models

There are other models or theories used in health promotion: the ► theory of reasoned action, also called ► theory of planned behavior (Seibt 2003f); the Diffusion of Innovation theory (Seibt 2003g); the Communication-Behavior Change Theory (Seibt 2003h); the Attribution Theory (Seibt 2003i); ► social marketing (Seibt and Lehmann 2003k), etc. Another group of theories includes those of changes in organizations for the creation of health-supportive organizational practice and those for the development of healthy public policy and community development (for a short description of those, see Nutbeam and Harris 2004 or Glanz et al. 2002).

Health Promotion Outcomes

Definition

Health promotion outcomes, as personal characteristics and skills, as well as social norms and actions, organizational practices and public policies which are attributable to a health promotion activity, are defined by WHO. They represent the most immediate results of health promotion activities and are generally directed towards changing modifiable determinants of health. Health literacy, public health policy, and community action for health are included as health promotion outcomes. Health promotion outcomes often produce a broader range of changes and effects than initially intended by the program.

Health Promotion – Setting

Andreas Fuchs
Forschungsverbund Public Health Sachsen-Sachsen Anhalt e. V., Medizinische Fakultät, Technische Universität, Dresden, Germany
andreas.fuchs@tu-dresden.de

Definition

Setting is the place or social context in which people engage in daily activities in which environmental, organizational and personal factors interact to affect health and well being (WHO 1998).

Basic Characteristics

Settings are places or social conditions in which humans spend a huge part of their daily lives and which have a great influence on their health. Typical settings are work situations, areas of leisure time and schools. When carrying out interventions it is recognized that it is necessary to consider the living conditions of individuals and their settings. With regard to health promoting activities, need to be described and analyzed before implementing health promotion interventions. As individuals belong to and are influenced by a variety of settings, the formulation of the setting approach was an important step in the development of health promotion activities. Settings can be categorized in various ways: personal and individual (e. g. health risk related lifestyles), regional aspects (cities, regions, islands and countries), social as well as institutional (family, kindergartens, schools, associations or communities of interest).

The setting approach was first put forward as a health promotion concept in the ► Ottawa Charter in 1986 and it is the basis of the ► WHO ► healthy cities project; a long-term development project to place health on the agenda of cities around the world, and to build a constituency of support for public health at the local level (WHO 1998).

Numerous and widespread programs and interventions, mainly initiated by WHO, give credence to the fundamental importance of the concept of settings. Examples of settings include ► social networks, ► healthy islands, ► health promoting schools, ► health promoting workplaces (HPW), healthy cities and healthy vil-

lages, health promoting prisons, neighborhoods and ► health promoting hospitals.

The WHO initiative "Health 21" confirmed the setting approach as an important strategy in health promotion and was continued at the 4th Conference on Health Promotion in Jakarta, held in 1997. Settings were classified as central concept for strategies and interventions in social systems and organizations. Their focus was on organizational networks, not on the health risk behavior of individuals and their circumstances.

Therefore, the intention of WHO was to support the idea of settings in ► networks. The WHO/EURO initiative "Networking the networks" and other global networking activities are examples of these initiatives. They aim at creating a global alliance for health promotion. The whole concept of inter institutional and ► inter sectoral-collaboration and cooperation through network building was seriously promoted by WHO (WHO 1998).

Currently, discussions center not only on the concept of systems of networks in health promotion but also on the setting of health promotion networks; the fostering of networks is regarded as a necessity and long term prerequisites for health promotion will be established through network building (Broesskamp–Stone 2002).

Nevertheless, settings, as one part of health promotion interventions, need to be more specifically identified if implementations are to be successful. For example, community, city or workplace are not specific enough definitions; more particular information is required, such as which actors (e. g. ► target group, decision maker, professions, etc.) define the setting and careful consideration has to be given to the advantages and disadvantages their involvement incur. The success or failure of an intervention in health promotion activities in settings depends on the careful definition of these settings. This definition must not only describe the level of involved actors but also consider the addressed problems which are the target of the health promotion interventions (Grossmann, Scala 2003).

The advantage of defining settings is that the same intervention can be utilized to reach both actors and target groups at various levels; health promotion activities are combined, in a given setting, not only as individual measures but also as population related measures. Thus, all the participants of the setting define the potentials for health in a participative process and develop their own priorities and produce suggestions for improvement.

Health Promotion Theories

► Health Promotion Models

Health Protection

► Health Care

Health Record

Synonyms

Medical record; Patient record; Medical documentation

Definition

Health record refers to all patient records generated over an individual's lifetime by all health care providers

the patient was in contact with, and records every time that health services were used. It comprises the histories of all disabilities and illnesses, laboratory findings and results from other diagnostic procedures, and information on the therapies applied.

Health-Related Quality of Life (HRQOL)

Definition

In public health and in medicine, the concept of health-related quality of life refers to a person or group's perceived physical and mental health over time. Health-related quality of life is used to measure the effects of numerous disorders, short- and long-term disabilities, and diseases in different populations on their patients to better understand how an illness interferes with a person's day-to-day life. Health-related quality of life represents the functional effects of an illness and its consequent therapy upon a patient, as perceived by the patient.

Cross-References

► Indicator
► Quality of Life

Health Reporting

Definition

Health reporting is performed to follow the trends in health status of the population over time. Health reporting can be done using ► health indicators – changes of the indicator level in a specific period of time; by using indicator sets – a set of parameters used as a model to track progress of health goals over time; or by using health targets – formulated strategies adopted by several countries.

Health Research

Synonyms

Medical research; Clinical research

Definition

Health research is defined as investigative work undertaken on a systematic and rigorous basis using quantitative and qualitative methods to generate new knowledge aimed to impact on human physical, social and psychological well being.

Health Research and Indigenous Health

MIHAELA SERBULEA
International School of Homeopathy Japan, Yokohama, Japan
serbulea_m@hotmail.com

Synonyms

Medical research; Clinical research; Medical anthropology

Definition

Medical research encompasses a broad range of activities within basic and clinical research, all aimed at improving or maintaining human health. Clinical research involves research on human participants, while basic research refers to underpinning research from areas such as animal studies, psychology, statistics, economics, physics, chemistry, etc. (http://www.mrc.ac.uk/index/current-research/current-clinical_research/current-clinical_research_definition.htm) (UK Medical Research Council).
Research and indigenous health focuses on two main areas:

- Research on traditional medical practices
- Research on indigenous populations

Basic Characteristics

Research Methods

Research on Traditional Medical Practices Ethnobotanical surveys and phytochemical analysis of possible active compounds should be done ideally simultaneously with a study of the socio-cultural beliefs and rituals underpining the use of plants in traditional medicine.
Research on traditional medicine has focused on clinical and experimental medicine. In order to maximize the contribution of traditional medicine to health

care globally, cultural, social, political and economical aspects of traditional medicine should be researched (Bodeker 2000).

Protocols for clinical trials should be designed according to the specificities of the tested substance and the cultural sensitivities of the peoples who have used the therapies for generations. Guidelines developed by the World Health Organization state that if a traditional medicine is in customary use with no reported side effects, a fast-track toxicology regime (testing on two species of animal for a six-week period) with documentation is an adequate basis for starting Phase III clinical trials.

Research on Indigenous Populations *Epidemiological research* has shown that native populations have a significantly lower health status than that of the dominant population and that barriers exist to receiving formal health care.

Safety

Roy Chaudhury has offered a model for the clinical evaluation of herbal medicines which includes toxicity testing of the plant in two species of animal for acute and sub-acute toxicity, a modified, shorter toxicity testing if the plant has already been used in man or is in such use now and the administration of the total extract or combination of plants, if used, in exactly the same way as it is prepared and used by the population (Roy Chaudhury 1992).

Claims of curing, especially, life-threatening diseases, and traditional practices related to pregnancy and birth have to be evaluated in order to avoid dangers. For instance,further research is needed to determine the side-effects of Isihlambezo (herbs taken in some regions of South Africa during pregnancy for cleansing) on the pregnant woman, the fetus, the labor process and the outcome of pregnancy.

Several research projects are focused on studying the safe side of herbal medicine as well as adverse drug reactions and adverse reaction of herbal medicine when used simultaneously with Western medicine.

Government Involvement

Traditional healers in some countries want their governments to fund testing of their remedies because they believe it is the only way these effective medicines would be recognized as such and become more widely used.

Some governments have urged traditional healers to collaborate with scientific researchers to prove the safety of traditional medical practices, in addition to the age-old practice in the respective communities.

Funding

Despite the importance, very limited amounts, mostly from private funds, are allocated for research on traditional medicines, as compared to research of the most advanced techniques and pharmaceuticals for diagnosis and treatment.

Resources should be channeled towards research into the efficacy and safety of traditional medicines.

Ethics

Most healthcare-related research that has been externally sponsored in developing countries has not taken account of traditional medicine. In some circumstances, the belief systems of traditional healers and biomedical researchers may be so incompatible that the two groups will be unwilling or unable to collaborate in research. Such collaboration is desirable, or even essential, for research to be successful (The ethics of research related to health care in developing countries, Nuffield council on Bioethics).

Many developed countries sponsor healthcare-related research involving populations and patients in developing countries. The Human Genome Diversity Project uses indigenous peoples as subjects for genetic research raising concerns that they are largely unaware of the potential impacts of this research on their communities. Informed consent is taken lightly and short-term health benefits are being promised to attract participation. Indigenous peoples have frequently expressed criticism of Western science for failing to consider their cultural world views and ethical principles when seeking to find breakthrough information for the advancement of biotechnology, which is least likely to benefit the populations from whom the knowledge derived (http://www.ipcb.org/publications/primers/htmls/ipgg.html).

Conclusion

Research on traditional medical practices from a culturally appropriate perspective and taking into con-

sideration social, political and economical aspects of indigenous health care as well is needed to validate diagnostic and therapeutic procedures on which the majority of peoples in the developing world rely. Indigenous health addresses mainly symptoms of illnesses as well as aspects of palliative care entailing rituals involving the entire community and thus the principles of testing used for Western medicine do not apply. The holistic nature of traditional medicine requires a new paradigm of research, different from the methods prevalent in biomedicine.

The results of unprejudiced research on indigenous medicine would promote the integration of the two approaches into a modern health care system.

The advances in biotechnology and genetics in recent years has alarmed indigenous peoples as to the effects on their culture and future and raised concerns about the ethical treatment of populations which are uneducated in respect to the methods and purpose of this research.

Health Risk

Definition

Health risk from the environment comes about by the daily intake of toxic and carcinogenic chemical substances through the air, water and food which exceed recommended guideline values; these values should guarantee freedom from adverse effects to health over a life time of consumption.

Health Risk Assessment at Workplace

► Workplace Health Risk Assessment

Health and Safety Measures

Synonyms

Health and safety risk management

Definition

The law requires an employer to assess and manage health and safety risks. Risk management (► risk management and communication) involves the employer looking at the risks that arise in the ► workplace, and then putting sensible health and safety measures in place to control them.

There are three basic steps in managing the risk from workplace ► hazards:

1. eliminate hazards posed by equipment and work processes at their source (e. g. redesign the work process, substitute a safer chemical for a hazardous chemical, use new equipment);
2. if it is not practical to eliminate hazards, control the hazard to reduce the risk to workers (e. g. machine guards, noise enclosures, ventilation to dilute the concentration of a hazardous substance);
3. if it is not practical to control the hazard, protect workers from the hazard by using tools such as administrative controls, safe work procedures, effective safety training, proper supervision, or personal protective equipment.

Health Service

Definition

A health service is a permanent system of institutions aiming to meet the health needs of the population and to provide health protection for both individuals and the community.

Health Service Area

Definition

A health service area is a geographic area designated based on geography, political boundaries, population, and health resources, for the effective planning and development of ► health services.

Health Services Management

► Health Economics in Dentistry

Health Services Research

Synonyms

Routine health care research

Definition

Health services research is a multidisciplinary field of research that focuses on the study of the provision of individuals and populations with products and services related to health care. Goals are the evaluation of the effectiveness of health care measures under realistic conditions and the impact of influencing factors (e. g. insurance plans, costs, organization, structures, health technology, and quality of care). Health services research complements traditional clinical research. Its research domains are individuals, families, organizations, institutions, communities, and populations and ultimatly their health and well-beeing.

Health Services System

► Health Systems

Health Services System Reforms

► Health Systems Reforms

Health Setting

Synonyms

Living condition; Social system and organization

Definition

The place or social context in which people engage in daily activities in which environmental, organizational and personal factors interact to affect health and well-being. A setting is also where people actively use and shape the environment and thus create or solve problems relating to health. Settings can normally be identified as having physical boundaries, a range of people with defined roles, and an organizational structure. Examples of settings include kindergartens, schools, work sites, hospitals, villages or cities.

Action to promote health through different settings can take many different forms, often through some form of organizational development, including change to the physical environment, to the organizational structure, administration and management. Settings can also be used to promote health by reaching the people who work in them, or who use them to gain access to services, and through the interaction of different settings with the wider community.

Health Statistics

Definition

Health Statistics contain all relevant statistical information of the health status of populations or subgroups. In all developed health care systems, there are national health statistic centers identifying health problems, monitoring trends in health status and health service delivery of their population and identifying disparities in health status and the use of health care services by different subgroups. Health statistics are an important source of information for public health policies and programs and support medical research.

Health Status

Definition

The term health status describes the state of health of an individual, a group or a whole population that is measured at a particular time according to defined standards or indicators. The definition of these standards or indicators necessitates an evaluation of the degree of the individual's illness or wellness, basic physical and mental functionality and quality of life. The individual health status may be measured by a medical examination defining the presence or absence of life-threatening diseases, other diseases and their impact on the quality of life and risk factors of overall health. It may also be determined by asking the individual about his or her

health perceptions. As there is no single standard measurement for the health status of individuals or population groups, researches must define their own way of measuring.

Health Status Indicators

Definition

Indicators of health status are the essence of ► health indicators. They include mortality, morbidity (general rate and disease specific rates), generic health status, and composite health status measures. They are most widely used for comparisons between populations, for communication within the healthcare system, and for the coordination of future priorities in health of the community.

Health Strategy

Synonyms

Health action plan

Definition

Health strategy is defined as an elaborate and systematic plan of action in the organization of health care.

Health Subsidies

Synonyms

Subsidy; Voucher

Definition

A grant provided to individuals, organizations or institutions to purchase a restricted set of health-related goods and services. Consumer-side subsidies place purchasing choice in the hands of individual health care users, while producer-side subsidies support organizational or institutional provision of particular goods or services. These subsidies are primary granted by government or philanthropic foundations for the primary purpose of promoting a goal considered beneficial to the public welfare.

Health Surveillance

Synonyms

Medical surveillance

Definition

Health surveillance is the ongoing observation of the health status of the population and the factors that may affect it.
Health surveillance refers to the systematic collection, analysis, and interpretation of health data that has a significant impact on health, which is then used to drive decisions about health policy and health education. Health surveillance in occupational health refers to the application of medical tests and procedures to individual workers who may be at risk for occupational or work-related morbidity, to determine whether an occupational or work-related disorder may be present. A medical surveillance, also, applies tests and procedures on a group of workers with common exposures for the purpose of identifying individuals who may have occupational or work-related illnesses and for the purpose of detecting patterns of illness which may be produced by occupational exposures among the program participants. Medical surveillance represents the first step in ascertaining the presence of a work-related problem.
Occupational health surveillance entails the systematic monitoring of health events and exposures in working populations in order to prevent and control occupational hazards and their associated diseases and injuries. The purposes of occupational health surveillance is to identify the incidence and prevalence of known occupational and work-related diseases and injuries, and to find and evaluate other individuals from the same workplaces who may be at risk of similar disease and injury. Occupational health surveillance is an important means of discovering new associations between occupational agents and accompanying diseases.

Health System in Dentistry

DAVID KLINGENBERGER
Institute of German Dentists, Cologne, Germany
d.klingenberger@idz-koeln.de

Synonyms

Oral health care system; Oral health care services; Dental care delivery system

Definition

The health system can be described on a fairly general level as the "totality of organized social action in response to the occurrence of disease and disability and for averting risks to health" (Schwartz and Busse 2003). Although this definition is broad and likely to meet with a wide measure of acceptance, it is not very useful for operational purposes. A narrower and therefore more practical definition subsumes within the concept of the health system "all institutions and activities directed towards the provision and funding of health benefits to the population" (Hajen et al. 2000). In this less wide-ranging sense, the term "health *care* system" is also used. The "oral health system" can be defined in functional terms as "the combination of organizations, flows of finance, workforce training and structure, laws, regulations and accepted practice which are aimed at improving the oral health of individuals and communities" (Anderson et al. 1998).

History

Health systems have existed ever since people first attempted to protect their health and to treat diseases. Organized health systems in the modern sense, however, are an institution of the last hundred or so years and universal cover is predominantly confined to industrialized countries. In Germany the process of development towards an organized health system began in the second half of the nineteenth century (Tiemann et al. 2003). Nowadays, owing to its quantitative significance the health system is already commonly described as an "industry". Total health spending in Germany in 2005 amounted to 239 billion euro, or 10.7% of gross domestic product. Oral health care is estimated to account for about 1% of GDP.

Basic Characteristics

A "system" is generally understood to mean the totality of interconnected elements that influence each other and are organized for a specific purpose. The system of oral health care thus involves the interaction between dentists and patients, health insurance funds, associations of statutory health insurance dentists, associations of health insurance funds, professional dental organizations, associations and societies, the dental technology industry, health ministries and other government institutions, as well as other bodies. The objectives of the system are enshrined, for example, in the German Dental Association's "Oral Health Goals", which are in turn based on the World Health Organization's "Global Goals for Oral Health 2020":

1. Promotion of oral health and reduction of the effects of dental, oral and maxillofacial pathology on general health and on psychosocial development, with particular reference to at-risk groups.
2. Reduction of the effects of dental, oral and maxillofacial pathology on general health at both individual and population level by early diagnosis, prevention and efficient treatment of oral disease.

Given appropriate operationalization of the specified aims, for instance on the basis of the ▶ DMFT value for caries or the Community Periodontal Index (▶ CPI) for periodontal status, attainment of the system objectives can be assessed empirically by ancillary evaluative research.

Analysis reveals that the oral health system can be broken down into three components, of which the third is assignable to the individual sector (see Fig. 1). They are:

1. The oral health care system proper (the medical system).
2. The social, political and economic background to the oral health care system (health policy).
3. Patients' individual capabilities and attitude patterns (which are subject to influence by the oral health care system and the socioeconomic background) (health behavior of the general population).

Compared with the health system as a whole, the oral health system exhibits certain particularities: "Most oral care is provided as an outpatient service, and hospital oral health care is very limited. Among the reasons suggested for this are: (a) the elective nature of most dental treatment; (b) the highly individualistic nature of solo dental practice; (c) the relatively restricted use of dental auxiliaries; (d) the chronic rather than life-threatening nature of most dental diseases; (e) the minimal interest in and development of hospital-centered treatment in general dentistry; and (f) the relatively slow advances in oral health sciences compared to medicine" (Holst et al. 2002).

Comparative Oral Health Systems Research

The comparative analysis of health systems is concerned with the extent to which indications for the design of a health system can be derived from a comparison of differently structured health systems and from evaluation of experience gained in other countries. For the specific field of oral health care, the Manual of Dental Practice published by the Liaison Committee of the Dental Associations of the European Union (Kravitz and Treasure 2004) constitutes a good general survey of the various national oral health systems.

National differences in the design of oral health systems are largely attributable to the historical and cultural particularities of the countries concerned. Both the structure and organization of the system of oral health care and the level of benefits provided depend on a state's specific "► sociopolitical culture". The transferability of system elements between countries is consequently very limited. The outline of European health systems given in Table 1 reveals a number of common features that allow the systems to be assigned to just a few classes or "models" (Anderson et al. 1998; Holst et al. 2002; Klingenberger 2006).

As a rule, these models are not applied in pure form; that is to say, a given national health system may perfectly well include individual features of a different model and thereby assume a hybrid configuration. The Semashko model of the central and eastern European countries has developed in the direction of the Bismarck model since the "fall of the iron curtain" in 1989. Since all national health systems are faced with similar economic and demographic challenges and a concerted European health policy is proposed for the medium term (under the "Open Method of Coordination"), it is generally assumed that there will be a "► convergence of systems" – i. e. that the various models will develop in the direction of a "mixed system". The mixing of systems is already far advanced in some European states (the countries shown in parentheses in Table 1).

Measuring Health System Performance

An important aspect of comparative health systems research is international comparison of the performance of health systems – that is, the extent to which health goals (including oral health goals) are achieved and the resources required for this purpose. Anyone wishing to compare the performance of health systems faces two problems. First, generally accepted criteria for assessment must be identified (the assessment problem), and, second, the effect of the health system on the performance of other factors must be isolated (the problem

Health System in Dentistry, Table 1 Delivery models

Bismarck model (government-regulated social insurance system)	
• Oral health care is mainly financed through compulsory social insurance, with the option of voluntary private insurance • Contributions from employees and employers, usually as a fixed percentage of earned income; these contributions are pooled and disbursed by independent sickness funds • Provision relies mainly on private dental practitioners • Benefits cover most restorative dental care • There are also private insurance schemes in which patients pay their dentist directly and are reimbursed from the insurance company • Cost-sharing generally consists of the consumer's payment of a fixed percentage of expensive porcelain or gold restorations and fixed prostheses	*Countries*: Austria, Belgium, France, Germany, Luxembourg, Netherlands, (Switzerland)
Beveridge model (government-organized and tax-financed national health system)	
• Financing of oral health care used to be predominantly provided out of general and/or specific taxation, collected by central or regional government • Oral health care services are traditionally provided by publicly owned and managed institutions • Price and treatment profile regulation • Universal access to oral health care, but usually with defined levels of patient co-payments for treatment • Small but rising market share of voluntary insurance schemes	*Countries*: Denmark, Finland, Sweden, United Kingdom, (Norway), (Portugal), (Spain), (Italy), (Greece), (Ireland), (Iceland)
Semashko model (mixed system of Bismarck [financing] and Beveridge [provision])	
• Oral health care is mainly financed by compulsory social insurance • Comprehensive oral health care is provided free of charge to the whole population • Dentists are salaried public employees who operated from local or company-based polyclinics or hospital dental departments • Oral health facilities are publicly owned and the distribution of personnel, clinics, treatment and materials is planned • A small proportion of expensive services – mainly prosthetic services – is covered by patient-co-payment • Some private practice exists in several CEE countries, entirely paid for by patients on a fee-for-service basis	*Countries*: Central and eastern European countries (CEE)

of attribution) (Hajen et al. 2000). To permit the comparison of different health systems, the World Health Organization has developed an "overall health system performance" index, which takes account of the following five criteria of the performance of a health system (World Health Organization 2000):

- level of health (life expectancy)
- openness of the health system (accessibility)
- fairness of funding (distribution of burdens) and access to services (equity)
- status of medical care
- satisfaction of the population with the health system and individual satisfaction with one's state of health.

However, the World Health Organization's methodology has been criticized as unscientific. All multidimensional analyses are at risk of not comparing like with like – i. e. of failing to solve the assessment problem mentioned above. Statements about the performance of health systems should thus concentrate preferentially on detailed analysis of individual fields of care. A good example from the oral health care sector is the Euro-Z project, an empirical comparison of the prices of dental treatments in seven European countries (Kaufhold et al. 2001) ▶ (oral) health system performance.

Conclusion

The analysis of health systems is subject to a number of methodological problems, in consequence of which caution must be exercised in interpretation of the results. Yet health systems analysis can offer important early indications of feasible approaches to reform and of emerging trends. In the specific field of dentistry, a trend is becoming apparent, regardless of the particular system applied, for the proportion of expenditure accounted for by public funding to be reduced and for relatively more reliance to be placed on private ▶ models of finance. In the future, too, a greater role will be played by private service provision in the field of oral

health care. An early steering of health policy along lines based on the results of health systems analysis is desirable.

Health System Forms

Synonyms

Similar trends of health care systems reform

Definition

The basis of convergence theory is the hypothesis that industrial states with different forms of organization face comparable challenges and must accordingly develop similar solutions. The pressure of comparable problems, it is held, gives rise to similar requirements of adaptation and thereby results in an approximation of institutional, political and economic structures and strategies. A comparative study of health policies in the OECD member states concluded that "the most remarkable feature of the health care systems reform is the degree of emerging convergence". Transnational problems and trends in health care can be attributed to, for example, economic causes (mass unemployment or globalization), technical factors (innovative medical technology and consequent new treatment methods) and issues of population structure (demography and epidemiology).

Health System Indicators

Definition

Indicators of the performance of ► health systems are defined by effectiveness, appropriateness, efficiency, responsiveness, accessibility, safety, continuity, capability, and sustainability. Health system characteristics include the extent to which the system delivers good quality health actions to improve the health of the population. This is the most general term for health indicators, including indicators of health care provision, utilization, health care financing, and health policy.

Synonyms

Health care systems; Health services system

Definition

Health systems are usually characterized according to the predominant source of health care finance. With the notable exception of the health care system United States (US) – which is a mixed system – one predominant source of financing can be identified in most Organisation for Economic Co-operation and Development (OECD) countries, which is either taxes or social health insurance premiums.

Basic Characteristics

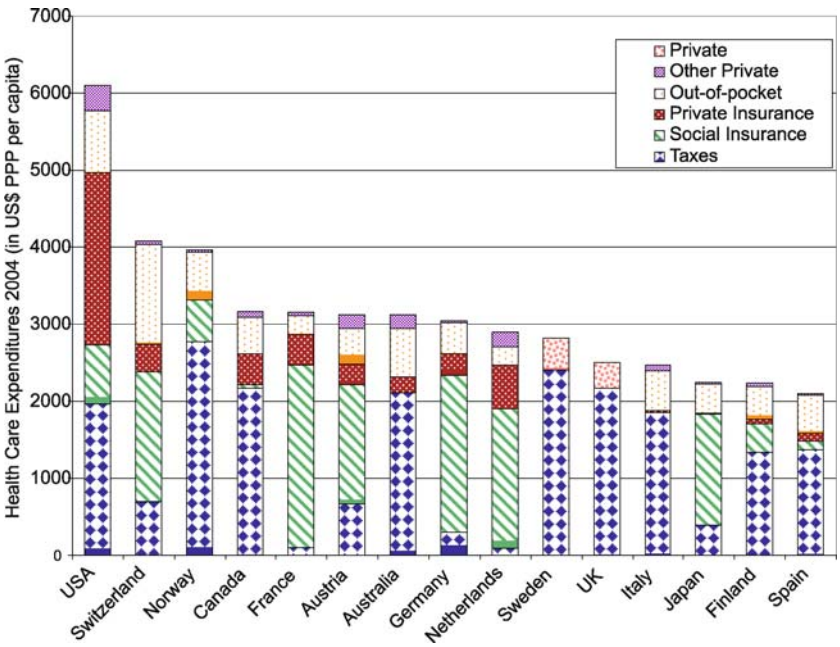
Typology of Health Care Systems

A typology of health care systems is necessarily rather crude, since divergent approaches towards the design of health care systems lead to diverging institutional arrangements. However, probably the most widespread approach for grouping health systems is by predominant mode of health care financing. Figure 1 illustrates the fact that no health care system is financed from one source only. However, with the notable exception of the US and maybe Switzerland, one predominant mode of financing can be identified. Countries such as Canada, Norway, Sweden, Finland, Australia, Italy, Spain, and the United Kingdom (UK) are predominantly financed out of taxes. Other health care systems such as those in France, Austria, Germany, the Netherlands, and Japan are financed primarily by social health insurance premiums.

Social Health Insurance Systems

The common feature of ► social health insurance systems is the fact that health care financing is administered by social health insurers at arm's length from government. In contrast to taxes, the premium income of social health insurers is earmarked for health care financing. As a consequence, social health insurance systems are less prone to under-funding than tax-funded health care systems – the Netherlands being an important exception (Brouwer et al. 2003). On the other hand, social health insurance financing may act as a drain on employment if premiums are linked directly or indirectly to labor costs (► labor market).

One important difference between social health insurance systems is whether health insurers are competing or not. In Austria and France, consumers are not able to choose between social health insurers; in contrast, there is considerable consumer choice in Germany, the Netherlands, and Switzerland (► health systems reforms, ► competition, health care). Moreover, social health insurance premiums are not the only source of



Health Systems, Figure 1 Health care expenditure and source of financing in selected OECD countries 2004, Source: OECD Health Data October 2006

health care financing in these countries. As a consequence, countries with social health insurance systems differ in the importance of secondary sources of financing. Except for Japan, private health insurance premiums are an important source of secondary health care financing in these countries. Only in Germany is private health insurance an alternative (► alternative private health insurance) to social health insurance – at least for part of the population (Wasem et al. 2004). This was also true for the Netherlands until 2005; however, social health insurance and alternative private health insurance were merged into one unified health insurance system in 2006 (Schut and van de Ven 2005).

Supplementary private health insurance is most important quantitatively in France (Turquet 2004; Wasem et al. 2004). Out-of-pocket payments are the biggest secondary source of health care financing in Switzerland. In fact, Switzerland is on the verge of becoming a mixed system, since tax-financing is also an important source of secondary health care financing.

Tax-Financed National Health Systems

In contrast to countries with social health insurance systems, health care financing in tax-financed countries is administered by governmental institutions. Health care is financed not by earmarked social health insurance premiums. Instead, it is usually financed out of general tax revenue. This means that health care has to compete with other items such as education and defense, which also have to be financed out of general tax revenue. As a consequence, rising health care expenditures may crowd out other public expenditures. Conversely, under-funding of health systems may occur if other spending items crowd out rising health care expenditures. Under-finding is therefore an important reason for long waiting times, which are a major problem in Canada and the UK (Hurst, Siciliani 2003; Oliver 2005). Table 1 shows that waiting times for specialist appointments and elective surgery are considerably higher in Canada and the UK than in the US and Germany. On the other hand, access problems due to cost are less prevalent in Canada and the UK than in the US and Germany.

Health Systems, Table 1 Waiting times among sicker adults in four countries in 2005

	CAN	UK	US	GER
Wait for specialist appointment (more than 4 weeks)	57%	60%	23%	22%
Wait for elective surgery (more than 4 months)	33%	41%	8%	6%

Source: Schoen et al. 2005

Mixed Systems

The US health system is often characterized as a system that is financed predominantly by private sources of finance. ► Private health insurance, co-payments, and charities indeed cover approximately 55 percent of health care expenditures in the US, which was equivalent to 3,375 US$ per capita in 2004. This amount exceeds *total* health care expenditures per capita in all other countries except Switzerland and Norway. However, another 2,727 US$ per capita are covered by public sources (taxes, social health insurance premiums) to finance public schemes for the poor and the elderly. This amount exceeds *public* spending on health care per capita in any other country except Norway (Woolhandler, Himmelstein 2002). As a consequence, the US health system is also characterized as a mixed system.

Although total health care expenditure per capita in the US is much higher than in any other country, only part of the population is covered by either private health insurance or public schemes. About 18 percent of the non-elderly population (over 46 million individuals) is uninsured (The Kaiser Commission on Medicaid and

Health Systems, Table 2 Access problems due to cost among sicker adults in four countries in 2005

	CAN	UK	US	GER
More than 1000 US$ out-of-pocket expenses for medical bills in the past year	14%	4%	34%	8%
More than 100 US$ out-of-pocket expenses for prescription drugs	16%	3%	30%	5%
Did not fill a prescription	20%	8%	40%	14%
Did not visit a doctor when sick	7%	4%	34%	15%

Health care system reforms; Health services system reforms

Definition

A number of health system reforms have been exceptionally important during recent years. First, a comprehensive health insurance reform has led to the abolishment of alternative private health insurance in the Netherlands. As a consequence, Germany is the only remaining Organization for Economic Co-operation and Development (OECD) country where social health insurance and alternative private health insurance continue to co-exist. Second, the establishment of the National Institute for Clinical Excellence in the United Kingdom set a trend for assessing the cost-effectiveness of health care services, which has also been taken up by other countries. Finally, the health insurance reform in Massachusetts may lead to the introduction of universal health insurance in other states of the United States (US) as well.

Basic Characteristics

This essay follows the typology that has been applied in the essay on ► health systems. For each type of health system, one country where major health system reforms have taken place has been selected.

Reforms in Social Health Insurance Systems: The Netherlands

At the beginning of the year 2006, the Dutch government introduced a fundamental reform of the Dutch health system. The aim of this reform was to improve the quality and efficiency of the health system by introducing a uniform health insurance system and intensifying ► regulated competition between health insurers (Schut and van de Ven 2005; Greß et al. 2007). The rather arbitrary separation between social health insurance and private health insurance of the past has been abolished. This is a major achievement, since policy makers in the Netherlands have been trying to introduce an universal health insurance system since the early 1990s (Schut and van de Ven 2005).

Although the new health insurance scheme is executed by private carriers, regulation of the system is essentially social (Paolucci et al. 2006). All health insurers are

obliged to accept all applicants, premium rate restrictions do not allow ► risk-rated premiums, and insurers are compensated by a health-based ► risk adjustment system. The new health insurance scheme is compulsory for all inhabitants of the Netherlands.

As a result of the reform, the health insurance market in the Netherlands has changed dramatically. Price competition between health insurers has become very fierce and consumer mobility has increased dramatically. While consumer mobility was dormant before the reform, consumers started actively comparing prices and options after introduction of the reform. While the short-term effects of the reform seem to be in line with the intentions of policy makers, it remains to be seen whether the same is true for the long-term consequences of the reform. One key aim of reform was that the new system would lead to a more efficient provision of health care services. However, so far, competition between health insurers is based primarily on price. As a consequence, the quality of health care services is not yet an important means for health insurers to attract consumers (► competition, health care).

From a comparative perspective, the Dutch reform is a rather fascinating example of cross-country policy learning. Some key features of the Dutch reform, such as the introduction of a universal health insurance system, mandatory coverage for the entire population, tax-financed premium subsidies for low-income consumers, and voluntary ► deductibles, can also be found in the Swiss health insurance system. What is more, shortly after the introduction of the reform in the Netherlands, policy makers in Germany became very interested in the design of the new Dutch system. As a result, some key features of the health care reform of 2007 in Germany look strikingly similar to the Dutch system. However, one very important difference between the system in Germany and those in the Netherlands and Switzerland remains: the rather arbitrary separation between social health insurance and private health insurance in Germany.

Reforms in Tax-Financed National Health Systems: United Kingdom

Towards the end of the 1990s, "► postcode prescribing" had become a key issue for the tax-financed National Health Service. Examples where access to certain treatments and services differed between health authorities were frequent, and controversies had emerged over access to a wide range of treatments. As a consequence, the ► National Institute for Health and Clinical Excellence (NICE) was established in April 1999.

NICE is supposed to provide guidance on the use of health services to the National Health Service. The guidance is based on appraisals of pharmaceuticals, medical devices, diagnostic techniques, and surgical procedures, as well as preventive services (Department of Health 1998). Appraisals result in recommendations for the use of health care services within the NHS that are binding for regional health authorities. If providers intend to use a service recommended by NICE, regional health authorities have to finance this use. NICE is supposed to consider not only the clinical effectiveness of services, but – given scarce resources – also the relationship between effectiveness and associated costs (Devlin and Parkin 2004; Greß et al. 2005). In this respect, NICE has been the pioneer of a development which has become imperative in many other countries as well – no matter if these countries are predominantly financed by taxes or by social health insurance premiums (Greß et al. 2007).

Reforms in Mixed Systems: United States

Health insurance coverage in the mixed US health financing system is not mandatory. As a consequence, almost 20 percent of the non-elderly population in the US is uninsured (► health systems). So far, any effort to introduce universal coverage in the US on a national level or even on a state level has been unsuccessful. However, in April 2006, Massachusetts enacted legislation that is supposed to provide universal coverage to state residents (Haislmaier and Owcharenko 2006). The Massachusetts Health Care Reform Plan requires all adults in the state to purchase health insurance. Moreover, employers are required to provide health insurance coverage to their employees or a pay a fine. Individuals receive government-funded subsidies in order to be able to buy health insurance. By May 2007, more than 100,000 previously uninsured individuals had gained coverage because of the reform. As a consequence, the Massachusetts plan has generated a great deal of interest on the national and state level and has ignited a broader debate about the feasibility of the introduction of universal coverage (Kaiser Commission on Medicaid and the Uninsured 2007).

Health Targets

Synonyms

Health goals

Definition

Health targets are based on outcomes and processes. They can be quantitative, such as immunization rates, or qualitative, such as the introduction of national health care programs and initiatives. While not a requirement, health targets should ideally be specific, measurable, accurate, realistic and time-bound ("SMART"), to enable better monitoring and management towards achieving those targets. Health targets facilitate the achievement of health policy and therefore represent a commitment of a system or legislative body to achieve specific pre-defined outcomes over a pre-defined period of time (► health outcomes). As they set priorities, they can be used to create high levels of commitment and they are the basis for follow-up activities and evaluation. Health targets can be applied nationally, internationally, or within systems on sub-national levels, such as public health care systems.

Numerous governments in the Member States of the WHO European Region and in OECD countries utilize health targets as an instrument and guidance for policy formulation and implementation.

Health targets are defined as follows in the WHO Health promotion glossary:

> They define the concrete steps which may be taken towards the achievement of health goals and it means a change in the health status of a population that can be reasonably expected within a defined time period. Setting targets also provides one approach to the assessment of progress in relation to a defined health policy or program by defining a benchmark against which progress can be measured. The implementation of health targets requires the existence of a relevant health indicator and information on the distribution of that indicator within a population of interest. It also requires an estimate of current and likely future trends in relation to change in the distribution of the indicator, and an understanding of the potential to change the distribution of the indicator in the population of interest.

Health Technology

Definition

Health technology includes a wide range of procedures, devices and equipment applied to the maintenance, restoration, and promotion of health. The technology comprises interventions at any stage of health

care, including primary prevention, early detection of disease and risk factors, diagnosis, treatment, rehabilitation, and palliative care.

Health Technology Assessment (HTA)

Ulf Maywald
Abteilung Ärzte/Apotheken, AOK Sachsen, Dresden, Germany
ulf@maywald.com

Introduction

Health Systems have developed differently and with varying degrees of complexity throughout the twentieth century. They share a common reason for their existence; that is the improvement of health for the entire population. Unfortunately, they share another characteristic: available resources are limited, and delivering health services therefore involves making necessary decisions. As a result, decision-makers need information about the available options and their potential consequences. It is now apparent that many interventions once thought to be advantageous have, in the light of closer evaluation, turned out to be at best of no benefit, or at worst, harmful to the individual and counterproductive to the system. This recognition has led to the concept of "evidence based medicine" (EBM), which argues that the information used by policy-makers to make decisions should be based on rigorous research to the fullest extent possible (Ham et al. 1995). Sackett defined ► evidence based medicine as "the conscientious, explicit and judicious use of current best evidence in making decisions about the care of individual patients". However, Sackett recognized that "there is some fear that evidence-based medicine will be hijacked by purchasers and managers to cut the costs of health care" (Sackett et al. 1996). As a consequence, he changed his definition four years later to define evidence based medicine as the integration of the best research evidence with clinical expertise and patient values.

EBM primarily affects medical (and health care) practice and focuses mainly on the individual level, whereas Health Technology Assessment (HTA) aims to influence health policy and focuses on the population. In other words, HTA offers a way of evaluating actual or potential health interventions, and helps to ensure that the limited resources available are well spent. Health care systems worldwide are under increasing pressure, and such pressure does not seem likely to diminish in the near future. Critical health ► policy analysis and HTA are needed more than ever in order to assist policy-makers in making difficult decisions and choices.

Definition

HTA has been defined as "a form of policy research that systematically examines the short- and long-term consequences, in terms of health and resource use, of the application of a health technology, a set of related technologies or a technology related issue" (Henshall et al. 1997). Given the broad context of HTA, it is not defined by a set of methods, but by its intention.

The aim of a HTA report is to support decision-making in the health sector by systematically assessing medical, economic, social, and ethical aspects of health. HTA is also a form of policy analysis. By nature, HTA is a multidisciplinary activity, which systematically evaluates the effects of a technology on health, on the availability and distribution of resources, and on other aspects of health system performance such as equity and responsiveness (European Observatory on Health Systems and Policies). In order to achieve the goal of supporting decision making, two preconditions have to be fulfilled: the reports have to meet explicit qualitative standards and they need to have an actual impact on the decision-making process in its context.

History

The term "technology assessment" was first used by the Subcommittee on Science, Research and Development of the House Science and Astronautics Committee of the US Congress in 1965. After a long process, the Subcommittee defined technology assessment as "a comprehensive form of policy research that examines the short- and long-term social consequences (e. g. societal, economic, ethical, legal) of the application or use of technology". Later, beginning with reports from the Office of Technology Assessment (1976), this general definition was applied to the health field as well. HTA began to develop in Europe in the early 1970s, with studies of expensive medical devices in several European countries, notably Sweden. The Swedish Planning and Rationalization Institute (SPRI) began stud-

ies of the then-new computed tomography (CT) scanner in 1972, and then developed a series of studies of the implications of health technology. By the mid-1980s, other European countries had begun to carry out such studies and to use the term "health technology assessment" to describe their work.

Policy Analysis, Policy Orientation and Context of HTA

HTA has been compared to a bridge between the world of research and the world of decision-making (Battista 1996). This bridge is intended to allow the transfer of knowledge produced in scientific research to the decision-making process. In order to achieve this, HTA is dedicated to the work of collecting and analyzing evidence from research in a systematic and reproducible way, as well as making it accessible and usable for decision-making purposes, normally by assessment reports (► policy analysis). HTA shares these principles with EBM and clinical practice guidelines (CPG) and, together with them, enables a body of best practice initiatives to be built (Perleth et al. 2001).

Assessments can be conducted on, for example, investment decisions (purchasing new equipment), or shaping of the benefit catalog (reimbursement of new services), as well as decisions concerning the organization of service provision (inpatient vs. outpatient services). For the purposes of HTA, the decision-maker's need for information is termed the policy question. Intensive cooperation between policy-makers and researchers is needed in order to clarify the underlying policy question and tailor the assessment to the decision-maker's information needs. The quality of this interaction is one of the main determinants of the value of evidence for policy-making (Innvaer et al. 2002). Unfortunately, this cooperation is inadequately established in many countries. Therefore, HTA exists alongside policy decisions and is insufficiently recognized by politicians and health care managers. It is crucial to explain the context of a HTA clearly, so that readers can better assess whether the report is relevant to their own problems. The context-embedded approach of HTA is a key advantage of these assessments because EBM is mainly focused on randomized controlled clinical trials, and the transferability of such results into policy decisions is questionable. In order to give an evidence-based solution to the problems addressed in the policy question, the researchers have to define the policy question in terms of safety, efficacy, and effectiveness, and psychological, social, ethical, organizational, professional, and economic aspects. These questions determine how the rest of the assessment will be conducted, the aspects that will be evaluated, and those that will not, as well as the profundity of the research regarding each of the aspects mentioned.

In each country, the adoption and use of health technology is influenced by many factors, including the perception and experience of health and disease, the cultural responses to technology, the nature of the medical profession in the particular country, industrial information and promotion, and the financial and regulatory system (► HTA, context of).

Aspects of HTA

Technology assessment is carried out by a multidisciplinary group because it requires wider expertise than any individual or single disciplinary group could be expected to have. It identifies the groups that will be affected by the proposed technology (the "parties at interest") and evaluates the impact of the technology on each party.

A thorough assessment requires attention to different aspects of health technology and health technology assessment. Such aspects include dimensions (i. e. safety, efficacy, or effectiveness), functions (i. e. using, doing, and supporting HTA), focus (i. e. treatment or prevention), and type of technology (i. e. drug, medical procedure, or preventive program), as well as types of healthcare provider (i. e. inpatient and outpatient), and decision level (► HTA, aspects of). A scheme of all of these aspects can provide a method for evaluation and further development of the HTA; identifying gaps in coverage and suggesting improvements for the future.

A relatively new field where HTA is being used is to assess patient safety technologies (► patient safety HTA). Regardless of widespread investment in patient safety technologies, especially in the UK but also in the US and elsewhere, little HTA has been done to establish the effectiveness of these technologies. The HTA and patient safety literature suggests there are four categories of assessment of patient safety technologies: HTA for existing safety technologies, for underutilized safety technologies, for emerging safety technologies, and for safety aspects of technologies with a non-safety primary purpose.

HTA Methodology

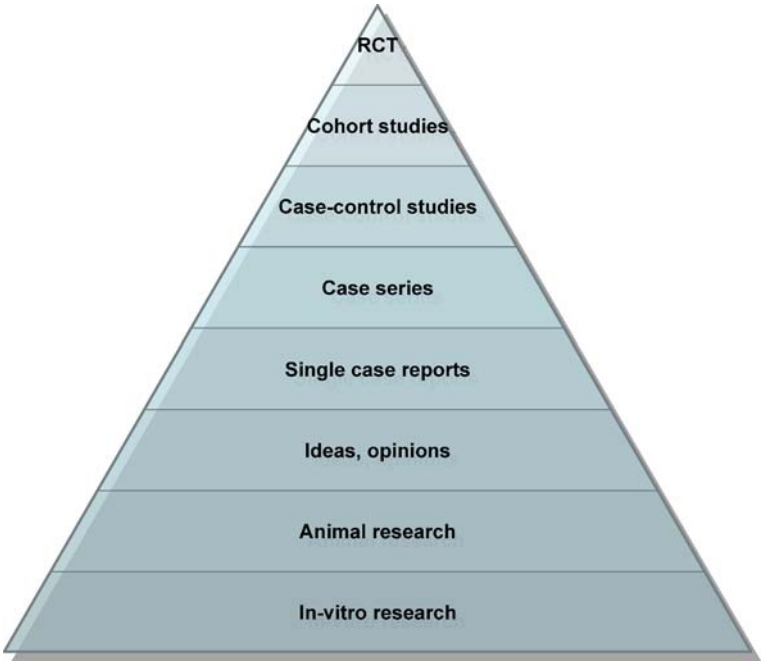
After consensus on the research questions has been reached, the task of the HTA is to retrieve, analyze, and synthesize the available evidence, and to prepare it in a way that is useful for decision-makers or politicians (► HTA, methodology). The researchers try to identify and collect the best available evidence that is suitable to give valid answers to the different aspects of the policy question. They then summarize this evidence. In some cases, it could be appropriate to provide recommendations for policy-making, or at least to outline resulting policy options.

A technical assessment of a pharmaceutical or medical device carried out by a program as a part of a regulatory decision can be called a HTA. Similarly, an ethical analysis concerning gene therapy, that is performed to clarify the implications of the therapy before deciding whether to provide it, can be considered a HTA. The most frequent activity in HTA is a synthesis or systematic review of available information, in particular on efficacy and cost-effectiveness, in order to assist different types of policy decisions. A prospective randomized clinical trial or prospective cost-effectiveness study done for policy reasons, as in the Netherlands or the UK, is also a technology assessment. On the other hand, clinical research or even clinical trials done solely for increasing scientific knowledge are not technology assessments.

Given the wide scope of HTA, it is not considered a discipline or a field; it is a systematic inter-disciplinary process based on scientific evidence and other types of information. It involves physicians, other clinicians, economists, social scientists, public health, and health service researchers, as well as ethicists. Additionally, the public and its representatives are more and more involved in HTA.

Role of Evidence

In the last decade, pressure to base decisions on evidence has been extended to other areas of health care, such as public health interventions and health care policy-making. In this context, evidence is understood as the product of systematic observation or experiment. The evidence-based approach relies mainly on research, that is, following a pre-established plan to systematically collect and rigorously analyze data. Evidence is the result of a search for practical, useful knowledge (Banta 2003). Additionally, the definition of ► evidence based medicine introduces the concept of best available evidence, which implies a "hierarchy of evidence". Since the evidence normally comes from research, it is important to consider the hierarchy of research designs as well as the quality of research execution. Some research studies are considered to be better than others; therefore, evidence from good research is generally considered better than evidence resulting from research of a lesser standard. HTA often assesses the potential effects of an intervention on health outcomes. In the evaluation of these effects, evidence from experiments is, in principle, superior to evidence from non-experimental observations. Furthermore, among experiments, some study designs are considered better than others, in consequence ranking higher in the hierarchy of research designs (Fig. 1: Hierarchy of research designs for evidence-based medicine). The rationale for a hierarchy of research designs is associated with the concept of EBM and involves considerations of validity, particularly internal validity. Internal validity is a form of experimental validity. An experiment is said to possess internal validity if it properly demonstrates a causal relation between two variables. Internal validity tells us how likely it is that an observed effect of an intervention is in fact attributable to that intervention. On the other hand, a study that readily allows its findings to be generalized to the population at large has high external validity, but not necessarily high internal validity. The extent to which the information provided by a study has clinical or policy relevance (the external validity) has also been defined as the "non-methodological quality" of the evidence (Lohr and Carey 1999). The more internal validity a research design has (the higher it is in the hierarchy of evidence), the more likely it is that the observed effect is truly attributable to the intervention. Further down in the hierarchy, the possibility increases that the findings from the study will be misleading. The design highest in the hierarchy is the randomized controlled (clinical) trial (RCT). However, a major problem of the gold standard study design for EBM, the RCT, is the poor external validity of the findings. Unfortunately, the external validity of RCTs is normally reduced as the participants and intervention delivery may not be truly representative of the population to whom the results should be applied later on. This can happen for a number of reasons; often only a very small proportion of the patients with a condition are considered eligi-



Health Technology Assessment (HTA), Figure 1
Levels of Evidence

ble for a trial. Additionally, important subgroups of the population are often systematically excluded, such as ethnic minorities, the elderly, and/or women. Furthermore, participants in research studies differ systematically from those eligible subjects who refuse to participate. Finally, yet importantly, research is often conducted in health care settings not representative of the usual health care setting.

The way in which an intervention has effects on health is referred to as its "directness". Evidence that a link is direct is thought to be better than evidence that a link is indirect. When there is only evidence on indirect links available, it is normally necessary to have evidence for each of the single indirect steps in the causal chain. A direct link can be established in a single study but several studies are needed for the establishment of a complete chain of indirect links. Directness is thus also related to the kind of parameters used to measure the effect of an intervention.

In contrast to the strict research hierarchy of the EBM concept, HTA reports try to judge and generalize their findings from different studies with different degrees of internal and external validity to make them suitable for decision makers who make decisions based not on the individual patient, but on the population.

The United States Task Force on Community Preventive Services has consistently developed a more elaborate hierarchy of research designs for the assessment of interventions. The authors introduced the concept of suitability for assessing the effectiveness of interventions (Briss et al. 2000), which goes beyond the internal validity of the research designs used. This approach is particularly interesting because it argues that the RCT is not always the most appropriate (or feasible) research design. It recognizes that other study designs—in particular, well-designed cohort studies—can produce data that are not obtainable from RCTs.

Assessing Research

The results from research are usually published in scientific journals. Consequently, searching for the best evidence is usually seen as synonymous with searching the literature for results of studies. Although it is desirable and sometimes necessary to search for evidence from sources other than the published literature, this is not always possible. Additionally, many systematic reviews and assessments focus mainly on published results and, as mentioned in the beginning, transparency and comprehensibility are necessary preconditions for a HTA report. Use of unpublished results always leads to problems in the verifiability of the report and should therefore be avoided. Sources for assessing studies to consider within a HTA report are mainly literature

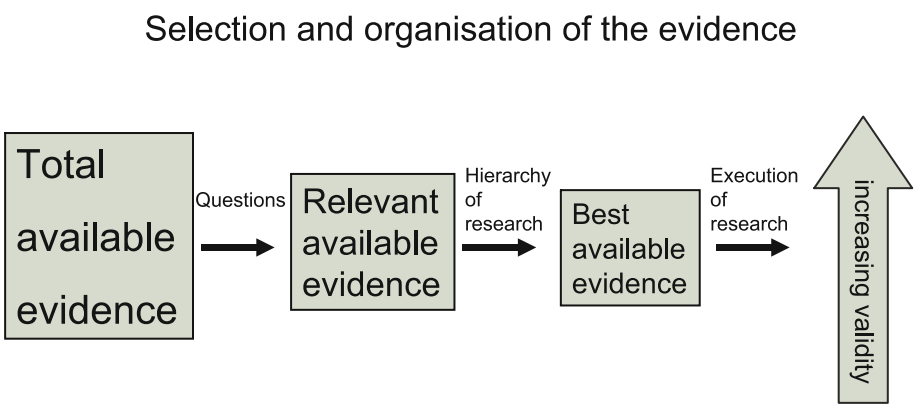
databases like Medline, EMBASE, Current Contents, etc. In addition, specialized ▶ HTA databases with complete HTA reports exist. The internationally recognized Cochrane Library is the best example of this type of database.

The concepts shown above allow for a broad classification of the available evidence on the effects of an intervention into different levels of quality. When evaluating an intervention, this approach can be used to limit the types of studies taken into consideration. Therefore, with the help of the hierarchy of research designs, it is possible to set a threshold concerning the types of research to be considered in the evaluation.

Several tools have been developed to assess and grade the quality of execution of single studies, following the same rationale as the hierarchy of research designs in Fig. 1. This rationale is higher quality = higher internal validity = higher level of evidence. A review identified 67 ways to assess and grade the quality of different study designs, most of which have been developed for assessment of the quality of RCTs (West et al. 2002). These grading algorithms allow ordering of a group of studies with the same design according to the quality of their execution, again generating a hierarchy. This approach makes it possible to organize the available evidence in a way that facilitates drawing conclusions and making recommendations. Figure 2 visualizes the process of organization and selection of evidence as it takes place when conducting systematic reviews as well as HTAs.

Summarizing the Identified Research

The group of studies selected as the best available to answer specified research questions is called the "body of evidence". A body of evidence is characterized by a combination of the hierarchy of research design, the directness of the evidence, and the quality of execution. Furthermore, factors such as the number of studies, the size of the effect, and the consistency of results across the group of studies are also relevant when judging the strength of the evidence. The challenge in HTA is to judge the evidence from different studies in order to give answers to the research questions and, based upon this, to the policy questions. In recent decades, several approaches have been developed to standardize the way researchers make judgments about the strength of the evidence that underlies their recommendations. To rate the strength of evidence, 40 different systems were developed (West et al. 2002). The concepts differ in the combination of factors required for the standard of evidence and the weight given to each when rating the strength of evidence derived from a group of studies. These systems also establish a link between the strength of the evidence and the strength of the recommendation. Strong evidence on the effects of an intervention allows for strong recommendations for or against the use of the intervention. Consequently, weak evidence only supports weak recommendations. There are several systems to standardize the process of grading the strength of recommendations, typically using letters (for instance A, B, C, etc.) to describe the grade of strength of a recommendation (West et al. 2002). If such a system is used in HTA reports, it is necessary that the authors provide information that allows the reader to interpret the grading of recommendations used. For each of the aspects of assessment in a HTA, the standard and relevance of available evidence needs to be assessed. The underlying rationale always consists of the same three key ques-



Health Technology Assessment (HTA), Figure 2
Selection and organization of the evidence

tions: are the research findings valid, are they relevant to the assessment questions, and how strong is the evidence?

Evidence Based Recommendations

The identification of strong evidence for the effectiveness of an intervention does not necessarily lead to the formulation of strong recommendations for or against its implementation in the health care system. Evidence of the effectiveness of health technology is only one part of the picture. Clinical recommendations consider (for the most part) only the benefits and disadvantages of one or more specific interventions.

The other parts of the picture, such as the impact on organization of the system, on resources available, on responsiveness, and on equity, also play a determinant role in the decision for or against the introduction or implementation of an intervention respective technology. Even with strong evidence of benefit for health from an intervention, the recommendations from a HTA may be against its implementation. When considering other factors, such as cost and cost-effectiveness issues, the burden of disease, needs and priorities, barriers to implementation, features of the health care system, cultural issues, etc., implementation can appear to be improper in a given context.

Normally, HTA explicitly considers such factors. However, for the assessment of these factors, RCTs do not occupy the highest place in the hierarchy of evidence since this study design is not appropriate to answer relevant questions besides clinical efficacy. In addition, the epidemiological approach is not always the appropriate method in these cases. Evidence obtained with empirical, social, or political science methods must therefore be considered in a HTA (► evidence based recommendations).

A consensus by the World Health Organization (WHO) Regional Office for Europe agreed a new definition of evidence in the context of HTA: "findings from research and other knowledge that may serve as a useful basis for decision-making in public health and health care" (WHO Regional Office for Europe 2004). This emphasizes the prospective relevance and validity of different study designs and research forms. It also goes further, acknowledging the value of evidence obtained with methods that—within the scope of some scientific discourses—are not considered scientific.

Impact of HTA

In addition to the dissemination and implementation of HTA recommendations, the evaluation of their effects is an important factor of HTA. Like other health technologies, HTA should be judged on the quality and size of its effects. In recent years, this aspect has received increased attention as HTA has begun to become an important part of health care policy-making in many countries (► HTA, impact of). However, the response of policy-makers shows that many of them do not see the importance of assessment. There is more interest in controlling costs then in steering health care. Consequently, even when good assessments are done, their impact on policy-making has been modest. The effects of HTA are linked with the assessing institution and the motivation of its commissioner (Gerhardus 2006). For best use of HTA, exact formulations of the impact aims are needed. As the first step in assessing a technology, the people concerned should be defined. These people have to formulate the aims and disseminate the recommendations of the HTA. Effects of HTA should then be evaluated, and if defined impact aims are not reached, a discussion should follow.

HTA Institutions

Many organizations throughout the world assess healthcare technology (► HTA, institutions). There is an evident need to cooperate and share information from different cultures. Since the beginning of HTA activities, efforts have been made to share experiences at an international level. The first meeting of the International Society for Technology Assessment in Health Care (ISTAHC, today called HTAi) in 1985 made evident the beginning of international networking in the field of HTA. HTAi represents mainly single researchers.

In contrast, the International Network of Health Agencies for Health Technology Assessment (INAHTA) represents agencies in different countries. It has now grown to 43 member agencies from 21 countries, and stretches from North and Latin America to Europe, Australia, and New Zealand.

All of the important HTA agencies in Europe recognize the need for improved coordination of HTA in Europe. There are several **European HTA Networks**. One of them is the HTA-Europe project, which aims to contribute to the effectiveness and cost-effectiveness of health care in Europe through improved HTA, and to

strengthen the coordination of HTA in Europe. A form of HTA exists in all of the old EU-15 member states, though with a high degree of diversity in institutionalization, impact and, financial equipment.

The Future of HTA

HTA is already an important force in Europe. Investments in HTA are growing, formal programs are being established at the national and regional level, and evidence is accumulating that HTA is making a difference in the cost-effectiveness and quality of health care. HTA is becoming a field of exceptional interest to policy-makers, because many health care interventions are not evaluated or inadequately evaluated. On the other hand, many beneficial and cost-effective technologies are not fully deployed for the benefit of the public. One key challenge is to base adoption and use of health technology on evidence such as that developed by HTA. Policies offer many possibilities for HTA; for example, coverage decisions, i. e. for pharmaceuticals, can be based on HTA. Determination of the number of services needed in an area can also be based on HTA. There are therefore many challenges for HTA at the national and regional levels of all countries.

Summary

HTA can provide a unique input into the decision-making processes of the health care system. In accordance with its broad concept, the principles and scope of HTA can be applied in order to assess the potential consequences not only of medical interventions, but also of organizational interventions, and even of health care reforms, since reforms can also be considered as interventions in the health system. HTA can offer several key features to decision-makers: a thorough assessment of the potential effects on health and the consequences of implementation of interventions for the health system, as well as for the economy and the society in which a technology is to be introduced or excluded.

To fulfill this task properly, evidence from different research traditions will have to be considered in one assessment, using a broad scope of evidence. The field of HTA has illustrated that it can identify technologies and produce meaningful assessments in a timely fashion. Technology assessment agencies have successfully involved leading physicians, administrators, and other professions in their work.

Nevertheless, some problems remain: despite the 20-year history of this field, many policy-makers do not see the importance of assessment. In fact, policy-makers sometimes have little interest in health care other than controlling costs. Even with coverage policy, which is being used increasingly to control costs, HTA is often not a part of policy-making. Much of the potential of technology assessment has not been realized. Even when good assessments are done, their impact on policy-making has been modest. However, there are great differences in adoption, implementation, and support of HTA between countries all over the world. Health technology itself is international and efforts to understand its benefits, risks, and costs must also become increasingly international. For this purpose, HTA is a promising way forward.

Health Telematics

Definition

Health telematics refers to health-related activities, services, and systems carried out over a distance by means of information and communication technologies, for the purpose of global health promotion, disease control, and health care; as well as education, management and research for health.

Health Transition

Definition

The health transition is the gradual change from a morbidity and mortality pattern driven by infectious, childhood and maternal diseases to a pattern of chronic, noncommunicable diseases occurring mainly in older age. The health transition is advanced not only in the industrialized countries, but also in high-income population segments of middle- (and even some lower-) income countries.

Health Warning Systems

Synonyms

Monition about health hazard

Definition

System of forecasting and targeted dissemination of a warning message regarding a hazard to human health and recommended actions to be taken by the people concerned.

Basic Characteristics

Health warning systems, e. g. based on forecasting extreme weather and floods, help to protect life, health, and property and enhance national economies. Some such systems have been put in place in several countries, and others are being envisaged.

In the United States (US), excessive heat is considered to be the main weather-related killer, causing more fatalities in an average year than floods, strong winds (such as tornadoes and hurricanes), lightning, and winter events (storms and extreme cold spells). During an average summer, there are over a thousand excess deaths in the US that could be attributed to heat. If deaths due to heart attacks, strokes, or respiratory illness are above normal during a heat wave, they could be considered heat-related deaths, even if they may not be registered as such by a medical examiner.

People living in cities with strong summer weather variability have the strongest weather-mortality relationship. They are not adapted (► adaptation) to extremely hot weather, which is infrequent and occurs irregularly. The number of deaths reported during an intense heat spell is higher in such cities than in many tropical

cities, where hot weather is a normal state. Early season heat waves can cause higher mortality, because human organisms have not adapted. People acclimatize better to the heat as the hot season continues.

There has been considerable progress in the design and implementation of health warning systems in the US, established to reduce effects of weather extremes as well as for seasonal prediction of infectious diseases. Warning systems are being developed to permit urban health agencies and local meteorological offices to issue prior advice to the public if a dangerous heat wave is imminent. The National Weather Service (NWS) of the National Oceanic and Atmospheric Administration (NOAA) in the US provides advance notice (with a forecast capability of five days) of extreme heat events for the protection of life and health, based on a single heat index value derived from temperature and humidity. The excessive heat warning program started in Philadelphia and is currently functioning in more than a dozen cities. A custom-made system is developed for each city, based on the specific conditions of meteorology of each urban area, as well as urban structure and demography. The NWS is developing a plan to expand a heat/health warning system to each of over 70 large US municipalities with populations exceeding 500,000. The system initiated in Philadelphia is now becoming a worldwide model for heat forecasting and collaborative attempts to construct heat/health warning systems for vulnerable large cities around the world have been undertaken in three continents: North America, Europe, and Asia.

The French lesson of August 2003 showed that the death toll of the heat wave was not foreseen and detected only belatedly. Health authorities were overwhelmed by the influx of patients. Retirees' houses had no air conditioning. The number of deaths exceeded the working capacity of undertakers and crematoria. This lesson demonstrates the need for establishing health and environment surveillance, and heat wave forecasting and warning. Air conditioning in retirees' homes proved efficient (yet they are very energy consuming, hence contributing to enhancement of the ► greenhouse effect and ► global warming).

The World Meteorological Organization (WMO) develops a number of global products and services relevant to the natural disaster management. For example, the WMO Tropical Cyclone Programme monitors all tropical cyclones around the Globe from their early stages of formation and throughout their lifetime, providing information on their behavior, movement, and changes in intensity, and on associated onset and development of storm surges and floods. The WMO's Severe Weather Information Center project, carried out in collaboration with the Hong Kong Observatory, has the goal of developing a centralized source of official tropical cyclone warnings and information from around the Globe.

Since deadly extreme heat events occur in many regions of the world, the WMO is working with the World Health Organization (WHO) to develop guidelines that any country can use to set up and run heat/health warning systems. These systems will include monitoring and prediction of conditions leading to intense heat waves, to be carried out by the national meteorological and hydrological services, the WMO's constituency, and with communication between the meteorological and health sectors. They will increasingly include special measures for intervention (by the health and social service sectors) to inform and better protect the most vulnerable members of society.

Long-term forecasts and seasonal forecasts, e. g. based on El Niño-Southern Oscillations (ENSO), are being used in many regions, e. g. for drought warning, to improve preparedness and reduce disaster-caused human and material losses.

Health of Women

► Women's Health

Healthy Ageing

Definition

A hypothesis that assumes an increase in longevity will increase the number of years lived in good health.

Healthy Cities

Definition

A healthy city is one that is continually creating and improving those physical and social environments and expanding those community resources which enable people to mutually support each other in performing all the functions of life and in developing to their maximum potential.

Healthy Island

Definition

A healthy island is one that is committed to and involved in a process of achieving better health and quality of life for its people, and healthier physical and social environments in the context of sustainable development.

Healthy Public Policy

Synonyms

Health control; Disease prevention; Health promotion

Definition

Health promotion is the process of enabling people to increase control over and improve their health. It involves the population as a whole in the context of their everyday lives rather than focusing on people at risk for specific diseases, and is directed toward action on the determinants or causes of health. The goal of a healthy public policy is health promotion. It is essential to create supportive environments, strengthen community action, develop personal skills and reorient health services.

Cross-References

► Disease Prevention
► Health Control
► Health Promotion

Healthy Subjects

Definition

Healthy subjects are people without any medical condition (including normal physiological and laboratory parameters) requiring treatment. The phrase is usually used for people participating in the early stages of clinical trials, where the kinetics and way of action of new pharmaceuticals is being established, or in studies to evaluate physiological or otherwise defined conditions. Because these individuals do not profit medically from such investigations, they are often financially compensated for their participation and any experimental risks are kept minimal and foreseeable.

Healthy Years Equivalent (HYE)

Definition

The concept of healthy years equivalent attempts to put the remaining lifetime spent in a limited health state relative to the time spent in perfect health. Individuals are asked to weigh the complete remaining lifetime directly. The concept of healthy years equivalent shows some relationship to the QALY concept but has not been fully implemented so far.

Hearing

Definition

A hearing is a procedural element of administrative proceedings and criminal proceedings as well as any type of lawsuits heard before courts. All individuals affected by administrative acts or court decisions have the right to receive a hearing where they are entitled to present their own facts and evidence and to challenge the administration's facts and opinions. Hearings are a crucial component of administrative and court procedure rules. Violation of the hearing right can result in unlawfulness of an administrative act or court order.

Hearing Impairment Caused by Noise

Synonyms

Occupational hearing loss

Definition

Hearing impairment is loss of normal hearing due to ► noise exposure. Occupational exposure to noise is quite frequent in metallurgy, construction, textile and many other industries. At the start of occupational noise exposure workers are faced with temporary hearing loss. This hearing loss is not only present during the exposure but also for a certain period after the exposure to noise. After several years of exposure, depending on ► individual susceptibility, this temporary hearing loss becomes permanent. A characteristic audiogram will show impairment in both bone and air conduction, with a maximum loss around 4.000 Hz which is symmetric and bilateral.

Heart Disease

Synonyms

Cardiac disease

Definition

A structural or functional abnormality of the heart, or of the blood vessels supplying the heart, that impairs its normal functioning. Heart disease is a general term that refers to any disease or condition of the heart, including coronary heart disease, hypertension, heart failure, congenital heart disease, disorders of the heart valves, heart infections, cardiomyopathy, conduction disorders, and heart arrythmias.

Heart Rate

Definition

Heart beats per minute.

Heat Cramps

Definition

Heat cramps is a medical condition occurring when the body is dehydrated and loses minerals due to excessive sweating. It is the least severe form of heat emergencies, which occur when human body is exposed to physical activity, in a hot environment, and without adequate water supply. The condition can occur in an occupational setting, in warm ► weather, in sportsmen, children, etc. The typical symptom is forceful and painful contractions of muscles exposed to intense activity: e. g. the muscles at the back of the calves (the gastrocnemius muscles) or the muscles of arms in sportsmen or workers. Heat cramps improve with rest, drinking water, and a cool environment.

Heat Exhaustion

Synonyms

Dehydration

Definition

Heat exhaustion refers to dehydration caused by prolonged physical activity without consuming adequate water, especially in a hot environment. This medical condition is characterized by impaired water homeostasis in the body. Symptoms of mild dehydration (loss of about 2% of body water) include headaches, visual impairment, decreased blood pressure, dizziness, thirst, discomfort, tiredness, and dry skin and mouth. In moderate dehydration (more than 5%) symptoms are lethargy, seizures, fainting, and sunken eyes. In severe cases

(with 10% to 15% fluid loss), muscles become spastic, paresthesia occur, skin is wrinkled, urination is greatly reduced, and the state may progress to delirium, unconsciousness, and death. Treatment includes re-hydration – replenishment of water and electrolytes orally or intravenously.

Heat Stroke

Hegemonic Masculinity

Synonyms

Dominating masculinity

Definition

To speak of hegemony is to seek to come to terms with a particular idea of political leadership or influence. Much of what might have been positive aspects of the term have dropped out of use after Gramsci. Instead, the word typically implies a "demanding" and "commanding" form of dominance. Now, when used adjectivally, it typically imputes negative connotations to the word it modifies. The ability to use the word to refer to predominant influences towards "the good" through example and through reason are now almost wholly lost. When used of masculinity, it invariably indicates a "hard" version of what is considered to be acceptable male functioning. Therefore, no capacity is left for a Macduff both to publicly mourn the loss of loved ones to the treachery of a trusted peer and to publicly vow to right an injustice in the political domain. For Shakespeare, Macduff represents a masculine influence that stands with peers to face openly the tyrant Macbeth rather than retreat into an inner world as does Hamlet.

Hemagglutinin

Definition

Hemagglutinin is a spike-shaped glucoprotein of the virus surface. At the present time, 15 serotypes are known. Hemagglutinin not only causes agglutination (clumping) of erythrocytes but also controls viral attachment and uptake. The virus can only bind to specific receptors. Not all hosts have the same types of receptors. Thus, contagiousness of an influenza virus depends on the serotype of viral hemagglutinin as well as on the host's receptor pattern.

Hematopoietic Stem Cells

Synonyms

Haematopoietic stem cells; Hemopoietic stem cells; Haemopoietic stem cells

Definition

A hematopoietic stem cell (HSC) is the common precursor of any myeloid or lymphoid cell type, for example white and red blood cells, platelets and lymphocytes. Like the precursor of vessel cells, the HSC derive from the hemangioblast in embryogenesis.
HSC are clonogenic (► clonogenicity) as verified in animal models using lethally irradiated mice. Theoretically, mice can be rescued if one single HSC is successfully transferred to the animal bone marrow. In vitro, HSC can be induced to differentiate into various cell types, for instance cardiomyocytes. Due to their low proliferation rate it is rather complicated to expand them in vitro. Therefore, they may not provide an ideal cell type

for cell replacement therapy, where besides safety, feasibility is the most important property.

Hemolytic Uremic Syndrome (HUS)

Definition

Hemolytic uremic syndrome (HUS) is a severe complication of an EHEC-infection. It is caused by bacterial toxins. HUS is assumed to occur in 6–8% of all EHEC-cases. Primarily, young children, older people and immunocompromised people are concerned. HUS causes a destruction of small blood vessels, a breakdown of red blood cells (hemolysis) and a reduced platelet count (thrombocytopenia). The impairment of the kidneys leads to progressive renal failure. Without treatment HUS can be lethal, in 10–30% terminal renal insufficiency develops.

Hepatitis

Synonyms

Inflammation of the liver

Definition

Hepatitis is inflammation of the liver that may be caused by several different viruses (A, B, C, D, E, F). Hepatitis A infection is acquired by ingesting contaminated food or water and is also called an illness of dirty hands implying poor hygiene habits as the cause of infection. Most common are hepatitis B and C infections that are acquired from contaminated blood or body fluids directly (e. g. needle) or during sexual contact. They may cause acute illness, as with hepatitis A infection, but also create many different long term consequences, including liver cancer.

Hepatitis A Immunization, Active

Synonyms

Hepatitis A vaccination, active

Cross-References

► Hepatitis A Vaccination, Active
► Immunization, Active

Hepatitis A Vaccination

Synonyms

Hepatitis A immunization

Definition

In hepatitis A vaccination, which was first permitted in 1996, whole inactivated viruses are administered. Two inoculations are given at an interval of 6–12 months, whereby the first vaccination already leads to a protective effect of almost 100% after 2 weeks. The second dose achieves long-term protection lasting at least 20 years. Although hepatitis A vaccination is one of the officially recommended vaccinations in some countries,

in other regions it is only administered for certain specified indications. There might be a higher risk of infection due to one's profession, due to residence in a community institution, in case of certain chronic diseases or when the subject is planning a journey to a region where endemic disease is present. Contraindications for the hepatitis A ► vaccine are acute illness with fever, and a known severe allergic reaction to components of the vaccine.

Hepatitis A Vaccination, Active

Synonyms

Hepatitis A immunization, active

Cross-References

Hepatitis B

Synonyms

HBV-Infection

Definition

Hepatitis B is a viral infection, which is transmitted by contact with blood or other body fluids of an infected person. Following an incubation period of 2–6 months, inflammation of the liver develops. The symptoms are elevated liver enzymes, icterus, fever, malaise and stomach ache. In 0.5–1% the infection takes a dramatic course, which leads to liver failure and – without transplantation – has a lethal outcome. In adults a chronic hepatitis is found in 5–10%, in children the incidence is much higher, in newborn babies even up to 90%. In a number of countries, up to 30% of the population suffers from chronic hepatitis B. During the course of years, 50% of people with chronic hepatitis B develop liver failure or liver cancer. In general, no medicinal therapy is given in acute hepatitis B, chronic courses can be treated with interferon alfa and various virustatics. To prevent hepatitis B infection, active and passive vaccination is possible (► immunization, active; ► immunization, passive).

Hepatitis B Vaccination

Synonyms

Hepatitis B immunization

Definition

A ► vaccine against hepatitis B has been available since 1981. There is no age limit for its use. For newborn babies whose mothers are infected with active hepatitis B, the inoculation process should be started directly after birth. In such cases, the first dose of active vaccine is given simultaneously with a passive hepatitis B immunization. Otherwise, hepatitis B vaccination is generally implemented 3 times from the third month of age as part of the 6-fold vaccination, or twice when no pertussis component is involved, at intervals of at least 4 weeks, followed by a further vaccination after 4–12 months. The protection rate achieved is 95–99%. Booster vaccinations are recommended for persons at risk, in particular for those individuals who come into contact with blood frequently, such as medical staff, police officers or prison staff. Contraindications for the hepatitis B vaccine are acute illness with fever, and a known severe allergic reaction to components of the vaccine.

Hepatitis B Vaccination, Passive

Synonyms

Application of hepatitis B immune globulin; Hepatitis B immune prophylaxis

Definition

If a pregnant woman suffers from a chronic active hepatitis B, that means Hbs (surface)- antigen can be detected, the risk of the newborn baby developing hepatitis B is 10–20%. For this reason, infants of HBs-Ag-positive mothers should receive a passive hepatitis B-vaccination directly after birth. Simultaneously, the active hepatitis B-vaccination is started. Another indication for the administration of hepatitis B immune globulin is contact of a non immune person with the blood of someone infected with hepatits B. Due to their profession, some individuals come into contact with blood frequently and thus face an enhanced risk of infection, in particular medical staff, police officers and prison staff.

Herbalism

Synonyms

Herbal medicine; Phytotherapy

Definition

Herbalism refers to the use of herbs to prevent and cure illness. Whole plants or their parts are used for treatment instead of separating and purifying the active constituents of plants. Plant derivatives may be highly active and concentrated in various parts of the plant. The season of the year and the time of day may affect the best time for gathering. These preparations are difficult to standardize, since they are complicated mixtures which may have hundreds of constituents.

Herd Immunity

Definition

Immunization involves both a direct benefit to the individual child as well as to those in the community who remain un-immunized and benefit from the immunization of the vast majority. The latter is called “herd immunity”.

Herpes Genitalis Infection

Synonyms

Infection with herpes simplex type 2

Definition

Following an incubation period of 2–12 days an infection with herpes-simplex virus can lead to lesions of the skin and the mucous membranes, cause general symptoms like fever, headache, painful swellings of the lymph nodes, or induce a severe systemic infection, which involves the whole organism. In local infections, firstly vesicles appear, which are arranged in groups, then the rupture of the vesicles leads to painful erosions, which develop into superficial ulcers. An effective therapeutic is aciclovir. Depending on the localization and the severity of the infection, aciclovir can be administered as an ointment, tablets or infusion. The viruses are not killed by the therapy, they can be reactivated at a later point of time.

Heterogeneity

Synonyms

Heterogeneousness

Definition

In the field of monogenic disorders, heterogeneity describes the phenomenon that the same phenotype can

be caused by different ► mutations. The different mutations can be located within a single gene (allelic heterogeneity) or may occur in different genes (locus heterogeneity). However, in contrast to polygenic disorders, a given individual harbors only one (autosomal-dominant) or two different mutations (autosomal-recessive) in one gene.

Heterogeneousness

► Heterogeneity

Heterotopic Pregnancy

► Ectopic Pregnancy

Heterozygosity/Homozygosity

Definition

Diploid organisms like humans carry two copies of each autosomal chromosome (paired homologous chromosomes) and thus, also two copies of each autosomal gene. One of the paired chromosomes (one of the two copies of a gene) is transmitted by the father, the other by the mother. If the sequence of the two copies (► alleles) of a gene is identical, the individual is homozygous, if the two copies of a gene contain different alleles, the individual is heterozygous. Autosomal-dominant disorders manifest when only one of the two copies of the underlying gene is mutated (heterozygosity). In contrast, autosomal-recessive disorders manifest when both copies of a gene carry either the same mutation (homozygosity) or two different mutations on each allele (compound-heterozygosity).

HETUS

Definition

High Risk (Prevention) Strategy

Definition

High risk prevention strategies represent preventive measures that focus on individuals who are judged most likely to develop a certain disease. They are valuable in addition to measures of prevention within the general population. One example for a high risk approach for stroke prevention is the treatment of hypertension in individuals that have previously suffered a transient ischemic attack (TIA). The high risk strategy falls mainly in the medical domain of secondary prevention (screening).

High Risk Workplaces

Definition

High-risk working places include all workplaces where in spite of completely or incompletely applied preventive measures and actions, health risks for workers still

exist that can endanger their safety and health. At high-risk places a higher risk of injuries, ► occupational diseases and damages exists, due to specific technological processes whereupon there is no possibility to apply the adequate occupational safety measures or due to specific demands related to specific health, physical, psycho-physical working ability of a person. Such high-risk workplaces include for example those in agriculture, logging, commercial fishing, etc.

With insight into risk and causal factors at workplaces, possible prevention strategies aimed at reducing risk, or interventions to interrupt the causal sequence of accidents should be considered. There is a wide range of protective technologies and strategies that has already been applied to workers' protection. The goal is the identification, development and implementation of effective preventive strategies to reduce the risk of injuries and occupational diseases to workers at the highest possible extent.

Hinduism

Definition

With some 900 million followers, Hinduism is the third most popular religion after Christianity and Islam. Its origins can be found in India. All believers take on the religion as a way of life, following the earlier Vedas scriptures.

Hippocratic Oath

Definition

The Hippocratic Oath concerns the doctor–patient relationship, focusing on the physician's code of conduct. It goes back to the forth century before Christ. The Oath stated: "I will use treatment to help the sick according to my ability and judgment, but I will never use it to injure or wrong them … And whatsoever I shall see or hear in the course of my profession … I will never divulge, holding such things to be holy secrets." Medical ethics consisted, therefore, initially, of these three, clear principles: ► beneficence, ► non-maleficence, ► confidentiality.

HIV/AIDS

Synonyms

HIV-infection; Acquired immunodeficiency syndrome

Cross-References

► AIDS
► HIV-Infection and AIDS

HIV (Human Immunodeficiency-Virus)-Infection

Synonyms

AIDS

Definition

Acquired immuno-deficiency syndrome (AIDS) results from the infection with the human immuno-deficiency virus (HIV). The virus is transmitted sexually or by inoculation with contaminated blood, but may be passed from mother to baby at birth. The highest risk is among homosexual or bisexual men, intravenous drug abusers, and people with multiple blood transfusions. AIDS infection is ► endemic in sub-Saharan Africa and India. Its origin is unknown. The virus damages the immune system and therefore the body's defense towards infections weakens. Carriers of HIV may be symptom-free for years, but after shorter or longer periods of time illness develops with various manifestations. AIDS is a fatal disease with new drugs helping relieve the symptoms, or prolong the survival period.

HIV-Infection and AIDS

Monika Korn
Klinik für Kinder und Jugendmedizin,
Friedrich Ebert Krankenhaus GmbH,
Neumünster, Germany
hkorn80663@aol.com

Synonyms

Infection with human immunodeficiency virus; Acquired immunodeficiency syndrome

Definition

AIDS is a chronical infectious diseases, which is caused by the HI (human immunodeficiency)-virus, and which is primarily transmitted by sexual intercourse or by reused contaminated needles of drug dependents. AIDS is characterized by a weakening of the immune system, which can neither be healed, nor prevented by a vaccination. Different drugs are available, which can impair the viral reproduction and delay the inevitably lethal course of the disease.

Basic Characteristics

History of AIDS and its Problems Nowadays

AIDS is a transmissible disease of recent times, which is caused by an infection with the HI (human immunodeficiency)-virus. Most probably, the HI-virus stems from the SI-virus (simian immunodeficiency virus), which can be present in chimpanzees. The SI-virus, however, developed from a combination of two different viral strains, which are found in guenons. As guenons are hunted and eaten by chimps, the chimpanzees were infected with the precursors of SI-virus. The first transmission to a human presumably took place in the middle of the 1950s by ingestion of chimp meat. In 1959, HIV-antibodies were detected in a man in Congo for the first time. The further spreading of the HI-virus among humans was caused by sexual intercourse or by contact with contaminated blood. As many years lie between the infection with the HI-virus and the onset of AIDS, the problems of this new infectious disease did not become relevant until the 1980s. Initially, AIDS seemed to concern only particular groups at risks. These groups were homosexual men, who faced a higher risk of infection due to frequent partner-swapping and the practice of anal intercourse, and drug dependents, who were infected by the virus through the reuse of contaminated needles. After an antibody test, which was developed by Robert Gallo in 1985, had become available, it quickly became clear that AIDS was much more dangerous than assumed initially. Within a short period of time, AIDS proved to be a global infection and a worldwide threat. In 1986, the virus was named "HIV", in the following year, AZT (Retrovir®), a ► nucleoside reverse transcriptase inhibitor (NRTI) was licensed as the first therapeutic substance. In 1988, the WHO declared December 1st as World AIDS Day. Two years later, a red ribbon became the sign of protest against the discrimination of HIV-infected people. In 1991, a loop of red silk ribbon established to be the international symbol of the fight against AIDS (Fig. 1). As a valuable parameter for therapy control, HIV-PCR (polymerase chain reaction) was introduced in 1994. During the following years, therapeutic possibilities were extended by the introduction of ► protease inhibitors (PI) (saquinavir in 1995), ► non-nucleoside reverse transcriptase inhibitors (NNRTI) (nevirapin in 1996), and a ► fusion inhibitor (enfuvirtide, 2003). With the awareness of the consequences of AIDS, the population of the industrial nations initially developed a kind of mass hysteria; during the course of 1990s the public interest slowly faded away, although the risk of AIDS remained unchanged. Unfortunately, knowledge about AIDS has decreased, especially among teenagers

HIV-Infection and AIDS, Figure 1 The Red Ribbon – the worldwide symbol for solidarity with HIV-positive people and those living with AIDS

and young adults. A lack of knowledge, promiscuity and careless sexual behavior with a high readiness to take risks make the fight against HIV more difficult. Furthermore, AIDS is frequently treated as a taboo subject. Many people do not know that they are infected, or they do not perform a test as they fear social discrimination. HIV-tests may not be available, especially in developing countries. Because individuals may be unknowingly infected and because the latency period is extended, transmission of the virus can easily be spread. Today, more than 40 million people are infected with HI-virus, 2.2 million are children under the age of 15 years. The most recent HIV-infections appear in Africa south of the Sahara; in these regions, the effects of AIDS are highly damaging. Meanwhile, 15 million children have become orphans due to AIDS, and by the year 2025 this number is expected to reach 25 million. Most of these orphans live in extreme poverty. Even if they are adopted by relatives, in most cases, the care they receive is not as good as that given to the biological children in the adoptive family. AIDS orphans are not only susceptible to exploitation and abuse but also their life expectancy is considerably shortened.
Further, a sufficient amount of therapeutics to treat AIDS is not available in developing countries.

The HI-Virus

The HI-virus is a RNA-virus belonging to the retrovirus group. One has to differentiate between the strains HIV-1 and HIV-2, both of which are divided into further subtypes. By the action of the enzyme reverse transcriptase, retroviruses integrate their genetic code into the genotype of the host's cells, that means, viral RNA is assimilated into the double-stranded structure of DNA. Other important viral enzymes involved in the process are integrase and a protease. HI-viruses bind to the so-called ► CD_4-receptors of T-lymphocytes (T4-cells, helper T-cells, CD_4-lymphocytes), which are responsible for cellular immunity. A complex of glycoproteins (Gp 120), which is found on the surface of HI-viruses, is responsible for the viral adhesion. The virus is highly adaptable and is able to develop different subtypes quickly. For this reason, it has an excellent survival capability because resistance to therapeutic measures can rapidly evolve. Due to the high mutation rate, the development of a vaccine has so far not been successful. HIV-infection is detected by the ► HIV-test. Virus load and CD_4 evaluation play an important role in determining the course of the disease.

Ways of Transmission

The HI-virus can be found in various body fluids. Blood, sperm, vaginal secretions, mother's milk and cerebrospinal liquor are contagious. On the other hand, no risks are associated with spittle, tears or sweat. Transmission of HIV by droplets or insect bites does not occur. The virus can be transmitted through microinjuries or larger lesions of the skin or the mucous membranes. Primarily, the virus is transmitted by sexual intercourse with an infected partner without the use of ► condoms. In the case of unprotected vaginal sex with an infected partner the woman's risk of infection is 0.05–0.15%, for the male partner 0.03–5.6%. These are average risks, but the individual risks have to be considered. Individual risks are markedly increased when there is a high virus load in the presence of other ► sexually transmitted diseases (STD), or if sexual intercourse is performed during menstruation. Another way of transmitting HI-virus is the re-use of contaminated needles in cases of intravenous drug consumption. Moreover, a pregnant HIV-positive woman can transmit the virus to her unborn child; the risk is about 25%. Babies can also be infected during the birth process or through breastfeeding. Blood transfusions are a further possible source of infection; thanks to the testing of blood donors, which was established in the middle of the 1980s, the actual risk of transmission by blood transfusion is minimal, at least in industrial countries. However, it has to be remembered that the HIV-test may remain negative for up to 3 months after an individual has become infected.

Course of HIV-Infection and AIDS

HIV-infection passes through three stages. Following an incubation period of 6 days to 6 weeks, the acute phase appears with flu-like symptoms (fever, headache, sore throat, exanthemas and swellings of the lymph nodes). It lasts 4–6 weeks. The following latency phase, in which there are no symptoms, can last for several years. After this phase, the so-called AIDS related complex (ARC) occurs. In this stage of the infection there are similar symptoms as in the first stage, but the symptoms do not disappear. The last stage of the disease, which in general takes a lethal course within two years,

demonstrates the complete AIDS clinical picture with ► AIDS-defining symptoms. There can be a considerable variability in the individual course of the disease. Fast progressors develop the clinical picture of AIDS within 5 years after the infection (5% of adults). Long-term non-progressors do not show any AIDS-defining symptoms even after a time interval of 15 years. In adults, the percentage of the latter group is 5%.

AIDS-Therapy

AIDS cannot be cured; it is only possible to delay the course of the disease and improve the quality of life. At the onset of therapy, the risk of developing AIDS and the long-term-toxicity have to be weighed up. Following the Centers of Disease Control and Prevention classification, there are 3 categories (A-C) according to clinical appearance.

- Category A is asymptomatic HIV-infection;
- Category B is defined by the presence of diseases, which do not belong to the AIDS-defining symptoms, but which can, most probably, be related to an immune deficiency.
- Category C consists of AIDS-defining symptoms.

Furthermore, the CD_4-status and the virus load are taken into consideration. Indications for an onset of therapy are a CD_4-value of 200–350 cells/pl, a CD_4-value of 350–500 cells/pl in combination with a high virus load, AIDS-defining symptoms and diseases, which indicate the presence of immunodeficiency. The primary aim of HIV-therapy is to reduce the virus load below the detection limit (< 50 copies/ml). Antiviral therapy (ART) is carried out as a combined treatment (HAART = highly active antiretroviral treatment). After an induction therapy with four of the available therapeutics, in most cases, maintenance therapy is carried out using three of the therapeutics; in general, 2 NRTI + 1 PI or 2 NRTI + 1 NNRTI. During the course of the disease, therapeutic drug monitoring is performed. Plasma levels of the drugs are determined in order to detect over- and/or underdosage. Moreover, CD_4-value and virus load are controlled regularly to evaluate therapeutic success. In the case of the development of resistances, changes in the medication will be necessary. Different databases supply information about current HIV resistance profiles (like http://hivdb.stanford.edu or http://www.hiv.lanl.gov/content/index). In HIV-treatment, so-called adherence plays an important role, meaning compliance with the therapeutic options. If > 5 % of drug applications are omitted, then an increase of virus load above the detection limit has to be expected. To achieve a good adherence, it is essential to inform the patient about the aims, necessity, complications and side effects of treatment.

HIV-Infection During Pregnancy and in Childhood

It has been found that in 90% of infected children, the HI-virus was transmitted vertically during pregnancy or breastfeeding. As infection with multiresistant viral strains is possible, a genotypic resistance test has to be performed. The administration of the antiviral drug nevirapin in pregnancy and birth by Cesarean section plays an important role in the "prevention of mother to child transmission" (PMTCT). In general, the course of HIV-infection is more severe in children and leads to death more quickly than in adults. In developing countries, 50% of the infected children die within the first two years of life, only a few survive beyond five years of age. In babyhood, there is an extremely high risk of developing AIDS-defining syndromes, like HIV-encephalopathy, pneumocystis-pneumonia or HIV-hepatopathy. For this reason, antiviral therapy should be given to all children below the age of one. In older children, the risk of AIDS and AIDS mortality correlate well with CD_4-values. Children should be given adequate therapy. Furthermore, consideration should be given to their whole social surroundings (caring persons, kindergarten, school, etc.).

Prevention of HIV-Infection and AIDS

The most important factors preventing HIV-infection are an informed population and the acceptance of safer sex (condom use).

Unfortunately, some years ago, in Africa, the Catholic Church claimed that condoms were not effective in the prevention of AIDS. The growth of such mistrust in the population makes information campaigns less effective. As promiscuous behavior amongst teenagers increases, sexual education, including information about sexually transmitted diseases, becomes a must for this age group.

In an effort to educate people in developing countries, companies of actors travel from one village to another performing show pieces about the AIDS problem.

In the case of a proved HIV-infection (positive HIV-test), a strengthening of the immune system should be striven for in order to delay the course of the disease. A healthy way of life with balanced diet, sufficient sleep and renunciation of smoking and drug consumption can help to achieve this aim.

To avoid the spread of HIV-infection, an easily available HIV-test which gives a quick result is necessary.

Postexposition prophylaxis (► postexposition prophylaxis (PEP) in HIV-infection) may be indicated in some situations. For example, inadvertent contact with contagious material (following a needle stick injury or some other kind of professional exposure) or the positive HIV-status of a partner does not becomes clear until after sexual intercourse has taken place.

Conclusion

HIV-infection, which is primarily transmitted by unprotected sexual intercourse, after a latency phase of several years leads to a deficiency of the immune system, which is called AIDS (acquired-immune-deficiency-syndrome). AIDS has become a disease with worldwide significance and far-reaching consequences for society. In developing countries, a great number of children suffer from the disease, either directly or indirectly by the loss of one or both parents. AIDS cannot be cured, a vaccination is not available, but the inevitable deadly course of the disease can be delayed by antiviral therapy. Information campaigns, the avoidance of unprotected sexual intercourse (without use of condoms) and the HIV-status of partners are of decisive significance in the fight against AIDS.

HIV-Test

Synonyms

Detection of HIV-Antibodies

Definition

HIV-test detects antibodies against the HI-virus. At first, a HIV search-test (HIV-ELISA-test) is carried out. In the case of a positive result, a second test follows for confirmation (Western blot method or immunoblot). According to the WHO, a person is assumed to be HIV-positive when antibodies against two different viral proteins can be detected. In further tests more detailed information of the virus' stems is revealed, and – after the onset of a therapy – testing of resistances is performed. Directly after the infection with the HI-virus, during the building antibodies phase, the test still shows a negative result. About 12 weeks after infection the detection of antibodies can assumed up be reliable. In newborns maternal IgG-antibodies are present, which leads to falsely positive test results. Due to this, in newborn children, a direct detection of the virus itself (e. g. PCR-test) is performed.

HMO

Definition

A Health Maintenance Organization (HMO) is a type of health care plan that provides a full range of healthcare services to its members. It offers prepaid, comprehensive health coverage for both hospital and physician

services. An HMO contracts with healthcare providers, e. g. physicians, hospitals, and other health professionals. Members are required to use participating providers for all health services. Members are enrolled for a specified period of time.

► Landfill

Holistic Medicine

Synonyms

Complementary medicine; Traditional medicine; Alternative medicine

Definition

Holistic medicine represents an approach to medical treatment based on the theory that living creatures and the non-living environment function together as a single integrated whole. The holistic approach to medicine insists on the study not only of individual disease but also of the response of people to their disease – physically, psychologically, and socially. A treatment plan must meet the unique needs of each individual, and all aspects of an illness are taken into account, such as the effects of the illness on personal relations, the family, work, and the patient's emotional well being. Holistic treatment prefers to encourage the patient's own capacity for self-healing, rather than having recourse to surgical or drug remedies, and emphasizes education and self-care, including proper diet and exercise.

Home- and Community-Based Services

Definition

Home and community-based services are ► health services provided in a patient's place of residence or in a non-institutional setting located in the immediate community. They may include home health care, adult day care, consultative-specialist health care, medical equipment services, or other interventions.

Homogeneity Analyses: "Fixed Effect" Model

Definition

Homogeneity analyses: "Fixed effect" model is a method of meta-analysis (and general statistical modeling) which estimates an overall single effect for an intervention. Variation of study estimates is assumed to be due to random (sampling) error within studies. This model assume that the exposure effect is constant across studies and that variation from one study to the next is due solely to within-study random variation. Fixed-effects models may allow the outcome to depend on several fixed effects, corresponding to several variables that characterize the studies. This method of meta-analysis ignores between study variability, and may overestimate the precision of the treatment effect if there is significant unexplained heterogeneity between the studies.

Homogeneity Analyses: "Random Effect Models"

Definition

Homogeneity analyses: "Random effect models" is a method of meta-analysis (and general statistical modeling) which estimates the effect of an intervention, assuming that variation in the meta-analysis is a combination of random sampling error within studies and variation between studies. Random effect models are more conservative than fixed effect models, giving estimates with wider ► confidence intervals. This method takes into account the possibility that other factors may modify treatment effects, and assumes that the studies

included in the review are a random sample taken from the distribution of the possible treatment effects. If random-effect models are used, then the rationale for model selection should be given, and estimates of among-study variation should be reported.

Hormone Replacement Therapy (HRT)

Definition

Hormone replacement therapy refers to the substitution with the female hormone estrogen alone (in a woman with no uterus) or estrogen and progesterone (in a woman with an intact uterus to prevent overgrowth of endometrial lining and consequently endometrial cancer) in the peri- and postmenopause to prevent signs and symptoms of the declining female hormone production in the ovaries. HRT is effective for menopausal symptoms as well as for the prevention of ► osteoporosis and hip fractures due to bone mass declines in the ► menopause. Because of the major adverse effects (increased risk of invasive breast cancer, cardiovascular diseases, stroke, phlebothrombosis) benefits and risk of HRT have to be weighed carefully and individually.

Hospice

► Palliative Medicine and Hospice Care
► "A Safe Place to Suffer"

Hospice Care

Synonyms

Palliation at home; Long term-care facility

Definition

Hospice and palliative care have a similar philosophy, namely the alleviation of symptoms (e. g. severe pain) for patients with end stage disease. But they represent differing aspects of the aim of 'a safe place to suffer.' Furthermore, their locations of treatment often vary. Hospice care is defined as 'a program that provides palliative care and attends to the emotional and spiritual needs of terminally ill patients at an inpatient facility or in the patient's home' (http://cancerweb.ncl.ac.uk/cgi-bin/omd?query=hospice&action=Search+OMD). Hospice care is most frequently provided in the patient's home, in long term care facilities or residential institutions.

Cross-References

► Palliative Care

Hospice Care in Children

► Paediatric Palliative Care

Hospice Chaplains

Synonyms

Geriatric chaplain

Definition

Hospice chaplains work in hospitals, seminaries or with volunteer organizations, which provide spiritual care for geriatric and terminally ill patients. They visit homes and retirement centers, often with the cooperation and assistance of voluntary helpers. The hospice chaplains, along with their team, provide a welcome relief from isolation and routine for most patients. Their visits mostly occur at weekly intervals on a one-on-one conversational basis which guarantees personal and intimate contacts that often lead to durable friendships.

► Inpatient Care

Hospital Epidemiology

Ljiljana Marković Denić
Institute of Epidemiology, School of Medicine, University of Belgrade, Belgrade, Serbia
denic@eunet.yu

Synonyms

Infection control

Definition

Hospital epidemiology and infection control have been synonyms for many years, and both refer to the discipline concerned with preventing the spread of infections within the healthcare setting. However, both of these terms have grown in terms of definition and function. *Infection control* refers to policies and procedures used to reduce or minimize the occurrence of hospital infections (► hand hygiene, cleaning/► disinfection/► sterilization, vaccination, ► surveillance, ► outbreak investigation, etc.). *Hospital epidemiology* is the use of scientific methodology to measure the necessity and effect of preventive strategies for hospital infection control.

Basic Characteristics

The fundamental roles of hospital epidemiology are to identify risks, understand risks, and eliminate or minimize the risks of hospital infections.

Hospital infection (HI), also called *hospital-acquired* or *nosocomial infection,* is an infection that originates or occurs in a hospital or other healthcare facility. The term "nosocomial" comes from two Greek words: "nosus" meaning "disease", and "komeion" meaning "to take care of".

The ► Centers for Disease Control and Prevention (CDC) has developed a set of definitions for surveillance of HI (Garner et al. 1988). The definitions combine specific clinical findings with results of laboratory and other tests. According to these definitions, a HI is an infection not present on admission, but acquired during a stay in hospital, that manifests itself either during hospitalization or in the period following a hospital stay. The majority of HIs become evident 48 hours or more following admission. HIs include occupational infections that healthcare workers acquire while performing their duties within a healthcare setting. All HIs can be classified as occurring in one of 13 sites. The most common types of HIs are ► surgical site infections, ► urinary infections, ► pneumonia, and ► bloodstream infections.

Epidemiology

Hospital infections occur worldwide and affect both developing and developed countries. Approximately 5%–10% of all hospitalized patients in developed countries acquire a clinically significant HI per year; the ► mortality rate attributable is about 10% (WHO 2002). The ► incidence rate for developing countries can be higher than 25%. HIs increase patients' morbidity and mortality, length of hospital stay, and treatment costs. HIs have occurred for as long as hospitals have existed. Reasons why nosocomial infections will be common in the future include the advancing age of patients admitted to healthcare settings; greater prevalence of chronic underlying diseases among admitted patients; increased use of aggressive medical and therapeutic interventions, including implanted foreign bodies and organ transplantations; growing numbers of immunocompromised patients; and transmission of ► antibiotic-resistant bacteria.

Etiology

Many different pathogens may cause HI. The infecting organisms vary among different patient populations, different healthcare settings and facilities, and different countries (Ducel et al. 2002). The most common nosocomial pathogens are bacteria, viruses, fungi, and parasites. These microorganisms may already be present in the patient's body or may come from the environment, contaminated hospital equipment, healthcare workers, or other patients.

Reservoirs

Reservoirs of HI may be animate (healthcare workers, patients' own endogenous flora, visitors) or inanimate in the environment, including equipment and medications.

Host

Exposure of a susceptible host to infecting agents is influenced by intrinsic factors (age at infection, birth

weight, sex, nutritional status, comorbid conditions and diseases, immunosuppression, immunization status, and psychological state of the host) and extrinsic factors (invasive medical or surgical procedures, medical devices, duration of antimicrobial therapy and hospitalization, and exposure to hospital personnel) (Mayhall 2004).

Environment

Environmental factors include a) physical factors such as building features, ventilation, water; b) biologic factors such as vectors; and c) social factors (socioeconomic status, sexual behavior, potable water, food preparation, and adequate waste disposal).

Mode of Transmission

Pathogens that cause HIs can be acquired in several ways.

a) *Endogenous infections*: bacteria present in the normal flora may cause infections due to transmission to sites outside their natural habitat.
b) *Exogenous infections*: bacteria can be transmitted through ► contact (direct or indirect); ► droplets or air; contaminated food, water or medications; or by arthropods or other insects. Contact transmission is the most important and the most common mode of transmission. Vector-borne transmission of infectious agents is of less significance in developed countries.

Risk Factors

All patients admitted to hospital are at some risk of acquiring a HI. The most vulnerable are neonates (especially premature babies), very old people, people with compromised nutritional or immune status, and those with comorbid conditions (such as diabetes). Other risk factors include a prolonged hospital stay, use of indwelling ► catheters, inadequate hand hygiene, and prevalence of antibiotic-resistant bacteria from the overuse of antibiotics.

Prevention

In the early 1970s, The CDC initiated the Study on the Efficacy of Nosocomial Infection Control Project (SENIC) to examine the ► effectiveness of HI surveillance and control programs. This project showed that approximately 32% of HIs are preventable if infection surveillance and control programs include four components: 1) appropriate emphases on surveillance activities and vigorous control efforts; 2) at least one full-time infection-control practitioner per 250 beds; 3) a trained hospital epidemiologist; and 4) feedback of wound infection rates to practicing surgeons (for surgical site infections) (Haley et al. 1980).

Although the components needed for prevention vary for the different types of HI, a variety of steps can be taken to prevent nosocomial infections, and include the following key components (Ducel et al. 2002):

- Adopting an infection control program which includes strict quality control of procedures known to lead to infection, and a surveillance program to track infection rates,
- Limiting transmission of pathogens through correct and frequent handwashing and glove use, aseptic practices, sterilization, disinfection, ► isolation strategies, and laundry,
- Limiting the risk of endogenous infections by minimizing invasive procedures and promoting cautious use of antibiotic medication,
- Protecting patients with appropriate antibioprophylaxis and vaccination,
- Prevention of infections in staff members,
- Continuing staff education.

Epidemiologic Methods Applied to Hospital Infections

Classic methods in epidemiology (► epidemiology, aims and scopes) are used to study HI. *Descriptive epidemiology* provides helpful tools to describe the distribution and frequency of HI, particularly in relation to persons (age, sex, race, marital status, personal habits, occupation, socioeconomic status, medical or surgical procedure or therapy, device use, underlying disease, or other exposure), time (duration of stay in hospital, pre- and post epidemic periods, seasonal variation, secular trends), and place (geographic occurrence of the HI or outbreak, medical or surgical ward of acquisition of infections). Information on each of these characteristics allows the formulation of a hypothesis about the source, reservoir, or the mode of transmission of a HI. In particular, descriptive data analysis may be performed in the early phase of the investigation of clusters of HI. ► Analytical studies are designed to test

hypotheses. Two types of analytical studies can be used: ► cohort studies and ► case-control studies. Examples of cohort studies include identification of risk factors for HI and risk factors for postoperative complications, and handwashing methods. A ► retrospective (historical) cohort study is widely used in the investigation of an outbreak of HI. Experimental epidemiology mainly consists of ► randomized clinical trials in hospital epidemiology. Examples are the following: prevention of catheter-related bloodstream infections, prevention of surgical site infections, prevention of ventilator-associated pneumonia, control of transmission of multiresistant microorganisms, etc.

Hospital Information System

Definition

A hospital information system is an ► information system for processing ► data, information and knowledge in hospital activities, i. e. on the secondary and tertiary health care levels. These electronic systems include electronic patient databases; applications for data access, retrieval, presentation, and distribution from several units (physicians' notes, nurses' notes, laboratory and other diagnostic tests, medications, etc); and communication technologies enabling simultaneous use by several users and transfer of information for several purposes: research, education, teleconsulting, etc.

Hospitals

Definition

Hospitals are licensed establishments providing mainly inpatient healthcare, i. e. diagnosing, treating and housing the sick and injured, and managing childbirth. Outpatients, i. e. patients who do not stay in the hospital after treatment, can receive examination, ► emergency care or other services not provided by doctors outside the hospital. Hospital health care delivery may be on a public (government-owned) or private (non-profit or profit making) basis. Hospitals are either providing necessary health care for all types of diseases or specialized in some medical areas (e. g. children's hospitals, mental hospitals). The hospital sector is in most countries strongly regulated by government law. Scope and

quality of inpatient health care services depend on the resources spent in the hospital as well as on the qualifications of the hospital staff and therefore may vary significantly from one country to another.

Basic Characteristics

History

The term 'hospital' comes originally from 'hospitium' meaning a place for guests. During Roman times, its meaning has extended to 'needing shelter'. Throughout the middle ages, hospitals were charitable institutions for the needy, aged, infirm, or young and hospitals were mostly dependent on the church. In the 16th century hospitals took on their modern meaning as institutions where sick or injured people are given medical or surgical care. In Europe, in the late 17th century, large facilities for the sick and poor were created, and, especially in France, hospitals have since been well established. During the 18th century there was a rising need for hospitals due to the increase in the urban population in larger industrializing towns, and hospitals became more and more independent from the church. But there was little that could be done in a hospital that could not be as well done in a home. Only with the progress of medicine and surgery has the hospital flourished. Toward the end of the 19th century, hospital care was revolutionized by the discovery of anesthesia, improvements in sanitation, establishment of hospital nursing schools, and other advances. After the World Wars, hospitals broadened the scope of their activities, becoming important centers not only for health care services but also for medical education, nurse training, medical research, and the provision of patient convalescence and social support. The development of ambulance services, transporting sick and injured people, made the modern hospital also the focus of emergency care. In conclusion, hospitals have changed from places providing care solely for the sick and poor to being the center of the medical world, occupying an important place in society from birth until death.

Types and Organization of Modern Hospitals

Today, inpatient hospital health care is delivered either by general hospitals or by specialized hospitals, for example, mental health and substance abuse hospitals or other specialty hospitals such as specialized heart disease hospitals.

General hospitals are licensed establishments which provide surgical and non-surgical diagnostic and medical treatment for inpatients, using specialized facilities and equipment for all types of diseases. Hospitals also may provide outpatient care such as examination, laboratory services, diagnostic X-ray services or emergency services which are not provided by outpatient doctors' offices. In some countries, a minimum number of beds is a required condition for registration as a hospital. Hospitals can be run by the government on a national, regional or community level (e. g. general acute hospitals, army and police hospitals, prison hospitals), by private non-profit organizations (e. g. the Red Cross) and by universities (teaching hospitals). Teaching hospitals, in addition to providing care, train health care providers, perform research and provide high level services such as organ transplantation.

Specialized hospitals, such as mental health and substance abuse hospitals, provide the whole spectrum of inpatient services needed for mentally ill people or people suffering from substance abuse disorders requiring typically longer lengths of stay. Services comprise general psychological, psychiatric and nutritional care along with other social services.

Specialty hospitals are licensed establishments for the care of patients with specific types of diseases or medical conditions. For example, specialized emergency centers, hospitals for tropical diseases, orthopedic hospitals, sanatoriums for rehabilitation or disease prevention. These hospitals may also provide outpatient services, laboratory and operating room services.

Hospital staff in modern hospitals are required in significant numbers to provide the whole spectrum of hospital services. Large hospitals may employ between 2000 and 3000 people which makes the management of a hospital a very complex task. The main groups of employees in a hospital are as follows:

- Clinical staff: Physicians or doctors responsible for the diagnosis, treatment and prevention of diseases and surgeons, specializing in performing surgery.
- Nurses performing diagnostic skills (e. g. history taking), therapeutic management (e. g. coordinating

consultations and referrals), and promoting health activities in collaboration with the patient.
- Laboratory staff and pharmacists.
- Administrative staff dealing with finance and accounting, salaries, supply, storage, staff recruitment and training, building maintenance, catering, laundry, etc.

Funding and Payment Systems

According to the health care system and regulatory framework in place, hospitals may be run by the government or independent non-profit organizations with public funding through taxes or social insurances (e. g. in most European countries). Or, hospitals may be privately run with a clear for–profit motive (e. g. in the United States).

Regardless of who owns the hospitals, the methods of financing have changed significantly during the two past two decades all over the industrialized world. There has been a clear shift from open-ended retrospective funding of inpatient health care towards funding based on ► prospective budgets or ► per-case payments. The change in financing methods of hospitals is due to the persisting need for ► cost containment as endlessly rising hospital expenditures are confronted with limited public and private financial resources. Budgets in general are based on historical spending and do not typically incorporate incentives to spend less than the fixed budget. Even annually revised activity-related budgets make it difficult to realize cost containment. Therefore, more and more hospital owners changed the financing method of hospitals towards per-case payments based on purchasing packages, i. e. contractual agreements between purchaser and provider, or on ► diagnosis related groups (DRGs).

Organizational and Structural Changes, Future Challenges

There are four main factors that influence the organizational and structural changes in hospital health care provision:

1. Evolution of disease and treatment
   Many large hospitals reflect the scientific, economic and social situation of the time when they were built, i. e. the early 20th century. Distinctive operative units divided into medical disciplines deliver services according to their own independent procedures. Changes in the presentation of diseases, for example the increasing advent of chronic diseases, have led to a growth in multidisciplinary treatment based on the idea of a health care chain. These scientific and technological changes in disease management (► disease management programs) require a redesign of most hospital structures as rigid and hierarchically organized disciplines do not favor the cooperation of interdisciplinary care-teams.
2. Health policies and payment systems
   The regulatory framework resulting from health policy changes as well as from changes in payment systems influence the investment and delivery of care in hospitals. Payment systems may, for example, privilege investments in hospital equipment but not in the maintenance of hospital buildings. ► Per-case payments based on DRGs may lead to higher admission rates or extensive equipment use not directly related to the health gain but to the higher reimbursement rate.
3. Progress in medical technology
   Advances in health technology, such as diagnostic imaging, intravascular ultrasound and minimal invasive surgery, have led to a considerable reduction in the average length of stay of a patient. This has led to an overall reduction in the number of hospital beds and a higher turnover in patients.
4. Improving quality programs
   Hospitals need to improve their quality of services in many aspects (► health care quality). There is a lack of coordination between services, often an inappropriate use of resources with respect to the quality delivered and scarce maintenance of building and equipment as well as a lack of information among hospital staff on costs and outcome. Improvement in the quality programs necessitates changes in the organization and management of hospitals. The current trend is to consider hospitals as industrial companies which must be organized, managed and evaluated. In this sense, management functions and clinical activities have to be provided with the shared common goal of health care quality. Many initiatives aiming to improve health care quality have been started: for example the introduction of ► clinical guidelines, continuing medical education, disease management programs and standards for health technology assessment.

The continuous development of medical knowledge and treatment practices together with the financial pressure of cost-containment and the rising expectations in terms of quality of care will inevitably lead to further changes in the organization and management of hospitals. The future challenges are two-fold:

1. to change the functional interaction between the levels of care, incorporating the idea of a health care chain to provide effective and integrated health care to the patients, and
2. to change the reporting measures in order to make the effectiveness of health services transparent with regard to patients' health quality.

Host

Definition

The host is the human or animal to which an agent acquires entry and in which it multiplies. The reaction of the host to infection is variable, resulting in an unapparent or clinical, mild or severe infection.

House Dust Mites

Synonyms

HDM; Dust mites; Domestic mites

Definition

House dust mites (HDM) are small arthropods approximately 0.3 mm in length. The biological family includes 47 species in 17 genera but those most frequently detected in human dwellings are *Dermatophagoides pteronyssinus*, *D. farina*, *Blomia tropicalis* and *Euroglyphus maynei*. The optimal air temperature for dust mite growth is between 18 and 27°C. Their major food source is skin scales and organic debris, but they are almost entirely dependent on ambient humidity for moisture. Feces, in the form of small airborne particles, have great allergenic potential due to protein residues, and inhalation of fecal particles is the main way of exposure. High levels of domestic mites and their allergens are usually observed inside homes in hot and wet climatic zones of the world but have now been found even in northern parts of Europe and North America, where cold and dry climates predominate. The highest mite densities are found in bedrooms and living rooms because these indoor spaces usually have large areas covered by textile materials. The most important adverse health effects due to biological indoor air contamination are asthma (primarily in children), atopic dermatitis, eczema, urticaria, allergic rhinitis, and conjunctivitis. Asthma is strongly associated with sensiti-

zation to indoor allergens, and among them HDM allergens are thought to be a major cause. Indoor relative humidity is the key factor that determines survival and development of house dust mites. For this reason, the most effective recommendations for reducing the HDM population and accumulation of allergens are maintaining relative air humidity below 50%, and encasing mattresses with a special mite-impermeable membranous material. Other recommended measures are improving ventilation, intense and frequent vacuum cleaning, reducing the total textile area in indoor spaces, and even removal of carpets and other floor coverings from the homes (especially from bedrooms) of those who suffer allergies to house dust mites.

HTA, Aspects of

Ulf Maywald
Abteilung Ärzte/Apotheken, AOK Sachsen, Dresden, Germany
ulf@maywald.com

Definition

Health Technology Assessment (HTA) is carried out by a multidisciplinary group because it requires wider expertise than any individual or single disciplinary group could be expected to have. While conducting a HTA, medical, methodological, ethical, social, legal, and economic aspects have to be considered, discussed and judged prior to formulation of the recommendations.

Basic Characteristics

Compared to assessing published medical evidence, the methods for assessing the ethical, legal, and social aspects of health technology by HTA are relatively undeveloped. One reason for this might be that integrating ethical inquiry into HTA is methodologically difficult. However, policy makers can only make well-founded decisions on the basis of HTA reports dealing with all of the aspects mentioned below.

Methodological Aspects

The core mission of HTA methodology is to promote the identification, development, and use of appropriate research methods so that health and social care can be built on the best possible evidence base. Consequently, the main purpose of HTA is to determine the available ► scientific evidence, including ► patient safety and risks, ► efficacy, and ► effectiveness.
Methodological aspects are discussed in detail under ► HTA methodology.

Economic Aspects

Because costs and efficiency have made technology prominent in health care policy-making, HTA has become much more focused on (and limited to) economic aspects of health technology, whereas general technology assessment lays greater emphasis on the societal context of technology, or the interactions between technology and society. Consequently, in HTA, different methods are seen as valid and viable. For example, HTA is much more dominated by quantitative (► quantitative research), comparative research than general ► technology assessment, where ► qualitative research is more often regarded as appropriate.

Ethical Aspects

Moral aspects have been on the HTA agenda since HTA itself was first used in Western societies in the early 1970s. The growing importance of biotechnology in medicine since then has added to an increasing awareness of ethical aspects. With relatively new issues like ► genetic testing, ethical questions have entered the agenda, going beyond the traditional clinical considerations. These ethical questions concern the possible impacts on society, and challenge our concept of health and disease as well as our understanding of human dignity, thus introducing a new quality into debates on health care and medicine. Regarding moral aspects, HTA has not matured as a comprehensive approach to evaluating health technology. Instead,

HTA has become much more focused on (and limited to) economic aspects of health technology, often with the consequence of insufficient consideration of ethical aspects of the new technology before a recommendation is made. Although there is no validated method for assessing values or ethics (in healthcare), at least three categories of ethical questions can be distinguished in HTA (Reuzel et al. 2004a):

- Issues related to essential concepts and definitions
- Issues related to the technology, which in health care focus on diagnosis, prevention, and therapy
- Issues related to resource allocation

Social Aspects

There is a need for ethical inquiry in HTA from the perspective that policy-making never appears to be based exclusively on economic (► cost effectiveness) data. Health technologies may have social and ethical consequences that influence policy-making and therefore need to be addressed in HTA. Typically, an ethical inquiry is carried out as an addition to conventional HTA, by including ► patient preferences or ► patient orientation of the procedure assessed in decision modeling, or by ► quality-of-life studies or discussions on equity and distributive justice (Reuzel et al. 2004a).

Legal Aspects

The structure of the legal systems in each particular country is determined by the basic structures of the medical and health care systems themselves. The difference between national health care systems, where the state determines the rules for accepted medical methods and products, and social insurance systems, which are more or less self-governing bodies, has to be observed within the framework of public legal regulations. Another important aspect relates to the local scope of decisions. In some countries, decisions based on HTA reports have effects at a national level, in other systems, only at a regional level. One problem is that the legal concepts for dealing with HTA recommendations, which leave considerable scope for interpretation, are relatively undetermined. Furthermore, the lack of consensus on the criteria and procedures of decision-making in HTA concerning health sciences as well as practice constitute unsatisfactory empirical facts, as well as a normative challenge.

A legal constitution of HTA has to guarantee the coherence of regulations in the different fields of law related to HTA (e. g. pharmaceutical law, law of medicinal products, statutory health insurance law) and the harmonization of their effects in the process of application (Francke 2006).

HTA, Context of

Ulf Maywald
Abteilung Ärzte/Apotheken, AOK Sachsen,
Dresden, Germany
ulf@maywald.com

Definition

Health Technology Assessment (HTA) has been compared to a bridge between the world of research and the world of decision-making. This bridge is intended to

allow the transfer of knowledge produced in scientific research to the decision-making process. A commonly accepted definition for the context of HTA does not exist because the context of HTA has to take a lot of different aspects into consideration. Besides the published evidence, for example, methodological, social, ethical, and legal circumstances have to be judged prior to giving a recommendation via a HTA report.

Basic Characteristics

Technology Assessment and Health Technology Assessment

► Technology assessment has been described as a comprehensive form of ► policy research that examines short- and long-term social consequences of the application of technology. Developing and/or using (health) technologies is based on value judgments, meaning that social, cultural, ethical, and legal factors are intertwined with the place of (health) technologies in society (Oortwijn et al. 2004). There is no sharp distinction between the terms technology assessment (TA) and health technology assessment with regard to the content because general TA tools can be and are applied to health technologies. Conducting HTAs does not begin and end with the HTA itself, but it is ideally embedded in a course of activities: first, the classification of pending problems; second, the prioritization of topics; third, conducting the research or assessment; fourth, appraisal of the recommendation; and last, its implementation.

Unfortunately, in many countries, the role of TA and HTA in the preparation of decision making and later implementation of these decisions is not well defined.

Perception of HTA

HTA exists alongside policy decisions and is often insufficiently recognized by politicians and health care managers. It is crucial to explain the context of a HTA report clearly, so that readers can better assess whether the report is relevant to their own problems. The context-embedded approach of HTA is a key advantage of these assessments, because ► evidence-based medicine is mainly focused on ► randomized controlled (clinical) trials, with questionable transferability of the results into policy decisions. In order to give an evidence-based solution to the problems addressed in the policy question, the researchers have to define the policy question in terms of safety, ► efficacy, ► effectiveness, and psychological, social, ethical, organizational, professional, and economic aspects of HTA (► HTA, aspects of). These questions determine how the rest of the assessment will be conducted, the aspects that will be evaluated and those that will not, as well as the profundity of the research regarding each of the aspects mentioned.

In each country, the adoption and use of health technology is influenced by many factors, including the perception and experience of health and disease, cultural responses to technology, the nature of the medical profession in the particular country, industrial information and promotion, and the financial and regulatory system.

HTA, Databases

Ulf Maywald
Abteilung Ärzte/Apotheken, AOK Sachsen, Dresden, Germany
ulf@maywald.com

Definition

Sources for assessing studies to consider within a health technology assessment (HTA) report are mainly literature databases like Medline, EMBASE, Current Contents, etc. For assessing HTA reports themselves, specialized *HTA databases* exist. Normally, these databases are full-text databases (► databases, full text).

Basic Characteristics

Because many organizations throughout the world assess healthcare technology with different focuses, there is an evident need to cooperate and share information from different cultures. The most important medium for sharing such information are HTA databases. The most important of these databases are:

The Cochrane Library

The major product of the ► Cochrane collaboration is the Cochrane Database of Systematic Reviews. The Cochrane Library is published four times a year and is available on CD-ROM and the Internet. Each issue contains all existing reviews plus an increasingly wider range of new and updated reviews. It is published and distributed by Wiley InterScience and is also distributed by a number of other distribution partners. The Cochrane Library is a single source of reliable evidence about the effects of health care. Cochrane reviews are based on the best available information about healthcare interventions. They explore the evidence for and against the effectiveness and appropriateness of treatments (medications, surgery, education, etc.) in specific circumstances. The reviews are mostly prepared by health care professionals who volunteer to work in one of the many ► Cochrane review groups, with editorial teams overseeing the preparation and maintenance of the reviews, as well as applying the rigorous quality standards for which Cochrane Reviews have become known. The activities of the Collaboration are directed by an elected Steering Group and are supported by staff in Cochrane Entities (Centers, Review Groups, Methods Groups, Fields/Networks) around the world.
The following Databases are included in The Cochrane Library:

- The ► Cochrane Database of Systematic Reviews
- The ► Database of Abstracts of Reviewsof Effects (DARE)
- The ► Cochrane Central Register of Controlled Trials (CCTR or CENTRAL)
- The ► Cochrane Database of Methodology Reviews (CDMR)
- The ► NHS Economic Evaluation Database(NHS EED)
- The Health Technology Assessment Database
- The ► Cochrane Database of Methodology Reviews (CDMR)

Databases of the Centre for Dissemination and Reviews (CRD)

The ► centre for reviews and dissemination (CRD) of the National Health Service (NHS) in the United Kingdom was established in January 1994, and aims to provide research-based information about the effects of interventions used in health and social care. It offers three databases: DARE, NHS EED and the HTA database.

Database of Abstract of Reviews of Effects (DARE)

The CRD created this database for reviews and dissemination in 1994. Potential reviews are identified by hand searching key medical journals, regular searching of bibliographic databases, and by scanning gray literature and selected websites. The database includes reviews of health and social care topics. It contains summaries of systematic reviews, which provide a critical commentary on the quality of the review.
Different kinds of records (structured and provisional abstracts, Cochrane Reviews published in journals, Cochrane "flag" reviews) are added to DARE at the end of every month.

NHS Economic Evaluation Database (NHS EED)

Databases like MEDLINE and EMBASE as well as magazines (which are hand searched) and working papers of specialized working groups and ► HTA institutions are the sources of the NHS EED. The database contains bibliographical information and appraisals of economic evaluations in which costs, outcomes of treatment, and care alternatives in health care are compared. Experts in the NHS write appraisals that give information about different aspects of the original study, like study population or study design. Study types that are investigated include economic studies, cost-benefit analyzes, cost-utility analyzes, cost-effectiveness analyzes, cost-minimization analyzes, and cost-consequence analyzes, as well as ► systematic reviews of economic studies.

International Health Technology Assessment (IHTA) Database

The ► IHTA database contains information on HTAs and is produced in collaboration with the ► INAHTA Secretariat, based at SBU, Sweden.

The database contains records of ongoing projects being conducted by members of INAHTA, as well as publications reporting completed technology assessments carried out by INAHTA members and other HTA organizations. The abstracts in the database are descriptive rather than analytical and do not form critical appraisals of the reports (i. e. the reports have not been evaluated by reviewers from the Centre for Reviews and Dissemination).

Many different types of research are included in the HTA database. As well as systematic reviews, the database contains ongoing and completed research based on trials, questionnaires, and economic evaluations. Where possible, the research type is stated in the title or abstract. In some cases there is an overlap between the DARE database (systematic reviews) and the NHS EED database (economic evaluations).

Database of the International Network for Agencies for HTA (INAHTA)

This database was developed in cooperation with the international network of public HTA agencies (International Network of Agencies for Health Technology Assessment, INAHTA) and contains information on the current HTA projects and published HTA reports of INAHTA members. Information includes evaluation of medical procedures and technologies in health care, and is available as various kinds of documents, such as HTA reports, studies, survey results, economic appraisals, and systematic reviews.

DAHTA Databases

The ► DAHTA database contains HTA reports and projects provided by the German Agency for Health Technology Assessment ► DIMDI (DAHTA@DIMDI). In addition, other institutions like the Federal Physicians' Chamber (Bundesaerztekammer) and the National Association of SHI-Accredited Physicians (KBV) use the database to publish their HTA projects. Current international HTA reports are continuously included, with German abstracts of international HTA reports added by the DAHTA database staff. The database contains studies concerning medical evaluation and cost-efficiency of drugs, therapies, and surgical procedures, as well as studies supporting management and organization systems of health services.

HTA-Europe Project

Definition

The HTA-Europe project was developed from a recommendation in the ► EUR-ASSESS project. In the HTA-Europe project, partners examined several preventive technologies in their respective countries, showing that prevention and screening procedures often seem to be prematurely adopted, without adequate assessment. The HTA-Europe project, as well as the EUR-ASSESS project, was aimed at improving coordination of HTA activities in the European Union. The main conclusion of this report was that it would be beneficial for the healthcare system of European Union countries for the European Commission to assist the establishment

of a coordinating mechanism for HTA at the European level.

HTA, Impact of

Ulf Maywald
Abteilung Ärzte/Apotheken, AOK Sachsen, Dresden, Germany
ulf@maywald.com

Definition

The Impact of Health Technology Assessment (HTA) is the sum of the broad and diverse effects stemming from a ► HTA program's activities.

Basic Characteristics

Like other health technologies, HTA should be judged on the quality and size of its effects. In recent years, this aspect has received increased attention. HTA has begun to become an important part of health care policy-making in many countries.

The goal of HTA is change; it should help to demonstrate problems and potentials in disease control. Topics chosen for assessment must be important to society and information should be presented in a form that is useful to the intended audience. Technology assessment identifies the groups that will be affected by the proposed technology and evaluates the impact of the technology on each party.

Furthermore, together with the dissemination and implementation of HTA recommendations, the evaluation of their effects is an important factor of HTA.

However, the response of policy-makers shows that many of them do not see the importance of assessment. There is more interest in controlling costs then in steering health care. That means that even when good assessments are done, their impact on policy-making has been modest. Some factors cause some HTA to have little impact; a prerequisite for the assessment to be effective is that it must be comprehended and accepted by those who use it. Furthermore, content and preparation of the assessment must be properly formulated for it to be interesting.

The effects of HTAs are linked with the assessing institution and the motivation of its commissioner (Gerhardus et al. 2006).

For best use of HTAs, exact formulation of the impact aims is needed. As a first step in assessing a technology, the people concerned should be defined. These people have to formulate the aims and disseminate the recommendations of the HTA. Effects of HTA should then be evaluated, and if defined impact aims are not reached, a discussion should follow.

Impact Measures

Measuring the impact of HTA is very difficult due to the multiplicity of other influences on the policy-making process and the difficulty of measuring the longer-term impacts of HTA (Hailey 1990). Studies of HTA impact should include at least three types of evaluation: context, implementation, and outcome (Peterson 1998). Context evaluation identifies environmental enablers and barriers that influence the impact of HTA products; implementation evaluation identifies critical processes and activities in producing HTA products that influence impact; and outcome evaluation identifies the extent to which the HTA products influence healthcare policy and decision-makers. Normally, products that present evidence with clear conclusions tend to have a greater influence on decision making than those that do not.

A widely used measuring method in HTA impact analyses is direct ► client interviews. This could be "product specific", semi-structured interviews with requesters and purchasers. However, even if a HTA does not result in instrumental utilization, this is not "no impact".

In conclusion, the current impact of HTA on policy decisions has not been clearly and systematically examined, and programs on this topic are not implemented, even in the countries that have been using HTA intensively for decades.

Definition

Many organizations throughout the world assess healthcare technology. In the past twenty years, there has been a rapid expansion of the international Health Technology Assessment (HTA) community, which today includes 42 public organizations in 21 countries, and numerous private and nonprofit organizations (Mulcahy and Walley 2005). Many efforts have been made to share experiences at an international level, like establishing the International Society for Technology Assessment in Health Care. This network stretches from North and Latin America to Europe, Australia, and New Zealand.

Basic Characteristics

HTA in Europe

HTA is currently managed actively in 16 European countries, the old Member States of the European Union, plus Switzerland. These countries have established different national programs, tailored to their own healthcare environment. The leaders are Sweden and Denmark, who began to assess health technologies in the early 1970s. A number of the States of Europe are deeply involved in HTA, including Spain, The Netherlands, France, Sweden, and the United Kingdom (UK). Other countries have more recently begun to support and use HTA, including Austria, Belgium, and Germany. In the UK, a centralized National Health Service (NHS) program was established in 1993. The UK program is noted for its strong relationship with the UK appraisal organization, the National Institute for Health and Clinical Excellence (NICE), which uses HTA as the basis for its guidance for the NHS. Some of the national agencies are outlined below:

United Kingdom: National Coordinating Center for Health Technology Assessment (► NCCHTA)

France: National Agency for Accreditation and Evaluation in Health (► ANAES, formerly ANDEM)

Spain: National Spanish Agency for Health Technology Assessment

Netherlands: The Netherlands Organization for Applied Scientific Research (► TNO)

Sweden: Swedish Council on Health Technology Assessment in Health Care (► SBU)

ISTAHC and INAHTA

The foundation of the International Society for Technology Assessment in Health Care (ISTAHC) in 1985 in Copenhagen had the aim of beginning and promoting international communication and co-operation. The ISTAHC now has more than 1000 members all over the world and is today called HTAi (www.htai.org). In 1993, the International Network of Agencies for Health Technology Assessment (► INAHTA) was created. This Network presently has more than 20 members, mostly from European Countries (www.inahta.org), and provides access to a database of HTA reports and ongoing assessments. Networks across Europe are necessary to avoid the gaps and duplication in coverage of HTA that have become increasingly apparent. One project was inaugurated in 1994, and called the ► EUR-ASSESS project. Part of the aim of this project was to establish a network of those working in HTA in Europe. The need for improved co-ordination of HTA in Europe led to a subsequent project, the ► HTA-europe project, which was organized by the TNO Prevention and Health Institute in the Netherlands. A third project, the European Collaboration for Health Technology Assessment (► ECHTA), explored the possibilities of institutionalizing HTA at a European level. One of the most prominent outputs of this project was the formulation of best practice guidelines for undertaking and reporting HTAs (Busse et al. 2002). The most recent project, which was officially started in January 2006, is the European Network for Health Technology Assessment project (► EUnetHTA project).

HTA in North America and the United States

The first formal activity in HTA was the Health Program of the US Office of Technology Assessment, established in 1975. In the United States, the Agency for Healthcare Research and Quality (► AHRQ), Veteran's Administration Technology Assessment Program, and a multitude of private healthcare organizations and companies each conduct their own HTA. This

often leads to a fragmented, duplicative and highly variable quality of HTA in that country (Perry and Thamer 1999).

HTA, Methodology

Ulf Maywald
Abteilung Ärzte/Apotheken, AOK Sachsen, Dresden, Germany
ulf@maywald.com

Definition

Methods for assessing health technology assessment (HTA) reports have to use best scientific practices and procedures. Despite policy goals, HTA must always be firmly rooted in science and the scientific method. The process must be carried out with integrity and results must be valid.

Basic Characteristics

Research Question

For best use of HTAs, exact formulation of the impact aims is needed. In a first step of technology assessment, the people concerned should be defined. HTA promotes the decision-making of different kinds of associations, such as ► healthcare providers (e. g. ► HMOs), ► statutory health insurance providers, purchasers, patients, or policy-makers. These people have to formulate the aims and disseminate the recommendations of the HTA. A policy question, formulated by decision makers, is then transformed into the correct ► research question.

Realization of HTA

The core mission of HTA methodology is to promote the identification, development, and use of appropriate research methods so that health and social care can be built on the best possible evidence base.
Consequently, the main purpose of HTA is to determine the available ► scientific evidence, including ► patient safety and risks, efficacy, and effectiveness. HTA researchers retrieve, analyze and synthesize the available evidence. A ► systematic literature review is one important element in determining the efficacy and safety of a technology. Evaluations are based on different research categories: randomized clinical trials (► primary research), systematic reviews (► secondary research), and ► treatment guidelines or synthesis of evidence (► tertiary research). The group of studies that are considered to be the best available to answer the questions posed is called the "body of evidence". It is characterized by a combination of factors, such as the hierarchy of research design, the directness of the evidence, and the quality of execution. The strength of evidence is also influenced by other factors. In judgment of the evidence, the number of studies, size of effects, and homogeneity or consistency of results across all included studies should not be neglected. In the completed HTA report, literature is presented in tables or by ► meta-analysis. The literature used is also prepared in a useful manner for decision-makers. The challenge is to judge evidence from different studies. Research is contracted to academic researchers and investigation centers; multidisciplinary teams in scientific institutions are advantageous for the realization of HTA reports.

HTA Reports

The product of the HTA process is the assessment report or HTA report. The methodology must be exactly and transparently documented. The way researchers make their judgments about the strength of the evidence that will underlie their recommendations should be pub-

lished in a distinct manner. A review has identified 40 different systems used to rate the strength of evidence; it therefore seems intelligible to explain the used system in the report (West et al. 2002). Rating of the strength of evidence causes a grading of recommendation. There are also several systems to standardize the process of grading the strength of recommendation. Using letters is a typical way to describe the strength of recommendations (West et al. 2002).

The HTA program of each country normally publishes its generated HTA reports. In addition, they should be included in the ► cochrane library and other worldwide ► HTA databases.

Quality of HTA Reports

There are high claims for the quality of HTA reports and their recommendations. However, different problems may be present in these reports, especially the risk of unsystemic literature research and valuation. To prevent these risks, many countries have established HTA methodology programs. The most well-known of these programs is the ► UK HTA methodology programme, coordinated by the National Coordinating Centre for Research Methodology (NCCRM) in Birmingham.

Outcomes of HTA Reports

The outcome of a HTA report is normally a determination of the appropriateness of payments for services in health care systems.

Generally, HTA is intended to assist decision-makers in adopting rational decisions concerning three principal issues related to new health technologies (Pan American Health Organization 1998):

- approval for market access,
- approval for their inclusion in services financed with public funds, and, if appropriate,
- proper dissemination within the health system.

With regard to existing health technologies, HTA is intended to orient rational decision-making with respect to three principal issues:

- withdrawal of financing for technologies proven to be inefficient,
- generalization of new applications of technologies that already exist in the public health system, and
- withdrawal of technology (or suppression of one of its indications) from the market (e. g. a drug such as thalidomide, which was withdrawn because of its side effects).

HTA Program

Definition

A HTA program is any governmental or private effort or structured program to promote HTA or several aspects of HTA in specific regions or worldwide. HTA programs include, for example, ► EUnetHTA and ► EUR-ASSESS.

Human Activity Integrating Risk Identification

► Risk Management

Human Capital Approach

Definition

The human capital approach is a method to estimate the ► indirect cost due to productivity loss. The value of the human capital is approximated by the value of an average individual's future earning. The entire period of absence from work due to illness is considered and valued by the achievable gross income. Over a long-time perspective, the human capital approach estimates higher indirect costs compared with the friction cost method.

Human Engineering

► Ergonomics

Human Factors

Definition

The terms ► ergonomics and human factors engineering are often used interchangeably. Initially ergonomics was more physiology and comfort oriented, while human factors engineering was more oriented to physical sciences. Ergonomics has traditionally focused on how work affects people, while the emphasis in human factors (engineering) is on the cognitive and perceptual factors leading to the design of systems that reduce the operation errors. "Human factors" is an umbrella term for several areas of research that include human performance, technology, design, and human-computer interaction.

Disaster impacts on human health

Definition

Relations of disasters to human health

Basic Characteristics

Even if disasters (► hazards, natural; ► hazards, technological) are not commonly perceived as public health events, they clearly lead to deterioration of human health over vast disaster-affected areas.

Direct health-related impacts of disasters are: deaths, injuries, ► communicable diseases, and mental health problems. Health effects may result from unsafe or unhealthy conditions (lack of safe drinking water, spoiled food supplies) following the disastrous event. Indirect effects arise through social and economic disruption, infrastructure damage, and population displacement.

There are short-term health effects, such as injuries and stress associated with the disaster, and long-term health consequences, such as malnutrition, psychiatric disorders, depression, anxiety, alcohol or substance abuse, functional disabilities, and domestic (children and spouse) violence.

Life-threatening situations may arise, e. g. in elderly and lonely people with severe health problems who were trapped and abandoned in their homes.

Population displacement following disasters leads to increases in communicable diseases resulting from crowding, lack of clean water and shelter, and poor nutritional status. Due to the very large number of people that may be affected, malnutrition and famine triggered by disastrous events may be among the most important consequences of natural disasters, and the resultant deaths may outnumber the direct fatalities.

In areas hit by a disaster with no evacuation warning, the hardship can be even more intense. Families spend nights huddled together in places they believe to be relatively "safer", which may not necessarily be safer in reality.

Disasters test the integrity of water supply systems and increase the risk of outbreaks of water-borne diseases. The impacts of disasters are particularly severe in less developed areas featuring environmental degradation and in communities lacking basic public infrastructure. Populations with poor sanitation infrastructure and a high burden of infectious disease often experience increased rates of diarrheal diseases after disaster events. Post-disaster increases in cholera and typhoid have been reported. After some disasters in less developed countries, such as the 2004 tsunami, there was a higher risk of disease outbreaks caused by polluted drinking water and a higher risk of communicable diseases.

There is much evidence of the impact of disasters on mental health. There may be considerable prolonged impairment by common mental disorders (anxiety and depression). Depending on how much suffering, death, and destruction they witness during a catastrophe, some survivors suffer from ► post-traumatic stress disorder (PTSD), the same disorder that afflicts combat veterans. PTSD is psychological damage that develops after a traumatic experience and is almost always a delayed reaction to the trauma. Symptoms might appear soon after the event, but they might not surface until several months or even years have passed.

Among the symptoms of PTSD are a vanished sense of security, fear of another disaster, hypervigilance, fatigue, poor concentration, somatic problems (sleep disturbances, appetite difficulties, etc.), feeling nervous or tense, depression, and anxiety/stress. These are the expected reactions of a person who is suffering PTSD and facing the fact that their life circumstances have changed dramatically. Dealing with death or injury of family members, loss of a home, radically transformed neighborhoods, joblessness, the inconvenience of extensive repairs, etc., can cause a state of long-lasting shock and the rational thinking processes of those affected may not function normally.

Those who experience disasters are prone to severe stress. Children suffer ongoing nightmares. They often cling to their parents and refuse to go to school. Moreover, children who do attend school after a traumatic disaster – even those who have typically behaved well – may develop serious discipline problems.

Health impacts of disasters also fall under the categories of ► medically unexplained physical symptoms (MUPS) and ► functional somatic syndromes (FSS).

Many survivors of a disaster have two life-changing experiences. First, when they endure the trauma itself (e. g., seeing floodwaters sweep away their homes, watching gale-force winds destroy their neighborhoods, or witnessing the sudden death of their family members, friends, or neighbors), which might undermine (even permanently and irreparably) their sense of security and their ability to cope with life's problems. Second, they may face ongoing disorder in their day-to-day lives.

Human Immunodeficiency Virus (HIV) / Acquired Immune Deficiency Syndrome (AIDS)

Synonyms

Human t-cell leukemia virus type III; Human t-cell lymphotrophic virus type III; Lymphadenopathy-associated virus

Definition

HIV is a retrovirus that is the cause of AIDS. The retrovirus gradually weakens the immune system by attacking Helper T cells. Two types of HIV exist: HIV-1 and HIV-2. HIV-1 is common worldwide, while HIV-2 is only common in West Africa. HIV is spread from person to person through blood, breast milk or other bodily fluids. This may occur through blood transfusions, hypodermic needles, or sexual contact. Mothers who have HIV while they are pregnant may spread the infection to their unborn child. An individual who has the retrovirus in their blood is called "HIV-positive". AIDS occurs when the HIV infection has severely damaged the immune system, a process that may take years. An HIV-positive person may or may not develop AIDS; however they can infect other people with the HIV virus.

Cross-References

► HIV-Infection and AIDS

Human Interaction

Synonyms

Interpersonal; Organizational interactions or relations

Definition

Human relations are defined as network of many different relations between humans either interpersonal or organizational relations.

Cross-References

► Human Relations

Humanitarian Agency

Synonyms

Aid agency; Aid organization; Relief organization

Definition

An aid agency is an organization dedicated to the support of people, animals, and nature in time of need. There are organizations within government as well as between governments as multilateral donors and as private voluntary organizations. Often humanitarian agencies are engaged in a special theme, such as the United Nations Children's Fund that supports children.

Humanitarian Aid

► Humanitarian Relief Operations

Humanitarian Relief Operations

Synonyms

Supporting measures; Humanitarian aid

Definition

Humanitarian relief operations assist victims of war, civil conflict, and natural disasters with material or logistical help. Particularly, it provides food and medicine. Aid is delivered by governmental agencies, non-governmental organizations, and humanitarian agencies to save lives, alleviate suffering, and maintain human dignity.

Humanity

Definition

It is based on humanitarian principles that ones duty is to strive to promote the welfare of mankind.

Human Relations

Lis Ellison-Loschmann, Neil Pearce
Center for Public Health Research, Massey University Wellington Campus, Wellington, New Zealand
n.e.pearce@massey.ac.nz

Synonyms

Social relations; Human interaction

Definition

Most commonly, the term 'human relations' refers to any interaction between individuals or groups. Over the last century a number of disciplines, particularly in the social science and humanities areas, have contributed to understanding and analyzing the complexity and character of human relations and how they operate at the individual, group and societal levels.

Basic Characteristics

Describing 'Human Relations'

People take part in many forms of 'human relations' every day, whether it is in one-to-one situations, with family, at social gatherings, as part of a group or work organization, at a political level and through interaction with their ecological environment (McMichael 2001). Human relations are an important focus across a range of disciplines within the social science field including psychology, sociology, politics, anthropology and economics. Although concepts and interpretation may vary between disciplines, it is generally recognized that a defining feature of human relations is its focus on interaction and communication. The term 'human relations' is often used interchangeably with that of '► social relations' having connotations of association, co-operation, mutual dependence and belonging.

Individual and Group Human Relations

Social relations form the basis of concepts such as social organization and social structure and a central focus for human relations has been the examination and analysis of relationships between individuals and groups of people. At the individual level, areas such as interpersonal behavior focusing on socialization and personality development, attitude formation and perception of self are all seen as being important aspects of human relations (Cooper and Denner 1998). Equally, the culture of families, which may be viewed as a social system with their own particular group processes, or whole communities, which also have their own structures and organization, and may be influenced by, for example, changing patterns in employment opportunities or altered patterns of demography in urban and rural communities, reflect a group level focus in the broader context of human relations.

At the societal level, analysis of unequal positions such as by class, ethnicity, and sex/gender may have a substantial political impact and assist in understanding the structural cause of such inequalities, offer potential solutions for resolving the problems and assist in the formulation of public policy, at national and international levels (Macionis 2005). For example, the recognition of indigenous rights in many countries has led to the establishment of health initiatives involving community workers, health professionals and educators, all committed to addressing health inequalities amongst indigenous peoples and facilitated information sharing between indigenous peoples (Ellison-Loschmann and Pearce 2006).

Human Relations Theory

The social world of adults is primarily patterned around work activity and it is within this area that human relations theory first developed as part of a wider focus on organizational structure and management in the work place. These trends were enhanced with increasing industrialization and the era of mass production and assembly-line work which became more common from the mid 19th century onwards. Human relations theory was developed in the early 1920s based on the work of Elton Mayo who examined the effect of social relations, motivation, and employee satisfaction on factory productivity (Rotemberg 1994). Other schools were established, for example, the 'Neo-Human Relations School' introduced in the 1950s, by Abraham Maslow and Frederick Herzberg which focused primarily on the psychological needs of workers (Adair 1990). The human relations approach stressed that organizational structure did not necessarily take precedence over social and emotional aspects associated with being part of a team or

feelings of job security and recognition, which were all important aspects in employee motivation.

Human Relations and Health

Human relations are constantly changing, adjusting and shifting to fit the context and environment in which they occur and all of these changes have health effects (Pearce and McMichael 2001). The *agricultural revolution* probably began in the "fertile crescent" of Southwest Asia and involved major environmental changes from the development of organized agriculture and the establishment of cities. These changes were initially reflected in a smaller human body size and, apparently, shorter life expectancy, but were followed by increased population growth. The *industrial revolution*, and the associated period of imperialism and colonialism, commenced in Great Britain in the late 18th century, and initially involved widespread social, environmental and economic disruption and life expectancy initially fell before beginning to increase again in the second half of the nineteenth century. We are currently undergoing the *information technology revolution* and an associated process of economic, social and cultural globalization. In industrialized countries, this is likely to prolong life expectancy for some, but not all, sections of the population. In developing countries, the benefits have been even more mixed, while the countries of Eastern Europe are experiencing the largest sudden drop in life expectancy that has been observed in peacetime in recorded human history with a major rise in alcoholism and "forgotten" diseases such as tuberculosis and cholera (Men et al. 2005).

These changes particularly affect those who may be most vulnerable in a society due to, for example, poverty, ethnicity, illness or political beliefs. It has been recognized that indigenous peoples may be exposed to an unequal burden of risk as a result of historical injustices which are perpetuated by present day government policies. For example, the major restructuring of health and social services in New Zealand during the 1980s resulted in a widening gap in inequality as evidenced in key determinants of health such as income, employment, and housing between Māori, the indigenous people, and non-Māori (Ellison-Loschmann and Pearce 2006). More recently, a number of studies have shown associations between (lack of) social networks, income inequality and (lack of) social capital and poor health in populations, although it is not clear that the observed associations are causal (Pearce and Davey Smith 2003).

Conclusions

Human relations draws on an eclectic range of ideas from across a number of disciplines, notably sociology and psychology, in order to understand the behavior and interaction between individuals, groups, organizations and societies and the ways in which these varying levels of interaction may be used to promote and influence change both locally and globally. Developments in the way people thought about work in the early 20th century helped shift the focus from a purely productivity driven environment towards one recognizing the 'human' elements of organizations albeit focused primarily on maintaining profitability. The constantly changing nature of human relations has various health effects at the individual, societal and global levels. Negative health effects are more likely to be experienced by vulnerable populations and a recent focus in a number of countries has been on addressing inequalities amongst indigenous peoples across a range of areas such as culture, education, health, and social and economic development.

Human Rights

Synonyms

Natural rights

Definition

Human rights are minimum standards of legal, civil, and political freedoms which guarantee dignity to people. To treat people as if they were not human beings is a violation of their rights. A basis for a universal and internationally protected code of human rights was established by the adoption and proclamation of the United Nations' Universal Declaration of Human Rights in 1948. The UN and other organizations work for the protection and promotion of human rights of all people around the world.

Human Rights and Public Health

ADEM KOYUNCU
Mayer Brown LLP, Cologne, Germany
akoyuncu@mayerbrown.com

Synonyms

Basic rights; Natural rights

Definition

The human rights are the elementary, natural and inalienable rights attributed to all on account of their existence as human beings. Human rights represent the institutionalized legal, philosophical, political and moral considerations about the inherent dignity and equal rights all human beings are entitled to and which the state has to respect and protect. The human rights aim to provide individuals with the basic personal, political and property rights as well as the basic freedoms. They ensure the individual's protection from state actions ("defense rights") and provide them with claims vis-à-vis the state to ensure their participation in the society's political, cultural and social life.

Basic Characteristics

History of Human Rights

The institutionalization of human rights derives from the idea that all human beings are naturally provided with basic rights that are inalienable and must be respected by the state and its institutions. The history of human rights goes back to ancient times. As one of the earliest legal documents, the Magna Carta of England (synonym: Magna Carta Libertatum) from the year 1215 acclaimed the existence of certain personal rights vis-à-vis the kingdom's powers. Among others, the Magna Carta proclaimed the individual rights that no "free man" should become arrested, deprived of his properties, attacked or imprisoned without a "lawful judgment". The Magna Carta must be regarded as one of the fundamental documents for the institution of the contemporary constitutional state.

Later, in the 17th century, several acts were created that implemented human rights into national law, such as the Habeas Corpus Act (1679) in England, protecting persons from unlawful detentions and, particularly, the English Bill of Rights (1689). Therein, positive personal rights were codified, which becomes obvious when reviewing the longer original title of the bill "*An Act Declaring the Rights and Liberties of the Subject and Settling the Succession of the Crown*". The English Bill of Rights has influenced future national constitutional documents as well as the Universal Declaration of Human Rights proclaimed by the United Nations in 1948. For example, "The Virginia Declaration of Rights" (1776) and the "United States Bill of Rights" (1791) were declared. Article 1 of the Virginia Declaration of Rights stated "*[T]hat all men are by nature equally free and independent, and have certain inherent rights, of which, when they enter into a state of society, they cannot, by any compact, deprive or divest their posterity; namely, the enjoyment of life and liberty, with the means of acquiring and possessing property, and pursuing and obtaining happiness and safety.*"

In 1789, France proclaimed the "Declaration of Human and Citizen Rights" ("*Déclaration des Droits de l'Homme et du Citoyen*") which similarly included positive human rights. After World War II, the United Nations then took on and furthered the acceptance of human rights. On 10 December 1948, the General Assembly of the United Nations adopted and proclaimed the "Universal Declaration of Human Rights" (United Nations 1948). A profound explication of single human rights would go far beyond the scope of this essay. However, in order to provide a full picture of the protected rights and because of its fundamental world-

wide importance, the "Universal Declaration of Human Rights" is reproduced in verbatim:

"Universal Declaration of Human Rights

Adopted and proclaimed by General Assembly resolution 217 A (III) of 10 December 1948

On December 10, 1948 the General Assembly of the United Nations adopted and proclaimed the Universal Declaration of Human Rights the full text of which appears in the following pages. Following this historic act the Assembly called upon all Member countries to publicize the text of the Declaration and "to cause it to be disseminated, displayed, read and expounded principally in schools and other educational institutions, without distinction based on the political status of countries or territories."

PREAMBLE

Whereas recognition of the inherent dignity and of the equal and inalienable rights of all members of the human family is the foundation of freedom, justice and peace in the world,

Whereas disregard and contempt for human rights have resulted in barbarous acts which have outraged the conscience of mankind, and the advent of a world in which human beings shall enjoy freedom of speech and belief and freedom from fear and want has been proclaimed as the highest aspiration of the common people,

Whereas it is essential, if man is not to be compelled to have recourse, as a last resort, to rebellion against tyranny and oppression, that human rights should be protected by the rule of law,

Whereas it is essential to promote the development of friendly relations between nations,

Whereas the peoples of the United Nations have in the Charter reaffirmed their faith in fundamental human rights, in the dignity and worth of the human person and in the equal rights of men and women and have determined to promote social progress and better standards of life in larger freedom,

Whereas Member States have pledged themselves to achieve, in co-operation with the United Nations, the promotion of universal respect for and observance of human rights and fundamental freedoms,

Whereas a common understanding of these rights and freedoms is of the greatest importance for the full realization of this pledge,

***Now, Therefore THE GENERAL ASSEMBLY proclaims THIS UNIVERSAL DECLARATION OF HUMAN RIGHTS** as a common standard of achievement for all peoples and all nations, to the end that every individual and every organ of society, keeping this Declaration constantly in mind, shall strive by teaching and education to promote respect for these rights and freedoms and by progressive measures, national and international, to secure their universal and effective recognition and observance, both among the peoples of Member States themselves and among the peoples of territories under their jurisdiction.*

Article 1.

All human beings are born free and equal in dignity and rights. They are endowed with reason and conscience and should act towards one another in a spirit of brotherhood.

Article 2.

Everyone is entitled to all the rights and freedoms set forth in this Declaration, without distinction of any kind, such as race, colour, sex, language, religion, political or other opinion, national or social origin, property, birth or other status. Furthermore, no distinction shall be made on the basis of the political, jurisdictional or international status of the country or territory to which a person belongs, whether it be independent, trust, non-self-governing or under any other limitation of sovereignty.

Article 3.

Everyone has the right to life, liberty and security of person.

Article 4.

No one shall be held in slavery or servitude; slavery and the slave trade shall be prohibited in all their forms.

Article 5.

No one shall be subjected to torture or to cruel, inhuman or degrading treatment or punishment.

Article 6.

Everyone has the right to recognition everywhere as a person before the law.

Article 7.

All are equal before the law and are entitled without any discrimination to equal protection of the law. All are entitled to equal protection against any discrimination in violation of this Declaration and against any incitement to such discrimination.

Article 8.

Everyone has the right to an effective remedy by the competent national tribunals for acts violating the fun-

damental rights granted him by the constitution or by law.

Article 9.

No one shall be subjected to arbitrary arrest, detention or exile.

Article 10.

Everyone is entitled in full equality to a fair and public hearing by an independent and impartial tribunal, in the determination of his rights and obligations and of any criminal charge against him.

Article 11.

(1) *Everyone charged with a penal offence has the right to be presumed innocent until proved guilty according to law in a public trial at which he has had all the guarantees necessary for his defence.*

(2) *No one shall be held guilty of any penal offence on account of any act or omission which did not constitute a penal offence, under national or international law, at the time when it was committed. Nor shall a heavier penalty be imposed than the one that was applicable at the time the penal offence was committed.*

Article 12.

No one shall be subjected to arbitrary interference with his privacy, family, home or correspondence, nor to attacks upon his honour and reputation. Everyone has the right to the protection of the law against such interference or attacks.

Article 13.

(1) *Everyone has the right to freedom of movement and residence within the borders of each state.*

(2) *Everyone has the right to leave any country, including his own, and to return to his country.*

Article 14.

(1) *Everyone has the right to seek and to enjoy in other countries asylum from persecution.*

(2) *This right may not be invoked in the case of prosecutions genuinely arising from non-political crimes or from acts contrary to the purposes and principles of the United Nations.*

Article 15.

(1) *Everyone has the right to a nationality.*

(2) *No one shall be arbitrarily deprived of his nationality nor denied the right to change his nationality.*

Article 16.

(1) *Men and women of full age, without any limitation due to race, nationality or religion, have the right to marry and to found a family. They are entitled to equal rights as to marriage, during marriage and at its dissolution.*

(2) *Marriage shall be entered into only with the free and full consent of the intending spouses.*

(3) *The family is the natural and fundamental group unit of society and is entitled to protection by society and the State.*

Article 17.

(1) *Everyone has the right to own property alone as well as in association with others.*

(2) *No one shall be arbitrarily deprived of his property.*

Article 18.

Everyone has the right to freedom of thought, conscience and religion; this right includes freedom to change his religion or belief, and freedom, either alone or in community with others and in public or private, to manifest his religion or belief in teaching, practice, worship and observance.

Article 19.

Everyone has the right to freedom of opinion and expression; this right includes freedom to hold opinions without interference and to seek, receive and impart information and ideas through any media and regardless of frontiers.

Article 20.

(1) *Everyone has the right to freedom of peaceful assembly and association.*

(2) *No one may be compelled to belong to an association.*

Article 21.

(1) *Everyone has the right to take part in the government of his country, directly or through freely chosen representatives.*

(2) *Everyone has the right of equal access to public service in his country.*

(3) *The will of the people shall be the basis of the authority of government; this will shall be expressed in periodic and genuine elections which shall be by universal and equal suffrage and shall be held by secret vote or by equivalent free voting procedures.*

Article 22.

Everyone, as a member of society, has the right to social security and is entitled to realization, through national effort and international co-operation and in accordance with the organization and resources of each State, of the economic, social and cultural rights indis-

pensable for his dignity and the free development of his personality.

Article 23.

(1) *Everyone has the right to work, to free choice of employment, to just and favourable conditions of work and to protection against unemployment.*

(2) *Everyone, without any discrimination, has the right to equal pay for equal work.*

(3) *Everyone who works has the right to just and favourable remuneration ensuring for himself and his family an existence worthy of human dignity, and supplemented, if necessary, by other means of social protection.*

(4) *Everyone has the right to form and to join trade unions for the protection of his interests.*

Article 24.

Everyone has the right to rest and leisure, including reasonable limitation of working hours and periodic holidays with pay.

Article 25.

(1) *Everyone has the right to a standard of living adequate for the health and well-being of himself and of his family, including food, clothing, housing and medical care and necessary social services, and the right to security in the event of unemployment, sickness, disability, widowhood, old age or other lack of livelihood in circumstances beyond his control.*

(2) *Motherhood and childhood are entitled to special care and assistance. All children, whether born in or out of wedlock, shall enjoy the same social protection.*

Article 26.

(1) *Everyone has the right to education. Education shall be free, at least in the elementary and fundamental stages. Elementary education shall be compulsory. Technical and professional education shall be made generally available and higher education shall be equally accessible to all on the basis of merit.*

(2) *Education shall be directed to the full development of the human personality and to the strengthening of respect for human rights and fundamental freedoms. It shall promote understanding, tolerance and friendship among all nations, racial or religious groups, and shall further the activities of the United Nations for the maintenance of peace.*

(3) *Parents have a prior right to choose the kind of education that shall be given to their children.*

Article 27.

(1) *Everyone has the right freely to participate in the cultural life of the community, to enjoy the arts and to share in scientific advancement and its benefits.*

(2) *Everyone has the right to the protection of the moral and material interests resulting from any scientific, literary or artistic production of which he is the author.*

Article 28.

Everyone is entitled to a social and international order in which the rights and freedoms set forth in this Declaration can be fully realized.

Article 29.

(1) *Everyone has duties to the community in which alone the free and full development of his personality is possible.*

(2) *In the exercise of his rights and freedoms, everyone shall be subject only to such limitations as are determined by law solely for the purpose of securing due recognition and respect for the rights and freedoms of others and of meeting the just requirements of morality, public order and the general welfare in a democratic society.*

(3) *These rights and freedoms may in no case be exercised contrary to the purposes and principles of the United Nations.*

Article 30.

Nothing in this Declaration may be interpreted as implying for any State, group or person any right to engage in any activity or to perform any act aimed at the destruction of any of the rights and freedoms set forth herein."

This declaration became internationally important and strengthened the basis and international acceptance of human rights even though it is not legally binding to the nations. This movement has led to the conclusion of international agreements on the furtherance of civil, political, cultural, economic and social rights and agreements against racial discrimination. The "Universal Declaration of Human Rights" formed the basis for the European "Convention for the Protection of Human Rights and Fundamental Freedoms" (synonym: "European Convention on Human Rights") in 1950. By virtue of this Convention, the "European Court of Human Rights" was instituted. Both the European Convention on Human Rights and the European Court of Human Rights have contributed significantly to the protection of human rights in Europe. Most national constitutions

worldwide have enacted national laws to include the human rights and values proclaimed in the "Universal Declaration of Human Rights" (Feldman 2006). The "Universal Declaration of Human Rights" is regarded as setting forth "the ethics of public health", as both pursue the same goal, which is "to provide the conditions under which people can flourish" (Annas 1998).

Human Rights and Public Health

With respect to the relation between human rights and public health practice, actions taken by public health departments can impact most of these human rights although some of them are more often affected. For example, isolations invade the individual's right to liberty, freedom of movement and assembly. Surveillance and data collection by public health departments invade the private sphere and the right to privacy, as may overreaching press coverage (*See* Kirchhoff 2005). Human rights with particular relevance in public health practice are the following:

- The right to life, liberty and security;
- The right to a standard of living adequate for health and well-being, including food and medical care;
- The right to social security;
- The right to property and not to be deprived of own property;
- The right to work and free choice of employment;
- The right to just and favorable conditions of work;
- The right to respect privacy and family life;
- The right to be treated equal before the law;
- The right to a fair trial (due process);
- The freedoms of movement and residence;
- The freedom from arbitrary arrest and detention;
- The freedom of expression and of assembly;
- The right to an effective remedy for violations of rights.

Human rights and public health are interwoven in many ways. As described in the essay about the legal basis of public health, the state's powers to conduct public health activities derive from the human rights of the people as members of the population. All individuals' rights to health, safety and life and their corresponding right to protect themselves (self-defense) are delegated to the state and its institutions. Therefore, it is the state's core duty and authorization to protect its people (i. e., the population) from harm to their health, safety and lives. Therefore, the public health service is not an end in itself but is aimed at the protection and promotion of the respective rights of the population. In this sense, the public health service is an instrument of human rights protection. Both act in the same direction and are "concordant in many important ways" (Bernheim et al. 2007) and "synergistic" (Mann 1997; Childress et al. 2003).

The concordance between public health practice and human rights is not disproved by the fact that public health actions may infringe the human rights of persons posing risks to the population. Public health practice has to protect the (rights to) health, safety and life of the population and, in so doing, must take measures against individuals who endanger the population. The elimination of risk by intruding individual rights is the result of prior legal balancing of the endangered human rights of the population and the human rights of the dangerous person. The fact that public health encroaches the rights of the latter in order to protect the rights of the former does not generally cause tension between human rights and public health. In such cases, the human rights of the population and the respective dangerous individual are in conflict and such conflicts must be resolved by legal balancing. In some situations, the public health actions may be inadmissible because the endangered goods of the population do not outweigh the affected individual's rights. In such cases, human rights are limits to public health practice. However, such conflicts do not constitute an antipodal position between human rights and public health.

Public health practice operates with relevance to human rights. The population members' rights to health, safety and life are the fundament, and the respective self-defense rights are the basis and justification for the existence of public health. In public health practice, conflicts regularly arise between the human rights of the protected population and the human rights of individuals who threaten the population's health (*See* also Childress et al. 2007). Such conflicts need legal resolution. This resolution must be grounded in a careful legal balancing of the conflicting rights.

Humidity

Synonyms

Moisture

Definition

Humidity is the amount of water vapor in an air sample. There are three different ways to measure humidity: *absolute* humidity, *relative* humidity, and *specific* humidity. Humidity is important in climate change (► climate and microclimate). Water vapor in the air, the humidity, plays an important part in the global climate. Like carbon dioxide, water vapor is a greenhouse gas. Relative humidity is the amount of water vapor actually in the air divided by the amount of water vapor the air can hold. Relative humidity is expressed as a percentage and can be computed in a variety of ways. One way is to divide the actual vapor pressure by the saturation vapor pressure and then multiply by 100 to convert to a percent. A device used to measure humidity is called a psychrometer or hygrometer. The US Environmental Protection Agency recommends keeping relative humidity between 30% and 60%, with below 50% preferred to control dust mites.

Hunter-Gatherers

► Indigenous Health Care Services

Hydatid Disease

► Echinococcosis

Hygiene

Definition

Hygiene is a discipline of social medicine. It refers to practices associated with ensuring good health and cleanliness. In a broader view, in scientific terms, hygiene is the maintenance of health and healthy living. Hygiene ranges from personal hygiene, through domestic, and up to occupational hygiene and public health.

Cross-References

► Public Health

Hygienic Hand Disinfection

Definition

Hygienic hand disinfection is performed to eliminate transient microorganisms from the skin. The hands are

rubbed with 3 ml of an alcoholic disinfectant (pressing twice on the pump dispenser) for at least 30 seconds. During the procedure, one has to bear in mind the nail folds and the area between the fingers. Rings and watches should not be worn. Hygienic hand disinfection should be performed before and after each contact with a patient, before and after contact with drains, urethral or venous catheters, tracheal tubes or other indwelling devices, and after contact with material which is suspected of contamination (blood, secretions, contaminated surfaces or objects). Furthermore, hygienic hand disinfection is necessary before all invasive procedures.

Hyperkinetic Disorder

Synonyms

Attention deficit/hyperactivity syndrome (ADHS); Attention deficit disorder (ADD); Attention deficit/hyperactivity disorder (ADHD); Childhood hyperkinesis

Definition

ADHD is a developmental and behavioral condition that affects children's ability to focus and pay attention. ADHD refers to inattentiveness, over-activity, impulsivity or a combination. Diagnosis of ADHD implies that the symptoms are out of the normal range of the child's age and development and affect family life, social life, and / or education. ADHD always begins in childhood but may also persist through adulthood. The disorder affects 3 to 5 percent of school-aged children.

Hyperkinetic Disorders

► Attention Deficit Hyperactivity Disorder (ADHD)

Hyperpyrexia

► Hyperthermia

Hypertension, Arterial

Synonyms

High blood pressure

Definition

Blood pressure is the force of the blood pushing against the walls of the arteries. Hypertension is defined as either systolic pressure consistently at 140 or higher or a diastolic pressure consistently at 90 or higher. The limits of a normal blood pressure are age-dependent. The higher the pressure over 120/80, the higher the risk of developing cardiovascular complications.

Hyperthermia

Synonyms

Hyperpyrexia; Heat stroke

Definition

Hyperthermia is an acute condition occurring when the body produces or absorbs more heat than it can dissipate. The heat-regulating mechanisms of the body eventually become overwhelmed and unable to effectively deal with the heat, and body temperature climbs uncontrollably. Symptoms include confusion, headaches, and low blood pressure, leading to possible fainting or dizziness. The skin is pale or bluish, and the subject complains of chills and trembling. This serious medical emergency requires immediate medical attention. Treatment includes immediate lowering of body temperature, and re-hydration.

Hypnotics and Sedatives

Synonyms

Tranquilizers; Depressants; Anxiolytics

Definition

Hypnotics and sedatives are central nervous system depressants with the capacity of relieving anxiety and inducing calmness and sleep. Several such drugs can

also induce loss of memory (amnesia), muscle relaxation or have anticonvulsant properties. In the past barbiturates were mainly prescribed as hypnotics and sedatives but their use decreased over the last decades because of a narrow therapeutic range. Today benzodiazepines as well as zolpidem and zopiclone are mainly prescribed.

Hypochondria

Synonyms

Health anxiety; Health phobia

Definition

Hypochondria is an exaggerated, uncorrectable fear that one is suffering from a physical illness even though, objectively, there is only a minor, if any, physical problem. The least variation of body function or feeling is constantly and erroneously interpreted as proof of a severe disease.

Cross-References

► Anxiety Disorders

Hypochondriacal Disorder

Definition

The essential feature of a hypochondriacal disorder is a persistent preoccupation with the possibility of having one or more serious and progressive physical disorders. Patients manifest persistent somatic complaints or a persistent preoccupation with their physical appearance. Normal or commonplace sensations and appearances are often interpreted by patients as abnormal and distressing, and attention is usually focused upon only one or two organs or systems of the body. Marked depression and anxiety are often present, and may justify additional diagnoses.

Hypomania

Definition

According to ICD-10, individuals with hypomania show a persistent mild elevation of mood, increased energy and activity, and usually marked feelings of well-being and both physical and mental efficiency. Increased sociability, talkativeness, over-familiarity, increased sexual energy, and a decreased need for sleep are often present but not to the extent that they lead to severe disruption of work or result in social rejection. Irritability, conceit, and boorish behavior may take the place of the more usual euphoric sociability. The disturbances of mood and behavior are not accompanied by hallucinations or delusions.

Hypothermia

Definition

Hypothermia is a medical condition in which the victim's core body temperature has dropped significantly below normal and normal metabolism begins to be impaired. This begins to occur when the core temperature drops below 35°C. If body temperature falls below 32°C, the condition can become critical and eventually fatal, and body temperatures below 27°C are almost uniformly fatal. Symptoms include ataxia, confusion, cold skin, gray complexion, peripheral cyanosis, shivering, tremor, weakness, and rapid breathing and heart rate, which slow and weaken as temperature decreases, leading to death. Treatment for hypothermia involves re-warming and warm intravenous fluids or "lavage" of the abdominal cavity with warmed fluids in a hospital setting.

Hypothesis Testing

Definition

Part of the statistical decision making process which uses sample data to evaluate the truthfulness of a hypothesis tested in a given population. The process is based on sample data with the aim of determining which of the two exclusion hypotheses (Null and Alternative Hypothesis) is probably true. Decision making regarding whether or not the null hypothesis is rejected is based on the group of observations. The process of statistical decision making regarding whether the results of the research depict only a coincidence or a real effect at the given probability level.

ICJ

► International Court of Justice

Identity

Synonyms

Personal identity; Individuality

Definition

Identity denotes distinct personality of an individual which is regarded as a persisting entity. It refers to distinct features in regard to manners, way of life, beliefs, culture, by which person may be identified. Also, it may be used to denote social, ethnic or ► cultural identity of distinct group.

IEC

► Ethics Committee, EC

► Indigenous Health, Asian

IHTA

Definition

The International Health Technology Assessment (IHTA) Database was created as a part of ECRI's (the US Emergency Care Research Institute, a nonprofit health services research agency and a Collaborating Center of the World Health Organization) longstanding collaboration with the US National Library of Medicine. It encompasses both peer-reviewed literature and the "gray" literature of hard-to-find technology assessment documents.

Illness

Definition

Illness is the individual's experience of disease; it varies from culture to culture and from individual to individual. It includes the patient's:

- sensations, feelings, discomforts, defenses, fears, understanding and beliefs about the condition;
- decisions on where to get help and how to follow prescriptions;
- attitude towards diseases and toward the physician;
- perception of the effects that the condition has on private and social life.

Cross-References

► Ailment

Illumination

Synonyms

Lighting; Light

Definition

Illumination refers to either artificial light sources such as lamps or to natural illumination of interiors from daylight. It is a term to express the density of luminous

flux incident on a surface. The symbol of illumination is E, and the equation is $E = dF/dA$, where A is the area of the illuminated surface and F is the luminous flux. It is the degree of visibility of our environment.

Illusion

Definition

A real existing object (e. g., a tree) appears to be an animated object (e. g., an angel).

► Immunization, Passive

Immune Privilege

Definition

The immune cells of every individual organism mature by selection and enrichment of the immuno-competent cells, implying that the cells can recognize own and alien cells. The body's immune system recognizes cells like bacteria or transplants because these express unknown surface markers, the major histocompatibility complexes (MHCs). Since embryonic stem cells are assumed not to present mature MHCs to the immune cells, they may not be recognized. Hence, they are considered to be immune privileged without being rejected under non-immunosuppressed conditions.

Synonyms

Vaccination, active

Definition

Vaccination is a procedure following a fixed pattern, whereby weakened or dead pathogens or parts of the same are introduced into the organism, with the aim of inducing the production of specific antibodies. An antibody memory is created, with the result that, in the case of contact with the same pathogen, an onset of the disease will be prevented by the organism's own defense mechanism.

Basic Characteristics

History

For thousands of years, it has been known that infectious diseases cause protection against a similar infection in later life. Immunization results in reliable protection against various diseases, mostly produced by viruses or bacteria. Since ancient times, epidemics have repeatedly caused fear and alarm, with countless people falling victim, even in Europe in the 18th century. This is the origin of the aphorism, "No one is safe from love or the pox". In the case of smallpox, in China, India and Turkey prior to the discovery of the first vaccine, variolation was commonly practiced, whereby pus from persons suffering from mild pox was transferred to healthy subjects. At the beginning of the 18th century, this technique came to England and in the following years reached continental Europe. The English physician, Edward Jenner discovered that patients who

had been infected with harmless cow pox remained almost immune to small pox. In 1796, Jenner developed a ► vaccine from the contents of a pustule taken from a milkmaid who had been infected by cow pox, which he then injected into an 8-year-old boy. The child remained healthy despite a later small pox infection. Jenner's discovery led to the beginning of the era of vaccination. The term "vaccination" stems from the Latin word vacca, meaning cow. This newly developed method replaced the unreliable and dangerous variolation and quickly became widespread. Although the foundation for vaccination had already been dated to the beginning of the 18th century, it was not until much later that the underlying reasons – such as the immune reaction that is decisive for the success of the vaccine – were understood. Even today, development in this field of research is not yet finished. For many infectious diseases there is, as yet, no vaccine, pathogens alter themselves, new pathogens are discovered or known pathogens suddenly become relevant for mankind. In the case of existing vaccines, incomplete spread of immunization prevents optimal protection from infections and their consequences. In industrialized countries, despite the availability of vaccines, the best possible disease prevention is hindered by so-called vaccination fatigue. One should also mention the increasing frequency of long-haul journeys undertaken by the inhabitants of the industrialized nations, often combined with a certain recklessness concerning the risk of infectious diseases.

Active Immunization

One must distinguish between active and passive immunization. Simultaneous vaccination refers to both active and passive immunization occurring at the same time. Passive vaccination will be explained in detail in a separate section. Active immunity comes about when the organism itself confronts the pathogen and builds up antibodies. When a patient recovers from an infectious disease, he achieves natural immunity or insensitivity. Artificial immunity is produced through active vaccination, whereby weakened or dead pathogens or parts of the same are introduced into the organism. In both cases, the patient produces antibodies, which are quickly able to activate defense mechanisms through an "antibody memory" if the person comes into contact again with the same pathogen. In this way, either a new infection does not occur, or the infection at least shows a mild course.

General Vaccination Programs

Even babies in the womb can come in contact with pathogens. As long as the infection is not a new one, the unborn child is generally protected by the mother's antibodies (immunglobulin IgG), which can pass through the placenta. After birth, the protective effect of the mother's antibodies, the so-called nest protection, decreases. The infant is exposed to potentially dangerous pathogens, in the face of which its immune system, being not yet fully developed, is easily overstrained. This is one of the reasons why, in earlier times worldwide and even today in the developing countries, infant mortality rates are highest in the first year of life. In order to protect infants from possibly life-threatening diseases, a specified vaccination program is put into action from three months of age. Various vaccines are combined together. The administration of these combined vaccines (► combination vaccination) reduces the effort involved and achieves protection against several infectious diseases simultaneously. Repeated vaccinations are necessary to achieve sufficient immunity. This is known as ► basic immunization. The organism's "immune memory" of several pathogens lessens over time. For this reason, booster vaccinations are needed, usually at intervals of 10 years, in order to ensure lasting protection. An overview of recommended vaccinations for infants, children and adolescents in Europe, according to recommendations of the WHO, is shown in Table 1 (http://www.who.int/immunization_monitoring/en/globalsummary/scheduleselect.cfm). It covers vaccinations for protection against bacille Calmette-Guérin (► Bacille Calmette-Guérin (BCG) vaccination) (see also ► tuberculosis and other mycobacterioses), diphtheria (► diphtheria vaccination), pertussis (► pertussis vaccination), tetanus (► tetanus vaccination), *Haemophilus influenzae* (► *Haemophilus influenza* ► B (Hib) vaccination), poliomyelitis (► polio vaccination), hepatitis B (► hepatitis B vaccination), measles (► measles vaccination), mumps (► mumps vaccination), rubella (► rubella vaccination), varicella (► varicella vaccination), meningococca type C (► menigococcal vaccination), and pneumococca (► pneumococcal vaccination). In other countries, additional vaccinations may be generally recom-

mended. In this regard, one may refer to the vaccination program of the American CDC (Center of Disease Control), http://www.cdc.gov/nip/recs/child-schedule.htm.

Indication Vaccinations

Apart from vaccinations generally recommended, other vaccines may be administered as indication vaccinations. This category consists of vaccinations against pathogens that are only found in certain countries or regions, or vaccinations that are relevant only for certain subgroups of the population who are at particular risk. An increased risk may be the result of age, existing diseases, or profession. Indication vaccinations include vaccinations against hepatitis A (► hepatitis A vaccination), yellow fever (► yellow fever vaccination), cholera (► cholera vaccination), enteric fever (typhoid) (► typhoid vaccination), rabies (► rabies vaccination), influenza (► influenza vaccination) or TBE (tick-borne encephalitis) (► tick-borne encephalitis (TBE) vaccination).

The Role of Vaccinations in the Society

Vaccinations aim to minimize or eradicate the appearance of certain infectious diseases. Morbidity, the rate of complication or hospitalization, mortality and risk of infection for high-risk patients should thus be reduced. This carries a substantial significance for the economy of a country. In order to be successful, vaccination cover must be at least 85%. The less complex a vaccination program is, the more chance it has of reaching a wide range of the public. The importance of vaccination as a preventive measure must be repeatedly impressed upon the population. Education and continuous checking of the rate of vaccination are indispensable. The fact that some diseases have become more

rare thanks to vaccination does not make these diseases less dangerous when they do occur.

Development of New Vaccines

When new vaccines are introduced, they must be appraised for their usefulness. For example, in the case of enteritis through rotaviruses, the greatest burden of disease and mortality certainly occurs in the Third World. However, even in the industrialized countries, large costs are incurred for families and for society, both from hospitalization and from the treatment of outpatients. Whether a vaccine that is desperately needed in the developing world is actually produced and made available in sufficient quantity depends on whether the manufacturer of this vaccine can also find a market for it in the industrialized countries. ► Rotavirus vaccination has meanwhile been accepted to be a worthy completion of the vaccination calendar in babies.

Complications, Contraindications and Anomalies of Vaccination

Although modern vaccines are safe and effective, reactions of differing severity can occur at the time when a vaccine is administered. It is not always easy to establish whether this connection in time is coincidental or causal. The probability of a causal connection is sufficient for the legal recognition of injury as a result of vaccination. While localized reactions, fever and exanthema occur relatively frequently but are not long-lasting, serious complications are seldom found among healthy subjects. The situation is different in the presence of immune deficiency. Patients with immune deficiency cannot react adequately to protective vaccinations, particularly where living vaccines are involved, but may instead be endangered by them. For certain patients with immune deficiency, vaccination with living vaccines is therefore contraindicated. The administration of living vaccines during pregnancy is also to be avoided. When giving a vaccination, one should also take into consideration the possibility of allergy to the constituent elements. On the other hand, special efforts should be made to vaccinate people with chronic heart, lung, renal and metabolic diseases, because these patients are at greater risk for infectious diseases. The widest possible vaccination cover is desirable for residents of community institutions as well as for the staff who work there. In conclusion, one might say that vaccination is an important area of preventive medicine and is of particular value in pediatrics. Through this procedure, some infectious diseases that would otherwise be serious are no longer a threat. However, the success of vaccination is still dependent upon its implementation, its acceptance by the population and on a sufficiently high vaccination rate. For many diseases no vaccine has yet been found, with the result that development in this field is not yet concluded. Moreover, the appearance of new infectious diseases creates further challenges for modern medicine.

Synonyms

Vaccination, passive; Inoculation, passive; Application of immune globulins; Immune prophylaxis

Definition

Passive immunization is a process by which ► antibodies are introduced into an organism. These antibodies, which are directed against a particular germ, provide an immediate protection and prevent any disease which may be caused by that particular pathogen.

Basic Characteristics

History

The first steps in passive immunization were taken in the late 19th century. The German physician and scientist Emil von Behring and the Japanese physician and bacteriologist Shibasaburo Kitasato worked together in Berlin, focusing their research on tetanus and diphtheria (http://nobelprize.org/nobel_prizes/medicine/articles/behring/index.html). In their immunological experiments they introduced blood from infected animals into healthy animals. Animals vaccinated by this technique proved to be immune against the given germ or its toxin. From this observation the scientists concluded that the antitoxins, which were transmitted by the vaccination, neutralized the bacterial toxins. Based on this discovery, they developed the first passive vaccine against diphtheria. During the 20th century medical research developed further vaccines. Both human and animal antibodies were used in their production. Recently, some monoclonal antibodies have been produced utilizing genetic technology, freeing the process of the need to rely on infected donors.

Characteristics of Passive Immunization

The essential characteristic of passive immunization is the transmission of antibodies. Due to these antibodies, the germ is combated immediately or its toxin is neutralized. The immune system of the vaccinated person is not stimulated, and thus no specific mechanisms of defence (building of antibodies) are initiated. For this reason, an immune (or antibody) memory is not built up. At a later date, the organism can neither "remember" the infection nor the passive vaccination. The antibodies vanish within 3–4 weeks; their protective effects weaken and slowly disappear. Because of the missing immune memory for the organism a new contact with the same germ is equivalent to a primary infection.

Use of Passive Immunization

The earliest passive immunization takes place in the womb during pregnancy, with maternal antibodies of the IgG type being transmitted to the unborn child. Thus the baby achieves an intrauterine protection against several infections the mother's immune system has already coped with and produced antibodies against. After birth the protection by maternal antibodies – the so-called ► nest protection – continues for a couple of months, supporting the still immature immune system of the baby. Later in life passive immunization may become necessary whenever an individual, who has come into contact with particular germs, does not have enough time to produce antibodies. This procedure is called ► post exposition prophylaxis. Most common examples are the passive immunizations against tetanus (► tetanus-vaccination, passive),

rabies (► rabies-vaccination, passive), rubella (German measles) (► rubella-vaccination, passive), varicella (► varicella immunization, passive) and hepatitis B (► hepatitis B-vaccination, passive). Furthermore, immune globulins can be administerd to prevent infectious diseases, like diphtheria, measles, mumps, hepatitis A, botulism and cytomegaly. A pre-exposition prophylaxis can be implemented to achieve protection against TBE (tick-borne encephalitis) (► TBE (tick--borne encephalitis)-vaccination, passive).

A person suffering from an immune deficiency or an immune defect will be unable to produce antibodies against particular pathogens. In this case, the administration of antibodies might be the only possible way to prevent serious infection. Moreover, several severe diseases (like cancer or chronic disease) or pregnancy can be an indication for the administration of passive immunization when there has been contact with particular pathogens.

Advantages and Disadvantages of Passive Immunization

As mentioned before, the greatest advantage of passive immunization is the immediately achieved protection. This might be the only possible way of protecting certain groups of people from life-threatening diseases. In most cases, passive vaccines are tolerated well. The disadvantages of passive immunization are the time-limited effect, the missing induction of an antibody-memory and the relatively high costs. And it cannot be ignored that most immune sera are still made of material extracted from human and animal donors; thus, there is always the risk of provoking an allergic reaction, and – despite all precautionary measures – there is always the risk of transmitting germs. In this connection, the possiblity of transmitting hepatitis B and HIV has to be mentioned. Recently, monoclonal antibodies have been produced by genetic technology, doing away with any need for donors; when using these products there is no risk of transmission of diseases or causing allergic reactions, moreover, by being independent of animal and human donors, a better availability of immune globulins can be achieved.

Impact Evaluation

Definition

Impact evaluation refers to the immediate effect of a program or process and the term outcome refers to the distant or ultimate effect or following definition: impact refers to the extent to which the program has changed the behavior of the participants. An impact evaluation will often certainly seek “changes in the desired direction.” Impact evaluation measures the short term effects of the health promotion program and is concerned with whether the objectives were achieved. It measures any changes in behavior, environment, health knowledge, social lifestyle or risk factors that were identified in the objectives.

Impairment and Disability

GERNOT LENZ
Forschungsverbund Public Health Sachsen-Sachsen Anhalt e. V., Medizinische Fakultät, Technische Universität, Dresden, Germany
gernot.lenz@gmx.de

Synonyms

Activity limitations; Participation restrictions; Handicap

Definition

According to the International Classification of Functioning, Disability, and Health developed by the World Health Organization (WHO), disability is defined as "the outcome or result of a complex relationship between an individual's health condition and ► personal factors, and of the external factors that represent the circumstances in which the individual lives". Impairments are defined as "problems in ► body function or ► body structure such as significant deviation or loss". Disability serves as an umbrella term for impairments, activity limitations, and participation restrictions.

Basic Characteristics

Background

There are over half a billion people in the world who suffer some form of physical, mental, or intellectual disability, with one third of those people being children. Chronic conditions constitute the most common causes of disability; examples include cardiovascular and chronic respiratory diseases, cancer, and diabetes; injuries, like those due to road traffic crashes, falls and landmines; mental illness; malnutrition; and HIV/AIDS and other infectious diseases. The main drivers for the growth of the disabled population are factors like population growth, aging, and medical advances that preserve and prolong life. As a consequence, there is a significant and increasing demand for health and rehabilitation services and, furthermore, environmental and attitudinal changes are necessary. Poverty is one key reason behind many disabilities and disability itself increases poverty even further. About 80% of people with disabilities live in low-income countries and the lives of many of those people are characterized by poverty, isolation, and despair. In most cases, people living in poverty only have limited access to basic health services like rehabilitation and education. The majority of developmental initiatives ignore the needs of people with disabilities. There are, for example, around 70 million people worldwide with hearing impairment and it is projected that in the developing world alone there will be approximately 190 million people with disability related to communication within 25 years time. This will result in considerable service implications.

Medical Model of Disability

Based on the medical model of disability, illness or disability is the result of a physical condition and intrinsic to the individual (it is part of that individual's own body). It may reduce the individual's ► quality of life, and causes clear disadvantages to the individual. As a consequence, curing or managing illness or disability revolves around identifying the illness or disability, understanding it, and then learning to control and alter its course. Therefore, a compassionate or just society invests resources in health care and related services. This should enforce the medical curing of disabilities, expand functionality, and/or improve functioning to allow disabled persons a more "normal" life. The medical profession's responsibility and potential in this area is central.

The medical model of disability is often cited by disability rights groups when evaluating the costs and benefits of various interventions, be they medical, surgical, social, or occupational. Often, a medical model of disability is used to justify large investment in these procedures, technologies, and research, when adaptation of the disabled person's environment might ultimately be cheaper and more attainable. Some disability rights groups see the medical model of disability as a civil rights issue, and criticize charitable or medical initiatives that use it in their portrayal of disabled people, because it promotes a negative, disempowered image of people with disabilities, rather than identifying disability as a political, social, and environmental problem.

Social Model of Disability

The social model of disability proposes that barriers, prejudice, and exclusion by society (purposely or inad-

vertently) are the ultimate factors in defining who is disabled and who is not in a particular society. It recognizes that while some people have physical, intellectual, or psychological differences from a statistical norm, which may sometimes be due to impairments, these do not have to lead to disability unless society fails to accommodate and include them in the way it would those who are "normal". The phrase "differently abled" is sometimes used to convey an aspect of the social model of disability, although the model is not generally taken as denying that some attributes (or loss of) can be seen (when unaided) as impairments.

The approach behind the model can be traced to the 1960s. In 1976, the UK organization Union of the Physically Impaired Against Segregation (UPIAS) claimed that disability was: "the disadvantage or restriction of activity caused by a contemporary social organization which takes little or no account of people who have physical impairments and thus excludes them from participation in the mainstream of social activities". In 1983, the disabled academic Mike Oliver coined the phrase "social model of disability" in reference to these ideological developments. He focused on the idea of an individual model (of which the medical was a part) versus a social model, derived from the distinction originally made between impairment and disability by the UPIAS. The "social model" was extended and developed by academics and activists in the UK, US, and other countries, and extended to include all disabled people, including those seen as having mental impairments or disabilities.

Criticism of the social model has come from the disabled community for not taking into account the physical body in its analysis of disabling factors. It has been described as too unbending in its concentration on structural societal factors and criticized for neglecting the cultural and experiential aspects of disability. Much of the criticism can at first be seen as well-founded, on the grounds that both individual and social factors influence everyday life for a person with an impairment. Still, the social model perspective, with its separation of impairment and disability, has undoubtedly yielded many political benefits and given a theoretical starting point for research, activism, and discussion. The influence of the social model has still been limited and hindered by its stand-alone stance in relation to the fields of medicine, rehabilitation, and technology.

The Integrated Model and ICF

The integrated model of disability attempts to bring together the medical and social perspectives. It enables people with disabilities to have a number of different roles including citizen and patient, among many others. One of the operationalizations is the WHO's International Classification of Functioning, Disability, and Health (ICF). The ICF is the most well known existing framework used for analyzing the functioning of people with disabilities. The ICF has broadened the focus from its predecessor, ICIDH-1 (International Classification of Impairment, Disability, and Handicap). ICIDH-1 presented a primarily medical and individual model for explaining disability, whereas ICF includes environmental factors along with activities and participation. The introduction of environmental and social response variables is a big step forward since ICF will be used by many health professionals and policy makers. The hope is that functionality will not be assessed on its own, but be qualified in relation to all other dimensions. However, there are issues with combining the two paradigms, as ICF will remain an instrument for measuring and classifying individuals predominantly on the level of impairment. Consequently, this makes the use of ICF as an integrative model complicated both from an individual and social model perspective. It can still be concluded that one aim of the ICF is to provide a tool for international comparability of health information and in this respect it may be successful.

Conclusion

Disability is both a complex and topical issue, and health professionals all over the world face patients with a wide range of disabilities seeking personalized advice and help. Besides medical model approaches, social model perspectives are also needed in rehabilitating science and engineering as they are fundamental for the control and self-determination of people with disabilities. The strict dichotomy between the medical and the social models should be replaced by an integrative model; ICF seems to be a step towards the right direction but still needs to be further refined. The social model perspective should be included without compromising its political benefits. This could be achieved by directing its focus towards the space between the individual and his/her surroundings and towards the func-

tional need and wishes rather than the mere functioning of the individual.

INAHTA

Definition

INAHTA – The International Network of Agencies for Health Technology Assessment – has the mission of providing a forum for the identification and pursuit of interests common to HTA agencies. INAHTA was established in 1993 and has now grown to 45 member agencies from 23 countries. The Network stretches from North and Latin America to Europe, Australia, and New Zealand.

Inborn

► Native

Incidence

Definition

Incidence is a word used in ► epidemiology. It refers to the number of people newly affected by a certain condition in a specific period of time. It can be given as a number (e. g. in these past six months there have been 24 new cases of lung cancer) or as a ratio, having as denominator the total number of people who can possibly be affected by the mentioned condition (e. g. the incidence of lung cancer for these past six months has been 3/100,000).

Cross-References

► Disease Frequency

Incidence Rate

Definition

The incidence of disease is defined as the number of new cases of disease occurring in a population during a defined time interval. The number is useful as a measure of the risk of disease.
The incidence rate is defined as the incidence divided by the sum of the different times each individual was at risk of the disease.
► Disease Frequency, Measures

Incidence Rate in Occupational Medicine

Synonyms

Disease frequency measure

Definition

The incidence rate is the number of new cases of injury disease during the calendar year divided by the number of ► workers in the examined group during the year, multiplied by 100,000. The incidence rate is an important source of information on risk of injury in an examined group; it is also a useful tool for follow up of implemented preventive measures.

$$I = \frac{NC}{W} \times 100.000$$

I = Incidence rate
NC = Number of new cases of injury during the calendar year
W = Number of workers in the examined group during the year

Synonyms

Indigenous people; Indigenous Africans; Pigmy people (Central and Western Africa); Maasai (Eastern Africa, Kenya, Tanzania); Nuba (Eastern Africa, Sudan); Ogiek (Eastern Africa, Kenya); Berbers (Northern Africa, Tunisia, Algeria, Libya, Morroco); Tuareg (Northern Africa, Sahara); Bushmen; San (Southern Africa, Kalahari Desert, Namibia, Botswana); Baka (Western Africa, Cameroon, Congo, Gabon, Central African Republic); Duala people (Western Africa, Cameroon); Ogoni people (Western Africa, Nigeria); Tubu (Western Africa, Southern Sahel)

Definition

There is no single and accepted definition of indigenous peoples. The two distinguishing features characterizing indigenous peoples are the ancient relationship with a defined territory and ethnic distinctiveness.
Indigenous peoples of Africa are comprised of several different groups.

Health

Indigenous populations differ in levels, patterns, and trends of health.

The San

The San are the most impoverished, disempowered, and stigmatized ethnic group in Southern Africa. They are the indigenous people of the southern African region and have inhabited the land for around 27 000 years. It is estimated that there are between 85 000 and 90 000 San spread across six countries with a population growth rate of around 2%. Small populations live in Angola (1200), South Africa (4350), Zambia (300) and Zimbabwe (2500); with the vast majority in Botswana (47 000) and Namibia (32 000).
The health status of the San across Southern Africa is closely linked to their poverty.

Alcohol and Domestic Violence

Alcohol consumption is very high in San settlements. This is due to loss of land, resources, and community relationships. Traditional gender equality is lost and women are disempowered which leads to domestic violence. This problem is a consequence of poverty, the loss of land and livelihoods after resettlement without a viable alternative.

HIV/AIDS

HIV/► AIDS is a major cause of death in Namibia and Botswana. In Namibia, national adult prevalence rose from 4.2% in 1992 to 23.3% in 2002. It accounts for over 25% of deaths in health facilities.

Botswana had the worlds' highest mortality rate (28 per 1000 population) and lowest life expectancy at birth of 35 years, with very high adult HIV/AIDS prevalence of 37.3% (2004). Although formally disaggregated data are not available, in 2002 the rate for the San in Ganzi was lower at 21.4% than the national average of 35.4%, indicating that the remoteness of the San, particularly in the Central Reserve, might have protected them from the high rates recorded elsewhere.

It is estimated that the situation in the resettlement camps is far worse.

In Namibia, accurate data for the San population are not available. In more isolated parts, especially in the north, the prevalence is lower. In the settlements it tends to be much higher.

The Pygmies

The Pygmies are the indigenous hunter-gatherers of the central African forests. They are comprised of at least 15 distinct ethnolinguistic groups including the Gyéli, Kola, Baka, Aka, Bongo, Efe, Mbuti, western Twa, and eastern Twa living in ten central African countries: Angola, Cameroon, Equatorial Guinea, Central African Republic, Gabon, Republic of the Congo (Congo), Democratic Republic of the Congo, Uganda, Rwanda, and Burundi. Their estimated total number is from 300 000 to 500 000 people.

Mortality

Mortality and fertility rates are high in Pygmy communities. Low fertility of Efe women in the Democratic Republic of the Congo is associated with high rates of inter marriage with Bantu and the prevalence of venereal diseases. In Aka communities in the Central African Republic, infectious and parasitic diseases are the main causes of death at all ages, particularly for men and boys.

Infant mortality rates in forest-dwelling Aka in the Central African Republic during the 1980s, and former forest-dwelling Twa in Uganda at the turn of this century, are reported as 20–22% and 20–21%, respectively. These rates are more than twice the national infant mortality rates (9.8% and 9.7%, respectively) cited by the World Bank in 2000; and in the Ugandan study are 1.5–4 times higher than nearby non-Twa communities. For children younger than 5 years, mortality rates of 27% reported in forest dwelling Mbendjele in northern Congo in the mid-1990s were 1.5 times higher than neighboring Bantu. In the study of Ugandan Twa, mortality rates for children younger than 5 years (40%) were 1.8–2.4 times higher than in non-Twa villages.

Loss of a forest-based life can be associated with increased mortality. The crucial importance of land for survival is indicated by a reported drop in mortality in children younger than 5 years from 59% to 18% when Twa families in Uganda were given land. Major causes of childhood death include malaria and measles. In the Central African Republic, a measles ► epidemic in the late 1970s resulted in 12% of all Aka deaths in the communities studied, regarded as a very high percentage considering the short duration of the epidemic. In Congo, mortality from measles was five times higher in Mbendjele children than neighboring Bantu communities.

Morbidity

Compared with neighboring Bantu communities, studies of forest-based Mbendjele, Aka, and Baka communities have documented lower prevalence of malaria, rheumatism, respiratory infections, ► scabies, ► goitre, syphilis, ► hepatitis C (three to seven times lower than Bantu communities), high blood pressure, and dental caries. However, ► leprosy, ► conjunctivitis, periodontal disease, tooth loss, and splenomegaly are more prevalent than in Bantu communities. High ► intestinal parasite loads are reported from Mbuti in the Democratic Republic of the Congo and Baka in Cameroon. In forest-dwelling Mbendjele in Congo and semi-sedenterized Kola in Cameroon, intestinal parasite rates were lower than or similar to neighboring farming groups, but predominantly village-based Aka in Central African Republic had higher prevalence of helminth and protozoan parasites than did Bantu coworkers.

► Yaws, a painful skin infection that can progress to destruction of soft tissue, cartilage, and bone, is more prevalent in forest-dwelling Pygmy communities than in neighboring groups. In Cameroon, Central African Republic, and the Democratic Republic of the Congo between the 1970s and 1990s, 3–50% of Gyéli, Baka, Aka, Mbendjele, and Mbuti surveyed had clinical symptoms of yaws. Serological examinations showed 20–90% of the population, most of them children, had latent infections. Prevalence was lower in communi-

ties receiving good medical care and information about hygiene.

In Cameroon and Central African Republic during the 1990s, Gyéli, Baka, and Aka were more often seropositive for filoviruses causing hemorrhagic fevers, including Ebola, than were neighboring subsistence farmers. Kola communities in northeast Gabon were badly affected in Ebola outbreaks. However, in the area of an outbreak of Marburg hemorrhagic fever in the Democratic Republic of the Congo, Mbuti surveyed in 2002 were seronegative for Marburg virus despite substantially higher exposure to wild animals, especially bats – one of the presumed reservoirs of filoviruses – than the local population. The risks to Pygmy communities of filovirus infection via their hunting activities are not well understood. Where forest dietary resources are depleted by destructive logging or commercial poaching and Pygmy people do not have lands on which to grow alternative foods, nutritional status decreases. Children and pregnant women are especially vulnerable, the problem being exacerbated by the breakdown of traditional foodsharing systems. Loss of forests also deprives Pygmy communities of their renowned traditional herbal pharmacopeia, which contains compounds active against diseases including helminthiasis, guinea worm, jaundice, malaria, diarrhea, toothache, and cough. As Pygmy communities spend more time outside the forest in fixed settlements, malaria increases and parasites accumulate because of increased population density and poor sanitation. Heavy infestations of ► chiggers (burrowing fleas) cause crippling infections. Traditional cultural mechanisms for dealing with tension and discord (such as nocturnal singing ceremonies to restore harmony between the group members and the forest) are eroded; alcohol abuse and domestic violence against women increase. Twa communities no longer living in the forest report malaria, intestinal worms, diarrhea, and respiratory illnesses as their most serious health problems, a morbidity profile similar to that of their non-Pygmy neighbors. In Rwanda and Burundi, 43% and 53% of Twa households were reported to be landless in 2003 and 2001, respectively – 3.5 times more than the respective national populations. The situation of the Ugandan Twa is similar. Without land, Twa are unable to meet family food needs, contributing to the increased childhood mortality. Severely disadvantaged living conditions increase the risk of illness: prevalence of inadequate housing, poor sanitation, and lack of safe drinking water were, respectively, six times, seven times, and two times higher in Rwandan Twa households than the national population in 2003.

HIV-1

Studies in the 1980s and 1990s in Cameroon and the Republic of the Congo showed a generally lower baseline prevalence of HIV-1 in Baka and Aka people (range 0–1.6%) than in neighboring populations (range 0–5.4%). The lower prevalence of HIV (and hepatitis C) infection in Pygmy communities could be because intermarriage with Bantu people is infrequent and monogamy is more common than among Bantus. Where intermarriage occurs it is almost always Pygmy women marrying out of their communities, their lower bride price and perceived higher fertility making them a more attractive prospect for Bantu men. Nevertheless, HIV prevalence is increasing in Pygmy populations, probably through increased contact with Bantus. Between 1993 and 2003, HIV infection reportedly increased from 0.7% to 4% in Baka Pygmies in the Yokadouma region of eastern Cameroon. The spread of sexually transmitted diseases increases with the influx of transient labor employed on logging camps, road building, and infrastructure projects. Pygmy women are at particular risk of HIV infection through rape, especially in zones of armed conflict, and also because of the belief of other ethnic groups that sexual intercourse with a Pygmy woman protects against backache, AIDS, and other ailments.

Access to Health Care

In much of rural central Africa, primary health services are absent, function only in a rudimentary way, or have been destroyed during conflict. Even where health care facilities exist, many Pygmy people do not use them because they cannot pay for consultations and medicines, do not have the documents and identity cards needed to travel or obtain hospital treatment, or are subjected to humiliating and discriminatory treatment. More than inaccessibility, public health services can fail to reach Pygmy communities because of active ► discrimination. Vaccination campaigns in Congo during 1996 prioritized the Bantu community, and treatments dispensed by health posts reach the Bantu community more than Pygmies. Bantu intermediaries responsible for delivering leprosy medication to

Pygmies can extort payment or labor from them. The high mortality of Pygmy children from measles and the higher prevalence of ► endemic diseases such as yaws and leprosy in Pygmy communities than in Bantu communities indicates their exclusion from government health services. The prejudice against Pygmy people, coupled with their poverty and inadequate government policies, prevents them from gaining basic citizens' rights including access to health care and land, and to education, employment, and justice. In the absence of government policies and programs providing equitable access to health care, Pygmy communities often depend on missionaries, nongovernment organizations, and development agencies.

Some programs have trained Pygmy primary-care workers and established ► dispensaries that are run by the community. With proper planning, ► health campaigns can reach Pygmy communities, despite their mobility and remoteness. In the mid-1990s, a privately organized campaign gave hundreds of Aka people in northern Congo the single shot of penicillin needed to cure yaws. In 2002, UNICEF vaccinated Pygmy children in the Democratic Republic of the Congo, Congo, and Central African Republic against poliomyelitis.

Over the past 5 years, attitudes of health staff in some areas have begun to change, and through the raising of awareness more Pygmy communities now know about the free services provided by the government. In Rwanda, 68% of Twa women have received antenatal vaccinations, and 90% of children younger than 5 years have received one or more of the DTaP (diphtheria, tetanus, and pertussis), polio, tuberculosis, and measles vaccinations. Economic empowerment programs run by nongovernment organizations are enabling Twa to generate incomes and so join local health insurance schemes and improve their living conditions.

Health Issues

Life expectancy at birth is 10 to 20 years less for indigenous people than for the overall population in a country. Infant mortality rates are up to 3 times greater than the national average.

Malnutrition and communicable diseases, such as malaria, cholera and tuberculosis, continue to affect a large proportion of indigenous peoples.

In some instances, higher suicide rates are indicative of the deterioration in conditions that affect mental health. Smoking, alcohol and substance abuse are significant health and social problems.

Cardiovascular diseases, diabetes, cancer, unintentional injuries and domestic violence are significant health problems among indigenous peoples, and many of these illnesses are associated with lifestyle changes resulting from acculturation.

Land displacement and contamination affects the food supply of indigenous people, increasing the likelihood of malnutrition and starvation.

In the past the indigenous peoples were decimated by infectious diseases (measles, typhoid, tuberculosis, influenza, ► smallpox). At present, communicable diseases continue to affect large indigenous populations. However, similar to the non-indigenous populations, health problems are injuries, alcohol and drug misuse, cancer, ischemic heart disease, kidney disease, obesity, suicide, and diabetes. HIV/AIDS ► pandemic is engulfing the non-indigenous majority populations and spreading to the indigenous groups. At present, some estimates put the figure of prevalence in non-indigenous populations at 30% and in non-indigenous at 20%. Bearing in mind the slow and insidious course of HIV/AIDS it is certain that this disease is going to be the major health problem in the indigenous population in the future. Since they have lower exposure to the health care facilities it is possible that they are going to be the last to have comprehensive measures to fight AIDS implemented.

Summary

Precise numbers and health indicators and determinants of health in indigenous communities are lacking.

Indigenous peoples tend to die younger and generally have lower health status than other population groups.

Infectious diseases and so-called life-style, chronic non-communicable diseases show the highest rates among indigenous populations.

Genetic predisposition, cultural and religious beliefs, health knowledge and practices all influence the health status of indigenous populations.

Definition

Indigenous peoples of Asia are different groups inhabiting vast regions of the (sub-) continent of Asia, including related islands, the Indian subcontinent, Central Asian Republics, the Middle East and Arabia.
The majority of the present-day indigenous peoples in the world (more than 150 million) inhabits the Asian continent and constitutes about 70% of the world's indigenous population.

Basic Characteristics

Demography and Contemporary Diversity

The contemporary indigenous population of Asia consists of culturally and linguistically different groups. Asia with its myriad of mainstream and indigenous languages poses a great challenge in the field of communication. Nowadays, many indigenous peoples in Asia speak a European language and have adopted the contemporary lifestyles of the nation states. At the same time there are a large number of Asian indigenous peoples who live in isolation within the nation states and do not have either linguistic or any other communication with the rest of the populations of these states.
Contemporary indigenous peoples in Asia mostly live in their own communities integrated within the present nation-states. Many of them have settled, for economic reasons, in industrial and agriculture centers, away from their native communities, where traditions are not handed down from the elders. Most Asian states deny that there are any indigenous peoples within their territories. Asians and their descendants are still facing deep-seated racism and xenophobia, lack access to economic, social and political opportunities, are deprived of their civil rights and liberties and are victims of violent hate crimes, racial profiling, discriminatory employment and unjust immigration policies and practices.

Contemporary Health Issues

The present situation of indigenous peoples in Asia in relation to health is, in many aspects, similar to problems of indigenous peoples worldwide. Indigenous peoples in Asia die younger and generally have lower health status in comparison with other population groups. Indigenous peoples suffer the worst health of any identifiable group in Asia.

Serious health problems from the past, such as different infectious diseases, still are an important cause of morbidity and mortality among indigenous peoples in Asia. Although the gap in health status between indigenous populations and the general populations has closed dramatically over the past generation, there is a continuing burden of disease with significant ► co-morbidity within the indigenous communities as compared to general population. What is more, the spectrum of disease differs, so skin infections, ear infections, trachoma and rheumatic fever are still predominant health issues in most indigenous communities. Most bear a triple burden of persisting infectious diseases, increasing chronic conditions, and a growing recognition of injuries and violence. Incomplete demographic transitions, HIV and AIDS, massive unplanned urbanization, and a host of social determinants of health compound these problems.

Indigenous communities are at greater risk from communicable diseases due to poor ► sanitation and hygiene practices. What is more, immunization programs are very inadequate or are used improperly in indigenous communities. Some serious health problems are caused by environmental issues such as pesticides, chemical fertilizers, and other kinds of pollution. On the other hand, certain cultural beliefs of indigenous peoples have negative consequences on health. There is an increase in ► sexually transmitted diseases including HIV/AIDS because of ► drug addiction, sexual trafficking and increased migrations, for example in North East India, Thailand and Burma. The World Health Organization data show that more than half of the indigenous children are deficient in calorie intake and ► malnutrition is still predominant, in comparison to overweight and obesity, among indigenous populations. However, pressure from centralized national governments has forced more and more indigenous peoples to adopt a ► sedentary lifestyle and therefore the number of nomadic tribes has decreased.

Health Services

One of the major problems is lack of data on health status, health needs and utilization of health care services as well as a scarcity of comprehensive research on health risks for indigenous peoples. One of the primary characteristics is lack to access to adequate and culturally appropriate health care. Very few indigenous individuals become health professionals. Another prominent feature is discrimination against traditional health practices. There are few existing guidelines that inform about optimal primary health care delivery and those that exist are often not relevant to the indigenous populations. Another common characteristic is that national estimates of health mask large variations within countries. One of the prominent features is weak public sector health care. Striking inequities in the provision of human resources, infrastructure, and effective services abound between regions of countries, socioeconomic classes, and rural and urban areas. There has been little improvement during the last decades, particularly in comparison with the international experience in comparable settings. Further research is essential to guide improvements in health systems and develop new initiatives.

Synonyms

Aboriginal people; Indigenous Australians; Torres Strait Islanders (Australia); Koori (New South Wales and Victoria); Murri (Queensland); Noongar (Southern and Western Australia); Yamatji (Central Western Australia); Wangkai (Western Australian goldfields); Nunga (Southern South Australia); Anangu (Northern South Australia); Yapa (Western Central North Territory); Yolngu (Eastern Arnhemland, NT); Palawah (Tasmania); Maori (New Zealand); Kanaka Maoli (Hawaii)

Definition

Indigenous peoples of Australia and Oceania are represented by large numbers of diverse communities and societies that inhabit the continental landmass of Australia and associated islands (Indigenous Australians, Torres Strait Islanders) as well as most islands of the Pacific Ocean and New Guinea.

The word "aboriginal" has been used in Australia to describe its indigenous peoples since 1789. But, the use of "aboriginal" as a noun has acquired negative, even derogatory connotation among some parts of the community who regard it as offensive. Some also tend to avoid widely accepted term "Australian aborigines" because of its historical association with colonialism. Since 1980s the most commonly used term to denote descendants of the first inhabitants of Australia is "indigenous Australians". Torres Strait Islanders' heritage and cultural history is distinct from mainland indigenous traits, but they are also referred to as indigenous Australians. The indigenous people of New Zealand are called Maori.

Basic Characteristics

Indigenous Australians

Origins There is no clear or accepted relationship between indigenous peoples of Australia with any nation worldwide. Although they migrated to Australia through Southeast Asia, they are not related either to any known Asian population, or to the peoples of Polynesia. On the basis of DNA analysis there is some speculation regarding their racial origins in India. During the course of time, they have been mostly isolated from other human populations, except from peoples of New Guinea due to trade and intermarriage in the years following the arrival of Europeans.

Demography At the time of of first European contact estimates say that between 250 000 and 1 million people lived in Australia. The greatest population density was found in the southern and eastern regions of the Australian continent, areas that are currently most populated. All indigenous Australians were hunter-gatherers and the ones living along the ocean and river coasts were also fishermen. None of the indigenous peoples practiced agriculture. Most indigenous communities were semi-nomadic, moving over a defined territory, following seasonal changes and food sources. They adapted well to great climatic changes that occurred over the years.

Contemporary indigenous Australians are mostly integrated within the modern nation-state of Australia but have kept their identity as indigenous peoples. In 2001, indigenous Australians constituted 2.4% of the total Australian population (492 700 people). Of the total number, 90% described themselves as Aboriginal, 6% as Torres Strait Islanders and 4% as both Aboriginal and Torres Strait Islanders. In comparison with the total Australian population, the indigenous Australian population is young: according to the data of the census on population and housing in 2001, half of the indigenous population was younger than 20.5 years as compared with 36 years for the non-indigenous population. Approximately 30% of the total indigenous Australians live in major Australian cities, but one in four (27%) live in rural and very remote areas constituting 45% of the population in remote regions.

Contemporary Health Issues Historical and political forces have shaped the present health status, health hazards and health care (► health care facility) in indigenous populations in Australia. Indigenous Australians suffer the worst health of any identifiable group in Australia. There has been little improvement during the last decades, particularly in comparison with

the international experience in comparable settings. The gap in health status between indigenous populations has closed dramatically over the past generation so that indigenous health is now comparable with that of the general populations.

The continuing ► burden of disease with significant comorbidity is greater in indigenous communities as compared to general populations. What is more, the spectrum of disease differs, so skin infections, ear infections, trachoma and rheumatic fever are still predominant health issues in most indigenous communities.

Over 60% of excess mortality in the indigenous Australian population is due to circulatory conditions (26%), injury and poisoning (16%), respiratory conditions (15%) and diabetes (8%).

Cardiovascular diseases are the leading cause of illness, hospitalization and death for both sexes in the indigenous population, responsible for 27% of male and 30% of female deaths. Standardized mortality rate ratios are 3.2 (men) and 2.8 (women) times higher in comparison with the total Australian population. Ishemic heart disease and cerebrovascular disease are the main causes. However, death rates due to chronic rheumatic heart disease are over ten times higher in comparison to the general Australian population.

Injury and poisoning are the second most common cause of death for men and third for women (particularly below 34 years of age for both sexes). Transport accidents account for 40% of the deaths in this category. Homicide and suicide are on the third place in this category and suicide mortality rates are 15 to 17 times higher in comparison to the general population.

For indigenous men the next most frequent causes of death are malignant neoplasia (rate ratio 3.0), respiratory disease (3.9) and endocrine, nutritional and metabolic disorders (mainly diabetes, 7.3). For indigenous women, after circulatory system disease, the most frequent causes of death are malignant diseases (1.6), endocrine, nutritional and metabolic disorders (11.7), injuries (2.9) and respiratory system diseases (3.6).

There is a marked rise of diabetes in the indigenous Australian population and decline of the diseases such as syphilis, tuberculosis, leprosy and bronchiectasis.

The estimated gap in ► life expectancy between indigenous and non-indigenous populations is 19–21 years. In 1998–2000, the life expectancy of an indigenous Australian was 21 years less for males and 20 years less for females than that of an average Australian.

In 2001, the age-standardized death rates for indigenous Australians were between two to four times that of no-indigenous Australians. The 2002 data show that age-specific death rate ratios are higher for indigenous Australians across all age groups, but rate ratios are particularly high for young to middle-aged adults. The extent of mortality rate variations between urban, rural and remote regions is uncertain, which indicates a problem with the quality of the data.

According to data on infant mortality rates, there have been improvements over the last 30 years. However, infant mortality rates remain three times higher in comparison with the total Australian population (for example in Western Australia 21.5 per 1000 live births). Indigenous Australian women contribute to 30% of total maternal mortality.

Poverty, unemployment, poor education, cultural disorientation, cultural beliefs, access to health care services are just a few major reasons for the poor health status of the indigenous Australians.

Health Services There is a lack in evidence-based information regarding health status, health needs and primary health care delivery and related problems in indigenous Australian communities. Existing guidelines that inform about optimal primary health care delivery are inflexible and often not relevant to indigenous populations. One of the problems is a continuous turnover of medical staff in the remote areas that are usually inhabited by indigenous people. Therefore, there is a continuous cycle of re-learning of optimal practice and a need to adjust to conditions that are very different from urban areas.

Since the 1970s the Aboriginal Community Controlled Health Services (ACCHS) have been implementing primary health care services in response to the indigenous peoples' perceptions that their health needs were not being met by the mainstream health services. The ACCHS model of participatory holistic primary heath care integrates illness care with disease prevention, intersectoral collaboration and advocacy for social justice. The factors identified as being responsible for poor health status are: discrimination, low income, poor education, substance abuse, remote locations with poor access to health services. For the urbanized indigenous Australians, other factors have been identified: social pressure which prevents access to health services as well as cultural differences resulting in poor com-

Indigenous Health – Australooceaninan, Table 1 Recommendations relating to indigenous primary health care.

Aboriginal and Torres Strait Targets, 1992	Increase to over 80% in 5 years and over 95% in 10 years, the proportion of Aboriginal and Torres Strait Islander communities that have access to community-controlled or community acceptable health service [target 3.17]. Within 5 years disparities in access to appropriate housing between Aboriginal and Torres Strait Islander communities and the wider societies will be reduced by 50%; and by 90% in 10 years [target 26.6].
National Aboriginal Health Strategy, 1989	The Working Party recommends that ... primary level Aboriginal health services presently being delivered by State governments should be transferred to existing or proposed Aboriginal community controlled primary level services.
ILO Convention Concerning in Independent Countries, 1989	Governments shall ensure that adequate health services are made available to the [indigenous and tribal] peoples concerned or shall provide them with resources to allow them to design and deliver such services under their own responsibility and control so that they may enjoy the highest attainable standard of physical and mental health.Health services shall, to the extent possible, be community based. These services shall be planned and administered in cooperation with the peoples concerned and take account of their economic, geographic, social and cultural conditions as well as their traditional preventive care, healing practices and medicines.The health care systems shall give preference to the training and employment of local community health workers and focus on primary health care while maintaining strong links with other levels of health care services. [article 25]

munication between indigenous Australians and health workers. Recommendations relating to indigenous primary health care are shown in Table 1

The Maori

Origins The ancestors of the Maori were Polynesian people originating from south-east Asia. In the Maori language the word *māori* means "normal" or "ordinary". In legends and other oral traditions, the word distinguished ordinary mortal human beings from deities and spirits. Early European visitors to the islands of New Zealand referred to the people they found there variously as "indians", "aborigines", "natives" or "New Zealanders". Māori remained the term used by Māori to describe themselves in a pan-tribal sense.

Demography Approximately half a million people constitute the Maori population in New Zealand that equals 14.7% of the total population. The median age of a Maori in 2001 was 21.9 years as compared to 34.8 years for the total New Zealand population.

Contemporary Health Issues As a population group, Maori have on average the poorest health status of any ethnic group in New Zealand. They inhabit the deprived geographical areas of New Zealand.
Compared to the increasing life expectancy for the non-Maori population since mid-1980s, little improvement has been seen in Maori life expectancy. Overall, Maori life expectancy at birth is more than 8 years less than non-Maori in 2001, for both genders.
The major causes of death are all chronic diseases. Cardiovascular disease, cancer, respiratory disease and injury are the major causes of death for both Maori and non-Maori. Ischemic heart disease is the leading cause of death for both Maori and non-Maori. Lung cancer was the second cause of death for Maori. Diabetes is among the top five causes of death for both genders in the Maori population, and is not so in the non-Maori population, either gender. The prevalence of heart disease among Maori is one a half times that in non-Maori. Total cardiovascular disease mortality is more than two and a half times higher for Maori than for non-Maori. The most common cancers registered for Maori females are breast, lung, colorectal, cervical and uterine, while in Maori males, lung, prostate, colorectal, stomach and liver are the most common.

Health Services There is evidence of disparities in access to health care between Maori and non-Maori people. The Government and the Ministry of Health have made it a key priority to reduce the health inequalities that affect Maori.
The ► maori health strategy (He Korowai Oranga) was launched in 2002 (Minister of Health and Associate Minister of Health 2002). It sets a new direction for Maori health development over 10 years, and provides

guidance at a strategic level on ways to achieve Maori health improvements and eliminate health inequalities. At the heart of He Korowai Oranga is the achievement of whānau ora, or healthy families. This includes public policies that actively:

- promote whānau well being;
- promote high-quality education;
- promote employment opportunities;
- promote suitable housing;
- promote safe working conditions;
- promote improvements in income and wealth; and
- address systemic barriers, including institutional racism.

Maori Health Action Plan (2002–2005) outlines what the health and disability sector will do to implement the strategy (including programs, policies and interventions). An updated Maori Health Action Plan (2006–2011) was released in June 2006. The New Zealand ► health strategy highlights the need for better access to relevant information to improve decision-making at both the health and disability sector level, and at the community level. Reducing inequalities in health is a key goal of the strategy.

The priority areas are:

- building quality data and monitoring Maori health;
- developing whānau ora based models;
- improving Maori participation at all levels of the health and disability sector, particularly workforce development and governance; and
- improving primary health care.

Maori Health Priorities are:

- immunization;
- injury prevention;
- diabetes;
- asthma;
- improving oral health;
- mental health;
- smoking;
- sexual & reproductive health; and
- drug & alcohol abuse.

First nations/people, Aboriginals, Ethnic groups; Occupational and geographical terms such as hunter-gatherers, Nomad, Hill people, etc.

Traditional healers: Medicine people; Bonesetter; Prayer-singers; Herbalists; Diviners;

Spiritual or faith healers; Traditional midwives; Birth attendants

Definition

The World Health Organization (WHO) has adopted a very general definition which describes traditional medicine (TM) as "knowledge based on the theories, beliefs and experiences ► indigenous to different cultures (► indigenous culture), either codified in writing or transmitted orally and used in maintenance of ► health as well as in the prevention, diagnosis, improvement or treatment of physical and mental illness. Traditional medicine includes diverse health practices, approaches, knowledge and beliefs incorporating plants, animals and/or mineral based medicine, spiritual therapies, manual techniques and exercises, applied singularly or in combination". One of the definitions given for 'African Traditional Medicine' by the WHO Centre for Health Development is "the sum total of all knowledge and practices, whether explicable or not, used in diagnosis, prevention and elimination of physical, mental, or societal imbalance, and relying exclusively on practical experience and observation handed down from generation to generation, whether verbally or in writing".

Ethnomedicine is a multidisciplinary approach of societies and cultures integrating psychology, sociology, ethnology and epidemiology for a global understanding of the disease beyond its biological reality.

Basic Characteristics

Acceptability

Traditional health systems take into account physical, mental, spiritual, social and ecological dimensions of well-being in a culturally specific manner. Contrary to western medicine, which studies the human being mechanically, starting from its functions, traditional medicines consider the person in its totality, including the social and ecological dimensions. Belonging to the same community as the patient, traditional healers share their vision, thus inspiring more trust in the curative power of their methods rather than in western medicine. In many instances, indigenous medicine is indissolubly connected to every-day life, through food requirements, as well as through important rituals in the lives of both the individual and communities where health, rather than disease is emphasized.

Availability

The vast majority of the planet's population does not have access to formal ► health care systems and traditional healers are the only source for health care and education. In Sub-Saharan Africa, the ratio of traditional healers to the population is approximately 800 times higher than that of medical doctors (1 : 500 versus 1 : 40 000) (Asian and Pacific Women's Resource and Action Series 1989).

Indigenous ► health care services utilize local resources to provide effective remedies.

Accessibility

Traditional medicine is advantageous because it is cheaper and geographically more accessible. Especially from the point of view of women, traditional medicine is preferred because little or no physical examination is required and the healers are often women. It is also seen as "soft" medicine as compared to modern medicine which is deemed too "strong" for women and children by Asian and Pacific women (Asian and Pacific Women's Resource and Action Series 1989).

Quality

Healers help individuals, families and communities strive for balance, harmony and good health. The training of a healer involves a very long apprenticeship with a respected medicine person and the process is expected to last a lifetime. The hardships supposed to be encountered are usually compensated by the highly respected status healers usually command in the community. Traditional practitioners are at the confluence of a non-religious pursuit of the sacred and a non-medical pursuit of health (http://www.mapn.org/).

History

Indigenous medicine was practiced in every community since the dawn of humankind and fairly advanced knowledge of surgery, obstetrical procedures and medicinal plants is noted. Colonizers introduced not only new diseases, but also a system of treatment not suited to the beliefs and social structure of

► indigenous peoples. Thousands of years of carefully researched and implemented methods were seen as negative in the process of "civilizing".

The process of de-culturalization included policies aimed at making independent and proud people dependent. As a consequence, the health situation of indigenous people lags far behind that of the majority population in industrialized countries such as Australia, Canada, New Zealand, and the U.S.A.

In the past few decades the modern world has considered indigenous medicine as a vision of the past. However, in the context of geographical isolation, poor economical resources and a lack of quality in ► public health care services, a revival of indigenous ► healing methods can be observed.

The approach taken by traditional doctors addressing all aspects of the ailing person (mental, emotional, physical, spiritual as well as communal) has inspired also non-Natives who are looking for a holistic approach to medicine, closer to nature and thus perceived as "softer", without the negative side effects of modern drugs and therapeutic procedures. Therefore, in some countries, indigenous medicine is used as "Complementary and/or Alternative" medicine.

Indigenous Health Care Services

Health disparities are directly and indirectly associated with social, economic, cultural and political inequities, the end result of which is a disproportionate burden of ill health and social suffering upon the ► aboriginal populations.

Friction is evident between 'Western' medicine or biomedicine that look at a "material causation" to understand and treat an illness; and traditional medicine that generally looks towards the "spiritual" origin such as witchcraft and displeasure by ancestors in order to cure an ailment (► disease, ailment) (Jolles and Jolles 2000). Traditional religion is often seen as having negative influence on health care, since the spiritual explanation of events, including diseases may delay the use of modern services.

However, regional and international bodies consider that indigenous peoples have the right to specific measures to improve their access to health services (► indigenous health services) and care. These services should be culturally appropriate and designed by indigenous peoples themselves. Maori healers believe that traditional healing services should be part of the public health system but controlled by themselves.

Recently, discussion about incorporating traditional medicine into national health programs is taking place in many countries. For example, Ugandan authorities are in the process of defining their policy towards traditional healers by creating a legal framework with an aim of establishing a parallel health sector.

Success stories showed that incorporating trained traditional health practitioners in ► primary health care programs are cost effective in providing essential and culturally relevant health services in communities. The key to success seems to be the respectful collaboration between traditional healers and medical doctors.

Obstacles to Integration of Indigenous Medicines in Mainstream Public Health Systems

For Native peoples the connection to their *traditional territories* is very strong and breaking the symbiotic relationship with their lands has a deleterious effect on their health.

Involvement of the community in public health policies does not necessarily include participation of traditional healers.

The *regulation* of traditional systems of medicine and of the products used in these systems is weak in most countries. This leads to misuse of the medicines by unqualified practitioners and loss in the credibility of the system.

Traditional medicine practitioners and manufacturers usually oppose any steps to strengthen regulation by the health authorities due to fears that regulation such as that applied to allopathic medicine is not suitable for traditional medicine and may stifle the ancient methods.

Environmental changes have also affected vital medicinal plants, animals and minerals. The international market for natural products, including those originated from endangered species, is increasing demand; the lure of economic gain, together with lack of information is exacerbating the situation.

Education and *language constraints* also constitute an obstacle to mutual understanding between the two approaches in health care, traditional versus the modern.

Traditional medicinal practices have also unproven, ineffective or even dangerous aspects. Careful, sensitive research is needed to validate many rituals and substances used for health purposes since times immemo-

rial. Also, much patience and tact are expected in order to change such mentalities and practices.
International aid consisting of export of technology and know-how raises concerns about the acceptability and sustainability and at the same time is leading to irreparable loss of traditional knowledge.

Conclusion

Western ► health care systems are confronted with serious difficulties when asked to solve the medical problems of indigenous people because these maintain *particular views* on health, disease and life in general and the national health policies are usually not adapted to the socio-cultural realities of these peoples.
Indigenous health care services are providing essential health care and education to the majority of the Earth's population but are still largely not officially recognized. In order to offer culturally relevant medical services to indigenous people, the infrastructure already in place needs to be strengthened. Traditional medicine systems and providers should be integrated with the overall health care programs in a manner that mutually benefits the entire health care system. However, there are still many obstacles to this integration, stemming mainly from the mutual distrust of practitioners from both paradigms. As has been shown in successful examples of integration, the key is education for reciprocal respect and collaboration.

Synonyms

Aboriginal peoples; Indian; Inuits; Métis (Canada); Native Americans; American Indian; Alaska Native; Eskimo (United States)

Definition

The Indigenous peoples are those peoples who inhabited the lands of Canada and the United States prior to the arrival of European explorers and colonists beginning in the late 15th century. Based on mitochondrial DNA (mtDNA) evidence, it is believed by scientists that these populations originally migrated into North America from Asia; estimates as to when this migration started vary from sometime between 60,000 years ago to as little as 12,000 years ago. Up to 5 distinct mtDNA lineages have been identified so far. The cultural, economic, political and social formations of these peoples at the time of contact were incredibly diverse. All of these cultural groups adapted to specific micro environments, and their social formations ranged from small, semi-nomadic hunting bands to densely populated, farming-based villages. After contact, rapid cultural changes ensued, the product of conflict with settlers, forced acculturation through government policies, inter-marriage, and the influences of an emerging North

American popular culture. In Canada, a unique mixed heritage (primarily Indian and French) group known as the Métis emerged at the end of the 18th century, and remain a distinct people today.

Basic Characteristics

Contemporary Diversity

The contemporary Indigenous population of North American is constituted by hundreds of culturally and linguistically diverse groups, sometimes referred to as bands or First Nations in Canada, and tribes in the United States. In the high arctic, the Inuit (► inuit) (Canada) and Eskimo (United States) populations can be found. Contemporary Indigenous peoples are now mostly integrated within the modern nation-states of Canada and the United States, yet also maintain separate identities as Indigenous peoples. There are some, however, especially in the more remote regions of northern Canada and Alaska, who remain more traditional in culture and language. Some Indigenous peoples are specifically recognized by the federal governments as such, while others are not. Such recognition renders the targeted Indigenous peoples the beneficiaries of federal aid programs, such as health and education.

Today, most Indigenous peoples speak a European language, sometimes in conjunction with their own language, and have adopted North American lifestyles to varying extents. A separate Indigenous identity remains, however.

Demography

There has been considerable debate over the question of population sizes for North American Indigenous people at the time of first contact with Europeans in the late 15th century. Estimates have ranged from one to two million up to 18 million; all such estimates suffer from a basic lack of data, however. What is certain is that the Indigenous population as a whole began to decline after contact, as a result of the spread of virgin soil epidemic diseases, conflict, dislocation, and the destruction of essential resources. The ► population nadir was reached in the early part of the 20th century, by which time some groups had disappeared altogether and others reduced in some cases by as much as 90%. After 1960, the Indigenous population began to increase significantly, although there has been some controversy over the identification of this population, given extensive inter-marriage with non-Indigenous peoples. By 2001, approximately 1.3 million Canadians claimed an Aboriginal ancestry; in the United States, some 2.4 million self-identified as American Indian or Alaska Native. This increase in population is reflected in a population pyramid weighted heavily toward the younger ages; in Canada, for instance, one-third of the Indigenous population is under age 15, compared to only 20% nationally.

There has also been a dramatic shift in residence experienced by the Indigenous population. While in both Canada and the United States tracts of land were set aside for some Indigenous peoples, known as reserves or reservations, beginning in the 3rd quarter of the 20th century a significant trend toward urbanization and off-reserve residence is noticeable. In Canada in 2001, about half of the Indigenous population lived in urban areas; at the same time in the United States, over 50% were living off reservation or in urban areas.

Contemporary Health Issues

The life-span of Indigenous peoples today, while improved, remains five to seven years less for men and women, respectively, than for the national populations. While morbidity and mortality from infectious diseases such as influenza, measles, poliomyelitis and diphtheria declined by the latter part of the 20th century, they were replaced by a variety of new health problems. Newly emerging infectious diseases, such as HIV/AIDS, combined with a resurgence in some areas of tuberculosis, demonstrate that infectious diseases remain a problem. Diseases such as diabetes, certain cancers (kidney, gall bladder, cervix), and cardiovascular diseases have increased in significance as causes of morbidity and mortality. Levels of obesity have also risen. There has also been an increase in injury and death due to alcoholism and substance abuse, accidents, violence, depression and suicide. These latter problems disproportionately impact individuals, especially males, in the 15 to 40 age ranges. Combined, all of these emerging health problems demonstrate the consequences of an historical process of colonization and the continued marginalization and poverty of the Indigenous population. Indigenous North Americans as a whole continue to experience disproportionally higher rates of unemployment, lower educational levels, and poorer hous-

ing and living conditions and community infrastructure, despite important strides made in the last few decades to erase health inequities.

Health Services

The respective federal governments are responsible for the delivery of health services to substantial portions of the Indigenous population. The First Nations and Inuit Health Branch in Canada and the Indian Health Service in the United States provide care to only some of the Indigenous population, however, that is, those officially designated as federal wards. Other Indigenous peoples must seek health services from provincial (Canada), state (United States) or municipal sources. Annual federal expenditures on health services are significant: nearly 700 million dollars in Canada, and over 2 billion dollars in the United States. Despite ever-increasing expenditures, however, consensus is emerging that health disparities will not be erased until broader political, social and economic changes ensue. In both countries, substantial health services are now delivered under local control as part of the broader movement of Indigenous self-determination, considered an important step in this direction.

Traditional Health Care Practices

At the time of first contact, Indigenous peoples had extensive health care systems involving, among other things, the use of plant medicines, basic surgery techniques, and ceremony. Spirituality was an essential component of much traditional health practice. There were a variety of health specialists, from herbalists (► herbalism) to ► bonesetters to ► shamans. Many of these practices eventually were threatened by colonial government policy and action, and much knowledge has since disappeared. However, in recent decades there has been a resurgence in traditional health practices, such as the ► sweat lodge and the use of symbolic healing ceremonies, as part of an Indigenous cultural revitalization. In many areas, these practices are being integrated with western biomedical and psychotherapeutic approaches to provide holistic care.

Synonyms

Native; Aboriginal; Indian; South american health

Definitions

Native South Americans

In the broad sense, they are the current inhabitants of South America who, independently from their degree of miscegenation and acculturation, identify themselves with the cultures and heritage of the original owners of the continent prior to the European invasion. Approximately 90% of them live in Peru, Bolivia, and Ecuador. In a narrower sense, particularly in these three countries, the 'natives' are a subset of the general population who have endured the invasion, mostly by living in remote areas of the Andes or Amazonia.

Indigenous Health

"Health for many Indigenous peoples is not merely absence of ill health, but also a state of spiritual, communal, and ecosystem equilibrium and wellbeing" (quoted in Stephens et al. 2006).

Basic Characteristics

Introduction

To deal with the topic of health among the native peoples of South America is dealing with the health levels of the poorest of the poor in the world. Even though there are no precise statistical data about their current health status, scattered evidence shows very grim figures. This situation of neglect cannot be explained just by the incompetence of the different medical systems of South American countries, but as the result of a historical process that began with the European invasion (Montenegro 2006).

The last continent to be peopled in the world, South America holds the complete cycle of human cultural development. This cycle, which ranges from the Paleolithic to the development of complex cultures, was abruptly interrupted at the end of the 15th century. Ever since, through war, imported diseases, slaving, and exploitation, this continent has witnessed their native inhabitants' near annihilation. Currently, our continent's indigenous peoples – the largest population of native inhabitants in the Americas – struggle to survive the indifference of mainstream culture.

Timeline

From public health's point of view, native life in the prehistoric period can be divided in two periods, Paleolithic and Civilization. The Paleolithic began around 12.000 B.P. with the arrival of the Paleoindians through the Panama strait, carrying along with them the seeds of civilization, as well as some well-humanized germs and parasites (e. g., tuberculosis). Civilization started approximately 5.000 B.P. in the central coast of Peru, with Caral pristine state based on fishing, agriculture, and trade.

1. **Paleolithic:** Physical anthropological studies on remains from different sites in the continent show different elements of the life of the earliest South Americans. First, they had a short lifespan, between 25 and 30 years of age. Second, although there was a high infantile rate of mortality, the scarcity of teeth and bone stress indicators account in general for a good nutritional level. Third, robust muscular insertions attest the tough active life of these ► nomadic hunters and gatherers.

   The settlers of South America brought with them a definite culture linked to a maritime lifestyle which

probably included some basic medical knowledge. The development of complex mummification techniques among the Chinchorro – 8.000 to 4.000 B.P. – cannot be understood as an isolated cultural achievement.

Among adults, most pathological conditions were linked to trauma with or without secondary infection (Verano and Lombardi 1999).

2. **Civilization:** Civilization in this part of the world started in the Central coast of Peru. As agriculture spread, population growth allowed the foundation of the first permanent settlements on especially selected places. This demographic growth determined the appearance of ruling classes, laws, and inequities. Therefore, the human remains from this period show a higher prevalence of chronic stress markers such as Harris lines and enamel hypoplasia, indicating a paradoxical deterioration of nutritional conditions (Cohen and Armelagos 1984).

   Although data are still scarce for this period, and considering the osteological 'blind spot' to detect acute illnesses, it is predictable that this period had an increase of infectious disease transmission among people living in towns and ► hamlets. Indeed, different intestinal parasitoses have been diagnosed both in coprolites and mummies dating from this period (Allison and Gerzsten 1998).

   On the other hand, there is a good record of chronic diseases and conditions, v.g. porotic hyperostosis and cribra orbitalia, representing chronic infantile anemia; clear cases of tuberculosis, syphilis and osteomielitis. Mummy studies have shown that many diseases that affect current populations existed in the past also in high levels (Allison and Gerzsten 1998). Recently, it has been shown that ► Chagas' disease has kept an almost constant high prevalence along millennia (Aufderheide et al. 2004).
3. **The Invasion:** When the Spanish and Portuguese conquistadors arrived in South America, their armies' path had been paved by lethal epidemics – smallpox, ► influenza, ► measles, better described as the 'McNeill effect' which, having arrived through land since Columbus's entrada, decimated the local populations and therefore, reduced the possibilities of resistance to a minimum level. Then, war, slavery, and oppression followed, which maximized the destruction of coastal and plains' populations and nearly did the same with the remnants of the Inca empire. Only very recently has paleopathology started to address this, less romantic, period of South American history (Verano and Lombardi 1999). There is no consensus on the figures, but Allison and Gerzsten have equated this process to a real holocaust (Allison and Gerzsten 1998).
4. **The Present:** The health statistics of South American native peoples, very often not directly recorded, show ► infant mortality, ► maternal mortality, life expectancy, and general morbidity rates worse than the local general statistics, which are themselves among the worst in the world. In addition to the traditional diseases introduced by the invaders, the imposition of western lifestyles and consumerism has created high rates of alcoholism, diabetes, STDs, and even AIDS among native populations. Moreover, the introduction of more modern problems such as drug trafficking, terrorism, and ► environmental poisoning, are damaging and endangering these feeble peoples even more.

   The best way to understand this phenomenon is through considering that there is still an ongoing cold war expressed by the ► disdain and even racism of mainstream South American societies towards the native minorities. This negative attitude permeates health systems which are "culturally inappropriate" (Montenegro 2006).

Conclusion

The poor level of health among indigenous South Americans today still represents the health level of their ancestors in their worst moment of history, the European invasion.

Since, as implied before, there is a fuzzy definition of what native means in this continent, it is important to understand that in a continuum of indigeneity, the more native the population, the more the chances for it to be poor and neglected by the formal health systems.

The historical evidence shows a continuum since the momentous episode of the European invasion until present. In order to face this shameful situation in a sustainable way, the real causes for it should be addressed, that is to end the war between the owners of the land and the heirs of the invaders, mainstream society. Such a process must have a multidisciplinary approach based on the indigenous peoples' initiative (Stephens et al. 2006).

Indigenous People's Health

Jelena Gudelj Rakić
Department of Food and Nutrition, Institute of Public Health of Serbia, Belgrade, Serbia
jelgud@gmail.com, jelgud@eunet.yu

Introduction

Discovery of the new continents half a millennium ago brought new inhabitants with different ways of life, cultures, religions, customs, and beliefs together. As invaders, the newcomers overpowered existing social, cultural, economic, and political structures of the host land. Colonial growth from the 15th century onward produced populations where only a group of people had ancestors who were inhabitants before the land was colonized. They survived in an atmosphere of severe disadvantage in relation to the newcomers. Although many of the countries have since regained their independence, the descendants of the colonizers have become the dominant group over the descendants of the original inhabitants, who became known as indigenous, native, or aboriginal.

Defining Indigenous Peoples

The term indigenous peoples has no universal, standard, or fixed definition. Although there is no single definition of indigenous peoples, an ancient relationship with a defined territory and ethnic distinctiveness are two distinguishing features (Durie 2003).

Usually, groups of people identified as "indigenous" are descended from the original or long-time inhabitants of lands now dominated by others. Nowadays, there are several widely accepted formulations made by internationally recognized organizations like the United Nations (UN), the International Labour Organization, the World Bank, the World Council of Indigenous Peoples, and national governments. According to these definitions, the contemporary working definition of "indigenous peoples" includes the following criteria to distinguish them:

- "Residence within or attachment to geographically distinct traditional habitats, ancestral territories, and natural resources in these habitats and territories;
- Maintenance of cultural and social identities, and social, economic, cultural and political institutions separate from mainstream or dominant societies and cultures;
- Descent from population groups present in a given area, most frequently before modern states or territories were created and current borders identified;
- Self-identification as being part of a distinct indigenous cultural group, and the display of desire to preserve that cultural identity" (WHO 2003).

Recently, in Erica Irene Daes' report of the Working Group on Indigenous Populations, indigenous peoples were defined according to the following:

- "Priority in time
- Voluntary perpetuation of their cultural distinctiveness
- Self-identification as indigenous
- Experience of subjugation, marginalization, dispossession, exclusion, and discrimination by the dominant society" (Havemann 1999).

Indigenous People's Health, Table 1 Characteristics of indigenity

Features	Key element
Primary characteristic:	
An enduring relationship between populations, their territories, and the natural environment	An ecological context for human endeavors
Secondary characteristics (derived from the relationship with the environment):	
The relationship endures over centuries	Time
The relationship is celebrated in custom and group inter-action	Identity
The relationship gives rise to a system of knowledge, distinctive methodologies, and an environmental ethic	Knowledge

Source: Durie M. Indigenous Knowledge within a Global Knowledge System

The term "indigenous" denotes both common characteristics as well as differences between the peoples who are called indigenous, since there is great diversity among indigenous populations worldwide. Other related terms for indigenous peoples include aborigines, native peoples, first peoples, Fourth World, first nations, and autochthonous.

Characteristics of indigenity are shown in Table 1.

Population and Distribution of Indigenous Peoples

Indigenous populations are distributed in regions throughout the globe. They inhabit all climate zones and all continents. Due to inadequacies of available data, it is very difficult to make precise estimates of the total population of indigenous peoples. According to recent sources, there are some 5000 indigenous groups in over 70 countries, with a total population of about 300–350 million, or around 6% of the global population (Howitt 1996). The numbers, conditions, and experiences of indigenous groups vary within a given region. Indigenous population estimates in America are shown in Table 2, represented as a total and as a percent of the total population in selected countries.

Among many indigenous peoples are the Indians of the Americas (for example, the Mayas of Guatemala, Aboriginal peoples of Canada, the Mapuches from Chile and Argentina, and the Tupies from Brazil, Bolivia, Paraguay and Argentina), the Inuit and Innu from circumpolar regions, the Saami from Northern Europe, the Aborigines and Torres Strait Islanders of Australia and Oceania (► indigenous health, australoceanian), the Maori of New Zealand, the Maasai from Kenya and Tanzania, and Pygmy peoples from Central and Western Africa (► indigenous health, africa) (Fig. 1). These and many other indigenous populations have retained their social, cultural, economic, and political characteristics over the centuries, which are clearly distinct from those of others living on the same territory. However, during the course of time, many indigenous groups have undergone drastic changes, and survived with populations ranging from a few dozen to hundreds of thousands or more. Some indigenous populations have disappeared from the world map due to severe illnesses or devastation by settlers, but others have recovered to a certain extent. The indigenous populations worldwide have lived through great climatic changes and adapted successfully to their changing physical environment. Indigenous peoples have also modified their environment, adjusting it to their needs.

Many indigenous populations now have a diverse profile, although the level of integration with other populations varies greatly. Some indigenous communities no longer inhabit their primary lands due to voluntary or forced migration, relocation, or because of suppression by other ethnic or cultural groups. Some indigenous communities remain settled in a certain location, while others have a nomadic lifestyle. The interaction between indigenous and non-indigenous societies throughout history has been very complex, ranging from disputes, conflicts, and armed resistance, to some degree of mutual benefit and cultural transfer. All of these interactions have contributed to a change in the characteristics of indigenous peoples as we see them today. Characteristics that are common for many indigenous groups include predominantly non-urbanized societies whose members rely on agriculture, hunting, and gathering for survival (Fig. 2).

Indigenous People's Health, Table 2 Indigenous population estimates in America in total and as a percent of the total population in selected countries

%	Total indigenous population	
	< 100.000	> 500.000
> 40	–	Peru Guatemala Bolivia Ecuador
5–40	Guyana Belize Surinam	Mexico Chile Honduras
< 5	Costa Rica Guyana Jamaica Dominica	Canada Colombia United States of America

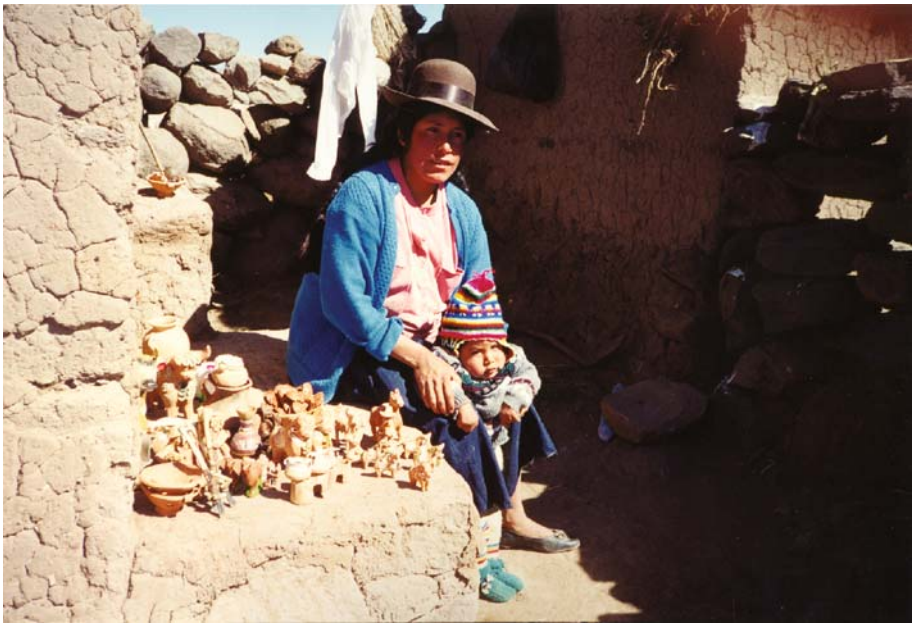
Historical Perspective of Indigenous Cultures

Throughout the course of human history, migrations of different nations have contributed to changes of the



Indigenous People's Health, Figure 1 Aymara woman with child, farm in southern Peru

Indigenous People's Health, Figure 2 Aymara woman in front of house, farm in southern Peru

world map in respect to cultural, socio-economic, and political features of the peoples inhabiting certain territories, as well as regarding religion and health.

Since the European conquest of the new continents from the 15th century onwards, indigenous inhabitants of North and South America (► indigenous health, south america), Australia (► indigenous health, australoceanian), New Zealand, and ► africa (► indigenous health, africa), have been deprived not only of land rights and access to life-sustaining resources, but they have also suffered cultural, social, economic, and political discrimination, which exists in some form even today. Armed resistance, diplomacy, and law have been tools in the quest for survival. Indigenous peoples are marginalized in contemporary societies, which are pushed by internationally recognized bodies like the UN and World Health Organization (WHO) to make necessary changes and provide equity for all, regardless of race, ethnicity, religion, or socio-cultural or political background.

Rights of Indigenous Peoples

During the course of history, whenever dominant neighboring states expanded their territories or far-away conquistadors acquired new lands by force, existence but also freedom, language, culture, tradition, and the social, economic, and political structure of indigenous communities was jeopardized. The ways in which indigenous peoples struggle for their rights are different today than they were in the past, as are issues regarding the rights of indigenous peoples. Although some groups have been successful in regaining the majority of their rights, others still live in the shadow of dominant settlers. That is why indigenous peoples in most parts of the world still seek recognition of their identities.

Indigenous peoples worldwide are concerned about many issues relating to their rights. Despite cultural and ethnic diversity, there are similarities between the problems and interests of the various indigenous peoples. The UN recognized and adopted the concept of human rights in the Universal Declaration of Human Rights, 1948. This declaration is comprised of basic principles of the rights of human beings to life, liberty, security, non-discrimination, equal protection under the law, marriage and family, religion, free expression, work, education, and political and cultural life (Harrison 2001).

In this declaration, the rights of indigenous peoples are not explicit, and therefore the Draft Declaration on the Rights of Indigenous Peoples was developed by the UN Working Group on Indigenous Populations in 2001 (United Nations 2001). It is recognized that the establishment and protection of rights of indigenous peoples are an essential part of human rights and a concern of the international community. In the above-mentioned Draft Declaration, the main bodies of the UN confirmed the fundamental importance of the right of self-determination of all peoples. Other rights are granted for indigenous groups as well: the right not to be subject to genocide of any kind (article 7) or moved from their territories by force (article 10), and the right to practice and revitalize their culture, language, tradition, and customs (article 12), as well as to transmit them to future generations (article 14). The right for education in their educational systems and institutions, in their language, with teaching appropriate to their culture and traditions is also set out (article 15). Indigenous peoples also have the right to maintain and develop their political, economic, and social system (article 21).

Despite marked progress in retrieving rights for indigenous peoples, a lot more has to be done in future for satisfactory realization of issues confronting indigenous peoples and other ethnic or national groups; primarily land rights, but also ► preservation of language and other issues. The role of internationally recognized bodies and organizations such as the UN is to raise public awareness and understanding of indigenous peoples' rights in order to improve the quality of their lives.

Self-Determination of Indigenous Peoples

► Self-determination or the right to self-determination is a theoretical principle that a population ought to be able to determine their own governmental forms and structures. Different political movements aim at recognition of an indigenous people's status as an independent or sovereign nation by national governments and international organizations. Indigenous peoples, however, maintain the struggle to achieve self-determination in all aspects of life including economic development, education, health, family, religion, land, natural resources, language, and arts. The right to self-determination has been most effectively employed in the decolonization movement. At the ratification of the UN Charter in 1945, the signatories introduced the right of all people to self-determination into the framework of international law and diplomacy. The relationship between indigenous peoples and governments has been changing over time, and collaborative programs aiming to achieve equal rights for indigenous communities are of the utmost importance.

Indigenous Issues

Many interactions between indigenous and non-indigenous communities have resulted in issues and concerns associated not only with the existence of indigenous peoples per se but also with their quality of life, cultural and linguistic ► preservation, human and land rights, political orientation and autonomy, exploitation of natural resources, and above all, health.

Indigenous People Health

Indigenous populations differ in levels, patterns, and trends of health. A commonly used definition of indige-

nous health and well-being was proposed by the National Aboriginal Health Strategy (NAHS) Working Party in 1989:

"Not just the physical well-being of the individual but the social, emotional and cultural well-being of the whole community. This is the whole-of-life view and it also includes the cyclical concept of life-death-life." (National Aboriginal Health Strategy Working Party 1989).

This explains that achieving health and well-being is an attribute of communities as well as of the individuals within a community; and it identifies cultural well–being as equally as important as physical, social, and emotional well-being (Devitt et al. 2001).

The 1999 Declaration on the Health and Survival of Indigenous Peoples by the WHO proposed a definition of indigenous health:

"Indigenous peoples' concept of health and survival is both a collective and an individual inter-generational continuum encompassing a holistic perspective incorporating four distinct shared dimensions of life. These dimensions are the spiritual, the intellectual, physical, and emotional. Linking these four fundamental dimensions, health and survival manifests itself on multiple levels where the past, present, and future coexist simultaneously." (WHO Committee on Indigenous Health 1999).

The Committee on Indigenous Health (COIH) was established in 1997 to:

1. Ensure indigenous representation and participation in development and planning related to health issues, policy, and initiatives.
2. Assess the globalization impact on indigenous health, from environment degradation, rights violation, and forced relocation.
3. Provide a consistent interface with international and intergovernmental agencies and to ensure the dissemination of information to the widest possible extent among indigenous peoples, the national government, and other stakeholders.

The COIH has been working closely with the Working Group on Indigenous Populations since 1997. The Committee has adopted a broader, holistic concept of health, as perceived by indigenous peoples. The Permanent Forum for Indigenous Issues was established under the auspices of the Economic and Social Council of the UN in 2002, and comprises 16 independent experts, half of whom are indigenous representatives.

Although the standards of health of indigenous peoples show differences between groups, similarities exist in worldviews, patterns of disease, health determinants, and healthcare strategies. What are common are the unacceptably large differences between the health of indigenous and non-indigenous populations in developed nations (Ring and Brown 2003). Poor socioeconomic conditions together with the loss of cultural cohesion, as stated in the report of the executive board of the WHO, have adversely influenced indigenous peoples' health. Indigenous inhabitants suffered from violence and loss of their land, resources, and political autonomy. Socio-cultural structures were imposed by settlers, and diseases introduced by conquerors drastically decreased the number of inhabitants in indigenous communities. Access to medical care and health services as well as access to health promotion and prevention programs were and, to a certain extent, still are limited, inadequate, and often culturally inappropriate for indigenous peoples. What is more, due to weak demographic and health information systems, there are obscure information on the number in the population as well as on health status, health indicators, and determinants of health in indigenous communities. There are differences between official statistical data and independent statistical estimates. Ethnicity together with poverty was proven to contribute significantly to disparities in health between population groups. Furthermore, insufficient research on health risk together with the above-mentioned differences represents an obstacle for making both local and global action plans for improving the health of indigenous peoples successful. One of the reasons for this may be the fact that health research still often fails to involve indigenous people in investigations; their viewpoint would contribute to more precise information and better understanding of health problems in indigenous communities.

Data indicate that indigenous people not only die younger, but also generally have lower health status compared with other population groups. For example, in the 18th and 19th century, infectious diseases such as measles, typhoid fever, tuberculosis, and influenza almost extinguished the Maori in New Zealand, Australian Aborigines, native Hawaiians, the Saami of Norway, native Americans, and the First Nations of Canada (Kunitz 1994). Epidemics of smallpox induced even greater impairment of health and higher mortality rates

(Waldram et al. 1995). The death rate was relatively low in regions where settlers did not invade vast land areas (Kunitz 1994; Waldram et al. 1995). Rates of malnutrition, tuberculosis, and dysentery were higher among Indians than in any other group in the United States, and infant mortality was two times higher among Indians than among other Canadians. In Australia, the death rate from infectious diseases was nine times higher on the Aboriginal reserves than in the rest of the nation. Health problems were related to economic status; therefore, poor health is an indicator of the social position of indigenous communities.

Industrialization, urbanization, and technological progress have brought along other health risks. The dynamics of the transition from various infectious diseases to so-called lifestyle illnesses differ in Western and indigenous communities. While the transition period in Western societies stretched over centuries, this process was compacted in time for most indigenous populations.

We witness the rise in lifestyle-related chronic diseases: vulnerability to injury, alcohol and drug misuse, cancer, ischemic heart disease, kidney disease, obesity, suicide, and diabetes have become the modern indigenous health hazards. Higher incidences of most noncommunicable diseases together with generally lower life expectancy are features that distinguish indigenous communities (Kunitz 1994). The estimated gap in life expectancy between indigenous and non-indigenous populations is 19–21 years in Australia, 8 years in New Zealand, 5–7 years in Canada, and 4–5 years in the United States (Australian Bureau of Statistics 2002; Ministry of Health, New Zealand 1999; Health Canada, First Nations and Inuit Health Branch, 2004; US Department of Health and Human Services, Indian Health Service, 1998). In Canada, for example, 31% of native people report some form of disability linked to high accident rates, poor housing, substance abuse, and chronic diseases like diabetes (PAHO 1998). Alaskan natives have the highest smoking prevalence, births to teenagers, and unintentional death rates compared with other ethnic groups. Hospitalization rates for cervical cancer among Maori women are three to four times higher than among European or other women.

There are at least four possible causes for such health status in indigenous populations: genetic vulnerability, socio-economic disadvantage, resource alienation, and political oppression.

Genetic factors do have a large influence on health, but constant interaction between our genes and the environment modifies the initial picture. This implies that few diseases are purely hereditary. Genetic causes have been investigated in diabetes, alcohol related disorders, and some cancers. Nevertheless, genetic factors seem to be less significant in comparison to socio-economic disadvantage, which often seems to be the principal cause of ill health in indigenous peoples. Poor living conditions, low education, unemployment, and low income are socio-economic determinants of ill health for many lifestyle-related diseases as well as injuries (National Health Committee 1998).

Both alienation from natural resources and cultural alienation are important factors for health status and health care: the former as a direct cause of poor health and the latter as a distinctive factor of effective health care. Susceptibility to disease and injury rises with loss of human rights together with dispossession of land, political autonomy, and loss of natural resources (Kunitz 1994).

Some of the above-mentioned factors have effect in a short period of time, such as direct influence of physical, i. e. environmental factors on health, while others, such as government policies and health care systems, have a long-term effect on health status, and not only in indigenous communities. Values, lifestyles, culture, and religion lie in between the two extremes.

Ethnicity, Culture, Religion, and Indigenous Health

Evidence shows that ethnicity, particularly in conjunction with poverty, contributes strongly to disparities in health between population groups. ► Ethnicity is a complex term that denotes common genealogy or ancestry, and cultural, behavioral, linguistic, and religious practices, all of which can affect health (Foliaki and Pearce 2003; Fig.s 3, 4).

An ethnic group may be referred to as a cultural community based on shared cultural, behavioral, linguistic, or religious practices. Existing differences in morbidity and mortality within and between ethnic groups can be explained by great lifestyle diversities (diet, housing, alcohol intake, smoking, physical activity, etc.) that emphasize the importance of environmental factors. High morbidity and mortality rates occurred in newly discovered lands, mainly after the indigenous people's land had been taken, destroying their economic base,

Indigenous People's Health, Figure 3 Traditional Indian Dance in Mexico

natural resources, food supply, and social networks; this is in contrast to the better preservation of land property by settlers from far-away regions that resulted in a lower occurrence of illness and death. More recent examples of disparities in incidence and prevalence of chronic diseases are those occurring in Eastern European and Pacific countries.

Access to health care is another important issue related to different ethnic groups. This refers primarily to the system of health care delivery including the profile of health professionals, availability of medical equipment, and location of facilities, but also to involvement of ethnic groups in modeling health policy and allocation of resources provided by health care systems. Access to medical care depends on many cultural landmarks, individual preferences of patients, and practices of health professionals (as discrimination, bias, and stereotyping, to mention a few; Evans et al. 2001).

A widely spread opinion is that ► culture is not something inherited, but something we learn throughout life. The definition of culture given by Wolcott, quoting Herskovits, gives the basis for understanding of the cultural concept: "Customary ways of thinking and acting" (Harrison 2001; Fig. 5).

Culture is defined by modern anthropologists as a system of shared beliefs, values, customs, behaviors, and artifacts that the members of society use to cope with their world and with one another, and that are transmitted from generation to generation through learning. Although there are many definitions of culture, all of them stress that all cultures are equally developed according to their own priorities and values; none is better, more advanced, or less primitive than any other is.

Understanding of the concept of culture is important for those living and working in communities different from their own, and especially for medical care professionals. Without understanding of the cultural concept, behavior that we come across that is different from what we are used to may appear illogical, strange, sometimes even frightening and stupid, and may be explained in a way that can damage or even endanger others.

Cultural concepts are rapidly changing, especially due to intercultural contact. The nature and status of interactions with other communities shapes the community's traits. Therefore, updating of information is necessary for those working in indigenous communities because their notions about certain cultures may be insufficient or inadequate due to changes over time. Moreover, special attention should be paid to avoiding stereotypes, i. e., expecting members of a certain cultural group to behave in exactly the same way as the majority of the group. In terms of health care, this means that each patient should be regarded as an individual, regardless of cultural traits expressed.

For indigenous populations it is important to recognize and acknowledge the value of their traditional culture as well as their right to preserve that culture if they choose to.

Religious practices have to be considered in terms of either health benefits or possible disturbing factors in the utilization of health care, depending on features of the specific indigenous group. For example, ► religion appears to be associated with health status in indigenous populations in North America (► indigenous health, north america), but there is little evidence

Indigenous People's Health, Figure 4 Fijian Traditional Dance

Indigenous People's Health, Figure 5 Traditional handcrafts and house wall decorations in Ghadames, Libya, Africa

for that in the indigenous peoples of Australia (Koenig et al. 2001).

Health professionals working in indigenous communities have to be aware of religious practices and beliefs of the indigenous group and trained for situations where it is indicated during assessment that religious issues might interfere with the treatment, so that they can react. There is a growing need for further research into the relationship between spirituality and health of indigenous groups for better understanding of patterns of ill health in such communities.

Health Knowledge and Health Practices – Traditional vs. Western

The concept of "indigenous medicine" is frequently defined as ▶ traditional medicine, i. e., any non-Western allopathic treatment or practice. However, in indige-

nous communities, the type of indigenous medicine is specific to that community as there are differences between indigenous communities. Cultural, traditional, and religious beliefs all influence both health knowledge and health practices of indigenous peoples. Understanding of illness as well as methods to overcome different ailments varies greatly not only between indigenous and other population groups but also within different indigenous communities. However, a holistic approach to health and disease is the cornerstone of health practices in indigenous communities. The ultimate goal is to reinstate the individual to a harmonious relationship with the social order; in that way, every aspect of an individual's well-being is taken into consideration and treated. In ► western medicine, healing strategies are focused on the physical condition of the patient. Because of the different approaches, each community has difficulty in accepting the other method.

Native Indians in America have a concept of wellness instead of health and illness. "Wellness" can be defined as the state when the mind, the body, and the spirit are all connected and in balance. One cannot be separated from the other. The medicine circle – having no beginning and no end – represents this concept of harmonious unity. The same principle exists in Asian cultures (► indigenous health, asia), where harmony of the two opposite forces of yin and yang is a prerequisite of good health.

According to data from the WHO, two thirds of today's world population primarily or exclusively uses traditional diagnostic and treatment practices. So-called Western medicine has been rooted in traditional health practices since the Hippocrates era. Advances in evidence-based scientific procedures and technologies have improved health knowledge, but in spite of evident improvements in health practices, there is a constant rise in morbidity and mortality of so-called noncommunicable diseases. There are several possible reasons for this. The apparent gap between Western and indigenous practices may explain such trends. Consideration of the entire country's health needs, the available resources and their utilization to benefit all members of society, including indigenous populations, is one of the issues of disagreement. The actual cause of the disparity may be the different health care priorities of indigenous and other population groups within the state. Moreover, according to health specialists, there are basic criteria all health operations should follow in terms of estimated needs, efficacy, and safety when providing health care. Medical practices must meet specific criteria. For indigenous communities, indigenous health practitioners are a legitimate reference source. However, Western societies often do not comply with practices that are not evidence-based and for which there is no adequate reference, which in turn raises the question of acceptable methodology to evaluate indigenous medical treatments. The scope of health conditions under the auspices of the national health care system has to be carefully defined.

Indigenous Health Services

There is a growing need for improvement of indigenous health services, which should provide a range of healing methods, including conventional professional services and traditional healing. Improved access to medical services for indigenous people enables earlier intervention, better scope, higher levels of compliance, and a greater sense of community participation and ownership (Evans et al. 2001).

Health practitioners in indigenous communities address illness in a different way compared with Western medicine doctors. There is a tendency to view illness as a consequence of or imbalance in nature or personal behavior. What is more, they link family, society, and the environment, and tend to treat the particular patient, not the disease.

It is important to recognize the limitations of both Western and indigenous medical practices and, especially areas in which they can complement one another. Sometimes, benefits from both health care systems are not available simply because there is no understanding or acceptance of the other ways of healing, with claims that they are not evidence-based or are even harmful. Some people from indigenous communities tend to refuse other forms of medical care since not only are they not familiar with modern technology and achievements but they also believe it could harm them. Therefore, health professionals in indigenous communities must have knowledge about the culture, beliefs, tradition, and religion of the population group. Only in that way can an applied health system be of benefit to society. Provision of health care should take into consideration all the above issues and the health care system should be reorganized in a way that is suitable for specific indigenous communities. Public health pro-

grams and services should also be extended to indigenous communities, as stated in the World Bank report of 2001 about indigenous peoples' health. Such programs should be appropriate to the particular community and its needs, for example, hiring or training bilingual staff, modifying the design of health care facilities (intercultural hospitals), paying attention to taboos related to age and gender differences, etc. What is more, indigenous medical practitioners should be valued as part of the health care system where possible. It is also necessary to coordinate and supervise treatments given to the same patient in order to avoid complications.

Of course, many problems occur in putting the changes detailed above into practice. Importance of priorities, criteria for determination of legitimate medical practices, and the scope of the health sector are the most important issues.

Many chronic, non-communicable health impairments can be avoided through primary, secondary, or tertiary ► health care services. Rates of avoidable mortality in indigenous communities are higher as compared with their non-indigenous counterparts. However, a large spectrum of these preventable diseases remains undiagnosed and untreated. For example, cardiovascular diseases, which account for the highest morbidity and mortality in indigenous communities, are preventable through regular, systematic diagnosis and treatment procedures. Regardless of the differences between health patterns and determinants of ill health in different indigenous groups, the most prominent issue is adequate primary health care services for prevention, and early diagnosis and treatment of conditions and illnesses that are widely spread in indigenous populations.

Another important issue is education of health professionals and inclusion of indigenous health practitioners. Together with socio-economic and macropolitical interventions in the domain of health care services, this will contribute to better organization and functioning of the health care system, incorporating traditional practices into Westernized medical care structure.

Health promotion activities including preparation and dissemination of culturally appropriate health materials in native languages, and inclusion of indigenous health practitioners in health promotion activities are important, as are promotion of mutual learning, capacity building, and sharing information through workshops.

Health for All – Inequities in Health

Inequalities in health status are an important measure of the quality of the health system. As indigenous peoples are not living in isolation from the nation state, they have equal rights to the guarantees of health for all citizens. In order to accomplish such a guarantee, policies need to assure that health services and programs are appropriate for the indigenous culture and coordinated according to the community's practices. This requires reconciliation between indigenous, i. e. traditional, and orthodox, i. e. Western, medical practices. The quality and scope of the health care system should be broadened in order to accommodate the needs of indigenous peoples. What is more, medical practitioners must have at least basic knowledge about important determinants of health in indigenous communities, above all their views of health and illness, and cultural and religious beliefs so that they can provide them with the most appropriate health care. This also includes the importance of health determinants outside the health sector that relate to those determinants. Health status depends on combined economic, social, environmental, cultural, and political factors. It cannot be addressed in isolation from them.

It is important to map the extent and nature of inequities in health, since without reliable data on disparities in health, policy makers and populations are less equipped to demand change and monitor progress. One of the basic problems is the inability to provide complete population health status data. Many factors underlie the cultural norms that generate and maintain inequities in health; these include gender discrimination, racism, corruption, and the joint effects of household income and race/ethnicity on health outcomes (social burden of ill health – example of the United States; Evans et al. 2001). Health care at all levels from primary care to public health interventions are more likely to be accessed by the rich than by the poor. The feasibility of designing and implementing a global strategy solely on indigenous people's health has to be considered for various reasons.

Health Research and Indigenous Peoples

Research projects in indigenous populations in the past were initiated and controlled by research institutions. There is evidence that shows ► health research contributes to improvement of health. Research projects

need to be carefully planned and well organized. Indigenous approaches to learning and health knowledge differ from orthodox Western practices, and therefore indigenous researchers are important contributors. Mainstream approaches may be effective as long as the requirement for responsiveness to the needs and expectations of the indigenous peoples is met. The value of specific research projects in indigenous communities led by indigenous people and based on indigenous methodologies and views is becoming increasingly apparent. Some approaches incorporate many contemporary and Western developments; still others prefer usage of traditional medicines and practices such as spiritual and traditional healing approaches.

Collaborative research in various indigenous populations can contribute to improving health as well as organization and planning of ► health care services in indigenous communities. In 2002, Australia, Canada, and New Zealand signed a memorandum of understanding on health research for indigenous health. This means that all three countries will equally participate in research with unique funding and research methodology, and that they will share the outcomes of research performed and use them to make policies for collaborative research between the three countries.

It is customary to make a research agreement before a research proposal is submitted for scientific and ethical review. This helps accomplish mutual understanding as well as reducing problems that may arise during research. Cultural and other traits of indigenous peoples are not sufficiently included by scientific or ethics guidelines and therefore indigenous peoples are reluctant to participate in projects. Clear direction, well defined funding, and inclusion of indigenous representatives enable more accurate research results to be obtained (WHO 2003).

Summary

Indigenous, native, aboriginal, or first peoples are descendants of the original or long-time inhabitants of lands now dominated by others. They are self-identified as indigenous and recognized as such by others.

Over the centuries, indigenous peoples have retained their social, cultural, economic, and political characteristics, which are clearly distinct from others living on the same territory. However, during the course of time, many indigenous groups have undergone drastic changes as a result of interactions between indigenous and non-indigenous societies. Characteristics common for many indigenous groups, even today, include predominantly non-urbanized societies whose members rely on agriculture, hunting, and gathering for survival. Throughout history, indigenous peoples have lived in an atmosphere of severe repression and disadvantage relative to others. They were deprived of their land rights and access to natural resources and have struggled to survive and preserve their language, culture, traditions, and socio-economic and political features. Discrimination exists, in some form, even today. Armed resistance, diplomacy, and law have been tools in the quest for the rights of indigenous peoples; for many centuries, they have struggled to regain their human rights. Today, it is recognized that the establishment and protection of rights of indigenous peoples are an essential part of human rights and a concern of the international community.

Despite cultural and ethnic diversity, there are similarities between the problems and interests of the various indigenous peoples. Indigenous populations differ in levels, patterns, and trends of health. The standards of health of indigenous peoples are different, but similarities exist in worldviews, patterns of disease, health determinants, and healthcare strategies.

Because of weak demographic and health information systems, there is obscure information on the number in the population as well as on health status, health indicators, and determinants of health in indigenous communities. Indigenous peoples tend to die younger and generally have lower health status than other population groups. Possible reasons for this are limited access to medical care and health promotion and prevention programs, and health services that are inadequate and often culturally inappropriate for indigenous peoples.

Infectious diseases in the past and so-called life-style, chronic, non-communicable diseases today (diabetes, cardio and cerebro-vascular diseases, cancer, alcoholism, and substance abuse) show the highest rates among indigenous populations. Genetic predisposition, cultural and religious beliefs, and health knowledge and practices all influence the health status of indigenous populations.

There is a growing need for improvement of indigenous health services to enable earlier diagnosis and treatment. It is important to recognize the limitations

of both Western and indigenous medical practices and, especially, to identify areas in which they can complement one another. Consideration of the entire country's health needs and the available resources, as well as their utilization to benefit all members of society, sets the basis for improvement of indigenous peoples' health as well as the population as a whole.

Regardless of the differences between health patterns and determinants of ill health in different indigenous groups, the most prominent issue is adequate primary ► health care services for prevention. Education of health professionals is equally important, especially in relation to ethnicity, religion, and culture of specific indigenous groups.

Research contributes to improvement of health. Research projects need to be carefully planned and well organized, and they must include indigenous health care professionals for more complete and valuable results.

Indigenous Representation Organizations

Definition

► Indigenous representation organizations are defined as organizations and bodies that represent rights and interests of indigenous peoples (► indigenous peoples, ► indigenous rights). In the United Nations indigenous peoples have representatives in form of the Working Group on Indigenous Populations (WGIP). In April 2000 the United Nations Commission on Human Rights adopted a resolution to establish the United Nations Permanent Forum on Indigenous Issues (PFII) as an advisory body to the Economic and Social Council with a mandate to review indigenous issues.

Also various organizations are devoted to the preservation or study of indigenous peoples, such as International Working Group on Indigenous Affairs (IWGIA), Indigenous Peoples of Africa Co-ordinating Committee (IPACC), Movement in the Amazon for Tribal Substinence and Economic Sustainability, Indigenous Dialogues, and others.

Indigenous Rights

Synonyms

Rights of indigenous people

Definition

The collective human rights of ► indigenous and local communities has been increasingly recognized – such as in the International Labor Organization (ILO) Convention 169 (1989) and the Draft Declaration on the Rights of ► indigenous peoples (1982–2006). The Rio Declaration (1992), endorsed by the presidents and ministers of the majority of the countries of the world, recognized indigenous and local communities as distinct groups with special concerns that should be addressed by states.

Indirect Costs

Definition

Value of the lost output (i. e., impairment or disability to work of a person) due to a disease or disorder, either short-term or long-term.

In health economics, the term indirect cost refers to all costs to the national economy of the society due to productivity loss. Indirect costs can be due to decreased efficiency, total absence from work through an illness, or premature death. Indirect costs can be estimated using the human capital approach or the friction cost method. Both approaches are based on the assumption that the lost productivity can be valued by the achievable gross income of the employed population.

Indirect Standardization

Definition

Applies the stratum specific rates of the standard population to the number of individuals in the corresponding stratum in each of the populations being compared. This method is called "indirect" because it does not use the actual morbidity and mortality rates of the populations being compared. This method yields standardized morbidity or mortality ratios (SMRs), one for each population being compared.

Individual Case Description

Synonyms

Case Report

Definition

An individual case description is the most basic type of descriptive study of individuals, consisting of a detailed report of the diagnosis, treatment, and follow-up of a single patient. It also contains some demographic information about the patient.

Individual Factors

► Personal Factors

Individual Health Factors

Synonyms

Personal Health Factors

Definition

The personal factors of an individual are the background features of the individual's life that are not part of a health condition or health state. Features like age, race, gender, educational background, personality, aptitudes, fitness, lifestyle, habits, upbringing, social background, profession, and past and current experience are examples of personal factors. Unlike for ► body functions and ► body structures, there is no official classification for personal factors.

Individuality

► Identity

Individual Susceptibility

Synonyms

Susceptibility; Vulnerability

Definition

Individual susceptibility is diversity in responsiveness among individuals to occupational and environmental exposures. It makes it difficult to determine actual risks, particularly at the low levels to which most people are exposed. The individual susceptibility is largely determined by genetic factors, which are very complex in nature. For example the toxicity of a number environmental and workplace chemicals is determined by a complicated balance of its toxicity and metabolic biotransformation. These processes are largely influenced by individual genetic factors, which are crucial in individual susceptibility. So, effects of exposure to a certain chemical are related to its toxic effects, intensity of exposure and individual susceptibility.

Indoor Air Quality

► Sick Building Syndrome

Indoor Climate

► Climate and Microclimate

Induction

Synonyms

Induction period

Definition

Induction is the interval between the causal action of a factor and the initiation of the disease.

Induction Period

► Induction

Industrial Physician

► Occupational Health Physician

Industrial Revolution

Definition

During the eighteenth century and particularly the nineteenth century, there was a dramatic change in both social and working practices throughout Europe. Much more emphasis was placed on industrial rather than farming practices.

Inequality

► Health Disparities

Inequality in Health

Definition

Inequalities in health refer to differences in both health experience and health status between countries, regions, and socioeconomic groups. Some inequalities are biological (e. g. genetic), others reflect socially determined population differences (environmental factors, behavior). Making valid comparisons of inequalities in health is very difficult, because the socioeconomic groups can be defined in various ways, including by occupation,

social class, or educational level, and because it is not possible to measure health status of each individual in a population by an objective health index.

Inequity in Health

Definition

Health inequities refer to the systematic, unfair, and unjust, yet potentially avoidable differences in access to health services across socially, economically, demographically, or geographically defined population groups or subgroups. Health systems are consistently inequitable, providing more and higher quality services to the well off, who need them less, than to the poor, who are unable to obtain them.

Infant and Child Mortality

Synonyms

Infant mortality; Under-five mortality

Definition

Infant and child mortality are deaths to children under age 1 and age 5. The infant ► mortality rate (IMR) is usually calculated by the number of deaths to infants under age one per thousand births in a given year. Despite its name, the IMR is not a rate; rather the IMR approximates the probability of dying before age 1. Child mortality (often called under-five mortality) is measured as probability, or the proportion of children dying before their fifth birthday. Like the IMR, under-five mortality is often reported per-thousand births. Child mortality can be determined using mortality rates, where available, or indirectly based on census data. Although infant and child survivorship have greatly improved throughout the world, mortality remains high in many developing countries. In Africa, about 10 percent of all children born will die before their first birthday; by age 5 the total proportion dead will exceed 17 percent.

Infant Health

► Child Health and Development

Infantile Paralysis

► Polio
► Poliomyelitis

Infant Mortality

Definition

Infant mortality is defined as probability of dying between birth and exactly one year of age expressed per 1000 live births.

Cross-References

► Infant and Child Mortality

Infant Mortality Rate

Synonyms

Infant death rate

Definition

The infant mortality rate is the number of deaths of infants under a year of age per one thousand live births during a calendar year. This rate is a useful indicator of the general level of health in a community. A high rate has been taken to indicate unfavorable external factors (poor water quality, inadequate food supply, inadequate education, substandard medical care), especially in developing countries. Infant mortality rates have significantly declined in developed countries, mainly due to improvements in basic health care.

Infection with Ancylostoma duodenale

Synonyms

Ancylostomiasis; Hookworm infection

Definition

The larvae of the hookworm can penetrate the intact skin. Via the blood they reach the lungs, where they can cause a hemorrhagic pneumonia. From the lungs

the larvae get into the bronchial system and the pharynx, where they are swallowed. In the intestines they develop into adult worms. The presence of hookworms in the bowel leads to abdominal pain, nausea and diarrhea. *Ancylostoma duodenale* is most frequently found in the Mediterranean area and in Eastern Asia. A similar worm causing the same symptoms is the *Necator americans*, which is mainly found in tropical Africa and America.

Infection with Bordetella pertussis

► Whooping Cough

Infection with Borrelia burgdorferi

► Lyme Borreliosis (LB)

Infection of Brain Tissue

► Encephalitis

Infection with Brucella

► Brucellosis

Infection with Clamydia trachomatis

► Chlamydia trachomatis Infection
► Teratoma

Infection with Clostridium botulinum

Synonyms

Botulism

Infection with Cryptosporidia

► Cryptosporidiosis

Infection with Dog Tapeworm

► Echinococcosis

Infection with Dog Tenia

► Echinococcosis

Infection with Ebolavirus

Synonyms

Ebola disease; Ebola fever

Definition

Ebola disease, which appears in Africa, occurs after an incubation period of 2–21 days. Lethality is 50–80%. The main source of primary infection is not really known yet. Ebola fever can be transmitted by monkeys or from one individual to another by contact with contagious body fluids. A vaccination is not available.

► Typhoid Fever/Paratyphoid

Infection with Sarcoptes scabiei

Synonyms

Itch

Definition

Sarcoptes Scabiei causes an infectious parasitic skin disease caused by the itch mite (*Sarcoptes scabiei*). It is acquired through close contact with an infested individual or contaminated clothing. The highest prevalence is in overcrowded and unhygienic communities. All clothing and bedding of the victim and his household should be disinfected. Disinfestation of the skin is accomplished by applying creams or ointments containing gamma benzene hexachloride or benzyl benzoate.

Infectious Disease

Synonyms

Communicable disease; Transmissible disease

Definition

Disease, resulting from the presence of microbial vectors that can be transmitted from one person or species to another.

Infectious Disease Epidemiology

Definition

Infectious disease epidemiology describes and analyses the mechanisms of transmission of infectious agents (e. g. airborne, vector-borne, sexual transmission), the biology of the infectious agent (e. g. infectivity, life cycle) including molecular epidemiologic features, the biology of possible vectors (e. g. mosquitoes or ticks), environmental factors (e. g. temperature) and the dynamics of infections in populations.

Synonyms

Communicable diseases; Transmissible diseases

Introduction

Infectious diseases have forever played an important role for mankind. For thousands of years, they were the most frequent cause of death, even in wealthy countries. Due to their sometimes disastrous effects they had great influence on both society and human beings' behavior. When infant mortality was high, family sizes were correspondingly high, to ensure heirs. Having an infectious disease could lead to social discrimination or even to complete isolation of the infected person. Even though therapeutic possibilities have improved, especially during the last century, infectious diseases remain a serious danger to public health; worldwide, they are responsible for millions of deaths every year (Table 1) and it is most probable that the infectious diseases will continue to be of global significance in the future. The multifaceted nature and mutability of infectious diseases remain a challenge for medical research. However, the unequal distribution of medical resources seems to be an indissoluble problem in worldwide health endeavors.

An infectious disease occurs when pathogens – primarily microorganisms – actively or passively get into a macroorganism (host), where they reproduce and cause symptoms, which lead to a more or less severe impairment of the host's health. Thus, exogenous agents are something that all the infectious diseases have in common. Otherwise, they are a very heterogeneous group of diseases which can be classified in various ways. To begin with, the pathogens themselves can be differentiated. Moreover, the origin of the germs and the routes of transmission vary. As for the macroorganism, different organs or organ systems can be involved, infection can be local or systematic, the course can be mild or severe, and long-term damage may or may not occur. Therapeutic and prophylactic measures do not only depend on the characteristics of the pathogen, but also on the characteristics of the macroorganism. Besides the general constitution and the presence of defense mechanisms (immune status), the success of a treatment is determined by the accessibility of the affected organ system. If prophylaxis is to be successful, it is necessary to take into consideration the mode of transmission so that certain hygienic rules and protective measures can be followed to avoid infection. The general population has to have an appropriate level of information; an understanding of reasons underlying the recommendations is indispensable for a successful fight against infectious diseases. A further important pillar of prevention is immunization, active (► immunization, active) and/or passive (► immunization, passive).

Research has shown that infectious diseases can have shared properties or extreme differences. Altogether, there is a complicated network and relationship between the microorganism – if harmless or pathogenic – and the macroorganism. To get an overview of the effects of infectious diseases many different aspects have to be considered.

Infectious Diseases, Table 1 Deaths caused by infectious diseases (WHO reports)

Infectious disease	1996 (in millions)	2004 (in millions)
Lower respiratory tract infection	4.4	3.9
Diarrheal diseases	3.1	2.2
Tuberculosis	3.1	1.6
Malaria	2.1	1.3
Hepatitis B	> 1.1	1
HIV/AIDS	> 1	2.8
Measles	> 1	0.454

Microorganisms

A microorganism is a microscopic entity with its own metabolism. Most microorganisms are unicellular bacteria, fungi, microscopic algae or protozoa. Viruses are responsible for most of the infectious diseases but, in the proper meaning of the word, they do not belong to the classification 'microorganism' as they cannot reproduce on their own, and they are dependent on a host's cell for their metabolic processes; viruses can only replicate intracellularly. Their classification is made according to their viral genome (nucleic acids RNA or DNA) and the shape of the protein coat (capsid). Prions (proteinaceous infectious particles), which were detected at the end of the last century, do not belong to the classification microorganism either.

Bacteria are unicellular organisms with a cell wall, but without a real nucleus. They are spherical or rod-

shaped and have a size of 0.5–5 µm. Reproduction, which is performed by binary fission, most frequently takes place extracellularly, but in some bacterial species reproduction can be either intra- or extracellular, and in a few only intracellular. In some cases, when conditions are unfavorable, some species can construct so-called spores. These are capsules which are resistant against extreme environmental influences.

Fungi (mycophyta) are classified according to their way of reproduction and construction of hyphae (a network of long hollow tubes). Their reproduction is both sexual and asexual. Some fungi produce highly-poisonous substances, so-called toxins. Like bacteria, fungi are widespread in nature. Yeasts, a special species of fungi, were used in Egypt for baking and brewing more than 5000 years ago. An infectious disease caused by fungi is called a mycosis. In humans, the most common fungus is the yeast *Candida albicans*. It can often be found on mucous membranes where it causes no harm.

Microscopic algae do not play any role in infectious diseases.

Protozoa are unicellular organisms with a cell wall, a nucleus and cell organelles. As a rule, reproduction takes place by dichotomy. In some species of protozoa (like sporozoa), however, during their developing cycle in the final host, the processes of reproduction is sexual. Protozoa, which show this phase of sexual reproduction, are, for example, plasmodia which cause malaria. Some, like ameba, can build spores, which are resistant to environmental influences and can survive and remain contagious outside of their hosts for a long time.

Microorganisms have existed for about 3.8 billion years, and they are the root of life on earth. In comparison with microorganisms, multicellular creatures appeared on our planet about 600 million years ago, and modern humans about 130,000 years ago. Microorganisms represent about 70% of the biomass on earth, their biodiversity is estimated to be about 2–3 billions species. Microorganisms can exist despite extreme environmental conditions, like great heat, extreme cold or complete darkness. Their various functions include different geochemical processes, which are essential for life on earth, like the production of elementary oxygen. Microorganisms which cause disease are said to be pathogenic and the virulence of a single strain within a bacterial species is the degree of its pathogenicity. Important factors affecting the level of pathogenicity are the poisons (toxins) which are produced by the bacteria.

One billion (10^{15}) microorganisms exist within the human body, which is 10–100-fold the total amount of cells making up the body itself. These microorganisms primarily are bacteria. In a healthy individual, the bacterial population (physiological flora) of the skin, eyes, respiratory, intestinal, urinary and genital tracts is similar. The urinary bladder, uterus and tubes in general are sterile. With a population of 100–10,000 bacteria per cm^2 of skin surface, the skin shows a low microbiological contamination. In a milliliter of spittle there can be found 10^9 bacteria, in a gram of stool up to 10^{12}. Among the intestinal bacteria, the highest percentage is made up of *Escherichia coli* (*E. coli*). The concentration of coli bacteria is used as an assessment of water quality (► water quality and waterborne infectious diseases), as it is an indicator of fecal contamination. The composition of bacteria and other microorganisms forms an ecologic balance. According to the requirements of the different regions, a characteristic milieu is built up. An acid pH-value provides protection against pathogens. This milieu is not only important for the skin, but also for the female genital tract. The acid pH-value of vaginal secretions, which is needed to prevent ascending infections, is maintained by lactobacilli (Dederlein flora). For an efficient digestion of food in the intestinal tract and for the production of vitamin K, different bacterial metabolic processes are necessary. In many regions of the body, macro- and microorganism live in a symbiotic relationship, to the benefit of both.

Most microorganisms do not cause any diseases; they are apathogenic, at least, as long as they stay in their appropriate location. However, if introduced to inappropriate locations, e. g. penetration into the tissues through lesions of the skin or the mucous membranes or into organ systems by other means, diseases can occur. Urinary tract infections, for example, are often caused by *E. coli*. Particularly in females, who have a very short urethra, germs can easily get into the urinary tract and cause an inflammation if cleansing of the anogenital region is not correctly carried out. The human defense system (immune system) recognizes germs as foreign material and builds up antibodies against them. Obligatory pathogen microorganisms cause infectious disease in all non-immune individuals. If the immune system is compromised, organisms which are normally

harmless to a healthy organism can become pathogenic causing disease.

Multicellular Parasites, Macroparasites

Multicellular parasites are divided into two groups, endo- and ectoparasites. As they are visible to the naked eye, they have been known since ancient times. Ectoparasites found in humans are the arthropods lice, fleas, mites, predatory bugs and ticks. Most of the ectoparasites closely adhere to the skin and feed on blood; mites causing scabies live in the upper layers of skin and feed on danders. If an ectoparasite is infected with a pathogen the germ can be transmitted to the blood during feeding. Thus, epidemic typhus is transmitted by lice, plague by fleas, chagas disease by predatory bugs and borreliosis and tick-borne encephalitis (TBE) by ticks. Endoparasites are found living inside the human organism, e. g. worms (vermes, helminthes). Worms are divided into roundworms (nematodes) and flatworms, e. g. tapeworms (cestodes) and flukes (trematodes). Worms can cause damage to tissues or block the lumen of the intestines, causing indigestion or even ileus. The presence of tapeworms in the gut leads to competition for nutrients; despite a sufficient food supply a loss of weight or symptoms of nutritional deficiency can appear. Hookworms, which feed on blood, can cause anemia.

History of Infectious Diseases

Although the history of infectious diseases is as old as mankind, it was not until the last few centuries that an understanding of these diseases was fully achieved. Throughout human evolution, from hunter-gatherer to farmer, humans have been confronted by animal germs, but as people crowded into cities and increased trade contacts epidemics developed. In medieval times, and beyond, people assumed that diseases were caused by a pollution of the air, the so-called miasma. This theory was thought to explain why some regions were prone to mass diseases of their populations. As for therapy, treatment of the air was considered to be effective; fire or balmy essences were thought to cleanse the atmosphere. Even before that, in the pre-Christian era, Hippocrates and Galen were famous supporters of the miasma theory. Also, disease was thought to be a punishment from the gods. Recovery from an infectious disease or the failure of its appearance was either explained by individual constitutions or by living conditions. Therefore, therapeutic recommendations primarily concerned changes in the way of life. So, it can be seen that throughout history theory determined treatment. The opinions of dictators, of the religious community and of society were determining factors and the Arts provided not only illustrations but reinforcement. Again and again, the fear of epidemics could be instrumental in influencing the population.

Historically, descriptions of epidemics were primarily produced by non-physicians. They observed that disease occurred in a healthy individual after contact with an infected person. Due to this empirical knowledge, people assumed that a contagious substance, the "contagiosum," was transmitted from one human to another. Thus, as early as in the Middle Ages, people used to burn the clothing of a person infected with black plague in order to avoid spreading the disease. The recognition of the transmissibility of diseases also led to the introduction of quarantine measures. As early as in 1500 AD, people in China and India, in their fight against smallpox, performed a procedure in which healthy children were exposed to infected material from a person suffering from smallpox (by scoring the child's arm veins). At the beginning of the 18th century, this technique of variolation was brought to England. Following empirical observations about cowpox and smallpox, at the end of the 18th century, Edward Jenner developed the first vaccine against smallpox. Jenner thus set the foundation stone of the era of active immunization (► immunization, active). Even though the development of the first vaccine was a decisive breakthrough, the principles of immunization could not be explained at that point in time. Ignaz Semmelweis, the renowned Hungarian gynecologist, who is accepted to be the founder of antisepsis (and glory is due to his efforts in the fight against childbed fever), could only explain his successes empirically as microbiological methods were not then available to him.

During the course of the 19th century, the primary philosophical analysis of infectious diseases was replaced by the scientific approach. If pathogens could be seen it would prove that they actually existed, so, the development of microscopy and the coloring methods established by Ehrlich (1882) and Gram (1884), which made bacteria visible, were great endorsements of the scientific method. The Frenchman Louis Pasteur (1822–1895) and the German Robert Koch (1842–

1910) were famous scientists and microbiologists of the 19th century well versed in the scientific method. Pasteur performed fundamental research into germ theory. He succeeded in proving that microorganisms were responsible for the processes of fermentation and decay. Moreover, he discovered that anthrax infection is caused by *Bacillus anthracis*. Robert Koch detected *Mycobacterium tuberculosis*, the pathogen which causes tuberculosis (► tuberculosis and other mycobacterioses). He managed to show that after isolating a germ from an infected individual and growing the pathogen in pure culture, the transmission of that culture to another person or an animal could cause the same disease. From these experiments, Koch advanced his theory on infectious diseases. During the second half of the 19th century many more infectious bacteria were detected. Within the course of the 20th century, specific therapeutics were developed; in 1945, for instance, the Scottish bacteriologist Sir Alexander Fleming was a co-winner of the Nobel Prize for the discovery of penicillin.

Today, a great number of antibiotics are available, effective against a variety of bacteria. Nevertheless, due to the ever-changing features of pathogens and the evolving of resistances, the development of new antibiotics is not yet finished. Thanks to technological progress and the development of the electron microscope, several viruses have been detected during the course of the 20th century. Scientists have succeeded in cultivating viruses and, utilizing the progress made in immunology, serologic methods have become available to detect viral infections. In 1977, aciclovir was licensed as the first virustatic drug, which is specifically effective against herpes viruses and varicellae. The development of vaccines has been driven forward since the end of the 19th century (Table 2). During the course of the 20th century, area-wide immunizations were carried out to provide protection for a high percentage of the population against infectious diseases. Vaccination programs for babies were established.

Documentation has always been an important part of medical activity. In communicable diseases, the registration of data is of special significance. This is due to the fact that although, initially, only a single individual may be infected, depending on the pathogen, a further spreading of the disease has to be feared. There is always the possibility that large numbers of the population might become infected and, thus, special measures might become necessary to control the infection. In 1948, the World Health Organization (WHO) was founded as a superordinate international institution of surveillance; further international, national and regional institutions form a network which deals with surveillance and outbreak management of transmissible diseases (► outbreak management and surveillance of infectious diseases). Nowadays, data interchange is considerably facilitated by modern communication techniques.

Due to the mutability of microorganisms, the history of infectious diseases will have no ending. New pathogens could appear and provide great diagnostic and therapeutic challenges to modern medicine, as HIV-infection (► HIV-infection and AIDS) and SARS showed only a few years ago. Also, already well known germs can make therapy difficult by the development of resis-

Infectious Diseases, Table 2 Chronological list of the introduction of vaccines

Year	Vaccine against
1796	Smallpox
1880	Cholera
1881	Anthrax infection
1884	Rabies
1906	Tuberculosis
1925	Diphtheria
1925	Tetanus
1937	Yellow fever
1940	Typhoid fever
1945	Influenza
1954	Pertussis (Whooping cough)
1955	Poliomyelitis
1963	Measles
1967	Mumps
1969	Rubella
1974	*Haemophilus influenzae* B
1974	Tick-borne encephalitis
1981	Hepatitis B
1985	Pneumococci

1996	Hepatitis A
1997	Rotaviruses
1999	Meningococci C
2006	Human papilloma virus (HPV)

I

tances. This problem especially has to be faced in tuberculosis (► tuberculosis and other mycobacterioses) and ► nosocomial infections. The unrestricted use of antibiotics and chemotherapeutics for medicinal therapy or animal fattening has led to the development of resistant and highly virulent pathogens. And through the influence mankind has on the environment, global warming and climatic changes, human beings will over and over again be confronted with new or changing and possibly pathogenic microorganisms.

Ways of Transmission

Infections can be transmitted directly from one individual to another or indirectly by different vectors. Infectious diseases which are transmitted to humans by vertebrates are called zoonoses (► zoonotic and parasitic infections). Several pathogens can be transmitted directly and indirectly. Depending on their resistibility, some germs can survive outside of their hosts for a time. One of the ways direct transmission takes place is by droplets: coughing or sneezing. Respiratory tract infections are primarily transmitted in this way. Besides simple upper airway infections, more serious diseases, like pneumonia, infectious mononucleosis or tuberculosis (► tuberculosis and other mycobacterioses), can occur. Moreover, most of the so-called childhood diseases like chicken pox or measles are transmitted by droplets. A further possibility of direct transmission is by smear infection, which takes place by contact with the skin or the mucous membranes. Communicable diseases in this category are primarily ► sexually transmitted diseases (STDs), and include ► HIV-infection and AIDS. Some ► parasitoses (► zoonotic and parasitic infections) are also transmitted from one individual to another by close contact, for example lice, fleas or scabies mites. In an intrauterine infection, pathogens from the maternal circulatory system reach the unborn child via the placenta. An infection inside the womb can kill the baby, lead to miscarriage or premature birth or cause dysplasias or impairment in the child's development. A transmission of an infectious disease can take place during birth. As for indirect transmission of diseases, there are several possibilities. Pathogens can easily enter an organism through open wounds. Wound infections with high lethality are tetanus and gas gangrene. Both diseases are caused by spore-building bacteria, which are found in the soil or in dust. A great number of infectious diseases are transmitted by foods or drinking water, polluted by human or animal excrement. Besides worm infections, the most typical fecal-orally transmitted (► food-safety and fecal-orally transmitted infectious diseases) or waterborne infectious diseases (► water quality and waterborne infectious diseases) are diarrheal in nature. The bite of a bloodsucking insect is a further mode of transmission. The type of insects responsible for spreading particular diseases depend on environmental factors, e. g. a high percentage of disease-spreading insects are primarily found in warmer regions – that is why the corresponding diseases are called tropical diseases (► tropical diseases and travel medicine). Due to the rising mobility of people and the increasing popularity of long-distance journeys, diseases transmitted by (tropical) insects also play a role in travel medicine (► tropical diseases and travel medicine). Among the tropical diseases, ► malaria, which is transmitted by the *Anopheles* mosquito, has far-reaching effects worldwide; however, yellow fever, sleeping sickness and leishmaniasis are of certain significance as well, especially in tropical regions. Fortunately, very few germs can penetrate the intact skin of a person. However, diseases are not only transmitted by insects; rabies is a very dangerous infection with a high lethality and is caused by the bite of an infected vertebrate and bilharziasis is a familiar infectious disease caused by *Schistosoma*, a genus of trematodes, which lay eggs within the host. As for health care services, there is the danger of transmitting infectious diseases by the hands of the staff or by contaminated material; pathogens can be transmitted by venous cannulae, central vein catheters, urinary (urethral) catheters, mechanical ventilation and surgical interventions. Germs, which are transmitted by blood or blood products, can get into a patient's circulatory system by a contaminated blood transfusion. Thanks to a careful examination of blood donors and blood conserves, nowadays, the transmission of disease by blood transfusion seldom occurs – at least in the industrialized nations. Apart from acquisition of droplet- and smear infections, medical staff face an enlarged risk of infection due to needle stick – or other injuries – when dealing with infected patients or contagious material. In this context, the transmission of hepatitis B and AIDS are of particular significance. Out with the health care system, transmission of infectious diseases takes place among drug addicts who re-use contaminated needles.

Course of Infectious Diseases

An infectious disease starts after a defined incubation period, the time interval between contact with the germ and the appearance of symptoms. While the incubation period is very short in food poisoning by bacterial toxins (only a few hours), it can last up to several decades in other transmissible diseases, like AIDS or leprosy. As a rule of thumb it can be said that the typical incubation period is about one week for bacterial infections and between one and four weeks for viral infections. As for worm infections, the incubation period lasts longer than a month. The severity of an infectious disease depends on various factors; the characteristics of the pathogen, the immune status of the affected organism and the therapeutic measures employed. Some germs can cause ► acute life-threatening infections. When the course of the disease is rapid and severe it is described as being fulminant. There is no time for therapeutic interventions, and one has to be prepared for a high lethality. Such acute infections develop quickly; they seem to start out of completely inconspicuous physical conditions. Very frequently, an acute course is seen in ► infectious diseases in pediatrics. But there are a number of infections with acute courses, which occur in all age groups, like ► influenza (► influenza and avian influenza) or diarrheal diseases. A less sudden course of infection is labeled subacute; chronic infectious diseases start slowly and last a long time. An acute infection can turn into a chronic disease, for example, hepatitis B. In recurrent infections the same germ is responsible for each episode. Relapses typically occur if there is an underlying disease or an immune deficiency. Latent infections extend over a long period of time with asymptomatic intervals in between. Thus people with syphilis or leishmaniasis can stay free of symptoms for years. The same situation is found in HIV infection; AIDS usually develops after a long temporary delay. So-called opportunistic infections only occur under particular circumstances, for example, in persons with a weakened immune system. Some pathogens can remain dormant for long periods, but, if anything causes pressure on the immune system an outbreak of the disease can result. Such negative influences can be stress, a medicinal suppression of the immune defense (e. g. corticosteroid therapy following transplantation) or the onset of immune deficiency. In general, with the recovery from an infectious disease, the pathogens are completely eliminated by the body's defense mechanisms. However, some previously infected individuals continue to expel pathogens after they become asymptomatic; they are called (permanent) shedders.

Defense Against Infectious Diseases

When a pathogen comes into contact with a host, it is recognized as a foreign substance, as an antigen. The macroorganism grapples with the germ and – most probably – tries to eliminate it. One has to differentiate between specific and non-specific means of defense. The skin is a part of the non-specific defense system. Its horny layers and its acid pH-value form a barrier, which hinders the entry of germs into the deeper layers of tissue. Spittle and tears contain lysozyme and other substances, which are able to kill bacteria or impede their growth; gastric acid can also kill various microorganisms. The ciliary cells of the upper respiratory tract waft incoming particles back up the tract. If pathogens reach the circulatory system, they are ingested by "eating cells" (phagocytes) and – if possible – killed. Additionally, blood serum contains proteins which form the complement system that supports the functions of non-specific defenses. The specific defense systems consist of two components: B-lymphocytes representing humoral defense and T-lymphocytes cellular defense. Contact with an antigen stimulates the lymphocytes to build antibodies (immune globulins, Ig), which are specifically directed against this antigen. While antibodies produced by the B-lymphocytes are released into the blood, antibodies produced by T-lymphocytes multiply at the cell membrane. T-lymphocytes directly interact with the antigen; the destruction of the pathogen is supported by macrophages. In a number of defense processes, B- and T-lymphocytes work together. In this cooperation, T-lymphocytes can either support (helper T cells) or suppress (suppressor T-cells) the activity of B-lymphocytes. After contact with an antigen, both B- and T-lymphocytes build memory cells. If a new contact with the same antigen occurs, the memory cells guarantee a quick response of specific defense mechanisms by releasing antibodies or immunocompetent T-lymphocytes. In immunocompromised individuals, the humoral, the cellular or both mechanisms of defense can be impaired.

Symptoms of an Infection

Inflammatory reactions are typical symptoms of infectious disease. Even in ancient times, the characteristics "dolor, rubor, calor et functio laesa" (pain, redness, heat and loss of function) were described. However, the inflammatory response can occur for other reasons than infection. Many infectious diseases also cause general feelings of illness, exhaustion, headache and rheumatic pains. Another common symptom is fever. Especially in children, a sudden increase of body temperature has to be expected. Further symptoms are due to the localization of the infection. Upper airway infections lead to colds with coughing and sneezing and may be accompanied by hoarseness and swallowing difficulties. When the lower respiratory tract is involved, sputum production and difficulties in breathing can occur. Infections of the gastrointestinal tract cause stomach ache or cramps, nausea, vomiting and diarrhea. If the central nervous system is affected then headache, impaired consciousness and neurological disorders predominate. Infections of the urogenital tract are characterized by discharge, burning micturition and itching.

Extension of Infections

When the infection is confined to the site of pathogenic entry it is called a local infection. The symptoms are restricted to a limited area, for example, wound infections. Moreover, ► sexually transmitted diseases (STD), like gonorrhea, trichomoniasis, condylomas and herpes genitalis, often initially only appear at the place of entry, e. g. the genital organs. If the whole intestinal tract can be taken as a single unit, then most diarrheal diseases and worm infestations could be classified as local. A focal infection is said to have occurred if pathogens travel to other organs via the blood. Some species of streptococci are known to spread into other organs when insufficient treatment has been given; specifically, they cause inflammation of cardiac valves and kidneys. After ingestion, flukes wander into various organs, where they cause symptoms; most frequently, liver and lungs are involved. The spread of pathogens throughout a whole organ system, or even over the whole organism, is called systemic infection. An inflammatory reaction, which concerns the whole body (SIRS = systemic inflammatory response syndrome), is called sepsis. Sepsis entails bacteremia, tachycardia, a changed body temperature (fever or hypothermia) and a changed white cell count (> 12 cells/nl or < 4 cells/nl).

Infectious Diseases Related to Organs and Organ Systems

Certain organs or organ systems are especially affected by infectious diseases. These are the airways and the gastrointestinal tract. Respiratory tract infections, which are most frequently transmitted by droplets, range from simple colds to severe pneumonias. Airway infections also include ► influenza and avian influenza. Another disease, which primarily concerns the lungs, is tuberculosis (► tuberculosis and other mycobacterioses). Respiratory tract infections are found in every age group. Worldwide, 3.9 million people die due to airway infections every year, further 1.6 million deaths are caused by tuberculosis. Pertussis is responsible for 300,000 deaths yearly. It is most dangerous for babies, as in this age group the infection can cause apnea. Due to infections in the pharyngeal region, especially in small children, a swelling of the mucous membranes leads to an impairment of ventilation in the middle ear, which results in the development of otitis media. A common form of gastrointestinal infection is diarrhea, which worldwide causes 2.2 million deaths a year. Diarrheal diseases, which are nearly exclusively transmitted fecal-orally, principally concern children. In general, the severity of the infection is determined by the amount of fluid loss. Due to a lack of therapeutic facilities, a great number of deaths occur in the developing countries. Infections of the liver usually do not show a deadly outcome in the acute phase; the problems arise when the disease turns chronic and progressive organic failure ensues. In comparison with other systems, infectious diseases of the central nervous system are quite rare. Unfortunately, these infections often show a more serious course. In a number of cases, persistent defects with neurological sequelae have to be expected. Some of the ► sexually transmitted diseases (STD) primarily or exclusively affect the genital organs, like herpes genitalis, condylomas or trichomoniasis, others spread into adjacent tissues or organs (like gonorrhea). Syphilis, which at first only concerns the genitals, can affect nearly all organs during the later stages of the disease. Hepatitis B and AIDS are sexually transmitted diseases which do not manifest in the genital organs at all. Infections of the muscular and skeletal systems, kid-

neys and lower urinary tract are not major public health issues as they have low transmissibility; these diseases are not transmitted from one individual to another, so there is no fear of spread to large groups of people.

Diagnostics of Infectious Diseases

Taking a case history and recording clinical features is the first step in the diagnosis of an infectious disease. For instance, typical childhood diseases, like chicken pox or measles, demonstrate characteristic rashes from which diagnoses can readily be made. The responsible pathogen does not always have to be detected by using expensive laboratory procedures; diagnostic costs should be reasonable. However, if therapeutic benefits are dependent on identification of a pathogen then any necessary investigations should be undertaken. But, in certain given situations, the expense of detection cannot be justified because it is hardly ever successful, e. g. countless numbers of viruses could be responsible for simple upper airway infections.

Some parasites, like lice, are visible with the naked eye, and it is also not difficult to diagnose an infestation of worms, like ascarides or pinworms, when they appear in the stool. Proglottides, which are segments of tapeworm, are also easily recognized, although worm eggs need to be detected microscopically.

Infections can be diagnosed by identifying the pathogens found in various body substances. To begin with, body fluids, like blood, urine or cerebrospinal fluid, can be examined. Most of the germs that cause gastrointestinal infections are detected in the stool. Moreover, sputum, pus, wound secretions or punctates of effusions can be used as well as samples from surgical interventions, biopsies or autopsies. Smear tests can be taken from different regions of the body (nose, throat, rectum, wounds).

Sampling and consignment of material must satisfy particular requirements. The transport container must be sterile, otherwise the sample may be contaminated by other pathogens. If the expected pathogen is sensitive to environmental influences, then further conditions might be necessary, like correct timing of sampling, special nutrient media, humidity, immediate processing, or transport at a definite temperature. An explicit labeling of the sample is necessary to ensure its correct allocation. The label has to contain the location from which the sample was taken and the patient's particulars. Blood agars and other media are used to culture bacteria and fungi. Large colonies can be seen with the naked eye, and the pattern of growth can lead to the identification of the bacterial family. Following staining a more detailed analysis can be performed under the microscope. Once a pure culture of bacteria has grown, the efficiency of antibiotics can be tested in vitro; depending on the impairment of bacterial growth, an antibiogram is made. Tuberculosis infection can also be detected by a skin test. Viruses grow in cell cultures, but they are only visible using electron microscopy. For clinical use, it is more practical to detect viruses by other methods.

Serological tests are based on antigen-antibody-reactions, which can be detected or made visible by various means, such as, complement binding reaction (CBR), hemagglutination inhibition test (HIT) and neutralization test (NT). Tests, which provide a differentiation of the immunoglobulin classes IgM, IgG and IgA, are immunfluorescence test (IFT) and enzyme immuno assay (EIA). The so-called "titer" is detected by stages of dilution. The titer is the highest dilution at which a reaction can clearly be seen. A 4-fold increase in titer within 10–14 days can be taken as proof of an acute infection. Besides serological methods, molecular biological tests can be used for the detection of pathogens. The presence of bacterial or viral nucleic acids can be proved by PCR (polymerase chain reaction) or LCR (ligase chain reaction); moreover, gene probes can be used.

Therapy of Infectious Diseases

The ► therapy of infectious diseases depends on the microorganism itself and on the individual features of the macroorganism. Because of a person's age, constitution or state of immunity, one and the same germ can cause an infection to take different courses, which might require varying therapeutic measures. Symptomatic and specific or causal treatments can be differentiated. Often a combination of therapy is necessary. Symptomatic therapy treats the symptoms of an infection, for example, fever, pain and fluid loss. A causal or specific therapy is directed against the pathogen itself. While there is a great number of effective antibiotics and chemotherapeutics for the treatment of bacterial infections, viral infection causal treatments are restricted to a few substances. In the industrialized countries,

one can treat symptoms and administer antibiotic and antiviral drugs even if the treatment is very expensive. Whereas in developing countries even necessary therapies cannot be carried through due to a lack of resources; as a result treatable infectious diseases may prove lethal.

Prevention of Infectious Diseases

Prophylactic measures aim at the avoidance of infectious diseases. General means of prevention are a healthy nutrition, a sufficient standard of living and a balanced way of life. A predisposition towards infectious diseases can be increased by various psychological or physical stress factors weakening the immune system. In socially underdeveloped regions, infectious diseases spread easily. These regions are not only found in the developing countries, but also in the slums or other poor districts of cities. Wars, refugee movements, impoverishment and the breakdown of public health systems facilitate the development of infectious diseases. Reducing poverty and bringing about peace in war-torn countries are thus important measures in the prevention of infectious diseases.

Preventative measures can be divided into exposition- and disposition prophylaxis. Exposition prophylaxis aims at avoiding contact with pathogens. It involves general protective measures, hygienic rules and recommendations that deal with infected humans or animals. All these measures help to stop the spread of an infectious disease. However, the success of preventative measures depends on a sufficient public knowledge about the characteristics of a given pathogen and its mode of transmission. In the case of sexually transmitted diseases, social taboos can be a hindrance to providing the population with the necessary information. A lack of appreciation of the problem and a high readiness to take risks makes sexually transmitted diseases a big problem among teenager and young adult groups. Large-scale educational campaigns primarily only deal with AIDS and give less attention to the other sexually transmitted diseases.

To avoid the bites of disease transmitting insects in tropical regions, various measures are recommended: the use of repellents, the wearing of covering clothing and the use of mosquito nets. As most of these insects are night-active, it is best to avoid being out of doors in the evening and at night. In tropical regions, people are warned not to bathe in stagnant waters to avoid the risk of infection by *Schistosoma (Bilharzia)*. Animals are another source of possible infection especially if in close contact, e. g. sharing living accommodation, or if professional work brings an individual into daily proximity (animal keepers, veterinarians or farmers).

Hygienic rules and instructions apply to the private sphere as well as to the food industry, waste- and effluent disposal systems and the public health system. Besides washing with clean water, the recommendation “cook it, boil it, peel it, or forget it” plays an important role wherever foodstuffs may be contaminated by pathogens, especially fecal germs. As pathogens reproduce more quickly at higher temperatures, there is a greater risk of fecal-orally transmitted infectious diseases (► food-safety and fecal-orally transmitted infectious diseases) in warmer countries. Where the water quality is poor and there is fecal contamination, waterborne infectious diseases can occur (► water quality and waterborne infectious diseases). In the prevention of transmissible diseases the guarantee of a sufficient supply of drinking water is of great significance. As for the food industry, special regulations have to be followed to avoid transmission of infectious diseases to/from employees and to keep products germ free. Due to the possibility of high contamination with pathogenic microorganisms, waste and sewage have to be strictly separated from the sources of drinking water. These conditions frequently cannot be fulfilled in the developing world and in these poorer countries, human and animal excrement often gets into the water, which is then used as a source of drinking water.

A problem, which also exists in the industrial nations, is the transmission of infections during hospital admissions. Due to the high resistance developed by hospital pathogens, these so-called ► nosocomial infections often are difficult to treat. Prevention requires that certain hygienic instructions have to be followed when dealing with patients. A transmission of pathogens on the hands of staff, or used instruments and materials, should be avoided as far as possible. In this connection, disinfection (hands, other parts of the skin, surfaces) and sterilization (instruments, gloves, surgical clothing and sheets) are important preventative measures. Standard hygienic procedures should become automatic processes. Infection control officers should enforce compliance to hygienic instructions and the achievement of quality standards.

If a contact with pathogens cannot be avoided or if a contact at least has to be expected, then disposition prophylaxis takes effect. Disposition prophylaxis aims at reducing an individual's susceptibility to pathogens. Possible measures are immunizations and chemoprophylaxis. Vaccination is classified into active (► immunization, active) and passive immunization (► immunization, passive). In active vaccination, weakened or inactivated pathogens, antigenic parts or germ products are inoculated into an individual. The immune system responds to these substances and builds up antibodies. When active immunization is completed, any new contact with the pathogen will evoke a defensive response, the organism is immune, that means it is protected against the infection. In general, immunity lasts for several years, and in some cases it can even be lifelong. In passive immunization an immediate protection against an infectious disease is achieved by the administration of antibodies (immune globulins). This kind of vaccination can be performed, within a certain time limit after contact with a pathogen, as a so-called postexposition prophylaxis. In passive immunization, the organism does not produce any antibodies of its own; the protective effect only lasts for 4–6 weeks.

Chemoprophylaxis entails the administration of antibiotics or chemotherapeutics. The best-known form is malaria prophylaxis, which is recommended for travelers going to endemic regions. Individuals who have been in close contact with people who have infections due to particular bacteria, like meningococci or *Bordetella pertussis* (whooping cough), should receive chemoprophylaxis. When congenital cardiac defects are present or a person has undergone cardiac valve replacement, antibiotic prophylaxis should be performed to prevent endocarditis, whenever surgical or dental interventions with gingival bleedings are necessary (Kirch 2003). Further indications for chemoprophylaxis are the presence of certain immune deficiencies, chronic diseases and vesicoureteral reflux (VUR). Moreover, splenectomized persons should receive an antibiotic prophylaxis.

Summary

Infectious diseases are caused by viruses, bacteria, fungi, protozoa, prions or parasites. These pathogens get into the human organism by different routes. The severity of the infection can vary from hardly noticeable to lethal. The human race has always been confronted by pathogens; infectious diseases have shaped and still shape society and contemporary history. Even in wealthy countries they have been the most frequent cause of death for thousands of years. Up to the 19th century the cause of infectious diseases was unknown and the measures which were performed could only be justified empirically. Then, thanks to the progress in microbiology, bacteria were detected as the cause of infectious diseases, vaccines were established for the prevention of transmission and effective treatments were developed. Modern diagnostic methods enable the detection of a great number of pathogens. Due to the variety and the mutability of microorganisms, new infectious diseases can still appear or well known diseases can become more difficult to treat because of the development of resistances. Thus, concerning diagnostic, therapeutic and prophylactic measures, the fight against infectious diseases remains a challenge for medical science. With the rising mobility of people, infectious diseases have become a subject of worldwide interest. As well as regional and national documentation and control, a worldwide network of surveillance and global recommendations concerning outbreak management is useful. A big problem, which particularly has to be faced in the developing countries, is the discrepancy between the measures which can theoretically be performed, and those, which – due to restricted resources – are actually available.

Infectious Diseases Control Law

ADEM KOYUNCU
Mayer Brown LLP, Cologne, Germany
akoyuncu@mayerbrown.com

Synonyms

Contagious diseases control law; Communicable diseases control law

Definition

Infectious diseases control law comprises the legal rules that are aimed at the prevention, detection and abatement of infectious diseases and the health risks resulting from such diseases. These legal rules regulate a central field of public health law.

Basic Characteristics

Background

Government activities to control and combat infectious diseases probably form the "oldest field of public health" (Grad 1990). Correspondingly, infectious diseases control law is probably the oldest branch of public health law. Many of the earliest public health interventions relate to the control of infectious diseases. In the Middle Ages, the plague (the black death) was devastating to Europe, leading to millions of deaths. In the 14th century, so-called "*Pestschriften*" were published in German, which translates as "*the Plague Writings*". These documents among others provided instructions to avert the risks of a plague epidemic and stand for early "epidemics-police" related activities (Schumacher and Meyn 1992). The instructions included notification of the disease, isolation of infected persons, quarantine for areas or whole cities, protective clothes for doctors and prohibition of immigration from plague affected places (Schumacher and Meyn 1992). In light of the plague threats, administrations and communities in the Middle Ages implemented measures like quarantine and isolation, which are still central tools in contemporary infectious diseases control. Many other infectious diseases (e. g., smallpox, tuberculosis, pneumonia, venereal diseases, AIDS) have played central roles in the development of public health and public health laws.

Infectious diseases are still a major practice area of contemporary public health. All jurisdictions have tak-

en measures to battle against infectious diseases and to prevent epidemics. Constitutions in some countries (e. g., Germany) even grant explicit authorization to control and abate communicable diseases. As with all other branches of public health law, infectious disease control laws also have certain characteristics.

General Legal Remarks

Public health actions to control infectious diseases have various sensitive contact points with individual rights. Some measures, like compulsory hospitalizations, significantly invade the individual's fundamental rights and autonomy. Legal measures to control infectious diseases may curtail numerous basic rights. The personal freedoms and rights regularly affected include personal autonomy, the right to privacy, the right to personal liberty, the freedom of movement, the right to bodily integrity and the freedom of religion, profession and occupational exercise as well as property rights. In light of the legal importance of these rights, public health actions must rely on law. This means that such actions need sufficient legal authorization and prior procedural and substantive legal balancing. Actions affecting constitutional rights must be based on law and are limited by the principle of proportionality as outlined in the essay on legal balancing of conflicting rights. As this area of public health operates very close to the individual's sphere, it is under regular scrutiny by affected individuals (by litigation) as well as the general public. Infectious diseases control laws are interwoven with several other branches of public health law. As such, the legal regulation of some products is close to the control of infectious diseases, particularly the regulation of drugs, vaccines and food. Food regulation laws are particularly aimed at the control of foodborne infectious diseases (e. g., botulism, enteric diseases, typhoid fever) and have significantly contributed to the reduction of these diseases (Kux et al. 2007). Infectious disease control laws are intertwined with the regulation of professions and businesses (e. g., health professionals, cooks, restaurants, food-processing businesses). In addition, environmental laws unfold supportive effects on the control of infectious diseases (e. g., water regulation). As another example, infectious disease regulation also has contact points with criminal law, which becomes apparent when reviewing court decisions that punish infectious persons who negligently or intentionally infect others (e. g., HIV-positive individuals having unprotected intercourse without disclosing their infection). Criminal law and tort law may also become relevant if public health officials enforce infectious disease control measures that are disproportionate and violate individual rights. The officials may be criminally prosecuted and they – together with their agency – may be liable for damages. In conclusion, infectious disease control operates in a complex and sensitive legal surrounding.

Traditionally, the laws related to the control of infectious diseases focused on the detection, treatment and combat of infectious diseases. Over time, this focus has shifted and nowadays additionally includes the prevention of infectious diseases. In contemporary public health practice, the prevention of infectious diseases is as important as the detection and handling of disease outbreaks. In most jurisdictions, the infectious disease control laws differentiate gradually between public health measures to prevent, to detect and to treat communicable diseases. Therefore, the legal means provided in this field will be discussed below based on this distinction.

Laws for Infectious Diseases Prevention

Law provides for infrastructural and operational public health means that also assist infectious disease prevention (*See* Gerberding et al. 2003; Gostin 2000). With respect to infrastructural means, law provides for the infrastructural creation of specialized regulatory agencies in charge of surveillance and the control of risks arising from the various sources. As such, the agencies in charge of food safety enforce strict food laws and take steps to combat foodborne diseases. Other agencies are in charge of vaccines or pharmaceuticals (e. g., antibiotics, antiviral drugs). Additionally, law allows the creation and funding of scientific institutions that conduct research to better understand illnesses and develop prevention strategies.

As *operational means*, law grants authority to fund information and health promotion campaigns. In the realm of infectious diseases control, worldwide campaigns for safer sex for the prevention of sexually transmitted diseases, particularly, HIV, are a well-known example. Information and education of the population is an increasingly important tool of contemporary public health. For prevention of infectious diseases (partic-

ularly, HIV/AIDS, hepatitis), the law also grants authority and funding for the supply of sterile needles to drug addicts.

Vaccinations are the central tool of infectious diseases prevention. The success of vaccinations is valued as one of the great public health achievements in the 20th century (CDC 1999). The immunization of the population (or parts of it) against certain pathogens has not only contributed to the battle against numerous infectious diseases (among others, the eradication of smallpox); vaccinations have also been subject to numerous lawsuits and legal disputes. Maybe the most influential decision was issued by the U.S. Supreme Court in 1905 when it decided the case of *Jacobson versus Massachusetts*. There, the court upheld mandatory smallpox vaccination in Massachusetts, which Reverend Henning Jacobson had challenged. The confirmation of the constitutionality of compulsory vaccinations by the U.S. Supreme Court significantly promoted the vaccination practice. This contributed to infectious diseases control in the past century and bolstered other areas of public health laws (Parmet et al. 2005). For example, in some jurisdictions mandatory vaccinations are provided before school admission or before taking on certain employments. In most jurisdictions, there are also laws that provide incentives for voluntary vaccinations.

For the prevention of infectious diseases, laws impose restrictions on access to certain professions. In most jurisdictions, carriers or persons under suspicion of being infected among others with the pathogens causing cholera, typhoid fever, hepatitis A or hepatitis E, will not be allowed to work in businesses or locations where food is processed. The same is true for eliminators of these germs. Therefore, it is part of infectious disease prevention that all persons are medically examined before carrying out or starting such employments. In addition, professional work with pathogens is normally limited by law. Regularly, such work is only allowed with a corresponding license granted to a limited group of professions like specialized medical doctors or microbiologists. Here, public health law limits the freedom of professional conduct in the name of the protection of the population.

Another part of infectious diseases prevention encompasses legal means that abate sources of infections. As an example, for the prevention of the spread of HIV/AIDS, in 1986 the Supreme Court of New York upheld the closure of the bathhouse New St. Mark's Baths in New York City. The closure was ordered by the administration as homosexual men met in the bathhouse and practiced high-risk sexual activities on a regular basis (Supreme Court of New York 1986). Such measures collide with the economic and professional rights of the bathhouse holder and the personal rights and freedoms of the bathhouse visitors (*See* Gostin and Jacobson 2006). The court's decision contains legal balancing between these rights and interests with the community interest in disease prevention.

Prevention of infectious diseases may also include advising partners of infected persons of the infection if there is reason that the infected will endanger them. Conversely, criminal laws prohibit and punish the negligent or willful infection of sexual partners by infected persons and, in this way, deter persons from such acts and contribute to the prevention of infectious diseases.

Laws for Infectious Diseases Detection

For infectious diseases detection, the establishment of a regulatory agency infrastructure is necessary. These agencies must be authorized to carry out surveillance and to collect information even if it is sensitive information affecting privacy. A central tool of infectious diseases detection is the establishment of a reporting system to obtain information about infectious persons and disease outbreaks. Most jurisdictions provide for laws imposing reporting and notification obligations on medical doctors, laboratories and other health professionals when they notice certain infectious diseases. For many diseases, laws impose duties to report the infection and personal information about the carrier. For some infections, it is sufficient only to report the infection without personal information. Such reporting obligations not only affect the privacy of the infected but also affect the freedom of occupation of the reporting health professionals.

Law also allows screening examinations in certain professions and population groups. The screening of pregnant women for a number of infectious diseases, including HIV-infection, is one example. The screening of schoolchildren, health professionals, prostitutes or food processing professionals are further examples.

Compulsory medical examinations and testing as well as involuntary commitment or hospitalization are means provided by law for the detection of infectious

diseases. These actions infringe the personal rights and freedoms of those persons suspected of being infected (Grad 1990; Gostin 2000). Therefore, such actions need sufficient legal authorization. Without such authorization, the conduct of compulsory examinations and compulsory hospitalizations would lead to criminal prosecution of the public health officers. If it turns out that the suspected persons were infected, laws must allow tracing of contacts and identification of persons potentially infected by the carriers (Gostin and Jacobson 2006; Moulton et al. 2007). Contact tracing, however, affects the privacy rights of the contact persons and of the infected person. Therefore, such action must be allowed by law.

Laws for Infectious Diseases Combat

Law provides tools in case of detected infectious diseases. Well-known instruments of infectious diseases control include the isolation of infected persons or the quarantine of potentially infected persons. Isolation and quarantine may be imposed on a mandatory basis as well as on a voluntary basis. Infected persons may be subject to involuntary commitment or hospitalization. Within hospitalization, they may be offered medical treatment. If necessary and if the person refuses such treatment, public health officials may order compulsory medical treatment if the disease would otherwise pose a significant risk. Such compulsory medical treatment combined with involuntary confinement is probably the most intrusive tool of infectious disease control. Therefore, it can only be applied in very few cases, where strict criteria are fulfilled (Gostin 2000; Grad 1990). Among others, the compulsory treatment must be performed *lege artis* and be in the interest of the infected as well as the community. According to legal balancing rules, the treatment must be effective in combating the risks and must be the least intrusive alternative.

The diagnosis of a contagious disease may lead to additional personal restrictions. Corresponding to the preventive measures above, a person may not be admitted or may no longer be allowed to practice professions in areas where the infection may cause health threats (e. g., food processing professions, health professions). Persons can even be subject to a ban from a profession. To cope with epidemic threats, governments and public institutions buy large amounts of antibiotics and other medications in order to be prepared for emergencies. Similarly, most governments have stocked up on vaccines. Against the background of the risks resulting from bioterrorist attacks, governments have also built stocks of antibiotics and antitoxins against relevant pathogens (*See* in the U.S. the "Strategic National Stockpile"). Such additional infectious disease control activities also need legal foundation, as the government must be authorized to pursue such measures, including their funding.

Perspectives

Infectious diseases control law has always been a major part of public health law. These laws increasingly focus on disease prevention. Contemporary infectious diseases control laws face new challenges from new pathogens and new disease mechanisms (e. g., SARS, avian influenza virus, HIV/AIDS). In addition, worldwide globalization and increased mobility and travel further facilitate the spread of (old and new) communicable diseases. As noted above, there are also new types of human-made public health threats, which particularly include bioterrorism.

Many of these new threats call for modifications of the traditional infectious diseases control strategies. They particularly call for intensification of international public health strategies; more so as most of these threats have to be regarded as global threats and not purely national issues. Therefore, international legal documents to combat infectious diseases like the International Health Regulations of the WHO may gain increasing relevance (*See* Gostin and Jacobson 2006). To a certain extent, globalization of infectious disease control laws should be underway. In summary, infectious diseases control law, which belongs to the oldest branch of public health, will remain a central part of public health practice and public health law.

Synonyms

Infectious diseases in childhood; Childrens' diseases; Childhood diseases

Definition

Due to their frequency in childhood, infectious diseases play an important role in pediatrics. They are divided into infections that exclusively or predominantly appear in children, or at particular stages of childhood (e. g. newborns or babies), and those which occur both in children and adults. The severity of an infectious disease can vary considerably at different phases of life.

Basic Characteristics

Special Features in Pediatrics

Children are not simply little adults. Even though they are targets of the same pathogens as adults, the consequences of an infection for children can be quite different. As the body surface is relatively greater in children, as is the percentage of water, clearly when replacement is required there is a relatively higher need for fluids and electrolytes per kilogram body weight. The younger a child is, the more it is endangered by fluid loss due to feverish infections or diarrhea.

At the time of birth, the immune system is still immature; thus infectious diseases in newborns and young babies can have severe or even deadly consequences. Pathogens can be transmitted intrauterinally, leading to congenital infections. On the other hand, directly after birth, children are protected against several – predominantly viral – infections by maternal ► antibodies, which they received intrauterinally. This so-called ► nest protection lasts for a couple of months.

As to the treatment of infectious diseases, again differences between children and adults are to be found. Besides the special features regarding ► body fluid balance, the treatment of infectious diseases in children can present specific problems, e. g. antibiotics can have developmental side-effects (like discoloration of teeth due to tetracyclines or damage to connective tissue and cartilage due to gyrase inhibitors) and several drugs are not licensed for children, due to a lack of evidence-based experience or for other reasons.

Even the transmission of infectious diseases has special pediatric features. Children often attend communal services (day-nurseries, kindergartens) or spend long

hours in large groups (for example in school or sports clubs). Their play and social behavior is characterized by close contact. Especially in younger children, there often is a common use of toys and other objects, like hygienic articles, dinner-services and drinking vessels; meals are frequently eaten together, sweets are often shared by biting off or licking. Due to these special environmental and behavioral conditions, the risk of transmission of infectious diseases is considerably increased. The close contact enables the spread of those organisms which need direct contact for their transmission, like ► lice (primarily head lice) and ► scabies. Early childhood is thus a time of exposure to highly contagious infectious diseases. A further aspect which has to be considered is the lack of, or at least an insufficient, knowledge of hygiene in children which puts them at high risk of the ► fecal-orally transmitted diseases.

The liability to infectious diseases is increased by insufficient nutrition. This factor is particularly significant in developing countries.

In infectious diseases, children often develop ► fever, and in younger children, ► febrile seizures frequently appear. An inflammation of the bones (osteomyelitits) has to be taken very seriously in childhood as damage to the epiphysis can impair bone length growth. Due to their mode of transmission, ► sexually transmitted diseases (STD) do not play a significant role in the field of pediatrics, however, on the one hand, some of the STDs can be transmitted to the child during pregnancy or birth, and, on the other hand, due to promiscuity and child prostitution, these social diseases do occur in children. Also, sexual abuse has to be taken into consideration.

Classic Childhood Diseases

Diseases, said to be classic childhood diseases, fulfill typical conditions: they are highly contagious (without preventive measure they appear in more than 90% of all children up to the age of five), and they usually leave a lifelong immunity.

Most of the pathogens are viruses. Since there are only restricted possibilities concerning the treatment of viral infections, active vaccination (► vaccination, active) plays a significant role in the prevention of childhood diseases. Vaccination programs concentrate on the first 18 months of life with boosters – or ► indication vaccinations – being given later in life. Consistent execution of the recommended vaccinations is still important.

Infectious Diseases in Pediatrics, Figure 1 Membraneous tonsillitis in infectious mononucleosis; photo kindly provided by Prof. Wilhelm Kirch, Dresden

The term "childhood diseases" sounds harmless and children's diseases are overcome without consequences in a high percentage of cases, but complications are possible and, at times, the diseases can be anything but harmless. For example serious infections are found in immunodeficient children; furthermore, childhood disease occurring later in life (in teenagers or adults) can run much more severe courses. As an example of the perilous nature of a childhood disease one has just to look at the history of ► measles. In the 16th century, the virus was brought to America by the Spanish conquistadores. As the natives did not have any means of defense (antibodies) against the disease, an outbreak of measles occurred leading to a great number of deaths. Besides measles, ► whooping cough, ► mumps, ► rubella, ► chicken pox, ► poliomyelitis and ► diphtheria belong to the classic childhood diseases. Other infections, which are commonly found in children, are ► erythema infectiosum, ► exanthem subitum, ► infectious mononucleosis (Fig. 1) and ► scarlet fever (Fig. 2). ► Tetanus is a transmissible disease, which can occur at any stage of life; the infection can be prevented by active and – if necessary – passive vaccination, even in babies.

Congenital and Neonatal Infections

In congenital infections, the pathogens have been transmitted to the unborn child via the placenta. In gener-

Infectious Diseases in Pediatrics, Figure 2 Early development of raspberry tongue in a 7-year-old boy with scarlet fever (2nd day of disease) (Lentze et al. 2002)

al, infections of the fetus only occur when the mother has no antibodies against the disease. As sensitivity to the different germs varies during pregnancy, the time of infection significantly determines the extent of the damage suffered by the unborn child. The important congenital infections are ► toxoplasmosis, rubella (► congenital rubella syndrome (CRS)), ► erythema infectiosum (► congenital erythema infectiosum), ► cytomegaly (CMV) (► congenital cytomegaly (CMV)), varicella (► congenital varicella) and syphilis (► congenital syphilis). If a newborn baby is suspected of having a congenital infection, a ► TORCH serology can be performed. Malaria can also be transmitted during pregnancy; but this problem quite exclusively concerns non-immune pregnant women who undertake a journey to tropical or subtropical regions. Since the 1980s, congenital ► HIV-infection and AIDS have gained in significance. Further congenital infections, which have to be mentioned, are ► hepatitis B infection and ► congenital listeriosis. Directly before or during birth, the child can be infected with germs from the mother's genital tract. Thus, infections with *Listeria* (► congenital listeriosis), herpes-simplex viruses (► congenital herpes-simplex infection), gonorrhea (► congenital gonorrhea), syphilis (► congenital syphilis), *Chlamydia trachomatis* (► *Chlamydia trachomatis* infection) or *Ureaplasma urealyticum* (► *Ureaplasma urealyticum* infection) can occur. Infections in newborns develop if amniotic infection syndrome or a premature rupture of the amnion is present. Ascending pathogens get into the amniotic fluid and are swallowed by the baby. They are resorbed in the intestinal tract and spread via the blood vessels. Often, the symptoms of a neonatal infection are non-specific (reduced muscle tonus, changed skin color, instability of body temperature) and require great experience on the observer's behalf. The most common pathogens in the first three days of life are Group B streptococci (GBS), *E. coli* and *Klebsiellae*. *Listeria* monocytogenes also play a certain role in neonatal infections. As the infecting pathogen is generally initially unknown, a fixed regimen of a combined antibiotic therapy is prescribed.

Respiratory Tract Infections

Respiratory tract infections are the most frequent infections at all stages of life (see sysnopsis), but there are some special features relevant to childhood. During the first 10 years of life, on average, every child falls sick with 3–8 respiratory tract infections every year, without an underlying increased liability to infections. Transmission takes place by droplets or direct contact with contagious secretions. Apart from time spent in communal services (kindergartens, schools), passive smoking is a risk factor of respiratory tract infections. Due to special anatomic features, babies can suck (drink) and breathe simultaneously. As they usually nearly exclusively breathe through their noses, a simple cold with impairment of nasal breathing causes considerable discomfort. An impaired ventilation of the auditory tube (eustachian tube), which connects the pharynx with the middle ear, leads to otitis media (an inflammation of the middle ear). Otitis media is most frequently seen in younger children due to their relatively large adenoids. Chronic effusion in the tympanic cavity can impair hearing and impede language development. In cases of recurring inflammations of the middle ear surgical interventions may be necessary, e. g. the removal of the adenoids (adenotomy), an incision of the eardrum (paracentesis) or the insertion of eartubes into the tympanic membrane. The airways of a child are narrower than those of adults. In children, a swelling of the mucous membranes leads to an impairment of breathing more readily than in adults. This is due to the dif-

ferences in the relative circular areas of the windpipe and bronchi ($A = \pi \times r^2$). The narrowness of the airway system plays an important role in ► spasmodic croup, which is a typical disease in younger children, as well as in bronchitis and ► bronchiolitis. The latter is frequently caused by ► respiratory-syncytial-virus (RSV) infection. ► Epiglottitis, which was feared in earlier times, nowadays seldomly occurs due to active HIB vaccination (► HIB vaccination, active). As for pneumonia, in general, the germs are the same in children as in adults, but some pathogens predominantly occur in particular age-groups. *Chlamydia*, for example, causes pneumonia in newborns, only plays a minor role in younger children, and again becomes more frequent in schoolchildren. In comparison with the incidence in adulthood, ► tuberculosis is quite rare in children.

Infectious Diseases of the Gastrointestinal Tract/Enteritis

Usually, infections of the gastrointestinal tract are ► fecal-orally transmitted diseases, with pathogens being swallowed in food, ► contaminated drinking water or after finger-to-mouth direct contact with the source of infection. The responsible germs are the same in children and adults but, due to the special features of children's anatomy and physiology, social associations and social behaviors, infectious enteritis is much more frequent and often takes a more serious course in childhood than in adulthood. As for babies and small children, enteritis due to rotavirus (► rotavirus infection) or ► Norwalk virus infection have to be mentioned as well as ► infection with *Clostridium botulinum* which is particularly dangerous in babies. To prevent rotavirus infection, an active rotavirus vaccination (► rotavirus vaccination , active) is available.

Urinary Tract Infections

Urinary tract infections are a common disease in childhood. In newborns, the infection is most frequently caused by a hematogenic spread (via blood vessels); in later age groups, infections usually ascend from the lower urinary tract. The severity of disease depends on whether infections concern the bladder (cystitis) or affect the kidneys (pyelonephritis). The appearance of urinary tract infections or of relapses is facilitated by anatomical abnormalities and functional disorders. The younger a child is the less specific are the symptoms. During the first months of life, urinary tract infections often present as a septic disease. Up to the eighth year of life, general symptoms of illness predominate, e. g. loss of appetite, stomach ache and an increased body temperature. Older children primarily report local symptoms, like frequent micturition (polyuria), dysuria or burning micturition. During urinary tract infections, a child, who is usually dry, may suffer nocturnal enuresis (bed-wetting). More than 80% of urinary tract infections are caused by *Escherichia coli*. *Proteus mirabilis*, *Klebsiella pneumoniae* and enterococci each are responsible for 3–5% of the infections. Diagnosis is made by the detection of an elevated amount of pathogens in the urine (>10^5 germs/µl in ► midstream urine). In younger children, urine usually has to be collected in plastic bags with an adhesive paper on one end; thus contamination is an easy possibility. Therapy depends on the severity of the infection and the sensitivity of the pathogens. In general, trimethoprim, aminopenicillins and cephalosporines are used. To avoid urinary tract infections, intestinal pathogens should be prevented from reaching the opening of the urethra. Particularly in girls, one has to pay attention to the correct cleansing of the anogenital region: it has to be wiped from the front to back and rubbing should be avoided. It is important to teach children this technique during their toilet training. In cases of known anatomical abnormalities, functional disorders or other risks of recurrent urinary tract infections, an antibiotic relapse prophylaxis may be necessary; usually, trimethoprim, cephalosporines or nitrofurantoin are prescribed.

Encephalitis/Meningitis

An inflammation of the brain tissue (► encephalitis) can be caused by a number of pathogens. While most infections can appear in all age groups, encephalitis due to ► congenital herpes simplex infection and congenital ► toxoplasmosis are more prevelant in newborns. Up to 65–80% of the bacterial inflammations of the membranes that envelop the brain (► meningitis) occur in childhood, especially during the first two years of life. In newborns, meningitis is treated with a combination of a 3rd generation cephalosporine (cefotaxime) and a broad-spectrum penicillin; for later age groups, ceftriaxone monotherapy is prescribed.

Septic Courses of Diseases

A ► sepsis is a systemic inflammatory reaction, which can lead to shock and organ failure with a possible lethal outcome. It is not very common in childhood; but one has to be prepared for sepsis in pediatric oncology and intensive care medicine. A feared septic disease in pediatrics is ► Waterhouse–Friderichsen syndrome (Fig. 3).

Infectious Mononucleosis

Synonyme

Mononucleosis Infectiosa; Glandular fever; Pfeiffer's disease; Monocyte angina; Infection with Epstein–Barr virus (EBV); Kissing disease

Definition

The Epstein–Barr virus belongs to the herpes group and is spread by droplets or direct contact. Following an incubation period of 8–21 days, Pfeiffer's disease starts with fever, fatigue and an angina involving the tonsils (ulcerated tonsils with white blobs); enlarged and tender lymph nodes are especially found in the cervical and occipital region and behind the ears. Furthermore, there is an enlargement of the spleen (splenomegaly) and the liver (hepatomegaly) and a mild jaundice (icterus). The infections shows a characteristic white cell count with the hallmark being so-called atypical lymphocytes; in most cases an elevation of the liver enzymes is also seen. Therapy is only symptomatic, the administration of ampcillin can cause an intense exanthem. Possible complications are myocarditis, nephritis and central nervous system involvement (meningitis, radiculitis). Due to the splenomegaly, in rare cases a rupture of the organ can appear even without trauma or following a trifling accident.

Infecundity

Synonyms

Sterility

Definition

Infecundity refers to the inability of a woman to conceive a viable ► pregnancy or of a man to impregnate a woman.

Cross-References

► Infertility

Inferential Statistical Tests

Definition

Employs data in order to draw inferences (i. e., derive conclusions) or make predictions. Typically, in inferential statistics, sample data are employed to draw inferences about one or more populations from which the samples have been derived.

Cross-References

► Statistical Tests

Inferential Statistics

Definition

Inferential statistics are statistical methods that make it possible to draw tentative conclusions (inferences) about a population based on observations of a sample selected from that population and, furthermore, to make a probability statement about those conclusions to aid in their evaluation. Inferential statistical methods allow us to compare small random samples and then to make statements about the much larger populations they represent with known probabilities of truth. Inferential methods typically take the form of confidence intervals and statistical tests.

Infertility

JANINE BARDEN-O'FALLON[1], AMY O. TSUI[2]
[1] MEASURE Evaluation, Carolina Population Center, University of North Carolina at Chapel Hill, Chapel Hill, NC, USA
[2] Population and Family Health Sciences, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, USA
bardenof@email.unc.edu, atsui@jhsph.edu

Synonyms

Infecundity; Sterility; Childlessness

Definition

Infertility is the inability to produce a ► live birth, usually after one or two years of regular, unprotected sexual intercourse. Clinically infertility is defined as one year of unwanted non-conception with unprotected intercourse in the fertile phase of the menstrual cycles (Evers 2002). There are two types of infertility: primary infertility, which is the inability to produce any live birth, and secondary infertility, which is the inability to produce a live birth after the birth of at least one child. These terms are related to fecundity, or the physiological ability to become pregnant (or impregnate a woman). ► infecundity, or primary sterility, refers to the inability to become pregnant at all, while secondary sterility refers to the inability to become pregnant after at least one conception. Frequently, infertility is used in reference to any point in the fertility process, capturing the inability to conceive, impregnate, carry a pregnancy to term, or produce a live birth.

Basic Characteristics

Levels and Trends

More than 80 million people around the world, or between 8–12% of couples, are affected by infertility at some point during their reproductive lives (Daar 2002). The majority of these people live in developing countries. Primary infertility (► infertility, primary) is the most common type of infertility worldwide, although Sub-Saharan Africa is an exception, where approximately 52% of infertile couples have been estimated to experience secondary infertility (► infertility, secondary) (Cates et al. 1985). Levels of infertility vary widely across regions and between countries. Historically, the "► infertility belt" of Central Africa has exhibited the highest rates of infertility. In past decades, infertility in these countries, which includes the Central African Republic, Cameroon, Chad, Niger and Nigeria,

is estimated to have affected as many as one-third of all couples trying to conceive.

Throughout the 1990s there has been a global reduction in the rates of primary infertility in women aged 45–49, fueled in large part by reductions of infertility in Africa. Improved nutrition in childhood is speculated to be a primary reason for declines in national infertility levels. The percent of women aged 45–49 childless in the Central African Republic dropped from 17% in 1975 to 8.4% in 1994 and in Mozambique from 12.3% in 1980 to 8.4% in 1997 (UN 2004).

A baseline of 5% of all couples is estimated to be sterile, irrespective of nationality. Table 1 shows primary infertility prevalence among women in the Sub-Saharan African region at the end of their childbearing years to be highest at 10.1%, while the lowest prevalence is among North African/Western Asian and Latin American women. Secondary infertility is relatively prevalent among women in North America, the Caribbean and Europe, ranging between 7 to 19%, with Asian women not far behind (6 to 14%).

Infertility, Table 1 Estimates of Infertility Prevalence by Region among Women 40–44 or 45–49

Region	Primary infertility %	Estimated range (%) of secondary infertility
Northern America	6.0	7–17
Caribbean	6.5	7–19
Europe	5.4	7–15
Latin America	3.1	4–9
Northern Africa and Western Asia	3.0	4–9
Sub-Saharan Africa	10.1	12–29
Asia and Oceania	4.8	6–14

Measurement

Clinical studies are the principal means by which to obtain data on cases of medically verified infertility and cause of infertility. Couples seeking pregnancy undergo physical examinations of cervical or uterine well-being and are followed up to assess semen quality, hormonal patterns during menstrual cycles and environmental exposures. Conversely, self-reports of infertility obtained from population-based studies, though medically unverifiable, can be used to measure the social burden of infertility as perceived by women and men themselves. Behavioral measures of infertility are drawn from data collected in censuses, large scale population-based surveys, vital statistics, epidemiological surveys, facility based studies, and clinical studies. Infertility is then approximated from the recorded absence of a ► live birth by age 40–44 among ever married women or from an open birth interval of five or more years among married women who are not using contraception and who do not report themselves as infecund.

Causes

Infertility can result from a number of preventable and non-preventable conditions related to the female (► "female factor infertility"), the male ("► male factor infertility") or the couple. While women are typically held responsible for fertility problems, male-factor conditions are present for at least half of all infertile couples. Non-preventable conditions leading to infertility include various anatomical, genetic, hormonal, and immunological problems that prevent a successful pregnancy. The prevalence of these non-preventable conditions do not vary much across or within populations, and are responsible for the core 5% of infertile couples. More often, infertility stems from preventable conditions and it is because these preventable conditions are more or less prevalent in any given population that variation in infertility rates can be significant. Preventable causes of infertility result from various infectious, environmental, or occupational factors. ► Pelvic inflammatory disease and ► tubal occlusions are two frequent and direct causes of infertility arising from ► reproductive tract infections.

Sexually transmitted infections (STIs) related to infertility include chlamydia, gonorrhea, trichomoniasis, and syphilis, which because of their asymptomatic nature are often not detected until permanent damage has occurred (Boerma, Mgalla 2001). The historically high prevalence of STIs in Central Africa is considered to be the main reason why infertility was so high in the region, and with the improvement of diagnosis and treatment, a main reason why infertility rates seem to be declining. HIV infection has also been linked to higher

► infecundity and intrauterine mortality. Other infectious and parasitic diseases associated with increased risk of infertility include tuberculosis, schistosomiasis, malaria, and sickle cell disease.

Certain health care procedures and practices also result in infections capable of leading to permanent damage of the reproductive tract. These include harmful sexual initiation rites and unhygienic obstetric practices in some parts of the developing world. Poor hygiene can lead to postpartum infection and sepsis, infection following the insertion of an intrauterine device (IUD), or septic abortion and subsequent complications. Largely because of the quality of health care, women in industrialized countries have a lower probability than their counterparts in developing countries of experiencing nosocomial infections that lead to infertility.

Some causes of infertility are related to exposure to potentially toxic substances found in the environment, such as arsenic, aflatoxins, or pesticides. Lower sperm count and quality have been linked to pesticide exposure. The ingestion of potentially toxic substances, such as caffeine, tobacco, or alcohol, can also result in abnormal sperm production leading to infertility.

Consequences

Infertility is a serious reproductive health problem that can have far reaching effects on women, men and communities (Van Balen, Inhorn 2002). In many cultures, infertility is highly stigmatized and can result in discrimination, exclusion, ridicule, and even abuse. In a number of societies infertility is an acceptable reason for divorce. Even in cultures where childlessness is socially acceptable, infertile couples may still struggle with feelings of inadequacy, shame, depression, and grief. Women usually bear the brunt of the blame and carry the heaviest burden of the problem.

The heavy psychological costs of infertility result in high social costs as well. Where infertility rates are high or the social consequences of infertility are severe, there is a general reluctance among women to practice contraception for fear of jeopardizing future fertility. Couples seeking help for infertility can burden limited health care resources. In cultures where traditional healers are commonly consulted, treatments can be painful, ineffective, and potentially harmful. In both developed and developing countries there has been a marked increase in the demand for infertility services, including ► advanced reproductive technologies (ART). In the United States, for example, 58,574 ART cycles were initiated in 1996 and 122,872 were initiated in 2003, an increase of almost 110% in seven years (CDC 2006). These procedures are expensive and produce a higher number of multiple births, thus increasing both the risk of serious health consequences for mothers and infants and the need for costly interventions.

Conclusion

Infertility should be an important public health concern, though it has often been treated as a "personal problem". Historically, more attention has been paid to addressing high fertility levels in developing countries rather than in assisting couples to meet their fertility goals. Infertility treatment can be costly and is not always effective. Conversely, efforts made at the prevention of infertility are less expensive and more often effective. Such prevention efforts include finding ways to assure adequate nutrition for females and to reduce ► reproductive tract infections (by increasing access to and improving STI services, implementing safer birth practices, promoting family planning, providing access to safe abortion services, etc); reducing the prevalence of endemic diseases such as malaria and tuberculosis, and providing education about the consumption of potentially harmful substances. Infertile couples who repeatedly seek help for insoluble problems place a burden on health care resources. Treating infertile couples should therefore also include sensitive counseling to avoid inappropriate treatment and discourage unnecessary help-seeking at multiple clinics; to help couples cope with the social and psychological consequences of infertility; and to help couples to consider non-medical options such as adoption.

"Infertility Belt"

Definition

The "infertility belt" is a region in Central Africa stretching from countries in West Africa to the Sudan, in which ► infertility has been estimated to affect as many as one-third of all couples.

Infertility, Primary

Synonyms

Childlessness

Definition

Primary ► infertility refers to the inability to produce a ► live birth among individuals who have never produced a live birth.

Infertility, Secondary

Definition

Secondary ► infertility refers to the inability to produce a ► live birth among individuals that have had at least one previous live birth.

Inflammation of Brain Tissue

► Encephalitis

Inflammation of Bronchioli

► Bronchiolitis

Inflammation of Conjuctiva

► Conjunctivitis

Inflammation of the Epiglottis

► Epiglottitis

Inflammation of the Liver

► Hepatitis

Inflammation of the Meninges

► Meningitis

Inflammation of Small Bronchi

► Bronchiolitis

Influenza

Synonyms

Flu; Infection with Influenza Virus

I

Definition

Influenza or flu, is an acute, highly infectious disease caused by a virus. There are three types of the virus, designated A, B, and C, but only types A and B cause more serious contagious infections. Influenza is difficult to diagnose in the absence of an epidemic, since it resembles many common respiratory ailments. It is characterized by sudden fever, prostration, weakness, and sometimes severe muscular aches and pains. Complications include bronchitis and pneumonia, that may be dangerous for infants and elderly.

Cross-References

► Influenza and Avian Influenza

Influenza and Avian Influenza

Synonyms

Flu; Grippe; Fowl pest; Fowl plague

Definition

Influenza is a worldwide infection of the upper respiratory tract, which is caused by strains of the influenza virus (A, B or C). Due to the high variability of the viruses and the resulting possibility of reoccurring epidemics and pandemics, surveillance programs and the yearly new development of an effective vaccine play important roles in the fight against influenza. Avian influenza is a disease in birds which is caused by different strains of influenza viruses; some of the subtypes can also be transmitted to humans.

Basic Characteristics

History of Influenza

In the writings of Hippocrates there is a description of an ► epidemic in North Greece with symptoms similar to influenza. The term influenza stems from the Latin word influere, which means 'flowing into' or 'creeping into.' Influenza ► pandemics have been reported since the 16th century, with the occurrence of at least 3 pandemics each century. The last century pandemics were Spanish flu in 1918, Asian flu in 1957, Hong Kong flu in 1968 and another pandemic that occurred in France and England in 1989. The worst of these pandemics was the Spanish flu, in which 500 million people were infected and about 40 million died. In 1931, the ► influenza A virus was detected in pigs by Richard Shope, in 1933, the research team of Wilson Smith, Christopher Andrewes and Patrick Laidlew detected it in humans. In 1940 the ► influenza B virus was isolated and the ► influenza C virus in 1949. Since 1945, an active influenza vaccination (► influenza vaccination, active) has been available. Because of the ability of the influenza virus to change its structure (variability), an influenza surveillance program was established by the WHO in 1946 (► WHO influenza surveillance program).

Characteristics of the Influenza Virus

Different surface glucoproteins are responsible for the antigenic qualities of influenza viruses. The most important glucoproteins and surface antigens are ► hemagglutinin (H) and ► neuraminidase (NA). Due to changes (mutations) of the glycoproteins, antibodies face difficulties in detecting the viral variants. Even if an influenza virus changes only slightly a new infection is possible. The switch of surface antigens is called antigen drift. In a simultaneous infection with two different influenza subtypes, an exchange of genetic material (genome segments) can take place. This procedure, which only seldomly occurs, is called antigen shift. Antigen shift leads to a much more pronounced change in surface antigens than antigen drift; it can result in a pandemic.

Classification of Influenza Viruses

When classifying influenza viruses, the subtype, location of first isolation, number and year of isolation are recorded. For influenza A viruses, the surface antigens hemagglutinin (HA) and neuraminidase (NA) are additionally recorded; the classification number of the subtype is noted (A/Hx Nx). Thus, the Spanish flu was classified as A (H1 N1), the Asian flu as A (H2 N2) and the Hong Kong flu as A (H3 N2).

Ways of Transmission and Course of Influenza

People often speak of 'flu' or 'the grip' when referring to harmless flu-like infections. Actually, flu is an infection with the influenza virus. Influenza is an infection of surfaces as the virus settles on the mucous membranes of the upper respiratory tract. Influenza viruses exist worldwide; they are transmitted by droplets and as direct contact or smear infections. Due to their resistance against frost, viruses can also be transmitted by contaminated water during the cold seasons. The incubation period lasts between a few hours and a couple of days; during this time infected persons are already contagious. The spread of influenza viruses, and the reason for the occurrence of pandemics, is due to the travel behavior of people or bird migration. A characteristic of influenza is its sudden onset. Usually, there is a general feeling of illness, with fever, shivering fits, headache, rheumatic pains, cough and cold symptoms. In mild cases patients recover within 1–2 weeks. Possible complications of influenza are pneumonia, inflammation of the brain (encephalitis) or the cardiac muscle (myocarditis). In severe cases acute respiratory insufficiency with an irreversible edema of the lungs can develop, which has a lethal outcome within a few hours.

Therapy and Prophylaxis of Influenza

Besides ► symptomatic therapy, influenza can be treated successfully by the administration of ► neuraminidase inhibitors. As their use requires careful assessment, amantadine (Symmetrel®, Pk-Merz®) and rimantadine (Flumandine®) meanwhile play only a minor role in influenza therapy. In cases of bacterial superinfection, antibiotics are administered. The most important prophylactic measure is active influenza vaccination (► influenza vaccination, active), which is carried out in October and November – just before the onset of the influenza season. Due to the variability of the virus, vaccination has to be repeated every year.

Occurrence and Transmission of Avian Influenza

Avian flu or fowl pest is a disease of birds, which has been known for more than 100 years. Primarily, it concerns poultry stocks. Pigeons, swallows, sparrows and songbirds are less susceptible for the infection. Fowl plague is caused by subtypes of the influenza A virus, the presence of hemagglutinin types 5 and 7 is responsible for severe courses. The subtype H9 N2, which is also found in birds, only causes mild symptoms in humans. The avian flu virus is transmitted in the feces of infected animals, primarily chicken. Humans can be infected by breathing in contaminated dust particles, having close contact with sick animals or failing to have hygienic habits (especially concerning hand washing). A high risk of transmission has to be assumed for people who live in close contact with poultry, maybe even in the same room, as well as for people who have professional contact with Galliformes (like chickenfarmers or veterinarians). Starting in Asia, infections of humans with the influenza A subtype H5 N1 appeared at the end of 2003. By the end of April 2006, worldwide, nearly 200 cases were registered by WHO; in Southeast Asia 50% took a lethal course. The symptoms and treatment of avian flu are similar to those of influenza (see above).

Prophylaxis of Avian Influenza

To prevent an infection with avian influenza, contact with ill or dead birds, especially wild birds, should be avoided. These rules of behavior should also be taught to children. The finding of dead wild birds should be reported to responsible authorities: police, fire department or the department of veterinary medicine. During the disposal of dead animals, the wearing of a protective equipment is recommended (gloves, mouth-nose mask and protective clothing). If suspicion of avian influenza in a dead animal is confirmed by laboratory tests, restricted areas (3 km) and areas of surveillance (10 km) have to be established around the location where the animal was found in order to prevent a further spread of the disease. As human infection due to transmission by dogs and cats cannot be excluded, pets should not be allowed to run free in these security areas. Moreover, feathers should not be collected. Special regulation of poultry stocking should be imposed (like a temporary prohibition of free-range farming). When journeying to regions at high risk of avian flu, people should avoid visiting animal markets and poultry farms. As influenza viruses are killed by temperatures of > 70°C, poultry products should be sufficiently heated before consumption. It has to be pointed out that fowl pest primarily is a disease in birds and that as long as the necessary security measures are followed, the risk of transmission to humans is small; thus hysteria is unfounded. Influenza vaccination does not protect against fowl

plague, but it helps to prevent a simultaneous infection by both viruses which could otherwise lead to new and possibly extremely dangerous influenza subtypes.
In conclusion, influenza and avian flu are infections of the upper respiratory tract with high fever, which are primarily (influenza) or exclusively (avian flu) caused by influenza A viruses. To avoid lethality, treatment with neuraminidase inhibitors should be introduced quickly. Surveillance programs and thought-through outbreak controls play important roles in the management of influenza and fowl plague.

Influenza A Virus

Definition

Influenza A viruses are characterized by a high frequency of genetic changes (mutations) and the formation of new groups. They are able to cause pandemics. The various subtypes of the virus prefer specific hosts. Humans and other mammals (e. g. pigs and horses) act as hosts. The main reservoirs of influenza A viruses are waterfowl.

Influenza B Virus

Definition

The influenza B virus was first isolated by Thomas Francis in 1940. It is only found in humans. Influenza B viruses are divided into two strains, the B/Victoria strain and the B/Yagamata strain.

Influenza C Virus

Definition

Influenza C virus was first isolated by RM Taylor in 1949. It is found in humans and pigs, and, in general, the course of the infection is mild. Influenza C viruses are not widespread. In contrast to the types A and B, influenza C viruses do not build neuraminidase. As there are only minor differences between the strains, subtypes were not defined.

Influenza Vaccination

Synonyms

Influenza immunization

Definition

The influenza vaccination has been available in the United States since 1945. It is recommended for persons suffering from chronic illnesses, in case of immune deficiency, if one's profession involves a risk of infection and for more elderly patients (60 years or more). Since influenza viruses are constantly changing, a new combined ► vaccine, which confronts the virus types currently in circulation, has to be developed every year. Therefore, vaccination must also take place annually. The rate of protection achieved is 70–90%. Contraindications for the influenza vaccine are acute illness with fever, and a known severe allergic reaction to components of the vaccine, as well as a relevant allergy to chicken protein.

Influenza Vaccination, Active

Synonyms

Active influenza immunization; Active flu vaccination; Active flu immunization

Cross-References

► Immunization, active

Informal Care

Definition

Informal care includes services that are not conducted by health professionals but are provided by family members and friends who are not paid for their support. In most cases, these informal care services are provided to disabled or ill people. Informal care services are an essential complement to the formal care given to people with ► chronic diseases and disabilities. Informal care givers support different aspects of personal care, e. g. administering medication and other treatments, providing nutrition and exercise regimens, assisting with personal hygienic activities, providing transportation to medical facilities and emotional support through complex illnesses. Another branch of informal care is the development of self-care which is relevant for people with acute and chronic diseases as they usually have to take part in their own care. Self-care also includes health promotion and disease prevention.

Cross-References

► Community Care

Informal Channels

Definition

Informal channels of communication are contact between the primary researcher and the literature researcher. There are no restrictions on the kinds of information that can be exchanged through informal channels. These channels do not have a third party that mediates the exchange of information. There are five principal forms of informal communication: personal contacts, solicitation letters, traditional invisible colleges, electronic invisible colleges, and the World Wide Web.

Information Architecture

Definition

Information architecture refers to a systematic, planned approach to building information systems. Information architecture includes databases, application standards, procedures, information use, confidentiality policies, information technology, hardware, software, and networks.

Information Asymmetry

Synonyms

Asymmetry of information; Asymmetric information

Definition

Information asymmetry is a situation in which the parties on opposite sites of a transaction have different information that is pertinent to the transaction. In health economics, the term usually applies to transactions between patients and health care professionals (physicians or nurses) or to transactions between health insurers and enrollees. Information asymmetries in health care are rather pervasive and have far-reaching consequences for the organization and regulation of health care markets.

Information Content

Definition

Information content often describes only the editorial content – the way data (as carriers of information) are represented to the viewer. This refers to the optical or audiovisual form of the data – text, image, video clip, or physical data. Information content is also described as the union of different information. Typically, information content consists of three parts: raw content, definition of structure and presentation form. Modern ► content management systems can separate these three parts, enabling automatic transport of knowledge.

Information Design

Definition

Information design is the science and practice of designing forms, reports, and computer screens, etc., so that the information they contain can be found rapidly and interpreted without error. Information design is based on psychological and graphical design theories, and empirical studies of human perception and decision making, using alternative formats for information.

Information Presentation

Definition

The use of information and creation of knowledge depends highly on its presentation. Information can be presented in several forms: as tables, graphics, images, video, sounds, signals etc.

Information Retrieval (IR)

Definition

Information retrieval is the process of accessing information from the computer's memory. There are several types of information retrieval systems. Systems based on the Boolean model retrieve information by creating an expression consisting of the desired terms and operators with the meanings "AND", "OR", and "NOT". Systems based on the ranking model retrieve information by creating a list of terms (without the need for operators), and the documents in the collection are ranked according to their similarity to the terms. Similarly, Relevance-Feedback is a model that ranks information by validity obtained from many users of the system. The information most frequently chosen is ranked higher in terms of relevance. The Thesauri model uses a thesaurus to capture relevant words and phrases and then lists a short definition of every word as well as its relationship to other words (synonyms, antonyms, special terms, etc.). Semantic nets are an expansion of the Thesauri model, where the relationship between terms is more generally captured – the relationship between words can be defined as "class", "subclass of" or "a part of".

Information System (IS)

Definition

An information system is a technologically implemented medium for recording, storing, and disseminating information, as well as for drawing conclusions from such information.

Information Technology

Definition

Information technology (IT) includes all matters concerned with the furtherance of computer science and technology and with the design, development, installation, and implementation of information systems and applications. IT architecture is an integrated framework for acquiring and evolving IT in order to achieve strategic goals. It has both logical and technical components. Logical components include system configurations, information flows, and mission, functional, and information requirements. Technical components include IT standards and rules that will be used to implement the logical architecture.

Informed Consent

Synonyms

Adequate understanding

Definition

The advance, written consent of an individual (or her legal guardian) to allow the acquisition, use, or disclosure of identifiable health information.

It should be voluntarily given by a competent patient when undergoing some procedures (e. g. invasive procedures) or when enrolling as a subject in medical research.. For the consent to be "informed" it is essential that proper and sufficient information should be given to the patient about the object of the consent, including its risks, for an adequate understanding of what is going to happen to him/her; however, together with what the informant (health worker, researcher, etc.) has said, it is also important to check that the person actually understands about the content of the consent. The

informed consent is based on the principle of ▶ autonomy and it is meant to protect the individual's right over his own body and health.

Informed Consent Form

Definition

An informed consent form is a document that includes details about the study, duration, procedures, risks, and benefits of the trial. Informed consent is a process by which people learn the important facts about the trial, which can help them to decide whether to participate or not. People who agree to take part in the study are asked to sign an informed consent form. Signing the form does not mean that people must stay in the study until its end. They can leave the study at any time.

The informed consent form has to inform subjects, or their legally acceptable representatives, about the project in such a way that it enables them to make, after ample time and an opportunity to inquire about the details of the trial, a decision on whether to participate or not in the trial, based on an appropriate knowledge of the potential risks and benefits of the project.

A written informed consent form, and any other written information to be provided to subjects, should contain certain information:

- the purpose of the trial (e. g. research);
- the trial treatment/s;
- the probability for random assignment to each treatment;
- the trial procedures to be followed, including all invasive procedures;
- the subject's responsibilities;
- those aspects of the trial that are experimental;
- the reasonably foreseeable risks or inconveniences to the subject and, when applicable, to an embryo, fetus, or nursing infant;
- the reasonably expected benefits, or that no benefits could be expected;
- alternative procedure/s or treatment/s that may be available to the subject, and their important potential benefits and risks;
- the compensation and/or treatment available to the subject in the event of trial-related injury;
- the anticipated prorated payment, if any, to the subject for participating in the trial, and the anticipated expenses, if any, to the subject for participating in the trial;
- that the participation in the trial is voluntary and that the subject may refuse to participate or withdraw from the trial, at any time, without penalty or loss of benefits to which the subject is otherwise entitled;
- that monitors, auditors, the EC, and the regulatory authority/ies will be granted direct access to the subject's original medical records for verification of clinical trial procedures and/or data, without violating the confidentiality of the subject, to the extent permitted by the applicable laws and regulations and that, by signing a written informed consent form, the subject or the subject's legally acceptable representative is authorizing such access;
- that records identifying the subject will be kept confidential and, to the extent permitted by the applicable laws and/or regulations, will not be made publicly available;
- if the results of the trial are published, the subject's identity will remain confidential;
- that the subject or the subject's legally acceptable representative will be informed in a timely manner if information becomes available that may be relevant to the subject's willingness to continue participation in the trial;
- the person/s to contact for further information regarding the trial and the rights of trial subjects, and whom to contact in the event of trial-related injury;
- the foreseeable circumstances and/or reasons under which the subject's participation in the trial may be terminated;
- the expected duration of the subject's participation in the trial, and the approximate number of subjects involved in the trial.

The text has to be written in such a way that it does not coerce or unduly influence a subject to participate or to continue to participate in a trial, it should not causes the subject or the subject's legally acceptable representative to waive or to appear to waive any legal rights, or releases or appears to release the investigator, the institution, the sponsor, or their agents from liability for negligence; it should be written as non-technically as practical and should be understandable to the subject or the subject's legally acceptable representative.

Prior to a subject's participation in the trial, the written informed consent form should be signed and personally

dated by the subject or by the subject's legally acceptable representative.

Infrastructure of Public Health

Definition

Public health infrastructure is the system supporting planning, performance, and evaluation of ► functions of public health and ► essential public health services in every community. It consists of three basic components: 1. human resources – professionals and public health agencies, 2. information systems – for efficient communication between public and private health organizations, the media, and the public, and 3. organizational and financial resources – the consortium of local and state ► public health departments and private partners.

Infrastructure and Service Delivery

WOLFGANG BÖCKING[1], DIANA TROJANUS[2]

[2] Forschungsverbund Public Health Sachsen-Sachsen Anhalt e. V., Medizinische Fakultät, Technische Universität, Dresden, Germany
wolfgang.boecking@web.de, dtrojanus@gmx.net

Synonyms

Service provision and infrastructure

Definition

Health care service delivery and the associated infrastructure encompass the full spectrum of health care services available in a country, their organization and delivery structures as well as their organizational interaction. Health care service delivery (or health care service provision) comprises the following main service sectors: Ambulatory or outpatient health care and dentistry, inpatient hospital health care, nursing and residential care facilities, provision of drugs and other medical goods, public health programs and general health administration and insurance. Each service sector has its own organization of service providers operating within a regulatory framework specific to that sector. All service sectors together form the infrastructure of the health care system providing access to goods for health for individuals on a local, regional and national level.

The scope and quality of health care service delivery and infrastructure vary from country to country and depend largely on the financial resources spent on health care as well as on the organization and processes of health care services.

Basic Characteristics

Sectors of Health Care Service Delivery

In most member countries of the Organisation for Economic Co-Operation and Development (OECD) a wide range of health care service providers can be observed. In order to compare countries in terms of health care provision and health care financing, OECD published the International Classification for Health Accounts (ICHA) which covers three dimensions: health care by functions of care, providers of health care services and sources of funding. The classification of health care providers gives a general overview of the different sectors of health care provision (OECD 2000):

Ambulatory or ► outpatient health care comprises offices of doctors or physicians, dentists and other health practitioners such as chiropractors, mental health specialists, speech therapists and physiotherapists. Other ambulatory services are delivered by medical and diagnostic laboratories, providers of home health care services, ambulance services (first aid), blood and organ banks and outpatient care centers for family planning, mental health, ► substance abuse, ► ambulatory surgery and dialysis.

Inpatient hospital health care is delivered either by general hospitals or by specialized hospitals such as mental health and substance abuse hospitals or other specialty hospitals. General hospitals are licensed establishments to provide surgical and non-surgical diagnostic and medical treatment for inpatients using specialized facilities and equipment. In some countries a minimum number of beds is a required condition for registration as a hospital. Hospitals can be run by the government on a national, regional or community level (e. g. general acute hospitals, army and police hospitals, prison hospitals), by private non-profit organizations (e. g. the Red Cross) and by universities (teaching

hospitals). Mental health and substance abuse hospitals provide whole spectrum of inpatient services needed for mentally ill people or people with substance abuse disorders with typically longer lengths of stay (i. e. psychological, psychiatric and other social services). Specialty hospitals comprise licensed establishments for patients with a specific type of disease or medical condition. For example, specialized emergency centers, hospitals for tropical diseases, orthopedic hospitals, sanatoriums for rehabilitation or prevention (► hospitals).

Nursing and residential care facilities comprise establishments providing a mix of health and social services for an extended period of time. Depending on a country's specific organization of the long-term care process, there are different types of nursing and residential care facilities. Nursing care facilities typically mean convalescent homes or nursing homes for the elderly. Residential mental retardation facilities address alcohol and drug addiction as well as mental convalescence. Community care facilities for the elderly consist of assisted living facilities or continuing care retirement facilities without nursing care. Moreover, there are group homes for the hearing or visually impaired as well as for disabled people without the need of nursing care.

Providers of drugs and other medical goods have organizations responsible for research and development, manufacture and sale. Pharmaceutical companies are in charge of the research and development as well as of the manufacturing of drugs. Pharmaceutical distribution companies assure the safe distribution of drugs to hospitals or pharmacies. Drugs are dispensed to the general public either by pharmacies or hospitals. Other medical goods are produced by specialized companies and sold by specialized suppliers who also often provide fitting and repairing services. Examples are suppliers of optical glasses and other vision products, suppliers of hearing aids and suppliers of other medical appliances.

Public health programs are provided publicly by a ministry of health or other governmental agency and privately by non-profit organizations in order to promote, protect and improve public health. Programs encompass disease prevention measures, health education, immunization programs, control of communicable diseases, sanitary measures, and protection against environmental hazards (► public health services).

General health administration and insurance companies are institutions and organizations engaged in the regulation of health care activities, the administration of health policy and health insurance. The government administration of health (e. g. Ministry of Health) formulates and administers the government policy in health, sets standards for the regulation and licensing of health care providers as well as for medical personnel in hospitals. Other agencies setting public health standards are the Food and Drug Regulation Agencies and agencies regulating safety in the workplace. The social health insurance funds administer publicly-provided compulsory social security programs for employees in the private sector, in the public sector (army, public transport, police) and for employers. These programs compensate the individual for the loss of income and the additional charges due to sickness. Private health insurance funds are fulfilling the same goals as the social insurance funds if they are substitutes for social insurance or they operate as a complementary insurance to the existing social insurance system (► health insurance).

Determinants of the Health Care Infrastructure

The infrastructure for the delivery of health care services depends on the resources which are spent on it, the political commitment and leadership to set standards for the health care delivery system. According to ► medical ethics, the health care infrastructure aims to assure equitable access to health care services for all individuals living in a country, sufficient health care for people in need, the prevention of damage as well as the respect for the rights and autonomy of individuals while services are being provided (Schwartz et al. 2003).

Although health care service delivery plays an important role in industrialized high income nations and infrastructure is generally well developed, most developing countries lack the resources and the political commitment to build the necessary infrastructure for health care services. Compared to the ideals of health care coverage and quality formulated in the industrialized world, health services in developing countries are still in their infancy.

Process of Change in Health Care Provision

Despite existing financial resources, industrialized countries are increasingly confronted with the financial

constraints of the ideal health care infrastructure. In the context of rapid scientific and technological progress, the coverage of the whole population with adequate health care services has become more and more expensive. As a consequence, the notion of cost-efficiency has entered the medical health care environment confronting health care providers with economic controlling mechanism and ► rationing. As a result, many countries have observed an orientation towards economic success (1) and a specialization of their health care service sectors (2).

1) The optimal provision of health care services in terms of quantity and quality have to be connected with economic success. Hospitals, for example, need the cooperation of their medical and management staff in order to produce effective and cost-efficient health care services. The application of ► diagnosis related groups (DRGs) as well as ► disease management programs (DMPs) are examples for the process of change in health care provision.
2) The independent provision of efficient health care services often lacks integration which is a unique success factor for service sectors like prevention, long-term care and rehabilitation.

In the future, industrialized nations will have to deal with changing environment patterns for their health care systems. The main future challenges for the service delivery and infrastructure can be summarized as follows:

- Epidemiological and demographic changes enhance the need for chronic care, home care and care for the elderly, thus challenging the actual health care delivery structure
- Economic pressure will influence the structure of service providers towards rationalized integrated care units
- Technological change will increase the economic pressure with new expensive therapeutic procedures and pharmacies, but also the influence on health care provision methods, for example with ► telemedicine.

INHPF

Definition

The International Network of Health Promotion Foundations (INHPF) was founded in 1999. This network is established to advance the work of health promotion foundations around the world. To accomplish this, INHPF engages in two core activities: The first core activity is enhancing the performance of existing Health Promotion Foundations (HPFs) through exchange, mutual learning and joint action. The second core activity is to mentor and support the establishment of new HPFs. Members of the International Network of Health Promotion Foundations are the following:

- Austrian Health Promotion Foundation
- British Columbia Coalition for Health Promotion
- Health Promotion Switzerland
- Health 21 Hungarian Foundation
- Korean Health Promotion Foundation
- Malaysian Health Promotion Foundation Initiative
- Polish Health Promotion Foundation
- Thai Health Promotion Foundation (ThaiHealth)
- South African Health Promotion Foundation Initiative
- Victorian Health Promotion Foundation (VicHealth)
- Western Australian Health Promotion Foundation (Healthway)

Inpatient Care

GERNOT LENZ
Forschungsverbund Public Health Sachsen-Sachsen Anhalt e. V., Medizinische Fakultät, Technische Universität, Dresden, Germany
gernot.lenz@gmx.de

Synonyms

Hospital care

Definition

Inpatient care is the treatment and/or care that is provided to a patient in a ► hospital, clinic, or other institution and which requires at least one overnight stay. The term inpatient dates back to at least 1760. Inpatients have to go through the full admission procedure and occupy a bed in an inpatient department of the institution. There is a tendency towards decreasing the number of hospital inpatients and strengthening ► outpatient care.

Basic Characteristics

Key Data

Inpatient care expenditures account for around 31% (excluding long-term care) of the total health care expenditures of the Organisation for Economic Co-operation and Development (OECD) countries, with a range from 21% (USA) to 42% (Iceland). Based on 2005 OECD data, there are on average around 4 ► acute care beds per 1000 population, ranging from 8.2 beds in Japan to 1 bed in Mexico. This can be compared with an average of 4.6 beds per 1000 population in 1990; this is in total contrast to the corresponding costs, which are mainly driven by advancements in ► health technology. The average length of inpatient stay in hospitals has steadily declined over recent years, mainly due to less invasive surgical treatments and ongoing efforts to control costs. The average length of stay for acute hospital care thus decreased from 8.8 days on average in 1990 to 6.6 days in 2004. This was primarily driven by the decline in length of stay in the European countries, especially the Nordic countries, Denmark, Finland, and Sweden. The average hospital spending per inpatient acute care day in the OECD

countries in 2004 was $793 (adjusted for differences in cost of living).

Structural Changes of Inpatient Care Delivery

Driven by changing disease patterns (like for example the increase of ► chronic diseases), there has also been a change in treatment methods. The inpatient structures in hospitals have developed accordingly, towards offering more integrated and interdisciplinary services. This integration goes beyond the boundaries of the hospitals themselves as it also includes integration with the other players in the health care chain like ► primary care and tertiary care, ► prevention, home care, ► long-term care, and rehabilitation. Furthermore, there are ongoing advances in both the health technology area and information technology. These advances have led to a significant reduction in length of stay as stated above and many hospitals had to face a reduction in number of beds and a higher turnover of patients. Consequently, many hospitals realized that they had to put more emphasis on recruiting not only medical but also managerial talent able to drive the required changes in administrative structures and procedures. Hospital management has emerged as an important discipline at the interface of health care and business administration. The hospital managers also have to cope with the fact that there is increasing consumer influence in the hospital sector, making patient satisfaction an important element of competitive differentiation as those satisfied patients might be willing to recommend or return to the hospital.

Competitive Pressure

In many countries, there is increasing competition in the inpatient care sector. The introduction of per-case payments like DRGs has resulted in a significant decrease in length of stays and put increasing cost and competitive pressure on the hospitals. The per-case payments allow for easier comparison of key outcome parameters of different hospitals like, for example, mortality rates or complication rates for specific tracer diagnoses. The outcome measures can be interpreted as an indicator of the quality of care of the hospitals besides other parameters like patient satisfaction rates, frequency of procedures, and waiting times. These quality of care parameters have increasingly become elements of a potential competitive differentiation in countries like the USA where part of this information is made publicly available and allows for comparison of hospitals. Dependent on the respective health care system, this information can furthermore be used by the health care payers as input for selective contracting negotiations with the hospitals.

Conclusion

The inpatient care sector around the world is struggling with the challenge to reduce utilization and length of stay in order to counteract steadily rising health care expenditures. Many countries promote outpatient care settings and shift services that have previously been performed on an inpatient basis to outpatient settings. In many developed countries, it can be expected that the number of inpatient settings will be reduced in the coming years. Hospital mergers and acquisitions with the objective of achieving ► economies of scale and ► economies of scope can be expected to rise, as already the case in several countries like the USA and Germany.

Inpatient Health Care

Definition

Inpatient health care includes all health care services that are delivered in hospitals or other medical institutions in which patients are staying overnight. It is delivered either by general hospitals or by specialized hospitals such as mental health and substance abuse hospitals or other specialty hospitals. Inpatient health care can also be delivered as long-term care in so-called nursing and residential care facilities comprising establishments with a mix of health and social services for an extended period of time. Moreover, there are group homes for the hearing or visually impaired as well as for disabled people without the need of nursing care.

In-Plant Health Service

Definition

In-plant health service refers to occupational health care services provided within an employer's facilities. In-plant health service is organized as a plant dispensary or infirmary. It usually employs a plant physician or occupational medicine specialist, a nurse or nurse practitioner. Responsibilities of in-plant health service may range from simple triage and first aid to fairly comprehensive primary care. Usually, large companies organized multidisciplinary occupational health departments with comprehensive health care units that, in addition to occupational health services, provide primary health services for the employees and, sometimes for employees' family members too.

In recent times "off-site" or community-based health care facilities have displaced in-plant services as the principal form of organization for providing occupational health services.

Insensitivity

► Resistance

Insolation

Synonyms

Solar radiation

Definition

Insolation is the incoming solar radiation that reaches a planet and its atmosphere or, by extension, any object exposed to solar rays, such as a spacecraft or building. It is exposure of an object to the Sun, or the intensity of incoming solar radiation incident on a units horizontal surface at a specific level. In construction, it is an important consideration when designing a building for a certain climate (► climate and microclimate). It is one of the most important climate variables for human comfort and building energy efficiency. Insolation depends on several factors: (1) the solar constant – that is, the amount of energy in a unit of time that reaches a unit plane surface perpendicular to the Sun's rays outside the Earth's atmosphere, when the Earth is at its mean distance from the Sun; (2) the Sun's elevation in the sky; (3) the amount of solar radiation returned to space at the Earth-atmosphere boundary; and (4) the amount of solar radiation absorbed by the atmosphere and the amount of solar radiation reflected at the lower boundary of the Earth. Insolation is commonly expressed in units of watts per square meter.

Inspection of the Workplace

Synonyms

Workplace monitoring

Definition

The most effective method of identifying health hazards (► workplace hazards) is through the systematic inspection of the workplace. Inspecting the workplace is the most obvious way to identify health hazards. An important purpose of an inspection is to observe the actual conditions in the workplace. An inspection should

locate any previously unidentified agents in the workplace and find out what they are. A review of identified hazards and a check for substances not properly identified or not included in the workplace inventory of hazardous substances should be carried out. Questions should be asked of workers and supervisors and hazard indicators, warning properties and health effects should be noted.

Institutional Health Services

Definition

Institutional health services are ► health services delivered either on an inpatient basis, in hospitals, nursing homes, or other inpatient institutions, or on an outpatient basis by departments of such institutions.

Integrated Care Pathways

► Clinical Pathways

Integrated Environment-Related Public Health Reporting

Definition

In the context of the public health action cycle, the environment and public health reporting services play a central role at the federal, state, municipal and communal levels. While public health reporting provides the data and information necessary for setting political public health priorities, environment-related reporting deals with assessing developments of environmental goals. The top priorities of environment-related reporting are therefore the various parts of the environment and the burden they can support. Public health reporting, on the other hand, focuses on health effects. A strict separation of environment-related and public health reporting is hardly possible, however. Accordingly, topics covered by environment-related reporting regularly touch on public health (e. g., contaminated land, air pollution), and topics covered by public health reporting likewise touch on the environment (e. g., diseases of the airways caused by exposure to fine particulate matter).

Since reporting is traditionally resource-related, environmental and public health data are not usually linked. This link is now to be established through interdisciplinary cooperation. Integrated environment-related and public health reporting should meet the growing need of experts and the general public alike for reliable and understandable information about the effects of environmental burdens on human health. However, environment-related public health reporting in Germany is only in its beginnings. As integrated reporting develops, indicator systems are needed to gauge factors like mobility, the living environment, food toxin burden, environmental behavior, etc. and the exposure or basic health risks resulting from them. The approach used by the German Environmental Office shows promise at the national level, and the WHO environmental health indicators at the international level.

Definition

Integrated Health Care describes a system of health care provision that combines all necessary health care services of inpatient and outpatient health care with a health insurance to provide the complete spectrum of medical care for the insured. Ideally, all parties involved, i. e. health care providers (physicians, hospitals, etc.), beneficiaries (patients) and purchasers (health insurances) are in balance meaning "that the medical resources match with the needs of patients and purchasers" (Coddington et al. 1994). According to the World Health Organization (WHO), the approach of integrated health care stands for an improved access to family- and community oriented ► primary care services, ensures ► continuity of care through an efficient and cost-effective system of secondary and tertiary hospital care (Gröne and Garcia-Barbero 2001).

Basic Characteristics

Background

In all countries with well developed health care systems, the provision of health care has become increasingly complex. Due to rapid technological progress, the delivery of medical services can be realized at different levels of care as demonstrated by the shift from inpatient to outpatient care. The changes in demographic and epidemiological patterns, e. g. people living longer and the increase of chronic diseases, require health ► prevention, treatment, and rehabilitation in multiple settings including long term care. Besides, there is a growing economic pressure claiming ► cost-efficiency and effectiveness of health care services. In this context, the notion of integrated health care has been born, calling for an improved coordination of different service levels, cooperation of all service providers and the involvement of the patients.

Health care delivery systems with a low integration level have experienced a certain number of inefficiencies over the past years, for example:

- Conflicting recommendations on treatment and medication
- Repetition of diagnostic procedures
- Inadequate transfer of patients between different care levels
- Late detection of complications or ► co-morbidities
- Lack of a comprehensive care strategy for chronically ill

As a result, many countries with developed health care systems, have adopted the approach of integrated health care in order to cope with current and future health care services demand focusing on improved access, quality and effectiveness as well as on economic efficiency (► infrastructure and service delivery).

Goals

According to the WHO European Office for Integrated Health Care Services, the goals of the concept of Integrated Health Care are twofold:

1. To bring together management, organization and delivery of services related to diagnosis, treatment, rehabilitation and ► health promotion.
2. To improve health care services in relation to access, quality (► health care quality), patient's satisfaction and cost-efficiency. This means in particular that countries should develop comprehensive primary health care services with family health physicians and nurses working with multi-professional teams. To assure ► continuity of care, the primary health care services are supported by a flexible system of hospital services ensuring patients' participation.

Scope

Many countries with well developed health care systems have adopted a wide range of strategies to achieve better integrated health care systems. According to the health care system in place, strategies vary from decentralization to centralization of health care services, the redefinition of the functions of inpatient health care to primary outpatient care. Some countries concentrate on horizontal integration in order to form multidisciplinary teams in one health care sector, others prefer vertical integration, meaning the integration of different sectors of care linking primary, secondary and tertiary care (► secondary care, ► tertiary care). Not only the type of integration varies from country to country but also their goals. Some integration strategies are mainly implemented to reduce cost, while others clearly focus on patient satisfaction, quality of care, and health outcome besides efficiency.

As the scope of the strategies varies from country to country, the terminology of integrated health care varies too. Depending on the country-specific environment, terms associated with health care integration strategies are "shared care", "seamless care", "disease management", "continuous care", "integrated care pathways" or "integrated delivery networks."

Some of the most discussed activities and measures towards integrated health care are:

- Linking levels of care to improve the coordination between primary health care, hospital care and home care and to enhance equity in access.
- Developing family medicine, the family physician and family nurse in order to broaden the approach of ► primary care by the integration of a multiprofessional health care team in primary care.
- Developing ► telemedicine (or ► e-health applications) as an important tool to improve access to services for patients in more remote areas and to offer distance learning for health care professionals.
- Improving hospital management with introduction of performance evaluation, incentives for health care professionals to promote health outcomes and

quality of care under the existing financial restrictions.
- Enhancing financing of health care through the identification of country-specific financing options to support health outcome, equity and ► cost-efficiency.
- Developing home health care on the community level for diseases best suited for home care in order to offer a valuable alternative to inpatient long term care facilities.

Strengths and Weaknesses

The concept of Integrated Health Care has a number of advantages concerning finances, access and organization issues:
- An integrated network of provider benefits from a cost-effective administration, group purchasing discounts and increased financial security due to a higher market share.
- As provider networks are typically of a larger size, they improve access to other providers and support systems, such as educational support and data and information systems.
- The organization of a large provider network allows strategic planning, a greater attention to health needs of the community and increased patient satisfaction.

But a few potential weaknesses of the concept of Integrated Health Care have to be mentioned:
- The convergence of providers requires that physicians are flexible and open toward changes that contrast with their former independency of practice. As physicians used to following their own professional rules, they may be reluctant to give up a certain degree of independence in order to follow new practice guidelines and comprehensive care approaches.
- The large size of a typical provider network requires connections through a sophisticated information system to assure the transfer of all relevant data. In reality, different providers often use different information systems and integration of these providers creates a risk of duplication or loss of information. The convergence of providers is a real challenge for the management of complex health care data (► health data management).
- Some provider networks may be challenged by the geographical distances between providers and the structural differences in the organization and care delivery process as well as the differences in services and staff.

Examples

World Health Organization (WHO) The areas of work of the WHO encompass various programs to develop knowledge, design suitable strategies towards integrated health care and advise member states how to better link the different levels of care. Ongoing activities are:
- development of performance indicators to evaluate integrated health provision systems
- identification and development of strategies to better link and coordinate health care services
- development and improvement of systems for planning and delivering health services

USA In the United States, several hundred integrated health care delivery systems have developed towards the provision of the whole range of necessary health care services in a user friendly environment without costly intermediaries and with the goal of continuous improvement of health outcomes. Integrated health care systems include a high degree of coordination of care with strong links between physicians and hospitals as well as many other integration aspects such as quality management, utilization controls, geographic reach and cost-efficient organization.
Furthermore, the recent development of Integrated Health Care Clinics has been very popular. These clinics offer comprehensive multidisciplinary health care facilities focusing on disease ► prevention, early detection, healthy lifestyle coaching, and include ► telemedicine.

UK In the UK, integration of health care has a long history in the National Health Service (NHS). Several reforms during the past decades aimed to administer and fund the different health care sectors in a coherent and efficient way. In 2006, the community services White Paper introduced a new approach to interprofessional and inter-agency coordination in which health care services are designed around the needs of the patient, rather than the patient being forced to fit around the services already provided. The aims of this approach of integration are focused on prevention, ► health promotion for all, the expansion of the delivery

of care and the improvement of flexibility and responsiveness. To achieve better integration of health care services in the UK, four priorities have been set:

1. User empowerment to put people more in control of their own health
2. Supporting self care to enable and enhance people's capacities of health independence
3. Better access to community services to ensure rapid and convenient health care provision
4. Integrated operational agreements to assure the provision of high-quality and cost-effective care

Intercultural Communication

MASON DURIE
Mãori Research and Development, Massey University, Palmerston North, New Zealand
m.h.durie@massey.ac.nz

Definition

Intercultural communication (► cross-cultural communication) refers to the ways in which people from different cultures comprehend each other and share information. ► Communication can take many forms and the potential for misinterpretation is high especially where language, behavior, values, customs, and expectations are sufficiently different to prevent a common basis for understanding. While language is a major form of communication, that can lead to an impasse where there is no common tongue, it is not necessarily the main impediment to understanding. Even when words are jointly understood, the nuances and world views which add value to them, can lead to quite divergent meanings and intentions. Nor are words the sole form of intercultural communication – artistic creations, rituals, social behavior, views on gender, age and disability, and perspectives on health and wellbeing color patterns of communication. Without an understanding of the cultural context within which communication occurs, inferences and implications can be wrongly drawn, simply not noticed, or incompletely appreciated.

Basic Characteristics

Language

The single most reliable pathway to culture is language. The language spoken by a group contains subtleties of meaning and idioms that are not always accessible in formal speech, the written word, or through second language acquisition. Language not only provides a means for the dissemination of information, but codifies world views, draws on metaphor and allusion, allows for wider social conventions to shape patterns of verbal exchange, and evokes emotional and spiritual triggers as much as cognitive prompts. Understanding the gist of words is a start towards communication with people from other cultures but does not necessarily lead to a complete appreciation of the meaning behind the words.

In some cultures it is polite to agree, especially with people who may be seen as important or superior. For example in response to questions from a doctor who is trying to establish the nature of pain by raising possible characteristics, a patient may agree with all suggestions (radiating, localized, dull, sharp, constant, intermittent) because it would be bad mannered to answer 'no'. Similarly in some cultures not answering a question can be a silent form of disagreement whereas in others it can be a proxy for assent.

As nations become more and more diverse and societies contain peoples from many cultures and languages, clearly it will become increasingly difficult to be sure that communication is always clear and well understood. This will present challenges for health workers. Though possibly conversant in two or three other languages they will not necessarily be familiar with the nuances of meaning across society as a whole. It may be more important to know when a communication barrier exists than to assume that limited language competency from either party will result in a good enough understanding.

Values

Underlying most cultures is a set of values that may be taken-for-granted by members of the group; in that sense are not openly discussed nor widely publicized outside the group. They are applied intuitively as a matter of course. Difficulties arise when a person with a different value system is not able to interact at the intuitive level so that the subtleties of interaction are missed or even unintentionally dismissed.

Time and Space To illustrate the point, people often hold different values related to the utilization of space and time. In some cultures, to pave the way for a closer relationship, physical distance is maintained until certain formalities have been completed. Traversing the distance prematurely can cause offence and create disquiet since space allows any risk from an encounter to be assessed before a commitment is made. However, in other cultures maintaining space creates unease and a sense of separation; the tendency will be to bridge the gap as quickly as possible in order to minimize anxiety and create a friendly environment. Formalities may be immediately replaced by first name informality, even a warm hug.

Similarly cultures have different understandings of time. Being 'on time' may be seen as less critical than allowing sufficient time, even if it goes against the dictates of the clock. In this instance priority is given to enabling the completion of essential tasks in an unhurried manner and not proceeding until a prior step has been ratified; the amount of time taken is considered a good investment for future relationships. Values surrounding time can be easily misconstrued in the clinical setting. The limited time available to do each patient justice can result in medical schedules that are time-based rather than patient-based. Many patients, however, will be reluctant to engage in an encounter if it seems they will be unable to complete follow through, and may simply opt for a face-saving superficial encounter that falls short of an adequate history and bypasses the substantial matter.

Diagnostic Confusion

Despite the acceptance of culture as an important ingredient in both assessment and management, a failure to appreciate the impact of culture on clinical realities has often led to misdiagnosis and gross mismanagement among ethnic minority groups. Schizophrenia has been over-diagnosed in African Americans and Hispanics living in the Unites States of America, especially among patients who meet the criteria for an affective disorder with psychotic features. Culture can also impact on the way a disorder is subjectively experienced. In some cultures depression might be experienced as a type of brain disorder, in others as a loss of body fluids such as semen, or as a possession by an external force.

Culture-based idioms of distress lead people from different cultures to different sources of help. Many people will seek medical advice, but others might rigorously avoid asking for help especially if the problem is perceived as a weakness or the result of some cultural infringement. And rather than seeking medical advice, help might be sought from an elder or community healer with whom there is a sense of rapport based on cultural alignment.

Many psychological assessment tools are culture bound or culture loaded. Quite apart from administration, they may not be sensitive enough to capture different cultural norms, or alternatively might suggest a higher level of distress than is actually experienced. Some people are reluctant to talk openly about emotions or personal distress but are less shy about describing symptoms on paper. In contrast, some respondents feel more or less obliged to satisfy the interviewer by ensuring that there are not too many questions left unanswered, or answered negatively. For most of the commonly used psychological assessment tools, standardization reflects predominantly white middle-class samples for which results may be inappropriately applied to other ethnicities.

Translating tests is an important step in making psychological tools accessible. Translation, provided it is not literal, nor simply based on transliterations, can communicate the intended concept with greater accuracy. Sometimes a back translation, into the sourced version is useful to respondents who may not be fluent in their customary language despite having retained customary ideas. The 'revised' version is in a conceptual form which makes sense. To be most useful, however, translation of assessment questionnaire schedules should also ensure that the format is consistent with cultural norms.

International Chemical Control Toolkit

Definition

In 2004, a Global Implementation Strategy was established under the auspices of the International Programme on Chemical Safety (IPCS). This Global Implementation Strategy aims to build and implement an Occupational Risk Management Toolbox, containing toolkits to manage different workplace hazards. The first such toolkit is the International Chemical Control Toolkit, which is available on the Internet through the ILO SafeWork Website. The hazard information employed by the Toolkit is either European Union (EU) label Risk (R) phrases or the hazard statements of the Globally Harmonized System for Classification and Labeling (GHS). The target for global implementation of the GHS is 2008.

International Classification of Functioning, Disability and Health (ICF)

Definition

The ICF is a classification of health and health related domains that describe body functions and structures, activities and participation. The domains are classified from body, individual and societal perspectives. Since an individual's functioning and disability occurs in a context, the ICF also includes a list of environmental factors.

International Conference of Harmonization ICH Harmonized Tripartite Guideline

Definition

The International Conference on Harmonization of Technical Requirements for Registration of Pharmaceuticals for Human Use (ICH) was a consultation exercise undertaken by the regulatory authorities of Europe (European Medicines Evaluation Agency [EMEA]), the US (Food and Drug Agency [FDA]) and Japan (Ministry of Health and Welfare, Tokyo) and representatives of the pharmaceutical industry, to discuss the requirements for drug evaluation and registration and to file guidelines. The Tripartite Guidelines is a system of guidelines that are legally binding in all three areas. Due to the fact that these regions represent an overwhelming share of the pharmaceutical world and that many other countries use either home certificates (pharmaceutical products that are registered in their country

of manufacture do not need registration/authorization after import) or accept documentation according to the Tripartite Guidelines for their own registration process, these Tripartite Guidelines are close to a global legal system. One of the Tripartite Guidelines is the guideline on ► good clinical practice.

International Court of Justice

Synonyms

World court; ICJ

Definition

The International Court of Justice is the primary judicial organ of the United Nations. It is located at the Peace Palace in The Hague, Netherlands. Its main functions are to settle legal disputes in accordance with international law submitted to it by states and to give advisory opinions on legal questions submitted to it by duly authorized international organs and agencies. The Court is made up of 15 judges voted by the United Nations General Assembly and the Security Council for nine-year terms of office.

International Decade of the World's Indigenous People

Definition

The United Nations General Assembly proclaimed 2005 to 2014, the Second International Decade of the World's ► Indigenous Peoples. The main goal of the new decade will be to strengthen international cooperation around resolving the problems faced by indigenous people in areas such as culture, education, health, human rights, the environment, and social and economic development.

International Ergonomics Association

Definition

The International Ergonomics Association (IEA) is the federation of forty-two individual ► ergonomics organizations from around the world. The IEA is governed by a Council with representatives from the Federated societies. The administration is performed by the Executive Committee that comprises the elected Officers and Chairs of the Standing Committees.

International Health Regulations

Definition

The International Health Regulations (IHR) are an international legal instrument which is legally binding on all WHO Member States who have not rejected them and on all Non-Member States of the WHO that have agreed to be bound by them. The purpose of the IHR, adopted in 1969, is to ensure maximum security against the international spread of diseases with a minimum interference with world traffic. The original IHR (1969) only applied to three infectious diseases: cholera, plague, and yellow fever. Because of their narrow scope of application, among other reasons, the IHR (1969) were revised by the WHO Member States. In May 2005, the World Health Assembly adopted the revised IHR (2005). The purpose and scope of the IHR (2005) are to prevent, protect against, control, and provide a public health response to the international spread of disease in ways that are commensurate with and restricted to public health risks, and which avoid unnecessary interference with international traffic and trade. The IHR (2005) also establish a single code of procedures and practices for routine public health measures at international airports, ports, and some ground crossings.

International Health Services

Branko Jakovljević
Institute of Hygiene and Medical Ecology, Faculty of Medicine, University of Belgrade, Belgrade, Serbia
bra@beotel.yu

Definition

The international health service is a system of health institutions that provide health services to people living in different regions, continents, or around the world. The essential function of the international health service

is to produce international public goods that transcend the borders of any given nation.

Basic Characteristics

Challenges of Globalization

► Globalization is the process of increasing economic, political, and social interdependence, and global integration, which occurs as capital, traded goods, people, concepts, images, ideas, and values diffuse across national boundaries (Taylor 2002).

Globalization has eroded national borders, making countries increasingly dependent on international trade. Even in the field of health, we are witnessing the worldwide distribution of both infective and non-communicable diseases, so that countries are facing similar health problems. Furthermore, global environmental threats pose a challenge to human health; e. g. ozone layer depletion has led to an increase in the incidence of skin cancer; and land degradation, air and water pollution, and the greenhouse effect are indirectly affecting health through various environmental alterations. Among the most powerful global forces are liberalization of trade, especially of harmful legal products such as tobacco, which has resulted in an increase in tobacco-related deaths worldwide; international transfer of illegal drugs (heroin, cocaine); and diffusion of medical technologies (which may have adverse health effects). Finally, numerous health problems occur as a consequence of population migrations, either due to war, environmental crisis, or economic collapse, and the increasing number of people traveling internationally every year contributes to the international spread of various diseases (Frenk et al. 1997).

As a consequence of globalization, governments of both developed and developing countries are turning to international cooperation to attain national public health objectives and improve the health status of their populations. The implementation of international laws can provide a legal foundation for international health commitments, financial and technical assistance, information exchange, scientific research, and surveillance worldwide (► global health policy).

Global Trade in Health Services

► Global trade in health services is the union of several global processes occurring in globalization that impact on health services (UNCTAD 1997; Chanda 2001; European Commission 2001). Global trade in health services is manifested in several ways.

First, it is reflected in the growing cross-border delivery of health services, both via traditional mail channels, and by electronic services or ► telehealth. The main idea of ► telemedicine was to provide health care to remote populations and to improve the quality of diagnosis and treatment, but the lack of supporting technology and infrastructure at present makes it ineffective in many developing countries.

Another global phenomenon is movement of personnel and consumers from one country to another. ► Consumers are moving to the countries that provide the best, safest, or cheapest service for diagnosis and treatment. Health care providers are moving around the world, seeking the best education, employment, or career opportunities. This global trade of people, services, and foreign investments has induced the establishment of many collaborative arrangements in health care – hospitals, clinics, and diagnostic and treatment centers, which can provide expensive and specialized medical services. Theoretically, this kind of trade should have improved health systems, but it might result in the development of a dual market, consisting of expensive health centers providing higher-quality health services to wealthy nationals and foreigners, and much lower quality, resource-constrained centers providing health services to the poor. The implications of global movement of health care providers can be both positive and negative. On one hand, transient mobility of health care providers certainly promotes exchange of knowledge among professionals, and upgrades skills and standards in the country of interest. However, a permanent outflow of health care providers presents a significant loss for the source country, both in the loss of highly trained personnel and loss of the public resources invested in their training (Chanda 2001).

Nevertheless, globalization is not to blame for all of these problems. It is the poor infrastructure, low standards, poor employment opportunities, loose health system, and low-quality health services in the source countries that cause global movement of consumers and health care providers. It is equally clear that, for many countries, some components of globalization, such as trade liberalization and technology transfer, could increase efficiency, welfare, and health. In gen-

eral, a gradual and selective investment in human and physical resources in the health sector, implementation of health policies, and strengthening of health systems is a highly preferable path of globalization of developing countries (Cornia 2001).

Just as national ► health systems are facing reforms in the light of globalization, the world health system must reinvent itself to meet the challenges of the future. The essential function of international health services is to produce international public goods that transcend the borders of any given nation. Those functions, referring to prevention, diagnosis, and treatment of diseases of global importance, are listed in the Health information section (► health information).

History of International Organizations

The first efforts to establish international health cooperation date from the mid-19th century, and the First International Sanitary Conference held in Paris in 1851. It was the first international convention organized in Europe to deal with the arrival and spread of pestilent diseases, particularly cholera, which was epidemic at that time. In 1902, the International Sanitary Bureau was established. This was the predecessor of the current Pan American Health Organization, an agency of the League of Nations, which was founded in Geneva in 1919. In 1945, three physicians, Drs. Szeming Sze of China, Karl Evang of Norway, and Geraldo de Paula Souza of Brazil, proposed the formulation of a single health organization that would address the health needs of the world's people. Their joint declaration to establish an international health organization was approved when the constitution of the **World Health Organization** (WHO) was adopted in 1946. April 7th 1948 was the date of implementation of the constitutional act of the WHO and has been celebrated as World Health Day ever since.

International Health Services Today

The WHO, through its six autonomous Regional Offices, is the leader in defining health goals in various regions of the world. In 1980, the Regional Office for Europe adopted a long-term European strategy "Health for All", which was expanded in 1998 into the policy named "Health21 – health for all in the 21st century" (WHO 1998). The two main aims of this policy – health promotion and protection, and reduction of diseases – are to be fulfilled through twenty-one targets for health. Some of these targets are focused on health systems, their gradual orientation towards better health gain, equity and cost-effectiveness, and the implementation of new policies and strategies based on the health for all principles. ► Equity, ► equality and solidarity in health development between and within countries are also supported. Other targets are more individual and oriented toward strengthening health throughout the life cycle; improving the physical, economic, social and cultural environment; and reducing diseases and injuries.

The WHO is dedicated to many international health programs:

- Global Strategy on Diet, Physical Activity and Health, which was developed and adopted in the 2004 World Health Assembly – it was recognized that a few largely preventable risk factors account for most of the world's disease burden. This strategy intends to provide significant change in diet habits and physical activity levels worldwide.
- Diabetes Action Now is a joint program of the WHO and the International Diabetes Federation. The overall goal is to raise awareness about diabetes and its complications, particularly in low- and middle-income countries, and to stimulate effective measures for the surveillance, prevention, and control of diabetes.
- The WHO Mental Health Policy Project is a comprehensive strategy to improve the mental health of the population using existing resources to achieve maximal benefits, to provide effective services to those in need, and to assist reintegration of people with mental disorders into community life.
- The Countrywide Integrated Noncommunicable Diseases Intervention (CINDI) program was established in the European Region. It presently includes 27 participant countries. It was developed with the aim of reducing modifiable risk factors, such as smoking and high blood pressure, by integrating health promotion and disease prevention.
- The Global School Health Initiative was established to increase the number of schools that can truly be called "Health-Promoting Schools". The aim is to mobilize and strengthen health promotion and education activities at the local, national, regional, and global levels. The Initiative is designed to improve the health of students, school person-

I

nel, families, and other members of the community through schools.
- The Healthy Cities Project was developed to support the solving of local problems in various communities. Whether the primary reason people convene involves children, environmental concerns, homelessness, safety, education, or other issues, the approach is to establish a collaboration among citizens and people from business, the government, and other sectors of society who recognize that their interconnection can be used to impact on the well-being of the entire community.

Critiques on the Work of International Health Organizations

Analysts criticize international health agencies for their bureaucracy, lack of coordination, and waste of resources, often leading to increased inequities and inequalities in health care (► inequity in health, ► inequality in health) for the world's most vulnerable populations, instead of improving health. Furthermore, international health agencies are said to be neglecting the new global health challenges, not only new emerging diseases and health risks, but also issues regarding the development of new medical technologies, interventions and research, the design and implementation of information systems, the status and reforms of national health systems, consumers' health protection, etc. (Antezana 1997; Frenk 1997).

Given the rising trends in globalization, it is inevitable that a question on equity in access to health services occurs. It is often true that cost-effective public health interventions do not reach the populations who need them. International agencies are constantly putting new conditions on governance, making their support dependent on implementation of patents, legislation, sanitary and veterinary norms, social clauses, etc.

Another critical failing in the work of international agencies is the implementation of health interventions in a way that is inadequate or unsuitable according to the epidemiological profile of the population. Due to the short-term funding of public health programs and rapid staff turnover in governments, donors and international agencies, and technical assistance groups, health interventions often have low coverage and do not contribute to the building of sustainable health systems (Victora et al. 2004).

Role of International Health Organizations in the 21st Century

Bearing all this in mind, the proposed role of the WHO in the 21st century is to (Antezana 1997):
- Be the world's health conscience: be an advocate for health, advance global health equity, and identify policies and practices that are beneficial or harmful for health,
- Provide leadership to a global alliance for health,
- Provide technical cooperation, with special attention being given to the poorest countries and communities,
- Establish global ethical and scientific norms and standards,
- Perform global surveillance and establish early warning systems for transnational threats to health,
- Initialize, undertake, and control global eradication, elimination, or control of selected diseases,
- Promote innovation in science and technology for health,
- Mobilize and be an advocate for resources for the poorest countries and communities.

European Community and Health Care

The activities of the European Community include a contribution to the attainment of a high level of health protection. The right to "Health Care" is described in the "Charter of Fundamental Rights of the European Union", agreed in Nice in 2000. This Right is defined as "Everyone has the right of access to preventive health care and the right to benefit from medical treatment under the conditions established by national laws and practices". The EU Committee on Health is very much concerned with the health systems of Member States, especially the flow of services, financing, quality of services, and education and training of professionals. Another important issue, yet not thoroughly developed, regulated, and implemented is cross-border health care. The ► EU Legislation and the Delivery of Services to Patients coordinates and regulates the delivery of health services between Member States (European Commission 2001).

Conclusion

Globalization, environmental changes, economic development, population explosion, urbanization, and

changes in health care systems have increased the need for international health services. Some developing health systems are unable to provide even basic health services and they would certainly benefit from preventive health, public health care, and education as a means of addressing current health threats. In such cases, international health organizations play an important role in supporting governments, national health systems, communities, and individuals in promoting health and preventing disease, or providing educational, technical, or organizational assistance in diagnostics, treatment, and rehabilitation of diseases.

International Programme on Chemical Safety

Definition

The International Programme on Chemical Safety (IPCS), established in 1980, is a joint program of three Cooperating Organizations – ILO, UNEP and the WHO – who implement activities related to chemical safety. The WHO is the Executing Agency of the IPCS, whose main roles are to establish the scientific basis for safe use of chemicals, and to strengthen national capabilities and capacities for chemical safety.

International Red Cross and Red Crescent Movement

Synonyms

Red cross

Definition

The International Red Cross and Red Crescent Movement is the world's largest international network whose stated principles are based on the concepts of humanity, impartiality, neutrality, independence, voluntary service, unity, and universality. The movement consists of the Geneva-based International Committee of the Red Cross, the International Federation of Red Cross and Red Crescent Societies, and numerous national societies. Currently, it is present and active in almost every country to protect human life and health, to ensure respect for the individual, and to prevent and alleviate human suffering without any discrimination based on nationality, race, religious beliefs, class or political opinions. The commonly used term "International Red Cross" is actually a misnomer because no official organization bearing that name exists.

International Research

Definition

The word "international" is used when a research project involves various countries. It is a very important factor for regulating a research protocol especially if one or more of the involved countries are of different cultures or socio-economic levels, which could lead to exploitation.

Internet

Definition

The Internet is technically a network of computer networks, or a set of protocols enabling connection and communication between computers.

Interpersonal

► Human Relations

Interpersonal Relations

► Social Relations

Intersectoral Cooperation

Synonyms

Multisectoral cooperation

Definition

Intersectorial cooperation is a recognized relationship between part or parts of different sectors of society that have been formed to take action on an issue to achieve health outcomes, or intermediate health outcomes, in a way which is more effective, efficient or sustainable than might be achieved by the health sector acting alone. Intersectoral action for health is seen as central aim for the achievement of greater equity in health, especially where progress depends upon decisions and actions in other sectors, such as agriculture, education, and finance. A major goal in intersectoral action is to achieve greater awareness of the health consequences of policy decisions and organizational practice in different sectors, and through this, movement in the direction of healthy public policy and practice. Increasingly intersectoral collaboration is understood as cooperation between different sectors of society such as the public sector, civil society and the private sector.

Synonyms

Program planning

Definition

An *intervention* is an intended, planned, and targeted operation in a system or process which aims at removing or preventing an undesirable phenomenon. In the context of health promotion and prevention, an intervention is a planned and systematically implemented activity taking place in current social structures, which aims at changing knowledge, attitude or behavior of a person, an organization, or a population. For this goal, an intervention can also target determinants of health behavior, e. g. the physical environment and political context. Usually, an intervention is part of a study and thus subject to evaluation (► evaluation, models) and assessment.

An *intervention concept* is a scheme for the different elements and activities that are required to achieve the intended outcome of a program. A concept is usually developed in the beginning of a health promotion and prevention activity, and it maps out detailed steps that have to be taken to design, implement and evaluate a prevention program. A concept usually encompasses the whole program cycle: analysis, strategy, implementation, evaluation, and sustainability.

Basic Characteristics

Background: Need for Procedural Concepts

The past three decades have seen a rapid growth in the quantity and range of preventive interventions. It became soon clear, however, that poorly defined and resourced programs had only modest impact, or led to social benefits which were hard to measure. In addition, with the expansion of innovative approaches, the skills and experience to translate program objectives into practice have not always kept up with the rapid changes. Over the past few years, increasing attention has thus been given to the question of how an intervention can be planned and managed, not only to ensure that programs are established on a secure footing, but also that they should meet measurable objectives and be sustainable over time.

Frameworks and Models for Intervention Concepts

As a consequence, several frameworks for a systematic planning process in prevention and health promotion have been developed since the 1980s. These frameworks offer guidance for designing intervention concepts, but it has to be kept in mind that there is no "one size fits all" concept for preventive interventions. The models for intervention concepts are procedural resources that map the path from the recognition of a need or problem to the identification of a solution. They are designed to enhance quality management of health promotion and prevention programs, but cannot provide solutions.

PRECEDE-PROCEED Model One of the most popular concepts is the PRECEDE-PROCEED framework, which has been proposed by Green and Kreuter in the early 1980s. The PRECEDE framework (referring to predisposing, reinforcing and enabling constructs in educational diagnosis and evaluation) is a framework for the process of systematic development and evaluation of health education programs. In this model, appropriate health education is considered to be the intervention (treatment) for a properly diagnosed problem in a ► target group, or target population. This model is founded in the social/behavioral sciences, epidemiology, administration and education. As such, it recognizes that health and health behaviors have multiple causations which must be evaluated in order to assure appropriate intervention. The PRECEDE model was subsequently expanded to become the framework to capture environmental factors influencing health, thus becoming a health promotion framework (PROCEED referring to policy, regularly and organizational constructs for educational and environmental development). This comprehensive framework has been used for the conceptualization of countless programs in numerous countries, forcing program designers to thoughtfully consider a wide range of individual and environmental determinants of health behavior and disease.

Social Marketing The concept of social marketing has evolved from the commercial sector; it is especially appropriate for ► mass media campaigns. Introduced by Kotler and Zaltman in 1971, this concept combines traditional approaches to social change with commercial marketing and advertising techniques in order to promote socially beneficial behavior change. The systematic planning process of social marketing makes use of methods from the commercial sector: setting measurable objectives; doing continual ► market research focusing attitudes, motives and behavioral patterns of the target group; combining strategic key procedures; developing products and services that correspond to genuine needs; creating demand for them through advertising; perpetually evaluating all procedures. In Anglo-Saxon countries, the social marketing concept has received widespread adoption and is subject to controversial scientific discussions.

Other Models Since the publication of the PRECEDE-PROCEED model, the health promotion and prevention area has recognized the importance of careful theory-based intervention planning. Similar planning frameworks have been developed. With a special focus on community-based interventions, the American Centers for Disease Control and Prevention (CDC) introduced The Planned Approach To Community Health (PATCH) in the mid-1980s, which is a process that involves and enables members of a ► community to plan, implement, and evaluate health promotion and disease prevention programs. The PATCH process helps a community establish a health promotion team, collect and use local data, set health priorities, and design and evaluate interventions. In 1998, Bartholomew et al. described a process for developing theory- and evidence-based health education programs

that they call "Intervention mapping". Another example is the "Generalized Model", a very straightforward and systematic concept that has been proposed by McKenzie and Smeltzer (2001) for program planning in health education.

Steps in Planning Prevention Interventions

Despite different underlying philosophies, there are some core elements that can be found in almost every prevention program concept. The process of an intervention development is usually composed of a series of steps, which are labeled differently in different frameworks, but comprise similar characteristics:

1. background analysis and needs assessment
2. priority setting, development of goals and objectives
3. development of action plan, strategies and materials
4. evaluation (► evaluation, models) of processes and results

Background Analysis and Needs Assessment Most conceptualization models begin by identifying peoples' quality of life concerns, their health problems, and the behavioral and environmental factors that cause the health problem. This requires program planners to conduct consultations and to collect comprehensive data on vital statistics including ► disability, ► prevalence, ► morbidity and ► mortality, on environmental factors such as climate, workplace, the adequacy of health care facilities, etc. In addition, the focus of this phase is to acknowledge the unique characteristics of the population to be served, inherent opportunities and challenges, to assess the capacity, including budgets and potential partners, and to identify preliminary areas of focus. This initial groundwork provides contextual information and a foundation for future planning activity. It generally narrows the scope of activity on a single or limited number of priorities and delimits the scope of activity to appropriate audience segments.

Development of Goals and Objectives The definition of the overall program goal and specific program objectives is a hallmark of health education planning processes. Using the scientific analysis of health problems and problem causing factors, the planners should now be able to identify health problems that are serious and/or prevalent enough to justify spending time, money and other resources, to establish priorities, and to pinpoint the factors that are amenable to intervention. In this phase, the time-frame of the goal as well as the target-group should be defined as well. The key components to good objectives have been described with the term SMART: specific, measurable, attainable, relevant, and time-bound. It is crucial to ensure that the goals and objectives are realistic and achievable.

Development of Appropriate Interventions After the development of program goals and objectives, every model addresses the development of the action plan. It is the selection of theory-based intervention methods and practical strategies to change (determinants of) health-related behavior and the production of the program components. This includes the methods of communication for reaching the target group, the message and material development, and the strategy formation. The strategies have to be organized into a sequence of tasks. This phase also focuses on clarifying roles and responsibilities, allocating resources and constructing a time frame.

Development of Evaluation Plan Tracking and assessment are common characteristics of every concept framework. Whereas the process evaluation is used to monitor the entire intervention process and examines whether the intervention or components of the intervention should be refined or modified, the impact or outcome evaluation measures the program effectiveness by assessing whether the intervention is achieving its objectives. It is important to clarify the purpose of the evaluation, select its scale and scope, determine the methodology and organize how the evaluation will be conducted.

Conclusion

Planning skills belong to the essential responsibilities of practitioners working in prevention and health education. Different procedural frameworks that guide the conceptualization of an intervention are available by now. If used effectively, these models force program designers to critically review experience and existing evidence about health promotion problems, and to carefully consider designing comprehensive programs that attempt to intervene on factors that are both important and changeable. Although the application of some of the models can be challenging, it encourages, never-

theless, thoughtful planning and contributes to quality management in prevention and health promotion.

julika.loss@uni-bayreuth.de

Definition

A strategy is a long term plan of action designed to achieve a particular goal. Originally confined to a military context (strategos: Greek "commander"), the term is increasingly used in public health. In health promotion and prevention activities, strategies are a set of decisions and actions that determine the long-run performance of an intervention. An intervention strategy is usually an umbrella plan encompassing a number of smaller plans and elements targeted at a defined population in order to prevent a specific health problem.

Basic Characteristics

Steps of an Intervention Strategy

An intervention's strategy aims to reach a ► target group in order to initiate and effect changes in their ideas and preventive behavior. Most strategies depend on a three-step process: analyzing the current situation, defining goals and/or objectives, and mapping a possible route to these objectives.

The starting point of the strategy development is thoroughly analyzing the psycho-social and demographic factors that determine the behavior of the target audience through market research. For preventive interventions, it is crucial to assess which factors determine health behavior, and to identify how people can be assisted in changing their behavior.

The strategy chosen for a campaign must correspond to the target group's special needs and preferences and also be compatible with its cultural and religious traditions. In addition, the strategy needs to be appropriate for the intervention's resources, environmental circumstances, and core objectives.

Strategies to influence health behavior, e. g. in terms of smoking, encompass a wide range from communication activities, aimed at the individual, to political interventions, aimed at the physical or legal context of the health problem (Table 1).

Communication Strategies

As ► health literacy is a necessary condition for preventive behavior, health education and information form an essential part of almost any preventive intervention. Communication of health related facts and promotion of the intended preventive behavior are thus important strategic aspects of an intervention. Interventions can

Intervention Strategies in Prevention, Table 1 Strategies to influence (determinants of) preventive behavior

Strategy	Example
Communication:	
• Health education, information, counseling	– mass media educative campaign on the prevention of tobacco use
• Motivation, attitudes	– mass media campaign using emotional appeals (e. g. drastically presenting perils or benefits of a behavior) and connecting image factors with a behavior
Political Interventions:	
• Supporting Measures	
– Changing the environment and context	– extending smoke-free areas in a community – removing vending machines for cigarettes
– Incentives	– Increasing taxes for tobacco – reducing insurance premiums for utilizing preventive services, e. g. joining quit programs
• Restrictive policy	– ban on tobacco advertising – smoking bans in public places

use different strategies to reach and communicate with the target group. Two main aspects that have to be considered for communication strategies are 1, the choice of communication channels, and 2, the message.

Distribution Channels: Mass Media Campaigns and Interpersonal Communication ► Mass media are undoubtedly the most important "vehicles" for creating awareness of health problems and their prevention, although their effectiveness varies greatly. Television, cinema, and radio (with due attention to the right broadcasting time) as well as magazines, newspapers, posters, brochures, leaflets, and other print media can be effective, depending on the target group. As a rule, the communication channels selected should be ones the target audience comes into contact with on a regular basis as well as perceives as being credible. Since the impact of mass media is only fleeting, however, the message has to be periodically repeated for a sustained effect. It is also essential to change the "advertising" campaign from time to time.

Notwithstanding the great importance and obvious success of mass media in preventive campaigns, interpersonal contacts and the services associated with them remain indispensable. Mass media can arouse interest, but personal consultation, motivation by promoters, or a doctor's concern can make all the difference between merely knowing about a preventive behavior, having a positive attitude toward it, and actually adopting the new behavior. With the special target group of children and adolescents, interactive measures have proven particularly effective, e. g. facilitated exhibitions offering quiz and discussion elements, group counselings or working with peer educators (► peer education).

It is advisable to combine both mass media and personal communication in the intervention strategy, as it was, for example, successfully realized in the German AIDS awareness campaign "Gib AIDS keine Chance" (*"Don't give AIDS a chance"*).

Promoting the Healthy Behavior: The Message Promoting preventive behavior, e. g. to quit smoking or to utilize cancer ► screening tests, is challenging. Although the offered behavior undoubtedly has a basic benefit (reduction of health risks in the long run), it is mostly one difficult to impart, as the behavior is usually associated with inconvenience and expenditures. Factors typically involved are the time lost or spent (e. g. in traveling and waiting for screening tests or courses), together with perceived barriers to adoption – be they psychological, social, or physical (fear of side effects or of missing an enjoyable habit). Connecting the preventive behavior with additional benefits and symbolic goods is crucial for promoting the behavior, e. g. by emphasizing the fun and better body feeling of doing sports, the opportunities that a long life offers etc. Whether subconscious and conscious fears and concerns can be dispelled and the target individuals can be persuaded of the advantages they may expect mainly depends on the clarity of the message, its sensitivity to the ► target group's concerns and language, and cultural considerations.

Therefore, great importance is attached to the selection of the message and the ways of communicating it to the target group. When employing mass media campaigns, it is important to decide whether the message should be delivered in a neutral and informative way, or whether certain emotions should come into play, e. g. humor or fear. Working with shock motives or slogans, e. g. showing severely ill patients suffering from lung cancer or AIDS, can have a high emotional impact on target individuals with high potential for changing behavior. However, shocking methods are controversial, for they have been shown to have effects to the contrary as well: if the message is too terrifying and threatening, people tend to suppress and negate its meaning. Using humor, e. g. by showing funny spots on the use of condoms, can normalize a formerly uncommon and socially unaccepted behavior, but not everybody understands all kinds of humor.

Another strategy, which is adopted from the commercial marketing and increasingly used in prevention campaigns, is celebrity testimonials: famous actors or sports stars describe their experience with and benefits of a preventive behavior. For example, numerous international soccer stars were involved in an EU nonsmoking campaign ("Feel free to say no"), and the German Felix-Burda-Foundation for Colorectal Cancer Research regularly launches a mass media campaign in magazines and broadcast media where German celebrities urge people to undergo screening for colorectal cancer. When using testimonials, the credibility of the chosen personalities with regard to the target group has to be considered.

It is indispensable that the message and the materials used for communication are pre-tested with representatives of the target group.

Capacity-Building and Management

Strategy implementation in preventive intervention involves the allocation of sufficient resources (financial, personnel, time, technology support), and assigning responsibility of specific tasks or processes to specific individuals or groups. In health promotion and prevention, the process of establishing a system's ability to perform or produce desired outcomes is known as "capacity-building". So in addition to mapping out strategies in order to reach the target group, planners of an intervention also need to build the necessary infrastructure and problem-solving capabilities.

Especially community-based multi-faceted prevention efforts depend on an organizational infrastructure which incorporates partnerships, alliances, networks, and ► community-organizing, in order to facilitate processes and to ensure sustainability. For example, if a local public health agency plans to start a campaign against drug abuse directed at young Russian immigrants, it is crucial to involve other people and organizations that are in contact with this target group. This can be social workers, drug counselors, language schools, orthodox churches, Russian youth clubs, etc. Furthermore, the program planners need to ensure that those social workers and practitioners involved in the program receive adequate teaching as to the background of the problem, the psychosocial features (attitudes, motivations, values, behavioral patterns) and needs of the concerned adolescents, and special problem-solving skills.

The strategy of an intervention also involves managing the process. This includes monitoring results, comparing to benchmarks and best practices, evaluating (► evaluation, models) the ► efficacy and efficiency of the intervention, and making adjustments and modifications to the intervention elements as necessary.

Intestinal Infection with Cestodes

► Intestinal Tapeworms

Intestinal Parasite

Definition

Intestinal parasites are parasites that populate the gastro-intestinal tract. In humans, they are often spread by poor hygiene related to feces, contact with animals, or poorly cooked food containing parasites. Parasites can get into the intestine through the mouth from uncooked or unwashed food, contaminated water, or hands, or by skin contact with larva infected soil. People can also become infected with intestinal parasites if they have mouth contact with the genital or rectal area of a sexual partner who is infected (e. g. oral sex). The most common groups of parasites are protozoans and parasitic worms.

Intestinal Tapeworms

Synonyms

Taeniasis; Intestinal infection with cestodes

Definition

Cestodes consist of a head (scolex) with suckers (by which it attaches to the intestine of the host), a kind of neck and several segments, the proglottids. The proglottids, which contain eggs, are expelled with the stool to ensure the spread of the worm. Humans are the definite host for beef tapeworms (*Taenia saginata*, 6–10m long), pork tapeworms (*Taenia solium*, 3–4m long) and the nearly extinct broad fish tapeworms (*Diphyllobothium latum*, up to 20m long); the corresponding animals are the intermediate hosts. Cestodes are spread worldwide. Infection is transmitted by the ingestion of meat or sausages containing the larval stages of tapeworms. In the gut the larvae develop to adult worms. Larvae of the pork tapeworm can also reach other organs, causing cysticercosis. An infection with the broad fish tapeworm is caused by the ingestion of fish that is infected with plerocercoids (larval stages). Symptoms of taenisasis can be nausea, vomiting and malaise. Moreover, there can be a loss of weight despite of an adequate food intake.

Intimate Partner Violence

Synonyms

Domestic violence; Family violence

Definition

Intimate partner violence (IPV) refers to sexual abuse, physical aggression and/or psychological abuse by an intimate partner. IPV includes harmful and potentially harmful acts, sexual coercion or assaults, threats to kill or to harm, restraint of normal activities or freedom and denial of access to resources. IPV may also be continuous exposure to behaviors designed to control and dominate.

Intoxication

Definition

Intoxication as the major acute impairment after heavy use of psychoactive substances is characterised by direct substance related effects: overreaching emotions, reduced inhibitions and uncontrolled behaviour (e. g. impaired balance).

Intracranial Injury

► Traumatic Brain Injury

Intranet

Definition

An intranet is a form of computer network, based upon ► world wide web and ► internet technologies, but whose scope is limited to one organization. Contrary to the Internet, access to an intranet is limited to defined users or user groups. An intranet may be connected to the Internet, so that there can be communication and flow of information between it and other intranets.

Intrauterine Growth Retardation (IUGR)

Synonyms

Intrauterine growth restriction

Definition

Intrauterine growth retardation is the growth restriction of a fetus resulting in a small for gestation age baby whose birth weight is below the 10th percentile for that gestation age. Depending on when during pregnancy the growth restriction occurs, you can have asymmetrical or symmetrical growth restriction. Asymmetrical growth restriction which is more common, is defined as growth retardation that occurs in the 3rd trimester, whereas symmetrical growth restriction results from growth restriction in the 1st or 2nd trimester.

Intrauterine Mortality

Synonyms

Fetal mortality; Fetal death

Definition

Intrauterine mortality refers to death prior to birth at any gestational age. Fetal deaths may be early (less than 20 weeks), intermediate (20 to 27 weeks), or late (more than 27 weeks). The birth of a dead fetus or infant is called stillbirth. The absence of breathing, heart beats, pulsation of the umbilical cord and definite movements of voluntary muscles are the signs of a stillbirth. Causes of intrauterine mortality may be genetic defects, infection (e. g. measles), maternal diseases (e. g. diabetes), dysfunction of the placenta, or other, unknown, causes.

Intrinsic Motivation

Synonyms

Internal motivation

Definition

The motivation or desire to do something based on the enjoyment of the behavior itself rather than relying on or requiring external reinforcement. It is evident when people engage in an activity for its own sake, without obvious external incentives (e. g. a hobby).

Inuits

Synonyms

Native Americans; Indigenous people of North America Eskimo (United States)

Definition

Inuit are Indigenous people inhabiting the far north regions of North America from northern Alaska to eastern Canada and Greenland.

Investigation

► Ethics, Aspects of Public Health Research

Investigational Protocol

Synonyms

Study protocol

Definition

The protocol is the set of rules by which a study is conducted. It usually contains information about the

objective, design, methodology, and organization of the experimental study. The protocol is carefully designed to safeguard the health of subjects in the study.

Cross-References

► Study Protocol

Investigator's Brochure

Definition

The investigators brochure describes the characteristics of the drugs or devices to be tested in a clinical trial. It has to contain an executive summary for quick reference, data concerning the physical, chemical, and pharmaceutical properties and formulation of the product (e. g. chemical name, generic and trade name when approved, all active ingredients, the investigational products pharmacological class and its expected position within this class), the results of all relevant nonclinical pharmacology and toxicology (e. g. single dose, repeated dose, carcinogenicity, irritancy and sensitization), reproductive toxicity, genotoxicity (mutagenicity), pharmacokinetic, and investigational product metabolism studies performed in-vitro or in animals, data concerning the investigated therapeutic and the possible unfavorable and unintended effects of the product, all previous established data concerning effects in humans like pharmacokinetics and product metabolism data, including metabolism and absorption, plasma protein binding, distribution, and elimination, bioavailability of the investigational product (absolute, and/or relative) using a reference dosage form, population subgroups (e. g. gender, age, and impaired organ function like kidney and liver), interactions (e. g. product–product interactions and effects of food), data on safety and efficacy and dose response that were obtained from preceding trials in humans (healthy volunteers and/or patients) and if applicable data from marketing experience.

Furthermore, the investigators brochure should contain the rationale for performing research with the investigational product, and the anticipated prophylactic, therapeutic, or diagnostic indication as well as a general risk–benefit evaluation of the product.

IQWiG

Definition

In 2003, as part of Germany's health system reform and modernization, legislation called for the establishment of a new national institute for German health care. The "Institute for Quality and Efficiency in Health Care" (IQWiG = Institut fuer Qualitaet und Wirtschaftlichkeit im Gesundheitswesen) was established as a private foundation by the Federal Joint Committee (G-BA), which self-administers the health services in Germany. The IQWiG is responsible for scientific evaluation of the use, quality, and efficiency of health care services and pharmaceuticals in Germany. Additional roles include the evaluation of clinical practice guidelines, making recommendations to disease management programs, and the publication of health information for patients and consumers. As a professionally independent scientific establishment, the Institute addresses questions relating to the quality and efficiency of services provided by statutory health insurance, and considering people's age, gender and living conditions.

IRB

► Ethics Committee, EC

Isolation in Clinical Medicine

Definition

In ► hospital epidemiology, isolation refers to the precautions that are taken in the hospital to prevent the spread of infection from an infected or colonized patient to susceptible persons. The CDC (► Centers for Disease Control and Prevention) and the Hospital Infection Control Practice Advisory Committee have prepared a guideline for isolation precautions in hospitals. This guideline contains two levels of precautions. The first level is Standard Precautions, designed for the care of all patients in hospitals regardless of their diagnosis or presumed infection status, because signs and symptoms of infection are not always obvious. Isolation practices include hand hygiene; the use of protective barriers such as masks, gowns and gloves; special handling of contaminated articles; and patients' placement in a private room or other alternatives. The second level (known as Transmission-Based Precautions), is designed for individuals documented or suspected to be infected or colonized with highly transmissible or epidemiologically important pathogens. There are three types of Transmission-Based Precautions: Airborne Precautions, Droplet Precautions, and Contact Precautions. They may be combined for diseases that have multiple routes of transmission.

Isolation of Persons to Prevent Transmission of Diseases

► Quarantine

Isolation in Public Health

Definition

Isolation in the public health context refers to the separation of individuals known to be affected by an ► infectious disease from the rest of the community.

Itch

► Infection with Sarcoptes Scabiei
► Scabies

Itching

Synonyms

Feeling of itchiness; Pruritus

Definition

Itching is an uncomfortable irritation of the skin, which causes the desire to scratch. It arises by a stimulation of free nerve endings, the transmission of the sensation to the brain shares common nerve pathways with the sensation of pain. The primary chemical in itching is histamine, which is released from mast cells. Histamine leads to a widening of the blood vessels with an increase in their permeability. With the inflow of fluids into the tissue free nerve endings are stimulated causing the sensation of itching. To soothe itching antihistamines (histamine-H1-receptor antagonists) can be used. They can be applied locally as ointments, creams or gels or systemically (oral or parenteral administration). Antihistamines are divided in two generations. The representatives of the first generation show additional sedating effects.

IUHPE

Definition

The international union for health promotion and education (IUHPE) is an international non governmental organization. Established for 50 years ago and located in Saint-Denis Cedex, France. IUHPE is a leading global network working to promote health worldwide and contribute to the achievement of equity in health between and within countries. The network is divided in regional offices that represent the organization all over the world. The mission of the International Union for Health Promotion and Education (the IUHPE) is to promote global health and to contribute to the achievement of X1equity in health between and within countries of the world considering the principles of the Ottawa Charter. The IUHPE is in close cooperation with ► WHO, UNESCO, UNICEF, and other major inter-governmental and non governmental organizations to influence and facilitate the development of health promotion strategies and projects all over the world.

Japan Encephalitis

Synonyms

Japanese encephalitis

Definition

Japan encephalitis is a virus infection transmitted by a mosquito, which is primarily found in Eastern and Southeast Asia. Following an incubation period of 4–14 days fever, severe headache, stomach ache, nausea and vomiting occur. Further symptoms are confusion and agitation. The disease can progress to a serious infection of the brain with motor or cranial nerve paresis, movement disorders and seizures. Reconvalescence can take several months, major neurologic sequelae can remain. For prophylaxis travelers into endemic regions should receive an active immunization. The vaccine is given on the days 0, 7 and 30.

Cross-References

► Acute Life-Threatening Infections

Jarisch-Herxheimer Reaction

Synonyms

Herxheimer reaction

Definition

A Jarisch–Herxheimer reaction can appear a short time after the onset of antibiotic therapy. Due to a massive destruction of pathogens, toxins are set free. These toxins cause a release of substances which support the inflammatory reaction (so-called mediators of inflammation). A Jarisch–Herxheimer reaction is characterized by flu-like symptoms, as fever, shivering fits, aching muscles and arthritic pain. It can be prevented or at least moderated by the administration of steroidsm (prednisolone) prior to the onset of antibiotic therapy.

Jawbone

Definition

The jawbone is the bone of the jaw, which comprises an upper jaw and a lower jaw. The lower jaw is the mobile component. It articulates at its posterior processes with the temporal bones of the skull on either side, called the mandibular/jaw joint. The upper jaw is more or less fixed with the skull. Jaws accommodate teeth.

Job-Related Stress

Synonyms

Job stress; Work stress; Workplace stress; Stress at work

Definition

Job-related stress can be considered to be a disturbed relationship between the worker and his or her ► work-

ing environment. It is a state characterized by high levels of arousal and distress and often by feelings of not coping. The experience of job-related stress is treated as essentially emotional in nature.
It originates, at least in part, with exposure to environmental agents that are generally referred to as "work-related stressors". Exposure to work-related stressors contributes to acute psychological, physiological, and/or behavioral changes. If these changes are persistent or recurrent, the onset of symptoms and subsequent (stress-related) illness may occur. The causes of job-related stress may also originate in factors intrinsic to the work content (workload, pace of work, design of work) and work context (role ambiguity, relationships with others, non-supportive organizational climate at workplace). Individual factors, such as personality and coping, as well as non-work factors (family demands and non-work-related social support), play a role as moderators of the relationship between job stressors and acute and chronic stress reactions. Current theories and models of job-related stress (the demand-control model – DC model; the effort-reward imbalance model – ERI model; the transactional model – TA model) are distinguished by major theoretical differences.

Job Stress

► Job-Related Stress

Job Task

Synonyms

Workplace conditions; Working environment

Definition

The term job task refers to working conditions, machinery, tools, layout, factory premises, or working climate that covers the ► workplace environment. It can also be workers' physical, social and mental workload; the psychosocial and organizational context of tasks (of the job) under which the work has to be performed or which influence the work (or job tasks); or the ► working environment.

Job Task Environment

Synonyms

Working conditions; Working environment

Definition

The working environment includes the surroundings, conditions and influences at work and ► workplace that affect an employee. In occupational health it refers to physical (physical, biological, chemical and ergonomic factors at work) and psychosocial work environments (work organization, inter-individual relationships at work, work culture, job security, etc.). The working environment may be considered as a part of a general environment, and there is an obvious inter-relationship between the working environment and the general environment. The identification of the working environment is essential if occupational health preventive actions are to change the working environment and prevent harm or promote benefit.

Kaplan-Meier Curve

► Kaplan-Meier Survival Plot

Kaplan-Meier Method

Definition

A distinguishing feature of survival data is the inevitable presence of incomplete observations. In these situations, each patient has a different length of follow-up. It is difficult to assign meaning to the term "proportion surviving" without specifying a fixed period of observation common to all patients. The Kaplan-Meier method can estimate the probability of surviving when patients have different lengths of follow-up. In the Kaplan-Meier method, the percentage of survivors at each death time is recalculated.
The chance of surviving one year is therefore

$$S_{365} = C_1 \times C_2 \times C_3 \times \ldots \times C_{364} \times C_{365}\,.$$

C_1 is the chance of surviving the first day,
C_2 is the chance of surviving the second day having already survived day one,
C_3 is the chance of surviving the third day having already survived days one and two, ...
C_{364} is the chance of surviving day 364 having already survived days one to 363, and
C_{365} is the chance of surviving day 365 having already survived days one to 364.

Kaplan-Meier Survival Plot

Synonyms

Kaplan-Meier curve; Time-to-event curve; Survival curve

Definition

Time-to-event analysis is a potentially powerful and informative method of analysis. In this analysis, clinical trials commonly record the length of time from study entry to disease endpoint for a treatment group and a control group. These data are commonly depicted by a Kaplan-Meier survival plot, from which the median and the mean can be derived. In Kaplan-Meier survival plot, the percentage of survivors is recalculated at each death time so that the curve takes on a characteristic appearance of horizontal and vertical lines when plotted.

Kappa Coefficient

Synonyms

Kappa statistics

Definition

Kappa coefficient is a measure of ► agreement between raters or measurement procedures for categorical data, such as diagnosis. This measure indicates the proportion of agreement that remains after correction for

agreement expected by chance. Kappa coefficient value less than 0.4 can be considered as poor, from 0.4 to 0.75 fair to good, and over 0.75 excellent agreement. A kappa coefficient of zero indicates agreement only by chance. Values of 1.0 and –1.0 indicate perfect agreement and perfect disagreement, respectively.

Kappa Statistics

► Kappa Coefficient

Katayama Fever

Synonyms

Systemic schistomoniasis; Systemic bilharziasis

Definition

Katayama fever appears when schistosomas release their eggs for the first time. According to the worm species this can be between two weeks and two months after the infection. Katayama fever is characterized by shivering fits, fever, cough and headache. Furthermore, there can be swellings of the lymph nodes and an enlargement of the liver and spleen. In most cases, the symptoms vanish within a couple of weeks, but severe courses with a lethal outcome are possible.

Knowledge-Based Information

Definition

The knowledge-based information is information derived from professional literature of a field of knowledge. In health care, knowledge-based information is derived from observations, interventions or research on many patients. Its purpose is to create new knowledge in the field of medicine, based on evidence, which in turn will be applied in the treatment of individual patients. Three categories are identified: primary knowledge-based information – original research reports in medical literature; secondary knowledge-based information – information that indexes the primary literature (i. e. Medline); and tertiary knowledge-based information – reviews or summaries of primary literature (textbooks, monographs, review articles).

Knowledge Management

Definition

Knowledge management is the process of the identification, mobilization and use of knowledge to improve decisions and actions. Medical knowledge management relates to the collection and studying of knowledge obtained from investigation studies, or systemic reviews in order to make it applicable and useful for medical purposes.

Kolmogorov-Smirnov Test

Synonyms

K-S test

Definition

The Kolmogorov-Smirnov one-sample test for normality is one of the most commonly used ► goodness-of-fit

tests. This test compares the sample cumulative distribution with the cumulative distribution function specified by the null hypothesis. The test is based on the maximum difference (D-statistic) between these two distributions. The K-S test is limited to continuous variables only. The null hypothesis states that the empirical distribution does not differ from normal distribution. If the D-statistic is greater than the critical one and the null hypothesis is rejected, it is concluded that the empirical distribution is not normal. The Shapiro-Wilk test is a more powerful alternative to the Kolmogorov-Smirnov one-sample test for testing normality.
The Kolmogorov-Smirnov two-sample test compares two empirical distributions and is based on the maximum difference between two cumulative distributions.

Labor Inspectorate

Synonyms

Workplace inspectorate; Work inspectorate

Definition

Labor inspectorate usually means a governmental inspection agency established by the national or municipal competent authority or other related authority for the purpose of labor force inspection. The purposes of labor inspection are the: maintenance of occupational safety and health, protection of workers' right and benefits, enhancement of harmonious relationships between workers and management, thus raising productivity and promoting social reconstruction and economic development. Labor inspections are carried out by public officials to secure the enforcement of the legal provisions relating to conditions of work and the protection of workers. Among the main tasks of the labor inspectorate the following are emphasized – inspection of dangerous machinery and equipment, examination and inspection of hazardous working sites, and, especially, education, training, publicity and guidance in the field of occupational health and safety.

Labor Market

STEFAN GREß, FRANZ HESSEL
Health Services Research and Health Economics, Department of Health Sciences, University of Applied Sciences Fulda, Fulda, Germany
stefan.gress@pg.hs-fulda.de, franz.hessel@sanofi-aventis.com

Definition

Health economics analyzes the labor market from several perspectives. One important approach concerns the repercussions of health care financing on employment. Direct links between rising health care costs and labor costs may result in rising labor costs and a drain on employment. Alternatively, a direct link between rising health care costs and labor costs may lead to less coverage – as has been the case in employer-sponsored health insurance in the United States (US). Another important approach analyzes indirect costs. Indirect costs are defined as the productivity loss due to a limitation of the health state by additional days of absence from work, early retirement, or premature death. Indirect costs are approximated by the average labor costs to compensate for the loss of productivity. The human capital approach and the friction cost method are two methodological tools to estimate indirect costs.

Basic Characteristics

Health Financing and the Labor Market

An important aspect of the design of ► health financing is the repercussion of health financing schemes on employment. If there is a direct link between health care expenditures and labor costs, rising health care expenditures lead directly to rising labor costs. If this is the case, rising health care expenditures increasingly drive a wedge between labor costs of the employer and net wages of the employee. As a consequence, microeconomic labor market theory generally assumes that incentives for the employee to work diminish. What is more, incentives for the employer to substi-

tute capital for labor – or to substitute cheaper labor from abroad for domestic labor – increase. Therefore, all other things being equal, employment goes down.

The macroeconomic consequences of a direct link between rising health care expenditures and labor costs for employment are less straightforward. Rising health care expenditures are spent on health care services, which in turn provide additional employment. The net employment consequences depend on the productivity of industries. If, for example, employment is lost in the manufacturing industry due to rising labor costs, the net employment effect is probably positive. Health care services are usually less productive due to a higher ratio between labor and capital. Nonetheless, if the link between rising health care costs and labor costs is weak rather than strong, the positive net employment effect of rising health care costs can possibly be increased.

In ► social health insurance systems with income-dependent premiums, the link between health care expenditures and labor costs is very strong – more so if employers pay for at least a part of income-dependent premiums, as is the case in Germany and the Netherlands. If health care expenditures increase, income-dependent premiums go up. Labor costs and the wedge between labor costs and net wages increase straightaway. Moreover, incentives for the substitution of labor by capital increase. All other things being equal, employment goes down.

In social health insurance systems with ► community-rated premiums, the link between health care expenditures and employment is less obvious. Rising premiums will not automatically lead to rising labor costs but to a decrease in disposable income of employees. This in turn will lead to less consumption or less savings for employees, but incentives for employment remain unchanged – at least in the short run. In the long run, rising health insurance premiums might lead to rising wage demands and – if the bargaining position of employees is strong – to rising labor costs for the employer.

In tax-funded health care financing systems, the strength of the link between health care costs and labor costs is different for direct taxes on income and indirect taxes on consumption. The link between health care expenditures and labor costs is very strong in tax-funded systems that rely on direct taxes to finance health care. This link is stronger the more the tax-system depends on income from employment as a tax-base. If health care expenditures increase, governments need to raise direct taxes on income. Again, all other things being equal, employment goes down because the wedge between labor costs and net wages goes up. Repercussions on employment will be even more pronounced if taxes on profits are increased as well.

The link between health care expenditures and labor costs is less pronounced in tax-funded systems that rely primarily on indirect taxes to finance health care. If health care expenditures increase, the government needs to increase indirect taxes. In the short run, incentives for the demand and supply of labor remain unchanged.

In the US, the majority of the non-elderly population takes out health insurance coverage through their employer or the employer of a family member. The link between health care costs and labor costs is even more direct than in social health insurance and tax-financed schemes, because employers pay the majority of health insurance premiums. However, in contrast to social health insurance schemes and tax-financed systems, employer-sponsored health insurance in the US is not legislatively mandated and is far from universal (Amelung et al. 2003; Greß et al. 2004). As a consequence, the long-standing link between work and employer-sponsored health insurance becomes weaker as health care expenditures and health insurance premiums rise and employers cut down coverage: "Because employer-sponsored insurance is voluntary on the part of businesses and employees, not all firms offer health benefits, not all workers are eligible for coverage, and not all employees choose to participate or can afford their share of the health premium" (Clemans-Cope and Garrett 2006, p. 1).

Indirect Costs

The costs of an illness or disease are differentiated into the direct cost related to diagnosis and treatment in or outside the health care system and the indirect costs (► costs of illness/costing process). Indirect costs are the key element in estimating the costs from a ► societal perspective. From all other perspectives to be chosen for the costing process, indirect costs are not considered in the estimation.

Indirect costs express the influence of a loss of productivity of the labor force due to ill health on the national economy. Indirect costs can be due to decreased efficiency or total absence from work through an illness – for a limited number of days of absence or early retirement – or due to premature death. In the latter case, the time period before the average age of retirement is taken into consideration in the estimation of indirect costs. There are two ways of calculating the indirect costs: (1) the human capital approach and (2) the friction cost approach. Both approaches are based on the assumption that the lost productivity can be valued by the achievable gross income of the employed population, and by that giving the labor a defined value. Using the human capital approach, the entire period of absence from work due to illness is considered and valued by the achievable gross income. Thus, for example, for an individual dying prematurely at an age of 35, the entire period of 25 to 30 years until the average age at the end of employment (retirement) is calculated. The human capital approach is based on economic theory and gives a maximum of the possible productivity loss (Sculpher 2001). The friction cost method more accurately estimates the actual loss of productivity in western industrial countries. It takes two main aspects of criticism against the human capital approach into consideration. First, a relevant part of the short-term absence from work, due to an influenza infection for example, is compensated for either by colleagues or by the employee himself when back at work. Second, in societies with a relevant percentage of unemployed people, a large percentage of positions will be taken by a previously unemployed individual after a certain time called the friction period (Koopmanschap et al. 1995). Using the friction cost method, only the shorter friction period is valued using the average achievable gross income. For the above-mentioned example of an individual dying at 35 years of age, the friction cost method gives a much lower estimation of the indirect costs compared with the human capital approach, which overestimates the actual productivity loss.

The human capital approach is considered to be the simpler and more frequently used approach and is therefore recommended by the majority of recommendations for economic evaluation studies, although it is also recommended that the friction cost approach should be calculated in an additional scenario or at least a ► sensitivity analysis should be carried out (Gold et al. 1996).

Labor and Occupational Safety Law

Adem Koyuncu
Mayer Brown LLP, Cologne, Germany
akoyuncu@mayerbrown.com

Synonyms

Employment and workers safety law

Definition

Labor and occupational safety law comprises the legal rules that govern three aspects. Labor law regulates the legal relationship between employers and employees (including worker unions) with respect to the employment and the corresponding rights and duties resulting therefrom. Occupational safety laws encompass the body of law that provides for both the safety and health of employees at the workplace as well as the compen-

sation of employees for work-related injuries and diseases.

Basic Characteristics

Background and Context

The safety and health of employees at work was already historically a main concern of public health practice. Occupational safety is still one of the core fields of public health law. The achievement "safer workplaces" was among the CDC's ten great milestones of public health in the 20th century (CDC 1999). In most jurisdictions, the laws governing occupational safety and health have been consolidated in distinct statutes (e. g., in the U.S., Germany, the UK, Australia). As a field of law, occupational safety laws may be regarded as a part of both public health law and labor law.

Labor law (synonym: employment law) must be differentiated from occupational safety laws even though both are associated with employment. Labor law is formed by the laws that govern the legal relationship between ► employers and their ► employees with respect to the mutual rights and duties arising from the employment. The subjects of labor law include the legal governance of employment contracts, wages, conditions and causes of termination, collective labor agreements, co-determination, employee participation and vacation entitlements. Labor law also provides for legal rules providing maternity protection (maternity leave), which have also contributed to "healthier mothers and babies", one of the ten great public health achievements of the 20th century (CDC 1999).

Occupational safety and health law focuses on two main concerns. *First*, it provides the rules to safeguard and promote the health of workers and their families by ensuring safer workplaces and healthier work conditions and, in so doing, also protects the community from health risks. *Second*, a part of occupational safety laws focuses on the handling (medical treatment, rehabilitation) and the compensation of work-related injuries and diseases (Reynolds 1995). Thus, occupational safety law focuses on the protection of workers, their families and the population.

The reason for the existence of distinct occupational safety laws is grounded in the factual and legal complexity of work life. *First*, there is a multitude of workplaces with a corresponding multitude of health and safety risks. This is particularly true in conjunction with the complexity of work processes, which need regulatory governance to protect all actors exposed to these threats. *Second*, work life is characterized by the legal dependence of employees on their employers. Without legal and administrative governance and standard setting activities, employees would hardly be able to enforce the same level of occupational safety from their employers. On the other hand, workplace safety is also in the employers' interest so that all three actors (employee, employer and administration) share this principal objective. However, occupational safety is associated with significant costs, which mainly the employer has to bear, again causing concerns for the employer. In light of this conflict-filled legal and factual environment, workplace safety and health as a public health concern needs strong legal and administrative supervision by specific public health laws and specialized administrative authorities. Occupational safety cannot be left to case-by-case-decisions between employees and employers.

Legal Means of Occupational Safety Law

Because of the multiplicity of health risks and the complexity of work life, the legal means of occupational health and safety regulation are manifold. They may be differentiated based on their starting points.

First, occupational safety laws provide for general legal means and authorizations. As such, the legislator has granted authorization to the government to establish and fund specialized occupational safety agencies. Within the scope of their targeted missions, these agencies dispose of legal powers and authorities vis-à-vis the public, employers and employees. Fundamentally, the agencies carry out the regulatory supervision of workplaces. They are also entitled to conduct their own research, set safety and health related standards and make rules. In doing so, the legislator makes laws with particular safety-related rules (e. g., maximum work hours). The government issues recommendations and "technical rules" which reflect the present state-of-the-art of workplace safety (Koyuncu and Kamann 2007). In this function, the administration has the additional right and duty to advise the employers and employees and support them in implementing new safety measures.

The role of the occupational safety agencies is embedded in a much more cooperative approach than in

other fields of public health law (Rischitelli and Silverstein 2007; Reynolds 1995). Nevertheless, occupational safety agencies are administrative agencies with sovereign powers. The regulatory supervision includes, among others, inspections, surveillance activities (e. g., reporting duties, data collection, inquiries) and administrative, civil and criminal penalties in the case of legal non-compliance, as well as drastic risk reduction measures like the closure of businesses and workplaces.

Second, occupational safety means are attached to employers. In most jurisdictions, occupational safety laws *inter alia* provide for:

- Mandatory (work-related) preventive medical examinations and exposure-dependent follow-up examinations at the expense of the employer;
- The right of employees to be informed about risks and hazards of the equipment and substances they handle at work (*See* Rischitelli and Silverstein 2007, on the "Hazard Communication Standard" in U.S. occupational safety and health law). These laws in favor of employees are also denoted as "right-to-know laws" (Judson et al. 2006): These public health laws grant the employees the right to know the risks and hazards of the substances and materials they work with;
- Safety related training: instructions whereby the employees may be statutorily obliged to attend such training as a prerequisite for commencing or continuing the employment;
- The use of personal protective equipment at work;
- Protection for particular groups (maternity protection, protection of disabled).

These measures are interwoven with further legal means of occupational safety regulation that focus on particular workplaces, their environment and the employer.

Third, occupational safety means are attached to the workplaces, work equipment and substances dealt with at work. These measures aim to realize the employers' duty to provide workers with workplaces and instruments that are as safe and healthy as possible. This general employer obligation can be subdivided into the following duties:

- Conduct exposure and hazard assessments for the workplaces;
- Provide employees with safe instruments and equipment;
- Limit the use of hazardous substances and, when such substances are used, inform the employees accordingly (hazard communication);
- Provide employees free of charge with personal protective equipment (e. g., earplugs, helmets, protective shoes, safety glasses, gloves. *See* Rischitelli and Silverstein 2007 for further examples);
- Pay for protective vaccination of employees (e. g., nurses, physicians, veterinarians, public health officers);
- Depending on the size of the workplace, they may have a duty to employ a company medical officer overseeing the workplace risks, examining, educating and training the employees and advising the employer on necessary safety measures;
- Reporting obligation with respect to work incidents and safety issues;
- Comply with government safety standards and recommendations;
- Keep records on workplace risks, accidents and medical findings of the employees;
- Implement protective measures for certain employee groups (mothers, pregnant women, disabled employees), including discrimination and mobbing protection.

The legal duties of employers with respect to occupational safety are multifaceted and dynamic in nature. Therefore, this non-exhaustive enumeration shall provide an insight into the spectrum of occupational safety and health regulation. These duties may vary and alter depending on the circumstances and the present risk-profile of the workplace, the equipment or the processed substances.

Fourth, occupational safety and health statutes govern the handling of work-related injuries and diseases. There is a duty to compensate workers as well as to support their rehabilitation and return to work. In many jurisdictions, laws have imposed a duty for the employers to insure the employees against work accidents and diseases. Such statutory insurances exist in most countries (e. g., "*gesetzliche Unfallversicherung*" in German speaking jurisdictions, "workers' compensation" in English speaking jurisdictions. *See* Judson et al. 2006, for the U.S.). This insurance, regularly funded by employers, covers medical and rehabilitation expenses after occupational injuries and diseases.

Particular Aspects

Occupational safety and health regulation is designed to protect workers and the public. At the same time, this public health area significantly affects the employers' economic rights, property and business interests. Therefore, a careful legal balancing between the protected public health interests and the infringed employers' rights is a fundamental prerequisite for occupational safety and health regulation. This is true on both the macro-level of legislation and the micro-level of case-by-case decision-making. Most occupational safety laws are the result of such legal balancing by legislators, which included the relevant stakeholders (worker and trade unions, employers' unions, public health agencies) in the legislation process.

Law-making and regulation in the realm of labor and occupational safety law must also respect the collective bargaining rights of worker and employer unions (► tariff autonomy). To a certain extent, such bargaining includes occupational safety aspects. As in labor law, the interests of employees and employers regularly collide; the collective bargaining rights are special institutionalizations of the legal balancing process in this realm.

Occupational health and safety is also a concern of international organizations and international law. Thus, since its foundation in 1919, the International Labor Organization (ILO) has also pursued workers' health and safety matters. The protection of workers against sickness, disease and injury arising out of their employment is one of the central practice areas of this organization. ILO activities include setting of labor-standards and guidelines as well as legislation proposals for implementation by the ILO Member States.

For the realization of occupational safety, cooperation between employers, employees and public health agencies is necessary. Occupational safety is in the interest of all these actors and in the population's interest. Thus, it is commented that the "tripartism" of employers, employees and regulatory agencies is a characteristic of contemporary occupational safety law (Reynolds 1995). In light of constantly altering work life, new techniques and newly emerging occupational health risks, teamwork between the three central characters of occupational safety will have to continue.

Lambliasis

Synonyms

Giardiasis; Infection with Giardia lamblia; Dysentery by Giardia lamblia

Definition

Giardia lamblia was named after its discoverers, Alfred Mathieu Giard and Vilem Dusan Lambl. It is a flagellate protozoon of worldwide significance which causes 200 million cases yearly. It is distinguished between active (trophozoites) and passive forms (cysts). The cysts are highly resistant against environmental influences and can survive in water for up to 4 months. In most cases the infection is caused by the ingestion of cysts in

contaminated water or food. Other vectors of transmission are flies. It has to be mentioned, that disease can occur with the ingestion of as few as 10 cysts. In the upper parts of the intestines the cysts change into trophozoites. After an incubation period of 1–10 weeks symptoms like diarrhea, flatulence and stomach ache can develop. Often the course of the disease is asymptomatic. In the lower part of the small intestine trophozoites change again into cysts, which are then expelled with the feces. Therapy consists of the administration of metronidazole, tinidazole or ornidazole; without treatment recurrent episodes of diarrhea are possible.

Land

► Country

Landfill

Synonyms

Dump; Tip; Hole

Definition

Landfill, also known as a *dump* (US) or a *tip* (UK), is a site for the disposal of waste materials by burial and is the oldest form of ► waste treatment. Historically, landfills have been one of the most common methods of organized waste management (along with incineration), and remain so in many places around the world. A method for final disposal of solid waste on land. The refuse is spread and compacted and a cover of soil applied so that effects on the environment (including public health and safety) are minimized. Under current regulations, landfills are required to have liners and leachate treatment systems to prevent contamination of ground water and surface waters. Most modern landfills are classified according to the type(s) of waste material disposed of into them: hazardous waste landfill, sanitary landfills, inert waste landfill and dumps. To be commercially and environmentally viable a landfill must be constructed in accordance with specific requirements, which are related to: location, stability, capacity and protection of soil and water through. In the late 20th century, alternative methods of waste disposal to landfill and incineration have begun to gain acceptance. Anaerobic digestion, composting, mechanical biological treatment, pyrolysis and gasification all began to be established in the market.

Lasers

Definition

LASER is an acronym for *Light Amplification by Stimulated Emission of Radiation*. A device that produces coherent electromagnetic ► radiation is a laser. All of the energy of emitted electromagnetic radiation is monochromatic—of one single color (essentially a single frequency or a single wavelength) focused in a very thin beam, with all its waves moving along together in the same phase. All other forms of radiation from ordinary natural or artificial sources are incoherent, containing many colors randomly arranged during propagation through the space. Depending on the type of laser, emitted radiation may be in any part of the so-called optical radiation range: a) ultraviolet spectral region; b) visible light; or c) any part of the infrared spectral band. There are a variety of useful applications of lasers in scientific laboratories, military devices, industry, medicine (e. g. eye surgery), optical fiber communications (radio, telephone, TV), laser screen pointers, and even in households, e. g. audio and video compact disk recorders/players, and laser printers. In enclosed systems under normal use, there is no health risk for consumers, but in other situations, this very intense energy can be harmful for human health. In those cases, adequate safety measures are required to protect eyes (from permanent retinal injuries or cataracts), and skin (damages range from minor skin reddening to severe burns). Depending on the total power output, all lasers are classified into four classes.

Lassa Fever

Definition

Lassa fever primarily appears in West Africa during the dry season. It is transmitted by feces or urine of infected rats (by ingestion of contaminated foodstuffs) or by direct contact with an infected individual. Without treatment, the infection takes a lethal course in 40% of cases. In 25%, massive internal bleeding occurs. Besides an inflammation of the heart sac (pericarditis), meningitis as well as cardiocirculatory and renal failure can develop. As a vaccination is not available, the compliance to hygienic rules and the avoidance of contact with rats play an important role in the prevention of Lassa fever. Moreover, special precautionary measures are necessary concerning contact with infected individuals.

Latency

Synonyms

Latent period

Definition

The term "latent period" is often used synonymously with "induction period", that is, the period between exposure to a disease-causing agent and the appearance of manifestation of the disease. It has been also defined as the period from disease initiation to disease detection.

Late Neonatal Mortality

Definition

Late neonatal mortality is defined as the death of an infant between 7 and 29 days of life.

Latent Period

Latent Schizophrenia

► Schizotypal Disorder

Latent Schizophrenic Reaction

► Schizotypal Disorder

Lateral Sclerosis

► Motor Neuron Diseases

Law

Definition

The term law encompasses the sum of the rules within a community, which are accepted as binding and which regulate the legal relationships among people, between people and state institutions and among the state institutions. Laws form the body of the basic rules of order in the community. Such rules can be laid down in legislated legal rules, thus, statutory laws like acts and bills (statutory law). Such rules can also be made through court decisions so that they are denoted as "case-law" or "common law". In addition, unwritten legal rules exist, deriving from long-standing and accepted customs, which are named customary law (in German-based jurisdictions "*Gewohnheitsrecht*").

Law of Delict

► Tort Law and Public Health

Law of Medical Informatics

Definition

The process of creating health information is complicated, since it includes skills of interpretating, organizing and structuring data obtained from the patient together with medical knowledge. Therefore, the information depends on the context of its production, which is formulated as the law of medical informatics: "Data shall

be used only for the purpose for which they were collected. If no purpose was defined prior to collection of the data, then the data should not be used."

Law in Public Health

Definition

Public health law is the authority and responsibility of the government to prevent and promote the population's health, at the same time respecting the rights of the person's privacy and property, as well as the rights of all groups in the society. Public health authorities have the power to regulate persons, health professionals and businesses in the health sector. Since public health is for the common good, public health policies can be put above individual privacy.

Law of Torts

► Tort Law and Public Health

Layman

Definition

A layman/laywoman is a member of an ethics committee who does not have specialized or professional knowledge of the area of research to be evaluated. It is important to have such members on ethics committees to ensure the legibility and comprehensibility of information materials prepared for "ordinary" patients and to provide a "common sense" approach to the evaluation of research projects.

Leading Health Indicators (LHI)

Definition

The Leading Health Indicators are a set of ► health indicators proposed within the "Healthy People 2010" objectives for measurement of the health of the U.S. nation in the 21st century. The Leading Health Indicators are physical activity, overweight and obesity, tobacco use, substance abuse, responsible sexual behavior, mental health, injury and violence, environmental quality, immunization, and access to health care. These indicators were selected because of their ability to motivate action, the availability of data to measure progress, and their importance as public health issues.

League Table

Definition

In league tables, health care technologies and interventions are ranked according to their relative cost-outcome ratio. The most prominent form is the QALY league table, which ranks according to the cost per QALY (► quality-adjusted life years). League tables might support health care decision makers in resource allocation decisions. Due to a number of methodological as well as ethical arguments against league tables, they are seen more as a source for further discussion than as an appropriate instrument to solely base resource allocation decisions on.

Legal Balancing of Conflicting Rights

Adem Koyuncu
Mayer Brown LLP, Cologne, Germany
akoyuncu@mayerbrown.com

Synonyms

Legal conflict resolution; Balancing of legal interests

Definitions

Legal balancing of conflicting rights is a tool for legal conflict resolution. It is relevant in situations where protected rights collide. Here, collision means that the

rights are in conflict as the pursuit, exercise or protection of one will limit the exercise of the other right. Broadly understood, legal balancing encompasses procedural and substantive law requirements. Public health administration has to balance conflicting rights by, first, observing procedural rights of affected individuals. Second, the administration must analyze, weigh and balance all involved rights within the decision-making process under the principle of proportionality.

Basic Characteristics

Conflicting Rights in Public Health Practice

In public health practice, there are many situations where individual rights collide with the population's health interests, for example, if a person is isolated because of an infectious disease. This isolation has been ordered in order to save the population's health. However, the isolation burdens the individual's rights and freedom. Therefore, before the decision to isolate a person is made, the individual's rights and freedoms must have been balanced with the population's interests, as these are the goods to be protected by the isolation. The public health officer has to balance the public interests with the individual's interests. Public health must protect the population from health risks without unduly violating the rights of those who cause the risks. In addition, public health practice has to balance the interests of the community and of those community members who do not want to be protected. This may be the case with mentally ill persons or persons refusing vaccinations or similar public health services (Jacobson et al. 2007).

Public health operates on sensitive grounds. It has the responsibility for the health, safety and well-being of the populations but public health also has to respect the rights of those who cause risks. The law protects both the population's and the individual's interests. In doing so, law limits the reach of public health practice. Many public health actions cannot be exercised as they would unjustifiably infringe individual rights. Here, it again becomes clear that law is "not necessarily an ally" of public health (Parmet 2007) and that public health law limits the exercise of powers by authorities (Gostin et al. 2007). The laws providing for the basic rights of the people impose limits on public health practice. As scholars comment, simultaneously representing the interests of the community as well as the interests of people who do not want to be protected or who may be burdened by public health practice "is challenging" (Jacobson et al. 2007). In practice, this challenge is met by legal balancing of the conflicting rights.

It is a central responsibility of public health agencies to balance "individual rights against public health necessities" (Gostin 1986). Public health law must not only balance conflicts between individuals and the public interest, it also commonly has to balance:

- Individual rights with other individual rights (e. g., occupational safety balances the employee's with the employer's rights);
- Individual rights with the rights of companies/businesses (e. g., when deciding to recall a consumer product from the market);
- The rights of companies/businesses with the rights of other companies/businesses (e. g., legal business and products regulation practice).

As the U.S. Supreme Court stressed in the famous *Jacobson v. Massachusetts* (1905) judgment, every member of the community is and remains "subject to manifold restraints for the common good". Public health law and, particularly, legal balancing have to ensure that these restraints do not exceed the necessary degree required for the protection of the population.

Practical Legal Balancing

Legal balancing of conflicting rights comprises the analysis of the dimension of a particular public health risk and the corresponding analysis of the restraints put on others by the public health actions. Based on the analyzed information, the legal balancing must weigh the benefits and burdens of the available public health actions in the particular case context and, conversely, weigh the affected personal rights. Figuratively, the population's interests and the individual's rights must be placed in each of the two bowls of a set of scales. Then, the two scale bowls must be balanced with each other in order to determine the lawful public health action. Legal balancing is a case-facts dependent procedure and is not mechanistic or mathematically calculable. However, it can be subdivided into two main stages:

- *First*, the process of information obtaining and analysis with respect to the public health risks, the available risk mitigation measures and the rights of potentially affected persons by these actions. In the fol-

lowing, this first component of legal balancing will be elucidated as "*procedural legal balancing*".

- *Second*, the weighing and balancing of the endangered public health and the rights and interests affected by public health agency actions in the particular context. Below, this second element will be discussed as "*substantive legal balancing*".

The two stages of legal balancing are interrelated. The careful *procedural legal balancing* lays the factual basis for the *substantive legal balancing*. Failures at each stage may lead to unlawfulness of a public health action. Therefore, when public health actions are legally challenged before courts, both stages of the legal balancing process are under scrutiny.

Procedural Legal Balancing

The procedural part of legal balancing shall guarantee a fair procedure and ensure that public decision-makers include all relevant facts in their decision-making process before burdening individual rights. Under U.S. law, this section of legal balancing is also known as "procedural due process" (*See* Stier and Nicks 2007 with U.S. Supreme Court decisions). Through this procedure, the administration shall become aware of all involved rights and interests that have to be considered. From the individual's perspective, this means that the procedural legal balancing provides him with procedural rights within the decision-making process. These rights are established for the protection of individual rights from undue deprivation by public authorities.

Individuals have several rights when they are subject to administrative proceedings. The law must design and the administration must carry out the administrative decision-making process transparently, objectively and impartially. Furthermore, all relevant case facts must be investigated comprehensively and form the basis for the final administrative order. These general requirements are composed of a number of specific procedural rights (*See* Stier and Nicks 2007; Grad 1990). They *inter alia* include the following ten basic elements:

1. The establishment of a general administrative decision-making procedure with transparent and clear criteria;
2. The exclusion of potentially partial persons (with conflict of interest) from the decision-making procedure;
3. The prior written notification of an envisioned administrative act to the addressees (an individual or legal entity). This notification must be complete and timely;
4. The duty of the administration to conduct ► hearings of affected individuals/entities;
5. The right of affected individuals/entities to access the underlying proceeding records;
6. The right of affected individuals/entities to file objections against the administration's opinion and facts;
7. The right of affected individuals/entities to challenge administrative findings, witnesses and expert opinions in conjunction with the right to present their own facts and evidence;
8. The right of affected individuals/entities to be represented by attorneys and legal counsel during the whole administrative proceeding;
9. The procedural right of affected individuals/entities to receive the reasons when a decision is made;
10. The right of affected individuals/entities to access judiciary review and, there, to challenge the administrative orders. The law must guarantee effective legal protection against undue infringements of individual rights by creating and funding an effective court system.

These procedural rights of affected individuals and, conversely, the administration's duties particularly guarantee that administrative agencies do not make decisions before having heard the affected individuals (or legal entities) or having given them the opportunity to present their own facts, opinions and means of evidence. Overall, these procedural elements ensure that authorities include all relevant facts in their administrative proceedings. In most jurisdictions, these procedural rights and duties are implemented into national administrative procedure laws. In doing so, the procedural legal balancing also serves the public trust and the "public accountability" of administrative agencies and their decisions (*See* Childress et al. 2002). The transparent and impartial administrative procedure is a critical element of procedural legal balancing.

Substantive Legal Balancing

Procedural legal balancing ensures that the public health agency investigates all relevant case facts and is aware of all involved rights and interests before a pub-

lic health action is ordered or enforced. After having obtained all relevant case facts, the agency has to carry out the *substantive legal balancing* (in the U.S.: "substantive due process"). Here, the agency has to sort the facts pro and contra its envisioned action and then weigh the arguments on both sides. In the next step, the identified public health interests and the rights and interests affected by the agency's action have to be balanced. As commented, balancing the population's interest with individual rights infringements is "one of the most complicated problems" of public health law (Gostin 2000a).

The outcome of substantive legal balancing might be an "all-or-nothing" decision for or against a public health action. It may, however, result in a compromise decision such that, instead of the initially envisioned action, a modified one is selected. Practically, substantive legal balancing encompasses several legal review steps. In the following, they are outlined in brief.

The public health agency has to evaluate the public health risks and assess whether the threats are in the scope of its mission and competency. The agency must determine whether there is legal necessity for it to exercise sovereign powers. Then, the risks must be analyzed (gravity, endangered population, dimension as to region and time, reparability). When the agency has identified risk-mitigation actions, it must assess which rights of individuals or legal entities might be impacted by the actions. If the conclusion is drawn that the action will intervene with rights of others and that these rights collide with the population's health interest, it has to enter the core substantive legal balancing process.

As the starting point for substantive legal balancing, it must be analyzed whether the legal system has already ruled that certain rights may not be infringed at all (e. g., a person may not be killed in the interest of the common welfare – the constitutional right to live does not allow altruistic executions). Many jurisdictions also set forth a hierarchy of rights spelling out that certain rights outweigh others. In public health practice, these considerations are particularly relevant on the legislation and policy-making level. For day-to-day practice, it can be noted that in public health practice, the populations' right to health and safety regularly collides with rights of individuals and other legal entities. As to weight and hierarchy, the public health interest tends to outweigh affected individual rights as behind the population's right to health there are hundreds and thousands of individuals. Nevertheless, the substantive legal balancing has to be performed on a case-by-case basis considering all case circumstances.

The core legal balancing of the population's health interests and the affected rights of individuals or legal entities has to ensure that these affections are as mild as possible (prohibition of excessive means) without selecting insufficient actions (prohibition of underusage). Overall, the public health agency should try to protect both colliding rights and, therefore, try to balance them in a way that, despite the necessity for public health actions, both rights are preserved as far as possible in that particular situation. Here, the constitutional law doctrine in Germany has established the "principle of practical concordance" (Hesse 1995: "*Prinzip praktischer Konkordanz*"). This principle requires that in cases of colliding constitutional rights, the conflict solving process should find a sound balance where both rights can still be exercised even though one might be impacted by the other. This means that administrators should try to avoid the eventuality where one of the colliding rights totally squeezes out the others. Therefore, administrative actions must be proportional with respect to the protected and the affected rights. To ensure practical concordance, the administrations follow the principle of proportionality (synonyms: principle of commensurability or – in German – *Grundsatz der Verhältnismäßigkeit*).

The principle of proportionality is an integral part of the constitutional state principle and also adheres to the constitutional rights. It is composed of five main criteria:

1. Legitimate objective
   The administrative action must be intended in the interest of the public health and common welfare and pursue a legitimate objective (Childress et al. 2002: "public justification").
2. Suitability (synonym: effectiveness; in German: *Geeignetheit*)
   The administration should only use means that can contribute to the public health objective (i. e., the averting of a particular danger). The action must at least be able to foster this achievement (Jarass and Pieroth 2007, with references to German Constitutional Court decisions). For example, the isolation of a patient with an infectious disease is suitable to mitigate the risk of an epidemic.

3. Necessity (German: *Erforderlichkeit*)
   The administration must select only such actions that do not overreach the level of intrusion that is necessary for the achievement of the public health objective ("least restrictive means" Gostin 2000b; Childress et al. 2002: "least infringement"). The criterion is violated if the end would have been achieved with less restrictive means. For example, the isolation of a patient with an infectious disease is necessary if no other means are available to control the risk of an epidemic spread. If, however, the usage of a mask or a voluntary treatment were equally protective, the isolation violates the principle of proportionality, as it was not necessary.
4. Reasonableness (synonym: reasonability, acceptability; German: *Angemessenheit*)
   When balancing the affected rights in light of all case facts, the means must be in reasonable relation to the end (in German: *Zweck-Mittel-Relation*. Gostin 2000b, for the U.S: "means/ends test" which is almost a verbatim translation of the German term). Obviously, there is a common understanding about the proportionality criteria in most jurisdictions. The reasonableness test requires that all circumstances of the individual case are balanced (Jarass and Pieroth 2007). The benefits of the action are balanced with its negative effects on individuals and legal entities. The scope and importance of these affected rights and the intensity of their invasion must be balanced with the scope and importance of the protected public interest. The intensity of the public health threat plays a crucial role for the balancing. Additional factors may be relevant (e. g., the costs of the action). Particularly, the extent of coercion and intrusion of individual rights and the subsequent compensations of affected persons play a role (e. g., monetary compensation after a condemnation).
5. Limitation
   The public health action that invades rights of individuals or legal entities may only last until the legitimate goal is achieved or it has turned out that this goal is no longer achievable.

The principle of proportionality is the fundament of the substantive legal balancing of conflicting rights. As such, it is accepted in most jurisdictions. In some jurisdictions, it is explicitly codified (e. g., Germany). The European Court of Justice has acknowledged that the "principle of proportionality" is an element of primary European Community Law. It is noteworthy that the principle of proportionality not only limits but also provides legal and moral guidance for the exercise of sovereign powers.

Relevance on all Levels of Public Health

Legal balancing of conflicting rights is relevant on all levels of public health law. Hence, it is part of the day-to-day practice of public health agencies, public health lawyers, courts and legislators and their legislative draftsmen. In their decision-making process, all of these actors have to meet the criteria of procedural and substantive legal balancing. Analysis of the public health threats and weighing of the negative consequences of public health actions is a necessary element of public health practice. It is critical to ensure that no rights of others are unduly infringed.

With respect to procedural legal balancing, on all levels of public health law, procedural instruments are in place to ensure that the persons affected by the decisions have the opportunity to present their arguments and facts (e. g., procedure laws at court, parliamentary hearings, administrative procedure laws and hearings). Thus, the decision-maker must become aware of all involved rights. Then, the substantive legal balancing weighs and adjusts the involved rights in order to find a reasonable solution to the conflict. In conclusion, legal balancing resolves legal conflicts. It belongs to the most important but also most challenging tasks of public health practice.

Legal Basis of Public Health

ADEM KOYUNCU
Mayer Brown LLP, Cologne, Germany

Synonyms

Legal foundation of public health; Legal fundament of public health

Definition

The legal basis of public health is rooted in the population's rights to health, safety and life. As the population is the sum of its individual members, it stands for the sum of the interests and rights of these individuals. The populations mandate the state via constitutions to safeguard and promote their health and to protect them from harm. The population's right to health, safety and life and the respective right to self-defense are the basis and justification for the existence of public health. Public health is not an end in itself. It is a state service and duty vis-à-vis the people, from whom all powers in the state derive. The state has to ensure a functioning public health system to safeguard and promote the population's health.

Basic Characteristics

Sources of Powers

States need sufficient legal powers to install public health systems and enforce individual public health measures. The main public health-related powers derive from the respective nation's ► constitution, which itself derives from the people. Each individual has the right to health, safety, life and self-defense, which is the right to protect himself from harm. Correspondingly, populations, which represent the sum of these individuals, also have the right to protect themselves from health threats. All populations have the right to protect themselves from harm to their health, safety and the lives of their members. In addition, the population – as each individual – has the right to take measures to promote its health. In democratic nations, the populations delegate these rights and powers through their national constitution to the state. All state powers derive from the people. Both the population's right to self-defense from harm and its right to promote its health are delegated to the state.

The state is the guardian of the common welfare and the individual rights and, therefore, has the constitutional duty and powers to take the appropriate measures to safeguard and promote the population's health. These powers are (in some jurisdictions) known as the "► police powers" (e. g., in the U.S.) or as "the danger defense powers" or in German speaking jurisdictions as *"Gefahrenabwehrrecht"*. The term "police" is rooted in the 19th century concept of the material "police", which included all state activities to avert dangers to public security and order and to eliminate offenses (Weber 2007). These powers include public health actions to protect individuals from harm to them-

selves, which is practically relevant for mentally ill persons or minors. In some jurisdictions, these paternalistic actions performed for the individual's own benefit are attributed to so-called ► *parens patriae* power of the state (Grad 1990; Gostin 2000; Bernheim et al. 2007).

In addition to the police powers, sources for state powers to safeguard and promote the public's health can derive from the power to regulate commerce and trade, the powers to collect taxes and the budget power, including the power to spend (Grad 1990; Gostin 2000). These additional state powers provide effective control tools as well as behavior-influencing means in the interest of the community's health and safety. For example, the power to control commerce allows the legal regulation of businesses and products as well as enabling the legal regulation of professions. The power to regulate trade allows the import of potentially harmful goods to be controlled and restricted. The tax power is a strong tool for influencing the behavior of individuals and companies as well as local municipalities. Through tax law, the state may create incentives for favorable behavior or may impose additional taxes on harmful products and acts to influence the population's behavior. The state also has the power to spend. Exemplarily, the U.S. Constitution authorizes the Congress (the U.S. legislator) to make "expenditures expressly for the public's health, safety, and well-being" (Gostin 2000). Similar laws exist in other jurisdictions, authorizing the state to spend in the name of the public's health. Overall, the police powers, the power to regulate commerce, trade and to collect taxes and the power to spend bestow the state with strong tools. In addition, constitutions regularly grant further powers to the state to provide additional means to directly or indirectly safeguard and promote the population's health. These powers particularly include the power to regulate the fields of labor, traffic, criminal law (► criminal law and public health), tort law, antitrust or environmental law (► environmental law and public health).

In conclusion, the legal basis of public health is rooted in the population's mandate to the state to protect it from harm. The legal means of public health are based on a variety of constitutional powers granted to the state. These allow it to take a broad range of measures to directly or indirectly safeguard and promote the public's health.

The Constitution and the State Organization

As highlighted above, the state's powers derive from the people. This assignment of powers is realized via the state's constitution. The constitution as the basic legal document of a state not only assigns powers to the state but also governs the state organization. In democratic jurisdictions, the constitutions provide the basis for the state organization and the powers allocated at the state institutions.

First, most constitutions institute a separation of powers in the country between the legislative, the executive and the judiciary powers.

Second, the constitutions arrange the legal responsibilities, authorities, duties and the scope of the powers granted to the respective state institutions. The constitutional state organization with its separation of powers and the attribution of responsibilities among these institutions is crucial for the understanding of how public health is practiced and which roles the state institutions play. The separation of powers is based on the split of the overall state powers into three separate areas. This leads to three different power fractions. As such, the legislative powers are assigned to the parliaments, the executive powers are assigned to the governments and the judiciary powers are with the courts.

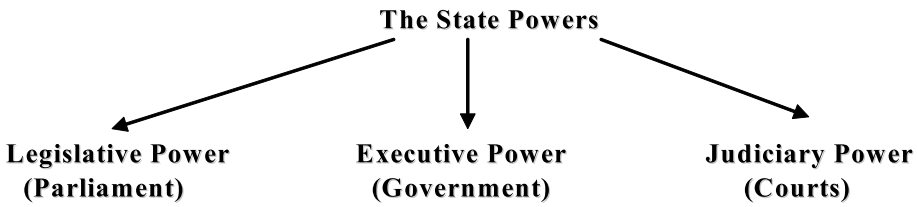
The separation of powers is intended to avoid an inadequate concentration of powers in one hand. By this separation, a system of checks and balances is installed (*See* also Gostin 2000). This constitutional separation of powers, as demonstrated in Fig. 1, describes the *horizontal separation of powers* on the national level in a country.

In addition to the horizontal separation of powers, for many countries a "vertical separation of powers" can be differentiated. This term refers to the differentiation and separation of:

- Federal powers;
- State powers of single states; and
- Local powers of municipal governments (self-administration).

The vertical separation of powers is particularly relevant in countries with a federal state organization consisting of a federal government and autonomous states with their own state governments and state constitutions (e. g., USA, Germany).

The two types of separation of powers play significant roles in the practice of public health. As such,



Legal Basis of Public Health, Figure 1 The Separation of Powers

► law has to clarify the responsibilities, competencies and interrelationships between the parties. With respect to the vertical separation of powers, law has to assign responsibilities among the three levels and provide for rules when federal competencies preempt state competencies. Particularly, to ensure emergency preparedness, law has to be made to dictate which institutions are in charge in an emergency situation and who is entitled to give instructions within the involved institutions. For example, after Hurricane Katrina in the U.S. (2005), the mayor of New Orleans complained that the federal government failed to adequately support the local institutions in coping with the natural disaster. Thus, it must be clear who of the three vertical powers is the responsible party when handling a certain public health threat, e. g., a natural catastrophe. In certain cases, it might be necessary that all three powers act to avert the threat. Therefore, a functioning public health system needs rules that provide for the competencies of the administrative institutions on the federal, state and municipal level. These rules are laid down in laws.

Correspondingly, rules are necessary to provide guidance in case of conflicting laws between the levels. Therefore, the constitution or enacted laws must provide for a clear hierarchy of laws. For example, for cases with conflicting legal rules for the same facts, the German law constitution ruled that "federal law breaks state law" (similarly, in the U.S.: "the federal law preempts the state law", Goodman et al. 2007).

Legal Actors in Public Health

The *parliament as the legislator* is the country's lawmaker. By law-making, the legislator is able to build the fundament of public health practice. The legislation follows a specific procedure laid down in the underlying constitution. The law-making process regularly includes public hearings and the involvement of practitioners as well as public health agencies. The parliament enacts statutes (e. g., bills or acts) and creates and funds state institutions. In addition, the parliament has the power to collect taxes, to budget and to spend so that major decisions on expenditures depend on the parliament.

The *government as the executive power* in the state is the central actor with respect to public health and ► public health law. As the executive power, the government is the central addressee of the people's (the population's) mandate to protect their health and safety. As early as 1776, the Virginia Declaration of Rights stated "[T]hat government is, or ought to be, instituted for the common benefit, protection, and security of the people, nation or community; of all the various modes and forms of government that is best, which is capable of producing the greatest degree of happiness and safety and …". The government must be the central actor of public health practice. Protecting public health and safety is probably the most important obligation and power of the government.

The government heads the state's administration. It oversees numerous administrative agencies, which may be regulatory or non-regulatory, and delegates powers to these agencies to accomplish their mission. The governments are entitled to draft and promulgate regulations. Administrative regulations are not statutes but they are nevertheless legally binding rules. They commonly specify general or abstract legal terms and rules (e. g., the current "state of the art").

Another powerful tool of the government and its agencies is the right to set standards and rules (e. g., for the maximum concentration of certain substances in the air). The setting of standards and rules is a widely used tool, particularly in environmental law and occupational safety law. Finally, the government and the administrative agencies are entitled to issue administrative orders to regulate individual cases.

The *courts represent the judiciary power*. Courts review enacted laws and interpret their legal rules. They enforce laws and resolve legal conflicts. They may

repeal laws as being in breach of the constitution. Courts are crucial for the enforcement of laws and they may be called if preliminary injunctions are necessary. Only courts are authorized to sentence a person to criminal punishment. Courts may grant remedies if individuals were improperly affected by the state institutions. They may also stop administrative actions and, in doing so, limit the power of the government.

As a new model of lawsuits, cases are brought to court where individuals demand the (state or local) government to take measures against a certain public health risk. As such, in Germany, a city government was convicted by the Federal Administrative Court to take appropriate public health measures to reduce the air pollution with regards to dangerous micro dust particles. This type of lawsuit is filed by private persons or public health advocacy organizations. It primarily intends to ensure and promote the public's health by calling for safeguarding government action.

Where statutory laws were lacking sufficient rules, courts have developed legal doctrines by case-law throughout all jurisdictions worldwide, not only in the common-law countries (for tort law, *See* McClurg et al. 2007). Overall, courts and judges have contributed significantly to the assurance and promotion of the public's health (Parmet and Daynard 2000). Their importance in contemporary public health seems to be increasing.

Among the *other actors*, private sector entities regularly act in the realm of public health. Governments and administrative agencies are entitled to include private sector service providers in the supply of public health services. Such cooperations need to be based on a corresponding ► contract. Non-governmental organizations also play an important role in the day-to-day public health service. In addition, international organizations with public health missions as well as international legal documents with public health relevance deserve particular attention. The international institutions, particularly, the World Health Organization (WHO), the United Nations Environment Program (UNEP) or the World Trade Organization (WTO) play increasingly important roles in an ever more globalized world. The legal handling of global public health activities will require legal grounding (e. g., international agreements), which might lead to a modification of the legal basis of public health.

Legal Issues in Public Health Genetics

JAMES G. HODGE, JESSICA P. O'CONNELL
Bloomberg School of Public Health,
Johns Hopkins University, Baltimore, MD, USA
jhodge@jhsph.edu

Definition

The communal and individualistic legal issues pertaining to the field of genetic science that assesses the impact of genes and their interaction with behavior, diet, and the environment on the public's health.

Basic Characteristics

Legal Issues Overview

Developments and advancements in genetic technology implicate a number of legal and ethical issues that must be considered when planning for and developing policies regarding public health genetics. Legislation and administrative regulations emphasize the importance of an individual's right to specific, written ► informed consent prior to ► genetic testing or screening. As the ability to access and identify individual ► genetic information has improved, individuals have become more concerned about the ► privacy of their identifiable data and potential unwarranted discrimination, particularly by employers and insurance providers, that could result from their disclosure. Additionally, advances in technology have enabled wider use of genetic information for public health, research, and forensic purposes through the creation of DNA databanks. The development and maintenance of DNA databanks have raised additional privacy concerns regarding the use and storage of genetic information.

In response to these concerns, laws have increasingly focused on issues related to public health genetics and the collection and use of genetic information. These laws tend to treat genetic information or genetic tests differently from other personally-identifiable health information by attempting to establish heightened protections for genetic data or tests. This legal trend is often referred to as ► genetic exceptionalism.

Informed Consent

Principles of ► autonomy strongly support an individual's right to informed consent prior to genetic testing or screening for public health purposes. Prior to the administration of a test, patients are entitled to explanations of the nature and scope of the information to be gathered, the meaning of positive test results, the underlying disease or condition, and any appreciable risks involved in the testing or activities following a positive result (Beauchamp and Childress 1994). With this information, patients can weigh the benefits of genetic testing against appreciable risks and make an informed decision. However, misunderstanding of complex genetic science and uncertainties in the meaning of test results can blur the value of informed consent (Gostin et al. 2001). Under most circumstances, there is little justification to mandate genetic testing or screening without informed consent in a public health context. Some public health initiatives involving genetic testing, such as mandatory newborn screening programs, are justified without consent by legal principles (a.k.a. parens patriae powers) allowing the state to protect the health of children (Khoury et al. 2000).

Privacy and Discrimination

Advances in technology in recent years have improved the ability to collect and store individual genetic data in electronic and inchoate databases. The proliferation of the databases and expanding demands for genetic data uses and disclosures contribute to individual concerns about the privacy of genetic data. Unauthorized uses or disclosures can lead (and have led) to discrimination on an individual or group basis through insurers, employers, government agencies, and others (Husted and Goldman 2002). Health, life, and disability insurers may seek to use genetic test results to limit or deny coverage (Hodge, Health Information Privacy 2004). They maintain that genetic information is necessary to

effectively assess risk and determine appropriate coverage. However, use of this information could unfairly limit access to health or life insurance, particularly for high-risk individuals for whom adequate coverage is essential. In an employment context, individuals fear that employers may reject applicants for positions or advancement based on their genetic information for two primary reasons: (1) to avoid having to pay high health care or health insurance costs in the future; and (2) to limit the costs of employing an individual with a disability or illness that could potentially hinder his or her production. Federal and state anti-discrimination laws (genetic-specific or otherwise) attempt to limit stigmatization of individuals on genetic bases (Rothstein 1998).

Though important, individual privacy interests in genetic information are not absolute. Others may have a "right to know" about an individual's genetic profile. Spouses, offspring, and close family members may claim a right to share in the knowledge of an individual's genetic test results. Public health officials conducting surveillance or health researchers performing longitudinal genetic studies also have legitimate claims to access an individual's genetic data (Hodge and Fuse Brown 2005). Such individual or communal needs for individual genetic information are supported by normative principles of beneficence or justice, or utilitarian ideals, but can impinge the privacy rights of individuals participating in public health ► genetic screening programs. Effectuating an appropriate balance between respecting individual interests and communal public health is critical (Gostin 2000).

DNA Databanks

The ability to use and store ► genetic information has increased significantly in recent years, mainly through the development of DNA databanks. DNA databanks are used in a public health context to gather large, representative samples of health data from patients and their health care providers. Genetic information is also used and stored for forensic purposes: to allow investigators to identify potential suspects in a criminal setting; to help identify victims of catastrophes; and to determine family relationships, such as paternity, between individuals. In addition, it can aid in matching organ donors and recipients who need transplants (Gostin et al. 2001).

Genetic collaborations among clinicians, researchers, and public health practitioners is ongoing. The federal Centers for Disease Control and Prevention (CDC) has gathered and banked over 19,000 DNA samples in the Third National Health and Nutrition Examination Survey (NHANES III) among non-institutionalized civilians in the United States between 1999 and 2000. Greater than 80% of the citizens of Iceland participated in a massive collection of identifiable genetic data for pharmaceutical research purposes in the late 1990's. Genetic researchers have used population-based disease registries to estimate absolute and relative risks of breast cancer for those with BRCA1/BRCA2 mutations. Through preventive screening, health promotion, and education, public health programs have the ability to bridge research findings with clinical and public health practice (McQuillan et al. 2003). Genetic databanks further this purpose by allowing genetic information to be efficiently organized and stored and making it readily available to public health practitioners. Yet, privacy concerns abound, thus necessitating strong ► confidentiality and security protections for public health genetic data (Gostin et al. 2001).

Genetic Exceptionalism

As mentioned above, individual ► privacy and anti-discrimination concerns relating to ► genetic testing have led many states to adopt genetic-specific privacy and anti-discrimination laws to protect persons from wrongful acquisitions, uses, or disclosures of individually-identifiable genetic data (Hodge, Ethical Issues Concerning Genetic Testing 2004). These laws treat genetic information differently from other personally identifiable health information and typically establish heightened protections. The premise underlying ► genetic exceptionalism is that genetic information needs special protections because it is different from other health data for many reasons (Gostin and Hodge 1999). Foremost among these is the predictive nature of genetic data. Unlike most other medical records that describe an individual's past or current health condition, genetic tests can identify (with varying degrees of confidence) increased risks of future diseases in otherwise healthy individuals (Gostin et al. 2001). However, considerable debate exists as to whether genetic data are sufficiently unique to garner additional protections that exceed other health information. Increasingly, federal and state

policymakers are refining legal privacy and antidiscrimination protections of genetic data or tests to reflect the view that such data or tests are part of the continuum of an individual's longitudinal health record. As a result, broader health privacy and antidiscrimination protections that include genetic data proliferate (Centers for Disease Control 2001).

Legal Regulation of Professions, Businesses, and Products

ADEM KOYUNCU
Mayer Brown LLP, Cologne, Germany
akoyuncu@mayerbrown.com

Synonyms

Commercial regulation

Definition

Legal regulation of professions, businesses, and products comprises the legal supervision of the entry of businesses and professions as well as their conduct. Another focus of this field is the regulation of public health relevant products, which includes control of the placement of products on the market, safety vigilance, and consumer oriented duties (e. g., information and instruction) during product marketing. Legal regulation of businesses and products also governs business or product-related commercial speech.

Basic Characteristics

Background and Context

Public health practice has to observe the conduct of a large number of businesses and the health effects of numerous products. Naturally, a wide range of public health risks is linked with the conduct of certain businesses and professions. The same is true for the marketing and use of a multitude of industrial goods and consumer products. Therefore, legal regulation of businesses and products is a major component and the centerline of contemporary public health practice. On the other hand, the rights to choose and conduct a profession and business as well as product-related property rights (e. g., a ► patent) are under the particular protection of the constitution. Therefore, the regulation of professions, businesses, and products operates on sensitive legal ground.

Among the ten great public health achievements of the 20th century in the U.S., published by the CDC, three are directly related to the public health regulation of businesses and products. These achievements are "safer and healthier foods", "motor vehicle safety", and "recognition of tobacco use as a health hazard"

(CDC 1999). The three achievements have particularly been realized through legal regulation of the respective business sections and products. This regulation included supervision of business conduct and product marketing, obligatory safety precautions, safety surveillance in the marketing period, and the regulatory accompaniment of these products and associated businesses that handle food, motor vehicles, or tobacco. In addition, among the ten great achievements, "safer workplaces" can be traced back to the regulation of industries and businesses as well as health relevant products (e. g., asbestos). This essay therefore deals with an essential working field of contemporary public health. For this field, a sufficient legal underpinning is essential.

Subjects of Legal Regulation

The public health activities under the heading of this essay focus on:

- Individuals engaged in public health relevant professions and businesses;
- Companies engaged in public health relevant industries and businesses;
- Products with potential impact on the public's health.

The *legal regulation of professions* in the realm of public health was first directed towards the regulation of health professionals (e. g., medical doctors, pharmacists, nurses, paramedics). Therefore, medical professions are subject to intensive statutory and administrative regulation. This includes not only ► licensing to access these professions but also stipulation of the education and training curricula to obtain the necessary qualifications. Some of these regulation elements will be discussed below. It is important to note that public health regulation of professions goes far beyond the health professions and encompasses several other professions with potential impact on the public's health. Among these professions, cooks, butchers, other food handling professions, retailers, constructors, truckers, restaurant operators, hairdressers, public health officers, and farmers may be identified, for example.

Corresponding to professionals, the *legal regulation of businesses and companies* engaged in public health relevant industries and businesses comprises companies with direct relevance to the public's health as well as companies with rather indirect public health reference. Again, the regulated businesses extend the scope of direct health-related businesses like pharmaceutical and medical device companies, hospitals, or drug stores. Moreover, the regulation includes, among others, the whole food and beverages industry, chemicals, construction (e. g., asbestos!), tobacco, clothes, toys (such as the worldwide product recalls in the year 2007 because of elevated lead concentrations in baby toys), electronic household equipment, rifles, and the waste industry. Substantively, the regulation of companies has two compartments:

- Regulation with respect to health risks to the general public; and
- Regulation with respect to health risks to company employees (occupational safety regulation).

The occupational safety laws will be subject to a separate essay. Therefore, in the following, the legal aspects of business regulation will be elucidated.

Finally, the *legal regulation of products* with potential impact on the public's health covers a variety of products that are hard to oversee. As with the regulated companies and businesses, the range of regulated products includes goods that are directly used in the health context (e. g., pharmaceuticals, medical devices, food) and other products with direct or indirect impact on the public's health (e. g., automotives, chemicals, toxic substances, construction materials, mobile phones, electrical equipment, clothes). The regulation of products also governs product-related information materials like package leaflets or instruction manuals.

Elements of Legal Regulation

To a considerable extent, the type of legal means applied within the regulation of professions, businesses, and products are similar and have similar starting points. Thus, for all three subjects, the regulation comprises the whole life-cycle of the respective product, business, or professional conduct. Therefore, life-cycle related regulation focuses on several distinct stages:

- Regulation of the access to a market for products, professionals, or companies (e. g., licenses, concessions, registrations, product marketing authorizations);
- Direct regulation and supervision of the business conduct or a product's marketing and use (e. g., inspections, sanctioning of legal non-compliance, regulation of advertising, setting compulsory safety standards, restrictions of product access by children

and adolescents, ban of materials for production and use);
- Indirect regulation of the business conduct (e. g., providing incentives through tax laws, indirect regulation by tort liability, criminal law prohibitions, and civil sanctions);
- Regulation of the continuation and end of the market presence (e. g., prohibition and closure of businesses; revocation of licenses and product marketing authorizations);
- Occupational safety regulation.

Accordingly, public health regulation is first relevant at the stage of access to a commercial market by a professional, a company, or a product. For professionals and businesses, public health agencies regularly require that a concession, license, registration, or other form of administrative permission is obtained. The licensures are a basic tool of public health practice and maybe the most important legal instrument of commercial regulation (*See* Gostin 2000). Similarly, products with public health relevance routinely need to fulfill particular requirements prior to entering the market. These requirements may consist of marketing authorizations (e. g., pharmaceuticals) with additional specific prerequisites like the conduct of clinical trials. Such product-related requirements commonly include technical and safety measures (*See* the technical safety requirements for automotives).

After having obtained market entry, regulation continues at the next stages. Public health agencies supervise the conduct of the business as well as a product's use and marketing and its safety findings. One particular element of this segment of regulation is the regulation of commercial speech (Gostin 2000; Gostin and Jacobson 2006). For a large number of products and businesses, public health authorities have imposed restraints on commercial speech; these consist of restrictions and prohibitions in advertising and public information (e. g., alcohol, tobacco, pharmaceuticals). Additionally, companies and manufacturers are forced to disclose safety-relevant information even if this disclosure is disadvantageous for the marketing of a product.

Regulation of business conduct and product marketing particularly includes regulatory surveillance, granting permission for the agencies to inspect the businesses, order inquiries, conduct hearings, and impose reporting duties. The agencies are entitled to impose legal restraints and limitations on the business conduct and product marketing, including trade restrictions. In case of emergencies, the agencies are entitled to inform the public about the health risks. This section of public health regulation may include manifold further obligations, which cannot be discussed in detail here.

Finally, for the regulation of business conduct and product marketing, the public health agencies need sufficient legal authorization. The powerful legal means in this realm include prohibition of businesses, closure of factories and businesses, ban from professions, revocation of licenses, and withdrawal of product marketing authorizations. The marketing of certain goods may be limited to certain people or (relevant for pharmaceuticals) to certain indications. Health departments and regulatory agencies may order the recall of products from the market and terminate their economic life-cycle.

Legal Regulation of the Pharmaceutical Industry

In conclusion, legal regulation in the interest of the population's health is attached to all steps of business conduct or product marketing so that public health agencies accompany the actors from their market entry up to the moment of market exit. A very good example for the regulation of businesses and products is the regulation of the pharmaceutical industry and the drugs as their products. In most jurisdictions, pharmaceutical companies must fulfill certain requirements prior to receiving a permit to conduct their business. They need to establish the personal and organizational infrastructure of the production process as well as undertaking pharmacovigilance duties. Prior to placing a drug on the market, the company must conduct clinical trials, which again have to follow strict rules. The clinical trials themselves need regulatory permission and an assessment by an institutional review board or ethics committee. Within the conduct of the studies, the Good Clinical Practice obligations expect attention. Based on the clinical trials, pharmaceuticals will be evaluated and, finally, receive a marketing authorization. After the receipt of this authorization, the product may enter the market. However, the production must observe Good Manufacturing Practice. During the whole marketing period, the pharmaceutical company must continuously review the safety profile of the drug. The company must establish a pharmacovigilance system in order to collect risk information in conjunction with the practical administration of the drug and take appropriate risk reduction

measures. The agencies must be informed about the obtained risk information. With increasing information, the marketing authorization regularly undergoes variations, which need to be coordinated with the regulatory agencies. In addition, the marketing authorization needs to be prolongated after certain periods of time. Within this review process, all information on the product's benefits and risks are collected and evaluated. Pharmaceutical companies must meet extensive reporting and notification obligations regarding safety information as well as (in many jurisdictions) mandatory insurances. During the marketing period, most jurisdictions prohibit extensive advertising and restrict product advertising accordingly. In Europe, public advertising for prescription drugs is not allowed. Finally, based on the pharmacovigilance information, the regulatory agencies decide whether the product should remain on the market or not. Further product-related regulations on pharmaceuticals cannot be elucidated at this point. In summary, pharmaceuticals and pharmaceutical companies are subject to closely meshed regulation throughout their whole lifecycle.

Legal Concerns

In accordance with comments of scholars, it must be noted that from a legal perspective the "public health regulation of commercial activity, like the regulation of professional behavior, is highly contested terrain" (Gostin 2000; *See* also Reynolds 1995). The regulation of professions, businesses, and products is associated with relevant ramifications on the rights and freedoms of the regulated individuals and companies even though it is necessary for public health and consumer protection purposes. In this realm, the economic liberty and property rights play important roles and limit the regulation. All individuals and companies have the right to choose and conduct a certain business. Therefore, regulation of access to a business or market is a far-reaching legal tool restraining the basic rights of individuals and companies. Similarly, the imposition of professional duties like mandatory reporting impacts the rights and freedoms of the regulated professional to conduct his business the way he feels most appropriate. Such obligations also have associated costs, which the professional or the company has to bear.

In addition to property rights, the business or product-related restrictions of commercial speech encroach the constitutional freedom of speech of professionals and companies. As another aspect, the legal regulation of products often impacts property rights and professional freedoms so that, prior to such decisions, careful legal balancing is necessary. In fact, the highly contested nature of the legal regulation of professions, businesses, and products calls for particular awareness of the conflicts between the public's right to health and safety and the economic rights, freedoms, and commercial interests of the professional market actors.

This area of public health practice has points of contact with a number of other public health practice fields. Among these, occupational safety regulation was already noted above. Additionally, information and communication in the scope of public health, infectious diseases law, environmental law, tort law, and criminal law as indirect public health regulation means are relevant in cases of misconduct. The right balance is necessary between the safeguarding and promotion of public health and the right to conduct business autonomously. Public health law does not intend to impede businesses and, therefore, has to navigate between enabling businesses and product marketing and controlling and, at the same time, mitigating the public health risks tied to these businesses and products.

Leishmaniasis, Cutaneous

Synonyms

Leishmaniasis of the skin; Oriental sore; Delhi boil; Baghdad boil; Balkan sore; Saldana

Definition

Cutaneous leishmaniasis primarily appears in South Europe, Asia and Africa. It is characterized by itching and papulous efflorescences of the skin, which later develop into sharply limited lesions (ulcers). One has to differentiate between two forms of cutaneous leishmaniasis, dry and wet. In the dry from, which is most frequently caused by *Leishmania tropica*, painless, dry ulcers develop. The moist form, which is most often caused by *Leishmania major*, is characterized by secreting ulcers, which sometimes enlarge. Within 3–18 months cutaneous leishmaniasis heals with scarring. Often, treatment is not necessary at all. Possible therapeutic measures are tissue injections with antimony preparations and the administration of dapsone, ketoconazole or amphotericin B.

Leishmaniasis, Mucocutaneous

Synonyms

Leishmaniasis of the mucous membranes; Uta; Espundia

Definition

Mucocutaneous leishmaniasis, which is caused by *Leishmania braziliensis*, is primarily found in South America. Infection starts with a reddening and swelling at the point of entrance, which later on ulcerates. During the course of the disease, the mucocutaneous membranes of the nose-throat-area can be involved. When spreading along the inner airways, the parasites can cause ulcerations and mutilations. Among other things, the nose septum can be involved; with the destruction of the septum the nose collapses, a so-called 'tapir's nose' results. Therapy consists of the administration of sodium antimony gluconate, meglumine antimoniate, pentamidine and allopurinol. Another effective substance for the treatment of mucocutaneous leishmaniasis is amphotericin B.

Leishmaniasis of the Mucous Membranes

► Leishmaniasis, Mucocutaneous

Leishmaniasis of the Skin

► Leishmaniasis, Cutaneous

Leishmaniasis, Visceral

Synonyms

Kala-Azar; Dum-Dum fever

Definition

Visceral leishmaniasis, which is also called "kala-azar" (Hindi for "black fever") or "Dum-Dum fever", belongs to the classic parasitoses. It is transmitted by the bite of the sand fly. Transmission is also possible by needle stick injury, transfusion, transplantation or as an intrauterine infection via the placenta. Kala-azar is characterized by an affection of inner organs; lymph nodes, spleen, liver and bone marrow are primarily involved. Visceral leishmaniasis starts with fever, stomach ache, diarrhea and loss of weight. As the disease progresses there are recurrent fever episodes, a reduced general condition, hepatosplenomegaly, edema, ascites and internal bleeding occur. Laboratory test results show anemia, low white blood cell count (leucopenia) and low platelet count (thrombopenia). Without therapy, kala-azar has a deadly outcome within 1–2 years; effective treatment can reduce lethality to 3–20%. Therapy consists of administration of intramuscular or intravenous pentavalent antimonial (Sb^v) compounds. For a couple of years, a new substance, miltefosin, has been available, which can be administered orally.

Leisure Time Physical Activity and Sedentariness

Dirk Steinbach, Christine Graf
Deutsche Sporthochschule Köln,
Köln, Germany
steinbach@dshs-koeln.de, c.graf@dshs-koeln.de

Definition

Leisure time physical activity refers to all of the behavior connected with ► physical activity that people engage in in their freely disposable time. Hence, there is a distinction between it and physical activity which is engaged in as part of gainful employment or in the context of daily life. In particular, however, the boundaries between leisure time activities and everyday activities are blurred because of their situational and subjective nature. As specific forms of leisure-time behavior which consciously aim at improving physical fitness, ► sport and exercise constitute the core area of leisure time physical activity.

Describing the same problem from the opposite perspective, sedentariness is a concept or term which refers to a physically ► inactive lifestyle. It is embedded in social and mental behavioral patterns and caused by current developments in the work and leisure sector of our societies (Brettschneider and Naul 2004).

Basic Characteristics

► WHO estimates that physical inactivity is the cause of approximately 2 million deaths a year. The proportion of physically inactive or insufficiently active people is estimated at 17% and 41%, respectively. These average figures are even exceeded in the developed countries and particularly in the major cities with their environments that are less conducive to exercise (WHO 2004). In modern Western societies, daily energy consumption has fallen by approximately 800 Kcal over the past five decades, which is the equivalent of walking 16 km (Hardman and Stensel 2003), and in Europe, two thirds of adolescents do not follow the recommendation of engaging in moderate exercise for an hour a day (Brettschneider 2004).

Leisure Time as a Sphere of Physical Activity

Until late in the second half of last century, the bulk of physical activity was engaged in during gainful employment. However, technological developments and structural changes in the working world, combined with shorter working hours, and particularly a shorter total working life, have led to a situation where only 20% of the population in the European Union today still engages in fairly intensive physical activity (EU 2003) within the framework of gainful employment. A similar picture emerges with regard to physical demands in the area of housework and mobility. For instance, the spread of washing machines in Germany rose from just 9% to 89% between 1962 and 1993 (Heßler 2001) and the proportion of journeys made by bicycle in the EU is a mere 5% (WHO 2000).

Not only has the total energy balance decreased overall as a result of the smaller amount of physical activity but there have also been significant shifts in terms of the context in which physical activity is carried out and can be carried out today. As a result, the functional correlation between work and leisure time has also changed. Instead of primarily contributing to regeneration after heavy physical work, leisure time and the activities undertaken during leisure time perform the

opposite function today and are therefore intended to compensate for a lack of exercise and psycho-social stresses at work.

Leisure Patterns and Behavior

Almost all empirical surveys prove that the leisure activities most frequently engaged in are predominantly sedentary and physically inactive recreational activities such as reading, resting, talking on the phone or watching television, while active habits play a subordinate role. With regard to physically active leisure-time activities, extensive data is available on sports activities. Other physically active habits during leisure time have only been recorded and analyzed sporadically owing to their less structured nature and the associated systemic difficulties. With regard to the spread of a sedentary lifestyle during leisure time, it is mainly the use of the media that has been investigated to date.

Sport During Leisure Time

The percentage of the population that actually regularly engages in sporting activity is relatively small. A comparative study of European Union countries which was conducted in 2004 was able to show that only 38% of the EU population engage in sporting activity at least once a week and only 17% do so 3 times or more per week. In the EU however, 51% of people do not engage in any form of sport whatsoever (EU 2004). The by and large low level of participation in sport becomes even clearer if the assessment is based on time budget data instead of on the self-reported frequency of sporting activity. Here, data from European time budget surveys carried out during the period from 1998 to 2002 shows that on average 15–30 minutes a day is spent on sport and exercise in the broader sense (including activities such as going for a walk or picking mushrooms). In no European country do people spend more than a quarter of an hour a day on sporting activity in the narrower sense. In the less active countries of southern Europe, the figure is in some cases even less than 5 minutes (van Bottenburg 2005).

This is average data. However, all of the studies conducted on sporting habits indicate that, in spite of the successful opening up and ► democratization of sport on the lines of the Sport for All movement, there are also still major differences in respect of regional participation in sport and different prevalence based on socio-demographic characteristics. Thus, an international comparison shows up a clear North–South divide with higher participation in sport in the Scandinavian and central European countries (van Bottenburg 2005). Furthermore, it is evident that men by and large are more active in a sporting sense than women and that younger people are more active than older people. However, the influence of gender and age on individual sporting habits is progressively declining (ibid.); socio-economic status and the level of education, on the other hand, continue to influence the likelihood of participation in sport as strongly as ever.

Use of the Media and TV Consumption

Use of the media, especially television, dominates leisure-time behavior in all developed countries. In Germany, for instance, 98% of the population above the age of 14 watches television at least once a week. The average viewing duration is 110 minutes for adults (► HETUS), 108–109 minutes for children and adolescents and significantly more for the over 65s (143 minutes). The results of research on changes in viewing duration are contradictory (Brettschneider 2004). The growing number of permanent viewers should be highlighted. Approximately 15% of European children and adolescents between the ages of 11 and 15 watch four hours or more of television a day. In some European countries, the figure is even close to 40% (ib).

Computer use also plays a major role in leisure-time behavior. However, unlike television, computer-related activities have not yet caught on equally in all developed countries or in all social classes. In Germany, for instance, significantly more frequent computer use during leisure time is evident in cohorts born before 1976 (HETUS). Similarly to TV consumption, the percentage of heavy users is also important here: 13% of adolescent Europeans spend 3 hours a day at the computer; at weekends, the figure even rises to 24% (Brettschneider 2004).

Conclusion

Physical inactivity and the high prevalence of a sedentary, inactive lifestyle are a huge threat to general health, although the problem is no longer confined solely to the highly developed societies of Europe and North America but has also spread to the less developed

countries. Against the backdrop of structural and technological development, an increase in physical activity for the majority of the population can only be achieved by boosting physical activity in the area of daily activities and by changing leisure-time behavior. In this regard, it must in particular also be ensured that no two-tier society develops in which people with a lower socio-economic status and educational background are also disproportionately often inactive and are thus exposed to a higher health risk. Measures that help target groups who are particularly at risk to change their leisure-time behavior and that make it possible for broad social classes to gain preferably barrier-free access to physically active leisure-time activities therefore represent an important and cost-efficient contribution to public health.

Leprosy

Synonyms

Hansen's disease

Definition

Leprosy is chronic, mildly infectious illness that produces, if untreated, various deformities and disfigurements. It is caused by the rod-shaped bacterium *Mycobacterium leprae*. The mode of transmission is not fully understood. It is thought to be transmitted by nasal discharges and skin sores, possibly also by contaminated objects and arthropods. Only 5% of those exposed acquire the disease. The onset is intermittent and gradual; symptoms may not appear until years after exposure. It is seldom fatal, but its involvement of the peripheral nerves destroys sensation and makes the patient prone to inadvertent injury.

Lethality

- ► Mortality

Level of Measurement

Synonyms

Scale of measurement; Taxonomy of data/variables; Steven's classification system

Definition

The level of measurement of a variable is a classification proposed in order to describe the nature of information contained within numbers assigned to objects or subjects, therefore within the variable. It refers to the degree to which characteristics of the data may be modeled mathematically. The most frequently used classification of measurement scales in biostatistics is one defined by Stevens, who proposed four level of measurement: nominal, ordinal, interval, and ratio. Each involves different properties (relations and operations) of the numbers or symbols that constitute the measurements as well as a set of permissible transformations.

The nominal scale (or Level of Measurement) only classifies or categorizes values of the variable. The ordinal scale is used to order or rank values of variables in addition to naming variables. For the interval scale, equal differences between measures represent equal differences in the values of the variable, and there is not an arbitrary zero point. In the ratio scale, any two adjoining values are the same distance apart and there is a true zero point (the complete absence of any amount of the variable).

Liability of Public Authorities

► State Liability

Liability Without Fault

► Strict Liability

Liberalism

Definition

Different approaches guide public health stakeholders in dealing with ethical dilemmas. Liberalism would stress human rights and individual opportunities and would protect the individual from some abuses which have taken place in the past in the name of the common good.

Liberalism and Libertarianism

Definition

Liberalism is a political philosophy that puts a high value on the liberty of each human being and rejects authoritarian control. So every person ought to do what s/he prefers to, as long as s/he treats other human beings with respect. Liberalism comes in two flavors: On the one hand, there are libertarians who hold the opinion that the state should guarantee complete individual freedom without infringement of personal choice. This means – in its extreme form – no government-provided social services, and only a bare minimum of taxes and trade regulation (e. g. merely a protection of ownership). Egalitarian liberals (► Egalitarianism), on the other hand, believe that the right of choice requires adequate resources. This implies a positive right to a minimum level of resources and services to ensure equal opportunities.

Lice

Synonyms

Pediculosis

Definition

Lice, wingless insects with six stout legs and claws, spend their whole life on their host and cling tightly to the host's hair. Eggs (0.5mm), the so-called nits, are laid near the proximal part of the hair shaft. They are attached with a specialized saliva, causing a bond which is difficult to separate. Eggs hatch into nymphs; following three nymphal stages, the adult stage is reached. The whole cycle of development (from the egg to the adult louse) lasts 30–41 days. The characteristic symptom of an infestation with lice is itching. One can distinguish between head lice (pediculosis capitis), body or clothing lice (pediculosis vestimentorum) and pubic lice (pediculosis pubis, ► sexually transmitted diseases, STD). As for children, the most common lice are head lice. Lice cannot jump; transmission from one individual to another takes place by direct contact. Away from their host lice can only survive for a short time, as they feed on blood and need specific surroundings (like a certain temperature). Nits can be scraped off the hair with a special nit comb, which is a comb with very fine and close teeth. The medical treatment consists of the application of malathion, pyrethrum or permethrin. The advantage of permethrin is that it has to be used only once. In cases of body or pubic lice, clothing and bedclothes should be washed at a temperature of at least 60°C. Lice at all their different stages (eggs, nymphs) can be killed by freezing or by keeping clothing, soft toys and other articles in plastic bags for a couple of days.

Licensing

Synonyms

Licensure

Definition

In administrative law, licensing means the regulatory legal tool to regulate professions, businesses, and products. The key instruments of licensing are licenses, permits, and other means of regulatory supervision of the entry and conduct of professions and businesses. The license stands for the regulatory permission to take on a regulated profession or a regulated business or to develop and market a product that is subject to governmental regulation (e. g., pharmaceuticals, medical devices). Governmental licenses are revocable. In contrast, under private law, licensing means agreements with which holders of intellectual property rights allow others to utilize these rights vis-à-vis a license fee.

Licensure

► Licensing

Life Expectancy

Synonyms

Survival; Years of life; Longevity

Definition

Life expectancy is a statistical measure defined as the expected (mean) survival of human beings based upon a number of criteria such as gender and geographic location. Popularly, it is most often construed to mean the life expectancy at birth for a given human population, which is the same as the expected age at death. However, technically life expectancy means the expected number of years remaining to live, and it can be calculated for any age.

Life expectancy is a summary measure of mortality and survival in a population, often used for comparisons across time and between countries. Using a demographic life table, life expectancy can be calculated from any exact age as the average number of years lived from a particular birthday. Life expectancy at birth is a statistical measure of the average length of life in a given population. For populations undergoing ► demographic transition, life expectancy can increase with age in the early years, reflecting high rates of infant and child morality and showing that those who survive the high-risk early period have better prospects of survival. After this early period, remaining life expectancy declines with age.

Life Skills

Definition

Life skills are defined as follows in the context of health promotion: Life skills are abilities for adaptive and positive behavior that enable individuals to deal effectively with the demands and challenges of everyday life.

Life skills are needed to maintain and use social contacts in cases of life crisis, disease, and disability. In addition, they include decision making and problem solving, creative thinking and critical thinking, self awareness and empathy, communication skills and interpersonal relationship skills, coping with emotions, and managing stress. Life skills encompass social and communicative abilities as well as personal, interpersonal, cognitive, and physical skills that enable people to control and direct their circumstances in life, and to develop the capacity to live with and produce change in their environment.

Lifestyle

Synonyms

Way of life

Definition

A lifestyle is based upon an individual organization and expressive arrangement of everyday life and it forms a synthesis of conscious intentions and unconsciously experienced behavior, attitudes and objectives, and contacts and interactions with other people.

Individual lifestyles can be found, in the same or similar manner, in other people. Lifestyles show correlation but also differences. Lifestyles are determined by gender, age, education, work income, ethnic groups and social ecological environment.

Lifestyle is a way of living characterized by identifiable patterns of behavior based on an individual's choice, influenced by the individual's personal characteristics,

their social interactions, and socioeconomic and environmental factors.

Lifestyle and Health Determinants

CHRISTIANE HILLGER
Forschungsverbund Public Health Sachsen-Sachsen Anhalt e. V., Medizinische Fakultät, Technische Universität, Dresden, Germany
Christiane.Hillger@tu-dresden.de

Introduction

Good health is the most valuable asset a person can ever own. Until the first half of the 20th century mortality and morbidity were mainly affected by communicable diseases such as infectious and deficiency diseases. In the last decades life expectancy has increased continuously and the transition from infectious to degenerative diseases has created new lifestyle-related health problems. Thus, the conditions have changed and chronic non-communicable diseases have become a major burden both in the developed and in the developing nations. There are many factors that influence an individual's health. Whether a person falls ill depends on various exogenous and endogenous reasons. Generally, the idea of health determinants includes the social, economic and physical environment and additionally the person's individual characteristics and behavior (WHO 2007a). Thus, individual lifestyle determinants have a strong effect on a person's well-being.

Determinants such as unbalanced diet, a lack of physical activity and substance abuse can be linked to a number of major health problems (European Commission 2007). There is ample evidence that these determinants cause for example diseases like certain cancers, obesity or cardiovascular diseases. Thus, many diseases are related to people's behavior (Koelen and van den Ban 2004). Especially deprived populations and children have a smaller chance to achieve a well established health status and are the population group with the highest prevalence of non-communicable diseases. These conditions are normally caused by poor nutrition, low physical activity levels, smoking or alcohol abuse. Combined with economic, social and cultural circumstances as well as gender aspects they interact and affect the individual's health status. Taking different living conditions into account it becomes clear that preventing the public's health is a challenging mission for the individual itself but first of all for policies, institutions, the global market and the community. For this reason campaigns and interventions that address health promotion should also focus on cultural and socioeconomic factors. Therefor, actions and interventions in various settings, such as kindergartens, schools, workplaces or local communities could be realized efficiently by practicing healthy behaviors and using preventive healthcare services.

But there is a great demand particularly for policymakers and public health institutions to interact, identify deficiencies in health systems, propose broad health targets and communicate to implement health policies on national and regional levels. Thereby the overall goal to promote the population's health can be achieved. On the other side public health policies should be transformed into action with respect to the individual responsibility of the population. People make different choices about the way they want to live and consequently affect directly their health and well-being. Accordingly, tobacco and alcohol consumption, high blood pressure and obesity are risk factors that cause at least one third of all diseases in developed countries like North America, Europe and the Asian Pacific (WHO 2002). It is obvious that these circumstances lead to a broader encouragement to the individual itself and certain population groups in their settings always in consideration with current scientific basis.

An individual's lifestyle consists of a broad range of determinants that have an impact on health and well-being. The underlying chapter provides an overview about relating determinants. It is divided in the following subtopics: nutrition, obesity, physical activity, leisure time physical activity and ► sedentariness (► leisure time physical activity and sedentariness), environmental health determinants, economical health determinants, social health determinants (► health determinants, social), psychological health determinants (► health determinants, psychological), alcohol consumption, drug abuse, substance abuse, tobacco consumption, reproductive health and the influence and

impact of health care systems according to health and lifestyle related aspects.

Nutrition

► Nutrition is a complex interaction that influences our daily life and is also influenced by various determinants. It covers not only human needs – for example absorption of liquid and solid foods to provide the body with essential nutrients – but effects significantly social issues. Different sensory characteristics eating and drinking can be seen as a pleasure. Cultural, economic and individual factors determine the quality of nutrition and nutrition habits as well as influencing factors like lifestyle and well-being. A healthy diet provides an adequate amount of each essential nutrient. Thus, a well-balanced nutrition is essential for promoting health and has a high impact on preventing nutrition related diseases.

Nutritional Recommendations like the Daily Reference Intakes (DRIs) provide fundamental information on basic nutrients needs for every population group and period of life to maintain the individual's health. DRIs incorporate current concepts regarding the role of nutrients and food components in reducing for example the risk of chronic diseases and are intended to plan and assess diets for healthy people (Dudek 2006).

What people are finally eat depends on their lifestyle, their preferences and dislikes. Often, consumed meals are too fat, too salty and do not consist of enough fresh components like vegetables, fruits or fresh herbs. The widespread overnutrition leads to problems such as overweight and obesity in the industrial countries. Consumers should be provided with information that is necessary to create a healthy and well-balanced diet with respect to aspects like dietary diversity or cultural differences in daily nutrition. This information needs to be scientific based and clearly described. Nutrition education should be intended to be an integral part of school curricula in order to let children of all age groups benefit early from prevention and health promotion.

Obesity

► Obesity is one of the greatest current public health challenges. The prevalence has tripled in many countries in the last two decades and is increasing at an alarming rate. A great prevalence of obesity in men and women as well as in children is recognized in populations living in the N and W of Europe, in Australia, Canada and the US (Crawford and Jeffery 2005). Children and additionally people in lower socio–economic groups are mostly affected. Overweight and obesity are strongly related to non-communicable diseases and contribute to a decrease in life expectancy (WHO 2006). According to this one's quality of life is influenced negatively and therefor obesity has a significant effect on economic costs and social development.

► Overweight and obesity are considered as a problem of energy balance. Inadequate diet with high energy intake and low physical activity result in a positive energy balance. Studies show that energy intake has risen in concert with the growing of obesity and is combined with a decrease in energy expenditure (Crawford and Jeffery 2005). Additional factors that have an influence on the course of overweight and obesity are for example the parental weight, genetic fundamentals as well as the preventive effect of exclusive breastfeeding during the first six month of life (European Commission 2004a). Excessive body weight often results in various diseases particularly cardiovascular diseases, diabetes mellitus type 2, high blood pressure, dyslipidaemia and certain form of cancer. Gastrointestinal, respiratory or psychological complications are due to both overweight and obesity.

In tackling and preventing overweight and obesity public health strategies and policy responses are very important key elements that may change the present situation. Especially children and their caregivers (family members and teachers) have to be addressed in public health programs and intervention because food habits occur in early childhood and have its implication up to adulthood. Behavior-oriented lifestyle programs should be preferred instead of pharmacotherapy. Public health approaches to obesity prevention have to address a broad range of influencing factors. Key elements that have to be focused on are nutrition and physical activity which have an important impact on energy balance and finally on the individual's health and well-being.

Physical Activity

Regular ► physical activity can be seen as one of the most influencing factors for quality of life and provides the basis for the maintenance of health and well-being. Being physically active regularly in a moderate-intensity helps to reduce various kinds of diseases and

almost all people of different ages benefit from regular (RKI 2005; Center for Disease Control and Prevention 2006). Children and their parents and even older people help to maintain their health by being physically active. It is recommended to be physically active at least 30 minutes each day (RKI 2005). Today, a large number of methodologically similar studies provide essential information on how, how often and what kind of physical activity the individual should aim at. Studies and questionnaires conclude their results in public recommendations. Furthermore, health education in public places, such as kindergartens, schools or companies may be useful to increase knowledge and competence of the whole population concerning an enhanced physical activity and so health-promoting environment. National policies have to aim at encouraging the population by providing more engagement in being physically active (WHO 2007a). Thus, a regular physical activity has numerous health benefits and reduces the risk for major chronic diseases.

Leisure Time Physical Activity and Sedentariness

During the past decades physical activity has declined in the daily life of most people living in industrial countries. Great distances to the workplace and modern life circumstances lead to a more inactive life. People tend to go by car or by public transport for short distances and working conditions in offices enhance the ► sedentary behavior (► leisure time physical activity and sedentariness) as well. Physical inactivity is characterized by a lack of sufficiently strong contractions of muscles. Furthermore, the metabolism is not adequately forced. Leisure time activity refers to all behaviors that are connected with being physically active in free time. Physical is believed to contribute to obesity and other diseases, such as type II diabetes, some kinds of cancer or heart diseases and thus, causes approximately 2 million deaths a year. According to this a predominantly sedentary lifestyle increases the risk for many non-communicable diseases.

Most people spend their free time by doing predominantly sedentary activities such as reading, or watching television instead of doing sports. Furthermore, time budget for additional physical activity is very limited when for instance working the whole day and caring of the family. Further impact on inactivity is given by socio-economic status and the level of education whereas gender does not have a dominant influence. Additionally, the use of the media, for instance television or computer, dominates leisure-time behavior in all developed countries. Regarding this present situation enhancing physical activity promoting to be one of the major objectives, especially for public heath policies from an evidence–based perspective. More studies are needed to develop an effective and applicable approach on how to best tackle people's physical inactivity. Efforts have to be multidisciplinary in order to encourage individuals and communities without disregarding environmental, transport community planning circumstances.

Environmental Health Determinants

Human health and environment are multi-causaly linked. Living conditions, workplace and individual lifestyle factors determine health and thus the quality of one's life. According to that, ► environment-related determinants of health (► health determinants, environmental) cover all physical, chemical, biological and psychological conditions that may have an effect both on the current as well as on future life (Kreisel 1998).

During the last decades environmental conditions have been improved, e. g. medical care has been well established, as well as hygienic circumstances, living and working conditions. This background leads to a high quality of life and an increased life expectancy. Nevertheless, there are various diseases that are attributable to environmental factors. Additionally, these differ between industrial and developing countries and between the East and the West of Europe and moreover, these are strongly depending on socio–economic aspects (EEA 2005).

While most of the people living in developing countries suffer from communicable diseases, caused by poverty and poor hygiene, the major burden of disease in industrialized countries are due to non-communicable diseases caused by changes in lifestyle through a modernized environment.

Currently, air pollution and climate change have the greatest impact on population health. As a result, diseases like respiratory illness and allergies have become a major problem and the relation of human health and environmental quality have become more precise and relevant due to ongoing research and policy activities. The public concern about the present situation demands

on science and research (EEA 2005). Moreover, the environmental influence on health-related quality of life is also linked to economy and health care system (e. g. increased illness and thus loss of working hours, high expenditures of health systems). Strategies that help to prevent and protect the environment and the population are urgently necessary since environment and human health as well as well-being interact from the beginning of life. Thus, prevention has to be aimed at identifying and reducing the risks.

Economical Health Determinants

A person's health status is additionally influenced by the environment. Health status and economical health determinants (► health determinants, economic) interact consistently, e. g. income affects the health status, well-being and quality of life in addition to social, psychological and individual characteristics. Within the framework of Public-Health-Issues health economics focus not only on economic analysis of health care and the financing of health systems but on the development of organization and financing of innovative profiles of health or medical care. In the present situation of well-established health systems it is of great importance how to analyze their costeffectiveness. The overall aim is to establish health services considering the needs of every person combined with acceptable cost and high-quality and to further go on in measuring the efficiencies of several programs or interventions in the field of public prevention and health promotion. Thereby important economical basics should be established by health policies to improve the population's health.

Social Health Determinants

Lifestyle and health are socio-culturally varying (► health determinants, social). Socio–economic position, social roles and circumstances or cultural factors are complex patterns also including sex and age. Thus, health status is influenced by socioeconomic development and vice versa. Lower socioeconomic status is the most powerful contributor affecting one's health: the lower one's socioeconomic status, the poorer one's health. Social inequalities in health are a key problem all over the world (Siegrist and Marmot 2006). Socio–economic factors greatly influence the health status. Level of education or occupational class can be seen as socio–economic indicators that have a big impact on health status. Mortality is between 28 and 53 per cent higher in the lower educational groups (Mackenbach 2006). Stable social networks and social support operate as protective determinants for coping with stressful situations in daily life. Thus, social capital is an individual resource that is fundamental for the social status, health and well-being. Another aspect of social health is employment. The absence of regular income and acceptance in society leads to higher morbidity and mortality. Unemployment is associated with adverse health outcomes. On the basis of the growing concern, evidenced-based strategies to reduce social health inequalities have to be focused on. Changes in lifestyle and modifications in the individual's environment should be first steps of an intervention to reduce social health inequalities on the population level.

Psychological Health Determinants

Health and its psychological processes contribute to an individual and productive life. Psychological determinants have a major focus on behaviors that contribute to health and illness (► health determinants, psychological). But unfortunately, in most parts of the world interest in mental health and related disorders is unsufficient especially if compared to physical health. According to the World Health Organization (WHO) mental health problems are increasing and today about 450 million people suffer from mental disorders that are responsible for 12% of burden of disease (more than on cancer) (WHO 2001).

Mental health itself is difficult to define and implicates more than the absence of mental disorders. The individual's behavior, social and economical circumstances have a high impact on mental health. Psychological well-being further is influenced by self-esteem, existence of life-tasks and goals, emotional well-being as well as the interaction of socio-economic lifestyle and psychological health.

Regarding public health issues it is essential to pay attention to the health of every individual. Primary prevention should be regarded as the first and most promising way to reduce the prevalence of mental disorders and is intended to address population groups at high risk. Policies should focus on the population's mental health by cost-effective services, mental health promotion programs, adequate care concepts or for example promoting a healthy lifestyle and therefor reduce the

risk for mental disorders and related conditions (WHO 2001).

Alcohol Consumption

According to the World Health Organization about 2 billion people worldwide consume alcohol beverages. The over-consumption and in connection with this alcohol dependency are related with high morbidity and mortality all over the world and implicates health and social consequences. People regard alcohol and its consumption as a part of culture, lifestyle and luxury. For most people alcohol is an integral part of daily life. Influencing factors are the socio–economic position, cultural factors but also social and political circumstances, like taxes and the availability of alcoholic beverages. ► Alcohol consumption can be divided in three main groups: moderate drinking, heavy drinking and excessive drinking (WHO 2004).

Particularly the number of young people who are seriously threatened by the use of alcohol is rising, especially by increased binge drinking. Young people drink in order to get drunk.

Heavy alcohol consumption is linked to numerous diseases. Depending on the period, the social circumstances, individual health and amount of alcohol a person drinks several health related problems can occur. Aggressiveness, physical disorders and alcohol poisoning are results of short-time alcohol consumption. Whereas liver cirrhosis, certain cancers, cardiovascular diseases or malnutrition reflect long–term heavy drinking. Additionally, the social network can collapse with loss of friends, family or job as major consequences.

Tackling the alcohol problems has to be an integral part of public health policies. Primary prevention throughout public programs or interventions should be already implemented in the surroundings of children and teenagers. This population group is at risk and premature alcohol problems may lead to further difficulties in adulthood. Policy initiatives should also aim at reducing the public availability of alcoholic beverages (WHO 2004).

Drug Abuse

► Drug abuse in this context is related to medication drug abuse, the consumption of a drug apart from a medical need. It covers psychological and physical symptoms and leads to behavioral changes. Drug abuse is one of the hardest ascertainable form of addictions. Women are more likely to abuse drugs than men and increased age is associated with higher prevalence of drug abuse. Analgesics, barbiturates, depressants but also anorectics are drugs often abused. Drug abuse may lead to drug dependence and increases the risk of physical, mental and social disorders (Faust 1996).

Furthermore, the use of drugs in daily life implicates hazards in road use and occupation and poor health is the consequence, too. Taking drugs is often combined with alcohol consumption and thus increases its effect on health. Another field of drug abuse covers doping, substances that positively influence muscular effort with adverse health effects.

Knowing that people who abuse drugs are often understated and harder to identify overall aims of public health strategies should focus on confirming the diagnosis of drug abuse in time for preventing further drug-abuse-related diseases. Prevention and health promotion may contribute to premature identification and education based on scientific evidence and with political encouragement.

Substance Abuse

Substance abuse (► substance related disorders) in this context describes the intake of substances with psychoactive properties that affect the central nervous system grouped according to their stimulating or hallucinogenic effect, such as alcohol, cannabis, nicotine or opioids. The regular use of psychoactive substances results in health threats on the basis of the addicting potential. Psychoactive substance do not only change mood for a short time. With regard to long-term intake of the mentioned substances health consequences of dependence or intoxication lead to higher risks for accidents, violence and mortality. These conditions result also in social problems as well as depression and physical dysfunctions.

People with poor social background like an adverse childhood combined with genetic susceptibility are vulnerable to substance abuse. Individual characteristics of a person may further interact.

Successful prevention of substances abuse may contribute to reduce costs for therapy and rehabilitation. Furthermore, preventive strategies should consider the need for primary prevention as well as efficiency of programs in the mentioned field.

Tobacco Consumption

► Tobacco consumption is the second leading cause of death and the fourth most common risk factor for diseases in the world (WHO 2007b). Smoking harms nearly every organ of the human body and causes many acute and chronic diseases, as the majority of cancers, particularly lung cancer though the existence of harmful and additive substances. In addition to this, smokers are high at risk for heart diseases, strokes or other fatal diseases. Especially maternal smoking during pregnancy is harmful to both the mother and the fetus. It causes low birth weight through inadequate supply of oxygen and nutrients via the umbilical cord and additionally results in long-term effects for the child after birth. This effect is also given if the mother is exposed to passive smoke from the environment (European Commission 2004b). Passive smoking endangers not only the own health but also the health of other people and this particularly vulnerable populations (e. g. infants, elderly etc.) (DHS 2003).

Regarding economical factors, public health costs of treating tobacco-caused diseases are enormous. Besides the above mentioned diseases smokers often are affected by chronic diseases that keep them away from work. Particularly poor, deprived individuals and families are influenced by the loss of money spend on tobacco, loss of income through illness and so forth. Furthermore, tobacco smoking and the exposure to tobacco smoke have social and environmental consequences.

For reducing the number of smokers, effective multilevel strategies on the national and global level have to be implemented in various settings. A high impact on combating the tobacco problem is known by public interventions, such as informing the population about the health risks of cigarette smoking or increasing prices on tobacco products. Additionally, prohibit smoking in public places, restaurants and work places have lead to reduced tobacco consumption. Only cost-effective and successful preventive strategies may bring long–lasting changes for a smoke-free environment in all public places. Although, smoking and its health effects are well-known, the problem of tobacco consumption and its serious consequences on public's health can only be solved with the aid and cooperation of all countries (DHS 2003). Early primary prevention can avoid that children and adolescents start smoking.

Reproductive Health

Reproduction needs a healthy population that has necessary resources, including individual decision-making and environmental basics. Sexual and ► reproductive health is a vital element of physical and emotional well-being. Complete physical, mental and social well-being lead to the ability that people are able to have a satisfying and safe sex life, that they have the competence to reproduce and the freedom to decide if, when and how often to do so and that men and woman have to be informed about safe, effective and acceptable methods of birth control. Furthermore, reproductive health focuses on techniques and services that contribute to reproductive health and well-being and prevents reproductive health problems (United Nations Fund for Population Activities 2007).

Safe reproduction is a part of existing knowledge about human sexuality and appropriate as well as good quality health information and services. Many people worldwide live in conditions of high-risk sexual behavior and face high risk of getting sexually transmitted diseases. In this regard the risk depends on a person's behavior. To ensure comprehensive and factual information for population, health care services, public health policies and programs should consider the needs and abilities of the whole population. All of them should be able to get the chance for own decision-making and be treated in the health-care systems. These circumstances are not only essential for family planning but first of all for preventing sexual transmitted diseases. As unsafe sex is the second most important risk factor for certain diseases and death effective interventions may help to make better reproductive health choices (WHO/RHR and CCP 2007c).

Health Care Systems

One's health is affected by ► health care systems, starting with care during pregnancy and delivery continuing over the whole life span. As an interdisciplinary field of research health care systems aim at promoting and maintaining the population's health. Thus, they have contributed to improve health. How they act and implement depends on which services are provided and how health care systems are organized. Institutional structures differ from nation to nation. Financing of these systems is guaranteed by both – public (taxes) and private funds (donations). As resources are limited a well-

established distributing system leads to the best possible dissemination of funds and services (WHO 2000).

Summary

Health as a substantial resource permits people to live in a well-established, socially, economically and productive life (von Lengerke 2001). There is no doubt that the individual's behavior influences certain lifestyle-related diseases such as cancer, overweight, cardiovascular diseases or suicides. Many of these diseases are linked to an unhealthy behavior, such as tobacco and alcohol consumption, poor dietary patterns and a lack of physical activity. Additionally, sexual transmitted diseases like AIDS or mental disorders are caused by unhealthy behavior. Therefor, most of the above-mentioned diseases could be prevented by a healthier lifestyle and behavior. This aim could be achieved by complementing prevention and health promotion effectively in all settings and at the international, national, regional and community level.

Life Table Analysis

Definition

Life table analysis involves stratifying patients by length of follow-up. Within each time stratum, a probability of failing is computed as the number at risk at the beginning of the interval. For each time stratum, the probability of surviving is one probability minus the probability of failing. The estimated probability of surviving to a particular time is the product of the probability of surviving each of the preceding time strata.

Life Threatening Illness

► End Stage Disease

Light

► Illumination

Lighting

Synonyms

Illumination

Definition

Almost 80% of sensations from humans immediate surroundings are received via the ocular system, but visible light is a key element because without light we can not see. Appropriate lighting has a positive influence on various aspects of human well being—visual capacity and perception, mood, and mental concentration and working ability. One of the most important tasks in designing our microenvironment is therefore to provide optimal lighting according to actual visual activities. In such lighting conditions, the level of fatigue may be significantly decreased or delayed; safety at work increased; and lower rates of traumatism and absenteeism ascertained. Lighting affects the comfort of occupants and/or workers, their health, work capacity, and company's productivity. Low illumination, excessive brightness (glare), flicker, 100-per-second modulation, or other lighting deficiencies may cause various adverse visual and/or nonvisual effects, and other consequences such as fatigue, eye strain, discomfort, visual impairments, headache, accidents, injuries, annoyance, etc. Daylight (or natural lighting), and electric (or artificial) lighting of interior spaces will be described here. The greatest source of daylight on Earth is the Sun, directly or indirectly entering working and/or nonworking interiors through properly designed windows, glazed doors, roof-lights, etc. Daylight is preferable in all of these spaces because of its good spectral composition, though its levels vary with time of day and time of year, and are highly related to climatic (lighting) characteristics of the region. On the other hand, electric light complements or replaces daylight, and two main groups of artificial light sources for indoor space illumination have been developed—incandescent sources (filament lamps or light bulbs), and fluorescent tubes. Artificial lighting may be designed as general uniform lighting (the whole space is illuminated to approximately the same illumination) or localized lighting (additional illumination for exacting visual tasks, e. g. overhead light in dentistry and in operating theaters and examination rooms in hospitals, microelectronic assembly, etc). The luxmeter is the most appropriate handy instrument for both daylight and electric lighting measurements.

Likelihood

Definition

In general use, the word likelihood is a synonym for probability but in statistics, it has a more specific meaning – it is the probability of the observed data given the probability model, which gave rise to the data. Like-

lihood is used to compare different possible candidate values for the parameters of the model. The one with the greatest likelihood is considered to be more likely. Parameter values for which the probability of the observed data is greatest are the most likely values, or maximum likelihood estimates. The ratio between likelihoods is used in hypothesis testing.

Likelihood Ratio

Definition

The likelihood ratio is the likelihood that a given test result would be expected in a patient with the target disorder compared to the likelihood that the same result would be expected in a patient without that disorder. A likelihood ratio test is a statistical test in which the ratio between the maximum likelihood under the null hypothesis and the maximum with that constraint relaxed is computed.

Linear Discriminant Function Analysis

► Discriminant Analysis

Linkage Analysis

Definition

Linkage analysis is a statistical technique which is widely used to identify markers (regions) on genes in the human ► genome with the aim of obtaining a crude chromosomal location of the gene or genes associated with a ► phenotype of interest. The analysis must be performed within families, because the specific marker allele associated with the disease generally varies from family to family, in accordance with the allelic distribution of the marker in the population.

Linkage Disequilibrium

Definition

Linkage disequilibrium is an excess or deficiency of certain combinations of ► alleles from genes or SNPs (► single nucleotide polymorphism) located on the same ► chromosome. Linkage disequilibrium has been observed in associations detected at the level of the gene product. For example, many of the associations between specific HLA alleles and various diseases may be due to linkage disequilibrium among alleles in the HLA region.

► Chromosome

Lipometabolism

Definition

Biochemical pathways to burn lipids.

Live Birth

Definition

Live birth is a birth in which the baby shows any sign of life, such as a heartbeat or involuntary muscle movement, irregardless of the duration of the pregnancy or the duration of the life of the child.

Cross-References

► Infertility

Living Conditions

Definition

Living conditions are defined as follows in the context of health promotion: Living conditions are the everyday environment of people; where they live, play, and work. These living conditions are a product of social and economic circumstances and the physical environment – all of which can impact upon health – and are largely outside of the immediate control of the individual.

Cross-References

► Health Setting

Local Health Departments

Definition

Local health departments are administrative or service units of local or state government concerned with health and carrying some responsibility for the health of a jurisdiction smaller than the state.

Local Health Effects

Definition

All or part of the body may be affected. A local effect occurs at the place where the hazardous agent contacts the body.

Local Knowledge

► Traditional Knowledge

Local Public Health Agency (LPHA)

Definition

Local public health agencies include the ► local health department, local board of health, and/or other local governmental entity designed to provide public health services to the jurisdiction. Local agencies are part of the state public health system.

Logistic Model

Definition

Logistic model is a statistical model of an individual's risk (probability of disease y) as a function of a risk factor x

$$P(y/x) = \frac{1}{1 + e^{-\alpha-\beta x}}$$

where e is the (natural) exponential function. This model has a desirable range, 0 to 1 and other attractive statistical features. In the multiple logistic model, the term β_x is replaced by a linear term involving several factors e. g., $\beta_1 x_1 + \beta_2 x_2$ if there are two factors x_1 and x_2.

Logistic Regression Analysis

Definition

Logistic regression analysis is a regression technique based on generalized linear models (► general and generalized linear model). The goal of logistic regression analysis is to find the best fitting biologically reasonable model to describe the relationship between a categorical, most usually binary or dichotomous, outcome (dependent or response variable) and a set of independent (predictor or explanatory) variables that could be categorical or continuous or both. For example, it is used to identify risk factors associated with disease occurrence. Logistic regression is also used to adjust statistically the estimated effects of each variable in the model for differences in the distributions of and associations between other independent variables. For example, it is used to assess interaction effects and to understand the impact of covariate control variables. The multiple logistic regression model is given by: $\log it(\pi) = \ln[\pi/(1\text{-}\pi)] = \beta_0 + \beta_1 x_1 + ... + \beta_k x_k$, where $X_1, X_2, \ldots, X_k$ are a collection of independent variables, π is a probability of success for binomial outcome variables and $\beta_0, \beta_1, \ldots, \beta_k$ are parameters of the model. Logistic regression applies the maximum likelihood estimation after transforming the dependent into a logit variable (the natural logarithm of the odds of the dependent occurring or not). In this way, logistic regression estimates the probability of a certain event occurring. A distinction can be made between binomial/binary (e. g., alive or dead), multinomial (e. g., several categories of prognosis) and ordinal logistic regression (when multiple classes of the dependent variable can be ranked), as well as between unconditional (no stratification variables) and conditional logistic regression (inclusion of stratification variables).

Loglinear Analysis

Synonyms

Loglinear modeling

Definition

Loglinear analysis is a multivariate statistical technique that can be applied to contingency tables (to explore the data or verify specific hypotheses) for analyzing the relationships and interpretation of qualitative, categorical data. Loglinear analysis, a type of multi-way frequency analysis, is an extension of the two-way contingency table, where the conditional relationship between two or more discrete, categorical variables is analyzed by taking the natural logarithm of the cell frequencies within a contingency table. For example, the frequency of different symptoms may be crossed by patient's age and gender or the number of suicides may be crossed by region and religion. Loglinear analysis may also be used as a regression method to predict the expected frequencies (table cell values) of a dependent variable, to understand the relative importance of different independent variables in predicting a dependent variable, and to confirm models using a goodness-of-fit test (the likelihood ratio). It is based on loglinear models (specialized cases of generalized linear models), with the assumption that a linear relationship exists between the logarithm of the dependent variable and the independent variables with a Poisson or multinomial distribution of data. The first distribution leads to Poisson regression, common in event history analysis. Like other forms of loglinear analysis, Poisson regression predicts the count or rate associated with each cell in the table formed by the factors. Logit and probit models extend the loglinear model to allow a mixture of categorical and continuous independent variables to predict one or more categorical dependent variables.

Loglinear Modelling

► Loglinear Analysis

Logopaedics

► Speech Therapy

Logrank Test

Definition

This method allows instant generalization to allow the comparison of several groups of patients with each other: for each group, the extent of exposure to risk of death on a particular day is still the proportion of patients who are in that group on that day multiplied by the number of deaths on that day. The total exposure in one group over an extended period is the sum of the separate exposures in that group on the separate days comprising the period. In any one period, the sum of all the Os (observations) will equal the sum of all the Es (extent of exposure). For example, if we were comparing four groups, A, B, C, and D, we would check that $O_A + O_B + O_C + O_D$ equals $E_A + E_B + E_C + E_D$ at the end of the analysis. Logrank significance levels or p-values may be estimated by comparing the sum of $\frac{(O-E)^2}{E}$ with an appropriate chi square distribution. $\frac{(O-E)^2}{E}$ can be calculated in each group and added up, one term from each group. The sum of all the $\frac{(O-E)^2}{E}$ calculations is termed $\chi 2$. If the symbol k denotes the number of groups being compared with each other, this has a $\chi 2$ distribution with $df = k - 1$.

Longevity

Synonyms

Years of life; Life Expectancy

Definition

Longevity is defined as the number of years of life that can be expected on average in a given population. It refers to the expected years of life at birth which is the calculated mean age of death, based on current mortality rates for all age groups. There are other indicators of longevity—life expectancy at age 1, 15, 45 and 65 (WHO's Health for All database) or 40, 60, 65 and 80 (OECD Health Data). Longevity is increased during the centuries due to improved sanitation, health care and prevention.

Longitudinal Study

Synonyms

Long-term observational trial

Definition

A longitudinal study is a research design in which subjects are followed over time with continuous or repeated monitoring of risk factors, health outcomes, or both. Such investigation can last months or years. Types of longitudinal studies include cohort studies (prospective and retrospective) and panel studies. While cohort studies sample a cohort (a group experiencing some event) in a selected time period and study subjects at intervals through time, panel studies sample a cross-section of the population and survey it at regular intervals. Because longitudinal studies are observational, they have less power to detect causal relationships than experimental studies. However, because of repeated observation at the individual level (at two different points in time at least, and often more) they have more power than cross-sectional observational studies. Longitudinal studies can be used for researching many topics.

Long-Term Care

GERNOT LENZ
Forschungsverbund Public Health Sachsen-Sachsen Anhalt e. V., Medizinische Fakultät, Technische Universität, Dresden, Germany
gernot.lenz@gmx.de

Definition

Long-term care comprises a variety of services provided to persons with a chronic illness or disability who cannot care for themselves for long periods of time and are therefore dependent on help with their basic ► activities of daily living. Demand for long-term care grows exponentially with age and is concentrated in persons aged 80 years and older. Long-term care usually involves provision of custodial and non-skilled care, such as assisting with normal daily tasks like dressing, bathing, and using the bathroom. This care component is often provided in combination with help with basic medical services such as help with wound dressing, pain management, medication, health monitoring, prevention, rehabilitation, or services of ► palliative care. Long-term care can be provided at home, in the community, in assisted living accommodation, or in nursing homes.

Basic Characteristics

Long-Term Care Settings

Long-term care is provided in different settings depending on the recipient's needs and preferences, the availability of informal support, and the source of reimbursement. Gerontological literature, therefore, often refers to a continuum of care. Among the different long-term care areas that have emerged, mainly driven by reimbursement policy, the ► nursing home is still the major institutional setting. Home and community-based care on the other hand refer to a wide variety of non-institutional long-term care settings, ranging from various types of congregate living arrangements to care recipients' own homes. The boundaries between institutional and non-institutional long-term care are blurred. Many ► assisted living facilities are large buildings that strongly resemble hotels or nursing homes in physical appearance and philosophy. Over the past decade, there has been considerable investment in home-care services among the Organisation for Economic Cooperation and Development (OECD) countries, driven by the goal to maintain disabled older people in their homes where possible rather than in care institutions; this also reflects the wishes expressed by older people themselves.

Providers of Long-Term Care

Long-term care provision can be differentiated into formal care and informal care. Formal care is long-term care services supplied by employees of any private or public organization; this includes care provided in institutions like nursing homes as well as care provided to persons living at home by professionally trained care assistants like nurses or untrained care assistants. A large proportion of the paid providers of long-term care are paraprofessional workers like certified nursing assistants in nursing homes or home care workers. The latter deliver the largest share of the primarily low-tech personal care and assistance with managing daily life. Informal care is the care provided by informal caregivers such as family members, relatives, friends, neighbors, and others, mostly those with a previously existing social relationship with the care recipient. Informal care is usually provided in the home and is typically unpaid. In several OECD countries, programs have been designed for persons who are cared for at home in order to allow a more individual choice among care options. Some of these programs incor-

porate payments to informal caregivers in the form of income support. They aim to increase flexibility and mobilize, or at least maintain, a broader carer potential that enables older persons to stay in the community longer and reduces the need for expensive institutional care.

Quality of Long-Term Care

Based on studies from several OECD countries, there is evidence that the quality of long-term care is variable and often does not meet the expectations of users. Quality issues are particularly reported for patients with dementia. Driven by concerns about poor quality of long-term care in many developed countries, several countries have initiated reforms, increased spending, and introduced or improved existing regulations for quality assessment and improvement. Usually, ► quality of care is classified into the dimensions of structure, process, and outcome. Quality regulations have developed in recent years from defining minimum requirements for structure and process of care towards complex assessment and improvement instructions that include instruments for outcomes measurement, strategies of continuous quality improvement, detailed documentation, and explicit requirements for protecting patients' rights, privacy, and participation. Yet, transparency about the quality of long-term care and the prevalence of ► adverse effects in most countries is still not made accessible to the public on a regular basis. Without combining improved measurement with transparency, the functioning of a market for long-term care services does not seem feasible. There is a growing consensus that reporting on quality in long-term care has to be on a more scientific basis and needs to become an integral part of the care process itself, including scientific collaboration at the national and international levels. For decisive improvements in quality, countries need to move on from setting standards of quality of infrastructure and process of care to measuring the quality of outcomes. One of the main challenges will be to back up administrative systems with better information, which ideally should be developed in an interactive way: data and indicators produced from administrative systems should be of a proven reliability and validity in order to have maximum potential for use in developing better policies and adjusting infrastructure.

Long-Term Care Financing

There are projections that public expenditure for long-term care as a proportion of Gross Domestic Product (GDP) in OECD countries could double by 2050. This leads to the question: to which degree may public systems be capable of compensating for increasing long-term care expenditures in the future? This also affects the private system, as it can be assumed that higher proportions of the costs will have to be born privately, which is already the case in a number of countries. Given the fact that policy-makers are concerned about the sustainability of their systems of long-term care financing, different strategies have been followed, often depending on the respective social protection systems. Some countries have raised additional contributions; while in others, concerns about rising expenditure have been seen as a reason to find ways to limit expenditure by increased targeting or raising user payments. Several OECD countries like Austria, Germany, Japan, and the Netherlands provide comprehensive coverage and therefore treat long-term care in more or less the same way as other health-related needs. Other OECD countries, like the US or the UK, provide a system for long-term care that depends in part or in whole on a means test of the recipient's income and/or assets, and therefore treats long-term care differently from the way other health-related needs are covered. Within the OECD countries, the share of GDP spent on publicly financed long-term care varies from 0.2% to 2.9%. Private long-term care insurance as primary cover has played a very limited role in most OECD countries. It is expected to play a stronger role in the future, especially in the market for voluntary complementary long-term care insurance to meet additional costs not covered by public programs.

Conclusion

Although there is no clear recipe for balancing public and private financing, several elements are essential to the design and implementation of a long-term care system for the future. The system should address the long-term care needs of people of all ages, recognizing that services and other accommodations must be tailored to people with varying degrees of physical and mental impairment. The long-term care system must be sensitive to the needs of the family of the person who requires long-term care. Although formal care should

not replace the efforts of family and friends, the repertoire of services should build the family into the process and ensure that the family is supported. The future long-term care system should also recognize all the options that can meet the residential and care needs of the individual, and recognize that these needs do not necessarily increase in neat, predictable steps. The system must be flexible enough to address the acute, chronic, and non-medical social needs—such as housekeeping and transportation—of the long-term care client, which may fluctuate over time. Clients who prefer more autonomy should have that option, although they should recognize the tradeoffs involved in managing their own care. Long-term care will be a major challenge of the twenty-first century, and therefore financing, delivery, and training strategies should be actively developed, integrating the lessons learned from the successes and failures in other countries and nations.

Low Birth Weight

Synonyms

Small for gestation age

Definition

Low birth weight infants are born less than 2500 gm measured within an hour of birth.

Low-Level Exposure

Synonyms

Threshold concentrations of hazardous substances

Definition

It is difficult to quantify precisely the effects of chronic low-level exposure to substances such as those which are released by textiles and furniture, ingested with food, or contained in household or personal cleaning agents. Establishing a causal connection between a recognized and defined form of exposure and a given disorder is often very difficult, if not downright impossible. From an ► environmental medicine perspective, however, this is especially important since particularly vulnerable population groups – those with a high individual susceptibility – can very well be exposed to substances either singly or in combination. Quantifying the effects of hazardous substances in the environment by

extrapolating from the uptake of allowable concentrations within the low dosage range is especially important for those substances which are present everywhere and so make it impossible to avoid exposure even when preventive measures (e. g., reducing immissions) are observed strictly.

Lung Affection with Yersinia pestis

► Lung Plague

Lung to Body Ratio

Definition

The size of the lung compared to the size of his or her body affects the lung's ability to absorb oxygen. Children tend to have a larger lung to body ratio than adults, often making them more susceptible to airborne pollution and irritants.

Lung Plague

Synonyms

Lung affection with Yersinia pestis

Definition

On the one hand, lung plague is caused by hematogenic spread of *Yersinia pestis* in patients with bubonic plague; on the other hand, it can be transmitted by droplets when coming into contact with a person suffering from lung plague. Following an incubation period of 1–2 days, the infected persons develop painful cough, black-bloody sputum, cyanosis of the lips and difficulties in breathing; lung edema develops. Without treatment lung plague takes a lethal course within 2–5 days in about 95% of the patients.

Luther, Martin

Definition

Martin Luther lived from 1483 to 1546. He believed in the salvation of man through faith. He was the founder of reformation. As a professor of theology (divinity), he sought to correct the failures of the Catholic Church by his orientation to Jesus Christ as the overall word of God. He made new discoveries in God's mercy, his preaching, and writings, but in particular, the Lutheran Bible, which had and still has much recognition.

Lyme Borreliosis (LB)

Synonyms

Lyme disease; Infection with Borrelia burgdorferi

Definition

In 2–4% the bite of a tick infected with the bacterium *Borrelia burgdorferi* leads to clinical manifestations, which are called Lyme borreliosis. In 70–80% of the symptomatic courses, after 1–3 weeks, a rash develops at the site of the bite. The so-called erythema migrans is a reddening, which spreads centrifugally and becomes pale in the center. Between 1 and 5 weeks (up to 3 months) after the tick bite, 15% of people develop neurological symptoms (neuro borreliosis). The most frequent symptom is a facialis nerve paralysis, but other symptoms such as meningitis, encephalitis or an affection of the peripheral nervous system, with pain and disorders of sensibility, can appear as well. Moreover, an infection with *Borrelia burgdorferi* can affect the joints. In the so-called Lyme arthritis, most often the larger joints are involved, primarily the knee joint. While an oral antibiotic treatment is sufficient for erythema migrans, in neuro borreliosis and Lyme arthritis parenteral antibiotic therapy is necessary.

Lymphogranuloma venereum (LGV)

Synonyms

Lymphopathia venerea; Climatic bubo; Duran-Nicolas-Favre disease

Definition

Lymphogranuloma venereum is primarily found in tropical regions. It is caused by various strains of the bacterium *Chlamydia trachomatis* (serotypes L1–L3); the incubation period varies between 2 and 30 days. In the primary stage, a painful vesicle develops in the genital region. This vesicle ruptures and heals within 2 weeks. During the second stage, which starts 3–4 weeks later, there are general symptoms of illness. Furthermore, a swelling of the lymph nodes of the groin appears, which is painful and can be as big as a fist, and which later ulcerates. When these ulcers heal, they leave scars and fistulas. Long-term complications and damage are granulomatous inflammations, an impairment of the lymphatic drainage as well as strictures and ulceration in the genital and anal region. Lymphogranuloma venereum is treated for three weeks with doxycycline, tetracycline or erythromycin.

Macrolide Antibiotics

Synonyms

Macrolides

Definition

Macrolide antibiotics have been used since 1952. The first substance available was erythromycin. In general, macrolides are given orally. Their effects are primarily on gram positive germs. Macrolides play a special role in the treatment of infections by chlamydia and mycoplasma. Due to their structure, these pathogens are classified between bacteria and viruses. As they do not have a proper cell wall, they are hardly sensitive to penicillin's and cephalosporins. Another infection, which can be treated well by macrolides, is legionnaires disease.

Maintenance Therapy

Synonyms

Substitution therapy; Methadone maintenance

Definition

Maintenance therapy (MM) in the context of substance dependence stands for prescribing psychoactive substances to currently dependent patients, who are unable to stop their problematic drug use. The most relevant examples are methadone, buprenorphine and recently legal heroin prescription (controversially discussed) for heroin dependents and nicotine replacements (patches, gums, nasal spray) for smokers. The therapeutic target is to reduce the negative health and social consequences of continued problematic drug use ("harm reduction"). MM is often combined with behaviour therapy programmes in order to reach abstinence as long–term goal, but quitting rates are unsatisfactory.

Major Elements (Macronutrients)

Synonyms

Macrominerals; Macroelements; Bulk minerals

Definition

Macroelements are dietary minerals needed by the human body in high quantities, generally more than 100

mg/day (as opposed to microminerals, which are only required in very small amounts). Macroelement composition is modified by a variety of natural processes and/or deliberate and accidental human activities. Concentrations depend mostly on the base on which the soil is formed (bedrocks). Soil may lose some elements by leaching; and agricultural chemicals and pollutants may be added. The presence of major elements as constituents of the human body are: oxygen, 61% (also forms the highest proportion of the lithosphere, i. e. 50%); carbon, 23%; hydrogen, 10%; and nitrogen, 2.6%; the rest is taken up by calcium, magnesium, sodium, potassium, and phosphorus.

Synonyms

Infection with plasmodia

Definition

Malaria is an infectious disease of worldwide significance, which is transmitted by the *Anopheles* mosquito in warm climates. The disease is characterized by recurrent fever attacks.

Malaria is an infectious parasitic disease that is common in Africa, Central and South America, the Mediterranean countries, Asia, and many Pacific islands. It can be acute or chronic and is frequently recurrent. The causative microorganism is *Plasmodium falciparum* and for completion of its life cycle both mosquito and man are necessary.

Basic Characteristics

History

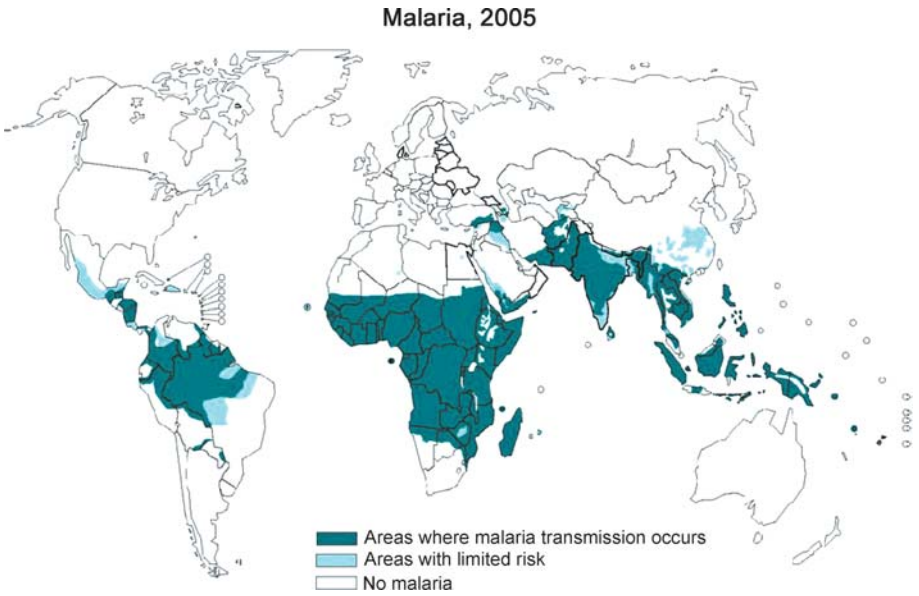
As early as in 400 BC, the Greek physician Hippocrates described a disease with the symptoms of malaria. A connection between fever attacks and climatic circumstances was assumed. Later reports of malaria, written by Roman physicians, are dated to the 2nd century AD. The relationship between fever and marsh areas gave malaria its name: malaria stems from Italian and means bad air. For hundreds of years, Peruvian Indians have been using cinchona bark to cure specific forms of malaria. Quinine, which is the effective alkaloid of the cinchona bark, was isolated at the beginning of the 1820s. It took another hundred years before further therapeutics against malaria were developed. At the end of the 19th century, ► plasmodia, the germs, which cause malaria, were detected in human blood; the ► *Anopheles* mosquito was found to be the transmitter of the disease. The step-by-step ► development of plasmodia was discovered in the first half of the 20th century. Malaria is still of significance today as 41% of the world's population lives in malaria-endemic regions. However, at present, 59% of the world's population lives in regions that have never had malaria or in which malaria has been wiped out – for example, by a draining of marsh areas, but, due to climatic changes (global warming), the WHO predicts that the incidence of malaria will spread as a result of an expansion of the climatic conditions favorable to *Anopheles* mosquitoes.

Transmission

Malaria is primarily transmitted in tropical or subtropical regions by the bite of an infected female *Anopheles* mosquito (Fig. 1). As the insects are night-active, in general, the bite takes place between sundown and sunrise, specifically inside houses or other kinds of living space. Plasmodia have been found in blood products, but, as plasmodia are sensitive to cold, cooling blood products makes them free of infection, they only become significantly infective in the case of a transfusion of untreated fresh blood. Other possible modes of transmission are through the re-use of contaminated needles or via the placenta to the unborn child, and, a rare situation, 'airport malaria' or 'luggage malaria', can be transmitted by the *Anopheles* mosquitoes being transported inside luggage from an endemic region; thus, not only travelers can be infected with malaria, but also airport staff or people who live in close proximity to airports.

Course of the Disease

According to the species of plasmodia, the incubation period varies between 7 and 24 days. Malaria



Malaria, Figure 1 Regions at risk of transmission of malaria according to the WHO, 2005 http://www.who.int/ith/maps/malaria2005_en.gif

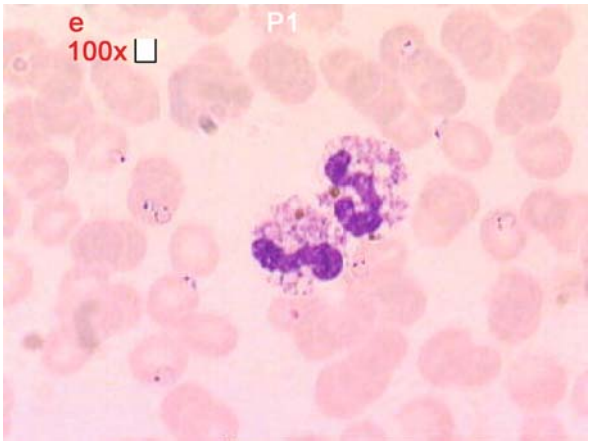
starts with fever and flu-like symptoms, as tiredness, headache and rheumatic pains. Additionally, abdominal symptoms, like nausea, vomiting or diarrhea, can appear. The further course of the infection is characterized by recurrent fever attacks (► fever attacks in malaria). During the fever-free intervals, plasmodia reproduce asexually; their release into the circulatory system leads to the next rise of temperature. Due to the destruction of red blood cells, anemia develops and there is a low platelet count (thrombocytopenia). The increased capture of erythrocytes in the spleen leads to an enlargement of the organ (splenomegaly). An affection of the kidneys and the liver may also be possible; frequently, there is a mild jaundice (icterus). Clumping of erythrocytes can impair blood circulation. The latter is extremely serious if the blood vessels of the brain are affected; in this case, cerebral malaria results, which leads to reduced consciousness, cerebral seizures, coma or even death. Malaria during pregnancy is dangerous as it often takes a more severe course than in nonpregnant women. Besides the transmission to the unborn child, possible complications are miscarriage, preterm birth and intrauterine growth retardation. A rare infection is blackwater fever (*Plasmodium falciparum*) in which hemolysis (destruction of the red blood cells) and acute renal failure occurs, causing high lethality. The name of the disease is derived from the urine, which is dark colored, nearly black.

Malaria in Children

Transplacental transmission of IgG-antibodies, produced by the mother who has been infected with malaria, protects the baby from those plasmodia. Moreover, the high percentage of fetal hemoglobin (HbF), which is present directly after birth, has a protective effect. HbF, like other structurally varied hemoglobin (as in case of sickle cell anemia), has a certain resistance against infections with plasmodia. As HbF is replaced by the adult form of hemoglobin, the protective effect declines within the first year of life. Due to the still immature immune system, the most serious courses of malaria are observed between the 1st and 4th–5th years of life. Every year, about a million children, primarily in this age-group, die of malaria, in most cases because of cerebral complications or multiorgan failure. Often, these children live in outlying villages where medical care is lacking.

Diagnostics

Anamnesis plays an important role in the diagnosis of malaria. While a connection between fever and malaria is quickly drawn in malaria-endemic regions, diagnosis is much more difficult in areas where *Anopheles* mosquitoes are not common. When the cause of fever is unclear, physicians should consider malaria as a possibility, especially if their patients have been travelers in tropical regions. A blood cell count will show that



Malaria, Figure 2 Malaria tropica, blood slide; *Plasmodium falciparum* infected erythrocytes (immature trophozoites, ring stage) and neutrophile leukocytes with toxic granulation, containing malaria pigment (homozoin); photo kindly provided by Dr. Christoph Borst, Neumünster

erythrocytes and thrombocytes are reduced. The parasites can be detected microscopically by the so-called ► thick drop method. The plasmodia species and the number of parasites can be determined (Fig. 2). Various malaria rapid tests are available, which provide a result within about 10 minutes. Other means of detection, like fluorescence stain or molecular biologic methods, are possible, but are not used in diagnosis because they are both time-consuming and expensive.

Malaria Prophylaxis

To prevent an infection with malaria, different strategies can be used. Due to the ecological consequences, an extensive killing of ► *Anopheles* mosquitoes by insecticides (DDT) is no longer carried out. Nowadays, they are only used locally for the inside of houses. Non-medicinal measures of protection aim at the avoidance of insect bites. In houses and in other living quarters, doors and windows should be equipped with insect screens and people should sleep under mosquito nets, the protective effect of which can be increased by an impregnation with 1% permethrin (effect of impregnation lasts for 6 months). It is important that the mosquito net does not have any tears and its entrance parts should overlap enough to prevent insect entry. As mosquitoes can also bite through the net, it must not rest directly on the skin, and the net should be carefully tucked under the mattress so that it does not slip out during sleep. Out of doors, covering clothing should be worn (long sleeves, long trousers, socks, closed shoes). Exposed parts of the body, including the skin at the edges of the clothing, should be treated with repellents (diethyltoluamid, DEET). For journeys to regions that are at high risk for malaria, ► malaria chemoprophylaxis should be carried out. Recommendations concerning protection against malaria in endemic regions are published by various organizations and updated regularly. A vaccination against malaria, which would be an effective prophylaxis for people living in endemic regions, is not available yet and is a current target of medical research.

Therapy of Malaria

Besides symptomatic measures to reduce fever and overcome nausea, drugs are available, used in accordance with the various species of plasmodia and their resistances. In infections that are not caused by *Plasmodium falciparum* (but by *P. vivax*, *P. ovale* or *P. malariae*), ► chloroquine (Resochin®, Aralen®) is an effective therapy. If resistances are suspected or treatment proves to be ineffective, ► mefloquine (Lariam®, Mephaquin®), ► atovaquon + proguanil (Malarone®) or ► artemether + lumefantrine (Riamet®) can be used. Following an infection with *Plasmodium ovale* or *P. vivax*, ► primaquine should be administered for recidivist prophylaxis.

During pregnancy, ► quinine (Quinora®, Quinerva®, QM-260®) can be given intravenously or orally, alternatively, mefloquine can be given after the onset of the second trimester. Due to the risk in pregnant women and the danger of hypoglycemia, close monitoring is necessary, particularly of blood sugar levels. Quinine + doxycycline or clindamycin is effective therapy for an infection with *Plasmodium falciparum*, or artemether + lumefantrine or atovaquon + proguanil can be used. In complicated cases, in-patient care is necessary, and even intensive care measures may become essential. In developing countries, the restricted availability of drugs and the lack of medical supplies limit therapeutic possibilities and are responsible for a great number of deaths from malarial infections. Travelers in these countries may resort to self treatment – standby- or ► self-therapy of malaria. Without medical treatment, the duration of a malarial infection varies depending upon the species of plasmodia involved; *Plasmodium*

falciparum 1–2 years, *Plasmodium vivax* or *P. ovale* 1.5–5 years and *Plasmodium malariae* can take up to 50 years.

In conclusion, malaria is an infectious disease that is caused by various plasmodia species that are found in tropical areas and which is transmitted by the bite of the *Anopheles* mosquito. The infection is of great significance in malaria-endemic regions. It is characterized by recurrent fever attacks and can take a serious or even deadly course. On the one hand, measures of protection aim at the avoidance of insect bites (use of insecticides, mosquito nets, suitable clothing), and on the other hand, medicinal prophylaxis can be performed, especially on travelers to malaria-endemic regions. Malaria can be treated with different effective drugs, the availability of which might be restricted in developing countries.

- ► Plasmodia (P. ovale, P. falciparum, P. malariae, P. vivax)

Malaria Chemoprophylaxis

Synonyms

Medicinal prophylaxis of malaria; Prophylactic therapy of malaria; Malaria suppression; Suppressive therapy of malaria

Definition

Chemoprophylaxis of malaria aims at the destruction of plasmodia, which are transmitted by the bite of an infected mosquito, thus preventing an outbreak of malaria. Prophylactic therapy is recommended for journeys into endemic regions that are at high risk of malaria, but not for long-term stays. Chemoprophylaxis has to be started 1 to 3 weeks before the onset of the journey and has to be continued for at least 4 weeks after leaving the endemic region. For medicinal prophylaxis ► chloroquin (Resochin®, Aralen®), ► mefloquin (Lariam®, Mephaquin®), ► atovaquon + proguanil (Malarone®) and doxycycline can be used. Before prophylaxis is carried out, the pros and cons have to be considered. On the one hand, the regional risk of a malaria infection has to be judged, on the other hand, possible side effects and long-term toxicity have to be taken into account. Special problems arise during pregnancy, especially when resistances against chloroquine are present. If it can be avoided, a pregnant woman should not travel to regions with a high risk of malaria.

Malnutrition

Synonyms

Improper nutrition; Undernutrition

Definition

Malnutrition is defined as deficiency of one or more of the essential diet ingredients. Primary malnutrition is caused by lack of essential nutrients such as vitamins, minerals or proteins. Secondary malnutrition is caused by failure of absorption or utilization of essential nutrients (as in disease of the gastrointestinal tract, thyroid, kidney, liver, or pancreas), by increased nutritional requirements (growth, injuries, burns, surgical procedures, pregnancy, lactation, fever), or by excessive excretion (diarrhea). In both cases a wide range of clinical abnormalities and metabolic effects may occur. In some regions of the world malnutrition may occur due to poor economy or climate conditions such as floods, drought or due to population size (e. g. overpopulation). Also malnutrition may result from poor eating habits.

Malta Fever

► Brucellosis

Mammography

Definition

Mammography is a procedure to detect diseases of the breast, particularly tumors of the breast by the use of X-rays. The radiographic examination of the breast is indicated to assist clinical detection of masses in the breast tissue, investigate secreting mamilla, follow-up of breast cancer treatment, and screening of the female population for preclinical – particularly precancerous – lesions in the breast. The guidelines for mammography screening (breast cancer screening) vary across countries as there is no consensus of the relation between benefits of breast cancer diagnosis at an earlier stage and the risk of radiographic examination and breast cancer treatment.

Managed Care

GERNOT LENZ
Forschungsverbund Public Health Sachsen-Sachsen Anhalt e. V., Medizinische Fakultät, Technische Universität, Dresden, Germany
gernot.lenz@gmx.de

Synonyms

Integrated health care delivery; Coordination of care

Definition

There is no generally admitted definition of Managed Care. The term Managed Care refers to a variety of structural and procedural issues that had a major impact

on the US health insurance system and health care structures and that were at least partly adopted by other health care systems in the aftermath. The principle of Managed Care is to manage and integrate the whole range of services that a patient needs with the theoretical aim of maximizing efficiency and effectiveness of health care delivery. A characteristic of Managed Care models is that the provider of health insurance steers and monitors the delivery of the respective health care services to a higher degree than usual. The strict separation between medical responsibility on the one hand and financing and administration on the other hand moves towards an integrated, cross-functional approach. Managed Care systems typically rely on a primary care physician who acts as a gatekeeper through whom the patient has to go to obtain other health services such as specialty medical care, surgery, or physical therapy.

The following elements summarize the key characteristics of Managed Care models:

- Diligent selection of the participating/approved health care providers (selective contracting)
- Limitation of utilization of health care services to selected providers, partially with a primary care physician assigned as "gatekeeper" and responsible for the overall care of members assigned to him/her
- Setting of financial incentives for the health care provider and insured person
- Development and review of ► treatment guidelines
- Ex ante evaluation of necessity and adequacy of specific services/procedures (e. g. ► preadmission reviews)
- Retrospective review in case of specific predefined incidents
- ► Cost-effectiveness analysis of new technologies

Basic Characteristics

Emergence and Evolution

The health delivery and management forms subsumed under the term Managed Care originated in the United States. First attempts can be traced back to the middle of the 19th century, yet it took until 1973 before Managed Care models gained increasing coverage when the US Congress enacted The Health Maintenance Organization Act as a cost-containment strategy. It offered loan guarantees and start up grants to encourage the development of alternative delivery systems. Managed Care plans, with utilization controls and preferred provider relationships, became an attractive alternative to ► indemnity insurance plans for many employers. In the 1980s, the Health Care Financing Administration (HCFA), also under severe pressure to contain cost increases, began a series of changes in ► medicare reimbursement policies. HCFA implemented revolutionary payment methods that prospectively paid providers an amount calculated on the basis of their past delivery of specific diagnosis-related services, and furthermore several states introduced selective contracting with health care providers which led to the emergence of another form of Managed Care, the Preferred Provider Organizations (PPO). As Managed Care in the US continued to respond to the changing market for health care coverage, new relationships were formed; hospitals merged to create health networks, physicians were affiliated through joint ventures with participating hospitals, Managed Care plans bought health networks to create integrated delivery systems, and employers joined together and assumed financial risk to create purchasing coalitions.

Managed Care Organizations

Although there are several forms of Managed Care, with partially smooth transitions between the different types, the following three categories can usually be differentiated:

- Health Maintenance Organizations (HMOs)
- Preferred Provider Organizations (PPOs)
- Point of Service Organizations (POS Organizations)

Health Maintenance Organizations Early in the 1970s, Paul Ellwood, MD, proposed a way out of the US Medicare budget crisis. He suggested that the federal government should turn to prepaid health plans to control costs. To do so, it would be necessary for the government to catapult these insurance plans from minor to major health care players. For the purpose of new legislation, these prepaid plans were renamed "health maintenance organizations" (or HMOs); the newly coined HMO term had (at that time) greater appeal. The HMO Act of 1973 was thus designed, debated, passed, and signed the face of US health care. As defined in the act, a federally qualified HMO would allow members access to a panel of employed physicians or a network of doctors and facilities including

hospitals in exchange for a subscriber fee (premium). In return, the HMO received mandated market access and could receive federal development funds. In practice, an HMO is an insurance plan under which an insurance company controls all major aspects of the health care of the insured. In the design of the plan, each member is assigned a "gatekeeper", a primary care physician (PCP), often a ► general practitioner, responsible for the overall care of members assigned to him/her. Specialty services require a specific referral from the PCP to the specialist. Non-emergency hospital admissions also require specific pre-authorization by the PCP. The conditions of the contracts between the HMO and the insured are usually the result of negotiations between the HMO and payers (employers, ► medicaid, Medicare). There are both "for-profit HMOs" and "not for profit HMOs", with the latter representing the minority.

Preferred Provider Organizations A preferred provider organization contracts with independent service providers to ensure health care delivery of its members. There are PPOs that cover the insurance risk and PPOs that transfer the risk to the buyer/financier of the PPO services, in general a conventional health insurer or self-insured company. The idea of a preferred provider organization is the provision of a substantial discount below the regularly charged rates to the insured members of the group without significant limitation of their choice of providers. Preferred provider organizations themselves earn money by charging an access fee to the insurance company for the use of their network. They negotiate with providers to set fee schedules, and handle disputes between insurers and providers. PPOs differ from health maintenance organizations (HMOs), in which insured persons who do not use participating health care providers receive little or no benefit from their health plan. PPO members are reimbursed for utilization of non-preferred providers, albeit at a reduced rate which may include higher deductibles, co-payments, lower reimbursement percentages, or a combination of these. Exclusive Provider Organizations (EPOs) are similar to PPOs but that they do not provide any benefit if the insured chooses a non-preferred provider, apart from some exceptions in emergencies. Another feature generally included in a PPO is utilization review, where representatives of the insurer or administrator review the records of treatments provided to verify that they are appropriate for the condition being treated rather than being performed largely or solely to increase the amount of reimbursement due, a procedure that many providers resent as second-guessing. A pre-certification requirement is also a near-universal feature, in which scheduled (non-emergency) hospital admissions and in some instances outpatient surgery as well must have prior approval of the insurer and often undergo utilization review in advance.

Point of Service Organizations Besides HMOs and PPOs, Point of Service (POS) Organizations have gained increasing importance. POS organizations combine the elements of HMOs and PPOs, as members can decide if they want to be served within the HMO or by an external provider at the moment of utilizing the health care service. When enrolling in a POS plan, the insured is required to choose a primary care physician for health care monitoring. This primary care physician must be chosen from within the health care network. The primary POS physician becomes the "point of service" and may then make referrals outside the network, although only some compensation will be offered by the health insurance company in such circumstances. For medical visits within the health care network, paperwork is completed for the insured. If the insured chooses to go outside the network, it is their own responsibility to fill out the forms, send bills in for payment, and keep an accurate account of health care receipts. The advantage for the insured is that they can on the one hand utilize the broad services offered within the HMO without or with only minor deductibles, but that on the other hand they are to a large extent reimbursed when using an external provider outside the HMO.

Adaptation of US Approach by Other Countries

Some elements of the US Managed Care system have been adopted by other countries. Switzerland was the first European country where HMOs characterized by capitation (per capita lump sum) and gatekeeping in form of the General Practitioner network systems were implemented. The development of managed health care in Switzerland relies on the belief that adequate economic incentives and competition result in cost reduction and high quality health care. While both of forms of Managed Care can reduce hospitalization rates, unlike US HMOs, Swiss HMOs cannot negotiate on price with hospitals by establishing preferred provider contracts.

The first elements of Managed Care have also been implemented in Germany, primarily in the context of introducing integrated service delivery offerings, which nevertheless, as of today, only play a minor role in the German health care system. Further Managed Care elements introduced in Germany were Disease Management Programs for specific chronic diseases, as well as Diagnosis Related Groups and a hospital reimbursement system. Other European countries like France, the UK, and the Netherlands have also introduced Managed Care elements.

Conclusion

In general, it can be shown in several studies that the Managed Care models in the US have led to a shift in health care delivery from the inpatient to the outpatient sector. Although the lower costs of Managed Care Organizations for inpatient care are partially outbalanced by higher costs for outpatient care and medication, the overall costs for health care delivery of a Managed Care Organization (MCO) are still lower than for traditional health insurers. With regard to quality differences between MCOs and traditional models, there is no clear-cut picture when analyzing the different studies. It can, however, be concluded that the quality of health care delivery within MCOs is not worse than within other delivery systems, which results in MCOs being a more efficient delivery model. The successful transferability of the US Managed Care approach to other countries strongly depends on the local regulatory environment, which is often not open to more competitive elements in health care delivery.

Managed Care Health Insurance

Synonyms

Managed care

Definition

Managed care health insurance refers to payment and delivery arrangements between health insurers and health care providers that are supposed to control and to coordinate the use of health care services in order to contain costs and to improve the quality of the provision of services.

Managed Competition

- ► Competition, Health Care
- ► Regulated Competition

Managed Health Care Plans (U.S.)

Definition

Managed health care plans in the United States are ► health insurances covering the risk of illness or injury of an individual by applying ► disease management programs (DM programs). Generally, managed health care plans have developed several DM programs to meet the needs of the insured suffering from differ-

ent ► chronic diseases. To provide health care services within a DM program, managed health care plans employ health professionals of their own or contract with ► disease management organizations. Managed health care plans may be privately financed and administered through insurance premiums and private insurance companies or publicly administered by the state and financed through public funds such as ► medicare and ► medicaid.

Management Damage Reduction

► Disaster Response

Management of Occupational Diseases

Synonyms

Administration

Definition

Management means the art, science, and technique of getting things done by deployment of material and human resources in systematic manner, and monitoring how, and how well, they are done. Management of ► occupational diseases deals with implementation of strategies and tactics that reflect objectives and goals in ► occupational health and safety. New management methods are aimed at putting people closer to the center of the processes. Co-workers are being more actively involved. Information, communication and cooperation are integral parts of management of occupational diseases.

Management of Oral Diseases

GUIDO HEYDECKE
Abteilung für Zahnärztliche Prothetik,
Universitätsklinikum Hamburg, Hamburg, Germany
gheydecke@uke.de

Synonyms

Dental treatment; Treatment options

Definition

Management of oral diseases is concerned with the treatment of all oral disorders and syndromes by pharmacological, dental and maxillofacial/oral surgical or orthodontic means. The management of dental and oral diseases is aimed at restoring oral health or restoring a condition that enables an individual to lead a "socially and economically productive life in a state of complete physical, mental and social well-being" (World Health Organization 2001).

Basic Characteristics

Oral Disease – Management and Disciplines

Oral diseases can affect all oral and dentofacial structures. Thus, the management of oral disorders includes all steps from the examination to the diagnosis and treatment of such illnesses. Oral diseases can affect all oral and dentofacial tissues; the hard tissues including bone and teeth as well as mucosal, pulpal, periodontal and glandular soft tissues.

Traditionally, the treatment of different types of diseases has been organized into a number of different (specialty) disciplines. Examples for each of the disciplines are listed in Table 1. Conditions within the discipline of *oral (and maxillofacial) surgery* include infections, trauma to maxillofacial structures and neoplastic diseases. *Operative (or conservative) dentistry* focuses on the treatment of caries and dental trauma including diseases of the dental pulp (endodontics). *Prosthodontics* is involved with the replacement of missing teeth as well as the treatment of functional structures such as the temporomandibular joint and jaw muscles. It is common to summarize all efforts to restore or replace teeth under the term restorative dentistry. *Periodontology or periodontics* is the specialty concerned with the diagnosis and treatment of illness of the gingival and periodontal tissues. *Orthodontics* or dentofacial orthopedics focuses on the diagnosis and treatment of defects in tooth position and the treatment of dentofacial deformities, mostly with regard to the alignment of the maxillo-mandibular relationship. Crossing these disciplines is *general (or family) dentistry*, which includes all treatments that can be provided in a primary care setting. *Pediatric dentistry* deals with the provision of dental services to children, and *geriatric dentistry* is focused on specialized treatment for the elderly and infirm patients.

Management of Oral Diseases, Table 1 Disciplines and their respective field within oral disease management

Discipline	Typical diseases	Typical treatments
Oral (maxillofacial) surgery	Oral cancer Maxillofacial trauma Infections of the salivary glands Mucosal lesions	Pharmacological treatment (infections) Surgical removal of teeth Surgical excision (mucosal irregularities, tumors) Surgical reconstruction Orthognathic surgery Bone grafting Placement of dental implants
Operative dentistry (including endodontics)	Caries Pulpitis	Anterior and posterior fillings Root canal treatment Esthetic corrections (tooth whitening, bleaching)
Prosthodontics	Partial edentulism Complete edentulism Myofascial pain Arthropathies Facial defects	Fixed restorations (crowns, partial crowns) Fixed partial dentures (bridges) Removable partial and complete dentures Dental implant restorations Maxillofacial prostheses Bite splints
Periodontics	Gingivitis Periodontitis	Closed debridement Open debridement (flap surgery)
Orthodontics	Skeletal dysgnathia Dental malalignment	Orthodontic positioning and alignment of teeth

M

Treatment of Oral Diseases

Surgical Treatments Oral cancer is among the conditions treated by surgical intervention (Howaldt 2000). Curative treatment is usually initiated by radical surgical removal of the tumor. Radical in this case means that all cancerous tissue can be removed. Surgical treatment can be supplemented by radiotherapy and chemotherapy. However, in some cases a curative approach is not possible without destruction of vital organs, thus palliative treatment with partial tumor removal (size reduction) followed by chemo- or radiotherapy can be carried out. The ultimate goal in the latter case is to restore the quality of life of the patient. Depending on the amount of oral and maxillofacial structures that are destroyed by cancer or ablative surgery, many such patients require reconstruction. Surgical reconstruction may also be required after maxillofacial trauma due to accidents. Bony structures can often be repositioned after trauma, however in some cases and after removal of parts of the jawbone due to tumor surgery, bone grafts can be used to replace missing bone. Other procedures are various types of flap surgeries or skin grafting to repair soft tissue lesions. In some cases, maxillofacial prostheses are required and delivered by prosthodontists. Other procedures provided by oral surgeons include the surgical removal of teeth including wisdom teeth. For these procedures, a surgical incision is made to lift a mucosal flap to enable access to the jawbone. Variable amounts of bone are then removed by osteotomy to get access to the structure to be removed. Wisdom teeth or residual roots can then be removed and the wound is closed by sutures. ▶ Dental implants are another treatment often provided by oral surgeons. These artificial tooth roots are usually made from titanium and used to replace missing teeth or to stabilize dentures.

Operative Dentistry Dental caries often results in large primary structural defects of one or multiple teeth. High and low speed motors are used to excavate the decayed enamel and dentine together with diamond and round burs. The resulting defects can be restored either by direct or indirect restorations. For anterior teeth (incisors and canines), direct restorations are made from tooth-colored resin composite materials. These can also be used for smaller fillings of posterior teeth (premolars and molars). ▶ Composite fillings are bonded to the remaining enamel and dentin using

an etching and bonding technique. For posterior teeth, amalgam has been used as a standard filling material; it as been used less in the past years due to controversies about its biocompatibility. Instead, gold ► inlays or ► onlays (partial crowns) can be made. If a more esthetically pleasing restoration is desired, inlays or onlays can be made from ceramic. If caries leads to an inflammation of the dental pulp, an *endodontic* or ► root canal treatment is carried out. The dental pulp is removed completely and the space is filled with a root filling material (Kidd et al. 2003).

Dental trauma is often caused by accidents in road traffic or households. Fractured tooth fragments can either be reattached using the bonding technique. If fragments are lost, the tooth can be restored with a resin composite filling. Larger defects may require a crown restoration. Traumatized teeth which have been partially or fully avulsed can often be splinted to adjacent teeth if the alveolus is intact. Primary healing of the traumatized periodontal and gingival tissues is often achieved, however, an endodontic treatment may be necessary. The prognosis of avulsed teeth is uncertain. If the integrity of the tooth as a whole is compromised beyond the loss of the clinical crown it usually cannot be replanted and the resulting gap will have to be closed using prosthetic restorations.

Prosthodontics If larger portions of dental hard tissues are missing they need to be replaced by prosthodontic means. Fixed prosthodontic (Shillingburg 1997) rehabilitations include full ► crowns. For posterior teeth, metal crowns are common whereas for anterior teeth, mainly tooth-colored crowns are used (porcelain fused to metal, all-ceramic) so that tooth shape and color are mimicked.

Small numbers of missing teeth can be replaced using ► fixed dental prostheses (fixed partial dentures; FPDs). As long as the gap is enclosed by teeth, these can be used as abutment teeth for fixed bridgework. The missing tooth itself is replaced by a pontic. Multiple gaps can be restored with multiple pontics, however, as a general rule, no more than three adjacent missing teeth should be restored using FPDs. Single or multiple missing units can also be replaced using ► dental implants. After the surgical placement of the jaw-anchored titanium screw and a healing phase, the final prosthodontic restoration is made and attached to the implant using a screw or cement joint. In most cases, fixed restorations will not only restore chewing and speech function but also restore the esthetic appearance so that the rehabilitation will not be detected by the untrained eye.

Multiple missing teeth often cannot be restored by fixed restorations anymore, unless multiple implants are placed. Thus, ► partial removable dental prostheses (removable partial dentures; RPD) (Jepson 2004) are required to rehabilitate patients suffering from partial edentulism. Such partial dentures consist of a base which is usually made from denture base resin (polymethylmethacrylate). The base is completed with industrially prefabricated denture teeth, the actual replacements for the missing natural teeth. Final RPDs often have a reinforcing metal substructure. The metal base extends to the attachments which are used to retain the denture in the patient's mouth. Attachments can be clasps which partially circumvent the remaining teeth; in addition, so called ► precision attachments or ► telescopic crowns (telescopic copings, double crowns) are used as attachments. Removable dentures can be worn at all times, but have to be removed by the patient for cleaning.

If all teeth are missing, ► complete removable dental prostheses (complete dentures; Geering et al. 1993; Zarb et al. 2004) are used to replace all of the missing teeth. Similar to partial dentures, a denture base made of pink acrylic resin is combined with denture teeth to make a complete denture. These dentures rely on the anatomy of the jawbone and the mucosal tissues for retention. Jawbone will be reduced by resorption over time, thus denture retention will decrease over time. Dental implants (Lindhe et al. 2003) can be used to improve retention and regain support of partial and complete dentures.

Periodontics ► Gingivitis and ► periodontitis make up for the second large entity of bacterial oral disease. Treatments for gingivitis and periodontitis include closed and open debridement of the root surfaces of the affected teeth. Surgical treatments comprise but are not limited to open flap surgery to gain access to cleaning sites and guided tissue regeneration to recreate periodontal attachment of the tooth to the jawbone (Lindhe et al. 2003).

Orthodontics Orthodontic diagnosis and treatments are mostly provided in specialist settings. Rotated,

inclined or malpositioned teeth are moved using minimal forces applied by removable or fixed orthodontic devices. Skeletal dysgnathy is mostly treated surgically through repositioning of the mandible and/or maxilla within the skull bone.

Delivery of Care and Goals of Dental Disease Management

The management of oral disease is mostly provided through individual treatment providers in ambulatory settings. Treatment providers are mostly general dentists, while orthodontic services are almost exclusively offered by specialists. Oral surgical procedures are mostly performed on an outpatient basis while extensive maxillofacial interventions are carried out in specialized hospitals.

The ultimate goal of managing dental disease is the 'restitutio ad integrum'. This may be achieved for some infectious diseases and low-grade trauma to soft and hard tissues and functional illnesses such as myofascial pain. However, for the restorative disciplines a complete restoration of the initial state is impossible, thus the goal mostly has been reduced to a disease free state of hard and soft tissues. In addition, for most restorative and prosthodontic (including periodontal and implant) treatment, goals can be expressed in terms of survival of the treated tooth or the restoration. However, survival does not reflect the patient perspective. This is achieved using patient based ratings of satisfaction, chewing ability (or function), oral comfort, ability to speak and of esthetics (Heydecke et al. 2003a). Furthermore, oral health related quality of life can be measured using specific questionnaires (Heydecke et al. 2003b).

Mania

Definition

Mania is characterized by an elevated mood out of keeping with the patient's circumstances. It may vary from carefree joviality to almost uncontrollable excitement. Elation is accompanied by increased energy, resulting in overactivity, pressure of speech, and a decreased need for sleep. Attention cannot be sustained, and there is often marked distractibility. Self-esteem is often inflated with grandiose ideas and overconfidence. Loss of normal social inhibitions may result in behavior that is reckless, foolhardy, or inappropriate to the circumstances, and out of character. Individuals can suffer from mania with or without psychotic symptoms. Manic patients with psychotic symptoms

also experience delusions (usually grandiose) or hallucinations (usually of voices speaking directly to the patient) or the excitement, excessive motor activity, and flight of ideas are so extreme that the subject is incomprehensible or inaccessible to ordinary communication.

Man-Machine System

Definition

► Human-factors engineers regard humans as an element in a "man-machine" system. A "man-machine system" means that the man and his machine have a reciprocal relationship with each other. A man is effectively a single channel device, although one that time shares. An ergonomically sound system provides optimum performance because it takes advantage of the strengths and weaknesses of both its human and machine components. This has always been done intuitively by good designers, but systems ergonomics aims to ensure that this is done systematically.

Mann Whitney (U) Test

Definition

A non-parametric test for comparing the distribution of a continuous variable between two independent groups. It is analogous to the paired-sample t-test, and can be used when the data are ordinal or not normally distributed.

Mantel-Haenszel χ^2 Test

Definition

Test for a null hypothesis of no overall relationship in a series of 2×2 tables for stratified data derived either from a cohort or a case-control study. It allows analysis of confounding and gives an adjusted odds ratio or relative risk. It can be used on categorical or categorized continuous data.

Maori Health Strategy

Definition

Maori ► health strategy sets the direction for Maori health development in the health and disability sector for the next five to 10 years. It is accompanied by the Health Action Plan that contains the governmental action plan for strategy implementation. This includes public policies that actively promote: whānau well being, quality education, employment opportunities, suitable housing, safe working conditions, improvements in income and wealth, and addressing systemic barriers including institutional racism.

Marburg Disease

► Marburg Fever

Marburg Fever

Synonyms

Marburg disease; Marburg virus disease

Definition

Marburg fever, which appeared first in Marburg (Germany) in 1967, is an Ebola-like hemorrhagic fever. The course is less severe than Ebola. The disease was transmitted by African green monkeys, which had been

imported from Uganda for medical trials. A vaccine is not available.

Marburg Virus Disease

► Marburg Fever

Marital Quality

Definition

Perceived and objective characteristics of a marital union. These characteristics may include self-evaluated assessments of satisfaction, fullfillment, and happiness of union partners. They may also involve self- or externally-evaluated aspects of marital interactions, such as conflict, communication, problem solving, sharing, and physical and/or emotional closeness. In addition to interpersonal dynamics, it involves structural aspects of a union, such as the cohabitation and separation history. Marital quality addresses the history and dynamics of social, economic, psychological and even sexual rights and reciprocity within the couple.

Market Research

Definition

Market research is the systematic collection and analysis of data about the consumers (or target individuals) and their preferences, the competitors and potential allies, appropriate methods of distributing messages and reaching ► target groups, and the effectiveness of marketing programs. Techniques in market research include telephone polling and focus group interviews. Using a social marketing approach, market research can also be applied in public health in the context of designing public health programs. It helps to answer questions such as: How does the target group think and behave as related to a health goal or health problem? How can the target audience be reached best? Which messages and materials work best?

Masculinity

► Sex/Gender

Mass Media

Synonyms

Mass communication

Definition

Mass media like print media, television, and radio, as well as the internet, refers to those media that are designed to be consumed by large audiences through the agencies of technology. In the context of health education, mass media is a tool for the transfer of information, concepts, and ideas to both general and specific audiences. They are important tools in advancing public health goals of health promotion campaigns.

Mass media is a term describing the form of communication designed to reach a vast audience, such as the population of a state or nation, without any personal contact between the senders and receivers. Examples would include newspapers, magazines, billboards, radio and television, as well as the internet. Mass media are tools for the transfer of information, concepts, and ideas to both general and specific audiences. They are important tools in advancing public health goals, e. g. through awareness raising campaigns.

Using mass media can be counterproductive if the channels used are not audience-appropriate, or if the message being delivered is too emotional, fear arousing, or controversial. Therefore, proper formative research is necessary, including questions on the choice of channels, attitudes of the priority audience, and message testing.

Matching

Definition

Matching is the process of making a study group and a comparison group comparable with respect to extraneous factors. It is a selection of study subjects so that major known confounders are evenly distributed across the study groups.

Matching is often done in case-control studies in which controls are selected to match the cases in some way, e. g., by age and sex. It can be used in some way in cohort studies, but this is uncommon. Matching can be done on an individual basis, with one or more controls

matched to each case so that for instance, each control is matched by year of birth to a specific case. Alternatively, frequency matching aims to select controls to match the general distribution of the confounding variables in cases. For example controls would be selected to ensure the same male to female ratio as cases.

Material Safety Data Sheets

Synonyms

Chemical safety data sheet

Definition

Material safety data sheets (MSDS) are the foundation of a successful safety and health program. They provide information that can be used during employee training and chemical exposure emergencies; they also give vital information to medical professionals caring for the affected employee. Their purpose is to communicate critical facts about the working safety with regard to the material. MSDS is a standardized document that serves to alert both the worker and the occupational safety and health professional about the relevant hazards at the workplace, as well as means of prevention of harm from a specific chemical substance. The information presented could then serve as a basis for the development of informational and instructional materials (such as curricula, guidelines, checklists, codes of practice, and warning notes), and for the selection of appropriate measures to either abate or reduce the risk of exposure.

The MSDS contains detailed information about the properties of hazardous material and the precautions to be followed for its use. Where prescribed by law, employers must maintain an inventory of chemical and biological agents.

Maternal Mortality

Definition

Maternal mortality is defined as probability of dying at giving birth expressed per 1000 deliveries.

Maternal Mortality Rate

Definition

The maternal mortality rate is the number of pregnancy-related deaths per 100,000 live births during the same year. According to the World Health Organization (WHO) "maternal death is defined as the death of a woman while pregnant or within 42 days of termination of pregnancy", but sometimes deaths up to one year after birth are included. The maternal mortality rate is a measure of the likelihood that a pregnant woman will die from maternal causes. This measure reflects not only the adequacy of pregnancy-related health care, but also the general level of socioeconomic development. Maternal mortality rates are very low in industrial countries.

Maternity

► Pregnancy

Maturation

► Child Health and Development

McNemar's Test

Definition

A special form of the Chi-squared test used in the analysis of paired (not independent) proportions. This non-parametric test compares two correlated dichotomous responses and is most frequently used in situations where the same sample is used, to find out the agreement (concordance) of two diagnostic tests or difference (discordance) between two treatments.

Mean

Definition

The mean is the most commonly used ► measure of central tendency. When used without any qualification, mean refers to the arithmetic mean. The sample mean is usually denoted by the symbol $\bar{x}$. The mean

of a set of observations $x_1, x_2, \ldots, x_n$ is defined as $\bar{x} = (x_1 + x_2 + \cdots + x_n)/n$, where n is the number of observations. Mean is based on all observations of the data set and consequentially is influenced by extreme values, either high or low. It is most useful when the data distribution is symmetric. Mean is not a good measure of central tendency if the data distribution is skewed or contains extreme values. One way to obtain a mean that does not depend on the extreme values is the trimmed mean. It can be calculated by removing a certain percentage of the lowest and the highest values of the distribution and then calculating the mean by using the remaining data. For example, a mean trimmed 10% is calculated by removing the lowest and highest 5% of the values. Two other means used in statistics are the geometric mean and harmonic mean.

Meaning

► Ethics and Religious Aspects

Measles

Synonyms

Rubeola; Morbilli

Definition

Measles, first described in the 10th century, is a viral infectious disease, which is spread by droplets. Humans are the only reservoir of the virus. Widespread epidemics caused a great number of deaths in the Middle Ages, and not without cause measles has been called the greatest killer of children in history. According to the World Health Organization, even in 2003 about 500 000 people, mostly children, died from measles. After an incubation period of 10–14 days the prodromal stage appears, which is characterized by fever and inflammatory reactions of the respiratory tract and the eyes. One can speak of the typical three Cs, which are cough, coryza (running nose) and conjunctivitis (red eyes). The second stage of the infection starts after 12–13 days with a reddening of the palate and the mucous membrane of the cheeks. Two to three days later the typical maculopapular rash delvelops, starting behind the ears and then spreading over the whole body. Possible complications are a swelling of the larynx (croup), pneumonia, corneal and retinal damage and inflammation of the brain (encephalomyelitis). A rare, but extremely feared complication is subacute sclerosing panencephalits (SSPE). SSPE is an inflammation of the whole brain, which appears months or years after infection with measles. The disease, which cannot be treated, is progressive and always leads to death. The most important measure to prevent an infection with measles is the active measles-vaccination (► immunization, active).

Cross-References

► Infectious Diseases in Pediatrics

Measles Vaccination

Synonyms

Measles immunization; Rubeola vaccination; Rubeola immunization

Definition

Living ► vaccines against measles have been available since the 1960s. Antibodies transferred to the unborn child through the mother's placenta may inhibit the success of the vaccine by neutralizing the vaccine's viruses. For this reason, the first measles vaccination should not take place before 11 months of age. A second vaccination is recommended at an interval of at least 4 weeks following the first vaccination, in order to provide immunity even when primary vaccination has failed. In the majority of cases, the combination vaccination against measles, mumps and rubella (MMR) is used. The protection rate of the vaccination is 99%, and probably lasts a lifetime. Measles vaccination leads to immunity quickly. An infection from the wild-type measles virus can be prevented by vaccination up to 48 hours after the measles' incubation. At 6 to 10 days after vaccination, 5% of cases show a mild course of the disease without any risk of contagiousness. Contraindications for measles vaccinations are immune deficiency, acute diseases with fever, pregnancy and a known severe allergic reaction to components of the vaccines or the carrier protein.

Measurement

Synonyms

Assessment; Judgment; Mensuration; Rating; Quantification

Definition

Measurement is the process in which numbers or other symbols are assigned to the characteristics of the units that are observed, in such a way that the relation between numbers or symbols reflects the relation between characteristics that are the subject of the research. In medicine various characteristics of individuals and indicators of health may be the object of measurements: e. g. clinical (presence of signs and symptoms, diagnosis, performance of a diagnostic procedure), physiologic-biochemical, physical, mental, psychosocial, epidemiologic (frequency of disease, rates), vital statistics, various aspects of health care, health related quality of life and patient perception and satisfaction.

An inherent property of every measurement procedure is ► error in measurement.

The most common bases for biochemical and physiologic measures are International System of Units (SI) which is a metric system based on multiples of ten (decimal system).

Definition

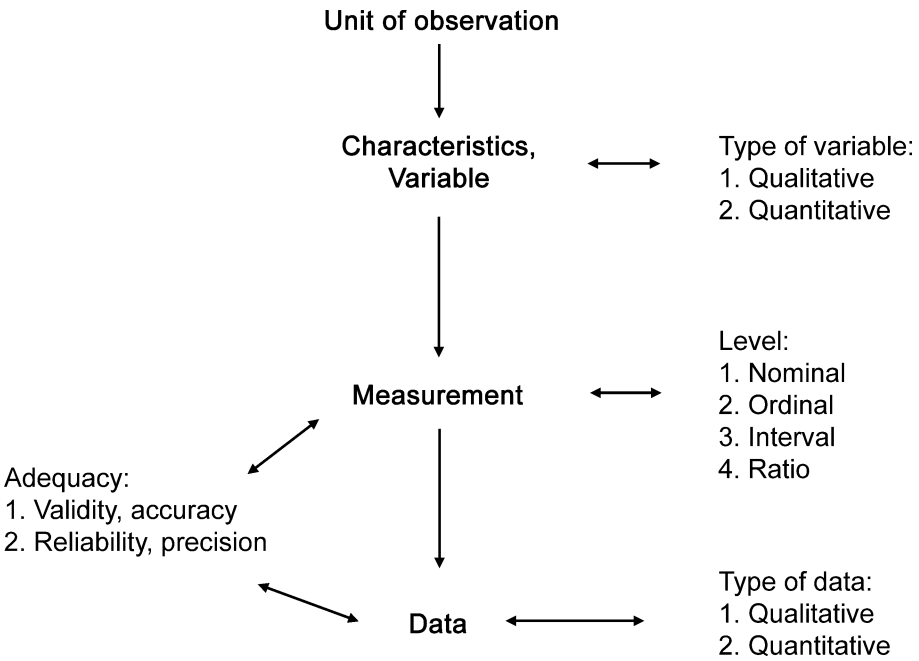
► Measurement is the process in which numbers or other symbols are assigned to the characteristics that are being observed.

Basic Characteristics

Measurement is the process in which numbers or other symbols are assigned to the characteristics of the units that are observed, in such a way that the relation between numbers or symbols reflects the relation between characteristics that are the subject of the research. Measurement is the process in which the numbers or other symbols are assigned to the characteristics of the units that are observed, in a way where the relation between numbers or symbols refelcts the realtion between characteristics that are the subject of the research. Figure 1 shows relation of measurement to unit of observation, variable and data, some of key terms in biostatistics (see synopsis Biostatistics).

In all measurements some degree of uncertainty is present, and it can be expressed as ► error in measurement. This means that, beside measured values (estimate of true value), each measuring has two other components: error limits and probability that the true value is within error limits. The errors that occur in the measurement process are inherent, and can be reduced only by more adequate measuring. The errors can be classified into two categories: systematic and random errors. Systematic error (bias) is the cause of predictable systematic overestimated or underestimated values. On the other hand, random errors are not predictable, and in a given measurement process they can result either in overestimated values or underestimated values.

The errors in the measurement process can originate from various factors such as poor instrument calibration, inaccurate response time within the instrument in relation to the changes in the measured variables, loading errors – influence of the instrument on the measured ► variable, conditions of the surroundings, human factors – inter-observer and intra-observer variability. Sometimes random errors occur because of 'noise' – small and quick changes in the environment or in the instrument itself. The measurement can be made more adequate by identifying and minimizing any error. Measurement adequacy subsumes various concepts such as ► accuracy, ► agreement, ► precision, ► reliability, validity (► validity, measurement) and repeatability and reproducibility are necessary concomitants associated with these concepts. Repeatability signifies the closeness of results of successive measurements obtained under near identical conditions while reproducibility signifies the closeness of results of successive measure-



Measurement: Accuracy and Precision, Reliability and Validity, Figure 1 Relation of measurement, unit of observation, variable and data

ments obtained under changed conditions, e. g. changes in techniques, technicians, instruments and/or laboratories.

► Accuracy refers to the closeness of the measured value to the correct value (marked as "reference", "criterion" or "gold standard"). In laboratory measurements the gold standard is defined by the referent laboratory. The gold standard is the method or procedure that is widely recognized as the best available, e. g. a diagnostic test that will reflect the true disease status (Feinstein 2002). When a test is carried out for diagnostic purposes it is called an index test (Webb et al. 2005). The index test results are then compared to defined gold standards as shown in Table 1, where the examinees are classified as positive or negative according to the gold standard and index test (Chernick and Friis 2003).

Measurement: Accuracy and Precision, Reliability and Validity, Table 1 Comparison of test results and final diagnosis

		True disease status		
		Diseased	Nondiseased	Total
Test result	Positive	*TP*	*FP*	*TP* + *FP*
	Negative	*FN*	*TN*	*FN* + *TN*
	Total	*TP* + *FN*	*FP* + *TN*	*N*

TP – true positive, *FN* – false negative, *FP* – false positive, *TN* – true negative, *N* – sample size

An estimate of diagnostic accuracy for the index test, as well as predictive values can be calculated:

1. Overall accuracy $= (TP + TN)/N$
2. Sensitivity $= TP/(TP + FN)$
3. Specificity $= TN/(FP + TN)$
4. Positive predictive value $= TP/(TP + FP)$
5. Negative predictive value $= TN/(FN + TN)$.

Unlike accuracy, agreement is examined in the absence of gold standards, and it refers to the closeness of two measured values, not to whether those values are correct or not (Feinstein 2002). When the measurement results are given as binary ► data, the agreement is estimated by ► proportion of agreement or ► kappa coefficient, and when given as continuous ► data agreement is estimated with ► Pearson's correlation coefficient (Pearson's r) or with intraclass correlation coefficient. In binary ► data the comparison between two raters or two measurement methods can be shown if a 2×2 table is used (Table 2).

The frequencies a and b represent the agreement of two raters, while the frequencies c and d disagreement. The ► proportion of agreement (percent of agreement) is the proportion of frequencies in cells a and d of total frequency: $(a + d)/N$ (Katz 1997).

When ► kappa coefficient approaches one, the possibility that two raters having the same results is a random phenomenon has to be considered (Feinstein

Measurement: Accuracy and Precision, Reliability and Validity, Table 2 Comparison of the results obtained by two raters

		Rater A		
		Yes	No	Total
Rater B	Yes	a	b	$a+b$
	No	c	d	$c+d$
	Total	$a+c$	$b+d$	N

2002). It is calculated through following formula: $\kappa = \frac{2(ad-bc)}{(b+c)N+2(ad-bc)}$. ► Kappa coefficient value less than 0.4 can be considered as poor, from 0.4 to 0.75 fair to good, and over 0.75 excellent (Fleiss 1981).

► Precision refers to the consistency of repeated results. The less the differences among repeated measures the larger the measurement precision. Precision is quantified by measures of variability (variance, standard deviation, coefficient of variation) and confidence intervals. These measures are called imprecision measures, as the higher the variation the less the precision.

Precision should not be confused with resolution (the smallest change of the measurement value that an instrument can show). In digital instruments resolution depends on the number of digits in the measurement result, and in analogous instruments it depends on the relation between the width of the measurement grade on the scale and the indicator width (Harlow et al. 2002). Generally, resolution is higher than accuracy on the instruments, thus the resolution does not limit the minimal changes of the measurement value that the instrument can detect.

Example 1:

A new automated analyzer for reticulocyte counting was to be evaluated in a study. Seventy blood samples were collected, and used to compare results obtained by the automated analyzer and those by manual (visual) counting, as well as to estimate the imprecision of these two methods.

The correlation coefficient between the results of these two methods was 0.96. Intra-assay imprecision was presented in the form of coefficient of variation (CV), and it was 19% for the automatized system, and 26% for the manual method. It was concluded that there is excellent concordance between these two methods and that the imprecision was less in the case of the automated analyzer (less CV) that was the subject of the evaluation.

Measurement: Accuracy and Precision, Reliability and Validity, Table 3 Arthroscopic and ultrasound findings of medial meniscus examination

		Arthroscopic findings of medial meniscus injury (gold standard)		
		Positive	Negative	Total
Ultrasound findings of medial meniscus injury	Positive	75	1	76
	Negative	1	11	12
	Total	76	12	88

Example 2:

The research goal was to estimate the diagnostic accuracy of medial meniscus ultrasound examination. Arthroscopic findings confirming the diagnosis of medial meniscus injury was taken as the gold standard. The findings, obtained in the course of arthroscopic and ultrasound examination are shown in Table 3.

These data resulted in the evaluation of diagnostic accuracy and predictive values for ultrasound examination:

- overall accuracy $= (75+11)/88 = 0.98$,
- sensitivity $= 75/76 = 0.99$,
- specificity $= 11/12 = 0.92$,
- positive predictive value $= 75/76 = 0.99$, and
- negative predictive value $= 11/12 = 0.92$.

In the same research the agreement between two doctors, who used ultrasound examination of medial meniscus, was tested. Comparison of the findings obtained by two doctors is shown in Table 4.

The proportion of agreement was $(73+10)/88 = 0.94$ (i. e. percentage of agreement 94%). Kappa coefficient was $\kappa = \frac{2(73\cdot10-3\cdot2)}{(3+2)\cdot88+2(73\cdot10-3\cdot2)} = 0.77$, which is in the region of excellent.

Measurement: Accuracy and Precision, Reliability and Validity, Table 4 Ultrasound findings of medial meniscus injury given by two examiners

		Rater B – findings of medial meniscus injury		
		Yes	No	Total
Rater A – findings of medial meniscus injury	Yes	73	3	76
	No	2	10	12
	Total	75	13	88

Many measurement in medicine is based on the results of questionnaires or scales. The measurement value is obtained as answers to several questions or items within the particular measurement instrument, questionnaire or scale. The measurement adequacy evaluation of such instruments depends on their ► reliability and validity. The concept of ► reliability is akin to the concept of ► precision, and the concept of validity is akin to the concept of ► accuracy (Krishnamurty et al. 1995). ► Reliability indicates the degree to which the measurement instrument is consistent, and validity is the relation between what is assumed to being measured by the instrument and what it is actually measuring (Nunnally and Bernstein 1994).

There are three ways to analyze reliability: internal consistency reliability, test-retest reliability and inter-rater reliability.

Applying the evaluation of the internal consistency we estimate the congruence of individual items on the scale. Each item is observed as a separate instrument for the measurement of an examined construct, so that coherence between them suggests that all items measure the same thing as the instrument as a whole. Applying alpha coefficient (Cronbach's alpha) and Kuder–Richardson formula – KR20 is the most frequent way to calculate internal consistency evaluation. Inter-rater reliability measures agreement of two or more raters that use the same information on the same analyzing unit. Inter-rater reliability is mostly evaluated by the application of intraclass correlation coefficient, ► Pearson's correlation coefficient, ► kappa coefficient, and rank correlation coefficient. Test-retest reliability is an estimation of the stability of scale over time that is a measure of the congruence of results obtained by repeated measurement on the same objects, under the proviso that there is no change in the condition of those objects.

Validity can be considered as the extent to which a measurement, test, or study measures what it purports to measure. Three major types of validity are content, criterion and construct validity. Content validity indicates whether the measuring instrument covers all areas under investigation. Criterion validity is empirically based, and relates to the correlation of the instrument with external criteria. Construct validity is applied when there is no adequate gold standard, existing instruments, criteria or other ► data against which results can be compared. It is possible to improve construct validity by developing a more fitting definition of the construct, derived from a set of related ideas, by finding a better way to measure that construct, and by giving an accurate explanation of the effects it has in clinical practice and research (Blacker 2000).

Example 3:

The research goal was to estimate the reliability and validity of the questionnaire on children's health status. The questionnaire is a parent-report instrument, and it consists of 30 questions that parents answered about their children's health status. The research was carried out on the representative sample of 1572 parents. The questionnaire showed good reliability of internal consistency (alpha coefficient $= 0.93$), and good test-retest reliability (Pearson's $r = 0.91$). Content and construct validity was estimated by correlation between questionnaire scores and data on health service use, presence of illness, disability and functioning, where the Pearson's r was above 0.82. It was concluded that estimating children's health status, through the administration of the questionnaire, is reliable and valid.

Measurement Error

► Error in Measurement

Measures of Association

Definition

Measures of association show the degree of ► relationship between two or more variables. These measures usually show the direction and strength of the ► relationship. The first step in discovering an association between variables can be a ► graphical representation of data pairs, using the scatter diagram, which allows a visual inspection for the possible association. Numerical assessment of association includes various measures. For two continuous variables the most commonly used measure of association is ► Pearson's correlation coefficient. Nonparametric counterparts for correlation between two sets of ranks are Kendall's tau, Spearman's rank correlation coefficient, Goodman–Kruskal gamma, and Somer's *D*.

For data in a ► contingency table, a measure of association shows the degree of association between categories of variables in rows and columns. For these data, measures of association include the phi coefficient, contingency coefficient, Cramer's V, Yule's *Q*, Goodman–Kruskal lambda, Tschuprov coefficient, and Sakoda coefficient.

For epidemiologic data, measures of association show the degree of association between exposure to risk factor and event occurrence (disease, injury, ...). Data measures of association, also called measures of risk, include measures such as ► relative risk, ► odds ratio and risk difference.

Measures in Case of Outbreak of Communicable Diseases

► Outbreak Management and Surveillance of Infectious Diseases

Measures of Central Tendency

Definition

Measures of central tendency describe the distribution of a set of values around a value or values at or near the middle of the set. The measures of central tendency that are most commonly used are ► mean, ► median and mode. ► Mean is computed by dividing the sum of all values by the number of values. ► Median is equal to the numerical value of the central data in the sequence of data ordered from the smallest to the largest. Mode is the value with the highest frequency of occurrence in a set of data. Which of these measures is used depends on the characteristics of the data. Mode can be applied with all levels of measurement, but is not useful with a set of data that has many values. Median can be applied with ordinal, interval and ratio levels of measurement, but is not useful with a set of data that has few values. Mean can be applied with interval and ratio levels of measurement, but is not useful when the data distribution is skewed or contains extreme values. For moderate asymmetric unimodal distributions an empirical relationship between the mean, median, and mode is given by mean – mode $\approx$ 3(mean – median).

Measures of Dispersion

Definition

Measures of dispersion show a degree of variation or dispersion of values of the observed variable around the measures of the central tendency. If the values tend to be grouped around the measures of central tendency, then these measures will be small, while if the values tend to be spread more around the measures of central tendency, then the measures will be large. The measures of dispersion can be divided into the measures based on quantiles and measures based on the deviation of observations from the mean. Measures of dispersion based on quantiles are (a) range – difference between

the largest and the smallest value, (b) interquartile range – difference between the first and the third quartile), and (c) interdecile range – difference between the first and the ninth decile (see essay Descriptive statistics). Measures of dispersion based on the deviation of observations from the mean are (a) variance – mean square deviation from the mean, (b) standard deviation – square root of the variance, and (c) coefficient of variation – relative measure of variation obtained by dividing the standard deviation by the mean and expressing this ratio in percentage (see essay Descriptive statistics).

Cross-References

► Descriptive Statistics

Median

Definition

Median is a ► measure of central tendency which is equal to the numerical value of the middle data in the sequence of data ordered from the smallest to the largest. When the number of data is odd, the median is equal to the middle data. It can be found in location $(n+1)/2$ of the set of values, where n is the number of values. When the number of data is even, the median is equal to the mean of the two middle data. The median divides the data into two parts of equal size and it is equal to the second quartile, fifth decile, fiftieth percentile (see quantiles), and nearly equal to the cumulative relative frequency of 50% on a cumulative frequency graph. The median is the best measure of central tendency if the data distribution is skewed or contains extreme values.

Median Survival Time

Definition

The median survival time is the time at which 50% of cases are resolved. Median survival is very often reported in survival analysis. The median survival time can be derived from a ► Kaplan–Meier survival plot.

Median Test

Definition

Assesses the difference in samples in terms of a contingency table. The number of cases in each sample that fall above or below the common median is counted and the Chi-square value for the resulting $2 \times k$ samples contingency table is calculated. The median test is particularly useful when the scale contains artificial limits, and many cases fall at either extreme of the scale.

Mediate

Synonyms

Mediation

Definition

The pre-requisites and prospects for health cannot be ensured by the health sector alone. More importantly, health promotion demands coordinated action by all concerned: by governments, by health and other social and economic sectors, by non governmental and voluntary organizations, by local authorities, by industry and by the media. People in all walks of life are involved as individuals, families and communities. Professional and social groups and health personnel have a major responsibility to mediate between differing interests in society for the pursuit of health. Health promotion strategies and programs should be adapted to the local needs and possibilities of individual countries and regions to take into account differing social, cultural and economic systems.

Mediation

Synonyms

Reconciliation

Definition

In ► health promotion, the process of negotiation and reconciliation of the different interests (personal, social, economic) of individuals and groups and of different sectors (public and private) in ways that promote health

and quality of life. This is one of the three health promotion action strategies of the ► Ottawa charter (WHO 1986). The strategy is based on the insight that producing change in people's lifestyles and living conditions inevitably produces conflicts between the different sectors and interests in a population. Such conflicts may arise, for example, from concerns about access to, use and distribution of resources, or constraints on individuals or organizational practices. Health professionals have a special responsibility for participation in this reconciliation process.

Medicaid

Definition

Medicaid is a US Government program providing medical care for certain individuals and families with low incomes. It is administered by the states and financed jointly by the federal government and the states. The program is covered under Title XIX of the Social Security Act of 1965. Within federally determined guidelines, the states define the individuals who qualify for the program and the duration, amount and scope of health care services covered. Eligible persons for Medicaid are in general children and their caretakers, pregnant women, disabled persons, blind persons or persons aged over 65 who demonstrate a need according to set income and asset standards. Medicaid is the largest source of funding for medical services in the United States for people whose resources and income are insufficient to pay for health care.

► Health Insurance

Medical Data

Definition

Medical data describes the state of health of a person and contains no personally identifiable information. Medical data are stored under a pseudonym, which is different than the user ID or other personal information. This prevents unauthorized association of this information. Medical data are stored exactly as entered by the record owner or by authorized individuals.

Medical Decision Analysis

Definition

Medical decision analysis is the scientific approach to health care decision-making under ► uncertainty. All relevant parameters potentially influencing the decision making process, such as alternative actions, events by chance including their probabilities of occurrence, and final consequences, are clearly stated and included in a model.

Medical Devices

Synonyms

Medical products

Definition

Medical devices are all kinds of instruments, appliances or substances that are used to diagnose, relieve or cure diseases. Medical devices are used in hospitals as well as in physicians' practices. They can also directly be used at the patient's home, as for example hearing aids or other devices specifically designed for several kinds of handicaps. The production and dispensation of medical devices is regulated by law in each country. Medical devices are, as ► drugs, subject to ► reimbursement by the health insurance. The reimbursement of medical devices may include a small part of ► co-payment by the patient depending on the specific contract of the health insurance.

Medical Documentation

► Health Record

Medical Economics

► Health Economics in Dentistry

Medical Education Information System

Definition

The medical education information system is a branch of ► health information system that provides easier learning and assimilation of knowledge from various fields of medicine and health care. It includes both paper publications (encyclopedias, dictionaries, handbooks, textbooks, journals) and electronic media (the Internet).

Medical Ethics

Definition

The branch of medicine that deals with the incorporation of an individual's interests, societal values, legal issues, and moral arguments into medical practice. It includes for example consent to treatment, confidentiality, research on human subjects, contraception and abortion, rationing of health care, and the prolonging of life in the event of serious irreversible brain damage.
Medical ethics is a discipline that evaluates the risks and merits of medical activities such as medical research and the delivery of medical services with regard to the protection of the interests of the patient, the provider and other health care institutions. According to medical ethical standards, all medical activities must be in conformity with current law and ethical standards.

Medical Geology

Medical Informatics

Synonyms

Health informatics; Health care informatics

Definition

Medical informatics is the systematic study of the identification, collection, storage, commutation, retrieval and analysis of information, data and knowledge about medical care services that can be used to improve decisions made by physicians and managers of health care organizations. The methods of medical informatics are used to aid information management in medical practice, education and research. This definition strongly supports the process of information management, rather than the use of information technology. Branches of medical informatics include bioinformatics, ► clinical informatics, ► consumer health informatics and ► public health informatics.

Medical Information

Synonyms

Clinical information; Patient-specific information

Definition

Clinical information is organized ► patient data and ► medical knowledge used to make clinical decisions. Both clinical and public health activities entail the organization of such data into useable information. For example, incidence of important cases of disease from surveillance programs and summary evidence from cohort studies or clinical trials are expressed as odds ratios for certain harmful and beneficial outcomes.

Medical Information System

► Health Information System

Medical Insurance

► Health Insurance

Medical Knowledge

Synonyms

Clinical knowledge

Definition

Medical knowledge is the collection of information about diseases, therapies, interpretation of lab tests etc, which is potentially applicable to decisions about multiple patients and public health policies. Medical knowledge should be based on sound evidence from clinical and epidemiological studies, using valid and reliable methods.

Medical Knowledge, Modern

► Health Knowledge, Western

Medically Unexplained Physical Symptoms (MUPS)

Medical Progress

Definition

Medical progress covers all kinds of technical and scientific innovations made in the medical area. New inventions in the field of pharmaceutical products (drugs and medical devices), in the field of diagnosis as well as disease therapy are considered to be part of the medical progress. In general, medical progress is associated with high research and development costs and new expensive medical equipment, drugs etc. In this case medical progress is the reason for an upward spiral of health care costs. But there are examples of medical progress enabling patients to live in healthier conditions

and preventing the need for hospital care due to the early detection of diseases and appropriate treatment with new drugs.

Medical Record

► Health Record

Medical Rehabilitation

Definition

Medical rehabilitation aims at developing and restoring the functional and psychological abilities of the individual to enable self-dependence and the leading of an active life. This includes developing methods of compensating for the loss or absence of a function or for a functional limitation. Medical rehabilitation measures derive from an medical scientific background and are usually carried out by physicians supported by nurses and therapists. In recent years, there has been a shift towards a more comprehensive model of rehabilitation including social rehabilitation and vocational rehabilitation. Unlike medical rehabilitation, with the physician having a leading role, the contemporary comprehensive rehabilitation approach is usually delivered by multidisciplinary ► rehabilitation teams.

Medical Research Information System

Definition

The medical research information system is a branch of ► health information system that enables health professionals to stay up to date with current medical investigations. One of the well known databases with over 600 000 biomedical papers a year is Medline, updated by the National Medical Library of the USA.

Medical School

Synonyms

Faculty of medicine

Definition

The primary objective of a medical school is teaching medicine to their students. It is a tertiary educational institution or part of it. The teaching years of medical schools are typically divided into a preclinical phase and a clinical phase. Besides enabling the students to become medical doctors, many medical schools also offer PhD or similar educational programs. Medical schools often do medical research and some of them also operate hospitals. The subjects taught at medical schools comprise human anatomy, biochemistry, immunology, neurobiology, genetics, and human biology. The entry criteria and structure of the programs at medical schools differ significantly around the world. In many countries, a doctor needs, in addition to the title conferred by the medical school, a license by a government authority.

Medical Specializations

GERNOT LENZ
Forschungsverbund Public Health Sachsen-Sachsen Anhalt e. V., Medizinische Fakultät, Technische Universität, Dresden, Germany
gernot.lenz@gmx.de

Synonyms

Medical specialties

Definition

Medical specializations are those specific fields of medicine where additional training and internship beyond medical school is required. They can be differentiated into non-surgical and surgical specialties. The medical specializations are reflected in the different

wards of an inpatient setting or in specialized outpatient practices. In many health care systems, the patient first has to attend an appointment with a general practitioner who acts as a gatekeeper and – if necessary – refers the patient to the corresponding specialist.

Basic Characteristics

Background

According to the Organisation for Economic Co-operation and Development (OECD), the number of physicians in OECD countries has increased by 35% between 1990 and 2005, to 2.8 million. This increase was driven largely by a 50% growth of specialists in the same period, and they now make up more than 50% of all physicians in most of the OECD countries. This increase is amongst other factors driven by the – in some OECD countries significant – higher income levels of medical specialists.

Education

Medical education in general and the training for becoming a medical specialist both differ significantly throughout the world. Entry-level education takes place at ► medical school and includes preclinical and clinical aspects. The preclinical part covers the basic sciences like anatomy, physiology, biochemistry, pharmacology, and pathology, whereas the clinical part teaches specific fields like internal medicine, pediatrics, obstetrics and gynecology, psychiatry, and surgery. Postgraduate education is usually undertaken as supervised practice in the form of an internship or provisional registration of around a year prior to full registration being granted. After that, further multi-year training is required to become specialist. In some countries, this period starts with a generalist training of some years before specialization may commence.

Non-surgical Specialties

There are numerous non-surgical specialties that are offered in general or specialized hospital settings and partly by outpatient physician practices. The specialties include ► anesthesiology, ► dermatology, ► internal medicine, ► neurology, ► nuclear medicine, ► obstetrics and gynecology, oncology (► cancer), ophthalmology (eye medicine), ► pathology, ► pediatrics, preventive medicine, ► psychiatry, ► radiation oncology, ► radiology, and ► urology. Each of these specializations includes several subspecialties.

Surgical Specialties

The surgical specialties are primarily offered in hospital settings, either ► inpatient or ► outpatient. Amongst the surgical specialties are the fields of ► cardiac surgery, ► hand surgery, ► neurosurgery, ► oral and maxillofacial surgery, ► orthopedic surgery, ► otolaryngology, ► plastic surgery, surgical oncology, ► thoracic surgery, and ► transplant surgery.

Conclusion

Considering the ageing society and the progress in treatment methods and technical devices in the health care sector in many countries of the world, it seems realistic to predict that the trends towards increased specialization amongst physicians will continue, although several countries are promoting an enhanced ► primary care model.

Medical Wastes

Definition

Medical waste is often described as any solid waste that is generated in the diagnosis, treatment, or immunization of human beings or animals, in research pertaining thereto, or in the production or testing of biologicals. It means human organs, tissues, body parts other than teeth, products of conception, and fluids removed by trauma or during surgery or autopsy or other medical procedure, and not fixed in formaldehyde. Medical waste may contain infectious agents. Incineration at high temperatures destroys many of the toxins and pathogens in medical waste and other hazardous wastes, in addition to reducing the volume. Medical waste shall be stored in rigid, leakproof containers with tight-fitting lids which have been labeled with a label which is marked with the international biohazard symbol and the word "Biohazard." Medical waste shall be transported from the point of generation to the storage area in rigid, covered containers.

Medicament

► Drug

Medicare

Definition

In the United States, Medicare is a federal health insurance program for the elderly (people over age 65) and for some individuals with disabilities. The program was enacted as Title XVIII under the Social Security Act in 1965 and consists of two parts: Part A covers inpatient care services and some long-term care arrangements, part B covers outpatient medical services. Part B requires usually a ► co-payment of 20%. The program is administered by the Health Care Financing Administration of the US Department of Health and Human Services. Eligible persons are people over 65, people entitled to Social Security disability payments for 24 months or more and people with end-stage renal disease.

Medicinal Treatment of Multiresistant Tuberculosis

Synonyms

Medicinal treatment of tuberculosis caused by multiresistant bacteria; Drug therapy in multiresistant tuberculosis

Definition

With a time scale of 21–24 months, the medicinal treatment of multiresistant tubercle bacilli is very long-lasting. The chances of healing depend on the number of drugs against which the germ is resistant; 75% in 3 drug resistance, 25% in 5 drug resistance. Different agents are used for therapy with a combination of at least 4 drugs being recommended. Drugs are chosen that are known to still be effective against the multiresistant germs. Other possible therapeutics are aminoglycosides (capreomycin, kanamycin), fluoroquinolones (ofloxacin, ciprofloxacin, levofloxacin) and thionamides (ethionamide, prothinamide). Moreover, the bacteriostatic substances PAS (para-aminosalicylic acid) and cycloserin can be used. As the treatment of multiresistant germs is very expensive, it is frequently not available in developing countries or other poor regions.

Medicinal Treatment of Uncomplicated Tuberculosis

Synonyms

Drug treatment of uncomplicated tuberculosis

Definition

Medicinal treatment of uncomplicated tuberculosis is carried out for a period of 6 months. During the initial phase, which lasts 2 months, a 3- to 4- fold combination is used. The 3-fold combination contains isoniazid (INH), rifampin (RIF) and pyrazinamide (PZA). In the 4-fold combination ethambutol (EMB) or streptomycin (STM) is additionally used. In the following stabilizing phase INH and RIF are given for 4 months. Side effects of INH, RIF and PZA primarily concern the liver, EMB can damage the nerves of the eye, and STM can impair hearing and renal function. Thiazetazon is only used in poorer countries in the absence of a HIV-infection; this substance also shows liver toxicity.

Mefloquine (Lariam®, Mephaquin®)

Definition

Mefloquine is derived from the alkaloids of the bark of the South American cinchona tree (quinine and quinidine). Its effect results from the impairment of the metabolic processes in plasmodia. Mefloquine is effective against all kinds of malaria. After the initial administration of the drug, further doses are given after 6 and 12 hours. Besides gastrointestinal symptoms, possible side effects are cerebral seizures, neuropsychological symptoms (halluzinations, states of panic), cardiac arrhythmias and a toxic epidermolysis.

Meiosis

Synonyms

Meiotic cell division

Definition

Meiosis is a process of nuclear division accompanying cell division that produces four separate nuclei for four new daughter cells which are haploid, that is, carry half the number of chromosomes of the parent cell's full diploid chromosomal complement. Meiosis bear many similarities to ► mitosis in terms of the phases of its cell-division, which are: 1) prophase I, 2) metaphase I, 3) anaphase I, 4) telophase I, 5) prophase II, 6) metaphase II, 7) anaphase II, and 8) telophase II. However, during meiosis there is an exchange of genetic information between homologous chromosomes, which does not occur during mitosis. During prophase I, as the duplicated chromosomes condense into bar-like bodies, joined at the centromere, they are aligned laterally with their duplicated homologous chromosome, called synapsis. This alignment is called a bivalent. During late prophase, the ends of the aligned homologous chromosomes are often exchanged at a point called a cross-over, of which there can be many between any set of homologous chromosomal arms. This process is called ► recombination. There can be many recombinations along a chromosome, although in general, there are fewer recombinations near the centromere than there are towards the ends of the chromosomal arms. At the end of prophase, crossover points called chiasmata still exist. During metaphase I, the bivalents are bound to the mitotic spindle, and in anaphase, the chiasmata disappear as the homologous chromosomes are pulled apart to their respective poles, taking along recombinant chromosomal arms. In telophase I, a nuclear envelope may or may not form, as a second round of division is about to be initiated. At this point in the division, each daughter cell has 46 chromosomes, all of which are non-identical, homologous chromosomes joined at their similar centromeres. Prophase II is short, and it occurs before the chromosomes have had a chance to replicated or enter an additional cell cycle. In metaphase II the chromosomes align on the metaphase plate, and the two homologous chromosomes, looking much like sister chromatids, are pulled apart to their respective poles in anaphase II.

In metaphase II, nuclear envelopes form around the cells, each with a haploid complement of 23 chromosomes. From one diploid parent cell, four haploid daughter cells have arisen.

Meiotic Cell Division

► Meiosis

Menarche

Synonyms

Menophenia; Initiation of the menstrual function; Establishment of the menses

Definition

Menarche is the first menstrual period, or first menstrual bleeding. Timing of menarche is influenced by both genetic and environmental factors, especially nutritional status, but it generally occurs about two years after onset of breast development (thelarche) and when growth in height slows after reaching its peak. Menarche occurs within a wide range, with most girls starting their periods at 12 or 13 years. Average age of menarche has declined in modern societies. It is one of the main signifiers of the onset of puberty.

(Mendelian) Models of Inheritance

► Mendelian Modes of Inheritance

Mendelian Modes of Inheritance

Synonyms

Modes of inheritance; (Mendelian) models of inheritance

Definition

In organisms which reproduce by the union of male and female reproductive cells (or, gametes), the expression of physical characteristics in offspring inherited from their parents through transmitted genetic information are governed by the principle of segregation and the rules of gene expression. The principle of segregation states that, in general, each copy of a gene present in the parental genomes has an equal probability of being transmitted to offspring to its homologue – a parent who possesses the variants *A* and *a* of one gene is equally likely to transmit either *A* or *a* to their offspring. However, the characteristics expressed by the offspring once its genome is set are governed by Mendelian modes of trait inheritance. Some gene variants may be preferentially expressed to others, and these variants are called 'dominant' while the less preferred variants are labelled 'recessive'. For example, at a fictional gene GZ1, there are two possible genetic variants, or 'alleles', B and b. A family has a father with a GZ1 genotype, the identity of both homologues at the site, or Bb; the mother also has genotype Bb, and their three children 1, 2 and 3 each have genotypes of BB, Bb and bb respectively. Accordingly, different manifestations of the trait influence by GZ1 are observed depending on the mode of inheritance:

1) If the allele B is dominant to the recessive allele b, and we are interested in the trait governed by B, we say that the trait follows a *dominant* Mendelian mode of inheritance. That is, the trait expressed by B will be expressed by any individual carrying even one copy of B. In the family described, the mother, father and children 1 and 2 all express the trait associated with B.
2) If the allele B is dominant to the recessive allele b, and we are interested in the trait governed by b, we say that the trait follows a *recessive* mode of inheritance. The trait expressed by b will be expressed in individuals carrying no copies of B. In the family described, only child 3 expresses the trait associated with b.
3) If alleles B and b do not compete, but are equally and/or differently expressed, we say that we observe a *codominant* mode of inheritance. The expression of the trait varies by genotype. In the family described, the mother, father and child 2 will express similar traits; child 1 and child 3 will express traits different from each other and their other family members.
4) If the allele B is dominant to the recessive allele b, and the variation in the level of trait is based on the number of copies of B which they possess, then we say that we observed mode of inheritance is *additive*. In the family described, child 1 would have the highest level of the additively-inherited trait; the mother, father and child 2 would have a similar level of the trait; and child 3 would have the lowest level of the trait.

Mendelian patterns of inheritance are similarly applied to sex chromosomes as they are to autosomes. In females, the above Mendelian patterns of inheritance are applicable to genes present on the two X chromosomes, while in males, whatever gene variant is present at a particular site on the X chromosome is automatically the variant which is expressed, as there is only one homologue of X in males. All variants at all genes on the Y chromosome are likewise expressed in males.

Mendelian Traits

Definition

Traits which are inherited from the transmission of genes in families following Mendel's laws of heredity.

Menigococcal Vaccination

Synonyms

Meningococcal immunization

Definition

The first monovalent (group C) meningococcal polysaccharide ► vaccine was licensed in 1974, further vaccines followed: in 1978 there was authorized another monovalent group C vaccine as well as a group A and a bivalent vaccine for both groups A and C; a quadrivalent vaccine (groups A, C, Y and W-135, MPSV4) was licensed in 1981. The meningococcal conjugate vaccine MCV4, which also protects against the subtypes A,C,Y and W-135, was introduced in 2005 and can be used for persons 11–55 years of age. The protection rate achieved by MPSV4 is 85–100 %, MCV4 is believed to have the same efficacy and most probably induces a longer-lasting protection than the polysaccharide vaccine. In general, vaccination is carried through in individuals two years of age or older as a single dose. If indicated, also younger children – from three months of age – can receive MPSV4. In these cases, a second dose should be given three months apart. In many countries meningococcal vaccination is not recommended in general but for people at high risk for infection, such as splenectomized persons, patients with terminal component complement deficiency (a kind of immune system disorder) or travelers to certain countries (e. g. the areas in sub-Saharan Africa known as the meningitis belt, which extends from Mauritania in the west to Ethiopia in the east). Contraindications for meningococcal vaccination are acute severe illness, a known allergy to any component of the vaccine or an allergic reaction to a previous dose of meningococcal vaccine.

Meningitis

Synonyms

Infection of the meninges; Inflammation of the meninges

Cross-References

► Acute Life-Threatening Infections

Meningococcal Septicaemia

► Waterhouse–Friederichsen Syndrome

Menopause

Synonyms

Pausimenia; Climacteric period; Climacterium

Definition

Menopause is the physiological or iatrogenic cessation of menstrual cycles (amenorrhea) due to decreasing ovarian function (consumption of all viable follicles). Average onset of menopause in women is 50.5 years. The physiologic menopause is established when menses have been absent for one year. Menopausal symptoms can range from nonexistent to severe and last from a few months up to ten years or more. Major symptoms of the perimenopause are hot flushes (vasomotor origin), vaginal discomfort and bladder symptoms.

Menophenia

► Menarche

Men's Health

RICK HAYES, SHELBY WILLIAMSON
School of Public Health, La Trobe University (Bundoora), Melbourne, Australia
r.hayes@latrobe.edu.au, m.williamson@latrobe.edu.au

Synonyms

Male health; Men's health and well-being; The health of boys and men; The health of men and boys

Definition

Men's health entails both the systematic exploration of the multi-dimensional factors (e. g., biomedical, psychosocial, structural, cultural historical) influencing the health of men and boys and the systematic elaboration of multi-level actions undertaken to engage these influences so as to improve or maintain the health of men and boys within their physical, social and spiritual contexts.

Basic Characteristics

Overview

While a concern for the health of men has no doubt always existed in some form in all cultures, men's health as a distinct area of critical intellectual and practical concern in the domain of public health is relatively recent in the West (Hayes 2003). In terms of research, government policy, and practical programmes and projects, men's health *per se* remains a relatively minor area of concern (Schofield et al. 2000; Macdonald, Crawford 2002). Where there is a focus, it tends to be on such issues as men's reproductive health or men's engagement in anti-social behavior. Additionally, such research continues to be fragmented by salient differences of political, social, and intellectual perspective (White 2005).

Historically, the social codes of most peoples have made distinctions between what constituted a virile man in contrast to a fecund woman, or between a pure or impure man and woman. However, these distinctions were more in the order of *phronesis*, or of wisdom concerning the processes constituting best practice for relating well with other persons, people groups, or cosmic powers. Increasingly, the distinctions are now found in the order of *techne*, or of knowledge concerning the processes constituting best practice for working well with 'things', such as the 'male body' or the 'male psyche'. However, there is a transition towards reintroducing salient aspects of *phronesis* again.

Late 20th Century Background

It is widely held that where once all people were measured on the basis of male experiences of disease and illness women began to question this basis of knowledge and practice with respect to their reproductive health in the middle years of the last century. During the political and cultural upheavals of the 1960s and 1970s in the West, women increasing demanded and received limited funds for and credibility from research that privileged women's health more broadly. 'Progressive' men engaged in commensurate reflections with regard to the psychological origins and manifestations of the 'oppression' of women by men generally, and by the medicalized professions specifically. Both men and women undertook somewhat more critical sociological analyses during the 1980s and 1990s. Concepts such as ► hegemonic masculinities' and ► expert dominance' were developed as devices for explaining the oppression of women and at least certain types of men, as well as the relatively negative health outcomes obtained by the oppressed (Rowan 1997).

Throughout this period, the dissemination of both quasi-scientific and mytho-poetically (see Rowan 1997) oriented paradigms through various media ensured that the general public would be 'educated' into the essential physiological and, hence, psycho-social differences between men and women. Ironically, these 'expert' sanctioned proposals of how people should deal with each other have been extremely popular with the larger public (e. g., Gray's *Men are from Mars, Women are from Venus*). However, these distinctions are not always equally valued by this public or by many health professionals.

For instance, the female psyche has become, paradoxically, the privileged template of the human 'soul' for many. Ostensibly because of the depredations of 'hegemonic' or 'demanding and commanding' masculinities, men are frequently both deemed to be and portrayed as sub-standard in this regard. In other words they are considered, for the most part, to be incapable of experiencing and expressing emotions adequately (*alexythimia*) or of engaging in appropriate self-care. Furthermore, as a result of the perceived unwillingness of western males to redeem their deficient 'souls', their bodies are considered to be doomed first to suffer a variety of typical diseases and, then, a premature (hence, meaningless) death.

Early 21st Century Transitions

Careful research into the histories, literatures and lives of working class, gay, and aboriginal men reveals a much more richly nuanced and variegated 'tissue' of ► embodied manhood than is typically acknowledged (Luck et al. 2000; Hayes 2003). This is also true of men who have fought in wars or worked in emergency services, who have endured experiences of mental ill-health, or who are under and unemployed. Instead of ► pathologising men, these stories support the growing impetus to take a more positive, primary health care approach to supporting the way that various men seek to live their lives personally and communally (Macdonald, Crawford 2002). Such an approach focuses on helping them to identify the knowledge, skills and attitudes that they wish to use or gain to achieve their aspirations both as individuals and members of groups.

For instance, while including stories of selfish ambition and hatred, the prisoner of war stories from the Pacific that emerged following World War 2 include recurring themes of tenderness, self-sacrifice and compassion collectively organized for the benefit of comrades (Nelson 1985). Additionally, it is well documented that the traumas of those who returned from the wars of the last century have negatively influenced their families for generations. Governments have conveniently suggested to these people that it is 'best you forget'. Western societies typically ignore the economic and political significance of the processes of socialization that prepare men to fight in wars or to work in hazardous industries. Little regard is collectively given to their contribution to the ill-health of men. Disaggregation of men's health statistics indicates that negative health outcomes for men, when compared to women, tend to be more salient for such men than for those socialized for other life outcomes (Luck et al. 2000).

Just as women's experiences of health and illness cannot be measured on the basis of male experiences, policy and practical programs aimed at improving men's health do not necessarily work well just because they have worked well for women. The lack of research into men's health in the West has resulted in less evidence calling for resources to be allocated to this area. For instance, even though the mortality rates are roughly equivalent in industrialized nations, research funding for the diagnosis and treatment of prostate cancer significant lags that of breast cancer in women.

The Emerging New Public Health Paradigm and Practice

Within the field of men's health, there is a growing call for a new approach in terms of public health practice. Rather than working within the negative paradigm of ► pathologising men's health, leading academics within the field, such as Professor John Macdonald at the University of Western Sydney (Australia), are advocating for a more ► *salutogenic* (health generating) approach. Following the medical sociologist, Aaron Antonovsky, Macdonald and Crawford (2002) urge health professionals and policy makers to focus on what generates or promotes health for men and that acknowledges and fosters their positive social value.

Important research in Australia indicates that men in "safe [non-shaming], well-facilitated groups [good group processes and dynamics] associated with their networks" (Hayes 2002, p. 83) can and will discuss and act upon their health concerns. Growing numbers of agencies and communities are recognizing the need to create opportunities for men to maintain their social connections in the face of growing rates of workforce redundancy for men over 50 years of age and decreased opportunities for non-consumerist leisure options for males of all ages. These opportunities for social connectedness benefit men in terms of both mental and physical health by providing for instrumental, affective and inspirational support. Additionally, research indicates that agencies that adopt policies, plans, procedures and protocols that work with men on their own "terms and turf" are more attractive and, therefore, beneficial to men than those which are heavily professionalized or feminized.

In terms of both the men and those who work with them effectively, social change is currently occurring through innovative, opportunistic, localized approaches rather than top down and whole of system approaches. As a movement, men's health is only beginning to gain momentum and it remains largely 'western' in ethos. This momentum is largely the result of voluntary efforts and "grass roots" initiatives. Linkages and networks are only recently beginning to be formed across multiple sectors and disciplines. National and international conferences on men's health are being held on a recurring basis. A number of peer-reviewed journals or newsletters are now being published to provide support for these endeavors: *Harvard Men's Health Watch, Journal of Men's Health and Gender, Journal of Men's Studies*, and the *International Journal of Men's Health*.

It is incumbent on those working with men to apprise themselves of the wide range of resources increasingly available to shed light on the complex biomedical, psycho-social, structural and cultural historical issues relating to men's health. (Luck et al. 2000) This can help to generate a more comprehensive, and less naïve, understanding of what engenders or endangers the health of men and the ones with whom they live, learn, work, worship and play.

Global Mortality Statistics

Variations in mortality between regions reveal substantive differences. For instance, in 2003 the World Health Organization (WHO) estimated that the life expectan-

cy for males at birth compared to women [x] in the various regions was: African 46[48], Americas 71[77], SE Asia 61[64], Europe 68[77], Eastern Mediterranean 61[64], Western Pacific 70[74]. (WHO 2005) In 2001, the leading cause of death for all males was related to non-communicable diseases (57%) such as cardiovascular diseases (27%), malignant neoplasms or cancers (13%), respiratory diseases (6%) and digestive diseases (4%); this was followed by communicable diseases (32%) such as non-respiratory infections and parasitic diseases (20%) and respiratory infections (7%); and, finally, injuries (12%) whether unintentional (8%) or intentional (4%) [n.b., percentages approximate] (WHO 2002).

Menstrual Cycle

Definition

The average length of the menstrual cycle is 28 days. Day one is by convention the first day of vaginal bleeding. The mean duration of the menstrual flow is between 2–6 days with an average blood loss of 20–60 ml. Ovulation generally occurs on day 14 (14 days before the first day of the next vaginal bleeding). The normal menstrual cycle is divided into two segments. The follicular phase (variable length: 10–14 days) and the luteal phase (14 days). During the follicular phase hormonal feedback promotes the development of a single dominant follicle which is prepared for ovulation. The luteal phase is the duration of time from ovulation to onset of menses in which the endometrium is prepared for the implantation of an embryo. If implantation with production of HCG does not occur, menstrual flow begins as a result of the shrinking of the corpus luteum resulting in a fall of progesterone, the gestational hormone.

Mental Health in Children and Adolescents

UWE RUHL
Institut für Psychologie, Universität Göttingen, Göttingen, Germany
uruhl@uni-goettingen.de

Definitions

Individuals < 18 years of age are divided into infants (1 month to 1 year of age), children (1–12 years of age), and adolescents (13–18 years of age).

Basic Characteristics

Introduction

Mental health and illness in children, and the measurement of mental health and illness, are somewhat different from that in adults. Overall, most mental diseases can strike a person at any age (e. g., depression, anxiety, ► conduct disorders). ► Attention deficit hyperactivity disorders show an early onset, usually in the first five years of life. For understanding the mental health of children, age, developmental stage, and timing factors are of high importance. A behavior that might be quite normal at one age (e. g., fear of darkness in young children) can be an indicator of a mental disorder at another age (► separation anxiety disorder of childhood, ► phobic anxiety disorder of childhood, ► social anxiety disorder of childhood). Developmental continuities have to be considered as well as developmental discontinuities (► speech and language developmental disorder, ► reading and/or spelling disorder, ► arithmetical skills disorder, ► motor function developmental disorder, ► childhood autism). The environment and adaptation of the child to the environment is another relevant factor in understanding mental health and illness in children (► elective mutism).

Epidemiology

The prevalence of mental disorders in children and adolescents is not as well documented as it is for the adult population. According to previous research and depending on diagnostic criteria, 10–20 percent of children and adolescents are estimated to have clinically significant mental disorders with at least mild functional impairment (e. g., Shaffer et al. 2000). In most studies, the conceptual definition of the "clinical significance" is taken into consideration. Barkmann and Schulte-Markwort (2005) distinguished three levels of hierarchy:

1. existence of psychological complaints
2. fulfillment of the diagnostic criteria for the determination of a mental disorder (e. g., according to ICD-10)
3. fulfillment of a severity or impairment criterion.

Federal regulations in the USA define a sub-group of mental disorders as "serious emotional disturbance" in reference to children under the age of 18 with a diagnosable mental disorder that severely disrupts the ability to function socially, academically, and emotionally. Finally, some studies use the classification "severe psychopathology" (defined as the presence of multiple mental disorders, i. e. ≥ 3). Different study designs and measurements make comparisons of studies difficult. The threshold of mental disorders may vary from culture to culture.

The MECA Study (Methodology for Epidemiology of Mental Disorders in Children and Adolescents) estimated that > 20% of U.S. children aged 9 to 17 had a diagnosable mental disorder. Preliminary results of the representative German child and adolescent mental health survey indicate that almost 22% of children show at least psychological disturbances (Table 1).

The frequency of mental illnesses symptoms is negatively associated with socioeconomic status. Parental mental disorders, parental conflicts, and single parenthood are risk factors for mental disorders in children (www.kiggs.de).

Mental Health in Children and Adolescents, Table 1 Prevalence rates of mental disorders in Germany and the USA

Mental disorders	German prevalence estimates*	U.S. prevalence estimates**
Anxiety disorders	10%	13.0%
Mood disorders	5.4%	6.2%
Disruptive disorders	7.6%	10.3%
Attention deficit hyperactivity disorder	2.2%	–

*Children and adolescents aged 7 to 17 years, Ravens-Sieberer et al. 2006. www.kiggs.de
**Children and adolescents aged 9 to 17 years, combined MECA sample. www.surgeongeneral.gov/library/mentalhealth

M

Consequences

Recent longitudinal studies suggest that a mental disorder in childhood or adolescence increases the risk of recurrence of this mental disorder as well as the incidence of another mental disorder in later life. For example, depressed adolescents with special risk factors (i. e., female gender, multiple depressive disorder episodes, elevated borderline personality disorder symptoms) are at elevated risk for recurrence of depressive disorders during young adulthood (Lewinsohn et al. 2000). Lieb et al. (2000) showed that somatoform disorders in adolescents and young adults were often associated with the development of other mental disorders in the following four years. Another result of the Early Developmental Stages of Psychopathology Study (EDSP) was that panic attacks were associated with high levels of comorbidity and multimorbidity across the diagnostic spectrum among adolescents and young adults in the community (Goodwin et al. 2004). The EDSP study is a prospective, longitudinal study designed to collect data on the prevalence, risk factors, comorbidity, and course of mental and substance use disorders in a representative community sample in Munich, Germany, which consisted of 3021 subjects aged 14–24 years at baseline. The study consists of a baseline (time 0) survey, two follow-up surveys (first follow-up survey was 14–25 months after baseline; second follow-up survey was 34–50 months after baseline), and a family history component (Wittchen et al. 2004).

Treatment

Treatment of mental disorders in children is not different from adult treatment, i. e., medication, cognitive-behavioral psychotherapy, family psychotherapy, psychoanalytic psychotherapy, and functional training (e. g., dyslexia) are relevant treatments. An additional and necessary special aspect of therapy for children is the work with parents, teachers and/or other important persons.

Future Research

Not all psychological disturbances or mental disorders existing in childhood and adolescence persist into adulthood. A substantial fraction of children and adolescents recover and do not suffer from recurrence or comorbidity of mental disorders. However, those children suffering from psychological disorders, and especially those with risk factors, need access to treatment as soon as possible. To optimize the recognition rate of mental health problems, the use of simple diagnostic screening instruments in general practice could be helpful, as well as special training of mental health professionals. Resources available to the affected children and their families (e. g., individual, family-related, and social) have to be supported. There is a strong need for more longitudinal epidemiological studies in Europe and worldwide in order to determine the prevalence rates of mental disorders, risk and protective factors, and therapy and service utilization. However, it is noteworthy that valid measures of need are absent since prevalence rates of mental disorders in epidemiological surveys are only an imperfect proxy for the need for treatment. Further, taking developmental aspects into consideration, there might be windows of opportunity during children's development when preventive or treatment interventions may be especially effective. Those windows of opportunity have to be identified.

Mental Health Economics

ISABEL HACH
Klinik für Psychiatrie und Psychotherapie,
Klinikum Nürnberg Nord, Nürnberg, Germany
isabel.hach@klinikum-nuernberg.de

Definitions

Economics is the science that studies the production, distribution, and consumption of resources. The word "economics" is from the Greek words "οἶκος", meaning "household, estate", and "νόμος", meaning "custom, law", and thus literally means "household management" or "management of the state". Health economics examines the supply of and demand for health and health care, and the economic analysis of health care systems and health care reforms. It also examines the economic evaluation of health care technologies and the measurement and valuation of health. Mental health economics is health economics in relation to mental health.

Basic Characteristics

Introduction

Health – not merely health care – has high economic importance. In mental health care, the uncertainty and variation in treatments are greater than in health care; the assumption of patient self-interested behavior is more dubious and less predictable than in mainly physically ill patients; the social consequences and external costs of mental illness are formidable. The European Brain Council (EBC) showed that the burden of brain disorders constitutes 35% of the total burden of all diseases in Europe (calculated in terms of DALYs, i. e. ► disability adjusted life years, for details s. http://www.europeanbraincouncil.org). Mental disorders account for about 25% of all DALYs lost in Europe, followed by cardiovascular diseases (17.1% of all DALYs lost, Kaplan and Laing 2004). Worlwide, mental disorders account for 15.4% of the burden of disease in established market economies. Major depressive disorder, schizophrenia, and obsessive-compulsive disorder are among the top 10 leading causes of disability (see Table 1). Morbidity costs comprise the major part of the ► indirect costs of all mental disorders. This indicates an important characteristic of mental disorders: Mortality is relatively low, onset is often in (young) adulthood, and most of the indirect costs are derived from lost or reduced productivity at the workplace, school, and home.

Mental Health Economics, Table 1 Disease burden by selected illness categories in established market economies, 1990 (Murray and Lopez 1996)

	Percent of Total DALYs*
All cardiovascular conditions	18.6
Ischemic heart disease	9.0
All mental illness	**15.4**
Unipolar major depression	**6.8**
All malignant diseases (cancer)	15.0
All respiratory conditions	4.8
All alcohol use	**4.7**
All infectious and parasitic diseases	2.8
All drug use	**1.5**

Costs of Mental Disorders in Europe and the U.S.A.

Andlin-Sobocki et al. (2005) developed a model to combine epidemiological and economic data on brain disorders in Europe (i. e., EU member countries, Iceland, Norway, and Switzerland). The epidemiological data are based on a systematic literature review of published European epidemiology data (Wittchen and Jacobi 2005). The economic costs were estimated using a ► bottom-up approach, i. e., the cost data were collected per patient and disease and aggregated to nation-

€ million	Healthcare costs	Direct non-medical costs	Indirect costs	Total costs
Mental disorders	**97221**	**9336**	**132985**	**239542**
Addiction	16655	3962	36657	57274
Affective disorders	28639	**	77027	105666
Anxiety disorders	22072	**	19301	41373
Psychotic disorders	29855	5374	**	35229
All brain disorders*	**135445**	**72200**	**178530**	**386175**

* All brain disorders include: Brain tumor, Trauma, Epilepsy, Migraine and other headaches, Multiple sclerosis, Parkinson's disease, Stroke and Dementia;
** Direct non-medical costs are missing for affective and anxiety disorders; indirect costs are missing for psychotic disorders

Mental Health Economics, Table 2 Costs of mental disorders in Europe (Andlin-Sobocki et al. 2005)

al levels with the help of prevalence data (in contrast to a ► top-down approach). The inherent problem of the bottom-up approach is double-counting due to comorbidity. This problem stems mainly of the epidemiological data (e. g., patients suffering from depression probably also suffer from comorbid anxiety disorders).

Mental disorders (i. e., addiction, ► affective disorders, ► anxiety disorders, ► psychotic disorders) made up 62% (i. e. 240 billion €) of the total costs of brain disorders in Europe (for details see Table 2).

About 50% of the costs of mental disorders are indirect costs and almost 40% direct healthcare costs. It should be noted, however, that direct medical (► direct medical costs) and non medical costs (► direct non medical costs) were not included in the costs of affective and anxiety disorders. Moreover, the ► indirect costs due to anxiety disorders only comprised lost work days due to sick leave. The authors conclude that their study probably underestimates the full economic burden of mental disorders in Europe.

In 1996, the United States spent more than $99 billion for the direct treatment of mental disorders, as well as substance abuse, and Alzheimer's disease and other dementias (the National health accounts was $943 billion total). More than two-thirds of this mental health amount ($69 billion) was for mental health services. Spending for direct treatment of substance abuse was almost $13 billion (more than 1 percent of total health spending), and that for Alzheimer's disease and other dementias was almost $18 billion (Mark et al. 1998).

Consequences

The costs of brain disorders will increase dramatically during the next two decades (Andlin-Sobocki et al. 2005). It is important to find out which systems of care are most effective (for details of the U.S. mental health service system see www.surgeongeneral.gov/library/mentalhealth/chapter6/); existing evaluation studies could not demonstrate a conclusive effectiveness because of missing control groups. Carrying out prospective field studies and increased research efforts (i. e., better prevention, better diagnostic assessment, better treatment, better health care systems) might be the only way to counteract this cost increase not only in European countries.

Elderly

Definition

Specific chronological markers for old age are defined in different ways by different authors. The definition of "older adults" varies, depending on different perspectives and purposes. Whereas gerontologists traditionally focus on individuals aged 60 years and older, the federal government of the U.S.A. uses age 65 as a marker for full Social Security and Medicare benefits. Researchers identify subgroups of "older adults" as "younger old" (ages 65–75), "older-old" (ages 75–85), and "oldest old" (ages 85+). Age ranges vary across studies.

Basic Characteristics

Introduction

The demographics of the industrial world are well known. It is important to understand the needs of older adults suffering from (and living with) mental disorders. There are age-dependent and treatment-relevant changes that have to be considered in the elderly. For example, ► pharmacokinetic and ► pharmacodynamic variables can influence the effect of a pharmacological therapy (those changes may occur in the ► absorption, ► distribution, ► metabolism, and excretion of psychotropic medications (► elimination)) as well as medical comorbidities, concomitant medication, cognition of older adults, hyperopia, and less available resources than younger people have.

Prevalence and Costs of Brain Disorders in Older Adults

Depression and hopelessness are not natural conditions of older age. Many older adults and, unfortunately, health care professionals as well mistakenly assume that depression is a normal consequence of physical, social, and economic difficulties in later life. Older people suffering from chronic or stressful physical conditions (e. g. hearing loss, mobility impairment) are a high risk population for depression. Depressive disorders in the elderly are both underdiagnosed and undertreated. Depression is one of the most frequent conditions associated with suicide in older adults (Conwell and Brent 1995). There is much misunderstanding about thoughts of death in later life. Depression, serious loss (e. g., death of a spouse, loss of a friend), and (terminal) illness trigger the sense of mortality, regardless of age. Periodic thoughts of death do occur. However, when actual dread of death does occur, it should not be dismissed as accompanying aging, but rather as a signal of underlying distress or depressive disorder. As compared to older persons whose depression began earlier in life, those whose depression first appears in late life are likely to have a more chronic course of illness. There is growing evidence that depression beginning in late life is associated with vascular changes in the brain. According to Narrow, about 6% of the U.S. population age 65 and older suffer from depressive disorders (i. e., major depressive disorder, dysthymic disorder, or bipolar disorder; http://www.nimh.nih.gov). Beekmann et al. (1999) found in a worldwide review an average prevalence of major depressive disorders of 1.8% in the elderly. The experience of depressive symptoms and subclinical depression, respectively, is much more prevalent. The symptoms of depressive disorders and ► dementias in an early state are very similar and often not to distinguish.

Some mild degree of memory decline can be normal with aging. Those normal changes usually mean a slower pace of learning and the need for new information to be repeated. However, more severe memory problems may indicate dementia or other serious cognitive illnesses. Dementia involves a loss of cognitive (memory and attention) abilities due to brain damage secondary to illness. Symptoms of dementia can include memory impairment, and difficulties with language, movement, object or face or word recognition, and difficulty making judgments, regulating emotions or shifting attention from one subject to another. Noteworthingly, dementia is not a part of regular aging – it is a physical disease of the brain. The prevalence rate of dementia dramatically increases with increasing age. The degree of care that an elder may require due to dementia will be variable, depending on whether dementia is due to

Alzheimer's disease (or similar progressive disease) or stroke, and how affected the elder is by the condition. Older adults' mild early memory problems may not require much care at all. While vascular (stroke) dementia will not necessarily get worse (e. g., if blood pressure is kept stable and low), Alzheimer's dementia is by nature a progressive disorder, which will result in more and more impairment over time. The costs of vascular dementia might be, especially in the beginning of the disease, somewhat higher than in AD due to the costs of cardiovascular medication. In the European member states (including the new member states) it is estimated that about 5.1 million people suffer from dementia (about two thirds of people with dementia have Alzheimer's disease). Wancata et al. (2003) have reported a dramatic increase of the dementia cases in Europe in the next 50 years (to approximately 11.9 million people). There is consistent evidence that costs of care for patients suffering from dementia are very high across European countries (e. g. National Dementia Economic Study NADES in Belgium: Total annual costs of a patient with dementia living et home: € 5,346; total annual costs of an institutionalized patient with dementia: € 27,620) (Scuvee-Moreau et al. 2002). ► Parkinson's disease is also a relevant illness, especially in older age. High-quality studies (i. e., use of established diagnostic criteria, inclusion of the entire age range of the population, and screening by an experienced neurologist) estimated prevalence rates of approximately 108 to 257/100,000 (Campenhausen et al. 2005). The mean total direct costs (e. g., drugs, outpatient visits, inpatient care) per patient per year are reported between 3360 € (UK; Findley 2003) and 8160 € (Germany; Spottke 2005).

Ageing Mentally Healthy

Different types of interventions have been successful in improving the mental health of elder people. Examples of universal strategies are: exercise interventions (e. g. aerobic, t'ai chi, other physical exercises) and improving social support through befriending (especially older women seem to profit from friendships and social support). Promising preventive interventions for selective and indicated elder populations include the use of patient education methods among chronically ill elderly (e. g. patients suffering from chronic pain) and their caregivers (e. g. psycho-educational programmes for caregivers of patients with ► dementia), early screening and interventions in primary care (e. g. screening of high systolic blood pressure and anti-hypertensive medication for prevention of vascular dementia and stroke). Early detection of depressive disorders in primary care can reduce the risk of suicide in older individuals. Because of the ► pharmacokinetic and ► pharmacodynamic concerns in older age, it is often recommended that clinicians "start low and go slow" when prescribing new psychoactive medications for older adults. Efficacy is great and side effects are minimized when initial doses are small and the rate of increase is slow. Better compliance with a pharmacological treatment regime may be achieved by giving simple instructions and by asking specific questions to make sure that the patient understands directions. An effective pharmacotherapy can also avoid premature institutionalization. Last, the avoidance of excessive disability is of high importance. For example, a co-occurring depressive disorder can contribute to excess disability by hastening functional impairment in patients with Alzheimer's disease or another severe and persistent mental illness. Hence, attention to comorbid mental disorders may reduce the functional limitations associated with mental and somatic impairments.

Meta-Analysis

Biljana Miličič
School of Dentistry, University of Belgrade, Belgrade, Serbia
bmilicic@eunet.yu

Synonyms

Quantitative synthesis; Quantitative research synthesis

Definition

The term meta-analysis will be used here to describe the quantitative procedures that the research synthesist uses to statistically combine the results of studies.

Basic Characteristics

Synthesizing Main Effects and Interactions

► Quantitative research synthesis is an extension of the same rules of inference required for rigorous data analysis in primary research. If primary researchers must specify quantitatively the relation of the data to their conclusions, the next users of data should be required to do the same. Before considering quantitative synthesis, it is important to take a closer look at some of the unique features off accumulated research results. In research synthesis, the most obvious feature of both main effects and interactions is that the results of separate tests of the same comparison or relationship will vary from one testing to the next.

Variability in Main Effect Test Differences in outcomes of tests of main effects can be caused by two classes of influence. One source of variance in the results of studies can be chance fluctuations due to the inexactness of sampled estimates-sampling error. The second source is variance in results created by differences in how studies are conducted or, who participates in them or, both.

Variability in Interaction Tests The factors that create variability in main effects can also affect variability in tests of interactions. Interaction effects are as susceptible to sampling error and procedural variation as main effects. The benefit of research synthesis underscores the importance of primary researchers presenting detailed information about the levels of variables used in their studies. Without specific information, research synthesists may not be able to conduct an across-study analysis.

Interactions in Meta-Analysis

There are two different ways that interactions could be statistically combined across a study.

Techniques for Combining Significance Levels of Independent Findings The separate p levels and re-

lationship strengths associated with each study's interaction test could be aggregated. The techniques for combining significance levels of independent findings allow the synthetists to cumulate the results of numerous tests so that overall conclusions can be drawn. In these techniques three assumptions are important. First, the individual findings that go into cumulative analyses should all test the same comparison or estimate the same relationship. Second, the separate tests that go into the cumulative analysis must be independent of one other. Third, the synthetist must believe that the primary researchers made valid assumptions when they computed the results of the tests.

1. Vote-counting methods can take into account the statistical significance of findings or focus only on direction of the findings. The most popular way to perform vote counts in research synthesis involves tallying the number of positive and negative findings regardless of their statistical significance. In these analyses, the synthesist categorizes findings based solely on their direction. If the null hypothesis is true – that is, if no relationships exist between the variables in the sampled population – it would be excepted that the number of findings in each direction will be equal. Once the number of results in each direction are counted, the meta-analyst performs a sign test (estimate Z score, for the overall series of findings) to discover the statistically significant frequency between findings in different directions:

$$Z_{vc} = \frac{(N_p) - (1/2N)}{1/2\sqrt{N}}$$

N_p = the number of positive findings
N = the total number of findings (positive + negative)
Vote counts should be described only when there is a large number of studies, and always be accompanied by more sensitive meta-analysis procedures.

2. Combined significance levels, by using the exact probabilities, the results of the combined analysis, take into account the different sample sizes and relationship strengths found in each comparison. The most frequently applied is called method of adding Z's (Z_{st} = z score for the overall series of findings):

$$Z_{st} = \frac{\sum_{i=1}^{N} Z_i}{\sqrt{N}}$$

Z_i = the standard normal deviation for the ith finding
N = the total number of findings in the series.
The method of adding Z's (Z_w the z score for the weighted combination of findings) can be modified to allow the meta-analyst to differently weight the results of different statistical tests. The meta-analyst might want to give added weight to findings based on larger sample sizes (because sample sizes affected significance levels):

$$Z_w = \frac{\sum_{i=1}^{N} W_i Z_i}{\sqrt{\sum_{i=1}^{N} W_i^2}}$$

W_i = the weighing factor associated with each finding

3. Fail-safe N answers the question "How many findings totalling to a null hypothesis confirmation (Z_{st}) would have to be added to the results of retrieved findings in order to change the conclusion that a relation exists"? The formula for calculating this number, when the chosen significance level is $p < 0.05$, is:

$$N_{FS.05} = \left(\frac{\sum_{i=1}^{N} Z_i}{1.645} \right) - N$$

$N_{FS.05}$ = the number of additional null-summing findings needed to raise the combined probability to just above $p < 0.05$

4. Combined significance levels and study-generated evidence are combined significance level techniques and results of vote-count.

Measuring Relationship Strength The primary function of the meta-analysis procedures described so far is to help the synthetist accept or reject the null hypothesis. Before a meta-analysis can be performed we must decide what statistics or effect measure will be used to describe the treatment effect. Each ▶ effect size index is associated with a particular research design in a manner similar to t-test being associated with two-group comparisons, F test associated with multiple group designs, and chi squares associated with frequency tables.

1. The ▶ *d* index measure of an effect size is appropriate when the means of two groups are being compared. The *d* index is typically used in association with *t*-test. Formula for calculating the *d* index is:

$$d = \frac{X_1 - X_2}{(SD_1 + SD_2)/2}$$

X_1 and X_2 = the two group means
SD_1 and SD_2 the average standard deviation of the two groups.
This formula assumes that the two groups have approximately equal sample sizes and standard deviation. If primary research does not report the means and standard deviation we can use the next formula for *d* index:

$$d = \frac{2t}{\sqrt{df_{\text{error}}}}$$

t = the value of the *t*-test associated comparison
df_{error} = the error degrees of freedom associated with *t*-test.

2. The ▶ *r* index is the most appropriate metric for expressing an effect size when the researcher is interested in describing the relationship between two continuous variables. Very often we do not have presented variances and covariances in primary research. Because of that, if only the value of the *t*-test associated with *r* index is given, the formula for its calculation is:

$$r = \sqrt{\frac{t^2}{t^2 + df_{\text{error}}}}$$

3. In the medical sciences, the ▶ odds ratio is most used. The researcher is often interested in the effect of a treatment on mortality or the appearance or disappearance of disease. Odds ratios are one way of expressing the size of the effect of a treatment on an even rate. The odds of an event are given as a ratio of the probability of occurring to the probability of it not occurring. The odds ratio is the ratio of the odds of an event in the treatment (or exposed) group compared to the odds in the control (or unexposed) group.

	With disease	Without disease
With treatment	*a*	*b*
Without treatment	*c*	*d*
Total	$a + c$	$b + d$

$$\text{OR} = \frac{a/c}{b/d} = \frac{ad}{bc}$$

$$95\%\text{CI}_{\text{OR}} = \exp[\ln \text{OR} \pm 1,96\text{SE}_{(\ln \text{OR})}]$$

When the event rate is very low or very high, the odds ratio is very similar to the ▶ relative risk. *Relative risk, relative rate or relative differences* of an event is the risk of the outcome in the treatment group divided by the risk in the control group.
▶ Number needed to treat (NNT) is a way of expressing the size of a treatment effect which is easier to interpret clinically. The NNT is the number of patients with a particular condition who must receive a treatment for a prescribed period in order to prevent the occurrence of specified adverse outcomes of that condition. This number is the reciprocal of the absolute risk reduction.

$$\text{NNT} = 1/\text{ARR}$$

$$\text{ARR} = \text{CER (control even rate)} - \text{EER (experimental even rate)}$$

$$95\%\text{CI} = 1/(\text{CER} - \text{EER}) \pm 1.96 \times \sqrt{\left[\frac{\text{CER}(1-\text{CER})}{Nc} + \frac{\text{EER}(1-\text{EER})}{Ne}\right]}$$

Nc = number of patients in the control group
Ne = number of patients in the experimental group

Combining Effect Sizes Across Studies

Once each ▶ effect size has been calculated, the meta-analyst averages the effects that estimate the same comparison or relationship. It is generally accepted that these averages should weight the individual effect sizes based on the number of participants in their respective samples.

1. *The d index.* For the *d* index, this procedures first requires the meta-analyst to calculate a weighting factor w_i, which is the inverse of the variance associated with each *d* index estimate:

$$w_i = \frac{2(n_{i1} + n_{i2})n_{i1}n_{i2}}{2(n_{i1} + n_{i2})^2 + n_{i1}n_{i2}d_i^2} \qquad d. = \frac{\sum_{i=1}^{N} d_i w_i}{\sum_{i=1}^{N} w_i}$$

n_{i1} and n_{i2} = the number of data points in Group 1 and Group 2 of the comparison

M

d_i = the d index of the comparison under consideration

$$95\%CI_{d.} = d. \pm 1.96 \sqrt{1 \Big/ \sum_{i=1}^{N} w_i}$$

2. *The r index.* Firstly, each r index is transformed into its corresponding z score, $z_{,i}$ and then the following formula is applied:

$$z. = \frac{\sum_{i=1}^{N} (n_i - 3) z_i}{\sum_{i=1}^{N} (n_i - 3)}$$

n_i = the total sample size for the ith comparison

$$95\%CI_{z.} = z. \pm 1.96 \Big/ \sqrt{\sum_{i=1}^{N} (n_i - 3)}$$

Analyzing Variance in Effect Sizes Across Findings

Another set of statistical techniques helps us discover why ► effect sizes vary from one study to another. In these analyses, the effect sizes found in the separate studies are the "dependent" or predicted variables, and characteristics of the studies are the predictor variables. For analyzing variance in effect sizes across findings we can use traditional inferential statistics, compared observed to expected variance and homogeneity analyses.

Traditional Inferential Statistics One way to analyze the variance in effect sizes is to apply the traditional inference procedures that are employed by primary research. There are problems. Traditional inference procedures do not test the hypothesis that the variability in effect size is due solely to sampling error. Therefore, the traditional inference procedures can reveal associations between design characteristics and effect sizes without determining first whether the overall variance is greater than expected by chance. Because effect sizes can be based on different sample sizes, they can have different sampling variances associated with them, that is, they are measured with different amounts of error.

Comparing Observed to Expected Variance In this method, the variation in the observed effect sizes is compared with the variation expected if only sampling error were causing differences in effect size estimates. This approach involves calculating the observed variance in the effect sizes from the known findings and the expected variance in these effect sizes given that all are estimating the same underlying population value.

Homogeneity Analyses Homogeneity analyses also compares the observed variance to that expected from sampling error. It includes a calculation of how probable it is that the variance exhibited by the effect sizes would be observed if only sampling error was making them different. Statistical models can be classified as "fixed effect" or "random effect models". A "fixed effect" model (► homogeneity analyses: "fixed effect" model) ignores between study heterogeneity and estimates the treatment effect as if it were a single true value underlying all the study results. "Random effect" models (► homogeneity analyses: "random effect models") take into account the possibility that other factors may modify treatment effects, and assume that the studies include in review a random sample taken from a distribution of the possible treatment effects. Both models express the uncertainty due to sampling in their estimates using ► confidence intervals. Usually the estimate of average treatment effects reported by both methods are very similar, but random effect models weight smaller studies proportionally higher than fixed effect models, which in some circumstance may lead to different estimates. This may be of particular concern if the identification of the smaller studies is affected by publication bias.

Here it is important to state explicitly, however, some circumstances in which the use of quantitative procedures in synthesis is not appropriate. First, quantitative procedures are applicable only to research syntheses and not to syntheses with other focuses or goals. Second, the basic premise behind the use of statistics in research syntheses is that a series of studies address an identical conceptual hypothesis.

Example In a meta-analysis the effect of selective decontamination of the digestive tract (SDD) on the rate of nosocomial infections was examined. Odds ratios (OR) together with their 95%CI were used for assessing the effect of treatment. OR for any study with this outcome is estimated, and then pooled OR. Information from 25 trials with 5964 enrolled patients was the base for aggregate data meta-analysis. Information

about nosocomial infection was obtained from 15 trials. In one study, 40/130 patients in the control group had infection and 21/147 in the group with SDD had nosocomial infection. OR for nosocomial infection, for this study is:

	With disease	Without disease	Total
With treatment	21(a)	126(b)	147(N_{1i})
Without treatment	40(c)	90(d)	130(N_{2i})
Total	61(M_{1i})	216(M_{2i})	277(Ti)

$\mathrm{OR} = 21 \times 90/126 \times 40 = 0.375$

$O - E$	V	OR	95%CI
21–32=-11	12	0.375	0.2–0.7

$$
\begin{aligned}
E &= (M_{1i}) \times (N_{1i})/T_i \\
V &= N_{1i} \times N_{2i} \times M_{1i} \times M_{2i}/T_i^2 \times (T_i - 1) \\
X^2 &= (O - E)^2/V = 10,08 \\
\mathrm{SE}_{(\ln \mathrm{OR})} &= 1/\sqrt{V} \\
95\%\mathrm{CI} &= \exp[\ln \mathrm{OR} + 1.96\mathrm{SE}_{(\ln \mathrm{OR})}] \\
&= \exp[-0.98 + 1,96 \times 1/3.46]
\end{aligned}
$$

For any study all these parameters must be examined and then pooled OR calculated:

$$\text{Pooled OR} = \exp\left(\frac{\sum (O - E)}{\sum V}\right) \quad \text{and}$$

$$95\%\mathrm{CI} = \exp\left(\frac{\sum (O - E) \pm 1.96\sqrt{\sum V}}{\sum V}\right)$$

OR equal 1 means no effect of treatment. An OR of less than 1.0 suggests that SDD results in a reduction in the relative odds of developing a nosocomial infection.

Metabolic Equivalents (METS)

Definition

Unit to characterize physical performance and the intensity of different types of exercise.

Metabolism

Definition

Metabolism is the transformation of (pharmacological) substances and their metabolites.

Metabolomics

Synonyms

Metabonomics

Definition

Metabolomics is the aggregate study of metabolites; a systematic study of the unique chemical fingerprints that are a result of specific cellular processes. Quantitative analytical approaches have been developed to identify metabolites that are modulated in response to treatment with toxic agents. Nuclear magnetic resonance (NMR) based fingerprinting has been applied to high-abundance metabolites. The metabolome represents the

collection of all metabolites in a biological organism, which are the end products of its gene expression.

► Measurement: Accuracy and Precision, Reliability and Validity

Methadone Maintenance

► Maintenance Therapy

Methicillin

Definition

Methicillin is a beta-lactamase antibiotic related to penicillin, which is no longer in use. In the 1960s methicillin was the first antibiotic drug against which staphylococci developed resistance. Nowadays, it is used as a test antibiotic, as resistances against methicillin can be assumed to be valid for other beta-lactamase-antibiotics.

Métis (Canada)

► Indigenous Health, North America

Microbiology

Definition

Microbiology is the study of micro-organisms which are living organisms that are too small to be seen with the naked eye, such as bacteria, viruses, fungi, algae, etc. As a branch of biology it examines the effects of such organisms on humans.

Microclimate

Definition

The term microclimate describes the condition of air in a certain closed space, usually referring to an occupational setting. The principle parameters of microclimate are air temperature, air pressure, air velocity, air humidity, and heat radiation, and their interactions.

Microwaves

Synonyms

MW

Definition

Electromagnetic ► radiation with a longer wavelength than infrared radiation but shorter than the radiation used in commercial radio broadcasting (radiofrequencies, RF) is called microwaves (MW). Wavelengths of MW are in the range from 1 mm to 1 m, and as the wavelength increases, the frequency decreases. The frequencies of the whole microwave region are about 300 GHz to 0.3 GHz (1 GHz equals 1 billion Hz), divided into extra high frequencies (EHG), super high frequencies (SHF), and ultra high frequencies (UHF), in decreasing order. The term radiofrequencies is restricted to frequencies below 300 MHz (0.3 GHz). Though natural sources of MW are the Sun and stars, man-made emitters far exceed natural sources, and are now likely to produce electromagnetic pollution. There are numerous useful applications of MW, such as radar (cloud detection meteorological radar, and shipborne navigational radar), satellite communications, microwave medical diathermal therapy, surgical diathermy, microwave ovens and heaters, television systems, altimeters, amateur radio, telemetry, etc. However, the fact that there are some dangers in MW device use must be emphasized because most people are exposed to low-level MW radiation and some of them, in certain occupations, may be exposed to higher levels. Most of the absorbed MW energy is converted into heat.

Midstream Urine

Synonyms

Clean-catch urine specimen

Definition

For proper urine analysis it is important to avoid bacterial contamination of the urine. After cleansing the urethral meatus a small amount of urine is passed into the toilet. The following amount – the midstream – is collected in a clean (sterile) container.

Migrant Children

LIANE SCHENK
Charité-Universitätsmedizin Berlin, Berlin, Germany
liane.schenk@charite.de

Synonyms

Young migrants; Children and adolescents from migrant families

Definition

The term "migrant children" comprises children and adolescents (► adolescence) whose life situation is shaped by their own experience of migration, by that of their families or by the status of belonging to an (ethnic) minority. Thus the children and young people have either migrated themselves or belong to the following generations. Their position in the life-cycle and the migration process is associated with special challenges and coping strategies that can have an impact on their health and health care behavior.

Basic Characteristics

Migration: A Cross-Generational Process

Migration may place its own particular imprint on the life-worlds of children and adolescents, both when they themselves are migrants or born into following generations. Seldom the decision to migrate is taken by one single individual; generally it is a project embraced by the whole family, a collective decision affecting it and future family generations. However, there are not just the expectations of the parents about the future prospects of their children that turn migration into a cross-generational process. Uncertainty about residence status, segregation tendencies, social disadvantage, and discrimination are some of the factors in the country of migration that can affect the life situations of migrant children and following generations in a different manner as they might affect lives of non-immigrant children and young people. Furthermore, the process of migration is associated with particular challenges to children and adolescents which are not shared by adult generations. In terms of rapid feats of assimilation such as learning the language and building social contacts, migrant children frequently adopt the role of mediators between parents and the host society, taking on adult functions whilst still minors. One of the most significant disruptions young migrants may experience is the disconnection between traditional modes of thought and perception in their families and the norms and values of the host society, a disconnection which they live out in a highly contradictory manner as travelers poised

between disparate cultural worlds. There is as yet no reliable body of research on whether and what impact such general conditions have on the health of children and young people from migrant families. Current studies suggest that migrant children – or sub-groups of children from migrant families – run greater health risks in certain areas of health than children from non-migrant backgrounds.

Health Risks or Benefits? Selected Findings

- Children who migrate from countries with a high prevalence of infectious diseases are a vulnerable group. In 2003 the risk of acquiring tuberculosis was 10.8 times as high among non-German children and adolescents than for their German counterparts. Children of migrants run a greater risk of infection at birth or from breastfeeding than children from non-migrants. In France, nearly 75% of newly reported cases of HIV are amongst women of foreign nationality, thus increasing the risk of perinatally transmitted HIV (► migrants, infectious diseases).
- Various research projects of ► unintentional injuries point at a connection between a migrant background and the risk of injuries. In Germany and Switzerland the rate of injuries was twice as high among migrant children as among their German and Swiss peers (Limbourg et al. 2003). Studies from other countries also indicate a higher propensity among ethnic minorities to be involved in accidents (Dowswell 2002). In the USA and Canada children of colored parents are a vulnerable group. Moreover, a study monitoring unintentional injuries in a German municipality showed an increased rate of unintentional injuries in migrant children compared to non-immigrant children. This elevation of the injury rate was most pronounced among boys aged 5–15 (Böhmann et al. 2004). Possible reasons for the higher incidence of accidents among migrant children include language barriers, social status and their provenance from regions with much less traffic.
- Genetic metabolic disorders are a form of hereditary impairment frequently noted not only in children of Turkish origin but in those from the Middle East and North Africa (Morocco). One explanation for the higher prevalence of such hereditary disorders among migrant children is seen in traditional ► consanguineal marriages (Stöckler-Ipsiroglu et al. 2005).
- In the USA, the Third National Health and Nutrition Examination Survey found clear ethnic differences in terms of cardiovascular risk factors (BMI, blood pressure, HbA1c, smoking and the fatty part of energy intake) among children and young people aged 6–24 years (Winkleby 1999). In Germany, surveys of first-year school children found a higher prevalence of overweight and obese children among the migrant group (Kuepper-Nybelen et al. 2005; Will et al. 2005).
- Ethnic origin has proved to be a further risk factor alongside socio-economic status for the prevalence of caries and the overall poor dental condition of children and young people. Such a connection has been demonstrated not just in developed industrialized countries like Norway, Sweden and Denmark, but also by studies in Arab and Latin American countries (Irigoyen 1999; Sundby 2003; Rajab 2002).
- Girls from migrant families from the Mediterranean area appear to have a high risk of suicide. For example, the suicide rate of Turkish girls and young women in the age group 10–17 years is almost twice as high as that for their German peers (Razum and Zeeb 2004). One possible explanation for this higher risk factor is that this age group has a particularly acute perception of the contradictions between the traditional gender expectations of the family and the cultural practices of mainstream society and that such contradictions can be perceived as irreconcilable.

However, it would be wrong to conclude that all children and young people from migrant families have a worse state of health or display more risk-prone behavior in terms of health care. Studies from Austria show, for instance, that the incidence of Sudden Infant Death (SID) is lower in the Turkish-speaking population than in the German-speaking population whilst in the Netherlands the incidence of SID among families of Moroccan origin was significantly lower than that among families originating from Turkey (Kytir et al. 1997; van Sleuwen et al. 2003). The causes of such a low level of SID risk were attributed to lower exposure to smoking and the nurturing structures of the (extended) family association. Migrant children from ethnic population with traditional lifestyles have lower prevalences of atopic disorders (bronchial asthma,

hay fever, skin affections) than populations with Western lifestyles, even after moving to a richer industrialized country (ISAAC 1998; Grüber 2005). Even so, as acculturation becomes more advanced, atopic risk factors also increase, among migrant children too. Studies into SID risk have showed similarly findings. It was noted that with increasing length of residence migrant groups tended to acquire the typical risk factor profiles found in the host country.

Challenges for Public Health

Such observations draw a diverse and patchwork picture. Compared to their peers with no migrant history, children and adolescents from migrant families appear more risk-prone in some health-related areas and less risk-prone in others. The migrant population itself continues to show significant differences in terms of their health and risk behavior. Migrant children can be differentiated by various factors including country of origin, the generation of immigrants to which they belong, gender and social status. In terms of the health care consequences arising from life situations of persons with migrant histories, a wide variety of factors are at work - of which the cultural background, the health care and social situation in the country of origin and the length of residence in the host country are only a few. Our current knowledge of the processes and mechanisms leading to health-related disparities between children and adolescents is still fragmentary. Furthermore, previous studies have put the focus very much on migration-induced risks to the detriment of resources like health-promoting habits or family cohesion. To date there are still no international studies which would allow us to analyze whether – and if so to what extent – the respective social conditions underpinning migration in their host countries impact on the health of children and young people of immigrant origin. It is the task of future research to address the migration process as a cross-generational experience in all its complex interplay of social class, gender, age and ethnicity.

Migrant Health

OLIVER RAZUM, FLORENCE SAMKANGE-ZEEB
Department of Epidemiology and International Public Health, School of Public Health, University of Bielefeld, Bielefeld, Germany
oliver.razum@uni-bielefeld.de, zodwa@freenet.de

Definition

Migrant health in the context of Public Health comprises policies and practices in relation to mobile populations. Migrant health not only addresses the needs of migrant populations, but also those of communities hosting migrants.

Introduction

The number of migrants worldwide is increasing. Moreover, migrants are traveling faster and to more destinations than ever before. Migration can have effects on the health of those migrating, both in positive and negative ways. For example, migrants face particular health risks at different stages of the migration process. At the same time, they may bring along resources that have a protective effect on their health. Immigration can also have health effects on the majority population of the host country. Increasing awareness of these risks and potentially positive effects has led to the emergence of migration health as a major public health concern (Wiedl and Marschalck 2001; IOM 2004a).

Definition of Migrants, Trends and Types of Migration

Definition of Migrants

In the World Migration Report 2005, the IOM defines migration as "a process of moving, either across an international border, or within a state. It includes migration of refugees, displaced persons, uprooted people and economic migrants" (IOM 2005). However, there is considerable ambiguity involved in the definition of migrants, and there is no definition that is universally agreed upon. Many countries are using their own definitions in their classification of travelers and migrants. International law distinguishes between nationals and non-nationals, for example, or between citizens, aliens, and immigrants. It also recognizes other categories such as refugees, asylum seekers and migrant workers (UNAIDS/IOM 2001). Migrants may be defined by their ethnicity or legal status and migration can be categorized using parameters of duration, motivation and distance. Labor migration, refugee migration, resettlement migration, internal migration and commuting are common and important categories (UNFMPA/IMP 2004). Often, migration does not occur directly between two places but involves one or several places of transit. Some of the reasons why people migrate are to join family members, for economic reasons or to continue their education in other countries. A considerable number are displaced persons, refugees or uprooted people (► refugees and internally displaced people). This Synopsis deals primarily with international migration; for health aspects of internal migration see ► migration, internal.

Migration can be voluntary or forced. In voluntary migration, a person or group of persons decide of their own accord to move. The decision could, however, have been brought about by economic or other pressures. In forced migration, on the other hand, the movement is due to external factors such as war, persecution or disaster. Often, push and pull factors, which can be economic, political, cultural, and environmentally based are simultaneously at work, making such classification only theoretical. An overview of different forms of migration is shown in Table 1.

Heterogeneity of Migrant Populations

The categorizations provided above do not fully reflect the heterogeneity of migrant populations. Migrants may differ considerably in socio-economic and cultural terms, even if they originate from the same country or region. In addition, the reasons and mode of migration, their legal status with respect to how long they can stay in the host country and under what conditions, especially the implications for their access to services and work, can all be different; and all these different factors can affect the health of migrants (Braunschweig and Carballo 2001).

Numbers of Migrants, Receiving Countries

The number of international migrants is increasing rapidly. In 2000, there were an estimated 175 million international migrants, more than double the 82 million from 1970 (IOM 2005). The UN estimates that by 2005, this figure had risen to 191 million, mean-

Voluntary migration	Involuntary/forced migration
Labor migration (including temporary contract workers)	Refugees/asylum seekers
Reunification of family members	Internally displaced persons (not always counted as migrants or refugees, ► Refugees and Internally Displaced People)
Educational purposes (students)	Environmental migrants
Persons returning to their countries of origin (return migration)	Trafficked persons
"Reintegration" – e. g. return of 'Aussiedler' (ethnic Germans) to Germany, of Jews to Israel	
Undocumented (irregular) migration	

Migrant Health, Table 1
Classification of types of migration

ing that 1 in 35 persons in the world is an international migrant; 95 million of them (almost 50%) are women (UN 2006). Table 2 shows the countries hosting the largest numbers of international migrants. There have recently been significant shifts in international migration. While traditional countries of immigration such Canada and the US continue to be attractive destinations, Russia, Germany and Ukraine are among the countries with the largest number of immigrants.

Most international organizations dealing with migrant issues base estimates of migrant numbers on data provided by the International Organization for Migration (IOM). Up-to-date figures by country can be found under http://www.migrationinformation.org/GlobalData/countrydata/country.cfm.

Country	Number of migrants in the country (in million, 2005)
USA	38.4
Russia	12.1
Germany	10.1
Ukraine	6.8
France	6.5
Saudi-Arabia	6.4
Canada	6.1
India	5.7
UK	5.4
Spain	4.8

Migrant Health, Table 2
Estimated number of international migrants in 2005, by country (UN 2006)

Changing Trends and Motives of Migration

Throughout history, humans have been moving from one place to another, internally as well as across borders. Contemporary migration, however, greatly differs from that of past times. The process of globalization has transformed the world. Due to modern technology capital, goods, service, information and ideas are rapidly being transferred from one country and continent to another. The benefits of the expanding global economy, however, are not evenly distributed. Growing social inequalities (► migrants, ► social inequalities), disparities in the standard of living as well as in levels of human security, are evident in different parts of the world. These rising differences have been associated with an increase in the scale and scope of international migration. Modern means of transportation as well as the opening up of borders between countries and regions have made it possible for people to travel further, faster and more easily than ever before. Migration is now a global issue, with all states of the world functioning as either points of origin, of transit or of destination, or at times as all three simultaneously (UNFPA/IMP 2004; IOM 2005; GCIM 2005).

Health in the Context of Migration

Role of Migrant Health

When related to the context of migration, the definition of health as given by the WHO translates into the physical, mental and social well-being of mobile populations as well as the communities affected by migration. Well-managed migrant health, including public health, not only promotes the well-being of everyone involved. The International Organization for Migration (IOM) argues

that it can also promote inclusion and understanding, thus facilitating the integration of migrants within communities, which, in turn, contributes to stable societies and enhanced development (IOM 2004b).

Historical Dimension of Migrant Health

The scope and patterns of migratory movements have never been static, and neither have the links and interdependencies between migration and health. They are evolving with the same complexity that characterizes migration (IOM 2003). Core issues relating to migration and health/illness today have a historic dimension and show a distinct continuity. An example of a concern that is centuries old and still causes worries today is the alleged importation of disease by migrants. During the plague epidemic in Europe in the 14th century, it was already acknowledged that human health and disease could be affected by migration. Formal systems of quarantine to hinder the flow of infectious disease through travel have existed for a long time and predate immigration laws (IOM 2003). Today, the general populations in target countries of immigration still worry about health problems such as epidemics being imported by migrants. Numerically, this is a small problem; furthermore, transmission is often restricted to the migrant populations (► migrants, infectious diseases). International travel for the purpose of business and tourism is far more common, and it carries a risk of disease spread, as the example of SARS shows.

In many industrialized countries of Western Europe, migrant health was for a long time restricted to keeping migrant workers sufficiently healthy so they could continue to work. It was expected that they would return to their countries of origin when ill or growing old. It is a relatively recent insight that migrant workers stay longer than initially expected. For example, they raise families in the host countries and in consequence often decide to remain there when getting old or chronically ill (► migrants, aging). Health services in many countries took a long time to improve access to health services for migrants, and a lot remains to be done (► migrants, access to health care). Concern has been raised that unless more attention is paid to the health and health care of migrants, they will remain socially secluded in many settings and not be able to benefit from the right to health due to every human being (the human rights perspective to migrant health).

As a consequence of the insights described above, a number of international and national legal instruments have been developed that set out the operational guidelines and structures for bodies concerned with health aspects of migration management. Some of these instruments (listed below) apply to people or workers in general, but it is important that they apply to mobile populations as well.

List of legal instruments setting out guidelines for bodies concerned with health aspects of migration: (IOM 2003)

- Since its formation in 1919, the International Labour Organization (ILO) recognizes the need to improve working conditions for both national and foreign workers.
- WHO constitution (1948): the enjoyment of the highest attainable standard of health is one of the fundamental rights of every human being without distinction of race, religion and political belief, economic or social condition.
- 1948: The United Nations Universal Declaration of Human Rights put forth all elementary human rights, including the right to health.
- The International Covenant on Economic Social and Cultural Rights of 1966 recognizes “the highest attainable standard of physical and mental health” for every human being and specifies steps to be taken to achieve this.
- In its 1977 Convention on the Legal Status of Migrant Workers, the Council of Europe refers to medical assistance for migrant workers.
- 1994: Programme of Action of International Conference on Population and Development (Cairo Conference or ICPD) urged governments to provide migrants and refugees with access to adequate health services.
- 1999: Final document proposing key actions for further implementation of Programme of Action of Cairo Conference urged governments in both countries of origin and of destination to provide effective protection for migrants and basic health and social services. Adequate international support to meet the basic needs of refugee populations including adequate accommodation, education, protection from violence, health services and basic social services such as clean water, sanitation and nutrition was also called for.

- 2002: The Second United Nations World Assembly on Aging in Madrid adopted an international plan of action calling for the integration of older migrants with their new communities by assisting them to sustain economic and health security.

Health Implications of Migration

Under normal circumstances, migration itself should not pose a risk to the health of those undertaking it. It is rather the conditions surrounding the process that can increase vulnerability to ill health. The risks concerned are related to the conditions before departure, during travel or in transit, on arrival or when settling in a situation of socio-economical disadvantage. For example, migrants who do physical work have a higher risk of injury and health sequelae leading to early retirement than the majority population of an industrialized country. In addition to physical stress, migrants experience a higher risk of psychosocial health problems. They may have to cope with temporary or permanent loss of contact to family and friends, disconnection with language, culture, homeland, loss of status, and loss of contact with their ethnic group. Psychological problems may be accentuated when migration is accomplished under adverse conditions (Carta et al. 2005). Irregular migrants are, in addition, exposed to considerable physical risks (see below).

Communicable Diseases in Migrants

Infectious diseases continue to be major causes of mortality and morbidity in certain parts of the world. This poses a challenge for health care providers and for national disease control strategies in countries receiving immigrants/refugees from areas where infections persist. The examples of tuberculosis and HIV are discussed below; for more general information see ► migrants, infectious diseases.

Tuberculosis is a disease that has been unevenly controlled globally. Consequently, a number of migrant-receiving countries are seeing changes in their TB profiles. For example, the incidence of new tuberculosis cases in Denmark increased in the early 1990s, with the proportion of foreign-born cases rising from 18% in 1986 to 60% in 1996. The Netherlands experienced a 45% rise in the number of reported TB cases between 1987 and 1995; at least 50% of these cases involved migrants. In Germany and France, migrants are three and six times, respectively, more likely to be diagnosed with TB than non-migrants are. Many migrants move into living conditions that are crowded and poorly maintained, a fact that plays a role in the spread of tuberculosis within migrant communities (Carballo et al. 1998).

The link between HIV and migration poses a challenge to governments and health care providers. Migrants who are prone to human rights abuses, economic deprivation, social inequalities (► migrants, ► social inequalities) and socio-economic instability are also particularly vulnerable to HIV. In many industrialized countries, migrants from high-prevalence countries were found to be disproportionally affected by HIV and AIDS. Many of these migrants discover their status late and fail to receive timely treatment. It is difficult to establish whether these persons were already infected when they arrived, or became infected in the destination countries. To avoid the double stigma of disease and foreignness, prevention efforts for migrants should be within the context of the overall national prevention strategy (IOM 2005).

Migration and Chronic, Non-Communicable Diseases

Migrants moving from one area to another, or from one country to another, ultimately "adopt" the health profile and risk factors for disease of the local population. This can happen at various speeds, depending on disease entity and country of origin. Migrants who "take along" a low risk of disease can maintain it for a long time, depending on their lifestyle (Razum and Twardella 2002). For example, the incidence of breast cancer and colon cancer in 'developing' countries is lower than in industrialized countries, and migrants benefit from this advantage. People migrating from countries with low mortality from coronary heart diseases (CHD) to countries with higher CHD mortality rates initially experience a mortality advantage. This advantage can be short-lived, however, as in the case of South Asian migrants to the UK.

It has frequently been observed that migrants experience a lower overall mortality than the majority population, in spite of being socio-economically disadvantaged. This phenomenon is discussed in the Essay ► migrant mortality, healthy migrant effect. Initially advantageous cause-specific mortality rates of immi-

grants may turn into a mortality disadvantage, however, when socio-economic conditions are unfavorable and access to health care is difficult. The duration of stay in the host country plays an important role in the modification of health status. There is substantial evidence for this 'acculturation' hypothesis. For example, South Asians in the UK originating from India, Pakistan or Bangladesh show higher rates of lung cancer and breast cancer than populations on the Indian subcontinent. In Canada, obesity among immigrants was found to increase with length of stay (Gatrell 2002).

Psychological Health of Migrants

Sluzki (2001) has identified five stages of the migration process shown in Table 3. Each of these stages may be associated with particular forms of stress or negative feelings for the migrants, which may in turn lead to psychological and physical health problems. Yet, the psychological burden of migration does not usually manifest itself soon after arrival in the host country. It is during the decompensation stage that problems, which may have been suppressed in earlier stages, present as somatic complaints. Exacerbations of chronic conditions for which care was not sought on time, because other concerns (such as basic survival) were more pressing, will also surface.

Migrant Health, Table 3 Stages of migration (Sluzki 2001)

Stage	Description
Planning	Characterized by excitement, anxiety, and tension. It may last hours, days or months
Migration	Duration may be only a few hours or up to years if living in a refugee camp
Over-compensation	Characterized by novelty and task-oriented adaptation. Usually lasts 6 months to 1 year after arrival
Decompensation	Characterized by acculturation and/or culture shock, loss, and mourning. Usually lasts 6 months to 1 year after arrival and may recur
Resolution, or stage of intergenerational support	Characterized by being occupied with rearing bicultural children or establishing a personal social network

Migrant Groups with Particular Health Risks or Poor Access to Health Services

A number of reports have documented the particular health risks, the reduced access to health care and the health consequences for migrants in many parts of the world. The unfavorable health outcomes observed have been linked to the lower entitlements for migrants in the receiving countries (Braunschweig and Carballo 2001; UNFPA/IMP 2004; IOM 2005). Migrants are not only exposed to poor working and living conditions, factors which are in themselves determinants of poor health. They also have reduced access to health care due to a number of political, administrative and cultural reasons not necessarily present for the native population. Different concepts of health and disease, language difficulties or the presence of racism are examples of barriers that migrants face (► migrants, access to health care; ► migrants, diversity management).

The risk of negative health outcomes is not equally distributed within the migrant population. For example, women may have a higher risk than men, due to poorer access to care or lack of empowerment. Migrants who do physical work experience a higher risk of industrial accidents compared to highly skilled computer programmers. In the following, selected risk groups are presented. More details are provided in dedicated essays.

Women

The increasing number of women migrants has led to more attention being paid to the particular problems they face during the migration process. As noted in the report "Meeting the Challenges of Migration" by UNFPA/IMP, migration can further female empowerment, e. g. by providing women with the opportunity to earn money as labor migrants, thereby becoming economically independent. However, there is also concern that migration of women can lead to an increase in their discrimination, exploitation, abuse and in their being at risk of being infected with sexually transmitted diseases such as HIV (UNFPA/IMP 2004). This issue is further discussed in the Essay ► migrants, sexual exploitation.

Migrating Adolescents and Children

Political turmoil, war and other social upheavals have led to a significant increase in the number of child and

adolescent migrants globally. In situations of forced migration, they face severe psychological repercussions, having to leave their homes and communities, schools and at times being separated from, or losing, their families. They also run the risk of being forced into childhood labor or trafficked for sexual purposes (UNFPA/IMP 2004). Also see ► migrants, sexual exploitation as well as ► migrant children.

Elderly Migrants

Elderly migrants have received scarce attention in public health debate and policy making up to date. Their numbers in host countries are, however, steadily rising as more and more migrants do no return to their countries of origin after retirement. The problems they face are not adequately dealt with by health and social services. Elderly migrants are vulnerable to discrimination not only based on age or gender, but also on race, ethnicity, religion, culture and language (Dietzel-Papakyriakou and Olbermann 2001). For more information see ► migrants, aging.

Victims of Forced Migration

Although the issues for the health of refugees are similar to those for other migrants, the basic problems are usually exacerbated. Forced migration has health consequences of a magnitude far greater than those associated with voluntary migration. Civil war, political persecution and the "ethnic cleansing" of the late twentieth century have led to the death of millions of people globally and to the detriment of the physical, mental and emotional health of many others. The displacement of refugees disrupt livelihoods, the production of food and the operation of health services (Gatrell 2002; UNAIDS/IOM 2001). The overcrowding in refugee camps, sexual violence, trauma of watching people, often family members, being killed and mutilated has far-reaching consequences for long-term mental health. Also see ► refugees and internally displaced people.

Asylum Seekers

Between the mid 1980s and the 1990s, the number of refugees and asylum seekers in industrialized countries increased substantially, with economic reasons gaining in importance. In consequence, many receiving countries revised their former openness to these population groups. Refugees and asylum seekers were not admitted into the country or confined in detention centers with only temporary forms of asylum. Asylum seekers living in the community in several countries face restricted access to work, education, housing, welfare and at times even to basic health care services. It can be assumed that post-migration stress adds to the effect of previous trauma and increases the risk of posttraumatic stress disorders and other psychiatric symptoms (Silove et al. 2000; Keller et al. 2003; Norredan et al. 2005).

Irregular Migrants

The mode of migration is also of importance for the health outcomes of the individuals concerned. Persons whose entry, residence and where applicable, employment in a host or transit country has been recognized and authorized by the State authorities are termed regular migrants. Of these, those who are able to plan their journeys, book a flight and make basic arrangements for their stay in the host country will be in a better position to take care of themselves than those fleeing persecution or war, with no resources of their own. Irregular migrants are those who enter, or remain in, a country of which they are not citizens without authorization. This category includes unsuccessful asylum seekers who do not observe a deportation order, smuggled or trafficked persons or persons who remain in the host country without renewing their stay permits when their official term of stay has expired. The risk of negative health consequences is substantial, starting with the often hazardous journeys they undertake to the intended host or transit country and consummating in the clandestine lifestyle they are forced to lead. Irregular migrants are also particularly vulnerable to racism, discrimination and xenophobia (Carballo and Nerukar 2001; ILO/IOM/OHCHR 2001; IOM 2005).

Health Opportunities of Migration

Unfortunately, discussions on migrant health are often focussing on health risks and adverse outcomes alone. This ignores that migrants tend to come from healthier and better-trained segments of sending communities. At the time of arrival, they are often in better health than the average of the host community. As migrant workers, they often expose themselves to higher risks in the workplace, in the agricultural and industrial sec-

tors as well as in domestic environments. However, relative to their countries of origin, they often have better access to health care and enjoy the benefits of the developed public health care system of industrialized countries (Razum and Twardella 2002). Thus, positive health effects may be considerable when compared to the situation before migration. In addition, there can be an indirect positive effect on the health of the population of origin: Remittances sent back home contribute towards improving the economic status of families, and thereby to improving their health (UNFPA/IMP 2004; IOM 2005). It is estimated that remittances from migrants to their home communities in developing countries exceed official development assistance and are only second to the foreign direct investment (IOM 2005).

Data on Migration and Migrant Health

Migration Data

Migration data form a vital part of the basis for formulating, implementing and evaluating migration related policies. Such data also assist in protecting migrants, in integrating migration issues into national development planning and in formulating target policies to reduce migration pressures (UNFPA/IMP 2004). The lack of migration data poses a major obstacle to developing effective migration policy and legislation and to sharing information amongst countries. The UNSD has issued guidelines and recommendations on concepts and methods to help countries in the collection and dissemination of their data. These recommendations are meant to improve the quality of data and promote the application of common definitions and concepts by countries to enhance the comparability of data internationally. Some of the obstacles to collecting comprehensive, accurate and timely migration data are associated with: (UN 2002)

- lack of specific and compatible definitions and poor comparability of data sources
- operational problems of how data are retrieved including the incompleteness of information over time, and
- political motivations that may influence how statistics are reported within and among governments.

In addition, some categories of migration data are particularly difficult to calculate or estimate. These include numbers relating to irregular migration, temporary/return migration and the gender dimension of migration. The fact that there is no single source of data to provide comprehensive figures on migration serves to make the situation more difficult. Administrative registers such as population registers, register of foreigners, residence permits, work permits, application for asylum and exit permits as well as border collection, census data and household surveys have been recommended as data sources. Most of these methods, however, have shortcomings. For instance, although residency permits constitute an effective way of counting the number of non-citizens at a given time, they often reflect the number of newcomers rather than the totality of persons with a migration background living in the country. Additionally, residency permits often no longer apply within free-trade areas and may therefore not be useful for data collection on particular nationalities in certain regions (UN 2002; UNFPA/IMP 2004).

Health Information Relating to Migrants

Health information relating to migrants comprises of representative and timely data on health, health behavior and health care uptake of migrants. Ideally, cost aspects should also be covered. Such data should form a vital part of the basis for formulating, implementing and evaluating policies related to the health of migrants. The data should be routinely collected, but often are not, or are collected but not routinely available or analyzed. A standard definition of the target group "migrants" should be used so that data are comparable within all administrative units of a country and over time. Even neighboring countries should use compatible definitions so that the effectiveness of different national policies towards the health of migrants can be compared. Improving availability and use of health information on migrants thus is one of the challenges facing Public Health policy literally everywhere.

Research on Migration and Migrant Health

The number of research centers around the world addressing migration related issues has increased in the past few years. This is particularly evident in developed countries, where governments are channeling more resources to migration research. Still, universities and private research bodies conduct much of the work. Countries such as Canada and Australia, which have 'in-house' research programmes linked to their

migration departments, are an exception. In developing countries, resources are rarely devoted to setting up migrant research programmes. This regional imbalance is accompanied by a difference in research priorities. For developed countries, topics such as asylum, irregular migration and migrant trafficking have priority. Developing countries, on the other hand, are interested in the whereabouts of their citizens and in strengthening collaboration between origin and destination countries (UNFPA/IMP 2004).

Research on migrant health takes two broad directions, one dealing with questions of equity in health and health care provision, the other investigating the role of nature vs. nurture in disease causation. Both encounter similar problems as those faced when collecting health information on migrants, such as finding an appropriate and operationalizable way of defining the group under study. Few countries such as Switzerland have conducted large-scale surveys on migrant health (► migrant health surveys). Epidemiological studies on disease causation compare the risks of populations of similar ethnic origin in different environments, i. e., in the country of origin and the host country. By analyzing variations e. g. in risk of coronary heart disease, the respective contributions of genetic traits and environment can be investigated.

Summary

The number of migrants (national and international) is constantly increasing. Governments and Public Health actors are continually faced with complex challenges when dealing with the various aspects of migration. Not only the health and welfare of the migrants should be considered, but also those of the communities they come in contact with during the process. In public debates, in policymaking and in research, migrants are often perceived as a homogeneous group. Migrants' gendered identities and cultural practices are often ignored. There is also little recognition of the gendered nature of refugee groups and the specific needs of female migrants. The heterogeneity of migrant groups and the varying definitions or classifications of the subgroups used make research and international co-operation difficult. The problem of reaching migrants, the lack of reliable migrant data, their isolation and the high mobility of certain migrant groups also pose challenges for health services and researchers alike.

Migrant Health Surveys

ALEXANDER ROMMEL
Wissenschaftliches Institut der Ärzte Deutschlands (WIAD) gem. e.V., Bonn, Germany
alex.rommel@wiad.de

Definition

Migrant Health Surveys are research projects designed to measure the health status and health behaviour of migrants through standardised interview questions and sometimes medical examinations. The corresponding questionnaires are used by interviewers in telephone or face-to-face interviews or have to be completed by the respondents themselves (self-administered questionnaires). In many cases, a Migrant Health Survey is part of a general health survey systematically considering migrants as a sub-group of the general population. According to scientific standards, a survey should be representative for a given population at national or regional level. If this sampled population comprises migrant groups, special efforts are needed to ensure their adequate representation in the study. In this respect, Migrant Health Surveys are characterised by migrant-oriented approaches at all stages of the study design (that is sampling, questionnaire construction, field work, contents and analysis).

Basic Characteristics

Sampling

The challenge of an adequate sampling procedure for Migrant Health Surveys starts with the *definition* of the term *migrant* as it shall be used in the study. The sampled migrant population of a survey can comprise the partially intersecting sub-sets of foreign nationals, naturalised immigrants, 2nd or 3rd generation immigrants, return migrants, asylum seekers, refugees and ethnic or minority groups. Facing this heterogeneity, researchers may decide to focus only on a few migrant sub-groups. Such deliberations particularly arise if the migrant sample is a sub-sample of the general population. Considering the fact that in most countries the migrant population is divided into groups of quite different sizes, a sample from the general population would represent only the largest of these groups in quantities that would allow stratified analyses. Consequently, in order to mirror the social and health related heterogeneity of the migrant sample population, it is recommendable to over-sample at least some migrant sub-groups. However, the issue of *over-sampling* involves the problem of identifying migrants in the general population. This task can be met using population register information like nationality or status of residence (Rommel et al. 2006) or by over-sampling and screening communities with high proportions of specific migrant populations (National Center for Health Statistics 1999; Erens et al. 2001).

Translation

The dataset of a Migrant Health Survey can only be said to be representative if all individuals of the sampled population had the same chance to be included in the study. As many migrants even of the 2nd or 3rd generation lack sufficient linguistic proficien-

cy of the national language of their host countries (*source language*), they would fail to understand many of the contents of the questionnaires mostly designed by host country nationals. To ensure the representative participation of migrants, one of the main tasks for Migrant Health Surveys is thus an adequate translation of the questionnaires into the migrants' mother tongues (*target language*) (Pennell et al. 2004; Schenk and Neuhauser 2005; Rommel et al. 2006). Otherwise the migrants, especially those less integrated, will refuse to participate in the study and the resulting migrant subsample will be biased. To critically evaluate questionnaires that have been translated in a language other than the mother tongue of the researcher, *forward/backward translations* independently done by various professional translators have proven to be useful (for procedures and problems cp. Small et al. 1999; Acquadro et al. 2004; Ponce et al. 2004; Rommel et al. 2006). For economic and pragmatic reasons, only a restricted number of languages can be covered. Consequently, predefined sub-samples for selected migrant groups may be favoured over a general population sample (see above).

Cross-Cultural Equivalence/Linguistic Validation

The adaptation of questionnaires to the needs of migrant groups is not confined to the translation act. During or after the translation process, it can be helpful to request the assistance of *bi-lingual experts* – at best migrants themselves – who are familiar with the characteristics of a determined migrant community as well as migrant specific health concerns (Pennell et al. 2004; Rommel et al. 2006). Their revision of the translated questionnaires is one possible step to ensure not only the *content validity* but also the *construct validity* of the translated instruments. While content validity only indicates the linguistically correct translation of contents, construct validity is achieved if an instrument in the target language measures the same scientific concepts as the corresponding items in the source language (Harkness et al. 2003; Bhopal et al. 2004; Ponce et al. 2004). This includes that expressions are not only translated correctly, but are also commonly understandable and verbalise comparable contents. In this respect, a further procedure established to scrutinise the comprehensibility of survey questions and the accuracy of underlying concepts is ► cognitive pre-testing through qualitative interviews or focus groups (Campanelli 1997; Acquadro et al. 2004; Bhopal et al. 2005). This procedure should be conducted by bi-lingual collaborators; its aim is to include linguistically less integrated migrants as the main target group of the translated questionnaires.

To definitely ensure construct validity before field work, extensive standard pre-testing under field conditions and subsequent statistical analysis would be necessary. Many statistical methods to assess construct validity are available (Harkness et al. 2003) and especially the preparation of standard indices for the employment in various languages and cultures underlies quite strict scientific rules (psychometric testing). However, for economic reasons, these procedures are frequently not included in the *standard pre-testing* of comparatively large questionnaires of multilingual population surveys. As a result, the final assessment of construct validity is postponed to data analysis after field work and researchers have to take the risk of partially suboptimal data quality. Nevertheless, even if the budget is restricted, standard pre-testing should not be given up completely. Even a few interviews in each language can provide information on how the questionnaires work in the field and interviewer debriefing can be applied to achieve final improvements before field work starts (Pennell et al. 2004; Rommel et al. 2006).

Field Work

The field work of Migrant Health Surveys should be announced well in advance by a bi-lingual letter which explains the aims of the study, clarifies issues of data protection and tries to dispel migrant-specific reservations against the quest for information on behalf of a public institution or research institute (Erens et al. 2001; Schenk and Neuhauser 2005; Rommel et al. 2006). The latter applies especially to migrant groups with mainly foreign nationalities which may fear for their status of residence or expect other supposed negative consequences. As a result of the translation and validation procedure, it is a characteristic of Migrant Health Surveys that *bi-lingual interviewers* familiar with the contents of the study and potential linguistic problems are at the disposal of the interviewees (Small et al. 1999; Erens et al. 2001; Rommel et al. 2006). In telephone or face-to-face interviews, either the whole field work has to be done by those interviewers or it must be indicated before and at the

beginning of the interview that the questionnaire can be alternatively completed in the mother tongue of the interviewee. In any case, the rate of interviews in languages other than the source language will increase considerably if the first contact is made by compatriots of the interviewees. In postal or ► examination surveys which use self-administered questionnaires, different language versions can be provided. It is then up to the respondents to choose the version they want to complete or to change languages depending on their comprehension of the individual questions.

Contents and Analysis

In addition to the well-established social, health and behaviour indicators of general health surveys, Migrant Health Surveys are characterised by *migrant specific topics*. As a minimum standard, indicators for the definition of the respondents' social and migrant status should be among the contents of the questionnaire. This comprises *education and vocational training abroad* (to measure correctly the social status), *place of birth* and *nationality* of the respondents and their parents (to identify naturalised migrants and to derive the generation after migration), *year of migration* (to derive length of stay) and *status of residence* or *motivation of migration* (to identify migrant groups, e. g. asylum seekers, students, immigrant workers, refugees, return migrants etc.) (Schenk and Neuhauser 2005). Moreover, depending on the research interest aspects of *integration* (e. g. language skills, language spoken at home, social networks, cultural practices), perceived *discrimination*, self-ascribed *ethnicity, religion* and *religiousness* or specific aspects of *service utilisation* (e. g. communication problems, culturally adequate care) can be taken into account (Rommel et al. 2006).

Regarding *analytical strategies* (► stratified analysis) for Migrant Health Surveys, two approaches can be distinguished. On the one hand, the analysis can focus on the comparison between host population and migrant groups. Simple content analyses of cross-tabulations give first insights into the differences and similarities between groups. In multivariate models the significance and intensity of differences in health and behaviour can be estimated, controlling simultaneously for general confounding effects like sex, age, social status etc. On the other hand, migrant-specific indicators cannot be compared with the host population. Instead, they provide a deeper understanding of specific living conditions and typical biographical configurations. Such data thus allow assessing the heterogeneity within the migrant population beyond ethnicity or nationality, and the corresponding effects on health and health behaviour.

Migrant Mortality, Healthy Migrant Effect

Oliver Razum
Department of Epidemiology & International Public Health, Bielefeld University, School of Public Health, University of Bielefeld, Bielefeld, Germany
oliver.razum@uni-bielefeld.de

Definition

The "Healthy Migrant Effect" describes an empirically observed mortality advantage of migrants from certain countries of origin, relative to the majority population in the host countries, usually in the industrialized world. Occasionally, it relates to a relatively lower morbidity of immigrants as well. The Healthy Migrant Effect also serves as an *ad hoc* explanation when migrants are found to have a better health status in spite of being socioeconomically disadvantaged. The Healthy Migrant Effect is not theoretically founded; it is often reduced to a presumed selection of healthy individuals at the time of migration (which is an insufficient explanation).

Basic Characteristics

Migrant Mortality: A Paradox

Socioeconomic status is known to be strongly and inversely associated with mortality: Those who are poor, unemployed or have a low educational attainment experience higher mortality than the rich, employed, and well-educated. In many destination countries, migrants have, on average, a lower socioeconomic status than the majority population. Their mortality, however, overall as well as for certain specific causes, is often lower in comparison – a paradox (Razum and Twardella 2002). This has been observed in the US, in Germany, in the UK, and in Canada (see Table 1). The mortality advantage of migrants has been called "Healthy Migrant Effect", thereby alluding to the "Healthy Worker Effect", the mortality advantage of workers in employment, relative to the general population (which also comprises diseased, non-working individuals with a higher risk of mortality).

What is the "Healthy Migrant Effect"?

Firstly, the question has to be resolved whether the observed mortality advantage of migrants is real or due to bias. One possible explanation is the "salmon bias". Its underlying claim is that gravely ill migrants tend to return to their countries of origin. This leads to a numerator-denominator (▶ numerator-denominator bias) mismatch and thus to an underestimation of mortality. Study designs that are based on repeated cross-sectional analyses are prone to this type of bias. For example, a considerably lower all-cause mortality was observed among male Turkish migrants in Germany than among German men (Razum et al. 1998). In a longitudinal design, however, their peers in the Netherlands had a higher mortality than Dutch men (Bos et al. 2004). Still, this observation cannot be generalized: Table 1 shows other large studies that found similar mortality advantages (Singh and Hiatt 2006; Ronellenfitsch et al. 2006; Sheth et al. 1999). Moreover, cohort studies which could rule out return migration confirmed that there are real and sometimes quite large mortality advantages of migrants (Swerdlow 1991; Abraido-

Migrant Mortality, Healthy Migrant Effect, Table 1 Mortality risk of migrants relative to the population of the host country

Origin	Host country	Data source	Measure	Relative Risk		Reference

China	Canada	Canadian Mortality Database	RR	0,55	0,63	(Sheth et al. 1999)
Mexico	USA	National Longitudinal Mortality Study	HR	0,57	0,60	(Abraido-Lanza et al. 1999)
Vietnam	England	National Health Service Register	SMR	0,64	0,56	(Swerdlow 1991)
Former USSR§	Germany	Population and Cause of Death Statistics	SMR	0,89	0,81	(Ronellenfitsch et al. 2006)
Mainly Latin America, Asia	USA	National Mortality Data	RR	0,77	0,84	(Singh & Hiatt 2006)

* Former "Guestworker" from Mediterranean countries (Turkey, Yugoslavia, Italy, Spain, Portugal); men and women combined
§ "Aussiedler" (return migrants of German origin). RR: *Relative Risk*; HR: *Hazard Ratio*; SMR: *Standardized Mortality Ratio*

Lanza et al. 1999). More studies based on individual follow-up are needed to analyze the size and direction of observed mortality differentials.

The data sets used for many of the studies listed above have an additional limitation: the association between socioeconomic indicators such as unemployment on the one hand, and health outcomes on the other, is merely ecological (► ecological association). Thus it remains unclear whether migrants with a low socioeconomic status have a higher or lower mortality than those of high socioeconomic status, and how social mobility of migrants affects their mortality. Only measurements at individual level can help to further clarify the determinants of trends in disparity. They should be complemented by measurements of community attributes such as the extent of discrimination. Clearly, present studies examine only selected aspects of the association between migration and health (Davey Smith 2000).

Explanatory Models

Given the many studies reporting a mortality advantage of migrants, this advantage may be real, rather than due to bias. Various explanations for an actually lower mortality of migrants, relative to the populations of origin and of the host country, have been proposed. The most common one is mainly healthy and active individuals migrate. Immigrants would thus have a mortality advantage. However, it is important to note that this advantage would be relative to the population from which the migrants originate – not necessarily relative to the population of the host country, as is usually implied (Razum and Twardella 2002). To better understand this effect, future migrant studies have to include the populations of origin of immigrants as well.

Another explanatory model interprets migration from low-income to industrialized countries as a speeded-up progression along the continuum of the ► health transition, thus in effect picturing migrants as time travelers. Relative to the situation in industrialized countries, these migrants come from a "past" stage of the health transition (Razum and Twardella 2002). They have been exposed to fewer or lower doses of risk factors for cardiovascular and other non-communicable diseases. They will experience a mortality advantage for such diseases even years after migration and the adaptation of a "Western" lifestyle because of the long lag-times between exposure and death. At the same time, they will immediately benefit from better access to medical care for infectious diseases and emergencies, further increasing their mortality advantage. To investigate the dynamics of these effects, duration of stay in the destination country needs to be measured. In addition, a detailed breakdown of ethnic and geographic origin is required because some disease risks are brought from the countries of origin.

Can the Paradox be Resolved?

To better understand mortality differentials and their change over time, three additional requirements would have to be fulfilled. The first one is to base future studies on an explicit model of migrant health and its determinants (Razum and Zeeb 2004), taking into consideration the complexity of the association between migration and health (Davey Smith 2000). Secondly, these determinants would have to be measured longitudinally and at individual level. Such a migrant cohort would, of course, also be useful to investigate the respective roles of nature and of nurture in disease aetiology.

A migrant cohort measuring behavioral and socioeconomic variables at individual level would require considerable resources, which many a migrant researcher has failed to obtain so far. Epidemiological migrant studies appear to have come to a dead stop for another reason, however (and this is the third requirement): An "ideal" prospective migrant study which could help to understand the mortality paradox would have to enroll individuals *before* they migrate (these individuals would be the very ones that are usually categorized as "lost to follow-up" in cohort studies because of moving abroad). Follow-up would need to continue in the country of destination and, in case of return migration, again in the country of origin. Achieving sufficiently large sample sizes, however, would be a challenge (Razum 2006).

Migrant Mortality and Public Health

Given the unexplained nature of observed mortality differentials, the mortality of migrants cannot be considered a good indicator for their socioeconomic and general health status. It is well conceivable that migrants from Mediterranean countries are disadvantaged in many respects in an industrialized host country of the north, and yet their cardiovascular mortality remains lower than that of the majority population for

many decades. This observation would merely reflect the mortality advantage of their country of origin relative to that of the host country. Some particular causes of death, however, are more informative with regard to equity in health care. Among these are infant mortality and maternal mortality. These should decline to levels close to those experienced by the majority population within a short time after migration if care is equitable (Razum and Zeeb 2004). Remaining differentials usually have to be interpreted as an indication of barriers that migrants face when accessing and utilizing health services in the host country.

Migrants, Access to Health Care

THEDA BORDE
Alice-Salomon-Fachhochschule, Berlin, Germany
theda.borde@gmx.de

Definition

Most health care services are insufficiently adapted to the socio-cultural diversity of the clientele they are trying to serve. Problems of access, the lack of cultural competence in health care providers, lack of special provisions (such as interpreter services, translated health education material) may all be structural barriers to access and to quality care. Differential impact of health care services may be linked to discriminatory practices in the health care system, inadequate health care concepts and structures dealing with diversity but also to a lack of skills of the health professionals. Such obstacles need to be overcome to improve access of migrants to health care services.

Basic Characteristics

Cultural Background or Socioeconomic Status?

Health care institutions and providers are increasingly challenged to understand and address the needs of an ethnically diverse clientele appropriately. The international interest in 'culturally responsive care' parallels recent developments in medicine such as patient-centered care, the enactment of charters of patients' rights, and the growing importance attached to the outcome of health care interventions and to patient satisfaction. Cultural differences, however, might be less of a barrier to equitable health and equitable access to health care services, than socio-economic factors, migration factors, discrimination and the selective impact of health care. As ethnic health patterns broadly reflect socio-economic differences between migrants/ethnic minorities and the majority population, it is essential to

develop policies to improve the socio-economic status and the general participation chances of these groups.

Because of legal, financial, linguistic or cultural reasons, it may be impossible or some difficult for migrants and ethnic minorities to access the health care system, or to receive the same quality of care as the majority population. Discrimination and racism have been observed in the domain of health care, and this at a systemic level as well as at the level of individual institutions and/or health care providers.

Some migrant groups (e. g. undocumented immigrant) have only very limited access to the health care system (e. g. limited to emergency care). Access to the health insurance system may not be possible without legal status and/or working permit, etc. Although most ethnic minorities are included in compulsory insurance systems, disparities in access to health care are not limited to direct access. Once they are patients in health care services, the quality of care they receive may be lower than that received by patients of the majority population.

Perceived Quality of Care

Migrant patients have shown to be less satisfied with, and less informed about, the treatment received in the hospital (Borde et al. 2002). Deficiencies in mental health care for migrants lead to a high rate of premature abandonment of treatments. Health professionals seemed to agree with their patients on the fact that the quality of care they delivered was below standards. Unresolved language barriers have been proved to dramatically affect the quality of care received by migrant patients (Bowen 2001; Jacobs et al. 2003). As such, access issues should be viewed as quality issues. Smedley, Stith and Nelson (2003) have added that substandard care for some groups, be it related to problems of access or of quality of services delivered, should raise the concern that the provision of care may be inconsistently and subjectively administered.

Language and Information

Linguistic barriers, combined with low socio-economic status, may also reduce access to information on the functioning and possible benefits of health care services. A lack of knowledge of the health care system and how to use it may hamper access and lead to inadequate use of health care services. As a result of language barriers, health care providers may fail to meet ethical standards in providing health care. Language barriers may result in failure to protect patient confidentiality, or to obtain meaningful informed consent (Kaufert and Putsch 1997). Consensus exists that the provision of professional health care interpreters is an important prerequisite to guarantee equitable access to, and quality of care to many ethnic minorities. Professional interpreters may have an important impact on the acceptability of health care services and patient satisfaction in ethnic minority groups.

Cultural Differences and Expectations

Partly culturally determined beliefs, concepts, types of behavior, traditions and religious convictions may have a profound impact on the expectations and interactions of ethnic minorities with the health care system. Cultural diversity may affect the cross-cultural health care encounter. Examples include views on nutrition/diet, explanatory models, different types of traditional healing systems, views on surgery and transplantation, autopsy, on communication with the diseased (e. g. the communication of bad news), visiting ill persons, the process of dying and death, religious rituals to be executed at birth/death, gender relationships (acceptability of a health care provider of the opposite sex to the patient), etc. (Henley and Schott 1999). When cultural differences are insufficiently taken into account (e. g. lack of respect for the values and convictions of ethnic minority patients), this may make health care services culturally unacceptable for these groups, leading to cultural barriers to care. When health care institutions lack cultural competence, this may affect the accessibility of the health care system.

Structural Discrimination

Cultural differences may only account for a small portion of the health problems experienced by ethnic minorities. Structural discrimination in the health care system, the experience of racist and discriminatory practices inside and outside the health care system, do seriously affect the expectations of ethnic minority patients and their interaction with the health care system. Health professionals and institutions need to gain awareness of these processes, learn to detect them, understand their possible impact on the outcome on

access, quality of care and treatment. The development of culture competence or cultural responsiveness would add to the efficiency and effectiveness of health care provision to ethnic minorities (Bischoff 2003; also ► migrants, diversity management).

Information, Education, Empowerment

Patient education, participation, activation and empowerment (► patient empowerment) have to be given more attention. Some populations may lack the knowledge and skills to use the health care system appropriately and to live a healthy lifestyle. Low 'health literacy', as this phenomenon has recently been labeled, may lead to health problems and to an inadequate use of health services. Undocumented migrants and refugees are often insufficiently aware of their (limited) rights to health care, and as such may not seek medical attention for their health problems. Ethnic minorities and migrants are often poorly reached by health education and promotion programs that are oriented towards middle class population. Culturally sensitive health/patient education programs are needed to give migrants more control over actions and decisions that influence their health. Of special importance are programs that inform on how to access and use the health care system in an effective way. Health information materials and programs, health promotion campaigns and interventions have to be tailored to the needs and characteristics of migrants and ethnic minorities considering their specific sociocultural life circumstances: it may be necessary to translate material, provide audio- or video-taped material for (semi)illiterate groups and groups with low educational status.

Research makes clear that it is important to involve members of the target groups in the preparation and implementation of health promotion initiatives for ethnic minorities. These can provide access, valuable information on strategies and self-organizations that can help to improve the impact of health promotion activities. At a systemic level, the quality of care could be improved through the active participation of ethnic minorities in needs assessment, program development, implementation and evaluation. In order to improve access of migrants to health care they need to be considered in the development of an integrated social/health policy and corresponding policies in health care institutions as a constitutive part of the population.

Definition

► Elderly persons are defined as those over 50 years of age in some European surveys (Weber et al. 2004). However, most international organizations and surveys refer to the ageing population as those over 60 years of age and to very old persons as being 80 years and older (United Nations 2002; Mette 2005).

Basic Characteristics

Significance for Public Health

Migrants are found to be a population group with specific health risks. Their access to health and social care facilities is often limited compared to that of the indigenous population (International Organisation for Migration 2003). These now well-known facts were explored and discussed in health sciences for several decades. More recently, the impact of these facts on the ageing migrant population has become apparent. Several discourses reflecting global and regional developments contributed to this attention: The fact that global ageing will be pervasive and enduring (United Nations 2002) and that this development will be accompanied by an epidemiological transition boosting chronic and old-age-related diseases led to new priorities in health care planning and delivery. Gerontological and geriatric aspects of care are now a major issue. This includes a growing awareness of the most vulnerable groups among the ageing population. The growing significance of migrants is also stressed by the sheer number of migrants world wide, and the expected increase in this number.

As a consequence, health planning and delivery have to take the constantly growing population group of elderly migrants into account on a regional scale. This is experienced as an unprecedented challenge, especially by countries which recruited migrant workers in the 1960s and 1970s in large numbers (in Europe: Germany, Netherlands, Belgium, Austria). Elderly migrants are a rapidly growing population group in these countries, as the available data of the European Union show (Eurostat 2005). European countries with a colonial past like France and United Kingdom had different immigration patterns which lead to a slightly less pointed population distribution with regard to the ageing population (Eurostat 2005). Nevertheless, ageing minorities pose also in these countries a specific challenge for planning of care. In addition, a broader diversity of ethnic and language groups among the ageing migrant population has to be considered. Thus, in many countries, specific demands of a rapidly growing ageing migrant population group have to be identified and new structures and resources for adequate care need to be created within a short period of time.

Health Determinants of Ageing Migrants

Migration is regarded as a potentially stressful event. Yet, the ability to cope with a new environment and to adapt to a new socio-cultural sign system is unequally distributed in the migration population. It is important to recognize this heterogeneity when assessing potential health care problems of ageing migrants and when establishing health and social care programmes for these migrants. Varieties are associated with the migrants' socio-cultural background (urban areas/remote areas/religion) and with the reasons for migration (Mette 2005; also ► migrant health). The following social and health-related risks in the intersection of old age (► socio-cultural definitions of old age) and migration are of special relevance for this population group:

- Low average incomes and high dependency rates on welfare
- Objective and subjective health problems and early ageing due to the effects of dirty and heavy work
- Health risks related to unfavorable housing areas
- Mental and psychological health problems resulting from migration-related experiences and hardships
- Psychosocial stress due to experiences of discrimination, maladaptation to the host country and an experience of having failed original objectives of the migration
- Experience of being stereotyped and lack of interculturally adequate institutional support in age- and health-related questions (also ► migrants, diversity management)
- Intergenerational conflicts as the second and third generation tend to cultivate life styles similar to the indigenous population. Yet, family networks as well as interethnic networks tend to be more reliable and supportive than those of the indigenous population
- Isolation in ethnic groups and tendencies of enhancing ethnicity and culture.

Social and Health Services for Ageing Migrants

A variety of social and health care services has been established in the last decades in countries of high income to support the elderly and very old and their families. Many of these services are criticized for being insufficient and insensitive to the specific demands of ageing migrants. Thus, ► socio-cultural barriers are hindering ageing migrants to use existing services and to

obtain adequate support for their needs. Lack of sufficient information dissemination about available services for ageing migrants is another aspect which seems to have a severe impact on their health and social care seeking behavior. Pressurized by the rapid population growth of ageing migrants and in acknowledging an increasing acceptance of (im)migration as a social fact and supported by anti-discrimination and patient rights regulations, welfare and health care organization committed themselves to a greater extent to an interculturally sensitive work. The following aspects are seen as central for this endeavor (also see Essay Improving Access of Migrants to Health Care):

- Enabling communication between migrants and service deliverer
- Dissemination of information in native languages for ethnic groups
- Changes in structure and processes of services to support an interculturally adequate outcome.

Putting intercultural aspects on the agenda fills a long documented gap in health and social care settings. However, evidence from health research is showing that the socio-economic status is the most important determinant in patterns and causes of disparities in health and health seeking behavior. In the long run, prevention of inequalities in the care of ageing migrants must be sought in policies supporting education and acculturation of migrants. Participation in economic and social life constitutes the main route for supporting the integration of migrants.

M

Definition

The term "diversity" refers to a social and cultural variety or heterogeneity in a specific context, especially on a national, local, organizational level, and even in kinships. Diversity is created by a range of components. The most important components are migration, racial or ethnic origin, nationality, mother tongue, religion or belief. These are combined with gender, sexual orientation, age, physical challenges and disability (cf. the EU Equality Directives 2000). Diversity is not a stable state; it is an ongoing process. International migration contributes in a very dynamic way to diversity. Public health professionals have to develop sensibility towards diversity and its management because diversity is strongly associated with the risk of unequal treatment.

Basic Characteristics

Driving Forces

Diversity is an emerging theme of the Public Health agenda (WHO 2003). The driving forces of diversity in Public Health are

- the ongoing globalization, the enlargement of the European Union,
- international migration (including refugees and asylum seekers) (GCIM 2005; IOM 2005) and labor mobility (including highly skilled health professionals),
- different stages of migrant integration on national and local levels,
- an evolving positive self-image of minorities and colored people,
- a rising awareness regarding health disparities between nations and groups.

Public Health is especially responsible for managing diversity in an appropriate way in order to reduce health disparities. Thereby, all functions of Public Health are challenged:

- Public Health as a professional service system with a social setting approach,
- Public Health as an employer responsible for both the diversity competence of management and staff and the agility and responsiveness of the organization,
- Public Health as a provider of training programs for health professionals,
- Public Health as a population related interdisciplinary science.

The European Union promotes the awareness regarding diversity and equality in order to reduce discrimination and to realize equal opportunities for all (EU Equality Directives 2000).

Old and New Patterns of Diversity

Diversity is context-bound. This means that the specific profile of a population is coined by national and local history as well as by political decisions. Some examples of particular population groups illustrate this: In Germany, so-called 'Aussiedler' are the largest immigrant group. They have a German background and immigrated from different countries and regions of the former 'Eastern bloc'. In Great Britain, the composition of the population is influenced by minorities and migrants from the former colonial empire. In the United States, autochthonous Indians contribute to the map of diversity (► autochthonous population). Furthermore, each country has developed an own system to classify and quantify diversity (European Kommission 2004).

Old patterns of national and local diversity are changing. Ongoing international migration and mobility, the processes of local inclusion or seclusion, relations between groups and an emerging self-confidence of minorities (e. g., black and colored people in predominantly white societies) are forces with an impact on the social construction of diversity and equality. The emerging new patterns of diversity are complex, ambiguous, and dynamic. In addition, the new diversity is not easy to quantify in statistical terms, because it is much more a social quality. Public Health professionals are forced to rethink the paradigm and concept of diversity in use. This is inevitable for monitoring the equal treatment of people from different backgrounds in an appropriate and non-discriminatory way.

Diversity and Equality

Diversity is not only a term for describing the manifold differences in a social context. In many cases, diversity is stereotyped and valued in a negative way. Migrants, refugees, and asylum seekers in particular are victims of ignorance and exclusion. In consequence, the term diversity is strongly coupled with the term equality. It is a social-political term which covers the potential discrimination of individuals and groups on grounds of diversity criteria. This means that diversity needs to be interpreted as a multi-dimensional approach of observing, analyzing, and promoting equality in Public Health. This implies a change in perspective: Diversity should not be conceptualized as a deficit and risk; it should be seen as an important resource, too.

Direct and Indirect Discrimination

It is important to take into account two types of discrimination: direct and indirect discrimination (EU Equality Directives 2000; Geiger 2006). Direct discrimination occurs where a person is treated less favorably than another in a comparable situation on grounds of diversity criteria. In comparison to indirect discrimination, direct discrimination is much more explicit.

Indirect discrimination can be subtle and occurs where an apparently neutral provision, criterion or practice would put persons from different background at a particular disadvantage compared with other persons. For example, migrants are not explicitly excluded from health services. Still, migrants face considerable barriers (e. g., lack of information, insufficient knowledge of

the foreign language, different cultural concepts) that hinder the access to relevant health services (WHO 2003; also ► migrants, access to health care). In everyday life, subtle and multiple forms of discrimination are predominant. Multiple discrimination is based on a combination of two or more stereotypes regarding diversity (e. g. elderly colored migrants) (WHO 2003).

Managing Diversity in Public Health

Managing Diversity – Internally and Externally Diversity is a challenge to Public Health organizations and professionals and requires a proactive management. Diversity management in Public Health covers both an outward-oriented and an inward-oriented strategy. The outward-oriented strategy promotes and favors services that are appropriate for, and responsive to, diversity by ensuring access for all; while the inward-oriented strategy seeks to increase diversity competence in the workforce in order to improve the services that have to meet diverse needs. Thereby, the so called '► demographic imperative' becomes a driving force of Public Health development. It is important to highlight that the implementation of diversity/equality policies and practices involve the entire Public Health system and the success strongly depends on the commitment of both management and staff.

Approaching Diversity – Options In the contemporary landscape of Public Health system one can find many different approaches to managing diversity. The most important are (Geiger, Razum 2006; compare Adler 2002):

- The diversity-free approach. This approach is based on ► parochialism or ► ethnocentrism. This means that the existing procedures are considered as the only or best way. Diversity is ignored or conceptualized as disturbance; potential biases are not reflected.
- The trans-diversity approach. The basic assumption of the trans-diversity approach is that it is possible to develop a Public Health standard and service for all groups irrespective their different backgrounds.
- The diversity-specific approach. This approach suggests that equality will be reached by health services exclusively conceptualized for specific groups. 'Positive action' could be seen as a synonym.
- The diversity-sensitive approach. The diversity-sensitive approach takes into account the complex processes of social diversity. The basic idea is that Public Health has to display a new dimension of reflexivity, flexibility, and quality respecting the divers and changing needs of the population. This approach is comparable to 'diversity mainstreaming'.

The diversity-specific approach and diversity-sensitive approach are the pillars of mainstreaming diversity – the preferred strategy of the European Union.

Mainstreaming Diversity – a Dual Strategy The European Union recommends a dual diversity/equality strategy: so-called 'diversity mainstreaming' as the dominant strategy combined with so-called 'positive actions' if required. Diversity mainstreaming is a continuous process. This means that each decision is coupled with considerations regarding the impact of and on diversity/equality (Commission der Europäischen Gemeinschaften 2005). Therefore, Diversity mainstreaming covers policies, provisions, processes, and practices in Public Health organizations. Positive actions are seen as additional specific programs. They are required to provide equality of access and equality of participation for the most disadvantaged groups.

Main Challenges The diversity/equality frame of reference is challenging the Public Health system. The most important aspects are:

- rethinking the concepts of diversity and the coupled strategies of managing diversity,
- matching the workforce and the workflow in Public Health organizations to the diversity profile of the population,
- developing performance indicators for monitoring the success of diversity management in Public Health.

Managing Diversity in Public Health can be seen as a professional and organizational strategy valuing diversity as a health resource, aiming to fight discrimination, and promoting equal health opportunities for all.

Definition

► Infectious diseases are caused by a variety of biological agents such as viruses, bacteria, fungi, parasites and their toxic products. They arise through transmission of the agent from an infected person, animal, or reservoir to a susceptible host where they trigger a pathological reaction. In contrast to non-communicable diseases, the population dynamics for infectious diseases are particularly influenced by the transmission patterns between infected persons or animals and exposed susceptible individuals.

Basic Characteristics

Background

In developed countries, a higher prevalence of infectious diseases can be observed among migrant populations compared to the native population. This is due to the fact that migrants often come from developing countries where infectious diseases are still rampant. There, infectious disease accounts for approximately 44% of overall mortality and substantial morbidity, a finding that has remained almost constant over the last decades (World Health Report 2004). This burden of disease includes also the sequelae of chronic infectious diseases such as cancer (e. g. hepatocellular carcinoma as a consequence of chronic hepatitis B or hepatitis C infection). In addition to sick individuals, healthy persons are also of great importance for the transmission dynamics in populations. They sometimes carry the infection without knowing (carriers) and may thus transmit it to susceptible individuals. Infections also represent an underestimated threat for people who travel from the Northern hemisphere to the developing world, be they migrants or tourists.

Examples of infectious diseases which contribute significantly to the burden of disease in migrant populations include tuberculosis, diarrhoeal diseases of various origin as well as hepatitis A, B and C. Further examples are vector-borne diseases such as malaria and dengue, sexually transmitted infections (HIV/Aids, syphilis, *Chlamydia* infections, hepatitis B, human papilloma virus infection) and *Helicobacter pylori*-associated diseases (Prüfer-Krämer and Krämer 2004, Rothenbacher et al. 1998, Van de Laar et al. 2003, Migliori and Centis 2002, Marschall et al. 2005, MMWR 2006).

Population Dynamics

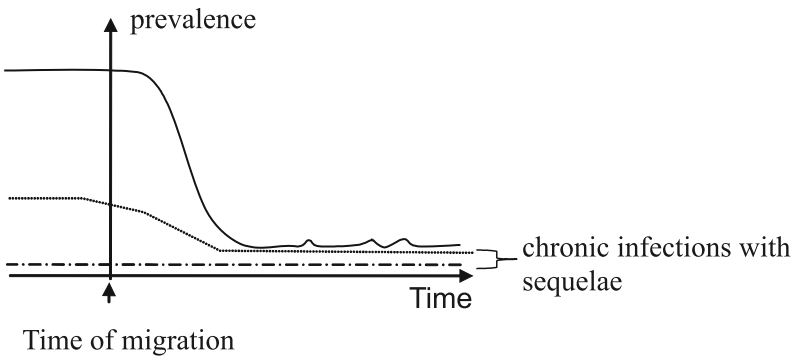
Migration from developing to developed countries bears opportunities as well as risks (epidemiological transition) for persons. Better management and treatment of infectious diseases in developed countries make it possible for known or newly diagnosed infections to be effectively treated. Where this occurs, the incidence and prevalence of acute infectious diseases such as malaria and hepatitis A in migrant populations may reach levels similar to those in the native population. However, it is possible that during visits to the country of origin, individuals again become exposed to infectious agents with a high local prevalence. They may thus acquire the infection and import it to the country of destination. We then observe an increase of incident cases and possibly outbreaks in the migrant population. In the case of chronic infections, a substantially high level of endemicity will remain even after long periods of residence in the country of destination. This may be the case for several chronic infections like tuberculosis, HIV/Aids, and hepatitis B and C (Fig. 1). Possible reasons are: 1. the infection is not diagnosed and therefore not treated. 2. The infection is treated, but insufficiently so. 3. Effective treatment for the infection is not available in spite of a correct diagnosis. 4. Social disparities prevent access to adequate health care.

Underutilization of Health Services

From a public health perspective, migrants are generally underserved or inadequately treated in their host countries, e. g. with regard to the management of infectious diseases. This has several reasons: 1. the patient's (migrant's) poor knowledge about the disease. 2. The physician's or health care worker's poor knowledge of rare tropical diseases. 3. The patient's limited access to health care facilities due to information deficits and language barriers (► migrants, access to health care). This mismanagement does not only relate to the medical treatment *per se*. More importantly, it also includes preventive activities such as the provision of vaccination to migrant children (► migrant children) or effective advice on the prevention of sexually transmitted diseases.

Public Health Recommendations

Public health programs are needed that address these issues and lead to a better health service for migrant populations. To start with, it has to be realized that migrant groups differ (► migrants, diversity management). In order to provide an effective service the origin of the migrant has to be considered, because the local endemic situation defines the *a priori* probability for a specific infection. Due to rising global migra-



Migrants, Infectious Diseases, Figure 1 Diagram showing the development of acute and chronic infections among migrants in relation to time of migration

tion rates it is necessary that public health programs in destination countries include continuing education of health care personnel regarding the changes in migration waves. This knowledge is necessary not only for specialists such as tropical diseases physicians but also for general practitioners, community doctors, nurses, and the migrant community itself. The training and/or establishment of specialists for migration medicine and public health are a further option for the future. Despite the high impact of infections on the burden of disease in migrants, these subpopulations lack adequate awareness and information. The distribution of information linked to campaigns against hepatitis B, sexually transmitted infections and tuberculosis through community-based participatory actions provides a promising option for creative and effective public health interventions. Finally, the improvement of infectious disease control in developing countries through effective vaccination programs, vector control, education and adequate treatment will possibly lead to extensive reductions in the burden of infectious disease there.

The increasing irregular migration requires special attention due to several reasons: 1. their often low socio-economic status is linked to higher prevalence rates and risky behavior (e. g. commercial sex, drug use). 2. Screening programs fail to reach irregular migrants. 3. Irregular migrants have very limited access to health care and treatment.

Need for Research

For Europe and other parts of the world, indicators for a monitoring system for infectious diseases in migrants and minorities has to be developed, using existing health-related data bases and surveys. Currently, there is very limited evidence-based research on migration and infectious diseases. There is a need for new epidemiological and public health studies in these subpopulations (► infectious disease epidemiology). The establishment of a European network of epidemiological observatories for the health of minorities will be helpful to generate an evidence base for public health policy. Such a network can produce comparable data on socio-demographic and health profiles of ethnic minorities with respect to infectious diseases.

Migrants, Sexual Exploitation

SIEGRID TAUTZ
Evaplan GmbH, Universitätsklinikum Heidelberg, Heidelberg, Germany
siegrid.tautz@evaplan.org

Definition

Globalization with its increasing cross-border movement of capital, goods and people facilitates human trafficking in its various manifestations such as forced labor (including sexual exploitation), organ trade and child adoption trade. As a consequence, there has been a world-wide increase in commercial sexual exploitation in recent years, in particular so of children. Children are most vulnerable to sexual exploitation. Their case will be presented as exemplary for a wider problem.

Sexual exploitation of children and young people encompasses a broad range of sexual acts including touching with sexual intent, sexual intercourse and display of pornographic material or sexual organs. *Commercial* sexual exploitation of children (CSEC) includes child prostitution, child pornography and child trafficking for the purpose of sexual exploitation.

Basic Characteristics

Legal and Human Rights Framework

According to international law, all forms of sexual exploitation of underage girls and boys constitute human rights violations. The most important international document is the *Optional Protocol on the Sale of Children, Child Prostitution and Child Pornography* which came into force in 2002 with the aim of combating sexual exploitation. It supplements the 1989 *UN Convention on the Rights of the Child*. The 1989 Convention states that all persons below 18 years are "underage", i. e. children, and hence need special legal protection.

The Scale of the Problem

Despite the marked increase of human trafficking and CSEC observed in recent years, there is no reliable, evidence-based estimate on the overall scale of the phenomenon, a weakness that stems from the nature of the problem of trafficking and CSEC: It happens illegally and is often linked to organized crime, and available data are often not disaggregated according to age (adults/children), sex and type of exploitation.

Recording and analysis of the phenomenon has not been standardized within (federal) states and internationally. Thus, one of the main crucial tasks in the combat against CSEC is to significantly improve and standardize data collection and analysis.

Where Does Commercial Sexual Exploitation of Minors Predominantly Occur?

A significant proportion of CSEC, especially child prostitution, is carried out by local perpetrators within their home countries. However, it is increasingly an international phenomenon, whereby the increase in *international* trafficking is associated with two political developments in particular: the opening of the borders between East and West, and economic globalization, whose logic implies the search for sites that allow the most profitable utilization of goods and people worldwide.

Currently, central regions of CSEC are (South) Eastern Europe, the Mekong Region (e. g. Thailand, Vietnam, and Cambodia), Eastern and Southern Africa, Brazil, Central America and the Caribbean. Sexual exploitation of minors within the tourist industry accounts for part of the problem in these regions. Central European countries are important destinations and transit countries for girls being forced into prostitution (May-Chahal and Herczog 2003; ILO-IPEC 2001, 2003; IOM 2001).

Causes and Background

The causes and contexts of CSEC are diverse and complex and underscore the inequalities between those who prostitute themselves or are forced into prostitution on the one side (supply), and those who pay for sexual services on the other (demand).

Gender-Specific and Cultural Aspects Females account for the major proportion of the victims whereas more than 90% of the perpetrators are male. One reason for this striking gender ratio is gender-specific violence and discrimination. In many societies, females are not only discriminated in terms of their reproductive, sexual and physical self-determination, but also suffer legal disadvantages. However, even if females do enjoy equal rights according to the respective national law, societies do not necessarily treat women as legal subjects, which may be attributed to cultural norms and practices.

Poverty and Transformation Processes Almost all country-specific surveys on CSEC state a lack of income sources as the most important driving force behind the fact that minors prostitute themselves (ILO-IPEC 2001). Sudden collapse of family structures and intra-familial violence can exacerbate the problem. In some parts of Africa and Asia, AIDS-orphans face a dramatic risk (ILO-IPEC 2002).

Major transformation processes, which are often accompanied by growing poverty, can lead to erosion of values and norms. Females are particularly affected by this, putting them at higher risk of becoming victims of sexual exploitation. This has for example been the case in countries of the former Soviet Union.

In regions of armed conflict as well as in post-war situations, destruction of the basic necessities of life and the

accompanying lack of opportunities to generate income make women and children vulnerable to commercial sexual exploitation and trafficking.

Paedo-Sexual "Demand" and the Growing Global Sex Industry The prerequisite for CSEC is the existence of a "market". Demand from adults for sex with children and for child pornography is on the increase throughout the world (► paedo-sexual behavior). This is evident in the global sex industry, which helps to create a profitable market for child prostitution. Sexual exploitation of women including minors – alongside trading in drugs and arms – is one of the most lucrative illegal businesses worldwide. Growing demand is also observed in the tourist sector.

Lack of Law Enforcement In many countries legal action against CSEC is inadequately pursued. Protecting women and children from sexual exploitation is often denied high political or legal priority. Inappropriate criminal prosecution signals a low risk to the perpetrators.

How Does CSEC Affect the Victims' Health?

The impacts of sexual violence on the victims' health are considered significant (Busza et al. 2004; WHO 2003). Effects can be short and/or long term and – depending on gender, age, and personal history – can vary considerably. To date there have been few investigations into the global public health problems resulting from the large numbers of children forced into prostitution (Willis and Levy 2002). It is known, however, that disorders resulting from sexual exploitation affect the personal health of victims and have implications for public health (Zimmermann et al. 2003; WHO 2003). They include:

- physical impact (injuries, particularly to internal and external sexual organs);
- psychosomatic impact;
- psychological impact (► post-traumatic stress disorders, loss of self-respect, depression);
- health-endangering behavior such as drug abuse, high-risk sexual practices;
- impact related to ► sexual and reproductive health (sexually transmitted diseases, HIV/AIDS, unwanted pregnancies and unsafe abortions);
- self-harm and suicide.

Trafficked women and girls are particularly seriously affected because their often illegal status forces them to avoid making use of public services. The fear of being handed over to the police, as well as the fear of being shunned and discriminated against by their families and peer group, complete the vicious circle.

Preventing and Combating CSEC

Intervention strategies involve developing and strengthening criminal law and its enforcement. They also include primary and secondary prevention and the protection and rehabilitation of victims. Since, in many cases, sexual exploitation takes place in connection with trafficking, cross-border networking between institutions in all sectors is crucial. In addition, the involvement of communities in particularly affected regions in identifying and solving problems has proven successful: Child traffickers and job brokers find it more difficult to commit their crimes in circumstances where there is social responsibility and respective control mechanisms. Strengthening the victims' life skills to develop self-protection mechanisms and self-confidence is considered to be another essential feature of primary and secondary prevention. Among the most important strategies however, are interventions to reduce poverty.

The Health Sector's Response

The health sector has so far responded weakly to the challenge with little involvement in the debate or interventions aimed at combating CSEC and rehabilitating its victims (Beyrer 2004; Busza et al. 2004). There are numerous fields of action, for example:

- The existing data base should be improved by epidemiological and qualitative investigation. Evidence-based results should then be used to develop public health interventions.
- Access to health care services must be adapted to suit the particular life situation of victims. This may include: treatment of injuries, diagnosis and treatment of sexually transmitted diseases, HIV/AIDS testing, antiretroviral treatment, ► emergency contraception ("morning-after pill"), post abortion care and safe abortions, psycho-social and trauma counseling, and the development of standardized examination protocols incorporating reference systems from child and youth protection organizations. To

tackle these challenges, inter-sectoral co-operation needs to be strengthened and personnel in the health sector needs to receive respective training.

Definition

In the context of migrants, social inequalities refer to disadvantages, e. g. in education, in working and living conditions and in economic resources, experienced by groups for whom their extra-territorial origins serve as identity marker in their host communities. In most countries, a considerable proportion of migrants lives in socially deprived conditions and therefore experiences social inequalities relative to the majority population. Such inequalities usually, but not necessarily, result in visible and measurable health disadvantages.

Basic Characteristics

Socioeconomic Status and Health

Most known societies are heterogeneous in socioeconomic terms; different parts of the population live under different socioeconomic conditions, have different levels of education, etc. Such differences often provide the basis for social stratification, e. g. in social classes. Socioeconomic status or social class is in general associated with health status. Frequently, a pronounced gradient is visible: The socially most advantaged groups have the best health status while the socially most disadvantaged groups tend to have the poorest health status (Townsend 1982; Wilkinson 1996; Helmert et al. 1997; Hart et al. 1998; Adler and Ostrove 1999). The pathways through which this association operates are complex; they include macroeconomic, social, environmental, and behavioral factors. These factors, together with genetic background and life course factors, act on the health status of an individual.

Being migrant increases the probability of living in socially deprived conditions or of being a member of the lower social classes. Such class membership is usually associated with a disadvantaged health situation. However, migrants differ from indigenous populations in many other aspects that are also relevant to health. The differences range from genetic background to lifestyle and nutrition (► migrant health). Thus, not all health differences of migrants are the result of social inequalities. It follows therefore that a disparity in risk is not necessarily an indication of inequity; equal risks, on the other hand, do not necessarily imply equity in health (► migrant mortality, healthy migrant effect).

In addition, migrants often face disadvantages in access to health care (► migrants, access to health care). To

M

some extent, this limited access may be explained by the social deprivation of migrants, although socially deprived non-migrants also encounter barriers to access. Deprived population groups, whether with or without a migration background, tend to have fewer health-related resources, e. g. a lower health literacy. In consequence, both groups have lower participation rates in prevention programs. There are, however, additional factors affecting access that are specific to the circumstances of migrants: discrimination, racism, language barriers, etc. Thus the question arises as to the degree to which inequalities in health risk among migrants are an expression of social inequalities, or of inequity in health care. Identifying and quantifying the contributing factors in a particular setting could help to develop appropriate strategies towards improving the health of migrants – as well as that of other disadvantaged groups.

Unfortunately, differences or similarities in the risk of specific diseases do not lend themselves as an adequate measure of equity. In a hypothetical example, similar mortality rates from cardiovascular disease (CVD) could be the result of rather different conditions that are not necessarily all a result of inequity. Consider the following scenarios:

- Migrants and indigenous populations have the same mortality from CVD and equal access to prevention and health care resources. This would obviously be an equitable situation.
- Migrants have a lower mortality from CVD (due to nature or nurture factors), but the potential benefit in risk is reduced by lower access to health care. This would be an inequitable situation, because the relative increase in risk among migrants would be avoided if migrants had equal access to health care, thus it would be unnecessary and unfair.
- Migrants have a naturally lower mortality from CVD, but the migration process increases their risk. Due to changes in their lifestyle or living conditions, rather than lower access to health care, migrants may experience a significant increase in risk up to the level of the indigenous population. If the increase is the result of unhealthy living or working conditions caused by social deprivation, and the effects of this deprivation could be avoided, this would constitute an inequitable situation. However, the increase could also be the result of deliberate changes in lifestyle that are not forced by social deprivation, e. g. a change in food habits. The increase in risk might then be indeed avoidable, but not necessarily unfair and so not an expression of inequity.

When morbidity or quality of life is considered, the picture is equally complex and findings are sometimes contradictory. For example, disadvantages in health status among migrants, compared to the majority population of the host country, sometimes become visible only in middle age. In order to assess for equity and fairness, it is therefore not sufficient to consider only risks. The objective of migrant-sensitive health care systems and research must be to analyze and consider the different needs, risks and their causes in different social groups (► migrants, diversity management).

Equitable Health Care for Migrants

There is no agreement in Public Health as to whether a health care system based on a libertarian (► liberalism and libertarianism), egalitarian (► egalitarianism) or utilitarian (► utilitarianism) framework is the best or the most fair (see Culyer 1993; Frankfurt 1997; Rawls 1999; Roberts and Reich 2002). From the point of view of migrants' needs, the objective of health care systems cannot be to produce equality in risk, but to care for individuals' needs in a fair way while respecting their differences (see Frankfurt 1997). A person will feel respected if his or her individual characteristics and needs as an individual are recognised and attended to. Respect, like equity, cannot be achieved by aiming merely at equality: Treating all persons the same way is not necessarily an indication of respect; it may simply be a consequence of not knowing the specific needs and wishes of specific groups (such as migrants). Equality would then merely be the lowest common denominator and an ideal "which must be implemented in the absence of considerations showing that an alternative is required" (Frankfurt 1997). In order to avoid the trap of the lowest common denominator, more research is needed on how migrants' needs differ from those of the majority population, and how these differing needs can best be met within the constraints of an existing health care system. The more knowledge there is about the specific risks and needs of migrants and other social groups, the more attention a health care system can pay to these differences.

There are various, partly overlapping strategies to overcome social inequalities that migrants are facing; if

successful, such strategies would contribute towards improving migrants' health. General social and economic measures such as transfers will not be discussed here. Examples of strategies with a strong focus on health and health care for migrants include:

- Diversity management; this is an approach on the side of the health care providers; it takes advantage of knowledge about differences between population groups to establish just, fair *and* respectful health services (► migrants, diversity management).
- Improving health literacy among migrants; this approach requires active contributions from both providers of services and from migrants themselves. Its objective is to help migrants to increase their understanding of all aspects of health and health care, including body functions, preventive measures, access routes to health care etc.
- Empowerment, which takes the idea of improving health literacy a step further. The empowerment of migrants seeks to enable them to identify the conditions that determine their health status and to find out how to change them. Attractive in theory, this approach poses many practical problems; it may suffer from low acceptability, especially among older and "traditional" migrants.

Social inequalities among migrants usually, but not always, show a negative impact on their health. Equity in health risks and outcomes among migrants, relative to the majority population, is a goal that may be difficult to achieve. Health care services need to be more responsive towards the needs of an increasingly diverse population. This will help to ensure that migrants and other minority groups are treated more fairly and respectfully. Social and economic measures seeking to improve the situation of disadvantaged groups in general should be designed in such a way that they also reach migrants, thereby contributing to better health of this group.

Department of Epidemiology and International Public Health, School of Public Health, University of Bielefeld, Bielefeld, Germany
maren.bredehorst@uni-bielefeld.de,
oliver.razum@uni-bielefeld.de

Definition

"Brain Drain" describes the emigration flows of highly skilled professionals. The term implies a loss of valuable competences to the migrants' place of origin. This loss may become a barrier to human and economic development. Brain drain occurs within and across national boundaries, but also between different sectors of the economy. Most commonly, the term is applied for international migration towards wealthier, industrialized countries. As for the health sector, nurses and medical doctors are at the focus of interest. Their emigration is regarded as having considerable impact on the health care systems in their home countries.

Basic Characteristics

Growing Demand for Health Professionals Worldwide

Demographic and epidemiological trends in both industrialized and developing countries have led to an

increasing demand for skilled health workers and will continue to do so. While countries in the North have to deal with an aging population and a greater share of chronic diseases, countries in the South are carrying a large ► burden of disease stemming from poverty and epidemics. HIV/AIDS in particular is a threat to health systems in developing countries as it is increasing the workload and at the same time diminishing the workforce (WHO 2006). Worldwide gaps in human resources for health result of a history of under-investment and deficient ► workforce planning. Not only is there a shortage of workers in total; their geographical distribution and the skill mix within professional teams is often inadequate as well. While migrant professionals help to reduce disparities between rural and urban areas within industrialized countries, their movement increases the disparities between countries (Geiger, Razum 2006). For example, 33% of doctors and 10% of nurses working in the United Kingdom trained abroad. In Germany, this accounts for 17,318 doctors and 26,284 nurses, equivalent to 6% and 3% of the respective total workforce (WHO 2006) (p. 98). While the importance of workforce planning in the health sector is increasingly recognized, it is hampered by a weak knowledge base. This is concerning the scale of the phenomenon as well as the effectiveness and efficiency of planning tools and policies (Chen et al. 2004; Diallo 2004).

Push Factors – Unfavorable Working Conditions

Low wages and an unsatisfactory work environment are the two major forces that drive health professionals to look for other employment opportunities. Surveys among nurses in Southern countries reveal that the wish to migrate is widespread. Besides the payment, they mention insurmountable workloads, unsupportive management and colleagues, and a lack of promotion opportunities as underlying reasons. Moreover, the situation and work morale is aggravated by the ongoing outflow of professionals (UNFPA 2006). Psychological exhaustion may also stem from working in a situation of violent conflict and disaster, or from being confronted with a growing demand for terminal care of AIDS patients. These conditions put health workers at an increased risk for their personal health and safety, which is often inadequately addressed (WHO 2006). Consequently, a number of health professionals resign from the health services in their place of origin, either to migrate or find work in other economic sectors. Table 1 illustrates the gaps that doctors from sub-Saharan Africa leave behind when they migrate to ► OECD countries. The number of those who have registered abroad constitute up to 29% of the home country workforce, as in the case of Ghana. Regarding nurses, this percentage even amounts to 34% in Zimbabwe. The largest total number of 13,496 migrant nurses from a single sub-Saharan country comes from South Africa (WHO 2006) (p. 100).

Pull Factors in a Globalized Labor Market

The increasing number of vacancies in the health sectors of many industrialized countries together with a much higher wage level and standard of living, is per se an attractive factor for health professionals from a resource-poor background. If the country of origin provides poor general living conditions, even taking up an unskilled job in an industrialized country might be an acceptable alternative. Information technology such as the World Wide Web helps to communicate vacancies around the globe easily. In addition, during recent years labor markets have been opened through ► trade agreements and the mutual recognition of diplomas. Agencies from countries such as Great Britain and the United States have even developed active overseas recruitment mechanisms to meet the shortages of nurses and doctors in their domestic health systems (Stilwell et al. 2004). This momentum is reinforced by growing communities of migrant health professionals who are already established in the respective host countries – some of them even having received their training there. They serve as links for others who are considering to migrate. Networks of such migrant workers often transfer considerable amounts of money – so called remittances – to their family members who remained back home, thereby increasing the attraction of work migration (IOM 2005).

How to Manage Migration of Health Professionals

Effective management of health workers' migration has to consider both sides: the push and the pull factors. The World Health Report 2006 proposes strategies for source countries and receiving countries of international migration. Most importantly, it emphasizes that the migration of health professionals has to be rec-

Source country	Total doctors in home country	Doctors working in eight OECD recipient countries[a]	
		Number	Percentage of home country workforce
Angola	881	168	19
Cameroon	3,124	109	3

Migration and Brain Drain, Table 1 Doctors trained in Sub-Saharan Africa working in OECD countries

ognized as a concern of the international community similar to any other emerging health crisis that single countries cannot deal alone with, such as natural disasters or infectious disease epidemics. The focus is on national leadership as governments are usually carrying the responsibility for public services, educational and financial policies (Chen et al. 2004). Strategies have to be adapted to national and professional particularities such as disease profiles, mechanisms of resource distribution, or the power of professional bodies.

As for source countries, the focus should be on training schemes that meet the actual needs, and on the improvement of local working conditions – which usually requires the support of receiving countries. The latter should also develop responsible recruitment policies and ensure that migrant workers are treated fairly (WHO 2006). ► Recruitment and retention schemes are of importance on both sides to move towards self-sufficiency and avoid the loss of professionals for the health sector.

There are examples of bilateral agreements to regulate the issuance and duration of work permissions, e.g. between South Africa and the United Kingdom. The Philippines encourage citizens who work abroad to send remittances through official channels and support the return of migrant workers by offering them scholarships and loans at preferential conditions (WHO 2006). A number of guidelines, tools and codes of practice have also emerged. However, such measures need to be evaluated to strengthen the foundation for future policy making and migration management (Chen et al. 2004; Stilwell et al. 2004).

Balancing Values: Ethics in Global Workforce Planning

The United Nations' ► millennium development goals are aiming to reduce worldwide childhood mortality by two thirds, and maternal mortality by three quarters until the year 2015. In the fight against HIV/AIDS, Malaria and other major diseases, unfavorable trends in incidence are to be reversed. These goals can only be achieved with a massive investment in the health workforce, particularly in countries most affected by these health problems. It seems to lie at hand to propose restrictions to the migration of health personnel. However, it is not only considered a breach of human rights to obstruct the movement of people, but it is basically impossible to stop migration from taking place (Chen et al. 2004). Even more, it is desirable to increase the number of highly qualified professionals from Southern countries who are working for international organizations and assume leadership in health. Thus ways have to be found – including both financial and non-finan-

cial incentives – to positively motivate health workers to remain where they are needed most, or to return after having gained experiences elsewhere (Stilwell et al. 2004).

Definition

Internal migration is the process of moving within a state. As with international migration, internal migration includes economic migrants as well as migration of uprooted people or displaced persons (IOM 2005).

Basic Characteristics

The number of internal migrants is assumed to be even higher than that of international migrants (► migration health). Still, internal migration receives little attention from the international community. Internal migration is often voluntary or economically based, but it can also be involuntary due to environmental degradation, developmental projects such as dam-building and conflict or unrest (UNFPA/IMP 2004). Some driving forces and associated consequences for health are described below.

Urbanization

Movements from rural to urban areas can have dramatic impacts on all aspects of life. The world's urban population has increased from one billion in 1960 to two billion in 1985. By 2003, almost half of the world's population was living in urban areas. There were 46 cities with 5 million inhabitants or more, among them 20 mega-cities with populations of 10 million or more. Thirty-three of the cities were in less developed countries. ► Urbanization is expected to continue in coming years. By 2007, the urban population is expected to be greater than the rural population for the first time ever (UN 2004).

The rapid growth of cities due to migration or natural population increase has outpaced governments' capabilities to provide basic services and economic opportunities to the expanding urban populations. Often migrants have to settle in shanty towns and slums where they are experiencing extreme poverty as well as lack of access to decent housing, sanitation, health-care and education (UNCHS 2003; UNFPA/IMP 2004).

Environment and Migration

In the past, attention was focused on persons displaced by conflict. However, an increasingly important cause of internal migration is ► environmental degradation resulting from natural disasters, the effects of war or of over-exploitation. According to the World Bank, an estimated 25 million people were displaced by envi-

ronmental degradation in 1998 (UNFPA 2001). Future research should also focus on other forms of displacement. Issues relating to land degradation and unsustainable agricultural practices are of particular importance. According to the United Nations Environment Programme (UNEP), over 300 million hectares of land have been degraded in Latin America and the Caribbean region. The main reasons are erosion caused by non-sustainable land use, nutrient depletion, chemical pollution, overgrazing and deforestation (UNEP 2002). As a consequence, rural populations will be unable to make a living off the land, which in turn prompts migration to the cities (UNFPA/IMP 2004).

Development-Induced Migration

Development projects such as the building of dams, roads, power lines, mines, pipelines and other infrastructure projects can force people to move off their land, thus leading to population redistribution. Between 1987 and 1997, an estimated 80 to 90 million persons worldwide are supposed to have been displaced due to infrastructure programs for the construction of dams, and for urban and transport development (Cernea 1997). As a consequence of some development projects, access to arable land is reduced, forcing people to migrate to cities. Government resettlement policies have not always been successful, even when they attempted to resettle populations close to their former homes so they could continue their traditional farming practices.

Conflict-Induced Migration

Migration induced by war and other conflicts is uncontrolled: when settlements are destroyed or have to be abandoned, urban pressure increases. Persons forced to leave their homes due to violence, internally or internationally, are particularly vulnerable (► refugees and internally displaced people). They lose traditional forms of living, rarely have access to economic opportunities or to basic services and tend to live in conditions of physical insecurity. Women, children and the elderly constitute the majority of the world's internally displaced people (IDPs). Women and girls are at risk of becoming victims of sexual violence and displaced children have been recruited as child soldiers (UNHCR 1994; Taipale et al. 2002; UNFPA/IMP 2004; OHCHR 2006).

The ► displacement of populations in conflict situations often means that health personnel are also displaced. As a consequence, health services are disrupted and vital access to care interrupted. Hence previously controlled diseases may re-emerge as epidemics, as the following examples demonstrate. During the 1980–1992 war in Mozambique, out of a population of roughly 16 million people, 3–6 million were internally displaced and about 1.5 million became refugees in neighboring countries. The number of children who were abandoned, orphaned or separated from their parents was estimated at about 250,000. Thirty to fifty percent of 1000 health posts and 200 health centres existing in the early 1980s were destroyed or forced to close. There were high rates of childhood malnutrition and epidemics of diseases such as cholera and measles. In Angola, trypanosomiasis, which had decreased from 2500 to 3 cases between 1949 and 1974, re-emerged during the conflict, with one in three Angolans being at risk (Taipale et al. 2002).

Millennium Development Goals

Definition

All 191 United Nations Members States made a commitment to the MDGs in 2000, with an aim to achieve them by 2015. The Millennium Development Goals are intended to promote human development in order to improve living conditions and address key global imbalances in poverty, hunger and disease. They are:

1. Eradicate extreme poverty and hunger.
2. Achieve universal primary education.
3. Promote gender equality and empower women.
4. Reduce child mortality. Improve maternal health.
5. Combat HIV and AIDS, malaria and other diseases.
6. Ensure environmental sustainability.
7. Develop a global partnership for development.

The Millennium Development Goals (MDGs) address major issues in worldwide human development, setting up measurable and time-bound targets. They have been agreed upon at the United Nations Millennium Summit in 2000. The eight MDGs cover the reduction of extreme poverty and hunger, universal primary education, equality between women and men, reduction of childhood mortality and maternal mortality, reversing trends in major diseases, environmental sustainability, and the establishment of a global partnership for development. Achievements in these areas are meant to be monitored through country-level and global reports and statistics.

Minimum Principle

Synonyms

Efficiency postulate; Economic principle

Definition

The minimum principle states that a given result must be obtained with the minimum possible expenditure of resources. For this reason it is also known as the economic principle. In accordance with the minimum principle, the goal to be achieved (which, in dentistry, is the desired treatment outcome or medical outcome) is specified and the resources used for its achievement are to be kept to a minimum. Under the maximum principle, on the other hand, a fixed volume of resources is provided and the aim is to obtain the best possible – i. e. the maximum – outcome from them. Both principles are forms of the economic efficiency postulate, which embodies an ideal in the sphere of welfare economics. Departures from this ideal state are indicative of uneconomic functioning and wastage of resources.

Minority-Status Effect

Definition

The minority status (concerning race, gender, religion, sexual orientation, etc.) exerts an influence independent of economic, social, and demographic disparities. This fact is described by minority-status effect.

Miscarriage

► Abortion

Missing Data

Synonyms

Missing values

Definition

Missing data occurs when data are planned but are not present in the database for a variety of reasons, such as the death of a patient or experimental animal, resettlement of the patient, non-response on a question in a survey, and an erasing or losing of the data. When a large proportion of ► data of some ► variable or some case is missing, it greatly complicates the statistical analysis. According to the ► probability model of occurrence, missing values can be missing completely at random, missing at random, and non–ignorable missing data (► data preparation). Several methods for treatment of missing data have been developed, such as mean substitution (► data preparation) and casewise or pairwise deletion. In casewise (listwise) deletion, cases will be excluded from analysis if they contain any missing data for any variables planned for the entire set of statistical procedures. In pairwise deletion, cases will be excluded from analysis if they are missing data for any variables chosen for the one particular statistical procedure.

Synonyms

Risk reduction strategies

Definition

Disaster mitigation is a complex of activities taken in advance of a hazardous event, which aim at preventing disasters from occurring (i. e. preventing hazards from developing into disasters), or reducing the adverse effects of disasters on society and the environment.

Basic Characteristics

Mitigation, focusing on long-term measures for reducing or eliminating risk, is the most cost-efficient method for reducing the impact of hazards (► hazards, natural; ► hazards, technological). Disaster mitigation can be achieved by reducing the hazard or the vulnerability of communities to the hazard, or by changing the environment in which hazards and communities interact.

A precursor activity to disaster mitigation is the identification and evaluation of risk of disasters (e. g. floods, landslides, earthquakes) that pose a risk to the population in an area of interest. The higher the risk (understood as a product of probability and impact of adverse events), the more urgent the undertaking of mitigation and preparedness efforts addressed to hazard-specific vulnerabilities. If vulnerability is low (e. g. no one is living in the area, like a desert), there is no risk (e. g. an earthquake occurring in a desert).

A rigorous and systematic ► risk management process helps communities to identify the most cost-effective disaster mitigation strategy – a combination of measures for the range of risks that they face. The plan of action for disaster mitigation reflects priorities determined by the community and stakeholders.

In some countries, a national framework for mitigation exists for the whole country, with the goals of improving the disaster mitigation system and reducing adverse personal, social, economic, and environmental impacts of disasters. The process of building the disaster mitigation strategy may include establishing rules of land-use planning (zoning), accounting for hazards in building codes, development of emergency preparedness systems, preparing and disseminating guidelines for natural hazards, and awareness building. Also important are cost-effect considerations, i. e. examining the costs of natural disasters and the benefits of disaster mitigation.

If the occurrence of natural disasters is spatially restricted (e. g. in flood-prone areas), three mitigation strategies are feasible: protect, accommodate, or retreat. Pro-

tection may be attempted as far as feasible in the cost-benefit sense. It may not be financially feasible to offer very expensive protection to a small community with low damage potential. Accommodating disasters means living with disasters rather than hopelessly trying to avoid them at very high cost. Finally, retreat can be interpreted as a permanent relocation of inhabitants of unsafe areas.

Important discussion of flood protection strategies dates back to the mid-19th century in the USA, when the Congress decided to embank the Mississippi river in a single channel isolated from its floodplain. This decision has largely influenced flood protection policy in the USA and elsewhere, leading to transformation of rivers and reduction of wetlands. In 1936, the US federal government assumed primary responsibility for flood damage reduction across the nation and over the next decades embarked on a multi-billion dollar program of structural defenses. Yet, despite dedicated long-term effort and high investments, the flood risk has not been eradicated, and never will be.

The process of building a flood preparedness system may include some, or all, of the following components:

- Flood risk assessment and mapping, conveying a valuable spatial message
- Rigorous implementation of zoning – land use management to limit the use of floodplains for the site of vulnerable elements (including human settlements, industrial infrastructure, etc.)
- Relocation of riparian inhabitants and structures out of the floodplain
- Raising flood awareness of the floodplain communities, and creating a flood preparedness culture
- Building an effective and reliable flood forecasting and warning system, and preparing plans for reaction to warning (e. g. evacuation, see below)
- Development of preparedness system for the case when the existing protection measures are not able to restrain the flood waters – flood evacuation preparedness includes identifying shelters and rescue equipment, and making emergency plans with clear division of competencies and responsibilities of agencies
- Engineering of structures in the floodplain to withstand flood forces (dikes, flood walls with opening barriers, dams, storm water drainage systems)
- Adaptation of building codes to flood hazard, e. g., building designs with elevated floor levels, use of flood-resistant building materials (water resistant materials, waterproof seals, strong foundations), placement of storage and sleeping areas high off the ground, and building houses on poles (like in southern Asia)
- Development of system of flood insurance
- Watershed management – storing as much water as possible (according to the "catch water where it falls" principle).

The mitigative measures listed above fall into categories of structural or non-structural means. The former are technological solutions, like flood dikes, dams, flood control reservoirs, and relief channels. The latter include legislation, insurance, and land-use planning (e. g. the designation of areas with low damage potential like parks or playgrounds to be used as flood zones).

Mitigation of (preparedness system for) other natural disasters include essentially similar types of components as in the flood preparedness example above, aimed at weakening the load and strengthening the system resistance.

In an earthquake preparedness system, it is necessary to improve the resistance of the system by seismic zoning. Land-use management should reduce development in geological areas known to amplify ground vibrations e. g. alluvial soils, reclaimed land. Upgrading structural design is needed, which can be achieved by engineering of structures to withstand vibration forces; compliance with seismic building codes; enforcement of generally higher standards of construction; adequately high design standards for important buildings; and strengthening of existing buildings (retrofitting) and items inside the building (securing of furniture, fridges, etc. to the walls). Earthquake forecasting is possible, albeit for an extremely short advance time, and it therefore makes sense to install automatic systems reacting to a forecast in a fraction of a second, by triggering power switches off (hence averting fires).

In a gale-wind preparedness system, land-use management can improve protection from wind, e. g. by planting of windbreaks. System resistance can be considerably improved by engineering structures to withstand wind forces; siting buildings on the leeward side of hillsides; adapting the wind-load parameter in building codes; good quality construction of wind-resistant buildings; adequately securing elements that could be blown away or cause damage; and trimming tree branches and cleaning gutters. It is necessary to develop severe-weather forecasting and warning systems, to

raise community risk awareness, and to provide safety shelters and evacuation plans.

A system for wild fire mitigation includes measures to constrain the wild fire (planting of fire-resistant vegetation and wild fire breaks) and to improve the system resistance. The latter category includes zoning (land use management to limit development in high wild fire risk areas); appropriate siting of structures (away from the top of slopes/ridges); building codes for fire hazards; using fire resistant building materials; removing wild fire 'fuel' (rubbish, branches, leaf litter) from around houses and gutters; and storing flammable materials (fuel, wood, paint) securely. Development of fire weather warning systems and improvement of community awareness of wild-fire risk is also necessary. A fire evacuation plan should be in place and sufficient water supply, hoses, and protective clothing should be available.

The raising of awareness leads to improved knowledge and the chance of avoiding risks. This includes avoiding buying property that is exposed to hazards (in a subsidence, flood plain, or landslide risk area). Many homeowners may not be aware that their home is located in a risk area until hazard strikes, and real-estate agents do not provide such information. Even if flood risk maps are commissioned by authorities, sometimes they are not disseminated, as the ruling powers want to avoid the likely disruptive consequences for the property market. It is worth noting that the EU Floods Directive requests that information on flood risk be openly available to the public.

Natural and man-made disasters (► hazards, natural; ► hazards, technological) can be considered in the sustainability context. On the one hand, they destroy human heritage and jeopardize ► sustainable development (the definition of sustainable development refers to "non-decreasing quality of life"). On the other hand, following the most common interpretation of sustainable development, disaster protection policies that could be considered inappropriate options of defense by future generations should be avoided. This is how several large structural flood defenses are often regarded. Changes leading to aggravating flood risk are perceived as negative. In some locations, people regret that levees (which do not guarantee perfect protection) have been built and low-lying areas developed. Now, the issue of river renaturalization may come about. Structural mitigation (e. g. large dams) may have adverse environmental impacts. Some large reservoirs, whose construction required breaking the continuity of the river, inundation of large areas, and/or displacement of a high number of people, do not match the principles of sustainable development. When considering past developments, there were often one-sided arguments supporting a decision on a flood protection strategy, with important aspects ignored. However, this was due to lack of knowledge and understanding and the fact that value judgments have changed with time.

Mitosis

Synonyms

Mitotic cell division

Definition

Mitosis is a process of nuclear division accompanying cell division that produces two separate nuclei for two new daughter cells that carry the same diploid complement of chromosomes as the parent cell's diploid chromosomal complement. Mitosis is most common in somatic (non-reproductive) cells, and is the fourth phase of the cell cycle: G_1, S, G_2, and *M*. After G_1, S, and G_2 phases of the cell cycle (collectively called interphase), mitosis begins by the cell's entry

into the first of four phases: 1) prophase, 2) metaphase, 3) anaphase and 4) telophase. Whereas in interphase, chromosomes are unwound and are long filaments of DNA spread throughout the nucleus, prophase begins with the condensation of each chromosomes into a tightly bound bar-like structure. As the DNA has been replicated in the S phase, the two identical copies of the chromosome, called chromatids, are bound together tightly at a knot shaped structure near the center of the chromosome, called the centromere, so that each bar-like structure appears X-shaped. In late prophase, the nuclear envelope disintegrates. During metaphase, the mitotic spindle forms, which is a structure with two poles centered at the site of the new nuclei of the daughter cells. Spindle fibers consisting of long microtubules attach to the centromere of each chromosome. While attached to these fibers, the chromosomes align along the equidistant plane perpendicular to the two poles, called the metaphase plate. In the next phase, anaphase, the microtubules attached to the centromeres pull one chromatid each out of each chromosome to their respective poles; this ensures a diploid complement for the new nuclei of each newly arising cell. In the final phase, telophase, a nuclear envelope forms around the collection of chromatids, which unwind from their bar-like bodies into the elongated strands present during interphase.

Model Building

Definition

Because health care systems involve the coordination of interacting resources and human activities, it is natural that they generate a range of organizational problems that are ripe for tackling with the scientific approaches of simulation modeling. It was found that even proper attention to such technical matters did not always prevent worthwhile models being ignored by those they were intended to assist. Concern has therefore turned to the aim of creating simulation models that are both technically accurate and actually used as decision aids. One possibility to assist in reaching this goal is direct client involvement in the building of and experimentation with the model. Effective model building requires strong systems analysis skills. The health systems engineer must also be able to initiate resolutions to strategic problems using knowledge of how organizational decisions are made.

Modelling

Synonyms

Economic modeling; Simulation; Microsimulation

Definition

A model is a simplified analytic representation of a real situation. Health economic modeling involves the simulation of events across populations and over time, where a mathematical framework permits the integration of facts and values for which real data are not available.

Basic Characteristics

Modeling is an analytic technique used to describe complete health care scenarios or components where no real data are available or where there is some doubt regarding the validity of the data. Health economic modeling is also applied in analyses where only part of the data are generated and not all data for a full analysis are available.

The underlying purpose of health economic modeling is to structure the available evidence on clinical processes and the related clinical and economic outcomes in order to support decisions about clinical treatment strategies and allocation of resources in health care. Therefore, economic models are very often developed for health care decision-making purposes (Weinstein et al. 1980).

Models are used in situations of ► uncertainty, where assumptions have to be made. The results are not subject to confirmatory testing, but are estimated in the best possible way. Assumptions might be necessary for unit costs, quantitative parameters such as incident case or prevalence rates, treatment efficacy or effectiveness such as survival rates and health state utilities, and structural issues like causal relationships between variables used (► cost effectiveness) (Drummond et al. 2005; Hunink et al. 2005; CADTH 2006).

Hence, models apply evidence on cost and consequences from many different sources. As it is not usually possible to base the complete calculation on primary data collected individually from the target population included, models are based on data from clinical trials, observational studies, insurance databases, case registries, and public health statistics. Usually, the primary data of randomized controlled trials or epidemiological analyses are combined with data from a number of different additional data sources such as administrative data from sickness funds (► claim's data analysis), routine data sets from official statistics, and reimbursement catalogs such as DRGs or fee-for-service schemes.

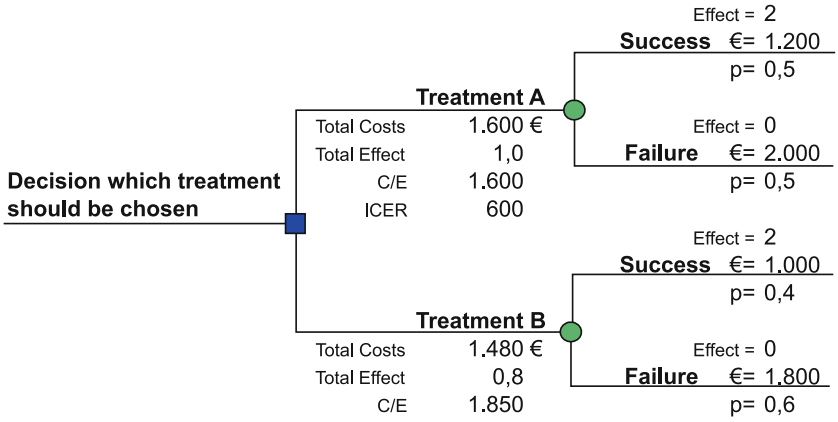
Health economic models could be applied for several purposes:

- Simplifying complex situations
- Outlining the progression of a chronic disease
- Extrapolating available efficacy data over a longer time frame
- Estimating the benefits of a technology that was analyzed under controlled conditions in patients receiving this treatment under real life conditions
- Amending missing elements of trial information by model components

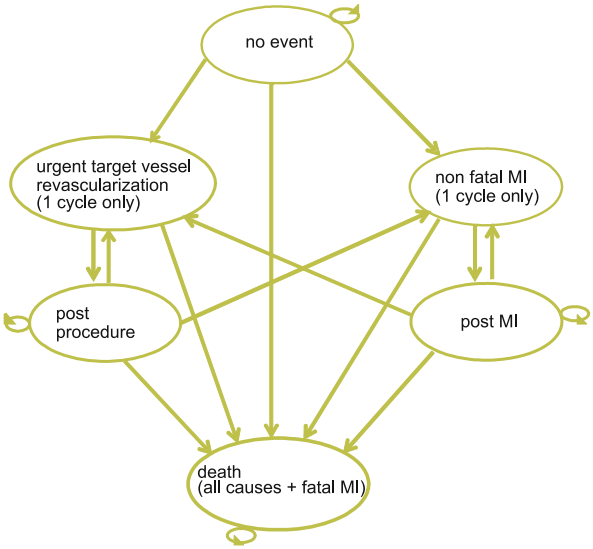
Models may be used in their simple form as a decision-tree analysis, which is particularly appropriate in acute event situations. However, when multiple alternatives arise and changes occur over time, this technology has to be amended – or alternative approaches have to be used. In this context, Markov Models are frequently applied for evaluating health care technologies (Weinstein et al. 2003; Gold et al. 1996; Bootman et al. 1996).

In decision analysis, a so-called decision-tree is generated, which helps to disaggregate a complex problem into smaller problems and elements for better understanding. A decision tree is a graphical structure in which decision and event nodes are used to represent different kinds of events, including decisions and uncertainties. Building the model comprises the following major steps:

1. The alternatives that are the subjects for decisions have to be clearly stated.
2. The consequences induced by the initial decision have to be identified and described, including all potential pathways that might occur. This step should also involve a decision on the time frame of the analysis.
3. Probabilities have to be attached to all consequences.
4. The target outcome parameter has to be identified.
5. The cost and outcomes alongside the different consequences have to be calculated.
6. Finally, a decision can be taken considering the underlying uncertainties reflected in a sensitivity analysis.



Modelling, Figure 1 Example Decision Tree



Modelling, Figure 2 Example Markov Model

The example provided outlines a simple decision situation: treatment A is an innovative treatment approach, which is more successful at higher costs. However, if the treatment option is failing, a second treatment is needed, which generates additional costs. Treatment B is the conventional treatment, with lower cost when comparing success and failure directly. By multiplying the probabilities with the costs and summing up the accrued cost for each decision alternative, a decision based on costs could finally be taken. Accordingly, this approach could be applied when identifying the potential benefits of alternative treatment approaches. Here, there is a hypothetical effect of two, e. g. life-year-gained (LYG), achieved with success and none with failure. Hence, treatment A generates a higher benefit compared with treatment B, which is the less costly alternative. The additional effect of treatment A could be obtained at an incremental cost of €120, which results in an ► incremental cost/effectiveness ratio of €600.

Markov models are more appropriate in modeling repeated events over time or progression of a disease where disease states could be experienced at more than one time. In a Markov model, the disease is represented as a restricted set of states (e. g. perfect health, impaired health, and death). Subjects move between the different states over time; these discrete time periods are so-called "Markov cycles". The chance of moving between states is calculated via transition probabilities.

The example provided outlines the treatment setting for patients after a coronary vascularization had been performed. The following states might arise in the example: revascularization with essential post-procedure activities in a follow-up cycle, a non-fatal myocardial infarction (MI) with a changed disease state after MI, and death. A transition from one state to another takes place with a certain probability after a pre-defined cycle length. By attaching estimates of resource use and health outcomes to the different states and transitions for an appropriate number of cycles, mid- to long-term costs and outcomes for patient cohorts could be generated.

One criticism of this modeling method, however, is that Markov models always assume constant transition probabilities between individual disease states over the course of time (Markovanian assumption) (Briggs et al. 1998). In reality, this probability is of course also influenced by specific corresponding factors. For example, the length of time spent by a patient in a particular disease state has an effect on the probability of transition to another state. It might be possible to account for this limitation by applying the so-called Markov processes, in which variable transition probabilities are inferred. This in turn requires substantial additional information that might not always be available.

Health economic models face different concerns and limitations. As they are based on assumptions, they are subject to bias. Extrapolation might become difficult for the time exceeding the follow-up period of randomized clinical trials or epidemiological studies. Taking these aspects of ► uncertainty into consideration, such models do not usually aim to achieve statistical confirmation of hypotheses made; they aim to describe the amount of uncertainty of different aspects of the model e. g. using ► sensitivity analyses. To deal with the uncertainty in the assumptions and the data used, techniques from Bayesian statistics and ► discrete-event simulations are implemented.

In addition, models are often perceived as "black boxes" when complicated mathematical models are calculated and validation is not performed. In order to solve these issues, models should be evaluated and carefully tested for computation errors in order to obtain optimal internal validity; results should be reviewed and it should be ensured that they are consistent with available data (face validity). If different models are available for the same problem, a cross-validation should be under-

taken, covering the discussion of differences in structure and underlying data.

All modeling activities have to include different levels of ► sensitivity analysis. At least a one-way sensitivity analysis should be performed, with a univariate variation of one variable at a time. The range of variation is a crucial issue and plausible ranges should be taken into account. Multivariate sensitivity analysis is considered the current state of the art, particularly for C/E ratios, as uncertainty pertains on both sides of the equation. This might be done with worst- or best-case scenarios. Other techniques in this context are bootstrapped estimates (► bootstrapping) and ► Monte Carlo simulation.

In health care settings, illustration of the course of diseases and patient pathways might sometimes be too complex to be modeled completely. This is due to the fact that, in addition to the wide range of different treatment strategies, the patient might also make different choices and flow differently through the system. Hence, a key step in modeling is to define the boundaries of the system to be modeled. A trade-off has to be made between including all environmental factors affecting the system and selecting only a few or no impacting factors at all. These decisions have to be guided by both availability of data or hypotheses and the feasibility of handling complexity.

Nevertheless, health economic models currently provide the best estimates relevant to decision-makers, particularly when trying to understand the future impact of newly implemented technologies (Buxton et al. 1998; Hunink et al. 2005).

Models of Behavior Change

► Health Behavior, Theories

Models of Finance

Synonyms

Health care funding

Definition

In a context of increasing international competition and falling public revenues, the issue of health care funding is central to health policy. The fundamental distinction to be made is between systems financed from general taxation and contribution-funded systems. With contribution-funded health benefits, the contributions are a charge mainly on labor. In view of the falling trend of the wage share, this form of funding is considered to be relatively unsustainable, so that more funds from taxation are called for to broaden the funding basis. As a rule, actual funding models are composites of three

sources – the state, employers and private households – whose proportions vary from country to country. In all systems a trend is now emerging for private households to be required to shoulder an increasing proportion of the funding burden by means of direct co-payments.

Moderators of Effect Size

► Effect Modifiers

Modes of Inheritance

► Mendelian Modes of Inheritance

Mode of Transmission

Definition

Transmission of an agent is its spread from a reservoir or source to a new host by one or more possible routes (direct or indirect). Direct transmission is the immediate transfer of an infectious agent from an infected host to a receptive portal of entry through which human or animal infection may take place. This may be by direct contact (such as touching, kissing, or sexual intercourse) or by direct spread of droplets by sneezing or coughing. Indirect transmission may be vehicle-borne, vector-borne, or air-borne.

Moisture

► Humidity

Molar

Definition

Molars are teeth in the back of the mouth used for mastication. Adult humans have 12 molars, three on both ends of the dental arch per jaw. The rearmost (third) molar in each group is called a wisdom tooth. Beside molars permanent dentition contains incisor teeth, canine teeth and ► premolars.

Molds

Definition

To grow, molds need oxygen, that means, they are aerobic. For their metabolism they depend on organic substances. The main part of the mold grows inside the foodstuff; the visible components, the hyphs, serve to reproduce and spread the spores through the air or by contact with objects. While the mold itself is not toxic at all, many species can produce poisonous substances, the mycotoxins. A moldy product should not be eaten, unless the mold is harmless and belongs to the characteristics of the product (like blue cheese).

Molecular Technologies to Detect Genetic Variations

Lucia Staber-Theune, Klaus Fuchs
Medizinische Laboratorien Dr. Staber und Partner, München, Germany
L.Staber-Theune@Staber-Partner.de

Definition

Molecular technologies are used to characterize, isolate, and manipulate the molecular components of cells and organisms. Thus, molecular technologies are the basic tools to study genetic information. Polymerase chain reaction is the most basic molecular technology. It is used to produce multiple identical copies of DNA (► deoxyribonucleic acid) fragments. Other key technologies include gel electrophoresis, ► allele-specific hybridization, DNA sequencing, and DNA chip technology.

Basic Characteristics

Polymerase Chain Reaction

Determination of DNA variations can be performed by polymerase chain reaction (PCR), a selective amplification of a well defined DNA sequence (target sequence) up to billions of copies. Initially high-molecular, genomic DNA (DNA template) is extracted from a blood sample or oral mucosa by affinity chromatography. PCR requires the following basic components: DNA template, sequence-specific and complementary

oligo-nucleotides (sense and antisense primer), a mix of four deoxynucleotides-triphosphate (dATP, dTTP, dGTP and dCTP) and a thermally stable DNA polymerase (e. g. Taq DNA polymerase), which incorporates the nucleotides complementary to the target DNA. A PCR buffer with Mg^{++} assures a suitable chemical environment for the DNA polymerase. Primers are short, artificial DNA strands (about 16–24 base pair long nucleotides) which determine the beginning and the end of the region to be amplified. A standard PCR reaction consists of 30–45 repetitive cycles comprised by the following three steps: denaturation, annealing and extension. PCR is carried out in a thermal cycler, a special equipment providing rapid and accurate changes in temperature required for each step of the reaction. At 95°C double stranded DNA, which includes the region of interest, is separated into its single strands by reversible melting of the hydrogen bonds that connect the two DNA strands (denatruation). Decreasing temperature to 50–60°C permits binding of the primers to the complementary, denaturated DNA or already amplificated fragments (annealing). Finally at a temperature of 72°C (temperature optimum of Taq-DNA-polymerase) each primer acts as a starting point for the replication by the DNA polymerase along the DNA template to a new strand (extension). As a result of duplication of the DNA region of interest, ideally in every cycle, the DNA amount increases exponential. However the real value is below the theoretical value of billions of copies. This is due to the inefficiency of PCR with increasing numbers of cycles. Complete reaction time is about one to two hours. Advantages of this easy and universal applicable method are robustness, specificity and sensitivity. Slightest traces of DNA can be detected and made available to diagnostic purposes. This benefit also recovers the greatest disadvantage: the risk of contamination. Thus it should be regarded not to contaminate the DNA sample with external DNA and therefore a control for contamination is arranged in every assay.

RFLP and Gel Electrophoresis

There are several possibilities to analyze amplificated DNA. The most common technical mode is *R*estriction *F*ragment *L*ength *P*olymorphism (RFLP). This technique may differentiate by analysis of patterns derived from cleavage of DNA by digestion with a restriction enzyme. Restriction enzymes are DNA cutting enzymes. They are able to recognize and cut DNA only at a particular sequence of nucleotides. As a result of point mutations additional restriction sites can emerge but then other restriction sites can be dropped out, by what the length of the fragments produced will differ from the wild type (normal sequence). By gel electrophoresis the fragments are separated from each other. After loading on a agarose gel the negatively charged DNA migrates according to fragment size in the electric field towards the positive charged electrode. Thereby different DNA patterns will be generated. The fragments are visualized by ethidiumbromide and UV-light. Applications for RFLP are the detection of known SNPs (► single nucleotide polymorphism) or mutations and affirmation of newly identified mutations.

Allele-Specific Hybridization of Probes

Synonyms Hybridization fluorescent-based mutation detection

5′nuclease Assay The application of probes specific to certain mutations allows beside detection also an allelic differentiation. The hybridization with allele-specific, fluorogenic probes is part of the routine diagnostics of SNPs or mutations. The *Taq*Man™ technology or 5′nuclease assay exploits the 5′endonucloeolytic activity of *Taq* polymerase to cleave an oligonucleotide probe during PCR amplification thereby generating a detectable signal. Therefore PCR is carried out with two primers and two allele specific DNA probes. Each probe is complimentary to one of the alleles of a SNP (normal or wildtype and mutant) and each is labeled with a different fluorophore. The probes are fluorescently labeled at their 5′ end and are non-extendable at their 3′ end by chemical modification (quencher molecule). During PCR the probe binds to the target sequence downstream from one of the primers and is displaced with cleavage by the 5′endonucleoytic activity of *Taq* polymerase during primer extension. Cleavage of the probe generates a signal, by dissociating the 5′fluorophore from the quencher molecule with an increase in fluorescence. The 5′endonucleolytic activity of the *Taq* polymerase is only enabled in presence of complementarity between target sequence and probe. The probe complementary to the wild type allele releases the fluorescence signal only in presence of the wild

type allele. In case of a heterozygous genotype the signal is decreased by half. In presence of a homozygous mutant no signal is emitted. The probe complementary to the mutant allele acts analogous. This amenable to automation assay offers the advantage of the allele being distinguished during or immediately after amplification without opening the amplification tube or processing the amplification product. This reduces time and erratic results due to post-PCR contamination.

Melting Curve Analysis Another method to analyze SNP or known polymorphisms is the detection by melting curve analysis using LightCycler™. Therefore PCR is carried out with two primers and two DNA probes representing either the wildtype- or the mutation-sequence. The two outer primer ensure amplification, the two interior probes permit differentiation of the alleles. The probes are labeled with two different fluorophore dyes: Probe 1 carries a fluorescein at its 3′ end whereas probe 2 carries a different label (LC Red 640 or LC Red 705) at its 5′ end. The underlying principle is the FRET (*f*luorescence *r*esonance *e*nergy *t*ransfer). When the two probes are brought into close contact by hybridization to the target sequence, FRET results between the two fluorophores. The first dye (donor-fluorophore) is excited by the LightCycler's Diode and emits green fluorescent light, which excites the LC Red dye (acceptor-fluorophore) attached to the second hybridization probe that subsequently emits red fluorescent light. The amount of measured fluorescence is proportional to the increasing amount of DNA generated during the ongoing PCR process. At the end of the PCR the samples are subsequently heated from a low temperature (e. g. 40°C) in small steps by continuous measurement of fluorescence. As the temperature increases, the probes are melting from its target, decreasing FRET. The melting temperature (T_m) of a probe is not only dependent on GC-content and length but also on the degree of homology to the target DNA-strand. When the probe is perfectly matched to the target, the the T_m is higher than with a mismatch. So each SNP can be distinguished by the characteristic $T_m$of each allele. Multiplex PCR is possible by using different fluorophores and/or different T_m's on each SNP.

DNA Sequencing

The search and the detection of unknown mutations requires elaborated methods. Gold standard is dideoxy sequencing. The basic principle is sequencing DNA after amplification by PCR. The technique utilizes DNA polymerase, the four deoxynucleotide-triphosphates (dNTPs) and with different fluorescent dyes labeled dideoxynucleotide-triphospates (ddNTPs) in low concentrations. The ddNTPs compete with dNTP for placement and terminate the DNA chain elongation base specifically. As a result all theoretically possible DNA fragments are generated. Electrophoresis is carried out by loading all four reaction products into one lane of a gel. After size-separation of the fragments by electrophoresis the particular base can be differentiated by laser light stimulation. The sequence is then determined by combinating the fragment sizes. The Editing is performed digital and verified by skillful technicians. In the meantime a higher automation rate is available by capillary electrophoresis in narrow glass capillaries filled with a viscous polymer. With this technique a mix of samples by 'lane tracking' is practically excluded.

DNA Chip Technology

DNA micro arrays are miniaturized devices which provide a format for the simultaneous analysis of many polymorphisms. For identification and systematization of SNPs high density oligonucleotide arrays like GeneChip™ are applicated. This array relies on the hybridization of biotin-tagged fragments of SNP-containing DNA to complementary DNA 25-mer oligonucleotide probes chemically tiled on a silicon wafer in an ordered array. Fragment selection by PCR is carried out on the DNA sample of interest to label the PCR products with biotin and to hybridize them then to the array. Successful hybridizations are detected fluorescently using a streptavidin-phycoerythrin conjugated molecule and an antibody-mediated signal amplification technique. Each oligonucleotide in the high-density array acts as an allele specific probe. To increase specifity, mismatch (MM) control oligonucleotides are used to recognize unspecific hybridization. These are identical to their perfect match (PM) partners except for a single base in a central position. Perfectly matched sequences hybridize more efficiently to their corresponding on the array and give stronger fluorescent signals over mismatched probe-target combinations. The hybridization signals are quantified by high-resolution fluorescent scanning and analyzed by computer software. DNA alterations such as heterozygote base-pair

polymorphisms or mutations, insertions and deletions can be identified.

Monition About Health Hazard

► Health Warning Systems

Monitoring

Definition

According to the *Merriam Webster Online Dictionary*, monitoring means "to watch, observe, or check esp. for a special purpose."

As defined by Last in the famous *Dictionary of Epidemiology*, "monitoring is the intermittent performance and analysis of routine measurements, aimed at detecting changes in the environment or health status of populations". It is distinct from surveillance, which is a continuous and ongoing process.

Monotheism

Definition

In the monotheistic view, there is only one god because religion is essentially a relationship with one god who is conceived as the only divine being.

Monte Carlo Simulation

Definition

Monte Carlo Simulation can be described as an advanced form of ► sensitivity analysis in health economic ► modeling, and is used to describe the uncertainty and to evaluate the model repeatedly. The deterministic analysis is repeated for a large number of parameters in the model. The values of the parameters are randomly drawn from realistic probability distributions and then statistically analyzed. By this means, a large number of artificial "individuals" are randomly put into the model.

Monthly Chance of Pregnancy

► Fecundability

Moral

Definition

In order that a free society could exist in a friendly manner, it requires standards of behavior that could be accepted as a norm. The basis of those norms can be found in earlier writings by interested groups of men who sought to regulate the conduct of the individual. Some of these rules have been readily adopted and others taken as guidelines. A good Christian would put them into everyday practice, all in good faith.

Moral Hazard

Definition

Moral hazard refers to disincentives that are created by the existence of health insurance, and implies inefficient overspending for medical care.

Moral Hazard, ex ante

Definition

Ex ante moral hazard refers to the effect that being insured has on behavior – e. g. by utilizing less prevention.

Moral Hazard, ex post

Definition

Ex post moral hazard leads to an increase in demand because the price of medical services covered by health insurance is lower than it would be if the beneficiaries of health insurance paid for these medical services themselves.

Morality

► Ethics and Religious Aspects

Morbidity

Synonyms

Disease incidence and prevalence

Definition

Morbidity refers to illness or injury. On an individual level, it describes the state of being diseased or having unhealthy complications from a medical treatment. On a population level, morbidity measures the rate of disease incidence and prevalence, i. e. how many new cases of diseases occur in a population and the number of people who suffer from a disease or injury.
In ► epidemiology, the morbidity rate defines within the framework of a given time period the number of people who will probably suffer from that disease. The ► morbidity rate describes potential or expected rates rather than actual rates.

Morbidity Rate

Synonyms

Percentage rate of ill people within a time period

Definition

The morbidity rate is the proportion of individuals who become ill with a particular disease within a susceptible population during a specified time period, e. g. a given year. It is usually expressed as a number of people afflicted per 1,000, 10,000, or 100,000 people. It can also refer to the percentage of people who have complications after a procedure or treatment.

Morbus Koch (Koch's Disease)

Synonyms

Tuberculosis; Tbc; Mycobacterium tuberculosis complex; Consumption; Phtisis ($\tau\iota\sigma\iota\sigma$); King's evil; White plague; Wasting disease; Scrofula; Pott's disease

Cross-References

► Tuberculosis and Other Mycobacterioses

"Morning-After-Pill" (Colloquial)

► Emergency Contraception

Mortality

Synonyms

Frequency of death; Lethality

Definition

Mortality rate, a measure of the number of deaths in some population.
Mortality rate is a measure of the number of deaths (in general, or due to a specific cause) in some population, scaled to the size of that population, per unit time. Mortality rate is typically expressed in units of deaths per 1000 individuals per year; thus, a mortality rate of 10000.5 in a population of 100,000 would mean 1,000,500 deaths per year in the entire population. It is distinct from ► morbidity rate, which refers to the number of individuals who have contracted a disease during a given time period (the ► incidence rate) or the number who currently have that disease (the ► prevalence rate), scaled to the size of the population.

Mortality Rate

Synonyms

Death rate; Fatality rate

Definition

The mortality or mortality rate is the ratio of the total number of deaths in an area to the population of that area to the total population. It can refer to deaths in general, or deaths due to a specific cause. The mortality is typically expressed in number of deaths per 1000 individuals per year. However, there are a number of different types of mortality rates as, for example, the fetal mortality rate, which expresses the ratio of fetal deaths to the sum of the births in that year.

Mortality rates are an important measure of the level of mortality within a ► population. Mortality rates are usually age-specific rates of deaths during a time period. The numerator is the total number of deaths to people in an age group during that period. The denominator is the total amount of exposure of people in that age group to the risk of dying during that time-period. The denominator is usually a measure of the person-years lived during the period by people in that age group, and is often estimated by the mid-year population size. Mortality rates are used to produce estimates of survivorship and of life expectancy in a population.

Motivation

ANDREAS FUCHS
Forschungsverbund Public Health Sachsen-Sachsen Anhalt e. V., Medizinische Fakultät, Technische Universität, Dresden, Germany
andreas.fuchs@tu-dresden.de

Synonyms

Willingness; Readiness; Needs

Definition

Motivation describes the situation of an organism in human and social science as well as in ethology that influences the direction, extent and kind of changing patterns of human behavior and action.

Basics Characteristics

Different roles have been assigned to motivational factors in the causation of behavior. Some have defined motivation as a non-specific energizing of all behavior. Others define it as recruiting and directing behavior, selecting which of many possible actions the organism will perform. According to Geen (1995), motivation refers to the initiation, direction, intensity and persistence of human behavior.

In psychology, motivation has been defined as the sum of separate ► motives that arouse, sustain and regulate certain behavior in an individual. A motive is characterized as behavior that is instigated by conscious or unconscious emotion or is a creation of the personality with the purpose of reaching a specific goal (Kehr 2004).

The word "motivation" is derived from the Latin term "motivus", which suggests the activating properties of the processes involved in psychological motivation.

One is motivated, by various means, to satisfy a need. For instance, if there is a need to influence other human beings an individual will be motivated to behave in a powerful and strong way towards others, or if there is a need to have contacts an individual will be motivated to socialize. The term motive is often used as a synonym for "need." Primary motives are based on physiological processes, e. g. the need to avoid hunger and coldness. Secondary motives are based on psychological processes, e. g. the need for achievement, or the need to demonstrate power and strength, or the need to secure contacts.

Motivation can also be classified as ► intrinsic motivation and ► extrinsic motivation. According to the theory of learning, motivation depends on internal and exter-

nal stimuli. Social conditions or characteristics of inorganic/inanimate objects are considered external stimuli.

Theories that explain and define the character of motivation have their roots in behavioral psychology. They provide a way to examine and understand human behavior in a variety of situations. Motivation theories are divided according to theories of needs (need theory) and processes (process theory). A range of theories schematize the development, in a formal way, the influence of the character of needs and the contents of these needs on human behavior.

The hierarchy of needs was notably promoted and defined by Abraham Maslow in his hierarchy of needs theory. He identified a set of needs that he prioritized into a hierarchy based on two conclusions:

- Human needs are either of an attraction/desire nature or of an avoidance nature.
- Because humans are "wanting" beings, once a desire is satisfied another desire will take its place.

The five levels of Maslow's needs, listed from basic (lowest, earliest) to most complex (highest, latest), are the following:

- Physiological needs like food, drink, and sleep.
- Security/safety: people want to feel safe, secure, and free from fear. They need stability, structure, and order.
- Social: this is a need for friends, family, and intimacy – for social acceptance and affection from one's peers. There is a need for social networks (e. g. ► social network).
- Self esteem: people want the respect of others and they want to be regarded as useful, competent, and important. People also desire self-esteem and need a good self image.
- Self-actualization: this highest motivation level involves people striving to actualize their full potential, to become more of what they are capable of being. They seek to attain self-fulfillment.

Some theories expand and modify the hierarchical theory of Maslow's needs: Alderfer proposed the ERG theory in which needs are divided into the categories of existence, relatedness and growth. The following theories were developed by various experts in the field of psychology:

- Motivation-hygiene theory developed by Frederick Herzberg.
- Theory X and Y established by Douglas McGregor.
- Acquired needs theory developed by David McClelland (Petri 1996, McClelland 1985).

According to Maslow, the most basic needs must be satisfied before successively higher needs can emerge. Cognitive psychologists such as Albert Bandura have suggested that individual mental processes, such as beliefs, play an important role in motivation, through the expectation of certain reinforcements for certain behaviors (Bandura 1992). Further theories explain how individuals select particular behaviors and how individuals determine if these behaviors meet their needs (process theories). Such theories are the Expectancy theory developed by Victor Vroom, the Equity theory established by J. Stacy Adams and the Rubikon model created by Heinz Heckhausen (Heckhausen 1989).

Motivation in Health Promotion and Disease Prevention

Motivation in relation to health promotion and disease prevention relates to the willingness of individuals to participate in health promotion interventions and to implement the recommendations for a healthy life style or the coping with disease in daily life. The motivation of individuals is essential if the suggestions of health promotion campaigns are to be followed. Motivation to participate in and implement health promotion issues through health education generates individual health behavior. Numerous concepts and models try to explain how individuals are motivated to participation in health promotion campaigns and interventions (for example ► the precede–proceed model, ► health belief model, (Rosenstock 1974) ► social learning theory, ► trans–theoretical model, ► theory of reasoned action, theory of planned action (Conner and Norman 1998). These theories and the theories of health behavior (► health behavior theories) contribute answers to the question of why people are motivated to change their behavior on health related issues (Schwarzer 1996). These models on health behavior explain an individual's readiness to change un-healthful behaviors (Sanders 1982). The basic premise is that behavior change is a process and not an event, and that individuals are at varying levels of motivation, or readiness, to change. This means that people at different points in the process of change can benefit from different programs for change, and the programs work best if matched to their stage of readiness.

Furthermore, models of health promotion (► health promotion models) try to explain behavior to help systematically plan, conduct and evaluate health promotion interventions or programs and to motivate individuals in participating health promotion. In modern public health practice today, usually a mix of concepts from different models is employed, and all major theories are examined for their applicability to a given intervention.

Motive

Definition

Motives are congenital psychological dispositions that enable an individual to perceive things and to sample, through this perception, emotions, to act in a certain manner and to have impulses for action. The psychology of motivation differentiates various kinds of motives.

Motor Function Developmental Disorder

Definition

The main symptom of the specific developmental disorder of motor function is a serious impairment in the development of coordination. General intellectual retardation or other important neurological disorders are excluded. In most cases, a careful clinical examination shows marked neurodevelopmental immaturities such as choreiform movements of unsupported limbs or mirror movements and other associated motor features, as well as signs of impaired fine and gross motor coordination.

Motor Neuron Diseases

Synonyms

Anterior horn cell disease; Familial motor neuron disease; Lateral sclerosis

Definition

Motor neuron diseases (MND) represent a group of neurological diseases characterized by a progressive deterioration of the motor neurons in the brain, brainstem, and spinal cord resulting in muscle weakness and wasting. Usually, arms and legs are affected first, often followed by shoulders and other muscles. In most cases, the intellectual capacity remains unchanged. MND usually develops in people over the age of 40, with the highest incidence in the 50–70 years age group. The clinical subtypes of MND are differentiated by the major site of degeneration of the motor neurons. They include amyotrophic lateral sclerosis (Lou Gehrig's disease), progressive spinal muscular atrophy, progressive bulbar palsy, and primary lateral sclerosis.

MOTT (Mycobacteria Other than Tuberculosis)

Synonyms

Atypical mycobacteria; Mycobacterioses

Definition

Mycobacteria of the MOTT-complex contain a great number of species, for example *Mycobacterium avium*, *M. fortuitum*, *M. intracellulare*, *M. kansanii*, *M. marinum* or *M. ulcerans* (germ, which causes Buruli ulcus). They can be found in nature (in water, in the soil or in foodstuffs) as well as in installations (water pipes). Mycobacterial infections are not transmitted from one individual to another. In general, the pathogens are taken up orally or small skin injuries act as portals of entry. Mycobacteriosis can lead to a positive tuberculin skin test result. The detection of mycobacteria does not necessarily indicate the presence of disease. A MOTT-infection with therapeutic consequences – a mycobacteriosis – is present in cases of fistulae, when the germ is isolated from tissue that should be sterile (lymph nodes, bones), when mycobacteria are isolated in skin granulomas or following the repeated isolation of the same germ. Due to resistances it may be difficult to treat mycobacterial infections.

Multi-Centric Study

Definition

A multi-centric study is a study that is conducted at more than one research or medical center. The benefits of such studies include a large number of subjects from different geographic places and the ability to compare results from all of them. The most common weakness of randomized controlled clinical trials is that they are very expensive. Because of the high costs, multi-centric trials that utilize cooperation between many research centers are becoming more common.

Multidisciplinary

Definition

The involvement of two or more disciplines or professions in the provision of integrated and coordinated services including evaluation and assessment activities.

Multifactorial

Definition

Due to many causes with small effects.

Multifactorial Disease

Synonyms

Disease with multiple etiology

Definition

Multifactorial disease such as ► work-related diseases, for example hypertension, coronary heart disease, chronic non-specific respiratory disease, low back syndrome, upper limb disorders, cancer, etc., are thought to be caused by complex interactions between genetic factors (polygenic basis) and various environmental factors. The term multifactorial means that there are many different influences acting together to cause the appearance of the disease. These include effects from a combination of genetic factors, none of which on its own would be likely to cause the disease, and environmental factors, which again would not cause the disease by themselves. It is believed that a particular combination of genetic and environmental factors act together in concert and trigger the development of multifactorial disease.

Different environmental factors will influence the development of different multifactorial diseases. Besides environmental and workplace factors (chemical, physical, ergonomic, or psychosocial stressors), non-occupational life-style factors (diet, weight, type and amount of exercise, and smoking and drinking) also place genetically susceptible individuals at risk of developing multifactorial diseases.

Multilevel Statistical Analysis

Synonyms

Hierarchical linear modelling; Multilevel statistical modelling

Definition

Multilevel statistical analysis comprises a broad spectrum of statistical techniques capable of statistical modeling and analysis of hierarchically structured data. For example, in population surveys, sample design typically mirrors the hierarchical population structure in terms of geography and household membership; for repeated measures data, time can be considered as another level that occurs within participants; for event history data, time spent in various states or situations is important; in studying mortality rates in a population, it is often of great concern to try to understand the factors associated with variations from area to area or community to community; in ecologic studies, a combination of direct observations of individuals (e. g. age and sex) – individual level variables, and observations of groups, organizations, or places (e. g. social organizations and air pollution) – and ecologic variables is usually present. Multilevel statistical analysis is usually a more advanced form of simple linear regression and multiple linear regression. Multilevel analysis allows variance in outcome variables to be analyzed at multiple hierarchical levels, whereas in simple linear and multiple linear regression, all effects are modeled to occur at a single level. Multilevel analysis has been extended to include multilevel structural equation modeling, multilevel latent class modeling, and other more general models.

Multiple Comparisons

Definition

Multiple comparisons is a term concerned with the interpretation of the multitude of hypothesis tests that might be undertaken on one set of data. The major sources of multiple comparisons are: multiple outcome measures, multiple treatment groups, multiple items in a questionnaire measuring an exposure variable, repeated measurements over time of a specific outcome measure and comparisons of outcome over subpopulations of subjects. Statistical analysis will give rise to many statistical tests with a high likelihood of finding many statistically significant test results purely by chance. The problem centers on the error rate that should be controlled either by multivariate global tests, adjusted marginal tests or by using summary measures.

Multiple Linear Regression

► Multiple Regression

Multiple Regression

Synonyms

Multiple linear regression; Multivariate regression modeling

Definition

Multiple regression is a multivariate regression method for analyzing the relationships between several independent or predictor variables and a dependent variable. It is used to model relationships between variables (exactly the conditional expected value of dependent variable given the values of independent variables) and determine the magnitude of those relationships. The models can be used to make predictions. In

general, multiple regression allows the general question "what is the best predictor of …" For example, what are the best predictors of success in high-school? Which personality variable best predicts social adjustment? Which of the multiple social indicators best predicts whether a new immigrant group will adapt and be absorbed into society or not, etc. Multiple linear regression assumes the best estimate of the response is a linear function of some parameters (though not necessarily linear on the predictors). If the relationships between the variables being analyzed are not linear in parameters, a number of nonlinear regression techniques may be used to obtain more accurate regression (for example, a multi-layer ► artificial neural network). If the response variable is not continuous, specific regression techniques are available, e. g., ► logistic or Poisson regression (► logistic regression analysis). A distinction can also be made between parametric (requires choice of the regression equation with one or a greater number of unknown parameters) and non-parametric regression methods (without specifying the form of the relationship between variables *a priori*, e. g., ► Cox's proportional hazards regression). Some authors prefer to use the term multiple regression analysis exclusively in the sense that it can also handle all analysis of variance problems (but the reverse is not true).

Multiple Sclerosis

Definition

Multiple sclerosis (MS) is a disease of the central nervous system characterized by numbness, weakness, loss of muscle coordination, and problems with vision, speech, and bladder control. It is an autoimmune disease meaning that the body's immune system attacks myelin, which is an important substance that serves as a nerve insulator and helps in the transmission of nerve signals. MS is progressive and often fluctuates with exacerbations and remissions often occurring over several decades. "Multiple" refers to the multiple places affected in the central nervous system and to the multiple relapses and remissions. Ultimately, in most patients, permanent disability and sometimes death occurs. The cause of MS is still rather unclear. Possible factors include genetic susceptibility, environmental factors, viruses, or a combination of these factors.

Multiple Sequence Alignment

Definition

For a group of related sequences, the determination of relatedness by aligning identical or highly similar amino acid or nucleotide residues at the same position. This problem is usually performed with successive pairwise alignment.

Multipotency

Synonyms

Pluripotency

Definition

By definition, multipotency is the capacity of stem cells to give rise to cells of the three embryonic germ layers. Hence, any cell type derived from the embryoblast but not from the trophoblast can be generated. Although the term pluripotency is a synonym for multipotency, it is generally used to point out a limited multilineage potential restricted to one or two embryonic cell lineages. A general consensus whether adult stem cells can cross lineage boundaries or not has not yet been found.

Multivariate Statistics

JELENA MARINKOVIĆ
Medical Statistics and Informatics, School of Medicine and School of Public Health, University of Belgrade, Belgrade, Serbia

Synonyms

Multivariable statistics; Multivariate statistical methods; Multivariate statistical analysis; Multivariate data analysis; Classification and prediction statistical methods

Definition

Multivariate statistics refers to methods that examine the simultaneous effect of multiple variables. Traditional classification of multivariate statistical methods suggested by Kendall is based on the concept of dependency between variables (Kendall 1957). If an interest centers on the association between two sets of variables, where one set is the realization of a dependent variable (or variables) and the other set is the realization of a number of independent variables, then the appropriate class of techniques would be those designated as dependence multivariate methods. If interest centers on the mutual association across all variables with no distinction made between variable types, interdependence multivariate methods are used (Dillon 1984).

Basic Characteristics

In the past 30 years, there has been an explosion of work in the theory and methods of multivariate analysis. This is partly due to an enormous increase in the use of these methods by biomedical, social, behavioral, and other researchers who analyze the simultaneous relationships of more than two variables. Beside that, mathematical tools (matrix algebra, vector geometry, probability distributions, and powerful types of analyzes for analyzing linear and nonlinear models such as general linear models or generalized linear models) that were needed as a theoretical basis for these methods have emerged. Another explanation of this explosion could be the easy access to computers and ► statistical packages that are capable of handling very sophisticated multivariate techniques; increasing statistical knowledge by researchers; increased collaboration with statisticians in different studies; and the growing concern of journal editors that poorly designed and analyzed studies would be published in their journals (Dawson-Saunders 1994).

Multivariate techniques differ from univariate and bivariate analyzes in that they direct attention away from the analysis of the mean and variance of a single variable, or from the pairwise relationships between two variables, and involve the analysis of covariances or correlations that reflect the extent of relationship between three or more variables, and analysis of distances which reflect similarity among variables. For example, a public health researcher/worker attempting to understand the role health determinants play in shaping the health status of a population might operationalize the concept of health determinants in terms of at least eight variables, relating to personal behavior and lifestyles, influences within communities which can sustain or damage health, living and working conditions, access to health services, and general socioeconomic, cultural, and environmental conditions. Similarly, if a public health researcher/worker is concerned with developing taxonomy for classifying individuals of a certain population on the basis of their socioeconomic position, information on education, social class, occupation, income, housing characteristics, and wealth may be collected, for example. Alternatively, a public health researcher/worker might prefer to measure socioeconomic status with as few variables as it is possible, only infant mortality in developing countries, for example.

Dependence multivariate methods usually seek to explain or predict one or more dependent variable (response, outcome variable(s)) based upon the set of predictor variables (independent, covariate, explanatory variables). Thus, there are two uses of dependence multivariate methods, prediction and description (explanation, classification). Interdependence mul-

tivariate methods, on the other hand, are less predictive in nature and attempt to provide insight into the underlying structure of the data by simplifying complexities, primarily through data reduction and through developing taxonomies and systems of classification. Some caution should be taken regarding the terminology concerning "dependent" and "independent variables" that is very common in statistical literature. This choice of terminology is unfortunate in that independent variables do not have to be statistically independent of each other. Indeed, these independent variables are usually interrelated in a complex way. Another disadvantage of this terminology is that a common connotation of the words implies a causal model, an assumption not needed for the multivariate methods described below (Afifi 1984).

Proper use of all multivariate methods requires that attention should also be paid to the type of measurement collected (measured on a nominal, ordinal, interval, or ratio scale) and the distributional form of the data analyzed. For example, several multivariate methods (e. g. ► multiple regression) require that the ► level of measurement be at the interval or ratio level, and that the distribution of the variables be multivariate normal. The classification of independent or dependent may differ from analysis to analysis, but the classification into Steven's system should remain constant throughout the analysis phase. Once these classifications are determined, it is possible to refer to Table 1 and decide what analysis should be considered.

Dependence Multivariate Methods

These methods are generally classed as regression type methods. This means that data can be partitioned into a response variable (y) and a set of possible predictor variables ($x_1, x_2, \ldots, x_k$). It is assumed that the value of the response variable is some function of the independent variables $\boldsymbol{x}$, i. e. in a generalized format: $y = f(\boldsymbol{x})$. Beside this deterministic part, the model has a probabilistic part – random error (ε). Together they form a statistical regression model (usually based on ► general or generalized linear models). This model (of dependence) is in fact the mathematical record of how one or several variables depend on other characteristics.

The basic steps used for dependence model building are model selection, model fitting, and model validation. In the model selection step, plots of the data, process knowledge, and assumptions about the process are used to determine the form of the model to be fitted to the data. Then, using the selected model and information about the data, an appropriate model-fitting method is used to estimate the unknown parameters in the model and to evaluate how effectively the calculated model fits the actual data for estimating the outcome variable. Models that fit the sample data well may not be successful predictors of response variables when applied to new data. Model validation involves an assessment of how the fitted regression model will perform in practice – that is, how successful it will be when applied to new or future data. If the model validation identifies problems with the current model, however, then the modeling process is repeated using information from the model validation step to select and/or fit an improved model. The model, if properly fitted and validated, can be used for prediction and/or classification.

Depending on the nature and the number of variables in the model, there are a great number of multivariate techniques that can be used to analyze dependence structure. These are ► multiple regression, ► discriminant analysis, ► logistic regression, ► proportional hazards regression (Cox regression), ► loglinear analysis, ► canonical correlation analysis, multivariate analysis of variance and covariance, path analysis, and structural equation modeling.

Interdependence Multivariate Methods

These methods look at the relationships between variables, with the primary aim of dimension reduction. Based on a typical data table that has n rows (e. g. units, cases, or objects) and k columns (variables), reduction can be seen as compression in one of two directions or both directions at the same time. This is a basis for three general categories of interdependence methods: geometrical or projection methods (reduction of columns leading to a small number of derived, new, variables which relate to more abstract features), classification methods (reduction of rows in order to group cases on the basis of their similarity over a range of variables), and hybrid methods, i. e. a combination of the previous two (reduction of the table in two directions simultaneously). The choice of multivariate method also depends on the nature of the data input.

The most frequently used interdependence methods are: ► principal component analysis, ► factor analysis,

Multivariate Statistics, Table 1 A Taxonomy of Multivariate Statistical Techniques under Steven's Classification (Adapted from Afifi 1984)

	Independent Variable(s)			
	Nominal or Ordinal		Interval or Ratio

► cluster analysis, multidimensional scaling, and correspondence analysis.

Extensions of Multivariate Statistics

► Meta-analysis is a way to combine the results of several independent studies on a specific topic. It can be viewed as an extension of multivariate analysis because of the idea of summarizing evidences (variables), keeping in mind that units of measurement are studies. More on this topic can be found in a separate essay – Meta Analysis.

Longitudinal studies are studies in which individuals are measured repeatedly through time, allowing the direct study of change. The sequential nature of the measures implies that certain types of correlation structures are likely to arise. Methods for longitudinal analysis can be seen as a special case of more general regression methods for clustered data (Fitzmaurice et al. 2004).

Multilevel models are statistical models applied to data collected at more than one level in order to elucidate relationships at more than one level. They include a hierarchy of nested (clustering of units into hierarchy)

effects to disentangle the influences of different levels (Goldstein 2003). For example, a multilevel study of the effects of schooling on academic achievement could study the effects of a particular classroom teacher (level 1), who is located in a given school (level 2), which is influenced by the policies of the district (level 3) within which the school is located. In ecologic studies, a combination of direct observations of individuals (e. g. age and sex) – individual level variables, and observations of groups, organizations, or places (e. g. social organizations and air pollution) – ecologic variables, is usually present. ► Multilevel statistical analysis combines analysis conducted at those two (or more) levels.

A time series is a sequence of observations made over time; for example, annual infant mortality rate, weekly admissions to an emergency center, or daily carbon monoxide concentration. Time series models are used to describe the dependence of the outcome at each time on predictor variables including covariates and possibly previous values in the series. The observations in the time series cannot be assumed to be independent as is the case in most multivariate statistical methods. Time series methods are therefore necessary to account for the correlation between repeated responses over time. The goals of ► time series analysis include description, explanation, prediction, and control (Diggle 1990).

An ► artificial neural network is a nonlinear statistical data modeling tool. It can be used to model complex relationships between inputs and outputs or to find patterns in data. Neural networks extend regression methods to nonlinear multivariate models (Hastie et al. 2001).

Conclusions

In conclusion, multivariate statistics is an important area of biostatistics and is of particular value in public health, keeping in mind that contemporary public health research has been becoming increasingly interested in attempting to explain complex rather than simple phenomena. The appearance of new multivariate statistical methods creates further challenges for modern public health.

Mumps

Synonyms

Parotitis epidemica

Definition

Mumps is a viral infection with an incubation period of 12–35 days, which is spread by droplets and direct contact. Humans are the only reservoir of the virus. Besides fever, headache, muscular pain and malaise, the onset of the disease is usually characterized by pain and swelling of the parotic gland. In most cases the swellings starts on one side, but in 70–80% the other side is affected just a little later. Complications that may occur are: inflammation of other salivary glands or

the pancreas and infection of the central nervous system which is expressed by meningitis or encephalitis. In men or boys who have passed puberty there is a danger of developing orchiditis which might cause infertility. The most important measure in preventing parotitis epidemica is active mumps-vaccination (► immunization, active).

Mumps Vaccination

Synonyms

Mumps immunization

Definition

The mumps ► vaccine was developed in 1967. Nowadays, it is generally applied in combination with the vaccination against measles and rubella (MMR). The patient receives the first inoculation at a minimum of 11 months of age and a second vaccination at an interval of at least 4 weeks later. The protection rate is 97–99%. The mumps vaccination is recommended in view of the complications that can arise from infection with the wild-type virus, especially in boys – orchitis and meningitis. Contraindications for mumps or MMR vaccination are immunodeficiency, acute illness with fever, pregnancy and a known severe allergic reaction to components of the vaccines or the carrier protein.

Murri (Queensland)

► Indigenous Health – Australooceaninan

Musculoskeletal Health

Synonyms

Health of muscles and skeletal system

Definition

► Physical activity contributes to the development of bone mass during childhood and adolescence and to the maintenance of skeletal mass during adulthood. Increased bone mineral density during adulthood is positively associated with aerobic exercise. Through its load bearing effect on the skeleton, physical activity influences bone density and bone architecture, – the higher the load, the greater the bone mass. Higher calcium intake has linked to increased bone density in short-term studies, but high protein intake and high dairy calcium intake are both related to increased risk of fractures in long-term prospective studies of men and women. Because ideal calcium intake for development of peak bone mass has not been determined, it has not been established to what extent increased calcium intake will prevent osteoporosis.

Mutation

Synonyms

Genetic mutation; Chromosomal mutation

Definition

Mutations are changes to the genetic material (usually DNA or RNA) that predispose the occurrence of a clinical ► phenotype (disease), i. e. pathogenic alterations. Mutations can be caused by copying errors during cell division or by the exposure to a multiplicity of endogenous or exogenous mutagens (radiation, chemicals, viruses). The mutational spectrum includes single base substitutions (point mutations), frameshift mutations (small insertions or deletions), microdeletions, and large-scale chromosomal alterations (deletions, duplications, rearrangements). If germ cells (sperms, oocytes) are affected by a mutation (germline mutation), this can be passed on to the next generation (hereditary disorders). In contrast, somatic mutations usually occur during lifetime *de novo* in somatic (non-germline) cells of an organism; they are not transmitted to descendants, but may lead to cancer and other age-related diseases.

Mutually Exclusive Categories Tests

Synonyms

Analysis of frequencies

Definition

Mutually exclusive categories tests are applied to data obtained from individuals categorized into mutually

exclusive categories according to one or more variable. Analysis of frequencies includes several statistical tests. ► Goodness-of-fit tests are applied in the analysis of data from one-way tables. The chi-square ► test of homogeneity and chi-square ► test of independence are applied in the analysis of two-way ► contingency tables. When frequencies in ► contingency table analysis are too small to apply a chi-square test, ► Fisher's exact test is more appropriate (see essay Analysis of frequencies). The McNemar test is appropriate in the analysis of data from matched pairs for dichotomous variables.

MW

► Microwaves

Mycobacterioses

► MOTT (Mycobacteria Other than Tuberculosis)

Mycobacterium tuberculosis

Synonyms

Pathogens that cause tuberculosis; Typical mycobacteria, tubercle bacilli

Definition

Mycobacterium tuberculosis, the germ that causes tuberculosis, is a rod bacterium. Due to the structure of its cell wall, it has to be classified as gram-positive although it only shows a poor uptake of stain. The ability of mycobacteria to resist decoloration by ethanol and acids is called "acid-fastness". In Ziel–Neelsen staining tubercle bacilli appear as red rods on a blue background. The pathogens can remain dormant in macrophages (human cells of defense) for years or even decades without causing any symptoms.

Mycobacterium tuberculosis Complex

► Morbus Koch (Koch's Disease)
► Tuberculosis
► Tuberculosis and Other Mycobacterioses

Mycotoxins

Definition

Mycotoxins are toxic metabolites of moulds present on raw or processed food or feed. Moulds grow in a humid atmosphere, so either the humidity of the space where products are kept or the quantity of water in the product (so called 'water activity') enhance mould growth. Moulds which are frequently present on food are *Aspergillus*, *Penicillium*, *Fusarium*, Alternaria, *Claviceps* and they produce Aflatoxins B1, B2, G1, G2, M1, M2. *Aspergillus flavus* produce Ochratoxin A and Cyclopiazonic acid. These toxins, along with patulin, zearalenone, fumonisins and others, produce acute and chronic hepatic lesions and could be carcinogenic. Mycotoxins are destroyed only on temperatures above 220°C, so conventional cooking temperatures are ineffective in lowering the levels of mycotoxins. Peanuts, corn, nuts, figs, coffee, beans are always tested for the presence of mycotoxins since they grow in humid regions where conditions for growth of moulds are optimal.

Myofascial Pain

Definition

Myofascial pain is characterized by discomfort or pain in the muscles that control jaw function and the neck and shoulder muscles.

Mythopoetic

Synonyms

Myth-making; Mythologizing

Definition

The term mythopoetic refers to a tendency to reduce the *mythoi* or cosmic stories of a people or culture into paradigms of human psychological functioning. Myths were once used by societies to relate experiences to the functioning of the whole and often hierarchical world order of a created world but mythopoeia is now used as a tool for individuals to gain personal insight into

their own psychological functioning. This is often done without due reference to or regard for the larger societal or cultural epoch. For instance, some enthusiasts of this approach to men's health assert that the archetypes of the priest, king, warrior and lover are to be found within each man and that healthy masculine functioning requires the adequate exploration, expression and integration of these archetypes within the male psyche. Unfortunately, anachronistic images and understandings of these archetypes are very often converted into self-help strategies and practices that lack suitable explanatory power or therapeutic value.

Nation

Synonyms

People; Population; Tribe; Society

Definition

A nation is a group of humans who share the same characteristics: common ► ethnic identity, as well as common language, religion, ideology, culture, and/or history. They are usually assumed to have a common origin. Therefore, the national population also has a degree of uniformity and homogeneity. A group of people with nothing in common, can not be defined as a nation. At least some of the characteristics must be exclusive to distinguish the nation from neighboring nations. It is possible that people with the same ethnic origin live in different nation-states and for that reason may be treated as members of separate nations.

National Health Service (NHS), United Kingdom

Definition

Since 1948 the National Health Service (NHS) has functioned as a national medical service in the United Kingdom. It is publicly funded by means of taxation. The NHS provides the majority of health care in the United Kingdom including primary health services, hospital and specialist services. Primary health services include general medical services provided by general practitioners, general dental services, pharmaceutical and ophthalmic services as well as ancillary services such as school medical service, care for mothers and young children, and midwifery. Hospital and specialist services comprise also research, pathological services, emergency services and long-term health care.

National Health Services

BRANKO JAKOVLJEVIĆ
Institute of Hygiene and Medical Ecology, Faculty of Medicine, University of Belgrade, Belgrade, Serbia
bra@beotel.yu

Definition

National Health Services are systems of health institutions that provide ► health services to people of a given nation, province, or state. A national health service has

responsibility for addressing resource issues relating to access, equity, and quality of health care. It assures the delivery of healthcare services on the three levels of intervention: primary, secondary, and tertiary prevention. Specific services delivered through national health systems are maternal and child health services, health services, health services for the elderly and disabled, occupational health services, etc. A national health service stimulates the education of qualified health professionals and stimulates the community to invest in the health sector in order to meet the health needs of the nation. Furthermore, it supports states and communities in their effort to plan, organize, and deliver health care, as well as strengthen the overall public health system.

Basic Characteristics

Health services provided by national health systems include a wide range of services that can be didactically divided into several groups. First of all, most health services are provided for an individual in the community, but some are aimed at the population (► population-based services). Furthermore, health services can be divided by the place where they are provided: ► institutional health services (provided in a health care setting), home care services (provided at home or in the community, ► home- and community-based services), or ► occupational health services (provided at the workplace). Finally, all health services can be grouped as ► preventive services, where services effective in promoting health and preventing the occurrence of disease = primary prevention (► prevention, primary), clinical services provided for detection of disease or risk factors at early, treatable stages = secondary prevention (► prevention, secondary), and long-term care and rehabilitative services = tertiary prevention (► prevention, tertiary).

1. *Primary prevention* refers to health services conducted before the onset of disease and includes health promotion, protection, and prevention of disease. This group of activities is sometimes referred to as non-specific prevention, because they are conducted in order to improve health status, i. e. to make healthy people healthier and less susceptible to diseases. This is why these activities go beyond strictly clinical services; they expand to the social, economic, and even political sphere of life. Primary prevention services include:
   a. Stimulation of physical activity, promotion of healthy eating habits, and promotion of healthy lifestyles – avoidance of risk behavior, such as use of tobacco, alcoholic beverages, drugs, or risky sexual behavior.
   b. Support to governmental and global actions for environmental protection – improvement of food and water supply, prevention of air, water and soil pollution, and prevention of climate changes.
   c. Support to ensure access to general and health education, and coverage for all. Health education is of prime importance for the establishment of attitudes related to health promotion, thereby influencing health-related behavior.
   d. Stimulation of professional education and employment, leading to financial security, and higher socio-economic standards.
   e. Primary prevention includes some medical activities and measures that are more disease-oriented and more specific than those mentioned above. National health services are obliged to direct and manage the immunization process. The coverage rate of immunization should be more than 80% of the population in order to achieve an epidemiological barrier to the diseases in a population. Obligatory immunization is provided in infancy and childhood, as well as in adulthood, according to specific indications.
   f. Genetic counseling is a preventive service provided for women of reproductive age and during pregnancy, aiming to control the occurrence of genetic malformations in the population.
   g. In order to control the transmission of infective diseases, national health services must provide measures for disinfection, and pest (insects and rodents) eradication, as well as sanitary improvement of the urban and rural settings by various technical measures (soil decontamination, regulation of waste disposal, controlling emission of hazardous substances, etc.).
2. *Secondary prevention* refers to services conducted in order to detect and treat diseases early, aiming to prevent further complications and disabilities. National health systems are providing populations with various services, including:
   a. Obligatory examinations from pregnancy and childbirth, through infancy and childhood (at regular intervals), and school age (every two years),

up to examination of the employed population (every year). Obligatory examinations are being criticized as unnecessary and financially devastating for society. However, the activities undertaken expand the level of early diagnosis of disease and they include measures of health promotion and protection as well, giving health education and stimulation of a healthy lifestyle.

b. Screening is the application of a test on the population in order to estimate the risk for the onset of disease. By screening, a healthy population is divided into two subgroups – those with low risk and those with high risk. It is in the latter group that diagnostic tests are performed in order to determine the occurrence of disease at an early stage. Screening tests performed in infancy include screening for genetic malformations (Down's syndrome), genetic conditions (cystic fibrosis), inborn errors of metabolism, congenital hypothyroidism and adrenal hyperplasy, hearing loss, and hip dysplasia. In adulthood, screenings are undertaken for breast, cervical, prostate, and bowel cancer, with many more suggested – for mental disorders, infectious diseases, etc.

c. The treatment of diseases is the most expensive service within the health system. It seems that the healthier the person is, the less willing they are to invest in health; however, the situation is vice versa when it comes to the disease, the person is willing to give everything to regain health.

3. *Tertiary prevention* includes health measures and activities conducted when the treatment of disease is terminated. Health services are related to:
   a. Rehabilitation, both physical and psychological,
   b. Provision of orthopedic facilities,
   c. Occupational and rehabilitation therapy of the disabled person,
   d. Reintegration into society, including education, re-qualification, and employment,
   e. Support of society as a whole to accept physically or mentally challenged persons in various ways i. e. organizing schools for the blind, deaf or mentally handicapped; providing schools and universities with access platforms for disabled persons; establishing clubs and supportive groups; providing additional health care at home; and adopting policies regarding employment or social help for people with disabilities.

Access to Health Service

Access to appropriate preventive care depends on many barriers, including those that involve the patient (► consumer), health professionals (► providers), and system of care (U.S. Department of Health and Human Services 2000; Docteur 2003).

- Patient barriers include lack of knowledge, skepticism about the effectiveness of prevention, lack of a usual source of primary care, and lack of money to pay for preventive care. Sexual orientation, cultural differences, language differences, geographic isolation, cultural norms, economic status, or environmental challenges also present important limitations in access to care. Certain people, such as those who are disabled, elderly, chronically ill, or HIV-infected, require access to health care providers who have the knowledge and skills to address their special needs.
- Health provider barriers include limited time to dedicate to each patient, lack of training (or specific skills), lack of effectiveness in work, etc. Another important issue is the timely availability of health services, problems can occur when demands for services exceed the capacity of the system to supply them on a timely basis (e. g. in emergency situations – earthquakes, floods, war conflicts).
- System barriers include lack of resources or attention devoted to health services – problems with the quantity and distribution of facilities (hospitals, ambulances, or medial equipment); problems with the quantity and distribution of health care professionals (e. g. small number of physicians or inadequate distribution of physicians in rural areas); financial barriers – lack of insurance coverage or inadequate reimbursement for services; and lack of systems to track the quality of care provided to the public.

Reforming the Health Systems to Provide Effective Health Services

Establishing a health system and improving the quality of health services it provides is a great challenge for every national government (► health systems).

The major indicators of *quality of health systems* are:

- sustainability – assuring that the current generation's need for high quality health services may be met without compromising the ability of future generations to meet their needs;

- efficiency – the production of the maximum possible outcome for a given level of expenditure;
- effectiveness – the extent to which health system interventions achieve defined health goals;
- equity – an equitable health system is one which ensures equality of opportunity, where anyone receives as much health care as anyone else in the same medical condition, regardless of any factors thought to be irrelevant e. g. income, race, sex, and age (Institute of Medicine 2001).

Health systems in many countries face major problems related to workforce shortages, misdistribution and waste of financial, human, knowledge, and other resources, poor quality health information, and shortfalls of essential health services, including problems with quality, and inability to scale up rapidly (WHO 2004). In order to meet these goals and to provide better health services, restructuring of health systems toward primary health care services is of prime importance (WHO Regional Office for Europe 2004). The advantages of strengthening primary care services are:

- Better access to health care services and therefore more equality in health care provision. The primary health care system is widespread, longitudinal, well coordinated and oriented toward community, i. e. accessible for the whole population. Access to health systems improves inequalities in health, which is important for both low-income and developed countries (Macinko 2003).
- Better quality and efficiency of care. Both general practitioners and specialists are obliged to provide the highest quality of health care, but the fact that primary care physicians provide continuous and comprehensive care may result in improved health outcomes. Improved access to primary care physicians and their gate-keeping function have added benefits such as less hospitalization, less utilization of specialist and emergency hospital care, and less chance of being subjected to inappropriate health interventions (Roberts 1998).
- Cost-effectiveness of health services. Primary health care, when compared with secondary care, was shown to be more cost effective, with lower use of diagnostic investigations, lower referral rates to secondary services, lower prescription levels, and lower tendency to use expensive technology (Franks, 1992; Starfield 2002).
- Patient satisfaction with health services. A comparison of ten Western countries suggested that users reported more satisfaction with health systems based on a strong primary care system (i. e. Denmark) when the influence of expenses on the health care was controlled with other countries (Mossialos 1997). However, patient satisfaction with primary care is strongly influenced by many other factors, such as the mode of care delivery, physician's style of work, continuity of care, etc.
- Better health of the population. International comparisons have revealed that countries with very weak primary care infrastructures have poorer performance on major aspects of health, especially for indicators early in life – low birth weight ratios, high postneonatal mortality rate and years of potential life lost in adulthood (Starfield 2002).

Conclusion

The factor that marks a difference between countries with overall good health and those with poor health at all ages is the strength of primary health care within the overall health services. Recognizing the role of preventive services across the continuum of care must be the base point for the development of projects and policies designed to help providers and patients shift to a prevention-oriented health care system.

National List of Occupational Diseases

Definition

National list of occupational diseases is a list of ► occupational diseases adopted by the competent national authority, in consultation with national occupational health experts and most representative organizations of employers and workers. The purpose of this list is prevention, recording, notification and, if applicable, compensation of occupational diseases. It is suggested that in ILO member countries these list have to include at least the diseases enumerated in Schedule I of the Employment Injury Benefits Convention, 1964 (amended in 1980). Also, it is suggested by ILO that other diseases with a proved occupational origin have to be included on that list. As each country has to decide on the contents of their own list there are huge differences in national lists of occupational diseases; thus international comparison of occupational disease incidence is almost impossible.

Native

Synonyms

Indigenous; Endemic; Autochthonous; Aboriginal; Genuine; Inherited; Inborn; Natural

Definition

The term native refers to denote indigenous origin, growth or production. It is used for members of the original inhabitants of a particular place (tribal, aboriginal). Also, it may refer to feature of being such by birth or origin, or occurring in nature pure, existing as such by nature.

Natural History

Definition

Natural history refers to the progression of a disease in an individual over time, including all disease-related stages from before initiation of a disease (the stage of susceptibility) until the resolution of a disease (the stage of recovery, disability or death). In other words, it is the evolution of a disease without medical intervention. The natural history model includes the several stages of the disease: stage of susceptibility, sub-clinical stage, clinical disease stage, and stage of recovery, disability or death.

Cross-References

► Preclinical Phase of Disease

Natural Rights

Synonyms

Human rights

Definition

In order to defend the individual against abuses by government, institutions and also by other individuals (e. g. a majority group), there have been in the last century some declarations which have pointed out some absolute rights of each and every human being. They embrace the most important aspects of life and in some countries some of them have been embodied into specific laws.

Cross-References

► Human Rights
► Human Rights and Public Health

Natural Science

Definition

A study of living and non-living matters and the description and definition of the information gathered. Chemistry, physics, and biology are traditionally included.

Natural Selection

Definition

The theory of natural selection states that changes in the ability of an organism to thrive in its environment caused by specific ► allele(s) in its ► genome will affect the ability of this organism to reproduce and thus affect the frequency of these alleles in future generations. Natural selection can be positive or negative in direction.

NCCHTA

Definition

The National Coordinating Center for Health Technology Assessment (NCCHTA) manages, supports

and develops the UK's National Institute for Health Research HTA program under contract from the Department of Health Research and Development Division. NCCHTA is based at the University of Southampton. The HTA program is a national program of research whose purpose is to ensure that high quality research information on the costs, effectiveness, and broader impact of health technologies is produced in the most effective way for those who use, manage, and provide care in the ► NHS. Once ► NICE has identified the technologies it wishes to appraise and the timetable leading to the publication of NICE guidance, the HTA program becomes the interface between NICE and the review groups contracted to produce the assessment reports.

Needs

► Motivation

Negative Predictive Value

► Screening

Negative Selection

Synonyms

Purifying selection

Definition

The process by which deleterious ► alleles are removed from the gene pool due to a reduction in fitness caused to the organism which carries them in its ► genome. This is often seen in genes which are functionally constrained, whereby any changes in the amino acid structure of the protein deleteriously affects its function. The ongoing process of occurrence and removal of deleterious alleles has been incorporated into the neutral theory resulting in the nearly neutral theory of evolution.

Neoplasms

► Cancer

Nephropathia epidemica (NE)

► Hanta Fever

Nested Case Control Study

Definition

A nested case-control study is a case-control study "nested" within an ongoing cohort study. Assessment of exposure may be time-consuming and costly. Instead of undertaking measurement on everyone in a cohort, it may be more efficient to construct a case-control study within the cohort once a significant number of cases of the disease of interest have emerged at follow-up (the cases for the nested case-control study). Thereafter, a control group could be selected among those from the cohort who had not developed the disease. Compared with case-control studies, a nested case-control study can reduce recall bias and temporal ambiguity. Compared with cohort studies, nested case control studies can have a lower cost and save time.

Nest Protection

Synonyms

Antibodies transferred during pregnancy

Definition

During pregnancy maternal ► antibodies of the IgG-type can pass through the placenta and are transferred to the unborn child. These antibodies protect the baby from a number of infectious diseases. After birth the protective effect remains for a while but it gradually declines with the antibodies being inactivated and vanishing completely within 3–6 months. Despite the presence of maternal antibodies there is no nest protection against pertussis (whooping cough).

Cross-References

► Immunization, Passive

Net Reproduction Rate (NRR)

Definition

Net reproduction rate (NRR) is the average number of daughters that would be born to a woman during her lifetime if she passed through her lifetime from birth to the end of her reproductive years conforming to the ► age-specific fertility rates (ASFR) and mortality rates of a given year. NRR is always lower than GRR because it takes into account the fact that some women will die before entering and completing their childbearing years. Also, NRR will be less than half the magnitude of the TFR. Replacement level ► fertility is said to have been reached when NRR=1.0 (► total fertility rate (TFR); ► gross reproduction rate (GRR); ► fertility replacement).

Network

Definition

A grouping of individuals, organizations and agencies organized on a non hierarchical basis around common issues or concerns, which are pursued proactively and systematically, based on commitment and trust. WHO actively initiates and maintains several health promotion networks around key settings and issues. Networks of networks are also being established. Examples include the WHO (EURO) initiative "Networking the networks" and global networking initiatives for health promotion in order to build a global alliance for health promotion.

Networks

Definition

A network is a grouping of individuals, organizations and agencies organized on a non hierarchical basis around common issues or concerns, which are pursued proactively and systematically, based on commitment and trust. WHO actively initiates and maintains several health promotion networks around key settings and issues like health promoting hospitals, cities, workplaces, etc.

Neural Network

► Artificial Neural Network

Neural Tube Defects

Definition

Neural tube defects are congenital defects of the central nervous system, including the spinal cord, skull and brain, resulting from failure of the neural tube to properly close during embryonic development. Defects may include anencephaly (absence of the skull), and protrusions of the brain or spinal cord (spina bifida). Neural tube defects may be detected prenatally by amniotic fluid or blood tests and by ultrasound technology. The intake of folic acid before and during the first weeks of pregnancy is effective in the prevention of neural tube defects.

Neuraminidase Inhibitors

Definition

Neuraminidase inhibitors impair the effect of neuraminidase. By blocking the virus release, the spread of the virus is inhibited. Two different substances are available: oseltamivir (Tamiflu®) can be given orally, zanamivir (Relenza®) is inhaled. The treatment with neuraminidase inhibitors should begin within 48 hours after the onset of infection. If therapy starts in time, severe courses and lethal outcomes can be prevented. Neuraminidase inhibitors are effective against influenza viruses A and B. As influenza C viruses do not produce neuraminidase, neuraminidase inhibitors are, of course, not effective against this subtype.

Neuraminidase (NA)

Definition

Neuraminidase is a viral protein, which plays an important role in virus release. Today, 9 different serotypes are known. Neuraminidase is built by influenzaviruses A and B, but not by influenzavirus C.

Neuro-Endocrine Immune-Network

► Psychoneuroimmunology

Neurology

Definition

Neurology refers to the medical specialty concerned with the diagnosis and treatment of disorders of the nervous system, which includes the brain, the spinal cord, and the nerves.

Neuropsychologist

Definition

A neuropsychologist has finished a special education in the neurobiological causes of brain disorders, specialized in diagnosing and treating these illnesses with a primarily medical approach. The field of neuropsychology has bonds with psychology and neurology and examines how the structure and function of the brain relate to specific psychological processes and overt behaviors. Neuropsychologists may work in academia, clinical settings, forensic settings, or industry.

Neurosurgery

Definition

Neurosurgery is the specialized branch of surgery that treats diseases that affect the ► central nervous system (CNS). A neurosurgeon is a physician who has received extensive training in the surgical and medical management of neurological diseases. Neurosurgery is one of the most sophisticated surgical specialties and includes advanced surgical and imaging technology and new research in molecular neurosurgery and gene therapy.

Neurotic Depression

► Dysthymia

Neutral Theory of Evolution

Definition

The neutral theory of evolution states that the majority of polymorphisms within a ► genome have no effect on the fitness of an organism. Changes within a population in the frequency of these alleles over time occurs by a process of genetic drift, caused by random sampling effects in the formation of successive generations. A neutral ► allele may be expected to increase or decrease in any given generation with equal probability, however, over time the neutral theory predicts that an allele will be either eliminated or fixed within the population by genetic drift. An equilibrium is produced by the counteracting effects of genetic drift homogenizing the gene pool and mutation introducing novel alleles into it. Genetic drift has the greatest effect in populations which are very small, such as ones which have undergone a population bottleneck.

New Testament

Definition

The New Testament provides the main source of religious information for devoted Christians. It readily accepts the Jewish scriptures taken out of the Old Testament. It contains some record of the speech and actions of Jesus Christ as well as records about some selected followers, especially the apostles.

NHS Economic Evaluation Database (NHS EED)

Definition

NHS EED has been funded by the Departments of Health of England and Wales to assist decision-makers by systematically identifying and describing economic evaluations, appraising their quality, and highlighting their relative strengths and weaknesses. NHS EED saves decision-makers time that might have been spent searching for studies in databases such as MEDLINE and EMBASE. The economic evaluation literature is recorded in many electronic databases and paper-based resources. A strength of the database is that not only

does NHS EED save time by gathering information together in one place, it also provides critical assessments of the quality of the economic evaluations included.

NICE

Definition

The UK's National Institute for Health and Clinical Excellence (NICE) is the independent organization responsible for providing national guidance on the promotion of good health, and the prevention and treatment of ill health. NICE produces guidance in three areas of health: public health (guidance on the promotion of good health and the prevention of ill health for those working in the NHS, local authorities, and the wider public and voluntary sector), health technologies (guidance on the use of new and existing medicines, treatments, and procedures within the NHS), and clinical practice (guidance on the appropriate treatment and care of people with specific diseases and conditions within the NHS). Although the methods for developing the various forms of guidance differ, all the development processes are underpinned by the key Institute principles of basing recommendations on the best available evidence and involving all stakeholders in a transparent and collaborative manner.

Definition

Friedrich Wilhelm Nietzsche was born on 5th October 1844 and died on 25th August 1900 in Weimar. He was a German philosopher and scholar of classical traditions.

Noise

GORAN BELOJEVIĆ
Institute of Hygiene and Medical Ecology, Faculty of Medicine, University of Belgrade, Belgrade, Serbia
gogibel@eunet.yu

Definition

Noise is a class of sounds that are considered as unwanted. ► Sound is produced by vibratory movement of molecules in solid bodies and fluids, causing a series of pressure changes.

Basic Characteristics

Physical Aspects of Noise

Sound frequency is defined as the number of sound pressure changes per time unit. It is expressed in Hertz units (1 Hz = one pressure change per second). Sound level is defined as the logarithmic ratio between the actual sound pressure (P) and the sound pressure at hearing threshold (P_0), according to the following formula:

$$L = 20 \log_{10} P/P$$

Sound level is expressed in decibel units (dB). Concerning the time characteristics of sound, it can be continuous or intermittent (pauses longer than 1 second), while a sudden change of sound pressure during a period shorter than one second is referred to as an impulse.

Public Health Importance

Noise is a ubiquitous noxious factor in living and occupational environments. Globally, some 120 million people are estimated to have disabling hearing difficulties caused in part by excessive noise exposure in the workplace or during recreational activities. It has been estimated that every fifth European citizen lives in so-called "black acoustic zones" with an ► equivalent continuous noise level over 65 dB measured in A, a ► frequency weighting that is considered to produce strong acoustical stress. Furthermore, every third European citizen may suffer from sleep disturbances due to exposure to

noise levels over 55 dB (A) at nighttime. In industry, about 50% of workplaces are exposed to unacceptable noise levels.

Hearing Impairment

Normal hearing is the ability to hear sounds in the frequency range from 16 Hz to 20000 Hz, and in a dynamic range of 10^{-12} to 10^{2} W/m^2. It is a well-known fact that hearing sensitivity decreases with age, and this physiological phenomenon is referred to as ► presbyacusis. Besides hearing impairment caused by profession, there is sociacusis – a hearing impairment provoked by life-style factors – frequent exposure to loud noise in discotheques or rock concerts, or from driving sport motorcycles. A person entering a very noisy area may experience a measurable loss in hearing sensitivity, but may recover some time after returning to a quiet environment. This phenomenon can be measured as a reversible or temporary shift in audiometric thresholds, and is called noise-induced temporary threshold shift (NITTS). It is usually followed by the symptom of tinnitus. Measurements of NITTS are made by comparing pre- and post-exposure ► audiograms. A typical audiogram of NITTS shows impairment in both bone and air conduction, because the loss is sensoneurial, with a symmetrical and bilateral loss that reaches a maximum of around 4000 Hz. If a person with NITTS is exposed to noise before full restitution of hearing, NITTS could turn into a permanent threshold shift (NIPTS). When NIPTS exceeds the arithmetic mean level of 25 dB at the frequencies 500, 1000, 2000, and 4000 Hz, this is referred to as noise-induced permanent hearing loss, which is incurable. The adverse effects of noise on hearing may be enhanced by a variety of ototoxic drugs and environmental chemicals. Ototoxic drugs include streptomycin, gentamicin, aspirin, and cisplatin. Ototoxic chemicals comprise asphyxiants (carbon monoxide, cyanides), organic solvents (toluene, styrene, carbon disulfide), and metals (lead, arsenic, and mercury).

Sleep Disturbances

The optimal sound level for normal sleep is 30 dB (A) L_{eq}. If the noise level is higher, disturbances may occur before, during, and after sleep. Effects before sleep include a prolonged time to fall asleep. During the sleep period, the most important ► electroencephalogram changes include shortening or absence of ► sleep stage 4, and awakenings. Sleep stage changes towards lighter sleep can be detected in the laboratory when sound pressure levels exceed 40 dB (A), while awakenings start at 45 dB (A). After-effects of noise-disturbed sleep include fatigue on awakening and during the whole day, and changes in mood, particularly depression and low mental performance.

Cardiovascular Effects

On acute exposure of humans to noise levels of about 90 dB (A), blood pressure may be raised as a consequence of the increased secretion of catecholamines; increased concentration of lipids in the blood and raised aggregation of thrombocytes may also be observed. The major cardiovascular diseases that have been studied for possible correlation with long-term exposure to noise are arterial hypertension and myocardial infarction. Professional exposure to noise above 85 dBA for 10–20 years brings a significantly higher risk of arterial hypertension. In community settings, noise levels are much lower and the results of epidemiological studies on the relationship between noise and cardiovascular diseases are not consistent.

Behavioral Effects

The effects of community noise may be evaluated by assessing the extent or degree of general annoyance among exposed individuals or the interference with different activities. A noisy environment can have a negative impact on various aspects of human behavior: a) overt everyday behavior patterns (e. g. opening windows, using balconies, TV and radio use, writing petitions, complaining to authorities), b) human performance on specific test tasks (school achievement, vigilance, choice-reaction time, short-term memory, air traffic control), c) social behavior (aggression, unfriendliness), and d) social indicators (residential mobility, hospital admissions, drug consumption, accident rates).

Mental Health

Noise is a stressor that may have a significant negative effect on the mental health of people with already pronounced neurotic traits and weak ability to cope with stress. The most frequent psychological symptoms

in people chronically exposed to noise are headaches, irritability and anxiousness, depression, insomnia, and fatigue. Consumption of tranquillizers and hypnotics is usually higher in these people.

Noise Counter-Measures

These measures are performed at the source of noise, or are used to prevent propagation of the noise to recipients. At the source, noise reduction and sound-isolation is performed on machinery, vehicles, planes, etc. The noise limit for light vehicles in Europe is 75 dB (A) and for heavy vehicles it is 80 dB (A). A reduction in traffic is enforced by regulations in the night period (22h–06h). Other measures to reduce noise are "pedestrian days" in busy streets and "car free days", when people are advised to use public transport or to go on foot to and from work. "Ecological traffic lights" warn drivers to turn off their engines while waiting for the green light. The measures to prevent propagation of noise include sound-isolating windows and doors, paving with asphalt, sound-isolating boards inside rooms, plant or concrete screens beside motorways, and ► active noise control. If these measures do not lower the level of noise to below 85 dB (A), ► personal hearing protection is needed. Earplugs, earmuffs, and helmets must have a minimal noise reduction effect of 15 dBA, 25 dBA, and 40 dBA, respectively.

Noma

Synonyms

Cancrum oris; Gangrenous stomatitis

Definition

Noma, from the Greek word "nomein" (to devour), is a devastating gangrene of the mouth, cheek and face. It starts with ulcers of the oral mucous membranes. Rapid, painless tissue breakdown continues and this gangrenous process can destroy soft tissues and bone within days. Noma is associated with high mortality and leads to disability and disfigurement in the survivors.

The disease affects almost exclusively young children in underdeveloped countries, particularly in Africa, who are living under conditions of severe malnutrition and poor sanitation that undermine their resistance. Frequently, the disease commences during the regression phase of illness such as measles, scarlet fever, tuberculosis, or immunodeficiency.

Several elements of a plausible aetiology have been identified: extreme undernutrition/malnutrition and poverty, a compromised immune system, poor oral hygiene, and an unidentified bacterial factor acting as a trigger for the disease.

Nomad

Definition

Nomad is defined as a member of a group of people who have no fixed home and move according to the seasons from place to place in search of food, water, and grazing land. Many of indigenous peoples worldwide used to have or adopted such a way of life.

► *Chlamydia trachomatis* Infection

Non-Infectious

► Non-Communicable Diseases

Non-Maleficience

Definition

Non-maleficience goes back to the ► hippocratic oath (forth century before Christ), which concerns the doctor–patient relationship, focusing on the physician's code of conduct. It stated: "I will use treatment to help the sick according to my ability and judgment, but I will never use it to injure or wrong them." To the letter it means " Not doing harm."

Nonmarital Birth Rate

► Nonmarital Fertility

Nonmarital Fertility

Synonyms

Out-of-wedlock childbearing; Nonmarital birth ratio; Nonmarital birth rate

Definition

Nonmarital fertility is childbearing by unmarried women, including women in cohabiting partnerships. One common measure is the nonmarital birth ratio, or the percent of all births that occurred to unmarried mothers. A second measure is the birth rate among unmarried mothers. The nonmarital birth ratio measures how common nonmarital childbearing is among new mothers or among newly born children, whereas the nonmarital birth rate measures the overall levels childbearing among unmarried women. The nonmarital birth ratio can increase even when the nonmarital birth rate declines, for instance if fewer women marry or if marital birth rates decrease.

Non-Nucleoside Reverse Transcriptase Inhibitors (NNRTI)

Synonyms

Drugs to treat AIDS; AIDS-therapeutics; Anti-HIV medications; Antiretroviral medications

Definition

Nonnucleoside reverse transcriptase inhibitors (NNRTIs) bind directly to the enzyme. The substances are very sensitive, thus resistance can easily develop. A problem, which has to be faced, is the possibility of cross-resistance, that means when there is a resistance against one NNRTI, all NNRTIs become ineffective. Available NNRTIs are efavirenz (EFV, SUSTIVA®), nevirapin (NVP, Viramune®) and delaviridin (DLV, Rescriptor®). The most frequent side effects are allergic reactions and liver toxicity, furthermore, exanthema can develop; as for efavirenz, central nervous system effects have been observed.

Nonparametric Test

Definition

Inferential statistical method that is sometimes referred to as distribution-free procedure. In general, these procedures can be used with nominal or ordinal measures and do not have assumptions requiring that distributions of variables be of certain shapes (in contrast to parametric procedures, which invariably require normal distributions and interval or ratio measures).

Non-Prescription Drugs

Synonyms

Over-the-counter drugs

Definition

Non-prescription drugs are medications that can be sold legally without a prescription, in contrast to drugs that are only available on prescription. In general, OTC drugs have to be primarily used to treat conditions that do not require a direct medical supervision and which must be proven to be reasonably safe and well tolerated.

Cross-References

► Over-the-Counter Drugs

Non-Specific Occupational Diseases

► Work-Related Diseases

Non-Specific Urethritis (NSU)

► Chlamydia trachomatis Infection

Non-steroidal Anti-inflammatory Drugs (NSAIDs)

Synonyms

Pain-reliever; Painkillers; Drugs against pain; Analgesics; Antipyretics; Drugs against fever

Definition

Prostaglandins play an important role in development and maintenance of inflammatory processes, pain and fever. For there synthesis two enzymes are necessary, cyclooxygenase (COX) 1 and 2. The effect of non-steroidal anti-inflammatory drugs (NSAIDs) is due to a more or less specific impediment of cyclooxygenases and thus of the synthesis of prostaglandins. As they are very effective against inflammation, fever and pain, NSAIDs are the most often used drugs, not only on prescription but also as self-medication. Due to their widespread use, the sometimes severe side effects of NSAIDs should be taken into consideration. In most cases these side effects relate to the gastrointestinal tract; gastrointestinal ulcers, bleeding or even perforation. The most common drugs in this group are acetylsalicylic acid (aspirin), diclofenac, ibuprofen, paracetamol and metamizole.

Non-Surgical Diagnostics and Therapy

► Internal Medicine

Noongar (Southern and Western Australia)

► Indigenous Health – Australooceaninan

Normal

Definition

The term normal can refer to:

1. a value of a diagnostic test which defines patients who are not diseased.
2. a value of a screening test which defines patients who probably do not have the disease.
3. a Gaussian distribution of variables or a normal distribution, the bell-shaped curve.

In a ► screening test, any value can be considered normal if no increased risk has been found to be associated with it. Normal can therefore be defined as any usual or typical value of some human characteristic (e. g. average weight). It is opposite of the abnormal or unusual.

Normal Distribution

Definition

A normal distribution is a theoretical probability distribution with a symmetric and bell-shaped probability density curve. This can be expressed mathematically using the formula:

$$f(x) = \frac{1}{\sigma\sqrt{2\pi}} e^{-(x-\mu)^2/2\sigma^2},$$

where σ is ► standard deviation, μ is the ► mean, e is approximately 2.72, and π are approximately 3.14. The shape of this curve is completely determined by the ► mean and ► standard deviation. A special type of normal distribution is the standard normal distribution in which $\mu = 0$ and $\sigma = 1$. Any normal distribution can be converted to a standard normal distribution by the transformation: $Z = (X - \mu)/\sigma$. With this formula any score from an original normal distribution can be converted to a ► z-score.

The normal distribution is the most important distribution in statistical theory. It was developed by de Moivre as an approximation to the ► binomial distribution, and later used by Laplace to study measurement error, and by Gauss in the analysis of astronomical data.

The normal distribution is depicted as curves which are mesokurtic symmetrical, or bell-shaped. The mean value corresponds to the highest point on the curve and is identical to the mode and median value. Many phenomena in medicine conform to a normal distribution and the variables most often tend to follow a Gaussian curve with most of the values grouped near the mean and few in the tails. Nevertheless, empirical distributions always possess some degree of distortion from an ideal normal curve:

1. When the mean increases, because of more extremely large values, the curve becomes skewed to the right or positively skewed and the mean becomes

greater than median and mode (mean > median > mode);
2. When the mean decreases, because of more extremely low values, the curve becomes skewed to the left or negatively skewed and the mean becomes less than the median and mode (mean<median<mode);
3. When the variance increases the curve becomes flattened – platykurtic distributions;
4. When the variance decreases the curve becomes more peaked – leptokurtic distributions.

Deviation of the empirical distribution from the normal distribution can be estimated by applying statistical tests, for example chi-square ► goodness-of-fit test or ► Kolmogorov–Smirnov test, for testing the null hypothesis that the sample data come from a normal population.

The normal distribution is widely used in statistics. Examples are (a) classic statistical tests based on assumptions about the normality of data, (b) determination of significance levels in many hypothesis tests and confidence intervals, and (c) approximation of other probability distributions by a normal distribution, such as ► binomial distribution or ► Poisson distribution. This is possible because of the central limit theorem, which states that regardless of the distribution of the parent population, the distribution of the sample means approaches a normal distribution for a large sample.

Nosocomial Infections

Monika Korn
Klinik für Kinder und Jugendmedizin,
Friedrich-Ebert-Krankenhaus,
Neumünster, Germany
hkorn80663@aol.com

Synonyms

Hospital-acquired infections; Infections occurring in hospital patients; Infections originating in medical facilities; Infections with hospital pathogens; Infections with hospital germs; Infectious hospitalism

Definition

Nosocomial infections are caused by microorganisms and appear in hospitals or other medical institutions (doctor's practices, out-patient care). Most frequently, they are transmitted by medical or nursing activities. The condition of hospital buildings and organizational processes play an important role in the development of infections with hospital germs.

Basic Characteristics

History

The term nosocomial infections stems from the Greek word for hospital, "nosokomeion" (νοσοκομειον). Ever since people have been treated in hospitals, infections have occured during their stays. How hospital-acquired infections develop began to be understood when bacteria and other microorganisms were detected as the cause of infectious diseases during the 19th century. In the middle of the 19th century, the Hungarian obstetrician Ignaz Philipp Semmelweis discovered that the high postpartum lethality in women was due to the transfer of germs on the unwashed hands of physicians (http://inventors.about.com/library/inventors/blantisceptics.htm). At the same time, the American physician Oliver Wendell Holmes engaged in studies about childbed fever (puerperal fever) revealed the same results as Semmelweis. The British surgeon and biologist Joseph Lister succeeded in showing that germs were spread through the air and that they stuck to the instruments and the hands of surgeons.

In 1867, Lister introduced phenol (carbolic acid) as an ► antiseptic and thus inaugurated the era of antiseptic surgery. Thanks to the establishment of hand washing, heat-sterilization of instruments and antiseptic measures the number of nosocomial infections considerably declined. Although standards are high today, hospital-acquired infections are still significant and costly.

Origin of Nosocomial Infections

Microorganisms exist worldwide and do not stop at the walls of a hospital or exempt physicians, nurses or other medical staff. Due to the multitude and the variety of germs, it is impossible to achieve absolute sterility. Up to 10% of patients acquire a nosocomial infection during their stay in hospital with the probability depending on the duration of the stay and the severety of the illness. Up to 25% of patients in intensive care units can be expected to develop a nosocomial infection. The most common infections are pneumonias and urinary tract infections. The development of a ► sepsis must also be mentioned. The most common nosocomial infections are caused by enterococci, staphylococci and bacteria of the family *Pseudomonaceae*. Many microorganisms belong to the natural flora of different parts of the body; whenever they penetrate into other, untypical regions, they can cause disease. As microorganisms are not visible to the naked eye, it is difficult to assess the danger of transmission. To avoid transmitting pathogens it is necessary to comply with particular hygienic rules. Developing countries often face the problem that, due to a lack of human resources and equipment, a sufficient hygienic standard cannot be achieved, but similar situations can facilitate the occurrence of nosocomial infections in industrial nations too. For example, the transmission risk is increased by certain structural conditions, such as a lack of space or substandard buildings. In this connection, the risk of ► legionellosis due to faulty water pipes and air-conditioning systems has to be mentioned. Also the quality and conditions of work of staff has to be taken into consideration; a lack of sufficiently qualified team members, missed training courses about hospital hygiene, rate settings, bad working conditions and a high workload can all cause a disregard of hygienic rules. The hands of medical staff are the most important mode of transmission of pathogens; infections are frequently caused by insufficient ► hygienic hand disinfection. Among the medical measures that facilitate the occurrence of nosocomial infections are: venous cannulation, central vein catheterization, urinary (urethral) catheterization and mechanical ventilation. The risk of infection increases if these procedures continue for a long time or if frequent manipulations are necessary. Also, in severe injuries, if the wounds have large surfaces or if the immune status is weakened, there is an increased risk of nosocomial infections. Moreover, it has to be mentioned, that the uncritical use of antibiotics has led to the development of (multi-)resistant strains of bacteria. These so-called problem germs can appear either in a single patient or in complete sectors of a hospital and are difficult to kill by antiseptic measures or antibiotic therapy.

Disinfection

Disinfection is a very important hygienic measure, not only used in medicine. By its means, objects, rooms, surfaces or parts of the body (hands and other parts) achieve a almost pathogen-free state. Disinfection has to be differentiated from ► sterilization. Disinfectants can eliminate pathogens, impair their growth or kill them. The reduction of germs at least has to reach the factor 10^{-5}. That means, that out of 100,000 germs only one microorganism survives. Mechanical disinfection involves hygienic hand disinfection as well as well as measures of washing and rubbing. Physical disinfection can be carried out with radiation (UV-light) and with moist or dry heat. Furthermore, a number of substances are effective chemical disinfectants. To be usable, disinfectants have to fulfill three criteria: the effects have to be reached within an acceptable time interval; the measure has to be tolerated well, that means, the disinfectant must not be toxic, and it must neither damage the materials nor be a smell annoyance; the disinfectant has to be efficient. There are, however, disadvantages to using disinfectants; one has to remember that there is no differentiation between useful and pathogenic germs, natural skin flora will be eliminated; the skin is degreased; skin irritations and eczema can appear; furthermore, the skin is more susceptible to allergens and fungal infections; unthinking disposal of disinfectants has a harmful environmental effect as the natural microbial balance is influenced (http://en.wikipedia.org/wiki/Disinfection).

Further Hygienic Measures/Prophylaxis

Members of the medical team should know that their own hands are the main source of infection when coming into contact with patients. Due to this fact, careful hygienic hand disinfection always has to be carried out. Drawing up standards concerning invasive procedures or the treatment of indwelling foreign bodies (catheters, drains, etc.) may help to make the execution of hygienic procedures automatic and increase compliance. Moreover, rational antibiotic therapy, which is exactly matched to the pathogens involved, is important. By the uncritical use of antibiotics, development of resistant (or even multiresistant) pathogens is facilitated. When multiresistant pathogens evolve, special hygienic measures are necessary; despite the increase in time and work they involve for the staff, as they prevent the spread of infection. Infected patients should be isolated with separate toilet facilities. Beside disinfecting their hands, the staff have to wear protective clothing (gloves, mouth-nose mask and protective coat). Materials, which even hint of being contaminated, have to be marked and properly disposed of. If diagnostic or surgical measures are necessary the infected patients must be placed at the end of the theater list. After any procedure, a total surface disinfection has to be carried out. The isolation of the patient does not end until the multiresistant organism cannot be repeatedly cultivated. Any carriers, including staff and other patients, must be treated until free of the infecting organisms. The application of these precautions against carriers of multiresistant germs is only necessary in hospitals and certain nursing care institutions as carriers present no risk to healthy individuals.

Multiresistant Problem Pathogens

► Methicillin- (or multi-)resistant ► *Staphylococcus aureus* (MRSA) and vancomycin-resistant enterococci (VRE) belong to the multiresistant pathogens, which are found in hospitals. It is important to differentiate between a ► colonization and an infection with a multiresistant germ. MRSA, which is spread worldwide, is characterized by a changed penicillin-binding protein. As this protein is resistant against beta-lactam antibiotics (penicillins, cephalosporines, carbapenems), treatment becomes more difficult. Factors which increase the risk of MRSA-infections are vascular catheters, wound drains, wounds with large surfaces and chronic skin lesions (decubitus ulcers, ulcus cruris). If a MRSA-infection needs treatment, linezolid, fusidic acid, ► vancomycin or teicoplanin can be used. However, vancomycin-resistant strains of MRSA have already appeared. An MRSA infection in the nasal vestibules can be treated with a local application of mupirocin ointment (Turixin®). VRE first appeared in 1994. Enterococci belong to the natural intestinal flora and are also found in the female urogenitary tract. Similar to MRSA, VRE show no higher virulence than germs of the same species which are sensitive to antibiotics. The mere presence of VRE is not dangerous, but an infection is difficult to treat as only a few effective antibiotics are available (http://www.who.int/csr/resources/publications/drugresist/WHO_CDS_CSR_EPH_2002_12/en/).

In conclusion, it has to be pointed out that, due to the omnipresence of microorganisms, the transmission of germs during a stay in hospital and the resulting occurrence of a nosocomial infection is a great problem even in modern medicine. To prevent hospital-acquired infections, hygienic rules have to be followed consistently, particularly hygienic hand disinfection. Furthermore, a critical use of antibiotics has to be instituted in order to avoid the development of multiresistant germs.

Notifiable Disease

Synonyms

Reportable disease

Definition

Notifiable (reportable) diseases are diseases that are required by law to be reported to governmental authorities by medical practitioners. They used to vary according to individual state laws. Each country will have its own arrangements for developing surveillance data according to its own needs and resources. The World Health Organization (WHO) maintains worldwide coverage of selected diseases and solicits the reporting of other diseases on a voluntary basis. By international law, plague, cholera, and yellow fever are reportable to the WHO. Data on these diseases are summarized in a weekly epidemiologic report prepared and distributed by the WHO.

Within the U.S., each state has its own laws concerning what diseases are reportable and how they should be reported to the state health department. The number of diseases reportable within the states varies from 35 to 120. State laws include penalties for not reporting reportable diseases.

The main concern of the modern statutory notification system is speed in detecting possible outbreaks; accuracy of diagnosis is only secondary.

Nuclear Medicine

Definition

Nuclear medicine is the branch of medicine that is concerned with the use of radioisotopes in the diagnosis, management, and treatment of disease. It usually uses small amounts of radioactive materials or radiopharmaceuticals, substances that are attracted to specific organs, bones, or tissues. The radiopharmaceuticals that are utilized in nuclear medicine emit gamma rays that can be detected externally by special types of cameras so that images can be formed to provide data and information about the respective area of the body.

Nucleoside and Nucleotide Reverse Transcriptase Inhibitors (NRTIs)

Synonyms

Drugs to treat AIDS; AIDS-therapeutics; Anti-HIV medications; Antiretroviral medications; Nukes

Definition

Nucleoside and nucleotide reverse transcriptase inhibitors (NRTIs) were the first drugs used for the treatment of AIDS. These substances, which are colloquially called “nukes”, introduce elements which disrupt viral reproduction. According to the characteristics of the agent used, the mistakes in viral construction appear at different parts of the virus. Thus the combination of different NRTIs can increase the antiviral effect. Azidothymidin or zidovudin (AZT, ZDV, Retrovir®), stavudin (D4T, Zerit®), zalcitabin (DDC, HIVID®Roche), didanosin (DDI, Videx®), lamivudin (3TC, Epivir®, Zeffix®), abacavir (ABC, Ziagen®), tenofovir (TDF, Viread®) and emtrictabin (FTC, Emtriva™) are some of the available NRTIs. They can be given as capsules or suspensions. Possible side effects are headache, stomach ache, nausea, diarrhea, exanthemas and an interference with the formation of blood.

Nukes

► Nucleoside and Nucleotide Reverse Transcriptase Inhibitors (NRTIs)

Null Hypothesis

Definition

A statistical statement of no effect or no difference. Since the statement of the research generally predicts the presence of an effect or a difference with respect to whatever it is that is being studied, the null hypothesis will generally be the hypothesis that the researcher expects to be rejected. The null hypothesis claims the results obtained from the study, experiment, or test are

no different from those obtained as a result of a coincidence. It is represented by the notation H_0.

Number of Children Born Alive

► Parity

Number Needed to Treat (NNT)

Definition

The number needed to treat (NNT) is a way of expressing the size of a treatment effect which is easier to interpret clinically. The NNT is the number of patients needed to be treated to prevent one additional bad outcome. This number is the inverse of the absolute risk reduction (ARR).

$$\text{NNT} = 1/\text{ARR}$$

$$\text{ARR} = \text{CER (control even rate)} - \text{EER (experimental even rate)}$$

NNT are always rounded up to the nearest whole number. The NNT is the number of patients who need to be treated with a given intervention/medication to prevent one bad outcome. It is the inverse of the ARR (absolute risk reduction): NNT = 1/ARR. Advantages of the use of the NNT are: incorporation of changes in baseline risk, greater clinical relevance than the absolute and relative risk reduction, and the possibility to compare the relative merits of drugs. Disadvantages are: placing emphasis on the positive side of therapeutic interventions, the lack of information on the magnitude of the baseline risk, and the lack of comparability for different baseline risks.

Number Treated Needlessly (NTN)

Definition

The NTN is the number of individuals who are treated with a given intervention/medication without benefit. The formula is: NTN = NNT − 1. Advantages of the NTN are: it incorporates changes in baseline risk, it is complimentary to the NNT, it can compare the relative burden of different interventions, and it encourages selective targeting of drug treatment versus a broad application of treatment results.

Numerator-Denominator Bias

Synonyms

Numerator-denominator mismatch

Definition

A numerator-denominator bias is a systematic distortion due to a denominator that does not match the numerator, or *vice versa*. For example, when calculating the mortality rate of a population, a numerator-denominator bias will occur if the numerator does not relate to the population in the denominator. This would be the case if the numerator contained *all* deaths that occurred within a particular country, whereas the denominator contained only the resident population. The mortality rate calculated on this basis would systematically overestimate the true mortality rate of the resident population as deaths among visiting foreigners would be included in the numerator, but the foreign population is not part of the denominator.

Nursing

► Breastfeeding

Nursing Bottle Syndrome

► Nursing Bottle Tooth Decay

Nursing Bottle Tooth Decay

Synonyms

Nursing-bottle syndrome (NBS)

Definition

Nursing bottle tooth decay is a severe kind of dental caries in young children caused by the frequent and

long lasting use of baby bottles with sugar-containing drinks or fruit juices. This kind of rampant tooth decay can either destroy the milk tooth or have negative effects on eating, speaking and the permanent dentition. In severe cases, all baby teeth are destroyed and have to be extracted under general anaesthesia. To prevent that kind of tooth decay it is recommended that children be encouraged to begin drinking from a cup as they approach their first birthday. At nap times or at night, children should not fall asleep with a bottle.

Nursing Homes

Synonyms

Residential health care facility

Definition

Nursing homes are residential health care facilities that provide institutional care for people recovering from an acute illness or suffering from a ► chronic disease, and who require skilled nursing care and 24-hour supervision. Besides the skilled nursing services, nursing homes offer significant assistance with ► activities of daily living as well as physical, occupational, and speech therapy. The objectives of the therapies offered are to enable the residents to recover from their disease or injury and to improve their ► functional ability. The majority of the residents, who are usually elderly, have chronic or long-term care needs that range from independent home care to care within intensive-care units of hospitals. The services offered by the nursing homes differ and range from nursing homes that offer only basic services to facilities with highly skilled and technologically state-of-the-art services that can be compared with medical units in hospitals.

Nutrition

Bremen Institute for Prevention Research and Social Medicine, Bremen University, Bremen, Germany
hassel@bips.uni-bremen.de, dreas@bips.uni-bremen.de, kurz@bips.uni-bremen.de

Synonyms

Eating; Ingestion

Definition

Nutrition is the absorption of liquid and solid food. Nutrition describes the processes whereby cellular organelles, cells, tissues – in short the whole human body – uses necessary substances which are obtained from food to maintain structural and functional integrity and to avoid deficiency. Nutrition is a complex interaction between internal or constitutional factors and external environmental factors which determine nutritional status. Nutrition is determined by cultural, social, economical and individual aspects. In addition to other ► lifestyle and environmental factors, nutrition influences health and well being. It is a major, modifiable and powerful element in promoting health, preventing and treating diseases and improving the quality of life. Nutrition is affected by consumption and communication. Nutrition contributes to prevention by containing vaccines like ► bioactive substances. Thereby it contributes to the physical, mental and social well being of people (Gibney et al. 2002; Gibney et al. 2004).

Basic Characteristics

Optimal balanced nutrition of a high quality has a major impact on health, well being and the quality of life. It is a complex interaction between internal and external environmental factors. The relationship between nutrition and health can be described in six quality levels:

Fulfillment of Demand

An ideal ► nutritional status provides the maintenance of all bodily functions of an organism, the avoidance of ► malnutrition and thereby it serves the maintenance of health and efficiency. In industrial countries there exists a big gap between food recommendations (► nutritional recommendations) and the supplied nutrients and the energy intake. Food is often too fat and it often consists of low fiber. Furthermore, salt, sugar and alcohol are consumed excessively. This malnutrition leads to a nutritionally adverse situation. The ongoing availability of food with a high energy supply in contrast to a low energy requirement is the main cause of the widely spread ► overnutri-

tion and obesity in industrial countries. ► Undernutrition and malnutrition are one of the main causes for diseases in the developing countries (► nutritional diseases). Malnutrition leads to diet-related diseases, e. g. protein-energy-malnutrition in developing countries (Leitzmann 2001; World Health Organization (ed.) 2003; Kasper 2007).

Prevention

Certain components of food, like bioactive substances or ► antioxidants fulfill, as protective elements, important preventive functions in the development of diseases.

Bioactive substances block the development of certain tumors and arteriosclerotic vascular diseases. The biggest group of these protective substances are ► secondary plant compounds. They are found in plants as pigments, growth regulators, repellents against vermins and parasites as well as aroma and scents. Approximately 1000 secondary plant compounds are absorbed daily. Thereof just a little group of approximately 100 substances has been investigated up until now. In a mixed diet approximately 1.5 g of secondary plant compounds are absorbed daily (Leitzmann 2001; Biesalski 2004).

Among other things antioxidants operate as scavengers in the human body. Free radicals emerge in the human body through tobacco smoking, certain drugs or UV-radiation. Free radicals are associated with diseases like tumors, arteriosclerosis and senile dementia. Antioxidants consist of vitamin C, E and carotenoids. A lot of vitamin C is bound, e. g. citrus fruits. The antioxidative effect can be best described by a little experiment with a sliced apple; the brownish coloration of the slice of an effected oxidation can be slowed down if it is dripped with lemon juice. Antioxidants appear in fresh fruits (e. g. citrus fruits) and vegetables (e. g. tomatoes, broccoli), herbs, nuts, coffee and tea. A rich vegetable diet which contains a lot of nutritional components provides good protection from chronic and degenerative diseases.

► Functional food products are frequently advertised as health improvers. This diverse food group consists of food and drinks, which are enriched with, for example, vitamins, bacteria cultures or secondary plant compounds. Good examples of functional food are pro- and prebiotica which are often offered in the form of yoghurts (► prebiotics, ► probiotics) (Biesalski 2004; Kasper 2007).

Pleasant Taste

People do not eat only to nourish themselves but also to enjoy the actual consumption of food and drink (► pleasant taste). Thereby food and drink are appreciated as individually learned sensual experiences. The sensual quality of food (► sensoric quality of food) gives a sense of enjoyment. The loss of the ability to taste, smell, judge the consistency and the color of food can lead to sensorial deprivation which can lead to a sensual loss or even to a lack of the ability to enjoy food at all.

The task of nutritional education is to develop and activate early sensuality and enjoyment. Those who enjoy develop situations of enjoyment and cultivate associations with the object of enjoyment, e. g. they choose dishes and refine them. Gourmets are in a position to maintain a proper balance, to control themselves and to accept abstinence. Enjoyment is one of the basic factors which leads to conserving health and, thereby, contributing to the well being of the individual (Thimm and Wellmann 2004; Kasper 2007).

Communication

Eating in a community takes place according to social rules. Common meals can be influenced through devotion, love and communication. People exchange views, share thoughts and experience, reach agreements and norms and values are facilitated. Common meals contribute to security and trust. They are also embedded in common care for each other and especially for children. In this way information can be exchanged, social behavior can be trained, relationships can be promoted and thus social well being can be enhanced. This “table community” symbolizes togetherness. Common meals offer a chance to develop social networks. Since the 70s common meals, taken with the family, have more and more been relegated to weekends; this development has led to a loss of social values and relationships (Hurrelmann 2002; Hurrelmann et al. 2006).

Lifestyle

Where, what and how much people eat and drink - in short their nutritional behavior (► behavior of nutri-

tion) – is basically influenced by their lifestyle; daily routine is affected by lifestyle which affects food preferences or dislikes and ways of eating and drinking.
In the course of the development of an individual, patterns of behavior are built up step by step until a whole individual lifestyle is adopted. Already by the stage of adolescence there are different styles found with regard to free-time and nutritional behavior. The "sportive type" for instance prefers healthy food; milk, fruit and vegetables are regularly on the menu. In contrast, the "television type" likes sweets, and rarely consumes healthy food. Whether adolescents follow a sportive or television orientated lifestyle may be, to a lesser degree, self-determined or dependent on their parents' influence, their education and social levels as well as on their educational environment. The nutritional behavior of adolescents and adults is part and parcel of their particular lifestyles and factors like attitude, knowledge, economic status and gender can have an influence (Gerhards and Rössel 2003).

Food Safety

Safe food, which is free from microorganisms, noxious and other hazardous substances that cause diseases, is an important condition for healthy nutrition (► food safety). Recent experiences with animals suffering from bovine spongiform encephalopathy (mad cow disease) have shown how quickly the global marketing of products can become an international health problem. The safety of food can be enhanced by a quality management system like the ► HACCP-concept. Furthermore, monitoring of the food supply by health officials is necessary (Gibney et al. 2004).
The six quality levels clarify that nutrition is determined by cultural, social and individual factors. Nutrition is a major, modifiable and powerful factor in promoting health, preventing and treating diseases and improving the quality of life. Thereby nutrition contributes to physical, mental and social well being. The slogan "You are what you eat!" concisely sums up the concept.

Nutritional Behavior

► Behavior of Nutrition

Nutritional Condition

► Nutritional Status

Nutritional Diseases

Definition

Nutritional diseases are diseases in which ► malnutrition plays an import role in terms of the development and course of the illness. Nutritional diseases are, for example, caries, obesity, obstipation, high blood lipids and arterial circulatory disturbances.

Nutritional Recommendations

Definition

Nutritional recommendations are guidelines for nutritional and energy intakes that are adapted to meet proper levels of ► nutrition and that avoid ► malnutrition and further the maintenance of health. They are produced by different international organizations such as WHO/FAO and by national expert panels in different countries such as the Food Nutrition Board, USA and the Deutsche Gesellschaft für Ernährung.

Nutritional Status

Synonyms

Nutritional condition

Definition

Nutritional status is the current body status of a person or a population group related to their state of nourishment. The nutritional status is determined by a complex interaction between internal or constitutional factors and external environmental factors like age, gender, ► nutrition, behavior, ► physical activity, diseases, ► food safety, social and economic circumstances. An ideal nutritional status occurs when the supply of nourishment conforms to the need for nourishment. People can have an optimal nutritional status or they can be under-, over- and/or malnourished. The nutritional status of an individual has consequences: an optimal nutritional status is a powerful factor for health and well being whereas ► malnutrition may increase to infection and chronic diseases, ► undernutrition may lead to increased infections and decreases in physical and mental development, and ► overnutrition may lead to obesity as well as to metabolic syndrome or type 2 diabetes.

Nutritionist

► Dietician

N-Year Event

Definition

Event whose magnitude is exceeded, on average, once in N years.

Obesity

MANFRED JAMES MÜLLER
Institut für Humanernährung und Lebensmittelkunde,
Agrar- und Ernährungswissenschaftliche Fakultät,
Christian-Albrechts-Universität zu Kiel,
Kiel, Germany
mmueller@nutrfoodsc.uni-kiel.de

Synonyms

Severe overweight; Adiposity

Definition

Obesity is defined as disease in which excess body fat has accumulated to such an extent that health is adversely affected. ► Body Mass Index (BMI, i. e. weight in kg / (height in m)^2) is the population measure of obesity BMI does not account for body composition and variations in fat distribution. Cut offs are defined according to BMI-associated morbidity. Ethnic populations differ in the level of risk associated with a particular BMI. In Caucasian adults BMI is normal between 18.5 and 24.9 kg/m^2. Values between 25.0 and 29.9 kg/m^2 correspond to overweight (overweight or preobese), >30.0 kg/m^2 denotes obesity. Obesity can be further classified into class I (moderate, 30.0–34.9 kg/m^2), class II (severe, 35.0–39.9 kg/m^2) and class III (very severe, >40.0 kg/m^2). In children and adolescents national and international BMI reference percentiles are used with the 90th and 97thP as cut offs for overweight and obesity, respectively. In the US 85th and 95thPs are used. The association between BMI and body fat varies according to body build and proportion as well as across populations. Alternatively direct measures of body fat (e. g. anthropometric or bioelectrical impedance measurements) are used in population surveys with values >25 (males) and >30% of body weight (females) denoting overfat. Abdominal (or visceral) fat carries the highest metabolic risk. Waist circumference (measured at the midpoint between lower border of the rip cage and the iliac crest) is a population measure of abdominal fat. Risk is increased above 94 (males) and 80 cm (females). Risk is substantially increased at >102 and >88 cm, respectively. The waist associated risk is independent and additive to the BMI-associated risk. The waist to hip ratio (w/h) is related to cardiovascular risk. w/h is the ratio between risk (i. e. w = excess abdominal fat) and protective factors (i. e. hip circumference is related to fat free mass). w/h-cut offs are >1.0 in males and >0.85 in females. Taken together weight, fat and waist characterize obesity and its health risks.

Basic Characteristics

Levels and Trends

There is a world wide increase in the prevalence of overweight and obesity. In adult populations prevalence of overweight plus obesity varies between about 30% (China) and more than 60% (industrialized countries). Corresponding prevalences of obesity range between 3 and above 25%. Prevalence of overweight children and adolescents is between 5 to 20% with considerable differences between countries, e. g. there is a north-south gradient in Europe with highest values in southern European countries. Trend data suggest steep rises in prevalences of overweight and obesity during the past 25 years, e. g. there is a 2- to 5-fold increase in overweight prevalence in children and adolescents in Germany. In non developed countries increases in overweight and obesity are strongly associated with transition and economic growth. A further increase in over-

weight and obesity is likely. According to the WHO prognosis for 2040 obesity prevalence will reach 50% in industrialized countries.

Causes

Overwight and obesity are mainly considered as a problem of energy balance. Thus the high intake of energy and energy dense foods (e. g. fast food), animal fat, sugar sweetened beverages, high portion sizes at concomitantly low energy expenditure due to low physical activity (due to increases in car ownerships, automatization at occupational and household work, low leisure time activities, urban residence) and high inactivity (i. e. sedentary lifestyle due to high TV and media use) all result in a positive energy balance. In population surveys crude proxies for inactivity such the amount of hours spent viewing TV per day or the number of cars per household show close associations with the prevalence of overweight and obesity. In addition increases in inactivity over time are closely related with rises in overweight and obesity. Breast feeding seems to be protective with respect to childhood overweight. Additional determinants of overweight and obesity are high parental weight and low socioeconomic status (SES). Genetic studies suggest a susceptibility of some people to become overweight and obesity under the influence of gene-environment interactions. However up to now this idea has not been substantiated. There are steep and inverse social gradients in overweight and obesity in children, adolescents and adults. The lower the social position the higher the prevalence of overweight as well as overweight-related co-morbidities. The inverse SES gradient in overweight remains after adjustment for SES-related lifestyle variables suggesting psychosocial factors in addition to health-related behaviors as determinants. Other factors promoting weight gain include smoking cessation, excess alcohol intake, drug treatment (e. g. tricyclic antidepressants, corticosteroids), certain endocrinological (e. g. Cushing disease) and genetic disorders (e. g. Prader Willi syndrome) as well as changes in social circumstances (e. g. marriage, birth of a child). In developing countries the trend towards industrialization and global market economies has improved living standards but also increased the risk of diseases (i. e. obesity, diabetes mellitus type 2, cardiovascular diseases). Obesity is the first of the so-called diseases of civilization to emerge. Taken together, obesity is considered as a complex multifactorial disease with considerable inter-individual variations.

Consequences

Health consequences of overweight and obesity include non communicable diseases such as type 2 diabetes mellitus, dyslididemia, insulin resistance and gallbladder disease with a more than 3-fold increase in relative risk (RR). Moderately increased risks (RR 2–3) are observed for hypertension, gout, cardiovascular disease and osteoarthritis. RR is slightly increased (RR 1–2) for certain cancers (breast cancer in postmenopausal women, endometrial cancer, colon cancer, prostate cancer), polycystic ovary syndrome, impaired fertility, low back pain and fetal defects associated with maternal obesity. In addition there are a number of psychosocial problems associated with obesity (e. g. body shape dissatisfaction, stigmatization). Eating disorders (i. e. binge eating, night eating syndrome) may be seen in up to 30% of severely obese patients seeking medical help. Life expectancy is reduced in overweight and obesity subjects. When compared with a 40-year-old normal weight subject 3 and 7 years of life are lost in overweight and obesity. Smoking is an additive health risk causing a further loss of 6 years of life in obesity individuals. In children health consequences of obesity include faster growth, psychosocial problems (e. g. due to stigmatization), persistence into adulthood (e. g. >80% in obesity adolescents), dyslipidemia, hepatic steatosis, impaired glucose tolerance, metabolic syndrome, orthopedic complications, cholelithiasis and hypertension. For example, in 10-year-old obesity children the prevalences of hypertension and dyslipidemia exceed 30% when compared to values below 5% in their normal weight counterparts.

Treatment and Prevention

Priorities to control the obesity epidemic include prevention of excessive weight gain, sustained weight loss as well as elimination of disparities in obesity and its complication. Principle strategies to prevent weight gain are reduction of energy intake (with an increase consumption in low energy dense foods like fruit and vegetables at concomitant decreases in sugar sweetened beverages and portion sizes), increase in energy expenditure (by increased both exercise- and non

exercise activities), decrease in inactivity (reduced TV and media use) and recommendation of breast feeding. Areas to intervene include (i) the individual (e. g. lifestyle counseling), (ii) family and household settings, (iii) kindergarten, school and workplace, (iv) community and neighborhood as well as (v) the macro-environment. Today most experience is in the (i), (ii) and (iii) areas. Studies on the feasibility and effectiveness of school– and community programs have only recently been undertaken. The information has been systematically analyzed in different Cochrane reviews.

Treatment strategies of the obese patient include diet (i. e. low calorie diets) together with increased physical activities as part of a behavior-oriented lifestyle program. Pharmaco-therapy tackles energy intake by reducing appetite and digestion of dietary lipids. In the severely obese with high co-morbidity bariatric surgery (e. g. gastric banding) may be indicated. Theoretically all these measures are capable of inducing significant weight loss as well as lessening co-morbidity. However, to present, experience suggests high efficacy but low long term (i. e. 3 to 5 year) effectiveness, i. e. none of the above mentioned strategies (except bariatric surgery) has sustained positive effects in terms of reduction of weight and co-morbidities. This is mainly due to low rate of adherence to protocols (e. g. during the first year less than 20% of the patients recruited followed dietary advice). However in controlled studies with high adherence rates significant weight losses were observed (e. g. a reduced energy intake by 600 kcal/d reduced body weight by 5 kg/year compared to the spontaneous increase of about 0.5 kg/year before treatment).

Most of our observations on prevention of childhood overweight have been carried out in the school setting. Health education as well as changes in school environment have been used to increase the knowledge and competence of children. Long-term follow up (i. e. up to 2 to 4 years) data suggest some improvements in knowledge and health-related behaviors but only minor or no changes in BMI prevalence and incidence. Selective positive effects were observed in children of normal weight mothers and high SES families. The intensity and expense of the program did not affect outcome. School-based health promotion works better in a health promoting environment. Family-based programs have been used for families of overweight and obesity children. These programs reach a high intensity but are expensive. There are some long-term experiences (i. e. up to 12 years) showing some long-lasting positive effects in terms of BMI. However this strategy reached high rather than low SES families thus increasing the SES gradient in overweight. Comparing family programs, school-based health promotion or more general measures (e. g. reducing TV advertising for snacks, sweets and soft drinks) BMI reduction of 1.7, 1.1 and 0.2 kg/m^2 per child have been calculated. However, expressing these data in terms of DALYs, 2700, 8000 and 37 000 respectively have been saved. These data argue in favor of general measures to prevent childhood overweight. More recently various community-led action plans resulted in effective long-term prevention. Different settings (e. g. community health centers, primary care, schools, after school programs, churches, sport clubs, fast food outlets) and experts (e. g. politicians, physicians, nutritionists) were involved resulting in community building, awareness raising and long-term (i. e. 3 to 8 years) effectiveness in terms of improved knowledge, lifestyle and nutritional status and costs.

Outlook

There is lack of intervention at government level. Obesity, like most other challenging public health problems, probably requires multifaceted educational and environmental interventions. These approaches work against a strong trend which favors consumerism and thus a high percentage of unhealthy lifestyle. This trend limits the success of health promotion. Overweight is not only a problem of low SES people or even the poor. Since there are considerable differences between all social groups, the gradient reflects problems between different SES groups within our societies. Then the obesity epidemic is an epiphenomenon of other (e. g. economic, educational, social) problems within our societies. Thus the solution of obesity problems follows the solution of economic, educational and/or social problems. Tackling the obesity epidemic indirectly by improving capabilities and thus autonomy as well as social participation of parents and children is health promoting. This does not neglect the value of an "ecological" approach (e. g. tackling the obesogenic environment). Changing the food environment, reconsidering the value and consequences of economic growth and consumerism as well as changing views about obe-

sity (i. e. reducing stigma) all add to the reduction of the incidence and prevalence of obesity.

Synonyms

Nonexperimental studies

Definition

An observational epidemiologic study is a type of study in which the investigator observes and measures the effect of a ► risk factor, diagnostic test, or treatment on a particular outcome but does not intervene (in contrast with an experimental study, no attempt is made to affect the outcome).

Basic Characteristics

Appropriate use of observational studies permits the investigation of prevalence, incidence, associations, causes, and outcomes. Where there is little evidence on a subject, such studies are cost effective ways of producing and investigating hypotheses before larger and more expensive study designs are embarked upon. In addition, they are often the only realistic choice of research methodology, particularly where a ► randomized controlled trial would be impractical or unethical. Observational studies can be classified into descriptive studies, which are usually undertaken when little is known of the epidemiology of a disease, and analytic studies, which are carried out when leads about etiology are already available.

Descriptive Studies

Descriptive studies provide information on patterns of disease occurrence in populations, particularly in relation to people, places, and times. Generally, the emphasis in these studies is on estimation (e. g. of the disease prevalence, the natural history of disease, the resources required to treat the disease, or attitudes and perceptions about the disease). These types of study can sometimes be used to generate hypotheses. Descriptive study designs include ► case reports, ► case series (an extension of the case report), and ecological (correlation) studies (► ecological study).

Analytic Studies

Analytic studies (hypothesis testing studies) are designed specifically to test causal hypotheses that have usually been generated from descriptive studies. The three major types of analytic studies are cohort studies (prospective and retrospective), case control studies, and cross sectional studies.

Cohort Studies (Synonyms: Follow-up; Incidence; ► Longitudinal Studies) Cohort studies are considered the strongest of all observational designs. In a cohort study, the investigator usually starts with two ► cohorts who are apparently free of the disease of interest – one exposed to a possible risk factor and another who are not exposed. These cohorts are then followed through time in order to determine the out-

come events (e. g. incidence) among the exposed and the unexposed. The follow-up period depends on the natural history of the outcome disease and the frequency of disease occurrence. The incidence in the exposed cohort is then compared with the incidence in the unexposed cohort. The resultant ratio is called ► relative risk or ► risk ratio (RR) and it is considered the best measure of effect. In addition to the relative risk, the ► attributable risk (AR) and ► population attributable risk (PAR) can be calculated (Gordis 2004).

Cohort studies are used to study incidence, causes, and prognosis. Because they measure events in chronological order, they can be used to identify cause and effect.

In a *prospective cohort study (concurrent cohort study)*, the investigator collects information on the exposure status of the cohort members at the time the study begins (or at the time the exposure occurs during the study), and identifies new cases of disease from that time forward (the cohort is "followed up" prospectively).

Example: A prospective cohort study on mortality in relation to smoking that took place between 1951 and 2001 in the United Kingdom has recently been published in the British Medical Journal by the eminent epidemiologist Sir Richard Doll and coworkers (Doll et al. 2004). The cohort was a group of 34,439 British male doctors listed in the British Medical Register. Information about their smoking habits was obtained in 1951, and periodically thereafter; cause-specific mortality was monitored for 50 years. The study revealed that, among the men born around 1920, prolonged cigarette smoking from early adult life tripled age specific mortality rates, but cessation at age 50 halved the hazard, and cessation at age 30 avoided almost all of the increase.

A problem that occurs when the cohort method is applied to the study of chronic diseases such as coronary heart disease or cancer is that large numbers of people must be followed up for long periods before sufficient cases accrue to give statistically meaningful results. The difficulty is further increased when there is a long induction period between first exposure to a hazard and the eventual manifestation of disease, as with most carcinogens, for example. An approach that can help to counter this problem is to carry out the follow up retrospectively. Obviously, such a study is only feasible when the health outcome of interest can be measured retrospectively (Coggon et al. 1997).

In a *retrospective cohort study (historical or nonconcurrent cohort study)*, the exposure status is established from information recorded at some time in the past, and disease incidence is determined from then until the present (i. e. the cohort is "followed up" retrospectively). The study period may be many years but the time to complete the study is only as long as it takes to collate and analyze the data (Gordis 2004).

Example: To determine whether the frequency and pattern of use of the accident and emergency (A&E) department by individuals with diabetes is different from that of the general population, a historical cohort of 696 individuals with diabetes and a non-diabetic comparison cohort, matched on age, sex, and general practice, was conducted in 1997. The use of an urban A&E department by the two cohorts was compared (number of visits between 1984 and 1996). Individuals with diabetes made more frequent visits to the A&E department than the general population. Since there was no excess of visits for injuries and the proportion requiring admission was similar, the hypothesis that they have a different threshold for attending was not supported (Goyder et al. 1997).

Case Control Studies (Case Referent Studies; Case Comparison Studies) In a case control study, the investigator selects two groups – a group of individuals with a disease of interest (or other outcome), called cases, and a suitable group of people without that disease, called controls. The history of exposure to suspected risk factors is then determined and compared retrospectively between "cases" and "controls". The measure of association in a case control study is called an ► odds ratio (OR). It is the ratio of the odds (chance) of exposure among cases in favor of exposure among controls. However, true incidence estimates cannot be generated from a case control study (Gordis 2004).

The starting point of most case control studies is the identification of cases. This requires a suitable case definition. Ideally, the cases studied should be a random sample of all of the patients with the disease. Selecting the controls is often a more difficult problem. The controls may be a matched (► matching) or unmatched random sample from the unaffected population.

Case control studies are often used to generate hypotheses that can then be studied by prospective cohort or other studies. They are useful for studying rare diseases or outcomes. When there is a long latent period between

an exposure and a disease, case control studies are the only feasible option.

Example: A case control study was conducted in order to assess possible relationships between potential risk factors and Graves' disease. The study included 100 newly diagnosed patients with Graves' disease and 100 controls matched with respect to sex, age (+/− 2 years), and type of residence (rural, urban). All the subjects were interviewed by the same doctor. The findings indicated that stressful life events, lack of social support, and family history of Graves' disease were significantly associated with the occurrence of Graves' disease (Janković et al. 1997).

► Nested case control studies and ► case cohort studies combine elements of both case control and cohort studies.

Cross Sectional Studies (Prevalence Studies; Surveys) In cross sectional studies, the presence or absence of both the exposure and the disease in a given population are measured at a point in time or over a short period. Prevalence rates among those with and without the exposure or at different levels of exposure are then determined and compared. Because both exposure and disease are measured at the same time, it is impossible to determine, in most cases, which came first. Therefore, cross sectional studies can suggest associations between an exposure and a disease but do not permit identification of cause and effect.

Cross sectional studies are the best way to determine the prevalence of diseases and they are appropriate studies for planning health care. They are relatively quick and inexpensive.

The principal summary statistic of cross sectional studies is the Odds Ratio (OR).

Among the more widely known cross sectional studies are the periodic national household (interview) surveys by the U.S. National Center for Health Statistics (NCHS), the annual (telephone) Behavioral Risk Factor Survey conducted by the U.S. Centers for Disease Control and Prevention (CDC), etc.

Comparison of Various Study Designs The decision to choose an appropriate study design is not an easy task. "There an only a handful ways to do study properly but a thousand ways to do it wrong" (Sackett and Wennberg 1997). Each observational study has its own strengths and weaknesses (Table 1) and there is rarely only one type of study design that is appropriate to answer a study question.

Observational Studies, Table 1 Comparison of cohort, case control, and cross sectional studies (Source: modified from Beaglehole et al. 1993)

Characteristics of the study	Cohort study	Case control study	Cross sectional study
Time required for study	Generally long	Relatively short	Relatively short
Cost of study	Expensive	Relatively inexpensive	Relatively inexpensive
Strength of causal inference	High	Medium	Low
Investigation of rare disease	–	Best	–
Investigation of rare exposure	Best	–	–
Study of multiple outcomes of an exposure	Best	–	Possible
Study of multiple exposures	Possible	Best	Possible
Measurement of temporal sequence	Best	Possible	–
Measurement of incidence rates and Relative Risk (RR)	+	–	–
Measurement of Odds Ratio (OR)	+	+	+
Selection bias	Low	High	Medium
► Recall bias	Low	High	High
Loss to follow-up	High	Low	–

Observer Bias

Synonyms

Interviewer bias

Definition

Observer bias means that investigators who know which treatment has been assigned to a given subject may be more watchful for certain side effects and benefits. The best protection against observer bias is to have neither investigator nor participants knowing the group to which the subject has been assigned. This type of study is called double blind. Protection against this bias is also possible in triple blind studies in which not only the participant and the investigator but also those responsible for data analysis do not know the group to which the participant has been assigned. In open trials, it is important to follow the experimental and control group with equal intensity for evaluation of the outcome.

Obsessive-Compulsive Disorder (OCD)

Definition

Obsessions are recurrent, intrusive thoughts, impulses, or images that are perceived as inappropriate, grotesque, or forbidden. A characteristic feature of an obsessive-compulsive disorder is the repetitive inner compulsion, perceived as tormenting, to think or do certain things. Common themes include contamination with germs or body fluids, doubts (i. e. the worry that something important has been overlooked or that the sufferer has unknowingly inflicted harm on someone), order or symmetry, or loss of control of violent or sexual impulses. The subjects often try in vain to resist their impulse. Compulsions are repetitive behaviors or mental acts that reduce the anxiety that accompanies an obsession or "prevent" some dreaded event from happening. These tasks or rituals are seen as being neither pleasant nor useful, but are designed to prevent events or situations that, objectively, are unlikely to occur. Compulsions include both overt behaviors, such as hand washing or checking, and mental acts including counting or praying.

Obstetrics and Gynecology

Definition

Obstetrics is the field of medicine specialized in the art and science of managing pregnancy, labor, and the time after delivery. Gynecology is the branch of medicine specifically concerned with the health of the female organs of reproduction and diseases thereof.

Occupational Accidents

Synonyms

Accidents at work

Definition

According to the ILO definition from 1998, occupational accidents can be define as accidents that happen at work and accidents on the way to and from work. As a result of occupation accidents, ► occupational injury, disease, or death can occur. Another definition describes an occupational accident as an unexpected and unplanned occurrence, including acts of violence, arising out of or in connection with work which results in one or more workers incurring a personal injury, disease or death. It is suggested that travel, transport or road traffic accidents in which workers are injured and which arise out of or in the course of work, i. e. while engaged in an economic activity, or at work, or carrying on the business of the employer should be considered as occupational accidents.

Occupational Cancer

Synonyms

Occupational malignant diseases

Definition

Occupational cancer is a group of different diseases that have the same feature, the uncontrolled growth and spread of abnormal cells and well documented association between occupational exposures to carcinogens and onset of disease. There are different national and international lists and classifications of potential carcinogens like: WHO International Agency for Research on Cancer (WHO IARC) (http://www.iarc.fr), National Institute of Occupational Health (NIOSH) (http://www.cdc.gov/niosh/topics/cancer/), Occupational Safety and Health Administration (OSHA) (http://www.osha-slc.gov/SLTC/carcinogens/index.html).

Occupational Disability

Synonyms

Workplace disability

Definition

Occupational disability can be described as a partial or complete loss of ► working capacity due to the ► chronic diseases or injuries related to ► occupational exposures. Disability at workplace usually results from repeated exposure to mild stressors or agents, rather than from a single incident. For example, some agents can cause or activate asthma; repeated or loud ► noises can lead to hearing loss; production pressure, such as piece-rate demands, can cause symptoms of psychological stress; and repetitive motions can lead to cumulative stress disorders (e. g. carpal tunnel syndrome). Exposure to such stressors can exacerbate disabilities that already exist and make them more debilitating. As a consequence, some workers are no longer capable of performing their specific job tasks or are partially or completely unable to perform any particular job.

Occupational Disease Incidence

Definition

Occupational disease incidence is the number of new cases of ► occupational disease in a given population. It can be calculated on a national, industrial, or even an individual enterprise level. Occupational disease incidence is less informative than occupational disease incidence rate (which is the number of new cases of occupational disease during the calendar year divided by the number of workers in the examined group during the year, multiplied by 100 000) due to fact that a denominator is missing. However, disease incidence can usefully be used in a situation where there is a stable population (when the number of workers does not vary in examined periods). In all other situations the use of incidence rate is much more suitable.

Occupational Disease Registry

Definition

Occupational disease registry is a register of officially recognized cases of ► occupational diseases. Registration is usually organized on a national level and the register is managed by the national institution responsible for occupational health. National legislation specifies the procedures for registration of occupational dis-

eases as well as procedures for its recognition. As each country decides on the amount and the structure of data in the occupational disease registry there is a huge variability among countries which causes a lot of problems in comparison at an international level.

Occupational Diseases

PETAR BULAT
Head of Occupational Toxicology Department, Institute of Occupational Health, Clinical Centre of Serbia, Belgrade, Serbia
bulatp@eunet.yu

Synonyms

Industrial disease

Definition

Occupational disease is any disease contracted as a result of an exposure to risk factors arising from work activity (ILO definition). This definition, like most of occupational disease definitions, specify causality between the disease and the exposure factor (physical, chemical, biological and others) present in the work/activity taken into account. On the other hand some definitions are focused on legal aspects of occupational disease, like the European Occupational Diseases Statistics (EODS) definition. According to EODS an occupational disease is a case of disease recognized by the national authorities as being caused by a factor at work.

Basic Characteristics

In contrast to the definitions of occupational diseases, which are similar in different countries, the systems of recognizing occupational diseases are not uniform. Generally, there are three systems:

- Open system (every disease with sufficient proofs that it is caused by ► occupational exposure is an occupational disease);
- Closed system (only diseases which are listed on the ► national list of occupational diseases can be recognized as occupational ones);
- Mixed system (a combination of open and closed systems).

Each of those three systems brings some advantages and disadvantages so there is no ideal system for occupational disease recognition. Even among countries applying a similar system there are a lot of differences. For example, in the European Union most countries use a 'mixed system' but there is a significant difference in a list of occupational diseases for each country. According to official EU sources in Italy there is a list of 58 occupational diseases, in France there are 98 tables of occupational diseases, in Germany a list of 67 occupational diseases, in Austria a list of 52 occupational diseases, and in the United Kingdom a list of 70 occupational diseases.

ILO propose a list with four groups of occupational diseases:

- Diseases caused by agents
  - Chemical (like: beryllium, cadmium, phosphorus, chromium, manganese, arsenic, mercury, lead, fluorine, carbon disulphide, the toxic halogen derivatives of aliphatic or aromatic hydrocarbons, benzene or its toxic homologues, nitro- and amino-derivatives of benzene or its homologues, nitroglycerine or other nitric acid esters, alcohols, glycols or ketones, etc.)
  - Physical (like: ► hearing impairment caused by noise, diseases caused by vibration, diseases caused by work in compressed air, diseases caused by ionizing radiations, etc.)
  - Biological (infectious or parasitic diseases contracted in an occupation where there is a particular risk of contamination)
- Diseases by target organ systems
  - Respiratory diseases (like: ► pneumoconioses caused by sclerogenic mineral dust (silicosis, anthraco-silicosis, asbestosis) and silicotuberculosis, bronchopulmonary diseases caused by hard-metal dust, cotton, flax, hemp or sisal dust (byssinosis), occupational asthma, extrinsic allergic alveolitis caused by the inhalation of organic dusts, siderosis, chronic obstructive pulmonary diseases, etc.)
  - Skin diseases
  - Occupational musculo-skeletal disorders
- ► Occupational cancer (caused by: asbestos, benzidine and its salts, chromium, vinyl chloride, benzene or homologues, ionizing radiations, tar, pitch, bitumen, mineral oil, anthracene, or the compounds,

products or residues of these substances, nickel compounds, wood dust, etc.)
- Other diseases

According to the ILO recommendation, 194 member states should develop a national list of occupational diseases including, at least, the diseases mentioned in the ILO proposal, but it seems that many countries did not follow that recommendation.

Besides differences in the systems of occupational disease recognition, there are huge diversities in prerequisite conditions for recognition of an occupational disease. Usually, there are two steps in the process: proving the disease is related to an occupation or working conditions and proving there has been exposure. As one might expect there are great differences in criteria for diagnosing disease among countries (for example almost every country has its own criteria for diagnosing silicosis or asbestosis). Then there is problem of proving that a worker was exposed to a certain risk factor exceeding the maximum levels established for regulatory purposes. Also, there is the problem of ► individual susceptibility so that even in a case where workplace exposure did not exceeded the maximum permissible values there is always a possibility that it caused disease in an individual. These mentioned differences are only a top of the iceberg problem compared to ► occupational disease incidence on an international level. It has to be said that some countries do not have a proper system for registering occupational diseases (► occupational disease registry) or possess a registry which is not functioning (some countries—not only developing ones—do not have a registry at all) so there are no reliable data on global incidence of occupational diseases. However, based on available data, incidence of occupational diseases in 2001 varies from 0.47 per 100 000 inhabitants in Armenia to 453.72 in Sweden. The estimated number of cases of occupational diseases per year worldwide is in the range 4 240 700–10 010 800. The estimated number of deaths due to occupational diseases per year is in the range 583 700–704 200.

According to the estimated annual incidence of occupational disease in the world (Leigh et al. 1999) musculoskeletal disorders are linked with more than 30% of the total number of occupational diseases.

The estimates of ► disability-adjusted life years (DALY) for 2000 shows that the selected occupational risk factors were responsible worldwide for 37% of back pain, 16% of hearing loss, 13% of chronic obstructive pulmonary disease (COPD), 11% of asthma, 9% of lung cancer and 2% of leukaemia (Nelson et al. 2005). Occupational disease compensation also varies amongst countries. Most of the developed countries compensate workers all direct and indirect losses caused by occupational disease. But some countries in cases in which the occupational disease does not cause a physical impairment or loss of earnings do not compensate anything except the costs of medical treatment. Nevertheless, the cost of occupational diseases to society has been estimated at 2–14% of the gross national product in different studies in different countries.

Occupational Diseases, Table 1 Estimated annual incidence of occupational diseases in the world

Pesticide poisoning	109 000
Other poisoning	122 000
Cancer	191 000
Mental disorders	318 000
Pneumoconioses	453 000
Noise-induced hearing loss	1 628 000
Skin disorders	1 895 000
Chronic respiratory disease	2 631 000
Musculoskeletal disorders	3 337 000

Occupational and Environmental Health

PETAR BULAT
Head of Occupational Toxicology Department, Institute of Occupational Health, Clinical Centre of Serbia, Belgrad, Serbia
bulatp@eunet.yu

Introduction

Occupational and environmental health are closely related disciplines that share a history, methodology, problems, etc. Development of medicine, science, technology, and society led to differentiation between those disciplines and nowadays they are fully separated with clearly different objectives in most countries.

Occupational and Environmental Health History

The history of occupational and environmental health (OEH) can be traced to the ancient period. In old Egypt, rules were established for burying corpses, cleaning streets, waste management, and food and water quality control. Observations of increased rates of illnesses and mortality among miners date back to Greek and Roman times. Hippocrates warned his followers to observe the environment in order to understand the origins of illnesses in their patients. However, Bernardino Ramazzini (1633–1714) is recognized worldwide as the father of preventive, and especially occupational, medicine. He published in a book in 1700: "De Morbis Artificum Diatriba" (Diseases of Workers). This was the first systematic study of trade diseases and was based on visits to workshops in Italy. Bernardino Ramazzini described diseases in a number of occupations such as painters, intellectuals, potters, midwives, miners, etc. He recognized mercurialism, lead intoxication among potters using lead glaze, etc. Bernardino Ramazzini emphasized the importance of data on occupation in patient history.

The real development of OEH started during the industrial revolution. The first OEH laws originate from the 19th century. During the 19th century, the first laws regulating child labor, work safety, and limiting working hours were established in England. In 1901 the first law regulating periodical check ups of workers was empowered in England. Subsequently, similar laws were empowered in Germany, France, and Russia. The first Institute of Occupational Health was established in Frankfurt (Germany) at the start of the 20th century. In 1910, the first clinic of Occupational Diseases was established in Milan (Italy), as was the first hospital for occupational diseases in New York (USA). The first scientific meetings on OEH started with a Berlin (Germany) conference on occupational diseases in 1890. The first international congress on occupational health (OH) was held in Milan (Italy) in 1906; during which the International Commission on Occupational Health (ICOH) was established. This organization is still active and plays a major role in international OH.

Since the start of the 20th century, development of OEH in developed countries has been much more rapid than in past centuries, especially in countries with developed industry where continuous development has occurred. In Russia, due to political reasons, a huge development of OEH was observed after the revolution. The same trend occurred in so-called Eastern countries after the Second World War, under Russian influence.

Occupational and Environmental Health Definitions

Occupational Health

Occupational health is a discipline devoted to the prevention and management of occupational injury, illness, and disability; and promotion of health and productivity of workers, their families, and communities.

Environmental Health

Environmental health comprises those aspects of human health, including quality of life, that are deter-

mined by interactions with physical, chemical, biological, and social factors in the environment.

Occupational Health Objectives

According to the joint committee of the International Labor Organization (ILO) and the World Health Organization (WHO) in 1950, occupational health should aim for:

- the promotion and maintenance of the highest degree of physical, mental, and social well-being of workers in all occupations;
- the prevention amongst workers of departures from health caused by their working conditions;
- the protection of workers in their employment from risks resulting from factors adverse to health;
- the placing and maintenance of the worker in an occupational environment adapted to his physiological and psychological capabilities and;
- to summarize: the adaptation of work to the man and of each man to his job.

In 1995, the ILO/WHO joint committee (Anonymous 1995) made an addition to the previous definition. They proposed that the main focus in occupational health should be on three different objectives (► occupational health objectives):

1. the maintenance and promotion of workers' health and working capacity;
2. the improvement of working environment and work to become conducive to safety and health and;
3. development of work organizations and working cultures in a direction which supports health and safety at work and in doing so also promotes a positive social climate and smooth operation and may enhance productivity of the undertakings. The concept of working culture is intended in this context to mean a reflection of the essential value systems adopted by the undertaking concerned. Such a culture is reflected in practice in the managerial systems, personnel policy, principles for participation, training policies, and quality management of the undertaking.

Beside the more global view on occupational health objectives from the ILO/WHO, there are many other more or less detailed views, like Felton's (1998). According to his view, OH objectives are:

- to protect the health and well-being of workers against the stressors and potential health hazards of the work environment;
- to place job applicants or current employees in work commensurate with their physical and emotional capacities, work that can be performed without endangering the worker or fellow employees and without damaging property;
- to provide emergency medical care for injured or ill workers and definitive care and rehabilitation for those with work-generated injuries or illnesses, in keeping with the medical, surgical, or psychotherapeutic expertise of the staff, medical department policy, managerial policy, and the availability of community resources;
- to maintain or improve the health of the worker through promotional, educational, counseling, or informational activities, preventive health measures including fitness or wellness programs, and periodic clinical reviews of health status.

Environmental Health Objectives

There are a number of classifications of environmental health objectives. Generally, environmental health objectives are:

- to ensure adequate and safe living conditions (flat, water, sanitation, environmental safety);
- to promote healthy lifestyles;
- to prevent and significantly reduce the morbidity and mortality arising from gastrointestinal disorders and other health effects by ensuring that adequate measures are taken to improve access to safe and affordable water and adequate sanitation for the population;
- to prevent respiratory diseases due to outdoor and indoor pollution in order to ensure an environment with clean air;
- to reduce the risk of diseases and disability arising from exposure to hazardous chemicals, physical agents, and biological agents in working and living environments;
- to prevent harmful effects on the environment from new technologies implemented in industry and agriculture, as well as to prevent abuse of natural resources.

In integrated health protection, environmental health has the foremost goal of protecting human health against harmful factors of the environment.

Environmental Factors

Air Quality and Pollution

Air pollution is any change in physical, chemical, radiological, or biological properties of air exceeding the adaptation mechanism of living beings and the environment. It can be classified as outdoor and indoor air pollution, with occupational and non-occupational exposure (► air quality and pollution) (Anonymous 1999; Backović et al. 2001).

Air pollution is the result of emission (into the air) of hazardous substances at a rate exceeding the capacity of natural processes in the atmosphere to alter, deposit, or dilute them. Natural processes, such as rain or wind, play an important role in the vanishing and/or alteration of chemical substances discharged into the atmosphere. The definition above relates to chemical outdoor pollution. Microbiological pollution, on the other hand, is primarily an indoor problem.

Air pollutants can be in any of three forms: gas, aerosol, or particle. An aerosol is a fine, mist-like suspension of liquid or solid. Particles, sometimes called particulates, are small specks of solid matter.

Classification of toxic substances in the air may be based on acute toxicity expressed through LD50 (the dose of a substance that kill 50% of the organisms in a test), or on carcinogenic potential. The most highly toxic substances are those that cause death or severe illness in a very small dose.

The general health effects of air pollution can be divided into four groups: short-term or acute respiratory effects, long-term or chronic respiratory effects, lung cancer, and no respiratory effects.

Wide scientific interest in indoor air quality is now quite understandable because of the variety of indoor environmental problems, increasing amount of time spent indoors, and numerous adverse health consequences.

Water Quality and Pollution

Water is essential for life and plays a vital role in the proper functioning of the Earth's ecosystems. The Water Supplies Department is committed to supply the public with water that is clear, odorless, wholesome, and free from pathogenic bacteria. In the treatment process, water quality throughout the supply system is continuously monitored by professionally qualified chemists through a series of physical, chemical, bacteriological, biological, and radiological examinations (► water quality and pollution).

Surface water is all water that is naturally open to the atmosphere, such as lakes, rivers, seas, and reservoirs. In addition to being an important source of drinking water and recreation, these waters are also vital parts of local and regional ecosystems.

Inadequate water supply and poor sanitation services lead to contamination through the input of sewage water into groundwater.

More than 2.6 billion people – forty per cent of the world's population – lack basic sanitation facilities, and over one billion people still use unsafe drinking water sources. As a result, thousands of children die every day from diarrhea and other water-sanitation and hygiene-related diseases, and many more suffer and are weakened by illness.

Every community water supplier must provide an annual report (sometimes called a consumer confidence report) to its customers. The report provides information on local drinking water quality including the water's source, contaminants found in the water, and how consumers can get involved in protecting drinking water.

In future, a sufficient quantity and excellent quality of drinking water can only be guaranteed through more integrated management of water resources.

Food Safety

Food is an essential human right, but food combination in a diet must be well balanced and nutritious overall. In modern societies, food habits are rapidly changing and many new foods are on the market. Cooking many foods makes them more palatable, and easier and safer to eat (Ekhard et al. 1996); however, poor cooking may destroy many valuable nutrients (► food safety).

The continual evolution of new and improved methods of agriculture and food processing is essential for feeding the world population. Some examples of developments which have benefited mankind are the use of pesticides, introduction of inorganic fertilizers, intensive rearing of livestock, use of antibiotics in animal husbandry, and introduction of food radiation as a means of food preservation.

National legislation sets standards for the production and distribution of safe foodstuffs. It is mostly oriented towards establishing regulations for:

- safe animal feeding (regarding recent BSE infection);
- animal welfare and husbandry (prevention of zoonoses);
- extensive requirements on hygiene of food;
- setting the list of contaminants and residues that arrive unintentionally into food;
- residues arrived at intentionally – pesticides, antibiotics, hormones;
- radioactive contamination of food;
- food additives;
- packaging materials and other materials coming into contact with food;
- novel food stuffs;
- emergency situations, like dioxin and other PCBs in food, or other chemical compounds present in food and known as industrial chemicals.

It must be stressed that legislation is only one part of solving the problem, but it is essential that there is always good hygiene and excellent cooperation between each individual concerned in food handling.

Soil Pollution

The soil is the surface layer of the Earth's crust that is not covered with water. It represents 1/3 of the continental part of the lithosphere, and reaches circa 150,000,000 m^2. The importance of the soil for people is reflected in agriculture, construction and location of buildings, engineering and infrastructure, and industries that exploit the Earth's goods. In all segments, the anthropogenic factor leads to permanent modification of the natural appearance and composition of the soil.

► Soil pollution can be defined as modification of natural characteristics, in a physical, chemical, biological, and radiological sense, by accumulation of a large quantity of natural materials or occurrence of new synthetic materials that disturb natural relations and disable self-cleaning or auto purification of the soil. Soil pollution can be a reason for chemical intoxication or infection of humans and all living beings. Pollution of the soil depends on both the emission and disposal of harmful materials and soil composition, structure, and physicochemical characteristics that influence accumulation and self-cleaning ability (Backović et al. 2001).

The polluted surface layer of the soil may be the source of comitial intoxication, infection, and infestation of people with microorganisms and parasites through water and food originating from that soil. It may also be the source of pollution of the air and water in a larger area in combination with the influence of meteorological factors.

The next important form in which the quality of the soil can influence health is if there is a lack of oligoelements, which is directly related to the natural chain of nutrition, where a low content of oligoelements in the soil leads to low content in plants and animal organisms, and finally to a lack in humans.

Climate and Microclimate

The world's climate is an integral part of the complex of life-supporting processes. Climate and weather have always had a powerful impact on human health and well-being (► climate and microclimate). However, like other large natural systems, the global climate is coming under pressure from human activities. Global climate change is, therefore, a new challenge to ongoing efforts to protect human health (Anonymous 2000).

According to the definition from the International Panel for Climate Change, the weather is day-to-day changing of atmospheric conditions, and climate is the average state of the atmosphere and the underlying land or water in a particular region over a particular time-scale (Kirch et al. 2005).

Radiation

Ionizing ► radiation represents the outermost frequency band of the electromagnetic spectrum and is capable of ionizing molecules of the irradiated substance, including biological media. During the interaction, ionizing radiation delivers a certain amount of energy to the irradiated substance, which results in changes of baseline characteristics of both the radiation and the irradiated medium.

Major types of radiation emitted as a result of spontaneous decay are alpha and beta particles and gamma rays. X-rays, another major type of radiation, arise from processes outside the nucleus.

Non-ionizing radiation is a general term for those electromagnetic waves that do not have sufficient energy to break the bonds between molecules and to produce ions (positive and negative electrically charged atoms or parts of molecules).

Non-ionizing radiation covers two main regions in the non-ionizing part of the electromagnetic spectrum:

- electromagnetic fields – static electric and magnetic fields, extremely low frequency fields, microwave and radiofrequency fields;
- optical radiation – ultraviolet radiation, visible light, and infrared radiation.

Noise

► Noise is a ubiquitous noxious factor in living and occupational environments in the modern world.
The most frequent psychological symptoms in people chronically exposed to noise are headaches, irritability and anxiousness, depression, insomnia, and fatigue. The consumption of tranquillizers and hypnotics is usually higher in these people.
The pathogenic concept that links noise with the well-known risk factors of cardiovascular diseases is based on a general stress model. Noise as a stressor stimulates the hypothalamopituitary-adrenal axis, the medulla of the suprarenal gland, and the sympathetic nervous system. Consequently, an increase in the release of circulating "stress hormones" occurs: ACTH, cortisol, adrenaline, and noradrenaline, which are of crucial importance in regulating arterial blood pressure and coronary circulation.

Urban Environments

A housing culture is a group of characteristics that represent the housing of a family, group of people, or population (► urban environments).
In choosing location, the important things are:

- size and configuration (10%)
- exposure – insulation
- climate conditions
- distance from water flows
- ground water
- distance from recreation zone
- number of inhabitants
- water supply options
- sewage disposition
- traffic connections – food transport

In each urban area, there are four zones: housing zone, economy zone, recreation zone, and vegetation zone.
The types of housing culture are semi rural, rural, semi urban, urban and ultra urban.
It is important to notice that proper housing is important for the health and well-being of an individual or family. Living on higher floors or living in inappropriately constructed and unmaintained buildings (for example with humidity walls > 3%) could seriously affect the health of inhabitants. In addition, sick building syndrome has to be mentioned, a consequence of modernly constructed buildings with inappropriate ventilation and/or lamination as well as noncritical use of synthetic materials in interior design. This syndrome is frequently connected with increased incidence of respiratory infections, cardiovascular diseases, and mental disorders.

Communal and Industrial Waste

Waste is something that is left over or that it is no longer needed. Waste can cause pollution and impact upon our environment if not properly managed. Disposing of waste that cannot be otherwise reused, recycled, or avoided in any other way also represents a waste of resources, a lost opportunity, and is a waste of money (► communal and industrial waste).
Waste is defined by the Environment Protection Act of 1970 as any matter prescribed to be waste and any matter, whether liquid, solid, gaseous, or radioactive, which is discharged, emitted, or deposited in the environment in such volume or manner as to cause an alteration of the environment.
Waste can be divided into many different types. The most common methods of classification are by physical, chemical, and biological characteristics. One important classification is by consistency of the waste. Solid waste is waste material that contains less than 70% water. This class includes such materials as household garbage, some industrial wastes, some mining wastes, and oilfield wastes such as drill cuttings. Liquid waste is usually wastewater that contains less than 1% solids. Such wastes may contain high concentrations of dissolved salts and metals. Sludge is a class of waste between liquid and solid; it usually contains between 3% and 25% solids, while the rest of the material is water-dissolved materials.

Workplace Factors

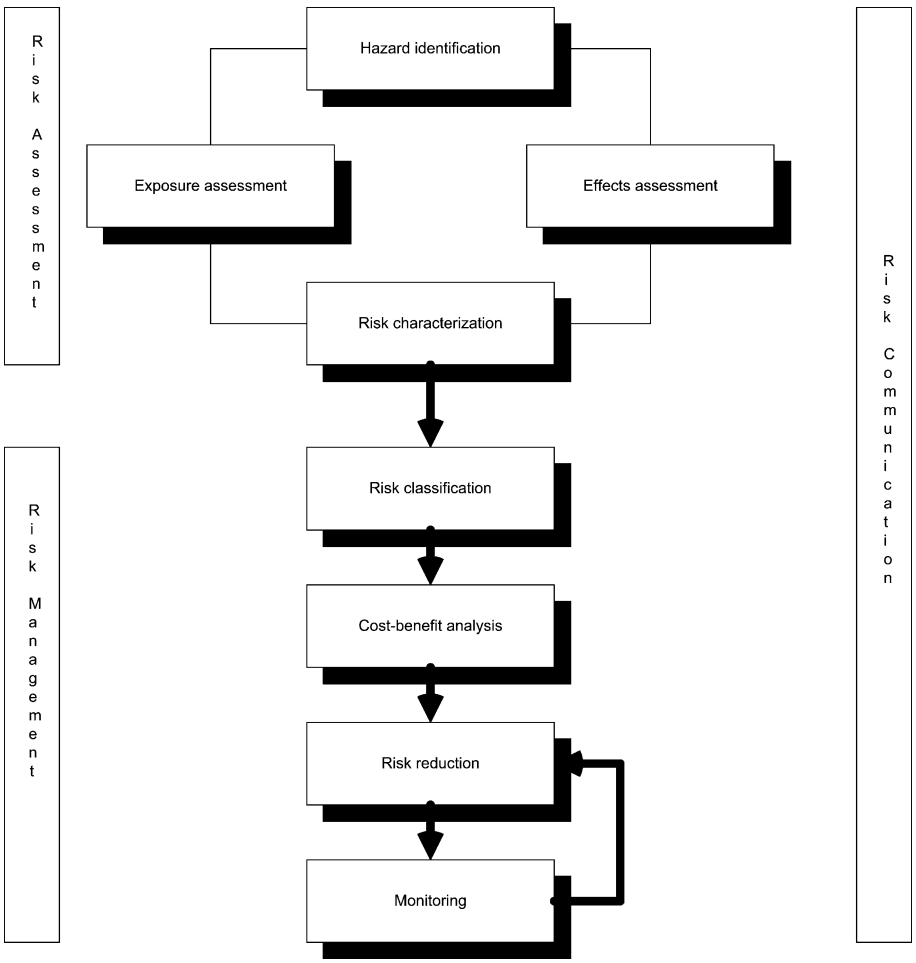
Workplace Hazards and Risk Assessment

Workers in almost every work place are exposed to some hazards. There are a number of different ► workplace hazard classifications, but the most common is classification into the following four groups:

1. Physical hazards:
   a. Exposure to high/low temperatures
   b. Mechanical hazards (noise, vibration)
   c. Ionizing and non-ionizing radiation
2. Chemical hazards:
   a. Gases
   b. Fumes
   c. Particles
   d. Fibers
3. Biological hazards:
   a. Bacteria
   b. Viruses
   c. Fungi
4. Psycho-Socio-Economicalhazards:
   a. Job stress
   b. Organizational factors
   c. Corporate closing and downsizing

In most cases, workers are not exposed to a single hazard. Usually, they are exposed to a number of different hazards. Exposure assessment, in some cases, is a rather complex task. Even in the simplest situations, when the worker is exposed to a limited number of well-known physical and chemical hazards, exposure assessment includes a number of rather complicated procedures of ambience and biological monitoring, job analysis, and evaluation. In more complex situations when the worker is exposed to new chemicals, various physical factors, work under stress, or a hostile environment, hazard assessment is rather difficult.

Modern OH involves a ► risk assessment during analysis of factors influencing the health of workers, besides analysis of hazards. It is the process of characterizing and quantifying potential adverse effects of hazards. In risk assessment, the goal is shifted from con-



Occupational and Environmental Health, Figure 1
Risk Assessment and Risk Management

cern for immediate hazards with readily perceptible linkages between a specific hazardous situation and an adverse outcome, to situations where there are only probabilistic linkages between exposure to an agent and the occurrence of an adverse health effect over a long period of time. Risk assessment usually includes hazard identification, exposure assessment, effects assessment and risk characterization (Fig. 1: Risk assessment and risk management). Once risk assessment has been completed, the focus turns to risk management decision-making, the process of selecting the appropriate response to the potential health hazard. Risk management usually includes risk classification, cost-benefit analysis, risk reduction, and monitoring (Van Leeuwen CJ 1995). During processes of risk assessment and management, effective risk communication with all stakeholders is of utmost importance (► risk management and communication). This includes communicating the nature and level of risks associated with certain processes or operations to workers, the local population, and regulatory authorities, as well as to plant managers.

As it has already been mentioned, workers in almost every workplace are exposed to different hazards that may cause occupational disease, work related disease, and/or occupational injury.

Occupational Disease

Occupational disease is any disease contracted as a result of exposure to risk factors arising from work activity (ILO definition) (Anonymous 2002). All definitions of occupational diseases specify causality between the disease and the exposure factor (physical, chemical, biological, and others) present in the work/activity taken into account.

In contrast with the definition of ► occupational diseases, which is often similar in different countries, the process of occupational disease recognition is not uniform. In most countries (such as Germany, France, and Belgium), there is a list of diseases that might be recognized as occupational and there is the possibility to prove that certain diseases are occupational. In some countries (such as Serbia), there is a so-called closed list system. In those countries, only diseases that are on the list of occupational diseases can be recognized as occupational. In contrast to that system, there is a so-called open system, operating without a list of occupational diseases. In some countries like the USA, each state has its own system for recording occupational diseases and there is no federal register. All of these differences make any international comparisons almost impossible. WHO data (2005) on occupational disease incidence rate (Table 1) clearly shows huge differences between countries. These differences cannot only be explained by differences in the process of recognition of occupational diseases. In addition, it should be noted that in Table 2, data on incidence are missing for a number of developed countries (EU members) (France, the Netherlands, Spain, Belgium, Italy, etc.).

Occupational and Environmental Health, Table 1 Occupational disease incidence rate per 100,000 population for the years 2000–2004

Work Related Diseases

Work related diseases are a group of diseases to which the workplace environment and/or performance of work contribute significantly as one of several causative factors (Lesage 1998). The lay public quite often misunderstands them as occupational diseases. Generally, the main difference between them is that in the case of occupational diseases there is a strong and/or specific relation to workplace hazards. In the case of work-related disease, it is not easy to prove that workplace hazards caused the disease, due to multifactorial etiology. Another important difference is that occupational diseases are compensable. In some cases, it is not easy to discriminate work-related disease from occupational disease, even for experts. Probably the best example is chronic bronchitis, which is in some countries is recognized as an occupational disease and in others as a ► work related disease.

In the last decades, musculoskeletal disorders (MSDs) became one of the major work-related problems in the population, often causing absenteeism. According to the UK Health and Safety Executive, 5.7 million working days were lost due to back pain in 2001/2002, 4.1 due to MSDs of upper limbs or neck and the total estimated loss was £5.7 billion (Buckle 2005). Even if ergonomics provides a tool for solving a number of problems that cause musculoskeletal disorders, they are not fully implemented even in developed countries.

Occupational Injuries

Occupational injury is any personal injury, disease, or death resulting from an occupational accident (Anonymous 2001). According to the ILO definition, an occupational accident is an unexpected and unplanned occurrence, including acts of violence, arising out of or in connection with work, which results in one or more workers incurring a personal injury, disease, or death. The ILO suggests that occupational accidents should include travel, transport, or road traffic accidents in which workers are injured and which arise out of or in the course of work, i. e. while engaged in an economic activity, at work, or while carrying out the business of the employer.

According to the Occupational Health and Safety Administration (OSHA) record keeping requirements, occupational injury is defined as any injury that results from a work accident or from an exposure involving a single incident in the working environment.

As almost every country has its own definition of ► occupational injury and accident, there are plenty of problems in comparisons at an international level. For example, there are differences in the inclusion or exclusion of commuting accidents from the total number of occupational injuries. There are also plenty of other problems in comparisons of occupational injuries. In some countries, regulations force employers to report every injury, even minor ones, whereas in some countries, employers must only report injuries that lead to sick leave. Furthermore, there is a problem of underreporting in some countries, as well as injuries among workers that are not officially employed. The data on occupational injuries in Europe (Table 2) probably give the best overview of the problems in registration and reporting of occupational injuries (WHO 2005). The paradox that developed countries have a higher incidence of occupational injuries than developing ones is mostly caused by the problems mentioned.

There is also a problem in comparing two injuries; from a statistical point of view, one minor accident resulting in a finger slash is the same as a serious accident resulting in a lost eye or death. To overcome that problem, tree indicators have been introduced: frequency rates, incidence rates, and days lost by economic activity.

Prevention of Occupational Accidents, Injuries, and Diseases

The estimate of global work-related deaths is around 2,000,000 per year and this number is likely to underestimate the real number of deaths due to limited data availability (Driscoll et al. 2005). The authors linked most of these deaths to diseases. It is also estimated that there are 263 million occupational accidents with 345,000 fatalities per year globally (Hämäläinen et al. 2006). These numbers clearly indicate a need for intensive preventive activities. In prevention of ► occupational injuries, accidents, and diseases, as well as ► work related diseases, there are a number of stakeholders: workers, employers, trade unions, ► company doctors, OH nurses, regulatory authorities, local communities, etc. Preventive activities in OH usually involve a multidisciplinary team that includes the company doctor, OH nurse, ergonomist, and others.

Occupational and Environmental Health, Table 2 Occupational injury incidence rate per 100,000 population for the years 2000–2004

Beside classical OH preventive activities in the last decades, a new concept of workplace health promotion has been developed. It includes a number of strategies that go far beyond education or communication, to accomplish significant behavioral changes among groups or individual workers (Engbers et al. 2005).

Summary

Occupational and Environmental Health, two closely related disciplines, are involved in a number of very important issues for the human population. Air and water quality and food safety affects not only the human population. The importance of these factors, as well as soil pollution, is enormous and in the coming years they will stay on the lists of global priorities. With social and industrial development, the waste management issue becomes more and more important. Industries as well as communities are faced with the fact that waste management takes a significant part of their budget. Industrial development is quite often followed by increased environmental and occupational exposures to noise and radiation. Decreasing such exposure is not always an easy task, especially in the case of environmental exposure. In an occupational environment, noise and radiation are only part of the workplace hazards. Nowadays, workers are exposed to a number of hazards that could cause adverse health effects. In the case of occupational diseases, the link between workplace hazard and adverse health effect is much more direct and specific than in the case of work related diseases, which have multifactorial etiology so it is not easy to prove that workplace hazards caused disease. Occupational injuries and accidents are rather frequent in developing as well as in developed countries. It is estimated that there are 263 million occupational accidents with 345,000 fatalities globally per year. The fact that around 2 million deaths per year are work related gives an impression of the importance of occupational health preventive activities. Workplace ► risk assessment, ► workplace health promotion, introducing ► ergonomics in modern industries and services, and availability of occupational health specialists (company doctors) for employees and employer are only a fraction of the occupational health preventive tools.

Occupational Exposure

Synonyms

Occupational factors

Definition

Occupational exposure can be defined as the presence of a substance or ► risk factor in the work environment external to the worker. Occupational exposures include physical factors (for example, ► noise, vibration, or ► radiation), chemicals (for example, dusts or solvents), biological agents (for example, bacteria or viruses), physical stress (for example, lifting heavy weights or repetitive strain injuries), and psychosocial stressors (for example, low control over job tasks or poor communications with workmates). Apart from the nature of occupational exposure, it is also characterized by the intensity, duration and frequency of exposure. Occupational exposure can occur in different time frames, such as: short-term, long-term and cumulative exposure. Although many occupational exposures may occur as environmental exposures for the general population, workers are usually exposed to higher levels, and are frequently the focus of research on health effects of these exposures and agents.

As occupational exposure does not result only from the presence of a harmful agent in the environment, it is sometimes defined as “the contact of a chemical, physical, or biological occupational agent with the outer boundary of an organism.”

Occupational exposure; Occupational factors

Definition

Occupational hazard is a general term covering all workplace hazards, i. e. attributable to all forms of environmental contamination and physical, ergonomic, psychological, and social stress.

Cross-References

- ► Occupational Exposure
- ► Occupational Factors
- ► Workplace Hazards

- ► Workplace Health

Occupational Health Care

Synonyms

Occupational medical health

Definition

Health care or healthcare means the prevention, treatment, and management of illness and the preservation of mental and physical well-being through the services offered by occupational health care services. The organized provision of such services may constitute a part of the national health care system.

Occupational health care refers to the care of the health of workers. It includes preventive health care, health promotion, curative health care, first aid, rehabilitation and compensation, where appropriate, as well as strategies for prompt recovery and return to work. Occupational health care is usually provided on the basis of the legislation (an occupational health care act). The goals of occupational health care are to reduce industrial accidents, to prevent occupational hazards/diseases, to reduce sick absenteeism and to achieve maximum human efficiency without unwanted health outcomes. The objective of occupational health care is a healthy and safe working environment, a well-functioning working community, prevention of work-related diseases as well as the maintenance of employees' working ability and functional capacity, and promotion of their health.

Occupational Health Care Service

Synonyms

Occupational medical health services

Definition

Occupational health care service refers to the institutionalized organizational arrangement that provides services in the field of occupational health care. Functionally, occupational health care service must be considered both as a part of country-level health infrastructure as well as a part of the infrastructure that exist for the implementation of relevant legislation on occupational health. There are a large number of models for occupational health care services because of variations in

national traditions, legislation and past experiences in the field of occupational health.

Occupational Health Department

Definition

The occupational health department is a part of the occupational health infrastructure. It is an organized enterprise within an establishment or in a health-care facility. It may consist of several occupational health units and a central (administrative) office. It usually offers multidisciplinary occupational health services for the enterprise (in-plant) or several enterprises at a local level.

Occupational Health Doctor

► Company Doctor

Occupational Health Needs

Definition

Occupational health needs may be viewed as (a) needs of an individual employee at his/her working environment (often specific and related to health and well-being of an employee), (b) needs of a company (often more general and related to reduction of occupational health risks and improvement of the health, safety and work ability of the employed population) or (c) needs on a national level (e.g. establishment of an national occupational health service system, or occupational injury prevention, etc.).

Health needs assessment in occupational health is a process of collecting information on ► workplace hazards and risks and on workforce characteristics, which are then analyzed to identify the occupational health issues and health problems of employed people. Results of needs assessments are considered in light of available financial and human resources, national and local tradition and experience, regulatory requirements and nature of the workforce. A health needs assessment will provide information on the prevalence and cost of different occupational health problems, both at the workplace and within the workforce, allowing assessment of prevention opportunities from both programmatic and financial points of view. Priorities and resource allocation can be agreed that will lead to improved occupational health provision and the overall health of a workforce.

Health needs assessment may also cover attitudes toward existing or potential employer policies.

Occupational Health Nurse

Synonyms

Company nurse

Definition

An occupational health nurse is responsible for the health and well-being of employees in the workplace. They could work in large enterprises, for private consultancies, as part of an ► occupational health and safety team, or alone. Occupational health nurses are involved in assessment of the work environment for potential health and safety problems; processes of health education and promotion for accident and disease prevention; delivering first aid, and health and safety training; providing first aid treatment; and in a number of other activities leading to better workplace conditions.

Occupational Health Objectives

SRMENA KRSTEV
Serbian Institute of Occupational Health,
Belgrade, Serbia
srmena@sbb.co.yu

Definition

Occupational health is a discipline devoted to prevention (► prevention of occupational diseases) and ► management of occupational diseases, accidents (Occupational Accidents) and disabilities (► occupational disability) and to elimination of ► occupational factors and conditions hazardous to health and safety at work (► occupational health and safety); development and promotion of healthy and safe work, ► work environments and work organizations; enhancement of physical, mental and social ► well-being of workers and maintenance of their working ability, professional and

social development at work, and productivity of workers; and enablement of workers to conduct socially and economically productive lives and to contribute positively to sustainable development (WHO 1995).

In practice, occupational health is most frequently understood as activity aiming at minimizing the risk to employees' health from occupational factors and preventing ► occupational accidents and diseases (Westerholm, Baranski 1999).

Basic Characteristics

Workplace and Occupational Hazards

► Workers represent a half of the global population (around 2.9 billion in 2005) (Eijkemans, Takala 2005). Their work sustains economic and social value of modern society. Worldwide, most adults, and many children spend much of their daily hours at work. However, the ► workplace can be a hazardous environment. Many workers are exposed to unacceptable levels of chemicals, biological agents, physical, psychological and ergonomic factors (Rom 1998). They face various kinds of job-related hazards, such as job insecurity, time pressure, increasing job demands, job-related stress, etc.

The International Labor Organization estimated that poor occupational health and safety resulted in 2005 in 270 million occupational accidents and 360 000 fatalities, and caused 260 million occupational diseases (ILO 2005). Altogether these lead annually to 2.3 million deaths of people at their best working age. Deaths, occupational diseases and injuries take a particularly heavy toll in developing countries. However, it is increasingly recognized that a healthy workforce is a prerequisite for success of economic and social policy and a necessary condition for the achievement of ► sustainable development (Fedotov 2005).

Major traditional occupational health needs still prevail among the global workforce, in particular in developing and undeveloped countries. In addition, due to the rapid changes in economy, technology and demography, such as growing ► globalization (internationalization), major changes in the enterprise structures, new patterns of work, aging of the workforce, child labor, etc., occupational health has been faced and challenged by these new occupational health risks (Cooper 2006). There is increasing evidence that workers' health is determined not only by the traditional and newly emerging occupational risks, but also by social inequalities, such as employment status, income, gender, race, health related-behavior, and access to health services (WHO 2006).

Main Occupational Health Objectives

The Joint International Labor Organization (ILO) and World Health Organization (WHO) Committee on Occupational Health on their Twelfth Session in 1995 updated the definition of occupational health, focusing primarily on three key objectives (Coppée 1998):

1. The maintenance and promotion of worker's health and ► working capacity;
2. The improvement of the working environment and work, to become conductive to safety and health; and
3. The development of work organization and working cultures in a direction which supports health and safety at work, and in doing so also, promotes a positive social climate and smooth operation, and may enhance the productivity of the undertaking.

This comprehensive concept is designed to include both occupational and non-occupational determinants of employees' health. It has been broadened considerably from simply protection against ► occupational hazards toward prevention and ► health promotion.

The 10 priority objectives were proposed for the development of occupational health in the WHO 'Global Strategy on Occupational Health for All – The way to Health at Work' (WHO 1995). These priority objectives of occupational health are as follows:

1. Strengthening of international and national policies for health at work and developing the necessary policy tools;
2. Development of a healthy work environment;
3. Development of healthy work practices and promotion of health at work;
4. Strengthening of ► occupational health services (OHS);
5. Establishment of support services for occupational health;
6. Development of occupational health standards based on scientific risk assessment;
7. Development of human resources for occupational health;
8. Establishment of registration and data system, development of information services for experts,

effective transmission of data and raising of public awareness through public information;
9. Strengthening of research; and
10. Development of collaboration in occupational health and with other activities and services.

These objectives emphasize the importance of primary prevention and ask and encourage countries to establish national policies and programs with required infrastructure and resources for occupational health. Further improvement of the health of workers requires combining efforts of occupational health safety with disease prevention, health promotion and tackling social determinants of health and reaching out to workers' families and communities. It is, therefore, obvious that current occupational health problems cannot be solved only by the health care sector. Other relevant factors, such as employment, social and economic development, trade, environmental protection, education, science and trade unions should be involved.

Occupational Health Physician

Definition

An occupational health physician (OHP) is a medical doctor who diagnoses and treats occupational diseases, work-related illnesses and injuries of employees, and conducts fitness-for-work physical examinations. He or she attends patients in-plant or at a hospital, and re-examines disability cases periodically to verify progress. An OHP oversees maintenance of case histories, health examination reports, and other medical records. They formulate and administer workers health programs, inspects plants and make recommendations regarding sanitation and elimination of health hazards. Most occupational physicians are engaged in private practice or in-plant services (► in-plant health service). The occupational physician is one of the core professions in the occupational health multidisciplinary team and plays a part in reducing the incidence of diseases and injuries, alleviating suffering and promoting and protecting people's health throughout their lives. The occupational physician is an expert adviser, part of the enterprise's senior management team, able to assist in planning and re-engineering the work process with regard to health and safety, legal requirements, good business and human resources practice.

In the past an important number of practicing occupational physicians lacked full formal training in the field of occupational medicine and did not hold appropriate board-certification in the specialty of occupational medicine. The term "occupational physician", therefore, does not necessarily imply obliged specialist preparation.

Cross-References

► Company Doctor; Industrial physician; Occupational physician

Occupational Health Risk

Synonyms

Workplace health risk

Definition

Occupational health risk is the probability that the health of an employee (or group of employees) will be adversely affected by exposure to an occupational health hazard within a specified time period or in specified circumstances. Occupational health risk is usually determined by two variables: the probability that a ► workplace hazard will result in an undesired health event and the severity that such a health event would have. It may be classified by qualitative terms or by quantitative values.

Occupational health risk is different from occupational health hazard. Occupational health hazard refers to the workplace agents (physical, chemical, biological, ergonomic or psychosocial) with an inherent potential to cause a harm.

Occupational Health and Safety

Synonyms

Occupational safety and health; Workplace health and safety; Worker's safety and health

Definition

Occupational health and safety, according to the ILO, is the discipline dealing with the prevention of work-related injuries and diseases as well as the protection and promotion of the health of workers. It aims at the improvement of working conditions and environment. Members of many different professions (e.g., engineers, physicians, hygienists, nurses) contribute to occupational safety, occupational health, occupational hygiene and improvement of the working environment.

Occupational health and safety also is viewed as a cross-disciplinary area concerned with protecting the safety, health and welfare of people engaged in work or employment. As a secondary effect occupational health and safety may also protect employers, customers, suppliers, and members of the public who may experience an impact from the workplace environment. As occupational health and safety is recognized as the field which has benefits for the worker (through maintenance of health) and for the enterprise (through improved productivity and quality) many countries established enforcing authorities to ensure that the basic legal requirements relating to occupational safety and health are met.

Occupational health and safety may involve interaction among many related disciplines, including occupational medicine, occupational hygiene, public health, safety engineering, health physics, ergonomics, toxicology, epidemiology, sociology and psychology.

Cross-References

► Workplace Health and Safety

Occupational Health and Safety Service

Synonyms

Occupational safety and health service; Workplace health and safety service

Definition

Occupational health and safety service refers to the institutionalized organizational arrangement that provides services in the field of ► occupational health and safety at the company level. Functionally, occupational health and safety service must be considered as a part of the infrastructure that exists for the implementation of relevant legislation on occupational safety and health at a national level. The type of arrangements and services varies from country to country and depends on legislation, local tradition and past experience.

Occupational Health Services (OHS)

Synonyms

► Workplace Health Services

Definition

Occupational health services (OHS) are services entrusted with essentially preventive functions and responsible for advising the employer, the ► workers and their representatives in the undertaking on the requirements for establishing and maintaining a safe and healthy working environment which will facilitate optimal physical and mental health in relation to work and the adaptation of work to the capabilities of workers in the light of their state of physical and mental health.

Provision of OHS means carrying out activities in the ► workplace with the aim of protecting and promoting workers' safety, health and ► well-being, as well as improving working conditions and the working environment. These services are provided by occupational health professionals, including occupational medicine and nursing, occupational hygiene, work physiology and physiotherapy, ► ergonomics, safety and psychology. In that sense, OHS are multidisciplinary and multisectoral, involving in addition to occupational health and safety professionals competent authorities, the employers, workers and their representatives.

OHS can function individually or as part of special service units of the enterprise or of external services.

Cross-References

► Workplace Health Services

Occupational Health Unit

Definition

An occupational health unit is viewed as a part of the occupational health infrastructure. In the past it was often just an extended part of the large in-plant health center which provided occupational health services for a company. Occupational health units may be organized as independent units or part of municipal health centers that provides basic occupational health services for small-medium enterprises or municipal workers.

Occupational Hearing Loss

Occupational Injuries

PETAR BULAT
Head of Occupational Toxicology Department, Institute of Occupational Health, Clinical Centre of Serbia, Belgrade, Serbia
bulatp@eunet.yu

Synonyms

Work injury; Workplace injury

Definition

Occupational injury is any personal injury, disease, or death resulting from an occupational accident (Anonymous 2001). According to the ILO definition, an occupational accident is an unexpected and unplanned occurrence, including acts of violence, arising out of or in connection with work, which results in one or more workers incurring a personal injury, disease, or death. The ILO suggests that travel, transport, or road traffic accidents in which workers are injured and which arise out of or in the course of work, i. e. while engaged in an economic activity, at work, or while carrying out the business of the employer, should be considered occupational accidents.

According to the Occupational Health and Safety Administration (OSHA) record keeping requirements, occupational injury is defined as any injury that results from a work accident or from an exposure involving a single incident in the working environment. There is therefore an important difference between an occupational injury and an occupational disease. An occupational disease is a consequence of exposure to one or more risk factors over a period of time; in contrast, occupational injury is the result of a sudden event (occupational accident).

Basic Characteristics

Even if it looks straightforward there are plenty of misunderstandings in the field of occupational injuries. For

example, there are differences in recognition of ► commuting accidents among countries. ILO labor statistics suggest that travel, transport, or road traffic accidents in which workers are injured and which arise out of or in the course of work but are not commuting accidents, should be considered as occupational accidents.

Occupational injuries cause a lot of harm especially to the victim and his family but also to society through direct and hidden costs. So, it is in public interest to decrease the number of occupational accidents. ► Registration of occupational injuries is one of the most important sources for prevention. The register provides necessary data for identifying workplace problems, and developing and implementing corrective measures. To fulfill those goals, the register must incorporate reasonable detailed data on the characteristics of occupational injury, like industry, how the incident happened, part of body affected, ► source of injury, ► cause of injury, date, time, number of lost workdays due to injury, data on the victim (age, gender, occupation), etc. There are many different schemes of registering occupational injuries; the two most common are the accident reporting system and the occupational injury compensation system but almost every country has its own modification of these systems. In some countries, regulations force employers to report every injury, even minor ones; in other countries, employer must only report injuries that lead to sick leave. Also, there is a problem of underreporting in some countries, as well as injuries among workers who are not officially employed.

There is also a problem of comparison of two injuries; from a statistical point of view, one minor accident resulting in a finger slash counts the same as a serious accident resulting in a lost eye or death. To overcome that problem, tree indicators have been introduced: ► frequency rates, ► incidence rates, and ► days lost by economic activity. Only having all these differences and difficulties in mind can we use available data. The yearly global estimates of occupational injuries causing at least 3 days absence are in the range of 181,957,318 to 345,718,904 with an average of 263,838,111 (Hämäläinen et al. 2006). This impressive number of occupational injuries is even more impressive if it is expressed as a daily average, which is around 720,000 occupational injuries. The same situation occurs with ► fatal occupational accidents; the global estimate is that there are 345,719 fatal occupational accidents a year, or almost 1,000 per day. The estimates of Nelson et al. (2005) suggest that in the year 2000 there were 850,000 deaths related to occupational exposure and among them 312,000 fatal occupational injuries, which is similar to the estimate of Hämäläinen et al. (2006). Nelson et al. (2005) estimate that 44% of the total of disability-adjusted life years (DALYs) lost due to work related fatalities could be linked to occupational injuries in the year 2000. They estimated that fatal occupational injuries caused a loss of 10.5 million years of healthy life.

According to Hämäläinen et al. (2006), the estimated number of fatal occupational accidents in India is 48,176; in China, 73,615; and in other Asian countries (including islands), 83,048 per year. So, those three regions account for more than half of total fatal occupational accidents in the world. It has to be mentioned that only a fraction of the global estimate of occupational injuries are reported to the ILO (3.9%).

Having in mind all these figures, it is obvious that occupational accidents are a serious public health problem. Comparing those estimated 350,000 fatal occupational injuries in the year 2000 with fatalities in road accident estimates for 1999; 1,200,000 (WHO 2001), and more conservatively 750,000–880,000 (Jacobs et al. 2000), gives a clearer picture of the importance of dealing with occupational injuries. However, comparison of the estimated total number of occupational injuries (345 million) with the estimated number of persons injured in road accidents (23–34 million, Jacobs et al. 2000) indicates the real magnitude of this problem.

Occupational Injury Prevention

In prevention of occupational injuries, a number of stakeholders are involved: workers, employers, trade unions, company doctors, ► occupational health nurses, regulatory authorities, local communities, etc. As in other cases when there are many stakeholders involved there is always a question (or a problem) of who is responsible. In this case, from a legal point of view, all stakeholders are responsible but most responsibility is on the employer. He is responsible for the occupational injury prevention program which usually contains the following:

- Identification and evaluation of risk for injury in the workplace;

- Measures for reducing risks including administrative measures and engineering interventions in the workplace environment;
- Risk communication;
- Occupational rehabilitation and return to work of injured workers;
- Management and development of safe work programs.

In many countries, especially developing ones, there is no adequate awareness of the necessity of such programs. In those countries, there is no stimulation for the employer to invest in safety, so such programs are very rare and depend on employer goodwill. Having in mind globalization and influences of multinational companies (even in cases where those companies in developing countries do not apply all the safety measures used in developed countries) one could expect that their presence in developing countries could lead to better understanding of occupational safety issues and particularly the importance of occupational injury prevention.

Occupational Stress-Mediated Disorders

Definition

Stress is viewed as a state of elevated activation of the autonomic nervous system with coordinated manifestations at the affective, cognitive, and behavioral levels. Occupational stress refers to cases where work is the sole cause of the experience of stress and associated symptoms of ill health. Occupational stress may affect health in the long run by (a) direct effects via sustained activation of the autonomic nervous system and enhanced neuroendocrine responses and (b) through unhealthy behavior that undermines self-control and therefore may contribute to occurrence and aggravation of multifactorial diseases. Occupational stress as a risk factor mediates the association between work exposure and some health disorders. It is widely conceptualized as lying, at least partly, on the causal pathway.

Common health outcomes linked to occupational stress include cardiovascular disease (hypertension, ischemic heart disease, and ischemic cerebral disease), musculoskeletal disorders (low back pain, upper limb disorders) and mental illness (depression). The health outcomes as a burnout, anxiety state, or depression may be recognized as real occupational stress-mediated disorders. Underlying pathophysiological processes include increased blood pressure, increased corticosteroid levels, increased peripheral neurotransmitters, sympathetic arousal, increased muscle tension, peripheral vasoconstriction, decreased immune system response, and stress-induced hyperventilation.

Occupational Therapy

Definition

Occupational therapy is a ► health care profession concerned with restoring physical functionality following disabling accidents and sickness. Its goal is to aid individuals in achieving the maximum level of independent function to become as independent as possible in carrying out daily life tasks. It addresses people of all ages, with a broad range of physical, mental, or developmental problems. The primary tool of occupational therapists is the active involvement of the patient in therapeutic tasks and activities.

Occupational Therapy in Palliative Care

Synonyms

Reconstruction aide

Definition

Occupational therapy is an applied science and health profession involving skilled treatment. Individuals undergoing occupational therapy develop, regain or maintain the abilities to participate in all facets of their lives ("skills for the job of living"). Thus they are prepared for a meaningful and satisfying way of life. Occupational therapy in palliative care provides: a) treatment for an improving performance of daily activities; b) home and job site evaluations and adaptive recommendations; c) performance assessments and treatment; d) adaptation equipment planning and training in their use; e) teaching assistance skills to family members and caregivers.

Occurrence

Synonyms

Frequency

Definition

In ► epidemiology, a general term describing the frequency of a disease or other attribute or event in a population without distinguishing between incidence and prevalence.

Odds Ratio (OR)

Synonyms

Cross-product ratio; Relative odds

Definition

Odds ratios are one way of expressing the size of the effect of a treatment on an even rate. The odds of an event are ratio of the probability of occurring to the probability of it not occurring. The odds ratio is the ratio of the odds of an event in the treatment (or exposed) group compared to the odds in the control (or unexposed) group.

$$\mathrm{OR} = \frac{a/c}{b/d} = \frac{ad}{bc}$$

$$95\%CI_{\mathrm{OR}} = \exp[\ln \mathrm{OR} \pm 1,96SE_{(\ln \mathrm{OR})}]$$

OR equal 1 means no effect of treatment. An OR of different from 1.0 suggests that positive or negative effect of treatment.

The Mantel-Haenszel method is appropriate for use in combining odds ratio.

The odds are a ratio of probabilities. The odds of exposure in a group is the number exposed divided by the number not exposed. If the odds of exposure among cases and controls in a case control study are determined, an odds ratio can be calculated as the ratio of two odds (odds of exposure among cases/odds of exposure among controls). An odds ratio close or equal to 1 indicates that the odds of exposure are very similar in the two groups. If the odds ratio is greater than 1, it indicates that cases are more likely to be exposed to a particular factor than controls, and if the odds ratio is less than 1, the opposite is true. The odds ratio (obtained from a case-control study) may be used as an estimate of the ► relative risk (obtained from a prospective cohort study) if the risk of disease in the population is low (less than 5%).

In medical research, the OR is favored for case-control studies.

Cross-References

► Relative Odds

OECD

Synonyms

Organisation for Economic Co-operation and Development

Definition

OECD is an international organization originating from the context the Marshall Plan implementation in Europe after the Second World War. Currently 30 countries are full members (mostly high-income countries within and outside Europe), which accept the principles of free market economy and representative democracy. The OECD is a forum for developing, analyzing and monitoring national and international policies in a wide range of sectors, e.g. trade, technology, environmental and social affairs. Dialog and capacity building activities also include a number of associated non-members. A focus of the OECD's work is on the compilation of comparable statistics, which allow for analysis and forecasts of economic developments.

The Organization for Economic Co-operation and Development (OECD) is an international organization of those developed countries that accept the principles of representative democracy and a free market economy. It originated in 1948 as the Organisation for European Economic Co-operation (OEEC), led by Robert Marjolin, to help administer the Marshall Plan for the reconstruction of Europe after World War II. Later its membership was extended to non-European states, and in 1961 it was reformed into the Organization for Economic Co-operation and Development. The organization provides a setting where governments can compare policy experiences, seek answers to common problems, identify good practice and co-ordinate domestic

and international policies. The mandate of the OECD is very broad, as it covers all economic, environmental and social issues.

Onchocerciasis

Synonyms

Onchocercosis; River blindness; Infection with Onchocerca volvulus; Dermatitis nodosa tropica

Definition

Onchocerciasis, which primarily occurs in Africa and Central and South America, is caused by the microfilaria *Onchocerca volvulus*. It is transmitted by blackflies, which breed in rapidly running water. Worldwide, about 20 million people are infected. With the bite, larvae get into the host organism. Within 10–20 months, they develop into adult worms. The worms settle in the subcutaneous tissue, where they appear as firm, nontender nodules, which can reach a size of 5 cm. Via lymphatic vessels the parasites can also reach the eyes. Without treatment, 10% of the eye infections lead to blindness. The medicinal treatment of onchocerciasis is administration of ivermectin (Mectizan®, Strometol®. Preventive measures include extermination of blackflies with insecticides, the prophylaxis of insect bites and the administration of ivermectin once yearly.

Opioid analgesics; Narcotic analgesics

Definition

Opioids are ► analgesics that reduce pain. The term is applied to opiate alkaloids and their synthetic analogues. Opioids are psychoactive drugs and they have the capacity to produce a sense of well-being (euphoria). In higher doses they can cause coma, seizures, respiratory depression and potential death.

Opportunistic Infections in AIDS

► AIDS-Defining Symptoms

Opportunity Costs

Definition

The concept of opportunity cost is based on the assumption of scarcity of resources for health care and the necessity for ► resource allocation. If the cost and the benefit of using one defined activity are not occurring, because the choice was made for an alternative, the opportunity cost is the cost and the value or benefit of the best alternative option. The concept of opportunity cost is important for all health economic analysis involving alternative resource use. It is particularly relevant for the determination of the cost of items without a market price.

Oral Diseases

Synonyms

Oral disorders; Dental diseases

Definition

Oral diseases comprise a range of conditions, including ► dental caries and ► periodontal diseases as the most important global oral health burdens, but also other important illnesses like oral cancer. They are highly prevalent and their impact on both the society and the individual is significant. Oral diseases affect a person's physical and psychological well-being and as a result reduce quality of life. The two most common conditions are to a great extent preventable.

Basic Characteristics

Dental Caries

Dental caries is among the most frequent chronic diseases in the world and is therefore still a major oral health problem in most industrialized countries. Between 60 and 90% of all schoolchildren and a vast majority of adults in developed countries and some states in Asia and Latin America suffer from tooth decay (Petersen 2003). The situation in most African countries is not that severe. Due to changing living conditions, it is expected that the incidence of dental caries will increase in many developing countries in Africa, particularly as a result of growing sugar consumption.

Dental caries can be defined as a localized destruction of the ► hard tooth tissue by microorganisms (infectious disease) leading to a ► cavity. It is a multifactorial disease and results from a combination of four factors:

1. host and teeth,
2. microorganisms (bacteria),
3. substrate (principally sucrose), and
4. time.

The hard tooth tissue is predominantly composed of calcium and phosphate in the form of hydroxyapatite. In the case of normal pH levels, there is a chemical equilibrium between the minerals of the tooth and the adjoining oral fluids – a balance between the tooth's re- and de-mineralization. If food particles remain on the tooth-surface, this balance is disrupted because the oral bacteria that adhere to the tooth surface (particularly *Streptococcus mutans*) metabolize the available substrate originating acid metabolites. These acids lead to a decrease of the pH-value, which results in a local demineralization of the tooth. With each exposure to sugar, the plaque pH falls sharply and rises slowly back to normal levels over the following hours. The bacteria also form extracellular polysaccharides, which they use to build and to increase the bulk of a covering named ► dental plaque.

A large amount of host factors inhibit the loss of mineral salts, for example the flow rate or the chemical composition of the saliva. The protective role of saliva against caries consists of simple dilution, buffering plaque acids, and being a source of minerals and immunological plaque inhibitory factors. However, the flow of saliva to the tooth surface is more and more restricted when dental plaque becomes established. Other conditions that promote demineralization are, for instance, plaque retention corners like ► approximal surfaces and a high frequency of ingestion.
