- HIV: Bilateral parotid enlargement seen as part of diffuse infiltrative lymphocytosis syndrome; see associated proliferation of CD-8 + lymphocytes
- Neonatal parotitis: The oral cavity is the primary source, but it can also spread from the bloodstream (usually gram-negative organism).

### ETIOLOGY

- Infectious:
  - Bacterial:
    - *Staphylococcus aureus* (most common)
    - Streptococcal species
    - Gram-negative organisms (*Escherichia coli*, *Klebsiella*, *Pseudomonas* species)
  - Granulomatous:
    - *Mycobacterium tuberculosis*
    - *Mycobacterium avium-intracellulare*
    - Actinomycosis
    - *Bartonella henselae*
    - *Francisella tularensis*
    - *Brucella* species
  - Viruses:
    - Mumps virus
    - Coxsackieviruses A and B
    - Echoviruses
    - Epstein-Barr virus
    - Influenza A virus
    - Parainfluenza viruses 1 and 3
    - Cytomegalovirus
    - Herpes simplex virus 1
    - Lymphocytic-choriomeningitis virus
    - HIV

- Sialolithiasis (stone)
- Foreign body (eg, seeds)
- Trauma
- Pneumoparotitis
- Sjögren syndrome
- Sarcoidosis (uveoparotid fever)
- Recurrent parotitis of children (idiopathic)

### COMMONLY ASSOCIATED CONDITIONS

- Viral illness (most common in children)
- Mumps (more commonly in the prevaccine era)
- Sialolithiasis (more rare in children)

## DIAGNOSIS

### HISTORY

- Infectious parotitis:
  - Bacterial (suppurative): History of progressive pain (ear or jaw), parotid swelling with fever, pain aggravated by chewing, malaise
  - Viral: Subacute pain (ear or jaw) and swelling for 7–9 days. Malaise, anorexia, mild fever. Swelling may be bilateral.
- Recurrent parotitis of childhood:
  - Peaks at 6 yr of age
  - Repeat episodes of fever, pain, and unilateral parotid swelling
  - Frequency is variable, and each episode may last up to 2 wk.
- HIV parotid enlargement: Seen in up to 20–50% of children with HIV and AIDS; median age of 4.6 yr for those with perinatal HIV

### PHYSICAL EXAM

- Swelling:
  - Typically pre- and postauricular
  - Often displaces ear upward and outward
  - Obscures angle of the jaw
- Pain:
  - Viral: Mildly tender parotid
  - Bacterial: Exquisite pain to touch, firmness, erythema, and induration
  - Chronic autoimmune: Nonpainful
- Secretions:
  - Normally, massage from posterior to anterior usually expresses clear saliva from the Stensen duct.
  - Purulent material may be seen with bacterial parotitis.
  - Yellow-tinged saliva may be seen with autoimmune parotitis.
- Swollen and tender testes may be seen with mumps epididymo-orchitis.
- Signs of meningitis may be seen with mumps.
- Painless, slow-growing mass seen with granulomatous parotitis: Signs of systemic TB are often absent with atypical *Mycobacterium*.
- Actinomycosis presents with a slow-growing, nodular gland with fistulas draining yellow or white material and often associated oral or cervical infections.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

- CBC:
  - An elevation in the WBC count or neutrophil predominance suggests bacterial parotitis.
- Amylase: Always elevated
- Anti-Ro and anti-La antibody may be seen with Sjögren syndrome.

##### Imaging

- US may be a useful screening tool for sialography. If US is positive for stones, cystic elements, or duct dilation, sialography is indicated. If US is normal or only shows a solid mass, there is no need for further imaging.
- X-ray sialography is the gold standard to look at parotid gland ducts: Contraindicated in acute infection

### DIFFERENTIAL DIAGNOSIS

- Cervical adenitis
- Dental abscess
- Preauricular adenitis
- Otitis externa
- Lymphangitis
- Parotid gland tumor
- Pneumoparotitis (wind instrument players)
- Branchial cleft abscess
- Gout
- Panniculitis
- Buccal cellulitis

## TREATMENT

### INITIAL STABILIZATION/THERAPY

- Rehydration
- Analgesia
- Parotid massage
- Discontinuation of any medications that decrease salivary flow
- Sialogogues that increase salivary flow (lemon drops, chewing gum)

### MEDICATION

- Ibuprofen 10 mg/kg PO/IV q6h PRN for fever or pain
- Acetaminophen 15 mg/kg PO/PR q4h PRN for fever or pain
- Most cases have a viral etiology. Antibiotics should be considered if a bacterial source is suspected.
- Clindamycin 10 mg/kg IV t.i.d.:
  - Coverage should be directed toward *S. aureus*, *Streptococcus*, anaerobes, and gram-negative organisms in suspected bacterial parotitis.
- Vancomycin 10 mg/kg IV q8h:
  - May be added if MRSA is suspected
- Ceftazidime 50 mg/kg IV q8h:
  - May be added to expand gram-negative coverage (namely *Pseudomonas*)

### SURGERY/OTHER PROCEDURES

- Surgical incision and drainage:
  - In neonatal bacterial parotitis or other severe bacterial parotitis and parotid abscess
  - If slow response to medical treatment or increase in fluctuance
- Surgical excision:
  - May be required with mycobacterial infection
- Tympanic neurectomy:
  - Cuts the parasympathetic fibers to the gland and thus increases secretion from the gland and may relieve sialectasis and further recurrent episodes

### DISPOSITION

#### Admission Criteria

- Suppurative parotitis:
  - Will often be ill appearing and require IV antibiotics. All neonates should be hospitalized.
- Critical care admission criteria:
  - Due to the potential for rapid deterioration, consider admitting neonates and young infants with acute bacterial parotitis to an ICU.

#### Discharge Criteria

The majority of patients can be treated as outpatients as long as pain is well controlled and oral hydration can be taken.

## FOLLOW-UP

### FOLLOW-UP RECOMMENDATIONS

Discharge instructions and medications:

- Parotid massage starts from the distal portion of the gland toward the duct opening.
- Oral hygiene, hydration, and sialogogues are a mainstay of outpatient treatment.

### DIET

Foods that increase salivary flow: Lemon drops, orange juice, etc.

### COMPLICATIONS

- Abscess formation
- Facial nerve palsy

### See Also (Topic, Algorithm, Electronic Media Element)

Mumps

### ICD9

- 072.9 Mumps without mention of complication
- 527.2 Sialoadenitis

### PEARLS AND PITFALLS

- Immunization has led to a 99% reduction in the incidence of mumps, with a concomitant decrease in cases of parotitis.
- Viral parotitis is more common than bacterial and is distinguished by mild parotid tenderness and absence of erythema or fever.
- Parotitis is a common presenting finding in patients with HIV.
- Without prompt, appropriate antibiotic therapy, acute bacterial parotitis may be fatal:
  - In neonates, deterioration may be very rapid; morbidity and mortality are high.
- If bacterial parotitis is suspected, antibiotic coverage should include *S. aureus*, *Streptococcus*, and anaerobes.

# PATENT DUCTUS ARTERIOSUS

Kimberly A. Randell

## BASICS

### DESCRIPTION

Persistent patency of the fetal ductus arteriosus (DA) beyond 3 mo of age:

- Accounts for 5–10% of all congenital cardiac defects (excluding premature infants) (1)

### EPIDEMIOLOGY

#### Incidence

- 0.5 in 1,000 term infants (2,3)
- 8 in 1,000 premature infants (2)

### RISK FACTORS

- Prematurity:
  - Found in 45% of infants <1,750 g and in up to 80% of infants <1,200 g (1)
- Maternal rubella infection
- Family history of congenital heart defect
- Birth asphyxia
- Birth at high altitude
- Maternal use of valproic acid
- Female gender (2 to 1 female preponderance) (2)

### PATHOPHYSIOLOGY

- In fetal circulation, the lungs are bypassed via the DA, which bridges the aorta and pulmonary artery.
- DA typically closes by 4–7 days of life in healthy neonates (4). Ductal closure occurs in response to decreased pulmonary vascular resistance, decreased prostaglandin levels, and increased arterial oxygen.
- Failure of the ductus to close, referred to as patent ductus arteriosus (PDA), allows left to right shunting from the aorta to pulmonary artery:
  - Shunting occurs during both systole and diastole, creating a continuous murmur.
  - The magnitude of shunting is dependent on resistance of the ductus and pulmonary vasculature.
- Shunting results in increased pulmonary blood flow, which may lead to cardiomegaly, CHF, and pulmonary HTN.
- Pulmonary HTN results in right to left shunting.
- Premature infants: PDA is due to decreased responsiveness of premature ductus to oxygen.
- Older infants and children: PDA is due to structural abnormality of ductal smooth muscle.

### ETIOLOGY

- Genetic
- Idiopathic:
  - Seemingly spontaneous PDA may actually be due to an underlying genetic predisposition combined with an environmental trigger.

### COMMONLY ASSOCIATED CONDITIONS

- In some patients, PDA is associated with other, more significant cardiac defects.
- In most cases of cyanotic congenital heart disease, the PDA is essential for pulmonary blood flow.

## DIAGNOSIS

### HISTORY

- Premature infants:
  - May be asymptomatic
  - Episodes of apnea/bradycardia
  - Cardiovascular instability
- Term infants and older children:
  - Small PDA is typically asymptomatic.
  - Moderate/Large PDA: Symptoms related to CHF
    - Tachypnea
    - Failure to thrive
    - Exertional dyspnea (including dyspnea with feeds)
    - Respiratory distress

### PHYSICAL EXAM

- Continuous heart murmur in 80–90% (5):
  - Initially, the murmur may be systolic only, with a continuous murmur developing around the 2nd to 3rd wk of life.
  - Loudest at the left upper sternal border or infraclavicular level
  - Described as “machinery” murmur
  - May have an associated thrill
  - With development of pulmonary HTN and right to left shunting, the 2nd heart sound (P2) increases and the murmur may disappear.
- Bounding pulses
- Wide pulse pressure
- Signs of CHF may be present:
  - Tachypnea
  - Rales
  - Tachycardia
  - Active precordium
  - Hepatomegaly
- Differential cyanosis: Cyanotic lower extremities, seen with pulmonary HTN

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

Lab testing is not needed for diagnosis of PDA, but the following labs are useful in cases associated with CHF:

- Arterial blood gas: Assess the degree of hypoxia and metabolic acidosis
- CBC: Anemia exacerbates CHF
- Electrolytes
- Digoxin level (if appropriate): Digoxin toxicity may present with symptoms of worsening CHF.

#### Imaging

Chest radiographs:

- Small PDA: Normal film
- Moderate/Large PDA: Cardiomegaly (due to left atrial and ventricular enlargement), increased pulmonary vascular markings
- PDA with pulmonary vascular obstructive disease: Normal heart size, marked prominence of pulmonary artery segment and hilar vessels

### Diagnostic Procedures/Other

- ECG:
  - Small PDA: Normal
  - Moderate PDA: Left ventricular hypertrophy
  - Large PDA: Concentric ventricular hypertrophy and left atrial hypertrophy
  - May see right ventricular hypertrophy if pulmonary HTN is present
- Echo:
  - Determine the size of the PDA and the direction/volume of shunting.

### DIFFERENTIAL DIAGNOSIS

- Other etiologies of a continuous murmur with/without bounding pulses:
  - Venous hum
  - Peripheral pulmonary artery stenosis
- Aortic insufficiency:
  - Truncus arteriosus
  - Coronary or systemic arteriovenous malformation
  - Pulmonary arteriovenous fistula
  - Collaterals in coarctation of the aorta or tetralogy of Fallot
- Ventricular septal defect with aortic regurgitation
- Aortopulmonary window:
  - Ruptured sinus of Valsalva aneurysm
  - Total anomalous pulmonary venous return draining into the right atrium

## TREATMENT

### PRE HOSPITAL

Assess and stabilize airway, breathing, and circulation.

### INITIAL STABILIZATION/THERAPY

- Address issues of airway, breathing, and circulation 1st.
- Supplemental oxygen is indicated even with normal oxygen saturation levels if the patient is in shock.
- Cautious use of IV fluids, as additional volume overload may worsen symptoms of CHF
- With certain types of congenital heart disease such as transposition of the great arteries, it is essential that a PDA remain open to allow mixing of oxygenated and deoxygenated blood. In these circumstances, prostaglandins may be used to maintain patency of the DA.

### MEDICATION

#### First Line

- Premature infants:
  - Initial management with fluid restriction and diuretics
  - Closure is indicated if the patient is symptomatic. Prophylactic PDA closure is controversial.
  - If closure is indicated, medical closure is the first-line treatment unless contraindicated (renal failure, platelet dysfunction or thrombocytopenia, necrotizing enterocolitis, postnatal age >2 wk).
  - The choice of indomethacin (initial dose is 0.2 mg/kg for PDA closure) or ibuprofen is cardiologist dependent.

- Term infants and older children:
  - Medical closure is not an option, as the PDA is due to structural abnormalities.
  - CHF is typically managed with diuretics and digoxin.
- Fulminant CHF:
  - Furosemide 1 mg/kg IV; provides diuresis and is associated with hypokalemia
  - Dopamine: Initial rate 2–5  $\mu\text{g}/\text{kg}/\text{min}$  (5–10  $\mu\text{g}/\text{kg}/\text{min}$  if severe hypotension); may increase to 20  $\mu\text{g}/\text{kg}/\text{min}$ . At low doses, provides inotropic support and increases renal perfusion. Adrenergic effects prevail at higher doses, with arrhythmias a potential side effect.
  - Dobutamine: Initial rate 2.5–5  $\mu\text{g}/\text{kg}/\text{min}$ ; may increase up to 20  $\mu\text{g}/\text{kg}/\text{min}$ . Adrenergic effects prevail at higher doses of both, with arrhythmias a potential side effect.

**Second Line**

If fulminant CHF is unresponsive to furosemide and/or inotropes, consider:

- Metolazone 0.1 mg/kg enterally; provides diuresis and is associated with profound hypokalemia
- Milrinone: Initial bolus 50  $\mu\text{g}/\text{kg}$  followed by 0.5–1  $\mu\text{g}/\text{kg}/\text{min}$ . Monitor closely, as the vasodilatory response may be profound. Other potential side effects include thrombocytopenia and fever.

**SURGERY/OTHER PROCEDURES**

- Premature infants:
  - Surgical ligation is indicated if medical therapy is unsuccessful or contraindicated.
- Term infants/older children:
  - Closure is indicated for symptomatic PDA or if left heart enlargement is seen. Recommendations for closure of an incidentally discovered “silent” PDA vary by cardiologist.
  - Options for closure include transcatheter closure or surgical ligation via thoracotomy or thoracoscopy.
  - Occlusion rate >90% with transcatheter closure (2)
  - Occlusion rate >95% with surgical closure (1,2)

**DISPOSITION**

**Admission Criteria**

Critical care admission criteria:

- Cardiopulmonary instability due to either CHF or pulmonary HTN

**Discharge Criteria**

- Well-appearing infants suspected to have a PDA and without signs of CHF or respiratory distress may be managed as outpatients.
- Responsible parents
- Cardiology follow-up ensured

**Issues for Referral**

- If unsure of diagnosis, referral to cardiology for evaluation and echo
- If increasing symptoms in a patient with known, unclosed PDA, cardiology consult for further management

**FOLLOW-UP**

**FOLLOW-UP RECOMMENDATIONS**

- Discharge instructions and medications:
  - For patients with unrepaired or suspected PDA, educate caregivers about signs of CHF: Exertional dyspnea (including dyspnea with feeds), tachypnea, and increased work of breathing
  - Prophylaxis for infective endocarditis is indicated if the PDA is not completely closed or if it is within 6 mo of closure. First-line antibiotic choice is a 1-time dose of amoxicillin 50 mg/kg PO.
  - Ensure that caregivers know when cardiology follow-up should occur.
- Activity:
  - Activity restrictions are not indicated in the absence of pulmonary HTN.

**Patient Monitoring**

Routine cardiorespiratory monitoring, including BP

**PROGNOSIS**

- The prognosis depends on the size of the PDA and degree of shunting and pulmonary overload:
  - A “silent” PDA may remain asymptomatic if untreated, although risk of infective endocarditis is increased.
- The prognosis after closure is typically excellent, with return of normal circulation and endocarditis risk decreasing to that of the normal population.
- For premature infants, the prognosis also depends on associated conditions (eg, degree of prematurity, necrotizing enterocolitis, etc.). 40–80% of PDA in premature infants will close spontaneously (1).
- Pulmonary vascular obstructive disease is not reversible.

**COMPLICATIONS**

- CHF
- Failure to thrive
- Pulmonary HTN
- Pulmonary vascular obstructive disease
- Recurrent pneumonia
- Infective endocarditis
- Aneurysm of PDA with/without rupture
- Left pulmonary artery and aortic obstruction in low-weight patients with large ducts undergoing transcatheter closure
- Additional complications in premature infants:
  - Necrotizing enterocolitis
  - Bronchopulmonary dysplasia
  - Intraventricular hemorrhage
  - Pulmonary edema with or without pulmonary hemorrhage

**CODES**

**ICD9**

747.0 Patent ductus arteriosus

**PEARLS AND PITFALLS**

- The most important risk factor for PDA is prematurity.
- Cyanotic congenital heart disease, with right to left shunting of blood, must be ruled out before attempts are made to close a PDA.
- Left untreated, a moderate to large PDA may result in significant long-term morbidity and mortality.

# PATENT URACHUS

Arezoo Zomorodi

## BASICS

### DESCRIPTION

A patent urachus is a free communication between the bladder and the umbilicus that results from failure of the urachus to involute during normal embryonic development.

### EPIDEMIOLOGY

- Urachal anomalies are exceedingly rare. Patent urachus accounts for 10–15% of all urachal remnants (1–3).
- More common in males
- Usually presents in the neonatal period

### PATHOPHYSIOLOGY

- The median umbilical ligament is a fibrous cord extending from the dome of the bladder to the umbilicus and results from obliteration of the urachus.
- During fetal development, the urachus connects the allantois to the bladder.
- In the 4th to 5th mo of gestation, the bladder descends into the pelvis, stretching the urachus and causing obliteration of its lumen.
- Abnormal regression can lead to urachal remnants including patent urachus, urachal sinus, urachal cyst, and vesicourachal diverticulum:
  - A patent urachus is a complete connection between the bladder and the umbilicus.
  - A urachal sinus occurs when the umbilical end of the urachus is patent but there is no connection to the bladder.
  - A patent section in the midportion of the urachus results in an urachal cyst.
  - A diverticulum develops when there is a residual connection between the bladder and the urachus.

### ETIOLOGY

Unknown

## COMMONLY ASSOCIATED CONDITIONS

Urachal anomalies can occur with other urogenital abnormalities including posterior urethral valves, vesicoureteral reflux, or duplicated renal collecting system in up to 37% of cases (1).

## DIAGNOSIS

### HISTORY

Persistent thin and clear fluid drainage from the umbilicus, especially in the newborn period

### PHYSICAL EXAM

- Presence of clear fluid drainage from the umbilicus in the absence of granulation tissue
- The umbilicus may have an abnormal appearance or be inflamed.
- Evaluate for other genital anomalies.
- The presence of omphalitis is uncommon.

## DIAGNOSTIC TESTS & INTERPRETATION

### Lab

#### Initial Lab Tests

- Urinalysis and urine culture:
  - Up to 36% of patients have urinary tract infections at presentation (1)
- Depending on age, if a urinary tract infection is found, further sepsis evaluation may be warranted.

### Imaging

- A sinogram can diagnose patent urachus definitively.
- A renal US and voiding cystourethrogram should be considered in patients with urachal anomalies in order to identify associated genitourinary abnormalities.

## DIFFERENTIAL DIAGNOSIS

- Umbilical granuloma
- Persistent omphalomesenteric duct
- Omphalitis
- Urachal sinus

## TREATMENT

### INITIAL STABILIZATION/THERAPY

- Most neonates with patent urachus will be stable.
- For those who appear unstable, initial focus should be on airway, breathing, and circulation, and proper support must be provided.

### MEDICATION

Associated urinary tract infections or skin infections should be treated with appropriate antimicrobial agents.

### SURGERY/OTHER PROCEDURES

Definitive therapy of patent urachus is surgical excision of the tract.

### DISPOSITION

#### Admission Criteria

- Urinary tract infection in young infant
- Other associated problems that would warrant admission, such as omphalitis, umbilical abscess, ill appearance, or dehydration

#### Discharge Criteria

Stable patients without omphalitis or other admission criteria can be discharged from the emergency department for outpatient workup and definitive treatment.

#### Issues for Referral

Refer to a urologist for evaluation of associated urogenital tract anomalies and definitive surgical excision.

## FOLLOW-UP

### FOLLOW-UP RECOMMENDATIONS

- Follow up with the primary care provider and with a pediatric urologist.
- Seek medical care for abdominal pain, vomiting, fevers, or erythema of the skin around the umbilicus.

### PROGNOSIS

- The prognosis for surgically resected patent urachus is excellent.
- Patent urachus presents earlier than other urachal anomalies and therefore definitive treatment is rendered before carcinogenic transformation.
- Postoperative complications are rare and have not been reported to leave long-term sequelae (1,2).

### COMPLICATIONS

- Infection: Urinary tract infection, cellulitis, omphalitis, and urachal abscess
- Unresected urachal remnants may cause adulthood carcinoma with poor prognosis.
- Bladder prolapse and eversion through a patent urachus is an extremely rare complication (4).

## CODES

### ICD9

753.7 Congenital anomalies of urachus

## PEARLS AND PITFALLS

- Umbilical drainage in the absence of granulation tissue should be evaluated for a patent urachus.
- Patients with a patent urachus should be evaluated for associated urogenital tract anomalies, including urinary tract infection.
- Consider possible patent urachus in patients diagnosed with umbilical granuloma who undergo multiple treatments without resolution.

# PELVIC INFLAMMATORY DISEASE

Cynthia J. Mollen

## BASICS

### DESCRIPTION

- Pelvic inflammatory disease (PID) is a spectrum of infections of the female upper genital tract (eg, endometritis, salpingitis).
- It is the most frequent cause of gynecologic visits in sexually mature females.

### EPIDEMIOLOGY

#### Incidence

- >1,000,000 cases diagnosed per year:
- ~20% of those in young women <20 yr of age

### RISK FACTORS

- Adolescence (15–19 yr of age): Biologic and behavioral factors
- Early sexual debut
- Increased number of sexual partners
- Prior history of PID
- Infrequent use of barrier contraception
- Intercourse during menstruation

### GENERAL PREVENTION

- Limiting number of sexual partners
- Utilizing barrier contraception
- Seeking care early for symptoms of an STI

### PATHOPHYSIOLOGY

- Ascending infection from the vagina and cervix to the uterus, ovaries, and fallopian tubes
- Prominent columnar epithelium in the adolescent cervix (as compared to squamous epithelium in the adult cervix) is more susceptible to infection.
- Menstruation makes females more susceptible to acquiring infection and promotes bacterial proliferation and spread due to the presence of newly exposed tissue present after sloughing of endometrium.

### ETIOLOGY

- Multiple organisms have been implicated in PID: *Chlamydia trachomatis* and *Neisseria gonorrhoeae* are common but not present in all cases.
- Other organisms include anaerobes, *Gardnerella vaginalis*, *Streptococcus agalactiae*, *Bacteroides fragilis*, and enteric gram-negative rods.

## DIAGNOSIS

### HISTORY

- A confidential, private interview with the adolescent may reveal a history of sexual activity and can allow for questioning related to contraception, number of sexual partners, and prior history of PID or another STI.
- PID should be considered in any sexually mature female who presents with abdominal or pelvic pain.
- The most common complaint is lower abdominal pain, often with onset during menses.
- Additional complaints include abnormal vaginal discharge, abnormal uterine bleeding, dysuria, dyspareunia, nausea, vomiting, and fever.
- Symptoms may be mild and/or vague.

### PHYSICAL EXAM

- The minimum criteria to diagnose PID are the presence of *either* cervical motion tenderness *or* adnexal *or* uterine tenderness in women at risk for an STI who present with lower abdominal or pelvic pain.
- Supporting findings include temperature >101°F, abnormal cervical or vaginal mucopurulent discharge, abundant numbers of WBCs on saline microscopy of vaginal secretions, elevated ESR or C-reactive protein (CRP), lab documentation of infection with *C. trachomatis* or *N. gonorrhoeae*.
- The abnormal physical exam findings present in patients with PID can be detected with the bimanual exam.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

- PID is nearly exclusively diagnosed clinically.
- Numerous adjunctive lab tests are useful:
  - Pregnancy test
  - Testing for *C. trachomatis* and *N. gonorrhoeae* (urine, vaginal, or cervical specimen) or cervical cultures for these organisms
  - Gram stain of vaginal secretions
  - CBC with differential
  - CRP and ESR
  - Urinalysis and urine culture
  - Testing for associated infection (eg, *Trichomonas vaginalis*, HIV; consider serologic testing for syphilis)

##### Imaging

Pelvic US (Doppler if considering ovarian torsion) should be considered if other pathology such as tubo-ovarian abscess (TOA) is suspected.

### DIFFERENTIAL DIAGNOSIS

- Ovarian torsion
- Ovarian cyst
- Ectopic pregnancy
- Intrauterine pregnancy
- Endometriosis
- Urinary tract infection
- Appendicitis
- Nephrolithiasis
- Inflammatory bowel disease
- Irritable bowel syndrome

**TREATMENT**

**MEDICATION**

**First Line**

- Refer to CDC guidelines for full medication regimen information.
- Inpatient: Cefoxitin 2 g IV q6h plus doxycycline 100 mg PO q12h
- Outpatient: Ceftriaxone 250 mg IM or IV in a single dose plus doxycycline 100 mg PO b.i.d. for 14 days, with or without metronidazole 500 mg b.i.d. for 14 days
- Penicillin or cephalosporin allergic, inpatient: Clindamycin 900 mg q8h plus gentamicin loading dose (IV or IM) 2 mg/kg, then 1.5 mg/kg q8h
- Penicillin cephalosporin allergic, outpatient: See below for treatment failures; CDC guidelines recommend consultation with an infectious disease specialist.

**Second Line**

- Consider for treatment failures:
  - Inpatient: Ampicillin/Sulbactam 3 g IV q6h plus doxycycline 100 mg PO b.i.d.
  - Outpatient: Due to increasing resistance of *N. gonorrhoeae* to fluoroquinolones, this class of antibiotics is no longer recommended for the routine treatment of PID. However, if parenteral cephalosporin treatment is not feasible (ie, significant penicillin allergy), cervical culture for *N. gonorrhoeae* should be obtained prior to initiating therapy; levofloxacin 500 mg per day for 14 days can be used if the organism is sensitive to fluoroquinolones.
- Patients with a TOA diagnosis should be treated with metronidazole or clindamycin in addition to cefoxitin and doxycycline.

**SURGERY/OTHER PROCEDURES**

Laparoscopy is only indicated when the diagnosis of PID is uncertain and surgical diagnoses are being strongly considered or for patients with a diagnosis of PID who have recurrent abdominal pain.

**DISPOSITION**

**Admission Criteria**

- Pregnancy: Because of the high risk for maternal morbidity and preterm delivery, these patients should be hospitalized and treated with parenteral antibiotics.
- Surgical diagnoses (eg, appendicitis) cannot be excluded.
- Failed outpatient therapy
- Inability to tolerate or follow outpatient regimen
- Severe illness (nausea/vomiting, high fever)
- Immunocompromised
- TOA

**Discharge Criteria**

- Adolescents who do not meet specific admission criteria and who have reliable follow-up can be discharged from the emergency department.
- Hospitalized patients can be discharged 24 hr after clinical improvement.

**FOLLOW-UP**

**FOLLOW-UP RECOMMENDATIONS**

- Patients should complete 14 days of doxycycline or other oral medication according to CDC guidelines.
- Patients discharged from the hospital after the diagnosis of TOA should also complete 14 days of metronidazole or clindamycin.
- Patients treated as an outpatient should have a recheck with their primary care provider in 48–72 hr.
- Sexual partners who have contact with the patient within 60 days of the onset of symptoms should be screened or treated empirically for *C. trachomatis* and *N. gonorrhoeae*.

**COMPLICATIONS**

- Recurrence
- TOA
- Fitz-Hugh-Curtis syndrome: Capsular inflammation of the liver
- Infertility
- Ectopic pregnancy
- Chronic abdominal pain

**ADDITIONAL READING**

- CDC. Sexually transmitted diseases treatment guidelines 2010. *MMWR Morb Mortal Wkly Rep.* 2010;59(RR-12):63–67.
- Tarr ME, Gilliam ML. Sexually transmitted infections in adolescent women. *Clin Obstetr Gynecol.* 2008;51(2):306–318.

**CODES**

**ICD9**

614.9 Unspecified inflammatory disease of female pelvic organs and tissues

**PEARLS AND PITFALLS**

- PID should be diagnosed and treated according to CDC guidelines.
- Given the significant long-term complications, clinicians should maintain a low threshold for the diagnosis and treatment of PID.
- Physical exam findings to meet the minimum diagnostic criteria include *either* cervical motion tenderness *or* adnexal *or* uterine tenderness.
- Documented infection with *C. trachomatis* or *N. gonorrhoeae* is not required to prove the diagnosis of PID.
- Symptoms may be mild and/or vague, warranting vigilance and routinely performing pelvic exam of sexually active girls with lower abdominal pain or other suggestive symptoms.

# PERICARDIAL EFFUSION/TAMPONADE

Lauren Daly

## BASICS

### DESCRIPTION

- Pericardial effusion and cardiac tamponade will be discussed in this topic.
- Pericardial effusion is the disease state in which an abnormal amount of fluid accumulates in the pericardial space.
- Cardiac tamponade is the emergent state of impaired ventricular filling:
  - Accumulation of fluid, blood, pus, or gas
  - Leads to cardiac constriction by an inflamed, thickened pericardium that causes a decrease in cardiac output
  - Potentially fatal

### EPIDEMIOLOGY

Cardiac tamponade has been reported in 5–28% of cases of acute idiopathic pericarditis.

### RISK FACTORS

- Risk factors for pericardial effusion are diverse and include:
  - Infections: Bacterial (purulent pericarditis), fungal, and viral (including HIV)
  - Hemorrhagic
  - Trauma
  - TB
  - Oncologic
  - Inflammatory (eg, systemic lupus erythematosus [SLE], rheumatic fever, scleroderma)
  - Post cardiac surgery
  - Medication exposure: Isoniazid, procainamide, phenytoin
  - Idiopathic
- Risk factors for cardiac tamponade include pericarditis and all other forms of pericardial disease associated with pericardial effusion.

### GENERAL PREVENTION

Cardiac tamponade can be prevented if the accumulation of pericardial fluid is recognized and treated early.

### PATHOPHYSIOLOGY

- The primary abnormality in cardiac tamponade is compression of all cardiac chambers as a result of increasing intrapericardial pressure.
- The accumulation of fluid within the pericardium overcomes the ability of the pericardium to stretch, causing compression of the chambers and decreased cardiac output.
- The rate of fluid accumulation is important:
  - Traumatic effusions often lead to rapid decompensation because of an inability of the pericardium to rapidly stretch.
  - Infectious and inflammatory causes, in which fluid accumulates more slowly, are far better tolerated because they allow for stretch and compensatory mechanisms to be activated.

- There is a characteristic pressure-volume curve in acute cardiac tamponade wherein an initial slow ascent in pressure is followed by an almost vertical rise when the limit of pericardial stretch is reached:
  - This is termed the “last drop phenomenon” and reflects how a pericardial effusion, even a relatively large one, can be well tolerated for a period of time followed by a rapid decompensation.

### ETIOLOGY

See Risk Factors.

### COMMONLY ASSOCIATED CONDITIONS

See Risk Factors.

## DIAGNOSIS

### HISTORY

- History of onset of respiratory difficulties after resolution of an upper respiratory infection may indicate pericardial disease.
- A history of chest pain that is relieved by sitting upright and leaning forward and made worse when supine is very characteristic of pericardial disease.
- Chest pain
- Palpitations
- Dyspnea
- Cough
- Syncope
- Malaise

### PHYSICAL EXAM

- Patients with pericardial effusion or tamponade may present with:
  - Pericardial friction rub
  - Distant heart sounds
  - Hypotension
  - Poor perfusion
  - Narrow pulse pressure
  - Electromechanical dissociation
- Signs of right heart failure or shock may be present.
- The Beck triad (hypotension, jugular venous distension, and diminished heart sounds) and pulsus paradoxus (> 10 mm Hg variation in systolic BP with respiration) are useful clinical signs to watch for but should not solely be relied on to identify impending cardiac tamponade:
  - The Beck triad is present in only 22–54% of cases of cardiac tamponade.
  - Pulsus paradoxus occurs in < 1/2 of patients with tamponade.

## DIAGNOSTIC TESTS & INTERPRETATION

### Lab

#### Initial Lab Tests

- CBC and/or C-reactive protein, blood cultures to assess for infection
- Cardiac enzyme screening: Troponin levels may be mildly elevated.
- Antinuclear antibody test to screen for SLE
- Pericardial fluid, if obtained, should be analyzed for:
  - Gram stain and culture
  - Cell count
  - Lactate dehydrogenase (LDH)
  - Total protein:
    - Elevation in LDH and total protein are indicative of an exudative fluid collection.

### Imaging

- Chest radiograph may show cardiomegaly in both pericardial effusion and tamponade; a pleural effusion may be present as well.
- Echo is the diagnostic procedure of choice for identifying pericardial effusion and acute cardiac tamponade:
  - Fluid in the pericardial sac
  - Effusions > 25–50 mL are seen as an echo free space during the cardiac cycle.
  - Right ventricular or atrial diastolic collapse
  - A circumferential effusion suggests a large effusion, as does collapse of the right side of the heart during filling.

### Diagnostic Procedures/Other

- ECG may show tachycardia, low-voltage QRS waves, or electrical alternans (alternating beat-to-beat variation in QRS amplitude) in effusion and acute cardiac tamponade.
- See information about pericardiocentesis under Surgery/Other Procedures.

### DIFFERENTIAL DIAGNOSIS

- CHF
- Hypertrophic cardiomyopathy
- Myocarditis
- MI
- Pulmonary embolism
- Tension pneumothorax
- Aortic dissection
- Vasovagal syncope

## TREATMENT

### PRE HOSPITAL

Assess and stabilize airway, breathing, and circulation.

### INITIAL STABILIZATION/THERAPY

- Assess and stabilize airway, breathing, and circulation:
  - Hemodynamic function is the most common issue requiring immediate intervention.
  - Pericardiocentesis for unstable patients
  - Emergency department thoracotomy for patients with penetrating chest trauma who are unstable after pericardiocentesis and fluid resuscitation
- Volume resuscitation is helpful in hypovolemic patients and may be a temporizing measure in euvoletic patients with symptomatic tamponade.
- In the stable patient, close monitoring of effusion and hemodynamic status is mandatory.

### MEDICATION

Analgesics, broad-spectrum antibiotics, and anti-inflammatories are administered based on the overall clinical picture and results of pericardial fluid analysis.

### SURGERY/OTHER PROCEDURES

- In the unstable patient in whom pericardial tamponade is suspected, first-line treatment is immediate pericardiocentesis.
- In addition to therapeutic pericardiocentesis to relieve tamponade, the procedure may be performed for diagnostic purposes to determine the etiology of effusion.
- After ensuring a patent/secure airway and sedating (if time allows), the patient is placed supine or in slight reverse Trendelenburg position.
- The patient is attached to cardiorespiratory and oxygen saturation monitors and continuous ECG recording.
- If available, the use of bedside US can aid visualization of cardiac structures.
- Under sterile conditions, a 20-gauge spinal needle attached to a 30–50 mL syringe is inserted below the xiphoid process at a 45-degree angle toward the left shoulder while maintaining constant negative pressure on the attached syringe.
- If US guidance is not possible, an alligator clip can be attached to the hub of the needle and connected to a grounded precordial lead on an ECG monitor, which will detect current if the needle touches the heart.
- The needle should be advanced until pericardial fluid is obtained or ECG changes are observed (ST-T wave changes, QRS widening, or premature ventricular contractions).

### DISPOSITION

#### Admission Criteria

- Children with newly diagnosed pericardial effusion typically should be hospitalized for monitoring and further diagnostic workup.
- Critical care admission criteria:
  - Patients undergoing pericardiocentesis should be admitted to an ICU.

#### Discharge Criteria

Patients with small pericardial effusion of known etiology and minimal or no symptoms from the effusion who are stable may be discharged.

#### Issues for Referral

Discharged patients should follow up with a cardiologist as well as other specialists with expertise in causal etiology, such as a rheumatologist, an infectious disease specialist, and an oncologist, etc.

## FOLLOW-UP

### FOLLOW-UP RECOMMENDATIONS

- Discharge instructions and medications:
  - Caregivers and patients should be aware of signs and symptoms suggestive of large effusion or tamponade that warrant immediate ambulance transport to a hospital.
- Activity:
  - Varies depending on etiology; typically, avoiding strenuous exercise until effusion is resolved is preferable.

#### Patient Monitoring

Monitor closely for signs of worsening disease or cardiac compromise.

### PROGNOSIS

Varies depending on the etiology

### COMPLICATIONS

- CHF
- Cardiogenic shock
- Death
- Complication rates with pericardiocentesis may be as high as 15%:
  - Dysrhythmias
  - Ventricular puncture
  - Hemopericardium
  - Pneumothorax
  - Laceration of coronaries of the inferior vena cava
  - Puncture of the esophagus or diaphragm
  - Infection

Pericarditis

## CODES

### ICD9

- 423.3 Cardiac tamponade
- 423.9 Unspecified disease of pericardium

## PEARLS AND PITFALLS

- Be aware of the "last drop phenomenon": An incremental increase in pericardial fluid volume will cause a steep increase in pressure, leading to rapid decompensation in a patient with a pericardial effusion.
- Do not rely solely on the appearance of the Beck triad or pulsus paradoxus to suspect pericardial effusion/tamponade, as these findings are neither sensitive nor specific.
- A history of chest pain that is relieved by sitting upright and leaning forward and made worse when supine is characteristic of pericardial disease.

# PERICARDITIS

Halden F. Scott

## BASICS

### DESCRIPTION

- Pericarditis is inflammation of the visceral and parietal layers of the pericardium, typically resulting in accumulation of fluid in the pericardial space.
- Constrictive pericarditis results from chronic inflammation resulting in thickening of and adherence of the pericardium to the heart.
- If the amount of fluid collection becomes too great, it can impinge on cardiac function by creating a pericardial tamponade.

### EPIDEMIOLOGY

- In children, pericarditis is usually infectious.
- Occurs most often in preteen children, with the highest incidence in children <2 yr of age
- Purulent pericarditis is most common in children <6 yr of age.
- In adults, 1 study suggests that 0.1% of hospitalized patients have pericarditis.

### RISK FACTORS

- Pyogenic bacterial infections such as meningitis, osteomyelitis, pneumonia, or epiglottitis
- Patients with recent cardiac surgery are at risk for post-pericardiotomy pericarditis.
- Radiotherapy to the mediastinum
- Exposure to causal medications

### PATHOPHYSIOLOGY

- Pericarditis is usually accompanied by some degree of pericardial effusion, a fluid collection between layers of the pericardium.
- The fluid collection may be purulent, serous, hemorrhagic, fibrinous, or chylous.
- When the pericardial effusion becomes large enough to cause hemodynamic compromise, it is considered cardiac tamponade.

### ETIOLOGY

- May be a primary, isolated problem or may occur as a manifestation of many systemic diseases
- Infectious diseases are the most commonly-identified cause in children
- Bacterial infections such as meningitis, osteomyelitis, pneumonia or epiglottitis:
  - Bacterial: *Staphylococcus*, *Streptococcus*, *Haemophilus influenzae*, *Neisseria meningitidis*, *Salmonella*
  - Viral (20–30% of cases have confirmed viral causes): Coxsackievirus and enteric cytopathogenic human orphan (ECHO) are most common. Other causative viruses include rubella, Epstein-Barr virus, adenovirus, influenza, and mumps.
  - *Mycobacterium tuberculosis*
  - Fungal infections: *Candida*, *Aspergillus*, *Histoplasmosis*, *Blastomycosis*, *Nocardia*
  - Parasitic: Amebiasis, toxoplasmosis, echinococcosis
- Inflammatory: Acute rheumatic fever, systemic lupus erythematosus, uremia, radiation, juvenile idiopathic arthritis, pancreatitis

- Traumatic: Chest wall injury, foreign body
- Postpericardiotomy syndrome
- Post-myocardial ischemia (MI) pericarditis
- Medications: Minoxidil, procainamide, cromolyn sodium, hydralazine, dantrolene, mesalamine
- Oncologic pericarditis is a result of direct extension of neoplastic cells into the pericardium, especially leukemia, lymphoma, and rhabdomyosarcoma.
- Chronic pericarditis syndromes include constrictive pericarditis, subacute effusive pericarditis, and blood dyscrasias.
- Idiopathic

### COMMONLY ASSOCIATED CONDITIONS

See Risk Factors and Etiology.

## DIAGNOSIS

### HISTORY

- Chest pain is described as sharp and is usually pleuritic. It frequently radiates to the back and upper shoulder.
- The patient may report pain relief by sitting up and leaning forward; pain may worsen when supine.
- Abdominal pain
- Dyspnea
- Preceding upper respiratory infection
- History should also include evaluation for common causes and systemic disorders, including rheumatic fever, autoimmune diseases, TB, and uremia.
- Congenital heart disease or history of Kawasaki disease might support a post-myocardial ischemia or post-pericardiotomy pericarditis.

### PHYSICAL EXAM

- Tachypnea and tachypnea typically are present.
- Chest pain: Retrosternal or precordial, usually sharp and pleuritic, worse with cough or inspiration, worse in reclining position, improved leaning forward
- Friction rub is heard up to 85% of the time without effusion but is less commonly heard with significant intrapericardial fluid.
- Muffled heart sounds with weak apical impulse suggest pericardial effusion.
- If pericardial effusion with tamponade physiology is present, hypotension, cool extremities, neck vein distension, hepatomegaly, and pulsus paradoxus are observed:
  - Beck triad: Muffled heart sounds, distended neck veins, decreased systemic arterial pressure

### DIAGNOSTIC TESTS & INTERPRETATION

- When pericarditis is suspected, several life-threatening coexistent processes must 1st be excluded. Immediate evaluation for pericardial effusion with tamponade physiology, myocardial ischemia, and myocarditis should occur.
- Although a causal agent is not always found, the emergency department may pursue an initial diagnostic evaluation for causes requiring immediate treatment, including purulent pericarditis, TB, and rheumatic fever.
- A 12-lead ECG should be obtained in all cases.

## Lab

### Initial Lab Tests

- Cardiac enzymes: May help distinguish myocarditis from MI. Increased serum cardiac troponin levels are common, with or without the increased MB fraction of creatine kinase (CK-MB). Epicardial inflammation is the usual cause of the elevated troponin; persistent elevations suggest myopericarditis.
- Inflammatory markers: CBC to assess for leukocytosis, C-reactive protein (CRP), ESR
- Blood culture in febrile patients
- Consider tuberculin skin test, antinuclear antibody, antistreptolysin O antibodies, and HIV serology if clinical suspicion for these etiologies.

### Imaging

- CXR to assess for effusion (water bottle sign)
- US allows detection of pericardial effusion, even if small, as well as cardiac function:
  - Echo to exclude pericardial effusion and to evaluate function if myopericarditis is suspected. An echo-free space between layers of the pericardium both anterior and posterior to the heart indicates a large effusion.

### Diagnostic Procedures/Other

ECG will demonstrate changes of epicardial inflammation (except in uremic pericarditis):

- Stage 1: Widespread ST elevation, PR depression. ST elevation in limb leads and precordial leads distinguishes ECG from ST elevations found in myocardial ischemia. Elevations are concave.
- Stage 2: Normalization
- Stage 3: Diffuse T-wave inversions, not always present
- Stage 4: May normalize, or T-wave inversions may persist
- Pericardial effusion: Diminished voltages
- Myopericarditis: May have more localized ST and T-wave changes suggesting ischemia. Arrhythmias may be seen.

### DIFFERENTIAL DIAGNOSIS

- MI
- Pulmonary embolism
- Pneumothorax/Pneumomediastinum
- Mediastinitis
- Gastroesophageal reflux
- Costochondritis
- Cardiomyopathy
- Myocarditis

## TREATMENT

### PRE HOSPITAL

Assess and stabilize airway, breathing, and circulation.

### MEDICATION

#### First Line

- Ibuprofen 10 mg/kg PO/IV q6h PRN
- Naproxen 5 mg/kg PO q8–12h PRN
- Aspirin:
  - Do not use for anyone with influenza-like symptoms due to risk of Reye syndrome.
  - In pediatric post-myocardial ischemia pericarditis, aspirin alone is recommended. NSAIDs and glucocorticoids may worsen outcome.
- Vancomycin 60 mg/kg/24 hr divided q6h, max single dose 1 g
- Gentamicin 5 mg/kg/24 hr; may be given as a single daily dose or divided t.i.d.:
  - Single daily dosing is for the purpose of decreasing ototoxicity and other adverse effects.

#### Second Line

- Prednisone dosing for pericarditis ranges from 0.25–1.5 mg/kg/day for 2–4 wk:
  - Glucocorticoids should be used in consultation with a pediatric cardiology or rheumatology subspecialist.
  - They are reserved for pericarditis refractory to NSAID treatment.
  - Autoimmune processes and uremic pericarditis have the best response to corticosteroids.
  - Tapering should only proceed if symptoms have resolved and CRP is normal.
- Colchicine has shown promise in adult studies. There is little data on its use in children with recurrent or refractory pericarditis.

### SURGERY/OTHER PROCEDURES

- In cases of tamponade with instability (hypotension, respiratory compromise), pericardiocentesis is a lifesaving procedure.
- Pericardiocentesis is indicated for diagnosis of purulent, tuberculous, or neoplastic pericarditis.
- Persistent symptoms from an effusion refractory to medical therapy may warrant pericardiocentesis.

### DISPOSITION

#### Admission Criteria

- Suspected bacterial etiology, posttraumatic pericarditis, pain refractory to oral NSAIDs, pericarditis of undifferentiated etiology, rapidly progressive course (suspected oncologic, systemic inflammatory illness, TB)
- Critical care admission criteria:
  - Cardiac tamponade, hemodynamic instability, dysrhythmia, MI, post-pericardiocentesis

### Discharge Criteria

- Most patients with newly diagnosed pericarditis require hospitalization. Consider discharge to home with cardiology follow-up for patients meeting all of these criteria:
  - Stable BP
  - Stable respiratory status
  - Absence of a large effusion
  - Normal cardiac troponin
  - Adequate pain control

### Issues for Referral

- Consider cardiology consultation for all cases of pericarditis, especially for patients with congenital heart disease, prior cardiac surgery, or tamponade.
- Purulent pericarditis or tuberculous pericarditis may warrant infectious disease consultation.
- Rheumatology consultation is recommended when autoimmune processes are likely.

## FOLLOW-UP

### FOLLOW-UP RECOMMENDATIONS

- Discharge instructions and medications:
  - NSAIDs for comfort with slow tapering after pain resolves
- Activity:
  - Patients should remain on bed rest until pain resolves. If they experience pain with return to activity, they should stop the activity and seek care.

### Patient Monitoring

Initially, patients should be on telemetry. Once myopericarditis, ischemia, and tamponade are excluded, 3-lead monitors are sufficient.

### PROGNOSIS

Viral and idiopathic pericarditis usually have a brief, self-limited course:

- A worse prognosis is associated with fever, subacute onset, immunosuppression, traumatic etiology, anticoagulant therapy, large effusion, tamponade, or myopericarditis.

### COMPLICATIONS

- Recurrence
- Cardiac tamponade
- Constrictive pericarditis
- MI
- Cardiac failure
- Shock

### See Also (Topic, Algorithm, Electronic Media Element)

Pericardial Effusion/Tamponade

### ICD9

- 420.90 Acute pericarditis, unspecified
- 420.99 Other acute pericarditis
- 423.2 Constrictive pericarditis

## PEARLS AND PITFALLS

- Patients often have subtle signs and symptoms; a high index of suspicion is necessary for proper diagnosis.
- Lab tests routinely performed in the emergency department may not reveal the diagnosis.
- With pericarditis, the friction rub waxes and wanes; a friction rub is heard best at end-expiration with the patient leaning forward. It is a scratchy sound loudest at the left sternal border, heard throughout the cardiac cycle.
- Glucocorticoids given early in the course of illness have been associated with increased recurrence rate, possibly because of an increased inflammatory response in viral pericarditis.

# PERICHONDritis, EAR

Jeffrey A. Seiden

## BASICS

### DESCRIPTION

Perichondritis of the auricle is an infection of the fascial layer surrounding the auricular cartilage, though the term is often used to describe infection of the cartilage itself.

### EPIDEMIOLOGY

- The incidence of perichondritis is unknown, though many centers have reported a dramatic increase in cases, likely related to the increasing popularity of “high” ear piercings.
- Epidemic outbreaks have been traced to single ear piercing locations with nonsterile equipment.
- Acupuncture of the ears may also result in perichondritis.

### RISK FACTORS

- High ear piercings: Infection typically occurs within 3–4 wk of the piercing.
- Contact sports resulting in blunt trauma to the ear (eg, wrestling, boxing)
- Diabetes mellitus or other immunodeficiency syndrome
- Mastoid surgery
- Burns involving the ear

### PATHOPHYSIOLOGY

- Auricular cartilage receives its nourishment via diffusion from the surrounding perichondrium.
- Blunt trauma can result in the accumulation of blood or fluid between the cartilage and its surrounding perichondrium and skin, thus disrupting its supply of nutrients. This can lead to cartilage necrosis and severe infection.
- Piercings or other penetrating trauma cannot only cause extensive cartilaginous damage, but it can also provide a point of entry for pathogenic bacteria.
- In immunocompromised patients (eg, diabetic patients), malignant otitis externa can extend to perichondritis with or without underlying osteomyelitis of the temporal bone.
- As the infection progresses, an abscess can form, thus disrupting the flow of nutrients to the underlying cartilage. This can result in necrosis and structural deformity.

### ETIOLOGY

- *Pseudomonas aeruginosa* is the most common causative organism identified in cases of perichondritis (95% of cases).
- *Escherichia coli* accompanies *Pseudomonas* in up to 1/2 of cases.
- *Staphylococcus aureus*, along with other skin flora, may also be causal.

## COMMONLY ASSOCIATED CONDITIONS

- Auricular hematoma (blunt trauma)
- High ear piercings
- Acupuncture of ears
- Ear burns
- Malignant otitis externa

## DIAGNOSIS

### HISTORY

- Most patients will report a recent history of ear trauma (blunt or penetrating), including high ear piercings.
- Patients present with a history of pain and redness of the pinna.
- Fever may be present.

### PHYSICAL EXAM

- Patients with the early stages of perichondritis may appear to have a superficial cellulitis of the pinna, with mild pain, local erythema, and warmth.
- As the infection progresses, there will be diffuse swelling, erythema, and warmth and tenderness of the auricle, though it may spare the lobule because of its lack of underlying cartilage.
- The auricle will be markedly painful with exquisite tenderness accompanying any deflection of the cartilage.
- If an abscess has developed, there will be an area of fluctuance noted as well.
- Typically, there is no evidence of otitis externa or otitis media.

## DIAGNOSTIC TESTS & INTERPRETATION

### Lab

#### Initial Lab Tests

- The diagnosis of perichondritis is based on clinical findings.
- Diagnosis may be corroborated by lab testing, which may reveal elevated inflammatory markers such as leukocytosis, C-reactive protein, or ESR.
- In patients with signs of systemic illness, blood culture may be warranted as well.
- In the presence of purulent drainage, culture of the fluid may assist in the identification of the causative organism.

### Imaging

- Imaging studies will not assist in establishing the diagnosis.
- If mastoid involvement is suspected, CT of that area may be useful.

## DIFFERENTIAL DIAGNOSIS

- Cellulitis: Usually without pain on deflection of the auricle
- Mastoiditis
- Otitis media
- Otitis externa
- Herpes zoster oticus
- Allergic reaction/edema
- Auricular hematoma

## TREATMENT

### MEDICATION

#### First Line

- Analgesic and antipyretic therapy; NSAIDs and/or opioids as needed
- Acetaminophen 15 mg/kg/dose PO/PR q4h PRN
- NSAIDs:
  - Consider NSAID medication in anticipation of prolonged pain and inflammation:
    - Ibuprofen 10 mg/kg/dose PO/IV q6h PRN
    - Ketorolac 0.5 mg/kg IV/IM q6h PRN
    - Naproxen 5 mg/kg PO q8h PRN
  - Some clinicians prefer to avoid due to theoretical concern over influence on coagulation and callus formation.
- Opioids:
  - Morphine 0.1 mg/kg IV/IM/SC q2h PRN:
    - Initial morphine dose of 0.1 mg/kg IV/SC may be repeated q15–20min until pain is controlled, then q2h PRN.
  - Fentanyl 1–2  $\mu$ g/kg IV q2h PRN:
    - Initial dose of 1  $\mu$ g/kg IV may be repeated q15–20min until pain is controlled, then q2h PRN.
  - Codeine or codeine/acetaminophen dosed as 0.5–1 mg/kg of codeine component PO q4h PRN
  - Hydrocodone or hydrocodone/acetaminophen dosed as 0.1 mg/kg of hydrocodone component PO q4–6h PRN

- Antibiotic therapy:
  - Early treatment with antibiotics is imperative.
  - Parenteral antibiotics are preferred.
  - Ciprofloxacin 10 mg/kg/dose IV b.i.d.
  - Fluoroquinolones are often the first-line choice for activity against both *P. aeruginosa* and staphylococcal species.
  - In older adolescents and young adults, oral ciprofloxacin may be sufficient, allowing for successful outpatient therapy.
  - Alternate regimen of ampicillin and gentamicin
    - Ampicillin 50 mg/kg/dose IV q.i.d.
    - Gentamicin 5 mg/kg/dose IV as single daily dose or 2.5 mg/kg/dose IV t.i.d.
  - Because of concerns regarding the use of fluoroquinolones in young children, empiric therapy with ampicillin and gentamicin in combination is an alternate regimen.

#### SURGERY/OTHER PROCEDURES

If a subperichondrial abscess is suspected, surgical incision and drainage (with or without debridement) is warranted in addition to parenteral antibiotic therapy.

#### DISPOSITION

##### Admission Criteria

- Most should be admitted for parenteral antibiotic therapy, especially younger patients or those with more severe disease.
- All patients with suspected abscess formation should be admitted.

##### Discharge Criteria

In some cases of mild infection in older adolescents, outpatient therapy may be considered, provided that very close monitoring is possible.

##### Issues for Referral

All patients with suspected perichondritis should be evaluated by an otorhinolaryngologist to assist in determining the need for surgical management.

## FOLLOW-UP

### FOLLOW-UP RECOMMENDATIONS

Discharge instructions and medications:

- Patients discharged from the emergency department with a diagnosis of perichondritis should be given oral ciprofloxacin and should have a follow-up appointment within 24 hr to monitor their response to therapy.

### PROGNOSIS

- The prognosis for patients with perichondritis depends on the severity of disease.
- Those with early perichondritis without abscess formation will generally have complete resolution with antibiotic therapy.
- More progressive infections can result in the need for multiple surgical procedures and loss of cartilage.

### COMPLICATIONS

- Loss of auricular cartilage with permanent deformity, known as cauliflower ear
- Cellulitis
- Systemic complications such as septic shock are extremely rare but have been reported.

### ADDITIONAL READING

### See Also (Topic, Algorithm, Electronic Media Element)

- Cellulitis
- Mastoiditis

#### ICD9

380.00 Perichondritis of pinna, unspecified

### PEARLS AND PITFALLS

- Diagnosis and initiation of treatment without delay is necessary to prevent permanent cosmetic damage resulting from loss of cartilage.
- Auricular hematomas resulting from blunt trauma must be evacuated, and a pressure dressing must be applied to prevent reaccumulation and resultant bacterial infection.
- Abscesses must be drained to prevent cartilage loss.
- Most children with perichondritis should be hospitalized and treated with parenteral antibiotics active against *P. aeruginosa*, *E. coli*, and *S. aureus*.

# PERIORBITAL CELLULITIS

Howard Topol  
Robert A. Belfer

## BASICS

### DESCRIPTION

- Periorbital cellulitis (POC) is inflammation and infection of the eyelid and skin around the eye.
- Periorbital tissue is located anterior to orbital septum ("preseptal"):
  - Layer of fibrous tissue that arises from the periosteum of the skull and continues into the eyelids
  - This tissue acts as barrier against spread of infection from preseptal tissues into the orbit.
- POC, therefore, does not progress to orbital cellulitis:
  - They are 2 clinically different entities.
- Distinguishing between periorbital and orbital cellulitis is essential in order to make appropriate decisions regarding imaging and antibiotic therapy.

### EPIDEMIOLOGY

#### Incidence

- Seen predominately in the pediatric population:
  - Most commonly in patients <5 yr of age
- More common than orbital cellulitis (1)

### RISK FACTORS

- Any condition predisposing patient to pneumococcal bacteremia (ie, asplenia or younger age (3–36 mo). Hematogenous spread of infection is one of the main mechanisms of disease.
- An abrasion or other disruption of the skin surrounding the eye, predisposing to locally invasive infection, is another risk factor.

### GENERAL PREVENTION

The advent of vaccines for *Haemophilus influenzae* (Hib) and *Streptococcus pneumoniae* has drastically reduced the incidence of POC secondary to bacteremia.

### PATHOPHYSIOLOGY

- Localized bacterial infection of the conjunctiva, eyelids, or adjacent structures:
  - Skin trauma
  - Insect or animal bites
  - Foreign bodies
- Hematogenous dissemination of nasopharyngeal pathogens to the periorbital tissue:
  - Especially in young children (infants <18 mo of age)
  - Usually preceded by viral upper respiratory infection for several days
- Sinusitis usually predisposes patients to orbital cellulitis, not POC.

### ETIOLOGY

- The etiology of POC caused by local trauma is similar to cellulitis of any cutaneous area:
  - Most commonly, *Streptococcus pyogenes* (group A strep), *Staphylococcus aureus*, and *S. pneumoniae*
  - In recent years, a greater proportion of cases have been associated with MRSA.
- *H. influenzae* type B had been the most common organism causing bacteremic POC prior to the introduction of the Hib vaccine.
- *S. pneumoniae* is currently the most likely pathogen in a child who has received the Hib vaccine series (2):
  - Incidence of pneumococcal bacteremia and POC is decreasing due to widespread use of the pneumococcal vaccine.
- Significantly less common organisms in case reports include *Acinetobacter* species, *Nocardia brasiliensis*, *Bacillus anthracis*, *Pseudomonas aeruginosa*, *Neisseria gonorrhoeae*, *Proteus* species, and *Pasteurella multocida*.

### COMMONLY ASSOCIATED CONDITIONS

- Skin trauma
- Insect bites

## DIAGNOSIS

### HISTORY

- Parents usually report acute onset of redness and swelling of periorbital area.
- Usually unilateral
- May include history of break in skin or insect bite
- Signs of systemic illness such as fever are absent with localized disease but are more likely in cellulitis resulting from bacteremia.

### PHYSICAL EXAM

- Local cellulitic reaction that may include erythema, induration, tenderness, swelling, and/or warmth of periorbital tissues:
  - Inflammation due to allergy, such as from an insect bite, may look very similar.
  - Presence of pruritus suggests allergy; presence of pain suggests cellulitis.
- Children with simple conjunctivitis and periorbital swelling typically do not have induration or tenderness of the preseptal region.
- Sinusitis with inflammatory edema may also be associated with a soft, boggy, nontender periorbital swelling.

- Chemosis (conjunctival swelling) is more common in orbital cellulitis but can also occur in POC.
- POC is characterized by the absence of proptosis, ophthalmoplegia, and decreased visual acuity:
  - These are indicative of orbital cellulitis.
- Visual acuity should be assessed in all children with POC.
- In severe POC, if the globe cannot be examined due to massive eyelid swelling, it may be difficult to rule out orbital cellulitis by the absence of above features:
  - Similarly, it can be challenging to distinguish POC and orbital cellulitis in young children who cannot report visual changes.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

- CBC and C-reactive protein demonstrate inflammatory changes.
- Blood culture performed before administration of antibiotics if fever or signs of systemic illness
- Conjunctival or nasopharyngeal cultures are not standard practice because of the high rate of contamination with normal flora, but they may help identify resistant organisms in select instances.

#### Imaging

- CT scans are not usually needed to make the diagnosis of POC. However, if orbital disease is suspected, orbital CT scan with contrast may define the extent of infection within the orbits and adjacent sinuses.
- Indications for orbital CT scan (3):
  - Inability to accurately assess vision (usually patients <1 yr of age)
  - Gross proptosis, ophthalmoplegia, deteriorating visual acuity, or bilateral periorbital edema
  - No improvement despite 24–36 hr of IV antibiotics
- Note: Imaging criteria have not been studied by controlled trials and are therefore based on clinical experience and case series.

**DIFFERENTIAL DIAGNOSIS**

- POC must be differentiated from orbital cellulitis:
  - Orbital cellulitis can be vision or life threatening and requires inpatient admission and possibly surgical drainage.
- Other infectious causes:
  - Styte
  - Chalazion
  - Dacryocystitis
  - Conjunctivitis
  - Sinusitis with periorbital edema
  - Dental abscess
- Noninfectious causes:
  - Blunt trauma
  - Tumor
  - Local edema (from hypoproteinemia and CHF)
  - Allergy
  - Local edema and allergy are usually bilateral.

**TREATMENT****INITIAL STABILIZATION/THERAPY**

- Assess and stabilize airway, breathing, and circulation.
- The mainstay of therapy is to provide antibiotics to treat the infection.
  - If cultures are to be obtained, antibiotics should be given after cultures are obtained.

**MEDICATION****First Line**

- Initial antibiotic choice should be aimed at the most probable causative organisms.
- For the afebrile child with evidence of local infection only, antibiotics should cover *S. pyogenes* and *S. aureus*.
- If there are signs of systemic illness and bacteremic etiology is a concern, treatment for *S. pneumoniae* should be initiated, even if the patient is fully immunized.
- Outpatient regimens:
  - Amoxicillin/Clavulanic acid 70–90 mg/kg/day PO divided b.i.d. × 7–10 days
  - Clindamycin 30 mg/kg/day PO divided t.i.d. × 7–10 days in areas with high rates of community-acquired MRSA
- Parenteral antibiotics:
  - Ampicillin/Sulbactam acid 100 mg ampicillin/kg/day divided q6h:
    - Adult dose: 1–2 g ampicillin IV q6–8h
  - Clindamycin 25–40 mg/kg IV divided q6–8h
  - Ceftriaxone 50–100 mg/kg IV either per day or divided b.i.d.:
    - Adult dose: 1–2 g IV per day or b.i.d., max single dose 4 g/24 hr

**Second Line**

Cefdinir 14 mg/kg/day PO divided b.i.d. × 7–10 days

**DISPOSITION****Admission Criteria**

- Suspicion for bacteremic disease
- <1 yr of age
- Toxic appearance
- Inability to tolerate oral/enteral feedings or antibiotics
- Failure of outpatient management
- Concern for orbital involvement
- Patients who do not meet these criteria can safely be managed as outpatients on oral antibiotics.

**Discharge Criteria**

- Afebrile for 24 hr with clinical improvement
- Ability to tolerate oral/enteral feedings or antibiotics
- Reliable outpatient follow-up

**Issues for Referral**

Ophthalmology consultation is indicated in all cases of suspected or proven orbital cellulitis. It is unnecessary to obtain any consults in uncomplicated POC.

**FOLLOW-UP****FOLLOW-UP RECOMMENDATIONS**

Discharge instructions and medications:

- Patients who have been discharged from the emergency department should be seen in 24–48 hr by a physician to measure improvement in clinical status. If there is no improvement or symptoms worsen, the patient should then be admitted for IV antibiotics.
- Patients should be instructed to return if they develop photophobia, decreased vision, pain with eye movement, or diplopia.

**PROGNOSIS**

The prognosis for POC is quite good. Since the advent of Hib and pneumococcal vaccines, the rate of bacteremic POC has significantly declined.

**COMPLICATIONS**

- Subperiosteal abscess and orbital collection only if orbital cellulitis is present
- POC with bacteremia can lead to sepsis if untreated.

**See Also (Topic, Algorithm, Electronic Media Element)**

- Chalazion
- Eye, Visual Disturbance
- Hordeolum
- Orbital Cellulitis
- Sinusitis

**CODES****ICD9**

- 376.00 Acute inflammation of orbit, unspecified
- 376.01 Orbital cellulitis

**PEARLS AND PITFALLS**

- POC and orbital cellulitis are 2 separate entities caused by different mechanisms. However, thorough physical exam and/or imaging may be required to distinguish between them.
- The lack of induration or preseptal tenderness helps to distinguish POC from the periorbital edema that may be associated with conjunctivitis or sinusitis.
- Patients with POC present with unilateral erythema, warmth, and swelling of periorbital tissues. Absence of ophthalmoplegia, proptosis, and decreased visual acuity must be documented.
- The most common causative pathogens are *S. aureus* and *S. pyogenes*.

# PERITONITIS

Toni K. Gross

## BASICS

### DESCRIPTION

- Peritonitis is inflammation of the peritoneum, which is the lining of the inside of the abdomen and all of the internal organs.
- Usually due to bacterial infection
- Classified based on pathophysiology:
  - Primary: Bacteria seed the peritoneum via hematogenous or lymphatic spread, translocation across bowel walls, or from indwelling catheters; referred to as spontaneous bacterial peritonitis.
  - Secondary: Results from inflammation, perforation of a hollow viscus, or extension of an abscess. The most common cause in children is appendicitis; other examples include pancreatitis, biliary tract disease, and pelvic inflammatory disease (PID).
  - Tertiary: Diffuse without a defined source or recurrent infection after an intervention

### EPIDEMIOLOGY

#### Incidence

- Spontaneous bacterial peritonitis in patients with nephrotic syndrome and ascites:
  - ~15% incidence (1,2)
- Peritoneal dialysis-related peritonitis:
  - 1 episode per 6–13 mo of treatment (3,4)
- Lifetime risk of appendicitis is 7–9% (3):
  - 20–30% perforation rate for age 8–18 yr
  - 60–80% perforation rate for age 0–5 yr

#### Prevalence

29% prevalence in patients admitted for portal HTN and ascites (5)

### RISK FACTORS

- Ascites
- Peritoneal dialysis
- Contrast or air reduction of intussusception
- Bowel perforation

### GENERAL PREVENTION

- Nephrotic syndrome patients should receive pneumococcal vaccination.
- Prophylactic use of penicillin in patients with nephrotic syndrome is sometimes recommended.
- Peritoneal dialysis patients should have a double-cuffed catheter with a downward-directed tunnel placed by an experienced surgeon (3).

### PATHOPHYSIOLOGY

Spontaneous, or primary, peritonitis:

- Translocation of bacteria into blood or lymphatic flow before seeding the peritoneum
- Ascitic fluid is a favorable environment for bacterial growth.

### ETIOLOGY

- Spontaneous bacterial peritonitis in nephrotic syndrome:
  - *Streptococcus pneumoniae*
  - Group A streptococcus
  - Gram-negative enteric organisms
- Secondary peritonitis:
  - Gram negatives and anaerobes
  - If multiple organisms are recovered, perforation should be suspected.

- Peritoneal dialysis-related peritonitis:
  - *Staphylococcus aureus*
  - *Staphylococcus epidermidis*
  - If nephrectomy has been performed, gram-negative enteric rods (3)
- Tuberculous peritonitis is very rare.
- Other causes include irritants or chemicals, such as blood, acid from the stomach, bile from the gall bladder, enzymes from the pancreas, or substances introduced during surgical procedures.
- Patients with inflammatory conditions such as systemic lupus erythematosus (SLE) can present with peritonitis due to inflammation of serosal surfaces or to primary or secondary infection.

### COMMONLY ASSOCIATED CONDITIONS

- Appendicitis
- Conditions causing ascites:
  - Cirrhosis, nephrotic syndrome, CHF
- Pancreatitis
- Cholecystitis, cholangitis
- PID
- Typhlitis (neutropenic enterocolitis):
  - Necrotizing inflammation of the cecum and ascending colon with 20% mortality (3)
- SLE
- Abdominal trauma

## DIAGNOSIS

### HISTORY

- Rapid onset of abdominal pain:
  - Pain worse with movement
- Fever
- Nausea and vomiting
- In patients who receive peritoneal dialysis, the 1st sign may be cloudy effluent (3).

### PHYSICAL EXAM

- Often will find position of maximal comfort is with legs bent at knees and hips to alleviate pressure on tender peritoneum
- Exam reveals obvious peritoneal findings
- Abdomen may be firm or rigid to palpation; severe abdominal tenderness:
  - Gentle percussion may reveal exquisite tenderness.
  - Rebound tenderness
  - Pain with tapping the heel or jumping
- Bowel sounds may be decreased or absent.
- Accumulation of ascitic fluid may be present.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

- CBC: WBC count and total neutrophil count are often elevated (6).
- C-reactive protein may be elevated ( $>10$  mg/L is sensitive,  $\geq 25$  mg/L is specific) (6).
- ESR may be elevated ( $>20$  is specific but not sensitive) (6).
- Urinalysis:
  - May demonstrate pyuria due to inflammation of ureter caused by adjacent infection
  - Pyuria associated with nitrites may indicate pyelonephritis as the cause of abdominal pain.

- Electrolytes:
  - Vomiting may cause electrolyte abnormalities.
- Blood gas and/or lactate level to detect acidemia, hypoperfusion, ischemia, necrosis

### Imaging

- Abdominal x-ray:
  - 2 views to evaluate for free intraperitoneal air or air-fluid levels
  - Positive findings include intestinal dilation, edema of the small intestine, peritoneal fluid, and absence of psoas shadow.
- US:
  - Use to evaluate for the presence of a mass, noncompressible appendix, intussusception, or free fluid
  - Especially useful for evaluation of biliary tract and urogenital structures
  - May identify typhlitis in chemotherapy patients
- CT scan:
  - More sensitive and specific for evaluation of the appendix
  - Will demonstrate cecal wall thickening in typhlitis
  - Cirrhotic patients with polymicrobial infection should have CT scan to evaluate possible intra-abdominal infection (3).

### Diagnostic Procedures/Other

- Paracentesis for WBC count, Gram stain, culture, protein, lactate dehydrogenase (LDH), pH, lactate:
  - Exudative ascitic fluid is turbid or cloudy and is secondary to inflammation.
  - Peritoneal fluid findings are common in peritonitis:
    - WBC  $>500$  cells/mm<sup>3</sup>; absolute neutrophil count  $>250$  cells/mm<sup>3</sup> (7)
    - Elevated protein count ( $>3$  g/dL or a ratio of fluid to plasma protein of  $>0.5$ )
    - Ratio of fluid to plasma LDH  $>0.6$
    - pH tends to be acidic at  $<7.31$
    - Elevated lactate level
  - Gram stain sensitivity is 10%: Samples of 10–20 mL per culture bottle are recommended.
- Exploratory operation may be required for definitive diagnosis:
  - Usually not undertaken in the case of clearly diagnosed PID or pancreatitis
- Diagnosis of peritoneal dialysis-related peritonitis requires at least 2 of these 3 criteria, diagnosed by centrifugation of 50–100 mL of effluent (3):
  - Organisms seen on peritoneal fluid Gram stain
  - $>100$  WBC/mm<sup>3</sup> with  $>50\%$  neutrophils
  - Symptoms of peritoneal irritation

### Pathological Findings

Findings will depend on etiology:

- Fluid in the peritoneal cavity may be cloudy, turbid, or purulent.
- Thickening or sclerosis of peritoneal membrane
- Intra-abdominal abscess
- Transmural thickening or rupture of the appendix
- Meckel diverticulum with inflammation or perforation

**DIFFERENTIAL DIAGNOSIS**

- Abdominal migraine
- Appendicitis, with or without perforation
- Constipation
- Crohn disease
- Ectopic pregnancy
- Gastroenteritis
- Inflammatory bowel disease
- Lower lobe pneumonia
- Meckel diverticulitis, with or without perforation
- Mesenteric lymphadenitis
- Necrotizing enterocolitis
- Pancreatitis
- PID
- Pyelonephritis
- Sickle cell crisis
- Typhlitis

**TREATMENT****PRE HOSPITAL**

Assess and stabilize airway, breathing, and circulation.

**INITIAL STABILIZATION/THERAPY**

- Assess and stabilize airway, breathing, and circulation.
- Treatment of hypoperfusion or shock: Rapid infusion of normal saline in 20 mL/kg boluses, to 60 mL/kg
- Electrolyte abnormalities should be corrected.
- Provide dextrose as needed.
- Metabolic acidosis should be corrected with sodium bicarbonate or Ringer lactate solution.
- Provide analgesia.

**MEDICATION****First Line**

- Parenteral antibiotic therapy:
  - Meropenem 60 mg/kg/day divided t.i.d. OR
  - Ampicillin 100–200 mg/kg/day divided q.i.d., gentamicin 7.5 mg/kg/day divided t.i.d., and clindamycin 25–40 mg/kg/day divided t.i.d. (8)
  - Treatment is for 10–14 days.
- For peritoneal dialysis patients, consider intraperitoneal administration of antibiotics (3):
  - Treatment duration is 2 wk.
  - Consider replacement of the peritoneal dialysis catheter.
- Opioids:
  - Opioid analgesia does not mask peritonitis (9).
  - Morphine 0.1 mg/kg IV/IM/SC q2h PRN:
    - Initial morphine dose of 0.1 mg/kg IV/SC may be repeated q15–20min until pain is controlled, then q2h PRN.
  - Codeine or codeine/acetaminophen dosed as 0.5–1 mg/kg of codeine component PO q4h PRN
  - Hydrocodone or hydrocodone/acetaminophen dosed as 0.1 mg/kg of hydrocodone component PO q4–6h PRN

- NSAIDs:
  - Consider NSAID medication in anticipation of prolonged pain and inflammation:
    - Ibuprofen 10 mg/kg/dose PO/IV q6h PRN
    - Ketorolac 0.5 mg/kg IV/IM q6h PRN
    - Naproxen 5 mg/kg PO q8h PRN
- Acetaminophen 15 mg/kg/dose PO/PR q4h PRN

**Second Line**

Inflammatory serous peritonitis (SLE) may be treated with prednisone 1 mg/kg/day PO b.i.d.

**COMPLEMENTARY & ALTERNATIVE THERAPIES****SURGERY/OTHER PROCEDURES**

Surgical consultation should be obtained early:

- Surgical exploration may be necessary
- Percutaneous drainage of abscesses may be performed initially

**DISPOSITION****Admission Criteria**

- In the absence of a surgical diagnosis, positive findings in 2 of 3 modes of evaluation—history, physical exam, or lab evaluation—should prompt admission (8).
- Intractable pain or vomiting
- Critical care admission criteria:
  - Hemodynamic instability, severe electrolyte derangements, or mental status changes

**Discharge Criteria**

Do not discharge a newly diagnosed patient from the emergency department.

**Issues for Referral**

- Surgical consultation is usually warranted.
- Nephrology consultation is recommended for peritoneal dialysis patients.
- Recurrent or resistant peritonitis may benefit from consultation with infectious disease experts.

**FOLLOW-UP****FOLLOW-UP RECOMMENDATIONS**

Discharge instructions and medications:

- Patients should return if pain worsens or persists; pain moves to a location consistent with acute appendicitis; or if vomiting, fever, or decreased urine output develops.

**Patient Monitoring**

Patients should be monitored at home for pain symptoms, appetite, and fever.

**DIET**

- Nephrotic syndrome patients may be on fluid restriction.
- Inflammatory bowel disease patients typically have dietary restrictions.

**PROGNOSIS**

Good prognosis for adequately treated peritonitis

**COMPLICATIONS**

Vary with etiology but can include:

- Persistent intra-abdominal abscesses
- Fistulas or bowel adhesions
- Renal failure
- Loss of peritoneal dialysis catheter
- Decreased effectiveness of peritoneal dialysis

**CODES****ICD9**

- 567.9 Unspecified peritonitis
- 567.23 Spontaneous bacterial peritonitis
- 567.29 Other suppurative peritonitis

**PEARLS AND PITFALLS**

- Pediatric peritonitis almost always reflects intra-abdominal pathology that will require surgical intervention; appendicitis most commonly.
- Perforated appendicitis is more common in children; localization of pain is more difficult, less-developed omentum is less able to wall inflamed appendix, and preverbal children may not communicate abdominal pain.
- Always consider spontaneous bacterial peritonitis caused by *S. pneumoniae* in nephrotic syndrome patients presenting with acute abdominal pain.

# PERTUSSIS

Rakesh D. Mistry

## BASICS

### DESCRIPTION

- Pertussis is a highly contagious respiratory infection caused by *Bordetella pertussis*.
- Characteristically, pertussis is a 3-phase illness lasting several weeks
- “Whooping cough” is the lay term to describe pertussis, owing to the dramatic inspiratory “whoop” that may be associated with coughing spells.

### EPIDEMIOLOGY

- In the U.S., 5,000–7,000 cases per year
- Annual incidence 3.6/100,000 in 2007
- Incidence has steadily increased since 1980s, including increases in adolescents and adults, leading to recent recommendations for booster vaccinations in these populations.
- Endemic in the U.S., with epidemics every 3–5 yr and the most recent in 2005
- Humans are the only known reservoir for *B. pertussis*:
  - In cases of infection, a thorough search for prior pertussis exposures is indicated.

### RISK FACTORS

- Age <12 mo: Significant immunity is not achieved until after the 2nd dose of vaccine. Infants <4 mo are at particularly high risk.
- Lack of primary pertussis vaccination series
- Waning pertussis immunity (may occur in adolescents and adults after 5–10 years)
- Epidemic exposure

### GENERAL PREVENTION

- Pertussis is vaccine preventable:
  - Primary pertussis vaccine series consists of immunization via DTaP (acellular vaccine) at 2,4,6, and 15–18 mo
  - Booster vaccine via Tdap is recommended for adolescents at age 11–12 yr.
- When caring for pertussis, the use of face masks and proper hand hygiene is necessary.
- Postexposure chemoprophylaxis with azithromycin is indicated for high-risk and close contacts of index cases, such as health care providers, schoolmates, and household members.
- Other contacts should be observed for 21 days for development of respiratory tract symptoms prior to initiation of antibiotic therapy.
- Students and staff with active pertussis should be excluded from school until completion of 5 days of effective antimicrobial therapy; this is also applicable to symptomatic health care workers.

### PATHOPHYSIOLOGY

- Transmission of *B. pertussis* occurs via the respiratory route by direct contact with mucosal discharge from respiratory secretions.
- *B. pertussis* has selective tropism for the ciliated epithelium in the human respiratory tract.
- Following infection, the incubation period for pertussis is typically 7–10 days.
- Active pertussis infection occurs in 3 phases:
  - Catarrhal phase (1–2 wk): Rhinorrhea, cough, similar to simple upper respiratory infection (URI)
  - Paroxysmal phase (1–2 wk): Prominent manifestations; paroxysms of harsh cough that may last 30 sec to minutes, followed by posttussive emesis, cyanosis, apnea, or classic inspiratory whoop in toddlers/school age
  - Convalescent phase (2–4 wk): Clinical manifestations of the illness subside, but patients may remain infectious.

### ETIOLOGY

- *B. pertussis*, a gram-negative rod is the principal organism associated with pertussis clinical illness.
- Occasionally, *Bordetella parapertussis* can produce a clinical illness that closely resembles that of *B. pertussis*.

## DIAGNOSIS

### HISTORY

- The initial stage of pertussis is very nonspecific and undiagnosed or misdiagnosed until the paroxysmal stage.
- Typical features of pertussis:
  - URI symptoms or cough and rhinorrhea
  - Severe cough, often paroxysmal (up to several minutes)
  - Postparoxysmal apnea, cyanosis, or posttussive emesis
  - Inspiratory whoop
- Often afebrile during acute illness
- Adolescents and adults often present with an insidious, chronic cough and typically do not manifest classic symptoms.
- Investigation for known or suspected pertussis contact should occur, such as an adult with chronic cough residing in the household.

### PHYSICAL EXAM

- Initial physical exam is often normal, especially in between cough paroxysms.
- Fever is typically low grade or absent.
- During cough paroxysms, infants may develop perioral or central cyanosis.
- Auscultatory exam of the chest is usually unremarkable. Crackles should raise concern for concomitant pneumonia; wheezing should elicit investigation for alternative diagnoses.
- Neurologic exam should focus on mental status, evaluating for encephalopathy.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

- CBC: Absolute lymphocytosis
- Polymerase chain reaction (PCR) is the most sensitive and specific method for detection.
- Direct fluorescent antibody testing may also be used; less sensitive than PCR.
- *B. pertussis* is a highly fastidious organism; culture is 100% specific, but the organism is extremely difficult to isolate in culture.

#### Imaging

CXR is recommended to detect pneumonia or complications such as pneumothorax.

### DIFFERENTIAL DIAGNOSIS

- Clinical illness that resembles pertussis:
  - *B. parapertussis*
  - *Chlamydia pneumoniae*
  - *Mycoplasma pneumoniae*
  - Respiratory syncytial virus
  - Adenovirus
  - *Mycobacterium tuberculosis*
- Other causes of chronic cough:
  - Bronchospasm
  - Allergic
  - Foreign body
  - Sinusitis
  - Cystic fibrosis

## TREATMENT

### INITIAL STABILIZATION/THERAPY

- Assess and stabilize airway, breathing, and circulation.
- Any patients with evidence of respiratory insufficiency or compromise or apnea should have prompt airway stabilization measures initiated.
- Additional supportive measures may include IV access and administration of isotonic fluids.

### MEDICATION

#### First Line

- Antimicrobial treatment to reduce severity of illness and decrease the infectivity:
  - To reduce illness severity, therapy must be instituted during the catarrhal phase.
  - Most patients go undiagnosed until the 2nd stage of illness.
- Since transmission can be prevented at any stage, antibiotics are recommended at any stage.
- Macrolide antibiotics most commonly used:
  - Azithromycin 10 mg/kg PO per day on day 1, then 5 mg/kg days 2–5:
    - Though not previously used for infants <6 mo of age, the safety of azithromycin has led to common use as a first-line agent for pertussis.
    - Azithromycin is as effective and is better tolerated than erythromycin.
  - Erythromycin 50 mg/kg/day PO divided q.i.d. for 14 days:
    - Oral erythromycin use in neonates is associated with the development of pyloric stenosis.
    - Erythromycin estolate preparation is preferred for better GI absorption.
  - Clarithromycin 15 mg/kg/day PO divided b.i.d. for 7 days is an alternative macrolide less commonly prescribed.

#### Second Line

Trimethoprim/Sulfamethoxazole 4/20 mg/kg PO b.i.d. × 14 days:

- Not recommended for those <2 mo of age

### COMPLEMENTARY & ALTERNATIVE THERAPIES

- Corticosteroids
- Albuterol
- Antitussives

### DISPOSITION

#### Admission Criteria

- Patients with severe disease manifestations (apnea, cyanosis, feeding difficulties) require hospitalization and supportive care.
- Infants <6 mo are at increased risk for apnea and respiratory fatigue from frequent cough paroxysms.
- Critical care admission criteria:
  - Patients with evidence of respiratory insufficiency, encephalopathy, severe apnea, or active seizure should be admitted to a monitored setting.

#### Discharge Criteria

- Older infants and children without severe complications of pertussis (apnea, cyanosis)
- Easy recovery from cough paroxysms

#### Issues for Referral

The local health department should be contacted for any case of pertussis.

## FOLLOW-UP

### FOLLOW-UP RECOMMENDATIONS

- Discharge instructions and medications:
  - Compliance with medications is critical.
  - Return to the primary physician or emergency department for worsening of respiratory symptoms.
- Activity:
  - Return to school after 5 days of antibiotic therapy.
  - Return to exercise when tolerated.

### PROGNOSIS

With treatment, the prognosis is excellent:

- Mortality is rare, estimated at 0.3%.
- Most deaths occur as a result of respiratory insufficiency or secondary bacterial infection.
- Risk of death is inversely proportionate to age; most deaths occur in infants.
- The degree of lymphocytosis on presentation may correlate with illness severity.

### COMPLICATIONS

- Pneumonia (22%) is the most common complication, either from primary pertussis or secondary bacterial infection:
  - Bacterial pneumonia is the most common cause of death in pertussis infection.
- Seizures (2%) from hypoxia during cough paroxysm
- Encephalopathy (1%) in infants
- Apnea, especially following a cough paroxysm
- Pneumothorax, pneumomediastinum, and subcutaneous emphysema

### ICD9

033.0 Whooping cough due to bordetella pertussis (B. pertussis)

## PEARLS AND PITFALLS

- Presentation during the catarrhal phase is often nonspecific; therefore, careful history, exam, and investigation for contacts with suspected pertussis is prudent.
- Patients are often afebrile or have a low-grade temperature; high fever is not usually present in pertussis infection and should elicit consideration of alternative diagnoses.
- Infants with frequent cough paroxysms, apnea, or cyanosis are at particularly high risk of severe illness and progression; any suspicion of complicated disease should prompt hospitalization.
- Antibiotics initiated in the paroxysmal phase may not shorten illness duration but may decrease disease transmission.

# PHIMOSIS

Sandra H. Schwab

## BASICS

### DESCRIPTION

- Phimosis is the inability to retract the foreskin over the glans of the penis in an uncircumcised male.
- Phimosis can be classified as physiologic or pathologic:
  - Pathologic phimosis results from adhesions or scar tissue.

### EPIDEMIOLOGY

- Physiologic phimosis occurs in almost all uncircumcised boys from birth to 1 yr of age.
- Pathologic phimosis rarely occurs before age 5 yr.
- By 3 yr of age, <10% of males have phimosis
- By early adolescence, <2% have phimosis (1).

### RISK FACTORS

- Forceful retraction of the foreskin
- Poor hygiene
- Infection
- Improper circumcision

### GENERAL PREVENTION

External cleansing, without retraction of the foreskin, during the 1st yr of life reduces traumatic scarring.

### PATHOPHYSIOLOGY

Incomplete separation of the adjacent epithelial layers between the foreskin and glans penis:

- Natural lysis occurs over the 1st years of life.

### ETIOLOGY

Infection or inflammation causes adhesions and scarring, which prevent easy retraction of the prepuce.

## COMMONLY ASSOCIATED CONDITIONS

- Balanitis, posthitis, and balanoposthitis
- Phimosis is an important risk factor for recurrent urinary tract infections (2).

## DIAGNOSIS

### HISTORY

- In the case of pathologic phimosis, parents or patients report inability to retract the foreskin that was once retractile after traumatic retraction or inflammation.
- Pathologic phimosis can present with urogenital symptoms including:
  - Penile pain and dysuria
  - Irregular urinary stream
  - Preputial ballooning during voiding

### PHYSICAL EXAM

- Phimosis is commonly graded on a scale of retractibility from 0–5 suggested by Kikiros et al. (3):
  - 0: Full retraction
  - 1: Full retraction with tight ring behind the glans
  - 2: Partial exposure of the glans
  - 3: Partial retraction, meatus just visible
  - 4: Slight retraction, meatus not visible
  - 5: No retraction
- The practitioner should note any inflammatory or traumatic changes, including:
  - Erythema
  - Edema
  - Tenderness
  - Bleeding
  - Scar tissue

- Careful replacement of the foreskin to its original position is imperative or paraphimosis may result:
  - Inability to replace the foreskin to the usual position after retraction, or paraphimosis, is a urologic emergency.
  - The retracted foreskin may act as a band, restricting blood flow from the glans.
  - Immediate reduction is necessary in order to avoid ischemia of the glans and foreskin.
  - In contrast to paraphimosis, males with phimosis do not typically have a constricting band or significant distal swelling.

## DIAGNOSTIC TESTS & INTERPRETATION

### Lab

Phimosis is a clinical diagnosis; therefore, no lab tests are necessary.

### Initial Lab Tests

- Consider urinalysis and urine culture in a patient with dysuria and phimosis.
- Consider serum electrolyte analysis if obstructive uropathy is considered.

## DIFFERENTIAL DIAGNOSIS

- Physiologic phimosis
- Urinary tract infection
- Postcircumcision phimotic ring
- Lichen sclerosus
- Paraphimosis
- Balanitis
- Balanoposthitis

## TREATMENT

### MEDICATION

Topical corticosteroids of varying potency are effective in correcting phimosis in children of all ages (4,5):

- Low-potency corticosteroids:
  - Hydrocortisone 1–2.5% ointment topically b.i.d. should be used initially
  - Potency may be increased as necessary to achieve results.
  - 3–6 wk of therapy is generally sufficient.

### COMPLEMENTARY & ALTERNATIVE THERAPIES

Gentle manual retraction of the foreskin in addition to topical steroid yields the best results.

### SURGERY/OTHER PROCEDURES

- Elective circumcision is commonly performed to correct phimosis.
- Preputial plasty or a dorsal slit procedure can be performed to relieve symptoms of phimosis.

### DISPOSITION

#### Discharge Criteria

Patients with phimosis do not typically require hospitalization.

#### Issues for Referral

Patients with symptomatic or pathologic phimosis should be referred to a urologist for evaluation or treatment.

## FOLLOW-UP

### FOLLOW-UP RECOMMENDATIONS

#### Patient Monitoring

Patients treated with topical corticosteroids should be monitored for local or systemic side effects including thinning of the skin or infection.

### PROGNOSIS

- Most studies report >70% success with conservative medical management (3–5).
- Circumcision is almost always successful in correcting cases of pathologic or symptomatic phimosis.

### COMPLICATIONS

- Recurrent urinary tract infections
- Genital pain
- Irregular urinary stream or voiding

### CODES

#### ICD9

605 Redundant prepuce and phimosis

### PEARLS AND PITFALLS

- In contrast to paraphimosis, phimosis is not a urologic emergency.
- Physiologic phimosis without complications is common and does not require treatment.
- Topical corticosteroids and gentle manual retraction are successful in treating the majority of patients with symptomatic or pathologic phimosis.

# PILONIDAL CYST

Maria Carmen G. Diaz

## BASICS

### DESCRIPTION

- The term *pilonidal* is derived from the Latin words “pilus” (hair) and “nidus” (nest).
- Pilonidal disease is a cutaneous disorder resulting from a reaction of hair follicles with the surrounding skin and subcutaneous tissues.
- Pilonidal disease is a spectrum of clinical presentations ranging from cysts and sinuses to abscesses. Presentations may be acute, chronic, or recurrent.
- Usually located in the sacrococcygeal region but may also occur near the umbilicus or on the chest wall.
- There have also been several case reports of pilonidal disease involving the hands of hairdressers, barbers, sheep shearers, and dog groomers (1).

### EPIDEMIOLOGY

#### Incidence

- True incidence is unknown; 1 report has shown an incidence of 26 per 100,000 people (2). There have also been reports of an estimated incidence of 0.7% in adolescents and young adults (3).
- Peak incidence in those 15–24 yr of age
- Incidence decreases after age 25 years.
- Rare after age 45 yr (1)

#### Prevalence

- More common in males than females, with ratios ranging between 2:1 and 4:1 (2,3)
- Average age at presentation is 21 yr for men and 19 yr for women (2).

### RISK FACTORS

- Most patients are hirsute (2).
- More common in patients with dark, stiff, or auburn hair (1)
- 38% of patients have a family history of pilonidal disease.
- Repeated local trauma and occupations requiring prolonged sitting have a higher incidence:
  - During World War II, this was also known as “jeep disease,” as it was seen in those who had spent long periods of time in vehicles.
- Repetitive exercising, such as doing sit-ups, is a predisposing factor.
- Obese patients have a higher incidence of recurrence (2).
- Obesity and smoking are risk factors for postoperative wound complications (4).

### PATHOPHYSIOLOGY

There are several theories:

- Hair follicles in the natal cleft may become distended with keratin; this then becomes infected and forms an abscess (5,6).
- Loose hair, leading with the root, collects at the natal cleft. Friction forces the hair to insert at the depth of the cleft. As more hairs are involved, a foreign body reaction occurs, leading to infection (1,3,5,7).
- Sinuses begin from a small midline opening lined by stratified squamous epithelium.
- Neutrophils, lymphocytes, and giant cells may infiltrate the sinus.
- Cysts are lined by chronic granulation tissue and may also contain hair shafts and epithelial debris (5).

### ETIOLOGY

- The etiology of pilonidal disease has been debated since the 19th century (5). It was initially felt to be an embryologic skin defect.
- Current prevailing theory is that it is an acquired disease, as it presents in teenagers/young adults and not at birth, it is more common in hirsute patients and in males, and certain occupations predispose to the disease.

### COMMONLY ASSOCIATED CONDITIONS

- Hirsutism
- Obesity

## DIAGNOSIS

### HISTORY

- Cyst/Abscess presents with pain in the sacral area:
  - Patients may complain of progressive discomfort or pain after physical activity or after prolonged periods of sitting when pilonidal disease is located in the sacrococcygeal region.
  - Patients may present with an abscess and complain of pain, swelling, and erythema. This is usually located 4–5 cm cephalad from the anus.
  - Patients may also complain of spontaneous purulent or serosanguineous drainage of the area. This may be acute or chronic and may be intermittent.
  - Patients do not typically have fever.
- Patients with pilonidal pit, sinus, or cyst may be asymptomatic.

### PHYSICAL EXAM

- Some patients have an asymptomatic midline pit in the presacral area.
- Acute abscess: Tender, fluctuant subcutaneous mass with surrounding erythema
- When located in the sacrococcygeal region, this is seen at the natal cleft. There may also be an opening at the midline natal cleft. Loose hair may be seen at the site.
- In hairdressers, barbers, sheep shearers, and dog groomers, this has been seen in the interdigital spaces (5).
- Chronic pilonidal sinus: The primary opening is usually at midline natal cleft; may have a secondary opening off of the midline.
- A complicated sinus will have multiple skin pits with purulent or serosanguineous drainage (3).

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

Cultures of the drainage may be helpful in tailoring antibiotic regimens.

##### Imaging

US may be helpful in identifying an abscess and, if one is present, defining its extent.

##### Diagnostic Procedures/Other

Most pilonidal abscesses will require incision and drainage. Bacterial cultures of the exudate will reveal the causative organisms(s).

##### Pathological Findings

*Staphylococcus aureus* is the most common bacteria cultured. *Bacteroides* species are the most common anaerobes (2).

### DIFFERENTIAL DIAGNOSIS

- Furuncle or carbuncle
- Anal fistula
- Hidradenitis suppurativa
- Perirectal abscess
- Pyoderma gangrenosum
- Infectious granuloma such as actinomycosis, syphilis, or TB
- Inclusion dermoid or teratoma
- Congenital dermal sinus, sacral dimple

## TREATMENT

### INITIAL STABILIZATION/THERAPY

- Initial stabilization should focus on pain management.
- The route of administration and potency of medication depends on the extent of the disease.

### MEDICATION

- EMLA or LMX cream applied to the area is effective to assist in providing analgesia. Additionally, application of EMLA or LMX results in spontaneous drainage in a large number of pilonidal abscesses:
  - The mechanism by which this results is unknown.
- If MRSA is prevalent in a community, then an antibiotic such as clindamycin should be chosen to treat pilonidal infections.
  - Clindamycin: 15–30 mg/kg/day IV/PO divided t.i.d.

### COMPLEMENTARY & ALTERNATIVE THERAPIES

Mildly symptomatic cysts require adequate hygiene measures: Careful washing, drying, and depilatory mechanisms.

### SURGERY/OTHER PROCEDURES

- Pilonidal abscess: Patients with an abscess may undergo incision and drainage in the emergency department.
- Consider procedural sedation depending on extent of abscess, age of patient, and patient/parental anxiety.
- Prepare the area with Povidine, and provide local anesthesia.
- Using an aseptic technique, make a longitudinal incision lateral to the midline.
- Evacuate pus and hair. Blunt dissection may be required to do this.
- Pack the wound with gauze, and apply a dressing.

### DISPOSITION

#### Admission Criteria

- The patient is highly febrile, ill appearing, or shows signs of systemic spread of infection such as with cellulitis.
- Underlying medical condition such as diabetes mellitus that may hinder wound healing
- Unable to arrange close outpatient follow-up or if the patient/family is unreliable
- The diagnosis is in question.

### Discharge Criteria

Most patients may be discharged home after emergent incision and drainage.

### Issues for Referral

- Pilonidal sinus and chronic or recurrent pilonidal disease require referral to a surgeon.
- The surgeon's primary goal is to eradicate the disease and minimize recurrence with low morbidity and disability. This is best done in the absence of acute infection.
- Common techniques used include fistulotomy and curettage, unroofing and marsupialization, wide local excision with or without primary closure, flap closure, and Z-plasty (1,3,8).

## FOLLOW-UP

### FOLLOW-UP RECOMMENDATIONS

Discharge instructions and medications:

- Rest and analgesics
- Antibiotics that include *S. aureus* and anaerobic coverage
- Local hygiene and depilatory mechanisms
- If an incision and drainage has been performed, ensure close outpatient follow-up for wound checks, removal of packing, and culture follow-up.
- Sitz baths once packing removed
- Dressing changes
- Return for recurrence of abscess.

### PROGNOSIS

Recurrence rate up to 50% (3)

### COMPLICATIONS

- Cellulitis
- Postoperative surgical site infection (4)
- Wound dehiscence
- There have been reports of malignant change to squamous cell carcinoma and verrucous carcinoma, but these are rare (2,5).

### CODES

#### ICD9

- 685.0 Pilonidal cyst with abscess
- 685.1 Pilonidal cyst without mention of abscess

## PEARLS AND PITFALLS

- Application of EMLA or LMX to a pilonidal abscess often results in spontaneous drainage.
- Patients with pilonidal disease have a spectrum of clinical presentations ranging from asymptomatic pits, painful abscesses, or draining sinuses.
- Emergent management involves pain control and incision and drainage of any abscess.
- Antibiotic choice should include coverage for MRSA and anaerobes.
- Recurrence rates approach 50%, so close outpatient follow-up is key in the management of this disease.

# PINWORMS

Susanne Kost

## BASICS

### DESCRIPTION

Enterobiasis is an infection with *Enterobius vermicularis*, commonly known as the human pinworm:

- Infection most commonly involves the GI tract but can spread to ectopic sites in the genitourinary tract.

### EPIDEMIOLOGY

- More prevalent in temperate and tropical climates
- Most common helminthic infection in the developed world and estimated to infect >40 million people in the U.S.
- Most common in preschool and school-age children; rare in infants

### RISK FACTORS

Risk increases in crowded conditions with poor hygiene, such as preschools

### GENERAL PREVENTION

- Hygiene, particularly hand washing and proper toileting
- Eggs can survive on surfaces for days, thus thorough cleaning of bathroom surfaces and washing of linens at the time of treatment of index case is recommended to avoid spread of infection.

### PATHOPHYSIOLOGY

- Life cycle of the parasite is fairly simple, accounting for its impressive infectivity.
- Eggs are deposited on the perianal skin by adult female worms that have migrated out of the colon, typically at night.
- Larvae inside the ingested eggs develop into an infective form within 6 hr of deposit, and if ingested by the same or another human host within 2–10 days, will hatch in the lumen of the small intestine over 4–6 wk.

- Adult worms live in the colon, with a life span of about 3 mo.
- Adult female worms can produce 10,000 eggs over a 6-wk life span.
- Humans are the only host.

### ETIOLOGY

*E. vermicularis* (pinworm) infection

### COMMONLY ASSOCIATED CONDITIONS

- Perianal itching
- Vulvovaginitis
- Colitis

## DIAGNOSIS

### HISTORY

- Most infections are asymptomatic.
- Most common presenting complaint is intense nocturnal perianal itching (pruritus ani), likely related to a combination of mechanical irritation or local allergy.
- Parents may report visualizing the worms when changing diapers or cleaning the child.
- Rare symptoms are related to the site of ectopic localization of worm burden, such as vaginal itch or discharge, dysuria, and abdominal pain.

### PHYSICAL EXAM

- Adult females are visible to the naked eye as mobile, white threadlike worms ~1 cm in length but are generally only seen at night.
- Evidence of perianal excoriation may be apparent and/or perineal irritation with or without vaginal discharge in females
- Physical exam of the perianal region may uncover other etiologies of pruritus, such as a foreign body, dermatitis, or streptococcal infection.

## DIAGNOSTIC TESTS & INTERPRETATION

### Lab

#### Initial Lab Tests

Diagnosis is confirmed by the visualization of adult worms or eggs; the most reliable method of collecting the eggs is via clear cellophane tape wrapped sticky-side out around a tongue blade, pressed to the perianal skin and then to a glass slide:

- Eggs appear under low-power microscopy as clear bean-shaped structures 0.5 mm in length.
- Highest yield will be in the early morning hours prior to bathing.
- Estimated 50% sensitivity with egg collection on 1st night of symptoms, up to 90% with 3 subsequent attempts
- A commercial adhesive device is available for this purpose, called a Swube pinworm paddle.

#### Diagnostic Procedures/Other

- Eggs are not typically released into the stool, thus stool studies are not usually helpful.
- Eosinophilia in peripheral blood is unusual, and blood tests are not indicated.

#### Pathological Findings

Pinworms are found after appendectomy in 1–3% of appendix specimens; the relationship of enterobiasis to appendicitis remains unclear:

- 1 study found pinworms in 17% of children undergoing colonoscopy for evaluation of rectal bleeding.

**DIFFERENTIAL DIAGNOSIS**

- Poor hygiene
- Diaper dermatitis
- Anal fissure
- Sexual abuse
- Hemorrhoid
- Bacterial infection
- Other helminthic infection

**TREATMENT****MEDICATION****First Line**

- Mebendazole: Children >2 yr, 100 mg PO once. Repeat in 2 wk to prevent reinfection with newly ingested eggs.
- Albendazole: Children <2 yr, 100 mg PO once; >2 yr, 400 mg PO once. Repeat in 2 wk:
  - Cure rates approach 100%, but it is important to treat contacts to prevent reinfection.

**Second Line**

- Ivermectin: Children >15 kg, 200  $\mu$ g/kg PO b.i.d. over 10-day interval
- Pyrantel pamoate at 11 mg/kg (max 1 g) has a cure rate of about 90%; consider use with hypersensitivity to mebendazole:
  - Increased side effects including GI symptoms and occasional neurotoxic effects
  - Use with caution in patients with anemia or liver disease

**DISPOSITION****Discharge Criteria**

Enterobiasis may be effectively managed on an outpatient basis unless associated with significant abdominal pain indicating a comorbidity.

**FOLLOW-UP****FOLLOW-UP RECOMMENDATIONS**

- Take medications as prescribed.
- Treat contacts.
- Clean surfaces and linens thoroughly.
- Keep fingernails short.

**PROGNOSIS**

The prognosis is excellent, though reinfection is common.

**COMPLICATIONS**

- Abdominal pain, nausea, emesis from massive enteric worm burden
- Eosinophilic enterocolitis
- Complications are unusual and are usually related to ectopic migration of adult worms to sites outside of the colon, such as the appendix or the genitourinary tract.

**See Also (Topic, Algorithm, Electronic Media Element)**

DPDx Web site (excellent diagram of the pinworm life cycle): <http://www.dpd.cdc.gov/dpdx/HTML/Enterobiasis.htm>

**CODES**

ICD9  
127.4 Enterobiasis

**PEARLS AND PITFALLS**

- Routine stool studies for ova and parasites will not typically reveal pinworm infection.
- Reinfection is common. Repeat the initial treatment in 2 wk and encourage good hygiene.

# PITYRIASIS ROSEA

Jennifer Adu-Frimpong

## BASICS

Pityriasis rosea was named by the French physician Camille Gilbert in 1860. The name is derived from Greek (*pityriasis* = “scaly”) and Latin (*rosea* = “pink”).

### DESCRIPTION

- Pityriasis rosea is a common skin condition, consisting of an acute, self-limited, exanthematous skin disease characterized by the appearance of slightly inflammatory, oval, papulosquamous lesions on the trunk and proximal areas of the extremities.
- A herald patch, often confused with tinea corporis, frequently precedes the generalized eruption.

### EPIDEMIOLOGY

#### Incidence

- Pityriasis rosea is most common in the spring and fall. The incidence is around 0.68 per 100 dermatologic patients, or 172.2 per 100,000 person-years (1).
- Pityriasis rosea affects all ages, but ~50% of cases occur before the age of 20 yr, with the greatest incidence among adolescents (2).

#### Prevalence

- The overall prevalence of pityriasis rosea has been calculated to be 0.13% in men and 0.14% in women (3).
- It is estimated to account for 0.3–4.8% of dermatologic outpatient visits (2).
- The prevalence in people between 10 and 29 yr of age is 0.6% (2).
- The male to female ratio is around 1:1.43 (4).

### RISK FACTORS

- Age: 10–35 yr (though the condition can occur at any age)
- The condition most often occurs in the spring and fall.

### PATHOPHYSIOLOGY

- The exact pathophysiology of pityriasis rosea is unclear.
- Increased amounts of CD4 T cells and Langhans cells are found in the dermis of patients with pityriasis rosea. This observation may indicate viral antigen processing and presentation; however, the evidence is not conclusive (4).
- A recent study noted a lack of natural killer cell and B-cell activity in pityriasis rosea lesions, suggesting a predominantly T-cell-mediated immunity in the development of the condition (5).

### ETIOLOGY

- Many common infectious microorganisms have been considered (eg, influenza A and B; parainfluenza I, II, and III; Epstein-Barr virus; parvovirus B19; herpesviruses 1, 2, 6, 7, and 8; and mycoplasma).
- Recent studies using polymerase chain reaction analysis have suggested a role for human herpesvirus (HHV)-6 and HHV-7, but this has not been confirmed (6).
- Certain drugs have been implicated in causing drug-induced pityriasis rosea (7). These include:
  - Bismuth
  - Barbiturates
  - Captopril
  - Methoxypropazine
  - Metronidazole
  - D-penicillamine
- Certain vaccinations, such as the BCG vaccine or the diphtheria vaccine, have been reported to cause similar eruptions.

### COMMONLY ASSOCIATED CONDITIONS

A study by Bjornberg et al. (8) suggested that possible associated or precipitating conditions include atopic or seborrheic dermatitis and mental stress.

## DIAGNOSIS

### HISTORY

- Determine if any close contacts have similar eruptions. This finding is uncommon because most cases of pityriasis rosea are sporadic, but it may be associated with a weakly contagious disease.
- Medication use
- Antecedent or current upper respiratory infection. About 1/2 the people who develop pityriasis rosea have signs or symptoms of an upper respiratory infection such as a nasal congestion, sore throat, or cough.
- Patients may have prodromal symptoms such as malaise, nausea, anorexia, fever, joint pain, lymph node swelling, and headache that may precede the appearance of the herald patch.
- Pruritus occurs in 75% of patients and is severe in 25%.

### PHYSICAL EXAM

- Patients with pityriasis rosea usually are afebrile and have no signs of systemic illness.
- Pityriasis rosea typically begins with a large (~1–2 cm in diameter) round or oval-shaped localized dermatitis called the herald patch.
  - The herald patch is often located on the back, chest, or abdomen; occasionally, it can be seen on the neck and legs.
  - The patch is characterized by a central salmon-colored area and a dark red peripheral zone. The areas are separated by a collarette of fine scales.
  - In atypical pityriasis rosea (20% of patients), the herald patch may be missing or confluent with other lesions.
- The secondary eruption appears at its maximum in about 10 days. This appears as pink patches, and the eruption is symmetric and localized, predominantly to the trunk and adjacent areas of the neck and extremities. Involvement is maximal over the abdomen and anterior and dorsal surfaces of the thorax.
- The secondary lesions are typically oval shaped and scaly. They are distributed in a classic “Christmas tree” pattern with their long axes following the lines of cleavage of the skin.
- The rash of pityriasis rosea is usually pink and scaly, but in darker-skinned children, the lesions may be gray, dark brown, or even black.
- Though the distribution of the rash may be peripheral, facial involvement may be seen in some children.
- The face, axillae, and groins are predominantly involved in pityriasis rosea inversus.
- The shoulders and hips are predominantly affected in limb-girdle pityriasis rosea.
- The lesions of pityriasis rosea may be large (pityriasis rosea gigantea of Darier), urticarial (pityriasis rosea urticata), vesicular, pustular, purpuric, and erythema multiforme-like.
- Oral lesions of various types have been reported with pityriasis rosea, including erythematous plaques, hemorrhagic puncta, and ulcers.
- Patients with severe pruritus, pain, and a burning sensation can be said to have pityriasis rosea irritata.
- Black patients typically have a more extensive rash and have been shown to have more facial (30%) and scalp involvement (8%) than Caucasian children.
- ~1/3 of black children have papular lesions, and 48% have residual hyperpigmentation (9).
- Lymphadenopathy is uncommon, but when present, it is usually observed in blacks.

**DIAGNOSTIC TESTS & INTERPRETATION****Lab****Initial Lab Tests**

- No diagnostic blood testing is available for pityriasis rosea. Therefore, lab testing is usually unnecessary.
- A rapid plasma reagin test may be considered because pityriasis rosea lesions can be confused with secondary syphilis.

**Diagnostic Procedures/Other**

- A fungal culture may be considered to distinguish a herald patch from tinea corporis.
- Rarely, a skin biopsy may be needed to diagnose pityriasis rosea when findings are nonspecific.

**DIFFERENTIAL DIAGNOSIS**

- Tinea corporis
- Eczema, including nummular
- Guttate psoriasis
- Secondary syphilis
- Erythema multiforme
- Lichen planus
- Lichenoid reactions
- Pityriasis lichenoides
- Kaposi sarcoma
- Scabies
- Tinea versicolor

**TREATMENT****INITIAL STABILIZATION/THERAPY**

Symptomatic treatment is all that is required.

**MEDICATION****First Line**

- Corticosteroid ointments will help ease itching and decrease inflammation:
  - 1% hydrocortisone applied topically t.i.d.
- Oral medications may help alleviate itching.
- Cetirizine:
  - 6 mo to 2 yr of age: 2.5 mg PO per day
  - 2–6 yr: 2.5–5 mg PO per day
  - >6 yr: 5–10 mg PO per day
- Diphenhydramine 1.25 mg/kg/dose divided q6h:
  - Doses >25–50 mg often cause sedation.

**Second Line**

- Prednisone 0.25–0.5 mg/kg PO per day, up to 40 mg/day for up to 5 days
- Acyclovir and famciclovir has been shown in 1 study to hasten resolution, especially if given within 1 wk of rash, but this treatment is not well-established (10).
- The association of pityriasis rosea with any virus, including HHV-7, is not yet firmly established; therefore, adopting routine antiviral therapy is premature (11).

**COMPLEMENTARY & ALTERNATIVE THERAPIES**

- Oatmeal baths
- Zinc oxide cream or calamine lotion
- Phototherapy using UVB light or sunlight
- The other drug class being used is macrolides such as erythromycin (12). The use of macrolides is, at best, considered experimental at this point.

**DISPOSITION****Discharge Criteria**

Children with pityriasis rosea may be managed as outpatients.

**Issues for Referral**

Referral to a dermatologist may be needed if there is not a clear clinical presentation and the diagnosis is uncertain.

**FOLLOW-UP****PROGNOSIS**

- The prognosis of pityriasis rosea is excellent.
- Pityriasis rosea usually goes away within 6–12 wk.
- <3% of affected individuals experience recurrences (13).

**COMPLICATIONS**

- Pityriasis rosea can cause severe itching, especially if one becomes overheated.
- Both postinflammatory hyperpigmentation and hypopigmentation may occur. This is more common in dark-skinned children.

**CODES****ICD9**

696.3 Pityriasis rosea

**PEARLS AND PITFALLS**

- The incidence of pityriasis rosea is greatest in adolescence, but it may be seen in all ages.
- Distinguishing features of pityriasis rosea include the presence of a herald patch, the symmetry of the rash, a lack of fever, and pruritus.
- Pityriasis rosea is a self-limited condition, but the rash may persist for weeks or months.

# PLEURAL EFFUSION

In K. Kim

## BASICS

### DESCRIPTION

- Pleural effusion is an abnormal accumulation of fluid in the pleural space.
- Empyema: Pus in the pleural space
- Chylothorax: Lipid in the pleural space
- Malignant effusion may result from lymphoma, leukemia, or metastatic disease.

### EPIDEMIOLOGY

#### Prevalence

Prevalence may be increasing (from 1/100,000–14/100,000 from 1993–2003).

### PATHOPHYSIOLOGY

- 2 types of pleural effusion: Transudative and exudative
- Transudate: Increased hydrostatic and/or decreased oncotic pressure results in leak of fluid.
- Exudate: Damage to the pleural surface alters its ability to filter pleural fluid with compromise of lymphatic drainage.

### ETIOLOGY

- Transudative:
  - CHF
  - Hypoalbuminemia, hypoproteinemia
  - Atelectasis
  - Cirrhosis
- Exudative:
  - Pneumonia
  - Empyema
  - Pericarditis, pulmonary embolism
- Pulmonary infarction:
  - Pancreatitis
  - Peritonitis
  - Systemic lupus erythematosus
  - Trauma, hemothorax, chylothorax
  - Drug/Toxin: Crack cocaine, Coumadin, methotrexate, nitrofurantoin
- Malignancy

### COMMONLY ASSOCIATED CONDITIONS

See Etiology.

## DIAGNOSIS

### HISTORY

- Underlying disease determines the symptomatology.
- Dyspnea and cough occur with large effusions or primary pulmonary etiology.
- Chest pain ranging from mild to severe:
  - Exacerbated by deep inspiration
  - Enlarging exudative effusions may decrease chest pain as larger effusions separate pleural and parietal pleura.
- To determine underlying etiology, ask about:
  - Fever
  - Weight loss
  - Facial rash
  - Arthralgia
  - Urinary changes

### PHYSICAL EXAM

- Decreased breath sounds
- Pleural rub
- Dyspnea
- Increase work of breathing:
  - Grunting
  - Nasal flaring
  - Retractions
- Dullness to percussion
- Other abnormal findings are dependent on the underlying etiology.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

- Assess pleural fluid after pleurocentesis.
- Normal pleural fluid: pH 7.6–7.7, protein content <2% (1–2 d/dL), <1,000 WBC/mm<sup>3</sup>, glucose similar to serum glucose, lactate dehydrogenase (LDH) level <50% of plasma LDH level
- Criteria for exudate:
  - Pleural fluid protein/serum protein >0.5
  - Pleural fluid LDH/serum LDH >0.6
  - Pleural fluid LDH >2/3 upper limit of normal serum LDH

- Pleural fluid hematocrit (Hct) >0.5 serum Hct suggests hemothorax.
- Pleural fluid WBC >10,000/mm<sup>3</sup> suggests parapneumonic effusion, empyema, pancreatitis, or malignancy.
- Pleural fluid glucose <50% of serum glucose suggests bacterial empyema, rheumatologic effusion, or malignancy.
- Pleural triglycerides >100 mg/dL suggest chylothorax.
- Pleural fluid amylase >200 IU/L suggests pancreatitis, empyema, or malignancy.
- Pleural fluid pH <7.0 suggests empyema.
- Gram stain and culture of pleural fluid
- Consider other assays as appropriate.

### Imaging

- CXR: AP view can detect effusion; consider decubitus view to detect smaller effusion.
- US is operator dependent but does not involve radiation; more sensitive than x-rays.
- Chest CT can detect effusion as well as intrapulmonary pathology.
- Both chest CT and US are more sensitive and able to detect loculation such as with empyema.

### Diagnostic Procedures/Other

- Thoracentesis
- Tube thoracostomy
- Using the least invasive technique is preferable: Needle aspiration is preferred over thoracostomy, and a smaller bore (ie, pigtail) chest tube is preferable over a larger one.
  - This is dictated by type of effusion expected; needle aspiration or small-bore chest tube are often ineffective to drain viscous or loculated effusion, such as empyema or hemothorax.

### DIFFERENTIAL DIAGNOSIS

See Etiology.

## TREATMENT

### PRE HOSPITAL

Address airway, breathing, and circulation issues according to Pediatric Advanced Life Support (PALS) guidelines.

### INITIAL STABILIZATION/THERAPY

- Address airway, breathing, and circulation issues according to PALS guidelines.
- Ensure analgesia.
- Treat underlying disease.

### MEDICATION

- Analgesics
- Ibuprofen 10 mg/kg PO/IV q6h PRN
- Morphine 0.1 mg/kg IV/IM/SC q2h PRN:
  - Initial morphine dose of 0.1 mg/kg IV/SC may be repeated q15–20min until pain is controlled, then q2h PRN.
- Antibiotics as appropriate for anticipated pathogen of pneumonia or empyema

### SURGERY/OTHER PROCEDURES

- Thoracentesis or tube thoracostomy
- Video-assisted thoracic surgery may be necessary for refractory pleural effusion.
- Pleurodesis

### DISPOSITION

#### Admission Criteria

Critical care admission criteria:

- Unstable patients or significant respiratory distress
- Most patients with a new diagnosis of pleural effusion should be admitted for monitoring as well as treatment of underlying disease.

#### Discharge Criteria

- Stable children with small pleural effusion secondary to pneumonia may be discharged from the emergency department.
- Patients with known etiology underlying pleural effusion who are asymptomatic may be discharged with close observation and follow-up with a primary care provider or subspecialist managing the underlying disease.

## FOLLOW-UP

### PROGNOSIS

- Depends fully on underlying etiology
- Prompt diagnosis and treatment reduces morbidity and mortality.
- Properly treated infectious etiology usually has excellent prognosis.
- Empyema in infants has 6–12% mortality
- Malignancy has a very poor prognosis.

### COMPLICATIONS

- Hypoxia
- Respiratory failure
- Shock
- Respiratory distress
- Recurrence
- Pneumothorax
- Hemothorax
- Re-expansion pulmonary edema

### ADDITIONAL READING

### CODES

#### ICD9

- 510.9 Empyema without mention of fistula
- 511.9 Unspecified pleural effusion
- 511.89 Other specified forms of effusion, except tuberculous

### PEARLS AND PITFALLS

- Pearls:
  - Bilateral pleural effusions are usually due to CHF.
  - Chest radiograph may take several months to resume a normal appearance after drainage of a pleural effusion.
  - With tumors, tube thoracostomy often causes pneumothorax because lung is incarcerated by tumor.
  - Sclerosing procedures are usually ineffective for malignancy.
- Pitfalls:
  - Insertion of chest tube into malignant tumor
  - Pleural effusion misdiagnosed as pleural thickening or infiltrate
  - Failure to recognize hemothorax or pneumothorax
  - Laceration of intra-abdominal organ after chest tube placement

# PNEUMONIA, ASPIRATION

Nicholas Tsarouhas

## BASICS

### DESCRIPTION

Aspiration pneumonia is inflammation of lung tissue occurring as a result of inhalation of gastric or oropharyngeal contents (toxic or nontoxic).

### EPIDEMIOLOGY

#### Incidence

- Aspiration pneumonia is the most common cause of death in children with neurologic impairment who have gastroesophageal reflux (GER) (1).
- Secondary bacterial infection may complicate up to 1/2 of all gastric aspirations.

#### Prevalence

- Not commonly seen in healthy children who have no comorbidities or other impairment
- A study of 58 children with cerebral palsy 6 mo to 12 yr of age found 41% with chronic aspiration (2).

### RISK FACTORS

- Neurologic impairment (chronic)
- Depressed mental status (acute):
  - Sepsis
  - Brain injury
  - Toxic ingestion
- Diminished gag reflex
- Swallowing abnormalities/dysphagia
- Esophageal dysmotility
- GER
- Esophageal anomalies (tracheoesophageal fistula)
- Bag-valve-mask positive pressure ventilation

### GENERAL PREVENTION

- There are varying NPO recommendations for patients being sedated for procedures, but:
  - There is no consensus.
  - Multiple factors are considered, including the urgency of the procedure (eg, rapid sequence intubation in the emergency department).
- Cricoid pressure (the Sellick maneuver) may minimize the gastric insufflation and regurgitation that may accompany bag-valve-mask ventilation.
- Aspiration of household hydrocarbons (eg, lamp oil) carries high morbidity; these products should be appropriately labeled, tightly sealed, and kept out of reach of children.

### PATHOPHYSIOLOGY

- Gastric aspiration: Inhalation of acidic stomach contents (pH <2.5) into the lungs that causes:
  - A severe chemical pneumonitis due to direct injury to the pulmonary alveolar-capillary membranes
  - In some cases, a delayed secondary bacterial invasion and infection
- Oropharyngeal aspiration: Inhalation of less acidic (pH >2.5) oropharyngeal contents into the lungs that may cause mild, transient, severe, or chronic pulmonary damage
- Hydrocarbon aspiration:
  - Intense, necrotizing, chemical pneumonitis
  - Aspiration enhanced by the following properties of these compounds: Low viscosity, low surface tension, high volatility

### ETIOLOGY

- Bacterial causes of aspiration:
  - Anaerobes
  - Gram negatives (*Pseudomonas* species)
  - Gram positives (*Staphylococcus* species)
- Chemical causes (Hydrocarbons):
  - Lamp oil
  - Turpentine, gasoline, kerosene
  - Furniture polish
  - Charcoal/Cigarette lighter fluid
  - Mineral spirits

### COMMONLY ASSOCIATED CONDITIONS

Cerebral palsy:

- Anterograde aspiration caused by oral-motor dysfunction
- Retrograde aspiration caused by GER

## DIAGNOSIS

### HISTORY

- A child with risk factors has an event that leads to acute onset of respiratory distress:
  - Vomiting
  - Gagging
  - Choking
  - Coughing
- There may be a history of GER or a comorbidity such as cerebral palsy or static encephalopathy

### PHYSICAL EXAM

- Tachypnea
- Increased work of breathing
- Retractions
- Crackles
- Decreased breath sounds
- Wheezing
- Fever (usually not initially)
- Cyanosis (severe aspirations)

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

- Pulse oximetry: May be normal but is usually <95% in severe cases
- A leukocytosis often supports a secondary bacterial infection but may also be seen with a pure chemical pneumonitis and has a low positive predictive value.

#### Imaging

CXR:

- May be normal initially
- Infiltrates may appear over 6–24 hr.
- Ultimately shows diffuse or localized infiltrates (unilateral or bilateral)

#### Diagnostic Procedures/Other

- Bacteriologic studies:
  - Blood cultures rarely are positive.
  - Sputum Gram stain and culture: These are rarely useful, as expectorated sputum is difficult to collect in young and impaired children, and these specimens are usually contaminated with normal oropharyngeal flora.
  - Tracheal aspirates: Commonly used but also fraught with contamination by normal flora
  - Bronchoalveolar lavage
  - Protected respiratory brush specimens

- If GER is suspected:

- Radionucleotide scan (“milk scan”) to rule out pulmonary aspiration
- Esophageal pH probe testing (24 hr) to assess frequency of GER.
- A video esophagram or modified barium swallow is the best way to evaluate swallowing in children suspected of having anterograde aspiration (3).
- A barium swallow also is useful to rule out anatomic entities as causes of reflux as well as to assess the severity of GER.

### DIFFERENTIAL DIAGNOSIS

- Bacterial pneumonia
- Viral pneumonia
- Fungal pneumonia
- Bronchiolitis
- Asthma
- Foreign body aspiration

## TREATMENT

### PRE HOSPITAL

- Oxygen should be administered to all patients suspected to have aspirated.
- Emesis should never be induced in suspected cases of hydrocarbon ingestion.

### INITIAL STABILIZATION/THERAPY

- Vigorous supportive care is the mainstay of therapy in aspiration pneumonia patients:
  - Oxygen
  - Positioning to prevent further aspiration
  - Suctioning
- Patients who are unable to adequately protect their airways with a poor or absent gag reflex require endotracheal intubation.
- Patients with severe respiratory distress may require respiratory support with mechanical ventilation.

### MEDICATION

#### First Line

Oxygen

#### Second Line

- Antibiotics:
  - Prophylactic antibiotics are not indicated.
  - If clinical suspicion is high for secondary bacterial infection, antibiotics should be used.
  - Community-acquired aspirations: Penicillin alone or ampicillin/sulbactam is commonly used.
    - Penicillin G: 100,000–250,000 units/kg/day IV divided q.i.d.
    - Ampicillin/Sulbactam: 150 mg/kg/day IV divided q.i.d.
  - Nosocomial aspirations: Clindamycin and gentamicin together or ampicillin/sulbactam monotherapy
    - Clindamycin: 25–40 mg/kg/day IV divided t.i.d.
    - Gentamicin: 7.5 mg/kg/day IV divided t.i.d.
- Corticosteroids:
  - Controversial
  - Generally not indicated

## COMPLEMENTARY & ALTERNATIVE THERAPIES

- Dietary changes: Avoiding spicy and acidic foods may be beneficial in cases of reflux.
- Body position after eating: Some patients may aspirate less with upright positioning after eating.
- Sleep positioning:
  - The American Academy of Pediatrics (AAP) Task Force on Infant Positioning and SIDS issued its recommendation on nonprone infant positioning in 1992.
  - A prospective study of 3,240 supine sleeping neonates in 2 hospital newborn nurseries from 2003–2004 found no episodes of apnea, cyanosis, aspiration pneumonias, neonatal ICU admissions, or death from spitting up (4).
  - Similarly, U.S. vital statistics from 1991–1996 showed no evidence of increased death from aspiration as a result of the AAP's "Back to Sleep" program (5).

## SURGERY/OTHER PROCEDURES

- Gastrostomy/Jejunostomy placement may be beneficial in children with severe or chronic aspiration syndromes:
  - This is especially helpful in those children with oropharyngeal swallowing dysfunction.
  - A prospective study found a 50% reduction in chest infections in children with cerebral palsy 1 yr after gastrostomy tube placement compared to the year before (6).
- Nissen gastric fundoplication is useful in some children with severe GER.
- A retrospective study of 366 children with neurologic impairment and GER found similar efficacy in gastrojejunostomy placement and gastric fundoplication in preventing aspiration pneumonia or improving overall survival (1).

## DISPOSITION

### Admission Criteria

- Most children diagnosed with aspiration syndromes should be admitted due to respiratory distress combined with a likely comorbidity.
- In addition to respiratory distress, other admission criteria include cyanosis, hypoxemia, dehydration, or inability to tolerate oral or gastric tube feedings.
- Critical care admission criteria:
  - Severe respiratory distress
  - Cyanosis
  - Hypoxemia
  - Compromised airway protective reflexes

### Discharge Criteria

- No respiratory distress
- Normal (or baseline) oxygen saturations
- Reliable parents who are comfortable with home management

### Issues for Referral

Chronic aspiration patients may need subspecialty referral depending on etiology:

- Pulmonary
- Gastroenterology
- Neurology

## FOLLOW-UP

### FOLLOW-UP RECOMMENDATIONS

- Discharge instructions and medications:
  - Return for respiratory distress, constant cough, persistent high fever, ill appearance, poor feeding, vomiting.
  - Oral antibiotics (amoxicillin/clavulanate) are usually prescribed to outpatients.
  - Amoxicillin/Clavulanate: 90 mg/kg/day divided b.i.d.
- Activity:
  - As tolerated

### Patient Monitoring

- If home oxygen monitoring is available (pulse oximetry), this can be utilized.
- Patient should not have significant increases in baseline oxygen requirements.

### DIET

- As tolerated
- Some children will require NG feedings while awaiting surgery.

### PROGNOSIS

With appropriate supportive care and selective use of antibiotics, the prognosis for recovery is usually good.

### COMPLICATIONS

- GER and aspiration may be associated with:
  - Chronic pulmonary disease from recurrent microaspiration
  - Reflex laryngospasm
  - Acute bronchospasm
- Recurrent pneumonia:
  - A study of 2,952 children hospitalized with pneumonia from 1987–1997 in a Toronto hospital found 238 who met criteria for recurrent pneumonia (7).
  - The most common cause was an underlying aspiration syndrome secondary to oropharyngeal muscular incoordination leading to inability to handle respiratory tract secretions.
  - This was present in 114 (48%) aspiration pneumonia patients.

### ICD9

- 507.0 Pneumonitis due to inhalation of food or vomitus
- 770.18 Other fetal and newborn aspiration with respiratory symptoms

## PEARLS AND PITFALLS

- Children with underlying neurodevelopmental abnormalities are most likely to develop aspiration pneumonias; healthy, normal children rarely aspirate.
- Suspect aspiration in a child who has suffered a brief choking, gagging, or coughing episode, followed by a brief period of apparent recovery, who then goes on to respiratory distress within 1 hr.
- Initiating antibiotics in cases of chemical pneumonitis rests on clinical suspicion, since the typical presentation of fever, respiratory distress, leukocytosis, and infiltrate on x-ray is identical to infectious pneumonia.

# PNEUMONIA, BACTERIAL

Suzanne Schmidt

## BASICS

### DESCRIPTION

- Pneumonia refers to inflammation and infection of the lower respiratory tract, usually confirmed by parenchymal infiltrates on chest radiograph.
- Bacteria cause a significant proportion of pneumonias and resultant complications in children.

### EPIDEMIOLOGY

#### Incidence

Greatest in those <5 yr of age, with an estimated annual incidence of 35–40 per 1,000 children in North America and Europe

### RISK FACTORS

- Underlying respiratory disease (asthma, bronchopulmonary dysplasia, cystic fibrosis, ciliary dyskinesia)
- Immunosuppression (HIV, sickle cell disease, inherited immunodeficiency, medication induced)
- Anatomic anomaly (tracheoesophageal fistula, pulmonary sequestration, congenital adenomatous malformation, bronchiectasis)
- Neuromuscular disease
- Aspiration
- Foreign body
- Trauma
- Smoke exposure

### GENERAL PREVENTION

Immunization with Hib vaccine and heptavalent pneumococcal vaccine has decreased the incidence of bacterial pneumonia.

### PATHOPHYSIOLOGY

- Protective mechanisms of the respiratory tract include secretory immunoglobulins, mucus production, and clearance by ciliary action and cough as well as activity of phagocytic cells and cell-mediated immunity.
- Viral infections may damage respiratory mucosa and impair these mechanisms.
- Bacteria transmitted by close contact or from colonization of the child's upper respiratory tract gain entry into the lower respiratory tract and cause infection. Less commonly, bacteria may enter the lung by hematogenous spread.

### ETIOLOGY

- Most pneumonias are a result of bacterial or viral infection. Often it is difficult to identify a particular causative organism.
- Coinfections with bacteria and viruses are common, occurring in 9–41% of children with community-acquired pneumonia.
- Overall, *Streptococcus pneumoniae* is the most common bacterial etiology, causing 27–44% of "typical" community-acquired pneumonia in children (1). It is the most common identifiable bacteria in hospitalized children with pneumonia.
- *Mycoplasma pneumoniae* and *Chlamydia pneumoniae*, causing "atypical" pneumonia, are the next most frequent pathogens, found in 7–14% and 6–9% of children with pneumonia.
- *Staphylococcus aureus*, *Haemophilus influenzae*, and group A streptococci are less common.

- Aspiration pneumonia: Consider gram-negative flora and anaerobic organisms.
- Age:
  - <60 days: Group B streptococci, *Listeria monocytogenes* and gram-negative enteric bacilli
  - 1–3 mo: *Chlamydia trachomatis* from the maternal genital tract causes a subacute interstitial pneumonia; *S. pneumoniae* begins to appear, rarely *Bordetella pertussis* or *S. aureus*
  - 2 mo to 5 yr: *S. pneumoniae* is most common, though there is evidence for an increasing role of atypical bacteria (*M. pneumoniae*, *C. pneumoniae*).
  - 5–18 yr: *M. pneumoniae* may be the most common bacterial cause in older children, *C. pneumoniae* and *S. pneumoniae* are still common.

## DIAGNOSIS

### HISTORY

- Patients may have a preceding viral upper respiratory infection.
- Common symptoms include cough, fever, and tachypnea.
- Abdominal pain and vomiting may be present with a lower lobe pneumonia or systemic illness.
- Neonates and young infants may present with nonspecific symptoms of fever, lethargy, poor feeding, and apnea.
- Occasionally, pneumonia may present as a fever without a source.
- The course of illness may suggest a particular etiology, though is not specific:
  - Typical bacterial pneumonia (*S. pneumoniae*, *S. aureus*, *H. influenzae*) classically presents with abrupt onset of fever and cough with varying degrees of respiratory distress.
  - Atypical pneumonia (*M. pneumoniae*, *C. pneumoniae*) may have a longer course with more systemic symptoms such as headache, sore throat, malaise, and myalgias in addition to cough and fever.
- History of ill contacts, travel, and immunization are important, including assessment of risk factors for *Mycobacterium tuberculosis*.

### PHYSICAL EXAM

- Assess vital signs with attention to temperature, respiratory rate, and oxygen saturation.
- Tachypnea is the most sensitive and specific sign of pneumonia in children (1).
- Children with possible pneumonia should be evaluated for increased work of breathing (retractions, accessory muscle use, nasal flaring, grunting) and hypoxia (cyanosis, pulse oximetry).
- Typical auscultatory findings may include crackles, rhonchi, and decreased breath sounds:
  - Some young children may have pneumonia with no abnormal breath sounds.
- Wheezing suggests a viral rather than bacterial cause (such as bronchiolitis) or *M. pneumoniae*.
- Other findings suggestive of pneumonia include dullness to percussion of lung fields and splinting due to pain.

## DIAGNOSTIC TESTS & INTERPRETATION

### Lab

#### Initial Lab Tests

- For a previously healthy child with uncomplicated pneumonia, routine lab tests are unnecessary:
  - Elevations in the WBC count or C-reactive protein are nonspecific and not necessary to make diagnosis.
  - These lab tests may be helpful if diagnosis is in question or to differentiate bacterial vs. viral lower respiratory infection.
- Blood cultures are not routinely recommended since an identifiable pathogen is infrequently found. Consider in ill, hospitalized patients.
- Nasopharyngeal swab for rapid viral testing may be helpful but does not rule out coinfection with bacteria.
- Diagnostic tests for *M. pneumoniae* and *C. pneumoniae* may be difficult to interpret:
  - Cold agglutinins are positive in 30–75% of patients with *M. pneumoniae* but can be present with other infections as well.
  - Serology for diagnosis of *M. pneumoniae* and *C. pneumoniae* are not helpful in the acute setting and may remain positive for prolonged periods of time.
- Gram stain and culture of sputum may be difficult to obtain in smaller children, and results may represent upper respiratory tract colonization.
- Culture and Gram stain from thoracentesis or lung biopsy may be helpful in ill patients with complicated pneumonia.
- Tuberculin skin testing should be considered if risk factors are present.

### Imaging

- Chest radiography typically demonstrates parenchymal infiltrates. Pleural fluid may be better seen on a lateral decubitus view:
  - Routine use of 2 views on CXR is not always necessary, as a lateral view typically does not contribute to the ability to diagnose or rule out pneumonia.
  - Patchy or peribronchial infiltrates are nonspecific and may occur with viral, bacterial, or atypical bacterial pneumonia.
  - Lobar consolidation, pleural effusion, or findings consistent with abscess or empyema suggest a bacterial etiology.
- Chest CT scan may be needed to further define complications of pneumonia, such as an empyema, cavitation, or bronchiectasis or when an underlying anatomic anomaly is suspected.
- US may be helpful for evaluation of fluid or infection in the pleural space.

### Diagnostic Procedures/Other

- Thoracentesis may be performed in complicated cases with a pleural effusion to aid in diagnosis.
- Chest tube placement may be necessary for drainage if pleural fluid is causing respiratory or cardiovascular compromise.

**DIFFERENTIAL DIAGNOSIS**

- Infectious diseases:
  - Viral pneumonia, bronchiolitis, croup, fungal and parasitic infections of the lung, *M. tuberculosis* infection
- Other causes of infiltrates or pleural effusion:
  - Pulmonary embolism, chemical pneumonitis, pulmonary hemorrhage, CHF, malignancy, collagen-vascular disease

**TREATMENT**

**PRE HOSPITAL**

Assess and stabilize airway, breathing, and circulation.

**INITIAL STABILIZATION/THERAPY**

- Assess and stabilize airway, breathing, and circulation:
  - Many children with bacterial pneumonia require supplemental oxygen.
- Children with bacterial pneumonia, especially neonates and infants, may present with respiratory failure or apnea, or with cardiovascular compromise from sepsis or dehydration.

**MEDICATION**

**First Line**

- Antibiotic therapy should be directed toward the most likely infecting organism if a bacterial etiology is suspected.
- Unless otherwise specified, treatment duration should be 7–10 days.
- Infants 0–60 days of age:
  - Therapy should be inpatient due to risk of sepsis, respiratory failure, and apnea.
  - IV ampicillin plus either gentamicin or cefotaxime
  - Consider adding erythromycin in infants 4–12 wk of age if concern for *C. trachomatis*.
- Children 2 mo to 5 yr of age:
  - Treat resistant *S. pneumoniae*. Consider adding coverage for atypical pneumonia with a macrolide.
  - Outpatient therapy:
    - Oral high-dose amoxicillin (80–90 mg/kg/day divided b.i.d.).
    - A 2nd-generation cephalosporin (high dose) with activity against resistant *S. pneumoniae* is an alternative (eg, cefuroxime, cefpodoxime, or cefdinir).
    - A single dose of ceftriaxone IV/IM may be given to initiate therapy.
  - Inpatient therapy:
    - IV ampicillin or a cephalosporin (cefuroxime, cefotaxime). Use high-dose to cover resistant *S. pneumoniae*. Consider adding a macrolide.
- Children >5 yr of age:
  - Coverage for both atypical pneumonia caused by *M. pneumoniae* or *C. pneumoniae* and typical pneumonia caused by *S. pneumoniae* should be considered. Macrolides effective for atypical pneumonia are generally not good choices for *S. pneumoniae*.

- Outpatient therapy:
  - Diffuse-pattern pneumonia in older child: Oral azithromycin 10 mg/kg/day once on 1st day, then 5 mg/kg/day once daily; consider erythromycin or clarithromycin as substitutes.
  - Lobar pneumonia in older child: Oral high-dose amoxicillin or cephalosporin
  - Overlapping clinical findings: Consider both azithromycin and amoxicillin.
- Inpatient therapy:
  - Typical bacterial pneumonia is more likely to result in the need for hospitalization: High-dose IV ampicillin or cephalosporin is preferred.
  - Oral or IV erythromycin, azithromycin, or doxycycline in children >8 yr of age may be added for atypical organisms.
- Patients >17 yr of age:
  - A fluoroquinolone alone may be given to treat typical and atypical bacteria.

**Second Line**

- Treatment failure:
  - If initially treated with a macrolide alone, switch to high-dose amoxicillin or cephalosporin.
  - If initially treated with amoxicillin or a cephalosporin, switch to a macrolide.
- There is no role for routine use of supplemental IV fluid or bronchodilators in the management of pneumonia.

**DISPOSITION**

**Admission Criteria**

- Increased work of breathing, hypoxia requiring supplemental oxygen, dehydration requiring IV hydration, vomiting with inability to tolerate oral antibiotics
- Neonates and young infants should receive initial treatment as inpatients.
- Critical care admission criteria:
  - Respiratory distress

**Discharge Criteria**

- Most healthy children with uncomplicated pneumonia can be treated as outpatients.
- No hypoxia, no increase in work of breathing or respiratory distress, ability to tolerate oral antibiotics and fluids

**Issues for Referral**

Refer to a pulmonologist for recurrent or persistent pneumonia.

**COMPLEMENTARY & ALTERNATIVE THERAPIES**

Zinc supplementation decreases mortality in developing nations with high mortality rates.

**FOLLOW-UP**

**FOLLOW-UP RECOMMENDATIONS**

Discharge instructions and medications:

- Oral antibiotic therapy
- Follow up with physician in 1–3 days.
- Return for increased work of breathing, persistent fever, or ill appearance.

**PROGNOSIS**

- Most healthy children show clinical improvement with antibiotic therapy in a few days.
- Mortality low in developed countries; leading cause of pediatric death in developing countries

**COMPLICATIONS**

- Local complications: Pleural effusion, empyema, lung abscess, pneumatocele, pneumothorax, and pericarditis
- Hematogenous complications: Bacteremia, sepsis, osteomyelitis, septic arthritis, meningitis

**CODES**

**ICD9**

- 482.9 Bacterial pneumonia, unspecified
- 482.30 Pneumonia due to streptococcus, unspecified
- 483.0 Pneumonia due to mycoplasma pneumoniae

**PEARLS AND PITFALLS**

- School-aged children may have either typical or atypical pneumonia and may require antibiotic coverage for both.
- Tachypnea is the most sensitive indicator of pneumonia in young children and infants.

# PNEUMOTHORAX/PNEUMOMEDIASTINUM

Kevin Ching

## BASICS

### DESCRIPTION

- A pneumothorax is a potentially life-threatening accumulation of air within the pleural space that results in the collapse of the ipsilateral lung:
  - Simple pneumothorax:
    - A nonexpanding collection of air that develops in the absence of trauma
  - Primary spontaneous pneumothorax:
    - No predisposing or comorbid lung disease
  - Secondary spontaneous pneumothorax:
    - A complication of predisposing lung disease (eg, asthma or cystic fibrosis)
  - Traumatic pneumothorax:
    - Develops from blunt or penetrating trauma or iatrogenically from surgical procedures or during mechanical ventilation
  - Tension pneumothorax:
    - Accumulation of intrapleural air that exceeds atmospheric pressure or an accumulation of air under pressure
  - Open pneumothorax:
    - A chest wall defect allowing air to communicate with the atmosphere
- A hemothorax is a collection of intrapleural blood (see Hemothorax topic).
- A pneumomediastinum develops when air accumulates within the mediastinum (spontaneous or traumatic).

### EPIDEMIOLOGY

#### Incidence

- The incidence of spontaneous pneumothoraces is highest in the newborn period (0.17 per 1,000 live births) (1).
- Among adults, the age-adjusted incidence for a spontaneous pneumothorax is (2):
  - Primary spontaneous pneumothorax: 7.4 and 1.2 per 100,000 for males and females, respectively
  - Secondary spontaneous pneumothorax: 6.3 and 2.0 per 100,000 for males and females, respectively
- The incidence of tension pneumothoraces is uncertain since needle decompression is used empirically and often in cases not involving a true tension pneumothorax.
- The incidence of a spontaneous pneumomediastinum in 1 study over a 4-year period was 1 per 12,850 admissions (3).

### RISK FACTORS

- Predominance in tall, thin males
- Repeated and vigorous vomiting or coughing
- Smoking, marijuana, cocaine, or inhalational drug abuse
- Anorexia (pneumomediastinum)
- Lung disease:
  - Asthma, bronchiolitis, chronic lung disease, cystic fibrosis, *Pneumocystis carinii* pneumonia
- Collagen vascular disease:
  - Marfan, Ehlers-Danlos syndrome, rheumatoid arthritis, dermatomyositis
- Iatrogenic: Positive pressure mechanical ventilation, subclavian venous catheterization
- Foreign body inhalation

### PATHOPHYSIOLOGY

- Air enters the intrapleural space through a defect in the visceral or parietal pleura:
  - A spontaneous pneumothorax occurs when a surge in transpulmonary pressure causes an alveolus to rupture and leak air.
  - A tension pneumothorax occurs when a disruption of the pleura or tracheobronchial tree produces a one-way ball valve communication that selectively allows air to enter but not escape:
    - Rising pressure collapses ipsilateral lung and shifts the mediastinum contralaterally.
    - Profound hypoxemia, compromised venous return, hypotension, and shock may result.
- When the size of a chest wall defect in an open pneumothorax exceeds the diameter of the airway, air moves preferentially inward through the defect.
- A pneumomediastinum occurs when air from ruptured alveoli or conducting airways dissects into the mediastinal space.

### ETIOLOGY

- Airway obstruction:
  - Foreign body aspiration
  - Asthma
  - Cystic fibrosis
- Valsalva maneuvers
- Barotrauma from mechanical ventilation or bronchoscopy
- Blunt or penetrating trauma (with or without rib fractures)
- Inadvertent conversion of an open pneumothorax to a tension
- Subclavian venous catheterization (pneumothorax only)
- Pulmonary infections
- Esophageal rupture (pneumomediastinum only)

## DIAGNOSIS

### HISTORY

- Simple pneumothorax:
  - Often asymptomatic
  - May develop with exertion or even at rest
  - Dyspnea
  - Pleuritic chest pain
  - Malaise
  - Rarely will see cough
- Tension pneumothorax:
  - Symptoms may be subtle if small
  - Chest pain
  - Dyspnea
  - Anxiety
  - Cyanosis
- Pneumomediastinum:
  - Often asymptomatic
  - May develop with exertion or at rest
  - Chest pain
  - Dyspnea
  - Neck pain

### PHYSICAL EXAM

- Pneumothorax:
  - Tachypnea
  - Tachycardia
  - Unilateral diminished (or absent) breath sounds
  - Hyperresonance on chest wall percussion
  - Hypotension:
    - Delayed finding in tension pneumothorax
  - Tracheal deviation:
    - Delayed finding in tension pneumothorax
  - Pulsus paradoxus:
    - Seen with tension pneumothorax
  - Jugular venous distension:
    - Seen with tension pneumothorax
  - Cyanosis:
    - Seen especially with tension pneumothorax
  - Altered mental status:
    - Rare in tension pneumothorax
- Pneumomediastinum:
  - Tachypnea
  - Tachycardia
  - Palpable crepitus due to subcutaneous emphysema
  - Hamman sign:
    - Precordial crunching sound synchronized with heartbeat

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

- Blood gas: Acidemia, hypoxemia, hypercarbia (or hypocarbia)
- Tension pneumothorax is a clinical diagnosis:
  - Treatment should not be delayed for lab tests or diagnostic imaging.

#### Imaging

- Traditionally, suspected tension pneumothorax has been treated immediately without imaging that would delay definitive treatment.
- Availability of bedside sonography makes it reasonable to immediately perform bedside sonography prior to needle decompression attempt in awake, stable patients.
  - This allows confirmation of presence of pneumothorax and determination of what needle/catheter length to use.
- Continue to use sonography during the procedure if needle decompression is needed.
- CXR:
  - Simple pneumothorax:
    - Air in the pleural cavity with hyperlucency on the affected side:
      - The hyperlucency represents the collapsed lung.
    - Tension pneumothorax:
      - Air in the pleural cavity with contralateral tracheal and mediastinal deviation
  - Pneumomediastinum:
    - Air in the mediastinal space
    - Subcutaneous emphysema
    - Hyperlucent ring around the right pulmonary artery (lateral view)
    - Hyperlucency visible between the pericardium and diaphragm, producing a “continuous diaphragm”

- Thymic “sail sign”:
  - The thymus is outlined and prominently shifted upward.
- Chest CT scan:
  - More sensitive than CXR in detecting a small pneumothorax or pneumomediastinum
  - Useful in detecting cystic lung disease

**Diagnostic Procedures/Other**

- Bedside US:
  - Limited bedside focused assessment with sonography for trauma (FAST) may be performed during or immediately after the primary trauma survey.
  - Absence of apical lung sliding and comet-tail artifact in pneumothorax:
    - 92–98% sensitivity and 99% specificity (4,5)

**DIFFERENTIAL DIAGNOSIS**

- Pneumothorax, hemothorax
- Pneumomediastinum
- Aortic artery dissection
- Pulmonary embolus
- Pneumonia, chest wall pain
- Pericarditis, pericardial effusion
- Cardiac tamponade
- CHF
- MI
- Diaphragmatic herniation
- Boerhaave syndrome
- Acute abdominal process:
  - Pancreatitis, appendicitis
  - Gallstones, ascending cholangitis

 **TREATMENT**

**PRE HOSPITAL**

- Assess and stabilize airway, breathing, and circulation (ABCs):
  - Administer supplemental oxygen, preferably by nonrebreather mask.
- Needle decompression (if tension pneumothorax suspected)

**INITIAL STABILIZATION/THERAPY**

- Manage ABCs:
  - Administer supplemental oxygen, preferably by nonrebreather mask:
    - This increases the rate of air resorption.
  - Establish large-bore IV access.
  - Cervical spine immobilization as appropriate
  - Consider positioning upright if lumbar spine has been cleared for injury.
  - Consider analgesia.
- Tension pneumothorax:
  - Needle decompression:
    - Performed at 2nd anterior intercostal space, midclavicular line
  - Tube thoracostomy:
    - Definitive therapy
    - If hemodynamically stable, consider procedural sedation.
    - Locate the 4th to 5th intercostal space and anterior midaxillary line.
    - Insert an appropriately sized chest tube.
    - Connect the tube to an underwater seal and vacuum device (inspect for air bubbles and/or blood).
    - Obtain CXR for confirmation of position.

- Open pneumothorax:
  - Consider intubation.
  - Occlusive flap-valve dressing (taped on 3 sides) to allow air to escape
  - Tube thoracostomy (see above)
- Simple pneumothorax:
  - Observation:
    - May be considered with a smaller (<25%) pneumothorax
    - Inpatient monitoring for young children and secondary spontaneous pneumothoraces
  - Needle aspiration:
    - Consider if larger (>25%) or for respiratory distress.
    - Simple pneumothorax, even if large, may be treated with needle aspiration and observation without initial tube thoracostomy.
  - Tube thoracostomy (see above):
    - Definitive therapy
    - Especially useful for recurrent spontaneous pneumothorax or failed aspiration
    - Consider an alternative small-bore pigtail catheter (6.5–10.5 French) using a modified Seldinger technique:
      - Potentially less painful, smaller scar
- Pneumomediastinum:
  - Conservative management with supplemental oxygen and analgesia
  - Mediastinotomy:
    - Performed by surgery if tension pneumomediastinum develops (rare)

**DISPOSITION**

**Admission Criteria**

- All secondary spontaneous pneumothoraces and pneumomediastinum require inpatient management.
- Critical care admission criteria:
  - Tension or open pneumothorax
  - Unstable simple pneumothorax or pneumomediastinum
  - Unstable vital signs:
    - Mechanical ventilation

**Discharge Criteria**

Older children with smaller (<25%) resolving primary spontaneous pneumothorax may be discharged:

- Only if good supervision and follow-up

 **FOLLOW-UP**

**FOLLOW-UP RECOMMENDATIONS**

- Discharge instructions and medications:
  - Return for any respiratory distress or increasing chest pain.
  - Adequate analgesia
- Activity:
  - Avoid strenuous activity, Valsalva maneuvers, scuba diving, and inhalational drug abuse.

**PROGNOSIS**

Early recognition and prompt management yield better prognoses.

**COMPLICATIONS**

- Cardiopulmonary arrest
- Hemopneumothorax, pneumopericardium
- Tension pneumomediastinum
- Pneumoperitoneum, empyema

- Trauma, Chest
- Trauma, Penetrating

 **CODES**

- ICD9**
- 512.0 Spontaneous tension pneumothorax
  - 512.8 Other spontaneous pneumothorax
  - 860.0 Traumatic pneumothorax without mention of open wound into thorax

**PEARLS AND PITFALLS**

- Pearls:
  - Tension pneumothorax should be rapidly decompressed without delay.
  - If a nonoccluded pneumothorax, smaller size tubes, such as a pigtail, are preferred for thoracostomy.
- Pitfalls:
  - When performing the FAST, scan several locations on the anterior chest wall since US can only identify a pneumothorax directly beneath the probe when it is small.

David J. Story  
Sari Soghoian

## BASICS

### DESCRIPTION

- Poison ivy, oak, and sumac are related members of the *Toxicodendron* genus:
  - The genus previously was named *Rhus*.
- The plants cause an allergic contact phyto dermatitis caused by oleoresins containing urushiol.
- Lesions are often linear, erythematous, and vesicular.
- It is a type IV hypersensitivity reaction that requires prior exposure and sensitization
- All parts of the plant contain the toxin.
- Person to person transmission can occur:
  - Also can be transferred by fomites, including nonwashed clothing, gloves, gardening tools, etc.

### EPIDEMIOLOGY

- 60–85% of the population is sensitized.
- Toxic species do not grow in the desert, >4,000 ft elevation, Alaska, or Hawaii.

### RISK FACTORS

- Living in wooded areas
- Pet ownership
- Hiking, camping
- Gardening

### GENERAL PREVENTION

- Barrier protection
- Avoidance of the plant: Classic mnemonic “leaves of three, let them be.”
- Decontamination: Wash skin with soap and water within 1–2 hr of exposure.
- Avoid a burning plant, as toxin can be inhaled leading to a severe systemic reaction.

### PATHOPHYSIOLOGY

- Urushiol is presented to the Langerhans cells in the skin after the initial exposure:
  - Urushiol is contained in other plants, such as mango, Indian marking nut, cashew shells, and Burmese lacquer tree. Exposure to these may cause illness identical to poison ivy.
- Langerhans cells present the antigen to the T cell, which then proliferates in the form of memory T cells.
- Re-exposure to the antigen triggers the activation of memory T cells, releasing interleukins, histamine, and interferons.
- Release of these substances causes the symptoms of *Toxicodendron* dermatitis.
- Lesions may appear hours after exposure.
- Lesions may continue to appear for weeks after exposure.

### ETIOLOGY

- *Toxicodendron rydbergii*: Western poison ivy
- *Toxicodendron radicans*: Poison ivy
- *Toxicodendron pubescens*: Eastern poison oak
- *Toxicodendron diversilobum*: Western poison oak
- *Toxicodendron vernix*: Poison sumac
- Nontoxicodendron plants, such as mango, cashew shell, Indian marking nut, Burmese lacquer tree

### COMMONLY ASSOCIATED CONDITIONS

Hypoxia/Acute lung injury if inhaled

## DIAGNOSIS

### HISTORY

- Exposure to *Toxicodendron* species:
  - Outdoor activities in the last several days
  - Prior episode of *Toxicodendron* dermatitis
- Intense pruritus and erythema are typical.

### PHYSICAL EXAM

- Assess airway and breathing that may be compromised due to inhaled allergen:
  - Wheezing, stridor, dyspnea, or respiratory insufficiency
- Pruritic rash along exposed body areas:
  - Rash is usually vesicular; may also be bullous, papular, or linear lesions
  - Erythema is invariably present.
- Rash may sometimes be severe, with extensive weeping lesions with associated skin breakdown.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

- None routinely necessary. The diagnosis is clinical.
- In rare cases of respiratory symptoms or acute lung injury, blood gas analysis may be useful.

##### Imaging

- None necessary. The diagnosis is clinical.
- In rare cases of respiratory symptoms or acute lung injury, CXR may be useful.

##### Pathological Findings

Erythema multiforme is a rare presentation.

### DIFFERENTIAL DIAGNOSIS

- Nontoxicodendron contact dermatitis
- Cellulitis
- Anaphylaxis, allergic reaction
- Photosensitivity

## TREATMENT

### PRE HOSPITAL

Clean hands and affected areas with soap and water.

### INITIAL STABILIZATION/THERAPY

- Assess and stabilize airway, breathing, and circulation:
  - Rarely, respiratory compromise may occur, most typically due to inhalation of smoke and particles from burning *Toxicodendron* species plants.
- Decontaminate skin of any remaining sap or plant particles if present.

### MEDICATION

#### First Line

- Topical medications: Use small amounts locally for duration of dermatitis:
  - Calamine or Caladryl lotion
  - Hydrocortisone cream 2.5% which is mild potency
  - Mometason cream 0.1%, which is a moderate potency steroid dosed once daily
- IvyBlock: Topical cream that contains bentoquatam, which binds urushiol in the tissue:
  - Must be applied before or immediately after exposure, prior to T-cell activation
- Oral antihistamine—sedating:
  - Nonsedating agents are less effective than sedating antihistamines but have benefit of less sedation.
  - It is reasonable to prescribe nonsedating medication for regular dosing with sedating antihistamine used PRN.
  - Diphenhydramine 5 mg/kg/day PO/IV divided q6h
  - Hydroxyzine 2–4 mg/kg/day PO divided q6h
- Oral antihistamine—nonsedating:
  - Loratadine: 2–5 yr of age, 5 mg PO daily; >5 yr, 10 mg PO daily
  - Cetirizine: 6–24 mo of age, 2.5 mg PO daily; 2–5 yr, 5 mg/day PO divided q12h; >5 yr, 5–10 mg PO daily
  - Fexofenadine: 2–11 yr of age, 30 mg PO b.i.d.; >12 yr, 60 mg PO b.i.d. or 180 mg PO daily
- Oral antihistamine H2:
  - Cimetidine 20 mg/kg PO/IV q12h
  - Ranitidine 2–4 mg/kg/d IV/PO divided q6–8h

**Second Line**

Corticosteroids may be necessary for severe reactions, particularly with severe skin breakdown or intractable pruritus or when the reaction is beyond a localized rash:

- Prednisone 1–2 mg/kg PO × 3–7 days or may give for 10–14 days with taper

**COMPLEMENTARY & ALTERNATIVE THERAPIES**

- Oatmeal baths
- Domeboro: Aluminum sulfate astringent
- Burow solution: Aluminum acetate astringent

**DISPOSITION****Admission Criteria**

- Respiratory symptoms: Wheezing, shortness of breath
- Severe generalized rash involving a large body surface area
- Inability tolerating food/drink
- Critical care admission criteria:
  - Severe respiratory symptoms or pulmonary injury requiring intubation

**Discharge Criteria**

- Most patients can be safely discharged from the emergency department.
- Patients without issues requiring admission should be discharged with home treatment.

**FOLLOW-UP****FOLLOW-UP RECOMMENDATIONS**

Discharge instructions and medications:

- Primary care provider follow-up as needed
- Barrier protection in outdoors
- Rapid washing of contaminated skin with soap and water following exposure can reduce or prevent the reaction.
- Wash all possibly contaminated clothing in soap and hot water.

**Patient Monitoring**

Monitor for development of secondary infection (cellulitis and/or abscess)

**DIET**

No dietary modifications are typically necessary:

- Mango, cashews, and pistachios contain urushiol.
  - Avoid exposure to these foods during severe acute reaction.
  - Consider avoiding these foods in patients with severe or life-threatening allergy.

**PROGNOSIS**

Limited dermatitis, completely resolves in 3 days to 3 wk

**COMPLICATIONS**

- Cellulitis
- Conjunctivitis
- Scarring
- Permanent hyperpigmentation

Contact Dermatitis

**ICD9**

692.6 Contact dermatitis and other eczema due to plants (except food)

**PEARLS AND PITFALLS**

- Although treatment is generally supportive, occasionally patients will present with severe systemic symptoms requiring hospitalization.
- Illness from poison ivy is due to chemical urushiol. This is contained in numerous other plants that cause identical illness, such as mango skin, cashew nut shell, Indian marking, nut, and Burmese lacquer tree.
- Plant resin should be thoroughly cleaned from the body, including from under fingernails.
- Fomites may be a source of ongoing exposure to urushiol. Ensure that any clothing or other materials are thoroughly washed after *Toxicodendron* exposure.
- Areas with loose, pendulant skin having the ability to stretch, such as penile skin, may become remarkably swollen.

# POLYCYSTIC KIDNEY DISEASE

Pradeep Padmanabhan

## BASICS

### DESCRIPTION

Polycystic kidney disease (PKD) is an inherited disorder marked by formation of renal cysts, either unilateral or bilateral, with variable compromise of renal function.

### EPIDEMIOLOGY

#### Incidence

- The incidence of autosomal dominant polycystic kidney disease (ADPKD), the most common inherited renal disease in children, is between 1/500 and 1/1,000 (1).
- The autosomal recessive polycystic kidney disease (ARPKD) variety is at least 10 times less common (2).

### PATHOPHYSIOLOGY

- ADPKD develops from genetic mutations involving the short arm of chromosome 16 (PKD1 gene), affecting the production of the transmembrane glycoprotein, polycystin, and the long arm of chromosome 4 (PKD2 gene), affecting polycystin 2:
  - These mutations account for >90% of children with ADPKD (3).
  - Children with the ADPKD2 gene present at an older age and have a milder course.
- ARPKD can be a result of mutations of genes encoding fibrocystin, which may be involved in the ciliary function in the kidneys:
  - Congenital hepatic fibrosis (biliary dysgenesis and periportal fibrosis) is always present in ARPKD.
- In both ADPKD and ARPKD, cysts develop in both cortex and medulla in the entire nephron.
- The variability in severity in PKD is influenced by both modifier genes and environmental factors.

### ETIOLOGY

Genetic: PKD is inherited as either autosomal recessive or dominant.

### COMMONLY ASSOCIATED CONDITIONS

- Osteodystrophy
- Nephrolithiasis

## DIAGNOSIS

### HISTORY

- ADPKD:
  - Typically, there are no symptoms until adulthood.
  - Less commonly, children and infants can present with abdomen pain, gross hematuria, or symptoms suggestive of urinary tract infection.
- ARPKD:
  - Failure to thrive and poor weight gain may be apparent in association with severe renal disease.
  - Can present with respiratory distress at birth or soon after due to pulmonary hypoplasia
  - Polydipsia and polyuria due to a concentrating defect can be present.

### PHYSICAL EXAM

- Vital signs may indicate HTN.
- Abdominal masses and hernias can be present in ADPKD.
- Characteristic facial features (Potter facies) in ARPKD in the newborn resulting from oligohydramnios:
  - Low-set ears
  - Flat nose
  - Retracted chin
- The decreased thoracic dimensions from oligohydramnios results in pulmonary hypoplasia with hypoxia and respiratory distress.
- Neonates with ARPKD presenting with respiratory distress often have large palpable abdomen masses.
- GI bleeding, ascites, and other features of hepatic fibrosis–induced portal HTN in older children are characteristic of ARPKD.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

- Urinalysis may identify pyuria or microscopic hematuria in children with ADPKD.
- Mild proteinuria may be present in up to 20% of children (4).
- Renal function and electrolyte abnormalities can be ascertained by the metabolic panel.
- Hyperlipidemia may be noted in up to 50% of children with ADPKD (1).

#### Imaging

- Renal US is the initial test of choice in PKD. Hyperechoic, bilaterally enlarged kidneys with cysts is diagnostic of PKD, especially if there is a family history of polycystic kidneys:
  - When there is a high pretest probability, a single cyst can be considered diagnostic.
  - Cysts may be unilateral initially.
  - Renal US alone cannot differentiate between ADPKD and ARPKD.
  - Initially, renal cysts may be absent in children <5 yr of age.
  - Infants may present with large hyperechoic kidneys without cysts.
  - Cysts may be noted in other solid intra-abdominal organs (liver, pancreas, and spleen) in ADPKD, unlike ARPKD.
- ARPKD may be associated with additional cysts in the biliary tree.
- US of asymptomatic parents may show renal cysts. This can help establish the diagnosis of ADPKD in symptomatic children when the family history is negative for PKD.
- Prenatal US can identify enlarged kidneys, with or without the presence of cysts; oligohydramnios signifies renal insufficiency.

- Echo may reveal left ventricular hypertrophy or, less commonly, mitral valve prolapse.
- Spontaneous pneumothorax, which may occur in ARPKD, may be noted by chest radiograph.
- Radionuclide renal scans can assess the functional status of the kidneys.
- CT scan or MRI may be useful if children have pain or evidence of infection since they are more sensitive than US in identifying abscess, hemorrhage, or stones.

### Diagnostic Procedures/Other

- Prenatal genetic testing is available and can identify ADPKD in families with known specific genetic mutations. Genetic testing by direct mutational analysis is essential to identify ADPKD early, as cysts usually present later in life.
- When renal cysts become infected, blood cultures are more likely than urine cultures to yield a pathogen.

### DIFFERENTIAL DIAGNOSIS

- Multicystic dysplastic kidney is not inherited, commonly unilateral, and characterized by absence of renal function:
  - In contrast to PKD, bilateral involvement can be fatal.
  - Cystic dysplasia can also be differentiated by reduced kidney size, altered shape, and other renal malformations.
- Medullary cystic kidney can be differentiated from PKD by the normal or smaller size of the affected kidneys.
- Inherited autosomal dominant disorders such as tuberous sclerosis or von Hippel-Lindau are associated with renal cysts.
- Meckel: Gruber syndrome consists of polycystic kidney, encephalocele, biliary dysgenesis, and polydactyly.
- Acquired cystic disease in children with chronic renal disease can be distinguished from PKD by the presence of small kidneys, absence of cysts in other organs, and negative family history.

## TREATMENT

### INITIAL STABILIZATION/THERAPY

- Children with ARPKD may present with end-stage renal failure at birth or at any time during childhood.
- Children with renal failure are at risk for pulmonary edema and dysrhythmias. Initially, the focus should be on supporting the airway, breathing, and circulation.

**MEDICATION**

- Acute and severe HTN in the emergency department must be treated. Options include:
  - Labetalol: 0.25–0.4 mg/kg IV over 1–2 min, max single dose 20 mg/dose; peaks 5–10 min and lasts 2–3 hr
  - Hydralazine: 0.1–0.5 mg/kg IV, max single dose 20 mg/dose; peaks 10–30 min and lasts 4–12 hr; may repeat in 15 min.
- Chronic HTN should be identified early and treated with drugs acting on the renin-angiotensin mechanism (angiotensin-converting enzyme [ACE] and angiotensin II inhibitors):
  - ACE inhibitors slow disease progression and decrease proteinuria (5):
    - Lisinopril:  $\geq 6$  yr of age, 0.07 mg/kg (up to 5 mg total) PO once daily, max single dose 0.60 mg/kg/day or 40 mg/day
  - Angiotensin II inhibitors have a better side effect profile than ACE inhibitors (eg, losartan [ $\geq 6$  yr of age], 0.7 mg/kg orally once daily, max single dose 50 mg daily)
  - Children with ARPKD may require medications even during infancy.
- Since vasopressin has been found to be elevated in ADPKD when HTN is present, newly developed vasopressin receptor antagonists may also have a role in slowing disease progression in the future.

**SURGERY/OTHER PROCEDURES**

Dialysis or kidney transplantation is indicated for end-stage renal disease.

**FOLLOW-UP****FOLLOW-UP RECOMMENDATIONS**

- When a positive family history exists, annual screening for HTN in asymptomatic children is recommended.
- Repeated US are also indicated, perhaps annually. In a large cohort study, kidneys enlarged rapidly in children with ADPKD compared to normal population. The increase in size was more prominent among those with HTN (6).

**PROGNOSIS**

- ARPKD can be fatal in utero or immediately after birth from pulmonary hypoplasia and respiratory failure. ARPKD with pulmonary hypoplasia is invariably fatal.
- In ARPKD, children who survive beyond the neonatal period have an 80% chance of survival beyond 15 yr of life (2).

- The prognosis in ADPKD is usually excellent. However, the identification of cysts in utero or in the newborn period, early enlarged kidneys, proteinuria, and presence of HTN adversely impact the prognosis.
- HTN usually presents in adolescence.
- Even though rupture of an intracranial aneurysm can be devastating, its incidence is extremely rare in children.

**COMPLICATIONS**

- Renal failure
- HTN
- Hyperkalemia
- Metabolic acidosis
- Pulmonary edema
- Peripheral edema
- Hematuria
- Pyelonephritis

**CODES****ICD9**

- 753.12 Polycystic kidney, unspecified type
- 753.13 Polycystic kidney, autosomal dominant
- 753.14 Polycystic kidney, autosomal recessive

**PEARLS AND PITFALLS**

- With PKD, HTN and urinary tract infections should be treated aggressively to slow disease progression.
- Evaluate for pneumothorax in neonates with cystic kidneys and signs of respiratory distress.
- Hypertensive children with ADPKD who present with changes in mental status or severe headache should be evaluated for cerebral aneurysms with MRI. However, routine imaging is not indicated, as aneurysms are extremely rare in childhood.
- Avoid nephrotoxic drugs in children with PKD, including prolonged or frequent use of NSAIDs.

# POLYCYSTIC OVARIAN SYNDROME

Raemma Paredes Luck

## BASICS

### DESCRIPTION

- Polycystic ovarian syndrome (PCOS) is a heterogenous disorder affecting reproductive and endocrine systems of women of child-bearing age:
  - Previously known as Stein-Leventhal disease or Stein-Leventhal syndrome
- The diagnosis of PCOS rests on the presence of at least 2 of the following findings (1):
  - Irregular menstrual cycles
  - Hyperandrogenism
  - Polycystic ovaries not resulting from other disorders
- Most common cause of infertility in women
- Most common endocrine abnormality in young women (2)

### EPIDEMIOLOGY

- PCOS is seen in 5–8% of women in their reproductive age (2).
- PCOS typically presents soon after menarche.
- The prevalence rate between black and white women is similar.
- The majority of women with PCOS are undiagnosed.

### RISK FACTORS

Prepubertal risk factors that are more common in patients with PCOS include:

- Congenital virilizing disorders
- Exaggerated and premature adrenarche
- Atypical sexual precocity
- Intractable obesity with acanthosis nigricans or metabolic syndrome
- Pseudo-Cushing or pseudoacromegaly in early childhood

### PATHOPHYSIOLOGY

- The disorder results from a derangement of the hypothalamic-pituitary-ovarian axis that produces an increase in luteinizing hormone (LH) secretion and excessive androgen production:
  - Elevated androgen levels, mainly testosterone, causes most of the constellation of symptoms.
  - Insulin resistance is also present in almost all patients with PCOS, regardless of their weight (3).
- Diagnosis includes combination of:
  - Cutaneous signs of hyperandrogenism (eg, hirsutism, severe acne, and/or pattern alopecia)
  - Menstrual irregularity; amenorrhea, oligomenorrhea, dysfunction uterine bleeding
  - Polycystic ovary
  - Obesity and insulin resistance

### ETIOLOGY

- Anovulation with elevated levels of androgens produced from ovaries
- Numerous causes of anovulation:
  - Obesity
  - Psychological
  - Medication induced

### COMMONLY ASSOCIATED CONDITIONS

- 37% of adolescent women with PCOS also have the metabolic syndrome (4).
- The metabolic syndrome should be considered if a patient has at least 3 of the following conditions:
  - Obesity
  - BP > 130/85 mm Hg
  - Fasting blood sugar > 110 mg/dL
  - Triglyceride levels > 150 mg/dL
  - Low HDL cholesterol < 50 mg/dL in women
- 10% of PCOS patients have type 2 diabetes mellitus (DM) (5).
- 50% of PCOS patients have nonalcoholic fatty liver disease (6).

## DIAGNOSIS

### HISTORY

- Menstrual problems:
  - Primary amenorrhea (lack of menarche by 15 yr of age)
  - Oligomenorrhea (missing >4 periods per year or >90 days without a menstrual period) after initially menstruating
- Excessive hair in secondary male distribution: On lower face and neck, sideburns, chest, abdomen, and inner thighs
- Persistent and treatment-resistant acne:
  - Sometimes the sole sign of hyperandrogenism
- Precocious puberty may be reported.
- Rapid weight gain with central truncal obesity:
  - Obesity often is the initial presenting complaint.

### PHYSICAL EXAM

- Assess vital signs, including weight and BP
- Obesity.
- Signs of androgen excess:
  - Hirsutism in secondary/sexual pattern of males, including on face, abdomen, legs
  - Alopecia: Typically occurs after long period of PCOS; may be absent in teenagers
  - Acne
- Polycystic ovaries may be palpated.
- Thinning of hair, especially in anterior and midline scalp, is seen in 1/2 of women with PCOS (7).
- Signs of insulin resistance:
  - Central abdominal adiposity
  - Acanthosis nigricans

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

- Hormone levels:
  - Follicle-stimulating hormone is normal or low.
  - LH is elevated.
- Elevated androgen levels:
  - Testosterone is elevated; may measure free testosterone or total testosterone.
  - Androstenedione is elevated.
- Evaluation of alternate causes of hyperandrogenism should also be initiated:
  - Elevated prolactin level is seen in patients with pituitary adenoma.
  - Elevated dehydroepiandrosterone sulfate (DHEAS) and 17-alpha-hydroxyprogesterone suggests adrenal tumors and adrenal hyperplasia as potential causes of the hyperandrogenism.
  - Abnormal thyroid function, cortisol levels, or insulin growth factor 1 suggests other etiologies of the androgen excess.
- Obtain lipid profile (total cholesterol, triglycerides, HDL, LDL) and fasting glucose level.

##### Imaging

- Transvaginal US may show:
  - Ovarian volume increased > 10.5 mL (3)
  - Polycystic ovaries:
    - > 12 follicles per ovary
    - Best performed in the 1st wk after menses
    - Polycystic ovaries may be seen in up to 23% of women without PCOS (8).
- Transabdominal US, as might be performed in virginal adolescents, is not as sensitive as transvaginal US.

##### Diagnostic Procedures/Other

Dexamethasone suppression test can be used to distinguish an adrenocorticotropin hormone–dependent adrenal source of androgens from other sources.

##### Pathological Findings

Polycystic ovaries are typically found, though this takes several years to develop:

- Might not yet be present in initial years after menarche

### DIFFERENTIAL DIAGNOSIS

- Late-onset congenital adrenal hyperplasia, from mild 21-hydroxylase deficiency, is the 2nd most common cause of androgen excess after PCOS.
- Cushing syndrome
- Androgen-producing tumors
- Hyperprolactinemia
- Medications such as anabolic corticosteroids and valproic acid can increase androgens.
- Medications increasing hirsutism: Glucocorticoids, phenytoin, diazoxide, or cyclosporine
- Hyperglycemia: DM
- Amenorrhea: Pregnancy
- Ovarian mass: Tubo-ovarian abscess, ovarian torsion, ovarian cyst

## TREATMENT

### MEDICATION

#### First Line

Combination oral contraceptive pills (OCPs), containing nonandrogenic progestin and estrogen, are the first-line medication in the treatment of PCOS:

- OCPs regulate the menstrual cycle and lower androgen levels, thereby improving hirsutism and acne (9).
- Ethinyl estradiol, in combination with a progestin component, is the most commonly prescribed OCP.
- There are >30 OCP formulations available in the U.S., and no single formulation has been found to be superior for the treatment of PCOS.
- The specific OCP choice should be discussed with a gynecologist or endocrinologist.

#### Second Line

- Metformin, which suppresses hepatic glucose production, may be used to treat insulin resistance associated with PCOS:
  - 500 mg orally b.i.d., max single dose 1 g
- Spironolactone is a diuretic medication. It has an idiosyncratic action as an antiandrogen; therefore, it may be used to treat hirsutism:
  - 1.5–3 mg/kg/day PO t.i.d.
- Initiation of metformin and spironolactone therapy should be made only after consultation with a gynecologist or endocrinologist.

### SURGERY/OTHER PROCEDURES

Shaving, bleaching, depilatory agents, laser therapy, or electrolysis can be used to remove unwanted hair.

### DISPOSITION

#### Admission Criteria

- Most patients with PCOS are managed on an outpatient basis.
- Admission may be warranted to expedite an evaluation definitive diagnosis or for complications of HTN or diabetes.

#### Issues for Referral

- Patients with PCOS should be referred to an endocrinologist for further management of the metabolic and hormonal abnormalities and to rule out other causes of hyperandrogenism.
- Referral to the gynecologist is indicated in patients with irregular menstrual cycles, dysfunctional uterine bleeding, or infertility.

## FOLLOW-UP

### FOLLOW-UP RECOMMENDATIONS

#### Patient Monitoring

- Patients should be regularly assessed for the development of HTN, diabetes, metabolic syndrome, and uterine cancer.
- Monitor electrolytes, lipid profile, and hemoglobin levels of patients who are on medications.

#### DIET

Lifestyle modification, including weight reduction, exercise, and smoking cessation, in conjunction with pharmacologic therapy is important in the long-term management.

#### COMPLICATIONS

- Amenorrhea
- Dysfunctional uterine bleeding
- Hirsutism
- Obesity
- Infertility
- Type 2 DM
- Metabolic syndrome:
  - HTN
  - Coronary artery disease
  - Stroke
- Endometrial and ovarian carcinomas (11)
- Breast cancer (postmenopausal)
- Psychiatric/Psychologic sequelae from cosmetic effects

Amenorrhea

ICD9  
256.4 Polycystic ovaries

### PEARLS AND PITFALLS

- PCOS is a syndrome with variable clinical presentations and may be difficult to recognize.
- PCOS should be considered in any adolescent with amenorrhea or irregular menstrual cycles, hirsutism, acne, or obesity.
- Adolescents with PCOS should be monitored for type 2 DM as well as the metabolic syndrome and its cardiovascular complications.
- Lack of hyperandrogenism rules out the diagnosis of PCOS.
- Ovarian hyperandrogenism of PCOS may not be evident until several years after menarche.

# POLYCYTHEMIA

Jennifer R. Marin

## BASICS

### DESCRIPTION

- Polycythemia, also known as erythrocytosis, is elevation of hemoglobin (Hgb) and hematocrit (Hct) caused by an excessive number of erythrocytes (1).
- Strictly defined, it is an absolute increase in RBC mass.
- It is characterized as either primary or secondary, which can be further distinguished as either congenital or acquired.
- Symptoms of hyperviscosity may typically manifest at Hct >55%.

### EPIDEMIOLOGY

- Neonatal polycythemia is the most common cause of polycythemia in the pediatric population:
  - 1–5% of all newborns in the U.S. have secondary acquired polycythemia (2,3).
- Polycythemia is an uncommon diagnosis in children, particularly the primary forms.
- Polycythemia vera is the most common form after the neonatal period.
- Rare mutations may result in high oxygen affiliation hemoglobinopathy causing polycythemia.

### RISK FACTORS

- Genetic
- Infants of diabetic mothers
- Large for gestational age newborns
- Intrapartum hypoxia
- Delayed clamping of the umbilical cord
- Cardiac disease
- Pulmonary disease
- Hemoglobinopathies

### PATHOPHYSIOLOGY

- Primary polycythemia: RBC compartment expands independent of extrinsic influences (1):
  - Primary familial and congenital polycythemia (PFCP) is caused by mutations in the EPO receptor gene.
  - Rare autosomal dominant disorder
  - Polycythemia vera is extremely rare in children (only 30 children have been described to date [3]) and is characterized by the clonal expansion of precursor cells in the blood.
  - Initially a proliferative phase with increase in all cell lines followed by a stable phase with normal values, then a “spent” phase with marrow fibrosis and pancytopenia
- Secondary polycythemia: Tissue hypoxia and commonly increased EPO (1):
  - Congenital forms of secondary polycythemia includes many identified Hgb variants with increased oxygen affinity.
  - Acquired secondary polycythemia seen in hypoxic states: Cardiac, pulmonary, renal, and hepatic diseases, chronic carbon monoxide exposure or heavy smoking, androgenic corticosteroid use, and with EPO-producing tumors.

- Neonatal polycythemia results from delayed cord clamping, intrapartum hypoxia, or increased erythropoiesis:
  - Infants of diabetic mothers, large for gestational age, or with endocrine or chromosomal abnormalities are at risk.

### ETIOLOGY

- Neonatal conditions:
  - Delayed cord clamping
  - Twin-twin transfusion
  - Maternal-fetal transfusion
  - Infant of a diabetic mother
  - Maternal heart disease
  - Placental insufficiency
  - Intrauterine growth retardation
  - Trisomy 21, 13, 18
  - Beckwith-Wiedemann syndrome
- Hypoxia:
  - Altitude
  - Cardiac disease
  - Pulmonary disease
- Hemoglobinopathy:
  - High oxygen affinity mutation
  - Chronic carbon monoxide exposure
- Hormonal:
  - Wilms tumor, adrenal tumors
  - Congenital adrenal hyperplasia
  - Cushing syndrome
  - Hypo/hyperthyroidism
  - Medication: Anabolic steroids, EPO
- Familial, congenital
- Performance enhancement/abuse: Blood doping, anabolic steroid use, EPO use
- Other: Renal transplant

## DIAGNOSIS

### HISTORY

- In neonates, delayed cord clamping, multiparous gestation, especially with disparate twin size
- In older children, a history of chronic heart or pulmonary disease may be reported.
- Time spent at high altitude, especially >5,000 feet
- Family history of polycythemia
- Many children with chronic polycythemia will be asymptomatic.
- Neurologic symptoms are most concerning:
  - Headache
  - Vertigo, dizziness
  - Paresis, paralysis, paresthesia
  - Cranial nerve deficit
- Various symptoms may be reported:
  - Weight loss
  - Weakness or malaise
  - Skin: Pruritus, bruising, red appearance, pain/burning in hands/feet, ulcerations in hands/fingers/toes/feet
  - Diaphoresis
  - Dyspnea
  - Other central neurologic symptoms that may be associated with stroke

### PHYSICAL EXAM

- Assess vital signs with attention to cardiovascular stability.
- Thorough neurologic exam to detect any CNS findings associated with stroke
- Skin plethora (especially the face) or a ruddy complexion
- Conjunctival plethora
- Splenomegaly may be present.
- In acquired secondary polycythemia, there may be features associated with the primary ailment (eg, clubbing, murmur with congenital heart disease).
- Most affected infants will have no clinical signs of the condition:
  - Acrocyanosis poor peripheral perfusion or plethora, respiratory distress, irritability, lethargy, or poor feeding may be present (2).

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

#### ALERT

Capillary measurements of Hgb and Hct are unreliable to diagnose polycythemia. If normal, these measurements may be used. If elevated Hgb or Hct results from a fingerstick or heelstick, a venous sample should be obtained before a diagnosis of polycythemia is considered.

#### Initial Lab Tests

- CBC: Age-specific Hgb and/or Hct values >2 standard deviations above the mean or >97th percentile in 2 separate samples (1):
  - Neonatal polycythemia: Hct  $\geq$ 65% or higher (2,4)
  - Relative polycythemia will occur with hypovolemia:
    - Consider when interpreting Hct in a child with dehydration.
    - This will correct with fluid resuscitation (1).
  - Thrombocytosis may also occur with polycythemia vera.
- Neonates may have associated hyperbilirubinemia, thrombocytopenia, and/or hypoglycemia (2,3).
- If polycythemia is present, testing to determine etiology is necessary:
  - SpO<sub>2</sub> <92% indicates a causal relationship with polycythemia and should prompt further evaluation into cardiopulmonary disorders (1).
  - Elevated serum EPO levels usually indicate secondary erythrocytosis.
    - EPO levels below the normal range suggest a primary polycythemia.
- Bedside glucose assessment in neonates
- Electrolyte, BUN, creatinine
- Urinalysis to evaluate for renal disease

#### Imaging

In the appropriate setting, consider:

- Echo: Cardiac shunting
- CXR: Pulmonary disease
- Abdominal sonography: Renal disease, splenomegaly

**Diagnostic Procedures/Other**

Bone marrow biopsy may be helpful to differentiate polycythemia vera from other myeloproliferative disorders.

**Pathological Findings**

Bone marrow histology can confirm the diagnosis of polycythemia vera if predominating erythroid and megakaryocyte proliferation are present (1).

**DIFFERENTIAL DIAGNOSIS**

Relative erythrocytosis: Decreased plasma volume (dehydration)

**TREATMENT****INITIAL STABILIZATION/THERAPY**

- Assess and stabilize airway, breathing, and circulation.
- Fluid administration to treat dehydration and decrease blood viscosity
- Emergent phlebotomy to treat hyperviscosity syndrome
- Severe complications, such as stroke, should be detected and treated immediately.
- Consider supplemental oxygen unless contraindicated.
- Investigation for other causes of the observed symptoms should be investigated (3):
  - If there is a relative polycythemia, the child should be resuscitated with IV normal saline to restore euolemia.

**MEDICATION****First Line**

- Fluid resuscitation with an initial bolus of 20 mL/kg normal saline:
  - Therapeutic in the setting of dehydration as well as elevated Hct/hyperviscosity
  - Repeated fluid administration is typically indicated.
- Hypoglycemia (see Hypoglycemia topic):
  - Infants are prone to hypoglycemia. Patients with a normal level of consciousness should drink simple carbohydrates such as juice or glucose gel immediately. If hypoglycemia does not improve, they should receive parenteral glucose immediately.
- 10% dextrose 5 mL/kg IV q5–10min PRN:
  - Preferred for infants
  - Higher concentrations of dextrose, such as D50 and D25 may cause phlebitis if prolonged infusion or tissue damage if extravasated.
- Administer supplemental oxygen if hypoxic.

**Second Line**

Aspirin:

- Only used in the absence of hemorrhagic complications or any findings suggestive of a viral syndrome.
- May reduce thrombotic events in those with primary polycythemia.
- For younger children, consult a pediatric hematologist.

**COMPLEMENTARY & ALTERNATIVE THERAPIES**

Antineoplastic medications may rarely be indicated: Hydroxyurea, imatinib, interferon-alpha:

- Only administer in consultation with a hematologist.

**SURGERY/OTHER PROCEDURES**

- Partial exchange transfusion: Combined phlebotomy with fluid replacement using normal saline:
  - Consultation with a neonatologist is strongly recommended before carrying out this procedure in an infant.
  - This procedure cannot be conducted by peripheral venous catheter in infants but can be conducted via  $\geq 22$ -gauge catheter in older children.
  - In infants, the procedure is typically performed via umbilical vessel catheter.
  - May be performed via femoral vein catheter or intraosseous needle
  - Performed in order to maintain a constant blood volume while decreasing Hct
  - Standard infant blood volume is 85 mL/kg.
  - Calculate the amount of normal saline to be used to replace blood removed to lower the Hct percent to the desired level, usually Hct 55%.
  - Volume to be exchanged (mL):
    - Estimated blood volume  $\times$  (patient Hct – desired Hct)  $\div$  patient Hct
  - Small aliquots of blood (3–10 mL) removed and replaced by the same volume of saline.
- Phlebotomy may be indicated in symptomatic disease with Hct  $> 55\%$ :
  - Perform with consultation of a hematologist.

**DISPOSITION****Admission Criteria**

- Consider admission of any patients with Hct  $> 60\%$  or neonates with hyperbilirubinemia, even if asymptomatic
- Critical care admission criteria:
  - Any patient with significant respiratory distress, neurologic issues, particularly stroke, or requiring exchange transfusion should be admitted to a critical care unit.

**Discharge Criteria**

Patients may be discharged home from the emergency department if they are stable and have appropriate follow-up.

**FOLLOW-UP****FOLLOW-UP RECOMMENDATIONS**

With the exception of asymptomatic neonatal polycythemia, patients should be referred to a hematologist for follow-up.

**COMPLICATIONS**

- Cerebrovascular accident
- Venous thrombosis
- Pulmonary embolus
- Hypoglycemia
- Neonates at risk for necrotizing enterocolitis, renal dysfunction, hyperbilirubinemia, hypoglycemia, increased pulmonary vascular resistance
- Bone marrow–related complications such as fibrosis

**ADDITIONAL READING****See Also (Topic, Algorithm, Electronic Media Element)**

- Cavernous Sinus Thrombosis
- Pulmonary Embolism
- Renal Vein Thrombosis
- Stroke

**ICD9**

- 289.0 Polycythemia, secondary
- 289.6 Familial polycythemia
- 776.4 Polycythemia neonatorum

**PEARLS AND PITFALLS**

- Neonatal polycythemia is the most common form of polycythemia.
- Polycythemia can lead to hyperviscosity syndrome, which can cause stroke and pulmonary embolism.
- Do not delay phlebotomy or partial exchange transfusion in symptomatic patients. Patient safety warrants consultation with a hematologist and, if appropriate, a neonatologist.
- Polycythemia vera is extraordinarily rare in children; therefore, always evaluate for a secondary cause of polycythemia.
- Dehydration may cause a relative or pseudopolycythemia.

# POLYURIA

Corrie E. Chumpitazi  
Manish I. Shah

## BASICS

### DESCRIPTION

- Polyuria results from a dysregulation in water balance leading to the excretion of large volumes of dilute urine.
- Defined as urine output  $>2 \text{ L/m}^2/24 \text{ hr}$  in children or  $2.5\text{--}3 \text{ mL/kg/hr}$ :
  - Functionally defined as inappropriately high urine output relative to circulating volume and osmolality
  - Increased urinary frequency in school-age children is defined as voiding more often than every 2 hr.
- Infants normally void between 6 and 30 times per day. Over the 1st 2 yr of life, the frequency of voiding decreases by 1/2 while the volume increases 4-fold. Children 3–5 yr of age void 8–14 times a day and after 5 yr of age void 6–12 times a day. Adolescents void 4–6 times a day.

### EPIDEMIOLOGY

#### Incidence

- Polyuria is a frequent complaint in the pediatric emergency department.
- Because most cases are secondary to another disease, the incidence depends on the primary cause.

### RISK FACTORS

- Urinary tract infection (UTI): See Urinary Tract Infection topic.
- Diabetes insipidus (DI): See Diabetes Insipidus topic.
- Diabetes mellitus (DM): Family history of type 1 DM (T1DM) significantly increases the risk by 2–8% if 1 parent is affected and up to 30% if both parents are affected (1):
  - Highest incidence of T1DM is in non-Hispanic Caucasian youths, followed by African American and Hispanic children.
  - Body mass index  $\geq 85$ th percentile is the greatest risk factor for development of type 2 DM (T2DM) as well as genetic risk, ethnicity, and insulin-resistant states (eg, puberty, polycystic ovary syndrome).
- Renal stones: Family history of renal stones is present in 16% of 1st-degree relatives and up to 33% if 2nd-degree relatives are considered as well (2).

### PATHOPHYSIOLOGY

- Bladder irritation: Infection, hemorrhage, chemical irritants, and renal stones induce frequent bladder spasms.
- Water overload: Increased free water intake results in increased excretion of free water from the kidneys.
- Increased glomerular filtration rate (GFR): An increase in renal circulation can increase GFR, such as in hypermetabolic states.
- Increased output of solutes: An increase in transport of solutes at the level of the glomerulus, such as glucose, sodium, and calcium, may lead to additional excretion of water.
- Decreased reabsorption of water in the distal renal tubule. This occurs either with an inadequate release of antidiuretic hormone (ADH) from the brain (central DI) or from the kidney's inability to respond to circulating ADH (nephrogenic DI).

### ETIOLOGY

- Water overload:
  - Primary (psychogenic) polydipsia: Increased water intake
- Increased GFR in hypermetabolic states:
  - Fever
  - Hyperthyroidism
  - Methylxanthine intake (caffeine, theophylline)
- Solute diuresis:
  - Glucose in DM, stress hyperglycemia
  - Calcium in hypercalciuria and hyperparathyroidism
  - Sodium bicarbonate in renal tubular acidosis, cystinosis, and Fanconi anemia
  - Sodium chloride in Barter syndrome and nephronophthisis
  - Direct effect on glomerulus receptors by medications such as carbonic anhydrase inhibitors (acetazolamide), thiazides (hydrochlorothiazide), loop diuretics (furosemide), and aldosterone antagonists (spironolactone)
- Decreased distal tubule reabsorption:
  - Central DI: Deficient secretion of ADH usually is acquired and idiopathic but rarely is caused by trauma, pituitary surgery, or hypoxic ischemic encephalopathy. Additionally, ethanol intake impairs ADH release.
  - Nephrogenic DI: Normal ADH but abnormal renal response. In children, it is most commonly X-linked recessive and manifests in males early in infancy. It may be acquired due to drug intake such as lithium.
- Structural malformations of the kidney: Obstructive uropathy, hydronephrosis, chronic pyelonephritis with reflux
- Chronic renal failure with concentration defect
- UTI
- Pregnancy
- Spinal cord pathology
- Constipation
- Ureteral or renal stones: Calcium oxalate and calcium phosphate calculi are the most common (3).

### COMMONLY ASSOCIATED CONDITIONS

Acanthosis nigricans with T2DM

## DIAGNOSIS

### HISTORY

- Rate of onset of polyuria
- Pattern of fluid intake including nighttime awakenings to drink
- Volume of urine output in a day
- Weight loss, poor growth, malaise, weakness in DM, diabetic ketoacidosis (DKA), or DI
- Fever, dysuria, or foul-smelling urine may indicate UTI.
- Last menstrual period and sexual history should be obtained to assess for pregnancy.
- History of polydipsia, polyphagia, weight loss, enuresis, nocturia, and lethargy suggest DM.
- Change in behavior or altered mental status (AMS) are concerning for DKA.

- Family history of DM and other autoimmune disorders such as rheumatoid arthritis, celiac disease, thyroid disease, and inflammatory bowel disease may be suggestive of DM.
- Medication history: Especially caffeine or diuretics
- Toileting habits to assess for constipation
- Failure to thrive, irritability, and low-grade fevers due to intermittent hyponatremia in infants with DI
- Signs of hypothalamic tumors: Headache, visual disturbances, growth changes, or sexual precocity

### PHYSICAL EXAM

- HEENT: Depressed anterior fontanelle (if present), sunken eyes, or dry mucous membranes suggest dehydration; visual field or optic disc abnormalities suggest of intracranial pathology
- Abdominal: Masses, renal enlargement, palpable bladder, palpable stool
- Genital: Irritation, adhesions, rash, stenosis, foreign bodies, trauma
- Rectal: Decreased anal sphincter tone, stool impaction
- Skin: Lumbosacral dimples, hairy patches, cutaneous dimples or tracts, acanthosis nigricans, lipomas, bruising, or signs of trauma
- Neurologic: Weak lower extremities, abnormal reflexes, AMS
- Back: Palpate for bony defects of the spine
- Extremity: Perfusion, capillary refill, skin turgor

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

- In most cases, urinalysis and bedside glucose are the only necessary tests:
  - Urine for specific gravity, urinalysis, microscopic exam. Dilute urine is seen with DI and primary polydipsia.
  - Bedside glucose: Polyuria occurs when serum glucose is  $\geq 180 \text{ mg/mL}$ .
- Electrolytes should be obtained if concern for DI or DKA:
  - Sodium  $> 145 \text{ mEq/L}$  in DI
  - Sodium  $< 137 \text{ mEq/L}$  in primary polydipsia
  - Pseudohyponatremia and hypo-/hyperkalemia may occur in the setting of DKA.
- If concern for DKA is present, stat blood gas is necessary to determine the need for insulin.
- Plasma and urine osmolality to determine the urine:plasma ratio: If  $> 0.7$ , indicates solute diuresis as seen in DM and intrinsic renal disease

#### Imaging

- Renal US should be performed to evaluate the presence of renal abscess or surgically correctable anatomic abnormalities or obstruction, if indicated.
- Noncontrast CT is the best imaging modality to detect urinary calculi.
- The following may be indicated after the emergency department evaluation (outpatient or inpatient evaluation):
  - Renal US and voiding cystourethrogram are recommended for girls  $< 3 \text{ yr}$  of age and all boys with a 1st UTI or if there is a family history of renal disease, abnormal voiding pattern, poor growth, HTN, or abnormalities of the urinary tract.
  - If central DI is suspected, MRI must be obtained to assess for pituitary masses, craniopharyngioma, or pinealoma.

## TREATMENT

### PRE HOSPITAL

- Bedside glucose
- IV fluids if dehydration is present

### INITIAL STABILIZATION/THERAPY

IV hydration as indicated

### MEDICATION

- UTI: Children requiring outpatient treatment for UTI may be discharged on antibiotics:
  - Cefixime 8 mg/kg/day divided q12–24r for 7 days, max single dose 400 mg/day
  - Amoxicillin or trimethoprim/sulfamethoxazole may be used if local pathogen resistance patterns warrant.
  - See the Urinary Tract Infection topic for further management details.
- DI: DDAVP (10  $\mu$ g intranasally or 0.2–0.3  $\mu$ g/kg SC may be used for central DI (4). See the Diabetes Insipidus topic for further management details.
- DKA: Insulin infusion 0.1 units/kg/hr. See the Diabetes Ketoacidosis topic for further management details.
- DM: Combination of long- and short-acting insulin given multiple times a day in conjunction with fingerstick glucose testing. See the Diabetes Mellitus topic for further management details.
- Renal stones: Pain management with NSAIDs or opioids, such as morphine 0.1 mg/kg IV/SC/IM repeated as necessary

### DISPOSITION

#### Admission Criteria

- Inpatient ward criteria:
  - Infants with suspected DI
  - Significant hypo- or hypernatremia
  - Significant dehydration
  - UTI indications for hospitalization include age <1 mo, urosepsis or potential bacteremia, vomiting or inability to tolerate oral medication, lack of outpatient follow-up, and failed outpatient therapy.
  - Children between 1 and 3 mo of age may potentially be treated with parenteral antibiotics on an outpatient basis (5).
- Critical care admission criteria:
  - DKA with significant acidosis, AMS, or concern for cerebral edema. Severe hypo- or hypernatremia may require critical care for intensive electrolyte and fluid management.

#### Discharge Criteria

- Children with a new DM diagnosis not in DKA may be discharged home with close follow-up with pediatric endocrinology.
- The majority of stones <5 mm in diameter will pass spontaneously, even in small children (3).

### Issues for Referral

- Polyuria following neurosurgery should be referred to the neurosurgical team.
- Structural renal disease should be referred to pediatric nephrology.
- Children with vasopressin deficiency should be referred to endocrinology or neurology for further workup.
- Every new DM diagnosis should be referred to a diabetes team qualified to provide up-to-date pediatric-specific education and support.
- For stone disease, urology consultation is indicated for unremitting severe pain, urinary obstruction, struvite calculi, urosepsis, and stones >5 mm in diameter that do not pass spontaneously after 2 wk.

## FOLLOW-UP

### FOLLOW-UP RECOMMENDATIONS

- Discharge instructions and medications:
  - Based on the underlying cause
- Activity:
  - Based on the underlying cause

### DIET

NPO status for all patients with hyperglycemia until blood gas and electrolyte studies are obtained

### PROGNOSIS

- UTI: The majority of children have no long-term sequelae. If symptoms fail to improve or worsen within 24–28 hr of antimicrobial therapy, coverage should be broadened while awaiting culture and sensitivity.
- DM: Visits with a diabetologist every 3 mo with assessment of glycosylated hemoglobin and yearly follow-up with urine collection to assess for microalbuminuria, ophthalmologic exams to assess for retinopathy, and blood tests for hyperlipidemia

### COMPLICATIONS

- DKA:
  - Cardiovascular collapse due to osmotic diuresis and dehydration
  - Hypokalemia caused by urine losses and correction of acidosis with insulin
  - Cerebral edema due to rapid fluid shifts
  - Central pontine myelinolysis due to rapid development of a hyperosmolar state
- Recurrent UTIs: May lead to renal scarring, which carries a risk of HTN, preeclampsia, and end-stage renal disease as an adult

## CODES

### ICD9

788.42 Polyuria

## PEARLS AND PITFALLS

- The cause of polyuria is often suggested from the history.
- In most cases, bedside glucose and urinalysis are the only necessary tests.
- Childhood nephrolithiasis typically presents with vague abdominal or flank pain; however, 17% are asymptomatic (2).
- If the diagnosis of renal stones is made, outpatient metabolic workup is necessary to look for underlying cause in preadolescents.

# PREGNANCY

Ilene Claudius

## BASICS

### DESCRIPTION

- Pregnancy is defined as the period of time, usually 40 wk, from the beginning of a woman's last period until birth of a baby.
- Last menstrual period (LMP): The LMP is the 1st day of the period beginning the cycle resulting in pregnancy.
- Estimated gestational age (EGA): The EGA is the age based on the time period from the LMP.

### EPIDEMIOLOGY

#### Incidence

- 4 million to 6 million per year (U.S.)
- 1 million teenagers

#### Prevalence

1.47% of the population per year

### RISK FACTORS

50% of pregnancies in the U.S. are unintended.

### GENERAL PREVENTION

- Improved health education programs
- Effective contraceptive use

### PATHOPHYSIOLOGY

Many changes in physiology occur as an effect of normal pregnancy, including:

- Increase in maternal plasma volume, cardiac output, and stroke volume with decreased systemic vascular resistance
- Decreased total lung capacity with increased tidal volume causing hypoventilation
- Slowed gastric motility

### ETIOLOGY

Penetration and fertilization of ovum by sperm are required for pregnancy to occur, and implantation in an appropriate uterine location is mandate. If the latter fails to occur, the pregnancy is considered ectopic (see Ectopic Pregnancy topic).

### COMMONLY ASSOCIATED CONDITIONS

- GERD
- Nausea, vomiting
- Edema
- Weight gain
- Syncope
- Musculoskeletal back pain
- Cholelithiasis
- Hemorrhoids
- Abortion, either therapeutic or spontaneous (see Vaginal Bleeding topics)

## DIAGNOSIS

### HISTORY

- Amenorrhea
- Date of LMP
- Concern for pregnancy
- Fatigue
- Nausea, vomiting
- Breast tenderness
- Urinary frequency
- Darkening of the areola
- Headaches

### PHYSICAL EXAM

- Abdominal distension
- Chadwick sign (bluish discoloration of the cervix and vagina):
  - Goodell sign (cervical softening)
  - Hegar sign (softening of the lower uterine segment)

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

- Urine pregnancy testing is sensitive to 20 IU/L (16–30 days after LMP).
- Serum beta-hCG can be performed qualitatively (threshold 25 IU/L) or quantitatively (threshold 1 IU/L)

### Imaging

- US: The gestational sac can be visualized at 5 wk from the LMP (beta-hCG of > 1,000 IU/mL)
- No other imaging is needed in the emergency department for the diagnosis and treatment of pregnancy.

### Diagnostic Procedures/Other

Fetal heart tones can be detected by handheld Doppler US at 10 wk after the LMP.

### DIFFERENTIAL DIAGNOSIS

- Consider urinary tract infection if urinary frequency exists.
- Abdominal masses, including ovarian cysts, can cause swelling that resembles a gravid uterus.
- Amenorrhea has an exhaustive differential covered elsewhere (see Amenorrhea topic).
- Germ cell tumors can secrete beta-hCG.
- Abnormal pregnancies such as ectopic or molar pregnancy (gestational trophoblastic disease)
- Consider other causes of nausea and vomiting.

## TREATMENT

### PRE HOSPITAL

None, unless symptomatic

- If possibly a late pregnancy, transport the patient in the left lateral decubitus position.
- Consider oxygen if there is any chance that oxygen to the fetus may be compromised.

### INITIAL STABILIZATION/THERAPY

- ABCs
- Pregnancy itself requires no treatment; treat underlying issue or symptoms.

### MEDICATION

- Symptomatic complications, such as hyperemesis gravidarum or urinary tract infection, may require medication.
- Medication classification should be checked, and risks and benefits weighed, prior to prescribing.

## COMPLEMENTARY & ALTERNATIVE THERAPIES

Multiple therapies including anise, fennel, ginger, acupressure, and acupuncture have been suggested for relief of pregnancy-related complaints.

## SURGERY/OTHER PROCEDURES

Patients desiring termination should be referred expeditiously for medical or surgical termination.

## DISPOSITION

### Admission Criteria

- Routine inpatient ward admission:
  - Possible ectopic pregnancy
  - Genitourinary infection with poor follow-up
  - Hyperemesis with inability to tolerate PO hydration
- Critical care admission criteria:
  - Before 20 wk, a fetus is not considered viable. Pregnant women should be admitted to the ICU based on their status.
- Most pregnancy-related complications requiring admission, like eclampsia, will occur after 20 wk EGA (see brief description of complications below).

### Discharge Criteria

- Follow-up assured
- Stable vitals signs (for pregnancy)

### Issues for Referral

- Any pregnant patient should be referred for counseling and further care.
- Transfer of a patient in labor is warranted under the Emergency Medical Treatment and active Labor Act (EMTALA) if the following criteria are met:
  - The patient has been stabilized to the capability of the transferring facility
  - The patient requires treatment at the receiving facility and the benefits of transfer outweigh the risks
  - The receiving facility has been contacted and has agreed to accept the patient
  - The patient is accompanied by copies of her medical records

## FOLLOW-UP

### FOLLOW-UP RECOMMENDATIONS

- Discharge instructions and medications:
  - Multivitamins with folic acid
- Activity:
  - Avoid smoking and recreational drugs, exercise beyond routine for the patient, hot baths, and hot tubs.

### Patient Monitoring

Regular obstetric visits are recommended.

### DIET

Avoidance of potential teratogens, alcohol, food high in mercury, unpasteurized cheese, cold cut meats, raw fish (sushi/sashimi), large amounts of caffeine

### PROGNOSIS

15–20% of diagnosed pregnancies end in miscarriage.

### COMPLICATIONS

- The likelihood of domestic violence directed toward the female increases during pregnancy.
- Eclampsia or preeclampsia
- Isoimmunization in the Rh-negative mother resulting from trauma or hemorrhage
- Spontaneous abortion
- Ectopic pregnancy
- Preterm labor
- Premature rupture of the membranes
- Chorioamnionitis
- Placenta previa
- Placental abruption
- Thrombotic phenomenon such as deep vein thrombosis or pulmonary embolism
- HELLP syndrome
- Congestive cardiac failure
- Cardiomyopathy

### See Also (Topic, Algorithm, Electronic Media Element)

- Ectopic Pregnancy
- Vaginal Bleeding during Pregnancy (>20 Weeks Gestation)
- Vaginal Bleeding during Early Pregnancy (<20 Weeks)

## CODES

### ICD9

V22.1 Supervision of other normal pregnancy

## PEARLS AND PITFALLS

### Pitfalls:

- Failure to consider pregnancy; patients may deny history of sexual activity for myriad reasons.
- Breach of confidentiality: Most states confer some degree of confidentiality with regard to matters of pregnancy and reproductive health.

# PRIAPISM

Jennifer Adu-Frimpong

## BASICS

### DESCRIPTION

- Priapism is an uncommon condition that causes a prolonged and often painful erection that occurs without sexual stimulation.
- The most common cause of pediatric priapism is hemoglobin SS (sickle cell disease):
  - Ischemic (no flow): Most common and painful
  - Nonischemic (high flow): Not painful
- Ischemic priapism is a urologic emergency.
- Persistent painless erection in newborns may be caused by birth trauma or polycythemia, but most are idiopathic. These usually resolve spontaneously within 2–6 days with no sequelae.
- Clitoral priapism is a much more rare entity that is not discussed here.

### EPIDEMIOLOGY

#### Incidence

- The overall incidence of priapism is 1.5 cases per 100,000 person-years (1).
- Priapism affects 2–35% of males with sickle cell disease (2).
- ~2/3 of all pediatric patients who have priapism also have sickle cell disease (3).

#### Prevalence

- Priapism presents in a bimodal distribution between 5 and 10 yr of age in children (3).
- Among patients with sickle cell disease, the prevalence is higher in men 19–21 yr of age (1,3).

### RISK FACTORS

Multiple medications may cause priapism, including:

- Antidepressants: Trazodone, fluoxetine, citalopram
- Antipsychotics: Clozapine, chlorpromazine
- Erectile dysfunction medications: Sildenafil, tadalafil, vardenafil
- Antihypertensives: Hydralazine, prazosin, phenoxybenzamine, guanethidine

### PATHOPHYSIOLOGY

- The pathophysiology of priapism involves the failure of detumescence as a result of underregulation of arterial inflow or failure of venous outflow.
- Ischemic priapism: Caused by an obstruction in the penis venous drainage, which results in a buildup of poorly oxygenated blood in the corpora cavernosa
  - This type usually affects boys with sickle cell disease.

- Low-flow priapism may result from leukemia, polycythemia, and multiple myeloma.
- Nonischemic priapism: Caused by an injury to the penis or perineum (the area between the scrotum and anus). The injury causes the artery within the erectile body to rupture and pump a large amount of blood to the penis.
- Tumescence is usually within the corpora cavernosa, though it can also involve the corpus spongiosum, especially in prepubertal boys.

### ETIOLOGY

See Risk Factors and Pathophysiology.

### COMMONLY ASSOCIATED CONDITIONS

- Sickle cell disease
- Coagulation disorders

## DIAGNOSIS

### HISTORY

- Duration of erection >4 hr is consistent with priapism.
- Clinicians should inquire about:
  - Duration of pain
  - Painful urination
  - Similar prior episodes
  - Genitourinary trauma
  - Comorbidities (eg, sickle cell disease, neoplasm, coagulation disorders)
  - Medication use
- Onset during sleep is typical of those with sickle cell disease.

### PHYSICAL EXAM

- Obvious painful erection is the key physical finding in any case of priapism.
- Penile priapism generally involves only the paired corpora cavernosa, with the glans and corpora spongiosum remaining flaccid or softly distended without rigidity.
- If there is spongiosal involvement, a firm, tender, engorged glans will be noted.
- Check for penile color, rigidity, and sensation (soft glans vs. firm glans).
- Assess for penile discharge, lesions, or evidence of local trauma.
- Rectal tone: Diminished or absent rectal sphincter tone may suggest spinal trauma or high spinal cord lesion or stenosis.

## DIAGNOSTIC TESTS & INTERPRETATION

### Lab

#### Initial Lab Tests

- Differentiation between ischemic and nonischemic priapism can be made by blood gas analysis of blood aspirated from the penis:
  - Ischemic priapism will result in acidemia and hypercarbia.
  - High-flow or nonischemic priapism will have normal blood gas results.
- CBC should be ordered to screen for leukemia and for all patients with sickle cell disease.
- Consider PT and PTT (in case the patient requires surgical intervention).
- Blood type and screen (or hold) for those with sickle cell disease, should exchange transfusion become necessary

### Imaging

Color flow penile Doppler imaging is the study of choice to differentiate high-flow from low-flow priapism. It can also identify and locate a fistula associated with high-flow priapism.

### DIFFERENTIAL DIAGNOSIS

- Urethral foreign body
- Peyronie disease

## TREATMENT

### PRE HOSPITAL

- Use of ice packs to the perineum and penis
- External perineal compression

### INITIAL STABILIZATION/THERAPY

- If priapism is due to sickle cell disease, treatment includes hydration, alkalinization, analgesia, and oxygenation to prevent further sickling.
- Consider hypertransfusion and/or exchange transfusions to achieve hemoglobin S level  $\leq 30\%$  and to increase the hematocrit level.

### MEDICATION

#### First Line

- Medical therapy for priapism will largely be institutional dependent.
- Oxygen
- IV fluids
- Analgesics:
  - Morphine 0.1 mg/kg IV/IM/SC q2h PRN:
    - Initial morphine dose of 0.1 mg/kg IV/SC may be repeated q15–20min until pain is controlled, then q2h PRN.
  - Ketorolac 0.5 mg/kg IV/IM q6h PRN
- Pseudoephedrine, 60–120 mg PO:
  - Used as first-line treatment in adults with priapism of short duration (ie, 2–4 hr)
  - There are no current pediatric dosing recommendations.

- Intracavernosal phenylephrine 100  $\mu\text{g}/\text{mL}$ :
  - Drug of choice for first-line treatment of low-flow priapism, especially for medication-induced priapism
  - It has almost pure alpha-agonist effects and minimal beta activity.
  - Phenylephrine alpha-agonist effects produce vasoconstriction of arterioles and decreased blood flow to the penis, achieving detumescence. See Surgery/Other Procedures for a description of intracavernosal phenylephrine administration.
  - The alpha-agonist should be avoided in patients with documented hypersensitivity, those on beta-blockers, and for severe HTN or ventricular tachycardia. Cardiac monitoring is recommended during administration.

### Second Line

- Terbutaline can be given 5 mg PO or 0.25–0.5 mg SC for persistent penile erection or priapism due to injection of pharmacologic agents:
  - Can be repeated after 15 min
  - There are no pediatric trials, but a literature review documents efficacy in a few case reports (4).
- Epinephrine used for intracorporeal irrigation:
  - Adverse effects were reported patients and included palpitations, changes in pulse rate, BP, and cardiac rhythm (5,6).

### SURGERY/OTHER PROCEDURES

- Aspiration of blood from the corpus cavernosum should be considered, especially for patients unresponsive to medical interventions.
- Another procedure in the treatment of low-flow priapism is aspiration of the corpora cavernosa followed by saline irrigation.
- Obtain a 19- or 21-gauge butterfly needle, 10 mL syringes, 3-way stop cock, sterile saline, and phenylephrine or epinephrine.
- Perform a penile block using local anesthetic such as bupivacaine without epinephrine to increase patient comfort and improve patient cooperation.
- In younger children, consider procedural sedation.
- Palpate the engorged corpora cavernosa, and insert the needle into the midshaft at 2 o'clock. Attach the stopcock to the needle. Aspirate the needle during insertion. Aspirate 10-mL aliquots for a total of 20–30 mL of blood into syringes. If detumescence occurs, stop.
- If priapism is still present despite the prior interventions, a diluted solution of phenylephrine may be used for irrigation. A diluted solution can be infused 10–20 mL at a time. If unable to irrigate with the diluted solution, straight intracorporeal injection of 200–500- $\mu\text{g}$  aliquots may be administered, taking care to not exceed a max single dose of 1,500  $\mu\text{g}$ .

- 10-mL aliquots of epinephrine and saline mixture can also be used to irrigate via the stopcock.
- Intracavernous injection of phenylephrine: Mix 1 mL of phenylephrine with 9 mL of normal saline. Inject ~0.3–0.5 mL of the mixture into the corpora cavernosa. Repeat q10–15min until mixture is used.
- Vital signs should be monitored throughout, and compression of the injection site should be continuous to prevent hematoma formation.
- If there is still no resolution despite the measures, then surgical management is needed (7).
- Surgical management involves placing shunts between the cavernosa and the spongiosum, which is done by a urologist in the operating room.

### DISPOSITION

#### Admission Criteria

- Sick cell patients needing hypertransfusion and/or exchange transfusions
- Intractable pain
- Intractable vomiting
- Priapism not resolved after emergency department management

#### Discharge Criteria

If stable and erection is resolved, the patient may be discharged with follow-up.

### FOLLOW-UP

#### FOLLOW-UP RECOMMENDATIONS

Discharge instructions and medications:

- Patients who have priapism of uncertain etiology should see a urologist for further treatment and workup.

#### PROGNOSIS

- The prognosis depends on the duration of symptoms, the patient's age, and the underlying pathology.
- Time to treatment is key.
- Prompt treatment decreases the risk of permanent sequelae.
- Morbidity can result from corporeal fibrosis due to persistent priapism and deep tissue infections of the penis.

#### COMPLICATIONS

- In very rare cases, unresolved priapism can lead to severe necrosis to the tissues of the penis.
- Erectile dysfunction
- Impotence
- Risk of ASPEN (association of sickle cell disease, priapism exchange transfusion, and neurologic events), a syndrome that can occur during the exchange transfusion that is characterized by headache, neurologic signs, and symptoms of cerebral ischemia

ICD9  
607.3 Priapism

### PEARLS AND PITFALLS

- Early consultation with a urologist is recommended, especially when less invasive measures in the emergency department fail to resolve the priapism or a low-flow condition is suspected.
- Rapid treatment to prevent permanent injury is warranted in cases of low-flow or ischemic priapism.

# PROCEDURAL SEDATION AND ANALGESIA

Susanne Kost

## BASICS

### DESCRIPTION

Procedural sedation and analgesia (PSA) is the administration of sedative and/or analgesic medications to facilitate patient comfort and procedural success during diagnostic or therapeutic interventions.

### EPIDEMIOLOGY

#### Incidence

2 large sedation registries track sedation data in the U.S.:

- The Procedural Sedation in Community ED registry (ProSCED) reported a mean of 0.5 pediatric sedations per 1,000 patient visits.
- The Pediatric Sedation Research Consortium (PSRC) reported 30,037 sedations from 26 hospitals over a 15-mo period.

### RISK FACTORS

- Potential risk factors for PSA complications include anatomic and physiologic factors that predispose to upper airway obstruction, active lower airway disease, cardiac disease, age <3 mo, obesity, and metabolic disorders that affect sedative clearance.
- A period of fasting, typically 6–8 hr for solids and 2 hr for clear liquids, is customary prior to procedures under general anesthesia due to the risk of emesis with aspiration.
- Fasting status should be considered prior to PSA, but the presumed benefits of fasting must be weighed against the risks of delaying an urgent procedure:
  - Several retrospective reviews have failed to demonstrate any correlation between fasting state and adverse events.
  - An expert consensus panel created a clinical practice advisory tool with specific fasting recommendation vs. procedural urgency and targeted sedation depth.

### PATHOPHYSIOLOGY

- Sedation states progress along a continuum from mild anxiolysis to general anesthesia depending on the type and amount of medication delivered and the individual patient response.
- PSA can be categorized into levels, commonly defined as:
  - Mild sedation (anxiolysis):
    - Normal response to verbal commands; cognitive functions and coordination may be impaired; airway, ventilation, and cardiac functions are maintained.
  - Moderate sedation:
    - Purposeful response to verbal commands or light tactile stimulation; spontaneous ventilation is adequate, though may see mild alteration in ventilatory effort and impairment in motor function; cardiac functions are maintained.
  - Deep sedation:
    - Depressed consciousness or unconscious state from which the patient is difficult to arouse; should respond purposefully to pain; may partially or completely lose airway reflexes, and spontaneous ventilation may be inadequate; cardiac function is usually maintained.
- General anesthesia

### ETIOLOGY

See Sedation Table (p. 1041).

## DIAGNOSIS

### HISTORY

A relevant pre-sedation history includes the following:

- Allergies and previous adverse reactions (including egg and soy, if using propofol)
- Current medications
- Prior problems with sedation
- Upper airway compromise such as sleep apnea or snoring
- Systematic review of problems, with particular attention to the pulmonary, cardiac, GI (reflux/vomiting risk), neurologic, and metabolic (hepatic and renal) systems
- Consider impact of current illness or injury on sedation risk (fever, trauma).
- Last oral intake

### PHYSICAL EXAM

- Baseline vital signs
- Upper airway assessment:
  - Mouth: For tongue size, dentition (loose teeth, orthodontia), and mouth opening (Mallampati classification)
  - Pharynx: For tonsillar hypertrophy
  - Jaw: For micro-/retrognathia, trismus
  - Neck: For limited mobility or neck mass, tracheal deviation
- Respiratory:
  - Breath sounds
  - Work of breathing
- Cardiovascular:
  - Heart sounds, rhythm
  - Peripheral perfusion
- Neurologic status:
  - Baseline mental status
  - Ability to control airway tone, secretions
  - Signs of cranial nerve dysfunction

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

Pre-sedation diagnostic studies are not generally indicated but may be considered in certain situations.

#### Initial Lab Tests

- Hemoglobin or hematocrit to assess oxygen-carrying capacity if anemia is suspected
- Metabolic panel if disorder is suspected
- Pregnancy test in sexually mature females

### DIFFERENTIAL DIAGNOSIS

Not applicable

## TREATMENT

- Maintain patient safety.
- Minimize pain and anxiety; maximize amnesia.
- Minimize patient movement.
- Timely return to baseline status
- PSA providers should possess an in-depth understanding of sedative pharmacology and potential complications and should have the knowledge and skills to rescue a patient from a sedation level deeper than intended:
  - Skills needed to perform basic airway maneuvers and successful bag-mask ventilation are essential.
  - A skilled observer who is not responsible for performing or assisting with the procedure should be assigned to monitor the patient's status.
- A commonly used acronym, SOAP ME, can assist in assuring adequate equipment preparation:
  - Suction: Source and catheters
  - Oxygen: Source and meters
  - Airway equipment: Adjuncts and bag-mask ventilation device
  - Pharmacy: Rescue and reversal drugs
  - Monitors (see below)
  - Extra equipment (special equipment for a given procedure or case)

### Patient Monitoring

Can be tailored to anticipated level of sedation and adjusted as appropriate if the patient slips into a deeper level of sedation than anticipated:

- Minimal sedation:
  - Observation of level of alertness and respiratory status
  - Pulse oximetry
- Moderate sedation:
  - Observation as above PLUS:
    - Continuous pulse oximetry
    - Continuous cardiac monitoring
    - BP at 15-min intervals
    - Consider capnographic monitoring.
    - ECG optional
- Deep sedation:
  - Observation as above PLUS:
    - Continuous pulse oximetry
    - Continuous capnography
    - Continuous cardiac monitoring
    - BP at 3–5-min intervals
    - ECG recommended

### MEDICATION

- See Sedation Table (p. 1041).
- Choice of medication is based on an assessment of the following:
  - Procedural factors:
    - Painful vs. painless
    - Need for immobility
    - Pharmacokinetics with regard to duration of procedure
  - Patient factors:
    - Anxiety and developmental level
    - Previous experiences (allergies/adverse reactions)
    - Contraindications

- Sedation is a continuum, and a given medication or combination of medications may produce variable responses. In general, however, the following recommendations are reasonable for most situations:
  - Anxiolysis/Mild sedation:
    - Low-dose benzodiazepine
    - Nitrous oxide 30–50%
  - Moderate sedation:
    - Higher-dose benzodiazepine or benzodiazepine plus opioid
    - Nitrous oxide 70%
    - Low doses of barbiturate
    - Dexmedetomidine
  - Deep sedation:
    - Higher doses of barbiturate
    - Etomidate
    - Propofol
    - Ketamine

### COMPLEMENTARY & ALTERNATIVE THERAPIES

- Child life providers and others skilled in techniques such as distraction or guided imagery may lessen or obviate the need for sedation.
- Hypnosis
- Oral sucrose is a useful adjunct for pain control for minor painful procedures in infants.
- Judicious use of topical and local anesthesia may lessen the need for systemic sedation.
- Several commercial infant immobilization devices are available for young infants (<5–6 kg) that may eliminate the need for sedation for imaging studies.

### DISPOSITION

#### Admission Criteria

Patients who experience a significant adverse reaction to sedation, such as need for prolonged respiratory support, severe allergic reaction, recurrent vomiting, or prolonged obtundation

#### Discharge Criteria

- Patients should meet established criteria prior to the discontinuation of monitoring or discharge from the emergency department, according to hospital sedation policy
- A number of published discharge scales are available, but the basic elements are similar:
  - Stable vital signs
  - Pain well controlled
  - Return to baseline level of consciousness
  - Adequate head control and muscle tone to maintain a patent airway
  - Adequate hydration; controlled nausea/vomiting

- Patients may be discharged when they are beyond the period of significant respiratory and/or cardiovascular adverse effects and are awake enough to tolerate oral hydration. For most of the agents discussed, this is achieved 60–120 min after its administration.

### Issues for Referral

Consider anesthesia consultation in patients with:

- Respiratory compromise or hemodynamic instability
- Known difficult airway, history of obstructive sleep apnea, or high-risk airway by exam
- American Society of Anesthesiologists (ASA) class >3
- Infants <52 wk postconceptual age
- Neuromuscular disease affecting brainstem or pulmonary function

## FOLLOW-UP

### FOLLOW-UP RECOMMENDATIONS

- Sedation recovery should take place in a monitored area equipped with suction, oxygen, and equipment for positive pressure ventilation.
- Vital signs and level of alertness should be documented at regular intervals until the patient is awake and interactive.

### COMPLICATIONS

- The ASA categorizes individuals on a general health basis; risk of sedation complications increases with increasing ASA status:
  - ASA 1: Normal, healthy patient
  - ASA 2: Well-controlled medical condition
  - ASA 3: Medical condition with systemic effects, intermittently associated with functional compromise
  - ASA 4: Poorly controlled medical condition with potential threat to life
  - ASA 5: Critical condition, not expected to survive without the procedure
- Several general statements apply to adverse events during sedation:
  - The vast majority of complications are respiratory.
  - The greater the sedation depth, the higher the risk of complications.
  - The majority of poor outcomes are related to failure of the practitioner to prepare for or recognize the complication.
  - Adverse events are not disproportionately associated with a specific drug or route of administration.

### See Also (Topic, Algorithm, Electronic Media Element)

The Society for Pediatric Sedation: <http://www.pedsedation.org>

### PEARLS AND PITFALLS

- A pre-sedation risk assessment is essential for anticipation of and reduction in the number of adverse events.
- The majority of PSA complications are respiratory, such as apnea, hypoventilation, or laryngospasm.
- Aspiration is an extremely rare adverse event associated with emergency department PSA.
- Although the needs for individual patients may vary, for most young children in the emergency department, deep sedation is the goal.
- Chloral hydrate is the oldest sedative in common use for children but is not recommended due to an inconsistent sedative effect and a poor side effect profile.

# PROLONGED QT INTERVAL

Maria Carmen G. Diaz

## BASICS

### DESCRIPTION

- Prolonged QT syndrome, or long QT syndrome (LQTS), is a disorder in which the patient has delayed ventricular repolarization causing QT prolongation on ECG.
- Patients with LQTS are prone to syncope, malignant ventricular arrhythmias, and sudden cardiac death.
- LQTS may be congenital or acquired.
- Congenital LQTS presents in childhood:
  - Jervell-Lange-Nielsen syndrome has an autosomal recessive pattern of inheritance and is associated with congenital deafness.
  - Romano-Ward syndrome has an autosomal dominant pattern of inheritance and is not associated with deafness.
- Acquired LQTS usually presents in the 5th or 6th decade of life but is also seen in childhood:
  - The most common causes of acquired LQTS are medications and electrolyte abnormalities (1).

### EPIDEMIOLOGY

#### Incidence

Congenital LQTS:

- Congenital LQTS has an incidence of 1:10,000–1:15,000.
  - Congenital LQTS accounts for 3,000–4,000 cases of sudden death each year (1).
  - Patients often present between 9 and 15 yr of age.
  - 60% of patients are symptomatic at diagnosis (1).
- 10% of children with LQTS present with sudden death.

#### Prevalence

The estimated prevalence of congenital LQTS is 1:5,000 (2).

### RISK FACTORS

Congenital LQTS:

- 1st-degree relatives of a known LQTS carrier
- Family history of syncope or sudden death
- Family history of sudden infant death syndrome (SIDS)
- Family history of an unexplained near drowning
- Congenital deafness
- Bradycardia in infants (1)

### GENERAL PREVENTION

- Screening ECG for at-risk individuals
- Avoidance of known triggers such as certain medications, physical activity, and stimulants

### PATHOPHYSIOLOGY

QT prolongation may occur due to a decrease in repolarizing potassium currents or an inappropriate late entry of sodium into the myocyte:

- Mutations in the ion channels of repolarizing cardiac potassium currents leads to delayed repolarization.
- Mutations of the sodium-channel protein causes a small persistent inward leak in cardiac sodium current leading to prolonged depolarization.
- 300 different LQTS mutations have been identified on 5 genes: 4 genes for potassium channels and 1 gene that forms the cardiac sodium channel (2,3).

### ETIOLOGY

- Congenital:
  - Jervell-Lange-Nielsen syndrome
  - Romano-Ward syndrome
- Acquired:
  - Myocardial ischemia
  - Cardiomyopathies
  - Hypokalemia
  - Hypocalcemia
  - Hypomagnesemia
  - Hypothermia
- Drugs:
  - Class 1A and class 3 antiarrhythmics: Quinidine, procainamide, disopyramide, sotalol, amiodarone
  - Antihistamines: Terfenadine, astemizole, diphenhydramine
  - Ketoconazole
  - Erythromycin, trimethoprim/sulfamethoxazole
  - Cisapride
  - Haloperidol, risperidone, thioridazine, amitriptyline
  - Organophosphates
- Genetic

### COMMONLY ASSOCIATED CONDITIONS

- Syncope
- Seizure
- Jervell-Lange-Nielsen is associated with congenital deafness.

## DIAGNOSIS

### HISTORY

- Syncope, especially if recurrent:
  - Syncope with exertion or vigorous physical activity
  - Syncope precipitated by intense emotion, stress, or loud noises
  - Syncope associated with chest pain or palpitations
- Children may complain of diaphoresis, palpitations, or light-headedness.
- May have spontaneous return of activity following syncopal episodes

- Dysrhythmia and/or sudden death may occur (1).
- Ask about family history of syncope and sudden death not only in 1st-degree relatives but also remote relatives (2).
- Ask about family history of deafness.
- Ask about medications used.

### PHYSICAL EXAM

- Vital signs with attention to heart rate and BP
- May be asymptomatic with normal physical exam; LQTS found on routine ECG
- Often, following full recovery from syncope, the physical exam is normal.
- Those with cardiomyopathy may have signs of CHF such as tachycardia, tachypnea, organomegaly, and pulmonary rales.
- Other patients may present with signs of cardiovascular collapse related to a dysrhythmia such as torsades de pointes or ventricular fibrillation.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

Obtain serum electrolytes and serum concentration level of offending medication if available to rule out acquired causes of LQTS.

##### Diagnostic Procedures/Other

- The QT interval should be manually measured from the earliest onset of the QRS complex to the end of the T wave.
- The QT interval should be measured in leads II and V<sub>5</sub> or V<sub>6</sub> with the longest interval being used.
- The QT interval should be corrected for heart rate using the Bazett formula ( $QT_c = QT/\sqrt{RR}$ ):
  - RR preceding the QT measured should be used for calculation.
  - 3 consecutive QT intervals and 3 consecutive preceding RR intervals should be measured and averaged for the greatest accuracy (1,2,4).
- If LQTS is suspected but the ECG is not conclusive, vagal maneuvers may show some abnormalities on ECG such as prolonged QT, prominent U waves, T-wave alternans (alternating polarity and amplitude), and ventricular dysrhythmias (1,3).
- Holter monitor: May sometimes be used to detect variable QT intervals that may occur throughout the day.
- Exercise testing has been used when the diagnosis of LQTS is in question but must be interpreted with caution (2).

**Pathological Findings**

ECG findings:

- In patients 1–15 yr of age:
  - A QTc >460 msec is prolonged.
  - A QTc of 440–460 msec is borderline and warrants further investigation.
  - A QTc <440 msec is normal (2).
- In infants <6 mo of age, a QTc of 490 msec is the upper limit of normal (4).
- A QTc ≥500 msec has consistently been shown to be associated with a high risk of cardiac events such as syncope, aborted cardiac arrest, and sudden cardiac death (2).
- Some patients with congenital LQTS have a normal or borderline QTc at rest but prolongation with exertion or beta-adrenergic stimulation (5).

**DIFFERENTIAL DIAGNOSIS**

- Vasovagal syncope
- Seizures:
  - Emergency department physicians should always consider obtaining a baseline screening ECG in patients presenting with syncope or new-onset seizure.
- SIDS may be related to congenital LQTS.

**TREATMENT**

**PRE HOSPITAL**

- Depends on the symptoms and presentation
- Support airway, breathing, and circulation per Pediatric Advanced Life Support (PALS) guidelines.

**INITIAL STABILIZATION/THERAPY**

- The initial treatment depends on the patient’s symptoms.
- Patients presenting with polymorphic ventricular tachycardia or torsades de pointes should receive magnesium 25–50 mg/kg IV (max single dose 2 g) (1).

**MEDICATION**

- Beta-blockers:
  - Eradicate dysrhythmias in 60% of patients and decrease mortality from 71% to 6%
  - Propranolol 2–4 mg/kg/day (1)
- Patients with asthma in whom beta-blockers are contraindicated may require pacemakers (1).
- If a patient has acquired LQTS, the underlying trigger or electrolyte abnormality must be corrected.

**SURGERY/OTHER PROCEDURES**

- Temporary transcutaneous ventricular pacing (1)
- Patients may require a permanent pacemaker, an implantable cardioverter defibrillator, or left cardiac sympathetic denervation.

**DISPOSITION**

**Admission Criteria**

Critical care admission criteria:

- Patients who are symptomatic or have cardiovascular compromise require admission.

**Discharge Criteria**

Patients who are asymptomatic at the time of their emergency department evaluation may be discharged home with close outpatient follow-up.

**Issues for Referral**

Refer all patients with a compatible history and borderline QT interval or prolonged QT to a cardiologist (1).

**FOLLOW-UP**

**FOLLOW-UP RECOMMENDATIONS**

Activity:

- Restrict from competitive sports.
- Avoid triggering factors such as medications, loud noises, stressful situations, and dehydration.
- Family members and close friends should receive CPR instruction.
- Consider having an automated external defibrillator at home (1).

**Patient Monitoring**

- ECG should be performed on all family members.
- Consider genetic testing.

**PROGNOSIS**

- The clinical course in patients with congenital LQTS is variable due to incomplete penetrance. These patients therefore require continuous risk assessment (2).
- Males between 1 and 12 yr of age with congenital LQTS have a higher rate of fatal or near-fatal cardiac events than females in this age group.
- Risk factors for cardiac arrest or sudden cardiac death in patients with congenital LQTS between 1 and 12 yr of age:
  - Boys:
    - A QTc >500 msec is associated with a nearly 3-fold increase in the risk of fatal or near-fatal events in boys with congenital LQTS.
    - Prior syncope
  - Girls:
    - Prior syncope (6)
- High-risk children with congenital LQTS (boys, QTc >500 msec, prior episode of syncope) have a 2% average annual life-threatening cardiac event rate despite beta-blocker therapy (6).

**COMPLICATIONS**

- Syncope
- Seizure:
  - Trauma/Injury associated with these occurrences
- Dysrhythmias
- Sudden death

**REFERENCES**

**CODES**

**ICD9**

- 426.82 Long qt syndrome
- 794.31 Nonspecific abnormal electrocardiogram (ecg) (ekg)

**PEARLS AND PITFALLS**

- Prolonged QT or LQTS should be suspected in patients with a history of recurrent syncope or near-syncope.
- ED physicians should also suspect LQTS in patients with syncopal or near-syncopal episodes associated with physical activity or emotional distress or if there is a family history of unexplained sudden death.
- If the EKG is nondiagnostic or borderline and there is a high suspicion for LQTS, arrange for close outpatient follow-up with cardiology.
- First degree family members of persons with LQTS should be screened for the disease.

# PSEUDOTUMOR CEREBRI

Parul B. Patel

## BASICS

### DESCRIPTION

- Pseudotumor cerebri is a clinical syndrome defined by signs or symptoms of increased intracranial pressure (ICP) such as headache and papilledema with normal CSF volume, normal mental status, and no other cause identified on neuroimaging.
- Elevated ICP is typical, but CSF analysis is normal.
- The diagnosis is one of exclusion.
- Also known as idiopathic intracranial HTN
- Specific diagnostic criteria (Dandy criteria):
  - Evidence of increased ICP (eg, headache, transient visual loss/change, tinnitus, papilledema, visual loss)
  - No other neurologic abnormalities or impaired level of consciousness
  - Elevated ICP with normal CSF
  - A neuroimaging study shows no etiology for intracranial HTN
  - No other cause of intracranial HTN apparent

### EPIDEMIOLOGY

#### Prevalence

1–2 per 100,000 population

#### Incidence

- Higher incidence in obese women 15–44 yr of age
- It has been diagnosed in children as young as 4 mo of age.

### RISK FACTORS

- Obese women of child-bearing age:
  - However, in prepubertal children, female gender and obesity are not risk factors.
- Recent weight gain
- Medications:
  - Growth hormone
  - Tetracyclines
  - Oral contraceptives
  - Corticosteroids
  - Cyclosporin
  - Lithium
  - Sulfa medications
- Hypervitaminosis A
- Lyme disease
- Hyperthyroidism
- Polycystic ovary syndrome

### PATHOPHYSIOLOGY

- Precise pathogenesis unknown
- Multiple theories:
  - Venous outflow abnormalities such as venous sinus stenosis
  - Increased CSF outflow resistance
  - Obesity-related increased ICP
  - Altered sodium and water retention
  - Abnormalities of vitamin A metabolism result in changes in arachnoid tissue.

### ETIOLOGY

No precise etiology has been identified.

### COMMONLY ASSOCIATED CONDITIONS

- Obesity in postpubertal children
- Cerebral venous sinus thrombosis
- Middle ear infection
- Vitamin A overdose
- Head injury
- Medication use

## DIAGNOSIS

### HISTORY

- Headache is the most common symptom:
  - Often subacute and progressive, over days to weeks
- Visual disturbances such as diplopia, strabismus, transient visual loss, blurry vision
- Tinnitus is commonly reported.
- Photophobia
- Phonophobia
- Retrobulbar pain
- Nausea, vomiting
- Infants and young children may present only with irritability, lethargy, or sleep or behavioral disturbances.

### PHYSICAL EXAM

- Most prominent changes are detected by ocular exam:
  - Papilledema is a universal finding and is usually bilateral.
  - Visual field loss
  - 6th nerve palsy is uncommon but may be seen.

- Various cranial nerve deficits are possible:
  - Strabismus
  - Vertical diplopia from 4th nerve palsy
- The remaining neurologic exam, including strength, tone, and coordination, is generally nonfocal.
- Neck pain or nuchal rigidity may be present, complicating a diagnosis of meningitis.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

- No lab test is necessary to make diagnosis, but since the diagnosis is one of exclusion, routine lab tests may be helpful to rule out other conditions.
- Commonly used lab assays such as CBC or basic metabolic panel will not be helpful in establishing the diagnosis.
- When obtaining an opening CSF pressure, CSF may be evaluated for cell counts, protein and glucose levels, and cultures.

#### Imaging

- MRI with contrast is the preferred imaging test to assess for an intracranial mass.
- CT scan if MRI is contraindicated or unavailable
- With pseudotumor cerebri, there should be no ventriculomegaly or other abnormalities.

#### Diagnostic Procedures/Other

- Lumbar puncture, if intracranial imaging excludes a mass:
  - Check opening pressure with the patient relaxed and lying in the lateral decubitus position with legs extended.
  - Intracranial HTN is defined by values  $>18$  cm H<sub>2</sub>O in children  $<8$  yr of age or  $>20$  cm H<sub>2</sub>O in children  $>8$  yr of age.
- Visual field testing to assess degree of optic nerve involvement. It is usually normal but deteriorates in severe cases.

### DIFFERENTIAL DIAGNOSIS

- Intracranial mass (tumor or abscess)
- Increased CSF production (choroid plexus papilloma)
- Decreased CSF absorption
- Obstructive hydrocephalus
- Obstruction of venous outflow (venous sinus thrombosis)

- Headache:
  - Migraine headache
  - Hypertensive headache
  - Cluster headache
- Intracranial hemorrhage:
  - Subdural hematoma
  - Epidermal hematoma
  - Subarachnoid hemorrhage
- Sinusitis
- Post-concussion syndrome

## TREATMENT

### INITIAL STABILIZATION/THERAPY

- Significantly increased ICP may be associated with the Cushing triad (HTN, bradycardia, and irregular respirations or apnea)
- Assess and stabilize airway, breathing, and circulation.
- Treatment goals are to alleviate symptoms and preserve vision.
- Perform lumbar puncture with large-volume CSF drainage.
- Discontinue medications that may be causal.

### MEDICATION

#### First Line

- Analgesics:
  - Acetaminophen 15 mg/kg PO/PR q4h PRN for pain
  - Ibuprofen 10 mg/kg PO/IV q6h PRN for pain
  - Morphine 0.1 mg/kg IV/IM/SC q2h PRN for pain:
    - Initial morphine dose of 0.1 mg/kg IV/SC may be repeated q15–20min until pain is controlled, then q2h PRN
- Diuretic or volume-modulating medications:
  - Acetazolamide 25 mg/kg/day IV/PO divided t.i.d.
  - Furosemide 1–2 mg/kg IV q4h
  - Furosemide generally has a much better side effect profile compared to acetazolamide.

#### Second Line

- Prednisone or prednisolone 1–2 mg/kg/day PO × 5 days:
- Corticosteroids use is controversial.

### COMPLEMENTARY & ALTERNATIVE THERAPIES

- Weight loss for obese children
- Repeated lumbar punctures to lower pressure, but this can be distressing and has a short-lived benefit; usually reserved as a temporary measure in children with severe headaches.

### SURGERY/OTHER PROCEDURES

- Lumbar puncture should be performed for diagnosis, CSF analysis, and CSF removal:
  - Opening pressure should be measured with the patient in the lateral decubitus position:
    - Opening pressure above 25 cm H<sub>2</sub>O is suggestive of pseudotumor.
  - May empirically drain 0.5 mL/kg of CSF
  - May drain CSF with titration to pressure of 12–15 cm
  - CSF removal should be done in a 2-step process if the initial pressure is >30 cm H<sub>2</sub>O CSF.
- For patients with progressive vision loss, optic nerve sheath fenestration (ONSF) or a CSF shunting procedure such as lumboperitoneal shunt (LPS)
- ONSF is favored in adults.
- LPS is preferred in those with intractable headaches, but ONSF is preferred in those with rapidly deteriorating visual function.

### DISPOSITION

#### Admission Criteria

Patients with intractable headache or compromise requiring ONSF or LPS

#### Discharge Criteria

Improvement or resolution of symptoms

#### Issues for Referral

All patients suspected to have pseudotumor cerebri should have an initial consultation with a neurologist and an ophthalmologist.

## FOLLOW-UP

### FOLLOW-UP RECOMMENDATIONS

Discharge instructions and medications:

- All children need to follow up with a neurologist and an ophthalmologist.

#### Patient Monitoring

- Regular follow-up visits with serial exams of visual acuity and for papilledema
- Intervals based on severity, duration, and response to treatment of clinical manifestation

### DIET

Low-sodium diet for obese patients

### PROGNOSIS

Data is limited, but children have better prognosis than adults, with spontaneous remission in most children.

### COMPLICATIONS

Visual field loss or decreased visual acuity in children reported in 13–27%

### CODES

#### ICD9

348.2 Benign intracranial hypertension

### PEARLS AND PITFALLS

- Pseudotumor cerebri should be suspected in children who have subacute and progressive headaches.
- Obese adolescent girls are at higher risk than other children.
- The disease is characterized by papilledema and raised ICP in the absence of ventriculomegaly or other etiology of intracranial HTN.

# PSORIASIS

Catherine H. Chung

## BASICS

### DESCRIPTION

- Psoriasis is a chronic, recurring, inflammatory disease characterized by round, well-demarcated, erythematous plaques or papules covered with silvery scales.
- In children <2 yr of age, psoriatic diaper rash is a common 1st presentation and often is recalcitrant to routine diaper dermatitis treatment (1).
- Most typically involves the elbows, knees, and/or scalp.
- Guttate psoriasis is a specific subtype that may also be the 1st manifestation of psoriasis:
  - Guttate lesions are droplike papules; this form is often triggered by group A streptococcal pharyngitis or perianal infection (2).
- Extracutaneous involvement is rare in children but may include nail pitting, arthritis, and uveitis.

### EPIDEMIOLOGY

#### Incidence

- No gender predilection
- Occurs more frequently in Caucasians and families with atopy (3)
- ~30–40% of adults with psoriasis manifest symptoms before 16 yr of age (1).
- 10% of patients present before 10 yr of age and 2% present before 2 yr (4).

#### Prevalence

The average prevalence in the U.S. is 1–3% (1).

### RISK FACTORS

- Genetic:
  - No parent affected: 4% (2)
  - One parent affected: 28% (2)
  - Both parents affected: 65% (2)
- Early-onset disease is linked to HLA antigen types B57, Cw6, and DR7 (4).

### PATHOPHYSIOLOGY

- Psoriasis is caused by activated T cells and dendritic cells found in psoriatic plaques.
- These cells release inflammatory cytokines such as tumor necrosis factor (TNF), which cause keratinocyte hyperproliferation.
- TNF levels are increased in psoriatic lesions compared with levels in uninvolved skin in patients with psoriasis and in normal individuals.

### ETIOLOGY

Triggers include trauma (Koebner phenomenon), sunburn or sun exposure, dry weather, viral or streptococcal infections, stress, cold weather, HIV disease, medications (beta-blockers, lithium, antimalarials), and withdrawal of systemic steroids (2).

### COMMONLY ASSOCIATED CONDITIONS

- Arthralgia
- Patients with severe psoriasis may be at increased risk for heart disease, HTN, and malignancy.

## DIAGNOSIS

### HISTORY

- Duration of the rash (chronic vs. intermittent) and location (scalp, face, extensor, trunk)
- Recent illness, trauma, exposure to cold, emotional stress, recent sore throat
- Recent medications history
- Improvement of rash with sun exposure
- Family history of psoriasis or atopy
- Patients <2 yr old may have a diaper rash that is unresponsive to steroids or antifungal medication.
- Most patients may report chronic, intermittent, pruritic red scaly plaques that appear after recent viral or strep infection.
- Patients may complain of itching and bleeding after a plaque is accidentally unroofed (Auspitz sign) (3).
- Associated symptoms such as arthralgias or nail pitting

### PHYSICAL EXAM

- Psoriasis can appear in multiple forms: Scaly plaques and guttate and pustular forms.
- The lesions may be solitary or multiple.
- They are commonly located on the elbows or knees but may also be distributed on the trunk, scalp (psoriasis vulgaris), flexural areas (inverse psoriasis), and diaper area.
- Guttate (droplike) papular lesions are 2 mm to 1 cm in diameter and are scattered symmetrically on the trunk, proximal extremities, and occasionally the scalp, face, ears, and distal extremities.
- Pustular psoriasis is a rare and serious subtype that appears as sterile pustules with an erythematous base localized on the palms or generalized on the body. It can be complicated by extensive disease, exfoliation, and bacterial sepsis (3).

- Diaper psoriasis: Well circumscribed, erythematous form involves the inguinal folds and can involve the periumbilical area.
- The scalp is a commonly affected area. Disease ranges from minimal erythema to thick, adherent white scales surrounding the hair shafts leading to hair loss.
- Unroofing of plaques can result in bleeding, a diagnostic criteria known as Auspitz sign.
- Scratching the surface of the skin may result in erythematous reactive lesions.
- Nail pitting and arthralgias have also been reported.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

- There is no diagnostic test for psoriasis.
- In severe cases, anemia, elevated ESR, hypoalbuminemia, and uric acid may be seen.
- In pustular psoriasis, leukocytosis and hypocalcemia may be seen.
- Rheumatoid factor is usually negative.

##### Diagnostic Procedures/Other

- Psoriasis is diagnosed clinically; however, skin biopsies may help if the diagnosis is questionable.
- Plaques may bleed when unroofed (Auspitz sign).

##### Pathological Findings

#### Biopsy:

- Plaque: Epidermal thickening, retention of nuclei in stratum corneum and mononuclear infiltrate
- Pustular: Focal collections of neutrophils in stratum corneum or subcorneal layer (Munro microabscesses)

### DIFFERENTIAL DIAGNOSIS

- Plaque psoriasis:
  - Nummular dermatitis
  - Tinea corporis
  - Seborrheic dermatitis
  - Atopic dermatitis
  - Lichen planus
  - Pityriasis rosea
  - Syphilis

- Psoriatic diaper rash:
  - Irritant diaper rash
  - Candidiasis
- Nail psoriasis:
  - Tinea unguium
  - Nail dystrophy
  - Lichen planus
- Pustular psoriasis:
  - Staphylococcal scalded skin syndrome
  - Sweet syndrome

## TREATMENT

- There is no well-established guideline for treatment.
- Therapeutic options should consider extent of disease and parental compliance.
- Treatments may be topical, systemic, or phototherapy:
  - Topical treatments are usually sufficient for localized or mild cases.
  - Systemic therapy should be reserved for severe cases.

## MEDICATION

### First Line

Topical therapy:

- Low-potency corticosteroids: 1–2.5% hydrocortisone t.i.d. for the face and intertriginous areas
- Mid-potency corticosteroids:
  - 0.025% fluocinolone ointment per day
  - 0.1% triamcinolone acetonide per day for the trunk
- Corticosteroid shampoos: Betamethasone valerate, clobetasol propionate, fluocinolone
- Flurandrenolide impregnated tape can be used for nail psoriasis.
- Tacrolimus ointment may be considered to avoid exposure to steroids.
- Moisturizers and emollients are adjunctive therapy.
- Coal Tar Preparation is a traditional and effective treatment; however, it may leave an odor and stain clothes.
- Anthralin 0.1–0.25% is applied to plaques on the trunk and is washed off after 30 min. It should be avoided on the face and intertriginous areas.
- Calcipotriene ointment is a vitamin D3 analog; not approved for children. It should be avoided on the face and intertriginous areas.

## Second Line

- Systemic therapy should be reserved for children with exfoliative, pustular, or severe plaque-type psoriasis recalcitrant to topical therapy.
- Systemic therapy may include methotrexate, cyclosporine, retinoids, and biologic agents (efalizumab, alefacept, infliximab, etanercept). These should be prescribed by a dermatologist.
- Antistreptococcal antibiotics may be used to eradicate streptococcal infection, a common trigger.

## SURGERY/OTHER PROCEDURES

UV phototherapy may be used alone or in conjunction with specific topical therapies.

## DISPOSITION

### Admission Criteria

Few patients require hospitalization, but extensive pustular or exfoliative psoriasis can result in insensible water loss or sepsis due to secondary infection (3).

### Issues for Referral

- Refer to a dermatologist if:
  - Local disease is unresponsive to topical steroids after 2 wk
  - Extensive disease requiring phototherapy
  - Extensive disease requiring systemic therapy
- Refer to a rheumatologist if the patient has joint disease.

## FOLLOW-UP

### Patient Monitoring

Watch for pustules or worsening extent of disease.

### Discharge-Instructions

- Avoid prolonged treatment with corticosteroids, and use low-potency drugs on the face.
- Avoid harsh soaps, minimize friction by avoiding tight-fitting clothes, and avoid vigorous brushing of scalp.

## PROGNOSIS

- Most cases are mild; however, psoriasis has a chronic, recurrent, and unpredictable course of disease.
- Psoriasis is a lifelong disease.

## COMPLICATIONS

- Extensive water loss or sepsis in severe exfoliative or pustular disease
- Rarely associated with superinfection
- Psoriatic arthritis, particularly with the plaque type

## CODES

### ICD9

- 696.0 Psoriatic arthropathy
- 696.1 Other psoriasis and similar disorders

## PEARLS AND PITFALLS

- There is no diagnostic test for psoriasis.
- Mechanical removal of the scales by scratching may result in small bleeding points, a diagnostic criterion known as the Auspitz sign.
- For classic plaque-type psoriasis, the clinical diagnosis is typically easy; other subtypes are often misdiagnosed initially.
- Overuse of topical steroids may result in skin atrophy and worsening disease.
- Excessive washing by parents or the patient may exacerbate the condition; instruction to avoid aggressive overcleaning or scrubbing plaques is important.
- The psychological stress, especially among adolescents, must be addressed.

# PSYCHOSIS

David Chao

Richard J. Scarfone

## BASICS

### DESCRIPTION

- There is no universally agreed-upon definition of psychosis:
  - Broadly defined as a severe disturbance of mental function with impairment in reality testing
  - Narrowly defined as the presence of delusions (fixed, false beliefs that are not rooted in cultural norms) and/or hallucinations (sensory perception that occurs without objective sources in the surrounding environment)
- May be secondary to primary psychiatric disorder or organic (medically-related) etiology, including substance use.
- 3 major categories of primary psychosis: Schizophrenia, acute reactive psychosis, and mood disorder (depressive or bipolar) with psychotic features
- Early recognition and treatment of primary psychotic disorders improves functioning and prognosis.

### EPIDEMIOLOGY

Primary psychotic disorders are among the top 10 causes of disability-adjusted life-years (disease burden) worldwide.

#### Incidence

- The incidence of schizophrenia is 1%.
- Primary psychotic disorders rarely occur prior to mid-adolescence.
- Peak age of onset is 18–25 yr in men and 25–35 yr in women (1).
- Presentations of psychotic symptoms outside of these ages should prompt rigorous investigation into organic etiologies.

### RISK FACTORS

Family history of psychotic or mood disorders:

- Concordance rate for schizophrenia in monozygotic twins is 55% vs. 13.5% in same-sex dizygotic twins (1).
- A greater incidence of mood disorders has been shown in relatives of psychotic patients, but the reverse has not been shown.

### PATHOPHYSIOLOGY

- Psychosis is traditionally linked to overactivity of dopamine in the brain, particularly in the mesolimbic pathway (“dopamine hypothesis”):
  - Dopamine-blocking drugs (antipsychotics) tend to reduce the intensity of psychotic symptoms, while dopamine-boosting drugs (amphetamines, cocaine) can trigger psychotic symptoms.
- There is recent evidence that dysfunction of glutamate and the NMDA receptor may play an even larger role in acute psychosis.

### ETIOLOGY

- Organic causes
- Neurologic: Tumors, infection, stroke, seizure disorder (especially temporal lobe epilepsy), cerebral hypoxia
- Metabolic: Electrolyte imbalance (ie, hypoglycemia, hypocalcemia), uremia/liver failure, porphyria, Wilson disease, Reye syndrome
- Endocrinologic: Thyroid disease, adrenal disease, diabetes mellitus
- Rheumatologic: Systemic lupus erythematosus, polyarteritis nodosa
- Infectious: Sepsis, meningitis, encephalitis, malaria, typhoid, subacute bacterial endocarditis
- Illicit substances: Amphetamines, stimulants (cocaine, crack), hallucinogens, inhalants, PCP, marijuana, alcohol, barbiturates, benzodiazepines, opiates
- Medications: Anticholinergics, antihistamines, antipsychotics, anticonvulsants, corticosteroids, hypnotics, over-the-counter cold medications, chemotherapeutic agents, antibiotics (especially quinolones), anesthetics
- Toxins: Heavy metals, carbon monoxide

## DIAGNOSIS

### HISTORY

- Features of psychosis: Aberrations in cognition, perception, mood, impulses, and reality testing (1)
- Positive symptoms (excess or distortion of natural functions): Delusions, hallucinations, disorganized thought/speech, grossly disorganized behavior
- Negative symptoms (decrease or loss of natural functions): Inappropriate or flat affect, isolation (apathy and social withdrawal)
- Associated features: Anhedonia (loss of interest or pleasure), poor insight into symptoms
- Premorbid symptoms of primary psychotic disorders are typically negative in nature: Social withdrawal, irritability, neglect of self-care, declining school performance, affective flattening (2)
- Most common symptoms of acute primary psychosis in adolescence: Auditory hallucinations, thoughts spoken aloud, delusions of external control

### PHYSICAL EXAM

- Organic psychosis: Patient typically is agitated, confused, disoriented, and distractible and demonstrates memory impairment (3).
- Features of the mental status exam include orientation, appearance, memory, cognition, behavior, relatedness, speech, affect, thought content, insight/judgment:
  - Key areas of derangement in a psychotic patient are relatedness, affect, and thought content.
- A patient with primary psychotic disorder may appear disheveled and withdrawn without demonstrating overt symptoms of psychosis.
- A psychotic patient may appear agitated, respond to internal stimuli, and speak/act bizarrely. Conversely, he or she may seem internally preoccupied and avert eye contact.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

- An initial presentation of psychosis should prompt an evaluation for organic causes:
  - Electrolytes, blood glucose, and toxicologic screens should be performed in all patients (4).
- Other lab testing should be guided by the patient’s history and physical exam.

#### Imaging

The acquisition of other diagnostic evaluations, such as head CT or MRI, electroencephalogram, or lumbar puncture should be guided by the history and physical exam.

### DIFFERENTIAL DIAGNOSIS

Factitious disorder (illness feigned for secondary gain)

## TREATMENT

### INITIAL STABILIZATION/THERAPY

- Ensure patient and provider safety:
  - Have the patient change into a hospital gown and secure belongings out of reach.
  - The patient should be under constant supervision by emergency department personnel (preferably 1:1 observation).
  - The exam room should be free of objects with which the patient can use to cause self-harm.
  - Universal precautions should be practiced.
  - Place the patient in a low-stimulus environment.
- Reassurance and verbal redirection should be attempted before pharmacologic or physical restraints are used:
  - Approach the patient in a calm and nonjudgmental manner.
  - Allow the patient to verbalize his or her feelings.
  - Explain to the patient what can be expected during the emergency department stay.
- The decision to restrain a patient should not be made lightly. Restraints can harm patients physically (numerous reports of patient death resultant from improper restraint use) and/or psychologically (lead to feelings of shame, loss of self-esteem, and frank posttraumatic stress disorder) (5):
  - Joint Commission for the Accreditation of Healthcare Organizations (JCAHO) guidelines mandate that health care institutions monitor use of restraints and develop protocols emphasizing the least restrictive practices possible.
  - Consider if a patient poses an acute danger to self or others.
  - Adequate staffing is needed to apply the restraints.
  - 1 member of the treatment team should act as a team leader and direct the rest of the team in the placement of restraints and ensure that restraints are applied safely.
  - Other members of the team should have minimal communication with the patient. The leader should briefly inform the patient of the need for physical restraints and debrief with the patient after restraints are applied.

- The patient should be reminded that the restraints were not applied as punishment but were applied to ensure safety.
- Staff members holding a patient should be reminded not to apply pressure to the patient's joints and to avoid contacting the face, neck, and torso in order to prevent suffocation and other serious injuries.
- Sedating and antipsychotic medications are commonly used as chemical restraints if physical restraints have failed or are inadequate:
  - No medications have been approved by the FDA for the purpose of pharmacologic restraint of patients.
  - Monitor the patient's vital signs, general condition, and changes in clinical status with attention to potential side effects.
  - A patient should be offered an oral form of a medication whenever reasonable before the intramuscular form is considered.
  - Sedating medications commonly used include antihistamines (eg, diphenhydramine) and shorter-acting benzodiazepines (eg, lorazepam).
    - Diphenhydramine or hydroxyzine 1.25 mg/kg up to 50 mg/dose PO/IM/IV (onset of action 5–15 min IM/IV and 20–30 min PO)
    - Lorazepam or midazolam 0.05–0.1 mg/kg (midazolam to 0.15 mg/kg) up to 4 mg/dose PO/IM/IV (may redose q60min) (onset of action 5–15 min IM/IV and 20–30 min PO)
- Phenothiazines (eg, chlorpromazine) and butyrophenones (eg, haloperidol) are the most commonly used antipsychotic medications used for acutely psychotic patients:
  - Haloperidol 0.1 mg/kg up to 5 mg/dose PO/IM: May redose q60min. Onset of action 15–30 min IM and 30–60 min PO.
- “Atypical antipsychotics” (eg, risperidone, olanzapine, quetiapine, ziprasidone) are newer agents that are being used with increasing frequency in the acute care setting:
  - Advantages of these medications are that they act more specifically on the “positive” symptoms of schizophrenia and result in decreased incidence of extrapyramidal symptoms and tardive dyskinesia when used long-term.
- The major side effect of typical antipsychotics is acute dystonic reaction, which is characterized by abnormal muscle tone or posturing:
  - Treatment for acute dystonic reactions are diphenhydramine 25–50 mg PO/IM/IV or benztropine 1–2 mg PO/IM.
- Antipsychotics, particularly the older agents, can prolong the QTc interval.
- Providers must remember that use of chemical restraints will likely alter clinical signs and symptoms and make evaluation of a psychotic patient more challenging.

## DISPOSITION

### Admission Criteria

- Further medical evaluation and has not returned to baseline functioning.
- At risk of harm to self or others but medically stable: Admit to a psychiatric hospital.
- Unable to attend to self-care and family unable to adequately provide care
- Persistently psychotic
- Newly diagnosed psychosis

### Discharge Criteria

A patient may be discharged home in the care of family members if team members feel that he or she is not at risk of harm to self or others and adequate outpatient follow-up is arranged.

## FOLLOW-UP

### FOLLOW-UP RECOMMENDATIONS

- Patients who are determined to have a primary psychotic disorder should receive follow-up psychiatric care.
- Patients who are diagnosed with organic-based psychosis should receive follow-up medical care.
- Patients with substance-induced psychosis should be stabilized medically and referred to substance-abuse counseling.
- Patients who are started on antipsychotic medications should have reassessment 2, 4, and 12 wk later and then every 3–6 mo thereafter to monitor for adverse effects.

### PROGNOSIS

- Prognosis of primary psychotic disorders is variable (6):
  - Most clinical and psychosocial deterioration in schizophrenia occurs within the 1st 5 yr of illness onset.
  - Schizophrenia and mood disorder with psychotic features are regarded as chronic diseases that often result in a lifetime of fluctuating symptoms and morbidity.
- Studies have shown that the earlier primary psychotic disorders are recognized and treated, the better the prognosis for affected patients.
- The rate of suicide in schizophrenics is high (5.6%), with most incidents occurring shortly after onset of illness.

## CODES

### ICD9

- 295.90 Unspecified type schizophrenia, unspecified state
- 298.8 Other and unspecified reactive psychosis
- 298.9 Unspecified psychosis

## PEARLS AND PITFALLS

- Psychosis can be secondary to a primary psychiatric disorder or organic pathology.
- Features suggestive of a primary psychosis include insidious onset, prediagnosis or family history of psychiatric disorder, normal physical exam, and auditory hallucinations.
- Symptoms of social withdrawal, irritability, neglect of self-care, and declining school performance combined with affective flattening and poor relatedness should prompt consideration of a primary psychotic disorder.
- A complete investigation into organic etiologies for an initial presentation of psychosis is warranted.

# PULMONARY CONTUSION

Katrina E. Iverson  
Curt Stankovic

## BASICS

### DESCRIPTION

- Pulmonary contusion is a bruise of the lung tissue.
- There is pulmonary parenchymal damage with edema and hemorrhage in the absence of an associated pulmonary laceration.

### EPIDEMIOLOGY

#### Incidence

- Most common injury associated with thoracic trauma in children
- Occurs in 30–75% of all blunt thoracic injury admissions (1)

#### Prevalence

Accounts for ~10% of all pediatric trauma admissions (2)

### GENERAL PREVENTION

- Correct use of child car seats
- Air bags and seat belts
- Protective athletic equipment

### PATHOPHYSIOLOGY

- Increased compliance of the pediatric skeleton makes chest wall injuries less common than internal organ injuries.
- In 80% of cases, an extrathoracic injury is present.
- Blunt force transmitted to the lung parenchyma results in damage to the capillaries:
  - Capillary damage results in blood and fluid filling the alveoli.
  - Gas exchange is impeded due to fluid-filled alveoli, resulting in ventilation-perfusion mismatch and hypoxemia.
  - Lung compliance decreases and consolidation and atelectasis occur as fluid collects in the alveoli.
  - Secondary inflammatory cascade worsens inflammation and edema, increasing the likelihood of respiratory difficulty and potentially respiratory failure.

### ETIOLOGY

- Blunt thoracic trauma:
  - Typically occurs during rapid deceleration when the chest wall collides with a fixed object
  - ~70% of all cases involve motor vehicles.
  - Commonly associated with a fall from height
- May be associated with crush, blast injury, gunshot to patient wearing body armor, or blow with an instrument that delivers great force such as baseball bat:
  - A significant amount of force is transmitted to the lung parenchyma.
  - Blast lung is a result of an explosion and results in a severe pulmonary contusion. It is a combination of blood-filled distal airways and pulmonary edema with damaged alveoli and vessels.

### COMMONLY ASSOCIATED CONDITIONS

- Extrathoracic injury
- Rib fracture or flail chest in adolescents

## DIAGNOSIS

### HISTORY

- History of trauma is typical.
- Time of injury, speed of collision, seat belt use, air bag deployment, and estimate of deceleration are all important historical factors.
- The mechanism of injury should increase the suspicion of pulmonary contusion (eg, motor vehicle collision, crush injury, blast, or blunt instrument).
- Difficulty breathing, dyspnea, or chest pain following trauma
- Hemoptysis

### PHYSICAL EXAM

- Assess vital signs, with attention to respiratory rate and oxygen saturation:
  - Tachypnea and tachycardia may be present and worsen with increasing pulmonary edema.
- Examine for thoracic trauma.
- Evidence of multisystem injury should increase suspicion:
  - Can see subtle onset of splinting respirations 6–12 hr post-injury
- Examine for thoracic trauma: The presence of thoracic wall ecchymosis or tenderness should increase suspicion of a pulmonary contusion:
  - Bony step-off or crepitus may indicate associated rib fractures.
- Tachypnea and tachycardia may be present and worsen with increasing pulmonary edema.
- Crackles or decreased breath sounds are rarely heard on auscultation.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

- CBC
- Blood type and cross-match
- Consider the following:
  - LFTs
  - Lipase
  - Urinalysis
  - Creatine phosphokinase
  - Myoglobin
- Arterial or capillary blood gas may reveal a low partial pressure of oxygen or a high partial pressure of CO<sub>2</sub> indicating poor gas exchange (3):
  - Blood gas is usually normal in the initial stages of pulmonary contusion.

#### Imaging

- Chest radiograph may reveal a consolidated area:
  - Initial chest radiograph is diagnostic in 75–97% of patients.
  - Consolidation secondary to a pulmonary contusion is not restricted by anatomic boundaries such as lobes or lung segments.
  - CXR findings lag behind the clinical picture and may underestimate the size of the contusion.
  - Radiographic findings may be delayed up to 12 hr post-injury.
  - CXR may not reveal the true extent of injury until 48 hr post-injury.

- CT scan is more sensitive than plain radiograph for identifying a pulmonary contusion, but its findings are often of little clinical importance (4).
- Consider echo for suspicion of myocardial contusion.

### Diagnostic Procedures/Other

- Obtain an ECG.
- Focused abdominal sonograph for trauma (FAST) exam to assess for pericardial effusion and general cardiac function
- Sonography may play a role in screening for pneumothorax, though this is user dependent and not yet clearly defined.

### Pathological Findings

- Blood- and plasma-filled alveoli
- Thickened alveolar septae
- Decreased alveolar diameter
- Increased neutrophils in lung tissue

### DIFFERENTIAL DIAGNOSIS

- Pulmonary laceration
- Hemothorax
- Pneumothorax
- Aspiration
- Pulmonary edema
- Myocardial contusion
- Pneumonia
- Trauma to the chest

## TREATMENT

### PRE HOSPITAL

- Assess and stabilize airway, breathing, and circulation.
- Administer supplemental oxygen, preferably by nonrebreather mask.

### INITIAL STABILIZATION/THERAPY

- Assess and stabilize airway, breathing, and circulation.
- Administer supplemental oxygen, preferably by nonrebreather mask.
- Ventilatory support
- Noninvasive positive pressure ventilation such as CPAP and BiPAP should be considered to treat atelectasis and correct hypoxemia prior to mechanical ventilation in a cooperative patient (3):
  - CPAP has been associated with lower mortality and nosocomial infection rates than with mechanical ventilation (3).
- Mechanical ventilation should be used to correct gas exchange, not for correction of chest wall mechanics (3):
  - Larger contusions have been associated with the need for mechanical ventilation.
  - High PEEP (10–15 cm H<sub>2</sub>O) may be required to keep open the alveoli due to decreased compliance (3).
  - Mechanical ventilation should be used judiciously since it prolongs hospitalization and is associated with a higher complication and mortality rate.
- Obtain vascular access.
- Continuous cardiopulmonary monitoring

**MEDICATION****First Line**

- Analgesic
- Ibuprofen 10 mg/kg PO/IV q6h
- Morphine 0.1 mg/kg IV/IM/SC q2h PRN:
  - Initial morphine dose of 0.1 mg/kg IV/SC may be repeated q15–20min until pain is controlled, then q2h PRN.
- Normal saline or lactated Ringer solution 20 mg/kg bolus repeated as necessary for fluid resuscitation

**ALERT**

- Avoid aggressive IV fluid resuscitation, which can worsen pulmonary edema and lead to death (3,4).
- Avoid oversedating to prevent hypoventilation and worsening atelectasis (3,4).

**Second Line**

- Diuretics are indicated in the event of hydrostatic fluid overload:
  - Furosemide 1 mg/kg IV q4–6h
- Local anesthetic for rib block to treat rib fracture:
  - Lidocaine: Max single dose of 4.5 mg/kg (without epinephrine) or 7 mg/kg (with epinephrine)
  - Ropivacaine 0.2%, 2 mg/kg:
    - Preferred over bupivacaine due to cardiovascular risk of bupivacaine
  - Bupivacaine 0.25%, 2–2.5 mg/kg:
    - Bupivacaine use imparts risk of cardiac dysrhythmia if inadvertently administered intravascularly.
- Antibiotics should not be routinely administered for prophylactic reasons:
  - Administer if fever and worsening respiratory status develop, increasing the concern for a secondary pneumonia (3).
- Steroids should be avoided (3,5).

**COMPLEMENTARY & ALTERNATIVE THERAPIES**

- Aggressive pulmonary therapy to help clear blood/fluid and prevent further atelectasis
- After resuscitation, fluids should be carefully administered to avoid increasing edema in the contused lung:
  - A pulmonary artery catheter may be useful to avoid fluid overload.

**SURGERY/OTHER PROCEDURES**

- Tube thoracostomy if a hemothorax or pneumothorax is present
- Surgical repair of severe flail chest:
  - Repair has been shown to reduce ventilator days, narcotic use, and dyspnea while improving lung volumes and mortality (6).

**DISPOSITION****Admission Criteria**

- All patients with a pulmonary contusion should be admitted for observation for worsening respiratory status and supportive care (3).
- Critical care admission criteria:
  - Any patient with a pulmonary contusion and severe tachypnea or hypoxemia
  - Admission for other severe injuries, such as myocardial contusion, or flail chest

**Discharge Criteria**

- No hypoxemia, tachypnea, or difficulty breathing
- CXR without evidence of pulmonary contusion

**Issues for Referral**

- Patients with prolonged exertional dyspnea or chest pain should be referred to pulmonology.
- Cardiology referral if associated cardiac injury

**FOLLOW-UP****FOLLOW-UP RECOMMENDATIONS**

- Discharge instructions and medications:
  - Continue analgesics as needed.
  - Incentive spirometry and avoidance of prolonged inactivity to decrease atelectasis
- Activity:
  - As tolerated

**Patient Monitoring**

- Continuous cardiorespiratory monitor while hospitalized
- Consider central venous and pulmonary arterial pressure monitoring to help guide fluid management.

**DIET**

Fluid restriction to avoid exacerbation of pulmonary edema

**PROGNOSIS**

- Variable prognosis depending on severity of contusion as well as associated injuries
  - Children have better outcomes than adults.
  - Mortality has been associated with pulmonary function at the time of admission.
  - The mortality rate is higher in ventilated patients.
  - Long-term complications are more likely with severe pulmonary contusions.

**COMPLICATIONS**

- Exertional dyspnea and persistent chest wall pain
- Pleural effusion
- Pneumothorax
- Hemothorax
- Pneumonia in 20%
- Acute respiratory distress syndrome in 5–20%
- Death

**ADDITIONAL READING****See Also (Topic, Algorithm, Electronic Media Element)**

- Fracture, Rib
- Trauma, Chest

**CODES****ICD9**

- 861.21 Contusion of lung without open wound into thorax
- 861.31 Contusion of lung with open wound into thorax

**PEARLS AND PITFALLS**

- Pearls:
  - It takes an average of 6 hr for a pulmonary contusion to be visible on chest radiograph.
  - IV fluid overload can result in pulmonary edema and death.
  - Hypoxemia secondary to a severe pulmonary contusion cannot be corrected with oxygen alone.
- Pitfalls:
  - Failing to recognize associated head and intra-abdominal injuries
  - Failing to realize that pulmonary contusions slowly worsen over a few days

# PULMONARY EDEMA

Pradeep Padmanabhan

## BASICS

### DESCRIPTION

- Pulmonary edema (PEd) is accumulation of fluid in alveoli, bronchioles, and interstitium.
- PEd may be life threatening since exchange of oxygen and carbon dioxide in the lungs can be compromised, resulting in respiratory failure.
- PEd may be due to increased hydrostatic pressures within the alveolar capillaries (increased pressure or cardiogenic PEd) or from damage of integrity of alveolar vasculature (noncardiogenic or increased permeability PEd) (1).
- Severe noncardiogenic PEd is termed adult respiratory distress syndrome (ARDS).

### RISK FACTORS

- Congenital heart disease, especially left-sided outflow tract obstruction
- Pneumonia
- Nephrotic syndrome
- Septic shock

### PATHOPHYSIOLOGY

- Specific mechanisms have been identified for various causes of PEd. It results from complex alterations of balance between intravascular, interstitial hydrostatic and colloid osmotic pressures.
- In cardiogenic PEd, the integrity of the alveolar capillary membrane is intact. Left-sided obstructive cardiac lesions (eg, aortic stenosis, coarctation of aorta) and hypervolemia increase the hydrostatic pressures within the pulmonary vasculature, whereas left to right cardiac shunts (eg, patent ductus arteriosus, ventricular septal defect) increase pulmonary blood flow.
- Protein loss (eg, burns, nephrotic syndrome) reduces colloid osmotic pressures and causes osmotic fluid shifts resulting in PEd.
- Alterations in vascular permeability (eg, sepsis, snake bite) and lymphatic drainage cause PEd. Damage to the alveolar-epithelial membrane can result from destruction of proteins and direct cell damage.
- Children exposed to hypoxia at high altitudes have increased incidence of pulmonary HTN with delayed closure of ductus arteriosus contributing to PEd.
- High altitude pulmonary edema (HAPE) is characterized by increased pulmonary artery pressures and decreased left ventricular function. In HAPE, carotid body stimulation in response to hypoxia leads to hyperventilation and significant respiratory alkalosis.

- Neurogenic PEd occurs from insult to the medullary centers controlling systemic and pulmonary arterial pressures. The increase in pulmonary and systemic arterial pressures results in PEd.
- Drowning in seawater results in significant fluid transfer by osmosis from vasculature into the alveoli, resulting in severe PEd.

### ETIOLOGY

- PEd can result from inflammatory conditions such as burns, drowning or near drowning, smoke inhalation, pneumonia, aspiration, and asthma.
- ARDS results from injury to the capillaries surrounding the alveoli. ARDS can occur in children.
- HAPE develops with sudden exposure to high altitudes (heights > 1,500 m). Speed of ascent, elevation reached above sea level, and inadequate prior exposure/acclimatization to heights contribute to development of HAPE (1).
- Neurogenic PEd can occur in marathon runners due to hyponatremia and in transfusion-related lung injury likely from HLA incompatibility.
- Re-expansion PEd develops when lung volume increases suddenly, usually after resolution of an event (eg, pneumothorax, lobar atelectasis, etc.).
- In neonates, delayed absorption of pulmonary fluid after birth can cause persistent PEd.
- Cardiogenic etiology includes CHF, endocarditis, myocarditis, and cardiomyopathy.
- Hypoalbuminemia/Decreased oncotic pressure may result from nephrotic syndrome, protein-losing enteropathy, hepatic failure, and renal failure.

### COMMONLY ASSOCIATED CONDITIONS

- Left to right cardiac shunts
- Cardiomyopathy
- Burns and smoke inhalations
- Nephrotic syndrome
- Sepsis

## DIAGNOSIS

### HISTORY

- The onset is usually rapid, especially with HAPE. Dyspnea, cough, difficulty breathing, and chest pain are main clinical features.
- Young children and infants may present with nonspecific symptoms initially, such as fussiness, decreased appetite, activity, and sleep, and later, grunting and cyanosis.
- Hemoptysis, indicating pulmonary hemorrhage, can be associated with noncardiogenic PEd.
- History of exposure to smoke or chemicals, drowning, or trauma should be obtained.
- The possibility of an infectious cause should be strongly considered in the absence of obvious etiology.
- Past medical history of heart or renal disease should be ascertained.

### PHYSICAL EXAM

- Assess vital signs, with particular attention to respiratory rate and oxygen saturation.
- Respiratory findings are most common: Wheezing, rhonchi, or rales with accessory muscle use may be present.
- Initially, when fluid accumulation is minimal, the exam may be completely normal.
- Child may exhibit respiratory distress with tachypnea, tachycardia, and retractions.
- On auscultation, decreased breath sounds (unilateral or bilateral) and rales may be noted.
- Cardiovascular evaluation may reveal edema, jugular venous distention, and abnormal heart sounds.
- A cardiogenic origin of PEd should be suspected by signs of CHF such as abnormal heart sounds (muffled, gallop rhythm), hepatomegaly, and venous congestion.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

- Arterial blood gas: The degree of hypoxemia (low pO<sub>2</sub>) correlates with severity. With HAPE, the initial respiratory alkalosis is replaced by acidosis due to the continued accumulation of fluid and poor gas exchange. Metabolic acidosis may be present depending on the cause (eg, sepsis).
- Elevations of brain natriuretic peptide (BNP) >500 pg/mL can support a cardiogenic origin of PEd, while values <100 pg/mL signify noncardiogenic PEd.
- In fulminant PEd, protein content of edema fluid obtained from tracheal aspirates can differentiate cardiogenic PEd (edema fluid–serum protein concentration <0.65) from increased permeability PEd (edema fluid–serum protein concentration >0.75).
- Hypermagnesemia may be noted in seawater drowning due to its high magnesium content.
- Other tests such as cultures of blood and/or sputum and toxicology screens should be guided by the history and exam.

#### Imaging

- CXR is the initial test of choice to diagnose PEd. However, CXRs may appear normal with minimal PEd, and the severity of disease is difficult to predict based on CXRs alone:
  - In cardiogenic PEd, cardiomegaly, hilar infiltrates, and pleural effusions are prominent features, whereas normal heart size and peripheral infiltrates point to noncardiogenic PEd.
  - Radiologic features of PEd include the Kerley A sign (linear lines along the hilum) or the Kerley B sign (lines along the periphery) and flattening of the diaphragm from obstruction of airways by bronchial fluid accumulations.
  - Fulminant PEd can obscure the underlying lung pathology (eg, pneumonias and atelectasis).
- CT scans, though more sensitive, have limited usefulness in critically ill children.

**Diagnostic Procedures/Other**

- ECG may manifest a right ventricular strain pattern (negative T waves in precordial leads) in cardiogenic PE<sub>d</sub>.
- Echo can identify valvular abnormalities and ventricular dysfunction in cardiogenic PE<sub>d</sub>.
- Exercise Doppler demonstrating raised pulmonary artery pressures may identify adolescents at risk of developing HAPE when exposed to high altitudes.

**DIFFERENTIAL DIAGNOSIS**

- Pneumonia
- Asthma
- CHF
- Pulmonary embolism
- Pericardial tamponade
- Pleural effusion

**TREATMENT**

- The management of PE<sub>d</sub> includes hemodynamic stabilization, improving oxygenation and ventilation, decreasing the work of breathing, clearance of fluid in lungs, and most importantly, treatment of the cause.
- Protection of the airway is critical and early intubation is advised in children who are likely to deteriorate.
- Measures to correct noncardiogenic PE<sub>d</sub> should also prevent worsening of lung injury in addition to supportive measures.
- In HAPE, immediate transportation of patients to lower altitudes is essential.

**MEDICATION**

- Supplemental oxygenation improves tissue oxygen delivery, decreases the work of breathing, and improve vascular permeability by removing inflammatory mediators:
- Vasodilators act quickly by decreasing vascular resistance (reduces cardiac afterload) and improving cardiac output and contractility:
  - Morphine 0.1 mg/kg IV/IM/SC q2h PRN:
    - Initial morphine dose of 0.1 mg/kg IV/IM may be repeated q15–20min until pain is controlled, then q2h PRN.
  - IV nitroprusside: Continuous infusion starting at 0.3–1 μg/kg/min
- Loop diuretics act immediately by venous dilatation (decrease pulmonary perfusion) and later by sodium and water clearance from the kidneys. Avoid diuretics in hypovolemia or shock. Diuretics are not indicated for HAPE, re-expansion PE<sub>d</sub>, and in persistent PE<sub>d</sub> in newborns:
  - Furosemide 1 mg/kg IV q6h
- Slow infusion of colloids such as albumin corrects decreased oncotic pressures associated with burns or nephrotic syndrome:
  - Albumin 0.5–1 g/kg/dose IV

**COMPLEMENTARY & ALTERNATIVE THERAPIES**

Ventilatory support by CPAP, BiPAP, and mechanical ventilation decrease preload and afterload, increase peak end expiratory pressure, redistribute alveolar fluid, and reopen collapsed alveoli (2,3).

**SURGERY/OTHER PROCEDURES**

- Continuous arteriovenous hemofiltration along with dialysis may be useful to remove excess fluid in children with renal failure.
- Surgical removal may be indicated for PE<sub>d</sub> from upper airway obstruction (eg, foreign body).

**DISPOSITION****Admission Criteria**

- Patients with newly diagnosed CHF should be admitted for workup and treatment.
- Critical care admission criteria:
  - Patients with unstable vital signs, requiring pressors, or ventilatory support by mechanical ventilation or CPAP/BiPAP

**Discharge Criteria**

Stable patients for whom life-threatening etiologies have been ruled out may be discharged with close follow-up.

**Issues for Referral**

Refer patients to a specialist such as a cardiologist, nephrologist, pulmonologist, etc. based on the etiology.

**FOLLOW-UP****FOLLOW-UP RECOMMENDATIONS**

- Children should be evaluated completely for risk factors before high-altitude trips for susceptibility to HAPE.
- Prophylactic beta-agonists and calcium channel blockers (nifedipine) have been found to be effective in reducing recurrences of HAPE in adults.

**PROGNOSIS**

- The prognosis is largely dependent on quick recognition and prompt and effective management as well as the underlying etiology.
- HAPE is rapidly reversible with descent to lower elevation and oxygen therapy. The rapid improvement suggests that significant lung injury with increased permeability may not be a feature of HAPE (4).
- Children with prior history of HAPE have a high rate of recurrence when they return to high altitudes.
- Persistent PE<sub>d</sub> in newborns resolves in 4 days with supportive care alone.

**See Also (Topic, Algorithm, Electronic Media Element)**

Congestive Heart Failure

**CODES****ICD9**

- 514 Pulmonary congestion and hypostasis
- 518.4 Acute edema of lung, unspecified

**PEARLS AND PITFALLS**

- PE<sub>d</sub> is difficult to diagnose in the initial phases when the exam and imaging can be normal.
- Since findings on physical exam and imaging studies can be nonspecific, a high index of suspicion is required. A history of predisposing comorbidities will offer clues to the diagnosis.
- Early intubation is preferred in PE<sub>d</sub> associated with burns or smoke inhalation due to increased risk of airway edema.
- While mechanical ventilation and CPAP improve pulmonary fluid clearance and correct respiratory failure, caution should be exercised as left ventricular ejection fraction can also be compromised.
- Positive fluid balance has been associated with poor outcome in PE<sub>d</sub>. Therefore, fluid status should be carefully monitored to prevent fluid excess.

# PULMONARY EMBOLISM

Raquel Mora

## BASICS

### DESCRIPTION

- Pulmonary thromboembolism (PE) is a pulmonary artery obstruction by thrombus, whether endogenous, exogenous, or local.
- PE most commonly results from a thrombus originating in a deep leg vein and embolizing to the lung.
- The size of the thrombus determines the severity of illness.

### EPIDEMIOLOGY

#### Incidence

- Clinically important PE occurs in 25 per 100,000 admissions:
  - Incidence after trauma is <1% (1).
  - Most cases are in adolescents.
  - Rare in child <5 yr old unless risk factors are present
- Incidence of PE in child with deep vein thrombosis (DVT) is 30%.

#### Prevalence

- 0.7/100,000 in the general pediatric population (2)
- Up to 40% of pediatric patients with thrombus have no known underlying predisposition:
  - >80% of these will later be determined to have a hypercoagulable state.
  - 4% have idiopathic thrombosis.

### RISK FACTORS

- Most patients have an identifiable risk factor.
- Age is not an independent risk factor for PE (3):
  - Those <1 yr old have the greatest risk (due to congenital malformations with risk factors for PE) with decreasing incidence thereafter (5).
- Sickle cell disease:
  - PE is the 2nd most frequent lung finding in patients admitted and at autopsy.
- Congenital heart disease
- Central venous lines:
  - Ventricular atrial shunts for hydrocephalus
  - Most important risk factor in children, especially neonates
  - >50% of catheter-induced DVT involve the upper extremities
- Neoplasm:
  - Solid tumors have 2.5 times relative risk for PE.
  - Leukemias, especially hyperleukocytosis
- Thrombophilia (congenital or acquired):
  - Inherited: Protein C or S or antithrombin III deficiencies, dysfibrinogenemia, factor V Leiden, congenital angiiodysplasia
  - Acquired: Conditions associated with reduced protein synthesis—systemic lupus erythematosus, antiphospholipid syndrome, nephrotic syndrome, liver disease, cystic fibrosis, malabsorption syndromes, burns
- Trauma:
  - In children, soft tissue extremity injury without fracture is a risk for thrombosis.
- Oral contraceptive use
- Pregnancy
- Abortion
- Septic thrombosis

- DVT:
  - Occurs less frequently in children than adults
- Surgery: Highest risk is cardiac.

### GENERAL PREVENTION

Prophylactic therapies for high-risk conditions:

- Low-dose heparin 1 U/kg/hr via IV (3)
- Aspirin 3–5 mg/kg/day
- Venal caval filters (IVC filters):
  - Does not prevent DVT
  - May cause caval thrombosis

### PATHOPHYSIOLOGY

- In the development of PE,  $\geq 1$  factors in the Virchow triad is typically present: Venous stasis, altered coagulation, and vessel injury (2).
- After trauma, thrombus typically develops after 2 wk; can occur <24 hr of trauma (3,6).
- Septic thromboembolism is predominantly due to *Staphylococcus aureus*.
- With PE, there is increased alveolar dead space and increased pulmonary arterial resistance and pressures.
- Perfusion is compromised with increased carbon dioxide levels and hypoxemia.
- If the PE is severe enough (obstructing >50% of pulmonary circulation), right heart failure and pulmonary HTN can occur.

### ETIOLOGY

See Risk Factors.

## DIAGNOSIS

### HISTORY

- >90% of symptomatic patients will have 1–2 risk factors for venous thromboembolism (7).
- Inquire about:
  - Dyspnea
  - Pleuritic chest pain
  - Cough
  - Hemoptysis
  - Tachypnea
  - Fever
  - Diaphoresis
  - Leg pain/swelling
  - Smoking
  - Oral contraceptive use
  - Past medical/surgical history
- No clinical prediction rules exist for children.

### PHYSICAL EXAM

- Tachycardia
- Tachypnea
- Rales
- Cyanosis
- Dyspnea
- DVT: Swelling, erythema, skin discoloration, warmth, tenderness, venous distension, subcutaneous collateral veins

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

- ECG, though findings are usually nonspecific.
- Arterial blood gas
- D-dimer level via ELISA (2):
  - Produced by breakdown of fibrin in clots
  - Highly sensitive in diagnosis of PE (96–100%), in patients with low to intermediate probability of PE
  - Not recommended for patients with high pretest probability of PE
  - Limited usefulness in children because many with PE have clinical conditions that are high risk for PE
  - Malignancy, pregnancy, or surgery are associated with false-positive D-dimer results.
  - Chronic or subacute PE may be associated with false-negative D-dimer results.
- Brain natriuretic peptide and troponin are used commonly in prognostication of PE outcome in adults; utility in children is unclear.

#### Imaging

- Noninvasive imaging has not been validated in children
- DVT:
  - Venogram (2):
    - Diagnostic standard in adults
    - Useful in upper extremities
    - Must perform bilaterally since high false-negative rate if unilateral
  - Duplex Doppler scan (2):
    - Sensitive in neck and proximal lower extremity veins
    - Less sensitive above groin, below knee, or in upper extremities
    - Difficult in young patients with smaller vessels
  - MRI venogram
    - Useful in pelvis and distal calf areas
- Pulmonary embolism:
  - CXR (2):
    - Not specific or sensitive
    - Parenchymal infiltrates
    - Atelectasis
    - Pleural effusion
  - Ventilation-perfusion scan (2,8):
    - Study of choice and highly sensitive
    - Mismatched defect in areas of absent/abnormally perfused lung that should be ventilated
    - Children typically have a uniform scan, so a perfusion defect is a more reliable finding compared to adults.
    - Ventilation scan requires aerosol inhalation and thus is technically difficult in infants and children <5 yr old.
  - Pulmonary angiography:
    - Gold standard
    - Lacks sensitivity due to technical difficulty in small children and is difficult to interpret in complex congenital heart disease or pulmonary disease
  - Spiral/Helical CT pulmonary angiography:
    - Preferred method in adults with high sensitivity
    - Utility in children is unknown.
- Echo:
  - Directly visualizes clot within the heart and/or central pulmonary arteries
- Magnetic resonance angiography (MRA):
  - Noninvasive
  - High sensitivity and specificity
  - No studies exist examining withholding anticoagulation after a negative MRA.

**Diagnostic Procedures/Other**

ECG usually is normal but may show:

- Nonspecific ST changes
- Left axis deviation
- S1Q3T3 pattern

**DIFFERENTIAL DIAGNOSIS**

- Septic thromboembolism
- Tension pneumothorax
- Pneumonia
- Pulmonary infarction
- Collagen vascular disease
- Air, fat, tumor, foreign body embolisms
- Pulmonary artery stenosis

**TREATMENT****INITIAL STABILIZATION/THERAPY**

- Assess and stabilize airway, breathing, and circulation.
- Supplemental oxygen or assisted ventilation as needed
- Massive PE results in hypotension and severe right ventricular strain and may result in rapid demise.

**MEDICATION****First Line**

- Presence of DVT with signs and symptoms concerning for PE warrants therapy for PE (2).
- Unfractionated heparin (9):
  - Loading dose 50–75 u/kg
  - Maintenance 20 u/kg/h in child > 1 yr
  - Maintenance 28 u/kg/h in child < 1 yr
- Low molecular weight heparin (10):
  - 1 mg/kg SC b.i.d. for children > 2 mo of age
  - 1.6 mg/kg SC b.i.d. for children < 2 mo of age
  - Faster therapeutic levels than heparin

**Second Line**

- Thrombolytics (8,11)
- Streptokinase:
  - Load with 2,000 units/kg over 30 min, then 2,000 units/kg/hr.
  - Mediate clot lysis as direct or indirect plasminogen activators.
  - Not definitively proven to be of greater benefit than heparin alone
  - No age restrictions
  - Indications:
    - Massive DVT
    - Massive PE
    - Hemodynamic instability
    - Unresponsive to heparin
- Coumadin:
  - Adjust dose to reach desired INR.
  - Start with 0.2 mg/kg load on day 1, then 0.1 mg/kg/day.
  - For chronic thrombotic disease
  - Discontinue if no hypercoagulability or thrombosis state.
  - DVT: Continue for 3 mo
  - PE: Continue for 6 mo

**COMPLEMENTARY & ALTERNATIVE THERAPIES**

Fresh frozen plasma may be used as a plasminogen source in infants before or during thrombolytic therapy.

**SURGERY/OTHER PROCEDURES**

- Surgical thrombectomy (2):
  - Open surgical or transvenous catheter
- IVC filter (2) indicated for:
  - Contraindications to anticoagulation
  - Recurrent PE with anticoagulation
  - Children > 10 kg

**DISPOSITION****Admission Criteria**

- All patients with new diagnosis of PE or DVT should be admitted.
- Critical care admission criteria:
  - Confirmed PE (2)
  - Evidence of acute DVT with clinical suspicion of PE, even if imaging studies are nondiagnostic

**Discharge Criteria**

If imaging studies exclude PE, there is a low pretest probability, and the patient is stable (2)

**FOLLOW-UP****DIET**

In breast-fed infants, vitamin K antagonists may be indicated since there is a low concentration of vitamin K in breast milk (12).

**PROGNOSIS**

- Thrombosis is the cause of death in ~2% of children hospitalized with DVT (5).
- Death is usually associated with the underlying medical condition.
- Catheter-related thrombosis: Mortality is >20% with significant morbidity:
  - PE > 15%
  - Recurrence 6%
  - Postphlebotic syndrome (swelling, discoloration, collateral circulation, or pain in affected limb ≥ 3 mo) is 9% (13).

**COMPLICATIONS**

- DVT
- Hemorrhage (result of therapies)
- Recurrent thrombosis
- Postthrombotic syndrome
- Hypotension
- Right heart failure
- Shock
- Death

Graham JK, Mosunjac M, Hanzlick RI, et al. Sickle cell lung disease and sudden death: A retrospective/prospective study of 21 autopsy cases and literature review. *Am J Forensic Med Pathol*. 2007;28(2):168–172.

**ICD-9 CODES**

- 415.12 Septic pulmonary embolism
- 415.19 Other pulmonary embolism and infarction

**PEARLS AND PITFALLS**

- Compared to adults, children with PE have different risk factors, medical conditions, and age-related physiology. This makes difficulty in extrapolating data from adult studies.
- PE is rare in children, but those with risk factors and respiratory signs or symptoms should have PE considered in the differential.
- In a child with established DVT and pulmonary signs or symptoms suggestive of PE, therapy should be initiated.

# PYLORIC STENOSIS

Sage Myers

## BASICS

### DESCRIPTION

Pyloric stenosis is hypertrophy of pyloric smooth musculature leading to narrowing of the canal of the pylorus:

- Progressive obstruction as the pylorus elongates and thickens over time
- Results in obstruction at the level of the gastroduodenal junction

### EPIDEMIOLOGY

#### Incidence

Incidence is 2–5 per 1,000 liveborn births in Western countries:

- Recent decline in incidence in many countries
- Decline in incidence is associated with a decline in the rate of sudden infant death syndrome in Denmark.
- Most common surgical condition in infants

### RISK FACTORS

- Increased incidence in males (4–5:1)
- Risk highest in 1st-born children and decreases with each subsequent position in birth order
- Increased risk in Caucasians
- Treatment with erythromycin increases risk, especially in 1st 2 wk of life

### PATHOPHYSIOLOGY

- Increased thickness of pyloric musculature leads to gastric outlet obstruction:
  - Causes inability of liquids to pass from the stomach to the duodenum
  - Results in vomiting after every feed
  - Repeated vomiting leads to dehydration and electrolyte imbalances.
- Metabolic disturbance of hypochloremic, hypokalemic metabolic alkalosis may result from excessive vomiting.

### ETIOLOGY

Unknown:

- Thought to be due to genetic predisposition in conjunction with environmental exposures
- 5 genetic loci have been identified to be associated with predisposition to pyloric stenosis

- 1 specific loci implicated in pyloric stenosis encodes for NOS1, which is the gene for neuronal oxide synthase. This critical enzyme is necessary for the production of nitric oxide and allows for relaxation of smooth muscle.
- No specific genetic pattern of inheritance but increased risk to 1st-degree relatives
- Some evidence for hypergastrinemia and increased gastric acid secretion in causal pathway for pyloric stenosis

### COMMONLY ASSOCIATED CONDITIONS

- Hyperbilirubinemia:
  - Called *icteropyloric syndrome*
  - Hyperbilirubinemia resolves after surgical correction.
  - Usually indirect hyperbilirubinemia
  - Multiple causes, but mainly are due to decreased hepatic glucuronyl transferase activity.
- Midgut malrotation
- Esophageal atresia
- Hypoplastic or absent mandibular frenulum

## DIAGNOSIS

### HISTORY

- Onset of vomiting in the 3rd to 8th wk of life; often described as forceful/projectile
- Vomiting becomes progressively more forceful and frequent over time.
- It is rare to have onset after 12 wk of age.
- Vomiting immediately after feed
- Child often appears very hungry just after having fed and vomited:
  - Referred to as the “hungry vomiter”

### PHYSICAL EXAM

- Olive-shaped mass in the epigastric region, sometimes palpable if the child is relaxed:
  - Hard, mobile, nontender mass; often substernal and just to the right of midline
- May observe reverse peristaltic waves across the upper abdomen, especially if the child has just fed or just before emesis
- If symptoms have been ongoing for a significant period of time, there may be signs of dehydration or hypovolemic shock:
  - Lethargy, sunken fontanelle, tenting of the skin, dry mucous membranes, delayed capillary refill
- If symptoms have been ongoing for a significant period of time, there may be signs of growth failure.

## DIAGNOSTIC TESTS & INTERPRETATION

### Lab

#### Initial Lab Tests

- Chemistry profile:
  - Hypochloremic, hypokalemic metabolic alkalosis is classic, although a normal basic metabolic profile does not exclude the diagnosis
  - May have elevation of BUN and creatinine due to dehydration
  - May have hyponatremia
- Urinalysis:
  - Paradoxical aciduria due to kidney conservation of sodium at the expense of hydrogen

### Imaging

- US has become the imaging modality of choice.
- US of the pylorus will show elongated and/or thickened pyloric musculature:
  - Pyloric canal length  $\geq 1.4$  cm
  - Circular muscle thickness  $\geq 0.3$  cm
  - May note “nipple sign,” caused by the mucosa of the crowded pylorus protruding out into the antrum of the stomach
  - Accuracy is operator dependent.
- X-rays of the abdomen may show a large, distended stomach.
- Barium radiologic studies should be obtained if alternative diagnoses (eg, malrotation with volvulus) seem likely:
  - Upper GI tract radiography may demonstrate contrast in the narrowed pyloric canal (called the *sign*) or as 2 parallel lines (the *double-track sign*), resulting from compression of pyloric mucosa.
  - Can also show a tapered point at the pyloric canal, called the *beak sign*
  - Finally, a bulge of the enlarged pylorus into the atrium of the stomach may produce a rounded projection and is referred to as the *shoulder sign*.
  - Can also be used to rule out malrotation or other anatomic causes of emesis
  - May note vigorous active peristalsis with fluoroscopy

### Diagnostic Procedures/Other

- Large gastric volumes found on placement of an NG tube support the diagnosis of pyloric stenosis.
- Endoscopy can show mucosa from the pylorus protruding into the antrum of the stomach as well as constant spasm of pylorus.

**Pathological Findings**

Although pathologic specimens are not usually sent from surgery, thickened smooth muscle with redundant pyloric mucosa would be seen.

**DIFFERENTIAL DIAGNOSIS**

- Overfeeding
- Gastroenteritis
- Urinary tract infection
- Sepsis
- Raised intracranial pressure
- Malrotation with volvulus
- Gastroesophageal reflux
- Antral web
- Gastric duplication
- Pyloric atresia
- Duodenal stenosis (preampullar)
- Hiatal hernia
- Adrenal crisis

**TREATMENT**

**PRE HOSPITAL**

Fluid resuscitation if significant dehydration:

- 20 cc/kg boluses at a time, and evaluate effect
- Consider additional boluses if the patient remains dehydrated.

**INITIAL STABILIZATION/THERAPY**

- Rehydration with normal saline should begin/continue to correct electrolyte and acid-base abnormalities.
- Once initial rehydration is complete, ongoing rehydration should be undertaken with D5.45 saline at 1.5 times maintenance.

**MEDICATION**

Prior to widespread use of surgical pyloromyotomy, medical therapy was used often. Now, due to curative success of surgery, medical treatment is rarely used in the U.S.:

- When used, IV or oral atropine is given to suppress muscle contraction and break the cycle of ongoing contraction, which is thought to lead to hypertrophy of the smooth muscle of the pylorus.

**SURGERY/OTHER PROCEDURES**

Surgical pyloromyotomy (Ramstedt procedure):

- Surgical incision made, longitudinally, through serosa and smooth muscle of the pylorus, down to submucosa
- Laparoscopic and open techniques are used and are likely equal with respect to operative time and complications.

- Electrolyte imbalances should be corrected before undertaking surgical correction.
- The child should remain without any oral intake in preparation for surgery as well as to maintain electrolyte and acid-base balance.

**DISPOSITION**

**Admission Criteria**

- Most children should be admitted while waiting for surgery.
- Critical care admission criteria:
  - Critical care services are required only for severe metabolic derangements or significant neurologic or cardiorespiratory dysfunction.

**Discharge Criteria**

Well-appearing patients without dehydration or severe metabolic disturbance may be discharged with close follow-up for definitive diagnosis by US or for surgery.

- It is critical that this only be done if reliable follow-up is certain and caregivers understand the gravity of the diagnosis.

**FOLLOW-UP**

**FOLLOW-UP RECOMMENDATIONS**

- The child should be seen within a few days of discharge by a pediatrician to ensure continued tolerance of feedings and evaluate weight gain.
- Feeds and activities at the time of discharge should be as per routine.
- Return of vomiting postoperatively should prompt a return to medical attention.

**DIET**

A full formula or breast milk diet can be resumed as soon as able to advance postoperatively.

**PROGNOSIS**

Surgery is curative:

- Failure of initial pyloromyotomy due to incomplete pyloromyotomy or recurrence of pyloric stenosis is rare; in recent literature is documented at <3%.

**COMPLICATIONS**

- Dehydration or hypovolemic shock
- Hypochloremic, hypokalemic metabolic alkalosis
- Intraoperatively, duodenal perforation is the most common complication.
- Postoperative vomiting and wound infection are possible short-term postoperative complications.
- Incomplete pyloromyotomy is an uncommon but possible postoperative complication.
- As with any abdominal surgery, postoperative adhesions are possible and may lead to obstruction at a time distant from the surgery.
- Mortality after pyloromyotomy is very low at <0.5%.

**CODES**

**ICD9**

- 537.0 Acquired hypertrophic pyloric stenosis
- 750.5 Congenital hypertrophic pyloric stenosis

**PEARLS AND PITFALLS**

- Patients with classic symptoms may have initial imaging by sonogram that is interpreted as normal only to subsequently be diagnosed with pyloric stenosis when the condition worsens.
- Hypochloremia, hypokalemic metabolic alkalosis is common.
- Parents will describe a hungry vomiter.
- Bilious emesis is not the result of pyloric stenosis.

# PYOGENIC GRANULOMA

Esther Maria Sampayo

## BASICS

### DESCRIPTION

- Pyogenic granuloma (PG), also known as lobular capillary hemangioma, is a benign acquired vascular skin lesion that is prone to recurrent bleeding or ulceration (1).
- These lesions are composed of proliferations of blood vessels and are not pyogenic/infectious or granulomatous in origin.

### EPIDEMIOLOGY

#### Prevalence

- Common in children and young adults
- Represents 0.5% of pediatric skin nodules (2)
- Mean age 6.7 yr
- 2–5% of women during pregnancies

### RISK FACTORS

- Areas of previous trauma, though most pediatric patients do not have history of preceding trauma (3)
- Associated with medications:
  - Retinoids
  - Protease inhibitors
  - Chemotherapeutic agents
  - Oral contraceptives (3)
- Also referred to as the “pregnancy tumor” or epulis and usually appears in the 2nd or 3rd trimester (4)

### PATHOPHYSIOLOGY

- PG is a disorder of angiogenesis whose underlying etiology remains unknown.
- Studies of the dermatologic side effects of retinoids and chemotherapeutic agents suggest that skin changes appear to be due to the down regulating effects of these medications on the epidermal growth factor receptor system (5).

### ETIOLOGY

- Exact cause unknown
- Proposed etiologies include:
  - Precipitating trauma
  - Hormonal influences
  - Viral oncogenes
  - Arteriovenous malformations
  - Bartonella infections
  - Angiogenic growth factors
  - Cytogenic abnormalities (2)

## DIAGNOSIS

### HISTORY

- Starts as a solitary dome-shaped red papule or nodule that is prone to bleeding or ulceration
- Grows rapidly within a few days to weeks
- Usually painless but can be tender
- Multiple eruptive PGs are extremely rare.
- Mean duration at the time of diagnosis is ~3 mo.

### PHYSICAL EXAM

- Solitary, small, friable, and bleeding lesion that looks like a raspberry or raw ground meat
- Red, brownish-red, or blue-black in color
- Sessile or pedunculated
- Average size 5–10 mm
- White collarette of scale often is seen at the base of the lesion.
- Most commonly located on the head and neck, trunk, and upper extremity (3)
- Most (88.2%) occur on the skin, and the rest involve mucous membranes of the oral cavity (3).
- Pregnancy tumor usually is on gingival or oral mucosa (4).
- Less common locations include the GI tract, nasal mucosa, larynx, conjunctiva, and cornea.
- PGs may occur within a port-wine stain.
- Satellitosis (a rare subcutaneous subtype) and a disseminated variant have been described. The majority of satellites occur on the trunk, often around the scapula (6).
- In contrast to PGs, hemangiomas:
  - Are the most common benign vascular tumors of childhood
  - Usually present in the 1st weeks of life
  - Grow rapidly
  - Regress slowly and never recur
  - Are only 5% of cutaneous hemangiomas demonstrating ulceration
  - May bleed, but very slightly and usually stop easily (7)

## DIAGNOSTIC TESTS & INTERPRETATION

### Lab

- The diagnosis can be made clinically, based on the typical appearance and location.
- Routine lab tests are not indicated.

### Imaging

In general, no imaging studies will establish the diagnosis or rule out other possible etiologies.

### Diagnostic Procedures/Other

- When unsure of the diagnosis, or there is atypical presentation, multiple lesions, or minimal bleeding, obtain a biopsy of the lesion to confirm the diagnosis and exclude malignancy.
- If malignancy is a concern, most clinicians will confirm the histologic diagnosis.

### Pathological Findings

- Histopathology reveals proliferation of capillary-sized blood vessels in a lobular arrangement.
- Hyperproliferation of the epidermis is typically present at the margins of the vascular growth, which results in a collarette of epidermis with ulceration and inflammation frequently superimposed (2).
- In contrast to PGs, hemangiomas demonstrate increased endothelial turnover characterized by rapid proliferation and slow involution, with phase-specific expression patterns of angiogenesis-related factors and inhibitors of blood vessel growth (7).

## DIFFERENTIAL DIAGNOSIS

- Hemangiomas
- Molluscum contagiosum
- Granuloma annulare
- Amelanotic melanoma
- Squamous or basal cell carcinoma
- Spindle cell tumors
- Bacillary angiomatosis
- Spitz nevus
- Acquired angioma

## TREATMENT

### INITIAL STABILIZATION/THERAPY

- Therapy is based on size, location, age of patient, and desired aesthetic results (8).
- Preferred treatment is curettage, which utilizes a small curette that allows the clinician to scrape off the lesion and remove abnormal vessels but spares the normal skin (9).
  - Usually only requires a topical anesthetic such as 1% lidocaine
  - Curettage has the advantage of fewer treatment sessions required to achieve resolution and better cosmetic results.
- Second-line treatment is electrocautery for lesions that fail curettage or are very small.
- Small lesions may regress after cauterization with silver nitrate or cryotherapy with liquid nitrogen; however, these treatments render a histologic diagnosis impossible.
- Other second-line treatments include: Blunt or shave removal, excision and electrodesiccation of the base of the granuloma (1)
- Small (<0.5 cm) superficial lesions may be treated successfully with the flash-lamp-pumped-pulsed-dye laser, though this is expensive (10).
- Larger (>0.5 cm) lesions may require shave excision followed by immediate pulse dye laser to the base; may be especially effective treatments for lesions involving cosmetically sensitive areas (10).

### MEDICATION

- Rarely requires antibiotic treatment
- Topical imiquimod 5% cream has also been shown to be effective (11) but may take a long time and results in oozing and crusting worse than the actual PG itself.

### SURGERY/OTHER PROCEDURES

Full-thickness surgical excision with closure offers the highest cure rate, especially for recurrences and failed outpatient treatment (8).

### DISPOSITION

#### Issues for Referral

Referral to a dermatologist or surgeon is indicated for removal of lesion that is bleeding recurrently, causing discomfort or cosmetic distress, or needs to be biopsied.

## FOLLOW-UP

### PROGNOSIS

- Recurrence rates after 1st treatment may be high secondary to feeding blood vessels that extend deep into the dermis:
  - 3.6%: Excision and closure (1)
  - 5%: Surgical or shave excision and/or curettage
  - 10%: Cautery
  - 15%: Silver nitrate (9,11)
- Adolescents and young adults are more prone to develop recurrent lesions after prior attempts at removal, especially on the trunk.
- At times, multiple smaller (satellite) PG can form after treatment (11).
- Usually resolve spontaneously after pregnancy without intervention
- Usually resolve after inciting drug is stopped
- In recalcitrant cases, the most effective treatment is total excision.

### COMPLICATIONS

- Recurrence of treated lesions
- Scarring
- Recurrent bleeding
- It is extremely rare to get anemia from bleeding or superinfection.

### CODES

#### ICD9

- 528.9 Other and unspecified diseases of the oral soft tissues
- 686.1 Pyogenic granuloma of skin and subcutaneous tissue

### PEARLS AND PITFALLS

- A PG is neither pyogenic or a granuloma, it is a rapidly growing small nodule prone to bleeding and ulceration.
- Almost all PGs bleed easily. If the lesion does not bleed with light rubbing, the diagnosis is unlikely.
- Seen most frequently on head and neck, upper trunk, and extremities
- Biopsy is recommended in atypical or recalcitrant cases to exclude malignancy.

# RASH, MACULOPAPULAR

Raina Paul  
Sarita Chung

## BASICS

### DESCRIPTION

Rash is characterized as:

- Papular: Solid, elevated, <1 cm
- Macular: Circumscribed, flat, different color than surrounding skin
- Maculopapular: Combination of the above

### PATHOPHYSIOLOGY

- Infectious: Activation of neutrophils causes an inflammatory response of the epidermis/dermis or, at times, a vasculitic-type response.
- Noninfectious:
  - Irritant: Damage by breaking or removing the protective layers of the upper epidermis → denatured keratin and alteration of water-holding capacity of skin → damage of the underlying living cells of the epidermis
  - Contact: Immunologic, nonimmunologic
  - Allergic: Type IV hypersensitivity reaction
  - Bites: Immune response to insect secretions

### ETIOLOGY

- Infectious:
  - Bacterial: Scarlet fever, syphilis, disseminated gonorrhea
  - Viral: Roseola, rubeola, rubella, erythema infectiosum, Epstein-Barr virus (EBV), molluscum, dengue, enterovirus, echovirus, coxsackievirus, adenovirus
  - Fungal: Tinea versicolor
  - Unknown but presumed viral: Pityriasis rosea, Kawasaki disease (KD), papular acrodermatitis
- Noninfectious:
  - Irritant, contact, or allergic dermatitis
  - Bites and infestations: Insects, scabies
  - Miscellaneous: Drug reaction, papular urticaria, erythema multiforme, psoriasis, pityriasis lichenoides, lichen nitidus

## DIAGNOSIS

### HISTORY

- The algorithmic approach is based upon the presence or absence of fever, ill appearing or not, generalized or not, recognizable clinical appearance or not:
  - Fever, ill appearing, recognizable: Erythema multiforme, rubeola
  - Fever, ill appearing, not recognizable: Dengue, KD, Rocky Mountain spotted fever (RMSF), ehrlichiosis
  - Fever, not ill appearing, recognizable clinical appearance: Coxsackievirus, erythema infectiosum, scarlet fever, early varicella
  - Fever, not ill appearing, not recognizable: Disseminated gonorrhea, drug induced, EBV, mycoplasma, roseola, secondary syphilis
  - No fever, generalized, chronic, recognizable: Molluscum, tinea versicolor
  - No fever, generalized, chronic, not recognizable: Lichen nitidus, pityriasis lichenoides, papular urticaria

- No fever, generalized, not chronic, recognizable: Contact, erythema infectiosum, erythema multiforme, pityriasis rosea, roseola, scabies
- No fever, generalized, not chronic, not recognizable: Drug, guttate psoriasis, insect bites, mycoplasma, rubella, scabies, secondary syphilis
- No fever, not generalized: Contact, insect bites, papular acrodermatitis, scabies
- See respective topics on Molluscum Contagiosum, Chickenpox/Shingles, Contact Dermatitis, Hand-Foot-and-Mouth Disease, Dengue Fever, Erythema Multiforme, Impetigo, Kawasaki Disease, Measles, Mumps, Pityriasis Rosea, Roseola Infantum, Rubella, Scabies, Scarlet Fever, Tinea Corporis, Tinea Versicolor, Stevens-Johnson Syndrome/TEN Spectrum, and Rickettsial Disease.
- Erythema multiforme: Immune-mediated hypersensitivity to drugs or infections
- Rubeola: Droplet spread; 1–14 days incubation; prodrome of cough, coryza, and conjunctivitis; fever followed by rash
- RMSF: Tickborne, infection with *Rickettsia rickettsii* may occur throughout the U.S., most prevalent in the Southeast and South Central states:
  - Within 3 days of tick bite: Fever, headache, myalgias, abdominal pain, ill appearance
- Ehrlichiosis: Due to *Ehrlichiosis chaffeensis* (human monocytic ehrlichiosis) or *Anaplasma phagocytophila* (human granulocytic ehrlichiosis):
  - Headache, fever, malaise, arthralgia, vomiting, rash less consistent (only 20%)
- Coxsackievirus: Prodrome of fever, anorexia, and mouth pain, then oral enanthem, then maculopapular rash
- Erythema infectiosum: Fifth disease, caused by parvovirus B19, well appearing
- Scarlet fever: Caused by group A streptococcus
- Gonorrhea: Rash in disseminated form, sexually active patients, history of vaginal or penile discharge
- EBV: 15% with rash (especially after treatment with amoxicillin), headache, malaise, fever, sore throat, milder in younger children
- Mycoplasma: Fever, malaise, cough
- Roseola: Herpes simplex virus 6, high fever, rash following defervescence
- Syphilis—sexually active:
  - Early, 1st yr; late, after 1 yr; latent, no findings, positive serology
  - Primary (early): Genital chancre
  - Secondary (early): Generalized rash 6 wk after chancre, malaise, fever, headache, sore throat, rhinorrhea, lymphadenopathy
  - Tertiary (late): Cardiovascular, neurologic, gummatous
- Molluscum: viral, 2 wk–1.5 yr duration
- Tinea versicolor: Adolescents, mild pruritis, can have family history, varying colors
- Pityriasis rosea: Initial herald patch (80%), then diffuse rash, often pruritic
- Scabies: Infestation from *Sarcoptes scabiei*:
  - Severely pruritic, highly contagious
- Guttate psoriasis: History of previous streptococcus, viral infection, or drug exposure; family history of psoriasis

- Rubella: Spreads cephalocaudally in 2–3 days:
  - Arthralgias, adenopathy, less commonly fever (unlike measles, well appearing)
- Papular acrodermatitis (Gianotti-Crosti): Associated with hepatitis B, other viral infections:
  - 85% <3 yr of age, lasts 2–8 wk
  - Low-grade fever and upper respiratory infection symptoms, followed by rash on extremities

### PHYSICAL EXAM

- Erythema multiforme: Symmetric, erythematous macules, target lesions, can coalesce and become vesiculobullous:
  - Favors palms, soles, extremities, face, mucous membrane involvement (mostly oral cavity) in 25%
- Rubeola- Koplik spots (white lesions on red base on buccal mucosa), maculopapular red rash, progresses cephalocaudally, eventually coalesces
- Dengue: 1st 1–2 days, generalized, macular rash, blanches, then generalized morbilliform rash, sparing palms and soles 1–2 days after defervescence:
  - If hemorrhagic: Vasculitic purpuric rash, fever, hypotension, occasionally hepatosplenomegaly and lymphadenopathy
- KD: ≥5 days fever with 5 criteria—rash, conjunctival injection, red cracked lips/strawberry tongue, erythema and swelling of extremities, unilateral cervical lymph node >1.5 cm:
  - Rash is fleeting or lasts 2–3 days; after acute illness is over → periungual, perineal palms/soles desquamation
- RMSF: Petechiae (nonblanching) on extremities (wrists and ankles) spreading centrally over 2 days, becoming confluent:
  - Conjunctivitis, edema, abdominal pain, focal neurologic signs, seizures, bleeding, gangrene
- Ehrlichiosis: Maculopapular rash, hepatosplenomegaly, rarely seizures, coma, cardiorespiratory failure
- Coxsackievirus: Oral lesions beginning as red macules on the posterior oropharynx/tonsils progressing to vesicles/ulcers, hands, feet
- Erythema infectiosum: Slapped cheek erythema, lacelike rash over extremities and trunk
- Scarlet fever: Generalized sandpaper rash, circumoral pallor, strawberry tongue, Pastia lines (red lines in antecubital fossa, axillae)
- Gonorrhea: Papules, petechiae, or pustules diffusely (disseminated disease)
- EBV: Pharyngitis, lymphadenopathy, splenomegaly, maculopapular rash within 4–6 days:
  - Enanthem (petechiae at junction of hard and soft palate) in 25%
- Mycoplasma: Maculopapular or urticarial rash (15%)
- Roseola: Discrete macules, begins on trunk
- Syphilis: Generalized, discrete, dull red, follows lines of cleavage on trunk, includes palms/soles (in secondary syphilis)
- Molluscum: Discrete, flesh-colored papules 2–3 mm, umbilicated centers, thighs and face
- Tinea versicolor: Pale in summer, hyperpigmented in winter, scaly macular, upper trunk and proximal arms

- Pityriasis rosea: Herald patch followed by generalized hyperpigmented rash on trunk
- Scabies: Linear burrows, excoriated papules
- Rubella: Erythematous macules, rarely coalesce, 1/3 have no rash
- Papular acrodermatitis: Flesh-colored papules (sometimes papulovesicular) on extremities, face, and buttocks; lymphadenopathy; 5% hepatosplenomegaly

**DIAGNOSTIC TESTS & INTERPRETATION**

**Lab**

**Initial Lab Tests**

- No labs are needed for most diagnoses.
- Rubeola: IgM, IgG titers
- RMSF: Skin biopsy gives diagnosis within hours, immunofluorescence assay serology confirms after 1 wk, definitive culture rarely done (too dangerous) (1)
- Ehrlichiosis: human monocyte- and human granulocytic-specific serology, intracytoplasmic inclusions (morulae) (2)
- Gonorrhea: Gram stain, culture from any site, nucleic acid amplification tests (less reliable from eye culture)
- EBV: Positive heterophile antibody (monospot is less sensitive <4 yr of age), IgM antibodies positive for up to 3 mo, IgG antibodies persist for life:
  - Lymphocytosis (often > 10% atypicals), anemia, thrombocytopenia, elevated transaminases
- Mycoplasma: IgM and IgG titers, (≥4-fold increase or single titer > 1:32):
  - Rises 7 days after infection, peak at 3–4 wk
  - Coombs positive hemolytic anemia
- Syphilis: Screen with nontreponemal tests (RPR, VDRL), confirm with treponemal (FTA-ABS, MHA-TP, TP-PA, TP-EIA), darkfield microscopy reveals spirochetes:
  - High alkaline phosphatase with only minimal elevation in transaminases
- Rubella: IgM titers, 4-fold rise in IgG titers, polymerase chain reaction in pregnant women for definitive confirmation
- Papular acrodermatitis: If ill or hepatomegaly, elevated aminotransferases, EBV and hepatitis B titers

**Imaging**

- KD: Echo may show coronary artery aneurysms.
- RMSF/Ehrlichiosis/Mycoplasma: CXR—diffuse (more common) or focal infiltrates
- RMSF/Ehrlichiosis with altered mental status: CT/MRI usually obtained and may show meningeal enhancement or rarely infarction

**Diagnostic Procedures/Other**

Scabies: Microscopic scraping of burrows

**DIFFERENTIAL DIAGNOSIS**

See the algorithmic approach in the History section.

**TREATMENT**

- Self-resolving: Erythema multiforme, rubeola, coxsackievirus, erythema infectiosum, EBV, mycoplasma (nonrespiratory), roseola, molluscum, pityriasis rosea, guttate psoriasis, rubella
- Contact, allergic, bites: Remove irritant, hydrocortisone, antihistamines
- Erythema multiforme: Remove offending agent; rinse mouth with mix of diphenhydramine, lidocaine, and aluminum hydroxides (1:1:1) (3):
  - Only safe and recommended for children old enough to swish and reliably spit to prevent lidocaine and diphenhydramine toxicity (~5–6 yr)
- Rubeola: Immune serum globulin within 6 days of exposure can prevent or modify disease (consider if immunocompromised, pregnant, <1 yr old), followed by vaccine 3 mo later if >15 mo old (contraindications include pregnancy, advanced HIV, severe febrile illness, recent immune globulin/blood product); administration of vitamin A may prevent xerophthalmia, blindness, and death.
- RMSF: Doxycycline (despite risk of teeth staining) (1), aggressive fluid management, mechanical ventilation, dialysis, transfusions, antiepileptic medication
- Ehrlichiosis: Doxycycline, rifampin if allergic (2)
- Scarlet fever: Treatment with a penicillin, cephalosporin, macrolide, or clindamycin prevents rheumatic fever.
- Gonorrhea: Ceftriaxone IM once or oral cefixime plus treatment for usual coinfection with chlamydia (azithromycin or doxycycline) (4)
- Mycoplasma: Erythromycin, clarithromycin, or azithromycin if lower respiratory infection
- Syphilis:
  - Early: Primary, secondary, latent <1 yr—1 dose of benzathine penicillin G
  - Late: > 1 yr, tertiary, unknown duration—3 doses of benzathine penicillin G
  - Neurosyphilis: q4h penicillin G for 10 days
  - Penicillin allergic: Doxycycline
- Molluscum: Curettage, cryotherapy, or laser for genital lesions only, usually self-resolving
- Tinea versicolor: 2 wk of any topical antifungal (terbinafine, clotrimazole, selenium sulfide), oral agents (except griseofulvin, terbinafine) for more extensive disease
- Scabies: Permethrin cream or ivermectin
- Guttate psoriasis: Self-resolving, UVB phototherapy for difficult cases

**DISPOSITION**

**Admission Criteria**

- Hemodynamic instability (RMSF, multisystem ehrlichiosis, dengue, KD)
- Inability to tolerate oral liquids, dehydration (erythema multiforme)
- Concerns for follow-up: Tertiary syphilis

**Issues for Referral**

Dermatology: Persistent molluscum, pityriasis rosea, guttate psoriasis

**PROGNOSIS**

- Varies depending on the etiology
- RMSF: 1.1–4.9% mortality, especially in children <2 yr old
- Ehrlichiosis: Can be fatal in immunocompromised

- Gonorrhea
- Kawasaki Disease
- Pityriasis Rosea
- Scarlet Fever
- Syphilis

**ICD9**  
782.1 Rash and other nonspecific skin eruption

**PEARLS AND PITFALLS**

- Fever, headache, and myalgias may occur after treatment for syphilis (Jarisch-Herxheimer reaction): Antipyretics for symptomatic relief.
- RMSF: Early treatment is key. Those who were treated within 5 days after the onset of symptoms were significantly less likely to die than those who were treated after the 5th day (6.5% vs. 22.9%) (5).
- Syphilis and pityriasis look very similar.

# RASH, NEONATAL

Naomi Dreisinger  
Robert J. Hoffman

## BASICS

### DESCRIPTION

- Rashes in the neonate are a common cause of parental concern and emergency department visits.
- Neonatal rashes range from benign, self-limited disorders to severe, life-threatening disease. It is the role of the emergency department physician to differentiate the serious from the benign.
- Vesiculopapular lesions are the most common type of rash in the neonate (1).
- Transient benign lesions to be discussed here include erythema toxicum neonatorum, transient neonatal pustular melanosis, acne neonatorum, miliaria, and milia.

### PATHOPHYSIOLOGY

- Erythema toxicum neonatorum: Blotchy erythematous rash that waxes and wanes
- Transient neonatal pustular melanosis: Uncommon benign rash presumed due to accelerated stimulation of negroid melanocytes caused by cytokines and growth factors released from inflammatory cells (2)
- Acne neonatorum (neonatal acne): Presumed due to the effect of maternal hormones (androgens) on newborn sebaceous glands. Also postulated as caused by *Malassezia* species, in which case the rash is called *cephalic pustulosis* (3).

- Miliaria: Miliaria is caused by sweat retention due to immaturity of the neonatal skin structure, causing sweat duct obstruction. 2 types exist:
  - Miliaria crystalline, caused by superficial sweat duct closure
  - Miliaria rubra, caused by deeper sweat duct obstruction
- Milia: Milia is caused by retention of keratin within the dermis of the skin.

### ETIOLOGY

See Pathophysiology.

## DIAGNOSIS

### HISTORY

- Erythema toxicum neonatorum: The most common cause of vesiculopustular lesions in the neonate. Typically appears on the 2nd or 3rd day of life. It is most common in full-term infants born at birth weights >2,500 g.
- Transient neonatal pustular melanosis: Always present at birth. More common in black newborns (5–15%) and in <1% of white newborns. Also, it may be the cause of freckling noted in many black infants.
- Acne neonatorum: Occurs in 20% of newborns. Typically appears within the 1st month of life and resolves within the 1st 4 mo of life without scarring.
- Miliaria: Different forms of miliaria occur in 40% of newborns (1). Lesions evolve over several days without causing any irritation to the newborn. Miliaria rubra is commonly recognized as “heat rash” or “prickly heat.”
- Milia: Occurs in 50% of newborns. This rash is a common cause of parental concern and appears spontaneously during the 1st month of life (3).

### PHYSICAL EXAM

- Erythema toxicum neonatorum: Erythematous 2–3-mm macules and papules that evolve into pustules. Each pustule is surrounded by a blotchy area of erythema causing a “flea-bitten” appearance (1). Lesions generally occur on the face, trunk, and proximal extremities, sparing the palms and the soles.
- Transient pustular melanosis: Begins as pustules that evolve into macular pigmentation surrounded by a scaly area. Lesions are typically on the chin, neck, upper chest, lower back, and buttocks.
- Acne neonatorum: Generally presents as closed comedones on the forehead, nose, and cheeks. Open comedones, papules, and pustules may develop as well.
- Miliaria: Miliaria crystallina presents as 1–2-mm vesicles without surrounding erythema. It appears on the head, neck, and trunk. Frail vesicles evolve, rupture, and desquamate and may persist for hours or days. Miliaria rubra appear as small erythematous papules and vesicles that tend to occur on covered portions of the skin.
- Milia: Appear as 1–2-mm pearly white or yellow papules that are most common on the forehead, cheeks, nose, and chin. They may also appear on the upper trunk, limbs, penis, or mucous membranes.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

- Diagnosis of benign neonatal rashes is clinical.
- If any suspicion for herpes simplex exists, careful evaluation including lab analysis is warranted.
- If testing of benign lesions is undertaken, the following are typical:
  - Erythema toxicum neonatorum: Cytologic exam of a pustular smear will show eosinophilia.
  - Transient neonatal pustular melanosis: Cytologic exam reveals polymorphic neutrophils and some eosinophils.

**DIFFERENTIAL DIAGNOSIS**

- Vesiculopapular lesions of infancy must be distinguished from more serious illness such as:
  - Herpes simplex virus, staphylococcal scalded skin syndrome, and *Candida*
- Infants with these illnesses will often appear acutely ill with a more atypical appearance to the rash. When in doubt, further testing and caution is advised.

**TREATMENT**

- Erythema toxicum neonatorum: No treatment is necessary; the rash is expected to fade within the 1st week of life.
- Transient neonatal pustular melanosis: Once the pustules have evolved into pigmented macules, these macules can easily be scratched off. If left, they will disappear on their own over the course of several weeks.
- Acne neonatorum: Generally, no treatment is indicated, but persistent lesions can be treated with 2.5% benzoyl peroxide lotion. (Caution: Before applying benzoyl peroxide to neonatal skin, choose a small area and apply to this area, watching to see if skin reacts adversely to the application.) (3)
- Miliaria: To treat, advise avoidance of overheating, removal of excess clothing, and cooling baths.
- Milia: Parental reassurance that this is a benign self-limited condition is all that is needed.

**DISPOSITION**

Patients with common neonatal rashes are discharged home with parental reassurance and pediatrician follow-up.

**REFERENCES**

1. O' Connor NR, McLaughlin MR, Ham P. Newborn skin: Part I. Common rashes. *Am Fam Physician*. 2008;77(1):47–52.
2. Taieb A, Boralevi F. Hypermelanoses of the newborn and the infant. *Dermatol Clin*. 2007;25:327–336.
3. Sethuraman G, Mancini AJ. Neonatal skin disorders and the emergency medicine physician. *Clin Pediatr Emerg Med*. 2008;9:200–209.

**ICD-9 CODES****ICD9**

- 706.1 Other acne
- 778.8 Other specified conditions involving the integument of fetus and newborn
- 778.9 Unspecified condition involving the integument and temperature regulation of fetus and newborn

**PEARLS AND PITFALLS**

- Benign neonatal rashes are a common cause for visits to the emergency department.
- It is critical to evaluate for more serious etiologies of rash such as herpes simplex and staphylococcal scalded skin syndrome.
- Fever is not associated with any benign neonatal rash.
- Parental reassurance and anticipatory guidance is helpful.
- Infrequently, a rash may be a sign of more severe systemic diseases or immunodeficiencies.
- Any significant change in appearance of the rash warrants follow-up for re-evaluation.

# RASH, PETECHIAE

Todd P. Chang

## BASICS

### DESCRIPTION

- Petechiae are nonblanching, palpable or nonpalpable, discrete skin lesions:
  - Petechiae <2 mm
  - Purpura >2 mm (see Purpura topics)
- They may be found as an isolated finding or combined with systemic complaints (eg, fever, altered mental status, other bleeding areas).
- The majority of petechiae in an otherwise healthy child are benign:
  - Petechiae may appear on the face, neck, or trunk above the nipples in a child with coughing episodes, vomiting, or other causes of increased intrathoracic pressure.
  - Petechiae in the soft palate are seen in group A streptococcal pharyngitis and do not routinely warrant further workup.

### PATHOPHYSIOLOGY

- Sudden increases in vascular pressure, such as during a Valsalva maneuver or a coughing episode, can increase intrathoracic pressures.
- This leads to loss of vascular integrity and RBC deposition into the skin surface.
- Alternatively, inflammation at the vascular intima (eg, vasculitis) disrupts tight junctions and also leads to loss of vascular integrity.
- Spontaneous petechiae occur when there is platelet or coagulation dysfunction from:
  - Intrinsic deficiency or abnormality
  - Extrinsic disruption from drugs, infection, etc.
  - Extrinsic thrombocytopenia (usually  $<50 \times 10^3/\text{mm}^3$ )

### ETIOLOGY

- Benign causes:
  - Increased intrathoracic pressure (eg, coughing, vomiting)
  - Palatal petechiae from streptococcal pharyngitis
- Platelet disorders—qualitative:
  - Von Willebrand disease (vWD)
  - Bernard-Soulier disease
  - Glanzmann thrombasthenia
  - Salicylate or NSAID exposure
- Platelet disorders—consumptive:
  - Idiopathic thrombocytopenic purpura (ITP)
  - Maternal ITP for newborns
  - Hemolytic uremic syndrome (HUS)
  - Thrombotic thrombocytopenic purpura
  - Crotaline envenomation (eg, rattlesnakes)

- Sequestration/Direct consumption:
  - Large hemangiomas
  - Arteriovenous malformations
  - Kasabach-Merritt syndrome
  - Bannayan-Riley-Ruvalcaba syndrome
  - PHACES syndrome
- Disseminated intravascular coagulation (DIC), sepsis
- Meningococemia
- Dengue fever
- Platelet disorders—poor production:
  - Aplastic anemia
  - Wiskott-Aldrich syndrome
  - Corticosteroid exposure
  - Marrow failure:
    - Chemotherapy
    - Viral suppression from parvovirus, Epstein-Barr virus, cytomegalovirus, adenovirus, HIV, varicella, hepatitis, herpes simplex virus, coxsackievirus
    - Malignancy: Leukemia, lymphoma, neuroblastoma
- Coagulopathy:
  - Hemorrhagic disease of the newborn (vitamin K deficiency)
  - Hemophilia
  - Factor deficiency
  - Dysfibrinogenemia
  - Hepatic failure
  - Warfarin or superwarfarin exposure (eg, brodifacoum)
  - Heparin, enoxaparin exposure
  - Antiepileptic exposure (eg, phenytoin, carbamazepine, valproic acid)
- Vasculitis or vascular defect:
  - Connective tissue diseases: Systemic lupus erythematosus, Ehlers-Danlos syndrome
  - Endocarditis
  - Scurvy (vitamin C deficiency)
- Other causes:
  - Trauma
  - Nonaccidental trauma/abuse
  - Rocky Mountain spotted fever
  - Ehrlichiosis

### COMMONLY ASSOCIATED CONDITIONS

- Significant vomiting, coughing, or other Valsalva maneuvers
- Thrombocytopenia

## DIAGNOSIS

### HISTORY

- Coughing or Valsalva history:
  - Benign petechiae appear following an intense episode of coughing or Valsalva.
- A careful history can help elucidate the cause of petechiae and whether it represents a life-threatening condition.
- Infectious history
- A history of fevers, constitutional symptoms, and lethargy suggest sepsis, DIC, or meningococemia.
- A past history of infection may suggest ITP, HUS, or viral suppression.
- Thorough bleeding history:
  - Patient and family history of excessive bleeding may suggest congenital bleeding disorders:
    - Prolonged epistaxes, gum bleeding, easy bruising, hematuria, or hematochezia/melena
    - Patient and family menstrual history
- Family bleeding history
- Trauma history:
  - Petechiae in patterns may be due to trauma independent of bleeding disorder.
- Medication or toxin exposure history can lead to diagnosis.
- Family oncologic or rheumatologic history may suggest a similar cause for petechiae.

### PHYSICAL EXAM

- General appearance: Unstable vital signs such as persistent tachycardia or hypotension may suggest life-threatening causes like sepsis or meningococemia.
- Altered mental status: Consider intracranial hemorrhage.
- Perform a thorough skin exam with all clothes off to determine the extent of the petechiae.
- Mucosal bleeding often indicates thrombocytopenia and may require treatment.
- Assess for hepatosplenomegaly, which may suggest an oncologic process or hepatic failure.
- Assess for systemic findings consistent with other disease processes, such as connective tissue diseases, endocarditis, etc.
- The lack of abnormal exam findings aside from petechiae is reassuring.

**DIAGNOSTIC TESTS & INTERPRETATION**

Testing is not routinely necessary for well-appearing patients with petechiae above the nipples.

**Lab****Initial Lab Tests**

- Screening tests for thrombocytopenia or coagulopathy are indicated with widespread petechiae or in an ill-appearing patient:
  - CBC
  - PT, PTT: Include a 1:1 correction
- LFTs (PT, transaminases, albumin, bilirubin, alkaline phosphatase, gamma-glutamyl transferase) if hepatic dysfunction is suspected
- Blood culture, type and cross, and DIC panel if unstable and infectious etiologies are suspected
- Hold extra blood (EDTA and non-EDTA tubes) for potential diagnostic tests: Von Willebrand factor antigen, factor levels, Ristocetin cofactor test, antinuclear antibodies, anti-DNA, other serologies.
  - Many titers are invalid if checked after the patient receives allogenic blood products.
- Urinalysis for Henoch-Schönlein purpura (HSP) or HUS.
  - A BUN and creatinine level should be done if the urinalysis is abnormal.
- Lumbar puncture (LP) should be performed if meningococemia or meningitis is suspected. However, it is contraindicated with any platelet abnormalities or coagulopathy. The LP may be delayed until the patient is more stable and able to tolerate the procedure.

**Imaging**

- Head CT:
  - If altered mental status (intracranial hemorrhage)
  - If suspecting abuse (fracture, hemorrhage)
- Skeletal survey if suspecting abuse

**DIFFERENTIAL DIAGNOSIS**

- Congenital nevi
- Small hemangioma
- Extramedullary hematopoiesis

**TREATMENT****PRE HOSPITAL**

- Initial stabilization with ABC support
- Protect the patient from trauma during transport.

**INITIAL STABILIZATION/THERAPY**

Treat for the specific cause of petechiae, if indicated.

**MEDICATION****First Line**

- Suspected meningococemia, sepsis, or meningitis:
  - Ceftriaxone 50 mg/kg IV q24h (adult max single dose 2,000 mg); q12h intervals recommended for meningitis OR
  - Cefotaxime 50 mg/kg IV q8h (adult max single dose 2,000 mg); q6h intervals recommended for meningitis OR
  - Meropenem 20 mg/kg IV q8h (adult max single dose 1,000 mg); 40 mg/kg recommended for meningitis

- Septic shock:
  - Dopamine 10  $\mu$ g/kg/min IV, max single dose 20  $\mu$ g/kg/min (titrate to effect)
- Phytonadione (vitamin K1) 10 mg IV or IM for vitamin K deficiency
- ITP is treated with either Rh<sub>0</sub>(D) immunoglobulin (WinRho SDF) or IV immunoglobulin (see Idiopathic Thrombocytopenic Purpura topic).

**Second Line**

Chemoprophylaxis for meningococemia is recommended for household contacts, day care contacts, or anyone with close contact with body fluids (see Meningococemia topic).

**DISPOSITION****Admission Criteria**

- Active bleeding
- Altered mental status
- Unstable vital signs
- No timely follow-up by pediatric hematology or child protective services in cases of abuse
- Renal impairment or electrolyte aberrations with HSP or HUS
- Thrombocytopenia with either leukopenia/lymphopenia or anemia. These patients need a bone marrow biopsy to rule out malignancy or marrow aplasia.
- Critical care admission criteria:
  - Presence of fever and petechiae or purpura warrants suspicion of meningococemia and ICU observation.
  - Persistent hypotension or respiratory failure requiring ventilatory support
  - Intracranial hemorrhage

**Discharge Criteria**

- No active bleeding
- Stable vital signs
- Follow up with hematology and a primary care provider.

**FOLLOW-UP****FOLLOW-UP RECOMMENDATIONS**

- In cases of hematologic disorders, pediatric hematology follow-up should be ensured. Most patients who are otherwise stable are able to see them in a few days.
- Child protective services must be activated in the emergency department in a patient with suspected abuse and/or neglect.
- Primary care provider or nephrology follow-up for HUS/HSP
- Activity:
  - In cases of thrombocytopenia, coagulation disorder, or platelet dysfunction, rough play or contact/collision sports should be discouraged due to risk of intracranial hemorrhage.

**ADDITIONAL READING**

- American Academy of Pediatrics. Meningococcal infections. In Pickering LK, ed. *Red Book: 2006 Report of the Committee on Infectious Diseases*. 27th ed. Elk Grove Village, IL: Author; 2006.
- Mandl KD, Stack AM, Fleisher GR. Incidence of bacteremia in infants and children with fever and petechiae. *J Pediatr*. 1997;131(3):398–404.
- Trapani S, Micheli A, Grisolia F, et al. Henoch Schonlein purpura in childhood: Epidemiological and clinical analysis of 150 cases over a 5-year period and review of literature. *Semin Arthritis Rheum*. 2005;35(3):143–153.

**CODES****ICD9**

- 782.7 Spontaneous ecchymoses
- 772.6 Cutaneous hemorrhage of fetus or newborn

**PEARLS AND PITFALLS**

- Pearls:
  - Quantify the menstrual history. A family with vWD may not know their level of bleeding is abnormal since the women in the family may all bleed similarly.
- Pitfalls:
  - Mistaking blanching lesions for true petechiae
  - Not examining all skin areas, including genitals, perianal area, palms/soles, scalp
  - Not suspecting meningococemia
  - Not administering antibiotics expeditiously in suspected meningococemia or sepsis
  - Not considering abuse as part of the differential diagnosis
  - Administering platelets to a stable patient with ITP

# RASH, PURPURA

Todd P. Chang

## BASICS

### DESCRIPTION

- Purpura are nonblanching, palpable or nonpalpable skin lesions of 2–10 mm:
  - Petechiae <2 mm (see Rash, Petechiae topic)
  - Purpura >2 mm but <10 mm
  - Ecchymosis >10 mm, may be raised or tender
- May change from purple to golden brown over weeks
- Purpuric lesions may be single or multiple.
- They may be found as an isolated finding or combined with more systemic complaints (eg, fever, altered mental status, other bleeding areas).
- The location of purpura is important in diagnoses, especially in trauma and abuse.
- Purpura fulminans is a severe form of rapidly progressive purpura with multiorgan failure. This is usually associated with meningococemia, though group B streptococcus has also been known to cause this in neonates (1).

### PATHOPHYSIOLOGY

- Loss of vascular integrity at the skin surface, whether from trauma, toxins, or infections, leads to a collection of RBCs in the skin surface.
- Alternatively, inflammation at the vascular intima (eg, vasculitis) disrupts tight junctions and also leads to loss of vascular integrity.
- Spontaneous purpura occurs when there is platelet or coagulation dysfunction from:
  - Intrinsic deficiency or abnormality
  - Extrinsic disruption from drugs, infection, etc.
  - Extrinsic thrombocytopenia (usually  $<50 \times 10^3/\text{mm}^3$ )
- As the hemoglobin deposits within the dermis degrade into biliverdin and bilirubin, the color of the purpura may change accordingly.

### ETIOLOGY

- Benign causes: Trauma to forehead, elbows, and anterior legs are common accidental areas for an active, ambulatory child.
- Platelet disorders—qualitative:
  - Von Willebrand disease (VWD)
  - Bernard-Soulier disease
  - Glanzmann thrombasthenia
  - Salicylate or NSAID exposure
- Platelet disorders—consumptive:
  - Idiopathic thrombocytopenic purpura (ITP)
  - Maternal ITP for newborns
  - Hemolytic uremic syndrome (HUS)
  - Thrombotic thrombocytopenic purpura

- Crotaline envenomation (eg, rattlesnakes)
- Sequestration/Direct consumption:
  - Large hemangiomas
  - Arteriovenous malformations
  - Kasabach-Merritt syndrome
  - Bannayan-Riley-Ruvalcaba syndrome
  - PHACES syndrome
- Disseminated intravascular coagulation (DIC), sepsis
- Meningococemia
- Dengue fever
- Platelet disorders—poor production:
  - Aplastic anemia
  - Wiskott-Aldrich syndrome
  - Corticosteroid exposure
  - Marrow failure:
    - Chemotherapy
    - Viral suppression from parvovirus, Epstein-Barr virus, cytomegalovirus, adenovirus, HIV, varicella, hepatitis, herpes simplex virus, coxsackievirus
    - Malignancy: Leukemia, lymphoma, neuroblastoma
- Coagulopathy:
  - Hemorrhagic disease of the newborn (vitamin K deficiency)
  - Hemophilia
  - Factor deficiency
  - Dysfibrinogenemia
  - Hepatic failure
  - Warfarin or superwarfarin exposure (eg, brodifacoum)
  - Heparin, enoxaparin exposure
  - Antiepileptic exposure (eg, phenytoin, carbamazepine, valproic acid)
- Vasculitis or vascular defect:
  - Connective tissue diseases: Systemic lupus erythematosus, Ehlers-Danlos syndrome
  - Scurvy (vitamin C deficiency)
  - Henoch-Schönlein purpura (HSP)
- Other causes:
  - Trauma
  - Nonaccidental trauma/abuse

### COMMONLY ASSOCIATED CONDITIONS

Thrombocytopenia

## DIAGNOSIS

### HISTORY

- A careful history can help elucidate the cause of purpura and whether it represents a life-threatening condition.
- Infectious history
- A history of fevers, constitutional symptoms, and lethargy suggest sepsis, DIC, or meningococemia.
- A past history of infection may suggest ITP, HUS, or viral suppression.
- Thorough bleeding history: Patient and family history of excessive bleeding may suggest congenital bleeding disorders:
  - Prolonged epistaxes, gum bleeding, easy bruising, hematuria, or hematochezia/melena
  - Patient and family menstrual history
- Family bleeding history
- Trauma history: Purpura in patterns may be due to trauma independent of bleeding disorder.
- Medication or toxin exposure history can lead to diagnosis.
- Family oncologic or rheumatologic history may suggest a similar cause for purpura.

### PHYSICAL EXAM

- General appearance: Unstable vital signs such as persistent tachycardia or hypotension may suggest life-threatening causes like sepsis or meningococemia.
- Altered mental status: Consider intracranial hemorrhage.
- Perform a thorough skin exam with all clothes off to determine the extent of the purpura.
- Observe patterns of purpura:
  - Lesions may be in an object pattern if an object was used in abusive trauma (eg, shaped like a belt buckle).
  - Purpura of only the lower extremities suggests HSP.
- Overt bleeding suggests a platelet disorder.
- Assess for systemic findings consistent with other disease processes, such as connective tissue diseases, endocarditis, etc.

**DIAGNOSTIC TESTS & INTERPRETATION****Lab****Initial Lab Tests**

- Unless the diagnosis of HSP is made, screening tests for bleeding disorders include:
  - CBC
  - PT, PTT: Include a 1:1 correction
- LFTs (PT, transaminases, albumin, bilirubin, alkaline phosphatase, gamma-glutamyl transferase) if hepatic dysfunction is suspected
- Blood culture, type and cross, and DIC panel if unstable and infectious etiologies are suspected
- Hold extra blood (EDTA and non-EDTA tubes) for potential diagnostic tests: Von Willebrand factor antigen, factor levels, Ristocetin cofactor test, antinuclear antibodies, anti-DNA, other serologies.
  - Many titers are invalid if checked after the patient receives allogenic blood products.
- Urinalysis for HSP or HUS.
  - A BUN and creatinine level should be done if the urinalysis is abnormal.
- Lumbar puncture (LP) should be performed if meningococemia/meningitis is suspected. However, it is contraindicated with any platelet abnormalities or coagulopathy. The LP may be delayed until the patient is more stable and able to tolerate the procedure.

**Imaging**

- Head CT:
  - If altered mental status (intracranial hemorrhage)
  - If suspecting abuse (fracture, hemorrhage)
- Skeletal survey if suspecting abuse

**DIFFERENTIAL DIAGNOSIS**

- Sturge-Webber syndrome
- Congenital nevi
- Hemangioma
- Phytophotodermatitis

**TREATMENT****PRE HOSPITAL**

- Initial stabilization with ABC support, if the patient is febrile, hypotensive, or has altered mental status
- Protect the patient from trauma during transport.

**INITIAL STABILIZATION/THERAPY**

Treat for specific cause of purpura, if indicated.

**MEDICATION****First Line**

- Suspected meningococemia, sepsis, or meningitis:
  - Ceftriaxone 50 mg/kg IV q24h (adult max single dose 2,000 mg); q12h intervals recommended for meningitis OR
  - Cefotaxime 50 mg/kg IV q8h (adult max single dose 2,000 mg); q6h intervals recommended for meningitis OR
  - Meropenem 20 mg/kg IV q8h (adult max single dose 1,000 mg); 40 mg/kg recommended for meningitis

- Septic shock:
  - Dopamine 10  $\mu$ g/kg/min IV, max single dose 20  $\mu$ g/kg/min (titrate to effect)
- Phytonadione (vitamin K1) 10 mg IV or IM for vitamin K deficiency
- ITP may be treated with either Rh<sub>0</sub>(D) immunoglobulin (WinRho SDF) or IV immunoglobulin (see Idiopathic Thrombocytopenic Purpura topic).

**Second Line**

Chemoprophylaxis for meningococemia is recommended for household contacts, day care contacts, or anyone with close contact with body fluids (see Meningococemia topic).

**DISPOSITION****Admission Criteria**

- Active bleeding
- Altered mental status
- Unstable vital signs
- No timely follow-up by pediatric hematology, or child protective services in cases of abuse
- Renal impairment or electrolyte aberrations with HSP or HUS
- Thrombocytopenia with either leukopenia, lymphopenia, or anemia. These patients need a bone marrow biopsy to rule out malignancy or marrow aplasia.
- Critical care admission criteria:
  - Presence of fever and petechiae or purpura warrants suspicion of meningococemia and ICU observation.
  - Persistent hypotension or respiratory failure requiring ventilatory support
  - Intracranial hemorrhage

**Discharge Criteria**

- No active bleeding
- Stable vital signs
- Follow up with hematology or child protective services and the primary care provider.

**FOLLOW-UP****FOLLOW-UP RECOMMENDATIONS**

- In cases of hematologic disorders, pediatric hematology follow-up should be ensured. Most patients who are otherwise stable are able to see them in a few days.
- Child protective services must be activated in the emergency department in a patient with suspected abuse and/or neglect.
- Primary care provider or nephrology follow-up for HUS or HSP
- Activity:
  - In cases of thrombocytopenia, coagulation disorder, or platelet dysfunction, rough play or contact/collision sports should be discouraged due to risk of intracranial hemorrhage.

## BASICS

### DESCRIPTION

- Urticaria is often referred to as “hives.” It may appear as blanchable, pruritic, raised, well-circumscribed areas of edema and erythema involving the epidermis and dermis.
- Urticaria may be classified clinically as acute (lasting  $\leq 6$  wk), chronic (lasting  $\geq 6$  wk), or episodic/recurrent.
- A large variety of urticaria variants exist, including acute IgE-mediated urticaria, chemical-induced urticaria (non-IgE mediated), urticarial vasculitis, autoimmune urticaria, cholinergic urticaria, cold urticaria, mastocytosis, Muckle-Wells syndrome, and many others.

### EPIDEMIOLOGY

#### Incidence

- Affects 15–25% of the general population at some time during their lifetime
- Affects both genders and all races
- Acute urticaria is more common in children and young adults.
- Urticaria affects 6–7% of preschool children and 17% of children with atopic dermatitis (1).
- Chronic urticaria is more common in adults, affecting women (60%) more than men (2).

### RISK FACTORS

- Previous episodes of urticaria
- Atopy
- Family history of atopy
- Asthma
- Allergic rhinitis
- Autoimmune disease

### GENERAL PREVENTION

Avoidance of known or suspected triggers

### PATHOPHYSIOLOGY

- Urticaria results from the release of histamine, bradykinin, leukotriene C4, prostaglandin D2, and other vasoactive substances from mast cells and basophils in the dermis.
- These substances cause extravasation of fluid into the dermis, leading to the urticarial lesion.
- Pruritus is a result of histamine released into the dermis.
- The activation of the H1 histamine receptors on endothelial and smooth muscle cells leads to increased capillary permeability.
- The activation of the H2 histamine receptors leads to arteriolar and venule vasodilation.
- Potential mechanisms:
  - Immune mediated: The type I allergic IgE response is initiated by antigen-mediated IgE immune complexes that bind and cross-link Fc receptors on the surface of mast cells and basophils, thus causing degranulation with histamine release.
  - Complement mediated: The type II allergic response is mediated by cytotoxic T cells, causing deposits of immunoglobulins, complement, and fibrin around blood vessels. This leads to urticarial vasculitis.

- Autoimmune mediated: The type III immune-complex disease is associated with systemic lupus erythematosus (SLE) and other autoimmune diseases that cause urticaria (3).
- Non-immune mediated: Degranulation of mast cells by physical stimuli; chemicals such as alcohol and radio contrast dye; some medications, such as morphine; and foods such as strawberries and shellfish

### ETIOLOGY

- Acute urticaria: Etiology undetermined in  $>60\%$  cases:
  - Known causes: Infections, foods, medications, environmental factors, latex, pressure, cold, heat, emotional stress, exercise, pregnancy
- Chronic urticaria: Etiology undetermined in as many as 80–90% cases:
  - A large percentage of these cases have an autoimmune etiology (eg, SLE, rheumatoid arthritis) (1).
  - Other causes: Hyperthyroidism, amyloidosis, polycythemia vera, malignant neoplasms, lymphoma, cryoglobulinemia, syphilis, cryofibrinogenemia, mastocytosis, Muckle-Wells syndrome, familial cold autoinflammatory syndrome

### COMMONLY ASSOCIATED CONDITIONS

- Atopy
  - Anaphylaxis
- Less common associations:
  - Thyroid autoimmunity
  - Celiac disease
  - *Helicobacter pylori* infection

## DIAGNOSIS

### HISTORY

- History is the most important tool in the diagnosis and evaluation for causes of urticaria.
- Ask about history of urticaria, duration of lesions, pruritus, blanching, when lesions occur, where lesions occur (pressure points), and parental suspicions regarding causes.
- Ask about family and personal medical history of wheezing, atopy, or angioedema.
- For acute urticaria, ask about possible precipitants, such as the following:
  - Recent illness: Fever, sore throat, cough, rhinorrhea, vomiting, diarrhea, or headache
  - Medication use including antibiotics, diuretics, aspirin, NSAIDs, iodides, bromides, quinidine, chloroquine, vancomycin, isoniazid, antiepileptic agents, and other agents
  - IV radio contrast media
  - Travel (amebiasis, ascariasis, trichinosis, strongyloidiasis, malaria)
  - Foods: Shellfish, fish, eggs, milk, soy, peanuts, cheese, chocolate, nuts, berries, or tomatoes
  - New perfumes, hair dyes, detergents, lotions, creams, or clothes
  - Exposure to new pets (dander), dust, mold, chemicals, or plants

- Pregnancy (usually occurs in last trimester and typically resolves spontaneously soon after delivery)
- Contact with nickel (eg, jewelry, jeans stud buttons), rubber (eg, gloves, elastic bands), latex, industrial chemicals, and nail polish
- Sun or cold exposure
- Exercise
- For chronic or recurrent urticaria, ask about:
  - Precipitants such as heat, cold, pressure, exercise, sunlight, emotional stress
  - Chronic medical conditions: Polymyositis, hyperthyroidism, SLE, rheumatoid arthritis, amyloidosis, polycythemia vera, lymphoma, and other malignant neoplasms
  - Other medical conditions that can cause pruritus (usually without rash), such as diabetes mellitus, chronic renal insufficiency, primary biliary cirrhosis, or other nonurticarial dermatologic disorders (eg, eczema, contact dermatitis)

### PHYSICAL EXAM

- Blanchable, edematous papules or wheals
- Vary in size from 1 mm to many centimeters—giant urticaria
- Variably pruritic (mild to intense)
- Angioedema
- Dermatographism

### DIAGNOSTIC TESTS & INTERPRETATION

- The diagnosis of urticaria is primarily clinical.
- Lab investigations should be guided by the history and is not necessary in most patients.

### Lab

#### Initial Lab Tests

- Acute urticaria:
  - No investigations are required unless suggested by the history.
  - IgE-mediated reactions can be confirmed by skin-prick testing (must stop antihistamines prior to having skin testing) and CAP fluoroimmunoassay (previously RAST) on blood.
- Chronic urticaria:
  - No investigations are required for the majority of patients with mild disease that responds well to H1 antihistamine agents.
  - For those with more severe disease, consider the following tests guided by the suspected diagnosis: a CBC with differential (eg, to detect the leukopenia of SLE), ESR, C-reactive protein, serum electrolytes, glucose, AST, ALT, antinuclear antibody, C3, C4, serology for infections, stool samples (for ova, cysts, and parasites), specific IgE (SIgE) testing, cryoglobulins, thyroid autoantibodies, thyroid function tests (4,5)

### Diagnostic Procedures/Other

- A skin biopsy should be taken from a new lesion if urticarial vasculitis is suspected.
- Challenge testing for physical urticarias (eg, cold urticaria may be induced by applying ice to the forearm for a few minutes and then allowing the skin to re-warm)
- Scratching the skin lightly may induce dermatographism.
- In vitro basophil histamine release assays for detection of histamine-releasing autoantibodies (not routinely available) (5)

**Pathological Findings**

Lesional biopsy for urticarial vasculitis may demonstrate leukocytoclasia, endothelial cell damage, perivascular fibrin deposition, and red cell extravasation (4)

**DIFFERENTIAL DIAGNOSIS**

- Erythema multiforme minor
- Mastocytomas
- Miliaria crystalline
- Miliaria rubra

**TREATMENT**

The primary treatment of urticaria is the removal of the inciting agent (when identifiable) and symptomatic relief.

**MEDICATION****First Line**

- 1st-generation antihistamine agents (sedating): Consider especially at night or in combination with non-sedating antihistamine agents:
  - Diphenhydramine 5 mg/kg/day PO/IM/IV divided q6–8h
  - Hydroxyzine 2–4 mg/kg/day PO divided q6–8h; 0.5–1 mg/kg/dose IM q4–6h as needed
  - Chlorpheniramine 0.35 mg/kg/day PO divided q4–6h
- Standard dose of a 2nd- or 3rd-generation H1 antihistamine agent: Such medication, though less commonly available and more expensive, only penetrates the blood-brain barrier to a slight extent and, thus, is less sedating than traditional 1st-generation antihistamines:
  - Cetirizine: Adults and children > 12 yr of age, 5–10 mg/day; children 2–5 yr of age, 2.5 mg (1/2 teaspoon) once daily; children 6 mo to 23 mo of age, 2.5 mg (1/2 teaspoon) once daily
  - Desloratadine: Adults and children ≥ 12 yr of age, 5 mg once daily; children 6–11 yr of age, 2.5 mg once daily; children 12 mo to 5 yr of age, 1/2 teaspoon (1.25 mg in 2.5 mL) once daily; children 6–11 mo of age, 2 mL (1.0 mg) once daily
  - Alternatives: Fexofenadine, levocetirizine, loratadine, mizolastine, acrivastine
  - Higher than standard dosages may be required to achieve an adequate response off-label, so must consider risk vs. benefit (4,5).
- Off-label addition of an H2 antihistamine (eg, ranitidine or famotidine) may give better control of urticaria than an H1 antihistamine taken alone (4,5).

**Pregnancy Considerations**

- It is best to avoid all antihistamines in pregnancy, though none has been shown to be teratogenic in humans.
- Consider pregnancy category and risk/benefit of any antihistamine prescribed during pregnancy.

**Second Line**

- Epinephrine 0.01 mL/kg IM (1:1,000 solution):
  - While recommended as first line for anaphylaxis and severe laryngeal angioedema, consider for severe pruritis or rapidly progressive urticaria.
- Antileukotrienes such as montelukast:
  - Not useful as monotherapy
- Corticosteroids:
  - In patients with severe acute urticaria, a short course of oral steroids may be of benefit (eg, prednisone 1 mg/kg/day in divided doses).
  - Prolonged courses of oral steroids for chronic urticaria should be avoided whenever possible, though this may be necessary for delayed pressure urticaria or urticarial vasculitis (4).

**COMPLEMENTARY & ALTERNATIVE THERAPIES**

- Immunomodulating therapies (eg, cyclosporine): Reserved for those patients with chronic autoimmune urticaria who have disabling disease that has not responded to optimal conventional treatments
- Relaxation techniques

**DISPOSITION****Admission Criteria**

Patients with urticaria can be managed as outpatients unless they develop laryngeal angioedema, anaphylactic shock, or have comorbidities that require inpatient therapy.

**Issues for Referral**

- For severe, poorly controlled urticaria, referral to an allergist/immunologist should be considered.
- A rheumatologist may be appropriate in cases of suspected urticarial vasculitis and in cases of chronic or recurrent urticaria.

**FOLLOW-UP****FOLLOW-UP RECOMMENDATIONS**

- Patients who develop angioedema or anaphylaxis should be sent home with an epinephrine autoinjector (EpiPen) and instructed on its use.
- Patients who have a poor response to initial therapies should follow up with their primary care provider to consider other options.

**PROGNOSIS**

- Most cases of acute urticaria resolve within 1–4 days.
- A retrospective study found that 44% of patients in a clinic with either acute or chronic urticaria had a good response to H1 antihistamines (6).
- In children, chronic urticaria usually resolves, with about 25% having disease remission within 3 yr of presentation.
- Those with autoimmune urticaria, physical urticaria, and pressure-induced urticaria have greater disease severity.

**COMPLICATIONS**

- Morbidity from chronic urticaria can be significant, as quality of life can be severely impacted.
- Depression
- Limited physical function

**CODES****ICD9**

- 708.0 Allergic urticaria
- 708.8 Other specified urticaria
- 708.9 Unspecified urticaria

**PEARLS AND PITFALLS**

- Ensuring that a systemic reaction including anaphylaxis is not present, including careful assessment of the airway and breathing, is the most critical action necessary.
- Urticaria can usually be classified on clinical presentation without extensive investigation.
- The cause of urticaria is often idiopathic.
- Antihistamine agents are the mainstay of therapy.
- Consider a brief course of oral corticosteroids for severe acute urticaria.

# RASH, VESICULOBULLOUS

Raina Paul  
Sarita Chung

## BASICS

### DESCRIPTION

Vesiculobullous rash is characterized as:

- Vesicle: Raised, fluid-filled lesion <0.5 cm
- Bulla: Raised, fluid-filled lesion >0.5 cm

### PATHOPHYSIOLOGY

- Disruption of cellular attachments
- Intracellular degeneration, edema (spongiosis), damage to anchoring structures of the basement membrane:
  - The above changes occur at various layers: Subcorneal, in the upper epidermis, intraepidermal, or subepidermal.

### ETIOLOGY

- Infection
- Infestations
- Contact irritants/caustics
- Medications
- Environmental exposure
- Congenital disorders
- Allergic reaction

## DIAGNOSIS

### HISTORY

- The algorithmic approach is based upon characteristic clinical appearance, chronicity (>4 wk), ill appearance, involvement of palms and soles, and age of patient.
- Characteristic clinical appearance: Rhus dermatitis and contact dermatitides, erythema multiforme, herpes zoster, varicella, herpes simplex virus (HSV), urticaria pigmentosa
- Noncharacteristic clinical appearance, chronic, congenital: Epidermolysis bullosa (EB), urticaria pigmentosa, epidermolytic hyperkeratosis, incontinentia pigmenti
- Noncharacteristic, chronic, noncongenital: Chronic bullous dermatitis, dermatitis herpetiformis, bullous pemphigoid
- Noncharacteristic, acute, ill appearing: Variola, varicella, HSV, hand-foot-and-mouth disease, toxic epidermal necrolysis (TEN), erythema multiforme, staphylococcal scalded skin syndrome (SSSS), systemic lupus erythematosus (SLE), vasculitis
- Noncharacteristic, acute, not ill appearing, no palm and sole involvement: Bullous impetigo, insect bites, vasculitis, burns, frostbite, rhus dermatitis
- Noncharacteristic, acute, not ill appearing, palms and soles, child <3 yr of age: Scabies, acropustulosis
- Noncharacteristic, acute, not ill appearing, palms and soles, adolescent: Tinea, id reaction

- Noncharacteristic, acute, not ill appearing, palms and soles, any age: Drug reaction, friction blisters, dyshidrotic eczema, vasculitis, frostbite
- Contact dermatitis: Allergic (lesions even beyond area of contact) and contact mediated (lesions only where direct skin contact)
- Herpes zoster: Rash is in a unilateral dermatomal distribution (1–3 dermatomes, most often thoracic), stabbing, throbbing pain, systemic symptoms in <20%:
  - History of prior varicella infection after which varicella zoster virus lies dormant in the spinal dorsal root ganglia, then reactivates
  - Pain often precedes rash.
- Urticaria pigmentosa: 75% occur in infancy, pigmented lesion that blisters after stroking or trauma (Darier sign), intensely pruritic:
  - Isolated (mastocytoma: usually of wrist) or generalized
  - Rarely associated with flushing, headache, dyspnea, wheezing, rhinorrhea, nausea, vomiting, diarrhea, and syncope (due to histamine release)
- EB: Group of inherited disorders that result in blistering of skin resulting from minor trauma:
  - Autosomal recessive or dominant; presents at birth, infancy, or adolescence
  - Blistering at intraepidermal, intralamina lucida, or sub-basal lamina area of skin
  - Involves area of trauma; occasionally involves nails, hair, teeth; can sometimes be severely scarring, deforming, and life threatening
- Incontinentia pigmenti: Rare x-linked dominant disease presenting in infancy; vesicles, ocular, dental, and CNS involvement
- Variola (smallpox): Begins on the face, monomorphic stage of all lesions:
  - Prodrome of fever, pharyngitis, headache, nausea, vomiting
  - Centrifugal spread: Macules, papules, pustules, vesicles
  - Has been successfully eradicated but is a potential bioterrorist agent
- Acropustulosis: Infants 2–12 mo of age, mostly hands and feet, erythematous macules that progress to vesicles and then pustules:
  - Resolves in 1 wk, often recurs in 2-wk cycles
  - Sometimes associated with scabies coinfection
- Tinea: Fungi that invade dead keratin of skin, hair, nails:
  - *Epidermophyton*, *Microsporum*, *Trichophyton* species
  - Pruritic lesions on any part of body, scalp lesions resolve in adolescence
  - Tinea pedis is most common.
- Id reaction: Acute onset of pruritic erythematous papulovesicular lesions 1–2 wk after a primary skin lesion (infectious or inflammatory)
- Dyshidrotic eczema: History of eczema, hyperhidrosis, contact allergies (eg, nickel)

- Frostbite: Prolonged exposure to cold resulting in tissue denaturation, cellular dehydration, inhibition of DNA synthesis:
  - Often digits, cold, firm, numb, burning
  - 1st degree (epidermis) to 4th degree (epidermis, dermis, subcutaneous tissues)
- Bullous impetigo: Exotoxin-mediated erythrodermal infection resulting in sloughing of the skin at the epidermal layer and can involve the buccal mucosa:
  - *Staphylococcus aureus* most commonly is implicated, less commonly group A beta-hemolytic streptococcus (GABHS)
  - Fever, lymphadenopathy occasionally present

### PHYSICAL EXAM

- Contact dermatitis: Localized, characteristic shape (circular lesion of nickel watch, linear area where poison ivy brushed against skin, etc.), erythematous, vesicular
- Varicella: Papules, vesicles, and pustules on an erythematous base in various stages
- Herpes zoster: Dermatomal, erythematous base, vesicular, pustular or crusting, painful (all in same stage), lymphadenopathy, conjunctival keratitis, rarely meningoencephalitis
- HSV: Vesicular anterior mouth lesions, genital lesions, finger lesion (herpetic whitlow), keratoconjunctivitis
- Urticaria pigmentosa: Several tan-brown lesions, mostly on trunk, some vesicular
- EB: Diffuse bullae of hands and feet and often the entire body:
  - More severe forms have joint contractures, deformity, organ involvement, sepsis, death
- Incontinentia pigmenti: Several stages of lesions beginning with linear vesicles and hyperpigmentation during infancy
- Variola: Lesions in same stage; begins on the face as macules and then papules, vesicles, pustules, then crusts; toxic appearing
- Hand-foot-and-mouth: Hand, foot, and mouth vesicles (usually posterior oropharynx lesions), at times other parts of body involved
- Stevens-Johnson syndrome (SSS)/TEN: Target lesions, erythematous macules that coalesce and can become frank bullae that shear easily, leaving denuded skin
- SSSS: Warm erythematous skin that quickly progresses to widespread bullae, sheetlike wrinkling of the skin and sloughing:
  - Bullae exfoliate in large sheets (Nikolsky sign)
- Scabies: Linear burrows, excoriated papules that can become vesicular
- Acropustulosis: Discrete papules, vesicles, and pustules on the palms and soles, sometimes the face, scalp, and trunk:
  - Healed areas are hyperpigmented.
- Tinea: Annular, scaly plaque with raised edges, often vesicular, hands and feet lesions in web spaces, and not often annular

- Id reaction: Distant from primary infection site, localized or more commonly diffuse:
  - Symmetric crops of erythematous papules, vesicles, bullae on palms and lateral aspects of fingers, occasionally soles and toes
  - With long-standing disease, fingernails may become dystrophic.
- Frostbite:
  - 1st degree: Waxy skin, erythema, hard, numb
  - 2nd degree: Erythema, edema, vesicles
  - 3rd degree: Blood-filled vesicles, progressing to eschar formation in weeks
  - 4th degree: Deep tissue damage and loss
- Bullous impetigo: Small to large vesicles/bullae that quickly burst, leaving denuded skin; the face is the most common site:
  - May begin as nonbullous impetigo with honey-colored crusts and pustules over an erythematous base

## DIAGNOSTIC TESTS & INTERPRETATION

### Lab

#### Initial Lab Tests

- Most rashes are diagnosed clinically.
- Herpes zoster: DFA of lesion base scraping for rapid sensitive results; polymerase chain reaction for confirmation; culture is less sensitive and slower (1); Tzanck smear (20% false negatives)
- Urticaria pigmentosa: Serum tryptase often is positive in diffuse disease; skin biopsy rarely is needed.
- EB: Skin biopsy analysis with electron microscopy or immunofluorescence (2), mutation analysis, blood cultures if lesions widespread, anemia in certain forms
- Incontinentia pigmenti: Genetic testing, skin biopsy
- Variola: Immediate reporting to CDC, viral swabs from pharynx, base of lesion
- Acropustulosis: No labs needed. CBC often shows eosinophilia.
- Tinea: Microscopic exam of skin scrapings treated with KOH reveal hyphae. Culture can identify species. Wood lamp reveals green fluorescence.
- Id reaction: Look for primary infection. If primary infection is fungal, id lesions will not reveal hyphae on skin scrapings.
- Dyshidrotic eczema (clinical diagnosis)
- Frostbite (clinical diagnosis): Patients may be systemically ill and thus further generalized testing may be necessary. (See Frostbite and Hypothermia topics.)
- Bullous impetigo (clinical diagnosis): Gram stain—neutrophils and gram-positive cocci in clusters (rarely chains if *Streptococcus*). Culture of bullous fluid reveals *S. aureus* or GABHS.

### Imaging

EB: If GI symptoms, evaluate with upper GI or endoscopy.

### Diagnostic Procedures/Other

Herpes zoster/HSV: Tzanck smear—unroof the vesicle; swab the base of the lesion/Wright stain reveals distinct giant cells with multiple nuclei.

## DIFFERENTIAL DIAGNOSIS

See the algorithmic approach in the History section.

## TREATMENT

- Contact dermatitis: Lukewarm oatmeal baths, emollients, burrow solution compresses, topical steroids (hydrocortisone, triamcinolone)
- Herpes zoster:
  - Acyclovir if within 72 hr of lesion onset (treat regardless if immunocompromised):
    - Valacyclovir has been used in adults.
  - Steroids only if diffuse and severe (1)
  - NSAIDs
  - Narcotics for pain control
- Urticaria pigmentosa: Avoid drugs that precipitate mediator release (NSAIDs, aspirin, codeine, morphine, etc.), H1 and H2 antihistamines, topical corticosteroids if localized
- EB: Symptomatic care, drainage of existing bullae to prevent extension, wound care with topical antibacterials, gauze coverage, systemic antibiotics if septic
- Variola: Vaccination within 4 days of symptoms attenuates disease, respiratory isolation
- Scabies: Permethrin cream or ivermectin if widespread disease
- Acropustulosis: Self-limited; if severe, topical steroids or oral dapsone
- Tinea: 2 wk of topical azoles. Extensive disease and scalp lesions require oral antifungals.
- Id reaction: Treatment of primary infection is necessary to eradicate the id reaction. Topical steroids, antihistamines for symptomatic relief.
- Dyshidrotic eczema: Self-resolving in 2–3 wk, topical corticosteroids, occasionally systemic corticosteroids; recalcitrant disease needs referral to dermatologist.
- Frostbite: Fluid resuscitation, whirlpool bath at 40–42°C, warm wet packs if not available, pain control:
  - Once thawed, elevate, immobilize, and keep sterile.
  - Debride clear blisters, and keep blood-filled ones intact.
  - 1–3 mo to determine viability of tissues
- Bullous impetigo: If large areas of involvement, fluid resuscitation, admission:
  - Otherwise, oral antibiotics: MRSA is common, so trimethoprim/sulfamethoxazole or clindamycin should be used (depending on local susceptibility patterns).
  - If not resolving, better anti-*Streptococcus* coverage such as cephalexin should be added.

## DISPOSITION

### Admission Criteria

- Refusal to drink, dehydration (hand-foot-and-mouth, HSV)
- Degree of skin denudation is so high that extreme fluid losses are likely (EB, SJS, TEN, SSSS, bullous impetigo)
- Risk of tissue damage is high (frostbite)
- Critical Care Admission Criteria:
  - Hemodynamically unstable (SSSS, SJS, TEN, variola)

### Issues for Referral

- Herpes zoster and HSV: Ophthalmologist if concern for keratoconjunctivitis
- EB: Physical therapy, dental, nutrition
- Frostbite: Early surgical consultation for extensive disease, possible compartment syndrome, rarely amputation

## FOLLOW-UP

### PROGNOSIS

- SJS: 10% mortality
- TEN: 50% mortality
- SSSS: Minimal mortality despite extensive lesions

## CODES

### ICD9

709.8 Other specified disorders of skin

## PEARLS AND PITFALLS

- Several diseases with severe morbidity and/or mortality may cause vesicobullous disease. Vesicobullous rash requires careful evaluation to ensure that no such disease exists or to appropriately treat if present.
- Herpes zoster: Lesions on the tip of the nose signify nasociliary nerve involvement; this mandates slit lamp exam with fluorescein stain to look for the dendritic corneal lesions of herpetic keratitis.

# RECTAL BLEEDING

Gregory Garra

## BASICS

### DESCRIPTION

- Bleeding from the anus typically results in passage of bright red blood (hematochezia).
- In clinical practice, differentiating anal bleeding from rectal or lower GI bleeding can be challenging.

### PATHOPHYSIOLOGY

Anal bleeding results from a number of etiologies (see Etiology section):

- The pathophysiology of anal fissure and rectal prolapse are described elsewhere.
- Hemorrhoidal enlargement results from straining and small-caliber stools from low-fiber diets.
- Solitary rectal ulcer syndrome is suspected to be a form of rectal prolapse in which a portion of the rectal mucosa is frequently forced into the anal canal and as a consequence becomes strangulated, causing congestion, edema, and ulceration.
- Direct trauma may result in mucosal and submucosal tear and hemorrhage:
  - Consider sexual abuse.

### ETIOLOGY

Etiologies vary with age and are typically benign:

- Infants: Anal fissures, rectal prolapse, constipation, sexual abuse
- Children: Anal fissures, hemorrhoids, rectal polyps, constipation, solitary rectal ulcer syndrome, sexual abuse
- Adolescents: Hemorrhoids, anal fissures, rectal polyps, solitary rectal ulcer syndrome, sexual abuse, sexual activity

### COMMONLY ASSOCIATED CONDITIONS

- In children, rectal prolapse is commonly associated with cystic fibrosis.
- Inflammatory bowel disease such as ulcerative colitis and Crohn disease

## DIAGNOSIS

### HISTORY

- Symptoms from hemorrhoids commonly include bleeding, prolapse, itching, and pain.
- Solitary rectal ulcer syndrome may present with a history of straining, anal pain, and passage of blood and mucus during defecation.
- The symptoms of anal fissure and rectal prolapse are described elsewhere.

### PHYSICAL EXAM

- Exam of the abdomen for:
  - Presence and quality of bowel sounds
  - Distention
  - Tenderness
  - Intra-abdominal mass
- Exam of the anus and perineum for fissure or fistula
- Digital rectal exam or anoscopy may demonstrate a palpable polyp.
- Stool blood testing

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

- CBC may demonstrate anemia in cases of chronic anal bleeding.
- Causes of rectal or lower GI bleeding should be investigated when the source of bleeding is unclear.
- Blood testing of stool to confirm the presence of blood

### Diagnostic Procedures/Other

Colonoscopy may be required in cases where the routine physical exam does not clearly delineate the source of anal bleeding.

### DIFFERENTIAL DIAGNOSIS

- Hematochezia should be differentiated from a number of foods and medications that impart a bloody appearance to stool.
- Causes of lower GI bleeding such as Meckel diverticulum, inflammatory bowel disease, and infectious colitis
- Hemorrhoids
- Beets, red licorice, Kool-Aid, gelatin, ampicillin, and bismuth preparations may pigment the stool and give the false appearance of hemorrhage or bleeding.
- Beef or red meat consumption may result in heme-positive stools.

## TREATMENT

### INITIAL STABILIZATION/THERAPY

- Treatment of conditions that result in anal bleeding is largely supportive.
- Hemodynamically unstable patients with exsanguinating hemorrhage require volume replacement, transfusion or packed RBCs, and immediate endoscopy for identification and control of hemorrhage.

**SURGERY/OTHER PROCEDURES**

Bleeding resulting from hemorrhoids may require banding or thrombosing.

**DISPOSITION****Admission Criteria**

- Profuse bleeding
- Altered vital signs
- Further evaluation is warranted for potentially dangerous causes of lower GI bleeding such as:
  - Meckel diverticulum
  - Inflammatory bowel disease

**Discharge Criteria**

Most patients with minimal anal bleeding can be discharged for follow-up as an outpatient.

**Issues for Referral**

Patients with anorectal trauma should be thoroughly evaluated for sexual abuse.

**FOLLOW-UP****FOLLOW-UP RECOMMENDATIONS**

Discharge instructions and medications:

- Dietary modification including increased liquid and fiber intake
- Bulk laxatives, decreased straining, and sitz baths may alleviate symptoms resulting from hemorrhoids or anal fissures.

**PROGNOSIS**

- The prognosis is dependent on the cause of the bleeding.
- Most etiologies are benign and self-limiting.
- Some etiologies, such as inflammatory bowel disease, may have a more debilitating course.

**ADDITIONAL READING**

- Stites T, Lund DP. Common anorectal problems. *Semin Pediatr Surg.* 2007;16:71–78.
- Teach S, Fleisher G. Rectal bleeding in the pediatric emergency department. *Ann Emerg Med.* 1994;23:1252–1258.

**See Also (Topic, Algorithm, Electronic Media Element)**

- Anal Fissure
- Colitis
- Gastrointestinal Bleeding: Lower
- Gastrointestinal Polyps
- Inflammatory Bowel Disease
- Rectal Bleeding
- Rectal Prolapse

**CODES****ICD9**

569.3 Hemorrhage of rectum and anus

**PEARLS AND PITFALLS**

- Always consider lower GI or rectal causes of anal bleeding.
- Inflammatory bowel disease and other causes of more proximal GI bleeding should be considered in cases of rectal bleeding for which an obvious cause, such as anal fissure or bleeding hemorrhoid, is not found.

# RECTAL PROLAPSE

Beverly A. Poelstra

## BASICS

### DESCRIPTION

- Rectal prolapse is a condition where a portion of the rectal tissue protrudes through the anus.
- 3 types:
  - Complete (full thickness):
    - All layers of the bowel are involved.
    - Also known as procidentia
    - Rare in children
  - Partial (incomplete):
    - Protrusion of mucosa only through the anal orifice
    - Most common type in infants and children
    - Bowel lumen may be visible centrally.
    - Mucosal folds in a radial pattern are characteristic (1).
    - Protrudes 1–3 cm
    - Usually a benign, self-limited condition, though very frightening to families
    - Cylindrical appearance with concentric folds, circular rings of tissue (1,2)
    - Usually >5 cm protrusion
    - Occurs in older patients and those with underlying disorders such as weak levator ani or loose attachment of rectum to pelvic structures (1)
  - Concealed or internal: Internal intussusceptions of upper rectum into lower and do not emerge through the anus
- May be accompanied by a small amount of rectal bleeding, or spotting, with mucus

### EPIDEMIOLOGY

#### Incidence

- Usually occurs at extremes of age, very young children and older adults
- Highest incidence is in the 1st years of life.
- Peak age at presentation is 2.5 yr.
- Rare after age 4 yr (3)
- Males and females are affected equally in infants and young children.
- In the older population, females greatly outnumber males by at least 5 to 1 (3).
- Cystic fibrosis is responsible for only ~1 in 10 cases of rectal prolapse in children:
  - Older studies suggest 20–30% prevalence in cystic fibrosis (4).
  - In patients receiving adequate pancreatic enzyme supplementation, only 2–3% are affected.
- Many cases are not reported, so the incidence may be underestimated.
- Less frequently observed in Western countries and developed nations

### RISK FACTORS

- Cystic fibrosis is a significant risk factor, but since cystic fibrosis is an infrequent disease, most patients with rectal prolapse do not have the disease.
- Conditions that cause increased abdominal pressure: Constipation, chronic cough, stool withholding during toilet training
- Diarrhea: Bacteria, parasites
- Malnutrition: In underdeveloped countries or in patients with malabsorption (cystic fibrosis, celiac).
- Rarely: Meningocele, rectal polyps, pertussis, laxity of supporting ligaments in pelvic musculature, postoperative complications in patients with repaired imperforate anus

### GENERAL PREVENTION

- Normalize the stooling pattern for patients with constipation or diarrhea.
- Comprehensive medical care for patients with cystic fibrosis: Pancreatic enzyme replacement, pulmonary medications to control cough

### PATHOPHYSIOLOGY

- Repeated straining, coughing, or other conditions that cause increased abdominal pressure eventually weaken the pelvic floor musculature.
- Malnutrition weakens rectal tissue and supporting structures.

### ETIOLOGY

- The majority of pediatric patients with rectal prolapse have chronic constipation (3).
- The mechanism is unknown in cystic fibrosis and diarrhea/constipation but is thought to be laxity of connective tissue between the submucosa and underlying muscle layer of the rectum.
- The causes differ significantly in adults, who frequently have pelvic musculature weakness (3).
- Malnutrition is a major cause in underdeveloped countries and in untreated celiac and cystic fibrosis patients.

### COMMONLY ASSOCIATED CONDITIONS

- Most frequent underlying conditions: Constipation, idiopathic, diarrhea, cystic fibrosis
- Chronic constipation—most common cause:
  - Due to prolonged straining at passing stool
- Diarrhea—various pathogens:
  - Bacteria, parasites, hookworm, amebiasis, *Clostridium difficile*
- Cystic fibrosis: Increased incidence of rectal prolapse but still relatively uncommon
- Malnutrition:
  - Cystic fibrosis, celiac disease due to malabsorption
  - Protein and calorie deficits in developing countries
- Rectal polyps: Act as lead point
- Complication of prior surgical procedures, such as imperforate anus repair

## DIAGNOSIS

### HISTORY

- The diagnosis often based on the parental report since spontaneous resolution is very common prior to medical evaluation (5).
- Parents may notice a dark, red mass protruding from the anus after defecating that may be accompanied by spotting of blood or mucus on underpants.
- The child may or may not report discomfort. Occasionally, the child complains of a lump.
- Patient or parents may also report diarrhea or constipation and foul-smelling stools.

### PHYSICAL EXAM

- Exam is aided by placing the patient in a reclining position in the parent's lap.
- Appears as a shiny, inflamed, deep red mass in the anal region
- The central orifice may be visible.
- Larger mass with circular rings that are circumferential in true, complete rectal prolapse
- Smaller mass with radial folds from the central lumen; usually partial prolapse of mucosa only
- Most obvious in a squatting position if the child will cooperate (5)
- If not visible, asking the patient to strain may provoke the prolapse. It may take several minutes to appear.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

- None usually indicated
- A sweat test is not indicated for a 1st episode of rectal prolapse unless other factors in the history such as cough, growth failure, or malabsorption are present:
  - Not indicated if anatomic abnormalities are present (4)

#### Imaging

- X-ray studies are not necessary for uncomplicated cases.
- Contrast enemas should be considered if intussusception of the bowel is suspected.

#### Diagnostic Procedures/Other

- Sweat test: In infants with recurrence, there is a strong association with cystic fibrosis.
- Sigmoidoscopy: Should be considered if rectal polyps are suspected

**DIFFERENTIAL DIAGNOSIS**

- Prolapsing polyp
- Large hemorrhoid
- Colonic intussusceptions
- Hirschsprung disease
- Prolapsing rectal tumor
- Colonic intussusception—can be distinguished by  $\geq 1$  of the following:
  - Ill appearance, abdominal pain, irritability, lethargy, vomiting, rectal bleeding (5)

**TREATMENT****INITIAL STABILIZATION/THERAPY**

- Prompt reduction should occur to prevent further swelling.
- Analgesics are not usually necessary and should not delay reduction.
- The child should be restrained in the manner preferable to the clinician and parent. Allowing the child to remain in the parent's lap might decrease the anxiety level of both the parent and child:
  - This may involve the child held by the parent or alternately restrained by staff who may more reliably restrain the child.
- With a gloved hand, place a finger on either side of the prolapse, providing firm, steady pressure with the thumbs. Alternately, the palm or butt of the hand may be used to force the prolapse back inside.
- Most prolapses will reduce easily and quickly.
- A piece of gauze placed on either side of the prolapse and the use of both hands may aid in gaining traction/friction against the prolapsed tissue.
- Sedation is rarely necessary but should be considered in difficult cases.
- If reduction is difficult or unsuccessful, obtain surgical consult and consider other diagnoses. Cover with saline gauze in the interim.

**MEDICATION**

- Should be directed to treating the underlying cause
- Antimicrobials for enteric pathogens
- Stool softeners, laxatives for constipation
- Pancreatic enzyme supplementation for cystic fibrosis

**COMPLEMENTARY & ALTERNATIVE THERAPIES**

- Buttock taping for recurrences has been recommended in the past, but no evidence exists for its effectiveness (1).
- Changing position of stooling (eg, reclining) is not of proven benefit (1).

**SURGERY/OTHER PROCEDURES**

- Consider surgical alternatives only if medical management and conservative measures have failed.
- Many patients get unnecessary surgery referrals.
- Sclerotherapy (hypertonic saline, dextrose, phenol, others):
  - Used as first-line treatment in pediatrics for incomplete prolapse if the patient has normal sphincter tone
  - Reserved for patients with multiple recurrences and  $>4$  yr of age
  - Injected circumferentially in the perirectal area
  - Causes fibrosis, preventing further prolapse
  - Success rate  $>90\%$  (3)

- Numerous surgical approaches ( $>300$ ) exist, as there are varied etiologies and no procedure with demonstrated clear-cut superiority (2)
- Pelvic floor disorders more likely to require surgical repair and are more common in older patients, patients with neurologic issues, and patients with previous bowel surgery.
- Only  $\sim 10\%$  of cystic fibrosis patients with rectal prolapse require surgical intervention.

**DISPOSITION****Admission Criteria**

- Patients for whom reduction is not possible should be admitted for surgical treatment.
- If sedation is required for reduction, most patients may still be safely discharged.
- In cases of intussusception, reduction or operative intervention is required.

**Discharge Criteria**

Successful discharge of the prolapse without comorbidities

**Issues for Referral**

- If symptoms recur, stool cultures are negative, and no other etiology can be determined, a referral to a gastroenterologist and sigmoidoscopy should be considered.
- Patients with pelvic floor disorders should have surgical referral in cases of recurrent prolapse.

**FOLLOW-UP****FOLLOW-UP RECOMMENDATIONS**

- Teach parents how to perform manual reduction for repeat cases.
- Address underlying etiologies for malabsorption, such as cystic fibrosis and celiac disease, and treat appropriately.
- Attempt to normalize consistency of stools.
- Stool softeners, laxatives, and a high-fiber diet are indicated in cases of constipation and stool withholding.
- Minimize the amount of time spent sitting and straining with passage of a bowel movement.
- If recurrences occur, consider re-evaluation of the putative etiology.

**DIET**

- High-fiber foods should be encouraged.
- Glutenfree diet for patients with celiac disease

**PROGNOSIS**

- The majority of patients with rectal prolapse do not have recurrences unless underlying conditions exist (2,3,5).
- The prognosis is less favorable if patients present after age 4 yr (3,5).
- Even in recurrent cases, most resolve without intervention.

**COMPLICATIONS**

- Incarcerated or ischemic rectal tissue
- Small, local ulcerations due to traumatic reduction or prolonged exposure of bowel
- Solitary rectal ulcer syndrome:
  - Rare complication in older teens and adults
  - On anterior wall of sigmoid
  - Presents as pain in the rectum, minor rectal bleeding, mucus discharge

**CODES****ICD9**

569.1 Rectal prolapse

**PEARLS AND PITFALLS**

- Rectal prolapse most commonly occurs during the 1st years of life.
- In recurrent cases, consider underlying causes.
- Chronic constipation is the most common cause in the pediatric age group in industrialized nations, followed by idiopathic.
- Cystic fibrosis should be considered, as this is a cause of increased abdominal pressure, due to coughing, as well as malabsorption. Confirm with a sweat test.
- A sweat test should be ordered for infants and children with recurrences in the absence of other clear etiology.
- Rectal prolapse is usually a painless condition. If significant discomfort is present, consider more serious, but rare, causes such as intussusception.

# RENAL VEIN THROMBOSIS

Jennifer Thull-Freedman

## BASICS

### DESCRIPTION

- Renal vein thrombosis (RVT) is the formation of blood clot in the renal vein or its tributaries.
- May extend into the inferior vena cava (IVC) and occlude the contralateral renal vein
- Clinical manifestations depend on whether presentation is acute or chronic.

### EPIDEMIOLOGY

- 90% of pediatric cases occur in infants <1 yr of age.
- 75% occur in those <1 mo of age (usually in the 1st 3 days of life).
- May occur in utero
- Male predominance of ~2 to 1 in the neonatal period
- The left renal vein is more likely to be affected (2:1).
- 30% are bilateral.

### Incidence

- 0.5 per 1,000 neonatal ICU admissions
- The incidence of venous thrombosis in children with nephrotic syndrome is ~3%.

### ALERT

Children with nephrotic syndrome should not have deep venipuncture or femoral venous catheterization unless no reasonable alternative exists.

### Prevalence

May account for 20% of neonatal hematuria

### RISK FACTORS

- Hypercoagulable states (nephrotic syndrome, malignancy, deficiency of protein C or S, factor V Leiden mutation, thrombocytosis, systemic lupus erythematosus, oral contraceptive use)
- Dehydration
- Sepsis
- Trauma
- Burns
- Kidney transplant (1–5% in the immediate posttransplant period)

- Cyanotic congenital heart disease (especially following angiography)
- Use of radiographic contrast agents
- In neonates: Umbilical vein catheterization, perinatal stress, polycythemia, and infants of diabetic mothers

### GENERAL PREVENTION

- Requires preventing or treating underlying conditions such as dehydration
- Avoid femoral venipuncture and femoral vein catheters in hypercoagulable states such as nephrotic syndrome unless benefits outweigh the risks.

### PATHOPHYSIOLOGY

- May be classified as acute or chronic
- Usually triggered by conditions of hypovolemia, hyperviscosity, low flow, or hypercoagulability
- Thrombosis usually begins in small intrarenal veins and progresses through intralobular and arcuate veins toward the main renal vein and the IVC.
- RBCs, platelets, and fibrin are consumed in the clot.
- Acute: Venous congestion and obstruction lead to infarction and hemorrhage.
- Chronic: Development of collateral venous drainage may mitigate renal damage.

### ETIOLOGY

- In neonates, RVT generally is seen with dehydration, shock, asphyxia, sepsis, or polycythemia (especially in infants of diabetic mothers).
- After infancy, RVT most commonly is seen in association with nephrotic syndrome or other hypercoagulable states.

### COMMONLY ASSOCIATED CONDITIONS

- IVC thrombosis (up to 50% of neonates)
- Adrenal hemorrhage (15–20% of neonates)

## DIAGNOSIS

### HISTORY

- Risk factors: Prenatal, birth, postnatal course; family history
- Symptoms depend on whether RVT is acute or chronic.
- Acute:
  - Flank pain
  - Hematuria
  - Oliguria (if bilateral)
  - Vomiting
  - Anorexia
- Chronic:
  - May have some of the above symptoms or insidious onset with few clinical manifestations
  - Rarely may present as pulmonary embolism

### PHYSICAL EXAM

- HTN (20% of neonates)
- Abdominal mass (45–60% of neonates)
- Edema or cyanosis of the lower extremities if the IVC is involved
- The diagnostic triad of palpable abdominal mass, gross hematuria, and thrombocytopenia only applies to acute RVT and is found in <20% of patients.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

- CBC (microangiopathic hemolytic anemia and thrombocytopenia in 50% of neonates)
- PT, aPTT, fibrinogen, D-dimer, fibrin degradation products:
  - Consumptive coagulopathy
  - Obtain coagulation studies prior to anticoagulation.
- Elevated BUN and creatinine
- Hypoalbuminemia if nephrotic
- Urinalysis:
  - Hematuria
  - Proteinuria

#### Imaging

- Imaging techniques that avoid use of contrast agents are preferred.
- US with Doppler is the initial investigation of choice:
  - Increased renal size (in 1st week), distorted renal architecture, loss of corticomedullary differentiation, and altered echogenicity (due to hemorrhage and interstitial edema)
  - Absence of blood flow where clot is present
- CT:
  - Shows enlarged kidney (acutely) and absence of opacification of renal vein if contrast enhanced
  - Usually not necessary if the diagnosis is made by US
- MRI: Comparable or superior to CT and avoids exposure to radiation and contrast agents
- Plain radiograph: May reveal renal enlargement during the acute stage
- Radionuclide scan will demonstrate decreased or no perfusion to the involved kidney.

**DIFFERENTIAL DIAGNOSIS**

- Other abdominal masses:
  - Multicystic dysplastic kidney
  - Polycystic kidney disease
  - Hydronephrosis
  - Renal and adrenal tumors
  - Wilms tumor
- Urolithiasis with urinary tract obstruction
- Hemolytic uremic syndrome
- Other renal vascular conditions:
  - Acute tubular necrosis
  - Cortical or medullary necrosis
  - Renal artery thrombosis
  - Glomerulonephritis

**TREATMENT****INITIAL STABILIZATION/THERAPY**

- Goals:
  - Preserve renal function.
  - Prevent thromboembolic events.
  - Treat underlying conditions.
- Correct hypovolemia.
- Consider anticoagulation.
- Manage HTN.
- Treat electrolyte abnormalities and renal failure.

**MEDICATION**

- Consultation with a pediatric nephrologist and hematologist with experience in treatment of pediatric thrombosis is advised:
  - The efficacy of anticoagulation therapy in pediatric RVT has not been evaluated by controlled studies.
  - Observational data in 1 study suggests that better outcomes are seen with anticoagulation.
- Anticoagulation therapy:
  - Heparin infusion
  - Low molecular weight heparin (enoxaparin)
  - Tissue plasminogen activator, streptokinase, or urokinase:
    - Considered with acute presentation, bilateral involvement, and evidence of renal impairment
    - Contraindicated if recent invasive procedures or CNS ischemia

**SURGERY/OTHER PROCEDURES**

- Thrombectomy for RVT is uncommon and rarely indicated:
  - RVT usually involves small vessels not amenable to surgical thrombectomy.
  - Could be considered if bilateral RVT and renal impairment are not responsive to anticoagulation
- Nephrectomy is uncommon but rarely is considered for persistent renovascular HTN.

**DISPOSITION****Admission Criteria**

- Children with confirmed or suspected RVT should be admitted to a hospital.
- Critical care admission criteria:
  - Fibrinolytic therapy
  - Severe HTN
  - Renal failure with life-threatening electrolyte disturbance
  - Severe coagulopathy

**Issues for Referral**

- Pediatric nephrology to provide input on management of renal failure, dialysis, and electrolyte and fluid balance
- Pediatric hematology to provide input on decision to treat with anticoagulation or thrombolysis and for investigation of possible underlying hypercoagulable conditions

**FOLLOW-UP****FOLLOW-UP RECOMMENDATIONS****Patient Monitoring**

Follow for development of renal atrophy, impaired renal function, and HTN.

**DIET**

May need modification if renal impairment exists

**PROGNOSIS**

- Depends on acuteness of thrombosis (slow progression of clot allows for protective development of collateral circulation)
- The left kidney is more resilient than the right due to the presence of collateral venous drainage.
- Renal atrophy is common.
- HTN in 20%
- Persistent renal insufficiency in 60–70% of neonatal patients
- Better prognosis for adequate renal function if RVT is unilateral

**COMPLICATIONS**

- Pulmonary embolism
- Consumptive coagulopathy
- Renal atrophy
- Renal failure
- Chronic tubular dysfunction
- Systemic HTN

Pediatric Thrombosis Program: The 1-800-NO-CLOTS service is a free consultative service for physicians worldwide on pediatric thromboembolism and stroke. Available at <http://www.1800noclots.ca>.

**CODES****ICD9**

453.3 Embolism and thrombosis of renal vein

**PEARLS AND PITFALLS**

- RVT presentation can be nonspecific. Maintain a high degree of suspicion in patients with known risk factors.
- Suspect RVT if a mass, hematuria, and thrombocytopenia are present.
- Avoid deep venipuncture in nephrotic patients.

# RESPIRATORY DISTRESS

Julia K. Deanehan  
Joshua Nagler

## BASICS

### DESCRIPTION

- Respiratory distress describes the body's response to difficulty in achieving adequate oxygenation and ventilation.
- It is characterized by abnormal respiratory sounds (eg, wheezing, stridor, grunting), rapid respiratory rate, or use of accessory muscles (nasal flaring, retractions).
- Respiratory distress can progress to respiratory failure if not rapidly identified and treated.
- Untreated respiratory distress with subsequent respiratory failure is the most common etiology of cardiac arrest in children.

### EPIDEMIOLOGY

#### Incidence

- ~10% of visits to the pediatric emergency department are for respiratory distress (1).
- ~5% of ambulance calls for pediatric patients are for respiratory distress (2).

### RISK FACTORS

- Patients with chronic pulmonary disease such as asthma, cystic fibrosis (CF), chronic lung disease (CLD), and recurrent aspiration
- Patients with cardiac disease may have reduced cardiopulmonary reserve.
- Patients who have suffered trauma with airway obstruction or impaired respiratory function
- Congenital anomalies may lead to varying degrees of airway obstruction.

### PATHOPHYSIOLOGY

- Respiration is a complex multisystem process involving 3 main functional components:
  - Mechanical structures (eg, chest wall, respiratory muscles including the diaphragm)
  - Gas exchange mechanism
  - Regulatory system (brainstem, chemical, and mechanical receptors)
- Disruption of any of these 3 components can lead to respiratory distress.
- In children, disruption of the normal function of the upper or lower airway is the most common reason for respiratory distress.
- Signs of increased work of breathing can result from airway obstruction, impaired chest wall mechanics, or parenchymal lung disease.

### ETIOLOGY

- Upper airway:
  - Infectious: Nasal congestion in infants, croup, peritonsillar or retropharyngeal abscess (RPA), epiglottitis/supraglottitis, tracheitis
  - Anatomic: Congenital anomalies, macroglossia, choanal atresia, tonsillar hypertrophy, vascular rings and slings, laryngomalacia, vocal cord dysfunction, extrinsic mass
  - Inflammatory: Angioedema, anaphylaxis
  - Trauma: Chemical or thermal burn
  - Foreign body aspiration (FBA)

- Lower airway:
  - Infectious: Bronchiolitis, pneumonia
  - Anatomic/Congenital: Congenital lobar emphysema, cystic adenomatoid malformation, sequestration
  - Inflammatory: Asthma, near drowning, aspiration
  - Exposure: Thermal or chemical burn, smoke, carbon monoxide, hydrocarbon
  - Trauma: Bronchial disruption, pulmonary contusion
  - Other: Interstitial lung disease, CLD, CF, pulmonary edema, mass
- Chest wall:
  - Kyphoscoliosis, pectus deformity, flail chest
- Pleural space diseases:
  - Pneumothorax, pleural effusion, hemothorax
- Nonrespiratory and systemic diseases:
  - CNS disease: Seizure, ingestion, neurologic injury, anatomic lesion
  - Sepsis
  - Cardiovascular disease: Pericardial effusion, congenital heart disease (CHD), CHF, pulmonary embolism
  - GI disease: Appendicitis, mass, ascites, bowel obstruction, esophageal foreign body
  - Metabolic disease: Metabolic acidosis, hyperammonemia, hyperpyrexia, salicylate ingestion

## DIAGNOSIS

### HISTORY

- Primary concern of patient/parents (wheezing, cough, stridor, dyspnea, tachypnea)
- Duration: Acute or chronic/recurrent
- Prodrome or precipitating events
- Presence of fever
- Associated signs or symptoms
- Prior treatments and response
- Past medical history:
  - Underlying conditions or prior surgery
  - Possible aspiration, ingestions, or exposures
- Current medications
- Allergies
- Immunization status
- Family history (eg, atopic conditions)
- Social history: Exposure to primary or 2nd-hand smoke

### PHYSICAL EXAM

- Initial exam should be focused and rapid.
- Vital signs, particularly respiratory rate and oxygen saturation:
  - Tachypnea is commonly present.
- General appearance:
  - Level of consciousness, appearance
  - Child's preferred position
  - Degree of distress
- HEENT exam:
  - Nasal flaring
  - Choanal atresia, craniofacial abnormalities
  - Nasal mucus, oral secretions/drooling
  - Swelling (uvula, peritonsillar, tonsillar, etc.)

- Respiratory:
  - Patency of airway, stridor, voice changes
  - Ability to speak in long phrases or sentences
  - Shape of chest (scoliosis, pectus deformity)
  - Symmetry of chest wall movement
  - Depth and quality of respirations
  - Air entry, symmetry of breath sounds
  - Retractions (supraclavicular, intercostal, subcostal) or other accessory muscle use
  - Grunting
  - Inspiration to expiration ratio
  - Rales, rhonchi
  - Wheezing (inspiratory or expiratory)
- Cardiac:
  - Rate and rhythm, presence of murmur
  - Perfusion (pulses, capillary refill time)
- Abdomen:
  - Hepatosplenomegaly, abdominal distension
- Extremities: Clubbing
- Skin exam: Pallor, cyanosis
- Mental status: Anxiety, combativeness, lethargy, somnolence

### DIAGNOSTIC TESTS & INTERPRETATION

- Immediate recognition and rapid intervention precede any diagnostic testing:
  - Workup may be deferred until severe distress is addressed.
- Further investigations are designed to assess the severity of illness and to determine the underlying etiology and direct further treatment.
- Pulse oximetry and end-tidal CO<sub>2</sub> testing provide a noninvasive measure of oxygenation and ventilation.

### Lab

- Arterial blood gas analysis may be obtained in any patient with cyanosis or severe distress to further assess oxygenation, ventilation, and acid-base status:
  - Venous blood gas may be used if inadequate oxygenation is not a concern.
- Selective further testing may be obtained as indicated, such as:
  - Electrolytes will identify acidosis or other metabolic derangements.
  - Toxicologic screen in suspected ingestions
  - CBC, disseminated intravascular coagulation panel, and appropriate cultures if concern for infection or sepsis

### Imaging

- Chest radiographs can be helpful in identifying pneumonia or airspace disease, hyperinflation (asthma, bronchiolitis, or FBA), effusion, mass, pneumothorax, chest wall deformities, evidence of trauma, cardiomegaly, or pulmonary edema:
  - PA and lateral films are most helpful.
  - Portable AP films for patients in severe distress
  - Lateral decubitus films help to identify layering effusions.
  - Expiratory or decubitus films help to highlight focal air trapping from FBA.
- Soft tissue neck radiographs:
  - May be indicated in some cases of upper airway obstruction: FBA, RPA, tracheitis, epiglottitis in the stable patient

- Barium swallow with an upper GI series can help to identify an esophageal foreign body, vascular rings and slings, or aspiration.
- Neck CT scan should be obtained:
  - To further evaluate potential RPA or congenital anomalies
- Chest CT if concerned for a necrotizing pneumonia, chest mass, congenital malformation, pulmonary hemorrhage, or pulmonary embolism
- Consider echo for concern of CHD, CHF, or pericardial effusion.

#### Diagnostic Procedures/Other

- Peak expiratory flow can be measured in patients old enough to perform this correctly. Results can be compared to normals based on age, weight, or height or to a patient's prior performance.
- Direct laryngoscopy, nasopharyngoscopy, or bronchoscopy may be required for evaluation of vocal cord movement, FBA, tracheitis, or epiglottitis/supraglottitis.
- ECG for cardiac disease

#### DIFFERENTIAL DIAGNOSIS

- Pain may result in tachypnea, which can be interpreted as respiratory distress.
- Anxiety or panic attacks may result in deep or rapid breathing resembling respiratory distress.
- See the Etiology section for the differential diagnosis of primary etiologies of respiratory distress.

## TREATMENT

#### PRE HOSPITAL

- Evaluate and maintain the airway.
- Administer supplemental oxygen.
- Assist respiration as needed.

#### INITIAL STABILIZATION/THERAPY

- Restoring adequate oxygenation and ventilation is the priority.
- Airway: Position the head and open the airway as needed with head-tilt chin-lift or jaw-thrust:
  - Suction as needed.
  - Consider nasal or oral airways.
- Breathing—administer supplemental oxygen:
  - For patients in significant distress or ineffective respiratory effort, assist ventilation with bag-mask ventilation, CPAP, or BiPAP.
- Endotracheal intubation may be required for patients who cannot protect or maintain their airway, cannot be successfully oxygenated or ventilated through noninvasive means, or when the clinical course is predicted to worsen.
- Specific interventions may be required for life-threatening conditions:
  - Heimlich maneuver for complete airway obstruction
  - Needle decompression of tension pneumothorax

#### MEDICATION

- Choice of medications will depend on the etiology of respiratory distress:
  - Status asthmaticus requires bronchodilator therapy such as albuterol or terbutaline as well as corticosteroids.
  - Croup may be treated acutely with nebulized racemic epinephrine and dexamethasone.
  - Anaphylaxis requires immediate epinephrine IM.
  - Pneumonia requires antibiotic therapy tailored to likely organisms based on age and/or radiographic findings.
  - Seizures require antiepileptic medications.
- See specific topics for recommended treatment of other diagnoses.

#### SURGERY/OTHER PROCEDURES

- Dependent on the etiology of respiratory distress:
  - Intubation or cricothyrotomy may be necessary for impending respiratory failure.
  - Thoracentesis or thoracostomy for pleural effusion or pneumothorax
  - Laryngoscopy and bronchoscopy for removal of airway foreign bodies
- See specific topics for recommended treatment for other diagnoses

#### DISPOSITION

##### Admission Criteria

- Any patient who requires supplemental oxygen to maintain desired oxygen saturation
- Patients requiring frequent bronchodilator or other respiratory treatments
- Any patient who is unable to tolerate oral intake of fluids or necessary medications
- Any child in moderate or severe distress or who is felt to be at risk for respiratory fatigue
- Critical care admission criteria:
  - Any patient requiring ventilatory support
  - Any child with impending respiratory failure
  - Obtundation or altered mental status (may be the cause of respiratory distress or may result from inadequate oxygenation or ventilation)
  - Patients requiring aggressive respiratory therapy (eg, continuous nebulizer treatments, terbutaline) are best served in a critical care unit.

##### Issues for Referral

Consultation from the emergency department should be done as necessary. Outpatient follow-up may be scheduled after consultation:

- Pulmonology for chronic lung conditions
- Cardiology for CHD, CHF, or pericardial disease
- Toxicology for ingestions or drug overdoses
- Otorhinolaryngology for airway obstruction or upper airway anomalies
- Surgery for thoracic masses, empyema, flail chest

## FOLLOW-UP

#### FOLLOW-UP RECOMMENDATIONS

See the Issues for Referral section.

#### PROGNOSIS

- Rapid treatment of respiratory distress can prevent progression to respiratory failure.
- Children in respiratory distress who are treated appropriately generally recover uneventfully.
- Respiratory decompensation following progressive respiratory distress resulting in prolonged hypoxemia or hypercarbia can have poor outcomes, with end organ damage or death.

#### COMPLICATIONS

Patients who experience a prolonged episode of hypoxemia may have end organ damage including the kidney, liver, or brain.

## CODES

#### ICD9

- 518.82 Other pulmonary insufficiency, not elsewhere classified
- 770.89 Other respiratory problems after birth
- 786.09 Other dyspnea and respiratory abnormalities

#### PEARLS AND PITFALLS

Pearls:

- Rapid evaluation and early treatment of respiratory distress, as well as anticipation and prevention of impending respiratory failure, are important for optimizing outcomes.
- Young children are at increased risk of respiratory distress because of anatomic and physiologic differences.

# REYE SYNDROME

Stephanie G. Cohen  
Amanda Pratt

## BASICS

### DESCRIPTION

- Reye syndrome (RS) is an acute illness characterized by alterations in the level of consciousness with noninflammatory encephalopathy and fatty degeneration of the liver.
- Symptoms typically develop after a viral infection in children, with many having received aspirin during the viral illness.
- The CDC definition characterizes RS as illness in a child <18 yr of age (1) with:
  - Acute noninflammatory encephalopathy (absence of CSF pleocytosis)
  - Characteristic liver histology or raised serum transaminases or ammonia (>3 times normal)
  - No other explanation for the illness

### EPIDEMIOLOGY

- Increasing incidence until 1980, when an association between aspirin use during the preceding viral illness and development of subsequent RS was discovered.
- Peak incidence was 555 cases in 1980.
- From 1994–1997, there were never >2 cases annually in the U.S.:
  - The CDC cautioned physicians and parents against the use of salicylates in children.
  - The incidence of RS declined with these warnings and currently is a rare disorder.
  - Although a strong association between aspirin use and the development of RS exists, full agreement regarding the pathogenesis of this disorder has not been determined.
  - Seen commonly during seasonal outbreaks of viral illnesses
  - Most common in those 4–12 yr of age (peak 6 yr of age)
  - Rural and suburban populations are more affected.
  - Mortality rate of 40%
- Many viral infections are found to be associated with RS:
  - Most commonly reported are influenza B and varicella
  - Other viruses include parainfluenza, adenovirus, coxsackievirus, cytomegalovirus, and herpes simplex virus.

### RISK FACTORS

Children with chronic medical conditions requiring regular use of salicylate-containing medications:

- Kawasaki disease
- Congenital heart disease
- Discontinuation of aspirin during intercurrent viral illnesses, even influenza, in patients on chronic aspirin therapy is not indicated.

### GENERAL PREVENTION

- Avoid the use of aspirin in pediatric patients with underlying viral illness.
- Administration of influenza and varicella vaccines may help prevent viral infections associated with RS.

### PATHOPHYSIOLOGY

- Major site of injury is the mitochondria.
- Hepatic mitochondrial enzymes (ornithine transcarbamylase, carbamoyl phosphate synthetase, pyruvate dehydrogenase) are reduced.
- Hyperammonemia may result from decreased activity of the enzymes.

### ETIOLOGY

The specific trigger of mitochondrial dysfunction is unknown but is thought to result from use of aspirin and/or antiemetics during the course of a viral infection.

## DIAGNOSIS

### HISTORY

- Biphasic course:
  - Prodromal febrile illness with resolution of symptoms
  - Within 5–7 days, there is development of abrupt onset of protracted vomiting and neurologic impairment.
  - Marked behavioral changes including delirium, combativeness, disorientation, and hallucination may occur.
- These typically develop in a child who was otherwise healthy prior to the viral illness.

### PHYSICAL EXAM

- GI:
  - Profuse vomiting
  - Hepatomegaly often is present with absence of jaundice/icterus.
- Neurologic:
  - Varying degrees of neurologic impairment with fluctuating personality changes
  - Deterioration in level of consciousness
  - As encephalopathy progresses, patients develop extreme irritability, combative behavior, agitation, confusion, delirium, coma.
  - Seizures

- Clinical staging of level of consciousness (1):
  - Stage I: Quiet, difficult to arouse, lethargic and sleepy, vomiting, lab evidence of liver dysfunction
  - Stage II: Deep lethargy, confusion, delirium, combative behavior, with purposeful or semipurposeful motor responses, hyperventilation, hyperreflexic
  - Stage III: Obtunded, light coma +/- seizures, decorticate rigidity, intact pupillary light reaction
  - Stage IV: Seizures, deepening coma, decerebrate rigidity, loss of oculocephalic reflexes, fixed pupils
  - Stage V: Coma, loss of deep tendon reflexes, respiratory arrest, fixed dilated pupils, flaccid/decerebrate; isoelectric electroencephalogram

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

- Elevation of serum aminotransferases (AST/ALT), ammonia, and lactate dehydrogenase (LDH)
- Prolonged PT/PTT
- Serum muscle enzymes (creatinine phosphokinase/LDH) may be elevated.
- The serum glucose level may be decreased.
- CSF with absence of pleocytosis and increased opening pressure

#### Imaging

Head CT may show signs of cerebral edema.

#### Pathological Findings

- Gross liver specimen is characteristic of yellow to white color from fatty accumulation of triglycerides:
  - Light microscopy shows a microvesicular fatty accumulation in hepatocytes without inflammatory lesions.
  - Electron microscopy is significant for alteration in mitochondrial morphology.
  - Biopsy should be obtained to evaluate for underlying metabolic or toxic liver disease, especially in children <3 yr of age.
- Brain tissue has a similar pattern of injury with marked edema.

**DIFFERENTIAL DIAGNOSIS**

- Inherited metabolic disorders:
  - Children presenting with symptoms of RS, especially those <3 yr of age, should be evaluated for inherited metabolic disorders (3)
  - Disorders of fatty acid oxidation
  - Organic acidurias
  - Disorders of oxidative phosphorylation
  - Urea cycle defects
  - Disorders of pyruvate metabolism
  - Disorders of carbohydrate metabolism
- Infections:
  - Meningitis
  - Encephalitis
- Toxin ingestion
- Toxic encephalopathy

**TREATMENT****INITIAL STABILIZATION/THERAPY**

- Addressing issues of airway, breathing, and circulation are paramount.
- Monitor and control for increased intracranial pressure.

**MEDICATION****First Line**

- No specific medications are recommended, as treatment is supportive.
- Infusions with dextrose (10–15%) may be necessary to control hypoglycemia that results from depletion of glycogen stores.
- Vitamin K, fresh frozen plasma, and platelet transfusions are indicated for patients with coagulopathy.

**Second Line**

- Hypertonic solutions, mannitol, and pentobarbital can be used to control increased intracranial pressure.
- Lactulose and neomycin can be administered to treat hyperammonemia.

**DISPOSITION****Admission Criteria**

Critical care admission criteria:

- All patients suspected of having RS should be initially admitted to an ICU.

**Discharge Criteria**

Patients may be discharged from the hospital when mental status returns to baseline and there is normalization of hepatic function.

**Issues for Referral**

Patients with recovery from severe disease may need neurodevelopmental evaluation.

**FOLLOW-UP****FOLLOW-UP RECOMMENDATIONS****Patient Monitoring**

The patient should be observed in the ICU with close monitoring of intracranial pressure and cerebral perfusion pressure.

**PROGNOSIS**

- The severity and duration of encephalopathy and elevation of intracranial pressure is the best predictor of eventual outcome:
  - Patients who progress to coma have high mortality rates with death due to cerebellar herniation.
  - Early diagnosis and treatment before the onset of coma can reduce fatalities.
- Patients with mild disease may have a rapid and complete recovery.
- Liver transplantation is not necessary, as the hepatic disease is reversible.

**COMPLICATIONS**

- Death
- Cardiovascular collapse
- Elevated intracranial pressure
- Hemorrhage
- Patients with severe disease may have subsequent neuropsychological deficits with intelligence, school achievement, visuomotor integration, and concept formation.

- Encephalitis
- Meningitis

**CODES****ICD9**

331.81 Reye's syndrome

**PEARLS AND PITFALLS**

- RS is the development of noninflammatory encephalopathy and hepatic dysfunction after preceding viral illness.
- The discontinuation of aspirin used to treat fever associated with viral illness has virtually eliminated the incidence of RS.
- Admission to a monitored setting is necessary.
- Children presenting with symptoms of RS, especially those <3 yr of age, should be evaluated for inherited metabolic disorders.

# RHABDOMYOLYSIS

Marcelo Sandoval

## BASICS

### DESCRIPTION

Rhabdomyolysis is an abnormal systemic release of muscle contents (creatine phosphokinase [CPK], myoglobin, potassium, phosphate, urate) caused by trauma, poisoning, infection, primary muscle disorders, and many other disease states.

### EPIDEMIOLOGY

#### Incidence

26,000 cases per year in U.S.

### RISK FACTORS

- Inherited myopathy
- Alcohol or drug use
- Medications as listed below
- Overexertion with or without risk factors
- Disaster situations

### GENERAL PREVENTION

- Appropriate construction of buildings in earthquake zones
- Furniture affixed to walls

### PATHOPHYSIOLOGY

- Sarcolemma keeps intracellular calcium low.
- Etiologies disrupt the cell membrane and lead to the following cascade:
  - Breakdown of sarcolemma sodium-calcium pumps allows calcium to enter the cell.
  - Calcium-dependent proteases cause destruction.
  - Ischemia and neutrophils cause damage.
  - Escape of cell contents: Myoglobin, potassium, phosphate, CPK, lactate, etc.
  - Myoglobin causes renal damage by direct toxicity in acidic urine.
  - Myoglobin precipitates with other proteins to obstruct renal tubular flow.
  - Volume depletion also leads to renal vasoconstriction and failure.
  - Hyperkalemia can lead to arrhythmias.
  - Calcium precipitates with phosphate, leading to systemic hypocalcemia.

### ETIOLOGY

- Adults: Trauma, toxicity, infection
- Children: Viral myositis, trauma
- Muscle injury is the most common cause overall:
  - Trauma, crush
  - Burn
  - Electrical injury
  - Muscle exertion: Strenuous exercise, marathon running, exercise in hot and humid conditions, exercise in individuals with an inherited myopathy or with poor physical training, status epilepticus, delirium tremens, tetanus, psychotic agitation
  - Muscle ischemia: Extensive thrombosis, multiple embolism, generalized shock, sickle cell crisis
  - Surgery: Immobilization, hypotension, ischemia due to vessel clamping
- Massive blood transfusion
- Hypothermia, hyperthermia
- Prolonged immobile state without trauma

- Drugs/Toxins: Alcohols, cocaine, amphetamines and analogs (methamphetamine and ecstasy), toluene, opiates, LSD, PCP, doxylamine, caffeine, carbon monoxide, snake venom, bee/hornet venom, hemlock, buffalo fish, tetanus toxin, mushroom poisoning
- Medications:
  - Most common: Haloperidol, phenothiazines, HMG-CoA reductase inhibitors (statins) and other cholesterol-lowering agents, antihistamines, selective serotonin reuptake inhibitors
  - Others include propofol, succinylcholine, halogenated anesthetic gases, isoniazid, zidovudine, antimalarials, methylxanthines, colchicine, corticosteroids, itraconazole, erythromycin, diuretics, cyclosporine, and barbiturates.
- Sports supplements including ephedra, caffeine, androgenic steroids, creatine, diuretics
- Neuroleptic malignant syndrome (idiosyncratic and not dose related)
- Metabolic disorders: Hypokalemia, hypophosphatemia, hypocalcemia, hyper-/hyponatremia, diabetic ketoacidosis, hyperosmolar state, hypoxia, hyperthyroid state (rare), pheochromocytoma (rare)
- Infections:
  - Viral: Coxsackievirus, herpesviruses, HIV, influenza B, cytomegalovirus, Epstein-Barr virus, adeno-/echovirus
  - Bacterial: Legionnaires disease, pyomyositis, salmonellosis, shigellosis, staphylococcus, streptococcus, listeria, tetanus, toxic shock syndrome, tularemia, gas gangrene, *Bacillus cereus*
  - Parasitic (malaria falciparum), protozoan (leptospirosis), rickettsial
  - Inherited myopathic disorders: McArdle disease, Tarui disease, CPT deficiency. These inherited myopathies can exacerbate any other cause.
  - In children <9 yr of age, most nontraumatic cases are due to viral illness with myositis.
- Immunologic disorders: Dermatomyositis, polymyositis
- Idiopathic

### COMMONLY ASSOCIATED CONDITIONS

- Crush syndrome
- Compartment syndrome
- Alcohol and drug abuse
- Immobility

## DIAGNOSIS

History and physical are insensitive in making the diagnosis.

### HISTORY

- Can vary dramatically, reflecting the underlying disease process
- Trauma or crush is usually obvious:
  - Consider child abuse in trauma with unclear details.
- If no trauma, consider drug toxicity, heat illness, and immobilization or overexertion states.
- Ask about reddish-brown urine and decreased urine output.

### PHYSICAL EXAM

- Hypo-/Hyperthermia
- Alert vs. obtunded
- Myalgia (only 40–50%)
- Neurovascular status of involved muscle groups if suspected compartment syndrome
- Hypovolemic state, dry mucous membranes, poor skin turgor, tachycardia, hypotension
- Decreased urine output
- Urine color (tea colored) is early sign.
- Children more often have absent physical findings.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

- Serum and urine myoglobin levels often are normal due to rapid metabolism and excretion.
- Serum CPK level is diagnostic; a level >1,000 units/L is considered positive:
  - CPK level is not always predictive of renal failure but most often is associated with a level >15,000 units/L.
- A urine dipstick test positive for heme but absent for RBCs suggests rhabdomyolysis.
- Microscopic urinalysis to look for pigmented tubular casts
- Because of rapid urinary excretion of myoglobin, up to 26% of patients with rhabdomyolysis have negative urine dipstick test.
- In children, heme <2+ on urine dip correlates with reduced risk of acute renal failure.
- Serum electrolytes: Potassium, calcium, magnesium, phosphorus, BUN, creatinine, uric acid, bicarbonate
- In addition to the preceding tests, consider:
  - ABG/VBG (baseline pH if considering bicarbonate therapy)
  - Urine/Serum myoglobin, but may be too transient to be useful
  - Serum glucose
  - LFTs including GGTP, lactate dehydrogenase, albumin
  - Toxicology screen in absence of physical injury
  - PT/PTT, platelet count, fibrinogen, fibrin-split products if disseminated intravascular coagulation (DIC) is suspected

#### Imaging

- Not normally useful in the emergency department. Consider the following tests:
  - Renal US to rule out long-standing renal failure (small shrunken kidneys) or renal obstruction (hydronephrosis)
  - MRI is 90–95% sensitive in visualizing muscle injury but does not change initial emergency department treatment.
- Other imaging as indicated

#### Diagnostic Procedures/Other

- Early ECG: Hyperkalemia or hypocalcemia before serum levels are available
- Measure compartment pressure if compartment syndrome is suspected.

**DIFFERENTIAL DIAGNOSIS**

- Conditions that may present with elevated serum CPK but are not rhabdomyolysis:
  - Nontraumatic myopathies including muscular dystrophies and inherited myopathies
  - Viral illness
  - Toxin exposure
  - Chronic renal failure
  - IM injections
  - Myocardial injury
  - Stroke
- Conditions with pigmented urine:
  - Hematuria
  - Food or toxin exposure with pigmented urine containing no blood or heme

**TREATMENT****PRE HOSPITAL**

- Rapid extrication in case of crush injury
- Early IV saline before extrication to prevent complications of restored blood flow to the injured limb (hypovolemia, hyperkalemia, etc.)
- Pediatric recommendation: 10–15 mL/kg/hr saline initially, then switch to hypotonic (0.45%) saline on arrival to the hospital. Add 50 mEq HCO<sub>3</sub> to each 2nd or 3rd liter to alkalinize the urine.

**INITIAL STABILIZATION/THERAPY**

- ABCs
- Immobilization of trauma/crush injuries
- Adult crush injury treatment literature extrapolated to children
- IV saline for hypovolemia at a rate of 1–1.5 L/hr (10–20 mL/kg/hr). Volume restored within 6 hr helps to prevent renal failure.
- May need 12 L/day, 4–6 of which should include HCO<sub>3</sub>. Use central venous pressure or urine output to assess adequacy of hydration.
- Diuretics only after patient's volume has been restored to keep urine output 200–300 mL/hr (3–5 mL/kg/hr).
- Mannitol: Diuretic, free radical scavenger; may help compartment syndrome
- Furosemide and other loop diuretics if indicated in management of oliguric (<500 mL/day) renal failure. Some believe it can be harmful.
- Bicarbonate: Alkalinize urine (pH >6.5); recommend its use as long as urine pH and calcium are monitored; potentially beneficial with CPK level >30,000 units/L
- Monitor for hyperkalemia frequently with serum levels and ECG:
  - Higher potassium correlates with more severe injury.
  - Treat hyperkalemia as usual, but do not use calcium unless it is severe.
- Hypocalcemia: Only treat if symptomatic (tetany or seizures) or if arrhythmias are present:
  - Calcium infusion can lead to hypercalcemia later as precipitated calcium mobilizes.
- HCO<sub>3</sub> can trigger symptoms by increasing free calcium binding to albumin.

**MEDICATION****First Line**

- HCO<sub>3</sub> as above to keep urine pH >6.5. Discontinue if urine pH fails to rise after 6 hr or if symptomatic hypocalcemia develops.
- Albuterol, insulin/dextrose, polystyrene resin (Kayexalate) for hyperkalemia treatment. Avoid calcium if possible.

**Second Line**

- Mannitol 20%: 50 mL (10 g) added to each liter up to 120–200 g/day (1–2 g/kg/day)
- Discontinue if failure to achieve diuresis and osmolal gap >55.

**SURGERY/OTHER PROCEDURES**

- Hemodialysis for refractory hyperkalemia, fluid overload, anuria, acidosis
- Central venous monitoring of volume
- Fasciotomy for compartment syndrome

**DISPOSITION****Admission Criteria**

- All but the most trivial elevations in CPK (<1,000 units/L) should be admitted, since complications can occur at any CPK level and are difficult to predict.
- Children seem to be less susceptible to renal complications.
- Critical care admission criteria:
  - Severe or symptomatic hyperkalemia or CPK levels >15,000–30,000 units/L
  - Underlying severe illness or trauma warranting ICU care

**Discharge Criteria**

Patients with levels <1,000 units/L may be discharged.

**PROGNOSIS**

- The prognosis depends on underlying cause; death from inciting trauma is the most common cause of fatality.
- For rhabdomyolysis without severe trauma, if there is no renal failure, there is very low mortality:
  - Renal failure: 3.4–30%
  - ICU deaths: 59% if renal failure, 22% without

**COMPLICATIONS**

- Myoglobin-induced renal failure in 5% of children
- Hyperkalemia leading to sudden death
- Hypocalcemia and acidosis
- Volume loss: Fluid sequestration in injured muscle or result of underlying illness
- Compartment syndrome of muscles in crush injury, worsened by IV fluid sequestration in damaged tissue
- Hepatic dysfunction in 25%
- DIC

**See Also (Topic, Algorithm, Electronic Media Element)**

- Compartment Syndrome
- Hyperkalemia

**ICD9**  
728.88 Rhabdomyolysis

**PEARLS AND PITFALLS**

- Pearls:
  - Suspect in unexplained renal failure.
  - Suspect if urine is heme positive without RBCs.
  - Suspect in drug, alcohol intoxication, heat illness, infections, and immobilization if the patient complains of muscle pain or weakness even without trauma.
  - Look for and treat hyperkalemia and volume depletion, but avoid calcium infusions.
- Pitfalls:
  - Delayed diagnosis
  - Failure to aggressively restore volume or treat potassium elevations
  - Alkalinization causing symptomatic hypocalcemia

# RHEUMATIC FEVER

Amanda Pratt

## BASICS

### DESCRIPTION

- Rheumatic fever (RF) is a delayed sequela of a group A streptococcal (GAS) throat infection.
- Acute, multisystem inflammatory disease:
  - May affect the heart, joints, skin, and/or CNS
- Diagnosis of the initial attack is based on the Jones criteria (updated 1992).
- Recurrence can occur and does not have to strictly adhere to the Jones criteria for diagnosis.
- Rheumatic heart disease (RHD) is an important sequela of RF.

### EPIDEMIOLOGY

#### Incidence

- Incidence in developed countries has significantly declined to  $\leq 10/100,000$  per year (1):
  - Improved diagnosis of GAS pharyngitis and use of antibiotics
  - Improved socioeconomic conditions and housing
  - Decline in rheumatogenic strains of GAS
- In developing countries, acute RF and RHD are estimated to affect nearly 20 million people:
  - RHD is the leading cause of cardiovascular death in the 1st 5 decades of life (2).
- Incidence peaks in children at 5–15 yr of age.

### RISK FACTORS

Increased exposure to GAS infections:

- Children
- Personnel in contact with children
- Military recruits
- Those living in crowded situations (eg, college dormitories)

### GENERAL PREVENTION

- Primary prevention involves prompt diagnosis of GAS pharyngitis and treatment with antibiotics.
- Secondary prevention involves long-term antimicrobial prophylaxis for patients with history of RF.

### PATHOPHYSIOLOGY

- The pathogenesis is incompletely understood.
- Likely an immune response:
  - Antibodies against the M proteins of certain strains of streptococci cross react with glycoprotein antigens in the heart, joints, and other tissue.
- Focal inflammatory lesions are found in various tissues:
  - Within the heart, these lesions are called *Aschoff bodies*
- It is possible that genetic susceptibility plays a role in contracting RF.

### ETIOLOGY

Sequela of GAS infection of the pharynx:

- Not associated with streptococcal infections at other sites, such as the skin

## DIAGNOSIS

### HISTORY

- Preceding history of GAS pharyngitis:
  - Typically occurs 2–3 wk after the pharyngitis
- Lack of evidence of a prior GAS pharyngitis makes the diagnosis of RF doubtful except in 2 specific situations:
  - Patients with indolent carditis may have low, or normal, antibody titers because the initial attack of RF may have been months or years prior to presentation.
  - Similarly, Sydenham chorea may be the only manifestation, as it is frequently a delayed finding.
- Patients with prior history of RF or RHD are at high risk for recurrent attacks of RF.

### PHYSICAL EXAM

- Diagnosis is based on the Jones criteria (updated 1992):
  - Diagnosis fulfills 2 major criteria or 1 major and 2 minor criteria.
- Major criteria:
  - Carditis:
    - Almost always associated with murmur of valvulitis
    - Rheumatic carditis should be suspected in a patient with no history of RHD with new apical systolic murmur of mitral regurgitation and/or basal diastolic murmur of aortic regurgitation.
    - Myocarditis and pericarditis in the absence of valvular involvement is unlikely to be rheumatic in origin.
  - Polyarthritis:
    - Most frequent major manifestation
    - Almost always migratory unless prematurely aborted with anti-inflammatory agents
    - Usually involves large joints, particularly the knees, ankles, elbows, and wrists
    - Rapid response to salicylates
  - Chorea:
    - Purposeless, involuntary, rapid movements of trunk and/or extremities
    - Often associated with muscle weakness and emotional lability
    - Occasionally unilateral
    - The latent period from acute GAS infection to chorea is usually prolonged and therefore may be the only manifestation.
  - Erythema marginatum:
    - Rare, but distinctive, manifestation
    - Erythematous, serpiginous margins with pale centers
    - Primarily on the trunk and extremities, not on the face
    - Transient, migratory, and can be induced by heat
    - Lesions are not pruritic.
  - Subcutaneous nodules:
    - Rare finding, most often present in patients with carditis
    - Firm, painless nodules
    - Found along extensor surfaces of tendons near bony prominences

- Minor criteria:
  - Arthralgia:
    - Not considered a minor manifestation when arthritis is present
  - Fever:
    - Generally present early

## DIAGNOSTIC TESTS & INTERPRETATION

### Lab

#### Initial Lab Tests

- Minor criteria also include lab findings:
  - Elevated acute-phase reactants:
    - ESR and C-reactive protein
- Evidence of preceding GAS infection is required to fulfill the Jones criteria:
  - Positive throat culture or rapid streptococcal antigen testing:
    - Negative rapid strep test should be confirmed by throat culture.
    - Only ~25% of patients have positive throat cultures at the time of diagnosis of acute RF.
    - A positive test may reflect chronic colonization.
  - Elevated or rising streptococcal antibody titers:
    - Antistreptolysin O (ASLO) is the titer most widely used.
    - If the ASLO is not elevated, then anti-deoxyribonuclease B (preferred) is usually done or antistreptokinase.
    - Using 3 different antibody tests, an elevated titer for at least 1 was found in ~95% of patients, except those with chorea alone, in which the number was ~80%.

### Imaging

CXR to assess heart size

### Diagnostic Procedures/Other

- Prolonged PR interval on ECG:
  - Not adequate criterion for carditis in children
  - Does not correlate with ultimate development of chronic RHD in children
- Doppler echo for the diagnosis of RF is controversial (3):
  - It is not necessary to perform this in the emergency department.
  - Highly sensitive and may detect physiologic rather than pathologic regurgitation
  - Currently should be used as adjunct to confirm clinical findings:
    - Should not be used as major or minor criterion to establish carditis in acute RF without accompanying auscultatory findings

### DIFFERENTIAL DIAGNOSIS

- Poststreptococcal reactive arthritis:
  - Shorter latent period between preceding GAS pharyngitis and the arthritis, about 10 days
  - Does not respond readily to acetylsalicylic acid
  - A small proportion subsequently develop valvular heart disease; therefore, observe closely for several months.

- Rheumatoid arthritis
- Systemic lupus erythematosus
- Lyme disease
- Malignancy
- Infective endocarditis
- Serum sickness
- Kawasaki disease
- Huntington chorea
- Tics

## TREATMENT

### MEDICATION

#### First Line

- Antibiotics to eradicate GAS regardless of the presence of pharyngitis:
  - Oral penicillin:
    - Adults/Adolescents: 500 mg b.i.d. or t.i.d. × 10 days
    - Children ( $\leq 27$  kg or 60 lbs): 250 mg b.i.d. or t.i.d. × 10 days
  - IM benzathine penicillin G:
    - Adults/Adolescents: 1,200,000 U × 1 dose
    - Children ( $\leq 27$  kg or 60 lbs): 600,000 U × 1 dose
  - Oral amoxicillin 50 mg/kg once a day × 10 days, max single dose 1 g
- Aspirin for typical migratory polyarthritis and mild carditis:
  - The usual dose starts at 80–100 mg/kg/day in children and 4–8 g/day in adults.
- Steroids, usually prednisone, typically recommended for more severe carditis associated with cardiomegaly or CHF:
  - The usual initial dose is 1–2 mg/kg/day, max single dose 80 mg/day
- Digoxin and diuretics for CHF

#### Second Line

- Antibiotics for penicillin-allergic patients:
  - Narrow-spectrum oral cephalosporins:
    - Cephalexin 500 mg/kg PO divided q.i.d.–b.i.d., adult dosing 500 mg PO t.i.d.
    - Cefadroxil 30 mg/kg/day PO divided b.i.d., adult dose 2 g PO divided b.i.d.
  - Oral clindamycin 20 mg/kg/day divided in 3 doses (max dose 1.8 g/day) × 10 days
  - Oral azithromycin 12 mg/kg once a day × 5 days, max 500 mg
  - Oral clarithromycin 15 mg/kg/day divided b.i.d. × 10 days, max single dose 250 mg b.i.d.:
    - Can cause prolonged QT interval
  - Erythromycin can be used, but there are much higher rates of GI side effects than with other agents.
  - GAS resistance may be high in some areas of the world; resistance rates to macrolides in most of the U.S. have been 5–8%.

### SURGERY/OTHER PROCEDURES

Cardiac surgery for patients with severe RHD:

- Valve repair is preferable to valve replacement when possible.

### DISPOSITION

#### Admission Criteria

- Admit patients with severe carditis, cardiomegaly, or CHF to an ICU.
- Patients placed on bed rest and monitoring for evidence of carditis
- Not all patients require hospital admission.

#### Issues for Referral

- Patients with carditis should be referred to cardiology.
- Primary care follow-up to ensure compliance with medication for prevention of recurrent episodes

## FOLLOW-UP

### FOLLOW-UP RECOMMENDATIONS

- Long-term antimicrobial prophylaxis is required to prevent recurrent RF:
  - Prophylaxis should start as soon as the treatment course for GAS is complete.
  - IM benzathine penicillin G q4wk (or q3wk in high-risk situations):
    - Adults/Adolescents: 1,200,000 U
    - Children ( $\leq 27$  kg or 60 lbs): 600,000 U
  - Penicillin V 250 mg PO b.i.d.
  - Sulfadiazine PO once daily:
    - Adults/Adolescents: 1 g
    - Children ( $\leq 27$  kg or 60 lbs): 0.5 g
  - Macrolide or azalide for patients allergic to penicillin and sulfadiazine: Dosing variable
- Duration of prophylaxis depends on cardiac involvement:
  - RF without carditis: 5 yr or until 21 yr of age (whichever is longer)
  - RF with carditis but no residual heart disease and no clinical or echocardiographic evidence of valve disease: 10 yr or until 21 yr of age (whichever is longer)
  - RF with carditis and residual heart disease and persistent clinical or echocardiographic evidence of valve disease: 10 yr or until 40 yr of age (whichever is longer), sometimes lifelong prophylaxis
  - Patients without clinical carditis may resume normal activity once pain and fever are resolved, typically 5–7 days.
  - Mild carditis requires 10–15 days of bed rest to ensure that there is no progressive deterioration.
  - Severe carditis requires several weeks of rest.

### PROGNOSIS

- The prognosis for a primary attack is excellent; only ~1% of patients die from fulminant RF.
- Recurrence risk is high if prophylaxis is not initiated and adhered to:
  - The risk of recurrence decreases with time.
- Patients with carditis in a primary attack have an increased risk of carditis with recurrent attacks.

### COMPLICATIONS

- RHD is a primary complication:
  - Leading cause of cardiovascular death in the 1st 5 decades of life in the developing world
- Severity of RHD increases with recurrent attacks of RF:
  - Secondary prevention noted above is critical.

### REFERENCES

1. Tibazarwa KB, Volmink JA, Mayosi BM. Incidence of acute rheumatic fever in the world: A systematic review of population-based studies. *Heart*. 2008; 94:1534–1540.
2. Gerber MA, Baltimore RS, Eaton CB, et al. Prevention of rheumatic fever and diagnosis and treatment of acute streptococcal pharyngitis: A scientific statement from the American Heart Association Rheumatic Fever, Endocarditis, and Kawasaki Disease Committee of the Council on Cardiovascular Disease in the Young, the Interdisciplinary Council on Functional Genomics and Translational Biology, and the Interdisciplinary Council on Quality of Care and Outcomes Research: Endorsed by the American Academy of Pediatrics. *Circulation*. 2009;119:1541–1551.
3. Ferrieri P. Proceedings of the Jones criteria workshop. *Circulation*. 2002;106:2521–2523.

### ICD9

- 390 Rheumatic fever without mention of heart involvement
- 391.0 Acute rheumatic pericarditis
- 391.1 Acute rheumatic endocarditis

### PEARLS AND PITFALLS

- A diagnosis of acute RF is in doubt if patients treated with salicylates do not improve substantially in 48 hr.
- A common avoidable error is premature administration of salicylates or corticosteroids before signs and symptoms of RF become distinct.
- Throat swab specimens should be obtained for all household contacts of a patient with acute RF and treated if positive.
- The Jones criteria are not intended to apply to recurrent attacks of acute RF.

# RICKETTSIAL DISEASE

Natasha A. Tejwani

Michael G. Rosenberg

## BASICS

### DESCRIPTION

- Rickettsial diseases are infections caused by obligate intracellular gram-negative coccobacilli that mainly belong to the genus *Rickettsia*.
- Rickettsial infections have overlapping clinical presentations and similar treatments but are subdivided based on unique epidemiologic characteristics and clinical manifestations:
  - Spotted fever group (SFG):
    - Many *Rickettsia* in this group with similar clinical and pathologic features including the prototypical Rickettsiosis known as Rocky Mountain spotted fever (RMSF).
    - This topic will focus on RMSF, the most common rickettsial infection in the U.S.
  - Typhus group (TG)
  - Scrub typhus
  - Ehrlichiosis and anaplasmosis group
  - Q fever: Though recently reclassified from the Rickettsiaceae family to the Coxiellaceae family, it will still be discussed in this topic.

### EPIDEMIOLOGY

- SFG:
  - RMSF (*Rickettsia rickettsii*): Occurs chiefly in summer in the U.S., especially the South Atlantic, Pacific, and West South Central regions. Other areas of Western Hemisphere with RMSF are Central and South America, Mexico, and southwestern Canada. RMSP usually occurs in children > 15 yr of age.
  - Mediterranean spotted fever (MSF) (*Rickettsia conorii*) has a wide geographic distribution including the Mediterranean, India, Africa, southern Europe, and the Middle East. It occurs mainly during warm summer months and in all ages.
  - Rickettsial pox (*Rickettsia akari*): Urban areas in Europe, Asia, and the U.S.
- TG:
  - Murine typhus (*Rickettsia typhi*): Worldwide distribution in warm coastal areas with rats (reservoir) and fleas (vector)
  - Epidemic typhus (*Rickettsia prowazekii*): Rare and occurs worldwide in areas of crowding or of poor hygiene: War, famine, poverty
- Scrub typhus (*Orientia tsutsugamushi*):
  - During the rainy season in rural Asia, Pacific Islands, Northern Australia
- Ehrlichiosis (human monocytic ehrlichiosis [HME] and anaplasmosis (human granulocytic anaplasmosis [HGA]):
  - Most cases of HME are in a similar distribution as RMSF: South Central/Eastern and Mid-Atlantic U.S.
  - HGA is found mostly in the upper Midwest and northeastern U.S. and also across Europe.
  - Both HME and HGA usually occur in adults >42 yr old but may occur in children.
  - HME and HGA also occur mainly in the spring and summer seasons. Anaplasmosis can occur in the fall through early winter secondary to *Ixodes scapularis* activity.

- Q fever group:
  - Worldwide distribution (except New Zealand)
  - Highest incidence in animal workers: Farmers, slaughterhouse workers, and veterinarians

### RISK FACTORS

- Patients with G6PD deficiency are at risk for fatal complications, usually within 5 days of onset.
- Immunocompromised patients

### GENERAL PREVENTION

- Avoid tick/flea/mite-infested areas.
- In infested areas, wear long sleeves and protective clothing and use insect repellent.
- Check children for ticks.
- Check dogs/cats for fleas and ticks.
- A vaccine for RMSF is in development.
- The Lyme vaccine LYMERix was recalled due to severe autoimmune reaction in many recipients.

### PATHOPHYSIOLOGY

- SFG:
  - RMSF: *R. rickettsii* transmitted from tick saliva invade the vascular endothelium, resulting in vasculitis, bloodstream dissemination, and systemic inflammation.
  - MSF (*R. conorii*): Almost identical with RMSF except that the eschar is the site of tick bite
  - Rickettsial pox: Transmitted by the mouse mite with the macrophage as the target cell
- TG:
  - Flea or louse acquire the rickettsial organism by feeding on an infected animal or human reservoir. The infected flea/ouse defecates on another feeding source and releases infected feces onto the host.
- Scrub typhus (*O. tsutsugamushi*):
  - Unclear pathogenesis; infection is spread by budding of infected cell plasma membrane
- Ehrlichiosis (*Ehrlichia chaffeensis*) and anaplasmosis (*Anaplasma phagocytophilum*):
  - Unclear pathogenesis. It appears similar to SFG and TG but does not cause vasculitis. May cause excessive inflammation and immune system and phagocyte activation.
- Q fever group:
  - Acquired by inhalation of contaminated airborne droplets or ingestion of contaminated foods with direct organ damage in lungs, heart, and liver
  - Nonarthropod vector, unlike the Rickettsia.

### ETIOLOGY

- SFG:
  - Infected tick, mite, and flea bites
- TG:
  - Murine typhus (*R. typhi*):
    - Flea feces
    - Rodent reservoir
  - Epidemic typhus (*R. prowazekii*):
    - Louse-borne disease
    - Primarily human reservoir
  - Scrub typhus (*O. tsutsugamushi*):
    - Bite trombiculid mite (chigger)
  - Ehrlichiosis and anaplasmosis:
    - Tick bites: Lone star tick, *Ixodes* species
    - Reservoirs: White-tailed deer and white-footed mouse

- Q fever group (*Coxiella burnetii*):
  - Intracellular organism that lives in macrophages, from unpasteurized milk and products of conception from farm animals
- Most rickettsial infections confer cross-immunity within the specific group (not across subgroups).

## DIAGNOSIS

### HISTORY

- Fever, headache, rash (with distribution and time line), malaise
- Tick bite and/or exposure to tick-infested area
- Travel history
- Exposure to farm animals, rodents, cats, dogs, deer
- Intractable headache

### PHYSICAL EXAM

- SFG:
  - RMSF: Rash appears within 48–72 hr with small, blanching macules, then maculopapular or petechial and may hemorrhage. Wrists and ankles are the initial site of rash, then trunk, sometimes with involvement of the palms and soles.
  - MSF: Pathognomonic tache noire (black spot; generally found on the head in children and on the legs in adults). Maculopapular rash appears on the 3rd to 5th day of fever starting on extremities; initially the head, then the neck, buttocks, palms, and soles.
  - Rickettsial pox: Nonpruritic macules that develop into vesicular papules that can mimic varicella lesions
- TG:
  - Rash: Appears on the 4th to 7th day, initially macular or maculopapular, then petechial. Initially appears on the trunk, then to extremities while sparing the head, palms, and soles.
- Scrub typhus:
  - Rash: Appears on the 5th to 8th day; macular or maculopapular mainly on the trunk but may extend to extremities
  - The bite site develops papule, then painless flat black eschar.
  - General lymphadenopathy
  - Hepatosplenomegaly
  - Conjunctivitis
- Ehrlichiosis and anaplasmosis:
  - Rash: Macular or macular papular; more common in children than adults and appears on trunks and extremities
  - Hepatosplenomegaly (~50% of children)
  - Edema of the face, hands, and feet are common.
- Q fever group:
  - Rash: Rarely present
  - Pneumonitis
  - Hepatosplenomegaly

**DIAGNOSTIC TESTS & INTERPRETATION****Lab**

- There are no reliable diagnostic lab tests in early phases of rickettsial diseases, though specific serologic tests are available.
- Nonspecific elevation of C-reactive protein; hepatic transaminases and thrombocytopenia may be present
- Indirect immunofluorescent antibody assay (IFA) and polymerase chain reaction are labs of choice for the spotted fever, typhus, and scrub typhus groups. Empiric therapy should be started based on clinical suspicion and not held awaiting lab test results.
- Q fever group:
  - Serologic testing to detect phase I and phase II antibodies. Perform IFA 4 wk apart to detect 4-fold rise in titers.

**Imaging**

- CXR:
  - In the Q fever group may reveal multiple round, segmental opacities
- Transesophageal echo:
  - Detects vegetations in Q fever endocarditis

**Diagnostic Procedures/Other**

- SFG:
  - Skin biopsy of the rash or eschar reveals rickettsial-infected endothelial cells/vasculitis.
  - ECG changes of myocarditis or dysrhythmia
- Scrub typhus (*O. tsutsugamushi*):
  - Biopsy of the rash or eschar reveals lymphohistiocytic vasculitis.
- Ehrlichiosis and anaplasmosis:
  - Buffy coat or peripheral blood smear reveals intracytoplasmic morulae within neutrophils.

**DIFFERENTIAL DIAGNOSIS**

- SFG:
  - Multiple diseases: Meningococcemia, measles, viral exanthems, anthrax, Lyme disease, syphilis, rickettsial infections, Henoch-Schönlein purpura, hemolytic uremic syndrome, Kawasaki
- TG:
  - Like the SFG, the differential diagnosis is broad, from sepsis, viral syndrome to other rickettsial diseases.
- Scrub typhus:
  - Malaria, dengue fever, leptospirosis, infectious mononucleosis
  - Other SFG infections
- Ehrlichiosis and anaplasmosis:
  - Arthropod infections including babesiosis, tularemia, RMSF, Lyme disease
  - Infectious mononucleosis
  - Kawasaki disease
  - Leukemia
  - Viral syndrome
  - Q fever
- Q fever group:
  - Fever of unknown origin
  - Culture-negative endocarditis:
    - Atypical pneumonia (*Mycoplasma pneumoniae*)
    - Myocarditis
    - Recurrent osteomyelitis
    - Cat scratch disease (*Bartonella henselae*)
    - Mycobacterial infections

**TREATMENT****INITIAL STABILIZATION/THERAPY**

- Assess and stabilize airway, breathing, and circulation.
- Antibiotic therapy is the mainstay of treatment.

**MEDICATION****First Line**

Doxycycline:

- <45 kg: 2.2 mg/kg q12h PO/IV for 5–10 days
- >45 kg, adult dosing: 100 mg q12h PO/IV for 5–10 days
- Rickettsioses usually respond to doxycycline, which is first-line therapy even in children. It is the drug of choice for all ages in this life-threatening disease.
- Dental staining in children <8 yr old is unlikely, as it is dose dependent and usually does not occur with 1 course of doxycycline.
- Use for at least 48 hr after the patient is afebrile with clinical improvement.

**Pregnancy Considerations**

Doxycycline 100 mg q12h PO/IV for 5–10 days. It is first line even in pregnancy because of the life-threatening nature of the disease and the superiority of doxycycline to other drugs.

**Second Line**

- Chloramphenicol 12.5–25 mg/kg/day IV divided q6h for 5–10 days:
  - If patient is allergic to doxycycline
  - Is not effective against ehrlichiosis
- Azithromycin 10 mg/kg PO per day for 3 days or clarithromycin 7.5 mg/kg PO q12h as alternative treatment in MSF:
  - If patient is allergic to doxycycline
- Tetracycline 25–50 mg/kg/day PO divided q6h, max single dose 2 g/day
- Rifampin 5–10 mg/kg IV/PO q12h, max single dose 600 mg/24 hr:
  - Used in doxycycline-resistant scrub typhus

**DISPOSITION****Admission Criteria**

Meningoencephalitis, coma, seizures, patient unable to tolerate oral medications

**FOLLOW-UP****FOLLOW-UP RECOMMENDATIONS****Patient Monitoring**

RMSF and Q fever may have cardiac complications; may need repeat ECG or echo.

**PROGNOSIS**

- Death and/or severe illness if delay in therapy
- Uncomplicated RMSF with early treatment has a good prognosis. Defervesce in 1–3 days with complete recovery in 7–10 days.
- Delayed treatment or survivors in untreated disease will defervesce in 2–3 wk.

**COMPLICATIONS**

- RMSF: CHF, arrhythmias, possible learning disability (mild)
- MSF: Phlebitis, venous thrombosis (more likely during pregnancy), pneumonitis, acute respiratory distress syndrome
- Q fever (chronic): Endocarditis, myocarditis, meningoencephalitis

**See Also (Topic, Algorithm, Electronic Media Element)**

- Fever
- Maculopapular Rash

**ICD9**

- 081.2 Scrub typhus
- 082.0 Spotted fevers
- 083.9 Rickettsiosis, unspecified

**PEARLS AND PITFALLS**

- Report rickettsial diseases such as RMSF and ehrlichiosis to departments of health.
- Dental staining in children <8 yr old is unlikely, as it is dose dependent and usually does not occur with 1 course of doxycycline.
  - Doxycycline is less likely than other tetracyclines to cause dental staining.
- The Weil-Felix test is not sensitive and not specific.
- Treat the patient with suspected rickettsial disease or Q fever immediately to decrease complications and shorten the disease course.

# ROSEOLA INFANTUM

Clare M. Hack

Michael D. Rosen

## BASICS

### DESCRIPTION

- Roseola is also known as exanthem subitum, roseola infantum, or sixth disease.
- It is an exanthematous viral illness occurring almost exclusively in infancy.
- Human herpesvirus-6 (HHV-6) and human herpesvirus-7 (HHV-7) are the most common viral etiologic agents.
- Classic course: Well-appearing child with fever to 40°C lasting 2–4 days, followed by defervescence and then an erythematous maculopapular rash that persists 1–3 days

### EPIDEMIOLOGY

#### Incidence

- HHV-6 infection peaks between the ages of 6 and 24 mo (1).
- Prospective study testing saliva of children <2 yr of age for HHV-6 DNA showed that 77% were infected by 24 mo (2).
- No seasonal pattern exists.
- The incubation period averages 10 days; range 5–15 days.
- Transmission of HHV-6 results from asymptomatic shedding of persistent virus in secretions (usually saliva) of a healthy human contact (1).

#### Prevalence

- HHV-6 is 100% prevalent in all children >4 yr of age.
- HHV-7 occurs slightly later, with prevalence of 90% at 6–10 yr of age (1).

### RISK FACTORS

- All infants are at risk:
  - Older siblings are an increased risk factor (2).
- Immunocompromised patients, such as bone marrow transplant (BMT) patients, may develop HHV-6 viremia manifested as fever, rash due to host reactivation or donor sources (1).

### PATHOPHYSIOLOGY

- Virus from saliva secretions enters the host through the oral, nasal, or conjunctival mucosa.
- HHV-6 infects activated T cells and cell lines of fibroblast, epithelial, and neural origin; can also be found in lymph nodes, salivary glands, kidney, brain, monocytes, and macrophages (1).
- HHV-7 may be found in activated T cells, salivary glands, monocytes, and macrophages (1).
- Latency is established primarily in peripheral blood mononuclear cells and salivary glands:
  - Other sites of latency include the kidneys, lungs, genital tract, and CNS (1).

### ETIOLOGY

- Primary infection with HHV-6 and less frequently HHV-7:
  - HHV-6 and HHV-7 belong to the beta-herpesvirus subfamily of herpesvirus.
  - HHV-6 has 2 variants, A and B; variant B causes >95% of HHV-6 roseola cases (1).
- Other viruses (echovirus) may also cause roseola.

### COMMONLY ASSOCIATED CONDITIONS

- Febrile seizures
- Otitis media
- Rarely associated conditions include the following: encephalitis, meningoencephalitis, pneumonia, hepatitis, and myocarditis.

## DIAGNOSIS

### HISTORY

- High fevers ranging from 38–40°C, averaging 39°C and lasting 3–5 days (1).
- Prior to the appearance of rash, it is possible that no other symptoms will be present.
- May include upper respiratory tract symptoms including rhinorrhea, pharyngeal inflammation, and conjunctival redness.
- Abdominal pain, vomiting, and diarrhea are infrequent complaints.
- Nonpruritic rash appears within 12–24 hr of fever resolution.
- Rash occurred only in 30% of primary infections of HHV-6 (2).
- HHV-7 primary infection is less likely to be associated with rash than HHV-6 (3).
- Febrile seizure may occur in 10–15% of patients (up to 36% of those 12–15 mo of age) (4).
- HHV-6 accounts for 20% of 1st febrile seizures (4).

### PHYSICAL EXAM

- Usually well appearing and afebrile
- Erythematous maculopapular rash on the trunk, spreading to neck, face, and proximal extremities (occurs in 30%)
- May also see cervical or occipital lymphadenopathy, eyelid edema, or erythematous tympanic membranes
- Ulcers at the uvulopalatoglossal junction (Nagayama spots) are common in Asia.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

- No lab testing is routinely indicated.
- Patients who present with fever prior sometimes undergo lab workup for fever without a source if presentation is prior to appearance of rash.
- It is important to identify HHV-6 and HHV-7 as causative agents for more serious illnesses such as encephalitis and pneumonia.
- Quantitative HHV-6 or HHV-7 DNA polymerase chain reaction of serum or CSF may be useful in distinguishing between active and latent infections (1).
- IgM and IgG may be elevated in primary infection and reactivation (5).
- Loop-mediated isothermal amplification method may prove to be a rapid diagnostic procedure (5).

### DIFFERENTIAL DIAGNOSIS

- Rubella
- Measles
- Scarlet fever
- Drug hypersensitivity/allergic reaction
- Enteroviruses
- Echovirus
- Parvovirus
- Other viruses

## TREATMENT

### INITIAL STABILIZATION/THERAPY

- Supportive care
- Manage febrile seizures or status epilepticus as per usual protocol.
- Antipyretics as needed
- Oral or IV hydration as needed

### MEDICATION

#### First Line

- Antipyretics (ibuprofen or acetaminophen) as needed for fever
- Analgesics (ibuprofen or acetaminophen) as needed for oral ulcers

#### Second Line

- Possible role for ganciclovir, foscarnet, or cidofovir for immunocompromised patients with HHV-6 infection per anecdotal reports (1)
- May also consider antivirals in treatment of serious infections with HHV-6 such as encephalitis, myocarditis, hepatitis, pneumonia

### DISPOSITION

#### Admission Criteria

- Severe complications such as meningoencephalitis or myocarditis warrant admission to an ICU:
  - These are complications of HHV-6 and HHV-7 infections, but their presence constitutes a different diagnosis than roseola infantum.
- Other complications such as pneumonia, hepatitis, dehydration, or inability to tolerate oral fluid may require admission.

#### Discharge Criteria

Patients with roseola are almost universally discharged from the emergency department.

#### Issues for Referral

Immunocompromised patient

## FOLLOW-UP

### FOLLOW-UP RECOMMENDATIONS

- Discharge instructions and medications:
  - Ibuprofen 10 mg/kg/dose PO q6h or acetaminophen 15 mg/kg PO q4h PRN for fever or pain
- Activity:
  - May return to day care/school when afebrile, even if rash persists

### PROGNOSIS

Uncomplicated roseola carries a prognosis for a full normal recovery.

### COMPLICATIONS

- Febrile seizure
- Dehydration
- Rare complications include meningoencephalitis, encephalitis, myocarditis, hepatitis, and pneumonia.
- In immunocompromised patients (eg, BMT), HHV-6 has been implicated in encephalitis, pneumonia, organ rejection, and graft versus host disease.

## CODES

### ICD9

- 058.10 Roseola infantum, unspecified
- 058.11 Roseola infantum due to human herpesvirus 6
- 058.12 Roseola infantum due to human herpesvirus 7

## PEARLS AND PITFALLS

- Roseola is a benign illness usually requiring no diagnostic evaluation and only supportive care for treatment.
- The expected progression is high fever, often with no associated symptoms, with development of fever after defervescence:
  - If both fever and rash are present, the illness is not roseola.
  - It is not uncommon for children who present during the febrile stage and no associated symptoms to have lab evaluation for fever without a source.
- Failure to consider other serious illnesses associated with fever and rash that require evaluation and treatment

# RUBELLA

Rebecca L. Vieira

## BASICS

### DESCRIPTION

- Rubella is a virus that causes a mild, self-resolving illness with characteristic rash. It is also known as German measles or 3-day measles.
- Transmission is via droplets from respiratory secretions.
- Rubella is moderately contagious.
- Maternal infection in early pregnancy can lead to serious birth defects.
- Vaccination against rubella is standard in developed countries to prevent complications of congenital rubella.

### EPIDEMIOLOGY

- In unvaccinated populations, the incidence of rubella is highest in school-age children.
- Prior to the development of rubella vaccine, epidemics of rubella occurred in the U.S. every 6–9 yr.
- 1964 was the year of the last outbreak in the U.S.
- Rubella is no longer endemic in the U.S. but is endemic in developing countries.
- Rubella occurs with regularity in the U.K. due to the large number of immigrants unimmunized for the disease.

### RISK FACTORS

- Unimmunized people who travel to countries where the virus is endemic
- Fetuses of mothers who acquire the virus during their 1st trimester are at risk of serious birth defects.

### GENERAL PREVENTION

- Vaccination prevents acquisition of the rubella virus.
- Droplet precautions prevent the spread of the virus from infected individuals to unimmunized persons.

### PATHOPHYSIOLOGY

- Spreads from an infected person by droplets and enters the body via cells of the nasopharynx, then spreads to regional lymph nodes, followed by the blood and other fluids within the body
- Incubation period is 14–21 days.
- Infectious period is typically 1 wk prior to and 5 days after development of rash.
- Up to 50% of cases may be subclinical.

### ETIOLOGY

- Member of the Togavirus family; small, enveloped RNA virus
- Humans are the only natural reservoir.

## DIAGNOSIS

### HISTORY

- Children typically have symptoms suggestive of an upper respiratory infection:
  - Low-grade fever
  - Headache
  - Cough
  - Rhinorrhea
  - Malaise
  - Rash
- Arthralgia or arthritis sometimes occurs.

### PHYSICAL EXAM

- Usually well appearing
- Low-grade fever
- Mild conjunctivitis
- Characteristic exanthem (sometimes preceded by several days of prodromal symptoms):
  - Erythematous maculopapular rash
  - The rash is fainter than the measles rash and does not coalesce.
  - Rash starts on the face and spreads caudally.
  - Rash is typically complete on the 1st day and disappears in 3 days.
  - Purpura or hemorrhagic complications uncommonly occur down the body.

- Lymphadenopathy of postauricular, occipital, and posterior cervical areas is often present.
- Arthralgia or arthritis may occur:
  - Knee, wrists, and fingers are typically involved.
- Encephalitis rarely occurs.
- Congenital rubella syndrome: Can include hearing loss, developmental delay, growth retardation, and cardiac and ophthalmic defects

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

- No lab tests are necessary in uncomplicated cases in children.
- CBC may be sent to assess for thrombocytopenia.
- Urinalysis to detect hematuria
- Patients who undergo lumbar puncture due to encephalitic symptoms may have slight elevation of monocytes in the CSF.
- Numerous tests, not typically indicated, are available for definitive diagnosis:
  - ELISA to detect rubella-specific IgM
  - Rubella antibody titer: Comparison of acute and convalescent serum specimens
  - Live virus may be isolated from the pharynx.

##### Pregnancy Considerations

- Pregnant women should be screened for immunity.
- If suspected in pregnancy, it is important to confirm the diagnosis with polymerase chain reaction or documentation of a 4-fold rise in the IgG antibody level.

### DIFFERENTIAL DIAGNOSIS

- Scarlet fever
- Measles
- Roseola infantum
- Rocky Mountain spotted fever
- Juvenile rheumatoid arthritis
- Other viral exanthems

## TREATMENT

### MEDICATION

- Antipyretics: Acetaminophen and/or ibuprofen may be used as necessary.
- Analgesics: Acetaminophen and/or ibuprofen are typically adequate.
- Immune globulin may be used in severe cases:
  - This will not prevent viremia but may lessen the severity of symptoms.

### DISPOSITION

#### Admission Criteria

- Severe thrombocytopenia with a platelet count  $<50,000 \times 10^{-6}/L$  with hemorrhage or  $<25,000 \times 10^{-6}/L$  without hemorrhage
- Encephalitis

## FOLLOW-UP

### FOLLOW-UP RECOMMENDATIONS

Discharge instructions and medications:

- Follow up with a primary care provider if symptoms do not improve.
- Use acetaminophen and/or ibuprofen for fever and analgesia.
- Return for severe headache, lethargy, or bleeding.

### PROGNOSIS

- The prognosis is generally excellent, with complete recovery and no sequelae.
- The prognosis is poor for neonates of mothers who contract the virus during their 1st trimester.

### COMPLICATIONS

- Hemorrhage resulting from thrombocytopenia
- Encephalitis is a rare but life-threatening complication.
- Chronic arthritis rarely occurs.
- Congenital rubella syndrome: Complications are worse with maternal infection early in pregnancy, include hearing loss, developmental delay, and cardiac and ophthalmic defects.

### CODES

#### ICD9

- 056.00 Rubella with unspecified neurological complication
- 056.8 Rubella with unspecified complications
- 056.9 Rubella without mention of complication

### PEARLS AND PITFALLS

- Pearls:
  - Mild course and characteristic rash distinguish disease.
- Pitfalls:
  - Failure to ask about immunization status of contacts
  - Failure to recommend isolation or quarantine during infective period, particularly avoiding contact with pregnant women
  - Failure to recognize disease in pregnant women

# SALMONELLA

Todd A. Mastrovitch  
Poonam Desai

## BASICS

### DESCRIPTION

- Salmonellosis is a common foodborne disease causing various clinical infections.
- Nontyphoid *Salmonella* causes infections that include asymptomatic carriage, gastroenteritis, bacteremia, and metastatic focal infections.
- *Salmonella typhi* and *Salmonella paratyphi A* cause typhoid or enteric fever.

### EPIDEMIOLOGY

- Prevalence of *Salmonella* infection varies depending on reporting techniques and inconsistent diagnoses.
- An estimated 1.4 million people are infected with nontyphoidal *Salmonella* in the U.S., resulting in 15,000 hospitalizations and ~400 deaths per year (1).
- Incidence of *Salmonella* infections peak at the extreme of ages, <4 yr or >50 yr (2).
- During 2003, 40% of the 43,657 reported cases of salmonellosis were among children <15 yr of age (3).
- The highest incidence of salmonellosis occurs in neonates secondary to decreased stomach acidity and buffering of ingested milk (2).
- In the U.S., most cases of documented typhoid fever occur from travel to developing nations (4).
- *Salmonella* infections occur commonly during warm summer months in temperate climates.

### RISK FACTORS

- Risk factors for *Salmonella* infections include hygiene, availability of safe water, and food preparation practices.
- The principal source of nontyphoidal salmonellosis is contact with infected animals.
- A *Salmonella* infection in chickens increases risk of contamination in poultry and eggs.
- Nosocomial infections can also occur due to contaminated equipment.
- HIV, leukemia, sickle cell disease, and chronic granulomatous disease are risk factors.

### GENERAL PREVENTION

- Providing a clean drinking water source
- Ensuring proper hand-washing techniques
- Proper food preparation
- Oral and parenteral typhoid vaccines are highly effective to prevent disease.

### PATHOPHYSIOLOGY

- Infections with *Salmonella* organisms occur with ingestions of contaminated food and water.
- Most nontyphoidal *Salmonella* do not extend beyond the local lymphatics of the gut.
- Nontyphoidal *Salmonella* organisms invade the intestinal mucosa, leading to enterocolitis with diffuse mucosal inflammation and edema.

- An important barrier to *Salmonella* infection is gastric acidity.
- Hypochlorhydria and the rapid gastric emptying time of neonates and young infants increases vulnerability to symptomatic disease.
- *S. typhi* invade the gut mucosa in the terminal ileum, possibly through adhering to specialized epithelial cells that overlie the Peyer patches.
- *S. typhi* crosses the mucosal barrier through a process of cytokine secretion, bacterial-mediated endocytosis, and translocation to lymphoid follicles in the gut.
- After penetrating the intestinal mucosa, *S. typhi* enters blood via the lymphatic system.
- This disseminates the bacteria.
- The severity, incubation period, and symptoms of acute salmonellosis depend on the dose of organisms ingested.

### ETIOLOGY

Salmonellae are gram-negative bacilli that belong to the family Enterobacteriaceae.

### COMMONLY ASSOCIATED CONDITIONS

- Dehydration
- Hypoglycemia

## DIAGNOSIS

### HISTORY

- Acute gastroenteritis is the most common clinical presentation of nontyphoidal salmonellosis.
- After an incubation period of 6–48 hr, there is an abrupt onset of nausea, vomiting, and crampy abdominal pain in the periumbilical area and right lower quadrant followed by watery diarrhea and sometimes diarrhea containing blood and mucus.
- Fever, headaches, chills, and myalgias are common symptoms.
- In healthy children, diarrhea is typically self-limiting and resolves in 3–7 days.
- A rare complication is *Salmonella* meningitis, which typically occurs in neonates and children  $\leq 1$  yr of age.
- Symptoms can persist for weeks in neonates, young infants, and children.
- The clinical course of typhoid fever can vary from fever to multisystem toxicity.
- The 1st week of illness presents with rising fever and bacteremia.
- The 2nd week is characterized by abdominal pain and "rose spot" rash.
- During the 3rd week, secondary bacteremia and peritonitis can lead to hepatosplenomegaly and intestinal bleeding and perforation.
- Other findings of typhoid fever include septic shock and altered mental status.

### PHYSICAL EXAM

- Physical findings of salmonellosis can vary depending on the clinical syndrome and serotype.
- Fever, dehydration, diffuse abdominal tenderness, abdominal distention, and copious diarrhea are common findings in *Salmonella* gastroenteritis.
- Fever, cervical adenopathy, relative bradycardia, abdominal pain and distention, and rose spot rash are typical findings in typhoid fever.
- A rose spot rash is described as a faint salmon-colored papular lesion located primarily on the trunk that fades with pressure.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

- CBC with differential
- Leukocytosis, often with thrombocytopenia, is common.
- C-reactive protein is elevated.
- Blood culture, particularly for typhoid fever
- Blood cultures are positive in early disease.
- Stool and urine cultures are positive after the 1st week of illness.
- Basic chemistry with LFTs
- Stool culture, with use of selective media such as MacConkey, Hektoen enteric, or xylose-lysine-deoxycholate (XLD) agar
- *Salmonella* gastroenteritis in children is best diagnosed with stool specimen for culture rather than rectal swabs.
- Metastatic focal infections can be diagnosed by obtaining cultures of pus or biopsy specimens

### DIFFERENTIAL DIAGNOSIS

- *Salmonella* gastroenteritis is clinically similar to gastroenteritis from other pathogens, but a differentiating factor is bloody diarrhea.
- *Shigella*, enteroinvasive *Escherichia coli*, enterohemorrhagic *E. coli*, *Campylobacter jejuni*, *Yersinia enterocolitica*, and *Clostridium difficile*, *Trichuris trichiura*, *Balantidium coli*, and *Entamoeba histolytica* are all possible causes of bloody diarrhea.
- Typhoid fever may mimic other febrile illness.
- In the early stages, typhoid fever may mimic acute gastroenteritis, bronchitis, or bronchopneumonia.
- Other differential diagnoses include malaria, brucellosis, TB, tularemia, leptospirosis, and rickettsial diseases as well as viral infections such as dengue fever, acute hepatitis, and infectious mononucleosis.

## TREATMENT

### PRE HOSPITAL

Administer IV fluid as needed.

### INITIAL STABILIZATION/THERAPY

- Assess and stabilize airway, breathing, and circulation.
- Rehydration, correction of electrolyte disturbances, and general supportive care
- Antibiotics are not generally recommended for treating *Salmonella* gastroenteritis because they may suppress growth of normal intestinal flora and prolong the excretion of *Salmonella*:
  - However, in infants <3 mo of age and in immunocompromised patients, appropriate empirical antibiotics must be given.
- For children with typhoid fever, antipyretic therapy should be provided.

### MEDICATION

#### First Line

- Ceftriaxone 50–100 mg/kg IV/IM per day, max single dose 2 g:
  - Preferred for bacteremia and extraintestinal focal *Salmonella* infections
- Ampicillin 200–300 mg/kg/day IV divided q6h, max dose 12 g/day
- Trimethoprim (TMP)/Sulfamethoxazole:
  - <2 mo of age: Do not administer.
  - >2 mo: 8 mg/kg/day (based on TMP) PO t.i.d.–q.i.d. × 14 days
- Ondansetron 0.15 mg/kg/IV/PO q6–8h PRN, max single dose 8 mg

#### Second Line

- Azithromycin may be used when there is resistance to oral first-line agents:
  - Day 1: 10 mg/kg PO, max single dose 500 mg/day
  - Days 2–5: 5 mg/kg PO, max single dose 250 mg/day
- Ciprofloxacin, though not routinely recommended in children, is typically highly effective. Often used in immunocompromised patients:
  - Children:
    - Not routinely used
    - Dosing 20–30 mg/day PO divided b.i.d., max single dose 500 mg
  - Adolescent/adult: 500 mg PO b.i.d. × 14 days

### COMPLEMENTARY & ALTERNATIVE THERAPIES

- Corticosteroid therapy is indicated in children with delirium, obtundation, stupor, coma, or shock in children with typhoid fever.
  - Dexamethasone:
    - 3 mg/kg IV once, then 8 doses of 1 mg/kg IV q6h
- Antidiarrheal agents
  - Loperamide:
    - 13–20 kg: 1 mg PO b.i.d.
    - 20–30 kg: 2 mg PO b.i.d.
    - >30 kg: 2 mg PO t.i.d.

### SURGERY/OTHER PROCEDURES

Surgery in rare cases of intestinal perforation

### DISPOSITION

#### Admission Criteria

- Young infants, immunocompromised patients, or others requiring parenteral antibiotics
- Dehydration, abdominal pain requiring parenteral analgesics, persistent vomiting uncontrolled with antiemetics
- Critical care admission criteria:
  - Unstable vital signs or other severe illness

#### Discharge Criteria

No dehydration or medical complications

#### Issues for Referral

For persistent symptoms or carrier state, refer to a pediatric infectious disease specialist.

## FOLLOW-UP

### FOLLOW-UP RECOMMENDATIONS

- Discharge instructions and medications:
  - Provide adequate antipyretic therapy.
- Activity:
  - Hand hygiene is critical.

#### Patient Monitoring

Monitoring of hydration and caloric intake is important in recovery from *Salmonella* disease.

### DIET

A soft, digestible diet is recommended unless the patient has ileus or distended abdomen.

### PROGNOSIS

- The prognosis of typhoidal salmonellosis depends on the age, state of general health, and causative *Salmonella* serotype.
- In immunocompetent children, full recovery usually occurs after *Salmonella* gastroenteritis.
- Young infants and immunocompromised children may have prolonged course and complications.
- Following clinical recovery of gastroenteritis, nontyphoidal *Salmonella* continues to be excreted in feces for a median of 5 wk.
- Despite appropriate antibiotic treatment, relapse can occur in 2–4% of patients with typhoidal salmonellosis.
- <2% of infected children will become chronic carriers of *S. typhi*.

### COMPLICATIONS

- Bacteremia, with severe morbidity and mortality in young infants and immunocompromised children
- Dehydration
- In patients with inflammatory bowel disease, rapid development of toxic megacolon, bacterial translocation, and sepsis can lead to fatality.
- Patients with AIDS may develop multisystem involvement, septic shock, and death.
- Hepatitis, cholecystitis, and jaundice are rare but may occur after typhoidal salmonellosis.
- Intestinal hemorrhage and perforation may occur in 0.5–1% of children.
- Rare cardiac complications include toxic myocarditis, endocarditis, arrhythmias, sinoatrial block, or cardiogenic shock.
- Psychosis, increased intracranial pressure, acute cerebellar ataxia, chorea, deafness, and Guillain-Barré syndrome are rare complications that can occur with typhoid infections.
- Parotitis, orchitis, and suppurative lymphadenitis

## CODES

### ICD9

- 003.0 *Salmonella* gastroenteritis
- 003.1 *Salmonella* septicemia
- 003.20 Localized salmonella infection, unspecified

## PEARLS AND PITFALLS

- Antibiotics are not indicated in most *Salmonella* infections.
- Even though fluoroquinolones are not recommended for children <10 yr of age, severe nontyphoidal salmonellosis may be treated with fluoroquinolones, especially in immunocompromised patients.
- Steroids given for >48 hr can increase the relapse rate.

# SALICYLATE POISONING

Kevin C. Osterhoudt

## BASICS

### DESCRIPTION

- Salicylate poisoning may occur with acute or chronic overdose of:
  - Acetylsalicylic acid (aspirin)
  - Methyl salicylate (oil of wintergreen, Bengay)
  - Bismuth subsalicylate (Pepto-Bismol)
  - Salicylic acid (keratolytic)
- The potentially toxic acute oral dose of acetylsalicylic acid is  $>150$  mg/kg.

### EPIDEMIOLOGY

- Analgesics are the most common drugs implicated in poisoning exposures among children  $<6$  mo of age.
- Salicylate preparations constitute 12% of all analgesic poisoning exposures reported to poison control centers.

### RISK FACTORS

- Use of salicylates in children, for which there are only rare or uncommon indications
- Aspirin is often marketed in combination with other pharmaceuticals, which may complicate drug overdose situations:
  - Adolescents frequently overdose on  $\geq 1$  drug.

### GENERAL PREVENTION

Keeping poisons inaccessible to children is the best preventative measure.

### PATHOPHYSIOLOGY

- Ingested drug is absorbed in the stomach and proximal intestine.
- Enteric coating may lead to significantly delayed drug absorption.
- In rare cases of topical poisoning, such as methyl salicylate, drug is absorbed transdermally.
- With aspirin poisoning, serum levels peak in 1–2 hr (regular aspirin) or 4–6 hr (enteric coated).
- Methyl salicylate, when ingested, results in rapid, severe toxicity that may progress to severe illness or death within hours.
- After oral overdose, absorption may be prolonged and erratic.
- Salicylate ingestion may produce gastritis and may trigger centrally mediated vomiting.
- After overdose, the elimination half-life becomes prolonged.

- As blood pH falls, the proportion of nonionized salicylate rises, and more salicylate shifts into tissues, including brain.
- Toxic salicylate exposures uncouple mitochondrial oxidative phosphorylation and increase oxygen consumption.
- Direct stimulation of the medullary respiratory center leads to hyperventilation and respiratory alkalosis:
  - Due to the inability to significantly increase tidal volumes, younger children may progress to metabolic acidemia without any preceding phase of respiratory alkalosis.
- Multiple metabolic derangements produce an elevated anion gap metabolic acidosis.
- Dehydration and electrolyte shifts are common:
  - Salicylate toxicity causes an obligate diuresis, and massive urinary fluid loss is common.
- Pulmonary and/or cerebral edema may occur.
- Therapeutic use of aspirin in children with influenza is associated with development of Reye syndrome.

### ETIOLOGY

See Description.

### COMMONLY ASSOCIATED CONDITIONS

- Vomiting
- Tinnitus
- Coingestion of other poisons

## DIAGNOSIS

### HISTORY

- Aspirin and other salicylate poisoning mimics many illnesses, and chronic overdose often results in delayed diagnosis.
- Timing of ingestion allows for proper consideration of the risks vs. benefits of GI decontamination.
- Vomiting, which may be due to gastric irrigation as well as centrally mediated vomiting, and abdominal pain is common.
- Tinnitus is frequently associated with serum salicylate level  $>25$  mg/dL.
- Diaphoresis is common.

### PHYSICAL EXAM

- Assess vital signs and pulse oximetry.
- Hyperpnea and/or tachypnea are common.
- Hyperthermia, which may be misinterpreted as fever, may be present.
- Hypoxia is uncommon and suggests pulmonary edema.
- Hypotension may be present, usually indicating severe dehydration, likely complicated by metabolic acidosis.
- CNS: CNS depression or seizures represent severe toxicity.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

- Assess bedside serum glucose in any patient with altered mental status. Hypoglycemia or hyperglycemia may occur.
  - Elevated anion gap metabolic acidosis is common.
  - Blood gas analysis: May show mixed respiratory alkalosis and metabolic acidosis:
    - Respiratory acidosis is an ominous sign of severe toxicity.
  - Salicylate level: Serum salicylate levels  $>60$ – $100$  mg/dL or  $30$ – $40$  mg/dL (chronic) indicate severe toxicity:
    - Serial salicylate levels are required to assess toxicity. Continue to check salicylate levels every 1–2 hr until levels are falling and it is clear the peak level has occurred.
  - Acetaminophen level: Assess the acetaminophen level in any patient with ingestion with intent of self-harm.
  - Urine:
    - Ferric chloride testing of urine will result in brown or purple color when several drops are dripped into urine containing salicylate.
    - pH testing: Allows monitoring of adequacy of urinary alkalization
- #### Imaging
- CXR is indicated in patients with hypoxia, abnormal lung auscultation, or other indicators of pulmonary edema.
  - CT of the brain may be indicated in patients with altered mental status for whom intracranial pathology is suspected.

### DIFFERENTIAL DIAGNOSIS

- Gastroenteritis
- Pneumonia
- Metabolic disease
- Ketoacidosis
- Sepsis
- Meningitis, encephalitis
- Other drug ingestion or toxicity

## TREATMENT

### PRE HOSPITAL

Assess and stabilize airway, breathing, and circulation.

### INITIAL STABILIZATION/THERAPY

- Assess and stabilize airway, breathing, and circulation.
- Endotracheal intubation, if performed, must be accompanied by hyperventilation to prevent worsening acidemia and salicylate distribution to the brain.
- Immediate seizure, cardiac arrest, and death may result from endotracheal intubation and failure to hyperventilate the patient.
- GI decontamination by use of activated charcoal or whole bowel irrigation may be indicated.
- Use of antiemetics to control vomiting may be necessary.
- Rehydration with normal saline is typically indicated. Massive diuresis from renal excretion of salicylate causes severe dehydration.
- Sodium bicarbonate administration to limit CNS salicylate concentrations is often indicated.
- Hypoglycemia is treated or prevented by administration of dextrose infusion.
- Hemodialysis may be indicated for severe toxicity.

### MEDICATION

#### First Line

- Activated charcoal:
  - 1 g/kg (max single dose 75 g) may be administered if aspirin is judged to be in the stomach or small intestine.
  - Many authorities recommend a 2nd dose of charcoal 2–4 hr after the initial dose if serum levels are still rising or if enteric-coated tablets were ingested.
- Sodium bicarbonate:
  - 1 g/kg bolus of sodium bicarbonate followed by infusion
  - Combine sodium bicarbonate with dextrose as follows:
    - 5% dextrose (D5 water) with 100–150 mEq/L of sodium bicarbonate (2 or 3 ampules of sodium bicarbonate) and 20–40 mEq/L of potassium chloride infused at 1.5–2 times maintenance requirements
    - Titrate fluid infusion to produce urine output of 1–2 mL/kg/hr
    - Titrate alkalinization to produce urine between 7.5 and 8, which maximizes the urinary elimination of salicylate by “ion trapping” effect

- Dextrose: May bolus 0.5–1 g/kg of dextrose solution for acute hypoglycemia. For dextrose infusion, see above.
- Ondansetron:
  - 0.15 mg/kg IV, max single dose 8 mg, may be repeated q45min to a max of 0.6 mg/kg.
  - Indicated for severe vomiting

### Second Line

Potassium chloride:

- 1 mEq/kg IV as infusion over 1–2 hr
- Indicated to correct severe hypokalemia. If uncorrected, the attempt to alkalinize urine will be unsuccessful.

### SURGERY/OTHER PROCEDURES

Hemodialysis is indicated for severe toxicity:

- Acute serum salicylate level >100 mg/dL
- Chronic serum salicylate level >60 mg/dL
- Severe acidosis or severe electrolyte disturbance
- Renal failure
- Persistent neurologic dysfunction
- Progressive clinical deterioration

### DISPOSITION

#### Admission Criteria

- Patients with intractable vomiting, enteric-coated pill ingestion, or need for observation may be admitted to a pediatric ward.
- Critical care admission criteria:
  - Unstable vital signs, severe toxicity, need for hemodialysis

#### Discharge Criteria

No severe toxicity, salicylate peak has occurred, or minimal exposure with no need for repeated salicylate levels

#### Issues for Referral

- Consider consulting a medical toxicologist to manage poisoning.
- Consult psychiatry for patients with intent of self-harm.

## FOLLOW-UP

### PROGNOSIS

- Varies with quantity of salicylate ingested
- Chronic salicylate toxicity usually has a delayed diagnosis and the most serious prognosis.
- A single acute ingestion >300 mg/kg is life threatening.

### COMPLICATIONS

- Nausea, vomiting
- Dehydration
- Metabolic acidosis
- Electrolyte abnormalities
- Disorientation, coma, seizures
- Noncardiogenic pulmonary edema
- Renal failure
- Cerebral edema and death

## CODES

### ICD9

965.1 Poisoning by salicylates

### PEARLS AND PITFALLS

- Methyl salicylate is the most concentrated salicylate and contains 7.5 g of salicylate in 5 mL. A single, small sip may be lethal to a young child.
- A single acute ingestion of >300 mg/kg of acetylsalicylic acid should be considered life threatening.

# SCABIES

Sunil Sachdeva

## BASICS

### DESCRIPTION

- Scabies is an infestation of the skin by the human mite *Sarcoptes scabiei* that is accompanied by intense pruritus:
  - The mite burrows into the stratum corneum and lays eggs.
- Animal scabies, or sarcoptic mange, occurs from contact with an infested canine:
  - Animal scabies burrow but cannot lay eggs, so the infection is transient.
- Norwegian scabies (crusted scabies) is a highly contagious and intense variant of human scabies that may become a whole-body infestation:
  - Norwegian scabies requires diligent use of medications and disposal or adequate cleaning of clothing, bedding, etc., to adequately treat the infestation.
- Postscabetic syndrome consists of persistent pruritus caused by hypersensitivity to mite antigen and may persist for weeks after the live mites have been eliminated.
- The mite is transmitted from direct skin-to-skin contact or less frequently by contact with infected clothing or bedding.

### EPIDEMIOLOGY

- Scabies affects all age groups.
- Epidemics occur every 15–30 yr.
- Humans are the sole reservoir for human scabies.

### RISK FACTORS

- Crowded conditions facilitate transmission.
- Poor socioeconomic conditions
- Young children
- Sharing of personal clothing and bedding
- Immunocompromise
- Atopic dermatitis

### GENERAL PREVENTION

- Bedding, clothing, and items of close contact should be washed and dried at high temperature (60°C) to eliminate mites.
- Family members and contacts should be treated concurrently:
  - In patients without previous scabies infection, it may take several weeks to develop pruritus, so asymptomatic close contacts should be referred for treatment.

### PATHOPHYSIOLOGY

- When fertilized, the female mite quickly burrows into the epidermis.
- It extends the tunnel by 2 mm a day and lays down 2–3 eggs at a time to a total of 10–25.
- It dies within the burrow within 30–45 days.
- Larvae hatch in 3 days, molt 3 times, and then come to the surface to mate.
- After a 2–3-wk maturation period, mating occurs; the male then dies, and the gravid female mite will burrow to repeat the cycle.
- Symptoms of scabies develop in 3–4 wk after initial infestation.
- Symptoms result from a delayed type IV hypersensitivity reaction to mite, eggs, saliva, and feces.
- On reinfection, symptoms develop within only a few days.
- Mites may live off of a host for up to 4 days.
- On average, the number of mites on a host is ~10–15.
- The main difference between Norwegian scabies and regular scabies is the number of mites on the host. Patients with Norwegian scabies are infected with thousands of mites.

### ETIOLOGY

The parasite *Sarcoptes scabiei* var *hominis*

### COMMONLY ASSOCIATED CONDITIONS

Impetigo

## DIAGNOSIS

### HISTORY

- Intense pruritus; worse at night when the mites are more active
- Rash:
  - Appearance and distribution change over time
  - May consist of burrows, papules, or vesicles
  - Older children and adults typically have rash distribution in webs of fingers/toes, axillae, wrists, waistline, and genitalia.
  - In infants and young children, the palms, soles, and face may be affected.

### PHYSICAL EXAM

- Parts of the body below the neck are usually affected.
- Affected skin may appear normal or may have rash present.
- The typical lesion is a small, erythematous, excoriated papule.
- Burrow is the pathognomonic lesion:
  - Long or thin; gray, red, or brown line
  - 2–15 mm in length
  - “S” shaped
- Secondary lesions are also common:
  - Excoriations
  - Vesicles
  - Nodules
  - Crusting
  - Pustules

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

- Clinical diagnosis is typically adequate.
- Skin scrapings over a burrow and exam under microscope:
  - Apply a drop of mineral oil on the area, and scrape with a no. 15 scalpel blade.
  - Put the scrapings on a slide and view microscopically; visualization of eggs, larva, or gravid female is diagnostic.
  - Rarely, skin biopsy is needed.

**DIFFERENTIAL DIAGNOSIS**

- Atopic dermatitis
- Papular urticaria
- Seborrheic dermatitis
- Psoriasis
- Infantile acropustulosis
- Lichen planus
- Pediculosis
- Pityriasis rosea
- Syphilis

**TREATMENT****PRE HOSPITAL**

Maintain precautions to prevent infection of prehospital workers and prevent infestation of supplies such as blankets and sheets.

**MEDICATION****First Line**

Permethrin cream 5% (Elimite) is the drug of choice:

- Apply to the entire body surface in young infants and below the neck in older children.
- Leave for 8–12 hr and then wash off.
- Usually, a single application is adequate.
- Some advocate a 2nd application after a week.

**Second Line**

- Scabicides:
  - Gamma benzene hexachloride 1% (Lindane) is also effective:
    - Single application for 8–12 hr is effective.
    - Considered to be more toxic for young children and pregnant women
    - The FDA issued a black box warning advising caution when used in persons <50 kg.
    - Not recommended for use in infants and contraindicated in premature infants
    - Lindane production was banned by an international United Nations–sponsored treaty as a persistent pesticide in 2009; production as an antiscabicide is the only exception to this rule.
    - Lindane is banned from use in some locations, such as California.
    - The adverse effect of Lindane warranting this is seizure and status epilepticus.
  - Crothamiton cream 10% (Eurax) may be used but is less effective:
    - Works by unknown mechanism of action and is an antipruritic and scabicide
    - May be useful in cases of pruritis in which the diagnosis of scabies is uncertain

- Use in children is off-label and not FDA approved
- Ivermectin 200  $\mu\text{g}/\text{kg}$  PO to max single dose of 3 mg is effective:
  - Only used in patients > 15 kg.
  - A 2nd dose after 2 wk is sometimes used to ensure clearance of mites.
  - This is an off-label use, as this medication is not FDA approved as a scabicide.
  - First-line therapy for Norwegian/crusted scabies
  - It is also indicated in the nodular form of scabies.
  - Preferred for treatment of large groups, such as in nursing homes
- Sulfur (5–10%) in petrolatum base applied topically:
  - May be used in older children and adults applied topically for 3 consecutive nights
  - Sulfur is recommended in children <8 wk of age and for pregnant and/or lactating women.
- Antipruritics:
  - Diphenhydramine 1.25 mg/kg PO q4–6h as needed:
    - Diphenhydramine and hydroxyzine are more sedating but more effective than nonsedating antihistamines.
    - Hydroxyzine: <2–6 yr of age, 12.5 mg PO q6–8h; >6 yr, 25 mg PO q6–8h as needed
  - Cetirizine: 6–24 mo of age, 2.5 mg PO daily; 2–5 yr, 2.5–5 mg PO daily; 6–11 yr, 5–10 mg PO daily;  $\geq 11$  yr, 10 mg PO daily as needed
  - Loratadine: 2–5 yr of age, 5 mg PO daily;  $\geq 6$  yr, 10 mg PO daily as needed

**SURGERY/OTHER PROCEDURES**

Crusted scabies requires removal of hyperkeratotic scale with 6% salicylic acid in petrolatum jelly.

**DISPOSITION****Admission Criteria**

Patients with severe topical or systemic superinfection

**Issues for Referral**

- Refractory or relapsing cases
- Social issues that may be contributory

**FOLLOW-UP****FOLLOW-UP RECOMMENDATIONS**

- Even after successful treatment, itching may persist for weeks.
- Patients with crusted scabies need strict isolation.

**Patient Monitoring**

- Patients need to be evaluated 2 wk after treatment.
- Appearance of fresh burrows indicates reinfection or treatment failure.

**PROGNOSIS**

If properly treated, full recovery without relapse is expected.

**COMPLICATIONS**

- Reinfection
- Secondary infection

**ADDITIONAL READING**

- Chosidow O. Scabies and pediculosis. *Lancet*. 2000;355:819–826.
- Habif TP. *Clinical Dermatology: A Color Guide to Diagnosis and Therapy*. 3rd ed. St. Louis, MO: Mosby; 2003.

- Victoria J, Trujillo R. Topical ivermectin: A new successful treatment for scabies. *Pediatr Dermatol*. 2001;18:63–65.

**CODES**

ICD9  
133.0 Scabies

**PEARLS AND PITFALLS**

- Failed 1st treatment or reinfection treatment should include scalp and neck application.
- Nails should be cut and cream applied under them.
- Patients should be informed that itching may persist for up to 2 wk with successful therapy.
- Findings for which scabies should be considered potentially causal:
  - Pustules on palm and soles of infants
  - Nodular lesion on penis or scrotum
  - Nocturnal itching
  - Small, crusted erosions on buttocks
  - Vesicles in web of fingers
  - Several members of the family affected

# SCARLET FEVER

Fidel Garcia

Catherine Scarfi

## BASICS

### DESCRIPTION

- Scarlet fever is a clinical syndrome including a characteristic scarlatiniform rash resulting from infection with a strain of *Streptococcus pyogenes* that elaborates streptococcal pyrogenic toxin:
  - Fever, pharyngitis, and cervical adenitis may also be present.
- Scarlet fever typically results secondarily from streptococcal pharyngitis but may also result from impetigo, pyoderma, or an infected wound.
- A very similar syndrome may occur after infection with certain strains of *Staphylococcus aureus*, known as staphylococcal scarlet fever.

### EPIDEMIOLOGY

#### Incidence

- Incidence of scarlet fever is cyclic, depending on the prevalence of toxin-producing strains and the immune status of the population.
- Incidence of pharyngeal disease is highest during the winter and spring.
- Infections are highest in children 5–15 yr of age, especially school-age children.

#### Prevalence

- By age 10 yr, 80% of children have toxin-specific antibodies.
- Up to 10% of the population contracts group A streptococcal pharyngitis, and 10% of these develop scarlet fever.
- Disease in neonates is uncommon, probably secondary to maternally acquired antibodies.

### RISK FACTORS

Close proximity environments: Day care, schools, dorms, military barracks, and homes

### GENERAL PREVENTION

- Prompt treatment of streptococcal pharyngitis leads to fewer cases of secondary disease/spread.
- Isolate children from school or day care until 24 hr after antibiotic therapy.

### PATHOPHYSIOLOGY

- Caused by infection with pyrogenic exotoxin producing group A beta-hemolytic streptococcus
- Group A streptococcus produces pyrogenic exotoxins A, B, and C, which are responsible for the scarlatiniform rash.
- Group A streptococcus is identified almost exclusively in humans.
- Mode of transmission is via salivary droplets and nasal discharge.

### ETIOLOGY

- See Pathophysiology.
- Group A streptococcus are normal inhabitants of the nasopharynx.

## DIAGNOSIS

### HISTORY

- Fever, sore throat, headache, and rash are classic symptoms.
- Nausea and/or abdominal pain are also common.

### PHYSICAL EXAM

- Many physical exam findings may be present, but only rash is necessary to make the diagnosis, other findings may or may not be present.
- Diffuse, finely maculopapular (sandpaper texture), erythematous eruption that blanches with pressure (scarlatiniform rash):
  - Erythema may be absent in those who are darkly pigmented, such as black or South Asian children
- Skin obtains a rough, goose-pimple appearance that classically has a sandpaperlike texture.
- Tender anterior cervical lymphadenopathy
- Exudative tonsillitis
- Palatal petechiae
- Circumoral pallor is common.
- White, coated tongue during 1st 1–2 days (white strawberry tongue)
- Red strawberry tongue with prominent papillae after day 3.
- Pastia lines may develop in the skin folds of joints.
- Rash appears 24–48 hr after the onset of symptoms and fades after 3–4 days.
- Desquamation of skin may occur within 1–3 wk.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

- No lab testing is necessary, diagnosis is clinical.
- Lab assay to confirm streptococcal pharyngitis, whether by rapid streptococcal agglutination or by throat culture, may be obtained.
  - This plays no role in diagnosis and is only for documenting infection for other purposes, such as frequent streptococcal infection that may warrant tonsillectomy.

### DIFFERENTIAL DIAGNOSIS

- Viral exanthems
- Toxic epidermal necrolysis
- Kawasaki disease
- Erythema multiforme
- Erythema infectiosum
- Infectious mononucleosis
- Pityriasis rosea
- Scabies
- Staphylococcal scalded skin syndrome (SSSS)

## TREATMENT

### INITIAL STABILIZATION/THERAPY

Ascertain hydration status of the patient and the capacity to tolerate oral hydration and medications.

### MEDICATION

#### First Line

- Penicillin, either oral penicillin VK or intramuscular benzathine penicillin, is treatment of choice:
  - < 12 yr of age: 25–50 mg/kg/day PO q.i.d. × 10 days, max 3 g/day
  - > 12 yr: 250–500 mg PO q.i.d. × 10 days (adult dose)
  - Though traditional penicillin dosing was q.i.d., use of the full daily dose divided b.i.d. is acceptable and may result in better compliance.
- Penicillin G benzathine:
  - < 12 yr of age: 25,000–50,000 U/kg single dose IM, max 1.2 million units.
  - > 12 yr: 1.2 million units single dose IM (adult dose)
- Antipyretics/Analgesics:
  - Acetaminophen 15 mg/kg/dose PO/PR q4h PRN
  - Ibuprofen 10 mg/kg/dose PO q6h PRN

**Second Line**

- Antibiotic therapy:
  - Amoxicillin, clindamycin, and 1st-generation oral cephalosporins are also appropriate alternatives.
  - Erythromycin estolate 20–40 mg/kg/day PO divided b.i.d.–q.i.d. × 10 days
  - Azithromycin 12 mg/kg/day PO per day × 5 days, max single dose 500 mg/kg/day
  - These are drugs of choice in patients with documented hypersensitivity to penicillins.
  - In geographic regions where macrolides are routinely used to treat streptococcal infections, *S. pyogenes* typically develops resistance to macrolide antibiotics.
    - *S. pyogenes* resistance to macrolides in the U.S. is low (<10%) but increasing.
- Dexamethasone PO/IM 0.6 mg/kg in a single dose (max single dose 10 mg) may reduce pharyngeal pain and severe tonsillar swelling (1).

**DISPOSITION****Admission Criteria**

- Inability to tolerate PO fluids and PO medications
- Severe dehydration secondary to inability to hydrate orally
- Systemic complications such as pneumonia with hypoxemia or respiratory distress, meningitis, or retropharyngeal abscess may result from streptococcal pharyngitis.

**Discharge Criteria**

Ability to tolerate PO fluids and PO medications

**Issues for Referral**

Development of complications:

- Rheumatic fever
- Poststreptococcal glomerulonephritis

**FOLLOW-UP****FOLLOW-UP RECOMMENDATIONS**

- Educate the patient and parents on the importance of completing the full course of antibiotics.
- Observe the patient for known complications.

**PROGNOSIS**

Appropriately treated scarlet fever typically resolves without sequelae.

**COMPLICATIONS**

- Rheumatic fever
- Peritonsillar abscess
- Poststreptococcal glomerulonephritis
- Sinusitis
- Pneumonia
- Septicemia
- Toxic shock syndrome
- Meningitis

- Abscess, Peritonsillar
- Tonsillitis

ICD9  
034.1 Scarlet fever

**PEARLS AND PITFALLS**

- Scarlet fever may be diagnosed clinically, and no lab testing is required.
- It is important to stress the importance of completing the full course of required antibiotics.

# SCROTAL MASS

Eileen C. Quintana

## BASICS

### DESCRIPTION

- This topic will describe scrotal masses other than hernias.
- Hydrocele is a collection of intrascrotal serous fluid in between layers of the tunica vaginalis.
- Spermatocele is a sperm-containing, benign cyst in the head of the epididymis.
- Varicocele is formed by dilated veins of the pampiniform plexus around the spermatic cord.
- Hematocele is a collection of blood in the tunical vaginalis around the testicle.

### EPIDEMIOLOGY

- Hydroceles are the most commonly found mass in newborn boys (up to 80%), followed by spermatoceles (30%) and varicoceles (20%).
- Congenital hydrocele is present in 6% of newborn males.
- Hematoceles are uncommon.

### RISK FACTORS

- Risk factors for hydroceles are prematurity as well as the use of peritoneal cavity for ventriculoperitoneal shunts, dialysis, and renal transplants
- Risk factors for hematoceles are injuries, particularly contact sports; direct blunt trauma, such as a kick to the groin; or penetrating trauma, such as gunshot wound, stabs, or animal (dog) bites.
- Elevated testicular temperature has been associated with varicocele formation in animal models.

### GENERAL PREVENTION

The use of protection and appropriate gear is the most effective method of preventing testicular trauma and its related consequences.

### PATHOPHYSIOLOGY

- Hematoceles occur when significant trauma causes intratesticular bleeding into the tunica vaginalis, a parietal layer lining the hydrocele sac.
- Hydroceles occur when the processus vaginalis remains patent:
  - Most patients with patent processus vaginalis do not develop hydrocele.
- A patent processus vaginalis that permits flow of peritoneal fluid into the scrotum results in a communicating hydrocele. Indirect inguinal hernias are associated with this type of hydrocele.
- In a noncommunicating hydrocele, a patent processus vaginalis is present, but there is no communication with the peritoneal cavity:
  - Noncommunicating hydroceles do not abruptly change in size and are not reducible, whereas communicating hydroceles may increase in size with Valsalva maneuver and may be reducible.
- Spermatocele formation is theorized to be due a distal obstruction.
- The pathophysiology leading to the formation of either spermatoceles and varicoceles is unknown.

### ETIOLOGY

- Unilateral hematoceles are most commonly caused by blunt testicular trauma in sports injuries, whereas bilateral hematoceles are due to penetrating trauma such as gunshot and stab wounds.
- Other causes for hematoceles are kicks to the groin, motor vehicle accidents, falls/straddle injuries, animal bites, and degloving injuries due to industrial/farming accidents.
- Hydroceles are usually congenital, but they also may be caused by local injury or infection with gradual fluid accumulation.
- Spermatoceles are due to agglutinated germ cells in the efferent ductules in animal models. In humans, their etiology is unclear.
- Varicoceles are commonly found on the left side due to an increased pressure on the left renal vein and the attachment angle and a lack of effective valves at the junction of the left testicular vein and left renal vein.

### COMMONLY ASSOCIATED CONDITIONS

Noncommunicating hydrocele may be associated with:

- Trauma
- Hypoalbuminemia
- Epididymitis
- Mumps
- TB
- *Wucheria bancrofti* or *Loa loa*
- Malignancy

## DIAGNOSIS

### HISTORY

- Hematoceles usually result from injury, so it is important to ask questions related to testicular/scrotal injury. Inquire about:
  - Hematuria
  - Dysuria
  - Inability to void
  - Abdominal pain
  - Vomiting
- Hydroceles, spermatoceles, and varicoceles are usually asymptomatic and found on self-exam or as an incidental finding.
- Hydroceles usually present with an enlarged painless scrotum without systemic or urinary complaints and are common in neonates.
- Patients with abrupt onset of significant scrotal pain should be presumed to have testicular torsion until noted otherwise by physical exam, imaging, or surgical exploration.

### PHYSICAL EXAM

- Hematocele:
  - Extreme scrotal/testicular pain
  - Swollen, severely tender testicle with a visible hematoma
  - Scrotal/perineal ecchymosis
  - In cases associated with penetrating trauma, the exam should focus on identifying entrance and exit sites.
  - Contralateral hemiscrotum and perineum should be inspected.
  - Exam of the femoral vessels, bilateral thighs, and abdomen should be performed to rule out associated injuries.
- Hydroceles are nontender swellings found superoanterior to the testis:
  - They are occasionally bilateral and may be associated with a hernia, especially on the right side.
  - There is lack of systemic signs of illness with normal abdominal and testicular exams.
  - Transillumination is the ability of light to shine through an object. Hydroceles generally do transilluminate, but this is a variable and nonspecific finding.
- Spermatoceles are found superoposterior to the testis and are painless. The diagnosis is dependent on US to differentiate from other causes of scrotal masses.
- Varicoceles can be described as feeling like a bag of worms or heaviness. Its exam is variable: Palpable venous distension to visible venous distension through the skin ("bag of worms"). These lesions are painless.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

- Obtain urinalysis and culture.
- Cultures for STIs should be obtained if warranted by the history and physical.

##### Imaging

- US with Doppler studies is valuable in evaluation of these lesions/masses.
- US can distinguish a hydrocele from a hernia and can assess for testicular torsion in the setting of scrotal swelling and pain.
- Nuclear studies may be helpful in children to determine if there is early, incomplete testicular torsion or following detorsion. Its sensitivity and specificity could be as high as 90%.

**DIFFERENTIAL DIAGNOSIS**

- Testicular torsion
- Torsion of the testicular appendix
- Epididymitis
- Orchitis
- Infection, abscess
- Neoplasm
- Inguinal hernias
- Insect bite

**TREATMENT****INITIAL STABILIZATION/THERAPY**

In cases of multisystem trauma, evaluate and resuscitate the patient accordingly, prioritizing airway, breathing, and circulation before addressing the genitourinary trauma.

**MEDICATION**

Analgesics may be required:

- Ibuprofen 10 mg/kg PO/IV q6h PRN
- Acetaminophen 15 mg/kg PO/PR q4h PRN
- Morphine 0.1 mg/kg IV/IM/SC q2h PRN:
  - Initial morphine dose of 0.1 mg/kg IV/SC may be repeated q15–20min until pain is controlled, then q2h PRN.

**SURGERY/OTHER PROCEDURES**

Surgical scrotal exploration is indicated if:

- Lack of blood flow on Doppler US
- Evidence of testicular injury
- Uncertain diagnosis
- Expanding mass

**DISPOSITION****Admission Criteria**

- Testicular trauma
- Lack of testicular blood flow
- Infection
- Expanding mass
- Strangulation, incarceration
- Concomitant hernias or any other indication for surgical exploration

**Discharge Criteria**

Asymptomatic patients with no evidence of testicular trauma, ischemia, or compromise could be discharged with appropriate urologic follow-up.

**Issues for Referral**

- Immediate urology consultation is warranted if surgical intervention is needed.
- Patients with hydroceles need to have close follow-up:
  - They are unlikely to spontaneously resolve in children > 1 yr of age.
  - They may be associated with hernias that could become incarcerated or strangulated.

- Spermatoceles require surgical intervention only when there is discomfort, pain, or progressive enlargement. Sclerotherapy is available but is less effective and may cause infertility.
- Varicoceles are primarily surgically treated; however, their presence does not necessarily mean a need for immediate surgery. Indications for surgery are persistent pain, testicular atrophy, and documented male infertility.

**FOLLOW-UP****FOLLOW-UP RECOMMENDATIONS**

Discharge instructions and medications:

- Minor trauma causing small hematoceles with intact testicles could be treated with scrotal support, NSAIDs, ice packs, and no activity for 24–48 hr. Follow-up is recommended within 7 days.
- After surgical intervention, follow-up is usually in 24–48 hr as per the individual urologist/surgeon's recommendations.

**PROGNOSIS**

- Most congenital hydroceles resolve spontaneously before 2 yr.
- If they appear later in life, the prognosis is directly related to the etiology.
- Similarly, spermatoceles have good overall prognosis.

**COMPLICATIONS**

- Untreated hematoceles could potentially lead to testicular infarction/ischemia, abscess formation, infertility, or testicular necrosis/atrophy.
- Rarely, large hydroceles, due to mass effect, may compromise the blood supply, leading to testicular ischemia.
- Untreated varicoceles may lead to infertility.

**See Also (Topic, Algorithm, Electronic Media Element)**

Testicular Torsion

**CODES****ICD9**

- 603.9 Hydrocele, unspecified
- 608.1 Spermatocele
- 608.89 Other specified disorders of male genital organs

**PEARLS AND PITFALLS**

- Unilateral hematoceles are most commonly caused by blunt testicular trauma in sports injuries, whereas bilateral hematoceles are due to penetrating trauma such as gunshot and stab wounds.
- Hydroceles are the most commonly found mass in newborn boys.
- In all cases of scrotal masses, US with Doppler studies may assist in establishing a diagnosis.
- Detecting the presence of testicular torsion is of paramount importance when evaluating a scrotal mass.
- In children, a painless scrotal mass or swelling is almost universally benign.

# SCROTAL PAIN

Andy Y. Chang

## BASICS

### DESCRIPTION

- Scrotal pain often is referred to as the “acute scrotum” in literature. Children do not suffer from chronic orchalgia. Subacute scrotal pain is a residual from an acute process.
- Scrotal pain has numerous etiologies: Testicular torsion, torsion of testicular appendages, epididymitis, trauma (see the Trauma, Scrotal and Penile topic), Henoch-Schönlein purpura (HSP), or acute idiopathic scrotal edema:
  - All of the above listed entities can present with scrotal swelling if the process has been present for some time.
  - Presentations without scrotal swelling are indicative of an acute process.
  - The 3 most common presentations of scrotal pain are:
    - Testicular torsion: 23–27% (1,2)
    - Torsion of testicular appendage: 31–46% (1,2)
    - Epididymitis: 19–38% (1,2)
- Nonpainful swelling or intermittent swelling can be indicative of a hydrocele or inguinal hernia.

### EPIDEMIOLOGY

#### Incidence

- Scrotal pain occurred in 0.13% of emergency department visits in a 2-yr period (2).
- Incidence of testicular torsion: 1 in 4,000 (3)

### RISK FACTORS

- Testicular torsion: The lack of proper fixation of the testis and epididymis to the scrotum, or “bell-clapper deformity”
- Epididymo-orchitis: Prepubertal boys with histories of dysfunctional voiding or postpubertal boys who are sexually active

### PATHOPHYSIOLOGY

- Scrotal pain can be due to local inflammatory and/or ischemic processes from testicular torsion, torsion of testicular appendage, or epididymo-orchitis.
- In the acute phase, pain from testicular torsion results from venous congestion causing increased intratesticular pressure and stretching of the tunica albuginea.
- Pain from trauma can be due to:
  - Inflammatory response
  - Subcapsular hematoma causing increased intratesticular pressure and stretching of the tunica albuginea

- Referred abdominal pain occurs because the testicle and epididymis are partially innervated by the aortic and renal plexuses, which share the same nerve roots that innervate the stomach and small intestine.
- Intermittent testicular torsion, where the testicle torses and spontaneously detorses, may occur.

### ETIOLOGY

- Postnatal testicular torsion is due to the bell-clapper deformity, where the tunica vaginalis attaches high on the spermatic cord, allowing for an abnormally mobile testis.
- Perinatal testicular torsion, known as extravaginal torsion, occurs due to lack of fixation of the tunica vaginalis to the scrotal wall.
- Torsion of testicular appendage likely occurs with a large body associated with a small, vascular pedicle.
- Epididymo-orchitis can occur in boys who have urinary tract infections, STIs, or retrograde flow of urine into both epididymides due to dysfunctional voiding.
- HSP can present as scrotal pain, which results from a systemic vasculitis.
- Other causes of scrotal pain include trauma, inguinal hernia, hydrocele, tumor, varicocele, cyst, and acute idiopathic scrotal edema.

## DIAGNOSIS

### HISTORY

- Helpful information includes onset of pain, quality of pain, duration of symptoms, recent trauma, previous episodes, fever, dysuria, urinary frequency, urinary urgency, hematuria, history of trauma, and abdominal symptoms (listed below).
- Patients with testicular torsion may only have abdominal complaints: Nausea, vomiting, and nonspecific abdominal pain.

### PHYSICAL EXAM

- Observe if the patient is in discomfort: Acute process (torsion of testicle or torsion of appendage, epididymitis, trauma)
- Abdominal exam for inguinal bulges, erythema, and fluctuance would indicate hernia.
- Inspect the testicle for position and lie, edema, and erythema.
- Probability of testicular torsion is highly likely with the absence of cremasteric reflexes (1).
  - Eliciting the cremasteric reflex repeatedly can attenuate the reflex and thus give a false, absent reflex.
- Testicles should be palpated, starting with the nonaffected side.

- Torsed appendix testis can present with:
  - A “blue dot sign,” located on the anterior, superior surface of the testicle
  - A firm, small mass with increased point tenderness
- Palpation along the spermatic cord may reveal a firm, tender mass immediately proximal to the upper pole of the testicle, indicating the point of torsion of the cord and indicative of testicular torsion.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

- Urinalysis, urine culture:
  - Should be obtained in all boys who do not have testicular torsion as the cause of scrotal pain
  - 40–90% of boys with epididymo-orchitis may have sterile cultures.
- Urine testing or urethral swab for gonorrhea and chlamydia for patients who are sexually active

#### Imaging

- Doppler US: 89.9% sensitivity, 98.9% specificity, 1% false-predictive value (4)
- Decreased or no flow to the affected side on Doppler US indicates testicular torsion.

### DIFFERENTIAL DIAGNOSIS

See Etiology.

## TREATMENT

All patients with scrotal pain at the time of the emergency department physical exam should have careful consideration of the etiology of the pain. If testicular torsion cannot be excluded by the history and physical exam, a testicular Doppler US or consultation with a urologist is recommended.

### INITIAL STABILIZATION/THERAPY

- Supportive measures
- Nothing PO until testicular torsion has been ruled out.

### MEDICATION

- For testicular torsion, appropriate pain relief with parenteral analgesics
- For torsion of testicular appendage, appropriate oral narcotics or NSAIDs
- For epididymo-orchitis, antibiotics (7–10 days):
  - 1st and penicillin-allergic choice:
    - Sulfamethoxazole/Trimethoprim (trimethoprim 6–12 mg/kg/day divided doses q12h)
  - 2nd choice:
    - Cephalexin 50 mg/kg/day divided q6–8h, max single dose 4 g/day, OR
    - Amoxicillin 25–50 mg/kg/day divided doses q12h OR
    - Nitrofurantoin 5–7 mg/kg/day divided q6h, not to exceed 400 mg/day

- For sexually active patients with epididymo-orchitis, antibiotics for STIs should also be implemented.
- NSAIDs for HSP
- Antihistamines or topical steroids for relief of acute idiopathic scrotal edema
- Antibiotics if cellulitis is present

### SURGERY/OTHER PROCEDURES

- Manual detorsion should be attempted with the aid of US, if available: 33% of torsion will be made worse (laterally torsed instead of medially torsed) (3).
- Patients strongly suspected of having testicular torsion should have emergent scrotal exploration with detorsion and orchiopexies. This is ideally done within 6 hr of onset of pain.

### DISPOSITION

#### Admission Criteria

- Admission is necessary in severe cases of epididymo-orchitis where concern exists for sepsis or need for IV antibiotic delivery.
- Patients with testicular torsion should have scrotal exploration in the operating room.
- Patients with testicular rupture should be repaired in the operating room.
- Consider exploration in the operating room for expanding testicular hematoma.

#### Discharge Criteria

For the majority of patients, once appropriate therapies have been dispensed, including surgical intervention, patients can be released home on the same day as treatment.

#### Issues for Referral

Patients with all other conditions should be referred to a pediatric urologist within 1–3 wk.

### FOLLOW-UP

#### FOLLOW-UP RECOMMENDATIONS

- Patients should follow up with a pediatric urologist in 1–3 wk.
- For torsion of testicular appendix or epididymo-orchitis, patients and parents need to be instructed to return to the emergency department if pain does not abate within 5 days or if pain suddenly increases in severity (could be new onset of testicular torsion).
- For reducible hernias or communicating hydroceles, the parents need to be instructed to observe for fever, pain, nausea, or vomiting as well as redness, firmness, or bulging over the inguinal region. These can be signs of an incarcerated hernia and require reduction and/or emergent evaluation.
- Appropriate medications for particular disease states as indicated above
- Scrotal support, rest, and limited activity for 5–7 days

### Patient Monitoring

- Patients and parents are instructed to report any sudden increase in testicular pain in case they ignore signs and symptoms of new-onset torsion.
- Proper warning to seek immediate medical attention for recurrence of severe testicular pain should be given to all scrotal pain patients and parents.

### PROGNOSIS

- Prognosis for testicular torsion is based on the time of intervention:
  - <6 hr: 90% testicular salvage rate (5)
  - 12 hr: 50% testicular salvage rate
  - >24 hr: <10% testicular salvage rate
- For all other etiologies for scrotal swelling, the prognosis is excellent for return to normal health.

### COMPLICATIONS

- Testicular torsion: Loss of testicle if not detorsed in a timely manner
- Epididymo-orchitis: Sterility, abscess, testicular-scrotal fistula, and testicular infarction

### CODES

#### ICD9

- 608.9 Unspecified disorder of male genital organs
- 608.20 Torsion of testis, unspecified
- 608.23 Torsion of appendix testis

### PEARLS AND PITFALLS

- Scrotal pain and missed testicular torsion is a highly litigious area of medical practice.
- Scrotal pain can be easily evaluated with a thorough history and physical.
- Doppler US is highly helpful and recommended if the diagnosis is unclear.
- Patients with high index of suspicion for testicular torsion should be evaluated by a urologist and surgically explored for definitive treatment with minimal delay:
  - US can be obtained if it does not delay urologic evaluation or surgical exploration in situations where testicular torsion is highly suspected.
- Exam in a cold room can cause contraction of the scrotum, diminishing the effectiveness of the cremasteric reflex exam. Thus, one of the 1st exams to perform after removing the boy's underwear or diaper is to elicit the cremasteric reflex.
- Undescended testicles are at increased risk of torsion compared to descended testicles. Thus, a high index of suspicion for testicular torsion should be had for patients presenting with vague abdominal complaints and pain on the side of the undescended testicles.

# SCROTAL SWELLING

Kajal Khanna  
Deborah R. Liu

## BASICS

### DESCRIPTION

- Scrotal swelling is a not uncommon chief complaint that may present acutely or gradually and may be painful or painless.
- Abrupt onset of painful scrotal swelling necessitates immediate evaluation.
- Some causes of painless scrotal swelling may be worked up nonemergently.
- Lesions primary to the scrotal contents, the scrotal wall or skin, or the inguinal canal may initiate scrotal swelling.

### EPIDEMIOLOGY

- Painful scrotal swelling:
  - Peak incidence of epididymitis: 8–12 yr of age (1)
  - Peak incidence of testicular torsion: 12–16 yr of age (1)
  - Torsion of appendix testis is distributed throughout 1–14 yr of age (1).
- Painless scrotal swelling:
  - Testicular tumors: 1 in every 100,000 boys per year (2); 1–2% of all pediatric solid tumors
  - Simple (scrotal) hydrocele is seen in 1–2% of male neonates (3).
  - Congenital inguinal hernia is reported in 0.8–4% of live births:
    - 13% of infants <32 wk gestation
    - 30% of infants <1,000 g birth weight (4)

### RISK FACTORS

- Testicular torsion:
  - Previous contralateral testicular torsion
  - History of intermittent torsion
- Hydrocele:
  - Ventriculoperitoneal shunt
  - Ehlers-Danlos syndrome
  - Peritoneal dialysis
- Inguinal hernia:
  - Prematurity
  - Cryptorchidism
  - Hypospadias or epispadias
  - Bladder exstrophy
- Epididymitis:
  - Obstructive anatomic abnormalities
  - Anorectal malformations
  - Indwelling urinary catheters
  - Recent urinary tract instrumentation
  - Sexual intercourse without a condom

### PATHOPHYSIOLOGY

- Testicular torsion involves cessation of blood flow to the testis. 2 types occur:
  - Extravaginal torsion:
    - Occurs in prenatal and neonatal age groups
    - Lack of testicular fixation in the scrotum allows the testis, spermatic cord, and tunica vaginalis to twist.
  - Intravaginal torsion:
    - Occurs in all age groups
    - Spermatic cord twists inside the tunica vaginalis due to high insertion on the cord, allowing the testis to turn freely within the scrotum
    - Testis has more transverse lie (“bell-clapper deformity”) and is more prone to twist.

- Torsion of appendix testis:
  - Appendix testis is a stalklike structure attached to the upper pole of the testis.
  - With torsion, progressive inflammation and swelling of the testis and epididymitis occur.
- Inguinal hernia:
  - Incomplete obliteration of the processus vaginalis leaves a sac of peritoneum extending all the way from the internal inguinal ring to the scrotum through which a protrusion of abdominal contents may occur.
- Hydrocele:
  - Collection of fluid between the layers of the tunica vaginalis surrounding the testis
  - Communicating hydrocele: Associated with the patent processus vaginalis allowing fluid to freely communicate with the scrotal portion of the processus
  - Noncommunicating (simple) hydrocele:
    - Accumulation of fluid within the tunica vaginalis resulting from delayed closure of the processus vaginalis
    - The processus is obliterated, and fluid is trapped within the tunica vaginalis.
- Varicocele: Ectatic and tortuous veins of the pampiniform plexus of the spermatic cord
- Spermatocele: Collection of sperm/fluid in the epididymis
- Testicular tumor:
  - Painless scrotal mass within the testis
  - May be primary testicular malignancy or metastasis
  - Testicular malignancy:
    - Germ cell tumor: 77%; yolk sac tumor: 82% of germ cell tumors
    - Gonadal stromal tumor: 8%
    - Gonadoblastoma: 1%
    - All others (lymphoma, leukemia): 14% of testicular malignancies
  - Metastasis by hematogenous and lymphatic spread

### ETIOLOGY

- Painful scrotal swelling:
  - Testicular torsion
  - Torsion of appendix testis
  - Epididymitis/orchitis
  - Inguinal hernia (incarcerated or strangulated)
  - Trauma:
    - Ruptured testis
    - Hematocele
  - Henoch-Schönlein purpura
  - Infection with *Wucheria bancrofti* (lymphatic filariasis)
  - Cellulitis, abscess

- Painless scrotal swelling:
  - Hydrocele
  - Inguinal hernia (nonincarcerated)
  - Varicocele
  - Spermatocele
  - Acute idiopathic scrotal edema
  - Testicular tumor
  - Allergic reaction
  - Bilateral painless scrotal swelling can be seen in nephrotic syndrome or other conditions producing generalized edema due to hypoproteinemia

## DIAGNOSIS

### HISTORY

- Painful scrotal swelling:
  - Historical features have not been found to be statistically significantly different between causes of painful scrotal swelling.
  - More likely to see systemic symptoms such as nausea and vomiting in testicular torsion than in other causes of painful scrotal swelling
  - Shorter duration of symptoms seen in patients with testicular torsion or torsion of the appendix testis (1)
  - Consider testicular rupture or testicular hematoma with history of traumatic event to the genitalia, associated scrotal discoloration, pain, or rapid onset of swelling and tenderness.
  - Henoch-Schönlein purpura:
    - May have acute or insidious scrotal pain
    - Scrotal pain may be only presenting complaint.
    - Usually accompanied by purpuric rash on the lower extremities and scrotum
  - History of travel
  - Sexual activity in adolescents
  - Fever
- Painless scrotal swelling:
  - Simple (scrotal) hydrocele: Commonly seen at birth and frequently bilateral
  - Communicating hydrocele:
    - History of variation in size
    - Tends to become larger as the day progresses due to upright position
  - Inguinal hernia:
    - Mass gets bigger with crying, bowel movements, and increased abdominal pressure.
    - Vomiting or abdominal pain may indicate strangulation or incarceration of hernia contents.
  - Varicocele is typically asymptomatic but may present with dull, aching scrotal pain or heaviness.
  - Exposure to allergen, pruritus
  - Generalized swelling or edema

**PHYSICAL EXAM**

- Painful scrotal swelling:
  - Observe scrotal asymmetry, position of testes
  - Scrotal erythema, discoloration, induration, fluctuance
  - “Blue dot sign” suggests torsed appendix testis.
  - Assess for cremasteric reflex. Absence of the cremasteric reflex suggests testicular torsion (1,5).
  - Isolated tenderness of the superior pole of the testis suggests torsion of the appendix testis.
- Painless scrotal swelling:
  - If painless scrotal swelling transilluminates, consider hydrocele or spermatocele.
  - Simple hydrocele:
    - Transilluminates, may be tense
    - Large hydroceles may extend toward the inguinal ring.
  - Communicating hydrocele:
    - Attempt to compress the hydrocele.
    - If fluid drains into the abdomen, patent processus must be present.
  - Inguinal hernia:
    - Swelling extends along the inguinal canal and into the scrotum
    - Palpating the hernia sac over the cord structures may be similar to that of rubbing 2 layers of silk together (“silk glove sign”).
  - Varicocele:
    - Typically left-sided
    - Painless mass above the testis
    - “Bag of worms” that disappears when supine
  - Spermatocele:
    - Distinct mass separate from the testis
    - Transilluminates as a cystic mass
  - Testicular tumor:
    - Very hard, nontender testis
    - Palpated within testis
    - Does not transilluminate

**DIAGNOSTIC TESTS & INTERPRETATION****Lab**

- Lab tests are generally not helpful.
- With nephrotic syndrome:
  - Urinalysis reveals proteinuria.
  - Serum tests: Hypoalbuminemia, hyperlipidemia
- With epididymitis, urinalysis may show pyuria.
- With testicular tumors, CBC, tumor lysis labs, serum alpha-fetoprotein (AFP), and serum hCG are useful:
  - Yolk sac tumors are associated with elevated AFP in 80% of patients.
  - Yolk sac elements will stain positive for AFP on immunohistochemical staining.
  - Teratomas: Not associated with elevated AFP levels and do not stain positively for AFP

**Imaging**

US with color flow Doppler is the most useful imaging technique:

- Testicular torsion:
  - Decreased or absent blood flow to the symptomatic testis and normal blood flow to asymptomatic testis (6)
  - Specificity of technically adequate studies is 100% (6).

- Torsion of appendix testis:
  - Normal to increased testicular blood flow
  - May see a small hyper- or hypoechoic mass adjacent to the superior aspect of the testis or epididymis (6)
- Epididymitis may also show normal to increased testicular blood flow.
- Traumatic hematocele; acutely echogenic fluid collection eventually organizes into complex septated cystic fluid (6)
- Testicular tumor:
  - Overall heterogeneity of the mass
  - Near 100% sensitivity for detecting testicular neoplasia
  - US cannot distinguish between benign and malignant intratesticular tumors.

**DIFFERENTIAL DIAGNOSIS**

- See Etiology.
- Normal testicular enlargement with puberty

**TREATMENT**

- For further, specific management, see topics on Testicular Torsion; Hernia; Henoch-Schönlein Purpura; Nephrotic Syndrome; Rash, Urticaria; and Scrotal Pain.
- Torsion appendix testis: Conservative management (analgesics, scrotal support, minimization of activity)
- Idiopathic scrotal edema: Conservative management (rest, scrotal support)
- All intratesticular masses should be assumed to be malignant until proven otherwise:
  - Treatment of malignant tumors is stage specific and involves chemotherapy, surgery, and radiation.
  - Testicular neoplasms require hospitalization or immediate follow-up with a pediatric oncologist.
  - Treatment is determined by pathologic grade and stage.

**DISPOSITION****Admission Criteria**

Depends on the diagnosis

**Discharge Criteria**

With the exception of testicular tumors or systemic diseases with localized scrotal swelling as a manifestation, painless scrotal swelling can generally be managed as an outpatient.

**Issues for Referral**

Depends on the diagnosis

**FOLLOW-UP****FOLLOW-UP RECOMMENDATIONS**

- Acute testicular torsion requires emergent evaluation by a urologist.
- Incarcerated inguinal hernia requires emergent evaluation by a urologist or surgeon.
- Reducible inguinal hernias may be evaluated electively as an outpatient.
- For patients diagnosed with epididymitis/orchitis or torsion appendix testis, patients should be instructed to return to the emergency department if there is no improvement in symptoms in 5–7 days or if there is sudden worsening pain.

**PROGNOSIS**

Depends on the etiology of the scrotal swelling

**COMPLICATIONS**

Depends on the etiology of the scrotal swelling

**PEARLS AND PITFALLS**

- Pearls:
  - To narrow the differential diagnosis, scrotal swelling may be categorized as painful or painless.
  - Acute onset of painful scrotal swelling requires emergent evaluation.
- Pitfalls:
  - While many causes of painless scrotal swelling may be evaluated and treated electively as an outpatient, a few require more emergent attention, such as testicular tumors.

# SEBORRHEIC DERMATITIS

Stephen M. Reingold

## BASICS

### DESCRIPTION

- Seborrheic dermatitis (SD) is a chronic and relapsing skin disorder (1).
- Lesions are scaly and erythematous (1):
  - Sebaceous gland distribution: Scalp (“cradle cap”), face, postauricular, intertriginous areas

### EPIDEMIOLOGY

Most common in infancy but also occurs in older children, adolescents, and adults (2):

- Usually begins by 5 mo of age and resolves by 1 yr of age
- Occurrence of SD as an infant does not predict disease occurrence as an adolescent or adult.

### RISK FACTORS

- Genetic predisposition may exist
- Colonization with *Malassezia*
- AIDS

### PATHOPHYSIOLOGY

- *Malassezia* yeast, *Pityrosporum ovale*, is a commensal skin organism believed to be contributory (3).
- Altered immune response to yeast may play a role.

### ETIOLOGY

Unknown but possibly multifactorial

## DIAGNOSIS

### HISTORY

- Skin rash with characteristic crusting or flaking of skin
- Usually begins by 5 wk of age
- There is absence of pruritus in infants, but older children and adolescents typically experience significant pruritus.
- Children and adolescents may have history of attempting to use multiple shampoos, creams, or lotions to treat.

### PHYSICAL EXAM

- Greasy yellow or orange scales on an erythematous base
- Cradle cap distribution in infants
- May involve the forehead, eyebrows, nasolabial folds, and retroauricular area
- Less commonly involves axillary and inguinal folds
- Posterior lymphadenopathy may be present.
- Adolescent presentation may be more similar to dandruff.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

No routine tests:

- KOH prep and fungal culture may help to differentiate from fungal infections.
- Biopsy is rarely needed.

### DIFFERENTIAL DIAGNOSIS

- Tinea capitis: Erythematous annular and scaly plaque with alopecia
- Atopic dermatitis: Usually presents at a later age, is accompanied by extreme pruritus, and is found on extensor surfaces in infants and on flexor surfaces thereafter. However, it may occur concomitantly with SD.
- Fungal coinfection: May be diagnosed with a KOH prep, or consider trial of antifungal cream
- Diaper dermatitis: Red plaques, nongreasy and on convex surfaces
- Psoriasis: Well-demarcated annular red-brown plaques on extensor surfaces, trunk, scalp, and diaper areas; may occur concomitantly with SD
- Exfoliative erythroderma: Diffuse desquamation. Consider erythrodermic SD (below).
- Histiocytosis: Purpura, petechiae, adenopathy, hepatosplenomegaly and erosions of the axilla, inguina or oral mucosa
- Erythrodermic SD (Leiner disease): Generalized skin involvement, failure to thrive, diarrhea, immune deficiency, metabolic disorder

## TREATMENT

### MEDICATION

#### First Line

- Mild application of olive oil or petroleum for 20 min and washed off in the bath is sufficient treatment for most cases:
  - Scraping with a comb may cause injury.
- Sulfur or salicylic acid shampoo topically for several days to treat infants
- Zinc pyrithione or selenium sulfide–containing shampoo is used for older children and adolescents (4).

#### Second Line

- Topical steroids: Hydrocortisone 1%, betamethasone 0.05%:
  - Typically, a low-potency steroid is the initial therapy, but moderate or high-potency steroids may be used in cases of low-potency steroid failure or severe disease.
- Topical antifungals: Ketoconazole 2% (5)
- Ketoconazole 3.3–6.6 mg/kg PO per day × 10 days

### DISPOSITION

#### Discharge Criteria

SD patients can be discharged home unless there is an associated indication for admission, such as HIV complications,

#### Issues for Referral

If the diagnosis is uncertain or symptoms are severe, refer to a dermatologist.

## FOLLOW-UP

### FOLLOW-UP RECOMMENDATIONS

Follow up if symptoms do not resolve with recommended therapy.

### PROGNOSIS

- Generally good (6)
- Symptoms usually resolve with treatment.
- Typically resolves within months

### COMPLICATIONS

- Erythroderma: Disseminated dermatitis covering most of body surface, prone to bacterial superinfection
- Recurrence of symptoms

- Diaper Rash
- Psoriasis
- Rash, Neonatal

## CODES

### ICD9

- 690.10 Seborrheic dermatitis, unspecified
- 690.11 Seborrhea capitis
- 690.12 Seborrheic infantile dermatitis

## PEARLS AND PITFALLS

- When occurring in flexural folds, SD may be misdiagnosed as diaper dermatitis.
- Beware of unusual presentations of SD.
- Consider differential diagnoses with presentations other than classic, typical SD.
- Presentation beyond infancy may represent other diseases.

# SEIZURE

Barbara Csányi  
Robert J. Hoffman

## BASICS

### DESCRIPTION

- Seizure involves transient occurrence of signs and/or symptoms causing cognitive, motor, or sensory dysfunction due to abnormal excessive or synchronous neuronal activity in the brain.
- Seizures are classified in several manners:
  - Seizure appearance:
    - Generalized tonic-clonic seizures are the most common and severe.
    - Partial complex seizures are focal.
    - Absence seizures are a unique form of seizure that do not pose a relevant physiologic risk to the patient. They will not be discussed here.
  - Fever status—febrile or afebrile seizure:
    - Febrile seizures occur in children 6 mo to 6 yr of age secondary to fever. See the Febrile Seizure topic for more information:
      - Typical or simple: Lasts <15 min, generalized tonic-clonic type of convulsions, between the age of 6 mo and 6 yr, no recurrence in the next 24 hr
      - If not meeting criteria above, then it is a complex or atypical febrile seizure
    - Afebrile seizure; occurring in the absence of detected fever
  - Provoked vs. unprovoked:
    - Provoked seizure has clear etiology that does not involve baseline neurologic issues (eg, hypoglycemia, drug ingestion, head trauma).
    - Unprovoked seizure: No clear trigger factor
  - Status epilepticus: 1 continuous unremitting seizure lasting >30 min or recurrent seizures without regaining consciousness between seizures >30 min
  - See the Status Epilepticus topic.
  - Epilepsy:  $\geq 2$  unprovoked seizures (not due to known causes such as fever, CNS infection, toxin, etc.)
  - Pseudoseizures, more appropriately called *nonepileptic paroxysmal events*, mimic seizures but do not involve abnormal, rhythmic discharges of neurons. They are caused by physiologic or psychologic conditions.

### EPIDEMIOLOGY

- Epilepsy occurs in 5/1,000 children.
- 1% of children have a seizure before adolescence.
- 5% of children experience a febrile seizure.
- Pseudoseizures are most common in adolescents and patients with seizure disorders.

### RISK FACTORS

- Epilepsy
- Family history of epilepsy
- Fever
- Hypoglycemia
- Drug abuse
- Head trauma
- CNS infection
- CNS malignancy
- Metabolic disorder

### GENERAL PREVENTION

- Anticonvulsants may prevent seizures in patients with seizure disorders.
- Use of protective helmets when bicycling or playing sports protects against head trauma.
- Vaccination may prevent CNS infections.
- Limiting access to toxins and medications can prevent toxin or medication-induced seizures.

### PATHOPHYSIOLOGY

- Abnormal excessive or synchronous neuronal activity in the brain can be provoked by different factors:
  - These include depolarizing/excitatory effects of GABA or lack thereof, agonism or excitatory effects of glutamate or other agonists at NMDA receptors, gap junction abnormalities, ionic milieu, hormonal influences, immature brain myelination, and other factors.
- Focal brain insults, such as head trauma, as well as an epileptic focus may involve a local focus of excessive neuronal discharge. This is usually apparent on EEG.
- Conditions with global brain insult, such as hypoglycemia, hypoxia, toxin exposure, or CNS infection, cause more global dysfunction. This global dysfunction is apparent on EEG.

### ETIOLOGY

See Description and Risk Factors.

### COMMONLY ASSOCIATED CONDITIONS

- See Risk Factors.
- Developmental delay

## DIAGNOSIS

### HISTORY

- Typically, a history of abnormal motor movement and/or impaired consciousness is given.
- Inquire about activity preceding the seizure event. This includes possible trauma, toxin exposure, antecedent fever or illness, and recent vaccinations.
- What was the patient doing before the seizure (minutes, hours)? What time of the day did it happen? Had the patient eaten that day?
- Twitching, eye deviation, aphasia, or aphasia suggest seizures.
- Palpitations, sweating, dizziness that suggest other causes
- Did the patient lose consciousness? This may be difficult to elicit in infants, but loss of postural tone is suggestive of generalized seizure. Speaking during an event or purposeful movement does not occur with generalized tonic-clonic seizure but may occur with partial complex seizure.
- Ask about any accompanying movements as well as eye deviation, urination, and loss of postural tone.
- Color change, particularly pallor, may occur prior to or during any seizure. Cyanosis may occur with severe seizures due to inadequate oxygenation during seizure. Breath-holding may also cause cyanosis.

- Quantify the number of seizures and the duration:
  - Caregivers may have difficulty quantifying the duration of seizure, but giving a reference, such as “Did the seizure last longer than a television commercial?” or “Was the seizure still occurring when the ambulance arrived at your home?” may be helpful.
- Were postictal symptoms present? Immediate recovery of normal mental status suggests etiology other than seizure.
- Ask the patient about aura and recollection of the event.
- Past medical history, including developmental milestones, current or recent medical treatment including vaccinations, previous seizure episodes, and any previous neurologic evaluation and diagnoses

### PHYSICAL EXAM

- Assess vital signs:
  - Fever may commonly be present. Rectal thermometry is preferred due to potential inaccuracy of other methods of measurement, such as tympanic and temporal measurement.
  - Note adequacy of respirations, oxygenation, and circulation.
- HEENT:
  - Evaluate for pupil size and reactivity, ears for infection, hemotympanum, and Battle sign.
  - Evaluate the oropharynx for evidence of infection or injury such as tongue or lip biting.
- CNS:
  - Note current mental status. Though the Glasgow Coma Score is intended for trauma, it is commonly used to gauge the level of cognitive function after seizure.
  - Infection: Meningismus if patient relaxed during the interictal period
- Respiratory: Note adequacy of air entry or rales, rhonchi, crackles, or wheeze suggestive of aspiration or infection.
- Dermatologic: Note rashes (eg, petechiae or ecchymosis), capillary refill, extremity temperature, and skin turgor.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

- Assess bedside serum glucose in any patient with altered mental status or recent seizure.
- Other assays may be indicated based on history, but no tests are routinely indicated:
  - Serum electrolytes may be assayed if there is specific concern about abnormality. Routine use is not helpful and not recommended.
  - In febrile or ill-appearing patients, evaluation for infection, such as urinalysis and culture, blood culture, CBC and C-reactive protein, and CSF analysis and culture
  - Serum anticonvulsant concentration, such as phenytoin, carbamazepine, or valproic acid level, in patients taking these medications.
  - Prolactin: Released in large amounts in tonic-clonic seizures; not 100% sensitive/specific but helpful to detect pseudoseizure

**Imaging**

CT of brain is rarely indicated:

- If trauma, focal neurologic deficit, or history is suggestive of an intracranial mass, emergent imaging is warranted.
- CT of the brain is not routinely indicated for seizure without associated problems.

**Diagnostic Procedures/Other**

- ECG
- EEG monitoring may be indicated if status epilepticus is present but is not routinely indicated from the emergency department:
  - This will typically be performed at a later time.

**DIFFERENTIAL DIAGNOSIS**

- Nonseizure motor activity:
  - Myoclonus
  - Fasciculation
  - Shivering
  - Sandifer syndrome
  - Pseudoseizure
  - Loss of consciousness from other etiology
- Apparent life-threatening event
- Syncope

**TREATMENT****PRE HOSPITAL**

- Assess and stabilize airway, breathing, and circulation.
- Check fingerstick glucose, and treat hypoglycemia if present.
- Administer anticonvulsant if indicated.

**INITIAL STABILIZATION/THERAPY**

- Assess and stabilize airway, breathing, and circulation.
- Supportive care, with maintenance of vital signs within acceptable limits
- Specific treatment for underlying etiology, such as fever or hypoglycemia

**MEDICATION****First Line**

- The traditional algorithm for medication administration is benzodiazepine × 3 doses followed by barbiturate.
- Due to the advent of highly effective medications such as fosphenytoin, propofol, and valproic acid, these newer medications may be used instead of barbiturates after initial use of benzodiazepines fails.
- Antipyretics:
  - Fever in children 6 mo to 6 yr of age may be due to febrile seizure. Treat with an antipyretic.
  - Acetaminophen 15–30 mg/kg PR; 30 mg/kg only appropriate for initial loading dose:
    - IV formulation expected in U.S. in 2011
  - Ibuprofen 10 mg/kg IV. Caldolor is a new parenteral ibuprofen formulation.
  - IV antipyretics have potential value in treating febrile status epilepticus.
- Benzodiazepines:
  - Diazepam 0.1 mg/kg IV, 0.5 mg/kg PR:
    - Repeat dosing IV q5min PRN.
    - Short-acting benzodiazepine; IV route preferred but may be given PR
    - Brief duration of action and little residual sedation but imparts risk of seizure recurrence

- Lorazepam 0.05 mg/kg IV:
  - Repeat dosing q5–10min PRN.
  - Longest-acting widely used benzodiazepine
  - Longest duration of anticonvulsant activity and longest postadministration sedation
- Midazolam 0.1 mg/kg IV/IM:
  - Repeat dosing q5min PRN.
  - Short-acting benzodiazepine, given by IM route if vascular access is not available
  - Brief duration of action and little residual sedation but carries risk of seizure recurrence

**Second Line**

If further treatment is required, refer to the Status Epilepticus topic.

**DISPOSITION****Admission Criteria**

Critical care admission criteria:

- Status epilepticus or severe underlying cause, such as head trauma

**Discharge Criteria**

Full recovery without neurologic deficit; no precipitant capable of causing recurrent seizures, such as toxin ingestion; and no etiology warranting admission such as head trauma

**Issues for Referral**

Patients should generally be referred to a neurologist. Provoked seizures, such as toxin exposure or hypoglycemia, may not need referral.

**FOLLOW-UP****FOLLOW-UP RECOMMENDATIONS**

- Discharge instructions and medications:
  - Take medications such as antipyretics or anticonvulsants as indicated.
- Activity:
  - Certain activity such as driving or swimming may be contraindicated.

**Patient Monitoring**

- Monitor for seizure recurrence.
- Monitor for anticonvulsant toxicity, such as dizziness or loss of coordination.

**DIET**

- Ketogenic diet for some seizure patients
- Limit or avoid caffeine and chocolate.

**PROGNOSIS**

- Varies with underlying etiology
- Patients with febrile seizures tend to have an excellent prognosis.
- Febrile or afebrile seizures may progress to epilepsy.
- Most patients with toxin-induced seizures have a good prognosis and make a full recovery.
- Seizure causing head trauma or CNS infection is more likely to cause permanent neurologic injury.
- Brief seizures <5–10min are not believed to result in any neurologic injury.
- Status epilepticus may result in permanent neurologic insult as well as high mortality.

**COMPLICATIONS**

- Tongue biting or trauma from striking the head or limbs during a fall or tonic-clonic movement
- Hypoxia, hypoglycemia, metabolic acidemia, and neurologic injury from prolonged seizure

**ADDITIONAL READING**

- Berg AT, Berkovic SF, Brodie MJ, et al. Revised terminology and concepts for organization of seizures and epilepsies: Report of the ILAE Commission on Classification and Terminology, 2005-2009. *Epilepsia*. 2010;51:676.
- Fein JA, Lavelle JM, Clancy RR. Using age-appropriate prolactin levels to diagnose children with seizures in the emergency department. *Acad Emerg Med*. 1997;4:202–205.
- Murphy CC, Trevathan E, Yeargin-Allsopp M. Prevalence of epilepsy and epileptic seizures in 10-year-old children: Results from the Metropolitan Atlanta Developmental Disabilities Study. *Epilepsia*. 1995;36:866.

**See Also (Topic, Algorithm, Electronic Media Element)**

- Febrile Seizure
- Status Epilepticus

**CODES****ICD9**

- 345.10 Generalized convulsive epilepsy, without mention of intractable epilepsy
- 345.40 Partial epilepsy, without mention of intractable epilepsy
- 780.39 Other convulsions

**PEARLS AND PITFALLS**

- Based on the history and physical exam, differentiate between seizure and other causes.
- Febrile seizures are typically benign, but determination if the child has serious bacterial infection including meningitis is critical.
- Afebrile seizures may herald epilepsy, but no lab testing or imaging is routinely necessary in the emergency department, only referral to neurology.
- Seizure without focal or other abnormal neurologic findings is not consistent with or suggestive of meningitis.
- Allow 5–10 min of seizure activity before giving a benzodiazepine while providing adequate support to maintain oxygenation.

## BASICS

### DESCRIPTION

- Sepsis is a response to infection manifested by evidence of systemic inflammatory response syndrome (SIRS) in the setting of infection.
- By definition, SIRS is defined as  $\geq 2$  of the following (1):
  - Temperature  $>38^{\circ}\text{C}$  or  $<36^{\circ}\text{C}$
  - Tachycardia
  - Tachypnea
  - WBC  $>12,000/\mu\text{L}$  or  $<4,000/\mu\text{L}$  or  $>10\%$  band forms
- Severe sepsis is SIRS associated with organ dysfunction, hypoperfusion, and hypotension.
- Septic shock is severe sepsis with hypotension despite adequate fluid resuscitation and the presence of perfusion abnormalities such as lactic acidosis, oliguria, and mental status changes.
- Most children with severe sepsis have significant underlying medical conditions.
- Mortality rates are in excess of 10% for children with severe sepsis.

### EPIDEMIOLOGY

#### Incidence

In children, it is estimated that there are  $>40,000$  cases of severe sepsis annually and an annual incidence of 0.56 cases per 1,000 children (2):

- Highest in infants at 5.16 per 1,000
- Lowest in children 10–14 yr of age at 0.20 per 1,000

### RISK FACTORS

- Infants and younger children
- Children with traumatic injuries
- Children with underlying medical conditions
- Immunocompromised children: Malignancy, HIV/AIDS, sickle cell disease, congenital immunodeficiencies
- Indwelling catheters and other fixed surgical devices

### GENERAL PREVENTION

Vaccinations against *Haemophilus influenzae* type b, *Streptococcus pneumoniae*, *Meningococcus*, and other childhood diseases have significantly decreased the rate of infections and sepsis.

### PATHOPHYSIOLOGY

- SIRS and sepsis are a combination of the direct influence from the infecting agent and the host response to infection that occurs from the cellular to organ level.
- Inflammatory mediators (cytokines) are induced, including tumor necrosis factor and interleukins. These are key players in the pathogenesis of sepsis.
- The initial response to sepsis is typically peripheral vasoconstriction and decreased capillary blood flow in order to preserve vital organ function.
- Initially, cardiac output is typically high/normal but may become low in severe septic shock:
  - Multiple organ dysfunction syndrome (MODS) develops in severe untreated or unresponsive septic shock.

### ETIOLOGY

- Bacterial:
  - Gram-negative including *Escherichia coli*, *Neisseria meningitidis*, *H. influenzae* type b, and *Pseudomonas aeruginosa*
  - Gram-positive including *Staphylococcus aureus*, *S. pneumoniae*, *Staphylococcus epidermidis* (in children with indwelling lines and hardware), and *Enterococcus* species
- Viruses including herpes simplex virus, influenza, enterovirus, and adenovirus
- Fungi including *Candida* species

## DIAGNOSIS

### HISTORY

- Fever, decreased feeding, and progressive lethargy
- Other historical features include:
  - CNS: Fatigue, confusion, encephalopathy
  - Pulmonary: Tachypnea, shortness of breath, cough
  - Renal: Oliguria, dysuria, concentrated or foul-smelling urine, flank pain
  - GI: Vomiting, diarrhea, loss of appetite, abdominal pain
  - Dermatologic: Rash, cool extremities
  - Genitourinary: Vaginal discharge, untreated or suspected STI, retained tampon or foreign body

### PHYSICAL EXAM

- The aforementioned defining signs of SIRS/sepsis (fever/hypothermia, tachycardia, tachypnea)
- Cardiovascular: Hypotension, poor pulses, bounding pulses in cases of compensated or "warm shock," delayed capillary refill ( $\geq 3$  sec)
- Pulmonary: Tachypnea, wheezes or rales
- GI: Abdominal tenderness (generalized or localized), peritoneal signs, hypoactive bowel sounds, flank pain
- CNS: Lethargy, confusion, agitation, nuchal rigidity
- Dermatologic: Generalized erythema (toxic shock syndrome), localized erythema (cellulitis, myositis, abscess), petechiae and purpura (meningococemia), mottled skin, cool skin
- Genitourinary: Adnexal tenderness and fullness, retained tampon or foreign body

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

- CBC with differential demonstrating WBCs  $\leq 4,000/\mu\text{L}$  or  $\geq 12,000/\mu\text{L}$  with an increased number of neutrophils or band forms
- Blood culture (aerobic and anaerobic)
- Urinalysis with leukocyte esterase, nitrites, or  $\geq 5$  WBCs/hpf and urine culture
- Electrolytes with abnormal sodium or potassium, evidence of metabolic acidosis, elevated BUN or creatinine, and elevated or diminished glucose
- Blood gas demonstrating metabolic acidosis, hypercarbia, or a calculated base deficit of more than 5.
- Elevated serum lactate
- Elevated C-reactive protein

- Consider a random cortisol level to assess for actual or relative adrenal insufficiency.
- If meningitis is suspected, CSF studies are indicated if the patient is stable.
- Prolonged PT, INR, PTT, positive D-dimer, elevated fibrinogen

### Imaging

Consider as indicated:

- Chest radiograph
- Abdominal radiograph
- Abdominal CT scan if intra-abdominal infection or malposition is suspected

### Diagnostic Procedures/Other

If a known or suspected source of infection exists, removal and appropriate testing is paramount.

### DIFFERENTIAL DIAGNOSIS

- Pneumonia
- Severe dehydration
- Toxic ingestion
- Acute renal failure
- Fulminant hepatic failure

## TREATMENT

### PRE HOSPITAL

- Airway and breathing:
  - Oxygen by nasal cannula or face mask if the airway is patent and breathing is spontaneous
  - Assisted breathing via bag-valve-mask, laryngeal mask airway, or intubation if unable to maintain oxygen saturations  $>95\%$
- Circulation:
  - Obtain IV or intraosseous access.
  - Administer 20 mL/kg normal saline (NS) over 15–20 min.
  - Repeat 20 mL/kg aliquots of fluid.

### INITIAL STABILIZATION/THERAPY

- Reassess airway and breathing:
  - Continue supplemental oxygen.
  - Intubate if unable to maintain adequate oxygenation/ventilation.
- Circulation:
  - Continue fluid resuscitation until signs of shock have resolved or if evidence of fluid overload develops (eg, pulmonary rales, hepatomegaly).
  - Volume resuscitation with isotonic fluids (NS or lactated Ringer) of at least 60 mL/kg is the mainstay of resuscitation.
  - Boluses should continue to be given over 15–20 min if symptoms of shock persist, such that at least 60 mL/kg are given in the 1st 1 hr (3).

### MEDICATION

#### First Line

- General: Broad-spectrum antibiotics to cover gram-positive and gram-negative bacteria:
  - Vancomycin 40 mg/kg/day IV divided q6h, max 2 g/day), AND
  - Ceftriaxone 50–100 mg/kg IV per day, max 2 g

- In the immunocompromised patient, additional coverage for *P. aeruginosa* and less typical bacteria is necessary:
  - Vancomycin 40 mg/kg/day IV divided q6h, max 2 g/day, AND
  - Ceftazidime 90–150 mg/kg/day IV divided q8h, max 6 g/day, OR
  - Cefepime 100 mg/kg/day IV divided q12h, max 1–2 g q12h
- For suspected intra-abdominal sources, coverage for enteric and anaerobic organisms is necessary:
  - Ampicillin 100–400 mg/kg/day IV divided q4–6h, max 12 g/day
  - Gentamicin: Dosing is based on age and weight (> 1 mo old: 2.5 mg/kg/dose IV q8h), AND
  - Metronidazole 30 mg/kg/day IV divided q6h or other similar coverage/combinations
- For penicillin-allergic patients, fluoroquinolones can be used for gram-negative coverage:
  - Ciprofloxacin 10–20 mg/kg/day IV divided q12h, max single dose 200–400 mg IV q8–12h
  - The use of fluoroquinolones in children is controversial.
- For suspected toxic shock syndrome, consider clindamycin (15–25 mg/kg/day divided q6–8h, max 4.8 g/day).

### Second Line

- Inotropic/Vasoactive agents are indicated if signs of shock persist despite adequate volume resuscitation.
- Lower levels of dopamine and epinephrine have predominantly beta-adrenergic effects (inotropy, chronotropy), while increasing doses have more alpha-adrenergic effects (vasoconstriction):
  - Dopamine starting at 5–10  $\mu\text{g}/\text{kg}/\text{min}$  to a max of 20  $\mu\text{g}/\text{kg}/\text{min}$
  - Epinephrine starting at 0.05  $\mu\text{g}/\text{kg}/\text{min}$
  - Norepinephrine starting at 0.05  $\mu\text{g}/\text{kg}/\text{min}$  for warm, vasodilatory shock:
    - Significant alpha-adrenergic effects (vasoconstriction) at starting doses
- Hydrocortisone 1–2 mg/kg (max single dose 50–100 mg IV) for suspected adrenal insufficiency

### COMPLEMENTARY & ALTERNATIVE THERAPIES

IV immunoglobulin has been used in the ICU setting for severe or persistent signs of sepsis.

### SURGERY/OTHER PROCEDURES

- If personnel and equipment are available, central venous access should be obtained if the patient requires inotropic or vasoactive agents.
- Due to the limited ability of long catheters to deliver fluid quickly, peripheral catheters or intraosseous needles are typically preferable to central venous catheters for rapid fluid delivery.
- For the stable, resuscitated patient, surgical evacuation of a known infection is suggested.

### DISPOSITION

#### Admission Criteria

Critical care admission criteria:

- Patients with ongoing symptoms of shock
- Patients receiving continuous infusions of inotropic/vasoactive agents

- Patients requiring positive pressure ventilation as part of the management of sepsis
- Any patient who has received  $\geq 60$  mL/kg of fluid resuscitation in <2 hr should be considered for ICU admission.

### Discharge Criteria

No patient with sepsis should be discharged from the emergency department.

### Patient Monitoring

- Continuous pulse oximetry.
- Continuous cardiorespiratory monitoring
- Noninvasive BP monitoring every 10–15 min
- Temperature at least every 60 min
- Continuous end-tidal  $\text{CO}_2$  monitoring in the intubated patient
- Consider invasive arterial monitoring.

### DIET

NPO

### PROGNOSIS

- Many studies of pediatric sepsis report a 10% mortality rate.
- Mortality is higher in infants and in children with underlying medical conditions.

### COMPLICATIONS

- Death is a potential outcome of sepsis. Other potential complications include but are not limited to:
  - Chronic lung disease in patients who need ventilatory support
  - Intracranial hemorrhage and CNS damage can occur in cases of disseminated intravascular coagulation
  - Digit and extremity loss, especially in cases of sepsis caused by meningococemia or when high doses of vasopressors are needed
- Invasive procedures have known complications including but not limited to:
  - Intubation (inability to establish airway after muscle relaxation, pneumothorax, subglottic stenosis)
  - Central venous access (bleeding, vessel damage, infection, pneumothorax in upper vessel central lines)
  - Abscess incision and drainage (vessel damage, nerve damage, bleeding)
  - Surgery
- Vasoactive agents can cause significant vasoconstriction, especially when administered through peripheral IVs, which may result in tissue ischemia and tissue necrosis.

### ADDITIONAL READING

Bell LM. Shock. In Fleisher GR, Ludwig S, eds. *Textbook of Pediatric Emergency Medicine*. 6th ed. Philadelphia, PA: Lippincott Williams & Wilkins; 2010.

### ICD9

- 038.9 Unspecified septicemia
- 785.52 Septic shock
- 995.90 Systemic inflammatory response syndrome, unspecified

### PEARLS AND PITFALLS

- Septic shock may present with another chief complaint (fever, a respiratory illness, abdominal pain, etc.), with shock only diagnosed as a result of assessment of perfusion.
- Common errors in management of shock are failure to recognize and failure to treat aggressively enough after diagnosis.
- Inadequate fluid resuscitation is common.
- Sepsis results from infection. Delay in antibiotic use leads to increased morbidity and mortality. Many antibiotics can be given IM.
- Adrenal insufficiency may present as hyperkalemia, hyponatremia, and hypoglycemia possibly with bronzed skin. Shock due to adrenal insufficiency requires steroid replacement, without which fluid resuscitation and pressors alone will be inadequate.

# SERUM SICKNESS

Kelly J. Cramm

## BASICS

### DESCRIPTION

- Serum sickness is a type III hypersensitivity reaction to foreign proteins or serum resulting from immune complex deposition in blood vessels and tissues with resultant complement activation and vessel and tissue damage.
- A clinical syndrome of rash, pruritus, malaise, arthralgia, proteinuria, and vasculitis results.
- Secondary serum sickness occurs in patients previously sensitized to the antigen:
  - The latent period and clinical course is shorter than primary serum sickness; however, the symptoms are normally exaggerated.
- Serum sickness–like reactions present a clinical syndrome similar to serum sickness but are not immune mediated.

### EPIDEMIOLOGY

#### Incidence

- The overall incidence of serum sickness is declining because of decreased use of animal sera and safer vaccinations (1).
- Antibiotic-associated serum sickness is most common in children <5 yr of age (2).
- Incidence of serum sickness is dose related (3).

### RISK FACTORS

- Administration of a drug known to cause serum sickness
- Administration of large amounts of rabies immunoglobulin, venom antiserum, or horse serum
- History of atopy

### GENERAL PREVENTION

- The only effective prevention is avoidance of the foreign antigen.
- Use of medications that consist only of Fab fragments as opposed to whole antibodies has tremendously reduced the incidence.
- Avoidance of antibiotics with high incidence of serum sickness, such as cefaclor

## PATHOPHYSIOLOGY

- After exposure to a foreign protein, it normally takes 7–10 days to develop symptoms. However, if pre-existing antibody is present, symptoms may develop within a few days.
- After administration of a foreign protein, there is antigen excess. These antigens incite the development of IgG (and sometimes IgM) antibodies with resultant antigen-antibody complexes. In usually 7–10 days, symptoms begin when immune complexes deposit in small vessel walls and tissues, giving rise to complement activation with subsequent inflammation, capillary leak, and tissue damage.
- Resolution of symptoms typically occurs within 1–2 wk as enough antibodies are formed to create antibody excess, thereby enabling clearance of the immune complexes from the circulation.

## ETIOLOGY

- Most common cause is a hypersensitivity reaction to drugs:
  - Antibiotics:
    - Penicillins
    - Cephalosporins (especially cefaclor)
    - Sulfonamides
    - Ciprofloxacin
    - Tetracycline
    - Metronidazole
  - Other drugs:
    - Thiouracil
    - Hydantoins
    - Barbiturates
    - Griseofulvin
    - Allopurinol
    - Captopril
    - Indomethacin
    - Procainamide
    - Rituximab
- Heterologous serum proteins:
  - Antivenin
  - Antitoxin
  - Antithymocyte globulin
  - Monoclonal antibodies
- Fibrinolytic agents:
  - Streptokinase

## COMMONLY ASSOCIATED CONDITIONS

Atopy

## DIAGNOSIS

### HISTORY

- New drug use within the last 2 wk
- Vaccinated within the last 2 wk
- Presence of:
  - Rash, especially urticaria
  - Arthralgia
  - Fever
- If the onset of symptoms was within a few days of exposure to medication, ask about previous exposures.
- Prior history of serum sickness or serum sickness–like reaction

### PHYSICAL EXAM

- Rash:
  - Commonly urticarial but can be serpiginous, morbilliform, vasculitic, and/or erythema multiforme–type rash on sides of hands and feet that becomes widespread
  - The rash may also start on abdomen and then become widespread.
- Fever
- Abdominal pain
- Nausea
- Vomiting
- Arthralgia
- Malaise
- Headache
- Blurred vision
- Polyarticular arthritis: Most commonly in the metacarpophalangeal and knee joints and usually symmetrical
- Tender lymphadenopathy (often generalized)
- Hepatosplenomegaly
- Pericardial friction rub (pericarditis)
- Acute renal failure (rare)
- Neurologic complications:
  - Cranial nerve palsies
  - Peripheral neuritis
  - Optic neuritis
  - Guillain-Barré syndrome
  - Encephalitis (rare)
- Respiratory problems (rare):
  - Dyspnea
  - Cyanosis

**DIAGNOSTIC TESTS & INTERPRETATION****Lab**

- No lab abnormality is reliably or universally present in patients with serum sickness.
- Leukopenia or leukocytosis
- Eosinophilia on peripheral blood smear
- Proteinuria
- Hematuria, usually microscopic rather than gross hematuria
- ESR may be elevated.
- C3, C4, and CH50 may be decreased.
- Polyclonal gammopathy or a transient monoclonal IgG spike

**Imaging**

CXR if pericarditis is suspected

**Diagnostic Procedures/Other**

ECG and echo if pericarditis is suspected

**Pathological Findings**

- Direct immunofluorescent staining of small blood vessels and renal glomeruli shows immune deposits.
- Biopsy of skin lesion reveals a perivascular lymphohistiocytic infiltrate.

**DIFFERENTIAL DIAGNOSIS**

- Systemic lupus erythematosus
- Acute rheumatic fever
- Poststreptococcal glomerulonephritis
- Rocky Mountain spotted fever
- Infectious endocarditis
- Infectious mononucleosis
- Kawasaki disease
- Henoch-Schönlein purpura
- Meningococcal infection
- Hypersensitivity vasculitis
- Viral hepatitis

**TREATMENT****INITIAL STABILIZATION/THERAPY**

- Discontinuation of the offending agent is the mainstay of treatment.
- Treatment is based on the severity of disease.
- The goal is symptomatic relief and monitoring for complications.

**MEDICATION****First Line**

- NSAIDs:
  - Consider NSAID medication in anticipation of prolonged pain and inflammation:
    - Ibuprofen 10 mg/kg/dose PO/IV q6h PRN
    - Ketorolac 0.5 mg/kg IV/IM q6h PRN
    - Naproxen 5 mg/kg PO q8h PRN

- Antihistamines:
  - Hydroxyzine 2 mg/kg/day divided q6–8h, max single dose 200 mg in 24 hr
  - Diphenhydramine 5 mg/kg/day divided q6–8h, max single dose 300 mg in 24 hr
- Corticosteroids: Prednisone 1–2 mg/kg/day for 7–10 days (max single dose 80 mg in 24 hr), followed by a 2-wk taper. Use only if severe.

**Second Line**

Angioedema: Epinephrine 1:1,000, 0.01 mL/kg SC (max single dose 0.3 mL)

**DISPOSITION****Admission Criteria**

Critical care admission criteria:

- Severe symptoms
- Severe glomerulonephritis
- Neurologic complications
- Cardiac complications
- Respiratory complications

**Discharge Criteria**

Most cases of serum sickness can be handled on an outpatient basis with close follow-up.

**Issues for Referral**

- Unclear diagnosis
- Infectious disease specialist (to select a different antibiotic if necessary)
- Nephritis (nephrology)
- Carditis (cardiology)
- Allergist (for ongoing management)

**FOLLOW-UP****FOLLOW-UP RECOMMENDATIONS**

Discharge instructions and medications:

- Advise the patient against use of the same drug in the future.

**Patient Monitoring**

Close follow-up is needed until symptoms resolve.

**PROGNOSIS**

Serum sickness is normally self-limited and resolves within several days to 2 wk after onset of symptoms.

**COMPLICATIONS**

- Nephritis
- Carditis
- Neurologic complications

- Dysrhythmia, Atrial
- Dysrhythmia, Ventricular
- Erythema Multiforme Rheumatic Fever
- Fever of Unknown Origin
- Kawasaki Disease
- Systemic Lupus Erythematosus
- Nephrotic Syndrome
- Urticaria

**ICD9**

999.5 Other serum reaction, not elsewhere classified

**PEARLS AND PITFALLS**

- Fever with associated rash is common with many childhood illnesses; the possibility of serum sickness should always be considered.
- Failure to discontinue the offending agent
- Failure to stress that the offending agent should never be administered again
- Diagnosing simple adverse drug reaction or drug allergy without recognizing the syndrome of serum sickness

# SEXUAL ASSAULT

Mary T. Ryan  
Kai M. Stürmann

## BASICS

### DESCRIPTION

- Sexual assault is unwanted sexual contact with or without penetration as a result of physical force or psychological coercion.
- Drug-facilitated sexual assault is the provision of alcohol or other mind-altering substances to render the person unable to consent with the intent of subsequently engaging in sexual contact:
  - Often, this is by use of an agent that induces chemical submission or coma.
- Statutory rape is intercourse between someone  $\geq 18$  yr with another under the age of consent.

### EPIDEMIOLOGY

#### Incidence

- Incidence unknown due to underreporting:
  - Only 1 in 10 cases of abuse in developed countries are reported to authorities (1).
- The U.S. Department of Health and Human Services estimates that  $> 100,000$  children in the U.S. are sexually assaulted annually.
- $\sim 1\%$  of children experience some form of sexual abuse each year (2).

### RISK FACTORS

- Cultures accepting of adult-child sexual relationships
- Poor parent-child relationships and any non-biologically related males living in the home
- Alcohol use is involved in  $\sim 20\%$  of cases involving adolescents.

### GENERAL PREVENTION

- Education about human sexuality and accepted social norms
- Health provider education to help in early detection and prevent re-abuse

### PATHOPHYSIOLOGY

- Traumatic injury results from a variety of factors:
  - Force used in physical assault
  - Force used to accomplish penetration
  - Penetration with foreign objects
  - Sexual immaturity of the patient
  - Lack of occurrence of natural stages of sexual arousal (vaginal lengthening, vaginal lubrication by mucoid secretion)
- Psychological harm may occur in any patient.

### ETIOLOGY

- Pedophilia is a well-recognized entity.
- Sociopathic psychiatric disorders
- Genuine ignorance of laws concerning statutory rape may also play a role in some cases.

## DIAGNOSIS

### HISTORY

- The suspicion of child or adolescent sexual assault may arise in a variety of ways.
- Direct disclosure by a child may occur.
- Caregiver may present with a specific concern:
  - Chronic sexual abuse may present with various nonspecific medical complaints or behavioral changes.
  - Genital or rectal pain, bleeding or discharge, bed-wetting, developmentally inappropriate activities, or social withdrawal
- Obtaining an unbiased history is essential and should be undertaken by an experienced provider.
- Use of open-ended questions to obtain information regarding who the person is, what body part was touched and how, and when and where did it happen. If possible, determine if exposure to semen or blood occurred.
- Obtain a comprehensive medical history, including medications and allergies.

### PHYSICAL EXAM

- When seen  $< 72$  hr post contact, the examiner will need to conduct a full exam to identify possible injuries, document findings, assess prophylaxis needs, and possibly collect forensic evidence.
- The general physical exam should be conducted in a systematic head to toe manner.
- The genital exam should be left until last.
- Good illumination is extremely important.
- In the younger child, the “frog-leg” position is ideal to view the external genitalia.
- The prone knee-chest position is ideal for evaluating the anogenital region. The lateral recumbent position is also acceptable.
- Female patients: Inspect the labia majora, labia minora, clitoris, urethra meatus, introitus, hymen, vestibule, and posterior fourchette/fossa navicularis. Document any erythema, abrasions, contusions, or tears.
- The hymen is best visualized by grasping the labia minora bilaterally and gently pulling downward and outward.
- The significance of hymenal notches or clefts depends on both the location and extent, and interpretation is best left to those with forensic training.
- Comment on vaginal discharge if present.
- A speculum exam is rarely needed for prepubertal girls unless there is active bleeding, in which case exam under anesthesia or under procedural sedation should be considered.
- Male patient: The penis, urethral meatus, scrotum, perineum, and anus should be visualized and erythema, abrasions, contusions, tears, or discharge documented.
- Observe the anus for tone, and the anal verge, rugae, and health of the perianal skin as well as discharge. Digital rectal exam is rarely indicated.

## DIAGNOSTIC TESTS & INTERPRETATION

### Lab

#### Initial Lab Tests

- Obtain cultures in all prepubescent children with symptoms or the finding of a vaginal or anal discharge prior to initiating treatment.
- In the prepubescent patient, appropriate cultures should also be obtained prior to STI prophylaxis for contact  $< 72$  hr.
- In adolescents, baseline STI testing before providing prophylaxis remains controversial.
- In postmenarchal patients, a baseline pregnancy test should be obtained before giving emergency contraception.
- “Routine” lab work (eg, metabolic profile or CBC) is not routinely indicated.
- Baseline testing for HIV, hepatitis, and syphilis should be obtained.

#### Imaging

- Photo documentation should be undertaken if injuries are identified.
- Colposcopy allows for magnification, and both photo and video recording of findings is possible.

#### Diagnostic Procedures/Other

- Colposcopic exam is generally indicated in the adolescent patient.
- Use of a Woods lamp may help to identify seminal fluids in the acute setting.
- In many locations, a specific sexual assault evidence kit is used. Familiarity with proper use and chain of custody is critical.
- Forensic evidence collection should be undertaken for patients presenting acutely, typically  $< 72$  hr post assault.
- The need for drug facilitated evidence collection should be considered on a case-by-case basis, especially in adolescents.

#### Pathological Findings

- Sexual assault may be diagnosed by a confirmed STI or pregnancy in a presexual patient or a patient without the capacity to consent for sex.
- Presence of semen on/in a non-sexually active female or sexually immature male may be diagnostic.

#### DIFFERENTIAL DIAGNOSIS

- Accidental trauma to the genital region or perineum may be mistaken for abuse (eg, penile hair tourniquet or straddle injury).
- Marked anal dilation from chronic constipation
- Dermatologic conditions (eg, contact dermatitis or lichen sclerosis) may mimic abuse.
- Infections (eg, pinworms or perianal streptococcal infection) may mimic child abuse.

## TREATMENT

### PRE HOSPITAL

Transport to a designated sexual assault or child advocacy center

### INITIAL STABILIZATION/THERAPY

- Medical needs are always given priority over forensic needs.
- Life-threatening injuries are very rare.

### MEDICATION

#### First Line

- Consider prophylactic interventions in patients presenting within 72 hr of contact.
- Regimens vary institutionally; immediate availability of particular agents in the hospital pharmacy might impact the choice of an exact regimen.
- If any questions, contact the CDC PEline at 1-888-448-4911 for the most current and patient-specific recommendation.
- Vaccination: Review tetanus and hepatitis B vaccination status:
  - If the hepatitis B vaccine has been completed, was the series complete and titer response adequate?
  - If unvaccinated or unknown, administer the hepatitis B vaccine and refer for completion or titers.
  - If unvaccinated or unknown and the source is known hepatitis B positive, administer immune globulin booster 0.06 mL/kg IM.
- Hepatitis B vaccine and refer for titers and follow-up testing
- STI prophylaxis: 5–8% chance for pediatric victims of sexual abuse to contract an STI
- Regimens:
  - Neisseria, gonorrhea, and *Chlamydia trachomatis*: Ceftriaxone 125 mg IM plus azithromycin 1 g PO or doxycycline 100 mg PO b.i.d.
  - *Trichomonas vaginalis* and bacterial vaginosis: Metronidazole 2 g PO × 1 dose:
    - GI side effects are common.
  - Syphilis: Low transmission risk. Prophylaxis is not recommended, but obtain follow-up serology. Initiate subsequent treatment if indicated.
- HIV prophylaxis: Nature of contact and time elapsed determines the need for HIV prophylaxis:
  - Data concerning the risk of HIV transmission from child sexual assault is lacking. Most available data are related to adult rape victims.
  - HIV relative risk: Anal receptive from HIV+ source = 1:30–1:125; Vaginal receptive HIV+ source = 1:600–1:2,000. Oral-genital is uncertain.
- Postexposure prophylaxis (PEP) HIV regime:
  - HIV prophylaxis: Time-dependent risk reduction with max benefit if <4 hr; not recommended >36 hr
  - Doses below are for patients ≥50 kg. For children, consult a local infectious disease specialist or contact the CDC PEline at 1-888-448-4911.
  - Recommend 28 days of combination therapy (Kaletra and Combivir or Truvada):
    - Kaletra 2 tablets PO b.i.d. AND
    - Combivir 1 tablet PO b.i.d. OR
    - Truvada 1 tablet PO per day
- GI side effects common; expensive regimen
  - Compliance is <25% for the 28-day course (2).
  - Baseline negative HIV test confirms the need for PEP.

- Emergency contraception: 2–4% risk of pregnancy post sexual assault. Risk is highest in the 3 days preceding ovulation:
  - Offer to all postmenarchal females
  - Use of emergency contraception provides 75% reduction in pregnancy.
  - Most effective if given <12 hr but can give up to 72 hr post exposure.
  - Confirm negative pregnancy test prior.
  - Multiple regimens exist, which vary by institution:
    - Plan B: Levonorgestrel 0.75 mg PO once and repeat in 12 hr
    - Lo-Ovral: Ethinyl estradiol 100 µg once and repeat in 12 hr
    - Ulipristal acetate (Ella) is a new medication for emergency contraception effective up to 5 days after intercourse:
      - Full details were unannounced prior to the printing of this text.
  - Nausea and vomiting are common with emergency contraception. If vomiting occurs soon after taking the medication, it may decrease the effectiveness in preventing pregnancy:
    - If emesis occurs <30 min after a dose, promptly take an antiemetic and repeat the dose.

#### Second Line

Antiemetics to prevent or treat nausea and vomiting from emergency contraception and PEP:

- Give 30 min to 1 hr prior to other medications.
- Metoclopramide 5–10 mg PO
- Ondansetron 4 mg PO

### COMPLEMENTARY & ALTERNATIVE THERAPIES

A patient advocate may be very helpful. This may be a parent, friend, or professional counselor.

### SURGERY/OTHER PROCEDURES

- Sexual assault evidence collection:
  - Within 72 hr of the sexual assault
  - In the prepubescent child, yield for evidence collection >24 hr appears higher from clothing and linens than from body cavity swabs; collect clothing if possible (4).
  - Kits complete with step-by-step instructions, swabs, envelopes, necessary paperwork, and Evidence Seal are typically available.
  - Protocols and kits vary from state to state.
  - The provider should be familiar with the procedure and collection process prior to the exam.
  - Referral to a rape crisis center or child advocacy center may be appropriate if the emergency department cannot provide these services.
- Drug facilitated evidence collection:
  - Collect evidence if warranted by history.
  - Many states have preprepared kits for use.

### DISPOSITION

#### Admission Criteria

- Significant associated injury
- Unsafe home environment

#### Discharge Criteria

- Most patients may be discharged from the emergency department.
- Child welfare reporting and clearance

#### Issues for Referral

Physicians in all 50 states are mandated reporters for all cases of suspected child abuse.

## FOLLOW-UP

### FOLLOW-UP RECOMMENDATIONS

Discharge instructions and medications:

- Take medications as prescribed.
- Follow up as recommended.
- Monitor for hepatotoxicity if taking PEP.

### Patient Monitoring

- Have a follow-up medical exam within 2 wk.
- Follow-up testing for hepatitis B and C, HIV, and syphilis at 6 wk and HIV at 3 and 6 mo
- Referral to a mental health professional for evaluation and counseling should be provided.
- Family may also benefit from such a referral.

### PROGNOSIS

- Depends on associated injury
- Physical injuries tend to be minor

### COMPLICATIONS

- STI
- Posttraumatic stress syndrome
- Pregnancy

## REFERENCES

### ICD9

- V71.5 Observation following alleged rape or seduction
- 995.53 Child sexual abuse

## PEARLS AND PITFALLS

- Normal physical exam does not exclude child sexual assault.
- Child sexual assault affects ~1% of children, and health care providers should maintain a high index of suspicion.
- Be familiar with institutional policies and state requirements governing forensic evidence collection.
- Statutory rape is not always a reportable offense. Be familiar with the area laws.

Adiana Yock Corrales  
Peter L.J. Barnett

## BASICS

### DESCRIPTION

STIs are infectious diseases spread from person to person through sexual contact (eg, oral, anal, or vaginal).

### EPIDEMIOLOGY

- STIs are a major cause of disease in adolescents; 25% of adolescents will develop an STI before graduating from high school.
- For infants and children, detection of an STI is an important warning sign of potential sexual abuse.
- Cervicitis and pelvic inflammatory disease (PID) rarely occur in prepubertal girls.
- ~85% of gonococcal and 50–75% of *Chlamydia trachomatis* infections in the female will be asymptomatic.
- Vulvar ulcers are rare and in young women can be caused by non–sexually transmitted causes (eg, Epstein-Barr virus, cytomegalovirus, group A streptococcus, Crohn disease, and Behçet disease).
- *Molluscum contagiosum* can be transmitted with sexual contact.
- Urethritis in males is commonly asymptomatic and presents after diagnosis of their sexual partners.
- The prevalence of STIs (National Health and Nutrition Examination Survey 2003–2004) was 24.1% for adolescents 14–19 yr of age:
  - The most prevalent STI was human papillomavirus (HPV; 18.3%) followed by chlamydial infection (3.9%) (1).

### RISK FACTORS

- Type of sexual activity determines risk of infection: Penile, vaginal or rectal penetration is more likely to lead to infection.
- The lack of use of barrier contraception
- Young age at 1st intercourse
- Frequency of unprotected sexual activity
- Multiple sexual partners
- Partners with multiple other partners
- Coexistence of other risk behaviors such as drug or alcohol misuse
- Physical and immunologic immaturity of the genital tract in adolescents
- Injuries of the genital tract

### GENERAL PREVENTION

- Patient education and counselling addressing risk factors
- Evaluation and treatment of sexual partners
- Vaccination for vaccine-preventable STIs or barrier contraception

### PATHOPHYSIOLOGY

- Typically, infection breaches the epithelium, either externally, within the urethra, or endovaginally.
- In females, transmission may spread from lower genital structures (vagina and cervix) to higher genital structures (endometrium, fallopian tubes, ovaries), and possibly to the peritoneal space via refluxed menstrual blood or by attachment to sperm.

### ETIOLOGY

- *C. trachomatis*
- *Neisseria gonorrhoeae*
- *Mycoplasma genitalium*
- *Ureaplasma urealyticum*
- *Trichomonas vaginalis*
- *Treponema pallidum* (syphilis)
- Herpes simplex virus (HSV)
- *Haemophilus ducreyi*
- Hepatitis A and B
- HSV types 1 and 2
- HPV

### COMMONLY ASSOCIATED CONDITIONS

- Coinfection between *N. gonorrhoeae* and *C. trachomatis* occurs in 15–20% of patients.
- The presence an STI increases the likelihood of another STI being present.

## DIAGNOSIS

### HISTORY

- All sexually active adolescent girls presenting with lower abdominal pain should be carefully evaluated for the presence of PID, salpingitis, and/or endometritis.
- Sexual history:
  - Dyspareunia or dysuria
  - Partner history and sexual orientation
  - Sexual activity (eg, oral, vaginal, anal intercourse)
  - Use of contraception (oral or barrier) and previous STIs
- Gynecology history:
  - Presence of external lesions, inguinal pain, or swelling
  - Vaginal discharge or bleeding: Type and frequency
  - Odor related to discharge
  - External irritation or pruritus of the vulva
  - Characteristic of menses: Regularity, flow, cramping
  - Possibility of pregnancy
- Symptoms suggestive of PID include:
  - Abdominal pain
  - Dyspareunia and dysuria
  - Vaginal discharge
  - Meno-/Metrorrhagia
  - Pain associated with menses
  - Fever, nausea, and vomiting
- In males:
  - Presence of external lesions, inguinal pain, or swelling
  - Urethral mucopurulent discharge
  - Pruritus
  - Dysuria
  - Acute onset of unilateral testicular pain and swelling, often with tenderness of the epididymis and vas deferens and occasionally with erythema and edema of the overlying skin

- Review of systems:
  - Constitutional symptoms: Fever, malaise, fatigue, weight loss
  - Eye: Conjunctivitis
  - ENT: Tonsillopharyngitis
  - Abdomen: Pelvic pain
  - GI: Nausea, vomiting
  - Musculoskeletal: Arthritis, osteomyelitis, pyomyositis
  - Anorectal: Proctitis, rectal bleeding
  - Skin: Pustules, papules, petechiae

### PHYSICAL EXAM

- External exam: Inguinal, vulval, and anal regions for Tanner staging and hair distribution. Inspect the anal area for tone, fissures, and other skin lesions.
- Prepubertal girls should be examined as such:
  - Supine “frog-leg” position OR
  - Knee-elbow position: This position gives a better view of the posterior hymen/anus.
- Examine for visible external lesions including masses or growths (condyloma), vesicles (HSV), or ulcerations (syphilis, lymphogranuloma venereum, granuloma inguinale)
- In sexually active girls:
  - Speculum exam visualizes the vaginal vault and cervix looking for discharge, blood, lacerations, ulcers, warts, and foreign bodies.
  - Single or bimanual exam for cervical motion tenderness and uterine and ovarian shape/size should also be performed.
- In males:
  - Inspect the foreskin, if present, to view the urethral meatus and frenulum.
  - Palpate the scrotum to assess the presence of tenderness and epididymal or testicular swelling.

### DIAGNOSTIC TESTS & INTERPRETATION

- Due to the high morbidity associated with PID, highly specific diagnostic CDC criteria use is recommended.
- Presumptive diagnosis is made when any one or more of the following minimum diagnostic criteria are present. The additional criteria may be used to aid in improving specificity of diagnosis.
  - Minimum criteria:
    - Uterine/Adnexal tenderness
    - Lower abdominal tenderness
    - Cervical motion tenderness
  - Additional criteria:
    - Fever >38.5°C
    - Cervical or vaginal mucopurulent discharge with presence of WBCs on microscopy
    - Elevated C-reactive protein and ESR
    - Lab documented: *N. gonorrhoeae* or *C. trachomatis*

### Lab

- Culture or nucleic acid probe for gonorrhea and chlamydia from the endocervix or urethra (males)
- Cultures for *N. gonorrhoeae* and *C. trachomatis* from the pharynx and anus, the vagina in girls, and the urethra in boys:
  - Nucleic acid probe for chlamydia is not specific enough to be used in cases of prepubertal disease or presumed sexual abuse. To prevent false-positive testing, culture is necessary.

- 1st-pass urine testing with nucleic acid amplification tests for chlamydia and gonorrhea if pelvic exam not indicated (eg, not sexually active)
- In males, if urethral discharge is present, this is an adequate substitute for intraurethral swab.
- Wet-mount microscopic exam of a vaginal swab specimen for *T. vaginalis* infection when suspected
- Vesicle or ulcer fluid culture for HSV may be obtained but is not routinely recommended or practiced.
- Serology for HSV confirmation is possible, but results are not available for days. Not routinely recommended.
- Direct immunofluorescence or dark-field microscopy for *T. pallidum* collected from a suspected lesion
- Serum specimens for syphilis, HIV, and hepatitis B surface antigen should be obtained.

### Imaging

Pelvic US: PID may demonstrate pyosalpinx or tubo-ovarian abscess complex.

### DIFFERENTIAL DIAGNOSIS

- Vaginal infections with *Candida albicans*
- Pyelonephritis or urinary tract infections (male/female)
- Appendicitis/Appendiceal abscess (male/female)
- Mesenteric lymphadenitis (male/female)
- Pregnancy, intrauterine or ectopic
- Ovarian torsion
- Endometriosis
- Testicular/Appendix testis torsion

## TREATMENT

### MEDICATION

- Urethral and cervical infections:
  - Adolescents:
    - Ceftriaxone 125 mg IM single dose PLUS
    - Azithromycin 1 g PO in a single dose or doxycycline 100 mg PO b.i.d. for 7 days
  - Infant/Child:
    - Ceftriaxone 125 mg IM in a single dose or spectinomycin 40 mg/kg (max single dose 2 g) IM in a single dose PLUS
    - Erythromycin 50 mg/kg/day PO q6h for 14 days; for children >45 kg, azithromycin 1 g PO in a single dose
- HSV: For antiviral treatment, refer to the Herpes Simplex topic.
- Primary and secondary syphilis:
  - For antibiotic dosing, refer to the Syphilis topic.
  - Lymphogranuloma venereum: For antibiotic therapy, refer to the Lymphogranuloma Venereum topic.
  - Granuloma inguinale: Treatment for 3 wk or until all lesions have healed:
    - Doxycycline 100 mg PO b.i.d. × 3 wk
    - Ciprofloxacin 750 mg PO b.i.d. × 3 wk
    - Azithromycin 1 g PO weekly × 3 wk
- PID:
  - For antibiotic dosing, refer to the Pelvic Inflammatory Disease topic.
- For therapy of anogenital warts, refer to the Genital Warts topic.

- Vaginal infections:
  - *T. vaginalis* or bacterial vaginosis:
    - Metronidazole 2 g PO × 1 dose or 500 mg b.i.d. for 7 days or vaginal metronidazole gel for 5 days OR
    - Clindamycin vaginal cream for 7 days or clindamycin 300 mg PO t.i.d. × 7 days
    - For children <45 kg, metronidazole 15 mg/kg/dose PO t.i.d. for 7 days
- Epididymo-orchitis:
  - Ceftriaxone 250 mg IM in a single dose plus doxycycline 100 mg PO b.i.d. for 10 days

### DISPOSITION

#### Admission Criteria

- Suspected tubo-ovarian abscess (TOA)
- PID in patients systemically unwell or for with presumed poor compliance
- Patient has failed outpatient treatment
- Patient is clinically ill or is at high risk for sequelae (eg, TOA, perihepatitis)
- Immunocompromised
- Inability to tolerate oral medications
- Pregnancy
- Inability to rule out surgical emergency such as acute appendicitis

## FOLLOW-UP

### FOLLOW-UP RECOMMENDATIONS

- Follow-up is needed for persistent symptoms or for recurrence within 2 mo of treatment.
- Prepubertal boys presenting with epididymitis should be referred for investigation of congenital abnormalities of the urinary tract.
- Partners should be notified, examined, and treated for the STI, identified or suspected, in the index patient.
- To avoid reinfection, patients and their sexual partners should abstain from sexual intercourse until therapy is completed.

### Patient Monitoring

- Retesting for *N. gonorrhoeae* and *C. trachomatis* 4–6 wk after completion of therapy for PID.
- All patients with a STI should be counseled and tested for HIV and syphilis.

### PROGNOSIS

- Generally excellent with early treatment
- Risk of future ectopic pregnancy or infertility increases with each successive episode of PID.

### COMPLICATIONS

- Infertility
- Ectopic pregnancy
- Chronic pelvic pain
- Perihepatitis (Fitz-Hugh-Curtis syndrome)
- Urethral stricture (males)
- Patients with genital ulceration such as lymphogranuloma venereum or granuloma inguinale have high risk for acquiring HIV.
- HPV associated with development of cancer such as cervical or penile carcinoma

- Vaginitis

## CODES

### ICD9

- 079.98 Unspecified chlamydial infection
- 098.0 Gonococcal infection (acute) of lower genitourinary tract
- 099.9 Venereal disease, unspecified

## PEARLS AND PITFALLS

- STIs in children may require investigation for potential sexual abuse.
- Diagnosis and treatment of STIs at an early stage prevents severe sequelae (eg, infertility).
- When treating STIs, physicians should treat for both chlamydia and gonorrhea.
- Pregnancy testing and HIV screening should be performed in a patient with an STI.
- Consider the psychological sequelae of disclosing an STI with a long-term or incurable prognosis, such as HSV, HPV, or HIV.
- Patients will often inquire about the incubation period and infectivity in order to ascertain from whom they contracted the STI. Disclose factual information, but avoid getting involved in determining from which sexual contact the STI was contacted.

# SHOCK, CARDIOGENIC

Marsha Ayzon Elkhunovich  
Vincent J. Wang

## BASICS

### DESCRIPTION

- Cardiogenic shock is a state of tissue hypoperfusion as a result of primary cardiac failure despite normal or increased left ventricular filling pressures.
- Cardiac preload remains normal to increased, which distinguishes cardiogenic shock from hypovolemic shock (decreased effective blood volume) and distributive shock (blood vessel dilation causing relative hypovolemia). All 3 types of shock are defined by decreased cardiac output and tissue hypoperfusion.
  - Obstructive shock is usually caused by cardiac or cardiothoracic etiologies and is managed similarly as cardiogenic shock:
    - Because of this, obstructive shock will be considered a variant of cardiogenic shock in this topic.
  - Septic shock is similar to distributive shock.
- Pediatric cardiogenic shock occurs primarily in neonates with congenital heart disease and children with myocarditis:
- In adults, MI is the most common cause.

### RISK FACTORS

Risk factors for specific conditions that cause cardiogenic shock:

- Infants of diabetic mothers have an increased incidence of congenital heart defects and cardiomyopathy.
- Asphyxia during birth predisposes infants to heart failure early in life.
- Infants of mothers with autoimmune disease, especially systemic lupus erythematosus, have an increased incidence of congenital heart block.
- Infants and children with a family history of cardiomyopathy and arrhythmias have a higher incidence of such conditions.

### GENERAL PREVENTION

Pulse oximetry screening in the newborn nursery helps to identify infants with cyanotic congenital heart disease. Done early and prior to discharge, this may identify conditions that may cause cardiogenic shock on closing of the ductus arteriosus (1).

### PATHOPHYSIOLOGY

- Cardiogenic shock occurs when cardiac output is inadequate because of:
  - Increased cardiac demand (eg, large ventricular septal defect [VSD])
  - Decreased/ineffective contractility (eg, arrhythmia or myocarditis) OR
  - Obstruction (eg, hypertrophic obstructive cardiomyopathy [HOCM])
- This leads to CHF and inadequate perfusion and oxygenation of all vital organs, including the heart muscle itself.
- Tissue hypoperfusion in turn leads to acidosis and electrolyte abnormalities, which have adverse effects on myocardial function and causes further myocardial depression and ischemia.

### ETIOLOGY

The etiology of cardiogenic shock stems from primary cardiac dysfunction, which may be categorized as follows:

- Structural heart disease (eg, single ventricle physiology, transposition of the great arteries, large VSD). See the Congenital Heart Disease topic.
- Obstruction (eg, severe aortic stenosis, coarctation of the aorta, obstructive intracardiac mass, HOCM, postsurgical valvular or vascular restenosis).
- Dysrhythmias:
  - Heart block: Congenital or from toxic ingestion
  - Supraventricular tachycardia
  - Ventricular tachyarrhythmias (associated with long QT syndrome or other dysrhythmias, trauma, etc.)
- Impaired contractility:
  - Myocarditis
  - Cardiomyopathy
  - Metabolic disease (eg, Pompe disease, pyruvate dehydrogenase deficiency, myotonic dystrophy, carnitine deficiency, propionic acidemia)
  - Severe hypoglycemia
  - Adrenal insufficiency
  - Ischemia caused by:
    - Coronary artery aneurysms
    - ALCAPA (anomalous left coronary artery from the pulmonary artery)
    - Acute MI
- Other:
  - Pulmonary HTN
  - Cardiogenic shock following intrapartum asphyxia (2):
    - Tricuspid insufficiency +/- mitral valve dysfunction (2° to papillary muscle infarct)
    - Right ventricle failure (2° to impaired coronary perfusion)
    - Left ventricle failure (with HTN initially, then hypotension)
  - Cardiac tamponade
  - Tension pneumothorax
  - Trauma (can induce tamponade, ruptured septum, pneumothorax, arrhythmia, etc.)
  - Ingestion/overdose (eg, cocaine, calcium channel blockers, beta-blockers, tricyclic antidepressants)
  - Postsurgical complications:
    - Thrombosis (eg, obstructed pulmonary blood flow in Blalock-Taussig shunt)
    - Dysrhythmia (see above)

## DIAGNOSIS

### HISTORY

- The etiology of cardiogenic shock will differ greatly in the neonate and older infant/child.
- Birth history (gestational age, delivery problems, neonatal ICU stay, mechanical ventilation, etc.)
- Antecedent symptoms (acute vs. insidious onset, failure to thrive, etc.)
- History of underlying conditions or surgeries (cardiac disease, metabolic conditions, etc.)
- Problems feeding, sweating with feeds, respiratory distress with or without feeding

- History of possible ingestions or exposures
- Current medications
- History of recent infections
- Systemic symptoms: Fevers, fatigue, decreased urine output, etc.
- Family history
- Allergies to rule out distributive shock secondary to anaphylaxis

### PHYSICAL EXAM

- General appearance:
  - A neonate or child in cardiogenic shock will appear ill with decreased responsiveness, gray/clammy extremities, and respiratory distress or may be in complete cardiovascular collapse.
- Vital signs:
  - Tachycardia (except in heart block or late stages of shock)
  - Tachypnea:
    - If not present, assess for apnea and impending respiratory failure.
  - Fever (or even hypothermia) is also possible, especially in an infant.
  - Variable BP: Usually hypotension, but normal BP or even elevated BP in the initial stages of shock
  - Widened pulse pressure is common.
- Skin and extremity exam:
  - Capillary refill time may be delayed.
  - Cool/clammy extremities may be present.
  - Bounding pulses may be felt in early stages, followed by poor, thready pulses in late stages of shock.
  - In a child with unknown history, chest wall scars suggest previous cardiac surgery.
- Respiratory exam:
  - Increased respiratory effort including grunting, flaring, or retractions
  - Agonal or irregular breathing
  - Patients most often have crackles on exam from pulmonary edema
- Cardiac exam:
  - Jugular venous distension
  - Evidence of heave, lift, or thrill
  - Evaluation of heart sounds with splitting
  - Presence of murmur
- Other:
  - Hepatomegaly
  - Check for pulses and presence of radiofemoral delay.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

- Capillary glucose measurement is necessary, as hypoglycemia should be rapidly corrected.
- Arterial blood gas analysis to check for acidosis, oxygenation, and ventilatory status
- Serum lactate for degree of acidosis
- Comprehensive metabolic panel and ionized calcium level should be checked for electrolyte disturbances, which may be corrected:
  - High potassium and low sodium in an infant may suggest adrenal insufficiency.
  - Elevated BUN, creatinine, and LFTs may be a sign of end organ damage.

- Coagulation studies and platelets to check for evidence of disseminated intravascular coagulation
- Hemoglobin level to determine if blood should be given to maximize oxygenation
- Type and cross-match in case of need for blood product transfusion

### Imaging

- Chest radiograph to evaluate for cardiomegaly, pulmonary edema, pneumothorax
- A focused abdominal sonograph for trauma (FAST) exam if trauma or for evaluation for pericardial effusion or pneumothorax
- Echo to evaluate for obstructive lesions, shortening fraction, and volume status if suspecting structural or functional heart disease

### Diagnostic Procedures/Other

ECG to look for evidence of dysrhythmias, ST changes, and low voltages

### DIFFERENTIAL DIAGNOSIS

- Hypovolemic shock
- Distributive (septic) shock
- Anaphylaxis
- Inborn error of metabolism

### TREATMENT

#### PRE HOSPITAL

- Assess and continuously reassess ABCs.
- Ensure airway patency, and administer supplemental oxygen as necessary.
- Bag-mask ventilation and sometimes endotracheal intubation may be necessary.
- Obtain access with an IV or intraosseous line.
- Administer fluid boluses with guidance from the base station.
- Administer CPR if necessary.
- Capillary glucose assessment and glucose supplementation as necessary

#### ALERT

In patients with cardiogenic shock, endotracheal intubation may lead to complete cardiovascular collapse. Intubate only if necessary, and be prepared to administer CPR if needed.

#### INITIAL STABILIZATION/THERAPY

- ABCs: See Pediatric Advanced Life Support (PALS) or Advanced Pediatric Life Support (APLS) protocols for initial stabilization steps. The goal of initial treatment is to restore tissue perfusion both directly and by correcting the underlying etiology.
- General:
  - Provide optimal ventilation and oxygenation.
  - Connect the defibrillator, and administer CPR if needed.
  - Obtain venous access, preferably peripheral and central venous.
  - Obtain arterial access for more accurate continuous BP measurements.
- Improve preload:
  - Begin fluid resuscitation (cautiously if known heart disease or evidence of CHF)

- Improve contractility:
  - Correct hypoglycemia with dextrose bolus.
  - Replace electrolytes as needed (specifically, calcium and potassium) to maximize myocardial function.
  - Correct acidosis with sodium bicarbonate or tromethamine (THAM).
  - Inotropic agents if needed
- Decrease afterload:
  - Administer vasodilators, avoiding hypotension.

#### ALERT

- In infants in whom heart disease is suspected, avoid administration of 100% oxygen during the resuscitation, as it can induce closure of the patent ductus arteriosus in neonates and cause overcirculation in the lungs in older infants.
- Use only enough supplemental oxygen delivery to achieve *adequate* oxygenation (3). See the Patent Ductus Arteriosus and Ductal-Dependent Cardiac Emergencies topics.

### MEDICATION

#### First Line

- Inotropic agents to increase cardiac output:
  - Dobutamine
  - Dopamine
  - Epinephrine
  - Isoproterenol (if heart rate is low)
- Antidysrhythmic agents for dysrhythmias:
  - Lidocaine
  - Digoxin
  - Adenosine
  - Esmolol
  - Amiodarone

#### Second Line

- Corticosteroids: First line if suspecting adrenal insufficiency
- Nitric oxide if pulmonary HTN
- Amrinone or milrinone should be used to decrease afterload in appropriate patients who have structural heart disease and/or poor contractility if the patients have an adequate BP.

### SURGERY/OTHER PROCEDURES

- Pericardiocentesis may be necessary in cardiac tamponade.
- Thoracentesis if large pulmonary effusions are present or to resolve a pneumothorax or hemothorax

### DISPOSITION

#### Admission Criteria

- Any patient who presents to the emergency department in cardiogenic shock warrants admission.
- Telemetry monitoring is necessary for any patient with a recent history of cardiogenic shock.
- Critical care admission criteria:
  - Need for ventilatory support
  - Need for inotropic support
  - Prostaglandin E2 infusion in an infant
  - High risk for cardiovascular collapse/dysrhythmia

### Issues for Referral

Consultation from the emergency department as necessary:

- Cardiology for most cardiogenic shock cases
- Toxicology for ingestions or drug overdoses
- Metabolism if known metabolic disease
- Trauma surgery if traumatic etiology

### FOLLOW-UP

#### PROGNOSIS

- Depends on the extent of tissue damage and the timing of intervention
- Some patients may require extracorporeal membrane oxygenation or a left ventricular assist device and may need cardiac transplantation in the future.

#### COMPLICATIONS

If prolonged tissue hypoperfusion and hypoxia, end organ damage such as to the kidney, liver, lung and/or brain

### CODES

#### ICD9

785.51 Cardiogenic shock

### PEARLS AND PITFALLS

- Pearls:
  - Initial treatment of shock should generally be the same regardless of etiology.
  - It is more important initially to start treatment and decrease further tissue injury than to determine the exact etiology.
- Pitfalls:
  - Performing invasive procedures on patients with cardiogenic shock (eg, intubation, line placement) may bring about complete cardiovascular collapse.
  - Not being prepared to administer CPR is a clinical pitfall.

# SHOCK, HYPOVOLEMIC

Kelly J. Cramm

## BASICS

### DESCRIPTION

- Shock is defined as an acute disruption of circulatory function resulting in an inadequate supply of oxygen and substrates to meet the metabolic demands of tissues.
- Hypovolemic shock is the result of inadequate intravascular volume, most commonly from a loss of blood, plasma, or other fluids. Inadequate intake is a less common cause.
- Types:
  - Early or compensated shock: Increase in cardiac output occurs in an effort to compensate for losses. Perfusion of vital organs (heart, kidneys, brain) is maintained.
  - Late or decompensated shock: The compensatory mechanisms are unable to meet the demands of the tissues. Cellular function deteriorates with resultant release of vasoactive mediators. Signs of end organ damage follow.

### EPIDEMIOLOGY

#### Prevalence

- Hypovolemia is the most common cause of shock in children (1).
- Worldwide, diarrheal disease and dehydration account for as much as 1/3 of all deaths among infants and children <5 yr of age (2).

### RISK FACTORS

- Neonate
- Febrile infant
- Debilitated patient
- Excessive losses
- Endocrine diseases such as:
  - Adrenal insufficiency
  - Diabetes mellitus
  - Diabetes insipidus

### PATHOPHYSIOLOGY

- A significant loss of intravascular volume leads to a reduction of cardiac preload, decreased cardiac output, and impaired peripheral perfusion.
- In the face of cellular hypoxia, anaerobic metabolism occurs with resultant lactate accumulation and acidosis.
- In an attempt to maintain cardiac output and BP, a stimulation of the sympathetic system follows.
- A catecholamine release results in peripheral vasoconstriction, improved myocardial contractility, and increased heart rate.
- Neuroendocrine factors increase the conservation of fluid by the kidneys. If losses continue and compensatory mechanisms are overwhelmed, decompensated shock occurs with circulatory failure and multiorgan dysfunction.

### ETIOLOGY

- Water loss:
  - Vomiting
  - Diarrhea
  - Fever
  - Heat stroke
- Blood loss:
  - Trauma
  - Surgery
  - GI bleed
  - Intracranial bleed (especially neonates)
- 3rd spacing:
  - Burns
  - Peritonitis
  - Sepsis
  - Nephrotic syndrome
- Renal losses (excessive urine output):
  - Diuretic use
  - Diabetes insipidus
  - Diabetes mellitus
  - Adrenal insufficiency

## DIAGNOSIS

### HISTORY

Focused questioning should evaluate for the following:

- Vomiting
- Diarrhea
- Poor oral intake
- Urine output
- Blood loss
- Blunt or penetrating trauma
- Pre-existing conditions/illness
- Surgical history
- Medication history (diuretics)

### PHYSICAL EXAM

- Tachycardia: Often the earliest sign of shock
- Pallor
- Cold and clammy extremities
- Decreased capillary refill
- Mottling
- Poor skin turgor
- Dry mucous membranes
- Sunken eyes
- Absent tears
- Lethargy
- Weakness
- Altered mental status
- Thirst
- Sunken anterior fontanelle
- Tachypnea
- Bradycardia (late finding)
- Hypotension (uncompensated shock)
- Decreased or no urine output

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

- Blood gas analysis:
  - Hypoperfusion and resulting anaerobic metabolism result in any or all of the following:
    - Metabolic acidemia
    - Elevated serum lactate
    - Elevated base deficit
- Low hemoglobin and hematocrit can be used to assess blood loss.
- High hematocrit can be seen in dehydration.
- High BUN to creatinine ratio (>20) may be associated with prerenal dehydration.
  - This lab finding is not sensitive or reliable as the sole evaluation for hypovolemia.
- High sodium, chloride, and potassium can be seen with dehydration.
- Elevated lactate and low blood glucose can both be indicators of hypovolemia and/or shock.
- Type and cross-match if fluid loss is a result of hemorrhage/trauma
- Coagulation studies (disseminated intravascular coagulation)

#### Imaging

- Evaluation of the trauma patient showing signs and symptoms of hypovolemia is directed toward finding the source of blood loss.
- A focused abdominal sonograph for trauma (FAST) exam may be performed if an abdominal injury is suspected. If the patient is stable, it is customary to obtain CT of the abdomen.
- Radiographs should be obtained if long bone fractures are suspected.
- CT of the brain is used to evaluate the severity of any suspected intracranial hemorrhage.

### DIFFERENTIAL DIAGNOSIS

- Sepsis or systemic inflammatory response
- Poisoning
- Anaphylaxis
- Obstructive left-sided cardiac lesions
- Adrenal insufficiency
- Inborn error of metabolism
- Systemic capillary leak syndrome

## TREATMENT

### PRE HOSPITAL

- Assess and stabilize airway, breathing, and circulation.
- Provide 100% oxygen.
- Control of bleeding with direct pressure
- Bedside serum glucose assessment
- Two large bore IV catheters
- If unable to obtain IV access, an intraosseous (IO) needle or central venous access should be obtained.
- Fluid bolus normal saline 20 mL/kg up to three times in 30 min if patient has severe fluid loss or is in shock.

### INITIAL STABILIZATION/THERAPY

- Early recognition of shock is vital.
- The goal is to restore tissue and organ perfusion by restoration of intravascular volume.
- Immediate and aggressive fluid resuscitation:
  - 20 mL/kg of 0.9% sodium chloride or Ringer lactate IV given rapidly
  - Repeat another 20–40 mL/kg after reassessment of vital signs and perfusion if necessary.
- Identify the site of fluid loss.
- Obtain central venous access if necessary.

### MEDICATION

#### First Line

- Medication is indicated for decompensated shock refractory to volume expansion alone.
- Dopamine:
  - At low doses (2  $\mu\text{g}/\text{kg}/\text{min}$ ), renal perfusion is improved.
  - At higher doses (5–10  $\mu\text{g}/\text{kg}/\text{min}$ ), cardiac output is increased.
  - Peripheral vasoconstriction and central BP may be increased at even higher doses (10–20  $\mu\text{g}/\text{kg}/\text{min}$ ).

#### Second Line

- Epinephrine is recommended for fluid-refractory dopamine-resistant shock:
  - Epinephrine stimulates both alpha and beta receptors, thereby increasing myocardial contractility and peripheral vasoconstriction. Blood is rerouted centrally, at the expense of the peripheral circulation, setting up a potential for ischemic damage to the extremities.
  - A typical dose is 0.1  $\mu\text{g}/\text{kg}/\text{min}$  IV and is titrated upward according to effect and adverse events.

- Dextrose:
  - If the glucose level is low, provide replacement therapy with 0.5–1 g/kg IV dextrose.
- Colloid:
  - If hypoalbuminemic or capillary leak, give 5% albumin 0.5–1 g/kg IV/IO
- Blood:
  - If  $\geq 3$  20-mL/kg volumes of crystalloid have been infused into a patient with presumed hemorrhage (eg, from trauma), administer packed RBCs.
  - 10–15 mL/kg packed RBCs IV/IO: Maintain hematocrit  $> 30\%$ .
- Sodium bicarbonate:
  - Consider the use of sodium bicarbonate after assuring adequate volume resuscitation and ventilation, at a dose of 1–2 mEq/kg.

### SURGERY/OTHER PROCEDURES

Central venous pressure monitoring will help fluid management in critically ill patients.

### DISPOSITION

#### Admission Criteria

Critical care admission criteria:

- All patients in hypovolemic shock must be admitted to a monitored unit for ongoing treatment.
- Management by a pediatric surgical team is indicated for trauma patients in hypovolemic shock from traumatic hemorrhage.

## FOLLOW-UP

### DIET

- In illnesses causing vomiting and/or diarrhea, avoid excessive intake of foods and drinks containing large amounts of simple sugars, such as juices, soft drinks, and gelatin.
- Parents should be instructed on the use of oral rehydration therapy (ORT). The recommended solution contains  $\sim 75$  mEq/L sodium and 75 mmol/L glucose and has a total osmolarity of 245 mOsm/L (3). Of readily available solutions, Pedialyte (Abbott Laboratories, Columbus, OH) comes the closest to this formulation. The child should receive 10 mL/kg of ORT for each watery stool or 2 mL/kg for each episode of emesis.

### PROGNOSIS

The prognosis is dependent on early intervention and the extent of volume loss.

### COMPLICATIONS

- Acute renal failure
- End organ injury
- Neurologic sequelae
- Death

## CODES

### ICD9

785.59 Other shock without mention of trauma

## PEARLS AND PITFALLS

- Heart rate is the most sensitive indicator of volume status in children.
- The 2 most common errors associated with shock are failure to recognize presence of shock and failure to treat aggressively enough after a diagnosis is established.
- Children may not become hypotensive until they have lost about 30% of their circulating volume. Use of BP alone for diagnosis will cause delay in the recognition of shock.
- The key to an optimal outcome is early recognition and aggressive treatment.
- Oxygen and fluids are the cornerstone of treatment.
- Though pressors may achieve an increase in BP, fluid boluses are the mainstay of therapy for hypovolemic shock.

# SHOCK, NEUROGENIC

Tracey Rico

## BASICS

### DESCRIPTION

- Neurogenic shock is characterized by severe autonomic dysfunction with vasogenic hypotension and a relative bradycardia as a result of spinal cord injury (SCI).
- It is attributed to the traumatic disruption of sympathetic outflow and to unopposed vagal tone. Typically, neurogenic shock occurs with injuries that are below the T6 vertebra.
- Spinal shock, often confused with neurogenic shock, refers to a transient but complete disruption of neurologic function below the level of spinal cord injury, which is characterized by loss of sensation, paralysis, and areflexia that may last from hours to months.
- SCI is an insult to the spinal cord resulting in a change, either temporary or permanent, in its normal motor, sensory, or autonomic function.

### EPIDEMIOLOGY

- <2% of pediatric trauma involves SCI.
- ~1,000 SCI are reported annually in the pediatric population in the U.S.
- <20% of patients with a cervical cord injury have the classical appearance of neurogenic shock when they arrive in the emergency department.
- It is uncommon in patients with lower cord injuries (1).

### RISK FACTORS

- Most neurogenic shock results from blunt trauma. <7% of penetrating SCIs show classic signs of neurogenic shock.
- Motor vehicle accidents are the most common cause (50%), followed by falls (36%), and sports-related injuries (2).
- Injuries commonly involve alcohol or drug use.
- Presence of a pre-existing congenital abnormality or acquired disorder of the spine

### GENERAL PREVENTION

- Use of age-appropriate seat belts and protective sports gear
- Implementation of strictly enforced age-related rules in contact sports such as hockey and football

### PATHOPHYSIOLOGY

- Neurogenic shock occurs when sympathetic denervation of the splanchnic outflow (T5-L2) results in arteriolar dilation and pooling of blood in the venous compartment, while interruption of cardiac sympathetic innervation (T1-4) promotes bradycardia and reduces myocardial contractility leading to unopposed parasympathetic outflow.

- SCI is a 2-step process involving primary and secondary mechanisms:
  - The primary SCI arises from the initial insult causing mechanical disruption, transection, or distraction of neural elements. It is maximal at onset and unlikely to be altered by therapeutic intervention.
  - The secondary injury unfolds in the hours to days following the initial insult. It encompasses an array of disturbances that include hemorrhage, ischemia, disturbances in mitochondrial function, apoptosis, and calcium-mediated injury (3).
- The higher the level of the precipitating cord injury, the more severe the neurogenic shock.

### ETIOLOGY

- The most common cause of neurogenic shock is SCI secondary to trauma.
- Other causes include hemorrhage, infarct, entities causing extrinsic compression, severe Guillain-Barré, and spinal anesthesia.
- In children <8 yr of age, spinal cord injury without radiologic abnormality (SCIWORA) is the leading type of SCI associated with neurogenic shock, while in children >8 yr of age fracture-subluxation injuries are the most common cause.

### COMMONLY ASSOCIATED CONDITIONS

- Ventilatory compromise/respiratory failure (up to 67%)
- Head injury (up to 60%)
- Multisystem trauma (up to 57%)
- SCIWORA (up to 20%)
- Noncontiguous spinal fractures (10–15%)
- Vertebral artery injury (20–46%) (4)

## DIAGNOSIS

### HISTORY

Neurogenic shock most commonly results from trauma, so it is important to ask questions surrounding the nature of the trauma and any symptoms that have occurred since then. Inquire about:

- Mechanism of injury
- Amount of time since the injury
- Any prior neck or back abnormalities, injuries, or surgeries
- Presence of pain in the neck or back
- Any weakness or paresthesias in the arms or legs
- Loss of bowel or bladder control
- Loss of sensation in the arms or legs

### PHYSICAL EXAM

- As with all trauma patients, initial clinical evaluation begins with a primary survey that focuses on life-threatening conditions. Assessment of airway, breathing, and circulation takes precedence. SCI must be considered concurrently.
- The patient in neurogenic shock may exhibit:
  - Respiratory compromise
  - Warm, dry skin
  - Hypotension
  - Bradycardia
  - Hypothermia
  - Priapism
  - Urinary retention/incontinence
  - Loss of rectal tone
  - Quadri-/Paraplegia
  - Piloerection below the level of spinal injury
  - Sweating above the level of injury

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

- Blood gas analysis, lactate concentration, and/or base deficit allows assessment of oxygenation, ventilation, and perfusion.
- Hemoglobin and hematocrit to evaluate oxygen-carrying capacity and to monitor for blood loss

#### Initial Lab Tests

- Plain radiographs may be inadequate to visualize the complete cervical spine and may miss 12–16% of spine fractures.
- Use of CT scan for all suspected areas of the spinal trauma has a higher sensitivity than x-ray and may be more time efficient and convenient:
  - If neurogenic shock is suspected, CT is the initial study of choice.
- MRI is much less sensitive than CT scan for the detection of fracture. However, it is superior in detecting injuries to ligamentous structures, the disc interspaces, and the spine itself. It is also useful for evaluating vascular injuries.
- MRI is the study of choice for the evaluation of SCIWORA.

#### Imaging

As indicated, consider:

- Focused abdominal sonograph for trauma (FAST) scanning
- X-ray of the cervical spine, chest, abdomen, and pelvis
- X-ray of injured extremities
- CT of the cervical spine, chest, abdomen, and pelvis

### DIFFERENTIAL DIAGNOSIS

- All forms of shock must be excluded 1st.
- Cardiac contusion
- Aortic dissection
- Transverse myelitis
- Guillain-Barré
- Extradural spinal cord compression

## TREATMENT

### PRE HOSPITAL

- Assess and stabilize airway, breathing, and circulation.
- Transport to a trauma center is highly preferable.

### INITIAL STABILIZATION/THERAPY

- As for all trauma patients, rapid identification and stabilization of life-threatening injuries should occur primarily.
- Advanced Trauma Life Support (ATLS) protocols should be followed. Airway management and support of breathing with protection of the entire spine should be instituted or continued.
- The cervical spine must be maintained in neutral alignment at all times, and the patient should be placed on a protective spinal board.

### MEDICATION

- Crystalloid IV fluids should be infused to maintain a mean arterial BP just above the 5th percentile for age and weight.
- Vasopressors/Inotrope should be used if fluid resuscitation is inadequate to ensure organ perfusion.
- Inotropic agents may be added to improve cardiac output and perfusion pressure:
  - Dopamine 2.5–20.0  $\mu\text{g}/\text{kg}/\text{min}$
  - Dobutamine 2.0–20.0  $\mu\text{g}/\text{kg}/\text{min}$
- If neurogenic shock with normal chronotropy and inotropy is found, then agents with more peripheral vasoconstrictive properties may be preferable, such as phenylephrine or norepinephrine.
- If severe or symptomatic bradycardia, treat with atropine 0.02 mg/kg IV q5min, max cumulative dose 1 mg in children and 2 mg in adolescents/adults:
  - Typical minimum dose to prevent paradoxical bradycardia is 0.1 mg.
- If closed compartment SCI is identified within 8 hr of injury, consider high-dose methylprednisolone.
  - Methylprednisolone: 30 mg/kg IV over 15 min, then 5.4 mg/kg/hr over the next 23 hr (caution: dosage based on adult guidelines; lack of high-level pediatric evidence):
    - Previously, steroids were recommended by the ATLS guidelines, but based on recent data this recommendation has been withdrawn.
    - Their routine use in spinal cord trauma varies from institution to institution.

### SURGERY/OTHER PROCEDURES

- Surgical decompression and vertebral fusion impart no apparent benefit or greater neurologic improvement in cases of a complete transecting SCI.
- Surgical treatment is directed to stabilization of the vertebrae to prevent additional injury to the cord and decompression of the spinal cord if compromised by a fracture or hemorrhage.
- Fracture dislocations are treated with traction, immobilization, and, if the injury is unstable, vertebral body fusion.

### DISPOSITION

Critical care admission criteria:

- All patients with neurogenic shock should be admitted to an ICU setting.

### Discharge Criteria

Patients with neurogenic shock will not be discharged from the emergency department.

### Issues for Referral

- Consultation with a pediatric neurosurgeon and/or a pediatric orthopedist is required.
- Because most patients with neurogenic shock have multiple associated injuries, consultation with a pediatric surgeon or a trauma specialist may be required.
- Once stabilized, early referral to a regional SCI center is best.
- Other reasons to transfer the patient include the lack of appropriate diagnostic imaging (CT scanning or MRI) and/or inadequate spine consultant support (orthopedist or neurosurgeon).

## FOLLOW-UP

### FOLLOW-UP RECOMMENDATIONS

- Discharge instructions and medications:
  - Follow-up after neurogenic shock and SCI usually is provided by appropriate definitive care specialist such as a neurologist, neurosurgeon, or physical medicine/rehabilitation specialist.
- Activity:
  - As recommended by specialists giving initial treatment and follow-up

### PROGNOSIS

- Patients with C1-3 tetraplegia have a 7 times higher mortality than those with paraplegia:
  - If they survive, they are likely to require long-term mechanical ventilatory support and will likely depend on others for help with almost all of their mobility and self-care needs (5).
- Individuals with T1-12 paraplegia can achieve functional independence in self-care, in bladder and bowel skills, and, at the wheelchair level, in all mobility needs.
- The likelihood for patients with SCI having at least partial recovery after a complete injury has been reported to be between 10% and 25%.

### COMPLICATIONS

- Paralysis
- End organ injury
- Shock
- Death

## CODES

### ICD9

785.59 Other shock without mention of trauma

## PEARLS AND PITFALLS

- Establish the diagnosis and initiate treatment to rapidly to prevent further neurologic injury from either pathologic motion of the injured vertebrae or secondary injury from shock or respiratory insufficiency.
- Frequently reassess and use continuous hemodynamic monitoring.
- Attributing hypotension to neurogenic shock in the setting of multiple trauma is a potentially devastating error. Neurogenic shock is a diagnosis of exclusion.
- Failure to adequately immobilize the spine when the mechanism of injury warrants such is an error with potentially severe repercussions.
- The 2 most common errors associated with shock are failure to recognize presence of shock and failure to treat aggressively enough after a diagnosis is established.

# SICKLE CELL DISEASE

Nagela Sainte

Juliette Quintero-Solivan

## BASICS

### DESCRIPTION

- Sickle cell disease (SCD) is a hemoglobinopathy that affects the qualitative synthesis of hemoglobins.
- Despite an identical critical mutation, SCD displays wide phenotypic variability from asymptomatic to severe.
- There are many genotypes involving at least 1 sickle (HbS) gene, most common being HbSS.
- Multiple genotypes:  $\beta$ -Thalassemia, HbS/ $\beta^0$  thalassemia, HbS/ $\beta^+$  thalassemia, HbSC, HbS/persistence of HbF, HbS/HbE, and sickle cell trait

### EPIDEMIOLOGY

#### Incidence

- Mutations occur in African, Mediterranean, Indian, and Middle Eastern populations.
- Most common single gene disorder in blacks:
  - In the U.S., HbSS affects 0.8% of black neonates.
- 8% of the blacks in the U.S. population are heterozygous carriers (sickle cell trait).

### GENERAL PREVENTION

Screening may allow couples to know if they are both carriers.

### PATHOPHYSIOLOGY

- It is a point mutation within the beta-globin gene of hemoglobin resulting in a glutamic acid to valine substitution.
- Deoxygenation causes abnormal Hb(HbS) to polymerize, resulting in red cell sickling.
- RBC sickling causing subsequent red cell membrane damage and rigidity

### ETIOLOGY

- Repeated deoxygenation cycles cause permanent damage to the RBCs that interact with vessel endothelium, triggering vaso-occlusion of tissue microcirculation and decreased RBC life.
- Vaso-occlusive crises occur secondary to red cell sickling, obstruction of microcirculation, and subsequent ischemia of tissues.
- Decreased RBC life results in hemolytic anemia.

### COMMONLY ASSOCIATED CONDITIONS

- Infection:
  - Vaso-occlusion of spleen microcirculation causes increased susceptibility of encapsulated organism: *Pneumococcus*, *Haemophilus*, *Neisseria meningitidis*, and *Salmonella* species.
  - Pneumococcal sepsis is a significant cause of morbidity and mortality in infants/children.
  - Increased risk of encapsulated organism infection secondary to functional asplenia
  - During the H1N1 influenza pandemic of 2009–2010, patients with SCD appeared to have higher morbidity and mortality and may have been at greater risk than other children.
- Aplastic crisis:
  - Temporary severe bone marrow suppression
  - Commonly associated with parvovirus B-19

- Acute pain crisis:
  - Repeated episodes of vaso-occlusion occur in musculoskeletal, bones and soft tissues.
  - Triggered by cold weather, dehydration, deoxygenation, infection, and/or acidosis
  - Dactylitis: Vaso-occlusion of soft tissue of digits; common presenting symptom before the age of 2 yr
- Acute chest syndrome:
  - Fever, respiratory symptoms, in the setting of new chest radiograph finding
  - Significant cause of mortality
  - Repeat episodes of acute chest syndrome increase the risk of subsequent episodes
- Cerebrovascular accidents:
  - Onset of neurologic focality/weakness, severe headache, mental status changes
  - Usually ischemic in children and can be silent
  - Transcranial Doppler is used to assess risk of future stroke.
- Splenic sequestration:
  - Large spleen secondary to sudden pooling of blood in spleen, life-threatening anemia, and shock
  - Occurs typically during the 1st few years of life in HbSS patients, but risk is lifelong in other sickle cell genotypes (HbS $\beta^0$ , HbS $\beta^+$ , and HbSC).
- Avascular necrosis of the hip:
  - Vaso-occlusion and interruption of blood flow to the femoral head can present as limp or hip, groin, or knee pain.
  - Leads to bone loss and loss of joint function
  - Plain films may be unremarkable or show sclerosis, bone deformity, or a subchondral radiolucent line (crescent sign).
- Priapism:
  - Painful prolonged erection or multiple clustered episodes may lead to fibrosis and impotence.
- Pulmonary HTN:
  - Seen in adolescents and adults with SCD secondary to chronic intravascular hemolysis
  - High morbidity and mortality
- Hepatobiliary disease:
  - Secondary to chronic hemolysis, chronic transfusion therapy, and vaso-occlusion; pigment gallstones, biliary sludging, cholecystitis, hepatitis, iron overload, hepatic infarct

## DIAGNOSIS

### HISTORY

- Results of newborn screen, immunization history, medications (including pain medications and dosages, antibiotic prophylaxis), surgical history, transfusion history, hospitalizations (acute chest syndrome, pediatric intensive care admissions)
- Baseline hemoglobin, spleen size, pulse oximetry, transcranial Doppler results, if known
- Symptoms related to SCD: Fever, bone pain, chest pain, shortness of breath, abdominal pain, vomiting, rashes, priapism, headache, lethargy, neurologic focal deficits

### PHYSICAL EXAM

- Common baseline findings: Mild tachycardia, mild artifactual decrease in pulse oximetry, scleral icterus, jaundice, flow murmur
- Evaluate painful extremity:
  - Discern between bony pain and other likely cause of pain, such as cellulitis, septic arthritis, trauma/fracture, or avascular necrosis of hip.
- Evaluate for signs of respiratory distress:
  - Tachypnea
  - Hypoxia
  - Rales, rhonchi, or other abnormal breath sounds
- Evaluate for sepsis/shock:
  - Consider BP and heart rate in settings of compensated as well as decompensated shock.
  - Capillary perfusion
  - Cool extremities
  - BP
- Evaluate for central neurologic injury with detailed evaluation of cranial nerves and full peripheral neurologic exam.
- Evaluate for acute abdomen.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

Serum CBC with differential, reticulocyte count, blood cultures, type and cross-match, serum electrolytes, BUN, creatinine, glucose, urinalysis and culture, and LFTs

#### Imaging

- CXR in cases with cardiorespiratory symptoms
- Abdominal US or CT scan in cases suggestive of abdominal pathology
- CT head or MRI brain in cases suggestive of stroke
- Plain films or bone scans in cases of persistent bone pain or suspected bone infection
- Echo with Doppler flow to assess for the presence of pulmonary HTN:
  - Cardiac catheterization remains the gold standard to assess risk of pulmonary HTN.

### DIFFERENTIAL DIAGNOSIS

- Most cases of limb pain will be vaso-occlusive pain crises, but consider trauma, osteomyelitis, and septic arthritis.
- In cases involving respiratory symptoms, consider viral upper respiratory infection, pneumonia, and pulmonary embolism.
- In cases of abdominal pain, consider appendicitis, intestinal infection, gastritis, pancreatitis, pelvic inflammatory disease, urinary tract infection/pyelonephritis, and trauma.
- In cases of mental status change, consider meningitis, encephalitis, sepsis, and drug/toxin exposure.
- Consider acute hemorrhage in cases of severe anemia.

## TREATMENT

### PRE HOSPITAL

Assess and stabilize airway, breathing, and circulation:

- Administer supplemental oxygen.

### INITIAL STABILIZATION/THERAPY

- Assess and stabilize airway, breathing, and circulation.
- Analgesics for painful vasoocclusive crises
- IV hydration, transfusion, or exchange transfusion as indicated
- Oxygen therapy for vasoocclusive crises and acute chest syndrome
- Antibiotics for febrile illnesses
- Acute chest syndrome: If respiratory symptoms, dyspnea, hypoxia, or new infiltrate on CXR, consider likely acute chest syndrome. This will require careful fluid management and use of less IV fluid hydration than in typical vaso-occlusive crises.

### MEDICATION

#### First Line

- For administration of analgesics, patients and parents will often know specific types and dosages that are typically effective:
  - Strongly consider following analgesic regimen that has previously been successful.
  - These doses may be significantly higher than recommended initial analgesic doses used for other conditions.
- Consider a patient-controlled analgesia pump for severe pain.
- NSAIDs:
  - Consider NSAID medication in anticipation of prolonged pain and inflammation:
    - Ibuprofen 10 mg/kg/dose PO/IV q6h PRN
    - Ketorolac 0.5 mg/kg IV/IM q6h PRN
    - Naproxen 5 mg/kg PO q8h PRN
- Opioids:
  - Morphine 0.1 mg/kg IV/IM/SC q2h PRN:
    - Initial morphine dose of 0.1 mg/kg IV/IM may be repeated q15–20min until pain is controlled, then q2h PRN.
  - Fentanyl 1–2  $\mu$ g/kg IV q2h PRN:
    - Initial dose of 1  $\mu$ g/kg IV may be repeated q15–20min until pain is controlled, then q2h PRN.
  - Codeine or codeine/acetaminophen dosed as 0.5–1 mg/kg of codeine component PO q4h PRN
  - Hydrocodone or hydrocodone/acetaminophen dosed as 0.1 mg/kg of hydrocodone component PO q4–6h PRN
  - Meperidine: Not recommended for routine use, but consider based on local practice.
- Acetaminophen 15 mg/kg/dose PO/PR q4h PRN
- Infection:
  - Ceftriaxone 50–75 mg/kg/day IV in single or divided doses, typical max single dose 1 g
  - Vancomycin 40 mg/kg/day IV divided q6–8h. Consider in sepsis or severe illness.
  - Clindamycin 25–40 mg/kg IV divided q6–8h. Consider in penicillin-allergic patients.
  - Ampicillin 50–100 mg/kg/dose q6h, max, typical max single dose 2 g:
    - Ampicillin could be considered if local bacterial resistance patterns make penicillin/ampicillin sensitivity likely.

### Second Line

- Hydroxyurea has been shown to decrease the episodes of vaso-occlusive crisis and acute chest syndrome; prescribed by a hematologist.
- Dosage provided by consulting hematologist
- Continue adjunctive therapies such as folic acid; if not given antibiotics for other reasons, continue use of prophylactic penicillin while in the hospital.

### DISPOSITION

#### Admission Criteria

- Most common need for admission is to receive parenteral opioid analgesics and IV hydration.
- Infants and children at high risk for sepsis/bacteremia, in particular pneumococcal sepsis
- Ill appearing or at risk of clinical deterioration
- Respiratory compromise, acute abdomen, splenic sequestration, aplastic crisis, severe pain, dehydration, or unclear diagnosis
- Unreliable follow-up care
- Critical care admission criteria:
  - Acute chest syndrome, stroke, or shock

#### Discharge Criteria

- Patients and parents often have a good sense of whether they are well enough for discharge or too ill to successfully remain as outpatients.
- Well appearing with normalization or near normalization of the condition
- No suggestion and/or evidence of serious respiratory, abdominal, neurologic, or infectious complications of SCD
- Acute pain crisis controlled with oral medications.
- Reliable follow-up and strict adherence to discharge instructions

#### Issues for Referral

- If acute chest syndrome, follow up with a pulmonologist.
- Surgery follow-up for cholecystectomy or rarely splenectomy

## FOLLOW-UP

### FOLLOW-UP RECOMMENDATIONS

- Discharge instructions and medications:
  - Take analgesics as needed; drink adequately to remain well hydrated.
- Activity:
  - As tolerated

### Patient Monitoring

- Follow blood culture results.
- Follow-up within 1 wk post discharge is strongly advised.

### PROGNOSIS

- Lifelong illness with no cure
- Varying degrees of severity
- Early recognition of symptoms, parental education, neonatal screening, immunization against pneumococcus, and penicillin prophylaxis have increased survival and decreased morbidity and mortality.

### COMPLICATIONS

- Acute chest syndrome
- Splenic sequestration
- Sepsis, particularly from encapsulated bacteria after autosplenectomy
- Cerebrovascular accident
- Bone infarct
- Failure to thrive
- Growth retardation/delayed puberty
- Cardiac complications, including heart failure and MI
- Renal failure, isosthenuria

### See Also (Topic, Algorithm, Electronic Media Element)

Stroke

### ICD9

- 282.60 Sickle-cell disease, unspecified
- 282.61 Hb-SS disease without crisis
- 282.62 Hb-SS disease with crisis

### PEARLS AND PITFALLS

- Pneumococcal sepsis is a major source of morbidity and mortality in infants and children.
- Early antibiotics and adequate pain management significantly improve morbidity.
- Patients with respiratory symptoms can acutely deteriorate into acute chest syndrome.
- Monitor spleen size in patients with splenomegaly.
- SCD patients are also at risk for non-SCD-related acute illness in the emergency department setting.

# SINUSITIS

Joseph F. Perno

## BASICS

### DESCRIPTION

- Sinusitis is a bacterial infection of the mucosa of the paranasal sinuses and nasal epithelium.
- Also known as rhinosinusitis
- May be acute <30 days; subacute 30–90 days; or chronic >90 days

### EPIDEMIOLOGY

- 14% of Americans claim to have had a previous diagnosis of sinusitis (1).
- 6–13% of children will have had 1 case of rhinosinusitis by the age of 3 yr (2).
- Affects 15–20% of the pediatric population yearly (3)
- Children average 6–8 upper respiratory infections (URIs) each year, and 0.5–5% progress to acute sinusitis (2).

### RISK FACTORS

- Viral URIs precede acute sinusitis in 40–90% of cases (3).
- Allergic rhinitis
- Asthma
- GERD
- Immune deficiency:
  - HIV
  - Congenital deficiency
- Cystic fibrosis (CF)
- Cyanotic congenital heart disease
- Immotile cilia syndrome
- Mechanical obstructions:
  - Facial trauma
  - Cleft palate
  - Choanal atresia
  - Nasal foreign bodies
- Dental infections

### GENERAL PREVENTION

Prevent or limit URI exposure:

- Reduced exposure to ill contacts
- Good hand hygiene
- Cleaning surfaces of contaminated objects (ie, toys at a day care center) with disinfectant

### PATHOPHYSIOLOGY

- Paranasal sinuses (maxillary, ethmoid, frontal, sphenoid): Air-filled spaces connected by small tubular openings (sinus ostia) that drain into the nasal cavity
- Inflammation of epithelial tissue in sinuses causes blockage of sinus ostia and poor drainage, leading to secondary bacterial infection (4).

- Beta-lactamase-producing bacteria commonly cause sinusitis.
- Sinuses develop throughout childhood:
  - Maxillary and ethmoid present at birth
  - Sphenoid sinus development occurs around age 5 yr.
  - Frontal sinus development occurs around age 7 yr.
  - Frontal and sphenoid sinuses are not fully developed until late adolescence.

### ETIOLOGY

- Most sinusitis is preceded by viral URI:
  - Rhinovirus
  - Adenovirus
  - Influenza
  - Parainfluenza
- Secondary bacterial infection occurs (5):
  - *Streptococcus pneumoniae* (35–42%)
  - *Haemophilus influenzae* (21–28%)
  - *Moraxella catarrhalis* (21–28%)
  - Group A beta-hemolytic streptococci
  - *Staphylococcus aureus*:
    - Increasing prevalence
    - More common in chronic type
  - *Pseudomonas aeruginosa*:
    - Common in CF patients
  - Fungi are an increasing factor in chronic sinusitis.

### COMMONLY ASSOCIATED CONDITIONS

- Otitis media
- Asthma:
  - No direct causal factor has been identified; treatment of sinusitis has shown improvement in asthma symptoms.

## DIAGNOSIS

### HISTORY

- Persistent and unimproved nasal discharge for >10 days; usually purulent:
  - Duration of symptoms separate simple viral URI from bacterial sinusitis, as most viral URIs resolve within 5–10 days.
- Nasal congestion and associated mouth breathing at night
- Cough:
  - Secondary to postnasal drip
  - Often worse at night
- Morning sore throat
- Fever lasting >48 hr
- Headache
- Facial pain
- Poor appetite
- Irritability

### PHYSICAL EXAM

- Nasal mucosa erythematous and swollen
- Purulent discharge in nose or dripping posteriorly into oropharynx
- Pharyngeal erythema
- Halitosis
- Periorbital swelling or facial tenderness:
  - More common in adolescents
- Transillumination of sinuses may be useful in adolescents or adults; if the sinus is not translucent this is indicative of fluid in the sinus.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

No lab tests are indicated for sinusitis.

#### Imaging

- Diagnosis of uncomplicated acute sinusitis can be made on clinical grounds alone. Imaging should be reserved for medically refractory cases or worsening symptoms during antibiotic treatment.
- Normal sinus x-rays rule out sinusitis.
- Abnormal x-ray findings:
  - Air-fluid level
  - Complete opacification
  - Mucosal thickening
- CT of the sinuses provides better visualization and is appropriate for:
  - Complications: Orbital/Intracranial
  - Frequent recurrences
  - If sinus surgery is contemplated
- Must consider cost and radiation exposure associated with CT
- Brain MRI is useful if there is concern for intracranial complications.

#### Diagnostic Procedures/Other

- Aspiration of the sinus is rarely performed due to invasiveness and cost, but fluid obtained from sinuses is the most accurate confirmatory method.
- Nasal swab cultures do not correlate with sinus aspirates and are not recommended.

### DIFFERENTIAL DIAGNOSIS

- Must differentiate uncomplicated viral URI from bacterial sinusitis
- Allergic rhinitis may be confused with bacterial sinusitis.

## TREATMENT

### INITIAL STABILIZATION/THERAPY

As with all patients, assessment of airway, breathing, and circulation should occur, but sinusitis should not interfere with these functions.

### MEDICATION

#### First Line

- Children receiving antibiotic therapy experience a clinical cure more quickly than children receiving a placebo (6).
- Historically, amoxicillin with starting doses of 45–90 mg/kg/day has been 1st choice:
  - Effective against *S. pneumoniae*
  - Limited effectiveness against beta-lactamase producers
- Shift of primary pathogen away from *S. pneumoniae* toward *H. influenzae* secondary to pneumococcal vaccine
- Current first-line therapy should be amoxicillin/clavulanate 90/6.4 mg/kg/day (7).
- May use oral cephalosporins; useful for penicillin allergy:
  - Cefdinir 14 mg/kg/day
  - Cefpodoxime 10 mg/kg/day
  - Cefuroxime 30 mg/kg/day
- Controversy exists for duration of therapy (2):
  - Minimum of 10 days for mild acute disease
  - Most recommend 14–21 days of therapy for severe acute disease.

#### Second Line

- Antipyretics/analgesics:
  - Acetaminophen 15 mg/kg/dose PO/PR q4h PRN
  - Ibuprofen 10 mg/kg/dose PO/IV q6h PRN.
  - Naproxen 5 mg/kg PO q8h PRN
- Azithromycin and clarithromycin may be used for penicillin/cephalosporin allergy.
- Combination of clindamycin and rifampin can also be used.

### COMPLEMENTARY & ALTERNATIVE THERAPIES

- Topical nasal corticosteroids may reduce nasal edema and improve sinus drainage:
  - May shorten duration of cough and drainage
- Antihistamines commonly used as adjunct therapy (2):
  - No studies to support usage in nonallergic children
  - May be helpful for underlying allergic rhinitis
- Saline nasal drops or sprays may be used (3):
  - No studies to support usage
  - May help eliminate nasal secretions
  - Decrease nasal edema
  - Mild vasoconstrictor of nasal blood vessels
- No evidence to support usage of systemic decongestants, mucolytics, or expectorants

### SURGERY/OTHER PROCEDURES

Nasosinus surgery may be considered for medically resistant rhinosinusitis (3).

### DISPOSITION

#### Discharge Criteria

Acute sinusitis should be treated as outpatient.

#### Issues for Referral

- Consider consultation to otorhinolaryngology for medically resistant acute sinusitis or chronic sinusitis.
- Consider referral to allergy/immunology for allergic and immunologic concerns.

## FOLLOW-UP

### FOLLOW-UP RECOMMENDATIONS

- Discharge instructions and medications:
  - Adequate hydration should be maintained.
  - Acetaminophen or ibuprofen for fever and headache as needed
- Activity:
  - The patient may return to school when fevers have resolved.

### PROGNOSIS

- Most patients show clinical improvement within 3–5 days of antibiotic therapy.
- Consider a resistant organism or other diagnosis if no improvement in 3–5 days.

### COMPLICATIONS

- Serious complications occur in 3–11% (1).
- Orbital complications are most common:
  - Preseptal or periorbital cellulitis
  - Orbital cellulitis
  - Optic neuritis
- Intracranial complications:
  - Meningitis
  - Epidural abscess
  - Subdural empyema
  - Cavernous sinus thrombosis

## CODES

### ICD9

- 461.0 Acute maxillary sinusitis
- 461.9 Acute sinusitis, unspecified
- 473.9 Unspecified sinusitis (chronic)

## PEARLS AND PITFALLS

- Duration of symptoms is most important in differentiating simple viral URI from bacterial sinusitis.
- When choosing antibiotic therapy, consider resistance patterns of bacteria in the community.
- Attempt to minimize imaging or diagnostic testing for acute bacterial sinusitis, as a clinical diagnosis is preferred.
- Assess for suppurative complications such as intracranial abscess, orbital cellulitis, and subdural empyema.

# SLIPPED CAPITAL FEMORAL EPIPHYSIS (SCFE)

Donna M. Simmons

## BASICS

### DESCRIPTION

- Slipped capital femoral epiphysis (SCFE) is a condition of the hip in which there is displacement of the femoral epiphysis through the physis.
- SCFE is the most common hip condition affecting adolescents (1).
- Usually occurs during a rapid growth period, and this never occurs after physal closure.
- Acute SCFE:
  - Symptoms <3 wk
  - Joint effusion
  - No remodeling
- Chronic SCFE:
  - Symptoms >3 wk
  - No effusion
  - Joint remodeling
- Stable SCFE:
  - Able to walk/bear weight on the affected leg
  - No effusion
  - Remodeling
- Unstable SCFE:
  - Inability to bear weight on the affected leg
  - Displacement of epiphysis from metaphysis
  - Effusion
  - No remodeling
- Acute on chronic:
  - Symptoms >3 wk duration with an acute exacerbation or change in symptoms
- Atypical SCFE:
  - Associated with renal failure, radiation therapy, or endocrine disorders
  - Age <10 yr or >16 yr
  - Weight <50% (2)
  - Height <10th percentile (3)

### EPIDEMIOLOGY

- A review of pediatric discharges from the Kids' Inpatient Database in both 1997 and 2000 showed an incidence of 10.8 cases in 100,000 children (4):
  - Boys: 13.35 cases in 100,000 children
  - Girls: 8.07 cases in 100,000 children
  - Rarely occurs in obese preschool children
- The incidence was found to be 3.94 times higher in African Americans and 2.53 times higher in Hispanic children than in Caucasians (4).

### RISK FACTORS

- Obesity
- Delayed bone age
- African American race
- Radiation therapy
- Chemotherapy
- Growth hormone deficiency
- Hypothyroidism

- Panhypopituitarism
- Hypogonadism
- Renal failure/Osteodystrophy
- Steroid use
- Down syndrome
- Rubenstein-Taybi syndrome

### PATHOPHYSIOLOGY

- During adolescence, there is a changing orientation of the femoral epiphysis from horizontal to oblique, and inherent weakness of the physal cartilage during the growth period renders the physis vulnerable to weight-bearing stress.
- With endocrine disorders, abnormal growth and mineralization of the cartilage is thought to weaken the growth plate, making it susceptible to shearing forces.

### ETIOLOGY

- Idiopathic in most cases
- Associated with mechanical and constitutional factors that weaken the physis:
  - See Risk Factors.
- Associated with endocrine abnormalities:
  - See Risk Factors.
- Trauma

## DIAGNOSIS

### HISTORY

- Typically seen in an obese adolescent with a limp because of groin, hip, or knee pain
- Pain may be isolated to the thigh or knee.
- Pain may be intermittent or constant for weeks.
- There may be a prior history of radiation treatment, renal failure, or treatment for endocrine disorders.
- There may be a history of trauma.
- May be asymptomatic or found on follow-up radiographs in a patient with previous occurrence of SCFE.

### PHYSICAL EXAM

- Limp
- Anterior hip may be tender.
- Painful range of motion of the hip
- External rotation of the lower extremity with the knee or foot pointing outward
- Flexion of the hip produces outward rotation of the knee
- Limited internal rotation or abduction of the hip
- Should have a normal knee exam

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

- Most cases of SCFE require no lab testing.
- For atypical cases:
  - Assess renal function, BUN, and creatinine.
  - T4 and thyroid-stimulating hormone to evaluate for hypothyroidism
  - Consider other endocrinopathies if short stature, age <12 yr or >16 yr.
- CBC, ESR, C-reactive protein and blood culture if there is suspicion for infection

### Imaging

- The gold standard for diagnosis is plain radiographs:
  - Views to order:
    - AP pelvis and Lauenstein (frog-leg) lateral views are best for obese patients with chronic SCFE.
    - AP pelvis and cross-table lateral views are best for acute, unstable SCFE.
    - Consider obtaining a lateral view if the AP view is normal. The epiphysis initially slips posteriorly and may be seen only on the lateral view.
    - Obtain radiographs of the opposite hip, as 20–40% of cases have bilateral SCFE (5).
  - Findings:
    - Widening, lucency, or irregularity (blurring of the junction between the metaphysis and the growth plate or diminished height of the epiphysis) of the physis in the preslip stage
    - Klein's line: A line drawn along the superior border of the femoral neck intersects the femoral epiphysis; normally, the epiphysis projects above the line. With SCFE, the epiphysis projects below this line to varying degrees depending on the displacement.
    - Blanch sign of steel: A crescent-shaped area of increased density caused by overlapping of the epiphysis onto the medial aspect of the femoral neck
    - SCFE is often described as the ice cream falling off the cone.
    - Chronic SCFEs show evidence of remodeling, callus formation.
    - Lateral radiograph may show a step-off at the anterior epiphyseal–metaphyseal junction.
- Severity of SCFE is based on the degree of slip/displacement of epiphysis seen on radiographs:
  - Mild SCFE is <1/3 the diameter of the femoral neck.
  - Moderate is >1/3 and <1/2 the diameter of the femoral neck.
  - Severe SCFE is >1/2 the diameter of the femoral neck.
- CT may be useful for asymptomatic, mild SCFE.
- MRI is helpful for detection of avascular necrosis (AVN), asymptomatic preslip (may show edema, widening of epiphysis), or when there is a high suspicion for SCFE with normal radiographs.
- Bone scan is useful for detecting AVN:
  - Shows decreased activity/uptake on the femoral side of the growth plate and increased uptake with new bone growth.
  - Chondrolysis will show increased activity/uptake on both sides of the growth plate along the acetabulum and femur.
- US is not used routinely; may be helpful with staging and follow-up of SCFE.

**DIFFERENTIAL DIAGNOSIS**

- Knee injury
- Pulled groin
- Hemarthrosis
- Septic joint
- Osteomyelitis
- Legg-Calvé-Perthes disease
- Transient synovitis
- Tumors

 **TREATMENT**

**PRE HOSPITAL**

Splinting/Immobilization

**INITIAL STABILIZATION/THERAPY**

- Immediate immobilization, non-weight bearing to prevent worsening of SCFE:
  - Wheelchair, stretcher
- Refer to an orthopedic surgeon immediately.
- Administration of pain medication
- It is important to determine whether the patient has an acute SCFE or an unstable SCFE, which requires immediate treatment to prevent further slippage and possible complications.

**MEDICATION**

- Local anesthetic:
  - Femoral nerve blockade with local anesthetic, preferably long acting, gives significant analgesia and reduces or eliminates analgesic requirement
  - Lidocaine (max single dose 5 mg/kg)
    - Anesthesiologists or interventional pain specialists typically have expertise in this field.
- Morphine 0.1 mg/kg IV/IM/SC q2h PRN:
  - Initial morphine dose of 0.1 mg/kg IV/SC may be repeated q15–20min until pain is controlled, then q2h PRN.
- Fentanyl 1–2 µg/kg IV q2h PRN:
  - Initial dose of 1 µg/kg IV may be repeated q15–20min until pain is controlled, then q2h PRN.
- Codeine/Acetaminophen dosed as 0.5–1 mg/kg of codeine component PO q4h PRN
- Hydrocodone or hydrocodone/acetaminophen dosed as 0.1 mg/kg of hydrocodone component PO q4–6h PRN

**SURGERY/OTHER PROCEDURES**

In situ fixation (pinning with a single screw):

- No reduction, as manipulation could result in further damage and disruption of the blood supply to the physis; increases risk of complications
- Consideration is given to pinning the unaffected side if there is a risk of contralateral SCFE, especially in children with endocrinopathies.

**DISPOSITION**

**Admission Criteria**

- Admit acute, unstable SCFE patients since they are more likely to develop complications.
- Bilateral SCFE

**Discharge Criteria**

Chronic, stable SCFE:

- Must avoid weight bearing to prevent further slippage
- Use crutches and bed rest until evaluated by an orthopedic surgeon for repair.

**Issues for Referral**

- Endocrinologist for atypical SCFE and endocrinopathy if suspected
- Nephrologist for renal disease
- Counseling for weight reduction

 **FOLLOW-UP**

**FOLLOW-UP RECOMMENDATIONS**

- Discharge instructions and medications:
  - Pain medications
- Activity:
  - If discharged for chronic SCFE, non-weight bearing and use of crutches
  - Resume activities when cleared by an orthopedic surgeon:
    - Generally after 12 wk or when weight bearing and pain has resolved

**Patient Monitoring**

- Immediate evaluation if symptoms of SCFE occur in the contralateral hip
- Radiographic follow-up during 1–2 yr after initial diagnosis or until physis closes

**PROGNOSIS**

- Mild SCFE patients have a good result with single pin in situ fixation, maintaining ability to participate in all activities once healed.
- 30–60% develop SCFE on the contralateral side, with most presenting within 18 mo of diagnosis (6).
- High incidence of contralateral SCFE with endocrinopathies

**COMPLICATIONS**

- Risk of progressive deformity without treatment
- AVN occurs most commonly with unstable SCFE and more severe SCFE and may be a complication of pinning due to injury to the lateral epiphyseal artery.
- Chondrolysis may be present before treatment, occurs if untreated, and may occur postoperatively. Single pinning rarely results in chondrolysis.
- Early osteoarthritis both with and without treatment
- Pin penetration into the joint
- Leg length inequality, limp

Slipped capital femoral epiphysis. Available at <http://www.eorif.com/Pediatrics/SCFE.html>. Accessed November 2, 2009.

**See Also (Topic, Algorithm, Electronic Media Element)**

- Fracture, Femur
- Limp

 **CODES**

**ICD9**  
732.2 Nontraumatic slipped upper femoral epiphysis

**PEARLS AND PITFALLS**

- Delay in diagnosis will result in complications such as AVN, chondrolysis, etc.
- Failure to consider hip pathology in patients with symptoms related to isolated groin, thigh or knee pain
- Failure to evaluate both hips given the incidence of bilateral SCFE at presentation
- Use of femoral nerve blockade with local anesthetic reduces or eliminates the need for analgesics.

# SPINAL CORD COMPRESSION

Audrey H. Le

## BASICS

### DESCRIPTION

Compression of the spinal cord occurs when extrinsic forces breach the structural integrity of the cord resulting in neurologic dysfunction.

### EPIDEMIOLOGY

#### Incidence

- The overall incidence of spinal cord injury in children is 1.99 per 100,000 (1).
- In a study of 122 children with spinal trauma, 33% had incomplete neurologic injury, while 17% had complete myelopathy (2).
- Spinal cord disease occurs in 4% of pediatric patients with newly diagnosed systemic malignancies. Spinal cord compression occurs in 3% of these patients (3):
  - Among these, sarcomas, germ cell tumors, and lymphomas are most common.

### RISK FACTORS

- Males are at higher risk than females for spinal cord injury.
- Black children have a higher frequency of spinal cord injury compared to other ethnicities (1).

### GENERAL PREVENTION

- Encourage use of seat belts and shoulder restraints. Motor vehicle collisions account for the majority of spinal cord injury (1).
- Counsel teenagers about safe driving.

### PATHOPHYSIOLOGY

- Traumatic extrinsic forces cause unnatural flexion, extension, rotation, or compression of the vertebral column, which invades the spinal canal space and compresses on the spinal cord:
  - Rarely, patients may have an epidural or subdural hematoma of the spine.
  - Secondary inflammation and swelling can cause morbidity as well.
- Neoplasms can gain access to the spinal canal from the paraspinal region, invade the epidural space, or metastasize to the vertebral column.

### ETIOLOGY

- Trauma
- Infection:
  - Vertebral osteomyelitis
  - Spinal epidural or subdural abscess
- Neoplasms, primary or metastatic:
  - Of the spine or structures surrounding the vertebral spinal column
- Rheumatic diseases

## DIAGNOSIS

### HISTORY

- Elicit any history of trauma and the mechanisms involved.
- Past medical history, including cancer and conditions causing immunocompromise
- Ask about past or current use of illicit IV drugs.
- Medications that can increase the tendency to bleed
- Recent surgeries or medical procedures, including an epidural or lumbar puncture
- Obtain a thorough history since early symptoms can be vague:
  - Symptoms may include:
    - Neck or back pain that may be radicular in nature, particularly when the cauda equina is involved
    - Pain that worsens on lying down.
    - Weakness of arms with cervical compression and weakness of legs with thoracic or lumbar compression
    - Bowel and bladder dysfunction
    - Sexual dysfunction in males

### PHYSICAL EXAM

- Physical exam will vary based on the level of the spinal cord affected.
- Fever is not reliably present with infection.
- Hypotension is present when injury to the spinal cord results in neurogenic shock:
  - Patients in neurogenic shock characteristically, though not universally, have bradycardia with warm, dry extremities.
  - In multisystem trauma, other causes for hypotension must be considered and excluded.
- Compression at or above the conus medullaris affecting the corticospinal tract will typically result in symmetric motor deficits:
  - In the upper extremity if above the thoracic spine
  - In the lower extremity when compression is at or below the thoracic spine
  - Hyperreflexia may be found below the level of the compression.
  - Babinski sign may be present.
- Compression below the conus medullaris may result in cauda equina syndrome:
  - Motor weakness and hyporeflexia of the legs, which may be asymmetric
- Sensory deficits, while less common than motor, can be found in most patients.
- Decreased anal sphincter tone may be present.
- Urinary retention secondary to bladder sphincter dysfunction may be present.
- Ataxia secondary to disruption of the spinocerebellar tract may occur.

## DIAGNOSTIC TESTS & INTERPRETATION

### Lab

- CBC, ESR, and C-reactive protein may be helpful screening tests if infection is suspected.
- PT, PTT, and INR if patient is on anticoagulation therapy or has a known or suspected bleeding disorder

### Imaging

- Plain radiographs may be used to screen for disruption of the spinal column in trauma.
- CT scans are required if radiographs inadequately show the areas of suspicion or if suspicion for injury remains despite normal plain films.
- MRI is the preferred imaging modality for spinal cord injury (4):
  - Also preferred for:
    - Atraumatic etiology for spinal cord compression, such as neoplasms and infections.
    - Plain radiographs provide inadequate screening since abnormalities are seen only after >50% of bone destruction has occurred.
    - The spinal column is often normal even as lesions such as abscess or hematoma impinge on the spinal cord.

### DIFFERENTIAL DIAGNOSIS

- Trauma:
  - Strained muscles or ligaments
  - Soft tissue contusion
- Infection:
  - Meningitis
  - Discitis
  - Osteomyelitis
- Arthritis
- Transverse myelitis
- Spondylolisthesis, spondylolysis
- Sickle cell vaso-occlusive pain crisis
- Referred back pain from conditions involving abdominal or pelvic organs
- Guillain-Barré syndrome
- Multiple sclerosis

## TREATMENT

### PRE HOSPITAL

- Assess and stabilize airway, breathing, and circulation.
- C-spine immobilization as indicated

### INITIAL STABILIZATION/THERAPY

- Assess and stabilize airway, breathing, and circulation.
- C-spine immobilization as indicated
- Evaluate for traumatic injury.
- Spinal infections and abscesses should be treated empirically with broad-spectrum antibiotics including coverage for MRSA (5,6).
- Provide analgesia as needed.

**MEDICATION**

**First Line**

- Methylprednisolone 30 mg/kg IV over 15 min, followed by an infusion of 5.4 mg/kg/hr over the next 23 hr (7–9):
  - Indicated for neoplastic or inflammatory etiology of spinal cord compression
  - Dosage derived from adult guidelines due to lack of high-level evidence in pediatrics
  - Steroids are no longer routinely used for spinal cord trauma, as current data has led to its withdrawal from Advanced Trauma Life Support (ATLS) guidelines. The decision to use steroids must be made on a case-by-case basis and is very institution specific.
- Antibiotics:
  - Vancomycin 40 mg/kg/day IV divided q6–8h, max single dose 1 g, PLUS:
    - A 3rd-generation cephalosporin: eg, ceftriaxone, 80–100 mg/kg/day IV divided q12–24h, max single dose 2 g/day, OR
    - A 4th-generation cephalosporin: eg, ceftazidime, 90–150 mg/kg/day IV divided q8h, max single dose 6 g/day; or cefepime 50 mg/kg/dose IV q8–12h, max single dose 2 g
- Neoplasms may be treated with any combination of radiation, chemotherapy, and steroids in consultation with an oncologist.

**SURGERY/OTHER PROCEDURES**

- Early decompression surgery within 24–72 hr in patients with acute spinal cord injury may improve neurologic outcome (7).
- Surgical treatment in conjunction with IV antibiotics may improve outcome in selected patients with spinal abscesses (8,9).

**DISPOSITION**

**Admission Criteria**

- Admit all with spinal cord compression.
- Critical care admission criteria:
  - Airway compromise or respiratory insufficiency
  - Cardiovascular insufficiency
  - Decreased mental status
  - Unstable lesion with potential for rapid progression

**Discharge Criteria**

Criteria for discharge after admission:

- Normal and stable hemodynamic parameters
- Relief of spinal compression and stabilization of condition leading to the compression

**Issues for Referral**

- Care for all children with spinal cord compression should be provided in conjunction with a trauma surgeon, orthopedic surgeon, and/or neurosurgeon.
- An oncologist or rheumatologist may need to be consulted based on the etiology of the lesion.

 **FOLLOW-UP**

**FOLLOW-UP RECOMMENDATIONS**

- Depending on the extent of injury and residual deficits, patients should be set up with physical and occupational therapy on hospital discharge.
- Some patients may benefit from discharge from the hospital directly into a rehabilitation center.

**PROGNOSIS**

- Children presenting with complete motor spinal cord injury have a poorer prognosis than those with partial lesions (10).
- A pediatric study found that those with lesions at higher neurologic levels have lower functional status at admission and discharge as well as poorer functional recovery (10).

**COMPLICATIONS**

- Paralysis and immobility, which can increase the risk of:
  - Pressure sores
  - Deep venous thrombosis
  - Lung infections
- Loss of bowel, bladder, and sexual function
- Muscle spasticity and/or limb contractures
- Autonomic dysreflexia

 **CODES**

- ICD9**
- 336.9 Unspecified disease of spinal cord
  - 952.9 Unspecified site of spinal cord injury without spinal bone injury
  - 953.9 Injury to unspecified site of nerve roots and spinal plexus

**PEARLS AND PITFALLS**

- Pearls:
  - Back pain is a common complaint for pediatric patients that is only rarely associated with a spinal cord lesion. A thorough history and examination is adequate to detect spinal cord compression.
  - Chronic back pain is uncommon in children.
  - Pain that becomes worse on lying down and occurs more at night may point to a pathologic etiology.
  - Any neurologic changes consistent with spinal cord compression, however subtle, warrant careful evaluation.
- Pitfalls:
  - Always advise repeat follow-up after a diagnosis of benign back pain until resolution.
  - Do not dismiss subtle signs in patients with a history of cancer or those who are immunocompromised.

# SPLENOMEGALY

Todd A. Mastrovitch  
Jewel Jones-Morales

## BASICS

### DESCRIPTION

- Splenomegaly is an enlargement of the spleen, which is anatomically located in the left upper quadrant of the abdomen.
- Splenomegaly is a feature of a broad range of diseases, as it is often the result of systemic disease and not the result of primary splenic disease.
- It is most commonly caused by infection, autoimmune disorders, or hemolytic anemia but may be a feature of neoplasm.
- The spleen may be palpable in 15–30% of healthy neonates, 10% of healthy children, and 2–3% of college freshmen.
- In children, normal splenic size is related to age, height, weight, and body surface area. The clinical exam is inaccurate in detecting small increases in the size of the spleen.
- An easily palpable spleen below the costal margin in children >3–4 yr of age should be considered abnormal until proven otherwise.

### GENERAL PREVENTION

In malaria-endemic areas, prophylaxis against malaria disease and strategies to control and prevent spread through mosquito inoculation

### PATHOPHYSIOLOGY

- The spleen is the largest lymphoid organ in the body.
- It serves as a filter to remove defective cells, clears circulating encapsulated bacteria, is a reservoir for platelets, and produces blood components if the bone marrow is unable to meet demands:
  - A normal-sized spleen can hold 1/3 of the circulating platelets, and an enlarged spleen can hold up to 90% of circulating platelets.
- The white pulp is the lymphoid tissue.
- The red pulp forms most of the splenic tissue and consists of splenic cords.
- The circulation through the cords is slow.
- This delay provides prolonged exposure of blood cells, bacteria, and particulate matter to the dense mononuclear-phagocyte elements in red pulp.

### ETIOLOGY

- Splenomegaly results from response to hyperfunction, abnormal blood flow, and infiltration.
- Metabolic disease: Gaucher disease, Niemann-Pick disease, amyloidosis
- Defective RBC removal: Sickle cell disease, thalassemia, spherocytosis, macroglobulinemia

- Benign and malignant infiltration: Histiocytosis X, acute and chronic leukemias, lymphoma, hemangiomas, abscesses, cysts, splenic metastases
- Organ failure: Liver cirrhosis, CHF
- Infection: Infectious mononucleosis, malaria, schistosomiasis, echinococcosis, leishmaniasis, TB, brucellosis, infectious mononucleosis, viral hepatitis, infective endocarditis
- Extramedullary hematopoiesis: Myelofibrosis, marrow damage by radiation, toxins

### COMMONLY ASSOCIATED CONDITIONS

- Infectious
- Neoplastic
- Hematologic disease
- Vascular disorders
- Hepatic disorders
- Metabolic disorders

## DIAGNOSIS

### HISTORY

- History of acute illness including fever, chills, sore throat, rhinorrhea, cough especially with viral infections
- Abdominal pain, back pain, early satiety due to splenic enlargement
- Weakness, fatigue, jaundice especially if hemolytic anemia
- Ingestion of hepatotoxic agents especially with hepatitis or portal HTN
- Abdominal trauma may be associated with splenic hematoma
- Bone pain, fever, malaise, lethargy, bruising more than leukemia
- Lymphadenopathy, weight loss, fevers with neoplasm

### PHYSICAL EXAM

- It is advised to begin palpation in the left lower quadrant to ensure that a massively enlarged spleen tip is not missed in the upper quadrant exam.
- Fever
- Ill appearance
- Palpable left upper quadrant abdominal mass or splenic rub
- Palpate for lymphadenopathy
- Pallor, petechiae, icterus
- Abdominal tenderness, distention, ascites, hepatomegaly
- Castell sign: Percussion of the enlarged spleen in the left anterior axillary line

## DIAGNOSTIC TESTS & INTERPRETATION

### Lab

#### Initial Lab Tests

- CBC with differential:
  - Peripheral blood smear helps detect sickle cell disease, hemolytic anemia, leukemia, malaria
  - Reticulocyte count for hemolytic anemia
- LFTs (AST, ALT, albumin, bilirubin)
- PT/PTT
- In the appropriate circumstances, consider:
  - Viral antibody titers to detect Epstein-Barr virus, cytomegalovirus, HIV, parvovirus, *Toxoplasma gondii*
  - Antinuclear antibody titer
  - Cultures: Bacterial/Fungal
  - Bone marrow biopsy
  - Reduced acid beta-glucosidase

#### Imaging

- US is used to confirm diagnosis and to confirm if the spleen is enlarged or if there is the presence of a space-occupying lesion.
- If no evidence of hemolytic disease but evidence of congestion, consider:
  - CT scan
  - MRI

#### Pathological Findings

- Tumor deposits in the case of lymphoma/leukemia
- Parasitemia in the case of malaria, leishmaniasis, schistosomiasis, etc.
- Infiltrative disease with lipids in Gaucher disease and with sphingomyelin in Niemann-Pick disease

### DIFFERENTIAL DIAGNOSIS

- Infectious—bacterial:
  - Bacteremia
  - Pneumonia
  - TB
  - Brucellosis
  - Tularemia
  - Syphilis
  - Leptospirosis
- Infectious—viral:
  - Epstein-Barr virus
  - Cytomegalovirus
  - HIV
  - Rubella
  - Herpes
  - Hepatitis A, B, C
- Infectious—rickettsial/protozoan:
  - Rocky Mountain spotted fever
  - Malaria
  - Toxoplasmosis
  - Trypanosomiasis
  - Babesiosis
  - Schistosomiasis
  - Visceral larval migrans

- Infectious—fungal:
  - Histoplasmosis
  - Kala azar
- Hematologic disease:
  - Hereditary spherocytosis
  - Early sickle cell disease during splenic sequestration crisis
  - Hemoglobin C disease
  - Thalassemia major
  - Autoimmune hemolytic anemia
  - G6PD deficiency
  - Isoimmunization disorders
  - Infantile pyknocytosis
- Vascular disorders:
  - Cavernous thrombosis of the portal vein
  - Budd-Chiari
  - Splenic vein thrombosis
  - Splenic hematoma
  - Splenic hemangioma
- Metabolic/Storage disease:
  - Gangliosidosis
  - Mucopolipidoses
  - Metachromatic leukodystrophy
  - Wolman disease
  - Gaucher disease
  - Niemann-Pick disease
  - Amyloidosis
- Neoplastic disease:
  - Leukemia
  - Lymphoma
  - Lymphosarcoma
  - Neuroblastoma
  - Histiocytosis X
  - Familial hemophagocytic reticulocytosis
- Liver disease/cirrhosis:
  - Biliary atresia
  - Wilson disease
  - Cystic fibrosis
  - Hereditary hemochromatosis
  - Congenital hepatic fibrosis
  - Autoimmune hepatitis
  - Primary sclerosing cholangitis
- Miscellaneous:
  - Serum sickness
  - Connective tissue disorders
  - Juvenile rheumatoid arthritis
  - Systemic lupus erythematosus
  - Sarcoidosis
  - Splenic hamartoma
  - Splenic cysts
  - Splenic trauma
- Nonsplenic upper left quadrant masses:
  - Large kidney
  - Retroperitoneal tumor
  - Adrenal neoplasm
  - Ovarian cyst
  - Pancreatic cyst
  - Mesenteric cyst

## TREATMENT

### PRE HOSPITAL

- Address issues of airway, breathing, and circulation.
- Consider IV fluid therapy if hypotensive.

### INITIAL STABILIZATION/THERAPY

- Address issues of airway, breathing, and circulation with focus on BP/circulatory function.
- Assessment for splenic sequestration that may necessitate exchange transfusion
- Assessment for splenic trauma that may require fluid/blood resuscitation and further radiologic studies
- Identification of patients who have an oncologic process that will require treatment at a pediatric tertiary care center

### MEDICATION

Analgesics or antipyretics may be used as indicated:

- Ibuprofen 10 mg/kg PO q6h
- Acetaminophen 15 mg/kg PO q4h PRN

### SURGERY/OTHER PROCEDURES

Splenectomy is uncommonly performed in children with splenomegaly.

### DISPOSITION

#### Admission Criteria

- Acute decompensation from severe anemia or splenic sequestration
- Presence of etiology requiring inpatient workup or therapy, such as neoplastic, infectious, or other causes

#### Discharge Criteria

- Stable hematocrit
- Plan of care for patients with medical conditions that have led to the splenomegaly

#### Issues for Referral

- Need for a pediatric subspecialist for oncologic and/or hematologic conditions leading to splenomegaly
- Need for referral to a pediatric infectious disease specialist to coordinate care of the infected patient with splenomegaly

## FOLLOW-UP

### FOLLOW-UP RECOMMENDATIONS

- Discharge instructions and medications:
  - Adequate oral fluid intake and caloric requirements for recovery from the condition that caused the splenomegaly
  - Possible medications to treat infections such as malaria or other parasitic disease
- Activity:
  - Patients with enlarged spleens should avoid contact sports and aggressive play until the splenomegaly has resolved.
  - For example, most patients recovering from mononucleosis are asked to stay out of sports for 1–2 mo.

### Patient Monitoring

Frequent checks with the primary care physician are recommended to determine the improvement of the swelling of the spleen.

### DIET

Diet as tolerated with plenty of oral fluids and nutrition to support the hematologic system with iron and folate.

### PROGNOSIS

- Most patients with mononucleosis make a full recovery within 1 mo.
- Depending on the other cause of splenomegaly, the prognosis varies.

### COMPLICATIONS

- As asplenic children are at risk of overwhelming postsplenectomy infection, nonoperative management may be considered a quality of care indicator.
- The estimated lifetime risk for developing overwhelming postsplenectomy infection ranges from 1–11% and is associated with a mortality of up to 50%.

## CODES

### ICD9

789.2 Splenomegaly

### PEARLS AND PITFALLS

- Children with acutely enlarged spleens should avoid contact, collision, or limited contact sports.
- Viral-related splenomegaly rarely lasts > 2 mo.
- Ensure appropriate immunization prior to splenomegaly.
- Counsel the family on the care of asplenic children.

# STAPHYLOCOCCAL SCALDED SKIN SYNDROME

Kyle A. Nelson

## BASICS

### DESCRIPTION

- Staphylococcal scalded skin syndrome (SSSS) is an exfoliative skin condition resembling a burn injury caused by exfoliative (epidermolytic) toxins (ETs) of *Staphylococcus aureus* (1).
- The severity of this toxin-mediated disease varies along a spectrum of localized areas of tender erythema and blistering (also known as bullous impetigo) to a generalized form with widespread skin exfoliation (1).
- Generalized SSSS is sometimes referred to as Ritter disease; in neonates, it is referred to as pemphigus neonatorum (1).

### EPIDEMIOLOGY

- S. aureus* is a common commensal organism. The nasal carriage rate is 1/3 in the general population (2,3). ~30% of neonates are colonized within 1 wk of birth (4–6).
- The overall carriage rate of *S. aureus* strains that produce ETs is ~5% (2,7,8).
- Although the *S. aureus* colonization rate is relatively high, most are asymptomatic carriers.
- Generalized SSSS occurs most commonly in neonates, infants, and children <5 yr of age and is rare in healthy adults.
- Adults diagnosed with SSSS usually have the localized form (1,9,10).
- While isolated cases occur, outbreaks have been reported in nurseries and day care centers.
- The incidence of SSSS may increase as rates of skin and soft tissue infections caused by *S. aureus*, including MRSA strains, are increased.

### RISK FACTORS

Comorbid conditions associated with poor renal function or immunosuppression (1,11)

### GENERAL PREVENTION

- In the health care setting, infected patients should be isolated, and hand washing as well as cleaning of instruments such as stethoscopes and BP cuffs are important preventive measures.
- Early treatment when there are few lesions of SSSS may limit progression of exfoliation (12).

### PATHOPHYSIOLOGY

- Blisters form due to loss of keratinocyte adhesion in the granular layer of epidermis (13).
- ETs are serine proteases that cleave the cell adhesion molecule desmoglein (Dsg) (13).
- The location of cleavage in SSSS is mid-epidermal. In contrast, the location of cleavage in toxic epidermal necrolysis (TEN) is subepidermal at the dermal–epidermal junction (1,10).
- In localized SSSS, *S. aureus* enters skin through some disruption, causes local infection, and releases ETs. Wide spread of ET is limited by anti-ET antibodies (1,11).
- In generalized SSSS, ET circulates throughout the body from a site of colonization (eg, nares, groin, umbilicus) or local infection (eg, wound, septic arthritis, osteomyelitis) and results in large areas of exfoliation (1,11).

- ETs have specificity to cause blisters only in the epidermis, not in stratified squamous epithelium of mucous membranes, which is a feature of TEN but not SSSS (1,11,13).
- ET are renally excreted; renal impairment plays a key role in limitation of disease severity (1,11).
- Adolescents and adults typically have higher levels of circulating antibodies and increased renal excretion of ET, so disease occurs less frequently except in immunocompromised persons.
- Age-related differences in antibody status and renal function are thought to be important in the higher rate of SSSS in young children (1):
  - Anti-ET antibodies can be found in ~90% of infant cord blood samples, but levels decline to ~30% between age 3 and 24 mo and rise to 50% after age 10 yr and up to 90% by age 40 yr (14).
  - While adult mice can excrete 1/3 of a test dose of ET within 3 hr, infants can only excrete 1/15 of the dose in that time (1,15).
- Anti-ET antibodies may limit progression of the localized form to generalized SSSS. In generalized SSSS, these antibodies are usually absent in acute testing but are present in convalescent testing.

### ETIOLOGY

- ET-producing *S. aureus* cause SSSS (1,10). Most strains belong to phage group II, though other groups can produce ETs (1,10,11). MRSA strains may cause SSSS (12).
- There are 2 types of ETs (ETA and ETB) associated with SSSS. ETA is most common, though geographic differences exist (1,10).

### COMMONLY ASSOCIATED CONDITIONS

- Many affected children are healthy without comorbidities.
- However, older children and adults with generalized SSSS may have comorbid conditions associated with immunodeficiency and/or poor renal function.

## DIAGNOSIS

### HISTORY

- Generalized SSSS may occur concurrently with localized overt or covert infection or follow an infection of the upper respiratory tract, conjunctiva, ears, or umbilical stump (1,10).
- In generalized SSSS, patients often initially have fever, malaise, lethargy, irritability, and poor feeding before onset of skin changes (1)
- In the localized form, there are usually no systemic symptoms or signs (1).
- Clues to diagnosis may be found in the onset and progression of the rash.
- In generalized SSSS, the rash usually begins as tender erythema initially on the head and neck that spreads to include nearly the entire skin surface within a few days. Characteristic large, fragile, thin-roofed blisters soon form, and skin peels in large sheets leaving denuded areas.
- It is important to inquire about previous infections including the involved organisms (if known) and successful treatment, as history of MRSA infections in the patient or close contacts may influence antibiotic choice.

### PHYSICAL EXAM

- The patient should be carefully examined for infectious foci, though this may be lacking in generalized SSSS (1,11).
- In localized SSSS, there are isolated areas of characteristic blisters that easily rupture. The surrounding skin appears normal (1,11).
- Neonates have lesions commonly around the umbilicus and in the perineum, while older children tend to have lesions on the extremities (11).
- In generalized SSSS, patients may appear ill depending on the stage and severity of disease.
- As the tender erythema progresses to widespread involvement, it may be more prominent in the flexural creases (1).
- Soon the patient develops large blisters and large areas of epidermal exfoliation (1).
- The Nikolsky sign is positive. Gentle rubbing pressure of skin will produce a blister, which can usually be demonstrated on both reddened and normal-appearing skin in SSSS (10,11).
- Eyes and mucous membranes are not involved in SSSS, a distinction from TEN (10).

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

- SSSS is typically a clinical diagnosis (11,12).
- No routine tests are available for rapid confirmation (16)
- Swabs of lesions for culture and sensitivity may be helpful to direct antibiotic treatment if initial treatment fails and to identify organisms responsible for secondary infections (11).
- S. aureus* may be isolated from blister fluid in localized SSSS but rarely from blisters or blood cultures of children with generalized SSSS.
- However, isolation of *S. aureus* takes time and is neither sensitive nor specific for SSSS.
- Tests such as polymerase chain reaction or ELISA may identify ET-producing *S. aureus* but are not routinely available.

#### Diagnostic Procedures/Other

If the diagnosis is uncertain, skin biopsy may be necessary and reveals characteristic mid-epidermal cleavage in SSSS.

#### Pathological Findings

Mid-epidermal cleavage site on histologic specimen (1,10,11)

### DIFFERENTIAL DIAGNOSIS

- TEN
- Erythema multiforme major
- Burn injury
- Kawasaki disease
- Toxic shock syndrome
- Bullous varicella
- Bullous disorders
- Pemphigus vulgaris
- Epidermolysis bullosa
- Scarlet fever
- Impetigo

TREATMENT

INITIAL STABILIZATION/THERAPY

Depending on severity, patients may show signs of dehydration, shock, and sepsis and should be treated accordingly.

MEDICATION

First Line

- An antistaphylococcal penicillinase-resistant antibiotic is the initial treatment of choice:
  - Oxacillin 40 mg/kg IV q8h
  - For mild infections, consider oral medication.
- Consider agents also effective against *Streptococcus* species:
  - Clindamycin 10 mg/kg IV q8h
- For generalized SSSS, strongly consider broad-spectrum beta-lactam antibiotics and treatment for possible secondary infection, particularly *Pseudomonas* (11):
  - Gentamicin 5 mg/kg IV single daily dose or 2.5 mg/kg IV q8h
- The need to treat for possible MRSA should also be considered based on history and local prevalence and susceptibility profiles.
- Use analgesics and antipyretics as needed.
- Opioids:
  - Morphine 0.1 mg/kg IV/IM/SC q2h PRN:
    - Initial morphine dose of 0.1 mg/kg IV may be repeated q15–20min until pain is controlled, then q2h PRN.
  - Codeine or codeine/acetaminophen dosed as 0.5–1 mg/kg of codeine component PO q4h PRN
- NSAIDs:
  - Consider NSAID medication in anticipation of prolonged pain and inflammation:
    - Ibuprofen 10 mg/kg/dose PO/IV q6h PRN
    - Naproxen 5 mg/kg PO q8h PRN
  - Some clinicians prefer to avoid due to theoretical concern over influence on coagulation and callus formation.
- Acetaminophen 15 mg/kg/dose PO/PR q4h PRN
- It is generally recommended to allow blisters to remain intact, and wound care for denuded skin should be provided.
- Corticosteroids should be avoided, as they are associated with poor outcomes including risk of secondary infection.
- Topical antibiotics and silver silvadiazene are not recommended.
- Disease is toxin mediated; new lesions may occur during the 48 hr after antibiotics are started but occur uncommonly thereafter and may be associated with treatment failure (11,12).

Second Line

If treatment fails, consider MRSA and/or secondary infection as causal (11):

- Clindamycin 10 mg/kg IV q8h
- Vancomycin 10 mg/kg IV q8h

SURGERY/OTHER PROCEDURES

Patients with widespread exfoliation of severe generalized SSSS may benefit from management at burn centers (10,11).

DISPOSITION

Admission Criteria

- Most should be hospitalized and treated with parenteral antibiotics.
- Consider hospitalization for localized SSSS if dehydration is not improved with initial treatment and there is potential for inadequate ongoing oral intake, significant pain not amenable to outpatient treatment, or secondary infection requiring inpatient care and/or observation.

Discharge Criteria

Consider discharge for well-appearing, adequately hydrated patients able to maintain hydration, with wound care at home, and those who have appropriate follow-up for re-evaluation.

Issues for Referral

If the diagnosis is uncertain, dermatology consultation may be necessary.

FOLLOW-UP

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

Follow-up should occur within a few days to assess status and signs of secondary infection.

PROGNOSIS

- Varies, but most patients heal without scar
- Pediatric mortality for generalized SSSS is <5% (1,10,11).

COMPLICATIONS

- Sepsis
- Shock
- Secondary infection

695.81 Ritter's disease

PEARLS AND PITFALLS

- It is critical to distinguish SSSS from TEN.
- Corticosteroids may be useful in TEN but worsen outcome in SSSS.
- MRSA may cause SSSS.
- While corticosteroids may be helpful in TEN, they are associated with poor outcomes in SSSS.

# STATUS EPILEPTICUS

Robert J. Hoffman

## BASICS

### DESCRIPTION

- Status epilepticus (SE) is defined as >30 min of continuous seizure activity or  $\geq 2$  consequential seizures in 30 min without full recovery of normal baseline mental status between seizures.
- All seizure types may result in SE:
  - Generalized tonic-clonic SE is the most dangerous to neurologic and cardiopulmonary function.
  - Simple partial SE may result without loss of consciousness.
  - Complex partial SE with altered mental status or cognitive changes.
  - Absence seizures as well as nonconvulsive SE occur rarely.

### EPIDEMIOLOGY

#### Incidence

- Incidence in children 20/100,000 per year (1)
- 10% of children with epilepsy will have SE.

### RISK FACTORS

- Epilepsy
- Previous history of SE
- Anticonvulsant medication noncompliance
- Head trauma
- Sedative hypnotic withdrawal

### GENERAL PREVENTION

Compliance on anticonvulsants

### PATHOPHYSIOLOGY

- CNS excitation results in positive reinforcement of excitation by release of excitatory neurotransmitters such as glutamate.
- Prolonged excitation during seizure activity may result in hippocampal damage and further excitatory amino acid release as an impetus for continued seizure activity.
- Main physiologic elements resulting in status SE is imbalance between neuroinhibitory and excitatory impulses.
- Neuroinhibition results from GABA agonizing GABA receptor. Medications that exploit this for therapy include benzodiazepines, barbiturates, valproic acid, and propofol.
- Neuroexcitation results primarily from glutamate and excitatory neurotransmitters at the *N*-methyl-*D*-aspartate (NMDA) receptor. Propofol and ketamine block the NMDA receptor as part of their anticonvulsant properties (2).

### ETIOLOGY

- Epilepsy
- Febrile SE
- Head trauma
- Electrolyte imbalance
- Hypoglycemia
- CNS infection
- Toxin exposure

### COMMONLY ASSOCIATED CONDITIONS

- Fever
- Infection
- Trauma
- Anticonvulsant medication noncompliance
- Drug or toxin exposure

## DIAGNOSIS

### HISTORY

- Epilepsy history and anticonvulsant use
- Recent fever or other infectious symptoms
- Vaccination history
- Metabolic or oncologic disease history
- Recent trauma
- Recent drug or medication exposure

### PHYSICAL EXAM

- Assess vital signs:
  - Note adequacy of respirations, oxygenation, and circulation.
- CNS:
  - Trauma: Abrasions, contusions, Battle sign, otorrhea, hemotympanum, rhinorrhea, raccoon eyes
  - Infection: Meningismus if the patient is relaxed during the interictal period
- Respiratory: Note adequacy of air entry or rales, rhonchi, crackles, or wheeze suggestive of aspiration or infection
- Dermatologic: Note rashes, petechiae or ecchymosis, capillary refill, extremity temperature, and skin turgor.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

- Stat bedside glucose analysis
- Serum chemistry, calcium, and magnesium
- Blood gas analysis with serum lactate
- Other tests as indicated: CBC, C-reactive protein, blood culture, urinalysis/culture, CSF analysis/culture
- Prolactin: Released in large amounts in tonic-clonic seizures; not 100% sensitive/specific, but helpful to detect pseudoseizure (3)

#### Imaging

Cranial CT may evaluate for intracranial lesion and hemorrhage and to assess for elevated intracranial pressure prior to lumbar puncture.

#### Diagnostic Procedures/Other

- ECG
- EEG monitoring is indicated in the management of SE and is necessary if paralysis is required:
  - Spectral-edge (BIS) monitoring may potentially be used as a surrogate for EEG. It is technically simple to determine and interpret and is more widely available.

### DIFFERENTIAL DIAGNOSIS

- Pseudoseizure
- Myoclonus, shivering, or movement disorder
- Sedative hypnotic withdrawal
- Strychnine toxicity
- Tetanus

## TREATMENT

### PRE HOSPITAL

- Assess and stabilize airway, breathing, and circulation.
- Correct hypoxia, hypoglycemia, or hyperthermia:
  - Administer anticonvulsant if protocol permits.

### INITIAL STABILIZATION/THERAPY

- Assess and stabilize airway, breathing, and circulation.
- Correct hypoxia, hypoglycemia, or hyperthermia.
- Certain conditions, such as hypoglycemia, hypoxia, hyponatremia, or toxin-induced seizure, require unique therapy. Standard treatment algorithms for SE will not correct these problems and may increase morbidity and mortality.
- If paralysis is needed, EEG monitoring is necessary.
- After seizure control, determine the underlying cause of seizure.

### MEDICATION

#### First Line

- The traditional algorithm for medication administration is a benzodiazepine  $\times$  2–3 doses followed by a barbiturate.
- Due to the advent of highly effective medications such as propofol and valproic acid, these newer medications may be used instead of barbiturates after initial use of benzodiazepines fails.
- Subsequent medication choice will vary depending on history and clinician preference.
- Benzodiazepine:
  - Diazepam 0.1 mg/kg IV, 0.5 mg/kg PR
    - May repeat IV dose q5min PRN
    - Short-acting benzodiazepine: IV route is preferred but may be given PR.
    - Brief duration of action and little postadministration sedation but imparts risk of seizure recurrence
  - Lorazepam 0.05 mg/kg IV
    - May repeat IV dose q10min PRN
    - Longest-acting widely used benzodiazepine
    - Longest duration of anticonvulsant activity and longest postadministration sedation
  - Midazolam 0.1 mg/kg IV/IM
    - May repeat IV dose q5min PRN
    - Short-acting benzodiazepine, given by IM route if vascular access is not available.
    - Brief duration of action; little postadministration sedation but imparts risk of seizure recurrence
- Barbiturate:
  - Phenobarbital 20 mg/kg IV over 20 min, max single dose 1000 mg/dose
  - Pentobarbital 5 mg/kg IV over 30 min
  - Barbiturates and benzodiazepines depress the CNS synergistically. If using benzodiazepine then barbiturate, anticipate respiratory depression and possible apnea:
    - For this reason, some centers use phenytoin or fosphenytoin as second-line treatment.

**Second Line**

- Antipyretics:
  - Fever in children 6 mo to 6 yr of age may be due to febrile seizure. Treat with an antipyretic.
  - Acetaminophen 15–30 mg/kg PR. 30 mg/kg is only appropriate for the initial loading dose:
    - IV formulation is expected in the U.S. in 2011.
  - Ibuprofen 10 mg/kg IV. Caldolor is a new parenteral ibuprofen formulation.
  - IV antipyretics have potential value in treating febrile SE.
- Pyridoxine: Empirically administer for seizure possibly due to pyridoxine deficiency or toxin:
  - 1 g IV for every 1 g of isoniazid ingested. If an unknown ingestion amount, give 2–4 g IV.
  - 25 mg/kg IV for seizure due to hydrazine ingestions or pyridoxine-dependent seizure
  - Is a GABA precursor and potentially beneficial for many types of seizures
  - An adequate dose is usually not stocked within the emergency department. Do not delay escalating therapy while awaiting the pyridoxine supply.
- Phenytoin 20 mg/kg or fosphenytoin as 20 phenytoin equivalents:
  - Phenytoin 20 mg/kg IV load over 20 min with continuous cardiac monitoring
  - Fosphenytoin can be given rapidly IV or IM:
    - Fosphenytoin causes less hypotension, may be given as rapid bolus, and does not carry risk of tissue necrosis if extravasated.
  - Phenytoin and fosphenytoin are equally effective and require the same duration of time to achieve seizure cessation.
  - Administer neither if the possibility of toxin-induced seizure exists; increases morbidity and mortality from toxin-induced seizures.
  - Do not give phenytoin/fosphenytoin without 1st checking phenytoin level: May cause toxicity.
- Propofol 1 mg/kg IV push, then PRN infusion 0.1 mg/kg/min up to 0.3 mg/kg/min (4,6):
  - The only anticonvulsant with GABA agonist and NMDA antagonist properties
  - May result in respiratory depression necessitating endotracheal intubation
  - Effectively the most powerful anticonvulsant available for emergency department use; is becoming more commonly used as second-line for disruption of status SE
- GABA-agonist infusion:
  - Midazolam, pentobarbital, or valproic acid may be administered by continuous infusion.
  - Valproic acid infusion/loading: Load 25 mg/kg IV over 5–10 min as a single dose
  - Midazolam infusion: Loading dose 0.15 mg/kg IV followed by infusion of 1 µg/kg/min. For every 5 min of seizure activity, double the infusion rate to a max rate of 16 µg/kg/min. If a continuous seizure, this would take 20 min to get to the max rate.
- Third-line medications:
  - Levetiracetam (Keppra) 20–40 mg/kg IV loading dose diluted in 100 mL of normal saline over 15 min; minimal safety/efficacy data (7)
  - Ketamine 1 mg/kg IV bolus followed by 0.05–0.1 mg/kg/min if necessary:
    - NMDA receptor antagonist, anticonvulsant and neuroprotective properties
    - Preserves protective airway reflexes and lack of cardiorespiratory depression
    - Little data and use in the U.S. (3)

- Anticonvulsant drug:
  - If available parenterally, an anticonvulsant used by seizure patients may be given.
  - Carbamazepine and phenytoin may cause seizure or toxicity in overdose. Do not give a loading dose without 1st determining the serum concentration. If a therapeutic serum level is already present, loading additional medication may result in toxicity.
- Inhalational anesthetics:
  - Traditional last-line medication for SE, administered by an anesthesiologist

**DISPOSITION**

**Admission Criteria**

- Consider admitting patients without known epilepsy for whom seizure etiology is uncertain.
- Admit if necessary for expedient neurologic evaluation and anticonvulsant medication loading.
- Critical care admission criteria:
  - Unstable vital signs, endotracheal intubation, or requiring anticonvulsant infusion

**Discharge Criteria**

Patients with resolved SE of known etiology may be safely discharged after asymptomatic:

- If on anticonvulsant medication, assurance that a therapeutic dosing regimen has been determined and the patient has adequate supply of medication
- Patients with resolved febrile SE, no CNS infection/injury, and normal mental status

 **FOLLOW-UP**

**FOLLOW-UP RECOMMENDATIONS**

- Discharge instructions and medications:
  - Take anticonvulsants as prescribed.
- Activity:
  - Seizure patients: Avoid driving motor vehicles or swimming until cleared by a neurologist.

**Patient Monitoring**

- Monitor for seizure recurrence.
- Monitor for anticonvulsant toxicity, such as dizziness or loss of coordination.

**DIET**

- Ketogenic diet for some seizure patients
- Avoid caffeine and chocolate.

**PROGNOSIS**

The prognosis varies depending on the underlying etiology of seizure and duration of seizure activity.

**COMPLICATIONS**

- Neurologic deficit
- Hyperthermia
- Rhabdomyolysis
- Disseminated intravascular coagulation
- End organ injury: Hepatic, renal, CNS
- Cognitive impairment
- Death

 **CODES**

ICD9  
345.3 Grand mal status, epileptic

**PEARLS AND PITFALLS**

- SE is a medical emergency that may result in permanent neurologic injury.
- Aggressive treatment to terminate seizure within 60 min of onset is critical.
- Aggressive anticonvulsant use is indicated. This may cause respiratory depression or apnea.
- A major pitfall is failure to escalate therapy; undertreatment is the greatest risk.
- Propofol has both GABA agonist and NMDA antagonist activity. It should be used readily in patients with SE in the emergency department setting.

# STEVENS-JOHNSON SYNDROME/TEN SPECTRUM

Stephen G. Flynn

## BASICS

### DESCRIPTION

- Stevens-Johnson syndrome (SJS) and toxic epidermal necrolysis (TEN) are severe idiosyncratic cutaneous hypersensitivity reactions characterized by diffuse bullous lesions and mucocutaneous involvement.
- There is a prodrome of malaise and fever, usually with sore throat and eye pain 1–3 days before onset of rash.
- SJS/TEN are considered a spectrum of the same hypersensitivity reaction in which epidermal detachment of <10% body surface area (BSA) is SJS, 10–30% detachment of BSA is SJS/TEN, and >30% detachment of BSA is TEN (1).
- Erythema multiforme (EM) had been considered to be a variant of SJS; it is now noted to be a distinct entity.

### EPIDEMIOLOGY

#### Incidence

- 2 cases per million each year for SJS, SJS/TEN overlap, and TEN (1)
- Affects patients of any age, gender, and ethnicity equally
- Incidence may be highest in spring months.

#### Prevalence

SJS is 3 times more prevalent than TEN (2).

### RISK FACTORS

- HIV—3-fold increased risk for SJS/TEN:
  - May be due to exposure to sulfonamides during treatment or immune dysregulation
- Genetic: Those with HLA-B1502 are at increased risk of SJS/TEN from carbamazepine/aromatic anticonvulsants:
  - Found in Asian/South Asian populations
- Rapid infusion of medication without slow titration of dose (ie, lamotrigine)
- Systemic lupus erythematosus
- UV light exposure or radiation exposure
- Medications (see Etiology)
- Infections (see Etiology)
- Re-exposure to the causative agent can lead to more severe future reactions.

### GENERAL PREVENTION

- The FDA recommends genotype testing on all Asian patients for HLA-B1502 before starting carbamazepine therapy.
- Slow titration of lamotrigine may reduce the likelihood of developing SJS/TEN.
- Avoid the use of those antibiotics, anticonvulsants, or other medications that are known triggers.

### PATHOPHYSIOLOGY

- SJS is an acute cell-mediated hypersensitivity reaction.
- Fas (a cell surface receptor) expressed on keratinocytes interacts with Fas ligand on activated T cells and natural killer (NK) cells causing caspase-induced apoptosis.
- Cytotoxic T lymphocytes and NK cells also induce apoptosis via perforin, granzyme B, and granulysin.
- Increased MHC-I on keratinocytes with overexpression of tumor necrosis factor- $\alpha$  is also postulated in the apoptotic process.

### ETIOLOGY

- Medications:
  - Anticonvulsants (especially carbamazepine, lamotrigine, Dilantin, phenobarbital)
  - Antibiotics (especially sulfonamides, penicillins, and cephalosporins in that order of frequency)
  - NSAIDs
  - Allopurinol
- Infections:
  - Herpes simplex virus
  - Mycoplasma

## DIAGNOSIS

### HISTORY

- Prodrome of 1–14 days after exposure to inciting agent:
  - High fever
  - Myalgia
  - Arthralgia
- Following the prodrome, a characteristic rash develops (see Physical Exam).
- Use of medications or concomitant infections known to cause SJS/TEN

### PHYSICAL EXAM

- Rash often starts on the trunk, spreading to the face and proximal extremities.
- Rash generally starts as macular lesions but may resemble “target lesions” seen in EM minor.
- Target lesions progress to raised, purpuric lesions and bullae:
  - The bullae coalesce, and epidermis sloughs.
- Lesions progress to full-thickness necrosis with blisters that easily break.
- Ulcers and bullae may form on all mucous membranes.
- Ophthalmic involvement includes severe dermatitis and conjunctivitis, which can lead to ulcerations, perforations, and scarring.

- Genital, buccal, and oral mucosal involvement with erythema and erosions can be seen in 90% of patients.
- The extent of BSA involvement distinguishes SJS from TEN, though there is overlap.
- Mucous membrane involvement distinguishes this from EM minor:
  - EM minor is marked by fixed lesions of raised erythematous papules, often with a central darkening or necrosis.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

- Routine lab testing will not be diagnostic.
- Screening for electrolyte abnormalities is indicated.
- Skin and blood cultures should be repeated regularly to assess for superinfection and bacteremia, respectively.

##### Diagnostic Procedures/Other

A histopathologic diagnosis of involved skin with formalin-fixed specimen and 1 immediate frozen section

##### Pathological Findings

- Keratinocyte apoptosis
- Inflammatory infiltration progressing to full-thickness necrosis of the epidermis leading to sloughing

### DIFFERENTIAL DIAGNOSIS

- Infectious:
  - Varicella
  - Staphylococcal scalded skin syndrome
  - Measles
  - Toxic shock syndrome
  - Toxic strep syndrome
- EM minor
- Kawasaki disease
- Henoch-Schönlein purpura
- Fixed drug eruption
- Anticonvulsant hypersensitivity syndrome
- Pemphigus
- Thermal or chemical burns
- Graft versus host disease

## TREATMENT

### PRE HOSPITAL

Assess and stabilize airway, breathing, and circulation.

### INITIAL STABILIZATION/THERAPY

- Assess and stabilize airway, breathing, and circulation.
- Airway support: Respiratory mucosal involvement can occur, leading to a need for mechanical ventilation. Early recognition of the potential for respiratory failure is paramount.
- As with burn patients, fluid resuscitation and support will be needed. Strict monitoring of pulse, BP, and urine output is needed.
- Discontinue use of the offending agent: Decreases mortality from 26% to 5% if inciting medication has a short half-life (1).
- Optimize supportive care, including fluid and electrolyte homeostasis, respiratory support, analgesia, nutritional support, and prevention of infection:
  - Care in a burn unit is often helpful, as the staff is familiar with unique nature of care, needs, and risks associated with this condition.

### MEDICATION

#### First Line

- Wound care: Permeable, nonadherent, comfortable dressing easily applied and removed for re-epithelialization:
  - For SJS, Acticoat (a nanocrystalline silver dressing) and AQUACEL Ag (a hydrofiber dressing with silver) have been used.
  - For TEN, Suprathel (a synthetic copolymer) has been used.
  - Early consultation with dermatology for treatment guidance is crucial to maximize patient outcome.
- Ophthalmologic management: Consider the following based on ophthalmologist recommendation:
  - Topical lubricants, corticosteroid eye drops, or topical antibiotics
- Oral care: Frequent mouth care with chlorhexidine oral rinses
- Prophylactic antibiotics are not indicated:
  - Antibiotics are indicated only for bacterial superinfection.

#### Second Line

- Use of corticosteroids or intravenous immunoglobulin (IVIG) is considered controversial, and neither is routinely recommended.
- Plasmapheresis has been used successfully for TEN refractory to corticosteroids and IVIG:
  - The success rate has been documented as high at 80% in the literature (3).

### SURGERY/OTHER PROCEDURES

Debridement of epidermis prior to application of occlusive dressings

### DISPOSITION

#### Admission Criteria

Critical care admission criteria:

- Patients should be admitted to a pediatric ICU or burn unit and kept in isolation.

#### Discharge Criteria

Patients diagnosed with SJS or TEN in the emergency department are not candidates for discharge home.

## FOLLOW-UP

### FOLLOW-UP RECOMMENDATIONS

- Skin care until all lesions have healed
- Ophthalmologic follow-up to manage eye complications

### DIET

- Pediatric patients with SJS/TEN spectrum have increased metabolic requirements.
- Resting energy requirements may be 30% above baseline.
- NG feeds or parenteral nutrition to meet extra caloric requirements and protect oral mucosal involvement may be indicated.

### PROGNOSIS

- The mortality rate of SJS is 5% (1).
- The mortality rate of TEN is 30–50% (1).
- Mortality rates are lower in children than adults.

### COMPLICATIONS

- Infections
- Electrolyte abnormalities
- Dehydration
- Hypovolemic shock
- Respiratory insufficiency
- Corneal ulceration

- Kawasaki Disease
- Rash, Vesicobullous
- Toxic Shock Syndrome

## CODES

### ICD9

- 695.13 Stevens-Johnson syndrome
- 695.15 Toxic epidermal necrolysis

## PEARLS AND PITFALLS

- SJS and TEN are part of a continuum of the same hypersensitivity reaction. SJS is marked by epidermal detachment of <10% BSA, while TEN involves >30% detachment.
- Morbidity and mortality are high, particularly with TEN.
- Care in a burn unit or center with experience in managing this condition is highly preferred.
- EM had been considered to be a variant of SJS; it is now noted to be a distinct entity.
- Medications are the most common trigger for both SJS and TEN.

# STOMATITIS

Abu N.G.A. Khan  
Faiz Ahmed

## BASICS

### DESCRIPTION

Stomatitis is an inflammation of the mucous lining of any of the structures in the mouth, including the cheeks, gums, lips, floor, or roof of the mouth:

- Herpangina is a disease caused by coxsackievirus group A and marked by stomatitis consisting of 1–2-mm oral vesicles, ulcers, and fever.
- Herpetic gingivostomatitis is caused by herpes simplex virus (HSV) and consists of 1–2-mm vesicular/ulcerative lesions primarily in the anterior part of the mouth, over the gums, and at the mucocutaneous junction of the lips.

### EPIDEMIOLOGY

#### Incidence

- Enteroviral infections occur commonly in summer and fall months.
- Acute herpetic stomatitis is common in children 1–3 yr of age.
- Recurrent aphthous stomatitis has a prevalence of 20–37% in children.

### RISK FACTORS

- Exposure to children with viral infection, especially in day care or hospital settings
- Poor oral hygiene
- Immunodeficiency
- Medication, radiation, or chemotherapy

### GENERAL PREVENTION

- Hand washing can prevent spread of viral infections.
- Contact isolation for children with viral stomatitis, especially in a day care setting

### PATHOPHYSIOLOGY

- Infection, inflammation, or trauma leads to interruption of the integrity of the mucosal epithelium.
- Ongoing inflammation leads to further denudation of the epithelium.
- Inflammatory cells and mediators can produce exudates and erythema of the ulceration.

### ETIOLOGY

The inflammation can be caused by conditions in the mouth itself (eg, poor oral hygiene), from mouth burns from hot food or drinks, or by conditions that affect the entire body such as infection, medications, allergic reactions, etc.:

- Viral infections (eg, coxsackievirus group A, HSV)
- Recurrent aphthous ulcers (usually caused by microtrauma, stress, hematinic vitamin deficiencies, food allergies, radiation or chemotherapy)
- Mechanical causes like dental braces causing oral ulceration

- PFAPA syndrome with periodic fever, aphthous stomatitis, pharyngitis, and adenitis. Usually is self-limiting. 1 dose of an oral steroid is usually helpful.
- Vincent stomatitis, also known as acute necrotizing ulcerative gingivitis (ANUG) or trench mouth, is characterized by gingival ulceration covered with grayish pseudomembrane, oral malodor, fever, cervical lymphadenopathy. This is associated with infection with spirochetes and fusobacteria that are susceptible to penicillin or macrolide antibiotics.

## DIAGNOSIS

Diagnosis is usually evident by history and clinical observation.

### HISTORY

- Focus on onset, duration, pain, and associated symptoms (eg, hand or foot lesions, dermatologic complaints, fever, past medical history, and exposure history)
- Symptoms: Fever, decreased oral intake, pain in the mouth, drooling
- Associated symptoms: Malaise, diarrhea, rash in the palm or sole, or other constitutional symptoms
- Chronic medical problems: Immunodeficiency states (eg, HIV and neutropenia), poor nutritional status, and inflammatory bowel disease are associated with development of mucosal ulceration.

### PHYSICAL EXAM

- Physical exam should focus on the eyes, ears, nose, throat, neck, and skin.
- Enteroviral infections are associated with small shallow ulcerations with smooth borders on the posterior oral cavity structures such as the tonsils, soft palate, and pharynx.
- Hand-foot-and-mouth disease, due to coxsackievirus (a type of enterovirus), consists of lesions in the mouth as well as the palms and soles.
- Herpangina consists of oral vesicles and ulcers, typically around the fauces, near the tonsillar pillars.
- HSV infections are shallow ulcers with irregular, erythematous borders that coalesce; they are found on the lips, tongue, and gingiva.
- Recurrent aphthous stomatitis lesions are usually round to oval and have a white-yellow fibrinous pseudomembranous cap.
- Gingivitis in association with stomatitis is usually present in drug-induced causes of stomatitis as well as with HSV.
- Herpetic whitlow is the transmission of herpesvirus and development of lesions on the extremities, notably the fingers, due to direct contact with lesions in the mouth.

- Oral thrush (moniliasis) is the most common form of stomatitis in infants and children with immunodeficiency.
- Aphthous stomatitis due to thiamine (vitamin B<sub>1</sub>) deficiency.
- Strawberry tongue in strep throat or Kawasaki disease
- Varicella may present with grouped vesicles or erosions on the tongue, gingiva, buccal mucosa, and lips. In severe cases, there may be lesions in the oral cavity, particularly on the soft palate.
- Smallpox may also present with small red spots on the tongue and in the oral mucosa following a prodromal period with fever. These then can become ulcerated.
- Stevens-Johnson syndrome presents with large irregular ulcers on any mucous membrane, which may occasionally be deep and hemorrhagic.
- Behçet syndrome and Reiter syndrome may have painless ulceration of the oral mucous membranes.

### DIAGNOSTIC TESTS & INTERPRETATION

A careful history and physical exam are often sufficient to effectively narrow the differential diagnosis. In uncertain cases, a biopsy of the lesions and/or referral to an otolaryngologist, dermatologist, or oral surgeon are appropriate.

### Lab

- Lab testing is not routinely indicated.
- A rapid strep test or throat culture may be done to rule out streptococcal pharyngitis.
- Parents will sometimes be very concerned about making a definitive diagnosis of herpetic infection:
  - This is possible but not routinely indicated.
  - HSV can be diagnosed with direct fluorescent antibody staining, rapid enzyme immunoassay, or viral culture of the lesion. Additionally documentation of seroconversion with HSV in the setting may corroborate the diagnosis.
  - Enteroviruses can be cultured from stool, nasopharyngeal, throat, CSF, and blood specimens. Polymerase chain reaction of CSF fluid also can diagnose an enteroviral infection.

### DIFFERENTIAL DIAGNOSIS

- Infection: Enteroviruses, including coxsackievirus, HSV, varicella, smallpox (variola), candidal infection, HIV-associated aphthous ulcers, etc.
- Hematologic (eg, cyclic neutropenia)
- Trauma
- Medication (eg, chemotherapy)

## TREATMENT

### INITIAL STABILIZATION/THERAPY

Analgesics:

- Acetaminophen or ibuprofen
- Acetaminophen with codeine may be used in severe cases, when intake of fluids is greatly affected by pain.

### MEDICATION

#### First Line

- Saltwater rinses for age-appropriate patients who will not drink the solution. Use normal saline, 1 tsp of table salt mixed with 16 oz of tepid water, or 1 tsp of baking soda with 32 oz of water q1–2h while ulcers are present. This may aid in reducing pain and shortening the duration of the ulceration.
- Magic mouthwash: Equal parts of diphenhydramine and Maalox or Kaopectate
- In cases of severe pain in children old enough to spit (ie, >4–5 yr of age), 2% viscous lidocaine may be used:
  - This must be undertaken with extreme caution, as lidocaine toxicity may occur if the medication is swallowed instead of spat.
- Acetaminophen 15 mg/kg/dose PO/PR q4h PRN
- NSAIDs:
  - Consider NSAID medication in anticipation of prolonged pain and inflammation
  - Ibuprofen 10 mg/kg/dose PO/IV q6h PRN.
  - Naproxen 5 mg/kg PO q8h PRN
- Codeine/Acetaminophen dosed as 0.5–1 mg/kg of codeine component PO q4h PRN

#### Second Line

- Silver nitrate in a single application for recurrent aphthous stomatitis has been shown to reduce the severity of pain without altering healing time.
- Topical NSAIDs or corticosteroids may be required for severe recurrent aphthous ulcers.
- Acyclovir can be given orally for herpes simplex infections to decrease the length of infection, but in order to be effective, it needs to be given within the 1st 48 hr of development of oral lesions.
- Acyclovir usually is more beneficial when used for household contacts who begin to exhibit symptoms and when treatment can be initiated early.
- Topical acyclovir has not been shown to be effective.

### DISPOSITION

#### Admission Criteria

- Dehydration with poor oral intake
- Manifestation of systemic illness that requires inpatient care

## FOLLOW-UP

### FOLLOW-UP RECOMMENDATIONS

- Young children should be followed closely.
- If dehydration occurs due to poor oral intake, IV hydration should be considered.

### DIET

- Encourage oral hydration.
- Soft, bland food or soft, soothing textures such as popsicles, gelatin desserts, pudding, or ice cream may be given.
- Avoid spicy, salty, or acidic foods.

### PROGNOSIS

- Most cases of stomatitis are mild and resolve within 1–2 wk.
- HSV stomatitis is most severe during the initial infection; however, it tends to recur in response to stress or trauma, as the virus has a long latent period within the cranial nerves, particularly the trigeminal nerve.
- Recurrent aphthous stomatitis also recurs in response to stress or trauma.

### COMPLICATIONS

- Dehydration, particularly in young children
- Infectious: Cellulitis, lymphadenitis, etc.
- Viral meningitis

### CODES

#### ICD9

- 054.2 Herpetic gingivostomatitis
- 074.0 Herpangina
- 528.00 Stomatitis and mucositis, unspecified

### PEARLS AND PITFALLS

- Dehydration as a result of stomatitis is more common in younger patients.
- Clearly explain the communicable nature of the infection, particularly if it is suspected to be herpetic, with special emphasis on avoiding contact with infants or neonates.
- Immunocompromised patients with stomatitis should be treated with acyclovir if herpes is considered to be the potential cause.

# STRABISMUS, CHRONIC (PRIMARY)

Shira Yahalom

Robert J. Hoffman

## BASICS

### DESCRIPTION

- Strabismus is a misalignment of the visual axis and is nearly always primary, which is the result of a congenital issue.
- Corresponding points fall on different parts of the retina, which leads to loss of stereopsis (depth perception).
- Esotropia is the inward deviation of the nonfixing eye.
- Exotropia is the outward deviation of the nonfixing eye.
- Secondary strabismus is acquired, usually acutely, and is much less common.
- This topic focuses on primary/chronic strabismus.

### EPIDEMIOLOGY

#### Incidence

The incidence of strabismus is thought to be 2.5–4%.

### RISK FACTORS

- Family history of strabismus
- Prematurity or low birth weight, especially if associated with retinopathy of prematurity

### PATHOPHYSIOLOGY

- During fetal development, embryonic eyes migrate from a lateral position to a frontal position, which results in increased overlap of each eye's visual field and provides depth perception.
- Proper alignment is required for maturation of the binocular neurons.
- Childhood strabismus disrupts this process and if not corrected will result in permanent loss of depth perception.
- Any strabismus persisting after 3 months of age is abnormal.

### ETIOLOGY

- Primary forms of strabismus include idiopathic esotropia and intermittent exotropia (occur when the child is viewing a distant object or when fatigued). They may also be associated with various congenital syndromes.
- Acquired esotropia is an accommodative esotropia and is the most common type of childhood esotropia.
- Constant exotropia is usually associated with neurologic delay, craniofacial syndromes, and structural abnormalities of the eye.
- Secondary/Acquired strabismus may be caused by retinoblastoma, cranial nerve palsies (due to trauma or infections), or any space-occupying lesions such as tumors, abscess, or hemorrhage. See Strabismus, Acute (Secondary) topic for more information.

### COMMONLY ASSOCIATED CONDITIONS

Amblyopia (decrease in visual acuity in an otherwise healthy eye) may result from untreated strabismus.

## DIAGNOSIS

### HISTORY

- History should include family history, age at onset of strabismus, and when the strabismus is noted (eg, constantly, when fatigued, different positions of gaze)
- Trauma, infections, and exposure to toxin or medication should be ruled out.
- Associated symptoms are not common with primary strabismus.

### PHYSICAL EXAM

- Complete physical exam and neurologic and developmental exam should be performed.
- Position of the eyes and the eyelids at rest should be noted.
- Presence of red reflex vs. leukokoria
- Pupillary reactivity and extraocular movements should be examined.
- Visual acuity evaluation will depend on the child's age.
- Specific tests to evaluate strabismus are the corneal light reflex, the cover test, and the cover/uncover test:
  - Corneal light reflex (Hirschberg test): Hold a small toy several feet in front of the child's face and a penlight next to the toy. With normal ocular alignment, the light reflection will be positioned at the same point in each eye. If a moderate to large deviation is present, deflection of the corneal light reflection will be noted.
  - Bruckner test: With a direct ophthalmoscope using the largest light, the patient looks directly at the light and the clinician determines if both pupils symmetrically fill with light, giving a red reflex. Asymmetric brightness or color between the 2 eyes or shadows in the pupil are abnormal.
  - Cover test: The child is asked to visually focus on a target. The examiner covers 1 eye while observing the opposite eye for movement. With normal ocular alignment, no movement is detected. Strabismus is present if the eye that is not covered shifts to refocus on the object. The test should be repeated on both eyes.
  - Cover/Uncover test: The child is asked to visually focus on a target. A cover is placed over 1 eye for a few seconds and then rapidly removed. The eye is observed for movement. If movement to refixate on the object is noted (becomes deviated while covered), then latent strabismus is present.

**DIAGNOSTIC TESTS & INTERPRETATION****Imaging**

CT/MRI is required only if an intracranial or intraorbital process is suspected, usually with secondary/acute onset strabismus but unnecessary for primary/chronic strabismus.

**DIFFERENTIAL DIAGNOSIS**

- Duane syndrome
- Moebius syndrome
- Brown syndrome
- Graves disease
- Congenital cranial nerve III or IV palsy
- Congenital familial exotropic ophthalmoplegia
- Congenital CNS insult
- Causes of secondary/acute strabismus

**TREATMENT****INITIAL STABILIZATION/THERAPY**

Primary forms of strabismus do not require emergency department treatment.

**SURGERY/OTHER PROCEDURES**

Treatment should be recommended by a pediatric ophthalmologist and usually consists of patching, eye exercises, surgical correction, or eyeglasses.

**DISPOSITION****Discharge Criteria**

Primary strabismus with no other findings on history or physical exam

**FOLLOW-UP****FOLLOW-UP RECOMMENDATIONS**

- All patients should be referred to an ophthalmologist and should follow up with their primary care provider.
- Strabismus may have a profound negative psychological impact on children due to social bias and teasing. Consider psychology/psychiatry referral when warranted.

**PROGNOSIS**

Prognosis is good if treated early, but strabismus may recur.

**COMPLICATIONS**

Delay in treatment may result in amblyopia.

**CODES****ICD9**

- 378.00 Esotropia, unspecified
- 378.9 Unspecified disorder of eye movements
- 378.10 Exotropia, unspecified

**PEARLS AND PITFALLS**

- Most cases of childhood strabismus are primary and do not require treatment in the emergency department.
- Secondary/Acute-onset strabismus warrants a thorough history and physical exam.
- All children with an initial diagnosis of strabismus who are discharged from the emergency department must be referred to a pediatric ophthalmologist.

# STRANGULATION

Joshua A. Rocker

## BASICS

### DESCRIPTION

- Strangulation is obstruction of air and/or blood flow in the neck by an external force.
- Due to the vulnerable anatomy in the neck, associated injuries may include damage to the skin, soft tissue, the airway, the esophagus, the C-spine, the CNS, and peripheral nerves:
  - Strangulation may be life threatening if any of these vital components are injured.
- Strangulation injuries include intentional and unintentional hangings; manual, ligature, and baton choking; and positional/postural asphyxia:
  - Positional/Postural asphyxia refers to oxygen deprivation from an airway obstruction caused by poor head or neck positioning.
- Autoerotic asphyxiation and the “choking game” are methods of willful choking that may result in serious unintended consequences.

### EPIDEMIOLOGY

#### Incidence

- The incidence of pediatric and adolescent deaths from strangulation is increasing (1).
- Female to male ratio ranges from 2:1–5:1.

#### Prevalence

- Between 1984 and 2004, infant mortality rates from accidental suffocation and strangulation in bed quadrupled from 2.8–12.5 deaths per 100,000 live births (2).
- 5.7% of 8th graders in an Oregon study had tried the choking game (3).

### RISK FACTORS

- The choking game is a practice often engaged in by school-aged children in which a child allows another to constrict the neck until loss of consciousness and postural tone occurs. The choking is then stopped, and the patient typically regains consciousness quickly.
- Erotic asphyxiation and autoerotic asphyxiation are choking during intercourse or masturbation to increase sensation during orgasm.
- Both have been associated with death
- For unintentional strangulation:
  - Poor parental supervision and access to hanging cords, ropes, and strings
  - Wide-spaced crib bars and open windows put children at risk for positional asphyxia.

### GENERAL PREVENTION

- Caution parents about the dangers of postural asphyxiation and hanging from loose cords.
- Pediatricians should mention the serious risk with any form of playing the choking game.

### PATHOPHYSIOLOGY

- Tracheal injury can cause asphyxia and hypoxemia.
- Venous obstruction can cause cerebral venous stagnation and cerebral edema.

- Arterial trauma:
  - Arterial dissection causing acute blood loss, cerebral hypoxia, and possible tracheal obstruction from resulting soft tissue swelling
  - Arterial vasospasm due to acute injury can cause low cerebral blood flow and cerebral hypoxia.
- Pressure to the carotid sinuses can cause increased parasympathetic tone:
  - Vagal overstimulation
  - Poor perfusion
- C-spine injuries can occur:
  - Hangman fracture: Bilateral pedicle fractures of C2 vertebrae associated with anterior dislocation of the C2 vertebral body:
    - Can result in fatal spinal cord injury
- Esophageal injury:
  - Serious infectious risk with high mortality rate

### ETIOLOGY

- Infants and toddlers:
  - Postural strangulation
  - Unintentional ligature asphyxia
- Manual strangulation from abuse
- Adolescents:
  - Accidental ligature strangulation
  - Intentional strangulation due to the choking game or autoerotic strangulation
  - Suicide and homicidal intent

### COMMONLY ASSOCIATED CONDITIONS

- Tracheal injury
- Aspiration pneumonia
- Venous and/or arterial injury
- Hypoxic neurologic injury
- C-spine injury
- Nerve injury (phrenic)
- Larynx/Hyoid/Thyroid cartilage injury
- GI bleed, esophageal injury
- Skin/Soft tissue injury

## DIAGNOSIS

### HISTORY

- Airway injury:
  - Dyspnea, stridor, and/or dysphonia
- Vascular injury:
  - Neck swelling, confusion, loss of consciousness, and/or neurologic deficit
- C-spine injury:
  - Pain, paralysis, and/or respiratory failure
- Esophageal injury:
  - Dysphagia, hematemesis, drooling, and/or chest pain

### PHYSICAL EXAM

- Superficial injury:
  - Abrasions, lacerations, contusions, or soft tissue swelling/tenderness
- Airway injury:
  - Neck ecchymosis or emphysema
  - Severe tenderness on gentle palpation of the larynx or thyroid cartilage
  - Stridor
  - Respiratory distress

- Vascular Injury:
  - Subconjunctival and skin petechiae
  - Expanding hematoma
  - Pulse deficits or bruits
  - Mental status changes, abnormal neurologic exam
  - Evidence of cerebral infarction
  - Loss of consciousness
- C-spine injury:
  - Paralysis
  - No respiratory effort
- Esophageal injury:
  - Crepitus
  - Drooling
- Nonspecific findings:
  - Mild cough
  - Hypoxia

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

- Blood gas if significant airway compromise
- CBC, blood type and cross if vascular injury
- Serum acetaminophen screening in patients injured with intent of self-harm

#### Imaging

- Chest/C-spine radiographs to assess for:
  - C-spine injuries
  - Subcutaneous emphysema
  - Aspiration pneumonia
  - Tracheal displacement
- Arteriography:
  - Assessment of vascular injuries
- Carotid duplex imaging with flow studies
- CT scan of the neck and/or brain:
  - Assessment of neck anatomy and cerebral injury or ischemia
- MRI of the head and/or neck:
  - Assessment of spinal cord/ligamentous injury or hypoxic cerebral injury

#### Diagnostic Procedures/Other

Fiberoptic laryngoscopy:

- Assessment and visualization of laryngeal injury

### DIFFERENTIAL DIAGNOSIS

- Anaphylaxis
- Angioedema
- Thyroid mass
- Aneurysm
- Epiglottitis
- Blunt neck trauma

## TREATMENT

### PRE HOSPITAL

- Assess and stabilize airway, breathing, and circulation:
  - If significant respiratory distress, anticipate a difficult intubation. Intubation is best performed in the emergency department.
  - Only attempt endotracheal intubation in field if bag-valve-mask ventilation is inadequate.
- C-spine stabilization if needed by the history, especially if the patient is unconscious

**INITIAL STABILIZATION/THERAPY**

- Assess and stabilize airway, breathing, and circulation according to Advanced Trauma Life Support (ATLS) and Pediatric Advanced Life Support (PALS) guidelines:
  - Endotracheal intubation if severe respiratory compromise or Glasgow Coma Scale <8.
  - Consider a laryngeal mask airway or surgical airway by cricothyrotomy or tracheostomy if unable to intubate.
- C-spine immobilization if concern of injury is based on the history or physical exam
- Elevate the head of the bed to facilitate cerebral vascular drainage.
- Administer antibiotics for neck injury with subcutaneous emphysema.
- Consider steroids for laryngeal edema.

**ALERT**

- If concern for airway compromise such as dysphonia, aphonia, or stridor, endotracheal intubation should be strongly considered and performed while the airway is still patent.
- In such cases, anticipate the potential for difficult endotracheal intubation.

**MEDICATION****First Line**

- Rapid sequence intubation
  - Premedicate:
    - Atropine if <6 yr: 0.02 mg/kg/dose IV, max single dose 0.5 mg
    - Lidocaine 1 mg/kg/dose IV:
      - Use to reduce airway hyperreactivity and HTN.
    - Fentanyl 1–2  $\mu$ g/kg/dose IV
  - Sedate:
    - Midazolam 0.1 mg/kg/dose IV:
      - Rapid onset
    - Etomidate 0.3 mg/kg/dose IV:
      - Concerns of adrenal suppression
    - Ketamine 1–2 mg/kg IV/IM:
      - Helpful if patient is hypotensive
      - Avoid if head injury is a concern.
    - Propofol 1–2 mg/kg IV:
      - Avoid if hypotensive.
  - Paralysis:
    - Depolarizing agent:
      - Succinylcholine 1 mg/kg IV
    - Nondepolarizing agent:
      - Rocuronium 1 mg/kg IV
      - Vecuronium 0.1 mg/kg IV
      - Pancuronium 0.1 mg/kg IV
- Neck injury with subcutaneous emphysema:
  - Ampicillin/Sulbactam 100–400 mg/kg/24 hr IV q6h, max single dose 1–2 g q6h
  - Clindamycin 25–40 mg/kg/24 hr IV q8h
- Laryngeal edema:
  - Dexamethasone 0.25–0.5 mg/kg IV/IM q6h

**Second Line**

Pain management:

- Opiates:
  - Morphine 0.1 mg/kg IV/IM/SC q2h PRN:
    - Initial morphine dose of 0.1 mg/kg IV/SC may be repeated q15–20min until pain is controlled, then q2h PRN.
  - Fentanyl 1–2  $\mu$ g/kg IV q2h PRN:
    - Initial dose of 1  $\mu$ g/kg IV may be repeated q15–20min until pain is controlled, then q2h PRN.

**SURGERY/OTHER PROCEDURES**

- Surgical airway if necessary:
  - Cricothyrotomy or tracheotomy
- Avoid deep exploration of the neck in the emergency department.
- Surgical repair of injuries:
  - C-spine, larynx, trachea, vascular, esophageal

**DISPOSITION****Admission Criteria**

- Patients with evidence of airway injury or respiratory distress should be observed for at least 12–24 hr to detect development of worsening respiratory distress.
- Pain management requiring parenteral analgesics
- Critical care admission criteria:
  - Need for mechanical ventilation
  - Potential risk for respiratory compromise
  - Significant vascular or esophageal injury
  - Presence of any neurologic sequelae from the event

**Discharge Criteria**

- Asymptomatic patients or patients with mild injury may be discharged home.
- Patients with any symptoms of airway injury, such as cough or hoarseness, should have the airway evaluated and discharged only after a 12–24-hr observation.
- No suicidal risk

**Issues for Referral**

- Consider early consultation with trauma, ENT, and general or vascular surgery.
- Psychiatric consultation should be obtained in cases of suicidal strangulation.

**FOLLOW-UP****FOLLOW-UP RECOMMENDATIONS**

- Patient and caregiver education
- Psychiatric counseling and treatment for suicidality

**PROGNOSIS**

Widely variable based on mechanism and severity, from no morbidity to death

**COMPLICATIONS**

- Pulmonary, airway
  - Tracheal contusion or fracture, tracheal stenosis, acute respiratory distress syndrome

- Skeletal injury
  - C-spine injury, larynx/hyoid/thyroid cartilage injury
- Esophageal strictures
- Neurologic sequelae:
  - Attention/Information-processing impairments, transient or permanent nerve damage, seizures, progressive dementia
- Scarring of neck tissue

**CODES****ICD9**

994.7 Asphyxiation and strangulation

**PEARLS AND PITFALLS**

- Pearls:
  - Practice early, aggressive airway management.
  - Beware for delayed airway compromise.
  - Use C-spine immobilization in hanging victims.
- Pitfalls:
  - Failure to look for other injuries or toxic ingestions in the suicidal hanging patient
  - Failure to obtain surgical consultation in those with serious neck injuries
  - Failure to refer for psychiatric evaluation

## BASICS

### DESCRIPTION

- Stridor is a respiratory sound caused by turbulent airflow through a partially obstructed upper airway.
- Stridor can be inspiratory, expiratory, or biphasic depending on the level of the obstruction.
- Causes of stridor can be differentiated by age of the child, duration (acute vs. chronic), and presence of fever.

### PATHOPHYSIOLOGY

- Stridor results from turbulent airflow secondary to upper airway obstruction.
- The respiratory phase and pitch of stridor varies depending on the location of narrowing:
  - Extrathoracic airway: Inspiratory stridor
  - Glottis: Biphasic stridor
  - Intrathoracic trachea: Expiratory stridor
  - High-pitched stridor generally results from subglottic or laryngeal obstruction.

### ETIOLOGY

- Infectious:
  - Laryngotracheitis (croup):
    - Most commonly parainfluenza type 1
    - Other causes: Influenza, respiratory syncytial virus, adenovirus, and rhinovirus
  - Epiglottitis/Supraglottitis:
    - *Haemophilus influenzae* type b (Hib), *Streptococcus pyogenes*, *Staphylococcus aureus*
  - Bacterial tracheitis:
    - *S. aureus*, *S. pyogenes*, *Streptococcus pneumoniae*, *H. influenzae*, *Moraxella catarrhalis*
  - Retropharyngeal abscess (RPA):
    - Usually polymicrobial
    - Often both aerobes and anaerobes
- Traumatic:
  - Blunt trauma to the neck
  - Caustic ingestion with injury to the larynx:
    - Alkali chemicals are usually more severe.
  - Thermal injury to the larynx:
    - Smoke inhalation
    - Drug abuse with smoke inhalation
    - Hot liquids
- Foreign body (FB) aspiration:
  - Laryngeal or tracheal FB
  - Esophageal FB compressing the airway
- Anaphylaxis/Laryngeal edema
- Laryngomalacia
- Congenital anomalies:
  - Laryngeal cleft or web
  - Tracheoesophageal fistula
  - Airway hemangioma
- Tracheal/Subglottic stenosis (congenital or acquired)
- Laryngeal papilloma: Human papillomavirus
- Laryngospasm:
  - Hypocalcemia
  - Anesthesia (ketamine, inhaled anesthetics)
- Spasmodic croup
- Angioneurotic edema

- External compression of the airway:
  - Vascular rings or slings
  - Mediastinal or neck neoplasms
- Vocal cord paralysis (congenital or acquired)
- Psychogenic or functional stridor:
  - Vocal cord dysfunction

## DIAGNOSIS

### HISTORY

- Onset of symptoms, preceding events, etc.:
  - Acute onset of symptoms most consistent with infection, injury, or FB aspiration
  - History of trauma
  - Exposure to smoke or hot liquids
  - Ingestion of caustic chemicals
  - History of choking or FB in the mouth
- History of fever suggests infectious etiology.
- Associated symptoms:
  - Upper respiratory infection symptoms suggest croup.
  - Dysphagia or sore throat is seen with tracheitis and epiglottitis in older children.
- Immunization status: Particularly Hib vaccine
- Positional: Laryngomalacia may improve with prone positioning.
- History of past intubations or airway procedures: Increased risk of subglottic stenosis

### PHYSICAL EXAM

- Vital signs:
  - Fever with infectious etiologies
  - Hypoxia with severe airway obstruction
- General: Assess position of comfort and degree of distress:
  - Sniffing position (leaning forward, head extended) favored with airway obstruction at or above the larynx
- Nose:
  - Rhinorrhea/Congestion associated with croup
- Oropharynx:
  - Increased secretions or drooling with epiglottitis, RPA, or FB
  - Evidence of thermal or caustic injury
  - Visible mass or FB
  - Change in phonation:
    - Hoarseness associated with croup, tracheitis, vocal cord paralysis, or papillomatosis
    - Inability to phonate is associated with complete airway obstruction.
- Neck:
  - Lymphadenopathy with infectious etiologies
  - Ecchymosis or crepitus from trauma
  - Palpable neck mass
  - Limited range of motion with RPA
- Respiratory:
  - Use of accessory muscles signifies significant obstruction.
  - Barky cough with croup

- Neurologic: Evidence of tetany or hyperreflexia suggesting hypocalcemia
- Skin:
  - Presence of cutaneous hemangiomas raises concern for airway hemangioma.
  - Urticaria suggests anaphylaxis.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

- Defer lab evaluation in children with marked distress.
- Consider labs based on suspected etiology:
  - RPA: CBC, C-reactive protein (CRP), and blood culture
  - Epiglottitis (only after the airway is secured): CBC, CRP, blood culture, and culture from the epiglottis
  - Laryngospasm: Calcium level

#### Imaging

- Need for imaging is guided by the patient's history, including presence of fever and chronicity of the stridor.
- Soft tissue neck radiographs:
  - Not routinely required for croup. If obtained, a narrowed subglottic area on the AP view ("steep sign") and ballooning of the hypopharynx on the lateral view may be seen.
  - If concern for epiglottitis, a lateral neck film may be obtained in stable, cooperative patients but should otherwise be deferred until the child's airway is secure. Findings are:
    - An enlarged epiglottis ("thumb sign")
    - Thickened aryepiglottic folds
    - Obliteration of the vallecula
  - Increased prevertebral width (greater than the width of the adjacent vertebral body) on lateral neck x-ray suggests RPA or mass.
  - A shaggy or irregular tracheal border can be seen with tracheitis.
- Neck CT scan should be obtained:
  - To further evaluate prevertebral space widening on lateral neck x-ray or with strong clinical suspicion for RPA
  - Following blunt anterior neck trauma to evaluate for laryngeal fracture
- PA and lateral CXR:
  - If suspicion for aspirated/ingested FB
  - Inspiratory/Expiratory or decubitus films can exaggerate asymmetry from localized air trapping.
  - Right-sided aortic arch may prompt further evaluation for a vascular ring or pulmonary sling.

#### Diagnostic Procedures/Other

- Improvement in stridor when placing a child prone supports the diagnosis of laryngomalacia.
- Nasopharyngoscopic/Bronchoscopic evaluation for persistent or recurrent stridor with concern for congenital anomalies, vocal cord dysfunction, laryngeal papillomatosis, or airway hemangioma

**DIFFERENTIAL DIAGNOSIS**

- Stertor: A low-pitched “snorting” sound associated with obstruction of the nasopharynx
- Wheezing: Usually an expiratory respiratory sound associated with lower airway obstruction
- See the Etiology section for the differential diagnosis of stridor.

**TREATMENT****PRE HOSPITAL**

Supplemental oxygen should be administered.

**INITIAL STABILIZATION/THERAPY**

- Any child with significant stridor at rest, respiratory distress, or hypoxemia should be placed on supplemental oxygen:
  - There is no evidence that humidified oxygen improves mild to moderate croup (1).
- Minimize distress to the patient, which may cause worsening stridor.
- If epiglottitis is suspected:
  - Keep the child in a position of comfort.
  - Defer all testing and invasive procedures (including inspection of the oropharynx with a tongue blade) until the airway is secure.
- Bag-mask ventilation and endotracheal intubation are required in any patient without a patent airway.

**MEDICATION****First Line**

- Croup:
  - Dexamethasone 0.6 mg/kg PO, IM, or IV  $\times$  1, max single dose 10 mg:
    - Should be given to all children with moderate-severe croup
    - May shorten duration of symptoms and decrease return visits in mild croup (2)
  - 2.25% racemic epinephrine (0.5 mL in 2.5 mL normal saline) nebulization for stridor at rest or severe respiratory distress:
    - Repeat doses may be given for persistent stridor.
- Epiglottitis/Bacterial tracheitis/RPA:
  - Ceftriaxone 50–100 mg/kg IV q12–24h, max single dose 2 g, OR
  - Ampicillin/Sulbactam (dosed as ampicillin) 200 mg/kg/day IV divided q6h, max single dose 2 g
- Anaphylaxis:
  - Epinephrine 0.01 mg/kg 1:1,000 IM
- Laryngospasm from hypocalcemic tetany:
  - Calcium gluconate 100 mg/kg IV, max single dose 800 mg

**Second Line**

Laryngomalacia:

- Often associated with GERD
- Ranitidine 3 mg/kg/dose PO b.i.d.

**SURGERY/OTHER PROCEDURES**

- Epiglottitis:
  - Immediate assembly of skilled airway team (anesthesiology and otolaryngology)
  - Emergency and surgical airway equipment should be readily available.
  - Whenever possible, the patient should be transported to the operating room for mask induction for direct laryngoscopy and endotracheal intubation.

- Tracheitis: Endoscopic visualization of larynx/trachea by otolaryngology, possible debridement, and endotracheal intubation
- RPA: May require incision and drainage
- Airway FB:
  - Patient with severe distress or respiratory arrest: Direct laryngoscopy with removal of FB with Magill or optical forceps and endotracheal intubation
  - Stable patient with confirmed or high suspicion for laryngeal or esophageal FB: Endoscopic removal by otolaryngology under general anesthesia

**DISPOSITION****Admission Criteria**

- Inpatient admission criteria:
  - Any child with stridor and associated respiratory distress, hypoxemia, or dehydration
  - Croup with recurrent stridor at rest despite therapy
  - Young children with stridor from anaphylaxis are commonly monitored for 24 hr for biphasic reactions.
- Critical care admission criteria:
  - Any child with respiratory failure, significant respiratory distress, or potential or impending airway compromise with any of these conditions:
    - Suspected epiglottitis, tracheitis, or RPA
    - Croup
    - Persistent stridor at rest
    - Caustic ingestions or thermal injury

**Discharge Criteria**

- Croup or any other acute etiology without stridor at rest, hypoxemia, or signs of dehydration
- Chronic stridor without signs of respiratory distress, or hypoxemia

**Issues for Referral**

- Otolaryngology consultation in the emergency department:
  - Epiglottitis
  - Tracheitis
  - RPA
  - Tracheal/Upper esophageal FB
  - Suspicion of vocal cord papillomatosis or airway hemangioma
  - Worsening chronic stridor of unclear etiology
  - Vocal cord dysfunction can be confirmed by nasopharyngoscopy if the diagnosis is uncertain.
- Anesthesia consultation:
  - Epiglottitis

**FOLLOW-UP****FOLLOW-UP RECOMMENDATIONS**

- Children discharged home with croup should follow up with their primary doctor within 24 hr.
- Infants with significant laryngo-/tracheomalacia or other congenital etiologies should have outpatient otolaryngology follow-up.
- Traditionally, parents of children with croup have been instructed to take their children out into cold air or expose them to humidified warm air. There is no data on the efficacy of humidified air in the home, and the benefit here may be replicated by any calming technique for the child in distress.

- Acute Respiratory Failure
- Anaphylaxis
- Croup
- Epiglottitis/Supraglottitis
- Respiratory Distress

**CODES****ICD9**

- 748.3 Other congenital anomalies of larynx, trachea, and bronchus
- 786.1 Stridor

**PEARLS AND PITFALLS**

- Pearls:
  - All procedures and interventions including visualization of the oropharynx should be avoided in a patient with suspected epiglottitis until a secure airway can be obtained in the operating room by appropriately skilled personnel.
  - A secure airway should be established in children with risk of thermal or chemical injury to the mouth and upper airway, as airway compromise can progress quickly.
- Pitfalls:
  - Poor positioning of a child during lateral neck x-ray may lead to a false-positive increase in the size of the prevertebral space. The child’s head should be extended and the x-ray taken during inspiration for best interpretation.
  - Poor aeration secondary to vocal cord dysfunction can lead to overaggressive treatment for status asthmaticus despite the obstruction occurring at the glottis.

## BASICS

### DESCRIPTION

- Stroke is a vascular event leading to acute focal or regional neurologic dysfunction as a result of inadequate perfusion and subsequent inflammatory sequelae in the brain.
- Symptoms last > 24 hr, and they may resolve or cause permanent neurologic injury or even death.
- Vascular pathology and thromboembolic events are common causes.
- Classically defined as being either ischemic (vascular obstruction) or hemorrhagic (vascular leakage or rupture)
- Cerebral venous sinus thrombosis (CVST) may not have classic neurologic deficits and is found primarily in neonates.
- Children with transient deficits (<24 hr) fitting the definition of transient ischemic attack (TIA) often have brain imaging that confirms stroke.

### EPIDEMIOLOGY

- A very recent large-scale study using retrospective analysis of radiology reports as well as traditional ICD-9 analysis supports the higher incidence of 4.5 per 100,000 per year.
- Most prior estimates based on ICD-9 data only were 2–2.5 per 100,000 per year:
  - Ischemic: 50–60%
  - Hemorrhagic: 40–50%
- Neonatal incidence may be as high as 1 in 3,000 live births
- Childhood (0–18 yr of age) CVST incidence is 0.3 per 100,000 per year, and almost 1/2 of these will be neonates.

### RISK FACTORS

- Acute ischemic stroke (AIS):
  - Sickle cell disease (SCD): 20% lifetime risk
  - Congenital or acquired heart disease
  - Infections (especially of the head and neck)
  - Moyamoya disease
  - Cerebral vasculitis (multiple causes)
  - Fibromuscular dysplasia
  - Chronic anemia
  - Head trauma
  - Prematurity
  - Prothrombotic disorders
  - Dehydration
  - Anemia
  - Leukocytosis
  - Previous AIS
  - Toxin (cocaine, amphetamine)
- Hemorrhagic stroke:
  - Arteriovenous malformations (AVMs)
  - Prematurity
  - Coagulation disorders
  - Thrombocytopenia
  - SCD
  - Brain tumors
  - CVST
  - Previous hemorrhagic stroke
  - Toxin (cocaine, amphetamine)

### GENERAL PREVENTION

- Optimal management of diseases/disorders known to be risk factors
- Exchange transfusion therapy for SCD patients decreases strokes in patients with high intracranial blood flow velocities.
- Hydroxyurea, nocturnal oxygen, and marrow transplants may decrease AIS in SCD.
- Current data suggests that daily low-dose aspirin may help prevent AIS.
- Low-molecular-weight heparin (LMWH) is recommended for children with high risk for recurrent cardiac embolism, CVST, and certain prothrombotic disorders.
- Warfarin indications (same as LMWH)
- Extracranial bypass or indirect revascularization may decrease the incidence of stroke in patients with Moyamoya.

### PATHOPHYSIOLOGY

- AIS:
  - Vascular obstruction, often by thrombus or embolus, or by vasoconstriction
  - Occlusion of vessel leads to tissue infarct.
  - Adjacent peri-infarct tissue also is at high risk for dysfunction due to peri-infarct edema.
- Hemorrhagic:
  - Blood flow interrupted to area supplied by ruptured vessel
  - Hemorrhage causes neuronal dysfunction by pressure effect as well as local inflammation.
  - Increased brain volume or obstruction of CSF flow may elevate intracranial pressure.
  - Tissue adjacent to the hemorrhagic infarct is at high risk due to peri-infarct edema

### ETIOLOGY

- Emboli
- Thrombosis
- Inflammation
- Direct trauma
- Mechanical occlusion
- Congenital vascular wall abnormality
- Weakness of “premature” vascular wall in neonates

## DIAGNOSIS

### HISTORY

- Sudden change in neurologic function, particularly with focal neurologic deficits
- Seizure may be the only symptom in neonates, young infants, and CSVT.
- Older children may have more classic symptoms of slurred speech and unilateral motor or sensory deficits.

### PHYSICAL EXAM

- Assess vital signs and perform a thorough neurologic exam:
  - Serial neurologic exam may be used to note progression.
- Neonates and young infants usually do not have focal deficits.

- Older children may have “classical” deficits such as:
  - Hemiplegia or hemiparesis
  - Ataxia
  - Dysarthria or dysphagia
  - Decreased level of consciousness
  - Visual defect
  - Other sensory deficit
  - Vomiting
  - Irritability

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

- Lab tests are not helpful in diagnosing stroke.
- Assess glucose in any patient with altered mental status, neurologic deficit, or behavioral change.
- Labs may identify electrolyte abnormalities, abnormalities of blood count such as polycythemia or thrombocytosis, and coagulopathy.

#### Imaging

- Sonography:
  - Used primarily in neonates; open fontanelle allows brain imaging.
  - Good in identifying parenchymal hemorrhage in neonates
  - Less sensitive than MRI or CT in identifying neonatal ischemic strokes
  - Portable, noninvasive
  - Transcranial Doppler is used to measure intracranial blood flow velocity and to assess stroke risk in SCD patients.
- CT scan:
  - Most readily available study
  - Most sensitive for identifying hemorrhagic stroke
  - May fail to identify early ischemic stroke
  - With an angiogram (CT angiography) will identify most vascular lesions that require immediate surgery (ie, larger more proximal vessels)
  - Not best for imaging smaller and more distal cerebral arteries
- MRI:
  - Usually not readily available at all times as an emergent study
  - Most sensitive for ischemic stroke
  - MR angiography, like CT angiography, gives good imaging of larger and more proximal cerebral vessels.
  - No radiation risk
  - Usually will require sedation
- Catheter angiography:
  - Best for detailed vascular imaging of all cerebral vessels
  - General anesthesia is required.
  - Invasive; higher complication rate than other studies
  - Smaller vessels make it much more difficult to perform in children < 1 yr of age.

### DIFFERENTIAL DIAGNOSIS

- Migraine headache
- Psychogenic problems
- Musculoskeletal abnormalities
- Delirium

- Todd paralysis (post-seizure)
- Neonatal seizures
- Reversible posterior leukoencephalopathy syndrome
- Vascular anomalies
- Intracranial infection
- Inflammatory disease
- Metabolic stroke
- Intracranial tumor
- Drug toxicity
- Idiopathic intracranial HTN

## TREATMENT

### INITIAL STABILIZATION/THERAPY

- Assess and stabilize airway, breathing, and circulation.
- Correct hypoxia and hypoglycemia.
- Maintain vital signs within acceptable limits, particularly BP/HTN:
  - Maintain appropriate cerebral perfusion pressure, and avoid excessive systemic and intracranial HTN.
- Stabilization of vital signs and temperature
- Correction of dehydration and anemia
- Treatment of any verified or suspected infections
- The goal is to minimize secondary brain injury and stroke-related nonneurologic injury:
  - Manage seizures; routine prophylaxis is not indicated.

### MEDICATION

#### First Line

- Due to lack of controlled trials, there is tremendous variability in the pharmacologic management of stroke in children.
- Ischemic stroke:
  - Aspirin or heparin is used, but not both.
  - Aspirin 2–5 mg/kg PO per day:
    - Considered by some to be the primary pharmacologic management of pediatric stroke
    - Used particularly if image-confirmed ischemic stroke, no thromboembolism, and anticoagulation therapy has been discontinued
  - Heparin for ischemic stroke:
    - Anticoagulation with LMWH or unfractionated heparin (UFH) may be used.
    - For confirmed extracranial arterial dissection
    - For central venous thrombosis
    - Documented intracardiac thrombus
    - For suspected cardiothrombotic or thromboembolic stroke, such as documented intracardiac thrombus, known risk factors such as right to left shunt, septal defects
    - UFH: Given intermittently or as infusion to prolong PTT to 60–80. Initial 50–100 mg/kg bolus IV, then repeat same dose q4h; as infusion loading dose, 75 units/kg over 10 min, then infuse 20 units/kg/hr and adjust rate to titrate to proper PTT
    - LMWH: Enoxaparin 1 mg/kg SC q12h to get antifactor Xa level of 0.5–1.0 U/mL
  - If SSD, then exchange transfusion: The goal is to reduce HbS to <30% and increase hemoglobin to at least 10 g/dL.
- Hemorrhagic stroke
  - Correction of intracranial hemorrhage risk factors such as low platelets, coagulation factor deficiencies, or prolonged INR

- Phytonadione (vitamin K<sub>1</sub>):
  - 1–2 mg/dose SC/IM, max single dose 10 mg
  - Avoid IV use due to potential severe anaphylactoid reaction.
  - May be necessary in neonates; may need if vitamin K–dependent coagulation disorder
  - Do not use vitamin K<sub>3</sub> or any other formulation, only phytonadione, vitamin K<sub>1</sub>.

### Second Line

- Tissue plasminogen activator (TPA) for ischemic stroke:
  - TPA is well established in adult AIS. Safety in children has not been established.
  - Usually given within a specific time frame from onset of stroke symptoms
  - Refer to a consulting neurologist regarding dosing.
- Hemorrhagic stroke—subarachnoid hemorrhage:
  - Nimodipine 60 mg PO q4h × 21 days
    - Safety is not established in pediatric patients. Use in patients > 12 yr of age; for younger patients, consult a neurologist.
    - For subarachnoid hemorrhage only
    - Prevents vasospasm in perihemorrhagic ischemic areas

### SURGERY/OTHER PROCEDURES

- Hematoma evacuation for cerebellar or large cerebral hemisphere hemorrhages
- Aneurysms and AVMs may be treated with surgery or endovascularization.
- Ventricular drainage: To treat hydrocephalus after intracerebral hemorrhage. If necessary, follow with ventriculoperitoneal shunting.

### DISPOSITION

#### Admission Criteria

- Admit all patients with acute stroke or TIA.
- Critical care admission criteria:
  - Hemorrhagic stroke
  - Ischemic stroke for which TPA is used
  - Increased intracranial pressure or extensive cerebral edema
  - Progressive neurologic deficit, deep peripheral neurologic deficits, or impairment of ability to protect

#### Discharge Criteria

If admission is not possible or appropriate specialty services are not available, then transfer to the nearest facility capable of managing the child.

## FOLLOW-UP

All patients need multidisciplinary follow-up with neurology and/or neurosurgery, physical therapy, and possibly psychological support for the patient as well as primary providers.

### PROGNOSIS

- The NIH Stroke Scale (NIHSS) has been modified for pediatric use (PedNIHSS).
- Early findings suggest that PedNIHSS  $\geq 12$  significantly predicts poor neurologic outcomes.
- 20–40% of children die after stroke.
- The mortality rate is higher for hemorrhagic strokes.
- 50–80% of surviving children will have neurologic abnormalities.
- The long-term overall prognostic outlook, though, is favorable for most pediatric stroke survivors in terms of educational and mobility outcomes.

### COMPLICATIONS

- Related to size and location of infarct
- May include but are not limited to:
  - Respiratory failure
  - Resultant (potentially fatal) acute and/or chronic increases in intracranial pressure
  - Permanent hemiplegia or hemiparesis
  - Chronic seizures
  - Profound motor, sensory, verbal, and cognitive delay

### See Also (Topic, Algorithm, Electronic Media Element)

- Sickle Cell Disease
- Seizure
- Altered Level of Consciousness and Coma

## CODES

### ICD9

- 431 Intracerebral hemorrhage
- 434.91 Cerebral artery occlusion, unspecified with cerebral infarction

### PEARLS AND PITFALLS

- SCD and congenital heart diseases are the highest risk groups.
- Perinatal stroke (28 days to 28 wk of age) is not easily recognized and often is missed.
- Exchange transfusion is the treatment of choice in sickle disease and ischemic stroke.
- Be wary of diagnosing TIA in a child: Treat and manage as though it is a stroke.
- Aspirin is first-line therapy for ischemic stroke.
- There is insufficient experience with TPA to demonstrate or refute benefit.
- Central venous thrombosis may present only with seizure or headache.

# SUBARACHNOID HEMORRHAGE

Tracey Rico

## BASICS

### DESCRIPTION

- Subarachnoid hemorrhage (SAH) refers to bleeding into the subarachnoid space, the area between the arachnoid membrane and the pia mater surrounding the brain and spinal cord.
- This may occur spontaneously, usually from an arteriovenous malformation (AVM) or ruptured cerebral aneurysm, or may result from head injury.

### EPIDEMIOLOGY

- Only 5% of cases of SAH occur in people <20 yr of age.
- SAH is rare in children <10 yr of age; only 0.5% of all cases occur in children at this age.
- From 40–50% of all acute traumatic deaths involve injury to the brain, and 50–75% of these will have an SAH (1).
- Pediatric intracranial aneurysms are rare, accounting for 0.5–4.6% of all aneurysms, and up to 74% of these present with SAH (2).
- The incidence of AVMs in children usually ranges from 15–23%.
- Intracranial hemorrhage is the presenting clinical manifestation in 75–80% of patients with undiagnosed AVMs (3).

### RISK FACTORS

- Congenital heart disease
- Connective tissue disorders
- Prematurity
- Breast-fed infants who do not receive vitamin K
- Birth trauma/Asphyxia/Instrument-assisted delivery
- Polycystic kidney disease
- Blood dyscrasias (hemophilia, sickle cell, vitamin K deficiency, thrombocytopenia)
- Child abuse, especially shaken/impact injury
- Drug exposure (cocaine, amphetamines)

### GENERAL PREVENTION

- Use of age-appropriate seat belts and protective sports gear can help moderate traumatic brain injury (TBI) and its related sequelae.
- Prenatal interventions, delivery by C-section, and postnatal administration of vitamin K

### PATHOPHYSIOLOGY

- The cerebral hemispheres are not fixed rigidly inside the skull and have considerable room to move:
  - Sudden violent motion may stretch axons and shear blood vessels, which can lead to SAH.

- Although the etiology of spontaneous SAH is diverse, the final pathway is a defect or disruption in the normal layers of the cerebral vasculature leading to a loss of integrity of the vascular wall:
  - Intracranial arteries are more vulnerable because their walls lack an external elastic lamina and contain a very thin adventitia.
  - If the integrity of the internal elastic lamina is compromised, with associated defects in the adjacent layers of the tunica media and adventitia, the probability of rupture or bleeding is increased and is related to the tension on the wall or pressure through the vessel.
- The acute symptoms of SAH depend on the amount of subarachnoid blood present and are attributed to the increase of intracranial pressure (ICP), decrease of cerebral perfusion pressure (CPP), and resulting ischemia.

### ETIOLOGY

- TBI is the most common cause of SAH, with motor vehicle accidents, falls, and sports-related injuries accounting for the greatest percentages.
- Children with spontaneous SAH were found to have:
  - Brain AVMs (31%)
  - Cerebral aneurysms (13%)
  - Cavernous malformations (15%)
  - Medical etiologies (14%)
  - Brain tumors (2.5%)
  - Undetermined etiology (25%)

### COMMONLY ASSOCIATED CONDITIONS

- TBI
- AVM

## DIAGNOSIS

### HISTORY

- Seizures, apnea, and loss of consciousness are the most common initial signs in infants.
- Children tend to follow the adult pattern:
  - Headache (thunderclap) (71%)
  - Convulsion (58%)
  - Nausea (19%), vomiting (47%)
  - Altered mental status (27%)
  - Loss of consciousness (>50%)
  - Photophobia and visual changes (19%)
  - Dizziness (10%)

### PHYSICAL EXAM

- Coma (74%)
- Fontanel bulging (68%)
- Elevated BP (>50%)
- Nuchal rigidity (35%)
- Bruit (3%)
- Focal neurologic deficit
- Fever (neonates and infants)
- Retinal hemorrhages, papilledema

## DIAGNOSTIC TESTS & INTERPRETATION

### Lab

- Immediately assess bedside glucose, as hypoglycemia may mimic symptoms of SAH.
- CBC may suggest sickle cell disease, blood loss, or thrombocytopenia.
- Check PT/PTT and INR.
- Blood gas analysis to evaluate the adequacy of oxygenation and ventilation

### Imaging

- Noncontrast CT will detect >90% of all SAH within the 1st 24 hr regardless of etiology (1):
  - The initial CT should be noncontrast, as contrast may obscure the presence of subarachnoid blood.
- MRI/MR angiography can distinguish vascular malformations. However, it is not as sensitive as CT scanning in demonstrating acute blood.
- Consider emergent angiography in patients who have a positive CT scan, a negative CT scan but positive lumbar puncture (LP), or in those with a very suggestive history despite negative studies:
  - Observation of small, stable SAH is an appropriate option.

### Diagnostic Procedures/Other

LP: If the CT scan shows no SAH, strongly consider performing an LP to evaluate the CSF for the presence of RBCs and xanthochromia.

### DIFFERENTIAL DIAGNOSIS

- TBI, including child abuse
- Migraine headache
- Vascular dissection
- Meningitis
- Cerebral venous thrombosis
- Hypoglycemia

## TREATMENT

### PRE HOSPITAL

Assess and stabilize airway, breathing, and circulation.

### INITIAL STABILIZATION/THERAPY

- Assess and stabilize airway, breathing, and circulation.
- In patients with acute neurologic deterioration, head elevation (30 degrees), hyperventilation (pCO<sub>2</sub> 26–30 mm Hg), and mannitol (1.0–1.5 g/kg) can lower ICP within minutes.

### MEDICATION

#### First Line

- Fluid management to maintain euvolemia, as dehydration increases the risk of cerebral infarction
- Antipyretics:
  - Acetaminophen 15 mg/kg PO/PR if febrile, as pyrexia can increase cerebral edema
  - Ibuprofen and naproxen carry theoretical risk of exacerbating hemorrhage.

- Anticonvulsants:
  - If seizure occurs, standard therapy includes the use of benzodiazepines, phenytoin, barbiturates, or propofol.
  - After seizure occurs, consider loading with phenytoin or fosphenytoin for seizure prophylaxis.
  - See the Seizure and Status Epilepticus topics for anticonvulsant dosing.
- Antihypertensives:
  - Nifedipine:
    - Children: 0.25–0.5 mg/kg/dose PO; bite and swallow or aspirate medication from a gel cap with a syringe and give sublingually; max single dose 10 mg
    - Adolescent/Adult: 10 mg PO; bite and swallow or aspirate medication from a gel cap and give sublingually
    - Nifedipine dosing in children or adolescents may be repeated q4–6h PRN.
  - Nicardipine:
    - Neonatal: Initial dose 0.5  $\mu$ g/kg/min IV and titrate infusion, max single dose 2  $\mu$ g/kg/min
    - Children: Initial dose 0.5–1  $\mu$ g/kg/min IV and titrate infusion, max single dose 5  $\mu$ g/kg/min
    - Adolescent/Adult: Initial dose 5 mg/hr IV and titrate infusion, increase by 2.5 mg/hr q15min to a max of 15 mg/hr
  - Labetalol:
    - IV intermittent dosing: 0.2–0.5 mg/kg/dose, range of 0.2–1 mg/kg/dose, max single dose 20 mg
    - IV continuous infusion: 0.4–1 mg/kg/hr, max single 3 mg/kg/hr
  - Avoid nitroprusside, as it may raise ICP.
- Mannitol:
  - Child, adolescent, adult:
    - 0.5–1 g/kg IV initial dose, followed by maintenance dose of 0.25–0.5 g/kg q4–6h
    - May use a test dose to assess initial response and urine output
    - Children's test dose: 200 mg/kg IV over 3–5 min
    - Adult test dose: 12.5 g IV over 3–5 min
    - Test dose endpoint is urine output: Children, 1 mL/kg/hr for 1–3 hr; adults, 30–50 mL/urine/hr for 2–3 hr

#### SURGERY/OTHER PROCEDURES

- Ventriculostomy for obstructive hydrocephalus can result in a dramatic and immediate clinical improvement.
- Microsurgical clipping or endovascular coiling of aneurysms whenever possible
- Treatment of an AVM depends largely on the size and location and can include conventional surgery, endovascular coiling, or radiosurgery.

#### DISPOSITION

Critical care admission criteria:

- All patients with acute SAH should be admitted to an ICU setting.

#### Discharge Criteria

Patients should not be discharged from the emergency department.

#### Issues for Referral

- Consultation with the neurosurgeon or neurointerventionalist must be initiated early.
- Many patients with traumatic SAH have multiple injuries. Therefore, consultation with a pediatric surgeon or a trauma specialist may be required.
- Patients with SAH require close hemodynamic monitoring; referral to a pediatric intensivist is also required.
- Patients with suspected SAH should be transferred emergently to the closest center with a CT scanner and, ideally, to a high-volume center where endovascular interventions as well as neurosurgical services are available.

#### FOLLOW-UP

##### FOLLOW-UP RECOMMENDATIONS

- Discharge instructions and medications:
  - Follow-up is typically with a definitive care subspecialist, such as a neurologist and neurosurgeon.
- Activity:
  - As recommended by a neurosurgeon

##### PROGNOSIS

- Survival correlates with the grade of SAH on presentation:
  - Reported figures include a 70% survival rate for grade I, 60% for grade II, 50% for grade III, 40% for grade IV, and 10% for grade V.
- Clinical outcome after severe TBI (Glasgow Coma Scale <7) showed that 61% children had severe disabilities, 35% had moderate disabilities, and 4% were normal (4).
- Larger hemorrhage is associated with worse neurologic outcome.
- The majority of newborns with a spontaneous SAH will make a complete recovery:
  - Infants do well after ICH because the incidence of vasospasm is lower and the presence of an open fontanel may be protective (5).

##### COMPLICATIONS

- Seizures
- Brain herniation
- Vasospasm and infarction
- Hydrocephalus
- Rebleeding

##### ICD9

- 430 Subarachnoid hemorrhage
- 772.2 Subarachnoid hemorrhage of newborn

#### PEARLS AND PITFALLS

- The goals for the emergency physician are to establish the diagnosis and initiate treatment to prevent secondary injury from the deleterious effects of cardiovascular instability or respiratory insufficiency.
- SAH is frequently misdiagnosed (in up to 12% of cases). Consider performing CT scan of the head and LP even if the CT scan is negative for blood. Do not forget to measure opening pressure and check for xanthochromia.
- Failure to address severe HTN or hypotension

# SUBDURAL HEMATOMA

Eric C. Hoppa  
Lois K. Lee

## BASICS

### DESCRIPTION

- A subdural hematoma (SDH) is a collection of blood in the potential space between the dura mater (outermost layer of the brain) and arachnoid membranes.
- SDHs may cause mass effect, which can lead to neurologic impairment if untreated.
- SDH should be considered in any patient with head trauma and altered mental status.
- They typically result from injuries with significant acceleration/deceleration forces, which apply shear forces to the subdural bridging veins. Abusive head trauma is a common etiology in children  $\leq 2$  yr of age.

### EPIDEMIOLOGY

#### Incidence

- The incidence of SDH varies by age but occurs most frequently in children  $\leq 2$  yr of age:
  - The incidence is 13 cases per 100,000 child-years in children  $< 2$  yr of age.
  - The incidence is 20–25 cases per 100,000 child-years in children  $< 1$  yr of age.
- There is an overall higher incidence in males.
- Mortality rates from SDH range from 10–20%.

### RISK FACTORS

- Newborns delivered by vacuum or forceps extraction
- Infants at risk for child abuse, including those with: disabilities, history of prematurity, young parents, an unstable family situation, or low socioeconomic status
- Significant falls
- Motor vehicle crashes without using the appropriate car seat/seat belt, especially in older children
- Predisposing medical conditions, including bleeding disorders, cerebral atrophy, treated hydrocephalus, arachnoid cysts, osteogenesis imperfecta, or glutaric aciduria type 1

### GENERAL PREVENTION

- Appropriate adult supervision to prevent falls
- Age-appropriate motor vehicle restraints
- Education of parents and adult caregivers on coping mechanisms to deal with crying infants and the risks of infantile shaking injuries

### PATHOPHYSIOLOGY

- SDH occurs as a result of shear forces or acceleration/deceleration injury resulting in either:
  - Tearing of bridging subdural veins OR
  - Hemorrhage from small cortical arteries
- Younger children typically sustain hemorrhage from bridging vein injury.
- SDHs from venous tearing are usually frontoparietal in location. Arterial injury is usually temporoparietal in location.

- Continued bleeding leads to mass effect. Then, signs of increased intracranial pressure (ICP) occur as the expanding hematoma displaces CSF, intracranial venous blood, and finally brain parenchyma within the fixed cranial vault. If untreated, brain herniation results in death.
- Bleeding continues until it is stopped by rising ICP or direct tamponade of the clot itself.
- Infants and young toddlers may tolerate elevated ICP better than adults because their cranial sutures may remain open up to 18 mo of age, and they have larger subarachnoid and extracellular spaces.
- Anemia from hemorrhage may precede signs of increased ICP in young children.
- Young children with open sutures may develop chronic, or acute on chronic, SDHs if they incur repeated episodes of abusive head trauma.

### ETIOLOGY

SDHs are typically sustained from trauma, including:

- Abusive head trauma with vigorous shaking and/or direct blows
- Deceleration forces from falls or motor vehicle crashes

### COMMONLY ASSOCIATED CONDITIONS

- SDHs are often associated with additional intracranial injuries: Subarachnoid hematoma, cerebral contusions, and diffuse axonal injury. These additional injuries often contribute to the clinical findings associated with SDHs.
- In abusive head trauma, there can be diffuse brain injury and hypoxic-ischemic injury, as well as retinal hemorrhages, and skull/skeletal fractures in addition to the SDH.

## DIAGNOSIS

### HISTORY

- Concerning mechanisms should prompt an evaluation for SDH:
  - Fall from a significant height ( $> 5$  feet)
  - Motor vehicle crash
  - Suspicion for abusive head trauma
- Patients may present with headache, visual changes, vomiting, lethargy, irritability, history of seizure, or history of loss of consciousness.
- Patients with small SDHs may be asymptomatic.
- Infants with SDHs may present with lethargy, irritability, seizures, repeated vomiting, or focal neurologic symptoms.
- Infants with chronic SDHs may present with macrocephaly or psychomotor developmental delays.

### PHYSICAL EXAM

- Assess vital signs, especially noting evidence of the Cushing triad: Bradycardia, HTN, and irregular respirations, which indicate elevated ICP and impending herniation.
- A complete neurologic exam, including age-appropriate Glasgow Coma Scale (GCS) score, a thorough motor assessment, and cerebellar function, should be performed.

- Pupillary exam noting reactivity to light and extraocular movements. Pupillary abnormalities may be a sign of impending herniation.
- Cerebellar SDHs can cause nystagmus and ataxia.
- Palpate the scalp for hematoma and step-offs in the skull.
- The anterior fontanelle should be assessed for fullness or bulging in infants.
- Head circumference should be assessed for children up to 18 mo of age.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

Lab tests are secondary to imaging tests:

- CBC and type and screen may be considered to assess for anemia and as part of the preoperative evaluation.
- Blood glucose may be useful, as hyperglycemia is associated with a poor prognosis in children with severe traumatic brain injury (1).
- PT, PTT, and INR should be sent to assess for coagulopathy and as part of a preoperative evaluation.
- Further lab studies such as urinalysis or AST/ALT may be sent in multiple trauma victims or in young children in whom abusive head trauma is suspected to screen for other occult injuries.

#### Imaging

- A noncontrast head CT should be obtained in patients with suspicion of SDH:
  - The CT appearance of SDH is classically a hyperdense crescentic or convex collection of extra-axial fluid.
  - Within the hyperdense area, there can be areas of hypodensity intermingled, representing older bleeding (hypodense) mixed with acute bleeding (hyperdense).
  - In contrast to epidural hematomas, SDHs cross suture lines but are contained by the falx and tentorium.
  - SDHs in the interhemispheric fissure or bilateral SDHs are more suggestive of abusive head trauma in infants.
- Other important findings include mass effect leading to midline shift, cerebral contusions, subarachnoid hemorrhage, loss of gray-white matter differentiation (indicative of cerebral edema), and transtentorial herniation.
- Skull films may be helpful in children  $< 2$  yr of age to identify a fracture, which would prompt a CT scan to evaluate for possible intracranial hemorrhage. However, absence of a skull fracture does not rule out intracranial hemorrhage.

### DIFFERENTIAL DIAGNOSIS

- Concussion
- Epidural hematoma
- Subarachnoid hemorrhage
- Diffuse axonal injury
- Scalp hematoma (in isolation)
- Skull fracture (in isolation)
- Postinfectious subdural effusion

## TREATMENT

### PRE HOSPITAL

- Prehospital care includes airway management based on the skill level of the prehospital care providers.
- C-spine immobilization must be maintained if there is suspicion of C-spine injury.

### INITIAL STABILIZATION/THERAPY

- The initial management of any patient with closed head injury should include a basic ABCs approach.
- Oxygen should be administered to keep oxygen saturation >95%.
- Endotracheal intubation is required to maximize oxygenation and ventilation and protect against possible aspiration in the following situations:
  - Depressed mental status (GCS <9)
  - Rapidly deteriorating mental status
  - Pupillary abnormalities
  - Respiratory insufficiency
  - Hemodynamic instability
- In patients who are endotracheally intubated, hyperventilation should be avoided unless there are signs of impending herniation. PaCO<sub>2</sub> should be maintained between 35 and 40 mm Hg to prevent cerebral ischemia.
- Patients with hypotension should receive fluid resuscitation (normal saline boluses of 20 mL/kg) to maintain cerebral perfusion pressure (CPP).

### MEDICATION

#### First Line

Mannitol (0.5–1 g/kg IV over 20 min) or hypertonic (3%) saline bolus (2–6 mL/kg IV) should be given for patients with impending herniation.

#### Second Line

Loading with antiepileptic medication (eg, fosphenytoin) is controversial. The rate of early posttraumatic seizures in patients with moderate to severe head injury is low (5–7%), and fosphenytoin minimally affects this rate (2). The risks and benefits of antiepileptic drugs must be carefully considered.

### COMPLEMENTARY & ALTERNATIVE THERAPIES

Elevate the head of the bed 15–30 degrees. This mild elevation may lower ICP without adversely affecting CPP.

### SURGERY/OTHER PROCEDURES

- There are no clear guidelines for surgical management.
- Emergent surgery should be considered for SDHs with the following:
  - Unilateral with midline shift on CT or located in the posterior fossa
  - Deterioration of mental status, evidence of elevated ICP, pupillary changes, hemiparesis, cerebellar signs, or other focal neurologic findings
- Nonoperative management with close observation is an option in patients with normal mental status, no midline shift on head CT, and patent basal cisterns on CT.
- A subdural tap may be a temporizing measure in an acute SDH with life-threatening increased ICP until definitive surgical care can be performed.

### DISPOSITION

#### Admission Criteria

- All patients with a SDH should be admitted to the hospital for close observation. Those with a small SDH and minimal or no symptoms may be considered for routine floor admission. Patients to be managed nonoperatively with abnormal GCS or neurologic findings or other complicating brain injury should be admitted to an ICU for close neurologic exam monitoring.
- The admitting hospital should have emergency access to head CT scanning, experienced pediatric personnel to monitor the patient's neurologic status, and appropriate operating room availability.
- Criteria for transfer to a pediatric trauma center after stabilization include:
  - GCS ≤12 in the field
  - Pediatric trauma score ≤8

#### Discharge Criteria

Patients should be observed for at least 24–48 hr after the injury or surgical intervention to evaluate for signs of hematoma expansion.

#### Issues for Referral

If a patient is being transferred for pediatric neurosurgical evaluation, endotracheal intubation should be performed to secure the airway in any patient with depressed GCS or neurologic abnormality.

## FOLLOW-UP

### FOLLOW-UP RECOMMENDATIONS

- Contact sports should be restricted until all SDH collections have resolved. Resuming activity is at the discretion of the neurosurgeon.
- Pediatric patients with severe traumatic brain injury may require ongoing neurorehabilitation.

#### Patient Monitoring

Patients may require re-imaging to monitor the status of the hematoma, depending on the initial SDH appearance.

### PROGNOSIS

- In general, the neurologic state of the patient on presentation predicts outcome.
- Worse prognosis is associated with patients with initial pupillary changes, coma, increased ICP, and more significant brain injury on CT.
- The type of head trauma and the severity of the associated brain injury, not necessarily the size of the SDH, determine the clinical severity of the patient.
- Though long-term outcomes are variable Jayawant et al. (3) found in a population-based study that 75% of infants with SDH either died or had significant disabilities.

### COMPLICATIONS

Delayed diagnosis can result in permanent neurologic sequelae, such as seizures, hemiplegia, cranial nerve abnormalities, or death.

### CODES

#### ICD9

- 432.1 Subdural hemorrhage
- 767.0 Subdural and cerebral hemorrhage due to birth trauma
- 852.20 Subdural hemorrhage following injury, without mention of open intracranial wound, with state of consciousness unspecified

### PEARLS AND PITFALLS

- Early consultation with a neurosurgeon is imperative, as patients may rapidly deteriorate.
- Maintaining adequate oxygenation and fluid resuscitation to maximize CPP helps prevent secondary brain injury/ischemia.
- Abusive head trauma should be suspected in infants with SDH in which the history is not consistent with the injury.
- Infants who have an SDH from suspected abuse require a thorough evaluation by a multidisciplinary team including child abuse specialists and an ophthalmologist. They should undergo ancillary testing (skeletal survey and a dilated retinal exam).
- Suspected abuse must be reported to the appropriate municipal child protective agencies.

# SUDDEN INFANT DEATH SYNDROME (SIDS)

Jose Ramirez

## BASICS

### DESCRIPTION

- Sudden infant death syndrome (SIDS) is the sudden unexplained death of an infant <1 yr of age.
- Typically, the patient was well when he or she was placed to sleep.
- The cause of death must be fully investigated:
  - Autopsy
  - Review of the death scene
  - Review of clinical and family medical history
- Risk factors have been identified (1).
- SIDS is a diagnosis of exclusion, and other diagnoses must be considered during the evaluation.

### EPIDEMIOLOGY

- 2,500 infant deaths per year are attributed to SIDS in the U.S.
- SIDS peaks between 2 and 3 mo of age.
- 90% of SIDS cases occur before 6 mo of age.
- Leading cause of death infants 1–12 mo of age (2)
- Early to mid 1990s: 1.2 SIDS cases per 1,000 live births
- 2002: 0.57 SIDS cases per 1,000 live births:
  - Mid to late 1990s “Back to Sleep” campaign:
    - 1994–2002: The percentage of infants sleeping prone dropped from 70% to <15%.

### RISK FACTORS

- Prone sleeping positions
- Maternal smoking during pregnancy
- Environmental tobacco smoke
- Overheating
- Soft bedding
- Inadequate prenatal care
- Young maternal age
- Prematurity or low birth weight
- More common in blacks, Native Americans, and Native Alaskans (3)

### GENERAL PREVENTION

- The “Back to Sleep” campaign by the American Academy of Pediatrics has led to a tremendous reduction in the incidence of SIDS and is the main prevention (4).
- Supine positioning during sleep is recommended, lateral positioning is acceptable if necessary, and prone positioning is not recommended (4).
- Use of infant pacifier while sleeping (4)
- Avoid excessively soft mattresses or excessive blankets (4).
- Avoid sleeping in same bed as parent.

### PATHOPHYSIOLOGY

- Uncertain etiology
- Speculation revolves around the infant’s ability to arouse in the presence of noxious stimuli.

### ETIOLOGY

- The causative factor resulting in SIDS is not known.
- Probable causes are varied:
  - May involve immaturity of the brainstem neuronal pathway

## DIAGNOSIS

### HISTORY

- Obtain history from caregivers and emergency personnel.
- Location/Position of the patient at the time of discovery; time of last meal
- Abnormalities noted by caregivers such as skin color change or movements
- Underlying medical conditions
- A comprehensive history to exclude potential diagnoses in the Differential Diagnosis section is essential.

### PHYSICAL EXAM

Look for any obvious signs of trauma to detect abusive trauma:

- Ecchymosis, burns, deformities, contusions

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

- Not useful for SIDS
- Consider obtaining CBC, C-reactive protein, blood, urine, and CSF cultures.
- Postmortem blood analysis for metabolic disorder

#### Imaging

Postmortem skeletal survey is typically carried out by the medical examiner rather than in the emergency department.

### DIFFERENTIAL DIAGNOSIS

- Sudden unexpected infant death
- Infectious processes:
  - Sepsis
  - Myocarditis
  - Meningitis
  - Encephalitis
- Cardiac:
  - Dysrhythmia, prolonged QT syndrome
  - Cardiomyopathy
  - Congenital heart defect
- Respiratory:
  - Asphyxiation
  - Bronchiolitis
  - Pneumonia
  - Pertussis

- CNS:
  - Cerebral edema
  - Intracranial mass
- Trauma:
  - Accidental or nonaccidental trauma
  - Suffocation
  - Subdural hematoma
  - Drowning
- Systemic infection
- Dehydration
- Hyper- or hypothermia
- Poisoning/Toxicologic
- Metabolic, genetic, endocrinologic disorders:
  - Adrenal hyperplasia
  - Inherited metabolic disorders (eg, fatty acid oxidation disorders)

## TREATMENT

### PRE HOSPITAL

Resuscitation according to standard Pediatric Advanced Life Support (PALS) protocol

### INITIAL STABILIZATION/THERAPY

Assessment and resuscitation according to standard PALS protocol:

- Cessation of resuscitation as indicated for absence of vital signs, especially if absent for > 10 min
- Cessation of resuscitation if rigor mortis is already present
- Consideration of resuscitation for hypothermic patients

### DISPOSITION

- SIDS cases should be referred to the medical examiner's office.
- Social work evaluation and support for the family

### Issues for Referral

- To complete autopsy, refer to the medical examiner if this does not routinely occur in cases of infant death.
- Law enforcement exam of the site where the infant died
- Review of the child and family's medical history
- Refer the case to the medical examiner.

## FOLLOW-UP

### FOLLOW-UP RECOMMENDATIONS

- Follow-up pertains only to forensic and pathologic/postmortem evaluation.
- Family members may be provided with referral to SIDS support groups.

## CODES

ICD9

798.0 Sudden infant death syndrome

## PEARLS AND PITFALLS

- Support is available from the Sudden Infant Death Syndrome Alliance (1-800-221-7437).
- Advocate the supine sleeping position.
- History of the event and past medical and social histories are essential.

# SUICIDE

Chiraag Gupta  
Christopher S. Amato

## BASICS

### DESCRIPTION

- Suicide is the act of terminating one's own life voluntarily.
- Suicidal ideation is thoughts or ideas that revolve around suicide or death.
- Suicide attempt:
  - Failed or aborted suicide activity
  - May be true attempt at suicide or suicidal gesture
- Suicidal gesture is action taken to communicate potential for self-injury.

### EPIDEMIOLOGY

Suicide is the 3rd leading cause of death among those 15–24 yr of age.

### RISK FACTORS

- Family history of depression in 1st-degree relatives
- Peer problems
- Prior depressive episodes
- Academic difficulties, learning disabilities
- Interpersonal dysfunction
- Chronic illness
- Family dysfunction or caregiver/child conflict
- Social withdrawal
- Excessive seeking of reassurance
- A negative viewpoint about:
  - The perceptions or the intent of others
  - Interpreting events
  - Coping with stress
- History of anxiety disorder
- History of early losses
- ADHD

### GENERAL PREVENTION

- Regular psychiatric care for patients with psychiatric issues
- Good support systems (family, friends, etc.)
- Antidepressant use in depressed patients

### PATHOPHYSIOLOGY

Likely multifactorial, but depression is thought to involve changes with the interaction serotonin and norepinephrine neurotransmitters have within the limbic system.

### ETIOLOGY

- Intertwined with depression
- 2% of children estimated to have major depressive disorder (MDD)
- 4–8% of adolescents are estimated to have MDD.

### COMMONLY ASSOCIATED CONDITIONS

- Comorbid psychiatric disorders are very prevalent (40–70%) in children and adolescents with MDD.
- Most frequent comorbidities are:
  - Anxiety
  - Substance abuse
  - Physical abuse
  - Sexual abuse
  - Disruptive behavior disorders

## DIAGNOSIS

### HISTORY

- Ask questions in a nonjudgmental way that is appropriate for the developmental age of the patient.
- To detect key signs of suicide, use the mnemonic *IS PATH WARM*:
  - *I*deation: Talking about or threatening to kill or hurt oneself; looking for ways to kill oneself; talking or writing about death, dying, or suicide
  - *S*ubstance abuse
  - *P*urposelessness
  - *A*nxiety: Anxiety, agitation, or changes in sleep pattern
  - *T*rapped: Feeling like there is no way out
  - *H*opelessness
  - *W*ithdrawal: Withdrawing from friends, family, and society
  - *A*nger
  - *R*ecklessness
  - *M*ood changes

- Directly determine acuity of suicidality:
  - Previous suicide attempts?
  - Depressed?
  - Preoccupied with thoughts of suicide?
  - Substance abuse?
  - Exposure to violence?
- Use pointed questions:
  - How often?
  - Have you ever wished you were dead?
  - Have you thought of hurting yourself?
  - Establish duration of suicidal thoughts
- Is there a plan? Details of plan?
- Ability to carry out plan (eg, access to firearms, toxins)?
- Use multiple sources for obtaining the history:
  - Patients may lie to avoid hospitalization or may not admit to substance abuse.

### PHYSICAL EXAM

- Vital signs
- Level of consciousness and orientation
- Toxidromes
- Organic causes (eg, enlarged thyroid)
- Signs of previous suicide attempts, sexual or physical abuse, or substance abuse
- Scars, bruising, or track marks

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

- Toxicologic screen
- Aspirin and acetaminophen levels
- Quantitative alcohol level
- Pregnancy in females
- Test for organic causes as indicated (eg, thyroid disease, inflammatory bowel disease [IBD], systemic lupus erythematosus [SLE], Addison disease)

**DIFFERENTIAL DIAGNOSIS**

- Psychiatric:
  - MDD
  - Dysthymic disorder
  - Bipolar disorder
  - Substance-induced mood disorder
  - Bereavement
  - Adjustment disorder
- General medical conditions:
  - Thyroid disease
  - Addison disease
  - Postconcussive syndrome
  - Metabolic disorders
  - Autoimmune (SLE and IBD)
  - Infectious (HIV, Epstein-Barr virus)

**TREATMENT****PRE HOSPITAL**

- Assess and stabilize airway, breathing, and circulation.
- Hemorrhage control as needed for self-inflicted trauma

**INITIAL STABILIZATION/THERAPY**

- Primary goal during acute suicidal crisis is to keep the patient safe.
- Address medical/poisoning/trauma issues.
- Immediate psychiatric evaluation (in-house psychiatrist or crisis team)
- Continuous 1 on 1 supervision/observation:
  - Keep patient, as well as staff, safe from harm.

**MEDICATION****First Line**

- Benzodiazepines:
  - Lorazepam 0.05 mg/kg/dose IV, max single dose 2 mg
- Antipsychotics:
  - Haloperidol: 6–12 yr of age, 2–5 mg/dose IM/IV × 1 dose
  - Ziprasidone: > 12 yr, 1–20 mg IM × 1 dose
  - Olanzapine: > 12 yr, 10 mg IM × 1 dose
  - Aripiprazole: > 12 yr, 9.75 mg IM × 1 dose

**ALERT**

- Droperidol is not FDA approved for treatment of agitation or psychosis, though it has been widely used for this purpose.
- In addition to lack of FDA approval, there is an FDA black box warning due to risk of cardiac dysrhythmia with this medication.

**DISPOSITION****Admission Criteria**

- Patients at risk for repeated attempts at self-harm should be hospitalized:
  - Use of potentially lethal methods
  - Attempt to conceal suicide activity
  - Concurrent psychiatric disorder
- Poor social support

**Discharge Criteria**

- Outpatient therapy can be pursued for low-risk individuals.
- Medically stable with no risk of imminent suicide
- Caregivers must stay with the patient indefinitely.
- All potential sources of harm must be removed, including firearms and drugs.
- Psychiatry follow-up within 48 hr:
  - No proven utility of “no-suicide” contracts to protect physician or patient

**Issues for Referral**

- Psychiatric follow-up
- Substance abuse counseling as needed

**FOLLOW-UP****FOLLOW-UP RECOMMENDATIONS**

Specific instructions/follow-up as per psychiatry or as per inpatient physicians

**COMPLICATIONS**

- Repeat suicide attempt
- Homicide
- Injury from failed suicide attempt

**CODES**
**ICD9**

- V62.84 Suicidal ideation
- 300.9 Unspecified nonpsychotic mental disorder

**PEARLS AND PITFALLS**

- Suicide is a leading cause of death of adolescents and young people.
- Recognize the effect of concurrent psychiatric disease or substance abuse on potential lethality.
- *IS PATH WARM* to determine acuity of suicidality.
- Rely on multiple sources of information for history, as the patient may lie to avoid hospitalization.
- Address medical/poisoning/trauma issues.
- Early psychiatry/crisis involvement is useful.
- High-risk patients should be admitted.
- Only low-risk patients with good support and close follow-up can be safely discharged.

# SYMPATHOMIMETIC POISONING

Robert J. Hoffman  
Yuki Yasaka

## BASICS

### DESCRIPTION

- Sympathomimetic poisoning produces the clinical syndrome typically described as “sympathomimetic.”
- Overdose from sympathomimetic agents occurs secondary to the use of prescription drugs, nonprescription drugs such as over-the-counter (OTC) cold medicine (eg, pseudoephedrine), dietary supplements (eg, ephedra, synephrine), and illicit drugs (eg, cocaine, amphetamine, methamphetamine).
- The sequelae of sympathomimetic overdose are generally related to the neurologic and cardiovascular systems.
- Severe problems may include agitation-induced hyperthermia, cardiac dysrhythmia, HTN, myocardial ischemia and infarction, cerebrovascular accident (CVA), seizure, and cardiovascular collapse.

### EPIDEMIOLOGY

#### Incidence

- Cocaine, methamphetamine, and ecstasy are the 3 most common illicit sympathomimetic drugs causing emergency visits in the U.S.
- Prescription stimulants such as methylphenidate and albuterol are often frequent causes of intentional as well as unintentional poisoning.

### RISK FACTORS

Prescription sympathomimetics, such as methylphenidate, pose some risk factors for both the recipient of the prescription as well as siblings.

### PATHOPHYSIOLOGY

- Relevant pathophysiology is based on the adrenergic receptor type stimulated by the drug involved.
- The adrenergic receptors of relevance include alpha<sub>1</sub>, beta<sub>1</sub>, and beta<sub>2</sub> receptors.
- Combined alpha- and beta-agonists:
  - Ephedrine and pseudoephedrine stimulate both alpha and beta receptors.
  - Excessive cardiovascular stimulation results in symptoms qualitatively similar to those that occur with catecholamines.
  - Ephedrine and pseudoephedrine have weaker penetration of the CNS relative to drugs of abuse:
    - As a result, users may suffer from systemic complications of the relatively larger doses necessary to achieve the CNS “high” of other stimulants.
- Nonelective beta-adrenergic agonists:
  - Isoproterenol, rarely used, is the prototypical nonselective beta-agonist causing the following:
    - Tachycardia, hypotension, tachydysrhythmia, myocardial ischemia, and flushing due to its cardiostimulatory and vasodilatory properties
  - Commonly, CNS effects of anxiety, fear, and headache occur.

- Selective beta<sub>2</sub>-adrenergic agonists are commonly used, and these include albuterol, levalbuterol, salmeterol, terbutaline, and others.
- Common adverse effects include:
  - Tachycardia, palpitations, and tremor
  - Hypotension, often with widened pulse pressure
  - Nausea, vomiting, and sometimes diarrhea
  - Hyperglycemia and hypokalemia
  - Elevation of creatine phosphokinase (CPK) as well as troponin occur and are inconsequential. MI is never expected to occur in otherwise healthy children with selective beta<sub>2</sub>-agonist exposure.
  - Anxiety, fear, and headache also may occur.
- Alpha<sub>1</sub>-selective agonists include phenylephrine and phenylpropranolamine, though the latter is no longer commercially produced in any meaningful quantity in the U.S.
- HTN due to direct vasoconstrictive effects is the most common effect.
- Reflex bradycardia may occur, particularly with phenylpropranolamine.
- Headache due to elevated BP and even CVA may occur.
- Serotonin syndrome may result from serotonergic excess, especially from ecstasy (MDMA).
- MDMA may also result in SIADH due to its activity to cause antidiuretic hormone release:
  - Most commonly occurs in females

### ETIOLOGY

- Exposure to sympathomimetic agents
- See Pathophysiology.

### COMMONLY ASSOCIATED CONDITIONS

Many sympathomimetic agents are capable of producing psychiatric symptoms, particularly psychosis:

- Indistinguishable from schizophrenia

## DIAGNOSIS

### HISTORY

- The clinical effects of these agents in overdose vary based on receptor selectivity.
- Most agents have some degree of combined alpha- and beta-adrenergic activity in overdose.
- HTN, tachycardia, acute coronary syndromes, and pulmonary edema, as well as cerebrovascular injury, anxiety, sense of impending doom, fear, and headache, may all occur.
- At very high doses, even agents not considered to be centrally acting will cross the blood-brain barrier and result in CNS symptoms.
- Headaches, seizure, or coma are CNS findings of most concern.
- Chest: Chest pain due to dysrhythmia, myocardial ischemia, MI, etc., may be a complaint.
- History of exposure may be helpful but is often unavailable or deliberately concealed, particularly the use of illicit drugs such as cocaine, methamphetamine, and MDMA.

- The use of OTC medicines, such as multisymptom cold preparations or dietary supplements, may be obtained.
- Have a high suspicion of sympathomimetic overdose especially in patients with the sympathomimetic toxidrome.
- The onset of symptoms usually occurs within 1 hr.
- Typically, prescription and OTC sympathomimetic agents are insufflated (snorted) or orally administered inhalation.
- For illicit drugs, insufflation, oral ingestion, and injection are used.
- Injection results in immediate, more intense effect; cocaine, amphetamine, and methamphetamine are the sympathomimetics most commonly injected.
- Sympathomimetic toxicity following ingestion typically peaks at 1–4 hr and lasts 4–8 hr, but sustained-release preparations may alter this time course.

### PHYSICAL EXAM

- Sympathomimetic toxicity is a clinical diagnosis.
- Vital sign derangement is the most common and most reliable indicator of toxicity.
- Mental status changes are also common though less reliable, as they do not occur with the same regularity and may be the result of toxicologic or psychiatric phenomenon.
- The patient’s general appearance (eg, agitation, diaphoretic, delirium, psychotic) is often suggestive of toxicity.
- HEENT: Headache, mydriasis, visual changes, epistaxis
- Tachycardia and HTN are the most common vital sign abnormalities.
- Skin: Diaphoresis, flushing, track marks associated with IV drug use
- CNS: Focal neurologic findings may occur and are particularly concerning for the possibility of CVA.
- CNS stimulation or agitation is very common, including severe psychomotor agitation and psychosis.
- Muscle rigidity, rhythmic shivering or shaking, and altered mental status may be associated with serotonin syndrome.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

- Diagnosis is clinical; assays are adjunctive.
- Unless for specific forensic indications such as malicious poisoning or child abuse, drug of abuse screening is not recommended and is not useful.
- Assess the serum acetaminophen level in patients with ingestion with intent of self-harm.
- Measure electrolytes, BUN, creatinine, and glucose as indicated:
  - MDMA may result in SIADH and severe hyponatremia, especially in females.
- Cardiac markers (eg, CPK-MB, troponin) are appropriate to screen for cardiac injury.
- Assessment of urine for myoglobin and/or serum CPK levels may be useful to evaluate for rhabdomyolysis.

**Imaging**

Head CT if coma or focal neurologic deficits

**Diagnostic Procedures/Other**

ECG to detect dysrhythmia or ischemia

**DIFFERENTIAL DIAGNOSIS**

- Hyperthyroidism, thyroid storm
- Anticholinergic syndrome
- Pheochromocytoma
- Withdrawal syndromes
- Mania
- Subarachnoid hemorrhage
- Serotonin syndrome
- Neuroleptic malignant syndrome
- Other situations of increased endogenous catecholamine release

**TREATMENT**

**INITIAL STABILIZATION/THERAPY**

- Assess and stabilize airway, breathing, and circulation.
- Sedation with benzodiazepines as necessary to relieve cardiovascular and psychomotor stimulation
- Cooling may be required to treat hyperthermia.
- Maintaining vital signs within acceptable limits and controlling patient agitation are commonly required.
- Unless there is a contraindication, at least maintenance IV fluid should be administered to prevent rhabdomyolysis as well as potential dehydration.
- Use of specific cardiovascular medications may be needed.
- Antipsychotics, such as haloperidol, are contraindicated because these medications may lower seizure threshold, impair heat dissipation, and increase risk of cardiac dysrhythmia.
- Agitated patients may initially require physical restraint. Quickly convert to chemical restraint.

**MEDICATION**

**First Line**

- Benzodiazepines:
  - Useful to control psychomotor agitation as well as excess cardiovascular stimulation
  - The quantity required will be directly related to severity of sympathomimetic poisoning.
  - Large doses may be required for sedation.
  - Lorazepam in doses of 0.1 mg/kg IV q15min (initial max single dose 2 mg) titrated to effect is preferred due to predictable duration of action.
  - Diazepam 0.1 mg/kg IV q5–10min titrated to effect may also be used.
  - With benzodiazepine dosing, if 3 repeated administrations of a given dose have not achieved effect, double the dose. For example, after diazepam 10 mg IV is given 3 times, double the dose to 20 mg IV.
  - When doubling the dose of lorazepam, wait 30 min between the last dose and the new escalated, higher dose.
- Vasoconstrictive effects may be managed with a variety of medications.

- Phentolamine 0.1 mg/kg/dose (max single dose 5 mg) IV repeated q10min PRN
- Antihypertensives:
  - Nifedipine:
    - Children: 0.25–0.5 mg/kg/dose PO; bite and swallow or aspirate from the gel cap and give sublingually, max single dose 10 mg
    - Adolescent/Adult: 10 mg PO; bite and swallow or aspirate from the gel cap and give sublingually
  - Nicardipine:
    - Neonatal: Initial dose 0.5 μg/kg/min IV and titrate infusion, max single dose 2 μg/kg/min
    - Children: Initial dose 0.5–1 μg/kg/min IV, titrate infusion, max single dose 5 μg/kg/min
    - Adolescent/Adult: Initial dose 5 mg/hr IV, titrate infusion, increase by 2.5 mg/hr q15min to a max of 15 mg/hr
- Sodium nitroprusside 0.3–10 μg/kg/min IV, titrated to effect

**Second Line**

- A beta-blocker may be used only if an alpha-blocker is concomitantly administered.
- Use of a beta-blocker without alpha blockade may cause paradoxical increase in BP and death:
  - Labetalol:
    - IV intermittent dosing 0.2–0.5 mg/kg/dose, range of 0.2–1 mg/kg/dose, max single dose 20 mg
    - IV continuous infusion 0.4–1 mg/kg/hr, with max 3 mg/kg/hr

**SURGERY/OTHER PROCEDURES**

- Severe hyperthermia should be treated with active cooling.
- Patients with core temperature ≥ 107°F should be placed in an ice bath and have core temperature monitored.

**DISPOSITION**

**Admission Criteria**

- Any patient with severely deranged vital signs, end organ manifestations such as chest pain, severe headache, focal neurologic deficit, or agitation should be admitted.
- Critical care admission criteria:
  - Severely deranged vital signs or evidence of end organ injury, such as MI, stroke, or hepatic injury

**Discharge Criteria**

Vital signs within safe limits, normal mental status, and end organ injury

**Issues for Referral**

- Patients with intentional substance abuse should be referred for drug counseling.
- Patients exposed to stimulants as a result of parental abuse or neglect should be referred to appropriate child protective authorities.

**FOLLOW-UP**

**PROGNOSIS**

Varies depending on end organ injury that may occur:

- If there is no end organ damage, full recovery is typical.

**COMPLICATIONS**

Cardiovascular, including dysrhythmia, MI, and CVA

**ADDITIONAL READING**

**See Also (Topic, Algorithm, Electronic Media Element)**

Cocaine Poisoning

**CODES**

**ICD9**

971.2 Poisoning by sympathomimetics (adrenergics)

**PEARLS AND PITFALLS**

- Young, healthy patients typically tolerate sympathomimetic exposure very well.
- End organ injury such as CVA and MI are the main causes of morbidity and mortality.
- Large doses of benzodiazepines may be required for sedation. After 3 attempts at sedation with a given dose, double the medication dose.

# SYNCOPE

Casey W. Buitenhuis  
Marianne Gausche-Hill

## BASICS

### DESCRIPTION

- Syncope is a transient loss of consciousness and postural tone with spontaneous recovery (1).
- A loss of cerebral blood flow mediated by a low-flow state, depleted intravascular volume, or diminished cardiac output from obstructive, arrhythmogenic, or neurally mediated pathways is causative.
- In contrast to their adult counterparts, most causes of syncope in the pediatric population are not life threatening (2). However, cardiac causes of syncope should be excluded.

### EPIDEMIOLOGY

#### Incidence

15–50% of all children will have at least 1 episode of syncope prior to age 18 yr (1–3). Syncope is unusual unless associated with a seizure disorder in children <6 yr of age (2).

### RISK FACTORS

- Family history of early cardiac death (<45 years in age)
- Family history of unexplained deaths at a young age (eg, sudden drowning)
- History of structural heart disease
- Recent illness causing dehydration
- Previous syncopal episode

### GENERAL PREVENTION

- Avoidance of known or suspected triggers
- Early investigative diagnosis for those at risk for cardiac syncope

### PATHOPHYSIOLOGY

- In vasovagal syncope, also known as vasodepressor or neurocardiogenic syncope, a stimulus causes an exaggerated increase in vagal tone, manifested by temporary bradycardia and hypotension.
- In orthostatic syncope, conditions leading to diminished intravascular blood volume causes decreased cerebral perfusion pressure on assuming an upright position, with resultant loss of consciousness.
- Cardiac syncope:
  - Obstructive: A fixed or dynamic outflow obstruction causes a reduction in global cardiac output, thereby causing reduced cerebral perfusion pressure and syncope.
  - Dysrhythmogenic: A reduction in heart rate (HR) by a pathologic conduction abnormality (eg, sick sinus syndrome, atrioventricular [AV] block) or increase in HR by a pathologic tachydysrhythmia (eg, Brugada syndrome, long QT syndrome) causes a reduction in cardiac output and resultant syncope.

### ETIOLOGY

- Vasovagal syncope: Implicated in >50–80% of cases of pediatric syncope (2)
- Orthostatic syncope (eg, dehydration, anemia, blood loss, exercise, diabetes mellitus, pregnancy)
- Cardiac syncope:
  - Obstructive:
    - Hypertrophic ventricular septum
    - Hypertrophic obstructive cardiomyopathy (HOCM): Relatively common (1 in 500) disorder characterized by asymmetric ventricular hypertrophy causing left ventricular outflow obstruction during exertion and resultant syncope or sudden death
    - Valvular aortic stenosis: Relatively rare condition but can present with syncope and sudden death
    - Myxoma
    - Vegetation
  - Anomalous coronary artery: Rare but can manifest as syncope from myocardial ischemia or infarction
  - Dilated cardiomyopathy
  - Acute myocarditis
  - Dysrhythmias:
    - Long QT syndrome: Disorder of myocardial repolarization characterized by prolongation of the QT interval and increased risk of sudden cardiac death due to the potential to degenerate into polymorphic ventricular tachycardia:
      - Inherited forms: Jervell and Lange-Nielsen syndrome and Romano Ward syndrome
      - Acquired prolonged QT often is caused by medications (eg, quinidine, sotalol, antihistamines, antipsychotics) or electrolyte abnormalities (eg, hypokalemia and hypomagnesemia).
    - Brugada syndrome: Inherited channelopathy that results in characteristic ECG and risk of sudden death from ventricular tachyarrhythmia
    - Pre-excitation syndrome: Multiple syndromes (eg, Wolff-Parkinson-White) cause ventricular tachyarrhythmia and resultant death.
    - Catecholaminergic polymorphic ventricular tachycardia: Ventricular tachyarrhythmia provoked by emotional upset or catecholamine surge
    - Arrhythmogenic right ventricular cardiomyopathy
    - Congenital short QT syndrome:
      - Mutations in the gene responsible for potassium channels results in QTc <300–320 milliseconds.
  - Congenital heart disease or pulmonary HTN are rare causes of syncope in children.
- Other:
  - Pulmonary embolus
  - Hypothyroidism
  - Breath-holding spells typically occur in children 6–24 mo of age, disappearing by school age.

## DIAGNOSIS

### HISTORY

- A complete history is essential.
- Ask about activities immediately before or during the syncopal event:
  - Prolonged upright posture, volume loss, or emotional trigger may indicate a vasovagal etiology.
  - Syncope during or after exercise or recurrent syncope should raise concern for a cardiac etiology.
  - A sudden startle, auditory stimulus, or emotional or physical stress may be the inciting factor in syncope from long QT syndrome.
  - Hair grooming or hair cutting may lead to a form of neurocardiogenic reflex syncope (4).
- Obtain a complete description of the event:
  - A prodrome of sweating, dizziness, light-headedness, nausea, and visual changes preceding the event are associated with vasovagal syncope.
  - Symptoms on standing are indicative of orthostatic syncope.
  - Shortness of breath, chest pain, or palpitations prior to or during the event possibly indicates a cardiac etiology.
  - Abnormal motor activity after a syncopal event is not uncommon, but recovery to baseline is usual. Any prolonged recovery raises suspicion for a seizure disorder.
- Ask about significant past medical history:
  - Congenital heart disease
  - History of arrhythmia
  - Previous syncopal events
  - Menstrual history (pubescent females)
  - Sexual history (pubescent females)
- Detailed family history, noting especially:
  - Early cardiac death (<45 yr)
  - Familial cardiomyopathy
  - Arrhythmia
  - Unexplained death at a young age
- Previous history of vasovagal syncope

### PHYSICAL EXAM

Complete physical exam should be performed, including:

- Orthostatic vital signs: HR increase >20 bpm or systolic BP decrease <20 mm Hg raises suspicion for orthostatic syncope.
- BP should be measured in all 4 extremities if clinically indicated. A coarctation can present with syncope and would demonstrate differential readings between upper and lower extremity BPs.
- Cardiac auscultation:
  - HOCM murmur is outflow murmur that decreases in intensity with squatting and increases with Valsalva maneuver.
  - Murmur at the right sternal border raises suspicion for aortic stenosis.
  - Diastolic murmurs are *always* abnormal.
- An age appropriate neurologic exam

**DIAGNOSTIC TESTS & INTERPRETATION**

- ECG is the mainstay investigation despite its low diagnostic yield (5).
- Additional investigations are low yield except when indicated by the history and physical exam.

**Lab****Initial Lab Tests**

- Fingerstick glucose measurement
- Hemoglobin may be performed for those at risk for anemia.
- A urine pregnancy test is mandatory in sexually mature females.

**Diagnostic Procedures/Other**

- An ECG should be performed on all patients with syncope (3,5). The following findings are clinically significant (1):
  - Nonsinus rhythms, excessive brady- or tachycardias or AV blocks
  - Evidence of myocardial injury
  - An abnormally long or short QTc interval
  - Findings suggestive of Brugada syndrome (RSR in V1 and V2 with ST elevation)
  - Findings suggestive of a pre-excitation syndrome (ie, delta wave)
  - Epsilon waves may indicate arrhythmogenic right ventricular cardiomyopathy.
  - Ventricular hypertrophy and strain patterns may indicate HOCM, valvular disease, or pulmonary HTN.
- Echo is low yield and should be reserved for patients suspected of having cardiac etiology by the presence of any of the following (6):
  - Abnormal ECG
  - Exercise-induced syncope
  - Pathologic murmur
  - History of heart disease
  - Concern for hypertrophic cardiomyopathy
- EEG if a seizure disorder is suspected; may be obtained as outpatient

**DIFFERENTIAL DIAGNOSIS**

- Breath-holding spells
- Complex migraine
- Conversion disorder
- Hypoglycemia
- Malingering
- Pseudo seizure
- Seizure
- Self-strangulation or autoerotic asphyxia

**TREATMENT****INITIAL STABILIZATION/THERAPY**

- Vasovagal syncope: Avoidance of precipitating factors can prevent future recurrences.
- Orthostatic syncope:
  - The mainstay of therapy is fluid resuscitation.
  - Isotonic crystalloid is the first-line therapy at 20 mL/kg IV; repeat PRN.
  - If bleeding is clinically suspected, packed RBCs may be transfused at 10 mL/kg.
- Dysrhythmic syncope: Treatment includes medical therapy (see below) and cardiac pacing (pathologic bradyarrhythmias).
- Structural heart disease: Critical aortic valvular disease justifies a cardiologic consultation.

**MEDICATION**

- Medications are directed toward the precipitating cause of syncope and should be initiated in conjunction with a cardiologist.
- A non-dihydropyridine calcium channel blocker (eg, verapamil, diltiazem) may be used in arrhythmogenic tachyarrhythmias.
- A beta-blocker (eg, metoprolol, atenolol, carvedilol) may be used in dysrhythmic tachyarrhythmias and long QT syndromes.

**DISPOSITION****Admission Criteria**

- Consider admission for the following:
  - Abnormal ECG
  - Clinical evidence of cardiovascular disease
  - Chest pain with syncope
  - Cyanosis
  - Apneic or bradycardic episodes
  - Abnormal neurologic exam
  - Refractory orthostatic hypotension
  - Other emergent medical condition causing syncope
- All patients with suspected cardiac syncope should be admitted to the hospital with cardiology consultation.

**Discharge Criteria**

Most patients with syncope may be discharged from the emergency department if there are no high risk factors present.

**Issues for Referral**

- Patients with correctable, but recurrent, orthostatic syncope should be referred to their primary care provider for tilt testing to rule out autonomic dysfunction.
- Children who are of the age to operate a motor vehicle should be advised not to drive.

**FOLLOW-UP****FOLLOW-UP RECOMMENDATIONS**

Patients with non-life-threatening syncope should be referred to their primary care provider for continued management.

**PROGNOSIS**

- Those with vasovagal syncope have a 36% chance of recurrent syncope at 3 yr (1).
- Cardiac syncope has 31% recurrence within 3 yr and 30% chance of death in 1 yr if untreated (1).

**COMPLICATIONS**

- Significant injury (motor vehicle accident, trauma, drowning) as a consequence of a syncopal event
- Recurrence of syncope

**CODES****ICD9**

780.2 Syncope and collapse

**PEARLS AND PITFALLS**

- Perform a complete history including relevant personal and family history in a syncopal patient.
- Obtain an ECG in patients with cardiac syncope.
- Perform a pregnancy test on sexually mature females.

# SYNDROME OF INAPPROPRIATE ANTIDIURETIC HORMONE SECRETION (SIADH)

Ara Festekjian  
Lilit Minasyan

## BASICS

### DESCRIPTION

- SIADH is a disorder of antidiuretic hormone (ADH) secretion in the absence of hyperosmolality or hypovolemia.
- SIADH is characterized by impaired free water excretion with subsequent fall in sodium concentration.
- Most common cause of normovolemic hyponatremia (1):
  - Hyponatremia is defined as serum sodium concentrations  $<130$  mEq/L.
- Clinical criteria used for SIADH case diagnosis (2):
  - Hyponatremia
  - Hypo-osmolality of plasma
  - Continued renal excretion of sodium during hyponatremic state
  - No clinical evidence of hypovolemia
  - Urine osmolality greater than anticipated with respect to plasma osmolality
  - Normal renal, adrenal, and thyroid function

### RISK FACTORS

- Head injury:
  - Must differentiate from cerebral salt wasting (CSW)
- Positive pressure ventilation
- Medications/Drugs:
  - Phenothiazines, tricyclic antidepressants, serotonin reuptake inhibitors
  - Thiazide diuretics
  - Various chemotherapeutic agents such as vincristine, cisplatin, and cyclophosphamide
  - Ecstasy (MDMA)
- Strenuous exercise: Marathon runners (3)
- Excessive intake of beer

### PATHOPHYSIOLOGY

- ADH acts on distal renal tubules and collecting ducts causing reabsorption of free water.
- SIADH develops when there is continued secretion of ADH irrespective of plasma osmolality. Excess water retention results in hyponatremia.
- Occurs in the setting of elevated concentrations of plasma arginine vasopressin (AVP) with a urine osmolality that is inappropriate for plasma hypo-osmolality (2)

### ETIOLOGY

- CNS disorders:
  - Meningitis, encephalitis, brain abscesses, MS, Guillain-Barré syndrome, lupus cerebritis, subdural hematoma, subarachnoid hemorrhage, head trauma
- Malignancies:
  - Lymphomas, thymomas, leukemia, brain and pituitary gland tumors
- Pulmonary infections:
  - Pneumonia, lung abscess, aspergillosis, TB
- AIDS and AIDS-related complex
- ADH-producing tumors

### ASSOCIATED CONDITIONS

- Acute intermittent porphyria
- Shy-Drager syndrome

## DIAGNOSIS

### HISTORY

- Identify the underlying disease processes as noted in the Etiology section.
- Symptoms may be nonspecific.
- Weakness, headache, nausea/vomiting, abdominal pain, dizziness
- More serious symptoms include seizures, coma, ataxia, and altered mental status.

### PHYSICAL EXAM

- Signs may be nonspecific, similar to history.
- Signs on exam vary from general weakness to focal neurologic deficits.
- Signs on exam related to underlying conditions/risk factors
- BP is usually normal.
- Patients generally appear euvolemic without signs of edema or dehydration.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

- Complete electrolyte panel: Need to confirm true hyponatremia in the absence of hyperlipidemia, renal insufficiency, nephrotic syndrome, or hyperglycemia (2)
- Free T4 and thyroid-stimulating hormone: Need to confirm normal thyroid function (2)
- Serum cortisol: When underlying adrenal insufficiency is suspected as a cause (2)
- Plasma ADH is elevated except in the setting of nephrogenic SIADH (2).

- Normal to low plasma urea, plasma uric acid, and anion gap (2)
- Urine osmolality is usually increased ( $>200$  mOsm/L) (2):
  - Important to measure urine osmolality to confirm hypotonicity, especially in the setting of pseudohyponatremia or hyperglycemia
- Urine sodium (with normal salt intake) is usually increased ( $>30$  mEq/L): Its presence does not confirm the diagnosis nor does its absence rule out the diagnosis (2).
- Fractional excretion (FE) of sodium and uric acid is usually elevated (4).
- Additional lab tests as indicated by clinical presentation (2):
  - For example, CSF studies for meningitis

### Imaging

- No specific imaging modality for SIADH
- Imaging performed should be guided by the clinical setting of underlying risk factors and etiology:
  - For example, CT of the head for seizures or mental status changes

### Diagnostic Procedures/Other

Administration of isotonic saline in patients with SIADH will result in rapid salt excretion (FE sodium with increase  $>0.5\%$ ) (4).

### DIFFERENTIAL DIAGNOSIS

- CSW: Considerable overlap exists between SIADH and CSW; the primary distinction lies in the assessment of the effective arterial blood volume (EABV):
  - SIADH is usually a volume-expanded state, wherein CSW EABV is contracted.
- Severe hypothyroidism
- Glucocorticoid deficiency
- CHF
- Cirrhosis
- Renal failure
- Primary polydipsia
- Water intoxication:
  - Excessive dilution of infant formula

**TREATMENT**

- Fluid restriction is the mainstay of treatment.
- Acute symptomatic hyponatremia, particularly of seizures (2):
  - Hypertonic (3%) saline is given until the symptoms resolve or a safe sodium level of 120 mEq/L is reached (the level does not need to return to normal):
    - 5–6 mL/kg of 3% sodium chloride generally raises serum sodium levels sufficiently to ameliorate acute symptoms.
    - The remainder of the correction may be done more gradually once acute symptoms are relieved.
- Fluid restriction: Usually several days may be required:
  - Ameliorate thirst by substituting ice chips for fluids.
- Gradual correction of hyponatremia:
  - If hyponatremia is thought to be acute in onset (<48 hr), sodium may be safely corrected over 24 hr.
  - If hyponatremia is of chronic or more gradual onset, correct sodium at a rate of 0.5–1 mEq/L/hr:
    - Unless acutely symptomatic

**MEDICATION**

- Medications other than sodium chloride should be reserved for cases refractory to fluid restriction and for patients with very high urine osmolality:
  - Avoid in patients with brain lesions where removal of lesion will likely lead to resolution of SIADH.
- Demeclocycline 600–1,200 mg/day:
  - Potential nephrotoxicity (monitor creatinine regularly)
  - Blocks renal effect of ADH
- Furosemide 0.5 mg/kg IV push may be used to affect diuresis.

**ALERT**

- Overly rapid correction of hyponatremia may lead to central pontine myelinolysis and severe neurologic deficits.
- Higher urine osmolality indicates higher plasma AVP levels, thus it is less likely that fluid restriction will be successful.

**COMPLEMENTARY & ALTERNATIVE THERAPIES**

- Niravoline, a kappa-opioid agonist, may have clinical application in cirrhotic patients.
- Vasopressin receptor antagonists are currently under development for possible clinical use.

**SURGERY/OTHER PROCEDURES**

As indicated by the clinical scenario and underlying conditions

**DISPOSITION**

**Admission Criteria**

- Patients with new-onset SIADH, symptomatic patients, and patients with sodium <125 mEq/L should be admitted for inpatient monitoring and therapy.
- Critical care admission criteria:
  - Acute symptomatic hyponatremia with seizures and altered mental status

**Discharge Criteria**

- Known underlying cause of SIADH
- Asymptomatic
- Safe serum sodium level, generally >125 mEq/L
- Reversal of underlying causes or removal of offending agents

**Issues for Referral**

Specialty care based on underlying condition

**FOLLOW-UP**

**FOLLOW-UP RECOMMENDATIONS**

Discharge instructions and medications:

- Continuation of fluid restriction
- Appropriate instructions for infant formula preparation

**Patient Monitoring**

- Close monitoring of serum sodium levels
- Monitoring as indicated by underlying medical conditions

**DIET**

- Fluid restriction
- Adequate salt supplementation with furosemide use

**PROGNOSIS**

- Based on underlying diagnosis
- Poor prognosis in patients with permanent brain damage

**COMPLICATIONS**

- Central pontine myelinolysis, severe neurologic deficits, and death may result from overly rapid correction of hyponatremia.
- Neurologic deficits and other complications related to underlying condition

**REFERENCES**

**See Also (Topic, Algorithm, Electronic Media Element)**

Hyponatremia

**ICD9**  
253.6 Other disorders of neurohypophysis

**PEARLS AND PITFALLS**

- It is difficult to differentiate between SIADH and CSW in the setting of traumatic brain injury. Therapy is radically different:
  - SIADH is treated with fluid restriction, whereas CSW is treated with aggressive sodium supplementation.
- It is more critical to base hypertonic saline treatment on symptoms rather than serum sodium level.
- Treatment outcomes are better when based on treating underlying conditions.
- Overly rapid correction of hyponatremia may result in demyelination syndrome.

# SYPHILIS

Jennifer H. Chao

## BASICS

### DESCRIPTION

- Syphilis is an infectious disease transmitted either via sexual activity or perinatally.
- It is known as the “great imitator” due to its various stages and various presentations.

### EPIDEMIOLOGY

- The incidence of syphilis has paralleled that of HIV infection in the 1980s and 1990s, with higher prevalence in urban areas, the southern U.S., in homosexual men, and in those with HIV.
- The rate of primary and secondary syphilis is 3.8 per 100,000 persons in the U.S. from 2007 data:
  - ~50% of these cases were reported from southern states.
  - There were 430 congenital cases, or a rate of 10.5 cases per 100,000 live births, in 2007.
- The number of total cases of syphilis reported in 2007 to the CDC was 40,920.
- The number of cases transmitted either by sexual contact or perinatally has been increasing in recent years.

### RISK FACTORS

- Multiple sex partners
- HIV infection
- Lack of prenatal care

### PATHOPHYSIOLOGY

See Etiology.

### ETIOLOGY

- The causative agent is the spirochete *Treponema pallidum*. It is ~10–13 microns in length and 0.15 microns in width. It is visible with dark-field microscopy and not by direct microscopy.
- It is a very slow growing organism with an estimated dividing time of 30 hr.
- It cannot be grown in artificial media and does not survive well outside of the host.
- The incubation period is 10–90 days.
- The spirochete is transmitted either by direct contact with a moist open lesion of either primary or secondary syphilis or transplacentally.
- Syphilis may be transmitted via infected blood transfusion.
- Nasal secretions of infants with congenital syphilis are highly contagious.

### COMMONLY ASSOCIATED CONDITIONS

Multiple STIs are associated with syphilis:

- HIV
- Gonorrhea
- Chlamydia
- Human papillomavirus
- Herpes

## DIAGNOSIS

### HISTORY

- Congenital syphilis may present as stillbirth, intrauterine growth retardation, recurrent unexplained fevers, a variety of rashes, cough, generalized edema, “snuffles” or nasal discharge, extremity pain, hepatitis, jaundice, or lymphadenopathy:
  - Most cases will present by 3 mo of life.
  - Late congenital syphilis may or may not be preceded by symptoms in early infancy. The symptoms of late syphilis present after 2 yr of age with bone, teeth, CNS, and skin disorders.
- Primary syphilis produces a painless genital ulcer at the site of inoculation, which is often not noticed. This heals within 3–6 wk.
- Secondary syphilis occurs weeks to months after initial infection. The presenting symptoms may include:
  - Rash that commonly involves the palms and soles
  - Fever, headache, malaise, anorexia, diffuse lymphadenopathy, and arthralgia
  - These symptoms may wax and wane for several years.
- Tertiary syphilis occurs up to 20 yr after initial infection and typically involves neurosyphilis. It may also involve gumma formation in skin, bone, viscera, or aortitis, which may present years to decades after the initial infection:
  - Up to 1/3 of patients with secondary syphilis will progress to tertiary syphilis if untreated.
  - Neurosyphilis is CNS infection that may occur at any stage of infection, particularly in those with HIV. It will occur in 5% of patients with syphilis who do not receive antibiotic treatment.
  - Neurosyphilis may present with a change in behavior, seizures, and neuropathies or be asymptomatic.

### PHYSICAL EXAM

- In congenital syphilis, the newborn may be small in size due to intrauterine growth retardation.
- In infants, there may be jaundice, hepatosplenomegaly, lymphadenopathy, erythematous or papulosquamous or vesicular rashes, palmoplantar scaling, warty lesions around the mouth and/or anus, snuffles, or eye redness.
- Late congenital findings may include a constellation of findings, some pathognomonic: Misshapen teeth, anterior bowing of the shins, “saddle nose,” frontal bossing and other bony changes, keratitis, deafness, symmetric painless knee swelling, or CNS involvement from behavior change to seizures and regression.

- The characteristic lesion of primary syphilis is  $\geq 1$  painless chancres. It has rolled edges and is the site of inoculation (generally on the genitals).
- Secondary syphilis findings may include a rash on the palms and soles, which may be maculopapular, papular, annular, pustular, warty (condyloma lata), and/or mucocutaneous with fever and diffuse lymphadenopathy.
- The tertiary findings of gummatous changes in skin or bone are unlikely seen in the pediatric population since they are seen between 15 and 30 yr after infection.
- An abnormal neurologic exam may or may not be seen with neurosyphilis.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

- In congenital syphilis, the CBC and CSF may be abnormal and should be obtained on all children:
  - The CBC may reveal anemia, leukocytosis, thrombocytopenia, or leukopenia.
  - CSF may show pleocytosis and increased protein.
- Screening tests include the venereal disease research laboratory (VDRL), the rapid plasma reagin (RPR), or the automated reagin test (ART); these tests measure antibody titers. These are nontreponemal tests that are inexpensive and provide quantitative results that can be used to monitor response to therapy:
  - The prozone reaction is false-negative nontreponemal reaction due to extremely high levels of circulating antibodies. Diluting the serum will yield a positive result and is typically done reflexively by pathology labs.
- A positive nontreponemal test should prompt confirmation with treponemal test: Either the fluorescent treponemal antibody absorption (FTA-ABS) or the *T. pallidum* particle agglutination (TP-PA) test:
  - If a person is positive for treponemal antibodies, he or she will likely be positive for life.
- CSF should be obtained on patients with clinical signs or symptoms of neurologic involvement:
  - If CSF is obtained, the VDRL should be performed on CSF. Interpretation of these results should be performed with consultation of an infectious disease specialist, given the high specificity but low sensitivity of this test.
- Given that in most institutions both the nontreponemal and treponemal test results are not immediately available, any patient with suspected syphilis who is not admitted should be referred for infectious disease follow-up for definitive diagnoses.
- Latent syphilis is a period when the only manifestations are serologic. The latent period is divided into early (within 1 yr of acquiring the disease) and late or unknown duration.

**Imaging**

- Long bone x-rays of children with suspected congenital syphilis may reveal the Wimberger sign, which includes bilateral medial metaphyseal lesions of the tibiae as well as periostitis or osteochondritis.
- Consider neuroimaging in patients with congenital syphilis and others for whom cerebral involvement is considered possible.

**Diagnostic Procedures/Other**

- Definitive diagnosis is made when the spirochetes are identified within a specimen either via dark-field microscopy or using direct fluorescent antibody tests.
- All patients diagnosed with syphilis should be tested for HIV.
- Fundoscopic ophthalmologic exam should be considered based on clinical presentation.

**DIFFERENTIAL DIAGNOSIS**

- Congenital syphilis:
  - Herpes simplex virus
  - Toxoplasmosis
  - Rubella
  - Cytomegalovirus
  - Osteomyelitis
- Primary syphilis:
  - Ulcerative lesions:
    - o Herpes simplex
    - o Chancroid (*Haemophilus ducreyi*)
    - o Reiter syndrome
- Secondary syphilis:
  - Pityriasis rosea
  - Tinea versicolor
  - Psoriasis
  - Id reaction
  - Viral syndrome, viral exanthema
  - Condyloma acuminata

**TREATMENT**

**MEDICATION**

**First Line**

- For congenital syphilis in those <1 mo of age: Aqueous crystalline penicillin G 100,000 U/kg/day divided q12h IV for the 1st 7 days, then 150,000 U/kg/day divided q8h IV for 3 more days (total of 10 days) or penicillin G procaine 50,000 U/kg/day IM daily for 10 days
- For congenital syphilis in those >1 mo of age: Aqueous crystalline penicillin G 200,000–300,000 U/kg/day divided q4–6h, given as 50,000 U/kg/dose IV for 10 days
- For primary syphilis and secondary or early latent syphilis (contracted in the last year): A single dose of penicillin 50,000 U/kg of benzathine penicillin IM, max single dose 2.4 million units
- For latent syphilis: 3 doses at 1-wk intervals of 50,000 U/kg of benzathine penicillin IM, max single dose 2.4 million units
- For neurosyphilis: Aqueous crystalline penicillin G 200,000–300,000 U/kg/day divided q4–6h, given as 50,000 U/kg/dose IV for 10–14 days, max single dose 4 million U q4h

**Second Line**

- If the patient with primary, secondary, or early latent syphilis is allergic to penicillin, he or she must be referred for skin testing and possible desensitization to penicillin.
- Known acceptable alternatives for the treatment of late latent syphilis or latent syphilis of unknown duration are doxycycline (100 mg PO b.i.d.) or tetracycline (500 mg PO q.i.d.), both for 28 days:
  - These carry risk of permanent teeth staining.

**DISPOSITION**

**Admission Criteria**

- All patients with congenital or neurosyphilis should be admitted.
- Patients without reliable follow-up should be admitted.
- Critical care admission criteria:
  - Consider intensive care admission for patients with congenital syphilis as well as tertiary syphilis.

**Discharge Criteria**

Patients with primary or secondary syphilis may be discharged with infectious disease follow-up.

**FOLLOW-UP**

**FOLLOW-UP RECOMMENDATIONS**

- Syphilis is a reportable disease throughout the U.S. Public health authorities should be notified of all cases.
- Sexual partner tracing will be performed by public health authorities, but this may be recommended to patients with sexually acquired syphilis while in the emergency department.
- Discharge instructions and medications:
  - All patients with a diagnosis of or suspicion of primary, secondary, or early latent syphilis should be referred to infectious diseases.
  - Quantitative nontreponemal serologic tests should be repeated at 6, 12, and 24 mo.
  - All adolescents must be instructed to refrain from sexual activity until fully treated. They should also be instructed to inform their partners.

**PROGNOSIS**

- Properly treated early primary syphilis has a good prognosis.
- Congenital syphilis and tertiary syphilis may have irreversible effects.

**COMPLICATIONS**

- Stillbirth
- Perinatal death
- Hydrops fetalis
- Prematurity
- Failure to thrive
- Meningitis
- Interstitial keratitis
- Permanent neurologic or cardiovascular system damage may result from congenital and tertiary syphilis.

- The Jarisch-Herxheimer reaction is an acute febrile reaction frequently accompanied by headache, myalgia, and other symptoms that may occur within the 1st 24 hr after therapy for syphilis. This is due to a sudden release of endotoxins as the spirochetes are being killed:
  - Patients should be informed about the possibility of this reaction.
  - The Jarisch-Herxheimer reaction occurs most frequently among patients who have early syphilis.

- Pelvic Inflammatory Disease
- Sexually Transmitted Infections

- ICD9**
- 091.2 Other primary syphilis
  - 091.9 Unspecified secondary syphilis
  - 097.9 Syphilis, unspecified

**PEARLS AND PITFALLS**

- Given the increasing incidence and various presentations, syphilis should be included in the differential diagnosis of many chief complaints.
- If the diagnosis is in question, refer the patient to an infectious disease specialist for proper follow-up.
- There have been reports of inappropriate use of combination benzathine/procaine penicillin (Bicillin C-R) instead of standard benzathine penicillin (Bicillin L-A). Practitioners should be aware of the similar names of these 2 products to avoid inappropriate treatment.
- Patients with HIV may have atypical serologic patterns.
- Congenital syphilis is possible in a child born to a seronegative mother if the infection was acquired in late pregnancy.
- Never use umbilical cord blood as an assessment for neonatal syphilis.
- Patients exposed within 90 days may be seronegative and should be treated presumptively.

# SYSTEMIC LUPUS ERYTHEMATOSUS

Ara Festekjian  
Lilit Minasyan

## BASICS

### DESCRIPTION

- Systemic lupus erythematosus (SLE) is an autoimmune disease of unknown etiology potentially affecting multiple organ systems including the kidneys, lungs, CNS, and immune system.
- Heterogeneous and unpredictable in its presentation, clinical severity, and clinical progression
- Challenging to diagnose and treat, particularly in younger patients

### EPIDEMIOLOGY

#### Incidence

Incidence rates of 2–10 per 100,000 persons per year, with rates much higher in females (1)

#### Prevalence

- Prevalence rates of 20–70 per 100,000
- Childhood rates overall are lower, especially in children <5 yr of age.
- Rates vary across continents (Asia and Africa > Europe and the U.S.) and ethnic backgrounds (Asians > blacks > Caucasians) (1).

### RISK FACTORS

- Greatest risk factor is gender: Reproductive-age women carry the greatest risk.
- Increased incidence if 1st-degree relatives with SLE
- Asians, blacks, and Hispanics develop the disease earlier in life.

### PATHOPHYSIOLOGY

- Abnormal production of autoantibodies directed against various antigens (particularly DNA) throughout the body
- Circulating and tissue-bound immune complexes are deposited at antigen sites and directly lead to tissue damage through complement activation cascades.
- Nervous system: Seizures, cerebritis, psychosis, stroke, cerebral venous thrombosis, pseudotumor cerebri, transverse myelitis, and peripheral neuritis
- Pulmonary: Acute hemorrhage, pulmonary infiltrates, pleuritis
- Cardiovascular: Pericarditis, myocarditis, valvular thickening, and endocarditis (Libman-Sacks disease), conduction abnormalities, coronary artery vasculitis and thrombosis
- Renal: Glomerulonephritis, nephrotic syndrome, HTN, renal failure leading to end-stage renal disease
- GI: Pancreatitis, hemorrhage
- Hematologic: Autoimmune hemolytic anemia, thrombocytopenia, leukopenia, anemia of chronic disease

### Pregnancy Considerations

Recurrent fetal loss as a complication of antiphospholipid syndrome may be the only manifestation of SLE.

#### ALERT

- Neonatal lupus: Immune complexes (maternal IgG autoantibodies that cross the placenta) deposited near the atrioventricular node in the neonate lead to permanent heart block requiring cardiac pacing.
- Most commonly, complete heart block

### ETIOLOGY

- The SLE cause remains unknown.
- Factors thought to contribute to the disease process include genetics, hormones, and socioeconomic status.
- Drug-induced lupus: Lupuslike disease occurring after exposure to drugs such as anticonvulsants, sulfonamides, and antiarrhythmic agents

### COMMONLY ASSOCIATED CONDITIONS

- Immunodeficiency
- Ulcerative colitis
- Malignancies

## DIAGNOSIS

- Based on the American College of Rheumatology criteria for diagnosis (2)
- Presence of  $\geq 4$  of the following 11 criteria is diagnostic for SLE:
  - Malar rash: Fixed erythema, flat or raised, over malar eminences, sparing the nasolabial fold
  - Discoid rash: Raised erythematous patches with adherent keratotic scaling and follicular plugging
  - Photosensitivity: Skin rash as a result of unusual reaction to sunlight by patient history or physician documentation
  - Oral ulcers: Painless oral or nasopharyngeal ulceration by physician documentation
  - Arthritis: Nonerosive arthritis involving  $\geq 2$  peripheral joints
  - Serositis: Pleuritis or pericarditis
  - Renal disorder: Persistent proteinuria  $>0.5$  g/day or evidence of cellular casts on urine microscopy
  - Neurologic disorder: Seizures or psychosis with absence of offending drugs or known metabolic derangements (uremia, ketoacidosis, or electrolyte imbalance)
  - Antinuclear antibody (ANA): With absence of drugs associated with drug-induced lupus
  - Hematologic disorder:
    - Hemolytic anemia with reticulocytosis
    - Leukopenia
    - Lymphopenia
    - Thrombocytopenia
  - Immunologic disorder:
    - Positive antiphospholipid antibody OR
    - Antibody to native DNA OR
    - Antibody to Sm nuclear antigen OR
    - False-positive serologic test for syphilis

### HISTORY

- Nonspecific symptoms include fever, weight loss, lymphadenopathy, and malaise.
- Other organ-specific symptoms as related to pathophysiology and not listed by classification criteria include:
  - Neurologic: Memory loss, labile mood
  - Pulmonary: Hemoptysis, shortness of breath
  - Cardiac: Chest pain, shortness of breath
  - Renal: Nocturia, hematuria
  - GI: Bleeding, pain from pancreatitis or vasculitis

### PHYSICAL EXAM

- Nonspecific findings include fever and vital sign changes (HTN or hypotension, tachypnea)
- Other organ-specific findings not specifically listed under classification criteria include (3):
  - Neurologic: Paraplegia, paraparesis, vision loss
  - Pulmonary: Hypoxemia with crackles
  - Cardiac: Distended neck veins, cardiac tamponade
  - Renal: Localized edema or anasarca
  - GI: Tenderness from pancreatitis or, less commonly, peritonitis
  - Hematologic: Vasculitic lesions, petechiae
  - Skin: Urticaria, erythema multiforme, and alopecia (rarer findings)

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

- CBC:
  - Coombs-positive hemolytic anemia
  - Autoimmune thrombocytopenia
  - Leukopenia or lymphopenia
  - Pancytopenia
- If seizure or psychosis, consider assessment of CSF.
- Coagulation factors: Lupus anticoagulant
- Complement levels C3, C4: Both expected to be low at diagnosis and disease flare
- Comprehensive metabolic panel:
  - Electrolytes, BUN, creatinine: Assessment of renal function
  - Total protein: Elevated due to hypergammaglobulinemia from abnormal lymphocyte activation
  - Albumin: Low when associated with nephrotic syndrome as a renal manifestation or low if chronically ill presentation
- ESR: Nonspecific marker of extent of inflammation (trends may be more informative especially when associated with anemia)
- C-reactive protein: Another marker of inflammation
- Cultures: Blood, urine, CSF
- Immune labs:
  - ANA: Titer of  $\geq 1:1,080$  (positive predictive value is 100%); titer of  $\leq 1:360$  (negative predictive value is 84%) (4)
  - Anti-DNA
  - Anti-Sm: Sm nuclear antigen
- Urinalysis: Proteinuria, hematuria, cellular casts, low specific gravity in light of dehydration (also consistent with history of nocturia)

**Imaging**

- Specific imaging may be indicated.
- Chest radiography: Tachypnea, shortness of breath, friction rub
- US:
  - Cardiac: Evaluation of ventricular function, pericardial effusion
  - Abdomen: Evaluation of kidneys, pancreas
- Head CT: Seizures, intracranial hemorrhage, psychosis

**Diagnostic Procedures/Other**

ECG may be indicated if pericarditis or other cardiac complication is considered.

**Pathological Findings**

Renal biopsy: More often performed in the setting of disease progression and treatment monitoring (demonstrating immune complex deposits)

**DIFFERENTIAL DIAGNOSIS**

- Juvenile rheumatoid arthritis
- Acute rheumatic fever
- Mixed connective tissue diseases

**TREATMENT****INITIAL STABILIZATION/THERAPY**

- Assess and stabilize airway, breathing, and circulation.
- Therapy is based on the type/severity of the organ system involved.
- Life-threatening presentations require critical care, pulse steroid or cytotoxic therapy, and appropriate subspecialty consultation.

**MEDICATION**

- NSAIDs may be used for musculoskeletal complaints:
  - Ibuprofen 10 mg/kg/dose PO/IV q6h PRN
  - Ketorolac 0.5 mg/kg IV/IM q6h PRN
  - Naproxen 5 mg/kg PO q8h PRN
  - Some clinicians prefer to avoid ibuprofen due to the rare occurrence of aseptic meningitis.
- Acetaminophen 15 mg/kg/dose PO/PR q4h PRN
- Corticosteroids:
  - Prednisone 1 mg/kg PO daily with taper (5)
  - Consider pulse therapy with methylprednisolone 30 mg/kg/dose IV.
  - Adverse effects include HTN, gastritis, osteopenia, cushingoid body habitus, cataracts, and weight gain.
- Cyclophosphamide (high vs. low dose, may be in conjunction with corticosteroids) followed by azathioprine:
  - Adverse effects include premature gonadal failure, leukopenia, and increased risk for severe infections.
  - Select dosing in conjunction with a rheumatologist.
- Rituximab (a monoclonal antibody directed against the CD20 receptor on B lymphocytes):
  - Select dosing in conjunction with a rheumatologist.

**COMPLEMENTARY & ALTERNATIVE THERAPIES**

Bone marrow transplantation may be used.

**DISPOSITION****Admission Criteria**

- Acute flare-ups that may require additional pulse steroid therapy: Consult with rheumatology.
- Organ system based:
  - Infectious disease:
    - Severe infections
    - Opportunistic infections (eg, aspergillosis)
    - Leukopenia (absolute neutrophil count <1,000/mm<sup>3</sup>)
  - Neurologic: Lupus cerebritis
  - Pulmonary: Pleural effusion or pulmonary hemorrhage
  - Hematologic: Anemia or thrombocytopenia requiring transfusion
  - GI: Pancreatitis or GI hemorrhage
  - Toxicity from treatment
- Critical care admission criteria:
  - Life-threatening presentations, pericardial effusion or tamponade, acute renal failure, severe pulmonary or GI hemorrhage

**Discharge Criteria**

- Well appearing
- Not neutropenic
- Baseline renal function

**Issues for Referral**

Close monitoring by a pediatric rheumatologist

**FOLLOW-UP****FOLLOW-UP RECOMMENDATIONS****Patient Monitoring**

- Serologic parameters of disease activity
- Response to therapy

**DIET**

- Low-fat diet, especially for pancreatitis
- Low-salt diet, with renal insufficiency

**PROGNOSIS**

- 10-yr survival >90% (3)
- Causes of death from active disease include renal failure, pulmonary hemorrhage, intestinal vasculitis, and disseminated intravascular coagulation.
- Causes of death from disease complications/treatment: Infections, cardiovascular events, GI bleeding, malignancies

**COMPLICATIONS**

- Severe systemic infections (meningitis, gram-negative sepsis, and opportunistic infections)
- Seizure disorder, neurologic deficits, blurry vision, or complete vision loss
- Renal disease leading to dialysis

- Pulmonary hemorrhage, pulmonary HTN, pulmonary aspergillosis
- Cardiovascular disease: Early atherosclerosis and MI, Libman-Sacks endocarditis, subacute bacterial endocarditis
- Hematologic: Severe anemia and thrombocytopenia with secondary consequences
- GI: Chronic pancreatitis, failure to thrive

**ICD9**

710.0 Systemic lupus erythematosus

**PEARLS AND PITFALLS**

- Neonatal disease has a distinct clinical presentation different from childhood or adult SLE.
- Chronic steroid therapy may require additional dosing when the patient is acutely ill.
- Difficult to differentiate clinical presentation because of underlying disease activity or secondary complication
- Disease is more difficult to treat in males.
- A false-positive serologic test for syphilis can serve to fulfill 1 of the diagnostic criteria.

# TACHYCARDIA

Adam Vella  
V. Matt Laurich

## BASICS

### DESCRIPTION

- Tachycardia is defined as a ventricular rate in excess of the age-related normal range.
- Detailed age-specific normals for heart rate as well as other ECG parameters are published (1).
- A basic guideline for the definition of tachycardia in beats per minute (bpm) is:
  - < 1 yr of age: > 180 bpm
  - 1–4 yr: > 150 bpm
  - 5–11 yr: > 130 bpm
  - > 12 yr: > 100 bpm
- Tachycardia represents a sign or symptom rather than a specific disease.
- The differential diagnosis is wide, ranging from life-threatening causes, both cardiac and noncardiac, to common self-limited conditions.
- The main pathophysiologic categories are sinus tachycardia, supraventricular tachycardia (SVT), and ventricular tachycardia (VT).
- The chief role of the emergency physician is to determine the type and etiology of tachycardia and treat if necessary.

### EPIDEMIOLOGY

- Tachycardia is common, and sinus tachycardia is the most common variety of tachycardia.
- The majority of previously healthy patients will have sinus tachycardia due to a febrile illness, mild to moderate dehydration, or anxiety.
- SVT is the most common tachyarrhythmia, with epidemiologic peaks in infancy and adolescence.

### RISK FACTORS

- Congenital heart disease (CHD) and drug exposure are risk factors for various arrhythmias.
- Risk factors for SVT include Wolf-Parkinson-White (WPW) syndrome and other aberrant pathways.
- Risk factors for VT include electrolyte abnormalities, myocarditis, and myocardial ischemia.
- Risk factors for torsades de pointes: Long QT syndrome, congenital or acquired (electrolyte abnormalities, drug exposure)

### PATHOPHYSIOLOGY

- Tachycardia may be due to normal or pathologic alterations in physiologic conditions or to dysfunction of the cardiac conduction system.
- The normal pacemaker for the heart is the sinoatrial (SA) node.
- The atrioventricular (AV) node delays electrical impulse prior to conduction to the ventricles.
- The bundle of His transmits the impulse rapidly through the ventricles.

### ETIOLOGY

- Sinus tachycardia occurs when the SA node responds normally or abnormally to an alteration in physiologic conditions, such as:
  - Increased physiologic demands (eg, fever)
  - Normal response to stress (pain, anxiety)
  - Depressed myocardial function (myocarditis, pericarditis, endocarditis)
  - Pathologic changes (left to right shunts, AV valve regurgitation, anemia, hypovolemia, hypoxia, anaphylaxis, hypoglycemia, hyperthyroidism, pheochromocytoma, sepsis, pulmonary embolus, seizure)
  - Drug-induced elevated resting sinus rate (eg, decongestants, beta-agonists)
- SVT is caused by abnormalities above the ventricle:
  - Abnormal focus of automaticity (eg, ectopic atrial tachycardia)
  - Accessory route of electrical conduction, which results in a reentrant circuit within the atrium or to the ventricles:
    - Atrial flutter: Reentrant circuit within the atrium
    - AV nodal reentrant tachycardia
    - AV reciprocating tachycardia: Abnormal accessory pathway that bypasses the normal AV node conduction
- VT is caused by abnormalities originating below the AV node. VT includes ventricular fibrillation and torsades de pointes
- Life-threatening cardiac disorders often cause sinus tachycardia, SVT, or VT:
  - Hypertrophic cardiomyopathy
  - Cardiomyopathy
  - Myocarditis
  - Pericardial effusion/tamponade
  - CHF
  - Myocardial dysfunction
  - Sick sinus syndrome
- Sinus tachycardia, SVT, and VT may result from other miscellaneous insults such as toxic exposure and electrolyte imbalance (hyperkalemia, hypocalcemia, hypomagnesemia).

### COMMONLY ASSOCIATED CONDITIONS

- CHD repaired or unrepaired
- Febrile illness
- Drug ingestion

## DIAGNOSIS

### HISTORY

- Symptoms depend on age of the patient and the rate and duration of tachycardia.
- Patients with sinus tachycardia or SVT may be asymptomatic, but chest pain, light-headedness, palpitations, dyspnea, or syncope may also occur.
- Patients who have been in SVT for > 24 hr may complain of cool extremities and pallor, suggesting low cardiac output.
- VT patients may complain of palpitations, syncope, cool extremities, and lethargy.
- Fever, anxiety, and pain are commonly associated with sinus tachycardia.

- Recent medications (eg, cold preparations, herbal medications, dietary supplements such as ephedra), drugs of abuse, toxic exposure, or caffeine use
- Recent illness:
  - Gastroenteritis could cause hypovolemia.
  - Fever may cause sinus tachycardia.
  - Recent viral illness could suggest myocarditis.
  - Recent streptococcal infection suggests possible rheumatic fever.
- Heart disease/Surgery: Predisposes to arrhythmias
- Family history of sudden death (hypertrophic cardiomyopathy) or deafness (long QT syndrome)
- Feeding difficulty or failure to thrive in infants suggests CHF.

### PHYSICAL EXAM

- Quickly evaluate cardiovascular stability prior to complete exam: BP, pulse oximetry, perfusion, tachypnea, mental status
- Fever itself can cause tachycardia (~9 bpm for every increase of temperature by 1°C in infants) (2) and is also associated with Kawasaki disease, rheumatic fever, and viral myocarditis.
- HTN and diaphoresis, along with headache, suggest pheochromocytoma.
- Dry mucous membranes and poor skin turgor suggest hypovolemia.
- Thyromegaly, widened pulse pressure, proptosis suggest hyperthyroidism.
- Tachypnea, rales, hepatomegaly suggest CHF.
- Pallor suggests anemia.
- Rate irregularity suggests arrhythmia.
- Distant heart sounds, narrowed pulse pressure, and pulsus paradoxus suggest pericardial effusion with tamponade.
- Gallop suggests myocardial dysfunction.
- Murmur suggests structural heart disease.
- Fever or hypothermia, poor perfusion, bounding pulses suggest sepsis.

### DIAGNOSTIC TESTS & INTERPRETATION

ECG is the single most important diagnostic test for patients presenting with tachycardia:

- For asymptomatic sinus tachycardia, ECG may not be necessary.

### Lab

- If unexplained arrhythmia or ill appearance: Serum electrolytes, glucose, calcium
- CBC, C-reactive protein, blood cultures if concerned for sepsis
- Wound cultures and nasopharyngeal cultures if concern for toxic shock syndrome
- Throat culture, ASO, anti-DNase B if concern for rheumatic fever
- Thyroid-stimulating hormone, T3, T4 if concern for hyperthyroidism
- Troponin if concern for myocarditis or myocardial ischemia
- If unexplained sinus tachycardia:
  - Consider CBC, thyroid tests, 24-hr urine catecholamine studies as an outpatient.

### Imaging

CXR is indicated to evaluate for pulmonary pathology, cardiac size and silhouette, and pulmonary vascularity.

**Diagnostic Procedures/Other**

- ECG (standard 12-lead and rhythm strip) is essential for initial diagnosis (eg, differentiating sinus tachycardia from atrial or ventricular arrhythmias):
  - Sinus tachycardia:
    - P-wave axis is 0–90° (up in lead 1, aVF)
    - Narrow QRS complex
    - QRS associated with every P wave
    - Changes in rate are typically gradual rather than abrupt.
    - Rate usually is <220 in infants and <180 in children.
  - SVT:
    - Ectopic atrial tachycardia: Abnormal P-wave axis, narrow complex (QRS <0.08 sec), warm up and cool down, atrial rate = 100–240, may see AV block
    - Atrial flutter: Classic “saw-tooth” flutter waves (best seen in inferior leads), atrial rate 150–400, ventricular rate a multiple of atrial rate
    - AV nodal reentrant tachycardia/AV reciprocating tachycardia: P wave absent or abnormal, narrow complex (unless also has bundle branch block or aberrant conduction), heart rate not variable, no warm-up/cool-down period, infant rate usually >220, child rate usually >180
  - VT:
    - Defined as ≥3 consecutive premature ventricular contractions: Wide QRS complex, abnormal QRS axis
    - Torsades de pointes: Polymorphic VT in which QRS morphology changes over time
    - Ventricular fibrillation: Rapid, chaotic QRS complexes without effective cardiac output
- Compare current ECG to a prior ECG
- ECG/Rhythm strip is also useful for ongoing management of arrhythmias concurrent with attempts at cardioversion/defibrillation or medical correction of arrhythmias.
- Resting ECG during a period of normal heart rate may reveal a predisposing condition:
  - WPW: Short PR interval, delta wave (slurring of initial component of QRS)
  - Long QT syndrome: Predisposes to torsades de pointes and VF
- Echo is indicated if acute tachydysrhythmia to assess pericardial effusion, cardiac function, or structural heart disease.
- As outpatient:
  - Holter monitoring for stable patients with intermittent symptoms
  - Exercise testing if symptoms during exercise

**DIFFERENTIAL DIAGNOSIS**

- Normal heart rate for age
- See Etiology.

**TREATMENT****PRE HOSPITAL**

- Assessment and treatment with the use of an automated external defibrillator (AED) in children >1 yr of age
- Use a pediatric AED system if 1–8 yr of age.

**INITIAL STABILIZATION/THERAPY**

- Support ABCs per the Pediatric Advanced Life Support (PALS) guidelines (3).
- Wide-complex tachycardia in the unstable patient is most likely VT (SVT with bundle branch block or aberrant conduction is also possible):
  - With pulses, poor perfusion: Synchronized cardioversion (0.5–1 joule/kg; if ineffective, increase to 2 joules/kg)
  - Pulseless arrest: Defibrillation (2 joules/kg; if ineffective, increase to 4 joules/kg)
- Unstable SVT should also undergo synchronized cardioversion (0.5–1 joule/kg; if ineffective, increase to 2 joules/kg)
- In stable SVT, the patient may attempt a vagal maneuver (Valsalva, blowing on thumb, bearing down, standing patient on the head, ice on the face).
- Correct underlying electrolyte abnormalities (hyperkalemia, hypocalcemia, hypomagnesemia)
- Toxic exposures require specific treatment.

**MEDICATION****First Line**

- Acute SVT: Rapid IV adenosine should be attempted if IV access is available:
  - 1st dose is 0.1 mg/kg, max single dose 6 mg.
  - 2nd dose is 0.2 mg/kg, max single dose 12 mg.
- Chronic SVT: Use medicine to alter circuit refractoriness (eg, digoxin, beta-blockers).
- VT with hemodynamic compromise should undergo synchronized cardioversion as described above with the possible addition of:
  - Amiodarone 5 mg/kg IV over 20–60 min OR
  - Procainamide 15 mg/kg IV over 30–60 min
- Symptomatic VT without hemodynamic compromise:
  - Lidocaine 1 mg/kg IV push, followed by continuous infusion
- Torsades de pointes:
  - Magnesium sulfate 25–50 mg/kg IV, if initial cardioversion fails
- For sinus tachycardia, medicine may be needed to treat the underlying cause, such as antibiotics for sepsis or IV fluids for dehydration.

**Second Line**

Chronic SVT: Use medicine to alter refractoriness of the circuit (eg, procainamide, flecainide, sotalol, amiodarone).

**SURGERY/OTHER PROCEDURES**

- Radiofrequency catheter ablation may be performed if arrhythmias resulting from accessory pathways cannot be controlled medically.
- Hypertrophic cardiomyopathy and CHD require specific surgical repair.

**DISPOSITION****Admission Criteria**

- Sepsis, anaphylaxis, refractory hypovolemia
- Any tachycardia requiring cardioversion or defibrillation.
  - Consider admission for SVT requiring adenosine for termination.
- Patients with abnormal ECG or cardiac exam and a significant family history (sudden death, early MI, long QT syndrome) may need admission.
- Critical care admission criteria:
  - Unstable vital signs refractory to treatment
  - VT, ventricular fibrillation, SVT refractory to treatment

**Discharge Criteria**

- Patients with sinus tachycardia of a known benign cause may be safely discharged.
- Criteria for other types of tachycardia vary; see specific arrhythmias for more detail.

**Issues for Referral**

Depends on the etiology

**FOLLOW-UP****FOLLOW-UP RECOMMENDATIONS****Patient Monitoring**

If a new onset or significant change in symptom pattern, SVT or VT should have cardiology follow-up.

**PROGNOSIS**

Depends on the etiology

**COMPLICATIONS**

Dependent on the etiology

**REFERENCES**

**CODES****ICD9**

- 427.1 Paroxysmal ventricular tachycardia
- 427.89 Other specified cardiac dysrhythmias
- 785.0 Tachycardia, unspecified

**PEARLS AND PITFALLS**

- The upper limit of normal heart varies by age.
- The main pathophysiologic categories are sinus tachycardia, SVT, and VT.
- ECG is essential for differentiating the etiology.

# TAPEWORM AND CESTODE INFESTATIONS

Todd A. Mastrovitch  
Lily Ning

## BASICS

### DESCRIPTION

Tapeworms cause 2 major types of zoonotic disease depending on whether humans are the definitive or intermediate host:

- When humans serve as the definitive host, adult tapeworms infect the GI tract and interfere with nutrition but typically cause less severe disease.
- When humans serve as the intermediate host for the cestode larvae, much more serious disease results.

### EPIDEMIOLOGY

Cestode infection, most commonly tapeworm, is increasing in the U.S. pediatric population due to widespread global immigration and travel.

### Prevalence

- Highest risk for *Taenia* species occurs in Central America, Africa, India, Southeast Asia, and China:
  - U.S. prevalence of *Taenia saginata* is <1% because cattle are generally uninfected.
- Cysticercosis (ingestion of eggs of the *Taenia solium*) is common in Central and South America, Southeast Asia, Korea, and China:
  - It is thought that 20–50% of cases of seizure disorders in these areas are due to cerebral cysticercosis.
- *Diphyllobothrium latum* is found in bodies of freshwater fish in the temperate climates of Europe, North America, and Asia:
  - In the U.S., prevalence is highest in Alaska and the northern states.
- *Hymenolepis nana* is the most common cestode infection in humans, and infection rates are highest in children:
  - Prevalence is greatest (5–20% in children) in warm and dry climates such as the Mediterranean, Near East, India, and South America.

### RISK FACTORS

- Children have increased risk for tapeworm infections due to poor hygiene and a propensity for placing objects in their mouths.
- Exposure to animals such as dogs and livestock that are intermediate hosts
- Traveling in developing countries with lower sanitation and food preparation standards

### GENERAL PREVENTION

- Frequent hand washing decreases the chance of accidental transference of eggs to the oral cavity.
- Properly cooking food to recommended temperatures will kill eggs and larvae.

### PATHOPHYSIOLOGY

- Beef tapeworm:
  - Cattle (intermediate host) ingest *T. saginata* in contaminated feed. The eggs hatch, releasing embryos, which penetrate the cow intestinal mucosa, enter the bloodstream, and ultimately settle in tissues as larvae.
  - Larvae in undercooked beef are consumed by humans and mature into adult tapeworms in the human (definitive host). They grow up to 25 m in length.

- In the majority of cases, the attachment of the tapeworm to the small intestine is relatively benign and asymptomatic.
- There is mild irritation and inflammation at the site of attachment but no other alteration to intestinal physiology.
- Rarely, the tapeworms can migrate to unusual sites such as the appendix and the bile and pancreatic ducts, leading to obstruction with an acute presentation.
- Fish tapeworm:
  - Sewage containing *D. latum* eggs contaminate freshwater sources, and larvae hatch in the water. The larvae are consumed by crustaceans and fish, and if these are eaten uncooked by humans, infection in the human occurs. The larvae mature into adult tapeworms in the human intestine.
  - *D. latum* has an affinity for vitamin B<sub>12</sub> and causes megaloblastic anemia in 2–9% of infections.
  - In severe cases, pancytopenia, glossitis, dyspnea, and loss of vibratory sense/proprioception (posterior column degeneration) can be seen.
- Pork tapeworm:
  - Humans are the only definitive host for the adult pork tapeworm.
  - Pigs ingest *T. solium* eggs, which ultimately result in larvae (cysticerci) in various tissues.
  - Cysticerci may be ingested in humans who consume undercooked pork.
  - Humans (intermediate host) ingest food contaminated with human feces containing *T. solium* eggs. The eggs hatch, liberating embryos that may penetrate through the intestinal mucosa and by bloodborne distribution enter the brain, eye, muscle, subcutaneous, or other tissue, where they develop into cysticerci.
- Human cysticerci disease:
  - These eggs produce a 2–5-mm fluid-filled cyst containing the juvenile stage of the parasite.
  - The cysts may remain viable for 5–10 yr before degeneration, which causes a strong immunologic response from the host.
  - The cysts then either resorb or calcify.
  - Cysticerci cause inflammation and mass effect from their presence in muscle or in the brain.
  - Clinical signs can be seen immediately if the cysts obstruct CSF flow or if the initial parasitic invasion is so large as to create mass effect in the brain, which presents as fulminant encephalopathy.
  - Parenchymal cysticercosis: Seizures and focal neurologic deficits are dependent on location.
  - Intraventricular cysticercosis: Hydrocephalus and increased intracranial pressure (ICP)
  - Meningeal cysticercosis: Meningeal irritation and increased ICP
  - Spinal cysticercosis: Spinal cord compression, nerve root pain, transverse myelitis, and meningitis
  - Ocular cysticercosis: Decreased visual acuity, retinal detachment, iridocyclitis, and orbital mass effect

### ETIOLOGY

Various etiologies exist for the different cestode infections discussed in this topic include *T. saginata* (beef tapeworm), *T. solium* (pork tapeworm), *D. latum* (fish tapeworm), and *H. nana* (dwarf tapeworm). See the Pathophysiology section.

### COMMONLY ASSOCIATED CONDITIONS

- Anemia
- Malnutrition
- Failure to thrive

## DIAGNOSIS

### HISTORY

- Since the majority of tapeworm infections are relatively asymptomatic, most complaints are vague: Abdominal pain/discomfort, anorexia, nausea, weight loss, or malaise.
- With more severe infections, diarrhea, crampy abdominal pain, and pruritus ani can be present.
- Some patients may observe passing some of the segments of the tapeworm in their stool. These proglottids resemble rice or seeds in the stool.
- History of travel to developing countries may be elicited.

### PHYSICAL EXAM

- The physical exam, like the history, is relatively nonspecific in most tapeworm infections.
- Signs of anemia
- Abdominal tenderness, sometimes with palpably distended abdomen, may be present.
- Jaundice may occur with *Echinococcus* due to hepatic cysts. These are sometimes palpable.
- Pulmonary hydatid cysts from *E. granulosus* may cause cough, dyspnea, and hemoptysis; rupture may cause anaphylaxis.
- CNS:
  - New-onset seizures are a typical manifestation of neurocysticercosis and some species of *Echinococcus*.
  - Neurocysticercosis may present with alteration in mental status, signs of elevated ICP, or meningitis.
  - Both neurocysticercosis and vitamin B<sub>12</sub> deficiency due to fish tapeworm can present with delirium or hallucinations.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

#### Initial Lab Tests

- Beef tapeworm:
  - Identification of scolex in stool
  - Ziehl-Neelsen stain of stool or perianal adhesive tape preparations identifies eggs.
  - Collection of proglottids from stool
  - ELISA detects *Taenia* antigen in stool.
- Pork tapeworm:
  - ELISA test and immunoblot in combination for parenchymal cysticercosis
  - Stool samples for intestinal worms as for beef tapeworms

- Fish tapeworm:
  - Stool samples for eggs and proglottids are diagnostic.
  - Mild eosinophilia (5–15%) may be present.
  - 50% of patients have low vitamin B<sub>12</sub> levels.
  - 2% have megaloblastic anemia.
- Dog tapeworm:
  - Characteristic eggs may be identified in stool or perianal adhesive tape preparations.
- Echinococcosis:
  - IgE levels are elevated. Eosinophilia is present in <25% of infected patients.
  - Mild elevation of hepatic enzymes may be present with hepatic hydatid cysts.
  - Casoni skin test (injection of hydatid fluid into dermis) may yield an erythematous plaque.
  - Serologic test is falsely negative in 10–50%.

**Imaging**

- Imaging is used to diagnosis cysticercosis:
  - Contrast-enhanced CT or MRI may reveal cysticerci; surrounding edema represents a dying parasite, and calcification represents a resolved infection.
  - MRI: Best detects cysts in the brain and spinal cord and diagnoses 60% of the cases missed by CT scan.
- Hydatid cysts are detected by US, CT, or MRI.

**DIFFERENTIAL DIAGNOSIS**

- Gastroenteritis
- Irritable bowel syndrome
- Inflammatory bowel disease
- Biliary and renal colic
- Appendicitis
- Pruritis ani also occurs in pinworm infections.
- Pernicious anemia, bone marrow toxins, and dietary restrictions may present similar to the megaloblastic anemia caused by *D. latum*.
- Other causes of the neurologic symptoms of cysticercosis include CNS tumors, meningitis, encephalitis, brain abscess, idiopathic causes, and other etiologies of epilepsy.

**TREATMENT**

**INITIAL STABILIZATION/THERAPY**

- Assessment of ABCs
- Manage seizures per seizure protocols.

**MEDICATION**

**First Line**

- Praziquantel:
  - 5–10 mg/kg (single dose) for *Taenia* and *Diphyllobothrium* (efficacy of 95%)
  - 25 mg/kg (single dose) for *Hymenolepsis* with a repeat dose in 10 days (efficacy of 95%)
- Vitamin B<sub>12</sub> (25–250 μg PO daily) should be given if there is evidence of vitamin B<sub>12</sub> deficiency in *D. latum* infections.
- Treatment for cysticercosis is necessary for complicated or multiple cysts:
  - Albendazole: 3 cycles of 15 mg/kg/day PO divided b.i.d. for 28 days with 14-day drug-free intervals between each cycle: Unestablished in children <2 yr of age OR
  - Praziquantel 50/kg/day PO divided t.i.d. for 28 days: Unestablished in children <4 yr of age

- For seizure control: Diazepam 0.05–0.1 mg/kg/dose IV over 2–3 min q15–30 min, not to exceed 10 mg; repeat in 2–4 hr PRN)
- To decrease inflammatory response: Methylprednisolone (loading, 2 mg/kg IV; maintenance, 0.5–1 mg/kg/dose IV q6h) for the 1st several days of albendazole or praziquantel use.

**Second Line**

Niclosamide (not available in the U.S.):

- 1 g for children 11–34 kg
- 1.5 g for children ≥34 kg

**SURGERY/OTHER PROCEDURES**

- Surgery may be required for hydatid cysts > 10 cm or if secondarily infected.
- Surgery may be required for removal of intestinal tapeworms that persist despite medical therapy or for intestinal obstruction.
- Surgery is needed for ocular, ventricular, and spinal cysticercosis.
- Placement of a VP shunt is needed to treat hydrocephalus due to cysticercosis:
  - Shunt placement should occur prior to medication use due to an increase in ICP that occurs after the initiation of pharmacologic therapy.

**DISPOSITION**

**Admission Criteria**

Critical care admission criteria:

- Intractable seizures due to neurocysticercosis
- Mass effect or increased ICP
- Obstruction of bile/pancreatic ducts/appendix

**Discharge Criteria**

- Solitary parenchymal cysticercosis cyst usually resolves without need for treatment.
- Once medically treated, intestinal tapeworm infections can be discharged with follow-up.

**Issues for Referral**

Neurology consult for neurocysticercosis is warranted to evaluate disease resolution.

**FOLLOW-UP**

**FOLLOW-UP RECOMMENDATIONS**

Discharge instructions and medications:

- Beef tapeworm:
  - Check stool for eggs and proglottids 1 mo after completion of therapy.
- Pork tapeworm:
  - Repeat CNS imaging at 2 mo intervals with continued therapy until successful elimination of brain cysticerci.
- Fish tapeworm:
  - Stool exam 6 wk after therapy
- Dog tapeworm:
  - No follow-up is required, but the appearance of proglottids in the stool > 1 wk after treatment indicates treatment failure.
- Echinococcus:
  - Requires prolonged follow-up with imaging
- Care must be taken to prevent autoinfection or dissemination to others; proper hygiene including frequent hand washing is needed.

**DIET**

Be cautious about hygiene and properly cooking foods.

**PROGNOSIS**

- >95% of patients receiving appropriate treatment are cured.
- Neurocysticercosis may result in permanent neurologic impairment.

**COMPLICATIONS**

- Obstruction of the appendix, intestine, or pancreatic/bile ducts
- Vitamin B<sub>12</sub> deficiency
- Cholangitis, cholecystitis
- Pancreatitis
- CNS and neurologic complications of neurocysticercosis and B<sub>12</sub> deficiency

**See Also (Topic, Algorithm, Electronic Media Element)**

- Abdominal Pain
- Seizure

ICD9  
123.9 Cestode infection, unspecified

**PEARLS AND PITFALLS**

- Neurocysticercosis should be considered in the differential diagnosis for all patients with new-onset seizures who are originally from endemic areas such as Central and South America.
- If CT scan is negative and suspicion is high, consider MRI.
- Corticosteroid use should be started prior to initiating treatment for cysticercosis to prevent increased edema and mass effect.
- Good personal hygiene should be stressed, especially during the 1st few days of treatment as eggs continue to be released from the dying tapeworm, increasing the risk of autoinfection.

# TEETHING

Shilpa Patel

Dewesh Agrawal

## BASICS

### DESCRIPTION

- Teething refers to the combination of behaviors and symptoms observed in some infants, typically between 4 and 18 mo of age, as a result of the inflammation and sensitivity that can occur as primary (deciduous) teeth penetrate the gums.
- During the 16th century, teething was considered a medical diagnosis worthy of admission and a cause of mortality. Though this idea has been criticized since the 17th century, physicians as of 2002 still attribute symptoms more commonly due to a more severe illness to teething (1).
- Recently, 2 prospective cohort studies showed that no symptom cluster could reliably predict the emergence of a tooth and that systemic symptoms should be evaluated independent of the teething (2,3).

### EPIDEMIOLOGY

- Teething typically begins by age 4–6 mo.
- All 20 deciduous teeth have usually erupted by 30 mo of age.
- Most children have some irritation attributable to teething.

### PATHOPHYSIOLOGY

- Teething is normal.
- Teething is typically symmetric.
- Order of appearance of primary teeth (mean ages of eruption):
  - Mandibular central incisors (5–7 mo)
  - Maxillary central incisors (6–9 mo)
  - Lateral incisors (7–10 mo)
  - 1st molars (12–16 mo)
  - Canines (16–18 mo)
  - 2nd molars (20–28 mo)
- Girls' teeth often erupt sooner than those of boys.
- Preterm infants have delayed eruption when using chronological age but fall within normal range when corrected for prematurity.

### ETIOLOGY

Discomfort is caused by the eruption of teeth from the developmental crypt in the alveolar bone through the mucosa into the oral cavity.

## DIAGNOSIS

### HISTORY

The following signs and symptoms have been studied in relation to teething (2–4):

- Mild irritability/Fussiness
- Drooling/Increased salivation
- Chewing on or mouthing objects
- Pulling or rubbing the ear
- Poor feeding
- Poor sleeping
- Mild diarrhea
- Perioral rash or erythema
- Mild fever (temperature  $<38^{\circ}\text{C}$ )

### PHYSICAL EXAM

- Careful inspection of the gums should reveal the presence of newly erupted or erupting teeth.
- The child should be nontoxic appearing with an otherwise normal exam.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

- Typically unnecessary
- Depending on the age of the child and the clinical index of suspicion, labs may be ordered to rule out a more serious illness.

### DIFFERENTIAL DIAGNOSIS

- Normal age-appropriate development for children 4–6 mo:
  - Drooling: Children are learning to sit up at this age and also to swallow their saliva in their new sitting position; therefore, they drool more, irrespective of teething.
  - Chewing on objects: Developmentally, hand–eye coordination allows children to explore their environment by mouthing objects.

- The differential diagnosis for teething includes infectious illnesses, as the timing of tooth eruption coincides with waning immunity from maternal antibodies and an increase in exposure to germs from mouthing objects:
  - Viral illness
  - Acute otitis media
  - Gingivostomatitis
- More serious illnesses to consider that may be the source of the symptoms being attributed to teething:
  - Urinary tract infection, pyelonephritis
  - Sepsis
  - Meningitis
  - Child abuse
  - Macroglossia (hypothyroidism)

## TREATMENT

### MEDICATION

#### First Line

- Palliative
- Refrigerator-chilled teething rings or pacifiers
- Parents may attempt gentle massaging or rubbing the gums with their fingers.
- Acetaminophen (15 mg/kg PO q4–6h) and ibuprofen (10 mg/kg PO q6–8h for children  $>6$  mo of age) PRN

**ALERT**

- Teething rings or devices must be 1 single piece and large enough to avoid choking:
  - They should only be used as instructed by the manufacturer.
- Teething gels are not recommended as many contain benzocaine. Oral benzocaine carries a risk of local anesthetic toxicity in excess dose and a risk of methemoglobinemia.
- Discussion of home remedies that the family plans on using, or uses, should occur to warn parents of potential hazards:
  - Honey and botulism
  - Hot mixtures and burns
  - Unknown items that may contain lead or mercury

**DISPOSITION****Admission Criteria**

- Admission is not necessary for teething.
- An infant may meet admission criteria to rule out serious bacterial infection or dehydration due to another illness.

**Issues for Referral**

Routine dental screening at 1 yr of age (5)

**FOLLOW-UP****FOLLOW-UP RECOMMENDATIONS****Patient Monitoring**

- Primary care providers should educate parents about teething and empower them to appropriately care for their child.
- It is important to communicate that while local symptoms such as drooling or chewing on objects may be related to teething, systemic symptoms are more likely related to an underlying illness.
- Although it is normal for infants to have their 1st teeth erupt as late as at 8 mo of age, a workup for delayed eruption is not indicated until 12 mo of age.

- The following are causes of delay in tooth eruption:
  - Familial delayed eruption
  - Impacted teeth
  - Hypothyroidism
  - Hypopituitarism
  - Gaucher disease
  - Down syndrome
  - Osteopetrosis
  - Rickets
- Complete failure of tooth eruption is associated with:
  - Albright hereditary osteodystrophy
  - Ectodermal dysplasia
  - Williams syndrome
  - Oto-palatal-digital syndrome (Taybi syndrome)

**DIET**

- No changes in diet are necessary.
- Adequate PO intake should be ensured.
- As the eruption of teeth often indicates to parents that children can start new foods, anticipatory guidance should be provided regarding foods that are choking hazards despite the presence of teeth: Hot dogs, nuts, seeds, whole grapes, hard candy, raw vegetables, fruit chunks, and chewing gum.

**ADDITIONAL READING**

Markman L. Teething: Facts and fiction. *Ped Rev*. 2009;30:e59–e64.

ICD9  
520.7 Teething syndrome

**PEARLS AND PITFALLS**

- Always consider other, more serious diagnoses when evaluating a child for systemic symptoms attributed to teething.
- Teething should not be considered an explanation for or sole cause of fever (temperature >38°C).
- Educating parents about teething symptoms and treatment is critical in caring for the teething child.

# TENDON LACERATION

Besh Barcega

Nelson H. Bansil

## BASICS

### DESCRIPTION

This topic will discuss tendon lacerations of the distal extremities with an emphasis on tendon lacerations of the hand.

### EPIDEMIOLOGY

#### Incidence

- Incidence of flexor tendon injuries in children is unknown.
- Extensor tendon injuries are more common than flexor tendon injuries because of their more superficial anatomic location.
- The most common region for flexor tendon lacerations in children is between the flexor digitorum superficialis (FDS) and the proximal edge of the first annular pulley (zone II, commonly called *no man's land*) (1).

### GENERAL PREVENTION

- Close adult supervision whenever a young child is using a sharp instrument
- Care should be taken when children are playing around a lawn mower.
- Use of protective equipment is recommended for older children and teenagers handling machinery.

### PATHOPHYSIOLOGY

- Flexor tendon injuries are more difficult to diagnose and more difficult to repair than extensor tendon injuries because of the complex anatomy of flexor tendons:
  - Flexor tendons are located in the deeper layers and involve multiple numbers of pulley mechanisms:
    - The FDS tendon flexes the proximal interphalangeal joints.
    - The flexor digitorum profundus (FDP) lies below the FDS and flexes both the proximal and distal interphalangeal joints.
- Extensor tendons are located in a relatively superficial position and highly susceptible to injury.
- Complete tendon repair promotes intrinsic tendon healing mediated by fibroblast and inflammatory cells. However, tendon repair may lead to scar formation and adhesions, which in turn may result in a functional deficit.

### ETIOLOGY

- Trauma is the primary cause of tendon lacerations.
- Common mechanisms of injury include accidental laceration from broken glass or knives, table saws or farm equipment, motor vehicle accidents, crush injuries, animal bites, burns, sports injuries, and suicide attempts:
  - Crush injuries tend to involve more extensor tendon lacerations.
  - The most common mechanism of finger flexor tendon injury is by cut glass (2).

### COMMONLY ASSOCIATED CONDITIONS

- Because of their close anatomic proximity, tendon injuries are often associated with nerve and vascular injuries.
- Lacerations from crush injuries may also have associated fractures.

## DIAGNOSIS

### HISTORY

- Obtain a detailed history of the mechanism of injury:
  - Assess risk for foreign body contamination.
  - Assess risk for a self-inflicted injury or injury from an assault.
- Determine whether the tetanus status is up-to-date.
- Determine if past medical history such as a history of hemophilia, diabetes, and chronic steroid or immunosuppressant use will require additional treatment interventions or will affect wound healing.
- For hand and finger injuries, determine hand dominance and whether the child participates in an activity that requires detailed use of the fingers such as piano or violin playing.
- For lower extremity injuries, determine if the child participates in an activity that involves detailed use of the foot such as soccer or ballet.

### PHYSICAL EXAM

- Visual inspection of the wound:
  - Document the location, length and depth, integrity of surrounding tissue, amount of bleeding, and presence or absence of debris.
- Assess and document vascular integrity distal to the laceration by checking distal pulses and capillary refill.
- Assess and document neurologic integrity:
  - Observe the resting position of the involved extremity:
    - A digit in extension rather than part of the usual finger cascade (where the tips flex towards the thenar eminence) likely has a flexor tendon injury.
  - Assessment of active and passive range of motion along with sensory deficits:
    - Extensor tendon injury is suggested if the injured digit is more flexed compared to other digits with full extension.
    - Flexor tendon injury is suspected if there is inability of flexion of the interphalangeal joint of the affected digit while immobilizing other digits.
    - When testing specifically for an FDS laceration, remember to immobilize the proximal interphalangeal joint of the involved digit(s) to avoid the effect of the FDP.
    - Normally, compression of the forearm causes passive flexor motion.
- Assess for joint stability for lacerations along any joint.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Imaging

AP and lateral radiographs of the involved extremity should be obtained if there is a high index of suspicion for a fracture or a retained foreign body.

### DIFFERENTIAL DIAGNOSIS

Partial-thickness skin lacerations, lacerations with associated fractures, or crush injuries may present with a concern for a tendon laceration if the extremity is held protectively due to pain.

## TREATMENT

### PRE HOSPITAL

- Assess neurovascular integrity.
- If possible, irrigate any dirty wound area with water or normal saline.
- Application of gauze or pressure dressing to control bleeding
- May need to splint the affected extremity:
  - Ensure neurovascular integrity post-splinting as well.
- Administer appropriate analgesia.

### INITIAL STABILIZATION/THERAPY

- Assess and stabilize airway, breathing, and circulation, and look for other associated injuries as per Advanced Trauma Life Support (ATLS) and Pediatric Advanced Life Support (PALS) algorithms.
- Ascertain that tetanus status is up-to-date.
- Consider antibiotic therapy for wounds involving human or animal bites or those with significant foreign debris.

### MEDICATION

#### First Line

- Analgesia:
  - Opioids:
    - Morphine 0.1 mg/kg IV/IM/SC q2h PRN:
      - Initial morphine dose of 0.1 mg/kg IV/SC may be repeated q15–20min until pain is controlled, then q2h PRN.
    - Fentanyl 1–2  $\mu$ g/kg IV q2h PRN:
      - Initial dose of 1  $\mu$ g/kg IV may be repeated q15–20 min until pain is controlled, then q2h PRN.
    - Codeine/Acetaminophen dosed as 0.5–1 mg/kg of codeine component PO q4h PRN
    - Hydrocodone or hydrocodone/acetaminophen dosed as 0.1 mg/kg of hydrocodone component PO q4–6h PRN
  - NSAIDs:
    - Ibuprofen 10 mg/kg/dose PO/IV q6h PRN
    - Ketorolac 0.5 mg/kg IV/IM q6h PRN
    - Naproxen 5 mg/kg PO q8h PRN
- Acetaminophen 15 mg/kg/dose PO/PR q4h PRN
- Tetanus 0.5 mL IM if unknown or incomplete immunization status

- Antibiotic therapy for wounds involving human or animal bites:
  - Ampicillin/Sulbactam 75 mg/kg/dose IV q6h, max single dose 2 g
  - Amoxicillin/Clavulanate 45 mg/kg/day b.i.d. or t.i.d. (depending on formulation) PO for 7–10 days, max single dose 500–875 mg
- Antibiotic therapy for wounds with significant amount of foreign debris:
  - Cefazolin 50 mg/kg/dose IV q8h, max single dose 2 g
  - Cephalexin 75 mg/kg/day PO divided t.i.d. for 3–5 days, max single dose 500 mg
- For penicillin-allergic patients or if more anaerobic coverage is desired:
  - Clindamycin 30 mg/kg/day IV/PO divided t.i.d., max 300 single dose mg

### Second Line

Preoperative antibiotic prophylaxis:

- Cefazolin 50 mg/kg/dose IV

### SURGERY/OTHER PROCEDURES

- Surgical consultation is recommended for:
  - All flexor tendon lacerations (3)
  - Tendon lacerations associated with neurovascular compromise, suspected joint involvement, and/or fractures
  - Concern for compartment syndrome
  - Wounds that have a significant amount of foreign debris
  - Wounds sustained from bites
  - All tendon lacerations involving the lower extremity
- Primary closure of isolated extensor tendon lacerations of the hand and finger(s) can be repaired by an experienced emergency department physician:
  - Local, digital, or regional anesthesia is recommended:
    - 1% or 2% lidocaine
    - Traditionally, the use of lidocaine containing epinephrine has been avoided.
    - Lidocaine with epinephrine is often used by surgical specialists making such repairs, and multiple studies demonstrate safety of epinephrine use in digits.
  - Procedural sedation may be required if the patient is uncooperative during the repair.
  - A bloodless field can be created by using a tourniquet technique with either a Penrose drain or BP cuff depending on the site of the laceration.
  - Extension of the laceration in a Z-plasty fashion allows for proper exposure to assess for tendon damage(s).
  - Repair should be done with 4-0 nonabsorbable, synthetic suture, such as Mersilene, using a modified Kevlar stitch.
  - Dorsal splint immobilization of involved digit or extremity after the laceration(s) is repaired:
    - For young children, a bulky dressing that extends to the forearm may be required to maintain adequate immobilization and prevent early removal of the splint and dressings.

- Early primary repair of all complete lacerations is preferred:
  - If immediate primary closure is not possible, proper wound care and skin closure can be done once the involved tendon tips are tagged with a nonabsorbable suture so that they can be identified if they become retracted.
  - Protected immobilization with a bulky dressing and/or splint should be applied after the wound is repaired.

### DISPOSITION

#### Admission Criteria

- Patients who have sustained a tendon laceration with a high risk for infection should be admitted for IV antibiotic therapy if they are unable to obtain adequate follow-up.
- Patients with poorly controlled pain or whose injuries raise concern for compartment syndrome should be admitted.

#### Discharge Criteria

Patients may be discharged after adequate wound care if they have good pain control and can follow up as described in the Follow-Up section.

#### Issues for Referral

- Patients with forearm and hand tendon lacerations who cannot get immediate primary repair should be seen by a hand or plastic surgeon within 24–72 hr.
- Patients with isolated lower extremity and foot lacerations who cannot get immediate primary repair should be seen by a podiatrist (foot lacerations), an orthopedist, or a general surgeon within 24–72 hr.

### FOLLOW-UP

#### FOLLOW-UP RECOMMENDATIONS

- Discharge instructions and medications:
  - Adequate oral analgesia
  - Antibiotic prophylaxis as described above
  - Instruct the caregiver not to remove the bulky dressing or splint and to keep the dressing and splint clean and dry.
  - Follow-up for lacerations repaired in the emergency department:
    - Follow-up in 2 days with the primary care provider or by a surgeon if concerned for possible wound infection
    - Suture removal in 7–14 days
- Activity:
  - Physical therapy may be needed for extension and flexion exercises 5–6 wk post-repair.

#### PROGNOSIS

- Extensor tendon injuries are associated with better functional outcome than flexor tendon injuries (2).
- Flexor tendon injuries can create lifelong disability despite early surgical repair and rehabilitation.
- A partial tendon laceration of 60% may still heal with normal function (4).

#### COMPLICATIONS

Joint contractures or stiffness, limited range of motion, infection, adhesions, poor cosmetic appearance, postoperative tendon rupture, and failure of repair

- Trauma, Hand/Finger

#### ICD9

- 842.10 Sprain of unspecified site of hand
- 845.10 Unspecified site of foot sprain
- 848.9 Unspecified site of sprain and strain

### PEARLS AND PITFALLS

- Providing adequate analgesia prior to exam of the laceration will aid with the physical exam.
- The diagnosis and extent of a flexor tendon injury with or without neurovascular damage is always difficult in a frightened child; therefore, surgical exploration is recommended if there is any uncertainty.
- A partial (<60%) extensor or flexor tendon laceration generally only requires conservative management with proper wound care, skin closure, and splinting.
- Failure to diagnose and treat tendon laceration in a timely fashion may result in permanent disability.
- A partial tendon laceration of 60% may still heal with normal function.

# TENDONITIS

Bhawana Arora  
Usha Sethuraman

## BASICS

### DESCRIPTION

- Tendonitis refers to a painful overuse tendon injury.
  - The term is a misnomer since most instances are noninflammatory in nature.
- Tendinopathy is a painful condition in and around tendons in response to overuse.
- Tendinosis is the histopathologic finding of tendon degeneration without inflammation.
- Common affected sites are:
  - Knee: Patellar and quadriceps tendon
  - Lower leg: Achilles tendon
  - Foot: Tibialis posterior tendon
  - Forearm: Flexor and extensor tendons (medial and lateral epicondylitis)
  - Shoulder: Rotator cuff and biceps brachii tendon

### EPIDEMIOLOGY

- 11% of runners have Achilles tendinopathy (1).
- 16% of the population suffer from shoulder pain (2).
- Tendinopathy of the forearm extensor tendons affects 1–2% of the population (3).

### RISK FACTORS

- Extrinsic factors:
  - Type of occupation
  - Training errors in sports predispose to Achilles tendinopathy:
    - Especially poor technique or footwear
  - Hard, slippery, or uneven surfaces
- Intrinsic factors:
  - Malalignment and biomechanics
  - Muscular insufficiency, imbalance
  - Gender (women < men), age, and genetics:
    - Estrogen may have a protective effect.
    - Age predisposes to tendon lesions.
    - Increased incidence in blood group O
    - The alpha 1 type V collagen (COL5A1) gene, which encodes for a structural protein, has a role in Achilles tendinopathy (4).
  - Systemic diseases such as Marfan syndrome, Ehlers-Danlos syndrome, and rheumatoid arthritis

### GENERAL PREVENTION

- Use of correct footwear, orthoses, soft insoles, and ankle braces
- Gradual introduction of activity
- Proper conditioning and stretching exercises

### PATHOPHYSIOLOGY

- The exact pathogenesis is unclear.
- Tendons transmit muscle forces to the skeleton and are subjected to repeated mechanical loads.
- Histology shows no or minimal inflammation.
- Degenerative change is predominant.
- Mucoïd degeneration and fibrinoid necrosis in tendons
- Microtearing and proliferation of fibroblasts

### ETIOLOGY

- There are 3 main theories:
  - Mechanical: Repeated loading within the normal physiologic stress range causes fatigue and eventually tendon failure
  - Vascular: Tendons heal poorly because of poor blood supply
  - Neural: Alteration to neural homeostasis such as excess substance P may be causal.
- The exact etiology is likely to be a combination of the above mechanisms.

### COMMONLY ASSOCIATED CONDITIONS

- Diabetes mellitus, rheumatoid arthritis
- Obesity
- Marfan syndrome
- Ehlers-Danlos syndrome

## DIAGNOSIS

### HISTORY

Need to elucidate what type of training or activity led to the tendinopathy:

- Achilles tendinopathy:
  - Heel pain
  - Runners and other athletes have an increased incidence.
  - Increased mileage, change in running surface, and poor footwear are causes.
  - Validated, simple functional assessment scores of the Victoria Institute of Sport Assessment (VISA-A) questionnaire can help to grade symptoms and determine patient function (5).
- Patellar tendinopathy:
  - Insidious onset of anterior knee pain
  - Common in those who participate in jumping and running
  - Pain worse when changing position from sitting to standing or when walking or running uphill
  - The VISA questionnaire is used for scoring (6).
- Popliteus tendinopathy:
  - Associated with lateral knee pain
  - Running downhill is a risk factor.
- Medial epicondylitis:
  - Common in Little League pitchers, golfers, bowlers, and carpenters
  - Pain is located at the medial elbow.
- Lateral epicondylitis:
  - Pain at the lateral elbow that becomes worse with grasping and twisting
  - A history of playing racquet sports or manual labor is common.
- Rotator cuff tendinopathy:
  - History of participating in overhead activities such as painting, swimming, and throwing sports
  - Deep ache in the shoulder and painful range of motion are typical symptoms.
- Bicipital tendinopathy:
  - Pain is in the bicipital groove.
  - Worsens when flexing the shoulder or supinating the forearm

### PHYSICAL EXAM

- Achilles tendinopathy:
  - Localized tenderness 2–6 cm proximal to the Achilles insertion on the heel
  - Pain with resisted plantar flexion of the ankle and passive dorsiflexion of the ankle
- Patellar tendinopathy:
  - Tenderness at patellar tendon insertion into the lower pole of the patella
- Popliteus tendinopathy:
  - Tenderness at the posterior lateral joint line:
    - Tendon palpated when lateral ankle of the affected leg rests on the opposite knee
    - Lateral collateral ligament is most prominent in this position. The popliteus is palpated just anterior to it and above the joint line.
    - With patient supine, the knee flexed to 90 degrees, and the leg rotated internally, resisted external rotation elicits pain (as described by Webb) (7)
- Medial epicondylitis:
  - Pain on palpation of the medial epicondyle of the elbow
  - Pain at the elbow with resisted flexion of the wrist
- Lateral epicondylitis:
  - Pain over the lateral epicondyle
  - Pain at the elbow with resisted dorsiflexion of the wrist
- Supraspinatus (rotator cuff) tendinopathy:
  - Pain on palpation over the greater tuberosity
  - Jobe test for supraspinatus function:
    - With both arms abducted to 90 degrees (held slightly in front of the body) and arms fully pronated, comparative resistance is placed on both arms to compare strength and presence of pain.
    - Inability to hold the arm up or presence of pain is suggestive of rotator cuff disease.
- Bicipital tendinopathy:
  - Pain to palpation over the anterior shoulder
  - Focal tenderness over groove on humerus
  - Pain with biceps resistance test (ie, shoulder flexion against resistance with elbow extended and forearm supinated)

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

- Lab studies are usually not necessary.
- May be needed for autoimmune evaluation

#### Imaging

- Radiographs may be indicated if a history of trauma is present:
  - Findings usually are normal.
  - A fleck of bone may suggest an avulsion fracture at the site of tendinous insertion.
  - A roughened appearance of the bone at the site of tendon insertion suggests periostitis.
- US and MRI are reserved for:
  - Unclear diagnoses
  - Unimproving pain or conditions

- US:
  - Alterations in tendon morphology and echogenicity are seen:
    - Mucoid degeneration and tendon tearing diminish echogenicity.
  - Calcifications can also be appreciated.
- MRI is accurate in accessing:
  - Tendon pathology, cartilage injuries, bony abnormalities, and ligamentous injury

### DIFFERENTIAL DIAGNOSIS

- Ankle injury, arthritis
- Knee injury, bursitis, plantar fasciitis
- Carpal tunnel syndrome
- Compartment syndrome
- Deep venous thrombosis, osteomyelitis
- Rotator cuff injuries, tenosynovitis

## TREATMENT

### PRE HOSPITAL

Ice compresses

### INITIAL STABILIZATION/THERAPY

- The mainstay of tendinopathy management remains conservative treatment.
- The goal of treatment is analgesia and to return to activity:
  - Rest or decrease activity level:
    - No clear recommendations
    - Patients should restrict painful activities.
  - Ice is recommended for the 1st 24–48 hr.
  - Splinting and/or immobilization; sling for rotator cuff tendonitis
  - Strengthening and stretching exercises after pain has subsided:
    - Eccentric strength training describes application of a load (ie, muscular exertion) to a lengthening muscle.

### MEDICATION

#### First Line

NSAIDs:

- Consider NSAID medication in anticipation of prolonged pain and inflammation:
  - Ibuprofen 10 mg/kg/dose PO/IV q6h PRN
  - Ketorolac 0.5 mg/kg IV/IM q6h PRN
  - Naproxen 5 mg/kg PO q8h PRN

#### Second Line

- Peritendinous corticosteroid injection:
  - Used when NSAIDs, rest, and strength training have been ineffective.
  - The efficacy of locally injected steroids is debated.
  - Not recommended for the Achilles tendon due to potential of Achilles tendon rupture
  - Avoid repetitive and direct corticosteroid injections into any site.
- Topical glyceryl trinitrate (GTN):
  - Patches placed directly over affected tendons deliver nitric oxide:
    - Potent signaling molecule that stimulates collagen synthesis in tendon cells (8)

### COMPLEMENTARY & ALTERNATIVE THERAPIES

Experimental stages:

- Prolotherapy: Injection of dextrose and lidocaine intratendinously to stimulate a repair response
- Sclerotherapy: Injections of a sclerosing substance (eg, polidocanol) to reduce neovascularity (9)
- Aprotinin: Broad-spectrum protease and matrix metalloproteinase (MMP) inhibitor that may be injected peritendinously (10)

### SURGERY/OTHER PROCEDURES

Surgical consultation if after 6 mo of diligent physical therapy in combination with adjunct medical treatments there has been no improvement in symptoms or function

### DISPOSITION

- Discharge if diagnosis is certain
- Follow-up care with a primary care provider within 1–2 wk is appropriate.

### Issues for Referral

Orthopedics follow-up for patients with symptoms resistant to conservative therapy

## FOLLOW-UP

Discharge instructions:

- Immediate:
  - RICE (rest, ice, compression, and elevation of affected extremity) therapy; short course of NSAIDs for pain
  - Avoid activity that aggravates the condition.
- Subacute:
  - Begin an eccentric heavy load exercise program.
  - Change in training routine and/or equipment
  - Consider second-line therapies.
- Long-term:
  - Continue physical therapy as described.
  - Avoid aggravating factors.

### Patient Monitoring

Explain to patients that a prolonged recovery (often 3–4 mo) is likely and that they should not be discouraged by ongoing symptoms during rehabilitation.

### PROGNOSIS

- Very good with rest and conservative therapy
- The recovery time is weeks to months.
- Recurrences are common.

### COMPLICATIONS

- Recurrence, chronic disability
- Tendon rupture
- Adhesive capsulitis (frozen shoulder)

## CODES

### ICD9

- 726.64 Patellar tendinitis
- 726.71 Achilles bursitis or tendinitis
- 726.90 Enthesopathy of unspecified site

### PEARLS AND PITFALLS

- Pearls:
  - Primary disorders of tendon are degenerative in nature.
  - There is no evidence to support many commonly used treatments.
  - Eccentric loading training programs have excellent results in chronic tendinopathy.
- Pitfalls:
  - Risk of tendon rupture, especially with multiple steroid injections

# TESTICULAR TORSION

David O. Kessler

## BASICS

### DESCRIPTION

Testicular torsion is a surgical emergency that can result in the loss of a testicle:

- Rapid diagnosis and detorsion is necessary to maximize the likelihood of testicle survival.
- Torsion is caused by a twisting of the spermatic cord, resulting in compression of the testicular artery within and reduced or absent blood flow to the ipsilateral testicle.
- It is the most common cause of testicular demise in adolescent males.

### EPIDEMIOLOGY

#### Incidence

Testicular torsion occurs in 1 in 4,000 males <25 yr of age each year (1):

- More common in adolescence

### RISK FACTORS

- Adolescence
- Bell-clapper deformity:
  - 90% of cases are due to this congenital malformation (1).
  - Tunica vaginalis covers the spermatic cord in addition to the testicle and epididymitis, allowing the testicle to rotate freely within the tunica vaginalis and therefore increasing its risk for twisting.
  - Seen in 12% of males (1)
- Trauma is responsible in 4–8% of cases (2).

### GENERAL PREVENTION

Wearing athletic supporters during participation in sports limits testicular motion.

### PATHOPHYSIOLOGY

Twisting of the spermatic cord leads to venous compression and congestion, increasing scrotal swelling and resulting in further compromise of blood flow through testicular artery:

- If uncorrected, this will eventually lead to testicular ischemia and necrosis.

### ETIOLOGY

There is usually no inciting event recognized for testicular torsion. 90% have a bell-clapper deformity (1).

## DIAGNOSIS

### HISTORY

- A patient with testicular torsion will most often present with excruciating pain.
- Scrotal swelling
- Nausea and/or vomiting
- Other concerning historical data includes:
  - Previous history of torsion
  - History of trauma

### PHYSICAL EXAM

- A torsed testicle is typically tender, with scrotal swelling and erythematous overlying skin:
  - Testicle may have a horizontal lie.
  - Testicle may be elevated.
- Absent ipsilateral cremasteric reflex:
  - Cremasteric reflex may be absent if <30 mo of age (1).
- The Prehn sign refers to the pain relief on lifting the testicle:
  - Is classically associated with epididymitis
  - However, this is not reliable enough to rule out testicular torsion:
    - Worsening or no change in the pain seen with torsion

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

- If testicular torsion is suspected and testicular detorsion cannot be achieved, preoperative labs should be drawn and a urologist consulted immediately.
- Other labs can help to evaluate for other diseases in the differential diagnosis:
  - Urinalysis, CBC, gonorrhea/chlamydia polymerase chain reaction and/or culture

#### Imaging

- Imaging can be helpful in establishing a testicular torsion diagnosis and evaluating for other causes.
- However, testicular torsion is a clinical diagnosis, and surgical exploration should be done when suspicion is high despite imaging studies.
- US with Doppler can be used to detect blood flow to the testicle:
  - Less invasive and more readily available
  - Most commonly used at nearly all institutions
  - May be limited in children because flow is harder to detect, which may lead to false-positive results
  - False negative may also occur, particularly if intermittent torsion occurs or if the patient presents early before full arterial occlusion has occurred (3).
  - High-resolution US has been used to evaluate the contents of the spermatic cord and to look for twisting. This approach may have a higher sensitivity for detecting torsion in children (4).
- Radionuclide scintigraphy detects torsion ~100% of the time; however it is usually not as widely and readily available as US, which limits its clinical utility (1).

**DIFFERENTIAL DIAGNOSIS**

- Acute hydrocele
- Testicular neoplasm
- Several processes may cause an acutely painful scrotum:
  - Epididymitis
  - Orchitis
  - Trauma (ruptured teste or intratesticular hemorrhage)
  - Varicocele
  - Incarcerated hernia
  - Torsion of the testicular appendage
  - Henoch-Schönlein purpura
  - Necrotizing fasciitis of perineum known as Fournier gangrene
- Intra-abdominal pathologies that can cause pain:
  - Appendicitis
  - Renal colic, nephrolithiasis
  - Pancreatitis

**TREATMENT**

**INITIAL STABILIZATION/THERAPY**

- Adequate analgesia should be given to patients with testicular pain.
- If testicular torsion is suspected, a urologist should be consulted early in the process, who may opt to go directly for surgical exploration if suspicion is high enough.

**MEDICATION**

**First Line**

- Opioids:
- Morphine 0.1 mg/kg IV/IM/SC q2h PRN:
    - Initial morphine dose of 0.1 mg/kg IV/SC may be repeated q15–20min until pain is controlled, then q2h PRN.
  - Fentanyl 1–2 µg/kg IV q2h PRN:
    - Initial dose of 1 µg/kg IV may be repeated q15–20min until pain is controlled, then q2h PRN.

**SURGERY/OTHER PROCEDURES**

- Surgery is the main intervention for highly suspected or confirmed testicular torsion.
- Bedside manual detorsion may be attempted as long as this does not delay definitive treatment:
  - This is done, after adequate sedation or analgesia, by rotating the testicle 180 degrees from medial to lateral.
  - Occasionally, the testicle may be rotated a full 360 degrees and would require 2 turns in order to fully relieve the torsion.

**DISPOSITION**

**Admission Criteria**

- Patients with testicular torsion should be admitted.
- Patients for whom a diagnosis is suspected but not established (eg, intermittent torsion) should be carefully monitored with a low threshold for surgical exploration based on symptoms.
- Patients for whom manual detorsion at the bedside was successful should undergo exploration and orchiopexy since their chance for recurrence is high.

**Discharge Criteria**

If clinical suspicion is low and/or imaging has established an alternative diagnosis, patients may be discharged with instructions for when to follow up with urology or a primary care provider.

**Issues for Referral**

When in doubt, consult a urologist.

**FOLLOW-UP**

**FOLLOW-UP RECOMMENDATIONS**

Discharge instructions and medications:

- Discharge instructions are usually provided by the subspecialty service after exploration and orchiopexy.
- Anyone with testicular pain who has been given an alternative diagnosis should still be cautioned to return immediately if testicular pain returns.

**PROGNOSIS**

Surgical exploration and restoration of blood flow leads to salvaging the testicle in 90% of cases if done <6 hr after symptom onset. The success rate falls to ~1/2 after 12 hr (5).

**COMPLICATIONS**

- Testicle loss
- Infertility

**REFERENCES**

**ADDITIONAL READING**

**See Also (Topic, Algorithm, Electronic Media Element)**

- Epididymitis - Orchitis
- Orchitis
- Scrotal Pain
- Scrotal Swelling
- Trauma, Scrotal and Penile

**CODES**

**ICD9**

- 608.20 Torsion of testis, unspecified
- 608.21 Extravaginal torsion of spermatic cord
- 608.22 Intravaginal torsion of spermatic cord

**PEARLS AND PITFALLS**

- Pearl:
  - Testicular torsion is a clinical diagnosis and should be treated promptly. Delay in recognition and definitive management of torsion can lead to permanent loss of the testicle.
- Pitfalls:
  - Imaging modalities are less reliable in the pediatric population and can create problems with false-positive or false-negative results.
  - Infants <30 mo may not have a cremasteric reflex.

# TETANUS

Naomi Dreisinger  
Robert J. Hoffman

## BASICS

### DESCRIPTION

- Tetanus is a neurologic disease caused by neurotoxins produced by an anaerobic gram-positive, spore-forming rod: *Clostridium tetani*.
- Disease is defined clinically as the onset of acute hypertonia or painful muscle contractions and generalized muscle spasms without other apparent medical cause. 3 basic forms of tetanus exist: Neonatal tetanus, localized tetanus, and cephalic tetanus.
- All 3 forms manifest as tonic muscle spasm. Cephalic tetanus, caused by wounds of the head, nostrils, or face, results in trismus; therefore, tetanus disease is commonly called *lockjaw*.

### EPIDEMIOLOGY

#### Incidence/Prevalence

- Few cases occur in the developed world; in 2008, there were 19 cases of reported tetanus in the U.S. No cases involved individuals < 19 yr of age.
- Neonatal tetanus is endemic in developing countries due to lack of maternal immunization and nonsterile umbilical cord care.
- Epidemic wound tetanus occurred in survivors of the 2004 tsunami, with a low case fatality rate of 18% (1,2).

### RISK FACTORS

- Neonatal tetanus risks:
  - Lack of maternal immunization
  - Unsterile umbilical cord care at delivery (3,4)
  - Application of any nonsterile material to the umbilical stump, such as clay or herbs
  - Home or nonhospital childbirth
- Localized and cephalic tetanus:
  - Contaminated wounds, especially in unimmunized or partially immunized populations
  - IV drug abuse

### GENERAL PREVENTION

- Primary immunization with tetanus toxoid (vaccination at 2 mo, 4 mo, 6 mo, 15 mo, and 4 yr of age) provides protection for most people for at least 10 yr.
- Booster immunization is recommended at 10-yr intervals. For a puncture or a wound containing devitalized tissue (burns, frostbite, crush injury), it is recommended to administer a booster at 5 yr (4).
- Maintenance of sterility prevents hospital- and birth-related wound infection.
- Maternal vaccination prevents neonatal tetanus.

### PATHOPHYSIOLOGY

- Organism releases toxin, which is disseminated hematogenously and taken up by motor and autonomic peripheral nerve endings. The toxin then travels to the CNS.
- Muscle spasms are caused by the release of neurotoxin, which travels to the CNS. The toxin blocks inhibitory neurons, resulting in unmodulated excitatory transmission to the muscle groups (5)

### ETIOLOGY

*C. tetani* produces 2 toxins: Tetanospasmin and tetanolysin. Tetanospasmin is the toxin primarily responsible for disease. In the CNS, tetanospasmin prevents the release of GABA and glycine (3).

## DIAGNOSIS

### HISTORY

- History of recent wound (including burns, frostbite, and crush injuries)
- Clinically, onset of hypertonia or painful muscular contraction should alert practitioners to the possibility of tetanus.
- Suspicion should be high in patients who are not fully immunized.
- Incubation period is generally 1–60 days.
- Prognosis is generally worse for disease onset with shorter incubation periods.

### PHYSICAL EXAM

- Erythema and edema of the affected area accompanied by painful muscle spasms, hyperreactivity, and generalized muscle rigidity of surrounding muscle groups
- Often accompanied by nonspecific signs such as low-grade fever and general malaise
- Classic sardonic smile, risus sardonicus, is caused by intractable facial muscle spasm.

### DIAGNOSTIC TESTS & INTERPRETATION

Complicated diagnosis because anaerobic organisms are difficult to grow. Additionally, wounds can be frequently contaminated with *C. tetani*, so organism presence does not prove presence of disease.

### Lab

- Diagnosis is primarily clinical, and diagnostic testing is generally not necessary.

- If confirmation is needed, recent tetanus infection is suggested by the presence of IgM or a 4-fold increase in the level of IgG.
- Consider checking electrolytes, calcium, phosphorous, and magnesium to evaluate for possibility of seizures or hypocalcemia.

#### DIFFERENTIAL DIAGNOSIS

- Classic tetanus is a distinct entity.
- Seizures, hypocalcemia, and strychnine poisoning may present with tetany.
- Retropharyngeal, parapharyngeal, and dental abscesses may cause trismus similar to tetanus.

#### TREATMENT

##### INITIAL STABILIZATION

Supportive: Airway management as needed:

- Supportive medical care is the primary treatment.
- Ensuring adequacy of respiratory and circulatory function is paramount.
- Airway support, which may require endotracheal intubation, is often needed.
- Prevention of excessive motor activity
- Local wound excision and debridement is of unclear benefit due to the toxin-mediated nature of disease.

##### MEDICATION

- Human tetanus immune globulin (TIG) 3,000–6,000 U given in a single IM dose
- Antibiotics: Oral metronidazole (30 mg/kg/day divided q6h) is the antimicrobial agent of choice. Parenteral penicillin G (100,000 U/kg/day divided q4h or q6h) is an alternative treatment therapy. Treatment should be for 10–14 days.

- Benzodiazepines, propofol, or other sedatives for general muscle relaxation and CNS sedation to prevent hyperreactivity
- Ketamine was used with success to sedate tetanus victims of the 2004 tsunami.

#### DISPOSITION

##### Admission Criteria

Other than for localized tetanus with minimal symptoms, a critical care setting is advised.

#### CODES

##### ICD9

- 037 Tetanus
- 771.3 Tetanus neonatorum

#### PEARLS AND PITFALLS

- Generalized muscle spasm of unknown etiology, especially in a neonate, should elicit suspicion.
- Patients without full immunization, especially lacking primary immunization, are at risk.

# TETANUS PROPHYLAXIS

Naomi Dreisinger  
Robert J. Hoffman

## ALERT

Complete primary immunization (2 mo, 4 mo, 6 mo, 18 mo, and 4 yr of age) as well as a booster dose every 10 yr is required for presumptive tetanus immunity.

## BASICS

### DESCRIPTION

- Tetanus toxoid is protective against the acquisition of tetanus disease. Primary tetanus immunization may be required to attend elementary school in the U.S.
- Tetanus toxoid is required for wound prophylaxis in children >7 yr of age.
- There are 4 types of tetanus toxoid available:
  - Diphtheria, tetanus toxoid, and acellular pertussis (DTaP)
  - Diphtheria and tetanus toxoid (DT)
  - Adult-type diphtheria and tetanus toxoid (Td)
  - Tetanus toxoid, reduced diphtheria toxoid and acellular pertussis (Tdap)
- DTaP is recommended for children 6 wk to 6 yr of age. If pertussis vaccine is contraindicated, DT alone should be used.
- Minor febrile illness is not a contraindication to vaccination.

- Contraindications to DTaP use include:
  - Seizure or collapse after DTaP
  - Crying nonstop for  $\geq 3$  hr after DTaP
  - Brain or nervous system disease within 7 days of DTaP dose
- Tdap should be administered as prophylaxis in children 10–18 yr of age (1).

### Pregnancy Considerations

Lack of maternal immunization causes risk to the mother and the neonate during delivery. Immunization with tetanus toxoid, Td, or Tdap is not contraindicated in pregnancy. If a pregnant woman has not completed her primary immunization series, she should attempt to do so before delivery. 2 doses of Td should be administered at least 4 wk apart, with the 2nd dose at least 2 wk before delivery.

### GENERAL PREVENTION

- Clean wounds: Patients who have received  $\geq 3$  doses of tetanus toxoid do not require further immunization if the most recent dose was within 10 yr.
- Dirty or devitalized tissue wounds (eg, burns, crush injury, frostbite, or wounds contaminated with dirt, saliva, soil, or feces): Patients who have received  $\geq 3$  doses of tetanus toxoid should receive booster immunization within 5 yr.
- Children who have received <3 doses of tetanus toxoid should be administered tetanus toxoid for clean wounds and tetanus toxoid and tetanus immune globulin (TIG) for other wounds (2).

## EPIDEMIOLOGY

- Immunization practice in the U.S. has significantly altered the epidemiology of tetanus disease. Since 1999, <40 cases have been reported annually (1).
- Epidemic wound tetanus occurred in survivors of the 2004 tsunami, with a low case fatality rate of 18%.

## TREATMENT

### MEDICATION

- TIG is administered IM at a dose of 250 U when needed for wound prophylaxis (1).
- If TIG is unavailable, intravenous immunoglobulin (IVIG) or equine tetanus antitoxin may be given as an alternative.

**ALERT**

- The adverse effects of all tetanus toxoid vaccines are well described:
  - They are so rare and/or minor that the risk of not administering tetanus prophylaxis far outweighs the risk of vaccine use.
- Historically, many significant adverse reactions were associated with DTP (discontinued), while very few adverse reactions occur with DTaP:
  - Mild local reactions (redness, induration, and injection site tenderness)
  - Constitutional symptoms including fever, fussiness, crying
  - Brief generalized seizures may occur after DTaP, usually seen in febrile children after the 3rd or 4th dose in the vaccine series.
  - Hypotonic-hyporesponsive episodes (collapse or shocklike state) are less common with DTaP.
  - Persistent inconsolable crying for  $\geq 3$  hr observed after DTP vaccination is less common after DTaP.
  - Guillain-Barré syndrome is a rare adverse event that has been reported after DTaP.

**DISPOSITION****Discharge Criteria**

- Most patients who present to the emergency department for tetanus prophylaxis will be discharged home.
- Admission should be considered in patients with wounds that appear infected.

**FOLLOW-UP****FOLLOW-UP RECOMMENDATIONS**

- Contact or follow-up with the primary care provider is recommended to assure immunization status.
- In cases where a dirty wound is present, follow-up in 1–2 days is recommended for wound recheck.

**REFERENCES**

- Fiorillo L, Robinson JL. Localized tetanus in a child. *Ann Emerg Med*. 1999;33(4):460–463.
- Jeremijenko A, McLaws ML, Kosasih H. A tsunami related tetanus epidemic in Aceh, Indonesia. *Asia Pac J Public Health*. 2007;19 Spec No:40–44.

**CODES****ICD9**

V03.7 Need for prophylactic vaccination with tetanus toxoid alone

**PEARLS AND PITFALLS**

- Failure to recognize the need for which tetanus prophylaxis is needed.
- Inappropriate administration of tetanus toxoid when not indicated: Giving tetanus toxoid for clean wounds in patients with last booster  $< 10$  yr previously
- Intermittent national shortages of tetanus toxoid warrant appropriately judicious use.
- The incubation period of tetanus is 7 days, with 15% of cases occurring in  $< 4$  days. If tetanus status is unknown at the time of emergency department treatment but can be verified within 1–2 days, tetanus toxoid can be withheld until the status is confirmed.

# TETRALOGY OF FALLOT

Asha G. Nair  
Kerry Leupold

## BASICS

### DESCRIPTION

Tetralogy of Fallot (TOF) is a cyanotic congenital lesion comprised of 4 elements: Ventricular septal defect (VSD), right ventricular outflow tract obstruction (RVOTO), overriding aorta, and right ventricular hypertrophy.

### EPIDEMIOLOGY

#### Incidence

- 7–10% of all congenital cardiac malformations
- Most common cyanotic congenital cardiac defect in the postinfancy period

### RISK FACTORS

Parents with TOF

### PATHOPHYSIOLOGY

- The degree of RVOTO and the size of the VSD determine the pathophysiology.
- Nonrestrictive VSD: Systolic pressures are equal in the left and right ventricles.
- Direction of shunt is dependent on extent of the RVOTO:
  - With severe obstruction, shunt is right to left, resulting in decreased pulmonary flow and cyanosis.
  - With mild obstruction, left to right shunt results in pulmonary overcirculation and cardiac failure (as in isolated VSD).

### ETIOLOGY

- Associated with trisomy 21, DiGeorge syndrome, Alagille syndrome, 22q11 deletion
- Reported associations include untreated maternal diabetes, phenylketonuria, intake of retinoic acid, or alcohol during pregnancy.

### COMMONLY ASSOCIATED CONDITIONS

- Cyanosis
- Dyspnea
- Failure to thrive
- Clubbing

## DIAGNOSIS

### HISTORY

- Many patients are diagnosed prenatally via fetal US.
- Patients with significant RVOTO present with cyanosis but may be otherwise asymptomatic.
- Acyanotic or “pink tetralogy” patients present with symptoms of VSD including poor feeding, easy fatigability, poor weight gain, and CHF.
- “Tet spells”: Cyanotic episodes that present in older children due to increased RVOTO or decreased systemic vascular resistance (SVR):
  - The shunt will become right to left, resulting in cyanosis, hyperpnea, and irritability.
  - Mobile patients may have a history of squatting; putative reason is to perform Valsalva maneuver and diminish Tet shunting.

### PHYSICAL EXAM

- Assess vital signs, with close attention to BP and pulse oximetry.
- Cyanotic or acyanotic depending on the degree of RVOTO
- Murmur present at birth: Single and loud S2 with harsh, loud, systolic ejection murmur heard at middle to left lower sternal border
- Continuous murmur from patent ductus arteriosus may be present.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

- Bedside glucose assessment
- Other lab tests may be considered as indicated for the workup of patients with cyanosis and dehydration:
  - CBC
  - Serum chemistry

### Imaging

#### CXR:

- Cyanosis secondary to considerable RVOTO may result in decreased pulmonary vascular markings and normal heart size. A boot-shaped heart is characteristic.
- Acyanotic patients may have cardiomegaly and increased pulmonary vascular markings and blood flow secondary to decreased RVOTO.

#### Diagnostic Procedures/Other

EKG: Right axis deviation and right ventricular hypertrophy; large R waves in the anterior precordial leads and large S waves in the lateral precordial leads

### DIFFERENTIAL DIAGNOSIS

- Primary pulmonary causes of cyanosis, including pulmonary HTN
- Congenital methemoglobinemia
- Other cyanotic heart lesions, including the 5 “T’s”:
  - Transposition of the great arteries
  - Tricuspid atresia
  - Total anomalous venous return
  - Truncus arteriosus
  - Critical pulmonary stenosis

## TREATMENT

### PRE HOSPITAL

Assess and stabilize airway, breathing, and circulation:

- Administer supplemental oxygen.

### INITIAL STABILIZATION/THERAPY

- Assess and stabilize airway, breathing, and circulation.
- Treatment of hypoxic spells:
  - Administer supplemental oxygen.
  - Initially positioning may be attempted: Knee-to-chest position to increase SVR
  - IV fluid bolus 10–20 mL/kg given to patients without known CHF
  - Pharmacologic treatment may be necessary: Several medications may be useful, including morphine and phenylephrine.
  - A severe spell may require endotracheal intubation and mechanical ventilation.
  - If acidemic, sodium bicarbonate may be indicated.

**MEDICATION****First Line**

- Morphine 0.1 mg/kg SC/IV/IM  $\times$  1:
  - Typically, first-line medication due to availability, ease of administration, and clinician familiarity
  - Mechanism by which this improves Tet spell is uncertain:
    - Possibly by decreasing respiratory rate, heart rate, overall sympathetic tone, or combination
- Phenylephrine 5–10  $\mu$ g/kg/dose IV q10min PRN:
  - Used to increase SVR
- Sodium bicarbonate 1 mEq/kg IV  $\times$  1–2 doses to treat if severe acidemia

**Second Line**

- Use beta-blockers if first-line medications fail:
  - Some authors advocate use of beta-blockers as a first-line medication prior to phenylephrine.
- Beta-blockers relax infundibular spasm:
  - Esmolol 100–500  $\mu$ g/kg IV over 1 min followed by 25–100  $\mu$ g/kg/min infusion:
    - Titrate to effect.
    - Used for immediate effect in the emergency department; short duration of action makes esmolol titratable.
    - Less experience with use of this medication in pediatrics
  - Propranolol:
    - IV: 0.01–0.02 mg/kg/dose IV infused over 10 min
    - PO: 0.25 mg/kg/dose q6h
    - Time to clinical effect is longer, but medication is longer acting and there is greater pediatric experience using it.

**SURGERY/OTHER PROCEDURES**

Palliation: Systemic-to-pulmonary arterial shunt (Blalock-Taussig):

- There is a trend toward completing the repair of TOF in the neonatal period.

**DISPOSITION****Admission Criteria**

- Patients requiring pharmacologic intervention should typically be admitted to monitored setting.
- Critical care admission criteria:
  - Children receiving phenylephrine or esmolol infusion should be admitted to a monitored setting.

**Discharge Criteria**

- Patients presenting with Tet spell that corrects spontaneously or with positioning only are candidates for discharge.
- Typically, patients requiring pharmacologic intervention are admitted.
- Cyanotic newborns can be discharged with surgery later in infancy.

**Issues for Referral**

- Long-term follow-up with a pediatric cardiologist, with minimum of every 6–12 mo, is recommended.
- Patients with residual cyanosis, arrhythmias, or conduction disturbances may require more frequent visits.

**FOLLOW-UP****FOLLOW-UP RECOMMENDATIONS**

Discharge instructions and medications:

- Patients should take medications as prescribed and follow up with a cardiologist as recommended.

**PROGNOSIS**

- Uncomplicated TOF has mortality of 2–3% in the 1st 2 yr.
- Common complications include worsening RVOTO, residual VSD shunting, arrhythmias, and conduction delays (complete heart block, atrioventricular dysfunction).

**COMPLICATIONS**

- Cyanotic Tet spells
- Neurodevelopmental delay
- Failure to thrive
- Bacterial endocarditis
- Stroke
- Sudden cardiac death
- Postoperative:
  - Aortic root dilation
  - Subclavian steal syndrome

**ADDITIONAL READING**

**See Also (Topic, Algorithm, Electronic Media Element)**

- Cyanosis
- Cyanotic Heart Disease
- Ductal-Dependent Cardiac Emergencies
- Shock, Cardiogenic

**ICD9 CODES**

745.2 Tetralogy of fallot

**PEARLS AND PITFALLS**

- Hypoxic spells are medical emergencies and are treated with positioning, morphine, and agents to decrease infundibular spasm and increase SVR.
- Patients with cyanotic TOF are generally otherwise asymptomatic.
- Patients with pink TOF may have symptoms of CHF.
- Vasodilators should be avoided in patients with TOF, as they may instigate a hypoxic spell.

# THRUSH

Kelly J. Cramm

## BASICS

### DESCRIPTION

- Thrush (acute pseudomembranous candidiasis) is an opportunistic fungal infection in the mucous membranes of the mouth.
- Thrush is most commonly caused by *Candida albicans*.
- While common in infants, thrush may be seen in older children with an underlying systemic disease or a compromised immune system.
- Thrush is often the result of antibiotic therapy or inhaled corticosteroid use.
- Thrush may be the 1st sign of HIV infection.

### EPIDEMIOLOGY

#### Incidence

- Up to 37% of newborns may develop thrush during the 1st several months of life (1).
- As many as 90% of patients with acute leukemia and 95% of HIV-infected patients will develop thrush during the course of their illness (2).
- Frequency of infection is increasing due to:
  - Rise of HIV infection
  - Increase in candidal species other than *C. albicans*
  - Emerging resistance to antifungals
  - Advances in medical management such as chemotherapy

### RISK FACTORS

- Antibiotic use (current or recent)
- Inhaled corticosteroid use
- Immunodeficiency
- Diabetes mellitus
- Iron-deficiency anemia
- Xerostomia
- High-carbohydrate diet
- Malnutrition
- Pacifier use
- Poor oral hygiene
- Maternal vaginal candidiasis at time of delivery
- Extremes of age

### GENERAL PREVENTION

- After using an inhaled corticosteroid or after taking a liquid oral antibiotic, rinse the mouth with water.
- Use a spacer with inhaled corticosteroids.
- Wash bottle nipples and pacifiers daily.
- Practice good oral hygiene.
- Although controversial, patients on chemotherapy or being treated for HIV may benefit from prophylactic antifungal agents.

### PATHOPHYSIOLOGY

- *Candida* often lives on mucosal and skin surfaces.
- *Candida* is acquired vertically from the birth canal of the mother. It is present as oral flora in 20–60% of the health population.
- Any disruption of the host environment can cause its proliferation and consequent infection.
- Organisms may be acquired during passage through the birth canal.
- Colonized nipples of the mother, bottle, or pacifier can cause infection.
- Disruption of normal flora following a course of antibiotic therapy is a common reason for infection.

### ETIOLOGY

The most common is *C. albicans*. Other causes include *Candida tropicalis*, *Candida glabrata*, *Candida pseudotropicalis*, *Candida guilliermondii*, *Candida krusei*, *Candida lusitanae*, *Candida parapsilosis*, and *Candida stellatoidea*.

### COMMONLY ASSOCIATED CONDITIONS

- Current or recent antibiotic use
- Asthma (use of inhaled corticosteroids)
- HIV infection and other immunocompromised conditions
- Diabetes mellitus
- Sjögren syndrome

## DIAGNOSIS

### HISTORY

- Asymptomatic or may experience mouth pain
- Fussiness
- Refusal to take oral feedings
- White patches on the oral mucosa
- Unable to wipe off white plaques in the mouth
- Medication history (antibiotics or inhaled corticosteroid use)
- Chronic medical conditions
- Recurrence
- History of maternal vaginal candidiasis or maternal sore/cracked nipples

### PHYSICAL EXAM

- White spots or plaques on the tongue, palate, and other areas of oral mucosa
- Plaques are difficult to remove, differentiating them from milk or other oral secretions.
- Removal of lesions with a tongue blade reveals an erythematous, irritated mucosa.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

Diagnosis is clinical, but if in doubt or for academic purposes, a potassium hydroxide (KOH) preparation or fungal culture is diagnostic.

#### Pathological Findings

- KOH scraping from mucosal surface shows *Candida* pseudohyphae and budding yeast forms.
- A cultured scraping from a mucosal surface will grow *Candida* species.

**DIFFERENTIAL DIAGNOSIS**

- Candidal glossitis
- Aphthous stomatitis
- Viral gingivostomatitis
- Oral hairy leukoplakia
- Geographic tongue
- Lichen planus
- Traumatic lesions
- Plasma cell stomatitis
- Milk or food debris

**TREATMENT****MEDICATION****First Line**

- Nystatin solution (100,000 units/mL) applied to the oral mucosa after feedings q.i.d. for 7 days. Continue treatment for 48 hr after resolution of symptoms:
  - Premature and low birth weight infants: 1 mL/dose applied with nonabsorbent swab to lesions
  - Infants: 2 mL/dose applied with nonabsorbent swab to lesions
  - Children: 4–6 mL swish and swallow
- Clotrimazole 10 mg oral troches t.i.d. or q.i.d. dissolved in the mouth for 3 wk

**Second Line**

- Fluconazole 6 mg/kg/day IV/PO loading dose followed by 3 mg/kg/day IV/PO for 14 days
- Itraconazole: Swish 200 mg (20 mL) in mouth for several seconds daily for 14 days
- Ketoconazole 5 mg PO daily for 14 days

**COMPLEMENTARY & ALTERNATIVE THERAPIES**

- For recurrent thrush in infants, topical nystatin applied to the mother's nipples may reduce transmission in breast-fed infants.
- Gentian violet:
  - Infants: 4 gtt of 0.5% solution applied topically daily until plaques clear
  - Children: 1% solution applied topically daily until plaques clear

**DISPOSITION****Admission Criteria**

- Severe dehydration
- Spread to trachea with respiratory compromise (very rare in immunocompetent host)

**Discharge Criteria**

Well appearing and able to take oral food

**Issues for Referral**

Concern for immunocompromised condition may warrant referral to an infectious disease specialist or immunologist.

**FOLLOW-UP****FOLLOW-UP RECOMMENDATIONS**

Discharge instructions and medications:

- Antifungal therapy as outlined above
- Be sure to sterilize all objects placed in the mouth to prevent reinoculation.
- Return for poor feeding, decreased urine output

**Patient Monitoring**

Close follow-up is necessary if the patient is an infant with pain and poor oral intake.

**PROGNOSIS**

- Excellent prognosis in healthy individuals.
- If immunocompromised, the chance of recurrence is high.

**COMPLICATIONS**

- Complications are rare and typically develop only in immunocompromised patients.
- Esophagitis or tracheitis may occur.
- Oral candidiasis can spread to virtually every organ system.

**REFERENCES**

1. Goins A, Ascher D, Waecker N, et al. Comparison of fluconazole and nystatin oral suspensions for treatment of oral candidiasis in infants. *Pediatr Infect Dis J.* 2002;21(12):1165–1167.
2. Akpan A, Morgan R. Oral candidiasis. *Postgrad Med J.* 2002;78:455–459.

**ADDITIONAL READING**

- Su CW, Gaskie S, Jamieson B, et al. Clinical inquiries. What is the best treatment for oral thrush in healthy infants?. *J Fam Pract.* 2008;57(7):484–485.

**ICD-9 CODES**
**ICD9**

- 112.0 Candidiasis of mouth
- 771.7 Neonatal candida infection

**PEARLS AND PITFALLS**

- Thrush is a common problem and typically does not indicate a serious underlying disease.
- Consider the possibility of a serious underlying disease, such as HIV, in a child outside of infancy who is not currently on or who has not received recent antibiotic therapy or inhaled corticosteroid therapy.
- Persistence of appropriately treated thrush for  $\geq 2$  mo should also alert the possibility of an immunocompromised state.
- Do not forget to treat the breast-feeding mother if her infant has recurrent thrush or she has sore or cracked nipples. Treatment is with nystatin cream applied to the nipples after each feed.

# THYROGLOSSAL DUCT CYST

Sylvia Baszak

Ewa Grochowalska

Juliette Quintero-Soliban

## BASICS

### DESCRIPTION

- Thyroglossal duct cyst (TGDC) typically manifests as a midline neck mass near the level of the hyoid bone.
- This congenital defect may result in an accumulation of fluid (cysts) appearing along the route of thyroid gland migration from the base of the tongue to the final position in the anterior neck.
- Usually asymptomatic but may become infected or form an abscess, fistula, or draining sinus

### EPIDEMIOLOGY

- Most common benign congenital neck mass
- Appears most commonly at 2–10 yr of age
- Male to female ratio is 1:1.

### PATHOPHYSIOLOGY

- A TGDC is formed by persistent thyroglossal duct secretory epithelial cells and subsequent dilatation anywhere along the midline migration of the thyroid gland.
- Embryologically, the thyroid gland begins its migration along the duct from the floor of the pharynx toward its final position anterior to the trachea.
- Failure of the duct to involute after the migration increases the risk of cyst formation.
- The cyst may contain functional thyroid tissue.

### ETIOLOGY

See Pathophysiology.

## DIAGNOSIS

### HISTORY

- Asymptomatic neck mass
- Symptomatic neck mass with any of the following:
  - Pain
  - Overlying erythema
  - Drainage
  - Mass fluctuating in size
  - Fever
  - Change in voice quality
  - Dyspepsia
  - Dysphagia
  - Dyspnea

### PHYSICAL EXAM

- Nontender neck mass is common.
- If infected, the mass may be tender, erythematous, and/or fluctuant with or without drainage.
- The mass is most often found between the hyoid bone and the thyroid gland.
- May be slightly off of the midline of the neck
- An uninfected mass is typically round, smooth, and firm.
- The mass is vertically mobile with swallowing or tongue protrusion.
- May cause change in voice quality
- Respiratory distress or stridor may be present.

## DIAGNOSTIC TESTS & INTERPRETATION

The diagnosis of TGDC is often clinical.

### Lab

#### Initial Lab Tests

- Thyroid function tests
- Consider CBC and/or C-reactive protein if considering an infected mass or abscess.

### Imaging

- Consider US to determine the location, size, and composition of the mass (cystic vs. solid).
- CT scan of the neck if:
  - Uncertain diagnosis OR
  - Concern about airway impingement

### DIFFERENTIAL DIAGNOSIS

- Lymphadenopathy
- Lymphadenitis
- Malignancy
- Thyroid disease
- Trauma (eg, hematoma)
- Dermoid cyst
- Midline branchial cleft cyst
- Cystic hygroma
- Midline cervical clefts: Very rare
- Ranula

**TREATMENT**

**MEDICATION**

- Antibiotics should provide coverage for oropharyngeal flora:
  - Cysts may contain *Haemophilus influenzae*, *Staphylococcus epidermidis*, *Staphylococcus aureus*, and *Streptococcus* species
- For mild infections, oral antibiotics should suffice.
- Consider IV formulations for moderate to severe infections.
- Amoxicillin/Clavulanate PO:
  - Children  $\geq 3$  mo of age and  $< 40$  kg: 80–90 mg/kg/day amoxicillin component divided b.i.d.
  - Adults and children  $\geq 40$  kg: 875 mg/dose b.i.d.
- Ampicillin/Sulbactam:
  - Children  $\geq 1$  mo of age: 200 mg/kg/day IV/IM divided q6h IM/IV
  - Adolescent/Adults: 1–2 g IV/IM q6–8h
- Clindamycin:
  - Children  $< 40$  kg:
    - o 30 mg/kg/day PO divided q8h OR
    - o 40 mg/kg/day IV/IM divided q8h
  - Adults and children  $\geq 40$  kg:
    - o 450 mg/dose PO q8h OR
    - o 1,800 mg/day IV/IM divided q6–12h

**SURGERY/OTHER PROCEDURES**

- Operative incision and drainage may be performed by a surgeon if there is an infection with abscess formation.
- Definitive management is complete surgical excision. The Sistrunk procedure is an elective excision to prevent recurrence, infection, or malignancy of the cyst.
- Preoperative test: Radioactive iodine or technetium thyroid scan to assess that the cyst is not the only source of normally functioning thyroid tissue.
- Fine-needle aspiration, not routine, may be required for atypical presentation of a midline neck mass.

**DISPOSITION**

**Admission Criteria**

- Toxic illness, systemic symptoms, young age
- Critical care admission criteria:
  - Airway compromise

**Discharge Criteria**

- No infection or only mild infection
- No airway involvement
- Reliable follow-up

**Issues for Referral**

Follow up with an ENT or pediatric surgeon.

**FOLLOW-UP**

**FOLLOW-UP RECOMMENDATIONS**

Discharge instructions and medications:

- An infected cyst should have reliable follow-up.
- Patients not admitted should be warned to seek medical attention if showing signs of worsening infection, systemic illness, or airway compromise.

**Patient Monitoring**

Monitor for increase in size of the mass or for difficulty in swallowing or breathing.

**PROGNOSIS**

- Recurrence of cyst after surgical excision via Sistrunk procedure is  $< 5\%$ .
- Carcinoma, usually papillary thyroid, is  $< 1\%$  of all cysts.

**ADDITIONAL READING**

**See Also (Topic, Algorithm, Electronic Media Element)**

- Branchial Cleft Cyst
- Cystic Hygroma
- Neck Mass

**CODES**

**ICD9**

759.2 Anomalies of other endocrine glands, congenital

**PEARLS AND PITFALLS**

- TGDC is the most common benign congenital neck mass.
- It may present as a painless neck mass or an overtly infected neck mass.
- Thyroid function may be affected.
- A TGDC may cause airway obstruction.

# TICK BITE

Michael L. Epter

## BASICS

### DESCRIPTION

- Tick bites cause human disease through transmission of bacteria, viruses, and protozoa.
- Range of clinical presentation: Dermatologic, constitutional (febrile illness), hematopoietic, cardiovascular, neurologic (tick paralysis)

### RISK FACTORS

- Exposed skin
- Forests, savannahs, brushlands, caves, burrows, nests, woods, tall grass, meadows
- April–September months
- Outdoor activities in endemic areas (northeastern/north central U.S.)

### GENERAL PREVENTION

- Protective clothing (long sleeve shirts/pants/hats)
- Application of insect repellants:
  - N,N-diethyl-3-methylbenzamide (DEET) 10–35%:
    - Safe in children (>2 mo of age): Risk of toxicity 0.05–0.1% of users
    - Apply to skin/clothes: Do not apply to the face
    - Safe in pregnancy/lactation
  - Picardin (>2 yr of age)
  - Permethrin (apply to clothes only)
- Bathe after activity in high-risk areas.

### PATHOPHYSIOLOGY

- Anaphylaxis: IgE mediated
- Tick paralysis: Neurotoxin → reduced motor action potential/nerve conduction velocity
- Babesiosis: Infection of erythrocytes → hemolytic anemia
- Ehrlichiosis: Infects bone marrow cells (especially leukocytes)
- Tickborne relapsing fever (TBRF): Antigenic variation (alters outer surface membrane antigens/proteins)
- Rocky Mountain spotted fever (RMSF): Invasion of endothelial cells

### ETIOLOGY

- U.S.: *Amblyomma*, *Dermacentor*, *Ixodes*, *Ornithodoros*
- Tick paralysis: *Dermacentor andersoni* (western U.S./Canada), *Dermacentor variabilis* (eastern/southeastern U.S.)
- Babesiosis: *Ixodes* (northeastern U.S.)
- Ehrlichiosis: *Amblyomma americanum*, *D. variabilis*, *Ixodes*
- Tularemia: *A. americanum*, *D. andersoni*, *D. variabilis*
- TBRF: *Ornithodoros*
- Southern tick-associated rash illness (STARI): *A. americanum*
- Colorado tick fever (coltivirus): *D. andersoni*

- Powassan virus (flavivirus): *Ixodes*, *D. andersoni*
- RMSF: *D. andersoni* (western U.S.), *D. variabilis* (eastern U.S.)
- Tickborne lymphadenopathy (TIBOLA)/*Dermacentor*-borne necrosis erythema lymphadenopathy (DEBONEL): *D. marginatus*
- Q fever (rarely caused by ticks): *Dermacentor*
- Lyme disease: *Ixodes*

### COMMONLY ASSOCIATED CONDITIONS

- Tularemia—6 clinical syndromes: Ulceroglandular (most common, 80%), glandular, oculoglandular, oropharyngeal, typhoidal, and pneumonic
- Chronic Q fever: Endocarditis

## DIAGNOSIS

### HISTORY

- Seasonal exposure
- History of tick bite (may not be known)
- Febrile illness:
  - Babesiosis (85%)
  - Ehrlichiosis
  - Tularemia
  - TBRF (multiple febrile-afebrile periods)
  - Colorado tick fever (intermittent fever, febrile for 1 day, afebrile 2–3 days, repeats)
  - Powassan virus (seizures/encephalitis)
  - Q fever

### PHYSICAL EXAM

- Discovery of tick on the skin:
  - Most common sites: Head/neck/groin
- Dermatologic:
  - Local: Macule, papule, plaque, vesicles, necrotic ulcerations, petechiae, purpura, allergic dermatitis, urticaria:
    - Erythema migrans (~90%), borrelial lymphocytoma (earlobe), acrodermatitis chronica atrophicans: Lyme disease
    - Eschar: TBRF, tularemia, rickettsial disease (except RMSF), TIBOLA/DEBONEL (most often at scalp with painful lymphadenopathy)
    - Morbilliform eruption palms/soles: RMSF (96%)
  - Secondary infection: Cellulitis, erysipelas, ecthyma, impetigo
  - Anaphylaxis
- Constitutional: Fever, headache, myalgias, arthralgias, nausea, vomiting, anorexia, malaise

- Neurologic:
  - Tick paralysis:
    - Ascending flaccid paralysis
    - Gait disturbance (most commonly truncal ataxia with wide-based, staggering gait)
    - Sensory deficit is rare.
    - Guillain-Barré syndrome like (ophthalmoplegia, dysarthria, areflexia)
    - Respiratory paralysis
  - Cranial nerve (CN) palsy (CN VII → Lyme)
  - Seizures
  - Meningitis
  - Encephalitis with or without myelitis (flavivirus):
    - If present: Flaccid poliomyelitislike paralysis of arms, shoulders, levator muscles (head)
- Cardiovascular:
  - Conduction disturbances (atrioventricular block → Lyme)
  - Myocarditis, pericarditis

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### CBC:

- Babesiosis → hemolytic anemia
- Ehrlichiosis → pancytopenia
- TBRF → thrombocytopenia (>33%)

#### Diagnostic Procedures/Other

- May send tick to pathology for identification of species as well as pathogen
- Peripheral smear:
  - Babesiosis: Intraerythrocytic parasites
  - Ehrlichiosis: Intracytoplasmic inclusions within monocytes/leukocytes (morula)
  - TBRF: Spirochetes on Giemsa/Wright-stained smear

### DIFFERENTIAL DIAGNOSIS

- Tick paralysis: Guillain-Barré syndrome, Miller-Fisher syndrome, acute cerebellitis
- Acute febrile illness
- Arthropod bite
- Erysipelas
- Cellulitis, contact dermatitis
- Drug eruption
- Erythema infectiosum
- Meningococemia

## TREATMENT

### INITIAL STABILIZATION/THERAPY

- ABCs
- Supportive therapy
- Tick removal:
  - With blunt/rounded forceps, grasp mouthparts as close to the skin as possible and pull perpendicular (upward). Apply disinfectant to the bite site.
- Do not squeeze the tick body during tick removal → injection of saliva → theoretical propagation of infection.
- Avoid petrolatum, suntan oil → increased tick attachment time → propagation of infection.

### MEDICATION

#### First Line

- Babesiosis (most cases are self-limited):
  - Azithromycin 10 mg/kg (max single dose 500 mg) PO on day 1, then 5 mg/kg × 6–9 days AND
  - Atovaquone 20 mg/kg (max single dose 750 mg) PO q12h × 7–10 days
- Ehrlichiosis (therapy should continue until 3 days beyond defervescence):
  - Age >8 yr and <45 kg: Doxycycline 2.2 mg/kg (max single dose 100 mg) PO q12h × 5–14 days
  - Age <8 yr and <45 kg: If severe disease may use doxycycline, otherwise rifampin 10 mg/kg (max single dose 600 mg) PO q12h × 7–10 days
  - >45 kg: Doxycycline 100 mg PO q12h × 5–14 days
- Tularemia:
  - Streptomycin 15 mg/kg IM q12h, max 2 g/day, OR
  - Gentamycin 2.5 mg/kg IM/IV q8h × 10 days
- TBRF:
  - Age >8 yr: Doxycycline 100 mg b.i.d. × 7–10 days
  - Age <8 yr:
    - Penicillin V: 25–50 mg/kg/day (max single dose 500 mg) PO divided in 4 doses × 7 days OR
    - Penicillin G: 25,000–50,000 IU/kg/day IV divided in 4 doses × 7 days
- Lyme/STARI:
  - Age >8 yr: Doxycycline 100 mg b.i.d. × 14–21 days
  - Age <8 yr: Amoxicillin 50 mg/kg PO q8h × 14–21 days
- RMSF (treat for 3 days after apyrexia):
  - <45 kg: Doxycycline 2.2–5 mg/kg (max single dose 200 mg/day) IV/PO q12h
  - >45 kg: Doxycycline 100 mg b.i.d. IV/PO
- TIBOLA/DEBONEL: Same as RMSF
- Q fever (usually self-limited):
  - Age <8 yr: Doxycycline 100 mg b.i.d. × 14 days; if endocarditis, add hydroxychloroquine 200 mg t.i.d.

#### Second Line

- Babesiosis (most cases are self-limited):
  - Clindamycin 7–10 mg/kg (max single dose 600 mg) PO/IV q8h plus quinine 8 mg/kg (max single dose 650 mg) PO q8h × 7–10 days
- Ehrlichiosis:
  - Age >8 yr: Tetracycline 25–50 mg/kg/day PO in 4 divided doses × 5–14 days
  - Rifampin 10 mg/kg PO q12h × 7–10 days
- Tularemia:
  - <45 kg: Doxycycline 2.2 mg/kg IV q12h × 14–21 days or chloramphenicol 15 mg/kg IV q6h × 14–21 days or ciprofloxacin 15 mg/kg IV q12h (max 1 g/day) × 10 days for children >12 yr of age
- TBRF:
  - Erythromycin 30–50 mg/kg/day (max single dose 2 g/day) PO divided in 2–4 doses × 7 days
- STARI:
  - Azithromycin 20 mg/kg PO q12h × 1 day, then 10 mg/kg PO daily × 4–9 days
- RMSF (treat for 3 days after apyrexia):
  - Chloramphenicol 12.5–25 mg/kg PO/IV q6h × 5–10 days

### COMPLEMENTARY & ALTERNATIVE THERAPIES

Babesiosis: In severe cases (eg, end organ damage/hypotension), consider exchange transfusion coupled with antimicrobial therapy.

### DISPOSITION

#### Admission Criteria

- Cardiopulmonary involvement/compromise
- Neurologic signs (tick paralysis)
- Moderate to severe disease requiring IV therapy
- Dehydration
- Immunocompromised
- Secondary infection requiring IV antibiotics (eg, cellulitis/pneumonia)
- Inability to tolerate PO
- Severe lab abnormalities (eg, anemia)

#### Discharge Criteria

Patients not meeting the above admission criteria can be discharged home with appropriate follow-up.

#### Issues for Referral

All patients should be assessed by their pediatrician for fever resolution, relapses, secondary infections, and failure to respond to initial antibiotic regimen.

## FOLLOW-UP

### FOLLOW-UP RECOMMENDATIONS

Patients should seek further medical care for new or worsening symptoms, such as secondary infection, no improvement within 72 hr of antimicrobial treatment, persistent/recurrent fever, spread of lesion(s).

#### Patient Monitoring

- Assess for respiratory compromise.
- Monitor for Jarisch-Herxheimer reaction (>50%) for at least 4 hr after antibiotic treatment in TBRF.
- Avoid anticoagulation therapy in patients with RMSF: Increased risk of hemorrhage.

### PROGNOSIS

- Most cases of tickborne illness are self-limiting and/or respond to antibiotic therapy.
- Tick paralysis: Often resolves after removal of tick within 24 hr
- 10% die from respiratory paralysis.

### See Also (Topic, Algorithm, Electronic Media Element)

- Lyme Disease
- Rickettsial Disease

### CODES

#### ICD9

- 082.40 Unspecified ehrlichiosis
- 088.82 Babesiosis
- 989.5 Toxic effect of venom

### PEARLS AND PITFALLS

- A negative tick bite history does not exclude the diagnosis.
- Consider coinfection since ticks can carry >1 pathogen: Presentations may be atypical.
- Transmission of disease typically requires attachment >24 hr. There is no data to support antimicrobial prophylaxis to prevent tickborne disease.

# TINEA CAPITIS

Sunil Sachdeva

## BASICS

### DESCRIPTION

- Tinea capitis is a dermatophyte infection of scalp, hair, and the pilosebaceous apparatus.
- It occurs in different forms, such as grey patch disease and black dot disease, etc.
- It is commonly known as ringworm.

### EPIDEMIOLOGY

- Tinea capitis occurs nearly exclusively in preteen children.
- Incidence is increasing in America, while decreasing in Asia.
- 34% of household contacts are asymptomatic carriers.

### RISK FACTORS

- Much more common in blacks than other races:
  - Blacks are affected ~30 times more than the general population.
  - Tight hair braiding may be contributory.
- Most commonly affects those 3–8 yr of age but can be seen in those 2–14 yr:
  - Rare after age 16 yr and before age 2 yr
- More common in males than in females
- Infection is more common in congested urban environments.
- Exposure to dogs and cats predisposes to infection with *Microsporum canis*.

### PATHOPHYSIOLOGY

- Dermatophytes are keratophilic fungi that invade the stratum corneum due to ability to metabolize keratin.
- Prepubertal sebum lacks fungistatic properties.
- Spores are shed in the air and get deposited on the scalp of susceptible hosts.
- Direct person-to-person contact is not necessary.
- Spores grow into hyphae, which invade skin 1st and then the hair and pilosebaceous apparatus.

- Ectothrix-type hyphae break through the cuticle of hair. Spores are found on the outside shaft of the hair.
- Endothrix-type spores are found only in the shaft of hair.
- Black children have hair with increased coiling of hair shaft, making them more prone to infection.

### ETIOLOGY

- *Trichophyton tonsurans* is responsible for ~90% of infections in North America and causes black dot type of disease.
- *M. canis* is responsible for most of the rest of infections in North America and causes grey patch type of disease.
- *M. canis* is responsible for the majority of infections in the rest of the world.
- Other dermatophytes responsible are *Microsporum gypsum*, *Trichophyton schoenleinii*, *Trichophyton verrucosum*, and *Trichophyton rubrum*, etc.

## DIAGNOSIS

### HISTORY

- Scaly patch on the scalp
- Area(s) with loss of hair on the scalp
- Boggy swelling in the scalp area that may be painful
- Swellings on the back of the neck
- Pruritis

### PHYSICAL EXAM

- Black dot tinea capitis (BDTC):
  - It is the most common type in America.
  - Earliest lesions are:
    - An erythematous scaling patch on the scalp
    - 1–4 cm in diameter
    - Easily overlooked
  - Areas of alopecia may appear
  - Hairs are broken off close to the scalp, giving the appearance of black dots
  - Boggy, elevated, indurated, sometimes tender, nodular mass (kerion) may be present.
  - Folliculitis may be present.
  - Suboccipital lymphadenopathy may be present.
  - Papulovesicular eruption on the face or trunk may occur that is due to id reaction (hypersensitivity reaction) to scalp infection.

- Grey patch tinea capitis (GPTC):
  - Well-demarcated grey scaly patch on the scalp
  - Little local inflammation
  - Discolored hair covered by spores break ~1 mm above the skin creating a grey area, hence the name *grey patch*
  - Folliculitis may be present but is less common.
  - Suboccipital lymphadenopathy may be noted.
- Fluvus:
  - Seen with severe infection caused by *T. schoenleinii* and *M. gypsum*
  - Lesion is called *scutula* and consists of yellow foul-smelling crusts surrounding infected, matted hair.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

- Lab testing is typically unnecessary.
- Wet mount KOH preparation of hair and exam under microscope
- Fungal culture on Sabouraud medium may be sent.
- Wet cotton swab method of sample collection (by rubbing it over affected area and sending for culture) is the most convenient method.

#### Diagnostic Procedures/Other

Exam under Wood lamp may be helpful, but not all fungi will fluoresce:

- *M. canis* produces green fluorescence under Wood lamp.
- *Trichophyton* does not fluoresce.
- Patients with kerion have a positive skin test to *Trichophyton* antigen in most cases.

#### Pathological Findings

- In BDTC, spores are seen inside the hair shaft (endothrix).
- In GPTC, spores are surrounding the hair shaft (ectothrix).

### DIFFERENTIAL DIAGNOSIS

- Alopecia areata
- Seborrheic dermatitis
- Atopic dermatitis
- Psoriasis
- Trichotillomania
- Scalp abscess
- Pediculosis

## TREATMENT

### MEDICATION

#### First Line

Griseofulvin is the drug of choice. It is effective and safe:

- Micronized griseofulvin 20 mg/kg (max single dose 1 g/day) PO for 6–8 wk
- Ultramicronized 10 mg/kg PO for 6–8 wk

#### Second Line

- Terbinafine PO for 4 wk:
  - <20 kg: 62.5 mg/day
  - 20–40 kg: 125 mg/day
  - >40 kg: 250 mg/day
  - Terbinafine can also be used in pulses of 1-wk treatments with 2 wk in between the pulses. 3 pulses are advised.
  - Approved by the FDA for treatment in children >4 yr of age
  - Terbinafine may not be effective in treatment of *M. canis*.
- Fluconazole 6 mg/kg/day PO for 4–8 wk
- Itraconazole 5 mg/kg/day PO for 4 wk:
  - Fluconazole and itraconazole have multiple drug interactions.
  - Fluconazole and itraconazole not approved by the FDA to treat tinea capitis in children.
- Fungal sporidical agents such as 2% ketoconazole or 1% selenium sulfide shampoo twice a week reduces the surface colony count.
- Selenium sulfide 2.5% shampoo to affected area for 10 min daily for 1–2 wk
- Oral prednisone has not been proven to be of benefit.

### DISPOSITION

Patients should be discharged with follow-up to ensure eradication of infection and to assess for medication side effects.

#### Issues for Referral

Refer to a dermatologist when:

- Diagnosis is not uncertain
- Treatment failure
- Recurring episodes

## FOLLOW-UP

### FOLLOW-UP RECOMMENDATIONS

Discharge instructions and medications:

- Patient should follow up in 2–4 wk after the start of griseofulvin.
- If good improvement, griseofulvin is prescribed for 2 wk and then stopped.
- If recovery is not satisfactory, griseofulvin is continued for another 4 wk and follow-up should be scheduled.

#### Patient Monitoring

If griseofulvin is given for >8 wk, hepatic transaminases should be assayed to detect hepatotoxicity.

#### DIET

Better absorption of griseofulvin is achieved if medication is taken with fatty food such as cheese or milk.

#### PROGNOSIS

- If the medication is started early and the course is completed, the prognosis is good.
- If the condition is not treated or inadequately treated, it may leave permanent scarring and patches of alopecia.
- In 1 study, only 57% of patients were given oral treatment and only 19% completed 6 wk of therapy.

#### COMPLICATIONS

- Secondary infections
- Alopecia

### See Also (Topic, Algorithm, Electronic Media Element)

- Eczema
- Pityriasis
- Tinea corporis

### CODES

#### ICD9

110.0 Dermatophytosis of scalp and beard

### PEARLS AND PITFALLS

- Griseofulvin remains the drug of choice, but there are recent reports of resistance to it.
- Consider dermatophyte resistance to an antifungal if  $\geq 1$  full course of griseofulvin is completed compliantly without cure.
- Spores may remain viable on personal items and clothing, which need to be cleaned to avoid reinfection.
- Kerion is an immunologic response, and wet mount preparation and fungal cultures may be negative due to destruction by an inflammatory process.
- Patients should be treated 2 wk beyond the time when wet mount preparation and/or cultures are negative.
- Presence of occipital adenopathy with scaly alopecia has great positive predictive value for positive fungal culture.
- Noninflammatory scaly patches are difficult to distinguish from seborrheic dermatitis.

# TINEA CORPORIS

Sunil Sachdeva

## BASICS

### DESCRIPTION

- Tinea corporis is a superficial dermatophyte fungal infection of the skin that typically involves the stratum corneum.
- It excludes infection of palm, soles, and nails.
- It is commonly known as ringworm.

### RISK FACTORS

- Hot and humid environment
- Adolescent age group
- Contact sports (wrestling)
- Association with dogs/cats
- Patients with cellular immune deficiency
- Atopic dermatitis

### PATHOPHYSIOLOGY

- Infection occurs after deposition of viable spores or hyphae on a susceptible host
- Incubation period is 1–3 wk.
- After inoculation, infection spreads centrifugally in the outer layer of the skin.
- Central clearing occurs by host defenses.
- In general, infection occurs from person-to-person contact.
- Transmission with fomite or contaminated soil also occurs.
- Domestic animals such as dogs and cats are commonly causal.
- Different fungal species have different infectivity and inflammatory potential.

### ETIOLOGY

- Can be caused by wide variety of dermatophytes
- *Trichophyton rubrum* and *Trichophyton mentagrophytes* are the most common causes of infection.
- In children, *Microsporum canis* is a frequent cause.
- Other fungi involved are *Trichophyton verrucosum*, *Trichophyton tonsurans*, and *Epidermatophyton floccosum*.

### COMMONLY ASSOCIATED CONDITIONS

- Tinea capitis
- Tinea pedis
- Tinea cruris

## DIAGNOSIS

### HISTORY

- Presence of a round patch of rash that has been increasing in size
- Pruritic
- Painless
- Dry

### PHYSICAL EXAM

- Papulosquamous type:
  - Mildly erythematous, round, papulosquamous patch initially
  - Subsequent central clearing, giving an annular appearance
  - Raised, erythematous, scaly margins
  - Lesions are more common on exposed parts of the body.
  - Any area may be involved from extension from pre-existing infection.
  - There may be > 1 lesion.
  - Lesions are initially discrete but may coalesce and become confluent.

- Vesicular type:
  - Inflammatory response is more intense.
  - Fine vesicular lesions are present at the advancing margins.
- Granulomatous type:
  - Seen in children treated with topical steroids, immunocompromised hosts, and females who have inoculated the fungus while shaving their legs.
  - Also known as Majocchi granuloma
  - Consists of firm, nontender skin nodules with overlying crust or plaque

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

- It is a clinical diagnosis in most cases.
- Confirmation can be done with light microscopy of KOH wet mount preparation.
- Fungal cultures can be sent in difficult cases.

#### Diagnostic Procedures/Other

Wood lamp may be used to detect fluorescence of lesion:

- Not all fungi fluoresce.
- *Trichophyton* does not fluoresce.
- *Microsporum* fluoresces green.
- *Tinea versicolor* fluoresces yellow or yellow-green.

#### Pathological Findings

Microscopy demonstrates septate hyphae.

**DIFFERENTIAL DIAGNOSIS**

- Granuloma annulare
- Nummular eczema
- Psoriasis
- Erythema chronicum migrans
- Fixed drug eruption
- Herald patch of pityriasis rosea
- Pityriasis versicolor

**TREATMENT****MEDICATION****First Line**

Topical antifungal creams are the treatment of choice:

- Miconazole 2% cream applied b.i.d. × 14 days
- Clotrimazole 1% cream applied b.i.d. × 14 days

**Second Line**

- Terbinafine 1% cream applied b.i.d. × 7–14 days may be used in resistant cases:
  - Terbinafine may not be effective against *M. canis* infection.
  - Immunocompromised patients and patients with Majocchi granuloma may require systemic antifungal agents.
- Griseofulvin:
  - Microsize 10–20 mg/kg/day (max single dose 1 g) PO taken daily with dairy or fatty food for 3 wk
  - Ultramicrosize 10–15 mg/kg/day PO daily
- Other alternatives are:
  - Itraconazole 3–5 mg/kg PO daily × 1–2 wk
  - Fluconazole 3 mg/kg PO daily × 1–2 wk
  - Terbinafine cream (also as gel or solution):
    - Apply cream 1–2 times daily for 1–2 wk
  - These alternatives are more effective than griseofulvin but are more costly and not FDA approved for use in children and pregnant women.
  - They also have multiple drug interactions.

**DISPOSITION****Discharge Criteria**

Patients should be discharged with a plan for follow-up if the rash does not improve or if they have received oral antifungal agents other than griseofulvin.

**Issues for Referral**

In cases with unclear diagnosis or refractory infection, referral to a dermatologist should be considered.

**FOLLOW-UP****FOLLOW-UP RECOMMENDATIONS**

- Patients need to be re-evaluated in 2–3 wk if the rash has not improved.
- Cream should be applied over and beyond the lesion.
- Incomplete therapy is a frequent cause of recurrence.
- If the infection is with *M. canis*, check pet animal for infection.
- Avoid contact sports during the period of tinea infection.

**Patient Monitoring**

If not improving, re-evaluate the patient or consider alternative medication.

**DIET**

Consider taking dairy or fatty food with griseofulvin to enhance absorption.

**PROGNOSIS**

- Most tinea corporis resolves with initial therapy.
- Some cases may require multiple treatments, though this is typically due to noncompliance.

**COMPLICATIONS**

- Recurrent infection
- Permanent alteration in skin pigment

**ADDITIONAL READING**

- Andrews MD. Common tinea infections in children. *Am Fam Physician*. 2008;77(10):1415–1420.

**See Also (Topic, Algorithm, Electronic Media Element)**

- Eczema
- Pityriasis
- Tinea Capitis
- Tinea Versicolor

**ICD9**

110.5 Dermatophytosis of the body

**PEARLS AND PITFALLS**

- Consider alternate diagnoses such as granuloma annulare or guttate psoriasis in cases that do not respond to therapy.
- Consider resistant fungal species in cases that do not respond to therapy.

# TINEA VERSICOLOR

Sunil Sachdeva

## BASICS

### DESCRIPTION

- Tinea versicolor is a common benign chronic superficial skin infection.
- It is more appropriately called *pityriasis versicolor* because it is not a true tinea infection.
- It is caused by *Malassezia* group of fungi.
- Round to oval macules that vary in color from white to pink to brown

### EPIDEMIOLOGY

- Various reports find incidence between 2% and 8% of the population.
- *Malassezia* species (with or without disease) may be found on skin in 20% of infants and 90–100% of the adult population.
- In tropical areas, disease mostly affects the 10–19-yr age group.
- In temperate areas, it mainly affects the 17–24-yr age group.

### RISK FACTORS

- Tropical environment
- High humidity
- Adolescence
- Family history of pityriasis versicolor
- Cushing syndrome
- Malnutrition
- Pregnancy
- Oral contraceptive use

### GENERAL PREVENTION

Patients with recurrent pityriasis versicolor may use selenium sulfide topically to prevent its development.

### PATHOPHYSIOLOGY

- Pityriasis versicolor results from a shift in the relationship between a resident yeast flora and its host.
- *Malassezia* yeast commonly colonizes the skin and somehow converts to a parasitic mycelia form and invades the skin.
- Exact factors involved in this conversion are not known.
- Genetic factors and local factors affecting chemical composition of the sebum may play a role.
- Depigmentation may be produced due to inhibition of tyrosinase in hyperactive melanocytes by azelaic acid produced by *Malassezia*.
- The cause of hyperpigmentation is not known.
- Hyperpigmented patches have abnormally large melanosomes, and hypopigmented patches have small melanosomes.

### ETIOLOGY

- The *Malassezia* group of fungi are responsible for pityriasis versicolor.
- Most common species cultured from lesions are *Malassezia globosa* and *Malassezia sympodialis*.
- *M. globosa* is most frequently associated with the disease.
- *M. sympodialis* is found most commonly on normal skin:
  - *Malassezia slooffiae* and *Malassezia furfur* are also found, though less commonly.

## DIAGNOSIS

### HISTORY

- The presenting complaint is  $\geq 1$  discolored patches of skin.
- Itching may be present.
- The patch may be discovered as an incidental finding without complaints.

### PHYSICAL EXAM

- Round to oval macules on the skin
- Well demarcated
- Lesions may remain discrete or become confluent.
- Vary in color from white to pink to tan to brown
- Mostly found on the trunk and proximal parts of limbs
- Young children may have facial lesions.
- Rarely, involvement of eyelids, axillae, and perineum
- Lesions may be hypopigmented on dark skin or hyperpigmented on light skin.
- Lesions have scales, especially at the borders.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

- Typically a clinical diagnosis
- Confirmation can be done by microscopic exam of wet mount KOH preparation.
- Fungal culture can also be done, especially to determine the species.

#### Diagnostic Procedures/Other

Wood lamp exam may be helpful (yellow-green fluorescence) if positive but is only positive in 1/3 of cases.

**Pathological Findings**

“Spaghetti and meatball” pattern of hyphae and blastospores is seen on microscopic exam of KOH preparation.

**DIFFERENTIAL DIAGNOSIS**

- Vitiligo
- Pityriasis alba
- Pityriasis rosea
- Seborrheic dermatitis
- Tinea corporis
- Secondary syphilis

**TREATMENT****MEDICATION****First Line**

- Topical antifungals are first-line treatment.
- Selenium sulfide 2.5% in suspension or foam applied for 10 min per day for 10 days
- Tolnaftate 1% cream applied to affected area b.i.d. for 2–3 wk
- Gel form of ketoconazole applied for 10 min per day for 10 days:
  - Application is done on the entire skin surface from neck to thighs.

**Second Line**

- Miconazole, clotrimazole, and econazole creams are also effective but more expensive.
- Topical clotrimazole is the preferred treatment in pregnancy.

- Oral medications are appropriate for patients with extensive or resistant disease:
  - These medications are significantly less safe than topical treatments.
  - Ketoconazole 400 mg PO × 1 dose or 200 mg/day for 5 days
  - Itraconazole 400 mg PO per day for 3–7 days
  - These systemic therapies are effective in 90% of cases.
  - These medications are not FDA approved for use in patients <12 yr of age and pregnant women.
  - These systemic antifungal medications have multiple drug interactions and hepatotoxicity.

**Pregnancy Considerations**

Ketoconazole and itraconazole are not FDA approved for pregnant women.

**DISPOSITION****Issues for Referral**

- Uncertain diagnosis
- No response to treatment

**FOLLOW-UP****FOLLOW-UP RECOMMENDATIONS**

- Many patients will experience frequent recurrences.
- Topical application with selenium sulfide for 10 min every 2–3 wk is helpful in prevention of recurrence.
- Infection from clothing and garments can be avoided by discarding or washing them in boiling water.

**PROGNOSIS**

- It is a benign condition.
- Recurrence or relapse is common.

**COMPLICATIONS**

- It is a cosmetic problem.
- Can generate emotional problems in the common age groups

- Pityriasis
- Tinea Capitis

ICD9  
111.0 Pityriasis versicolor

**PEARLS AND PITFALLS**

- Repigmentation may take many weeks even after successful treatment.
- Patients should be advised that healing will continue after medication use stops.
- Exam under Wood light returns to normal before repigmentation.
- Sunlight accelerates repigmentation.
- Lack of scales with scraping after treatment indicates successful treatment.
- Using same clothes without cleaning may cause reinfection.

# TINNITUS

Benjamin Heilbrunn  
Deborah R. Liu

## BASICS

### DESCRIPTION

- Tinnitus is a rare complaint in children and, even more rarely, a life-threatening issue meriting immediate intervention in the emergency department.
- This topic will provide the emergency physician with a basic knowledge of tinnitus in order to properly diagnose, classify, consult, and refer patients to appropriate subspecialists.
- Tinnitus is defined as any abnormal noise or perceived sound by the patient when no external acoustic stimulus exists.
- Tinnitus may be divided into:
  - Objective tinnitus:
    - Internal noise or somatosounds that may be audible to a physician
  - Subjective tinnitus:
    - Noise perception when there is no noise stimulation of the cochlea
    - Not audible to others

### EPIDEMIOLOGY

Review of multiple studies of children 5–18 yr of age shows a prevalence of tinnitus in:

- Normal hearing: 6–29%
- Moderate to severe hearing loss: 30–100%
- Profound hearing loss: 23–35%
- Mixed or unstated hearing loss: 24–44% (1)

### RISK FACTORS

- Age: Slight increased risk for increase in age
- Female gender
- Hearing loss
- Noise exposure
- Motion sickness
- Hyperacusis

### PATHOPHYSIOLOGY

- Tinnitus can be triggered anywhere along the auditory pathway.
- The exact pathogenesis is unclear.

### ETIOLOGY

- Objective tinnitus:
  - Vascular disorders may present as arterial bruit or venous hum on physical exam:
    - Vascular etiologies heard as arterial bruits:
      - Petrous carotid system
      - Vascular loop abnormalities of the internal auditory canal, which may present in young healthy patients whose symptoms are worse in the evening
    - Vascular etiologies heard as venous hum:
      - Intracranial HTN, which may be caused by otic hydrocephalus or pseudotumor cerebri
      - Dehiscent jugular bulbs: Symptoms change with positioning
      - Arteriovenous (AV) shunts: Congenital (rare) or acquired (trauma or tumor)

- Neurologic disorders:
  - Palatomooclonus: Irregular clicking sound in the ear
  - Idiopathic stapedial muscle spasm: Cracking, rumbling noise in the ear
- Eustachian tube dysfunction—patulous eustachian tube is the most common type:
  - The eustachian tube remains abnormally open.
  - “Roaring” sound with respiration
  - Echo with patient’s own speech
  - Occurs with pregnancy, significant weight loss, temporomandibular joint syndrome
  - Symptoms may improve when lying down.
- Subjective tinnitus:
  - Usually due to otologic disorders, often from the same conditions that cause hearing loss (see the Hearing Loss topic):
    - Otitis externa or media
    - Tympanic membrane (TM) perforation
    - Abnormalities of ossicular bone chain
    - Barotrauma
    - Acoustic neuroma
    - Ménière disease: Excessive accumulation of endolymph in membranous labyrinth:
      - Recurrent episodes of vertigo
      - Unilateral aural fullness
      - Tinnitus
      - Hearing loss
  - Ototoxic medications: Cause bilateral tinnitus due to damage to hair cells, cranial nerve VIII or CNS connections:
    - Analgesics (aspirin, NSAIDs)
    - Antibiotics (aminoglycosides, erythromycin, chloramphenicol, tetracycline, vancomycin)
    - Chemotherapy medications (bleomycin, cisplatin, mechlorethamine, methotrexate, vincristine)
    - Loop diuretics (eg, furosemide)
    - Others (heavy metals, antidepressants, quinine, chloroquine)
  - Neurologic disorders:
    - Head trauma
    - MS
    - Migraine headaches
  - Metabolic abnormalities:
    - Hypo- or hyperthyroidism
    - Hyperlipidemia
    - Anemia
    - Vitamin B<sub>12</sub> deficiency
    - Zinc deficiency
  - Psychogenic causes:
    - Depression
    - Anxiety
    - Fibromyalgia

### COMMONLY ASSOCIATED CONDITIONS

Hearing loss

## DIAGNOSIS

### HISTORY

- Subjective or objective
- Unilateral or bilateral
- Pulsatile or continuous or episodic:
  - Pulsatile is often vascular in origin.
  - Continuous is associated with hearing loss.
  - Episodic is associated with Ménière disease.
- Characterize the quality of tinnitus (eg, ringing, humming, buzzing, roaring, rumbling, clicking).
- Situation of onset
- Associated symptoms: Vertigo, aural fullness, pain, drainage, disequilibrium, facial paralysis, sound distortion, headache
- Exposure to loud noises:
  - Quantify number of exposures or hours per week
  - Earphone use
- Exposure to ototoxic medications
- Any aggravating or precipitating factors

### PHYSICAL EXAM

- The following are emergent signs and symptoms that require further emergency department workup or immediate inpatient evaluation:
  - Acute onset nystagmus: Intracranial mass
  - Hemotympanum or TM perforation: Head trauma, barotrauma, or blast injury
  - Objective auscultatory findings of arterial bruits or venous hums: AV malformations, AV shunts, or increased intracranial pressure
- Head:
  - Signs of trauma
  - Evaluate if change in head position alters tinnitus.
- Eyes: Presence of nystagmus
- Ears:
  - External ear canal:
    - Cerumen impaction
    - Foreign body
  - TM:
    - Effusion
    - Perforation
    - Cholesteatoma
    - Hemotympanum
  - Evaluate TM for rhythmic contractions synchronous with noise, which may indicate idiopathic stapedial muscle spasm.
  - Evaluate for hearing loss with Weber and Rinne tests (see the Hearing Loss topic).
- Mouth: Observe the palate for myoclonic jerks.
- Neck:
  - Palpate for enlarged thyroid.
  - Palpable thrill
  - Audible bruit
- Heart: Check for arrhythmia, murmur.
- Neurologic: Complete exam, including cranial nerves

**DIAGNOSTIC TESTS & INTERPRETATION**

- Immediate evaluation of tinnitus is dictated by suspicion of acute pathology and clinical stability.
- Most tinnitus can be evaluated on an outpatient basis.

**Lab**

- General screening labs are usually not helpful.
- Consider the following, selectively:
  - CBC:
    - Rule out anemia or B<sub>12</sub> deficiency as causes of subjective tinnitus
    - Necessity of CBC dictated by other clinical findings such as tachycardia
  - Thyroid function studies
  - Serum salicylate level

**Imaging**

- Most causes of tinnitus do not require emergent imaging.
- For pulsatile tinnitus when there is concern for AV fistula, AV malformation, aneurysm, or tumor, the following imaging modalities may be helpful if otorhinolaryngology or neurology consultation is not available to guide management:
  - CT of the brain with contrast
  - MRI of the brain
  - Angiography of the brain
- For nonpulsatile tinnitus associated with concerning physical exam findings such as nystagmus, hemotympanum, or perforated TM, immediate imaging should be dictated by mechanism of injury or clinical suspicion of new-onset or evolving intracranial pathology.

**Diagnostic Procedures/Other**

Evaluate for associated hearing loss.

**DIFFERENTIAL DIAGNOSIS**

- See Etiology.
- Auditory hallucinations
- Aura of migraine headaches

**TREATMENT**

- Beyond supportive recommendations and appropriate referrals, rarely does tinnitus warrant emergent or immediate treatment.
- If the exam or evaluation raises concern for AV fistula, AV malformation, aneurysm, tumor, or trauma, subspecialty services such as vascular surgery, general surgery, trauma surgery, or neurosurgery should be consulted for immediate treatment.
- Treatment provided by the emergency physician should be focused on underlying causes that can be improved with immediate intervention:
  - Otitis media
  - Otitis externa
  - TM perforation
  - Barotrauma
  - Pseudotumor cerebri
  - Migraine headaches
- Please see specific topics on the above pathologies for treatment recommendations.

**MEDICATION**

- Medication treatment for tinnitus has not been proven to be successful:
  - Medication for pediatric tinnitus should be prescribed by a otorhinolaryngologist.
  - Limited research exists regarding medication for pediatric tinnitus.
  - Adult patients have had some success with a variety of medications such as misoprostol, gabapentin, lidocaine, and dexamethasone.
- If tinnitus is due to an ototoxic medication, discontinuation of the drug may prevent progression.

**COMPLEMENTARY & ALTERNATIVE THERAPIES**

If otorhinolaryngology consultation is not immediately available, the emergency provider can suggest techniques to reduce tinnitus-associated distress or awareness:

- Masking:
  - White noise generators (eg, fans)
  - Quiet music
  - Sound of running water
- Biofeedback
- Cognitive therapy and counseling
- Tinnitus retraining therapy
- Avoid suggesting seeking a quiet environment, as this may paradoxically increase awareness of tinnitus.

**SURGERY/OTHER PROCEDURES**

- Surgical intervention is dependent on the specific etiology of the tinnitus.
- Procedures may require various subspecialty surgical teams (otorhinolaryngology, vascular surgery, neurosurgery).

**Issues for Referral**

- For all but minor (eg, otitis media, otitis externa, TM perforation) causes of subjective and objective tinnitus, outpatient otorhinolaryngology consultation is indicated to obtain full audiology evaluation and counseling regarding options.
- For patients with pulsatile or arterial causes of tinnitus, surgical consultation is warranted:
  - As some vascular causes of tinnitus (eg, AV shunts) can be life threatening, immediate consultation is suggested to determine if the patient should be seen in the emergency department, admitted, or scheduled at the next available outpatient appointment.
  - For intracranial lesions, immediate consultation with a neurosurgeon is recommended.
- Patients with palatoclonus or idiopathic stapedial muscle spasms may require neurologic consultation for long-term management:
  - Emergent consultation is not required.

**DISPOSITION****Admission Criteria**

The need for admission is dependent on the specific etiology of the tinnitus.

**FOLLOW-UP****FOLLOW-UP RECOMMENDATIONS**

In addition to otorhinolaryngology follow-up and/or other surgical subspecialists, some patients with tinnitus may have concurrent anxiety or depression, which may warrant outpatient counseling.

**PROGNOSIS**

- Depends largely on the etiology of tinnitus
- In children with sudden hearing loss, tinnitus appears to be a positive predictive factor in hearing recovery (2).

Hearing Loss

**CODES****ICD9**

- 388.30 Tinnitus, unspecified
- 388.31 Subjective tinnitus
- 388.32 Objective tinnitus

**PEARLS AND PITFALLS**

- Pearls:
  - Pulsatile tinnitus may be secondary to a life-threatening vascular etiology, which manifests as arterial bruits or venous hums on physical exam.
  - Unilateral subjective tinnitus with a normal ear exam may indicate intracranial pathology such as tumors or infarction and thus requires immediate attention.
- Pitfall:
  - Avoid suggesting seeking a quiet environment, as this may paradoxically increase awareness of tinnitus.

# TOXIC ALCOHOLS POISONING

Robert J. Hoffman

## BASICS

### DESCRIPTION

- Toxic alcohols include ethylene glycol (EG), isopropyl alcohol, and methanol.
- EG is a sweet, odorless, colorless liquid used as automobile antifreeze solution.
- Isopropyl alcohol is used as rubbing alcohol; it is also used in liquid soaps and for other uses.
- Methanol is used in windshield wiper fluid, Sterno, and other products.
- EG and methanol are the most dangerous, associated with metabolic acidosis with anion gap:
  - Ingestion of only several milliliters of EG or methanol may result in death.
- Fomepizole is antidotal for EG and methanol.

### RISK FACTORS

- Having poisons accessible to children
- Storing poisons in containers other than the original container, such as beverage bottles
- Isopropyl alcohol toxicity via dermal absorption rarely occurs in infants or young children with permeable skin.

### GENERAL PREVENTION

- Poison proofing homes
- The use of environmentally friendly antifreeze containing propylene glycol may avoid antifreeze toxicity in pets and children.

### PATHOPHYSIOLOGY

- All toxic alcohols are intoxicants.
- They may cause altered mental status or coma similar to ethanol.
- CNS depression may result in respiratory depression requiring ventilatory support.
- EG and methanol are metabolized to toxic by-products resulting in severe morbidity or mortality.
- Both EG and methanol are associated with development of an anion gap metabolic acidosis:
  - EG is metabolized to oxalic acid, then glycolic acid, and ultimately calcium oxalate crystals, which precipitate in renal tubules and cause renal failure.
  - Methanol is metabolized to formaldehyde, then formic acid, which may damage the retina and cause visual impairment or blindness.
- Metabolism of EG and methanol to toxic metabolites is prevented by inhibiting alcohol dehydrogenase with either fomepizole or ethanol.
- Isopropyl alcohol is metabolized to acetone and does not require fomepizole therapy.

### ETIOLOGY

- EG
- Isopropyl alcohol
- Methanol

### COMMONLY ASSOCIATED CONDITIONS

- Ethanol exposure
- Other toxin exposure

## DIAGNOSIS

### HISTORY

- Typically, there is a stated history of exposure.
- Early after exposure, no signs or symptoms may be present:
  - Due to the severe toxicity and potential lethality, any possible exposure should be fully evaluated and managed in the hospital.
- Inebriation may result from toxic alcohols.
- GI:
  - Isopropyl alcohol may cause severe GI irritation or hemorrhage.
  - Nausea and vomiting may occur with any toxic alcohol ingestion.
- Respiratory:
  - Tachypnea and/or hyperpnea may occur with EG or methanol due to metabolic acidemia.
  - Respiratory depression or apnea may result from severe intoxication in young children.
  - Coughing or dyspnea due to aspiration of a toxic alcohol or inhalation of isopropyl alcohol fumes
  - Abnormal breath sounds or hypoxia may be result from aspiration of toxic alcohol.
- Ocular disturbance may be a late finding associated with methanol toxicity.

### PHYSICAL EXAM

- Tachycardia and hypotension are the most frequent vital sign abnormalities that occur.
- Neurologic abnormalities may include ataxia, CNS depression, coma, dysarthria, focal neurologic changes, hyporeflexia, hypotonia, nystagmus, or seizure.
- GI effects may include gastritis, emesis, hematemesis, pain, or pancreatitis.
- Ophthalmologic findings may include blurred vision, diplopia, hazy vision, or nystagmus.
- Constricted visual fields, hyperemic optic disc with retinal edema, and transient or permanent blindness may result from methanol exposure.
- Respiratory irritation from isopropyl alcohol inhalation or respiratory depression from any toxic alcohol ingestion may occur.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

#### Initial Lab Tests

- Lab testing is key in diagnosis/management.
- Osmolal or anion gap or acidemia are the most important findings in the initial evaluation of toxic alcohol exposure.
- Check serum electrolytes, BUN, creatinine, and glucose.
- Fluid and electrolyte abnormalities from EG or methanol may include hypokalemia, hypocalcemia, hypomagnesemia, and elevated anion gap metabolic acidosis.
- Acetonemia and ketonemia may result from isopropyl alcohol ingestion.
- Hypoglycemia may be associated with toxic alcohol exposure as well as with ethanol therapy.

- Hematuria, renal insufficiency, or renal failure may occur, particularly from EG.
- Development of metabolic acidemia and/or anion gap and osmol gap from EG or methanol:
  - Initially, an osmolal gap may occur.
  - An elevated osmol gap can be used to rule in, but not exclude, toxic alcohol exposure.
  - An elevated osmolal gap indicates the presence of unmeasured solute such as ethanol, EG, isopropyl alcohol, or methanol.
  - Absence of an osmolal gap does not exclude toxic alcohol exposure.
  - Osmolal gap is calculated as follows: Osmol gap = calculated serum osmolality – measured osmolality
  - Measured osmolality is determined by the lab.
  - Calculated osmolality:  $2 \times [\text{Na}(\text{mEq/L})] + [\text{BUN}(\text{mg/dL}) \div 2.8] + [\text{glucose}(\text{mg/dL}) \div 18]$
  - Normal osmolal gap is  $<15 \text{ mEq/L}$ .
  - If elevated, osmolal gap should be presumed due to toxic alcohol exposure.
  - Early after ingestion, an osmol gap, but no anion gap, will be present.
  - As metabolism of EG or methanol occurs, an increased anion gap metabolic acidemia results with EG or methanol toxicity. This effect is not immediate.
  - Absence of anion gap early after ingestion is expected and does not rule out ingestion.
  - Elevated anion gap metabolic acidemia suggests EG or methanol toxicity.
  - Acidemia is an indication for use of fomepizole or ethanol as well as a potential indication for hemodialysis.
  - Isopropyl alcohol only causes elevation of the osmol gap, not the anion gap.
- Blood gas analysis should be performed to assess for the degree of metabolic acidemia in any patient with low serum bicarbonate:
  - Initial use of venous blood gas to screen for abnormality is acceptable.
- Repeated blood gas 1–2 hr if acidemic:
  - Serum level of EG, isopropyl alcohol, or methanol should be obtained.
  - False elevation of serum lactate level may occur with EG.
  - An EG or methanol level  $>20 \text{ mg/dL}$  is an indication for fomepizole or ethanol infusion.
  - An EG or methanol level  $>50 \text{ g/dL}$  is an indication for hemodialysis.
- Check serum ionized calcium in EG toxicity, as severe symptomatic hypocalcemia and cardiac dysrhythmia may result.
- Urinalysis in suspected EG exposure:
  - Oxalate crystals suggest poisoning.
  - Absence of crystals does not exclude the possibility of EG toxicity.
  - Fluorescence of urine is unreliable and neither sensitive or specific for exposure.
  - Proteinuria and hematuria may be present with EG or isopropyl alcohol exposure.

- Serum osmolality or osmolarity may be useful in predicting the level of EG, isopropyl alcohol, or methanol level if rapid lab quantification cannot be performed.
- Serum ethanol level should simultaneously be performed to determine the quantity of ethanol contribution to the osmolal gap.
- Acetaminophen and salicylate levels if intentional ingestion or intent of self-harm

**Imaging**

Neuroimaging to rule out intracranial pathology may very rarely be indicated.

**Diagnostic Procedures/Other**

ECG in any symptomatic patient

**DIFFERENTIAL DIAGNOSIS**

Acetone, diethylene glycol, ethanol, iron, isoniazid, lactic acidemia, mannitol, methanol, propylene glycol, renal failure, salicylates, toluene, and various forms of ketoacidosis

**TREATMENT**

**INITIAL STABILIZATION/THERAPY**

- Assess and stabilize airway, breathing, and circulation.
- Consultation with a poison control center or medical toxicologist, if available, is recommended.
- For ingestion <1 hr previously, an attempt to aspirate gastric contents with an NG tube is reasonable.
- Treatment for EG or methanol exposure should focus on acid-base correction and preventing organ damage.
- Hemodialysis should be considered for:
  - Any significant metabolic acidemia from EG or methanol
  - Evidence of end organ damage, particularly if metabolic acidemia is present
  - Profound hypotension or life-threatening symptoms from isopropyl alcohol toxicity
- IV fluid therapy is routinely used:
  - To maintain adequate BP
  - In patients who are unable to take PO
  - Preventing urinary calcium oxylate crystals
  - IV fluid may be helpful to prevent renal injury if rhabdomyolysis occurs.

**MEDICATION**

**First Line**

- Fomepizole is strongly preferred for EG and methanol exposure.
- Fomepizole and ethanol inhibit alcohol dehydrogenase, but fomepizole is highly preferable; ethanol has many severe adverse side effects, while fomepizole does not.
- Indications for fomepizole or ethanol include:
  - Serum level of EG or methanol >20 mg/dL
  - Metabolic acidemia with EG or methanol
- The use of fomepizole or ethanol will prolong the half-life of EG and methanol:
  - Without therapy, the EG half-life is 3–4 hr and methanol is 14–20 hr.
  - With fomepizole or ethanol, the EG half-life is 12 hr, and methanol is 30–50 hr.
- Some need for fomepizole therapy longer than several days to be an indication for hemodialysis.
- The use of fomepizole for prolonged duration to avoid hemodialysis is costly but acceptable.

- Fomepizole:
  - The loading dose is 15 mg/kg IV.
  - Maintenance: 10 mg/kg IV q12h × 4 doses
  - Fomepizole induces its own metabolism; after 4 maintenance doses, the maintenance dose is increased to 15 mg/kg q12h thereafter.
  - Each dose is diluted into normal saline or D5W and infused over 30 min.
  - Each time after hemodialysis is performed, a loading dose must be readministered.
- Ethanol:
  - Administered as a 10% solution in D5W
  - The ethanol loading dose is 10 mL/kg of a 10% solution infused IV over 1 hr:
    - This dilution requirement requires a very large quantity of free water administration.
  - Maintenance dose of 1–2 mL/kg/hr of 10% ethanol is then given IV.
  - Target blood ethanol level: 100–125 mg/dL
  - Check ethanol every 2–4 hr, and check serum glucose hourly.
  - PO ethanol may be used if IV is not available and the patient is willing and capable of drinking.
    - This is possibly feasible in adolescents.
  - Use alcohol with extreme caution in Asians, as aldehyde dehydrogenase deficiency may result in severe illness and hypotension.
- Sodium bicarbonate 1 mEq/kg IV may be needed in repeated doses to treat acidosis:
  - The use of sodium bicarbonate infusion may protect against end organ damage.
  - If used, after loading 2 ampules of bicarbonate in each 1 L of D5W given as maintenance fluid

**Second Line**

Continue these secondary medications until EG or methanol levels are undetectable.

- Leucovorin 1–2 mg/kg IV q6h for methanol ingestion; hastens elimination of formic acid
- Pyridoxine and thiamine hasten elimination of EG metabolites:
  - Pyridoxine 1–2 mg/kg IV q6h, max single dose 100 mg
  - Thiamine: <20 kg, 50 mg IV q6h; >20 kg, dose 100 mg IV q6h:
    - Infuse over at least 5 min.

**DISPOSITION**

**Admission Criteria**

- EG or methanol ingestion, suspected or proven
- Most patients should be admitted and followed 12–24 hr to detect development of acidemia or other abnormalities.
- Critical care admission criteria:
  - Unstable vital signs

**Discharge Criteria**

- EG/Methanol:
  - Asymptomatic with undetectable EG or methanol level and no metabolic acidemia
  - Inpatients must be medically and metabolically stable for at least 12–24 hr prior to discharge, no anion gap or metabolic acidemia, stable renal function, and normal vision
- Isopropyl alcohol: No intoxication, no significant GI symptoms, and little or no osmol gap after 4–6 hr

**Issues for Referral**

- Nephrology for renal failure or if dialysis is needed
- Ophthalmology if retinal toxicity from EG

**FOLLOW-UP**

**PROGNOSIS**

- For EG and methanol exposure, prognosis depends on the degree of toxin metabolism.
- For isopropyl, prognosis depends on severity of intoxication.

**COMPLICATIONS**

Blindness, coma, hepatic injury, HTN or hypotension, myocarditis, temporary or permanent neurologic injury, pancreatitis, renal failure, respiratory depression, rhabdomyolysis, seizure, shock, and death may occur.

**ADDITIONAL READING**

- Barceloux DG, Krenzelok EP, Olson K, et al. American Academy of Clinical Toxicology practice guidelines on the treatment of ethylene glycol poisoning. Ad Hoc Committee. *J Toxicol Clin Toxicol.* 1999;37:537.

**CODES**

**ICD9**

- 276.2 Acidosis
- 980.1 Toxic effect of methyl alcohol
- 980.2 Toxic effect of isopropyl alcohol

**PEARLS AND PITFALLS**

- A small dose of EG or methanol may be fatal.
- Patients with lethal ingestions may initially be asymptomatic.
- Lab assays are key to assessment.
- Obtain serum level of suspected toxic alcohol.
- As an antidote for EG or methanol, fomepizole use is highly preferred over ethanol.

# TOXIC SHOCK SYNDROME

Jennifer H. Chao

## BASICS

### DESCRIPTION

- Toxic shock syndrome (TSS) is a shock state that is accompanied by fever and erythroderma.
- It is the result of bacterial toxin: Toxic shock syndrome toxin-1 (TSST-1), produced by 20% of *Staphylococcus aureus* isolates
- Toxic strep syndrome is clinically similar to TSS but instead is caused by *Streptococcus pyogenes*.
- The CDC has a case definition:
  - Fever: Temperature  $\geq 102.0^{\circ}\text{F}$  ( $\geq 38.9^{\circ}\text{C}$ )
  - Rash: Diffuse macular erythroderma
  - Desquamation: 1–2 wk after onset of illness, particularly on the palms and soles
  - Hypotension: Systolic BP  $\leq 90$  mm Hg for adults or  $< 5$ th percentile by age for children  $< 16$  yr of age; orthostatic drop in diastolic BP  $\geq 15$  mm Hg from lying to sitting, orthostatic syncope, or orthostatic dizziness
  - Multisystem involvement ( $\geq 3$  of the following):
    - GI: Vomiting or diarrhea at onset of illness
    - Muscular: Severe myalgia or creatine phosphokinase level at least twice the upper limit of normal
    - Mucous membrane: Vaginal, oropharyngeal, or conjunctival hyperemia
    - Renal: BUN or creatinine at least twice the upper limit of normal for lab or urinary sediment with pyuria ( $\geq 5$  leukocytes per high-power field) in the absence of urinary tract infection
    - Hepatic: Total bilirubin, ALT, or AST levels at least twice the upper limit of normal for the lab
    - Hematologic: Platelets  $< 100,000/\text{mm}^3$
    - CNS: Disorientation or alterations in consciousness without focal neurologic signs when fever and hypotension are absent
  - Lab criteria:
    - Negative results on the following tests, if obtained:
      - Blood, throat, or CSF cultures (blood culture may be positive for *S. aureus*)
      - Rise in titer to Rocky Mountain spotted fever, leptospirosis, or measles
  - Case classification:
    - Probable: A case that meets the lab criteria and in which 4 of the 5 clinical findings described above are present
    - Confirmed: A case that meets the lab criteria and in which all 5 of the clinical findings described above are present, including desquamation, unless the patient dies before desquamation occurs

### EPIDEMIOLOGY

- Incidence is 3.4/100,000 women 15–44 yr of age
- $> 60\%$  of cases occur in women.

### RISK FACTORS

- Younger age
- Females
- Caucasians
- Use of superabsorbent tampons
- Any wound that contains packing
- Chronic diseases or immunodeficiency
- Preceding varicella infection

### GENERAL PREVENTION

Avoid prolonged use of tampons or wound packing.

### PATHOPHYSIOLOGY

- SST-1 is a superantigen.
- Superantigen have distinctive properties:
  - Activate up to 20% of T cells at a single time, resulting in overwhelming cytokine release
  - The massive cytokine storm (release of interleukin 1 and 2, tumor necrosis factors, and interferon-gamma) results in fever, proteolysis, and hypotension with shock.
- Other syndromes resulting from staphylococcal toxins are food poisoning from staphylococcal enterotoxin B, with severe vomiting and rarely hypotension leading to death and staphylococcal scalded skin syndrome from staphylococcal exfoliative toxin.

### ETIOLOGY

- *S. aureus* infection
- *S. pyogenes* infection
- Initially when described, TSS was associated with use of superabsorbent tampons.
- In 1980, there were 812 reported cases.
- Currently, 50% of cases are from nonmenstrual causes, including:
  - Surgical wounds
  - Postpartum wounds
  - Sinusitis or nasal packing for epistaxis
  - Burns
  - Osteomyelitis

### COMMONLY ASSOCIATED CONDITIONS

- Influenza
- Varicella
- Menstruation
- Pneumonia
- Sinusitis
- Necrotizing fasciitis

## DIAGNOSIS

### HISTORY

- A source of infection should be sought: Skin infection or packing of any kind in the body should be cultured (tampon, recent operation, nasal packing, etc.).
- The most common initial symptom of toxic strep syndrome is pain, diffuse or localized, that is abrupt in onset and severe.
- Fever
- Chills
- Myalgias
- Malaise
- Vomiting, diarrhea
- Confusion
- Rash

### PHYSICAL EXAM

The CDC case definition should be applied.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

- CBC: Platelet count  $< 100,000/\text{mm}^3$
- Blood culture
- Serum electrolytes: Bicarbonate is often low due to acidemia.
- Creatine phosphokinase:  $\geq 2$ -fold increase
- Renal: Increase in BUN or creatinine  $> 2$  times normal or sterile pyuria
- Hepatic: Total bilirubin or transaminases greater than twice the normal value
- Hematologic: Thrombocytopenia  $< 100,000/\text{mm}^3$
- Hepatic function assays: Elevated total bilirubin; ALT, AST greater than twice the upper limit of normal
- PT/PTT/fibrinogen split products/D-dimer: May be elevated in disseminated intravascular coagulation (DIC)
- Wound culture
- Urinalysis: Sterile pyuria is often present.
- Consider obtaining serology for Rocky Mountain spotted fever, rubeola, leptospirosis, and hepatitis B if in doubt.
- Isolation of *S. pyogenes* from a normally sterile site with above meets the case definition. Recovery of *S. pyogenes* from a nonsterile site with above is a probable case.

**DIFFERENTIAL DIAGNOSIS**

- Septic shock
- Staphylococcal or streptococcal scalded skin syndrome
- Scarlet fever
- Kawasaki disease
- Invasive group A streptococcal infection
- Stevens-Johnson syndrome
- Rocky Mountain spotted fever
- Leptospirosis
- Meningococemia

**TREATMENT**

**PRE HOSPITAL**

- Assess and stabilize airway, breathing, and circulation.
- Administer supplemental oxygen.
- Isotonic crystalloid bolus at 20 cc/kg for hypotension or significant tachycardia

**INITIAL STABILIZATION/THERAPY**

- Assess and stabilize airway, breathing, and circulation.
- Administer supplemental oxygen.
- Isotonic crystalloid bolus at 20 cc/kg for hypotension or significant tachycardia
- Management of shock and maintenance of acceptable tissue and organ perfusion is critical:
  - In addition to IV fluid, administer vasopressors as needed for shock.
- Remove any packing that may be contributory, such as tampons, nasal packing, or wound packing:
  - Consider vaginal irrigation with povidone.

**MEDICATION**

**First Line**

- Antibiotics that are effective against *S. aureus* (including MRSA) and *S. pyogenes* should be initiated.
- It is unclear if antibiotics alter the clinical course, possibly because the syndrome is toxin mediated. Even after administration of bactericidal agents, the responsible toxins remain.
- Clindamycin 40 mg/kg IV q6h:
  - Lincosamide antibiotic with variable activity against MRSA but useful for TSS because the mechanism of action is to inhibit protein (toxin) synthesis.

- Vancomycin 15 mg/kg/dose IV q6h:
  - Useful for MRSA
- Linezolid: Patient <12 yr of age, 10 mg/kg/dose IV q8h; > 12 yr, 600 mg IV q12h:
  - Useful for MRSA
  - Nafcillin 100 mg/kg/24 hr IV divided q4h, max daily dose 1.5 g IV

**Second Line**

IV immunoglobulin may be effective in toxic strep syndrome; it is unclear if it is helpful in TSS:

- Dose is 400 mg/kg IV over 2–4 hr

**COMPLEMENTARY & ALTERNATIVE THERAPIES**

Corticosteroids are sometimes used but are of unproven benefit.

**SURGERY/OTHER PROCEDURES**

- Removal of infected packing is mandatory to remove the source of the toxin.
- Surgical debridement is commonly practiced to treat infected wounds, but it is unclear if this is useful due to the toxin-mediated nature of the disease.

**DISPOSITION**

**Admission Criteria**

Critical care admission criteria:

- All patients with TSS should be admitted to a critical care unit.

**FOLLOW-UP**

**FOLLOW-UP RECOMMENDATIONS**

All patients with toxic shock should be admitted.

**Patient Monitoring**

Patients should be placed on a cardiorespiratory monitor, with close monitoring for clinical deterioration.

**PROGNOSIS**

TSS has a 5% case fatality rate, usually resulting from ARDS or myocardial injury

**COMPLICATIONS**

- Acute respiratory distress syndrome
- Myocardial injury
- Shock
- Multisystem organ failure
- DIC
- Acute renal failure
- Hepatic failure
- Cerebral injury
- Death

- Abscess topics
- Cellulitis
- Food Poisoning

**CODES**

**ICD9**  
040.82 Toxic shock syndrome

**PEARLS AND PITFALLS**

- TSS may rapidly progress to shock, multisystem organ failure, and death.
- Packing or a foreign body such as a tampon or wound packing must be removed.
- Erythroderma may be missed in severely hypotensive patients or in patients with dark pigmentation.
- Skin will desquamate 1–2 wk after onset.

# TRACHEITIS

Jose Ramirez

## BASICS

### DESCRIPTION

- Tracheitis is an acute infectious inflammatory response in the trachea.
- It is an uncommon upper airway infection in isolation:
  - However, patients with tracheostomies commonly develop tracheitis.
- Also known as bacterial croup, membranous croup, or membranous laryngotracheobronchitis:
  - It is a medical emergency with significant potential for airway compromise and high mortality rate.
  - Significant risk for respiratory failure

### EPIDEMIOLOGY

- Viral prodrome is common.
- More commonly occurs during fall and winter flu season
- Up to 75% of patients are coinfecting with influenza type A
- Age range from early infancy to adolescence
- Mean age is 5 yr.

### Prevalence

- Rare condition
- 1 study reports 0.1/100,000 children (1)
- Prevalence of tracheitis in children with tracheostomies is unknown.

### RISK FACTORS

- Preceding upper respiratory infection, particularly crouplike illness
- Possible novel influenza strains
- Tracheostomy

### GENERAL PREVENTION

Vaccination with *Haemophilus influenzae* type b and pneumococcal vaccines as well as seasonal influenza vaccination

### PATHOPHYSIOLOGY

- Epithelial damage from a viral infection or mechanical trauma such as intubation or surgical procedure predisposes to bacterial suprainfection.
- Patients with tracheostomies have a much higher incidence of tracheitis.
- Mucosal damage results in:
  - Tracheal wall edema, epithelial sloughing, and copious mucopurulent material
  - A pseudomembrane may form.
  - Occlusion of the airway may result as disease progresses.
- Toxic shock syndrome or toxic strep syndrome may ensue if *Staphylococcus aureus* or *Streptococcus pyogenes* is causal agent.

### ETIOLOGY

- Bacteria:
  - *S. aureus* is most common, also group A beta-hemolytic streptococcus, *Moraxella catarrhalis*, and nontypeable *H. influenzae*.
  - *Pseudomonas aeruginosa*; other gram-negative enteric bacteria may be associated with nosocomial infections and are more common in patients with tracheostomies.
  - *Mycoplasma pneumoniae*, *H. influenzae* type b, and *Corynebacterium diphtheriae* are uncommon pathogens.
- Viruses: Influenza, parainfluenza, respiratory syncytial virus, and measles virus

## DIAGNOSIS

### ALERT

- Children presenting with severe croup or crouplike illness should have bacterial tracheitis considered in the differential diagnosis.
- Severe crouplike illness that does not improve with standard therapy of nebulized racemic epinephrine and steroid administration warrants evaluation for bacterial tracheitis.

### HISTORY

- High fever
- Nonpainful cough, often barking (dog or seal)
- Antecedent upper respiratory infection is often reported, particularly respiratory symptoms similar to croup.
- Acute deterioration of condition with rapid progression to high fever and respiratory distress
- Productive cough with copious amounts of secretions
- Subacute bacterial tracheitis may have more indolent progression of symptoms.
- For patients with tracheostomies:
  - Persistent tracheal secretions
  - Color and consistency of secretions
  - Use of antibiotics
  - Results and susceptibilities of previous tracheostomy cultures

### PHYSICAL EXAM

- General appearance:
  - Patient is typically toxic in appearance with stridor, cough, and high fever.
  - Patient has significant cough, preference for a supine position, is comfortable lying flat, and does not drool; these help differentiation from epiglottitis.
- Respiratory:
  - Respiratory distress
  - Dyspnea with increase in work of breathing
  - Stridor
  - Barking cough
  - Wheezing
  - Hoarseness of voice and dysphonia may be present.
- Tracheal secretions for those with tracheostomies:
  - Consider tracheal suctioning of these patients to observe secretions.

### DIAGNOSTIC TESTS & INTERPRETATION

Diagnosis is based on clinical presentation and either:

- Radiographic evidence of intratracheal membrane
- Bronchoscopy demonstrates purulent secretions or laryngotracheal inflammation.
- Or tracheal aspirate with positive Gram stain/culture (2,3)

### Lab

- Tracheal aspirate for culture and Gram stain
- CBC is not specific.
- Blood cultures have poor yield.

### Imaging

- Soft tissue cervical radiographs:
  - AP: Steeple sign similar to findings in croup
  - Lateral: Pseudomembrane detachment with ragged appearance
- AP/Lateral CXR if pneumonia is suspected:
  - Up to 60% of patients may have a positive infiltrate on chest radiograph.
  - Patients with tracheostomies should have chest radiographs obtained routinely.

### Diagnostic Procedures/Other

- Definitive airway control:
  - Consider rapid sequence induction and/or elective endotracheal intubation.
  - Prepare for potential surgical airway intervention.
- Bronchoscopy
- Vascular access should be obtained (3).

### Pathological Findings

Large amounts of mucopurulent material in trachea

### DIFFERENTIAL DIAGNOSIS

- Croup:
  - Patients not as ill appearing and may respond to racemic epinephrine
- Epiglottitis:
  - Tend not to cough as much and also prefer the tripod sitting position
  - Patients with tracheitis do not have the drooling that is commonly associated with epiglottitis.
- Foreign body aspiration:
  - Lack of fever or upper respiratory infection symptoms
- Tumor:
  - Papillomatosis from human papillomavirus
  - Laryngeal tumor
  - Hamartoma
  - Hemangioma
- Congenital:
  - Tracheal stenosis
  - Vascular ring or sling
  - Laryngotracheal web or cleft
- See the Stridor topic.

## TREATMENT

### PRE HOSPITAL

- Assess and stabilize airway, breathing, and circulation:
  - Oxygen as needed
  - Advanced airway management if needed
- Maintain child calm.

### INITIAL STABILIZATION/THERAPY

- Airway management and control
- 60–80% may require intubation.
- Prepare for emergent laryngoscopy and intubation.
- Adequate suction is crucial:
  - Unlike croup, nebulized racemic epinephrine is ineffective.
  - Have a secondary endotracheal tube in the event of clogging of the 1st endotracheal tube by mucopurulent material.
  - Antibiotics (see below) (3,4)

### MEDICATION

#### First Line

- Ceftriaxone 100 mg/kg/day IV divided q12h
- Vancomycin 10–15 mg/kg IV q6h

#### Second Line

- Clindamycin 25–40 mg/kg/day IV divided q8h
- Tracheostomy patients:
  - Trimethoprim/Sulfamethoxazole 5 mg/kg/dose PO/IV q12h
  - Amoxicillin/Clavulanic acid 25 mg/kg/dose PO q12h
  - Consider ciprofloxacin 10 mg/kg/dose IV q8h.

### COMPLEMENTARY & ALTERNATIVE THERAPIES

- Definitive airway control if ill appearing
- IV hydration
- Steroids have sometimes been used adjunctively, but definitive data about efficacy is lacking.

### SURGERY/OTHER PROCEDURES

- Endotracheal intubation:
  - A 1 size smaller endotracheal tube may be needed because of airway narrowing.
  - An extra endotracheal tube may be needed for replacement of mucopurulent plugging of the 1st endotracheal tube.
- Prepare for emergent intubation:
  - In the operating room setting if possible
  - Preparation for potential cricothyrotomy or tracheostomy

### DISPOSITION

#### Admission Criteria

- All patients with respiratory distress/failure should be admitted to a critical care unit.
- All patients without tracheostomies should be admitted to a critical care unit.
- Patients with tracheostomies may be admitted for:
  - Failure of outpatient antibiotics
  - Presence of respiratory distress/failure
  - Presence of concurrent pneumonia
  - Hypoxemia

#### Discharge Criteria

Selected patients with tracheostomies may be discharged from the emergency department:

- No oxygen requirement
- No respiratory distress
- Ability to tolerate oral (gastrostomy tube) antibiotics

#### Issues for Referral

- Transfer to a pediatric tertiary care center with available critical care staff and an accessible ENT surgeon
- Anesthesia or ENT for assistance in airway management.

## FOLLOW-UP

### FOLLOW-UP RECOMMENDATIONS

Close monitoring for recurrence of symptoms is essential.

#### Patient Monitoring

- Critical care monitoring (4):
  - Mechanical ventilation
  - Sedation
  - Elevated risk for multiorgan system failure, respiratory failure, cardiopulmonary arrest, pneumonia, septic shock, acute respiratory distress syndrome (ARDS)
- Outpatient management of patients with tracheostomies (4):
  - Respiratory comfort
  - Ability to tolerate feedings
  - Markers of dehydration
  - Persistence of symptoms warrants admission for further treatment.

### PROGNOSIS

Significant morbidity and mortality

### COMPLICATIONS

- Pneumonia, ARDS, septic shock
- Respiratory failure, multiorgan system failure
- Cardiopulmonary failure and arrest
- The average period of tracheal intubation is 6–7 days.
- Additionally, for tracheostomy patients:
  - Tracheal bleeding
  - Tracheal mucus plugging

## CODES

### ICD9

- 464.10 Acute tracheitis without mention of obstruction
- 464.11 Acute tracheitis with obstruction
- 464.20 Acute laryngotracheitis without mention of obstruction

## PEARLS AND PITFALLS

- Consider tracheitis in patients who present with crouplike illness and toxic appearance that does not improve with standard treatment for croup.
- Be prepared for emergent airway intervention.
- Effective communication with appropriate consultants: ENT, anesthesia, critical care
- Prepare for emergency tracheostomy.
- Prompt antimicrobial treatment
- For patients with tracheostomies, the best guide to antimicrobial therapy is the growth and susceptibilities from previous tracheostomy cultures.

# TRACHEOESOPHAGEAL FISTULA

Sandy Saintonge  
Todd A. Mastrovitch

## BASICS

### DESCRIPTION

- Tracheoesophageal fistula (TEF) is a malformation resulting in abnormal connection between the trachea and the esophagus.
- Rarely can be acquired as a complication of infection, trauma, or caustic ingestion.

### EPIDEMIOLOGY

#### Incidence

- Congenital TEF occurs in ~1/3,500 to 1/4,000 live births.
- >90% of congenital cases are associated with esophageal atresia.
- The incidence of acquired TEF is unknown.

### RISK FACTORS

- Prenatal exposure to methimazole used to treat maternal hyperthyroidism
- The acquired form may be a consequence of tracheal injury due to caustic ingestions, battery ingestion, or prolonged intubation.
- TEF can also rarely be a complication of respiratory tract malignancies.

### PATHOPHYSIOLOGY

- The congenital form is due to abnormal development during the embryonic period.
- Tracheal injury due to prolonged intubation or high cuff pressure, ingestion of caustic substances, and infection can directly damage the tracheal tissue, leading to fistula formation.

### ETIOLOGY

Several theories related to aberrant embryonic foregut development exist.

### COMMONLY ASSOCIATED CONDITIONS

- 2/3 of patients with TEF have other associated anomalies (cardiac, genitourinary, atresias, skeletal, and CNS).
- Congenital TEF is usually associated with esophageal atresia.
- May be associated with other congenital malformations, including cardiac, GI or genitourinary, musculoskeletal anomalies
- Specific association with trisomy 13, 18, and 21

## DIAGNOSIS

### HISTORY

- History of polyhydramnios may be present.
- Respiratory symptoms at or shortly after birth may be secondary to aspiration of gastric contents.
- Excessive salivation that requires suctioning
- Coughing, choking, or respiratory distress during feeding
- Older children may have history of recurrent pneumonias, chronic respiratory problems, or refractory bronchospasm.

### PHYSICAL EXAM

- Vital signs: Tachypnea or hypoxemia may indicate atelectasis, tracheal compression, or aspiration pneumonia.
- HEENT: Abnormal ocular findings may suggest associated syndrome, excessive salivation, perioral cyanosis.
- Lungs: Persistent cough, recurrent cough with feeds; retractions, crackles and/or wheeze with pneumonia or pneumonitis, hoarseness or barking cough:
  - Typically nonfocal if no acute infection
  - There may be evidence of increased respiratory secretions if the defect is large.

- Abdomen: Depending on the specific type of TEF, a flat or scaphoid abdomen may be present. Alternatively, abdominal distention may be present.
- There may be evidence of associated congenital anomalies of the musculoskeletal system.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

- No routine lab tests are necessary.
- Consider serum CBC and blood culture if the patient is febrile.

#### Imaging

- Obtain a chest radiograph to assess for pneumonia.
- To confirm the presence and location of fistula, consider upper GI series, esophagram, or 3D CT scan.

#### Diagnostic Procedures/Other

Flexible bronchoscopy or esophagoscopy can be used to localize the fistula and directly evaluate the anatomy.

### DIFFERENTIAL DIAGNOSIS

- GERD
- Tracheomalacia
- Aspiration pneumonia
- Esophagitis
- Esophageal diverticulum
- Zenker diverticulum

## TREATMENT

### PRE HOSPITAL

Routine management of airway, breathing, and circulation

### INITIAL STABILIZATION/THERAPY

- If ill appearing, address ABCs per the Pediatric Advanced Life Support (PALS) algorithm.
- Correction of hypovolemia or metabolic disturbance

### SURGERY/OTHER PROCEDURES

- Surgical correction is the definitive treatment.
- Primary end-to-end anastomosis via thoracotomy or thoracoscopy is the typical method of surgical correction.

### DISPOSITION

#### Admission Criteria

- Critical care admission criteria:
  - Evidence of respiratory distress, especially requiring mechanical ventilation
- Other cases may be admitted to a general ward preoperatively.

#### Discharge Criteria

Reinstitution of oral hydration and oral tolerance of foods.

#### Issues for Referral

Development of recurrent pneumonia may prompt the need for pulmonology consultation or repeat surgical evaluation to revise the TEF repair.

## FOLLOW-UP

### FOLLOW-UP RECOMMENDATIONS

Discharge instructions and medications:

- Close monitoring after surgery for repeat TEF developing; potential postoperative antibiotics and gastric acid-reducing medicine if reflux is a consideration.

### DIET

Slowly return the patient to a normal diet after surgery. After the postoperative period, nutrition and oral fluids as tolerated.

### PROGNOSIS

Surgical repair is often curative: Survival rate is 100% in healthy children but decreases to 80–95% in those with comorbidities.

### COMPLICATIONS

- Untreated TEF can lead to lung abscess, bronchiectasis, recurrent pneumonia, acute respiratory distress syndrome, respiratory failure, and death.
- After surgery, anastomotic leak occurs in up to 17%.
- After surgical repair, complications include refistulization or stricture formation.
- Esophageal dysmotility occurs in >75%.
- Gastroesophageal reflux occurs in 40–60%; this persists into adulthood.

### ADDITIONAL READING

- Achildi O, Grewal H. Congenital anomalies of the esophagus. *Otolaryngol Clin North Am.* 2007;40(1):219–244.
- Crabbe DCG. Isolated tracheo-oesophageal fistula. *Paediatr Respir Rev.* 2003;4(1):74–78.

- Orenstein J, Peters J, Khan S, et al. Congenital abnormalities: Esophageal atresia and tracheoesophageal atresia. In Kliegman RM, Behrman RE, Jenson HB, et al., eds. *Nelson Textbook of Pediatrics.* 18th ed. Philadelphia, PA: WB Saunders; 2007.

## CODES

### ICD9

- 530.84 Tracheoesophageal fistula
- 750.3 Congenital tracheoesophageal fistula, esophageal atresia and stenosis

## PEARLS AND PITFALLS

- Most cases of TEF are diagnosed in the neonatal period or early infancy.
- Patients with known TEF who present with new exacerbation of respiratory or GI symptoms should be thoroughly evaluated to rule out issues other than TEF as causative.
- Diagnosis of isolated TEF can be challenging and requires a high index of suspicion.
- Infants with TEF and concomitant esophageal atresia may demonstrate polyhydramnios on prenatal US.

# TRANSFUSION REACTION

Broderick J. Franklin

## BASICS

### DESCRIPTION

- A transfusion reaction (TR) is any undesired physiologic response due to the transfusion of blood or a blood product.
- TR most commonly is due to immune complex interactions but may also be due to other causes (volume transfused, infectious agents, temperature, etc.).

### EPIDEMIOLOGY

- The following is the generally accepted frequency of TR.
- Acute reactions (generally within 1st 6 hr):
  - Febrile nonhemolytic transfusion reaction (FNHTR): 1:50–1:1,000 (all blood components); highest rates with platelets
  - Simple allergic: 1:20–1:4,000 depending on component
  - Severe allergic: 1:20,000–1:50,000
  - Circulatory overload: 1:100–1:6,000 (highest for CHF, end-stage renal disease)
  - Transfusion-related acute lung injury (TRALI): 1:5,000–1:90,000:
    - 2nd or 3rd most common cause of transfusion-related death
  - Acute hemolytic transfusion reaction (AHTR): 1:13,000–1:180,000:
    - Most common cause of transfusion-related death
  - Bacterial sepsis: 1:500,000–1:500,000 (higher rates in platelets):
    - 3rd most common cause of transfusion-related death
- Delayed reactions (generally 2 days to 2 wk):
  - Alloimmunization to RBC antigens: 1:10–1:100
  - Hemolytic TR: 1:4,000–1:11,000
  - Graft versus host disease (GVHD): 1:4,000,000

### RISK FACTORS

- Patients who have received multiple transfusions
- Patients with baseline “high-states” volume (eg, CHF, renal failure)
- Previous febrile TRs
- Receiving emergency un–cross-matched blood
- GVHD risk factors: Hematologic malignancies, immune deficiencies, newborns, marrow stem cell recipients, recipients of blood from 1st-degree relative, recipient of HLA-matched components (excluding stem cells)
- Previous transfusion while pregnant
- Female donor plasma or apheresis fresh frozen plasma (FFP)
- Donor products that are not leukocyte reduced

### GENERAL PREVENTION

- Any institution where blood or blood products are transfused to patients should ensure the following:
- Strict adherence to guidelines for the collection of blood and identification of blood products and recipients
  - Pretreat with acetaminophen if known history of transfusion fevers.
  - Leukocyte reduction filters if history of transfusion fevers or allergic reactions

- Pretreat with diphenhydramine if history of allergic reactions during transfusions.
- IgA-deficient recipients require plasma products from IgA-deficient donors to prevent severe allergic reactions.
- High-risk patients for volume overload (CHF, renal failure) should be given diuretics after transfusion.
- GVHD risk: *Irradiate* all lymphocyte-containing blood products. Leukocyte reduction will not prevent GVHD.
- Rapid and/or large-volume transfusions should be warmed.
- Use of male-only donors for FFP and apheresis platelets
- Use of leukocyte-reduced products whenever possible

### PATHOPHYSIOLOGY

- FNHTR:
  - Antibodies against donor WBC HLAs in compatible blood products
  - WBC-released cytokines and complement cause fever.
  - Accumulated proinflammatory mediators in nonblood products (increase related to length of storage)
- Allergic reaction—minor:
  - Recipient’s IgE antibodies react with allergen(s) in donor plasma.
  - This leads to cytokine release from mast cells and basophils.
- Major allergic reaction (anaphylaxis):
  - Usually in IgA-deficient recipient
  - Anti-IgA IgE antibodies bind to IgA in donor plasma.
  - Results in anaphylaxis
- AHTR:
  - Caused by ABO incompatibility
  - Recipient’s plasma antibodies attack donor RBC antigens
  - Donor RBCs are destroyed.
  - Extravascular hemolytic reactions caused by antibodies to Rh or non-ABO antigens
- Delayed hemolytic TR:
  - ABO incompatibility just as in AHTR
  - Low antibody levels = delayed response
- Circulatory overload:
  - High osmolar load of blood products draws volume into the intravascular space.
- TRALI (2 proposed mechanisms):
  - Donor WBC anti-HLA and antigranulocyte antibodies in plasma injure recipient lung tissue.
  - Activation of “primed” recipient neutrophils by donor plasma antibodies, lipids, and cytokines
  - Higher incidences are found in female-donor FFP and apheresis platelets.
- GVHD:
  - Usually due to immunocompetent-donor T lymphocytes attacking tissues of immunocompromised host
- Massive transfusion complications:
  - Dilution of clotting factors
  - Volume overload
  - Hypothermia
  - Hypocalcemia (citrate binding of calcium)
  - Metabolic alkalosis and hypokalemia from large amount of citrated cells

- Sepsis:
  - Bacterial infection causes overwhelming sepsis: High mortality rates

### ETIOLOGY

- Human error/clinical error is the most common cause for hemolytic reactions due to incompatible blood.
- Compatible blood immune-mediated TRs are caused by “normal” antibody-antigen reactions.
- Other (nonimmune) contributing factors to adverse reactions:
  - Volume transfused
  - Rate of transfusion
  - Temperature of transfused product
  - Contamination of blood component during collection or processing

## DIAGNOSIS

### HISTORY

- In acute reactions, the history is based on patient or subject’s symptoms and/or observation of nurses during or shortly after transfusion.
- FNHTR: Fever, chills, headache, anxiety; difficult to initially distinguish from hemolytic reaction or sepsis
- Minor allergic reactions: Pruritis
- Major allergic reactions: Headache, dizziness, shortness of breath, nausea, vomiting, diarrhea
- AHTR: Fever, chills, nausea, headache, joint and muscle pain, oliguria, hematuria
- Delayed hemolytic reaction: Same as acute but later; usually less severe and may even be asymptomatic
- Circulatory overload: Shortness of breath
- TRALI: Shortness of breath, cough
- GVHD: Fever, vomiting, diarrhea, abdominal pain
- Massive transfusion: Chills, shortness of breath, abdominal pain, muscle cramps
- Sepsis: Chills, rigors, fever, dyspnea, dizziness

### PHYSICAL EXAM

- Physical exam findings themselves are not specifically diagnostic but usually are part of a constellation of signs and symptoms.
- FNHTR: Rise of 1.8°F or 1.0°C above pretransfusion temperature, tachycardia
- Minor allergic reaction: Urticaria
- Major allergic reaction: Stridor, wheezing, hypotension, urticaria, tachycardia
- AHTR: Fever, hypotension, tachycardia
- Delayed hemolytic reaction: Fever but often no physical exam findings
- Circulatory overload: Tachypnea, rales, wheezing, hypoxemia
- Acute lung injury: Tachypnea, hypoxemia, hypotension, fever
- Massive transfusion: Hypothermia, wheezing, rales, muscle spasms
- GVHD: Rash, fever
- Sepsis: High fever, tachycardia, low BP

**DIAGNOSTIC TESTS & INTERPRETATION****Lab****Initial Lab Tests**

- No diagnostic test for most reactions
- Coombs test, haptoglobin, lactate dehydrogenase, bilirubin, and urinalysis may aid in diagnosing hemolytic reaction.
- CBC, LFTs in suspected GVHD; pancytopenia and elevated transaminases
- If undergoing massive transfusion, serially measure: PT/PTT, calcium, potassium, and pH, after every 15–20 mL/kg packed RBCs
- The above should also be measured at any time there are signs/symptoms of coagulopathy.
- Sepsis: Culture of donor product and recipient blood

**Imaging**

CXR may be helpful in diagnosing volume overload and acute lung injury.

**Pathological Findings**

- In GVHD, skin biopsy typically shows vacuolation of basal epithelial cells, lymphocytic infiltration, and necrotic keratinocytes.
- In GVHD, HLA analysis of circulating lymphocytes will identify lymphocytes with different HLA type than that of the host.

**DIFFERENTIAL DIAGNOSIS**

- Allergic reaction
- Fever
- Hemolysis
- Sepsis
- CHF
- Hypocalcemia
- Hyperkalemia

**TREATMENT****INITIAL STABILIZATION/THERAPY**

- Immediately discontinue transfusion.
- Maintain normal saline infusion.
- Verify patient and blood identifiers; do not discard any units or packs of blood products, as they may be needed for subsequent testing.
- Clinically assess the patient.
- Send posttransfusion specimen and donor blood product to the blood bank to test for ABO compatibility and cultures.
- If isolated urticaria only: Many institutions allow continued transfusion of the same unit.
- All other reactions will require new blood product.
- Medication, when used, does not eliminate reaction but helps to ameliorate symptoms.

**MEDICATION**

- The use of medication in the emergency care setting will depend on the type of TR.
- AHTR: Furosemide 1 mg/kg/dose IV q8h to maintain urine flow
- FNHTR: Acetaminophen 10–15 mg/kg PO/PR q4h, max single dose 650 mg

- Anaphylactic reactions:
  - Epinephrine 0.01 mg/kg/dose IM/SC, max single dose 0.5 mg. Using 1:1,000 solution 0.01 mL/kg, empiric dose 0.3 mL IM/SC
  - Diphenhydramine 1.25 mg/kg IV/PO q6h
  - Dexamethasone 0.3 mg/kg IV/IM/PO, max single dose 15 mg
  - Methylprednisolone 1 mg/kg/24 hr IV divided q6–12h
- Minor allergic reaction: Diphenhydramine 1.25 mg/kg/dose IV/PO q6h, max single dose 50 mg
- Transfusion-related lung injury: Oxygen
- Volume overload:
  - Oxygen
  - Furosemide 1 mg/kg IV q4–8h mg/kg IV
- Complications from massive transfusion: May require calcium, potassium, or FFP

**SURGERY/OTHER PROCEDURES**

- Foley catheter to ensure and measure continuous urine output in hemolytic reaction
- Mechanical ventilation if severe respiratory compromise from volume overload, hemolytic reaction, or anaphylaxis
- Acute lung injury will require mechanical ventilation in 70–75% of patients.

**DISPOSITION****Admission Criteria**

- Admit *all* with suspected AHTR, TRALI, GVHD, volume overload, bacterial contamination, and severe allergic reactions.
- Any patient requiring transfusion for *new* diagnosis of anemia in the emergency department should already be admitted, no matter how minor the reaction.
- Febrile reaction with additional symptoms or with fever that does not resolve after 2 hr

**Discharge Criteria**

Discharge from the emergency department only for patients with chronic asymptomatic anemia and TR that have:

- Minor allergic reactions
- Brief (<2 hr) FNHTRs
- Delayed hemolytic reaction with stable hematocrit and only minor symptoms
- Clinically stable after 4–6-hr observation period

**Patient Monitoring**

Cardiac monitoring and pulse oximetry for all patients receiving transfusions

**PROGNOSIS**

- Simple febrile, minor allergic, delayed hemolytic, and volume overload patients almost always respond to symptomatic management with virtually no associated mortality or serious sequelae; the overwhelming majority of TRs are one of these low morbidity reactions.
- Posttransfusion anaphylaxis in general has a mortality rate of 0.6–2%.

- AHTR: Usually responds to treatment if caught early, but mortality is 17–20%.
- TRALI: Most resolve within 72 hr, but mortality may be as high as 6–10%.
- GVHD: Mortality may be >90%.

**COMPLICATIONS**

- Acute lung injury
- Shock
- Multisystem organ failure
- Death

**See Also (Topic, Algorithm, Electronic Media Element)**

Anaphylaxis

**ICD9**

- 780.66 Febrile nonhemolytic transfusion reaction
- 999.80 Transfusion reaction, unspecified
- 999.89 Other transfusion reaction

**PEARLS AND PITFALLS**

- Serious reactions may initially appear minor, so fully investigate *all* febrile reactions.
- Make sure that appropriately prepared components are ordered when indicated (ie, leukocyte poor, irradiated, etc.).
- Observed patients to be discharged for a minimum of 4 hr after symptom onset even if all seems well 1–2 hr after symptoms.

# TRANSIENT SYNOVITIS

Brandon C. Carr

## BASICS

### DESCRIPTION

- Transient synovitis (TS), also referred to as toxic synovitis, is a benign, self-limited inflammation of the synovial lining.
- Most commonly affects the hip joint
- Most commonly diagnosed cause of painful hip in children

### EPIDEMIOLOGY

#### Incidence

- 0.4–0.9% of annual pediatric emergency department visits (1)
- Accounts for 30% of all nontraumatic limps (2)
- The risk of a child developing TS at some point is 3% (1).

### RISK FACTORS

- Preceding viral upper respiratory infection (3)
- Sex: Males are affected twice as often as females (3).
- Autumn season (1)

### PATHOPHYSIOLOGY

- Exact mechanism unknown
- Viral agents suspected, as the condition often follows a viral upper respiratory infection
- Minor trauma and allergic predisposition has been suggested.

### ETIOLOGY

Unknown

## DIAGNOSIS

### HISTORY

- Child usually between 3 and 8 yr of age
- Refusal to walk or limp, sometimes insidious onset
- Symptoms usually present for <1 wk.
- Pain in hip, knee, or leg
- May occur 1–2 wk after an upper respiratory infection

### PHYSICAL EXAM

- Generally well appearing
- Afebrile or low-grade fever usually not exceeding 38°C
- Hip typically held in flexion and external rotation
- Most commonly unilateral, but bilateral in 5% of cases (3)
- Able to maintain passive range of motion without guarding

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

- TS is a diagnosis of exclusion: Lab testing is necessary to exclude other diagnoses, but there is no confirmatory test for TS.
- WBC count
- ESR
- C-reactive protein
- These initial lab studies assessing inflammation may be slightly elevated but are usually normal.

### Imaging

- The typical approach includes hip x-ray including a frog-leg (Lauenstein) view.
- X-ray of the femur and tibia/fibula may also be considered to rule out fracture or lesion.
- If pathology such as avascular necrosis of the femoral head is in question after x-rays, radionuclide bone scan may be obtained.
- Hip US may demonstrate a joint effusion.
- MRI may play a role in the evaluation of hip pain.

### Diagnostic Procedures/Other

Arthrocentesis is the gold standard for diagnosing and excluding septic arthritis:

- This is usually conducted based on suspicion of septic arthritis, which may include fever, abnormal lab tests, hip effusion, and physical exam.
- In TS, the synovial fluid is clear with a low WBC, absence of organisms on Gram stain, and negative cultures.

### DIFFERENTIAL DIAGNOSIS

- Septic arthritis
- Juvenile rheumatoid arthritis
- Legg-Calvé-Perthes disease
- Lyme disease
- Osteomyelitis
- Slipped capital femoral epiphysis (SCFE)
- Tumor
- Fracture
- Serum sickness
- TB
- Psoas abscess
- Foreign body in sole of the foot

## TREATMENT

### MEDICATION

Ibuprofen 10 mg/kg PO q6h; provides analgesia and anti-inflammatory effect

### SURGERY/OTHER PROCEDURES

Arthrocentesis may be indicated to evaluate for septic arthritis.

### DISPOSITION

#### Admission Criteria

Ill-appearing or febrile child, abnormal initial lab values, inability to passively move the hip, or any other concerns for septic arthritis

#### Discharge Criteria

- Patients for whom a more serious differential diagnosis, particularly septic arthritis, have been eliminated.
- Availability of close follow-up

#### Issues for Referral

Those children whose symptoms do not resolve with a brief period of rest and analgesics or whose symptoms progress need orthopedic evaluation.

## FOLLOW-UP

### FOLLOW-UP RECOMMENDATIONS

- Children should be observed closely with repeat exams for progression of symptoms.
- Consider serial WBC, ESR, and C-reactive protein in uncertain cases.
- Discharge instructions and medications:
  - Ibuprofen 10 mg/kg PO q6h PRN
  - Close observation
  - Rest and resume activity as tolerated.

### PROGNOSIS

TS typically resolves without sequelae.

### COMPLICATIONS

Recurrence rate of 4–17% in 6 mo (4)

### ICD-9 CODES

#### ICD9

- 727.00 Synovitis and tenosynovitis, unspecified
- 727.09 Other synovitis and tenosynovitis

### PEARLS AND PITFALLS

- Pearl:
  - TS should only ever be a diagnosis of exclusion.
- Pitfall:
  - Failure to rule out concerning differential diagnoses including septic arthritis, fracture, and SCFE

# TRANSVERSE MYELITIS

Michael R. Baker  
Peter L. J. Barnett

## BASICS

### DESCRIPTION

- Transverse myelitis is a focal inflammatory disorder of the spinal cord resulting in acute or subacute onset of bilateral motor, sensory, and autonomic dysfunction.
- Weakness of other symptoms typically happens in a very acute manner over hours and in many patients with maximal dysfunction within the 1st 24–36 hr.
- Transverse myelopathy is similar but broader in scope and refers to any acute impairment of spinal cord function.
- Requires evidence of acute inflammation within the spinal cord (MRI or CSF finding)

### EPIDEMIOLOGY

- Incidence is 1–8 new cases per million people per year.
- 28% of cases <18 yr of age; bimodal peak at 0–2 yr of age and 11–18 yr

### RISK FACTORS

- 40% of pediatric patients have had a viral illness within 3 wk of disease onset.
- 30% of pediatric patients have had immunizations within 1 mo of disease onset.

### COMMONLY ASSOCIATED CONDITIONS

See Etiology.

### PATHOPHYSIOLOGY

- Abnormal activation of the immune system causing inflammatory changes in the spinal cord
- The idiopathic form is thought to be secondary to postinfectious autoimmune-mediated injury involving molecular mimicry or microbial superantigens.
- Variable histologic changes reflect heterogeneous underlying etiologies:
  - White matter changes include demyelination and axonal injury
  - Variable gray matter inflammation
  - Variable degree of monocyte and lymphocyte invasion with local astroglial and microglial activation.

### ETIOLOGY

Either idiopathic or due to a heterogeneous group of inflammatory disorders:

- Infection:
  - Viral (HIV, herpes simplex virus, varicella zoster virus, cytomegalovirus, Epstein-Barr virus)
  - Bacterial (mycoplasma, Lyme disease, syphilis)
  - Rarely fungal or parasitic
- Demyelination disorders:
  - Multiple sclerosis
  - Acute disseminated encephalomyelitis
  - Neuromyelitis optica
- Connective tissue and granulomatous disorders:
  - Systemic lupus erythematosus (SLE), Sjögren, scleroderma, Behçet, mixed connective tissue disease
  - Sarcoidosis

## DIAGNOSIS

### HISTORY

- Young children may present with nonspecific symptoms such as irritability, abdominal pain, or reluctance to weight bearing.
- Back pain/stiffness and fever is common.
- Spinal cord dysfunction is bilateral; however, it is not necessarily symmetrical and may present with:
  - Inability to bear weight or reduced spontaneous movement of limbs
  - Limb paraesthesia or sensory loss
  - Urinary urgency or retention
  - Fecal incontinence
- There is progression to peak symptoms between 4 hr and 21 days from onset.
- Enquire about risk factors and disease associations:
  - Infectious symptoms (eg, fever, cough, diarrhea)
  - Recent history of immunizations
  - Previous neurologic deficits (MS)
  - Symptoms of underlying connective tissue disorder (eg, rashes, genital/oral ulcers, hematuria, pleuritic chest pain, joint pains)

### PHYSICAL EXAM

- Neurologic signs are bilateral but not necessarily symmetrical.
- May have respiratory involvement (hypoventilation) or autonomic dysfunction (HTN, tachycardia/bradycardia) if high cord lesion
- Clearly defined sensory level, most commonly:
  - Thoracic > cervical > lumbar > sacral
  - May spare joint and vibration sensation

- Motor weakness in lower limbs +/- upper limbs, initially flaccid but becoming spastic over days to weeks
- Bladder dysfunction:
  - Loss of anal wink and tone
  - Palpable bladder
- Absence of cranial nerve dysfunction. If there is evidence of optic neuritis, consider MS, neuromyelitis optica, or acute disseminated encephalomyelitis (ADEM).

### DIAGNOSTIC TESTS & INTERPRETATION

Essential to the diagnosis of transverse myelitis is evidence of spinal cord inflammation as demonstrated by:

- CSF pleocytosis
- CSF elevated IgG index AND/OR
- Gadolinium-enhanced spinal MRI
- False negatives may occur with these tests. Improved sensitivity may occur by repeat testing in 2–7 days.

### Lab

#### Initial Lab Tests

- CSF (after spinal imaging) for microscopy, culture, sensitivities, viral studies, glucose, protein, IgG index, and oligoclonal bands
- Other tests detect any underlying inflammatory or infectious disease:
  - Full blood exam and film, renal function, liver function
  - Anti-SSA, Anti-SSB, antinuclear antibodies, and complement (eg, SLE, connective tissue disorders)
  - Blood culture, viral and bacterial serology, and polymerase chain reaction (eg, infectious causes)

### Imaging

- As diagnosis requires confirmation of inflammation of the spinal cord, imaging is typically used.
- Gadolinium-enhanced spinal MRI in order to rule out compressive etiology and to confirm diagnosis of acute transverse myelitis:
  - Focal area of increased T2 signal +/- gadolinium enhancement
  - From 1 segment to the entire cord may be involved, average length is 6 segments (1)
- CT spine if expected delay in obtaining MRI or history of trauma to exclude compressive etiology

### Diagnostic Procedures/Other

- Visual evoked potentials to assess for optic neuritis
- Baseline respiratory function tests
- Baseline renal US and urodynamic studies are often obtained, as bladder dysfunction is common.

**DIFFERENTIAL DIAGNOSIS**

- In young children, the presentation of transverse myelitis is frequently nonspecific with symptoms and signs poorly localized to the spinal cord or impaired gait:
  - Discitis
  - Osteomyelitis
  - Arthritis
  - Fracture
  - Slipped capital femoral epiphysis
  - Avascular necrosis of the femoral head
  - Myositis
  - Causes of abdominal pain
- In those with clear neurologic dysfunction, consider:
  - Stroke
  - Multifocal demyelination:
    - MS
    - ADEM
    - Neuromyelitis optica
  - Spinal cord vascular lesions:
    - Ischemia/Infarction
    - Arteriovenous malformations
  - Cord compression:
    - Tumor
    - Abscess
    - Trauma
    - Disc herniation
    - Spondylolisthesis
  - Metabolic disorders:
    - B<sub>12</sub>, folate, or copper deficiency
  - Paraneoplastic syndromes
  - Radiation myelopathy
  - Peripheral neuropathy:
    - Guillain-Barré syndrome

 **TREATMENT**

**INITIAL STABILIZATION/THERAPY**

- Issues of airway, breathing, and circulation should be addressed.
- Other urgent complications, such as acute urinary retention, should be addressed.

**MEDICATION**

**First Line**

- High-dose IV steroids (eg, methylprednisolone 1 g/1.73 m<sup>2</sup>/day for 5 days:
  - Small case series suggests that this speeds recovery and improves long-term outcome.
- Patients with disease associated with transverse myelitis should have therapy targeted at the underlying disease (eg, antibiotic/antiviral medication or immunomodulatory therapy).

**Second Line**

The following therapies may be used in steroid-resistant or severe disease (limited evidence):

- Plasmapheresis
- Pulse dose IV cyclophosphamide 500–1,000 mg/m<sup>2</sup>

**DISPOSITION**

**Admission Criteria**

- All children with proven or suspected transverse myelitis should be admitted for monitoring and further investigation +/- initiation of treatment.
- Critical care admission criteria:
  - Respiratory involvement
  - Rapidly progressive neurologic symptoms
  - High cord lesion

 **FOLLOW-UP**

**FOLLOW-UP RECOMMENDATIONS**

Early involvement of a rehabilitation-focused multidisciplinary team including neurology, physiotherapy, and occupational therapy

**PROGNOSIS**

- Majority show neurologic improvement that begins within 1–3 mo
- Recovery may continue for up to 2 yr.
- Up to 20% have recurrent episodes.
- Persistent bowel and bladder dysfunction is common (>75%).
- Generally:
  - 1/3 recover with no or mild sequelae (eg, constipation)
  - 1/3 have moderate deficits (eg, mild gait disturbance, spasticity, urinary urgency)
  - 1/3 have severe long-term disabilities (eg, inability to walk, absent sphincter control, ongoing sensory deficits)

**COMPLICATIONS**

- Spasticity and contractures
- Pressure areas
- Chronic pain and dysesthesias
- Bowel dysfunction including constipation and incontinence
- Bladder dysfunction including urgency and urinary retention

**See Also (Topic, Algorithm, Electronic Media Element)**

- <http://www.myelitis.org>
- Weakness

 **ICD-9-CM CODES**

**ICD9**

- 323.02 Myelitis in viral diseases classified elsewhere
- 323.52 Myelitis following immunization procedures
- 323.82 Other causes of myelitis

**PEARLS AND PITFALLS**

- Pearls:
  - If onset is very brief or very long, consider other etiology:
    - <4 hr: Consider ischemic etiology (requires urgent imaging).
    - >21 days: Consider MS or compressive etiology.
  - Compared with transverse myelitis, in MS there is:
    - Previous neurologic dysfunction with recovery
    - Partial spinal cord dysfunction
    - Sensory > motor involvement
    - Spinal cord lesion <2 segments long
    - White matter lesions on MRI of the brain
    - Oligoclonal bands on CSF analysis
  - Guillain-Barré syndrome can be differentiated from transverse myelitis, as in Guillain-Barré there is:
    - Ascending sensory and motor deficits
    - No clear sensory level
    - Less commonly bowel and bladder involvement
    - May have cranial nerve involvement
    - No abnormalities on spinal MRI
- Pitfalls:
  - Failure to recognize early respiratory involvement
  - Failure to diagnose a compressive myelopathy
  - Failure to consider transverse myelitis in the young child with irritability and back or abdominal pain

## BASICS

### DESCRIPTION

- Abdominal injury may result from blunt or penetrating trauma.
- Blunt trauma results from increased pressure or direct force to the abdomen.
- Penetrating trauma results from violation of the abdomen by a missile, such as a bullet, or an object such as a knife, utensil, etc.
- The spleen is the most common abdominal organ injured, and the liver is 2nd most common injured organ (1):
  - The spleen and liver lie outside the protective bony rib cage and are therefore more prone to injury.

### EPIDEMIOLOGY

- Abdominal trauma is a major cause of morbidity and mortality (2) in pediatric trauma:
  - ~1.5 million children are injured.
  - Results in 500,000 pediatric hospitalizations
  - 120,000 with permanent disability
  - 20,000 deaths
- For penetrating trauma, males have the highest morbidity and mortality:
  - Blacks have the highest mortality, followed by Hispanics, then whites.
  - Most deaths from penetrating trauma are homicide.

### PATHOPHYSIOLOGY

- Blunt trauma results in disruption of tissue by compression, shearing, or stretching.
- Penetrating trauma may result in direct tissue and organ injury as well as laceration leading to hemorrhage.
- Due to the amount of destructive energy imparted, morbidity and mortality from penetrating trauma is greatest with high-velocity missiles such as rifle shots, then lower-velocity missiles such as handgun shots, and lowest with simple stab wounds.
- High-velocity missiles typically result in much greater injury.
- Laceration of solid organs leading to blood loss
- Rupture of hollow organs leading to blood loss and peritoneal contamination:
  - Peritoneal contamination may need 6 hr to manifest as peritoneal irritation.
- Blood loss may manifest as tachycardia and skin changes to anemia, hypotension, and confusion.
  - See both acute to delayed presentations (hours to days)

### ETIOLOGY

- The most common mechanisms of blunt injury are motor vehicle collisions and falls. Other mechanisms include all-terrain vehicle and bicycle accidents, other sports injuries, and nonaccidental trauma:
  - Nature of injury is affected by whether seat belts or helmets were worn.
- The common mechanisms of penetrating injury are gunshot and stab wounds.
- Solid organs are more frequently injured than the viscus organs.

## COMMONLY ASSOCIATED CONDITIONS

Can be associated with multisystem injuries:

- Waddell's triad:
  - Femur fracture with associated abdominal or thoracic injury and head injury

## DIAGNOSIS

### HISTORY

- A focused history to include events leading to presentation, medications, past medical history, allergies, and last eaten meal:
  - Once hemodynamically stable, a detailed history can follow.
- Developmental maturity affects the quality of historical information:
  - Seek history from guardians and witnesses of the accident scene such as paramedics.
  - For stab wounds, the size of the weapon or object, position of the person wielding the object relative to the patient, and path or direction of the weapon
  - For gunshots, the type of weapon, distance from shooter, and number of gunshots

### PHYSICAL EXAM

- Initial exam focuses on ABCs:
  - Once hemodynamically stable, a detailed physical exam can follow.
  - Remember to roll the patient and examine the back.
- Predictors of intra-abdominal injuries, besides abdominal tenderness, are abdominal wall ecchymoses (seat belt signs) (3), abdominal abrasions, abdominal distension, and absent or hyperactive bowel sounds.
- Other signs of intra-abdominal injury include nausea or vomiting, dyspnea, or left shoulder pain with inspiration (Kehr sign) from diaphragmatic irritation.
- Abnormal vital signs (tachycardia, hypotension) or altered mental status may indicate ongoing intra-abdominal blood loss.
- Continued or delayed abdominal pain or tenderness suggest late presenting intra-abdominal injuries.
- Physical exams are unreliable in children with diminished mental status or distracting injuries or in those who have been intubated.
- Exploration of abdominal stab wounds and select low-velocity abdominal gunshot wounds.

## DIAGNOSTIC TESTS & INTERPRETATION

### Lab

#### Initial Lab Tests

Selective testing is useful in both unstable and stable patients (4):

- Type and cross is essential in unstable patients.
- Consider CBC, liver transaminases, and urinalysis:
  - CBC: Serial monitor for ongoing blood loss in solid organ injuries
  - Elevated transaminase levels (ALT > 125 U/L and AST > 200 U/L) are indicative of liver injuries.
  - Urinalysis: Gross hematuria is useful, but microscopic hematuria is controversial (1,5).
- Venous blood gas to determine base deficit may be helpful to quickly determine the level of blood loss and guide IV hydration.
- Limited utility in initial amylase, lipase, coagulation studies, and general chemistries (4)

## Imaging

- CXR, upright KUB may reveal free air under the diaphragm in penetrating trauma:
  - Bullet as well as path of bullet may be visible on abdominal x-ray.
- Plain film of pelvis:
  - Fracture of pelvis and gross hematuria may indicate genitourinary injury.
- Abdominal and pelvic CT is the most common method to image the abdomen:
  - Used in patients who are hemodynamically stable
  - Helpful in evaluating the retroperitoneal space and solid organs
- Grading of liver trauma is done per American Association for the Surgery of Trauma (AAST) guidelines.
- Splenic imaging is to be performed when there is left upper quadrant tenderness, left lower rib fractures, evidence of left lower chest/abdominal contusion, or left shoulder pain (Kehr sign). AAST grading criteria is used here as well.
- Intestinal injuries are much less common than solid organ injuries: 2% of all patients, prospective series (2):
  - Associated with deceleration trauma (lap belt injuries)
  - Injury patterns include perforation, intestinal hematoma, and mesenteric tears with bleeding.
  - Indicative CT findings include pneumoperitoneum, extravasation of contrast, and bowel wall edema (subtle).
  - High index of suspicion for those children with appropriate mechanism and/or corresponding exam
- Pancreatic injuries often show late lab and CT findings:
  - Often associated with a fall into a bicycle handlebar
- Kidneys are the most commonly injured organ within the retroperitoneal space:
  - They are less protected and more mobile.
  - Commonly associated with motor vehicle collision
  - Flank tenderness is seen in association with hematuria.

## Diagnostic Procedures/Other

- US (focused abdominal sonography for trauma [FAST]) may be considered (6):
  - Limited sensitivity ranging from 45–55%:
    - Dependent on operator experience
  - ~40% of abdominal injuries are not associated with free fluid, so this limits the utility of the FAST exam.
  - Even with the detection of free fluid, nonoperative management in those children without symptoms is common.
- Deep peritoneal lavage has limited utility in the pediatric population.

## DIFFERENTIAL DIAGNOSIS

- Lower thoracic injuries, which may cause abdominal pain
- Coexistence of penetrating injuries; exacerbation of chronic or pre-existing medical problems in blunt abdominal trauma

## TREATMENT

### INITIAL STABILIZATION/THERAPY

- Assess and stabilize airway, breathing, and circulation per Advanced Trauma Life Support (ATLS) guidelines:
  - Administer supplemental oxygen, preferably by nonbreather mask.
  - Rule out hypoglycemia, especially in those children with altered mental status.
  - Fluid administration to maintain isovolemia is essential:
    - Placement of Foley catheter, assuming no blood at the meatus, no perineal hematoma or ecchymoses, and normal prostate exam, will help monitor success of fluid resuscitation.
- Maintain normothermia, especially in infants and toddlers, because of greater heat loss by their larger body surface area.
- IV broad-spectrum antibiotics are advocated when peritoneal contamination is suspected.
- Appropriate use of opiates for pain control. Monitor vital signs and mental status changes.

### MEDICATION

#### First Line

- Oxygen is to be administered, especially in those who are in extremis or unstable.
- Hypotensive patients will need isotonic crystalloid given as a 20 mL/kg bolus, up to 3 boluses:
  - If after 40 mL/kg IV has been given and a 3rd bolus is needed, consider transfusing packed RBCs at 10 mL/kg.

#### Second Line

- Tetanus booster for patients with open wounds who are not current
- IV broad-spectrum antibiotics:
  - Cefoxitin 40 mg/kg IV q6h

### SURGERY/OTHER PROCEDURES

- Hemodynamic instability, evisceration, high-velocity gunshot, and most other gunshots warrant exploratory laparotomy.
- Solid organ injuries from blunt trauma are typically managed nonoperative through observation or angiography in hemodynamically stable patients (7):
  - Nonoperative failures result from errors in clinical judgment, missed CT findings, and nonprotocol therapies.
- Blunt trauma requires operative management when there is hemodynamically instability, acute/subacute blood loss, or peritonitis.
- Viscus injuries require operative management because of the risk of peritoneal contamination and blood loss:
  - Even if delayed operative management, the prognosis is usually not adversely affected (5).

### DISPOSITION

#### Admission Criteria

- Ruptured viscus:
  - Peritonitis on physical exam
- Patients with inadequate home environment
- Critical care admission criteria:
  - Hemodynamic instability, requirement for extensive hemodynamic monitoring or pressors
  - Multisystem organ injuries
  - Mechanical ventilations, patients requiring ventilator support
  - Mechanism of trauma, when there is considerable energy and/or forces

#### Discharge Criteria

- Normal exam and low suspicion of intra-abdominal injury
- Discharge patients with normal physical exams and normal abdomen and pelvis CT scans (8).

#### Issues for Referral

- Involve trauma surgeons as soon as possible in the setting of significant abdominal trauma, especially with unstable vital signs.
- Transfer patients when there are no CT capabilities or no pediatric surgical consultants or pediatric intensivists.

## FOLLOW-UP

### FOLLOW-UP RECOMMENDATIONS

Discharge instructions and medications:

- Advise the caregivers to monitor for development of abdominal pain and tenderness, changes in feedings, changes in bowel or bladder functions, and respiratory difficulty.
- There is a delayed presentation of bowel injuries and pancreatic injuries, > 1 day post-event.

- Trauma, Perineal

### ICD9

- 868.00 Injury to unspecified intra-abdominal organ without mention of open wound into cavity
- 868.10 Injury to unspecified intra-abdominal organ, with open wound into cavity
- 959.12 Other injury of abdomen

### PEARLS AND PITFALLS

- Consider multisystem injuries due to widely distributed force over a smaller body size.
- The liver and spleen are especially prone to injuries.
- Children have high physiologic reserves to maintain BP when blood volume loss reaches 25–30%. Monitor heart rate as an indicator for impending shock.

# TRAUMA, ANKLE

Yu-Tsun Cheng  
Vincent J. Wang

## BASICS

### DESCRIPTION

- Ankle trauma in the pediatric patient encompasses a wide range of injuries:
  - This topic focuses on bony and physeal injury.
  - Selected soft tissue injuries will be discussed:
    - See the Ankle Sprain topic.
- Salter-Harris (SH) classification of physeal fractures:
  - SH-1: Physeal separation
  - SH-2: Extends transversely through physis and exits through metaphysis (+ triangular fragment known as the Thurston-Holland or corner sign)
  - SH-3: Extends transversely through physis and exits through epiphysis
  - SH-4: Fracture line passes through epiphysis, across physis, and exits metaphysis
  - SH-5: Crush injury to physis:
    - Comparison views of unaffected limb may aid in diagnosis.
  - SH-6: Perichondral ring injuries:
    - Often from penetrating trauma
- Clinical significance of SH classification:
  - SH-2 with higher risk of growth arrest (ossification progresses from epiphyseal to metaphyseal side)
  - Given involvement of articular surface, SH-3 and SH-4 often require anatomic reduction.
  - Growth arrest and functional disturbance are very likely with SH-5 and SH-6.
- Danis-Weber classification of distal fibular fractures:
  - A: Below ankle mortise, stable fracture
  - B: At the mortise, +/- stable depending on concomitant injury to medial side
  - C: Above the mortise, unstable fracture requiring open reduction internal fixation (ORIF)

### EPIDEMIOLOGY

- ~2% of children in the emergency department present with acute ankle and mid-foot injury.
- Ankle fractures account for ~5% of pediatric fractures:
  - Male > female
  - Peak incidence in those 8–15 yr of age
  - Isolated distal fibular fractures are the most common fracture of the lower extremity (1).
- 0.1% of children per year will sustain an ankle fracture.

### RISK FACTORS

- Regarding ankle trauma:
  - Sports participation
  - Obesity (2)
  - Inadequate rehabilitation following prior injury
- Regarding ankle fractures:
  - Sports participation
  - Puberty (period of rapid skeletal growth)

### PATHOPHYSIOLOGY

- The ankle is a hinge joint with the ankle mortise composed of the lateral and medial malleoli and the undersurface of the tibia (plafond).
- Body of the talus inset into mortise:
  - Body of the talus is wider anteriorly than posteriorly:
    - Ankle more stable in dorsiflexion
    - Ankle less stable in plantar flexion
- Skeletally immature bones have unique anatomy:
  - Cartilaginous growth centers (physis, apophysis)
  - Cortex less dense with thicker periosteum (greater deformation capacity)
  - Robust vascular supply (greater and faster remodeling potential)
- Physeal plates weaker than ligaments and tendons in children:
  - Rapid bony growth relative to soft tissues adds further stress to physeal plates (especially in active children).
- Injury patterns different in the skeletally immature ankle:
  - Both medial and lateral ligamentous structures arise from the tibial and fibular epiphyses, respectively:
    - Consider with caution the diagnosis of ankle sprain or strain in the younger patient.
  - Closure of the distal tibial physis progresses from central to medial and then lateral, leading to unique fracture patterns in the skeletally immature (Tillaux and triplane).

### ETIOLOGY

- Peroneal subluxation/dislocation:
  - Mechanism of injury involves hyperdorsiflexion +/- eversion.
  - Suspect in lateral ankle injury with sensation of recurrent snapping over lateral malleolus
- Select sports-specific injuries to consider:
  - Dancers: Posterior ankle impingement from an os trigonum
  - Figure skaters: Malleolar bursitis due to friction from the boot
  - Ice hockey: Anterior tibialis tendon laceration:
    - Wearing the boot tongue downward is a risk factor (boot lace laceration).
  - Snowboarding: Fracture of lateral talus due to ankle inversion (snowboarder fracture)
- Maisonneuve fracture:
  - External rotation with eversion transmits a force that injures the medial ankle, then ruptures the anterior tibiofibular ligament, disrupts the syndesmosis, and finally results in a proximal fibular fracture.
- Tillaux fracture:
  - External rotation force pulls the anterior inferior tibiofibular ligament at its attachment to the anterolateral portion of the distal tibial physis.
- Triplane fracture:
  - External rotation forces result in fracture of the distal tibial physis where the fracture line extends in 3 planes (transverse, sagittal, coronal).

- Ankle dislocation:
  - Requires high energy force with the ankle, typically in plantar flexion
- Consider child abuse or pathologic lesions if the fracture pattern does not match the history or stated mechanism of injury.

### COMMONLY ASSOCIATED CONDITIONS

Ankle injuries may be associated with foot injuries:

- Lisfranc injury
- 5th metatarsal bone:
  - Styloid avulsion fractures and apophysitis
  - Fracture at the metaphyseal–diaphyseal junction (Jones fracture)

## DIAGNOSIS

### HISTORY

- Mechanism of injury:
  - Most common mechanism: Inversion with plantar flexion and internal rotation
  - Consider sports-specific injuries: See the Etiology section for details.
- Timing/Duration of injury: Acute vs. chronic
- “Pop” suggests torn ligament, fracture, or tendon subluxation/dislocation.
- Prior ankle injury or surgery
- Ability to continue activities after injury
- Location of pain and swelling
- Inquire about numbness, tingling, coolness
- Inquire about constitutional symptoms
- Tetanus vaccination history
- Lack of trauma should prompt more detailed questioning:
  - Juvenile rheumatoid arthritis: Morning stiffness, other joint complaints
  - Gonococcal arthritis: Sexually active adolescents

### PHYSICAL EXAM

- Compare vs. the unaffected ankle.
- Proceed with a slow and gentle approach
- Inspection (deformity, swelling, effusion, ecchymoses)
- Assess the foot since mechanisms injuring the ankle also can affect the foot.
- Palpation (know your anatomy, start away from injury, palpate proximal fibula, palpate distal tibial and fibular physes, palpate base of 5th metatarsal and navicular bones):
  - Distal fibular and tibial physes located ~2 cm from tip of either malleolus
  - Tenderness to palpation (TTP) over the lateral talus (1 cm inferior to the tip of the lateral malleolus) after an inversion injury suggests a fracture to the lateral talus.
  - TTP over the proximal fibula following external rotation with eversion of the ankle suggests an unstable Maisonneuve fracture.
- Assess: Neurovascular integrity, range of motion, strength
- Stress testing (see the Ankle Sprain topic for details): Anterior drawer, talar tilt (inversion stress test), squeeze test, external rotation

**DIAGNOSTIC TESTS & INTERPRETATION****Imaging**

- Plain radiographs:
  - Physseal TTP is an indication for x-rays.
- Ottawa Ankle Rules (OAR):
  - Studies support the use of OAR in pediatric patients >6 yr of age (sensitivities ranging from 98.5–100%) as a reliable tool to exclude significant ankle and midfoot fractures (3,4).
  - Obtain ankle x-rays (AP, lateral, and mortise views) with acute injury with pain in the malleolar region and any of the following:
    - Bony TTP along the distal 6 cm of the posterior edge of either malleolus
    - Inability to weight bear 4 steps immediately after the injury or in the emergency department
- Syndesmosis (high ankle) injury:
  - Consider stress views (ankle slightly dorsiflexed while applying an external rotation force).
  - Radiographic ankle mortise widening supported by AP views demonstrating:
    - Medial clear space (lateral border of medial malleolus to medial border of talus measured at level of talar dome) >4 mm
    - Tibiofibular overlap (of anterior tibial tubercle and lateral malleolus) <6 mm
- Accessory ossicle:
  - Often bilateral and can differentiate from fracture with comparison views and clinical correlation (TTP)
  - Has smooth, rounded cortical surface
  - May appear displaced after ankle injuries
- Maisonneuve fracture:
  - X-ray the entire length of the fibula.
- Suspected triplane fractures should undergo CT scanning (before or after casting), which is superior to plain radiographs, to assess the fracture pattern and determine treatment (inadequate closed reduction or fragment displacement >2 mm is an indication for ORIF).

**DIFFERENTIAL DIAGNOSIS**

See Etiology.

**TREATMENT****PRE HOSPITAL**

- Immobilize suspected fractures prior to transport (reduces pain)
- Assess neurovascular status regularly.
- Consider closed reduction of fracture or dislocation if transport to a medical center is delayed or neurovascular status is compromised.

**INITIAL STABILIZATION/THERAPY**

- Reverse neurovascular compromise.
- Provide adequate analgesia.
- Identify injuries requiring an orthopedist.
- With fractures, when neurovascular integrity is ensured, provide an insulated cold pack with elevation and immobilization in a bulky compressive dressing with splinting:
  - Cover open fractures with a wet sterile dressing.
- For distal fibula, nondisplaced SH-1 and SH-2 fractures or avulsion fractures:
  - Short leg walking cast (SLWC) or walking fracture boot
  - Splinting with protected weight bearing is an alternative (1).

- Isolated nondisplaced or minimally displaced Danis-Weber A fracture:
  - SLWC or walking fracture boot
  - Splinting with protected weight bearing
- Small, isolated, nondisplaced avulsion fractures of the lateral or medial malleolus:
  - SLWC, splint, or walking fracture boot
- Nondisplaced SH-1 fracture of the distal tibia:
  - SLWC or splint
- Nondisplaced SH-2 fracture of the distal tibia:
  - Long leg cast or splint
- Orthopedic consultation indicated for:
  - Fractures with neurovascular compromise
  - Open fractures
  - Unstable fractures (including Maisonneuve, bi- and trimalleolar, Danis-Weber B or C, fracture-dislocations, fractures on 1 side with ligament disruption on the other)
  - Displaced SH-1 and SH-2 fractures
  - SH-3 (including Tillaux), SH-4 (including triplane), SH-5, SH-6 fractures
  - Displacement of fragments >2 mm

**MEDICATION**

- Ibuprofen 10 mg/kg PO Q6h PRN
- Acetaminophen and codeine:
  - Acetaminophen 15 mg/kg PO q4h PRN
  - Codeine 1 mg/kg PO q4h PRN
- Morphine 0.1 mg/kg IV/IM/SC q2h PRN:
  - Initial morphine dose of 0.1 mg/kg IV/SC may be repeated q15–20min until pain is controlled, then q2h PRN.

**DISPOSITION****Admission Criteria**

- Neurovascular compromise
- Need for operative fixation

**Discharge Criteria**

- Appropriate immobilization if indicated
- Adequate pain control
- Appropriate follow-up

**FOLLOW-UP****FOLLOW-UP RECOMMENDATIONS**

- Discharge instructions and medications:
  - Appropriate cast care (keep dry; return immediately for any tightness or numbness felt in the distal extremity or foot)
  - Elevate the affected limb.
  - Pain control
  - Follow up with orthopedics/sports medicine to observe for appropriate healing and vigilance regarding growth arrest in the skeletally immature.
- Activity:
  - In context of appropriate follow-up, tolerance of pain may guide the patient's return to activity.

**PROGNOSIS**

Most pediatric ankle fractures will heal without significant long-term complications.

**COMPLICATIONS**

- Growth arrest:
  - Distal tibial physis contributes to 40% length of the tibia, and the distal fibular physis contributes to 20% growth of the lower extremity:
    - Growth arrest at the distal fibula is rare.
- Angular deformities
- Osteoarthritis and ankle stiffness
- Osteomyelitis

**REFERENCES**

**ICD-9 CODES**

- 824.8 Unspecified fracture of ankle, closed
- 837.0 Closed dislocation of ankle
- 959.7 Other and unspecified injury to knee, leg, ankle, and foot

**PEARLS AND PITFALLS**

- Consider with caution the diagnosis of ankle sprain or strain in the younger patient.
- Correlate the x-ray with clinical findings (may simply have an accessory ossicle).
- Limit reduction attempts (preferably 1) to spare further physseal injury.
- Anatomic reduction and alignment are important to limit complications of physseal injury.

## BASICS

### DESCRIPTION

- Common thoracic organs at risk for blunt injuries are the heart and lungs, with additional concerns for the great vessels, esophagus, tracheobronchial system, diaphragm, ribs, and thoracic wall.
- Most children who die as a result of blunt thoracic trauma die from associated injuries:
  - However, intrathoracic injuries are the major cause of mortality in children with penetrating chest trauma.
- This topic focuses primarily on blunt thoracic trauma.

### EPIDEMIOLOGY

- Thoracic injuries account for 4–6% of children hospitalized for trauma (1).
- Chest trauma accounts for up to 26% of pediatric trauma deaths (1).
- Up to 40% of chest trauma patients will have additional extrathoracic injuries (2).

### PATHOPHYSIOLOGY

- Injuries may occur via compression, direct trauma, or acceleration/deceleration forces:
  - Pulmonary contusions result from shearing and bursting forces, which in turn lead to alveolar disruption, alveolar hemorrhage, and interstitial edema.
  - Blunt cardiac injuries range from a myocardial contusion to myocardial rupture with or without valve involvement.
- Anatomic differences exist between adult and pediatric patients:
  - Children have highly compliant chest walls due to greater cartilage content and incomplete ossification of ribs:
    - As a result, bending of the ribs without breaking is often seen.
  - Children have a mobile mediastinum:
    - As a result, pneumothoraces, hemothoraces, and diaphragmatic hernias may decrease systemic venous return from the kinking of the great vessels.

### ETIOLOGY

The most common etiologies are motor vehicle crashes, pedestrian accidents, and falls.

### COMMONLY ASSOCIATED CONDITIONS

Can be associated with multisystem injuries, such as head, spinal, and abdominal injuries

## DIAGNOSIS

### HISTORY

- A focused history should include events leading to presentation, medications, past medical history, allergies, and the last meal eaten:
  - Once hemodynamically stable, a detailed history can follow.
  - Developmental maturity affects the quality of historical information.
- History of trauma is typical:
  - Mechanism of injury
  - Time of injury, speed of collision, seat belt use, air bag deployment and estimate of deceleration are all important historical factors.
  - An EMS scene report is helpful.
- Difficulty breathing, dyspnea, or chest pain following trauma
- Hemoptysis

### PHYSICAL EXAM

- Initial exam should focus on airway, breathing, and circulation:
  - Assess vital signs, with attention to respiratory rate and oxygen saturation.
  - Once hemodynamically stable, a detailed physical exam can follow.
- Predictors of thoracic injuries are chest crepitance, subcutaneous emphysema, nasal flaring, hemoptysis, chest retractions, diminished or absent breath sounds, and tachypnea.
- Pneumothorax, hemothorax, and pneumohemothorax will have decreased breath sounds on the affected side, abnormal percussion sounds and, at times, tracheal deviation away from the affected side if tension is present.
- Rib fractures often result in bony tenderness and respiratory distress associated with pain with respiration.
- Pulmonary contusions are often associated with hypoxemia, hypercarbia, and tachypnea.
- Traumatic asphyxia is often associated with cyanosis, hemoptysis, and subconjunctival hemorrhages on the chest, face, and neck.
- Tracheobronchial injury may manifest as a pneumothorax, hemothorax, pneumomediastinum, hemoptysis, or subcutaneous emphysema:
  - Suspect this injury when there is a persistent pneumothorax that does not resolve after a tube thoracostomy, a continuous air leak, or a persistent pneumomediastinum.
- Great vessel injuries are associated with 1st rib and sternal fractures, upper extremity HTN, or lower extremity pulse deficits.
- Diaphragmatic rupture may mimic signs and symptoms of a pneumothorax, but bowel sounds may be auscultated in the chest:
  - Nearly 1/2 the patients do not have physical findings or signs of external trauma (1).

## DIAGNOSTIC TESTS & INTERPRETATION

### Lab

#### Initial Lab Tests

No specific lab test is useful in the initial management of blunt thoracic injuries:

- CBC to monitor hematocrit and any ongoing blood loss, if any concerns
- Any routine lab assays used for patients with trauma or preoperatively
- Consider ECG and cardiac enzymes when concerned about cardiac injury:
  - Troponin I is more sensitive than CK-MB.

### Imaging

- Chest radiograph is the initial radiologic study indicated:
  - As per Advanced Trauma Life Support (ATLS) recommendations, the cervical spine, pelvic, and AP chest radiographs should be obtained to screen for injuries.
  - When present, thoracic injuries were identified in 63% on the initial CXR (3).
  - Opacification of lung parenchyma is seen on CXR within 3.5 hr after the trauma (4).
- Fluoroscopy:
  - Can be used to diagnose diaphragmatic rupture
- Chest CT is more sensitive than CXR:
  - Consider helical chest CT for definitive imaging.
  - CT identified 30% more thoracic injuries and changed the management of 15% of those with normal CXR (5).

### Diagnostic Procedures/Other

- US, in the proper clinical situation, allows for the diagnosis of pleural fluid, pneumothorax, pulmonary contusion, pericardial tamponade, diaphragmatic rupture, and sternal fractures.
- Echo is especially useful in symptomatic patients with hypotension.
- Consider rigid or flexible bronchoscopy for airway injuries, especially for tracheobronchial injuries.
- Consider esophagram or endoscopy for the diagnosis of esophageal injuries.

### DIFFERENTIAL DIAGNOSIS

Referred pain from other organ systems such as the GI tract (perforated viscus), nervous system (neuropathic pain), or vascular system (dissection)

## TREATMENT

### PRE HOSPITAL

Assess and stabilize airway, breathing, and circulation:

- Administer supplemental oxygen, preferably by nonrebreather mask.
- Remember to consider spinal immobilization when appropriate.

**INITIAL STABILIZATION/THERAPY**

- Assess and stabilize airway, breathing, and circulation per ATLS and Pediatric Advanced Life Support (PALS) guidelines:
  - Administer supplemental oxygen.
  - Needle decompression of tension pneumothorax:
    - 6.7% of blunt thoracic injuries require surgery or thoracostomy tube (1).
- IV crystalloid when concerns of intravascular volume loss:
  - After 2 IV normal saline boluses of 20 mL/kg in the setting of shock, consider a packed RBCs transfusion.
- Analgesics as needed
- Involve surgical consultants as soon as possible for patients with unstable vital signs or concerns of significant injuries.
- In rare cases, antiarrhythmic and inotropic agents may be needed for symptomatic patients.
- Medical control of the BP via beta-blocker (eg, labetalol) can reduce shear forces when great vessels injuries occur.
- Antibiotics such as a broad-spectrum antibiotics that may include penicillin, aminoglycoside, clindamycin, or metronidazole for esophageal rupture due to contamination by GI flora into the mediastinum

**MEDICATION****First Line**

- Opioids:
  - Morphine 0.1 mg/kg IV/IM/SC q2h PRN:
    - Initial morphine dose of 0.1 mg/kg IV/SC may be repeated q15–20min until pain is controlled, then q2h PRN.
  - Fentanyl 1–2  $\mu$ g/kg IV q2h PRN:
    - Initial dose of 1  $\mu$ g/kg IV may be repeated q15–20min until pain is controlled, then q2h PRN.
- Penicillin G 150,000–300,000 units/kg/day IV given in divided doses q4–6h
- Gentamicin 2.5 mg/kg IV q8h
- Clindamycin 20–40 mg/kg/day IV in divided doses q6–8h
- Metronidazole 30 mg/kg/day IV in divided doses q6h

**Second Line**

Dopamine 5–20  $\mu$ g/kg/min IV if shock is unresponsive to fluid administration

**COMPLEMENTARY & ALTERNATIVE THERAPIES**

- Aggressive chest physical therapy is the mainstay for rib fractures, chest wall injuries, and pulmonary contusions.
- Mechanical ventilation:
  - May be used as a treatment modality when a pulmonary contusion encompasses >25% of a lung on chest CT

**SURGERY/OTHER PROCEDURES**

- Thoracostomy tube is placed for pneumothorax and hemothorax, especially if patient will require surgical exploration or mechanical ventilation.
- Consider a thoracotomy when a thoracostomy tube drains 15 mL/kg of blood or 3–4 mL of blood per kilogram per hour after placement.
- Resuscitative thoracotomy that leads to the greatest survival rate occurs in those children with vital signs at the time of emergency department arrival. Survival is 14.3% (6).
- Surgical exploration may be a necessary option when studies to determine the presence of diaphragmatic rupture are equivocal.

**DISPOSITION****Admission Criteria**

- Most children with injury to the lungs and cardiac vessels with ongoing or the potential for abnormal vital signs need to be admitted for observation.
- Critical care admission criteria:
  - Patient requiring mechanical ventilation
  - Patients requiring extensive hemodynamically monitoring
  - Patients requiring close and frequent neurologic monitoring

**Issues for Referral**

- Transfer patients when there is no pediatric surgical consultant and/or pediatric ICU.
- The following conditions will likely need surgical intervention:
  - Hemodynamic instability despite resuscitative efforts
  - Identified great vessel injury
  - Identified esophageal injury
  - Identified airway injury involving > 1/3 of the diameter of the bronchus

**FOLLOW-UP****FOLLOW-UP RECOMMENDATIONS**

Discharge instructions and medications:

- Advise caregivers to monitor for the development of chest pain, difficulty breathing or shortness of breath, difficulty swallowing, or lethargy.

**PROGNOSIS**

- ~78% of children with thoracic trauma can be managed by nonsurgical means, either observation or thoracostomy tube (7).
- 7% of all patients with thoracic trauma will need surgical exploration for repair of the chest (1).

**COMPLICATIONS**

- Retained hemothorax leads to the development of empyema or fibrothorax.
- Impaired pulmonary mechanics
- Pulmonary embolism, stroke
- Pseudoaneurysm, deep vein thrombosis
- Mediastinitis, esophageal fistula or stricture
- Bronchopleural fistula, hemothorax
- Pneumatocele, abscess, or empyema
- Atelectasis, pneumonia
- Ventricular aneurysm formation, septal defect
- Pericarditis
- Arrhythmia, MI

- Hemothorax
- Myocardial Contusion
- Pneumothorax/Pneumomediastinum
- Pulmonary Contusion
- Trauma, Abdominal
- Trauma, Neck
- Trauma, Penetrating

**CODES**
**ICD9**

- 862.8 Injury to multiple and unspecified intrathoracic organs without mention of open wound into cavity
- 875.0 Open wound of chest (wall), without mention of complication
- 959.11 Other injury of chest wall

**PEARLS AND PITFALLS**

- Because of small body-to-surface area, thoracic injuries rarely occur in isolation.
- Thymic shadow in young children may make interpretation of the mediastinum difficult.
- Remember that spine fractures may occur with crushing or axial loading mechanism.
- Pulmonary contusion and aspiration pneumonia look similar on CXR.
- The rib cage is highly malleable in children and can withstand significant forces without showing overt external signs of trauma even though major internal organ injuries may be present.

# TRAUMA, DENTAL

Janice Kezirian

Barry G. Gilmore

## BASICS

### DESCRIPTION

- Mouth injuries can result in fractured, displaced, or lost teeth; negatively affect function and appearance; and have psychosocial effects on the child.
- Primary or permanent teeth may be involved:
  - Primary teeth: Incisors erupt between 6 and 16 mo of age and shed at 6–8 yr. Canines and molars erupt at 16–33 mo and shed at 9–12 yr.
- Types of injuries (1):
  - Fracture: Traumatic crack or break in the tooth involving enamel, dentin, cementum, or alveolar bone. Pulp may or may not be exposed.
  - Luxation: Traumatic injury to periodontal ligament; may or may not result in tooth displacement and/or injury to alveolar bone.
  - Avulsion: Traumatic, complete displacement of tooth

### EPIDEMIOLOGY

- Dental injuries are the most common type of facial injury, affecting 1/2 of children (2,3).
- Most occur between 8 and 12 yr of age (2,3).
- Most trauma to primary dentition is at 1.5–3.5 yr of age, when children are learning to walk and run (4).
- In school-age children, boys are twice more likely to sustain dental trauma than girls (2,3).

### RISK FACTORS

- Anterior, prominent, protruding teeth have less protection.
- Developmental stage (issues with mobility)
- Disabilities (seizures, cerebral palsy) place children at risk for falls or nonaccidental trauma.
- Orthodontics
- Sports participation
- Sex (male), age (toddlers), season (summer)

### GENERAL PREVENTION

- Most dental trauma is preventable.
- Minimize falls, traffic accidents (use of car seats or restraints), violence, and sports injuries.
- The use of mouth guards and facial protective gear; orthodontics to prevent protruding teeth

### PATHOPHYSIOLOGY

- Trauma in primary teeth (1,4):
  - Apex of root of an injured primary tooth sits next to underlying permanent tooth germ, which can be disrupted when the primary tooth is traumatized, especially with intrusions or injuries leading to pulp necrosis.
  - Premature loss of primary incisors leads to delayed eruption of permanent incisor.
  - Intruded primary teeth may cause ectopic eruption of underlying permanent teeth, requiring extraction.
  - Can cause abnormal enamel formation in underlying permanent tooth
- Trauma in permanent teeth can result in loss of tooth if vitality of periodontal ligament and pulp is not preserved (1).

### ETIOLOGY

- Falls: Most common cause of dental trauma; occur in toddlers due to ambulation mechanics
- Motor vehicle crashes: Risk of confounding injuries or accompanying injuries
- Violence: Inflicted trauma, assault
- Sports: Older children
- Eating hard foods

## DIAGNOSIS

### HISTORY

- Medical and health history:
  - Medications and medication allergies
  - Cardiac disease (may need endocarditis prophylaxis)
  - Bleeding and seizure disorders
  - Tetanus immunization status
  - Time of last meal
- History of present illness:
  - Events surrounding the injury (where it occurred, clean vs. dirty) affect severity of injury and need for antibiotics and/or tetanus prophylaxis.
  - Time of injury and (if appropriate) time interval between injury and replantation
  - Conditions under which the tooth was stored
  - Other injuries (headache, bleeding from ears or nose, vomiting)

### PHYSICAL EXAM

- Assure airway patency:
- Extraoral inspection
  - Asymmetry, malalignment, malocclusion
  - Jaw or lip deviation during opening and closing of mouth; temporomandibular joint (TMJ) or mandibular pain/limitation
  - Hematoma, laceration, foreign body:
    - Mastoid bruising (Battle sign): Nonaccidental vs. accidental trauma
    - Chin ecchymosis: Condylar fracture
- Extraoral palpation:
  - TMJ tenderness, crepitus
  - Orbital rim or nose tenderness, instability
  - Numbness, loss of sensation
- Intraoral inspection (soft and hard tissue):
  - Color and quality of gums and mucosa
  - Hematoma, laceration, abrasion, active bleeding:
    - Sublingual hematoma (body of mandible fracture)
  - Determine which type of tooth/teeth are injured or missing (primary vs. permanent):
    - Tooth numbering for primary: Number from A–T starting with the tooth farthest back in the upper right jaw (A) to farthest tooth on upper left side (J) and then farthest tooth in lower left jaw (K) to tooth farthest back on bottom right (T).
    - Tooth numbering for permanent (Universal Numbering System). Number from 1–32 starting with tooth farthest back in upper right jaw (#1) to farthest tooth on upper left side (#16) and then farthest tooth in lower left jaw (#17) to tooth farthest back on the bottom right (#32).
  - Injured tooth/teeth color, cracks, chips, contamination
  - Alveolar socket coagulum or fracture
  - Periodontal ligament damage: Bleeding from around tooth (2,3)

- Intraoral palpation (soft and hard tissue):
  - Bite assessment (bite alignment, pain on bite)
  - Salivary glands
  - Tooth position, percussion, and mobility
- Determine type of injury (fracture, luxation, avulsion) (1–4)
- Fractures:
  - Ellis class I: Cracked tooth enamel
  - Ellis class II: Crown fracture, uncomplicated: Fracture of enamel-dentin; tooth appears broken; no pulp exposure
  - Ellis class III: Crown fracture, complicated—fracture of enamel-dentin with pulp exposed; blood coming from inside the tooth
  - Ellis class IV: Crown/root fracture—enamel, dentin, and cementum fracture; pulp exposed (complicated fracture, Ellis class IV) or not (uncomplicated fracture); tooth mobile
  - Root fracture: Dentin and cementum fracture; pulp exposed (complicated fracture) in most cases; tooth mobile, may be displaced
  - Alveolar (bone) fracture: Tooth-containing segment mobile, usually displaced
- Luxation:
  - Concussion: Tooth tender, not displaced or loose; periodontal ligament is inflamed; no bleeding
  - Subluxation: Tooth loose, not displaced; periodontal ligament is inflamed or torn; bleeding present
  - Lateral luxation: Tooth displaced, bleeding present, and alveolar bone contused or fractured
  - Intrusion: Tooth driven into the socket; periodontal ligament compressed; alveolar bone may be fractured; bleeding may be present; crown height shortened
  - Extrusion: Tooth out of socket; bleeding present; tooth appears elongated mobile
- Avulsion: Tooth out of socket; bleeding present; alveolar bone may be fractured

### DIAGNOSTIC TESTS & INTERPRETATION

#### Imaging

- Panorex: Standard for imaging
- Plain facial films: Less specific
- CT of facial bones: For complex injuries or suspected facial or mandible fracture

### DIFFERENTIAL DIAGNOSIS

Other concurrent facial fractures and injuries:

- Le Fort (facial) and mandible fractures

## TREATMENT

### PRE HOSPITAL

- Wound irrigation with running water
- Compression of injured area with gauze or cotton to stop bleeding
- Avulsion of permanent tooth: Retrieve tooth. Avoid touching or cleaning root. If dry, wash briefly (10 sec) under cold running water (do not scrub), and reposition. Have child bite on gauze to hold tooth in place.
- If unable to reposition, place in a storage medium (Hank's Balanced Salt Solution; Save-a-Tooth; cold milk; saline).
- Do not replace avulsed primary teeth.

**INITIAL STABILIZATION/THERAPY**

- Objectives (1):
  - Optimize healing of the periodontal ligament and neurovascular supply.
  - Maintenance of tooth integrity and pulp health
  - Restoration of normal appearance and function
- Pain management during replantation of avulsed permanent tooth:
  - Topical anesthetic gel
  - Nerve block (inferior alveolar most common)
  - Oral pain control
  - Procedural sedation may be required.
- Tetanus prophylaxis
- Ellis class I fractures: Primary and permanent teeth (2,4):
  - No immediate treatment necessary
  - Nonurgent filing of rough edges by dentist
- Ellis class II fractures: Primary and permanent teeth (2,4):
  - Prescribe antibiotics if prolonged exposure or dirty wound.
  - Covering of exposed dentin and repair of fracture by dentistry
- Ellis class III fractures:
  - Typically very painful, analgesics required
- Primary tooth (4):
  - May need extraction to prevent further damage
- Permanent tooth (2):
  - Antibiotics, covering of exposed pulp by dentistry, possible root canal
- Root fractures:
  - Primary tooth: Extraction (4)
  - Permanent tooth: Splinting (duration depends on extent of damage to root) (2)
- Concussion: Primary and permanent teeth (2–4):
  - No immediate treatment necessary
  - Pain management and dentistry follow-up
- Subluxation:
  - Primary tooth (4):
    - No intervention or splinting, depending on tooth mobility
  - Permanent tooth (2,3):
    - Splinting
- Lateral luxation:
  - Primary tooth (4):
    - No intervention, passive repositioning, extraction, or splinting, depending on tooth mobility
  - Permanent tooth (2,3):
    - Repositioning and splinting
- Intrusion:
  - Primary tooth (4):
    - Usually re-erupts in 3–4 wk
    - Extraction if 100% intruded because may compress underlying tooth bud
  - Permanent tooth (2,3):
    - No intervention. Allow tooth to re-erupt. Once it does (3–4 wk), dentistry will reposition and splint.
- Extrusion:
  - Primary tooth (4):
    - Extract if very mobile.
  - Permanent tooth (2,3):
    - Repositioning and splinting by dentistry
- Avulsion:
  - Primary tooth (4):
    - Control bleeding.
    - Rule out aspiration, intrusion, or fracture.
    - No replacement of tooth

- Permanent tooth (3):
  - Minimize handling.
  - Extraoral dry time <30 min: Replant and splint as soon as possible.
  - Extraoral dry time 30–60 min: Soak avulsed tooth in 1% doxycycline solution in saline for 5 min prior to replanting and splinting.
  - Extraoral dry time ≥60 min: Soak avulsed tooth in topical fluoride and rinse with saline, then soak in 1% doxycycline solution in saline for 5 min prior to replanting and splinting.

**MEDICATION**

- Local anesthetic:
  - Nerve blockade or infiltration with local anesthetic gives significant analgesia and reduces the analgesic requirement.
  - Lidocaine, max single dose 5 mg/kg
- Opioids:
  - Morphine 0.1 mg/kg IV/IM/SC q2h PRN:
    - Initial morphine dose of 0.1 mg/kg IV/SC may be repeated q15–20min until pain is controlled, then q2h PRN.
  - Codeine/Acetaminophen dosed as 0.5–1 mg/kg of codeine component PO q4h PRN
- NSAIDs:
  - Ibuprofen 10 mg/kg/dose PO/IV q6h PRN
  - Naproxen 5 mg/kg PO q8h PRN
  - Acetaminophen 15 mg/kg/dose PO q4h PRN
- Antibiotics:
  - Penicillin VK 25–40 mg/kg/day PO divided q6–8h × 5 days
  - Doxycycline (>8 yr of age): 100 mg PO b.i.d. × 5 days

**DISPOSITION****Admission Criteria**

Inability to tolerate soft or liquid diet

**Discharge Criteria**

Home if stable and able to swallow

**Issues for Referral**

- Need immediate dental referral for:
  - Primary tooth completely intruded
  - Permanent tooth intrusion, luxation, extrusion, or avulsion
  - Crown or root fracture
- Refer all other injuries to dentistry within 24 hr for baseline exam and radiographs.

**FOLLOW-UP****FOLLOW-UP RECOMMENDATIONS**

Discharge instructions and medications

- Antibiotics for avulsions or dirty wounds
- Wound hygiene with chlorhexidine swabs
- Pain control

**DIET**

Soft diet as needed for 2 wk

**PROGNOSIS**

Prolonged extraoral dry time (>60 min) decreases chances for successful replantation (3).

**COMPLICATIONS**

- Infection
- Tooth malformation, impacted teeth, or eruption problems in underlying developing permanent teeth
- Failure of replantation of avulsed permanent teeth or inflammatory or replacement resorption
- Ankylosis or tooth submergence

**ADDITIONAL READING****See Also (Topic, Algorithm, Electronic Media Element)**

- Abscess, Dentoalveolar
- Fracture, Mandibular
- Fracture, Orbital
- Fracture, Zygoma
- Trauma, Facial

**CODES****ICD9**

- 873.63 Open wound of internal structures of mouth, tooth (broken) (fractured) (due to trauma), uncomplicated
- 873.73 Open wound of internal structures of mouth, tooth (broken) (fractured) (due to trauma), complicated

**PEARLS AND PITFALLS**

- Replanting an avulsed permanent tooth with <30 min extraoral dry time greatly increases chances for successful replantation.
- Do not miss alveolar or mandibular injuries.
- Replanting wrong end of tooth into the socket
- Missed foreign body (tooth fragment) in the soft tissue or in the airway
- Do not mistake an intruded tooth for a fracture.

Cindy Ganis Roskind

## BASICS

### DESCRIPTION

- Elbow bones are particularly at risk to trauma in the pediatric patient due to multiple articulations and physes (growth plates) within the joint:
  - Articulations:
    - Humeral trochlea and ulnar notch
    - Capitellum and radial head
    - Proximal radius and ulna
  - Growth plates:
    - Capitellum
    - Radial head
    - Medial epicondyle
    - Trochlea
    - Olecranon
    - Lateral epicondyle
- Also at risk in elbow injury are the arteries and nerves that course through the joint, including the brachial artery and its branches and the median and ulnar nerves.

### EPIDEMIOLOGY

- 65–75% of all fractures in children occur in the upper extremity.
- Common elbow injuries:
  - Supracondylar fractures (SCF):
    - 60% of pediatric elbow fractures
    - Most common pediatric fracture requiring surgery
    - Peaks at 5–7 yr of age
  - Lateral condylar fractures (LCF):
    - 10–20% of pediatric elbow fractures
    - Similar age distribution as SCF
  - Medial epicondylar fractures (MEF):
    - 10–12% of pediatric elbow fractures
    - Peaks at 7–15 yr of age
    - Associated with elbow dislocations (50%) (1)
  - Radial head and neck fractures:
    - 4–5% of pediatric elbow fractures
    - Radial head fractures are less common than radial neck fractures because the radial head is mostly cartilaginous in children (1).
  - Olecranon fractures:
    - 5–7% of pediatric elbow fractures
    - 50% are associated with another injury (1).
  - Distal humeral physal fractures
    - Associated with nonaccidental trauma in >50% of young children
  - Elbow dislocations:
    - 5% of elbow injuries in children
    - Peak at 12–13 yr of age
    - Frequently associated with MEF
  - Radial head subluxation (Nursemaid's elbow):
    - Most common upper extremity injury in children <6 yr of age
    - Peaks at 2–3 yr of age

### RISK FACTORS

High risk for elbow fractures due to:

- More frequent falls from a height while playing
- Tendency to brace fall with outstretched arms
- Unique composition of growing bones, including unfused growth plates and high proportion of collagen and cartilage to bone

### PATHOPHYSIOLOGY

Pediatric bone contains more collagen and cartilage than adult bone and has a thicker periosteum:

- Increased collagen makes the bones less resistant to stress than the ligaments; thus, children are prone to fracture a bone when an adult would injure the ligaments.
- Collagen impedes the propagation of traumatic forces along bones, decreasing the risk of comminuted fractures.
- Increased cartilage in the bone makes it more difficult to detect fractures on radiographs.

### ETIOLOGY

- Most elbow fractures occur after a fall onto an extended arm:
  - SCF, olecranon fractures, and elbow dislocations usually occur by this mechanism.
  - Direction of dislocation is typically posterior (1).
  - LCF occur when the arm is outstretched and under varus stress.
  - MEF occur when the arm is outstretched and under valgus stress.
  - Radial head and neck injuries occur when the outstretched arm is supinated.
- Elbow injuries that typically do not result from a fall on an extended arm:
  - Humeral physal fractures: Forceful twisting (rotary force) on the upper extremity
  - Radial head subluxation: Sudden traction on the arm when the elbow is extended and the forearm is pronated
  - Flexion-type SCF: High-energy direct blow to the back of the elbow

## DIAGNOSIS

### HISTORY

- Situation, mechanism, and timing
- Decreased use of injured extremity
- Potential for other associated injuries

### PHYSICAL EXAM

- Inspection:
  - Note any deformity, skin abrasions, ecchymosis, or swelling.
  - Observe movement and use:
    - Lack of movement may indicate paralysis or restriction of movement due to pain.
- Palpation:
  - Identify the point of maximal tenderness.
  - Palpate the entire limb to identify concomitant or unidentified injury:
    - Clavicular fractures may be confused with elbow injuries in a child restricting movement due to pain.
- Range of motion: Passive and active
- Neurovascular exam:
  - Pulses and capillary refill:
    - Capillary refill is a more sensitive indicator of perfusion than a palpable pulse (1).
    - Consider compartment syndrome if pulselessness, pallor, parasthesia, paralysis, or pain on passive finger extension.

– Sensory and motor assessment:

- Assess motor function by having the patient make a “thumb’s up” (radial nerve), tight fist over the thumb (median nerve), and an “ok” sign (anterior interosseous nerve) (2).

### DIAGNOSTIC TESTS & INTERPRETATION

#### Imaging

- Plain radiographs of the elbow should be obtained if there is history of trauma and the presence of swelling, deformity, or bony tenderness:
  - At least 2 views should be obtained
  - AP view, in extension:
    - Displays the lateral and medial epicondyles and the articular surfaces
  - Lateral view, at 90 degrees flexion:
    - Displays anterior and posterior fat pads and the relationship of the distal humerus to the bones of the proximal forearm
    - In a normal elbow, a narrow anterior distal humeral fat pad may be visible, but no posterior fat pad or widened anterior “sail sign” should be visible.
    - Normal alignment is confirmed by drawing a line along the anterior humerus. This line should pass through the middle 3rd of the capitellum on the lateral view.
    - A line drawn down the middle of the radius should also pass through the center of the capitellum on every view.
    - Best view to diagnose SCF
  - Lateral oblique view:
    - Not always obtained
    - Can be useful in diagnosing LCF as well as evaluating for joint displacement
- Radiographs are not indicated if the history and exam are consistent with radial head subluxation.

#### Diagnostic Procedures/Other

- Physical exam and radiographs are usually sufficient to diagnose elbow fractures and dislocation in the majority of pediatric patients.
- US may be helpful in younger children to identify fractures in the unossified areas of the elbow (1), though it is not commonly used.

#### Pathological Findings

- In posterior dislocation of the humerus, the anterior humeral line will pass through the anterior 3rd of the capitellum or entirely anterior to it.
- Deviation of radius from axis in line with capitellum may indicate an LCF or radial head dislocation:
  - Radial-capitellar alignment is preserved with distal physal fractures, but there is loss of the capitellar-humerus alignment on x-ray.
- Fat pads:
  - Most useful in diagnosing nondisplaced, occult distal humeral fractures
  - Displacement of the fat pads on radiograph reflects hemorrhage or effusion in the elbow joint and indicates evidence of an occult fracture in the majority of patients (1).

#### DIFFERENTIAL DIAGNOSIS

- Effusion
- Contusion
- Sprain, strain
- Bursitis
- Arthritis

## TREATMENT

### PRE HOSPITAL

- Splint to immobilize fractured bones:
  - Especially important for unstable fractures that may compromise the neurovascular structures (eg, SCF, LCF)
  - Assess pulses pre- and post-splinting.
- Rest, ice, and elevation

### INITIAL STABILIZATION/THERAPY

- Splinting, rest, ice, and elevation, if not done earlier
- If open fracture, IV antibiotic prophylaxis

### MEDICATION

#### First Line

- Opioids:
  - Morphine 0.1 mg/kg IV/IM/SC q2h PRN:
    - Initial morphine dose of 0.1 mg/kg IV/SC may be repeated q15–20min until pain is controlled, then q2h PRN.
  - Fentanyl 1–2  $\mu$ g/kg IV q2h PRN:
    - Initial dose of 1  $\mu$ g/kg IV may be repeated q15–20min until pain is controlled, then q2h PRN.
  - Codeine or codeine/acetaminophen dosed as 0.5–1 mg/kg of codeine component PO q4h PRN
  - Hydrocodone or hydrocodone/acetaminophen dosed as 0.1 mg/kg of hydrocodone component PO q4–6h PRN
- NSAIDs:
  - Consider NSAID medication in anticipation of prolonged pain and inflammation.
  - Some clinicians prefer to avoid NSAIDs due to theoretical concern over influence on coagulation and callus formation.
  - Animal studies have raised concerns that NSAIDs may negatively influence bone healing; however, there is no clinical evidence in humans.
  - Ibuprofen 10 mg/kg/dose PO/IV q6h PRN
  - Ketorolac 0.5 mg/kg IV/IM q6h PRN
  - Naproxen 5 mg/kg PO q8h PRN
- Acetaminophen 15 mg/kg/dose PO/PR q4h PRN
- If open fracture, then cefazolin 25 mg/kg/day divided q8h, max 1 g

### SURGERY/OTHER PROCEDURES

- Displaced fractures and some nondisplaced fractures may require closed reduction with possible percutaneous pinning:
  - SCF, LCF, physeal fractures, radial neck fractures, olecranon fractures, elbow dislocations
- If closed reduction fails or vascular insufficiency with suspected artery entrapment remains after closed reduction, open reduction is then performed:
  - Minimally displaced fractures of the lateral condyle or olecranon may require open reduction.

### DISPOSITION

#### Admission Criteria

Admission should be considered for:

- Displaced fractures
- High-risk injuries for compartment syndrome:
  - Elbow dislocations
  - Displaced SCF
- Open fractures

#### Discharge Criteria

- Injuries treated in a long arm posterior splint in the emergency department with close (24–48 hr) orthopedic follow-up:
  - Nondisplaced fractures including:
    - SCF, MEF, olecranon, and radial head/neck fractures
- A visible fat pad without fracture line may be splinted in the emergency department with delayed (1–2 wk) orthopedic follow-up.
- Radial head subluxation generally does not require orthopedic involvement or splinting.

#### Issues for Referral

Fractures requiring emergency department–based orthopedic evaluation:

- Open fractures
- Any neurovascular deficit
- Any LCF
- Any elbow dislocations
- Displaced SCF, MEF, or olecranon fractures
- Displaced radial head/neck fractures
- Distal humeral physes fracture:
  - Consider evaluation for physical abuse.

## FOLLOW-UP

### FOLLOW-UP RECOMMENDATIONS

- As outlined above
- Return for increase in pain or change in motor or neurovascular function
- Outpatient PO pain management:
  - As listed in the Medication section

### COMPLICATIONS

- Nerve and vascular injury:
  - SCF and elbow dislocations are at risk for compromise of the brachial artery as well as the median and ulnar nerves.
  - MEF frequently involve ulnar nerve injury.
- Compartment syndrome
- Loss of function or range of motion
- Physeal injury may cause stunting or asymmetric growth.
- Cubitus varus deformity:
  - The elbow sticks out from the body when the arm is extended and supinated.
  - May be seen after inadequate alignment following a displaced SCF
- Cubitus valgus deformity:
  - Exaggerated bend of the elbow with the forearm supinated
  - May be seen after inadequate alignment following LCF

- Fracture, Humerus
- Fracture, Supracondylar

### ICD9

- 812.41 Supracondylar fracture of humerus, closed
- 812.42 Fracture of lateral condyle of humerus, closed
- 959.3 Other and unspecified injury to elbow, forearm, and wrist

## PEARLS AND PITFALLS

- Pearls:
  - If fracture suspected, radiographs of the elbow should include at least an AP and lateral view.
  - Nondisplaced fractures, including elbow injuries with abnormal fat pads but no visible fractures, may be splinted with close orthopedics follow-up, except LCF, which requires emergent orthopedics evaluation.
- Pitfalls:
  - Failure to immobilize suspected fracture in the field or for radiographs may result in further injury due to instability.
  - Failure to consult orthopedics for any elbow injury that involves a displaced fracture, olecranon dislocation, or neurovascular compromise could lead to a worse functional outcome.

## BASICS

### DESCRIPTION

- Facial trauma can result from blunt force, penetrating force, or thermal/electrical injury.
- Injury can result in damage to the skin, soft tissue, nerves, blood vessels, facial bones, sinuses, or eyes.

### EPIDEMIOLOGY

#### Incidence

- 3 million patients with facial trauma present to emergency departments for care annually (1):
- The peak incidence of facial fractures is between 20 and 40 yr of age (1,2).
  - Boys are 1.8 times more likely to suffer from facial trauma (3).

#### Prevalence

- Children account for only 5–10% of all facial fractures (1):
  - Fractures are more common in older children, especially children > 10 yr of age (2).
- 50–70% of people involved in a motor vehicle collision have facial trauma (4).
- Facial fracture patterns change with age.

### RISK FACTORS

- Children are at lower risk than adults because their faces are proportionately smaller and their craniums are larger, providing protection.
- Younger children participate less in risky behavior than do older children, adolescents, and adults.

### GENERAL PREVENTION

- Seat belt and proper child restraint use in motor vehicles
- Helmet and sports equipment use during recreational activities

### PATHOPHYSIOLOGY

- Injury patterns to the face are associated with age due to structural changes, bone compliance, and sinus development.
- Fractures in adolescents and adults are more likely to be comminuted due to noncompliant bone and sinus development. Sinus pneumatization provides protection against fractures by absorbing impact.
- Forehead:
  - Prior to the age of 6 yr, fractures of the forehead typically extend to the orbital roof or vertex of the skull.
- Orbit:
  - Orbital floor fractures are common due to the thin bone of the medial orbital floor.
  - Orbital roof fractures are less common but are more likely in children < 7 yr of age due to a lack of pneumatization of sinuses.
  - Supraorbital rim fractures are rare due to localized thicker bone.
- Nose:
  - Nasal fractures are less common in children due to soft, compliant cartilage.
- Maxilla:
  - Fractures are rare in children < 10 yr of age.
  - 40% are associated with CNS injury.

- Le Fort classification: See the Fracture, Zygoma topic.
- Mandible:
  - Most fractures in children < 10 yr of age involve the condyle.

### ETIOLOGY

The most common causes of facial trauma are play accidents (58%), sports injuries (32%), traffic accidents (5%), and assault (4%) (3).

### COMMONLY ASSOCIATED CONDITIONS

~75% of pediatric facial trauma patients have associated injuries (3,4):

- Traumatic brain injury is reported to be associated in 1.4% of all craniomaxillofacial injuries (3).
- Concurrent cervical spine injury is more common in adolescents and adults than younger children.

## DIAGNOSIS

### HISTORY

- A clear understanding of the nature and direction of the forces involved is vital in understanding and correctly managing the injury and associated conditions.
- A history of comorbid conditions such as bleeding disorders, previous surgeries, and anatomic abnormalities is important.

### PHYSICAL EXAM

- In general, look for asymmetry or loss of prominences or range of motion, and palpate for step-off, tenderness, or crepitus:
  - Assess the cranial nerves.
- All lacerations should be explored to determine the depth and evaluated for the presence of a foreign body:
  - The status of the facial nerve's motor (efferent) and sensory (afferent) functions should be assessed:
    - Facial nerve injury may result in difficulty closing the eyelid, raising the eyebrow, or retracting the corner of the mouth.
  - Lacerations in the medial periorbital region should raise the suspicion for a lacrimal duct injury, and lateral periorbital lacerations should raise the suspicion for injury to the superficial branch of the facial nerve (4).
- Fractures of facial bones typically have localized tenderness:
  - Orbit:
    - Assess visual acuity and optic discs. Diplopia or pain may indicate an orbital rim fracture.
    - If eye pain, check for corneal abrasion.
    - Assess for step-off of bony orbit.
    - Anesthesia to the cheek, limited upward gaze, and enophthalmos may be associated with an orbital floor fracture.
    - Periorbital ecchymosis ("raccoon eyes") may be associated with an anterior skull base fracture.

### – Nose:

- Exam should focus on cosmetic and functional impairment.
  - Loss of nasal projection, depression of the nasal root, telecanthus, and subconjunctival hemorrhages are associated with nasal fractures.
  - Inspection for a septal hematoma
- Maxilla:
- The most common exam finding with a maxillary fracture is malocclusion, which may be complicated by mixed dentition.
  - Anesthesia of the cheek, upper lip, or teeth may be associated with a fracture near the infraorbital foramen.
- Mandible:
- Malocclusion is the cardinal sign of a fractured mandible.
  - Mandible fractures are associated with depressed contour of the cheek, inferior displacement of the lateral canthus, subconjunctival hemorrhage, and step deformities.
  - Preauricular pain, pain or limited mouth opening, and mobility of a bone segment are associated with mandibular fractures.
  - Temporomandibular joint (TMJ) dislocation is associated with contralateral chin shift and ipsilateral inability to bite down.
  - Palpate the TMJ and zygoma with the jaw in neutral position and through full range of motion.
  - Test occlusive ability by having patient bite and hold a wooden tongue depressor between the molars. Inability to resist the examiner withdrawing the tongue depressor is associated with jaw or tooth fracture.
- Teeth:
- Assess dentition, noting avulsed or fractured teeth.
  - Percuss teeth that patient complains are painful.
  - Carefully evaluate for Ellis fracture of teeth.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

Lab tests are not usually helpful or needed (1).

#### Imaging

- Face:
  - Plain radiographs of the facial bones are difficult to interpret in children due to diminished contrast provided by poorly pneumatized sinuses (2).
  - 3D facial CT with thin-cut axial and coronal views is the preferred imaging technique (2).
- Nasal bones:
  - Imaging for the evaluation of nasal fractures is not routinely indicated.
- Mandible:
  - AP and lateral mandibular radiographs will demonstrate most fractures (4).
  - Panorex radiography is the optimal view to evaluate for mandibular fracture.

**Diagnostic Procedures/Other**

- CSF leak will contain beta<sub>2</sub>-transferrin or glucose, while rhinorrhea will not.
- CSF may be detected by placing a drop of wound fluid on a piece of filter paper. CSF travels farther than serum with a “halo” appearance.

**DIFFERENTIAL DIAGNOSIS**

See Etiology.

**TREATMENT****PRE HOSPITAL**

- Assess and stabilize airway, breathing, and circulation.
- C-spine immobilization if indicated.
- Manage hemorrhage with direct pressure.

**INITIAL STABILIZATION/THERAPY**

- Assess and stabilize airway, breathing, and circulation per Pediatric Advanced Life Support (PALS) and Advanced Trauma Life Support (ATLS) guidelines:
  - Facial trauma may make oral intubation difficult. Nasotracheal intubation is contraindicated when there is significant facial or nasal trauma.
- Severe bleeding should be managed with direct pressure and by elevating the head of the bed by 45 degrees, assuming the lumbar spine has been cleared during trauma evaluation.
- Minor abrasions and “road tattoos” require meticulous debridement and removal of individual foreign particles.
- Analgesics are typically required.
- Topical or regional anesthetics are effective in managing pain associated with laceration repair.
- Nasal decongestants or vasoconstrictors are useful for epistaxis or edema with nasal trauma.
- The use of prophylactic antibiotics is controversial but should be used for animal or human bites, contaminated wounds, or the presence of foreign body.

**MEDICATION****First Line**

- Opioids:
  - Morphine 0.1 mg/kg IV/IM/SC q2h PRN:
    - Initial morphine dose of 0.1 mg/kg IV/SC may be repeated q15–20min until pain is controlled, then q2h PRN.
  - Fentanyl 1–2 μg/kg IV q2h PRN:
    - Initial dose of 1 μg/kg IV may be repeated q15–20min until pain is controlled, then q2h PRN
  - Codeine/Acetaminophen dosed as 0.5–1 mg/kg of codeine component PO q4h PRN
- NSAIDs:
  - Consider NSAID medication in anticipation of prolonged pain and inflammation:
    - Ibuprofen 10 mg/kg/dose PO/IV q6h PRN
- Acetaminophen 15 mg/kg/dose PO/PR q4h PRN

**Second Line**

- Lidocaine/Epinephrine/Tetracaine (LET/LAT) gel
- Lidocaine 1–2% with or without epinephrine for regional anesthesia such as maxillary nerve block
- Prophylactic antibiotics for facial fractures compromising sinuses or CSF are controversial:
  - Amoxicillin 80–90 mg/kg/day PO divided b.i.d.
  - Ceftriaxone 50–75 mg/kg/day IV.

**COMPLEMENTARY & ALTERNATIVE THERAPIES**

- Lacerations on the face may be closed up to 24 hr after injury due to excellent blood supply.
- Lacerations secondary to animal bites on the face may be closed by primary closure after thorough irrigation and initiation of antibiotics.
- Regional nerve blocks provide good anesthesia for laceration repair or some fractures.
- Tetanus update may be required.
- Nasal packing may be considered for severe epistaxis.

**Issues for Referral**

- Consult otolaryngology and a maxillofacial or plastic surgeon for facial fractures.
- An ophthalmologist should be consulted for direct ocular injury, orbital wall fracture, or a complex laceration to the eyelids.
- Dental referral for traumatic dental injuries

**SURGERY/OTHER PROCEDURES**

- Injuries to specialized structures such as nerves, major vessels, the Stensen duct, lacrimal duct, or extensive lacerations should be managed in the operating room (2).
- Displaced facial fractures typically require open reduction.
- Incision and drainage of a septal hematoma

**DISPOSITION****Admission Criteria**

- Admit for maxillofacial fractures.
- Critical care admission criteria:
  - Victims of major trauma may require critical care monitoring due to potential airway obstruction or associated injuries such as traumatic brain injury.

**Discharge Criteria**

Patients with isolated soft tissue injury may be discharged.

**FOLLOW-UP****FOLLOW-UP RECOMMENDATIONS**

Discharge instructions and medications:

- All facial abrasions, lacerations, and minor wounds should be managed with an antibiotic ointment multiple times per day.
- Give head injury instructions as needed.

**DIET**

Depends on the type and severity of injury

**PROGNOSIS**

Varies from full recovery to severe disfigurement and impairment of speech, eating, breathing, and cranial nerves

**COMPLICATIONS**

- Fracture malunion, growth arrest, and poor cosmesis
- Orbital muscle entrapment can result in muscular ischemia and fibrosis.
- Labial artery bleeding may occur 5–8 days post oral electrical burn.
- Cartilage necrosis and septal perforation as a result of septal hematomas

**ICD-9-CM CODES**

- 802.6 Closed fracture of orbital floor (blow-out)
- 802.8 Closed fracture of other facial bones
- 959.09 Other and unspecified injury to face and neck

**PEARLS AND PITFALLS**

- Approximating cosmetic landmarks such as the vermilion border of the lip or the margin of eyebrow during laceration repair is critical.
- Failure to recognize nerve injury or orbital muscle entrapment

## BASICS

### DESCRIPTION

- Pediatric foot and toe injuries are common due to cartilaginous and overuse injuries in a growing skeleton. Sports involving running, kicking, and jumping most often lead to foot and toe injuries in children.
- Fractures of the foot are discussed in a separate topic. The traumatic injuries to the foot and toe discussed here include:
  - Lisfranc midfoot sprain
  - Stress fractures in the foot
  - Apophysitis: Sever disease and Iselin disease
  - Osteochondroses: Kohler disease and Freiberg infraction
  - Turf toe and plantar fasciitis
  - Tarsal tunnel syndrome (TTS)

### EPIDEMIOLOGY

- Foot and ankle injuries were present in 12.1% of adolescents attending a sports medicine clinic in the U.S. (1).
- Basketball, soccer, and football injuries make up 44%, 27%, and 16%, respectively, of all injuries (2).
- 60% of Lisfranc injuries in children result from falls from a height (3).
- Stress fractures are up to 15% of all athletic injuries.
- Sever disease accounts for 8% of all overuse injuries in the pediatric population (4).
- Nerve compression syndromes of the foot, as TTS, are uncommon in pediatrics:
  - Specific etiologies for TTS can only be found in 60–80% of patients (5).

### RISK FACTORS

- Adolescent athletes are predisposed to more severe and frequent injury than young children due to their increased body mass and strength and changing flexibility (which decreases from age 10 to 13 years, and then increases again as muscle growth catches up with bone growth).
- Participation in year-round sports, playing with less protective equipment, inadequate stretching and conditioning drills can increase the risk of injuries.
- Certain activities, including basketball, soccer, football, gymnastics, and ballet, have a higher risk.
- Tight or ill-fitting footwear
- Runners' feet with excessive heel valgus or forefoot pronation are at risk for nerve compression.
- A cavus foot is prone to lateral foot injuries.
- Adolescent runners with excessive forefoot pronation may be susceptible to midfoot pain, plantar fasciitis, and stress fractures.

### GENERAL PREVENTION

Injury prevention strategies:

- Preseason physical exam
- Proper coaching and coping skills with stress
- Proper equipment and playing conditions

### PATHOPHYSIOLOGY

- Anatomic structures in the foot are in close proximity to each other. Therefore, injury with repeated foot/toe trauma is quite frequent.
- The Lisfranc joint of the midfoot at the 1st and 2nd metatarsal has no transverse ligament, which leaves only the joint capsule and dorsal ligaments to provide minimal support:

– Axial loading through the joint (as the foot is forcefully plantar flexed and slightly rotated) allows for the dorsal dislocation of the 2nd metatarsal.

- Stress fractures are the ultimate overuse injury, occurring when healthy bone is unable to withstand chronic repetitive submaximal loads on usually the metatarsal and navicular bones.
- Apophysitis or Sever disease is caused by irritation of the physis in the growing athlete:
  - The bony insertion sites of tendons in the foot (apophyses) are placed under constant stress from repeated muscle contraction.
- Osteochondroses are diseases of ossification centers that present as osteonecrosis followed by recalcification.
- Turf toe is usually due to forced hyperextension injury of the 1st metatarsophalangeal (MTP) joint with subluxation and joint capsule damage.
- Plantar fasciitis is associated with degenerative changes in the plantar fascia due to microtrauma to the plantar aponeurosis.
- Nerve compression syndromes are caused by partial or complete compression of peripheral nerves:
  - This causes pathologic changes in vessel-nerve barriers, reduced axonal flow, edema of the endoneurium and perineurium, and resulting intraneural fibrosis.

### ETIOLOGY

- Landing on the toes or bracing from a high fall can result in a Lisfranc sprain.
- Running, jumping, or intense walking can cause stress fractures.
- Chronic traction of the calcaneus from repetitive stress causes Sever disease.
- The etiology of osteochondroses is unknown.
- Playing on firm artificial surfaces and wearing highly flexible lightweight footwear can cause Turf toe.
- Plantar fasciitis is seen with jumping or prolonged standing and in individuals with a body mass index above the 97th percentile.
- Repeated trauma is the most common cause of TTS (ie, jogger's foot).

### COMMONLY ASSOCIATED CONDITIONS

- Metatarsal fracture
- Pes cavus, which refers to a high arch, is associated with a higher rate of foot and toe injury:
  - If unilateral, need to evaluate for Charcot-Marie-Tooth disease, Freidrich's ataxia, or other spinal pathology.
- Heel spurs are common with plantar fasciitis.
- Foot injuries are common with multisystem trauma and sometimes are overlooked.

## DIAGNOSIS

### HISTORY

- Often unreliable, and the entire lower limb should be evaluated with special attention to symptomatic areas.
- Patients with Lisfranc sprain present with dorsal foot swelling, pain at the midfoot, and inability to bear weight, especially when standing on tiptoes after the foot is forcefully plantar flexed.

- Stress fractures present with a history of insidious and worsening pain that is aggravated by activity and relieved with rest. Foot pain is localized to the involved bone.
- Athletes with Sever disease complain of heel pain that increases with activity.
- Midfoot pain and/or limping worse with weight bearing is consistent with Kohler disease.
- Gradual pain onset in forefoot worse with weight bearing/activity points to Freiberg infraction.
- An athlete playing on a hard surface, wearing flexible shoes, with increased ankle dorsiflexion and forced hyperextension of the 1st MTP joint, and complaining of pain over the plantar and medial 1st MTP joint is likely to have a Turf toe.
- Plantar fasciitis is common with inferior heel pain.
- With TTS, see:
  - Severe night pain relieved by walking
  - Burning
  - Tingling sensation aggravated by activity

### PHYSICAL EXAM

- Inspection of the foot and toes may reveal tenderness, swelling, deformity, or ecchymosis.
- Ecchymosis suggests a ligament tear or concurrent fracture.
- Plantar bruising should especially raise suspicion for a Lisfranc injury.
- Point tenderness aggravated by weight bearing points to stress fracture of the affected site.
- Localized tenderness of the posterior heel at the insertion of the Achilles tendon, heel-cord tightness, and weak ankle dorsiflexors are consistent with apophysitis.
- Localized tenderness, swelling, and erythema over the navicular are noted in Kohler disease.
- Turf toe is associated with maximal point tenderness at the plantar and medial aspects of the 1st MTP joint. More severe injury will exhibit marked swelling, decreased range of motion, and an antalgic gait.
- In patients with plantar fasciitis, there is localized tenderness at the anteromedial aspect of the heel with the foot in dorsiflexion.
- Digital compression of the tarsal tunnel for 30–45 sec or percussion over the tibial nerve will yield a radiating pain of the foot in TTS.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

If concern for rheumatic diseases or infection

#### Imaging

- Plain radiographs: AP, lateral, and oblique views:
  - Show periosteal reactions, apophysitis, soft tissue swelling, callous formation, or fractures:
    - Bony changes may not be obvious for 2–12 wk.
    - 50% of stress fractures never become apparent on plain films.
    - At times, radiographs of the contralateral foot/hindfoot are indicated for comparison.
    - Correlate findings with physical exam.
  - If a Lisfranc injury is suspected and non-weight-bearing plain radiographs are normal, then a weight-bearing view should be obtained.
  - Plain radiographs should be the initial diagnostic tool for stress fractures, Sever disease, atypical pain, or persistent symptoms.

- In Kohler disease, radiographs show increased sclerosis and narrowing of the tarsal navicular but may be difficult to diagnose because the normal tarsal navicular can have irregular ossification in the growing foot.
- In Turf toe, plain radiographs assist in narrowing the differential diagnosis and the evaluation for avulsion fragments.
- Plain radiographs are used to rule out other suspected causes of heel pain in plantar fasciitis if conservative treatment has failed.
- Radiography may reveal bony lesions in TTS (eg, osteochondroma) or a displaced fracture fragment.
- CT for intra-articular or stress fractures, subtle osseous injury, and other bony lesions. Fine-cut CT scanning allows more detailed analysis.
- MRI is necessary to identify cartilaginous injury and localized edema:
  - MRI can be used in refractory cases of plantar fasciitis to confirm the diagnosis.
- Bone scans may be necessary in certain settings, especially for subtle stress fractures, Lisfranc injuries, sesamoid bone fractures, and apophysitis.

**Diagnostic Procedures/Other**

An electromyogram may aid in the diagnosis of TTS, but the results should complement the patient’s history and physical.

**DIFFERENTIAL DIAGNOSIS**

- Idiopathic rheumatoid arthritis, other collagen vascular disease, and gout
- Seronegative spondyloarthropathy
- Septic arthritis, osteomyelitis
- Hemophilia, sickle cell disease
- Neurologic disorders
- Leukemia and other tumors

**TREATMENT**

**PRE HOSPITAL**

- Immobilization and no weight bearing
- Ice and elevation of the foot

**INITIAL STABILIZATION/THERAPY**

- Splint immobilization:
  - Lisfranc injuries are treated with a cast or walking boot for 4–6 wk.
- Use of NSAID medications is recommended widely for pain and inflammation.
- Relative rest is the initial treatment for stress fractures of the foot/toe.
- Apophysitis and osteochondroses are treated conservatively with rest, ice, NSAIDs, stretching, strengthening, and orthotics.
- Treatment for Turf toe should be individualized depending on injury severity:
  - It varies from supportive care to immobilization and crutches.
- Rest, ice, arch supports, facial heel-cord stretching, and strengthening are the initial treatment for plantar fasciitis.
- Conservative initial supportive measures are recommended for TTS.

**MEDICATION**

- Opioids:
  - Morphine 0.1 mg/kg IV/IM/SC q2h PRN:
    - Initial morphine dose of 0.1 mg/kg IV/SC may be repeated q15–20min until pain is controlled, then q2h PRN.

- Fentanyl 1–2 μg/kg IV q2h PRN:
  - Initial dose of 1 μg/kg IV may be repeated q15–20min until pain is controlled, then q2h PRN.
- Codeine or codeine/acetaminophen dosed as 0.5–1 mg/kg of codeine component PO q4h PRN
- Hydrocodone or hydrocodone/acetaminophen dosed as 0.1 mg/kg of hydrocodone component PO q4–6h PRN
- NSAIDs:
  - Consider NSAID medication in anticipation of prolonged pain and inflammation.
  - Some clinicians prefer to avoid due to theoretical concern over influence on coagulation and callus formation.
  - Ibuprofen 10 mg/kg/dose PO/IV q6h PRN
  - Ketorolac 0.5 mg/kg IV/IM q6h PRN
  - Naproxen 5 mg/kg PO q8h PRN

**COMPLEMENTARY & ALTERNATIVE THERAPIES**

- Nonimpact training (eg, swimming, deep pool running or cycling) facilitates healing and injury prevention in stress fractures.
- Extracorporeal shock wave therapy for plantar fasciitis has been described.

**SURGERY/OTHER PROCEDURES**

- Lisfranc injuries with gross displacement require operative treatment (6).
- Recalcitrant cases of Freiberg infraction may require surgical management (7).
- Surgery for Turf toe is restricted to cases with osteochondral injury.
- Surgical intervention in plantar fasciitis is indicated only after failure of aggressive and persistent conservative care.
- In TTS, surgical decompression may be necessary (5).

**DISPOSITION**

**Admission Criteria**

- Pediatric patients with multisystem trauma including severe foot/toe injury need admission.
- Any injuries to the foot/toe requiring emergent surgery (eg, Lisfranc sprain due to direct injury)

**Discharge Criteria**

- Well-controlled pain with normal neurovascular exam
- No evidence of compartment syndrome
- Timely and appropriate (specialty) follow-up

**Issues for Referral**

- Failure of conservative treatment
- Indications for aggressive initial management with early orthopedic referral
- More severe injuries (eg, Lisfranc injuries)
- TTS

**FOLLOW-UP**

**FOLLOW-UP RECOMMENDATIONS**

- Pain control as necessary
- Relative rest, ice, elevation, and crutches
- Primary care or orthopedic follow-up PRN
- Shock-absorbing insole or orthotic device
- After clearance by a physician, resume normal activity and training.

**Patient Monitoring**

- Watch for signs of compartment syndrome.
- Morbidity of pain in stress fractures, Turf toe, plantar fasciitis, and TTS

**PROGNOSIS**

- Most Lisfranc injuries have a good to excellent outcome (6).
- Most apophysitis and osteochondritis in children respond to conservative treatment.
- Turf toe resolution often is incomplete, with patient satisfaction being just over 50% (7).

**COMPLICATIONS**

- Chronic pain or inability to run and jump
- Arthrosis and disability may be seen in Lisfranc injury, especially with delayed diagnosis.
- Nonunion or malunion of stress fractures
- Progressive hallus valgus, hallus rigidus, and arthrosis can be seen with Turf toe.

**ADDITIONAL READING**

**See Also (Topic, Algorithm, Electronic Media Element)**

Fracture, Foot

**CODES**

**ICD9**

- 733.94 Stress fracture of the metatarsals
- 845.10 Unspecified site of foot sprain
- 959.7 Other and unspecified injury to knee, leg, ankle, and foot

**PEARLS AND PITFALLS**

- Rule out stress fractures, tumors, and infections with most apophyseal and osteochondritic conditions in children.
- Lisfranc midfoot injury initially is misdiagnosed in ~50% of patients.
- Reiter syndrome, ankylosing spondylitis, and psoriatic arthritis can mimic plantar fasciitis.

## BASICS

### DESCRIPTION

- Injuries to the hand and fingers may include bones, nails, soft tissues, tendons, arteries, nerves, or growth plates and most often occur in the home or during sports activities.
- Appropriate primary treatment and triage directly effects outcome.
- >95% of patients can be managed as an outpatient.
- Hair tourniquets may occur in infants (see the Hair-Thread Tourniquet topic).
- Hand compartment syndrome is a rare emergency associated with stings, bites, crush injury, or burns.
- Bite and stings to the hand carry an especially high risk for serious complications because the skin's surface is so close to the underlying bones and joints.
- High-pressure injection injuries occur in the workplace setting and may result in severe morbidity, sometimes with no initially obvious physical findings.

### EPIDEMIOLOGY

- 400–600/100,000 children < 16 yr of age sustain hand injuries each year (1–5).
- Bimodal age distribution: < 2 yr or > 13 yr of age
- In a review of 382 hand injuries over 8 mo in an urban pediatric emergency department:
  - Injuries were:
    - Lacerations (30%)
    - Fractures (20%)
    - Infections (4%)
    - Bites and stings (1%)
  - The 5th finger and thumb were the most common digits injured.
  - Proximal phalanx and metacarpal neck are the most common sites of fracture:
    - ~25% involve the growth plate.
    - ~50% of nail bed injuries presenting to the emergency department will have a concomitant fracture of the distal phalanx.
- 48% of bites and stings occur in children.

### RISK FACTORS

- Toddler age
- Adolescents: Sports, behavioral issues
- Home exercise equipment
- Access to machinery or power tools
- Presence of animals or chemicals in the home
- Children are at higher risk of infection than adults from fingertip injuries.

### GENERAL PREVENTION

- Safety evaluation of the home
- Supervised use of exercise equipment, machinery, or tools
- Monitored play with animals
- Avoid smoking: Directly relates to fingertip infection and healing potential.

### ETIOLOGY

- Mechanisms of injury include bites, crush, torsion, sharp laceration, burns, falls, clenched fist, or penetrating wound trauma.
- Age dependent:
  - < 2 yr of age: Crush injuries are most common.
  - > 13 yr: Torque or twisting injuries are most common.

### COMMONLY ASSOCIATED CONDITIONS

Most often an isolated complaint, but the patient must be evaluated for coexistent head or internal injuries and pathologic fracture.

## DIAGNOSIS

### HISTORY

- Hand or finger pain, deformity, and bleeding are the most common presenting symptoms:
  - History of acute injury with either urgent or delayed presentation:
    - Unwitnessed trauma in nonverbal children
    - Seeking medical attention only after observation or over-the-counter treatments have failed
- Constitutional symptoms such as fever and malaise may accompany delayed or late presentation with superimposed cellulitis, paronychia, or osteomyelitis.
- Clenched fist mechanism is more likely to indicate metacarpal injury.
- Hyperextension, torsion, or crush injury is more likely to involve the phalanx or fingertip.

### PHYSICAL EXAM

- Observation:
  - Deformity, swelling, ecchymosis, wounds
  - Overlap of fingers
  - Erythema, induration, rash, puncture wounds, or bite marks
  - Foul odor
  - Purulent discharge
  - Level of amputation/laceration:
    - Transverse
    - Dorsal oblique
    - Volar oblique
- Bone, joints, tendons:
  - Tenderness to palpation
  - Active and passive motion:
    - Flexor (profundus and superficialis)
    - Extensor
    - Mallet finger: Resting flexed position at the distal interphalangeal joint with maximal finger extension effort
  - Joint stability:
    - Stress collateral ligaments of interphalangeal and metacarpophalangeal joints at full extension and at 30 degrees of flexion to evaluate laxity. Compare to uninjured hand joints.
    - “Gamekeeper’s thumb”: Ulnar collateral ligament tear of thumb metacarpal phalangeal joint
- Nail:
  - Avulsion
  - Subungual hematoma: May require nail removal to evaluate for matrix injury

- Neurovascular:
  - Sensation to light touch in radial, median, and ulnar nerve distribution
  - 2-point discrimination volar, radial, and ulnar side of the digit
  - Axillary, brachial, radial pulses
  - Capillary refill
  - Allen testing for patent ulnar and radial wrist and digital arteries
  - Doppler or pulse oximetry

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

Consider CBC, ESR, C-reactive protein, and blood culture for infected bite and nonbite wounds.

#### Imaging

- Hand or finger x-rays with 3 views (AP/lateral/oblique) without overlying splints and minimal dressing
- CT or MRI if suspected osteomyelitis, abscess, ligament injury, occult fracture, or severely comminuted fracture

### DIFFERENTIAL DIAGNOSIS

- Congenital absence or anomaly
- Pathologic fracture with underlying bone or soft tissue disease
- Cellulitis without trauma (felon; see the Felon topic)
- Osteomyelitis without trauma

## TREATMENT

### PRE HOSPITAL

- Instruct prehospital providers to wrap amputated parts in wet gauze and not place directly on ice
- Pressure dressings or makeshift tourniquets for bleeding stumps
- Identify animal or human bite source and risk for rabies exposure

### INITIAL STABILIZATION/THERAPY

- Aluminum foam or other prefabricated splint stabilization of bony injury
- Apply pressure dressings or elevate tourniquet for bleeding control and thorough evaluation of injury.
- May require local analgesia, procedural sedation, or papoose for thorough exam

### MEDICATION

#### First Line

- Analgesia:
  - Acetaminophen 15 mg/kg/dose PO/PR q4h PRN
  - Ibuprofen 10 mg/kg/dose PO/IV q6h PRN
  - Ketorolac 0.5 mg/kg IV/IM q6h PRN
  - Naproxen 5 mg/kg PO q8h PRN
  - Codeine or codeine/acetaminophen dosed as 0.5–1 mg/kg of codeine component PO q4h PRN
  - Morphine 0.1 mg/kg IV/IM/SC q2h PRN:
    - Initial morphine dose of 0.1 mg/kg IV/SC may be repeated q15–20min until pain is controlled, then q2h PRN.
  - Fentanyl 1–2 μg/kg IV q2h PRN:
    - Initial dose of 1 μg/kg IV may be repeated q15–20min until pain is controlled, then q2h PRN.
- Tetanus prophylaxis
- Rabies treatment
- Antibiotic treatment:
  - See the Bite, Animal and Bite, Human topics.

**SURGERY/OTHER PROCEDURES**

- Irrigation and debridement of open or contaminated injuries or bite wounds under appropriate sedation or analgesia, with an arm or digital tourniquet if necessary:
  - Epinephrine should be used with caution or avoided in hand/finger anesthesia.
  - Arteries and veins in the pediatric hand/fingers are proportionally smaller. Epinephrine may risk small digital vessel vasospasm resulting in potential ischemia, tissue necrosis, or loss.
- Cast, splint, or buddy tape
- Attempted closed reduction of dislocations or displaced fractures:
  - There should be limited attempts at reduction of fractures through the growth plate due to risk of growth arrest with multiple reductions.
- Removal of foreign bodies
- Removal of nail plate for thorough exam of the sterile germinal matrix, followed by nail bed repair:
  - > 50% of subungual hematoma requires nail removal.
  - Antibiotics for open fracture of distal tuft
  - Suture or dermabond repair of nail bed laceration
- Complete amputation:
  - Keep pressure dressing on stump.
  - Place all amputated parts in saline-soaked gauze in a sealed plastic bag in an insulated box with ice.
  - Do not place amputated part directly on ice.
  - Simple transverse partial or complete distal (no bone exposed) tip amputations or avulsions may be irrigated and debrided with wet to dry dressing changes and allowed to granulate with reliably cosmetic, sensate, functional results.
  - Oblique amputations at the distal phalanx with nail bed involved or exposed bone or tendons should be irrigated and debrided, with absorbable stitch for nail bed repair, and rongeur the bone below the skin level.
  - Amputation of the finger proximal to the distal interphalangeal joint should be performed by a hand or microvascular surgeon.
- Partial amputation:
  - Use a light dressing with protective plaster or aluminum-foam splint to prevent kinking or twisting of the distal piece.
  - Repair by the emergency department or hand surgeon
- Consultation by a hand surgeon for:
  - Compartment syndrome
  - Revascularization and replantation
  - Tendon or nerve repair
  - Irreducible dislocation
  - Fixation of unstable fractures

**DISPOSITION****Admission Criteria**

- Need for surgical management
- Osteomyelitis or cellulitis or associated with bite injury or late presentation of open injury requiring IV antibiotics or surgery

**Discharge Criteria**

- Cleaned and stabilized injury in protective splint/cast with appropriate follow-up instructions
- Medication prescriptions as indicated
- May be discharged if no need for urgent surgical stabilization, reconstruction, revascularization, or IV antibiotics

**Issues for Referral**

- Timing:
  - Open injury, vascular injury, compartment syndrome irreducible dislocation: Immediate consultation in the emergency department or transfer to an appropriate tertiary care center
  - Bone reduction of stable injury within 1 wk:
    - Delayed referral will result in malunion.
  - Tendon or nerve repair within 1 wk
- Pathologic etiology: Oncology referral
- Safety or behavioral issues: Social services or psychiatric referral

**FOLLOW-UP****FOLLOW-UP RECOMMENDATIONS**

- Discharge instructions and medications:
  - Elevate hand above the elbow to decrease swelling and prevent vascular congestion. “Pledge of allegiance” or touching the opposite shoulder with the injured hand can be a more comfortable position than sling use.
  - Keep dressings clean and dry, and change as instructed.
- Activity:
  - No sports or weight bearing on the upper extremity until cleared by the primary care provider and consulting physicians
  - Behavioral modification

**Patient Monitoring**

- Evaluate for vascular sufficiency within 24 hr:
  - Proximal injuries, crush injuries: Follow for need for revascularization
- Follow up fractures for stability within 1 wk.
- Monitor for signs and symptoms of superimposed infection, cellulitis, or osteomyelitis.
- Long-term follow-up for growth arrest

**PROGNOSIS**

- Children have an excellent healing potential.
- Likely underestimated risk of lifelong issues with stiffness, scarring, or future degenerative joint disease
- Sports career ending injuries are possible.

**COMPLICATIONS**

- Osteomyelitis
- Growth plate arrest
- Loss of motor or sensory function
- Cosmetic deformity of fingertip or nail

**See Also (Topic, Algorithm, Electronic Media Element)**

- Bite, Animal
- Bite, Human
- Compartment Syndrome
- Felon
- Hair-Thread Tourniquet
- Tetanus Prophylaxis

**ICD9**

- 882.0 Open wound of hand except fingers alone, without mention of complication
- 959.4 Other and unspecified injury to hand, except finger
- 959.5 Other and unspecified injury to finger

**PEARLS AND PITFALLS**

- Identifying the mechanism of hand/finger trauma will best guide emergency treatment.
- During exam, make the patient as comfortable as possible in the supine position.
- Do not place amputated tissue directly on ice.
- If sutured, use absorbable (chromic or plain gut) stitches in the nail bed repair. Limit nonabsorbable suture use.
- Dermabond may be used to repair nail bed lacerations or to protect exposed nail bed.
- Never suture infected wounds:
  - Bite wounds should rarely be sutured.
- Growth plate injuries are more likely to sustain growth plate arrest.
- Patients must have close follow-up for wound check and tendon or nerve injuries.

# TRAUMA, HEAD

Russell Radtke  
Curt Stankovic

## BASICS

### DESCRIPTION

- Head trauma occurs with a blunt or penetrating force applied to the head:
  - May be associated with alterations of neurologic, psychosocial, or physical function
  - Wide spectrum of pathology and severity ranging from skin and soft tissue injury to intracranial hemorrhage and death
- Management should focus on rapidly identifying the primary injury, limiting secondary brain injury, and limiting unnecessary imaging to reduce radiation exposure.
- Severity of injury related to initial Glasgow Coma Scale (GCS) score: >12, mild; 9–12, moderate; <9, severe (1)

### EPIDEMIOLOGY

#### Incidence

- Annually, 600,000 pediatric emergency department visits, 65,000 hospital admissions, and 7,400 deaths (2)
- Brain injury is a leading cause of death and disability in pediatric trauma patients.

#### Prevalence

1:1,000 teenagers and 1:2,000 younger children are hospitalized with head injury each year.

### RISK FACTORS

- Risk increases as age decreases:
  - Children <2 yr of age are at increased risk and are difficult to assess (3–5).
  - Infants <3 mo of age are at greatest risk.
- Male to female ratio of 2:1
- Participation in contact sports

### GENERAL PREVENTION

Safety gates, proper vehicle restraints, helmets, and proper equipment use during contact sports and recreational activities

### PATHOPHYSIOLOGY

- Direct injury to tissues by physical trauma or acceleration/deceleration/rotational forces
- Primary brain injury is caused by contusion, shearing forces to axons and intracranial blood vessels, and direct penetration.
- Secondary brain injury is caused by hypoxia, hypoperfusion, and metabolic derangements/free radical damage.
- The most important cause of secondary brain injury is cerebral ischemia from inadequate cerebral blood flow. Flow can be improved by optimizing cerebral perfusion pressure.

### ETIOLOGY

Falls, motor vehicle crashes (MVCs), biking accidents, sports injuries, or child maltreatment

### COMMONLY ASSOCIATED CONDITIONS

- C-spine injury
- Multisystem trauma

## DIAGNOSIS

### HISTORY

- Historical information can stratify patients into different risk categories.
- High-risk mechanisms of injury include:
  - MVC with patient ejection, death of another passenger, or rollover; MVC vs. pedestrian or bicyclist without helmet, falls >5 feet (for children >2 yr of age) or >3 feet (<2 yr of age); head struck by high-impact object (3,4)
- Intermediate risk mechanisms of injury include any mechanism not mentioned above or an unwitnessed incident (3,4).
- Low-risk mechanisms of injury include:
  - Ground-level falls, running into a stationary object (3,4)
- High-risk symptoms include:
  - Loss of consciousness (LOC)  $\geq$  1 min, altered mental status (AMS), seizure, irritability or lethargy, vomiting  $\geq$  5 times or occurring for >6 hr (3–5)
- Intermediate-risk symptoms include:
  - 3–4 episodes of vomiting, transient LOC (<1 min), resolved lethargy or irritability, severe headache, and behavior not at baseline (3–5)
- Low-risk symptoms include:
  - Mild headache or resolution of signs or symptoms within 2 hr post injury (3–5)
- Vomiting or a transient LOC are not independent risk factors for intracranial injury (ICI) (3,5).
- Special attention to underlying medical problems or medications that may predispose patient to intracranial bleeding risk (hemophilia, anticoagulant use, alcohol use)
- Unclear or inconsistent history of injury should raise suspicion for nonaccidental trauma.

### PHYSICAL EXAM

- A detailed head, neck, and neurologic exam is critical as well as an exam searching for coexisting injuries.
- High-risk findings:
  - AMS, focal neurologic findings, signs of a depressed or basilar skull fracture, irritability, bulging fontanelle (3,4)
- Intermediate-risk findings:
  - Large nonfrontal scalp hematoma, nonacute skull fracture (>24 hr), behavior change (3,4)
- Low-risk findings:
  - Frontal hematoma, normal mental status, normal neurologic exam, no signs of skull fracture (3,4)
- Anosmia, rhinorrhea, otorrhea, hemotympanum, or ecchymosis behind the ear (Battle sign) may be associated with a basilar skull fracture.
- Parietal and temporal contusions are associated with a higher risk of traumatic brain injury (TBI).
- Cranial nerve VII palsy is associated with temporal bone fracture.
- Ptosis, lateral gaze palsy, pupil abnormalities, hemiparesis, posturing, or Cushing triad (bradycardia, HTN, irregular respirations) are findings associated with herniation syndromes.
- Evaluation of the fundi for retinal hemorrhages is mandatory if suspicious of child maltreatment.

## DIAGNOSTIC TESTS & INTERPRETATION

### Lab

#### Initial Lab Tests

- CBC, type and screen, BUN/creatinine, AST/ALT, amylase, lipase, and urinalysis (if suspecting multisystem trauma)
- Pregnancy screen (if appropriate)
- Drug and alcohol screens (if indicated)

### Imaging

- High-risk patients of any age should have a noncontrast head CT.
- Intermediate-risk patients should either have a head CT or be observed for 4–6 hr.
- Low-risk patients do not require imaging.
- A clinical decision rule should be used to identify very low risk patients and assess the need for imaging in patients who experienced minor head trauma and have a GCS of 14 or 15:
  - For children <2 yr of age:
    - Very low risk (absence of the following): AMS, nonfrontal scalp hematoma, LOC, severe mechanism of injury, palpable skull fracture, parental report of behavioral change (negative predictive value [NPV] 100%, sensitivity 100%) (4)
    - Intermediate risk (any of the following): Vomiting (3–4 times), LOC <1 min, resolved lethargy or irritability, behavior change, or nonacute skull fracture (3,5)
    - High risk (any of the following): AMS, focal neurologic findings, signs of basilar skull fracture, seizure, irritability, bulging fontanelle, skull fracture, vomiting  $\geq$  5 times or >6 hr, LOC  $\geq$  1 min (3,5)
  - For children >2 yr of age:
    - Very low risk (absence of the following): AMS, LOC, vomiting, severe mechanism of injury, signs of basilar skull fracture, or severe headache (NPV 99.9%, sensitivity 96.8%) (4)
    - Intermediate risk (any of the following): Transient LOC (<1 min), temporal or parietal contusion, vomiting, resolved irritability, headache, significant mechanism (5)
    - High risk (any of the following): AMS, palpable skull fracture, signs of basilar skull fracture (4,5)
- Skull radiographs have a limited role in the evaluation of TBI; however, they may be used initially to evaluate children <1 yr of age with minor trauma, no LOC, and no clinical signs of a skull fracture.

### Diagnostic Procedures/Other

- Skeletal survey if concerned about nonaccidental trauma.
- Consider C-spine, chest, and pelvic radiographs if evaluating multisystem trauma.

### Pathological Findings

- Lacerations, minor soft tissue injuries
- Skull fracture (linear, depressed, basilar)
- Epidural/Subdural hematoma
- Subarachnoid/Intraparenchymal hemorrhage
- Cerebral contusion, diffuse axonal injury
- Herniation (tentorial, foramen magnum, subfalcine, retroalar)

**DIFFERENTIAL DIAGNOSIS**

- Metabolic derangements resulting in depressed mental status (eg, hypoglycemia, diabetic ketoacidosis)
- Seizures or postictal state
- Intoxication

**TREATMENT****PRE HOSPITAL**

- Assess and stabilize airway, breathing, and circulation:
  - Administer supplemental oxygen.
- C- spine immobilization
- Direct pressure on bleeding wounds

**INITIAL STABILIZATION/THERAPY**

- Assess and stabilize airway, breathing, and circulation:
  - Primary goal is to limit secondary brain injury by preventing hypoxia, hypotension, or hyperthermia.
  - Airway management with rapid sequence intubation if GCS <8, diminished gag reflex, labored respirations, unmanageable oral secretions, or physical exam consistent with increased intracranial pressure (ICP)
  - Maintenance of C-spine stabilization
  - Direct pressure to vigorously bleeding scalp lesions
- Medications for the management of elevated ICP (see the Traumatic Brain Injury topic)
- Prophylactic broad-spectrum antibiotics are recommended for penetrating head injury.
- Consider prophylactic anticonvulsants for penetrating head injury, intracranial hemorrhage, or severe TBI.
- Judicious use of pain control; NSAIDs for headache associated with minor head injury

**MEDICATION****First Line**

- Ibuprofen 10 mg/kg/dose PO/IV q6h PRN
- Morphine 0.1 mg/kg IV/IM/SC q2h PRN:
  - Initial morphine dose of 0.1 mg/kg IV/SC may be repeated q15–20min until pain is controlled, then q2h PRN.

**Second Line**

Phenytoin or fosphenytoin: 20 mg/kg IV loading dose

**COMPLEMENTARY & ALTERNATIVE THERAPIES**

- Laceration repair for simple lacerations
- Meticulous debridement for contaminated wounds

**SURGERY/OTHER PROCEDURES**

- ICP monitor/drain placement
- Evacuation of hematoma, decompressive craniectomy, or debridement if penetrating injury

**DISPOSITION****Admission Criteria**

- Unreliable caretakers or abuse
- Persistent vomiting
- Abnormal vital signs or neurologic exam (even with normal imaging)
- Critical care admission criteria:
  - Comatose patients
  - Patients who are mechanically ventilated
  - Patients with an abnormal CT
  - Severe multisystem trauma

**Discharge Criteria**

- Normal neurologic exam
- No persistent vomiting or severe headache
- Neurologically normal patients with a normal head CT may be observed at home.
- No concerns for child maltreatment
- Isolated linear skull fractures without other issues may be discharged with close follow-up.

**Issues for Referral**

- Moderate to severe head injury requires evaluation by a neurosurgeon:
  - Evidence of an intracranial bleed, focal neurologic findings, depressed skull fracture, or evidence of impending herniation warrants immediate evaluation by neurosurgery.
- Concern for child maltreatment mandates the involvement of protective services/social work.

**FOLLOW-UP****FOLLOW-UP RECOMMENDATIONS**

- Discharge instructions and medications:
  - Return for changes in mental status or behavior, weakness/paralysis/blindness, persistent vomiting, unsteady gait, clumsiness, or worsening headache
- Activity:
  - After concussion, the child should not return to play until asymptomatic.
  - See return to play guidelines in the Concussion topic for details.

**Patient Monitoring**

- Cardiopulmonary monitoring
- Serial neurologic checks

**DIET**

NPO until ICI is ruled out

**PROGNOSIS**

Though highly variable, very low initial GCS is highly associated with long-term complications.

**COMPLICATIONS**

- Postconcussive syndrome
- Seizures
- SIADH, diabetes insipidus
- Cognitive impairment
- Death

**CODES****ICD9**

- 432.9 Unspecified intracranial hemorrhage
- 854.00 Intracranial injury of other and unspecified nature, without mention of open intracranial wound, with state of consciousness unspecified
- 959.01 Other and unspecified injury to head

**PEARLS AND PITFALLS**

- Pearls:
  - Aggressive prevention of hypoxia, hyperthermia, and hypotension is the best way to limit secondary brain injury.
  - Suspicion for serious ICI should increase as patient age decreases.
  - Early neurosurgery consultation can be lifesaving in cases of intracranial hemorrhage.
- Pitfall:
  - Maintain a high level of suspicion about the possibility of nonaccidental trauma, especially in younger children.

# TRAUMA, KNEE

Michael D. Baldovsky  
Barry G. Gilmore

## BASICS

### DESCRIPTION

- Knee pain is a common pediatric complaint in the emergency department.
- The knee consists of the distal femur, the proximal tibia and fibula, the patella, the anterior cruciate ligament (ACL), the posterior cruciate ligament (PCL), the medial collateral ligament (MCL), the lateral collateral ligament (LCL), and the medial and lateral meniscus cartilages.
- Additionally, the popliteal artery and vein and the tibial and common peroneal nerves run through the popliteal fossa.

### EPIDEMIOLOGY

#### Incidence

- Fractures of the knee occur in ~9% of knee injuries (1).
- ACL injuries are uncommon in children <12 yr of age with an incidence of only 0.5% (2).
- Meniscus injuries increase with age and occur more commonly in the medial meniscus. Only 5% of meniscus injuries occur in patients <15 yr of age (3).
- Patellar dislocations occur in 43/100,000 children. Dislocation is usually lateral, with other dislocations being rare (4).
- Knee dislocations are uncommon. Popliteal artery damage occurs in ~39% of anterior knee dislocations (5).

#### Prevalence

- The rate of injuries as well as the severity of injuries increases with age.
- Boys are injured more often than girls.

### RISK FACTORS

- The knee joint has relatively low stability.
- Younger children have open physes.
- Assessment of pain and tenderness is challenging in younger children.
- History may be unreliable in younger children.

### GENERAL PREVENTION

- Protective athletic equipment such as knee pads and knee braces
- Strength training to increase muscle strength and support around the knee joint
- Proper technique for exercise and sports

### PATHOPHYSIOLOGY

In younger children, fractures are more common than ligamentous injuries due to the relative strength of their ligaments compared to their growing bones.

### ETIOLOGY

Injuries usually result from high-energy or high-velocity activities that cause direct trauma to the knee or twisting of the knee.

### COMMONLY ASSOCIATED CONDITIONS

- Ligamentous injuries can cause avulsion fractures of the tibial spines.
- ACL injuries are associated with MCL and meniscal injuries.
- Knee dislocations can cause popliteal artery and peroneal nerve damage.

- Patellar dislocations/subluxations can have associated avulsion fractures.
- Patients with meniscal injuries may have an underlying discoid meniscus.

## DIAGNOSIS

### HISTORY

- ACL injuries: Can result from direct anterior forces applied to the tibia but more commonly are from twisting injuries with the foot planted. Patients report hearing a pop or snap during the injury and knee swelling soon after the injury. They also report a sensation of the knee buckling or giving out.
- PCL injuries: Can result from direct posterior forces applied to the tibia but more commonly are from twisting with the foot planted. Patients may have buckling or hyperextension of the knee.
- MCL/LCL injuries: Result from direct trauma to the lateral/medial knee producing valgus/varus stress. Patients report pain along the medial/lateral knee.
- Meniscus injuries: Result from flexion of knee and internal rotation of the tibia, which pulls the medial meniscus laterally, producing tears in the cartilage. Patients report joint line pain, locking of the knee, and knee swelling.
- Patellar dislocation: May result from direct trauma to the patella but more commonly occurs from a sudden twisting motion of the knee. The patients report a pop or tear followed by lateral displacement of the patella and knee swelling.
- Patellar subluxation: Similar history as patellar dislocation, but the patella is not dislocated
- Patellar fracture: Most commonly results from direct trauma to the patella but can occur from forceful quadriceps contraction
- Knee dislocation: Dislocation of the tibia on the femur. Usually the result of high-velocity trauma or trauma that causes hyperextension. Most dislocations are anterior or posterior, and many reduce spontaneously.

### PHYSICAL EXAM

- Compare the knees for asymmetry. Inspect the patient's gait. Assess for loss of the peripatellar grooves, which indicates a joint effusion.
- Neurovascular exam: Assess pulses, capillary refill time, muscle strength, and sensation distal to the knee.
- Palpate the knee joint for localized tenderness. Bony point tenderness may indicate a fracture. Tenderness along the joint line may indicate collateral ligament or meniscal injury.
- Ballottement test: With the patient supine, place 1 hand superior to the patella and the other hand inferior to patella. Apply pressure with the upper hand to create a fluid wave, and apply downward pressure to the patella. The test is positive for a joint effusion if the patella can be pushed downward.
- Anterior/Posterior drawer tests: Patient supine with knee flexed to 90 degrees. With the foot stabilized, pull/push the proximal tibia anteriorly/posteriorly. The test is positive for ACL/PCL injury if there is no discrete endpoint or there is increased movement compared to the healthy knee.

- Lachman test: Patient supine with knee flexed to 20–30 degrees. Stabilize the distal femur with 1 hand, and pull the proximal tibia anteriorly with the other hand. The test is positive for ACL injury if the patient has increased anterior movement compared to the other side.
- McMurray test: Patient supine with knee flexed and the foot externally rotated. The test is positive for medial meniscus injury when extension of the knee produces crepitus or pain along the medial joint line. Repeat the test with the knee flexed and the foot internally rotated. The test is positive for lateral meniscus injury when extension of the knee produces crepitus or pain along the lateral joint line.
- Apley compression test: Patient prone with knee flexed to 90 degrees. With the posterior thigh stabilized, apply downward force to the foot and internally and externally rotate the lower leg. The test is positive for meniscal injury if pain is elicited.
- Valgus/Varus stress tests: Patient supine with knee in 20 degrees of flexion. Examiner holds the lateral/medial knee with 1 hand and abducts/adducts the knee with external/internal rotation of the foot. Repeat maneuver with the knee in extension. The test is positive for MCL/LCL injury if the medial/lateral joint opens more than the healthy knee.
- Patellar dislocation: Patient holds the knee in mild flexion with the patella dislocated laterally and acute knee swelling
- Patellar apprehension test: With the knee extended, force is applied laterally to the medial patella. Flexion of the quadriceps muscle due to pain or hesitation is indicative of patellar subluxation. Patients also complain of tenderness of the medial patella.
- Patellar fracture: Tenderness over the patella and swollen knee. Assess for associated rupture of leg extensors.
- Knee dislocation: Tibia is displaced on the femur, usually anteriorly or posteriorly. Patients may have a popliteal hematoma or decreased/absent pedal pulses from associated popliteal artery damage. They may also have foot drop or numbness of the dorsal foot from associated peroneal nerve injury.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

- Lab tests should focus on other injuries.
- If surgery is required, the patient may need preoperative labs.

#### Imaging

- No radiograph is needed prior to reduction of obvious patellar dislocation.
- Obtain AP/lateral radiographs to identify fractures. Obtain sunrise views also if patellar fracture is suspected, if there is a patellar subluxation, or post patellar reduction:
  - Ottawa Knee Rules can determine if an x-ray is necessary. Rules have been shown to be applicable to children 2–16 yr of age (1).

- Ottawa Knee Rules: Acute knee trauma plus 1 of the following:
  - Tenderness at the head of fibula
  - Isolated tenderness of the patella
  - Inability to flex the knee to 90 degrees
  - Inability to bear weight immediately and in the emergency department
- Obtain MRI if the diagnosis is in question.

#### Diagnostic Procedures/Other

- Arthroscopy: Used to identify and possibly treat soft tissue or cartilaginous injuries
- Arteriogram: Used to identify vascular injury if the patient has decreased pulses or perfusion

#### Pathological Findings

- Rupture or partial tear of ligaments
- Tear in meniscal cartilages or loose cartilage in knee joint
- Vascular injury

#### DIFFERENTIAL DIAGNOSIS

- Knee fracture or joint dislocation
- Ligamentous/Cartilaginous injury
- Patellar dislocation/subluxation
- Plica syndrome: Synovial tissue remnants can become irritated by trauma or overuse causing knee pain, popping, or locking.
- Osteochondritis dissecans: The separation of a segment of bone and cartilage usually secondary to trauma and ischemia. Patients report pain, stiffness, and locking of joint. This can usually be detected on routine radiographs.

## TREATMENT

#### PRE HOSPITAL

- Assess ABCs 1st, then neurovascular status.
- Immobilization and pain control

#### INITIAL STABILIZATION/THERAPY

- Assess ABCs 1st, then neurovascular status.
- Immobilization if not already done
- Adequate pain control

#### MEDICATION

##### First Line

- Opioids:
  - Morphine 0.1 mg/kg IV/IM/SC q2h PRN:
    - Initial morphine dose of 0.1 mg/kg IV/SC may be repeated q15–20min until pain is controlled, then q2h PRN.
  - Codeine or codeine/acetaminophen dosed as 0.5–1 mg/kg of codeine component PO q4–6h PRN
  - Hydrocodone or hydrocodone/acetaminophen dosed as 0.1 mg/kg of hydrocodone component PO q4–6h PRN
- NSAIDs:
  - Consider NSAID medication in anticipation of prolonged pain and inflammation.
  - Some clinicians prefer to avoid due to theoretical concern over influence on coagulation and callus formation.
  - Animal studies have raised concerns that NSAIDs may negatively influence bone healing; however, there is no clinical evidence in humans.
  - Ibuprofen 10 mg/kg/dose PO q6h PRN
  - Ketorolac 0.5 mg/kg IV/IM q6h PRN
- Acetaminophen 15 mg/kg/dose PO/PR q4h PRN

#### COMPLEMENTARY & ALTERNATIVE THERAPIES

Protection, rest, ice, compression, elevation (PRICE):

- Knee immobilizer or brace
- Long leg casting with bivalve
- Crutches

#### SURGERY/OTHER PROCEDURES

- Arthroscopy, ligament repair
- Open reduction and internal fixation (ORIF)
- Popliteal artery repair

#### DISPOSITION

##### Admission Criteria

- Admit if there are other injuries requiring admission.
- Neurovascular compromise
- Fractures requiring ORIF
- Most patients with isolated ligamentous injuries can be treated as an outpatient.

##### Discharge Criteria

- No other unstable injuries
- Neurovascularly intact
- Pain well controlled
- Timely follow-up assured

##### Issues for Referral

- Emergent orthopedic surgery consultation for open or significantly displaced fractures, unsuccessful reduction of dislocations, compartment syndrome, decreased pulses, or significant weakness or numbness distal to injury
- Emergent vascular surgery consultation for obvious vascular ischemia
- Referral to an orthopedic surgeon as an outpatient for fractures, severe ligamentous injury, atypical dislocations, or if no improvement after 5–7 days
- Follow up with a primary care physician if mild injury and the patient is improving.

## FOLLOW-UP

#### FOLLOW-UP RECOMMENDATIONS

- Discharge instructions and medications:
  - Adequate pain control
  - PRICE, immobilization, and crutches
  - Return if poor perfusion, pain control is inadequate, or new neurologic concerns
- Activity:
  - Non-weight bearing for 1st 2–3 days
  - Early rehabilitation

#### PROGNOSIS

- Isolated ACL/PCL injuries and isolated MCL/LCL injuries may heal with conservative treatment unless the patient has continued instability.
- Isolated meniscal injuries may heal with conservative treatment unless persistent locking or other symptoms.
- Patellar dislocation/subluxation may heal with conservative treatment, but there is high chance of recurrence in children.

#### COMPLICATIONS

- Missed neurovascular injuries
- Growth arrest in fractures through the physes
- Nonunion of fractures
- Permanent decreased range of motion

- Fracture, Patella

## CODES

#### ICD9

- 822.0 Closed fracture of patella
- 836.50 Closed dislocation of knee, unspecified part
- 959.7 Other and unspecified injury to knee, leg, ankle, and foot

#### PEARLS AND PITFALLS

- Examine the hip and ankle in all patients with knee injuries, especially younger children.
- Ottawa Knee Rules may be used to exclude x-rays in pediatric patients.
- Failure to repeat the neurovascular exam

## BASICS

### DESCRIPTION

- Pediatric neck injuries are uncommon:
  - Divided into penetrating or blunt trauma
- Fractures of the C-spine are discussed in a separate topic (see the Fracture, Cervical Spine topic).

### EPIDEMIOLOGY

- Mortality ranges from 7–11% in penetrating neck injuries (1):
  - Penetrating neck trauma occurs more often in boys and in older children (average age 12 yr)
  - Concurrent vascular trauma is present in 25% of cases.
- Blunt neck trauma accounts for ~80–90% of pediatric neck trauma (2).

### PATHOPHYSIOLOGY

- Anatomic differences exist between pediatric and adult necks until about 8 yr of age:
  - Larger head and shorter neck lead to more flexion and extension injuries in children.
  - Ligaments are more elastic, making ligamentous injuries more common than fractures:
    - Pseudosubluxation of C2 or C3 is seen in up to 40% of children (3).
- The neck is divided into anterior and posterior triangles that can help identify injuries based on location:
  - The anterior triangle of the neck is defined by the boundaries of the mandible, sternocleidomastoid muscle, and the midline of the neck:
    - Contained structures include the internal jugular vein, carotid vessels, thyroid gland, larynx, trachea, esophagus, and lower cranial nerves.
  - The posterior triangle of the neck is defined by the boundaries of the trapezius muscle, sternocleidomastoid muscle, and clavicle:
    - Contained structures include the accessory nerve, subclavian artery, and the brachial plexus.
- The neck is also divided into 3 anatomic zones. Each zone has different risks, injuries, and management associated with it:
  - Zone 1 extends from the clavicles to the cricoid cartilage:
    - Contains the trachea, apex of lungs, carotid, vertebral and subclavian arteries, jugular veins, esophagus, thoracic duct, thymus, spinal cord, and brachial plexus
    - Zone 1 injuries are complicated by difficulty in exposure and control of proximal vascular injuries
  - Zone 2 extends from the cricoid cartilage to the angle of the mandible:
    - Contains the trachea, larynx, pharynx, esophagus, internal and external carotid vessels, jugular veins, recurrent laryngeal nerve, thyroid, parathyroids, spinal cord, and cranial nerves X–XII
    - Zone 2 injuries are easiest to diagnose and treat and may be controlled with direct pressure to wound site.

- Zone 3 extends from the angle of the mandible to the base of the skull:
  - Contains the pharynx, spinal cord, cranial nerves VIII–XII, carotid and vertebral vessels, and jugular veins
  - Zone 3 injuries are complicated by the lack of exposure and need for distal control of vascular bleeding.
- Blunt neck injury results from hyperextension or hyperflexion injuries, rotational forces, and direct blows. Symptoms may be less obvious than in penetrating injuries, so clinicians need to have a higher index of suspicion.
- Spinal cord injury without radiologic abnormality (SCIWORA):
  - Broad clinical spectrum of injury to nerve roots with sensory and/or motor dysfunction without evidence of vertebral fracture or malalignment on either plain radiographs or CT imaging of spine
  - Usually results from flexion-extension injury
  - More common in children
  - Inherent elasticity in the pediatric C-spine allows severe spinal cord injury to occur.

### ETIOLOGY

- The majority of pediatric penetrating neck wounds is a result of motor vehicle accidents and gunshot and knife injuries.
- Most pediatric blunt neck trauma results from motor vehicle accidents, but other causes include fights, sports injuries, handlebar injuries, and strangulation (child abuse or suicidal).

### COMMONLY ASSOCIATED CONDITIONS

- Consider coexisting injuries to other body parts such as the head, especially with blunt neck trauma.
- C-spine fractures

## DIAGNOSIS

### HISTORY

- A history of trauma is usually elicited from the patient, family member, or prehospital provider.
- Inquire about amount of blood loss, pulsatile lesions, wound locations, time of incident, mechanism of injury, and alcohol or illicit drug use.
- Ask about changes in voice, hoarseness, dysphagia, odynophagia, tenderness, or hematemesis.

### PHYSICAL EXAM

- Physical findings depend on location of injury.
- Look for entrance and exit wounds with penetrating injuries (knife, bullet wounds).
- Laryngeal or tracheal injuries may present as stridor, subcutaneous emphysema or crepitus, palpable fractures of cartilage, tracheal deviation, hoarseness or other voice changes, or respiratory distress.
- Pharyngoesophageal injuries may present as neck pain, bloody saliva or hematemesis, tenderness to palpation, odynophagia, or subcutaneous emphysema.

- Vascular injuries may present as profuse or pulsatile bleeding, shock, hemoptysis, expanding hematoma, hematemesis, carotid bruits or thrills, or unequal pulses.
- Lung injuries may present with cough, respiratory distress, retractions, decreased breath sounds, hemoptysis, tachypnea, agitation, hypoxia, tachycardia, pneumothorax, or hemothorax:
  - Auscultate the neck for bruits and the lungs for asymmetric breath sounds.
- Palpate the neck for thrills, crepitus, and masses.
- Violation of the platysma muscle may indicate more serious underlying injuries caused by penetrating trauma:
  - In cases of penetrating trauma, if the platysma is intact, the patient can likely be cleared of any significant underlying injuries.
  - This does not rule out injury from blunt trauma.
- Spinal cord lesions present with varied symptoms including quadriplegia (complete spinal cord transection), ipsilateral motor paralysis with contralateral sensory deficits (Brown-Sequard syndrome), urinary retention, fecal incontinence, and/or decreased strength in the upper arm with normal strength and sensation in the lower arm (brachial plexus injury).

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

- Any routine lab assays used for patients with trauma or preoperatively
- Alcohol screening if warranted

#### Imaging

- The location and type of injury dictate which imaging test should be performed.
- Chest radiograph can identify pneumothorax, pleural effusions, and widened mediastinum:
  - Should be performed in any zone 1 injury
- Cervical AP and lateral radiographs can evaluate for foreign bodies, fractures, widened prevertebral space, spinal malalignment, and subcutaneous emphysema.
- US:
  - Color flow Doppler US to evaluate for vascular injury
  - Duplex US may be useful in zone 2 injuries to evaluate vasculature:
    - Less helpful in zone 1 or 3 injuries due to anatomic limitations
- CT scan if necessary to evaluate for C-spine fracture or soft tissue injury
- MRI to identify spinal cord injury or SCIWORA:
  - Time constraints may not make MRI useful in the acute management of neck injury.

#### Diagnostic Procedures/Other

- Angiography:
  - If the patient is stable, angiography is the standard evaluation to look for vascular injury in both blunt and penetrating neck trauma.
- Flexible fiberoptic nasolaryngoscopy allows visualization of the airway, is minimally invasive, does not require general anesthesia, and does not endanger the C-spine (4).

- Bronchoscopy to evaluate for tracheal or bronchial injury
- Esophogography and/or contrast swallow to look for esophageal or GI injury
- Direct laryngoscopy to evaluate for oropharyngeal and tracheal injury

### DIFFERENTIAL DIAGNOSIS

Spinal cord injuries, C-spine injuries

## TREATMENT

### PRE HOSPITAL

- Assess and stabilize airway, breathing, and circulation:
  - Administer supplemental oxygen, preferably by nonrebreather mask.
  - Suction airway of secretions, if possible.
  - C-spine immobilization
  - Direct pressure to bleeding sites
- Impaled objects should not be removed.

### INITIAL STABILIZATION/THERAPY

Assess and stabilize airway, breathing, and circulation per Advanced Trauma Life Support (ATLS) and Pediatric Advanced Life Support (PALS) guidelines:

- Administer supplemental oxygen, preferably by nonrebreather mask.
- Maintain airway patency, control bleeding by direct pressure (not clamping), identify injuries, and prevent further injury.
- Airway control may be difficult with suspected C-spine fractures or penetrating injuries. The goal is to secure the airway and prevent further injury:
  - Consider early intubation if the child cannot maintain the airway. Orotracheal intubation is the preferred method.
  - Surgical airway may have to be considered if a difficult airway or in facial/mandibular trauma.
  - If possible, obtain an anesthesiology consult to assist in difficult airways.
- Emergently decompress a tension pneumothorax in those with respiratory distress and zone 1 injury
- If the patient has unstable vital signs, decreased Glasgow Coma Scale score, or shows signs of shock or excessive bleeding, place 2 large-bore IVs and start IV fluid resuscitation:
  - Consider blood replacement if no improvement after 2nd or 3rd IV fluid boluses.
  - Do not clamp actively bleeding vessels to stop hemorrhage, as this may damage the vessel wall. Direct pressure is the preferred method to control bleeding until the patient can undergo operative management.
- Consider prophylactic broad-spectrum antibiotics for penetrating neck injuries.
- Pain control

## MEDICATION

### First Line

- Opioids:
  - Morphine 0.1 mg/kg IV/IM/SC q2h PRN:
    - Initial morphine dose of 0.1 mg/kg IV/SC may be repeated q15–20min until pain is controlled, then q2h PRN.
  - Fentanyl 1–2  $\mu$ g/kg IV q2h PRN:
    - Initial dose of 1  $\mu$ g/kg IV may be repeated q15–20min until pain is controlled, then q2h PRN.
  - Codeine or codeine/acetaminophen dosed as 0.5–1 mg/kg of codeine component PO q4h PRN
- NSAIDs:
  - Ibuprofen 10 mg/kg/dose PO/IV q6h PRN
  - Ketorolac 0.5 mg/kg IV/IM q6h PRN
  - Acetaminophen 15 mg/kg/dose PO/PR q4h PRN
- Antibiotics:
  - Ceftriaxone 50 mg/kg/dose IV daily

### Second Line

- Previously, steroids were recommended by the ATLS guidelines, but based on recent data, this recommendation has been withdrawn.
- Tetanus immunization if indicated

### SURGERY/OTHER PROCEDURES

Immediate consultation with surgical colleagues when necessary:

- Historically, zone 2 penetrating injuries require surgical exploration, while zones 1 and 3 are more difficult to access and less likely to be explored.
- In patients with stable airway, there is a move toward selective exploration since high-resolution imaging by CT and MRI are available to identify injuries (4).
- Indications for operative management of penetrating neck injury include expanding hematoma, active bleeding, exposed airway, presence of foreign body, evidence of vascular occlusion, and shock (4).

## DISPOSITION

### Admission Criteria

- Patients with penetrating neck trauma should be admitted for observation.
- If zone 1 injury and normal radiographs, admit unless an arteriogram can be performed.
- Patients with spinal cord injuries or concerns of SCIWORA
- Critical care admission criteria:
  - Unstable vital signs, airway compromise, endotracheal intubation or mechanical ventilation, or associated severe or life-threatening injury

### Discharge Criteria

The following patients can likely be discharged, assuming no other systemic injury:

- Penetrating neck trauma not violating the platysma
- Blunt neck trauma with normal neck CT scan and no midline C-spine tenderness

## FOLLOW-UP

### FOLLOW-UP RECOMMENDATIONS

- Follow-up with a specialist is dependent on location and extent of injury.
- Consider antibiotic coverage for prophylaxis of penetrating neck injuries.
- Analgesics for pain management
- In patients with SCIWORA, immobilization of the C-spine is recommended for up to 3 wk (5).

## CODES

### ICD9

- 874.8 Open wound of other and unspecified parts of neck, without mention of complication
- 959.09 Other and unspecified injury to face and neck

## PEARLS AND PITFALLS

- Pearls:
  - Always maintain in-line C-spine stabilization during transport or intubation.
  - Always fully inspect the neck by removing the cervical collar.
- Pitfalls:
  - Removing impaled objects that may release tamponade and cause massive hemorrhage
  - Consider other coexisting injuries.
  - Consider intubation early if unstable vital signs, altered mental status, compromised airway, or considerable amount of blood loss.

## BASICS

### DESCRIPTION

- Penetrating wounds are injuries that pierce the skin and can cause internal damage:
  - Range from simple lacerations to multiorgan injury
- Morbidity and mortality is high.
- Type of weapon used impacts outcome:
  - Firearms produce most damage:
    - Shotgun wounds in small children have greater lethality than in adults.
    - Rifle shots are high velocity and have much higher lethality than handgun shots.
    - More disability with stabbing or piercing:
      - 10% of all chest traumas are penetrating, with stab wounds being the most common.
    - Impalement injuries occur at home due to falls or falling objects and may be fatal.
  - Specific management is guided by location, trajectory, and organs injured:
    - Care may be challenging and often requires rapid assessment and intervention.
    - Surgical intervention is frequently required.

### EPIDEMIOLOGY

- Represents only 10% of all pediatric traumas (1)
- Lethality 3-fold greater than blunt trauma (1):
  - Firearms represent 7% of all trauma-related admissions and 12% of case fatalities (1).
  - 30% of patients die before reaching a hospital and 12% die in the emergency department (2).
- Gunshot wounds (GSW) are the most common type and have the highest mortality rate (17%) (3).
  - Mortality from GSW to the head is 3 times higher than with other body areas (2).
- Mortality from penetrating trauma is high in children because of the close proximity of vital organs with the small pediatric body frame (4).

### RISK FACTORS

- Black males are more likely to sustain a lethal injury from assault (2).
- Fatality from self-inflicted injuries is highest among whites (2).

### GENERAL PREVENTION

- Health care personnel should advise parents of dangers of weapons in and outside the home.
- Safe use and storage of firearms

### PATHOPHYSIOLOGY

- Smaller body surface area and close proximity of a child's internal organs with one another often results in multiorgan injury.
- GSW are either low velocity (<1,000 feet/sec) or high velocity (>2,500 feet/sec):
  - Low-velocity firearms (eg, handguns) cause direct vascular injury.
  - High-velocity firearms cause cavitations and disruption of distant organs.

### ETIOLOGY

- Injuries may be accidental or intentional:
  - May be suicidal or homicidal in intent
- May be due to gunshots, knife stabbings, or other penetrating objects

## DIAGNOSIS

### HISTORY

History determines cause and mode of injury:

- An AMPLE history should be obtained:
  - A: Allergies to medications
  - M: Medications that the child is taking
  - P: Past medical history
  - L: Time of last meal
  - E: Events surrounding the trauma
- The scene report from EMS is often crucial.

### PHYSICAL EXAM

- Primary survey should be performed:
  - Airway:
    - Open? Patent? Able to speak? Any injuries?
  - Breathing:
    - Adequate and equal? Chest rise? Trachea midline?
    - Any open wounds?
  - Circulation:
    - Note heart rate, BP, capillary refill, and mentation.
    - Hypotension is a late sign of shock!
    - Any open, bleeding wounds?
  - Disability:
    - Neurologic exam every 5–10 min
    - Glasgow Coma Scale (GCS) score
    - Note focal deficits, and assess pupils.
  - Exposure:
    - If firearm, note any entry and exit wounds.
    - Log roll and examine the back.
    - Any impaled objects should be left in place.
- Secondary survey:
  - Head:
    - Note any orofacial trauma and missing teeth.
    - Feel for fractures in the face and head.
  - Neck:
    - Look for penetration of platysma.
    - Assess the zones of the neck:
      - Zone 1: Sternal notch to cricoid cartilage. Injuries to zone 1 involve intrathoracic structures and have the highest mortality.
      - Zone 2: Cricoid cartilage to angle of mandible. Zone 2 injuries are the most common.
      - Zone 3: Angle of mandible to base of skull
    - Vascular injuries commonly complicate penetrating neck trauma.
    - Signs of vascular trauma are expanding neck hematomas, pulsatile bleeding, stridor, or bruits.
    - Laryngeal trauma complicates 5.6% of nonintracranial fatal firearm injuries (5).

- Signs include hoarseness, stridor, subcutaneous emphysema, loss of anatomy, and hemoptysis.
  - Esophageal injuries may occur concurrently with laryngeal injuries.
  - Dysphagia, odynophagia, hemoptysis, and subcutaneous emphysema indicate esophageal penetration.
  - 10% of penetrating neck trauma has a spinal injury or brachial plexus injury
- Chest:
- Children with thoracic GSW are likely to be unstable and require thoracotomy.
  - 78% of all nonintracranial fatal penetrating traumas have thoracic injuries (5).
- Abdomen/Pelvis:
- Abdominal distension may be due to hemorrhage or free air.
  - Tenderness may be due to peritonitis or blood.
  - Perform an anogenital exam.
- Extremities:
- Evaluate extremities for fractures.
  - Neurovasculature exam
  - Determine pulse pressure indices (systolic pressure of unaffected limb/systolic pressure of affected limb).
  - Measure compartment pressures.

## DIAGNOSTIC TESTS & INTERPRETATION

### Lab

#### Initial Lab Tests

- CBC and type and screen
- Liver and pancreatic enzymes and BUN/creatinine if multisystem trauma
- Urinalysis

### Imaging

- Radiographs during the secondary survey:
  - Chest, C-spine, and pelvis films as indicated
  - Plain films may help determine trajectory and identify any foreign objects or fractures.
  - Unnecessary in children with GSW to the head since CT scan is definitive.
- Focused abdominal sonograph for trauma (FAST) exam is recommended for all thoracic and abdominal trauma patients.
- CT scans for penetrating head, abdominal, and thoracic trauma:
  - Helical CT with 3-mm cuts for spinal trauma
  - Helical CT angiography for stable zone 1 and 3 neck injuries:
    - However, angiography remains the gold standard for these regions of the neck.
- Angiography should also be considered in head injuries with fascio-orbital entry, transdural trajectory, or an intracranial hematoma, all of which place the patient at a 4-fold higher risk of traumatic aneurysm development (6).
- MRI for spinal trauma, knife wounds, and impalement

**Diagnostic Procedures/Other**

- Bronchoscopy for laryngeal trauma
- Flexible endoscopy for esophageal trauma:
  - Endoscopy followed by contrast esophagogram detects 100% of esophageal injuries (7).
- Diagnostic peritoneal lavage and laparoscopy are used less commonly.
- Color flow Doppler for vascular injuries

**DIFFERENTIAL DIAGNOSIS**

See other associated trauma topics for differential diagnoses of each body region.

**TREATMENT**

**PRE HOSPITAL**

- Assess and stabilize airway, breathing, and circulation with appropriate C-spine precautions:
  - Administer supplemental oxygen.
  - Most children requiring an airway can be effectively ventilated with a bag and mask.
  - Unless trained to do so, attempts should not be made to achieve a permanent airway.
- Notify and mobilize a surgical trauma team early.

**INITIAL STABILIZATION/THERAPY**

- Assess and stabilize airway, breathing, and circulation as per Advanced Trauma Life Support (ATLS) guidelines:
  - Identify and treat all life-threatening injuries during the primary survey.
  - Never attempt to remove penetrating objects.
- Consider pain control and IV antibiotics.
- Head injury:
  - Normalize oxygenation and ventilation.
  - Maintain normothermia or slight hypothermia.
- Neck injury:
  - Direct pressure to zone 2 bleeding injuries
  - Zone 1 and 3 injuries may require surgical exploration.
- Thoracic injury:
  - Assume mediastinal or pleural disruption.
  - Place chest tube early on affected side.
  - Autologous blood transfusions for large hemothoraces
  - Emergency thoracotomy in the emergency department for sudden loss of vital signs may be of some value (6).
- Abdominal injury:
  - Aggressive fluid/blood resuscitation
- Extremities:
  - Irrigate and cover open fractures.
  - Control bleeding with direct pressure.

**MEDICATION**

- Update tetanus status.
- Antibiotics:
  - For open wounds, cefazolin 50 mg/kg q8h IV
  - For intra-abdominal wounds, triple antibiotics:
    - Ampicillin 50 mg/kg/dose q6h IV
    - Gentamicin 2.5 mg/kg/dose q8h IV
    - Clindamycin 10 mg/kg/dose IV q8h (or can use 2nd-generation cephalosporin alone, such as cefoxitin 20–40 mg/kg IV q6–8h).

**SURGERY/OTHER PROCEDURES**

- Head: Early evacuation of hematomas, wound debridement, and aggressive control of intracranial HTN:
  - Improved survival with early surgery
  - Wound debridement reduces risk of infection, seizures, and other complications due to devitalized tissue.
- Neck: Expanding hematoma, hemorrhage, shock, laryngeal fracture, zone 1 and 3 trauma
- Oropharyngeal: Bleeding, impalement
- Chest: Thoracotomy if chest tube output is >20% blood volume or >2 mL/kg/hr, surgery for penetration of mediastinum or diaphragm, esophageal rupture
- Abdomen: Shock, evisceration, peritonitis
- Anogenital: Proctoscopy, vaginoscopy, cystoscopy
- Extremities: Open fractures, contaminated wounds

**DISPOSITION**

**Admission Criteria**

- All penetrating head trauma
- All penetrating neck trauma traversing the platysma
- All penetrating thoracoabdominal trauma
- All anogenital traumas for exploration
- Severe extremity traumas, contaminated wounds, or those with compartment syndrome

**Discharge**

Stable patients with no comorbidities with:

- Superficial wounds
- No penetration into major cavities
- No active bleeding or impaled objects

**FOLLOW-UP**

**FOLLOW-UP RECOMMENDATIONS PROGNOSIS**

- Prognosis is better in children than in adults.
- Increased mortality with:
  - Systolic BP <90 mm Hg (8)
  - Admission base deficit of >–8 (9)
  - Initial core temperature of <34°C (10)
- Head trauma—increased mortality with:
  - Transcranial GSW, bihemispheric lesions
  - Ventricular hemorrhage
  - Persistent raised intracranial pressures (10)
  - Fixed dilated pupils and GCS <8 (10)
- Spine: Best prognosis with incomplete injuries
- Abdomen: High mortality in vascular injuries:
  - Graded approach to care has best outcome:
    - Emergency laparotomy to control bleeding
    - Aggressive fluid resuscitation over the next 12–24 hr
    - Definitive repair when patient is stable
- Mediastinum: Increased mortality with stab wounds

**COMPLICATIONS**

- Loss of airway
- Severe brain or other afflicted organ damage
- Loss of function or infection
- Psychosocial problems

**See Also (Topic, Algorithm, Electronic Media Element)**

- Trauma, Abdominal
- Trauma, Chest
- Trauma, Head
- Trauma, Neck
- Trauma, Perineal
- Traumatic Brain Injury

**CODES**

**ICD9**  
879.8 Open wound(s) (multiple) of unspecified site(s), without mention of complication

**PEARLS AND PITFALLS**

- Penetrating trauma requires rapid response and aggressive treatment, especially IV fluid resuscitation.
- Early surgery for head injuries improves survival.
- Never remove embedded objects in the emergency department, as this may result in hemorrhage or other untoward effects on internal organs.

# TRAUMA, PERINEAL

Warees T. Muhammad  
Sandip A. Godambe

## BASICS

### DESCRIPTION

The perineum is defined as the region inferior to the pelvic diaphragm, lying between the thighs, and extending from the pubic symphysis to the coccyx. Structures in this region susceptible to trauma include the vagina, penis, urethra, scrotum, and anus.

### EPIDEMIOLOGY

- The most common etiology for perineal trauma is blunt trauma:
  - Sexual assault is always a concern and must be a consideration.
  - During wartime blast injuries, may become more common (1)
- Females:
  - Overall blunt trauma from a motor vehicle collision is the major cause for children 0–16 yr of age (2):
    - A significant cause of trauma is sexual assault in children 0–4 yr of age (2).
    - Falls, playground accidents, and bicycle accidents account for a large percentage of perineal trauma in children <10 yr of age (2).
    - Motor vehicle accidents are a major cause in 15–16-yr-old patients (2).
- Penile trauma:
  - Penile fractures occur mainly during sex. There is a low reporting rate.
- Testicular trauma:
  - Blunt trauma accounts for 85% (3,4).

### PATHOPHYSIOLOGY

- Blunt trauma results from the perineal structure being crushed between the offending force and the bony pelvis.
- Penetrating trauma causes damage by direct piercing of the perineal structure or disruption of its neurovascular supply.

### ETIOLOGY

- Vagina, urethra, scrotum, testicular and anus:
  - Straddle injury results from falling and landing on the cross bar of a bicycle or playground equipment.
  - Penetrating trauma and lacerations can be caused by sexual abuse or impalement from a foreign object.
- Penis:
  - Transection of the glans or amputation and degloving of the penile shaft may occur.
  - Penetrating trauma and lacerations can result from a foreign object or an animal bite.
  - Blunt trauma may occur from a fall, being struck with an object, or a sporting accident.
  - Entrapment of foreskin in a zipper
  - Penile fracture from direct force onto an erect penis

### COMMONLY ASSOCIATED CONDITIONS

- Females:
  - Head injury and pelvic fractures in patients <15 yr of age (2)
  - Pelvic and splenic injuries in patients  $\geq$ 15 yr of age (2)
- Males:
  - Penile trauma from gunshot wounds usually results in collateral damage to the surrounding perineal structures.

## DIAGNOSIS

### HISTORY

- Mechanism of injury
- Time and place of injury
- Parental account of injury
- Name of abuser if applicable:
  - High index of suspicion for sexual assault may be necessary since the history may not be readily given.
- Allergies
- Medications and immunization history
- Previous perineal pathology and surgeries
- Last menstrual cycle
- History of blood dyscrasias
- Time of last meal
- Treatment before arrival

### PHYSICAL EXAM

- Inspect the patient for life-threatening injuries as with all trauma patients and manage according to Pediatric Advanced Life Support (PALS) and Advanced Trauma Life Support (ATLS) guidelines:
  - A better exam is obtainable if the patient is relaxed and the exam is explained in a stepwise manner.
  - Differentiate between accidental and nonaccidental trauma.
- The frog-leg position is best to examine the genitals.
- Must properly examine the bowel and bladder:
  - Anal exam is best performed by placing children in the left lateral decubitus position, with the legs flexed at the hip, and allowing them to grab their knees.
  - Examine urethral meatus:
    - Ask the patient to provide a urine sample to confirm ability to pass urine without difficulty.
    - The presence of gross blood at the meatus may indicate upper or lower genitourinary tract injury.
    - If catheterization is deemed necessary, never catheterize if blood is noted at the meatus:
      - In males, do not catheterize without confirming the absence of a high-riding prostate gland.
- All lacerations must be fully evaluated to determine damage to surrounding structures and assess for fistula formation.

- Female:
  - Examine for tourniquet injury, which may result from entangled hair, bands, or rings.
  - Inspect the labia majora, labia minora, vaginal orifice, clitoris, and prepuce for lacerations, hematomas, foreign bodies, abrasions, or bruising.
  - If sexual assault is suspected, the integrity of the hymen should be assessed:
    - Perineal bleeding is less likely to be of vaginal origin if the hymen is intact.
    - Most straddle injuries involve the mons, labia minora, and clitoral hood. Straddle injuries to the hymen or posterior fourchette should raise concerns of sexual abuse.
  - Consider a speculum exam:
    - Avoid speculum use in prepubertal children.
    - Examine all the vaginal walls since missed vaginal wall injuries may result in fistula formation between the vagina and the bowel or bladder wall.
    - The pressure from an open speculum could mask bleeding, so careful release of the speculum and proper observation will prevent this from occurring.
- Male:
  - Examine for tourniquet injury, which may be due to hair, bands, or rings.
  - Inspect the skin for lacerations, hematomas, foreign bodies, abrasions, and bruising.
  - The penis should be checked for the integrity of the glans, blood at the meatus, swelling, fracture, foreign body, degloving, shape, extreme curvature, and lesions.
  - The scrotum should be evaluated for swelling, hematoma, laceration, and hernias.
    - Transilluminate the scrotum to assess for the presence of a free fluid collection.
  - The testicular exam should focus on the size, positioning, location, tenderness, and firmness:
    - Assess for cremasteric reflex.
    - A flattened or nonfirm testicle is suggestive of testicular rupture.
- Evaluate the anus for sphincter tone, bleeding, lesions, laceration, bleeding, and presence of a foreign body.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

- Urinalysis for any concerning trauma
- In many situations, other lab tests are not often necessary.
- If patient is hemodynamically unstable from blood loss, a type and screen may be appropriate.
- Serum or urinary hCG when indicated

#### Imaging

- Pelvic AP radiograph for suspected pelvic fracture or foreign body:
  - If there are concerns about penetrating trauma and a ruptured viscus, obtain an upright abdominal film (or cross-table lateral) to assess for free air.
- Contrast CT of the abdominal and pelvis for suspected foreign body and penetrating trauma

- Retrograde urethrography for suspected urethral injuries
- US for suspected scrotal and testicular damage:
  - Has limited role in the diagnosis of penile fracture

### DIFFERENTIAL DIAGNOSIS

- Hemangioma may mimic a hematoma.
- Slate gray spots on darker-skinned patients may mimic bruising.
- Normal hymen variation must be differentiated from hymen tear from penetrating trauma or sexual assault.
- Vaginal bleeding may be from normal menses or an anovulatory cycle.
- Peyronie disease (essentially fibrous scar tissue formation that results in penile curvature) must be differentiated from a penile fracture.
- Hydrocele vs. hematocele:
  - Hydrocele is a nontraumatic collection of serous fluid in the tunica vaginalis of the testis or along the spermatic cord.
  - Hematocele is synonymous with a hemorrhagic cyst. It is a swelling due to effusion of blood into the tunica vaginalis testis and is associated with trauma.

## TREATMENT

### PRE HOSPITAL

Place packing or pressure dressing to stop bleeding.

### INITIAL STABILIZATION/THERAPY

- Assess and stabilize ABCDEs according ATLS and PALS guidelines:
  - Fluid resuscitation for hemodynamically unstable patients
  - Control bleeding.
- Pain control
- Assess tetanus immunization status.
- Open fractures should be managed with immobilization, copious irrigation, IV antibiotics, and prompt orthopedic consultation.

### MEDICATION

#### First Line

- Opioids:
  - Morphine 0.1 mg/kg IV/IM/SC q2h PRN:
    - Initial morphine dose of 0.1 mg/kg IV/SC may be repeated q15–20min until pain is controlled, then q2h PRN.
  - Codeine/Acetaminophen dosed as 0.5–1 mg/kg of codeine component PO q4h PRN
- NSAIDs:
  - Ibuprofen 10 mg/kg/dose PO/IV q6h PRN
- Acetaminophen 15 mg/kg/dose PO/PR q4h PRN

#### Second Line

- Consider antibiotics in situations where there is a ruptured viscus and open fractures. Antibiotics that cover both gram positives and negatives should be administered:
  - Ceftriaxone 50–75 mg/kg IV divided q12–24h
  - Consider cefazolin and metronidazole, ceftioxin, or ampicillin/sulbactam preoperatively for patients with viscus trauma.

### SURGERY/OTHER PROCEDURES

- Superficial skin lacerations may be closed with absorbable sutures or allowed to heal at home with soaks in sitz baths.
- Rectal lacerations will require assistance from surgery or gynecology.

- Penile lacerations or fractures should be repaired within 3 days.
- Hematoma:
  - Small hematomas may be managed with conservatively with ice packs, scrotal support, and/or sitz baths.
  - A surgical specialist should evaluate large hematomas.

### DISPOSITION

#### Admission Criteria

- Multiple trauma
- Unsafe home environment/child protective services
- Rectal lacerations requiring extensive repair
- Penile fracture
- Critical care admission criteria:
  - Hemodynamic instability
  - Other concurrent life-threatening injuries

#### Issues for Referral

- Urology should be considered for consultation on all male patients with perineal trauma, with possibly the exception of superficial lacerations. Urology should also be considered for females with urethral injury.
- Surgery should be consulted on female patients with large vaginal hematomas, deep vaginal lacerations, penetrating vaginal trauma, and rectal trauma.
- Surgery consult is also warranted for additional evaluation of rectal trauma, viscus injury, and penetrating trauma that involves the abdomen or pelvis.
- Transfer patient to a trauma center if the current facility is not equipped to manage such patients.

## FOLLOW-UP

### FOLLOW-UP RECOMMENDATIONS

Discharge instructions and medications:

- Appropriate child care services must follow up with abused children.
- Adequate pain control
- A donut-shaped cushion for sitting will help relieve the discomfort of sitting on the injured perineum:
  - Recommend bed rest and application of ice packs for the 1st 24 hr.
  - Warm tub baths or sitz baths t.i.d. to q.i.d. after the 1st 24 hr

#### Patient Monitoring

- Return to the emergency department if unable to urinate or for worsening bleeding.
- Ensure follow-up with urology, surgery, or gynecology if intervention was required in the emergency department or the patient will need further evaluation of voiding, incontinence, defecation, wound healing, or drainage removal.

### DIET

NPO if surgical procedure is needed

### PROGNOSIS

- Blunt injury usually carries an excellent prognosis:
  - Vulvar hematomas will self-resolve.
- Patients with a gunshot wound to the penis and urethra usually heal well without difficulty of voiding (5).

- Fertility is ~62% in males with testicular trauma due to non–high-velocity gunshots (6).
- There is a significantly higher rate of testicular salvage for gunshot wound injury (75%) as compared to stab wound and lacerations (23%) (6).

### COMPLICATIONS

- Lacerations may become infected.
- Urethral injury may result in strictures.
- Missed or improperly repaired vaginal lacerations may result in fistula formation between the vagina and rectum or bladder.

## CODES

### ICD9

- 867.0 Injury to bladder and urethra without mention of open wound into cavity
- 959.14 Other injury of external genitals
- 959.19 Other injury of other sites of trunk

### PEARLS AND PITFALLS

- Pearls:
  - Check for pregnancy when appropriate.
  - Vaginal bleeding may be secondary to menses in a pubertal child.
  - Call appropriate authorities for suspected child abuse. Do not discard evidence.
- Pitfall:
  - Do not place a urinary Foley catheter if blood is noted at the meatus or if patient has a high-riding prostate gland.

# TRAUMA, SCROTAL AND PENILE

Maya Haasz  
Dennis Scolnik

## BASICS

### DESCRIPTION

- Testicular injuries include conditions such as rupture or fracture, dislocation, testicular hematoma, and rarely traumatic torsion.
- Isolated scrotal injuries are less worrisome and include hematoma, which may cause nonspecific swelling, laceration, abrasion, and contusion.
- Penile injuries are typically iatrogenic in infancy and result from blunt trauma in childhood.
- Adolescents may present with penile fracture.
- Mild injuries and superficial lacerations of the genitals can be treated in the emergency department and managed conservatively thereafter.
- For those injuries requiring surgical intervention, prompt management is essential to prevent complications such as infection, necrosis, and testicular loss.
- This topic will describe the more common genitourinary (GU) injuries, their emergency management, and indications for referral.

### EPIDEMIOLOGY

- Serious testicular injury is uncommon, with 85% of injuries caused by blunt trauma (1).
- Penile fracture is very uncommon, with only 1,331 cases reported from 1935–2001 (1).
- Testicular rupture is most common among adolescents and adults 15–40 yr of age.
- Sexual abuse is more commonly associated with rectal injury than scrotal and penile injuries.

### GENERAL PREVENTION

Scrotal and penile protection while participating in athletic events (eg, jockstrap with athletic cup)

### PATHOPHYSIOLOGY

- Testicular rupture or fracture is a tear at the level of the corpus callosum, with protruded seminiferous tubules (1).
- In testicular dislocation, a testicle has been relocated from its anatomic position, typically through the inguinal canal, due to trauma.
- Tear of the tunica albuginea at the level of the corpus cavernosum results in penile fracture (1).

### ETIOLOGY

- Testicular and scrotal injuries occur as a result of trauma, including straddle injury, motor vehicle collisions, and bicycle accidents as well as animal or human bites.
- Penile injury in the infant most often occurs as a result of circumcision complications.
- Trauma in toddlers and older children is usually due to blunt trauma.

- Hair tourniquet with strangulation is a less common cause of penile trauma.
- Very rarely, penile fracture can occur in adolescents, typically in association intercourse in which the male is positioned beneath the female.
- Sexual and physical abuse must be considered in all cases of GU injury.

### COMMONLY ASSOCIATED CONDITIONS

Perineal lacerations, pelvic and femur fractures, abdominal trauma

## DIAGNOSIS

### HISTORY

- A history of trauma such as straddle injury or an upward blow to the perineal area is typically present with complaints of local pain, swelling, bruising, or bleeding.
- Testicular dislocation requires significant trauma and may occur following a straddle injury.
- Hair tourniquets may present with a history of penile edema and erythema or nonspecific symptoms such as crying or irritability (2).
- Patients report hearing a cracking sound at the time of penile fracture, with immediate pain and rapid detumescence.
- Family history in cases of severe bleeding from the circumcision site.

### PHYSICAL EXAM

- Local tenderness, swelling, and ecchymosis
- Abrasion, laceration, or skin loss may be evident.
- Testicular dislocation presents with an empty scrotal sac, and the testicle may be palpable elsewhere. Associated fractures of the pelvic or femoral bones are common.
- Classically, penile fracture presents with “eggplant deformity,” or hematoma and edema of the penile shaft and deviation to the side opposite the injury. There may be a palpable clot at the fracture site known as a “rolling sign.”
- Hematuria, urinary retention, or blood at the meatus may indicate urethral injury. This is a common injury with penile fracture and necessitates further investigation (1).

### ALERT

- Remember associated urethral injury.
- Associated rectal injury or injuries incompatible with the history may be suggestive of abuse. A complete history and physical examination is warranted in all cases of GU trauma (3).
- Penetrating injuries may be associated with severe internal damage and relatively minor external manifestations.

## DIAGNOSTIC TESTS & INTERPRETATION

### Lab

- Urinalysis to assess for hematuria
- Consider CBC, PT, PTT, and blood type and cross-match if hemorrhage is significant.

### Imaging

- Scrotal/Testicular injury:
  - US (primary test):
    - Will define injury and assess testicular vascular flow
    - Note, however, that sensitivity and specificity are 75% and 64% respectively.
    - US will also help identify posttraumatic hematocele, epididymitis, and epididymal hematoma.
  - Other tests as clinically indicated:
    - Abdominal/Pelvic CT: Consider CT for suspected abdominal or pelvic injuries.
    - Retrograde urethrogram: Consider for suspected urethral injuries. Some centers perform this test routinely.
- Penile fracture:
  - US, cavernosography, or MRI can be used in equivocal cases of penile injury, though diagnosis is usually clinical.

## DIFFERENTIAL DIAGNOSIS

- GU injuries are typically accidental, but sexual abuse or nonaccidental trauma must be considered.
- The differential diagnosis for strangulation injury of the penis includes paraphimosis, balanitis, allergy, contact dermatitis, or insect bites.

## TREATMENT

### PRE HOSPITAL

- IV fluid administration if any signs of hemodynamic instability exist
- Apply local pressure for active bleeding.
- Cover open wounds with sterile gauze.
- Treat pain with oral or systemic analgesia.

### INITIAL STABILIZATION/THERAPY

- Initial stabilization as per Advanced Trauma Life Support (ATLS) guidelines.
- Consider tetanus booster if needed (1).

**MEDICATION****First Line**

- Analgesia: Initially consider oral acetaminophen or ibuprofen, but for more severe pain, use systemic narcotics.
- NSAIDs:
  - Ibuprofen 10 mg/kg/dose PO/IV q6h PRN
  - Ketorolac 0.5 mg/kg IV/IM q6h PRN
  - Naproxen 5 mg/kg PO q8h PRN
- Acetaminophen 15 mg/kg/dose PO/PR q4h PRN
- Opioids:
  - Morphine 0.1 mg/kg IV/IM/SC q2h PRN:
    - Initial morphine dose of 0.1 mg/kg IV/SC may be repeated q15–20min until pain is controlled, then q2h PRN.
  - Fentanyl 1–2  $\mu$ g/kg IV q2h PRN:
    - Initial dose of 1  $\mu$ g/kg IV may be repeated q15–20min until pain is controlled, then q2h PRN.
- Avulsion injuries secondary to animal or human bites should be treated with amoxicillin/clavulanic acid (dose based on amoxicillin component) 40 mg/kg/day PO divided in 2 or 3 doses for 5 days.

**Second Line**

- Cloxacillin or cephalexin each at 50 mg/kg/day in 3 divided doses for 5 days can be used as second-line agents for avulsion injury.
- Penicillin V 50 mg/kg/day in 2 divided doses for 5 days can be added for coverage of *Pasteurella multocida* in avulsion injury.
- For penicillin-allergic patients >8 yr of age, use doxycycline 2–4 mg/kg/day in 2 divided doses and clindamycin 30 mg/kg/day in 3 divided doses. Penicillin-allergic patients <8 yr of age should receive the same dose of clindamycin, along with trimethoprim/sulfamethoxazole 8–12 mg/kg/day of trimethoprim component in 2 divided doses.

**SURGERY/OTHER PROCEDURES**

- Manual reduction of testicular dislocation should be attempted.
- Prompt surgical intervention is required for suspected testicular rupture, torsion, or dislocation as well as for penile fracture and all penetrating genital trauma.
- Large hematoceles should be drained acutely in the emergency department using local analgesia and a large-bore needle.
- Superficial scrotal lacerations can be managed in the emergency department, but avulsion injuries may need a urologist. Extensive lesions and degloving injuries may require flaps or grafts in the operating room.
- Penile injuries may be closed primarily but must be referred to a specialist if extending to the corporal bodies or urethra.

**DISPOSITION****Admission Criteria**

- Need for operative intervention (see above) including significant skin loss, suspected urethral injury, suspected penile fracture, testicular rupture or dislocation
- Significant wound contamination
- Severe associated injury, especially pelvic fractures
- Critical care admission criteria:
  - Associated multisystem trauma
  - Unstable vital signs after initial resuscitation

**Discharge Criteria**

- Pain adequately controlled
- No significant bleeding or hematuria
- Able to void normally

**Issues for Referral**

- Consult urology emergently if the patient meets any of the above criteria for surgery, if there is a laceration through the dartos muscle, or if there is any sign of potential urethral injury.
- Minor trauma may be referred to urology as an outpatient.

**FOLLOW-UP****FOLLOW-UP RECOMMENDATIONS**

Discharge instructions and medications:

- Conservative management with scrotal support, ice, and elevation is appropriate for scrotal hematomas, hematoceles, and contusions that do not involve testicular injury.

**PROGNOSIS**

- In suspected testicular rupture, surgical intervention within 3 days improves testicular salvage from 32–45% to 80–90% (1).
- Delayed surgical intervention of penile fracture (>36 hr) increases the risk of chronic curvature (1).
- Associated severe injuries often dictate the outcomes of local injury to the penis and scrotum.

**COMPLICATIONS**

- Minimized with prompt surgical intervention
- Scrotal injury: Ischemia, infection, testicular atrophy, infertility
- Penile injury: Erectile dysfunction, penile curvature, urethral stricture, penile abscess, hematoma, scarring
- Both: Chronic pain, altered self-image

**ADDITIONAL READING**

Buckley JC, McAninch JW. Diagnosis and management of testicular ruptures. *Urol Clin North Am.* 2006;33(1):111–116, vii.

**CODES****ICD9**

- 608.20 Torsion of testis, unspecified
- 922.4 Contusion of genital organs
- 959.14 Other injury of external genitals

**PEARLS AND PITFALLS**

- Presence of urethral injury must be assessed in any patient with penile trauma.
- Remember to consider abuse as a cause for injuries.
- Remember to provide adequate antibiotic coverage for bite wounds.

## BASICS

### DESCRIPTION

- Pediatric shoulder trauma is relatively uncommon. Injuries requiring surgical intervention are even rarer.
- Most fractures in this area remodel rapidly, and the wide range of motion of the shoulder accommodates for most residual deformities.

### EPIDEMIOLOGY

- The incidence and prevalence of pediatric shoulder injuries varies with the type of injury and the age of the patient.
- Sternoclavicular joint injuries primarily consist of physeal separations, which mimic sternoclavicular joint dislocations.
- The clavicle is the most commonly fractured bone in the shoulder region, accounting for 10–15% of all children's fractures (1).
- Acromioclavicular (AC) joint dislocations are typically seen only after 16 yr of age.
- <2% of all traumatic shoulder dislocations occur in patients <10 yr of age, and about 20% occur in patients between the ages of 10 and 20 yr (1).
- >90% of shoulder dislocations are anterior dislocations of the humeral head in relation to the glenoid fossa.
- Scapula fractures and tears of the rotator cuff are rare before 21 yr of age.

### PATHOPHYSIOLOGY

- Anterior shoulder joint dislocation:
  - Usually occurs when indirect axial forces are applied to an abducted, extended, and externally rotated arm. This action leverages the humeral head out of the glenoid fossa.
- Posterior shoulder joint dislocation:
  - The injury force typically occurs to an adducted and internally rotated arm.
- Fracture separation of the proximal humeral epiphysis occurs since ligamentous attachments are stronger than the growth plate (until the epiphysis closes between 16 and 19 yr of age).

### ETIOLOGY

- Anterior shoulder dislocation:
  - Indirect trauma (usually from a fall on an outstretched arm)
- Posterior shoulder dislocation:
  - Seizure and sudden contraction of all the muscle groups of the posterior shoulder
- Scapular fracture:
  - Direct high-energy trauma and crushing injury
- Clavicle fracture:
  - Birth injury, medially directed impact to the shoulder, or direct trauma to the clavicle from frontal impact

- Brachial plexus injury:
  - Birth injury (difficult delivery)
- Joint capsular tear:
  - Forceful traction on a child's arm
- Fracture separation of proximal humeral epiphysis:
  - Backward fall or an attempt to break a fall with a hand

## DIAGNOSIS

### HISTORY

- Mechanism of injury: Fall, pull, direct/indirect trauma
- Severity of pain
- History of swelling or deformity
- Any associated injuries

### PHYSICAL EXAM

- Evaluate neurovascular status of the arm.
- Observe without clothes over the shoulder for positioning of the arm, swelling, deformity, or any asymmetry.
- If the child is anxious, examine the uninjured side 1st.
- Sensation over the deltoid muscle should be tested because the axillary nerve may be damaged during a shoulder separation.
- The patient's active and passive range of motion should be examined.
- When indicated, the apprehension test for shoulder subluxation is performed:
  - With the patient in the supine position, external rotation of the shoulder results in pain and the patient has the sensation of an impending dislocation.
- Clavicle fracture:
  - Arm droops down and forward, head may be tilted toward the affected side; localized swelling, tenderness, and crepitations may be present
  - A neonate's birth injury or an infant's greenstick fracture of the clavicle may go unnoticed until the focal swelling of the developing callus is noted
- AC joint sprain:
  - Find tenderness localized to the area over the AC joint or elevation of the clavicle above the acromion.
- Scapular fracture:
  - Find tenderness over the scapula.
- Anterior shoulder dislocation:
  - Shoulder is squared off with a prominent acromion process and often a palpable anterior fullness.
  - Arm is held in slight abduction and external rotation.

- Posterior shoulder dislocation:
  - Coracoid process is prominent with a palpable posterior swelling.
  - Arm is held in slight adduction and internal rotation.
- Rotator cuff tear:
  - Mild tenderness under the acromion when the arm is abducted; may have increasing pain when the arm is abducted passively between 80 and 120 degrees
- Fracture separation of proximal humeral epiphysis:
  - See mild swelling and local tenderness.

## DIAGNOSTIC TESTS & INTERPRETATION

### Imaging

- Plain x-rays:
  - AP views of the chest
  - AP view of the shoulder
  - Transscapular Y or axillary view of the shoulder
- Occasionally, CT scan of the chest

### Pathological Findings

- Clavicle fracture:
  - Radiographs are confirmatory, though visualization of nondisplaced fractures may require several views.
  - Typically, the proximal fracture fragment is displaced superiorly.
- Sternoclavicular joint displacement:
  - Radiographic visualization may be difficult.
  - Special views and/or CT scans are often required to define the degree and direction of displacement.
- Scapular fractures:
  - Fractures of the body and neck are usually well visualized on plain x-rays.
  - Adequate definition of glenoid injuries may require a CT scan.
- Anterior shoulder dislocation:
  - Hills-Sachs deformity (compression injury to the posterolateral aspect of the humeral head) and Bankart lesion (an injury of the anterior glenoid labrum due to repeated anterior shoulder dislocation) are possible findings.
  - Fractures of the greater tuberosity of the humeral head are seen in 15–35% (2).
- Posterior shoulder dislocation:
  - Often missed on AP film
  - Degree of overlap on x-ray is smaller and displaced superiorly, producing the "meniscus sign."
  - Axillary or scapular Y radiographs show the humeral head posterior or behind, respectively, the glenoid.
  - Usually find a posterior labral tear or detachment (reverse Bankart lesion)

## DIFFERENTIAL DIAGNOSIS

- See Etiology.
- When acute trauma has been excluded and bony injury is suspected, stress fractures always should be considered.
- Septic shoulder joint
- Hemarthrosis in shoulder joint
- Thoracic or cervical spine fracture
- Underlying rib fractures

## TREATMENT

### PRE HOSPITAL

Splint arm in the position of comfort while maintaining an adequate neurovascular exam.

### INITIAL STABILIZATION/THERAPY

- Assess and stabilize airway, breathing, and circulation.
- Exclude more serious injuries.
- Ensure no injury to axillary vessels.
- Restrict active movements of the affected shoulder.
- Adequate analgesia and muscle relaxation:
  - At times, procedural sedation may be required.
  - Intra-articular lidocaine injected into the shoulder joint

### MEDICATION

- Opioids:
  - Morphine 0.1 mg/kg IV/IM/SC q2h PRN:
    - Initial morphine dose of 0.1 mg/kg IV/SC may be repeated q15–20min until pain is controlled, then q2h PRN.
  - Fentanyl 1–2  $\mu$ g/kg IV q2h PRN:
    - Initial dose of 1  $\mu$ g/kg IV may be repeated q15–20min until pain is controlled, then q2h PRN.
  - Codeine/Acetaminophen dosed as 0.5–1 mg/kg of codeine component PO q4h PRN
  - Hydrocodone or hydrocodone/acetaminophen dosed as 0.1 mg/kg of hydrocodone component PO q4–6h PRN
- NSAIDs:
  - Consider NSAID medication in anticipation of prolonged pain and inflammation.
  - Some clinicians prefer to avoid due to theoretical concern over influence on coagulation and callus formation.
  - Animal studies have raised concerns that NSAIDs may negatively influence bone healing; however, there is no clinical evidence in humans.
  - Ibuprofen 10 mg/kg/dose PO/IV q6h PRN
  - Ketorolac 0.5 mg/kg IV/IM q6h PRN
  - Naproxen 5 mg/kg PO q8h PRN
- Acetaminophen 15 mg/kg/dose PO/PR q4h PRN
- Local anesthetic for intra-articular injection:
  - 1% lidocaine, max single dose 5 mg/kg

### SURGERY/OTHER PROCEDURES

- Anterior shoulder dislocation reduction techniques:
  - Traction/Countertraction: With the patient supine, hold continuous longitudinal traction to the arm and apply gentle countertraction from a sheet wrapped through the axilla and across the chest. The arm can be slightly internally or externally rotated if unsuccessful after several minutes.
  - Stimson maneuver: Place the patient prone with the arm dangling over the side. Hang 10–15 pounds around the wrist. The muscles usually fatigue in <20 min.
  - Scapular manipulation: With the patient prone and the arm hanging over the side of the bed, rotate the inferior portion of the scapula toward midline.
- Clavicular fractures:
  - Apply sling and swathe for 3 wk followed by 3 wk of restriction from sporting activities.

- Proximal humeral fractures:
  - Apply sling and swathe for several weeks:
    - Usually the only treatment necessary
    - Orthopedic follow-up is recommended.
- Humeral shaft fractures:
  - Apply sling and swathe for incomplete fractures.
  - Can use a sugar tong splint of the upper arm, followed by a sling to support the forearm for nondisplaced or minimally displaced fractures
  - Significantly displaced or comminuted fractures can be managed with a light hanging fiberglass cast.

### DISPOSITION

#### Issues for Referral

- Immediate orthopedic consultation is suggested for any completely displaced humeral shaft fracture, any humeral fracture angulated >20 degrees in children and 10 degrees in adolescents, and any fracture with evidence of radial injury. All humeral fractures should be referred for orthopedic follow-up within 5 days.
- Orthopedic consultation is suggested for scapular fractures and posterior shoulder dislocations, given the rarity of such injuries.
- Only rarely is orthopedic consultation or, for that matter, any follow-up necessary for a clavicular injury:
  - Exceptions include significantly displaced midshaft fractures, for which closed reduction is occasionally desirable; posteriorly and significantly anteriorly displaced medial fractures, grossly unstable distal injuries, and all open fractures.

## FOLLOW-UP

### FOLLOW-UP RECOMMENDATIONS

- Discharge instructions and medications:
  - Adequate pain management
  - Shoulder slings need to be in place for 2–3 wk.
- Activity:
  - At least 3 wk of restriction from sporting activities is recommended for most shoulder injuries.

### PROGNOSIS

- Most distal (or lateral) clavicular fractures heal uneventfully with no loss of joint stability.
- In younger children, even totally displaced proximal humeral fractures can remodel completely:
  - Severely displaced proximal physal humerus fractures in the older child often have a better long-term outcome after anatomic reduction.
- Though glenohumeral dislocations, once reduced, are not life or limb threatening, they do have a very high incidence of recurrence in adolescent patients.

### COMPLICATIONS

Injury to the axillary nerve, malunion of clavicular and humeral fractures

## CODES

### ICD9

- 810.00 Closed fracture of clavicle, unspecified part
- 831.00 Closed dislocation of shoulder, unspecified site
- 959.2 Other and unspecified injury to shoulder and upper arm

## PEARLS AND PITFALLS

- Pearls:
  - The possibility of abuse in young children should always be considered, especially if the injury is unexplained, the history is implausible, or the seeking of medical care was delayed unreasonably.
  - When a child <3 yr of age sustains a spiral fracture of the humerus, child abuse should be considered.
- Pitfalls:
  - Certain traumatic injuries of the shoulder can present as a challenge and diagnostic dilemma. The most important aspect of treating pediatric shoulder trauma is the ability to differentiate the serious injury from the mild.
  - Posterior sternoclavicular dislocations should be differentiated from medial clavicular physal injuries and promptly reduced.

## BASICS

### DESCRIPTION

Spinal cord injury (SCI) is a direct or indirect insult to the spinal cord resulting in either a temporary or permanent change in its normal motor, sensory, or autonomic function.

### EPIDEMIOLOGY

#### Incidence

Annual pediatric SCI rate of 1 in 1 million and an annual rate of young adult SCI of 17 in 1 million (1)

#### Prevalence

- Overall incidence of pediatric SCI in the U.S. is 1.99 cases per 100,000 children.
- It is estimated that 1,455 children are admitted to U.S. hospitals each year for treatment of SCI (2).

### RISK FACTORS

Anatomic and biomechanical features of the growing pediatric spine:

- Relatively larger head size
- Poorly developed muscles and ligaments
- Flexibility of the spine and the growth plates
- Elasticity and compressibility of the bone
- Flatter facet joints with more horizontal orientation

### PATHOPHYSIOLOGY

Numerous mechanisms are responsible for various injury patterns: Flexion, extension, rotation, axial (top) loading and distraction (pulling). These result in:

- Lack of blood flow to the spinal cord either by compression (due to mass effect or fractured or displaced vertebrae) or disruption
- The release of inflammatory mediators, which in turn can cause further swelling and cell and tissue damage

### ETIOLOGY

- Most injuries are caused by direct trauma or high-speed deceleration:
  - Motor vehicle collisions
  - Falls and sports-related injuries
  - Birth injuries and nonaccidental trauma
- Falls are more common in younger children; while sports-related injuries and motor vehicle accidents are more common in older children.

### COMMONLY ASSOCIATED CONDITIONS

Any condition that predisposes an individual to spinal column or cord injury:

- Down syndrome
- Turner syndrome
- Apert syndrome
- Mucopolysaccharidoses
- Congenital bone abnormalities
- Rheumatoid arthritis
- Ankylosing spondylitis

## DIAGNOSIS

### HISTORY

- History of trauma or suspicion of nonaccidental trauma
- Loss of consciousness may occur.
- Signs of trauma to the head, face, or trunk:
  - “Raccoon” eyes or Battle sign
  - Bruising and abrasions caused by seat and shoulder belt restraints
  - Localized midline back or neck pain
  - Lap belt mark with back pain may suggest Chance fractures.
  - Radiation of pain into  $\geq 1$  extremity

### PHYSICAL EXAM

- A complete head to toe exam
- Exam of the entire spinal column, looking for areas of tenderness, ecchymosis, hematoma, crepitus, deformity, and muscle spasm
- Detailed neurologic exam:
  - Mental status
  - When performing a neurologic exam, look for symmetry and, when deficits are apparent, try to establish sensory and motor levels.
  - Sensory: Evaluate light touch, pain, and joint position senses, and assess sensory levels of deficit:
    - C2: Occiput
    - C4: Clavicular region
    - C6: Thumb
    - C8: Little finger
    - T4: Nipple line
    - T10: Umbilicus
    - L1: Inguinal region
    - L3: Knee
    - S1: Heel
    - S5: Perianal area
  - Motor: Evaluate muscle strength in all muscle groups, and assess motor levels of deficit:
    - C5: Elbow flexion
    - C7: Elbow extension
    - C8: Finger flexion
    - T1: Finger abduction
    - L2: Hip flexion
    - L3: Knee extension
    - L4: Ankle dorsiflexion
    - L5: Great toe dorsiflexion
    - S1: Ankle plantar flexion
  - Evaluate rectal sphincter tone and the amount of residual urine after catheterization.
  - Check deep tendon reflexes and Babinski sign.
  - Absence of bulbocavernosus and cremasteric reflexes indicate spinal shock.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

- Trauma panel (definition varies by institution), based on severity of mechanism of injury
- CBC, type and cross-match
- Basic metabolic profile
- Liver and pancreatic enzymes and urinalysis
- Pregnancy screen, if age appropriate

### Imaging

Cervical (AP, cross-table lateral, and odontoid views), thoracic, and lumbar spine and pelvis plain radiographs based on clinical exam and patient complaints:

- To review C-spine films, remember ABCS mnemonic:
  - All 7 cervical vertebrae and T1 must be visualized:
    - Odontoid (open mouth) views are difficult to interpret in children  $<5$  yr of age and are comparatively of little value.
  - Airway
  - Alignment:
    - The lateral C-spine view should show 4 smooth contiguous lines along the vertebrae: Anterior and posterior marginal lines represented by the anterior and posterior aspects of the vertebral bodies, spinolaminar line, and posterior spinous line.
    - The ligamentous laxity and the horizontal orientation of the facet joints in young children can explain a step-off seen on the lateral C-spine radiograph at C2–3 and less commonly at C3–4 (pseudosubluxation). This should be  $<4$  mm.
    - Rupture of the transverse atlantal ligament will allow  $>4$  mm of anterior displacement of the atlas. In very young children, up to 5 mm may be considered normal.
  - Bones:
    - Age-specific ossification centers in the immature spine may be confused with injury.
  - Cartilage
  - Soft tissue:
    - The soft tissue retropharyngeal space at C2 should be  $\leq 7$  mm and the retrotracheal space at C6 should be  $<14$  mm. These areas may appear abnormally wide in a crying child.

Indications for further studies: If there is severe pain, presence of neurologic deficits, equivocal initial x-rays, or obvious abnormalities on plain x-rays:

- CT is the test of choice when defining fractures through the posterior elements (spinous processes, laminae, pedicles, and facets) and assessment of the spinal canal:
  - 3D CT may improve the yield.
- MRI is the test of choice to evaluate the spinal cord for compression, contusion, or spinal cord injury without radiographic abnormality (SCIWORA).

### Diagnostic Procedures/Other

A diligent search for other injuries such as solid organ and vascular injuries:

- Focused assessment with sonography in trauma (FAST) exam

### Pathological Findings

- Jefferson fracture: Fracture of the ring of C1 from axial loading; uncommon in children
- Hangman fracture: Hyperextension injury of C2
- Odontoid fractures: Usually growth plate injuries. The classic feature is severe pain.
- C3 to C7 fractures: Less common in children; usually ligamentous

- Chance fractures: Usually caused by lap belts; typically associated with abdominal injuries
- SCIWORA:
  - More common in the C-spine
  - Neurologic injury is usually severe.
  - Less common in older children

### DIFFERENTIAL DIAGNOSIS

- It is critical to differentiate severe pain or motor deficits as result of neurologic injury or trauma to other areas of the musculoskeletal system.
- Vascular (arteriovenous malformation, angioma)
- Infectious (TB, meningitis, retropharyngeal or epidural abscess, osteomyelitis)
- Neoplastic (lymphoma)
- Coagulopathy, or congenital abnormalities (osteogenesis imperfecta, achondroplasia)
- Guillain-Barré syndrome
- Transverse myelitis
- Dorsal root or peripheral nerve injury
- Torticollis

### TREATMENT

#### PRE HOSPITAL

- Assess and stabilize airway, breathing, and circulation.
- Immobilize spine with a cervical collar and long spine board:
  - If properly fitting cervical collars are unavailable, splint the head and body with towels or foam blocks and tape.
  - Maintain neutral position, and avoid any movement of the head and neck while full spinal immobilization is being performed.

#### INITIAL STABILIZATION/THERAPY

- Assess and stabilize airway, breathing, and circulation per Advanced Trauma Life Support (ATLS) and Pediatric Advanced Life Support (PALS) guidelines.
- For suspected spine injury, immobilize the patient immediately with a rigid cervical collar and a long spine board if not done earlier.
- Evaluate for associated injuries.
- Perform serial neurologic exams.
- Control of pain, preventing further injury, and stabilization of associated injuries
- Early consultations with neurosurgery and/or orthopedic surgery:
  - Transfer to a trauma center if necessary.

#### MEDICATION

##### First Line

- Opioids:
  - Morphine 0.1 mg/kg IV/IM/SC q2h PRN:
    - Initial morphine dose of 0.1 mg/kg IV/SC may be repeated q15–20min until pain is controlled, then q2h PRN.
  - Fentanyl 1–2 μg/kg IV q2h PRN:
    - Initial dose of 1 μg/kg IV may be repeated q15–20min until pain is controlled, then q2h PRN.

- NSAIDs:
  - Consider NSAID medication in anticipation of prolonged pain and inflammation:
    - Ibuprofen 10 mg/kg/dose PO/IV q6h PRN
    - Ketorolac 0.5 mg/kg IV/IM q6h PRN
    - Naproxen 5 mg/kg PO q8h PRN
- Acetaminophen 15 mg/kg/dose PO/PR q4h PRN

#### Second Line

Methylprednisolone 30 mg/kg IV over 15 min, then 5.4 mg/kg/hr over the next 23 hr. Caution: Dosage is based on adult guidelines; lack of high level pediatric evidence:

- Previously recommended by ATLS guidelines, but based on recent data, this recommendation was withdrawn.
- Routine use in spinal cord trauma is institution dependent.

#### SURGERY/OTHER PROCEDURES

Surgery reserved for fractures that are unstable or have neurologic injury.

#### DISPOSITION

##### Admission Criteria

All patients with proven or suspected spinal injuries must be admitted to the ICU.

##### Discharge Criteria

Only those patients without symptoms of SCI may be released from the hospital.

##### Issues for Referral

If neurosurgical or orthopedic consultation is not available, the patient should be transferred to a trauma center.

### FOLLOW-UP

#### FOLLOW-UP RECOMMENDATIONS

Close follow-up is essential, especially for those who have been treated with external braces. They may develop a progressive instability over time that was not immediately detected.

#### PROGNOSIS

- Mortality in spine-injured children is higher than adults and is estimated to be at 25–32% (3).
- Death is most often due to injuries to other organs, including the brain.

#### COMPLICATIONS

- Posttraumatic spinal deformity:
  - Prevalence approaches 100% in children who sustain a SCI prior to the age of 10 yr.
  - Scoliosis is the most common, followed by kyphosis and lordosis.
- Progressive spinal deformity, increasing pain, and neurologic deterioration may be associated with the development of a posttraumatic syrinx.

- Spinal Cord Compression

### CODES

#### ICD9

952.9 Unspecified site of spinal cord injury without spinal bone injury

### PEARLS AND PITFALLS

- Pearls:
  - Try to correlate radiographic findings with the patient exam.
  - Presence of paraplegia or sensory loss at a particular spinal nerve level strongly suggests spinal instability.
  - If unsure, leave the cervical collar in place.
  - Log roll the patient when SCI is suspected.
- Pitfalls:
  - Normal variants may cause difficulties for the inexperienced radiologist in the assessment of the spine:
    - Displacement of the vertebrae may resemble subluxation.
    - Variations of curvature may resemble spasm and ligamentous injury.
    - Growth centers may be confused with fractures.
  - Failure to acquire all 7 vertebrae and the top of T1 on the lateral film may result in missed fractures.
  - C-spine injuries above C6 can result in loss of respiratory muscle function.

# TRAUMA, VAGINAL

Valerie Davis

## BASICS

### DESCRIPTION

- Vaginal trauma includes:
  - Injuries due to blunt pelvic or abdominal trauma
  - Straddle injuries, which occur by falling astride a blunt object
  - Injuries due to penetration or impalement (including foreign bodies)
  - Intracoidal injuries and sexual abuse
  - Injuries associated with high-pressure water, such as jet skiing
- Range of injuries includes ecchymoses and minor lacerations to extensive lacerations requiring hemodynamic support and surgical repair.

### EPIDEMIOLOGY

0.2% of all pediatric injuries (1)

### RISK FACTORS

Straddle injuries from falling on a bicycle or toys, or while climbing into a bathtub (2)

### GENERAL PREVENTION

- Car seats and seat belts
- Bathtub and sport participation safety (2)

### PATHOPHYSIOLOGY

- Significant pelvic compressive forces have been associated with vaginal lacerations (2).
- Injuries also result from the sharp edge of a pelvic fracture in a motor vehicle collision.
- Straddle injuries result in minor lacerations or abrasions to the labia minora or posterior fourchette and bruising of the labia majora and mons pubis (3).
- Injuries to the hymen and vaginal lacerations suggesting penetration are suspicious for penetrating sexual abuse (3).

### ETIOLOGY

- Most commonly caused by straddle injuries (>80%) (2):
  - Resulting from falls on playground equipment and toys
  - Bathtub accidents
- Blunt trauma to the pelvis from motor vehicle accidents
- Accidental penetrating injuries
- High-pressure water injuries
- Consensual sexual activity
- Sexual abuse/assault

### COMMONLY ASSOCIATED CONDITIONS

- Blunt pelvic/abdominal trauma
- Perineal/Genitourinary injuries

## DIAGNOSIS

### HISTORY

- Clear and plausible mechanism for injury preferably is provided independently by both the child and adult witnesses.
- Document an accurate and thorough history. If there is a poor correlation between the history and physical exam, consider abuse (2).

### PHYSICAL EXAM

- Position the child in the frog-leg position. Younger children may be placed in their parent's lap. Apply lateral traction to the labia majora by grasping with the thumbs and index fingers and applying gentle outward and lateral traction (3).
- The child may also be examined in the knee–chest position, which is helpful to detect a foreign body (3).
- Consider a speculum exam:
  - Avoid speculum use in the prepubertal child.
  - Examine all the vaginal walls since missed vaginal wall injuries may result in fistula formation between the vagina and the bowel or bladder wall.
  - The pressure from an open speculum could mask bleeding. During the exam, observe closely and carefully release the speculum.
- Carefully examine the external genitalia to assess for vulvar ecchymoses or lacerations. Consider a rectal exam to indirectly palpate the vagina and check for lacerations:
  - Bleeding is unlikely to be of vaginal origin if the hymen is intact.
  - Describe the appearance, location, and size of the injuries. Photograph the injuries if there is concern for sexual abuse (2).
- Palpate the bony structures and prominences to look for subtle indications suggesting the presence of fractures.
- For an adequate exam, deep sedation or general anesthesia may be required.
- Examine the rest of the body for bruising or other injuries:
  - In all instances of suspected vaginal trauma, bladder and bowel wall integrity must be assessed by urethral catheterization and rectal palpation.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

- hCG
- Collect forensic evidence and test for *Neisseria gonorrhoeae* and Chlamydia trachomatis, syphilis, hepatitis B (if unimmunized), and HIV if concerned for sexual abuse/assault.
- For significant, prolonged bleeding, obtain a CBC.
- Type and cross for blood transfusion if indicated.

#### Imaging

Consider pelvic radiographs and/or CT to look for fractures, pelvic diastasis, radiopaque foreign bodies, or free intraperitoneal air if significant injury is present:

- Check upright abdominal radiograph to assess for free air under the diaphragm if concern for free air exists.

### Diagnostic Procedures/Other

Examine under deep sedation/general anesthesia if there is concern about inability to void/urethral injury, continued bleeding requiring suturing, expanding hematoma, or penetrating injury requiring inspection of the upper vagina (3).

- The integrity of the blood vessels of the pelvic floor needs to be assessed since they can be disrupted in penetrating vaginal injuries.
- IV urogram and/or cystoscopy to evaluate for urethra and bladder injuries

### DIFFERENTIAL DIAGNOSIS

- Urethral prolapse commonly presents as vaginal bleeding. Characteristic donut-shaped mass is diagnostic.
- Vulvovaginitis from infections such as group A streptococci, *Candida albicans*, or *Shigella* can present with vaginal bleeding.
- Poor hygiene, bubble bath use, and pinworm infections can present as pain, dysuria, and pruritus.
- Tumors such as sarcoma botryoides or other rare malignancies

## TREATMENT

### PRE HOSPITAL

- Manage airway, breathing, and circulation as per Pediatric Advanced Life Support (PALS) and Advanced Trauma Life Support (ATLS) guidelines.
- Do not remove impaled objects.

### INITIAL STABILIZATION/THERAPY

- Assess and stabilize airway, breathing, and circulation as per PALS and ATLS guidelines:
  - If necessary, administer supplemental oxygen, preferably by nonrebreather mask.
  - Control bleeding and fluid resuscitate if shock is present:
    - Vaginal packing can be used to control bleeding. It can be painful to remove in the prepubertal patient.
    - Ice packs can be used to control minor bleeding.
- Placement of a urinary catheter may be necessary if the child develops urinary retention.
- Administer appropriate pain control:
  - Oral analgesics or application of lidocaine jelly to the affected area
- Administer antibiotics to prevent STIs and medications to prevent pregnancy for sexual assault in adolescent patients (2):
  - See the Sexual Assault or Sexually Transmitted Infections topics for more information.
- Tetanus prophylaxis (Td, dTap) if indicated

### Pregnancy Considerations

Pregnant patients with vaginal trauma require urgent evaluation by obstetrics and gynecology.

**MEDICATION****First Line**

- Opioids:
  - Morphine 0.1 mg/kg IV/IM/SC q2h PRN:
    - Initial morphine dose of 0.1 mg/kg IV/SC may be repeated q15–20min until pain is controlled, then q2h PRN.
  - Fentanyl 1–2  $\mu$ g/kg IV q2h PRN:
    - Initial dose of 1  $\mu$ g/kg IV may be repeated q15–20min until pain is controlled, then q2h PRN.
  - Hydrocodone or hydrocodone/acetaminophen dosed as 0.1 mg/kg of hydrocodone component PO q4–6h PRN
- NSAIDs:
  - Consider NSAID medication in anticipation of prolonged pain and inflammation:
    - Ibuprofen 10 mg/kg/dose PO/IV q6h PRN
    - Ketorolac 0.5 mg/kg IV/IM q6h PRN
    - Naproxen 5 mg/kg PO q8h PRN
- Acetaminophen 15 mg/kg/dose PO/PR q4h PRN
- Topical lidocaine jelly 2% (Xylocaine<sup>M</sup>) can be applied directly to the genital–vaginal area:
  - 1 mL of jelly is 20 mg of lidocaine.
  - Max single dose is 6 mg/kg or 0.3 mL/kg
  - Use 5–10 mL in adolescents.
  - Apply for 5–10 min and then rinse.
  - Monitor total lidocaine dose if also injecting lidocaine SC.

**Second Line**

Consider prophylactic antibiotics in cases requiring surgical repair:

- Cefazolin 25–50 mg/kg/day IV divided q6–8h
- Cephalexin 25–50 mg/kg/day PO divided q6h
- Clindamycin 10 mg/kg IV/PO q8h

**SURGERY/OTHER PROCEDURES**

- Vaginal lacerations may be repaired under local anesthesia in older patients. Younger children will require deep sedation or general anesthesia.
- Laparoscopy/Laparotomy is indicated for signs of peritoneal irritation or ongoing hemodynamic instability (4).

**DISPOSITION****Admission Criteria**

- Concurrent head, chest, abdominal, or pelvic trauma that requires hospitalization
- Vaginal bleeding that has required an intervention such as packing or suturing
- Vaginal bleeding that has required a packed red cell transfusion
- Critical care admission criteria:
  - Hemodynamic instability requiring inotropic support
  - Other concurrent life-threatening injuries that require intensive care

**Discharge Criteria**

- Minor injuries without other concurrent system injuries
- Hemostasis achieved and ability to urinate documented

**Issues for Referral**

- Referral to a gynecologist, urologist, or pediatric surgeon for complex vaginal lacerations requiring repair.
- Refer to a child abuse specialist if suspicion of sexual abuse/injury.
- Refer to a mental health provider for sexually assaulted patients.

**FOLLOW-UP****FOLLOW-UP RECOMMENDATIONS**

- Discharge instructions and medications:
  - Adequate pain control
  - Sitz baths
  - Intermittent ice packs
  - Voiding in a tub can relieve the pain related to urination.
  - Return to the emergency department if unable to urinate or worsening bleeding.
- Activity:
  - Reduce activity for 24–72 hr to promote healing (2).

**Patient Monitoring**

Vaginal trauma involving primary closure or other significant injury should follow up with the pediatric gynecologist, urologist, or surgeon within 2 wk.

**DIET**

Patient should be NPO for exam under sedation/anesthesia.

**COMPLICATIONS**

- Most injuries will heal without sequelae.
- Injuries involving significant tissue damage are at risk for wound infection, wound dehiscence, scarring, and urethrovaginal or rectovaginal fistula.

**PROGNOSIS**

- Minor vaginal trauma heals quickly, and long-term complications are extremely unlikely.
- For more severe trauma, the prognosis depends on severity of injury and associated injuries.

- Trauma, Perineal
- Vaginal Bleeding
- Vaginal Discharge, Prepubertal
- Vaginal Discharge, Pubertal

**CODES****ICD9**

- 878.6 Open wound of vagina, without mention of complication
- 922.4 Contusion of genital organs
- 959.14 Other injury of external genitals

**PEARLS AND PITFALLS**

- Pearls:
  - Need to thoroughly examine all of the vaginal walls since improper diagnosis and healing can lead to fistula formation between the vagina and bladder or bowel wall.
  - Physical exams should always be performed in the presence of a chaperone.
- Pitfalls:
  - Failure to consider and evaluate for abuse
  - Failure to perform an adequate exam
  - Failure to consider pregnancy

# TRAUMATIC BRAIN INJURY

Rasha Dorothy Sawaya  
Cindy Ganis Roskind

## BASICS

### DESCRIPTION

- Traumatic brain injury (TBI) is an acquired form of brain injury secondary to an acute, open or closed head trauma:
  - Open head injury: Penetrating trauma through the skull
  - Closed head injury: Direct blunt trauma or from acceleration-deceleration forces causing a coup and countercoup effect
- TBI may present with minimal symptoms, transient neurologic deficits (immediate or delayed), permanent neurologic deficits, coma, or death.
- TBI can be focal or diffuse:
  - Focal brain injury:
    - Contusion: Bruise to the brain with or without abnormal neurologic findings
    - Intracranial hemorrhage
    - Intracerebral (parenchymal) bleed
    - Epidural hemorrhage: Injury to the middle meningeal vessels, diploic veins, or venous sinuses
    - Subdural hemorrhage: Rupture of bridging veins
    - Subarachnoid hemorrhage: Injury to the small vessels of the pia mater
  - Diffuse brain injury:
    - Concussion: Altered mental status secondary to trauma without loss of consciousness (LOC) and with a normal CT scan
    - Diffuse axonal injury: Microscopic brain injury of the white matter, often with prolonged coma

### EPIDEMIOLOGY

#### Incidence

- Each year in the U.S., TBI results in:
  - 2,685 pediatric deaths
  - 37,000 pediatric hospitalizations
  - 435,000 emergency department visits by children
- Twice as common in males than females
- High-risk age groups:
  - 0–4 yr and 15–19 yr (1)

### RISK FACTORS

Bleeding diathesis

### GENERAL PREVENTION

- Primary prevention:
  - Seat belt use
  - Constant and correct use of car seats
  - Helmets (bikes, contact sports)
  - Window guards
  - Safety gates
  - Shock-absorbing playground surfaces
  - Proper child supervision
- Secondary prevention:
  - Immediate and appropriate cardiorespiratory resuscitation

### PATHOPHYSIOLOGY

- Primary brain injury involving direct injury to the brain parenchyma that occurs in 3 phases: Hypoperfusion, hyperemia, and vasospasm
- Secondary brain injury causes cerebral ischemia as a result of:
  - Hypotension
  - Hypoxia, hypocarbia
  - Hyperthermia
  - Hyperglycemia
- Cerebral herniation:
  - Increase in intracranial pressure (ICP) secondary to mass effect from bleeding or swelling

### ETIOLOGY

- Leading causes of TBI in children in the U.S.:
  - Falls (28%)
  - Motor vehicle-traffic crashes (20%)
  - Struck by/against objects (19%)
  - Assaults (11%) (1)
- Leading cause of death secondary to TBI in children in the U.S.: Firearms (1)

### COMMONLY ASSOCIATED CONDITIONS

- C-spine injury
- Facial fractures
- Thoracic and abdominal trauma
- Neurologic changes (eg, seizures)
- Pelvic and long bone fractures

## DIAGNOSIS

### HISTORY

- Mechanism of injury to assess risk of severe TBI: Height of fall, speed of collision, etc.
- Symptoms suggestive of moderate to severe TBI:
  - Prolonged LOC
  - Altered mental status
  - Focal neurologic deficits
  - Seizures
  - Severe or worsening headache
  - Persistent vomiting
  - Lucid interval followed by new and worsening neurologic symptoms (altered mental status and headache)

### PHYSICAL EXAM

- Primary survey:
  - Vital signs:
    - Bradycardia, HTN, and irregular respirations: Impending brain herniation (Cushing triad)
    - Tachycardia and hypotension, other areas of blood loss
  - Secondary survey—complete physical exam:
    - Facial evaluation: “Raccoon” eyes, Battle sign, hemotympanum, CSF rhinorrhea or otorrhea, and cephalohematoma are all signs of skull fracture.
    - Chest/Abdomen/Extremity evaluation: Tenderness, ecchymosis, and deformity may indicate multiorgan injury.
    - Complete neurologic evaluation:
      - Glasgow Coma Scale (GSC) score: <8 suggests airway at risk
      - Pupillary exam (size, reactivity, symmetry)
      - Extraocular movements
      - Reflexes (brainstem and deep tendon)

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

- CBC, basic metabolic panel, liver enzymes, coagulation studies, type and screen
- Serum ethanol level if indicated

#### Imaging

- Noncontrast head CT scan:
  - Rapid diagnostic modality
  - Epidural hemorrhage: Biconvex hyperdensity
  - Subdural hemorrhage: Crescentic hyperdensity
  - Subarachnoid bleed: Hyperdense collection in subarachnoid spaces or basal cistern
  - Brain edema (diffuse brain swelling): Small ventricles, effacement of the sulci, loss of gray-white matter differentiation
  - Diffuse axonal injury: Small areas of cerebral hemorrhage
- Brain MRI in stable patients
- Transcranial Doppler
- C-spine plain radiographs or CT

### DIFFERENTIAL DIAGNOSIS

- Concussion or contusion
- Nonaccidental trauma

## TREATMENT

### PRE HOSPITAL

- C-spine immobilization
- Assess and stabilize airway, breathing, and circulation.

### INITIAL STABILIZATION/THERAPY

- Assess and stabilize airway, breathing, and circulation:
  - Intubation as per Advanced Trauma Life Support (ATLS) guidelines: GCS <8, severe maxillofacial fractures, aspiration risk, airway obstruction risk, inadequate respiratory effort, or impending airway compromise
  - Rapid sequence intubation (RSI) with in-line C-spine immobilization:
    - Preferably orotracheal intubation
    - Protects against the “pressure response,” which may increase ICP and worsen secondary injury
  - Appropriate fluid resuscitation to maintain adequate cerebral perfusion pressure:
    - Isotonic IV fluids to maintain hemodynamic stability and mean arterial pressure >70 mm Hg
- Disability and exposure to search for associated injuries
- Repeated serial exams

### MEDICATION

- Signs and symptoms of increased ICP:
  - 20% mannitol: 0.25 g to 1 g/kg/dose IV over 20–30 min
  - Hypertonic saline: 3% sodium chloride at 0.1–1 mL/kg/hr IV
  - Insufficient data to recommend universal use of mannitol or hypertonic saline in all patients with TBI (2)

- If RSI is to be performed, consider the following:
  - Premedication:
    - Lidocaine 1–2 mg/kg IV: Insufficient evidence that it prevents the increase of ICP (3)
  - Sedation and analgesia:
    - Etomidate 0.3 mg/kg IV: Usually maintains hemodynamic stability
    - Propofol 1 mg/kg IV
    - Thiopental 3–5 mg/kg IV: If hemodynamically stable
    - Fentanyl 1–3 μg/kg IV for pain
    - Ketamine: Should be avoided because of theoretical increase in ICP
  - Paralytics:
    - Rocuronium 0.6–1 mg/kg IV
    - Succinylcholine 1–2 mg/kg IV, 3–4 mg/kg IM: Theoretical risk of increased ICP secondary to fasciculations

**COMPLEMENTARY & ALTERNATIVE THERAPIES**

- Anticonvulsants:
  - Early (0–7 days) anticonvulsant administration may reduce the incidence of early posttraumatic seizure.
  - No evidence that it changes final outcome
  - No evidence that late (after 7 days) use of anticonvulsants reduces the risk of posttraumatic seizure (3)
  - Drug of choice: Phenytoin or fosphenytoin (20 mg/kg IV loading dose)
- The following may be considered for increased ICP:
  - Hyperventilation:
    - Insufficient data to recommend its use
    - Extreme hyperventilation may be harmful.
    - Target normocarbida and normal SpO<sub>2</sub> to prevent secondary brain injury
  - Consider elevating head 30 degrees.
  - Steroids: Not recommended and have been shown to increase brain injury (4,5)
  - Hypothermia:
    - Recent Cochrane review finds insufficient evidence to recommend hypothermia to prevent mortality/long-term complications (6).
  - High-dose barbiturates in hemodynamically stable patients with severe TBI and refractory increased ICP (4)

**SURGERY/OTHER PROCEDURES**

- Early neurosurgical evaluation:
- ICP monitoring if severe (4)
  - CSF drainage (4)
  - Decompressive craniectomy in severe refractory intracranial HTN
  - Depressed skull fractures with lacerations of the dura mater may require surgical repair.

**DISPOSITION**

**Admission Criteria**

- Consider ICU admission if:
  - Ongoing mechanical ventilation
  - Hemodynamic instability
  - Intracranial hemorrhage
  - Altered mental status or progressive or nonresolving neurologic changes
  - ICP monitoring
  - Neurosurgical interventions

- Consider floor admission for monitoring if:
  - Significant initial neurologic deficit
  - Neurologic symptoms such as disorientation or repetitive speech

**Discharge Criteria**

- Several clinical prediction rules have been developed to identify patients at low risk of clinically significant TBI:
  - PECARN rule:
    - Low-risk criteria for children <2 yr of age:
      - GCS 15; no palpable skull fracture; no parietal, occipital, or temporal scalp hematoma; no LOC >5 min; nonsevere mechanism; and acting normally
    - Low-risk criteria for children ≥2 yr of age:
      - GCS 15; no sign of basilar skull fracture; no history of LOC, severe mechanism, vomiting, or severe headache (7)
  - Canadian Assessment of Tomography for Childhood Head Injury (CATCH): The presence of any of the following risk factors predicts risk of TBI in children with minor head injury:
    - High risk (predicts need for neurologic intervention):
      - GCS <15 at 2 hr, open or depressed skull fracture, worsening headache, irritability
    - Medium risk (predicts brain injury on CT scan):
      - Signs of basal skull fracture; large, boggy scalp hematoma; dangerous mechanism of injury (8)

**Issues for Referral**

Consider transfer to a pediatric trauma center for patients with moderate to severe TBI.

 **FOLLOW-UP**

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**

- Avoid secondary brain injury:
  - Ensure adequate oxygenation and cerebral perfusion pressure.
- Serial CT scans depending on injury

**PROGNOSIS**

Depends on injury severity, secondary brain injury, and other organ system injuries

**COMPLICATIONS**

- Permanent neurologic deficits
- Seizures and brain death
- Death

**ADDITIONAL READING**

**See Also (Topic, Algorithm, Electronic Media Element)**

- Cerebral Contusion
- Epidural Hematoma
- Subdural Hematoma
- Trauma, Head

**ICD9**  
854.00 Intracranial injury of other and unspecified nature, without mention of open intracranial wound, with state of consciousness unspecified

**PEARLS AND PITFALLS**

- Pearls:
  - If TBI with hypotension, remember to evaluate other organ systems.
  - If intubation is necessary, secure the airway with in-line C-spine stabilization.
  - There is a need for high index of suspicion for nonaccidental trauma in cases of TBI in infants.
- Pitfall:
  - Avoid secondary brain injury by correcting hypotension, hypocarbia, hypoxia, hyperthermia, and hyperglycemia.

# TRICYCLIC ANTIDEPRESSANT POISONING

John Kashani

## BASICS

### DESCRIPTION

- Cyclic antidepressants comprise a group of pharmacologically related drugs that also have indications for depression, neuralgic pain, enuresis, migraines, and ADHD.
- Due to toxicity of cyclic antidepressants, as well as development of better, newer psychotropic medications, these medications are prescribed much less frequently than in the past.

### EPIDEMIOLOGY

#### Incidence

- Since the introduction of selective serotonin reuptake inhibitors, the incidence of cyclic antidepressants poisoning has decreased.
- However, the addition of various new indications for cyclic antidepressants has increased their availability.
- The comparative risk of death with a cyclic antidepressant is greater than that of a selective serotonin reuptake inhibitor, and cyclic antidepressant toxicity still represents a major concern.

### PATHOPHYSIOLOGY

- The cyclic antidepressants have a diverse pharmacologic profile.
- The antidepressant effect is thought to occur by inhibiting the reuptake of norepinephrine and serotonin.
- Cyclic antidepressants antagonize muscarinic acetylcholine receptors and are capable of producing anticholinergic signs and symptoms.
- Cyclic antidepressants antagonize peripheral alpha receptors producing vasodilatation and orthostatic hypotension.
- Cyclic antidepressants can block myocardial sodium channels and potassium channels, producing QRS and Qtc prolongation, respectively.

- Seizures occurring in cyclic antidepressant overdose are thought to occur by antagonism of the GABA receptor.
- Peak concentrations of cyclic antidepressants occur 2–8 hr after therapeutic dosing.
- The pharmacokinetics of overdose is not known. However, once ingested, cyclic antidepressants are rapidly distributed to the heart, brain, liver, and kidney.

### COMMONLY ASSOCIATED CONDITIONS

- Major depression
- Enuresis

## DIAGNOSIS

### HISTORY

- Patients may not be forthcoming with an overdose. If a tricyclic antidepressant (TCA) overdose is suspected, the clinician must reassess the patient frequently, as the patient may rapidly decompensate.
- It is not uncommon for patients to present to an emergency department with mild signs of toxicity and to develop life-threatening toxicity in a few hours.

### PHYSICAL EXAM

- The physical exam in TCA toxicity largely reflects various mechanisms of action.
- Tachycardia is seen and occurs through a combination of reuptake of serotonin and norepinephrine and anticholinergic effects.
- An altered mentation occurs secondary to the anticholinergic effects.

- Although hypotension is expected secondary to alpha receptor blocking effects, it is counteracted by the anticholinergic effects and the effects on serotonin and norepinephrine. Often patients have a normal or mildly elevated BP.
- Pupils are often mid-size secondary to the combination of the anticholinergic effects and opposing effects on alpha receptors.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

- Obtain bedside serum glucose in any patient with altered mental status.
- Baseline serum electrolytes may be all that is needed in mild toxicity. If seizures, arrhythmias, or an altered mentation is present, then LFTs and a creatine phosphokinase should be added.
- All women of child-bearing age should have a urine pregnancy test done.
- Cyclic antidepressants may be detected by urine drug screen for tricyclics. Physicians should not rely on a urine drug screen to guide management of a poisoned patient. Many drugs are known to cause a false-positive cyclic antidepressant screen, including carbamazepine, diphenhydramine, cyclobenzoprine, quetiapine, and orphenadrine.
- Quantitative cyclic antidepressant assays are available. Their clinical utility is limited because the test is not readily available and levels do not correlate well with toxicity:
  - A cyclic antidepressant level of  $> 1,000$  ng/mL is usually observed in significant clinical toxicity.

**Imaging**

- If aspiration is a concern, then a CXR is indicated.
- If an alternative diagnosis for an altered mental status is a concern, then CT of the head should be considered.

**Diagnostic Procedures/Other**

- ECG is a critical diagnostic tool. It will help guide therapy with a cyclic antidepressant overdose. Additionally, an ECG can help predict toxicity. It is recommended that a baseline and serial ECGs be obtained.
- There is a high incidence of seizure and ventricular arrhythmias and seizures with a QRS duration > 100 msec and 160 msec, respectively.
- A tall R wave in aVr, S wave in aVI, S wave in lead I are suggestive of cyclic antidepressant cardiotoxicity.

**DIFFERENTIAL DIAGNOSIS**

Antiarrhythmic overdose, anticholinergic toxicity, amantadine overdose, cyclobenzaprine overdose, Wellbutrin overdose, antipsychotic overdose

**TREATMENT****PRE HOSPITAL**

Control of airway and seizure activity are critical prehospital measures.

**INITIAL STABILIZATION/THERAPY**

- Assess and stabilize airway, breathing, and circulation.
- All patients with suspected cyclic antidepressant overdose need to be assessed promptly on presentation to the emergency department.
- Patients should be placed on cardiac monitors and continuous pulse oximetry, and IV access should be established.
- Patients should initially be frequently reassessed even if they do not exhibit signs of toxicity.
- If signs of toxicity are present, then anticipatory management or immediate intervention is warranted.
- Seizures occurring in the setting of a cyclic antidepressant overdose tend to be single and self-remitting.

- If QRS widening is present, then sodium bicarbonate should be administered. If Qtc prolongation is present, then magnesium should be administered.
- If an altered mentation is present, serious consideration should be given to endotracheal intubation.
- In absence of serious signs of toxicity, the supportive and anticipatory management is all that is indicated.

**MEDICATION**

- If QRS widening is present, then an IV bolus of sodium bicarbonate should be administered (1–2 mEq/kg) and an ECG should be checked ~15 min later. If the QRS duration shortens, then a sodium bicarbonate drip should be considered.
- If Qtc prolongation, then consideration should be given to administration of magnesium 20–40 mg/kg up to 2 g IV.
- Though seizures in the setting of TCA overdose tend to be single and self-remitting, the administration of benzodiazepines:
  - Diazepam 0.1 mg/kg IV (max single dose 10 mg) q5min PRN
  - Midazolam 0.1 mg/kg IV (max single dose 10 mg) q5min PRN
  - Lorazepam 0.05 mg/kg (max single dose 5 mg) q10min PRN

**DISPOSITION****Admission Criteria**

Critical care admission criteria:

- Patients with signs and symptoms of cyclic antidepressant toxicity should admitted to a critical care setting.

**Discharge Criteria**

Patients with a normal mental status and vital signs, after a sufficient observation period, can be evaluated by psychiatry and admitted accordingly.

**ADDITIONAL READING**

- Boehnert M, Lovejoy FH. Value of the QRS duration versus the serum drug level in predicting seizures and ventricular arrhythmias after an acute overdose of tricyclic antidepressants. *N Engl J Med.* 1985;313:474–479.
- Kerr GW, McGuffie AC, Wilkie S. Tricyclic antidepressant overdose: A review. *Emerg Med.* 2001;18:236–241.
- Liebelt EL, Francis PD, Woolf AD. ECG lead aVR versus QRS interval in predicting seizures and arrhythmias in acute tricyclic antidepressant toxicity. *Ann Emerg Med.* 1995;26:195–201.
- Malatynska E, Knapp RJ, Ikeda M, et al. Antidepressants and seizure-interactions at the GABA-receptor chloride-ionophore complex. *Life Sci.* 1988;43:303–307.
- Wolfe TR, Caravati EM, Rollins DE, et al. Terminal 40-ms frontal plane QRS axis as a marker for tricyclic antidepressant overdose. *Ann Emerg Med.* 1989;18:348–351.

**CODES****ICD9**

969.05 Poisoning by tricyclic antidepressants

**PEARLS AND PITFALLS**

- The most severe toxic effect of cyclic antidepressants is cardiac dysrhythmia. The use of ECG to screen for cardiotoxicity is highly sensitive and specific for TCA toxicity.
- Patients should remain on continuous cardiopulmonary monitoring and be reassessed frequently, as rapid deterioration may occur.
- The mainstay of therapy is supportive care, maintaining vital signs within acceptable limits, and treating cardiotoxicity.

# TUBERCULOSIS

Adriana Yock Corrales  
Peter Barnett

## BASICS

### DESCRIPTION

- TB infection occurs by the inhalation into the lungs of *Mycobacterium tuberculosis*.
- TB disease in children is frequently asymptomatic.
- In those who develop symptoms, most will have pulmonary manifestations, while 25–30% will have extrapulmonary TB (eg, superficial lymphadenitis, pleural, meningitis, military, or osteoarticular).

### EPIDEMIOLOGY

#### Incidence

- The interval between onset of infection and disease is generally 10–12 wk but can be up to 2 yr.
- The clinical presentation of TB disease depends on the site of infection, bacillary load, patient age, and host immunity.
- It is important to differentiate latent tuberculosis infection (LTBI) from TB disease. LTBI is defined as infection with *M. tuberculosis* as evidenced by a positive tuberculin skin test (TST) and lack of clinical or radiographic signs or symptoms of TB.
- Congenital infections occur, though rarely, in the setting of an untreated mother in the last trimester of pregnancy.

#### Prevalence

Data on the global prevalence of TB in children are sparse. In 2000, of 8.3 million new cases of TB worldwide, 11% occurred in children <15 yr of age and mainly in underdeveloped countries (80%).

### RISK FACTORS

- Age <5 yr
- Exposure:
  - Family member with known TB or positive skin test
  - Migrant farm workers
  - Refugee camps
  - Homeless people
- Immigration from a TB-endemic geographic area or refuge camp (Haiti, Southeast Asia, Africa, South and Central America, Eastern Europe)
- Visited by individuals with a chronic cough from these countries in the past or visited the above countries for a prolonged period
- Exposure to unpasteurized milk
- Higher incidence in:
  - Native Americans
  - HIV-positive people
  - Immunosuppressed state
  - Long-term steroid use

### GENERAL PREVENTION

- World Health Organization (WHO) guidelines recommend administration of BCG soon after birth to all infants in countries with high TB prevalence.
- BCG boosters are not recommended because of lack of evidence demonstrating efficacy.
- BCG vaccination is no longer recommended in children who are HIV positive.

- Prompt evaluation of household contacts of a child with suspected TB (via CXR) should occur prior to visitation to the hospital to prevent associated transmission of TB.
- Follow-up and contact tracing are key.

### PATHOPHYSIOLOGY

- The formation of a primary focus of infection, usually in the lung (Ghon focus), with recruitment of cell-mediated responses, causing regional lymphadenitis (primary complex). This may not be obvious on CXR.
- Development of a TST reaction is dependent on the adequate cell-mediated immune response:
  - This is often not fully developed in overwhelming disease, such as miliary TB or meningitis or large pleural effusions.
  - The cellular immunity usually develops 2–12 wk after initial infection.
- Primary TB, defined as disease progression of any part of the primary complex, is most common in younger children.

### ETIOLOGY

- TB is caused almost exclusively by *M. tuberculosis*; rarely, other atypical mycobacteria may cause infection.
- Humans are the only natural reservoir for *M. tuberculosis*. It is an aerobic, non-spore-forming, nonmotile acid-fast bacillus.

### COMMONLY ASSOCIATED CONDITIONS

- HIV infection
- Immunosuppression
- Malnutrition

## DIAGNOSIS

### HISTORY

- Close contact is defined as living in the same household as or in frequent contact with a source case with sputum smear–positive pulmonary TB.
- Pulmonary TB specific: Chronic cough, fever, hemoptysis, wheezing, fatigue, weight loss, and night sweats are far less common in children than in adults.
- Nonspecific and extrapulmonary: Failure to thrive, decreased appetite, nonpainful enlarged lymph nodes with or without fistula formation, altered mental status, and meningeal signs
- Osteoarticular signs (chronic)—Potter disease:
  - Insidious onset of back pain
  - Kyphosis at the thoracic and lumbar spine
  - Protective paraspinal spasm (will hold back hyperextended)
  - Spinal cord compression leading to motor weakness/sensory impairment in limbs or dysfunction of bladder or bowel
  - Joint involvement is monoarticular in 95% with limp-joint movement restricted and bone destruction in late stages.

### PHYSICAL EXAM

- Pulmonary TB: Physical signs may be mild compared with the extent of radiographic findings. These include rales, wheezing, and decreased breath sounds. Respiratory distress is infrequent.
- Pleural TB: Chest pain, decreased air entry, and often unilateral
- Adenopathy (frequently cervical or axillary)
- Enlarged liver or spleen
- Groin lump (extension of psoas abscess)
- Non-weight bearing (affecting bones/joints)
- Meningeal signs (nuchal rigidity): Late sign

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

- TST—Mantoux test:
  - TST is a definitive diagnostic test for exposure.
  - The TST is read as millimeters of induration at the injection site 48–72 hr later.
  - A skin test may become positive 3–6 wk after initial infection.
- Bacteriologic studies:
  - Mycobacterial culture may take 6–10 wk, and positive results are found in <50% of children:
    - Culture can be obtained from sputum, gastric aspirate, or bronchoscopy. Sputum should always be obtained in older children ( $\geq 10$  yr of age).
  - Gastric aspiration is done in children who are unable or unwilling to expectorate sputum:
    - A gastric aspirate should be obtained on 3 consecutive mornings. It has a better yield for diagnosis in young children with suspected pulmonary TB than expectorated sputum.
  - Bronchoscopy has a low yield in children with suspected pulmonary TB. It is only useful in the diagnosis of endobronchial TB.
- QuantiFERON-TB Gold:
  - This whole blood test can distinguish TB infections by *M. tuberculosis* from the ones caused by nontuberculous mycobacteria or BCG exposure.
  - It is unable to identify active from latent disease, and false negatives can occur in immunosuppressed patients.
  - It is still controversial in children, especially in those <2 yr of age because of test sensitivity.
- Nucleic acid amplification tests: Heterogeneous group of tests that use the polymerase chain reaction technique to detect mycobacterial nucleic acid. It is not available for the routine diagnosis of TB in children.
- Consider HIV testing in all patients with suspected or proven TB.

**Imaging**

CXR—manifestations of pulmonary primary TB:

- Intrathoracic lymphadenopathy of the hilar, mediastinal, and subcarinal nodes is present in 90–95% of children.
- Parenchyma changes are present in 70% of patients.
- Pleural effusion or atelectasis
- Miliary disease
- Residual calcification of lung primary focus or regional lymph nodes (occurring from 6 mo to 4 yr after infection); occurs in 17–25% of the patients

**Pathological Findings**

Histopathologic exam of a TB follicle consists of central caseous necrosis surrounded by lymphocytes, multinucleate giant cells, and epithelioid macrophages.

**DIFFERENTIAL DIAGNOSIS**

- Pulmonary infiltrate:
  - Community-acquired pneumonia or round pneumonia
  - Inhaled foreign body (chronic)
  - Atelectasis due to other processes
  - Other granulomatous disease (eg, histoplasmosis)
- Intrathoracic lymphadenopathy:
  - Infections caused by virus, bacteria, or fungus and nontuberculous mycobacteria
  - Malignancies or other granulomatous disease
- Subacute peripheral adenopathy:
  - Scrofula caused by nontuberculous mycobacterial infections
  - Cat scratch disease or toxoplasmosis
  - Malignancies
  - Partially treated pyogenic infection
- Meningitis:
  - Viral, bacteria (partially treated), fungal, and chemical meningitis

**TREATMENT****MEDICATION**

- Until sensitivities are known, a 4-drug regimen should be started:
  - Isoniazid (INH) 10–15 mg/kg/day PO in 1–2 divided doses, max dose 300 mg/day
  - Rifampicin 10–20 mg/kg/day PO in 1–2 divided doses, max dose 600 mg/day
  - Pyrazinamide 15–30 mg/kg/day PO in 1–2 divided doses, max dose 2 g daily
  - Ethambutol or streptomycin:
    - Ethambutol: Children, 20 mg/kg PO per day; adolescent (> 13 yr)/adult, 15–25 mg PO per day or 50 mg/kg PO twice weekly
    - Streptomycin: Children, 20–40 mg/g PO per day (max dose 1 g/day) or 20–40 mg/kg/dose twice weekly (max dose 1.5 g/dose); adolescent/adult, 15 mg/kg PO per day (max single dose 1 g) or 25–30 mg/kg/dose PO twice weekly (max single dose 1.5 g)
- Treatment with the initial 4 primary drugs is for 2 mo, followed by 4 mo of INH and rifampicin.
- If a cavity is seen on CXR or sputum specimens continue to test positive, or TB is miliary, disseminated, or meningeal, then subsequent treatment is 2 drugs for a total of 9–12 mo.

- If the patient has meningitis: Prednisolone 2 mg/kg daily for 4 wk. The dose should then be gradually reduced over 1–2 wk before ceasing. The dose can be increased to 4 mg/kg daily (max 60 mg/day) in seriously ill children.
- Treatment of LTBI (chemoprophylaxis) is important to prevent future disease activation and transmission to contacts: INH 10 mg/kg PO daily for 9 mo.
- Breast-feeding infants, patients with diets low in milk and meat, those with symptomatic HIV, and patients who are malnourished should receive pyridoxine, 25–50 mg/day, in addition to the above.

**SURGERY/OTHER PROCEDURES**

- Pulmonary resection may be required in drug-resistant cases because of the high likelihood of failure of the medication regimen.
- Surgical resection may also be required in advanced disease with extensive caseation necrosis, TB abscesses, and bronchopleural fistulas.

**DISPOSITION****Admission Criteria**

- TB meningitis
- Miliary TB
- Respiratory distress with pulmonary TB
- Spinal TB
- Severe adverse events, such as clinical signs of hepatotoxicity (eg, jaundice)

**FOLLOW-UP****FOLLOW-UP RECOMMENDATIONS**

Children and adolescents should be evaluated monthly to reinforce adherence, to monitor for toxicities, and to assess for possible progression or relapse.

**Patient Monitoring**

Routine measurements of hepatic and renal function and platelet count are not necessary during treatment unless patients have baseline abnormalities or are at increased risk of hepatotoxicity.

**PROGNOSIS**

- In children with uncomplicated TB, the outcome after treatment is excellent.
- The fatality rate in 1 report was 13% for children <3 mo of age with ~1/2 of the survivors developing neurologic sequelae.
- HIV-infected children who have culture-proven TB have a fatality rate as high as 39% despite TB treatment.
- Delayed diagnosis of congenital TB and onset of treatment contribute to ~40% mortality.

**COMPLICATIONS**

- TB meningitis occurs in 4%.
- Miliary TB
- Skeletal TB
- Renal TB
- Congenital TB
- Drug toxicity (eg, hepatitis and neurologic complications with INH, skin rashes with rifampin, ototoxicity with streptomycin)

**ADDITIONAL READING**

**See Also (Topic, Algorithm, Electronic Media Element)**

- Cough
- Pneumonia
- Weight Loss

**ICD9**

- 010.00 Primary tuberculous complex, unspecified examination
- 011.90 Unspecified pulmonary tuberculosis, confirmation unspecified
- 795.5 Nonspecific reaction to tuberculin skin test without active tuberculosis

**PEARLS AND PITFALLS**

- Resistance to isoniazid and rifampicin, whether or not resistant to other drugs, classifies disease as multidrug resistant.
- BCG is an effective vaccine in reducing TB meningitis and invasive TB in children <5 yr of age in countries of high TB prevalence.
- BCG boosters are not recommended, and primary BCG vaccination is no longer recommended in HIV-positive patients.
- Pediatric patients are more tolerant of anti-TB medications than adults; thus, regular monitoring of LFTs is not routinely required.

# TYMPANIC MEMBRANE PERFORATION

Efren A. Salinero  
Brandon C. Carr

## BASICS

### DESCRIPTION

Tympanic membrane (TM) perforation is a defect in the TM resulting in exposure of the middle ear.

### GENERAL PREVENTION

- Antibiotic treatment of acute otitis media
- Wearing fitted earplugs when diving
- Avoid diving when an upper respiratory infection or other condition resulting in eustachian tube dysfunction impairs ability to equalize middle ear pressure.

### PATHOPHYSIOLOGY

- The TM separates the middle ear from the external auditory canal.
- Disruption of this membrane may be caused by trauma originating external to the middle ear or from infection arising within the middle ear.

### ETIOLOGY

- Acute otitis media is the most common cause of perforation:
  - Failure to treat acute otitis media or use of the observation option as therapy increases risk of perforation.
- Trauma:
  - Direct blunt trauma to the ear, particularly by being slapped
  - Barotrauma:
    - Diving
    - Concussion secondary to blast or lightning
  - Penetrating trauma from instrumentation of ear canal, such as with a cotton swab
- Retained pressure equalizing tubes
- Complications of a surgical procedure such as myringotomy, tympanostomy, tympanostomy tube insertion, attempt at cerumen disimpaction

## DIAGNOSIS

### HISTORY

- Ear pain, usually mild
- Conductive hearing loss
- Tinnitus, vertigo, bloody or purulent otorrhea

### PHYSICAL EXAM

- Decreased hearing or auditory acuity
- Direct visualization of the TM with an otoscope usually will reveal a TM defect.
- Pneumatic otoscopy will demonstrate decrease or total lack of TM mobility; this may aid in detecting small perforation.
- Fistula test: Holding pressure with an insufflator for 15 sec may cause nystagmus or vertigo if the pressure is transmitted through the middle ear and into a labyrinth fistula.
- Loss of cone of light reflex
- Partial or complete perforation
- Purulent or bloody discharge

### DIAGNOSTIC TESTS & INTERPRETATION

- Perforation of a TM is a clinical diagnosis.
- Weber test (tuning fork on midline bone):
  - Sound should be equal or louder opposite to the injured ear due to increased bone conduction.
- Rinne test (air conduction detected after bone conduction fades) is usually normal or shows small conductive loss.

### Imaging

Cranial CT may be indicated to rule out skull fracture as indicated for blunt traumatic causes.

### DIFFERENTIAL DIAGNOSIS

- Temporal bone fracture
- Serous otitis media
- Acute otitis media
- Otitis externa
- Foreign body
- Ménière disease

## TREATMENT

### PRE HOSPITAL

Immobilize the C-spine if clinically indicated.

### INITIAL STABILIZATION/THERAPY

- After assurance of stable airway, breathing, and circulation, investigate for intracranial injury if indicated in the setting of trauma.
- Remove debris from the external canal.
- Do not irrigate, as this may force debris into middle ear; remove by Frazier suction or another similar method.
- Consult otolaryngologist for:
  - Significant active hemorrhagic otorrhea
  - Associated facial nerve paralysis
  - Hearing loss
  - Vertigo

### MEDICATION

- Topical antibiotics, preferably quinolones:
  - Ciprofloxacin otic suspension: 4 gtt b.i.d. to the affected ear for 7 days
  - Polymyxin B sulfate, neomycin sulfate, hydrocortisone (use otic suspension only): 3–4 gtt in the affected ear t.i.d.–q.i.d.
- Use systemic antibiotics if underwater TM perforation or for poor response to topical antibiotics:
  - Amoxicillin 80–90 mg/kg/day divided b.i.d.–t.i.d. × 10 days
  - Amoxicillin/Clavulanate 80–90 mg/kg/day divided b.i.d. × 10 days
  - Cefixime 8 mg/kg PO per day × 10 days

- May use topical aminoglycosides and polymyxins with caution due to ototoxic effects and vestibular dysfunction
- Antiemetics:
  - Meclizine 25–100 mg PO in divided doses t.i.d. in children > 12 yr of age
  - Dimenhydrinate 5 mg/kg/day PO divided q.i.d.; or, 2–5 yr, 12.5–25 mg PO q6–8h; 6–12 yr, 25–50 mg PO q6–8h; > 12 yr, 50–100 mg q4–6h
  - Ondansetron 0.1 mg/kg PO/IV q8h as needed

**SURGERY/OTHER PROCEDURES**

Tympanoplasty may be required for chronic perforation and hearing loss.

**DISPOSITION**

**Admission Criteria**

- Admission is rarely necessary.
- Associated injuries requiring admission
- Severe vertigo resulting in intractable vomiting or inability to ambulate

**Discharge Criteria**

Adequate control of symptoms

**Issues for Referral**

Persistent TM perforation and chronic suppurative otitis media suggest need for referral to an otolaryngologist.

**FOLLOW-UP**

**FOLLOW-UP RECOMMENDATIONS**

- Avoid underwater submersion of the ear for several weeks.
- Avoid forceful nose blowing.
- Protect the ear from water entry while bathing or showering.
- Follow up in 1–2 wk by a primary care provider or otolaryngologist.

**PROGNOSIS**

- Most perforations heal spontaneously within days to weeks.
- Forceful entry of water into ear with diving injury increases risk of infection.

**COMPLICATIONS**

- Persistent TM perforation
- Chronic suppurative otitis media
- Dislocation of ossicles
- Perilymph leak
- Cholesteatoma
- Hearing impairment
- Impaired language development in children
- Chronic infection of the middle ear with aerobic and anaerobic bacteria
- Chronic mastoid cavity infection

**ADDITIONAL READING**

**See Also (Topic, Algorithm, Electronic Media Element)**

- Otitis Externa
- Otitis Media

**ICD9**

- 384.20 Perforation of tympanic membrane, unspecified
- 384.21 Central perforation of tympanic membrane
- 384.22 Attic perforation of tympanic membrane

**PEARLS AND PITFALLS**

- Be vigilant to detect TM perforation in patients with otorrhea.
- Assess for associated issues in cases of traumatic perforation.
- Assess for other suppurative complications such as mastoiditis and intracranial abscess in patients with TM perforation secondary to otitis media.

# UMBILICAL GRANULOMA

Sunil Sachdeva

## BASICS

### DESCRIPTION

- Umbilical granuloma is an excess persistent tissue that remains on a baby's umbilical area after the umbilical cord detaches.
- Umbilical granuloma is the most common cause of umbilical mass.

### EPIDEMIOLOGY

It is thought to occur in 1 in 500 births, but no exact data are available.

### RISK FACTORS

- Not known
- More common with delayed cord separation

### GENERAL PREVENTION

- Good local hygiene
- Keeping the umbilical stump dry may be helpful.

### PATHOPHYSIOLOGY

- Normally, after the cord falls off, the area heals and keratinizes.
- In some cases after separation of the umbilical cord, usual skin growth does not occur and a moist pink or bright red mass occupies the area.

### ETIOLOGY

Unknown cause:

- It is postulated that incomplete epithelialization is due to mild infection at the base of the cord.

## DIAGNOSIS

### HISTORY

- Red or pinkish mass in the umbilical area
- Mild discharge or oozing may be present.
- Often found incidentally on routine exam

### PHYSICAL EXAM

- Red or pinkish mass in the umbilical area
- 3–10-mm lesion
- Moist and glistening
- There may be mild serous, serosanguineous, or seromucoid discharge.
- Surrounding skin may be erythematous.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Imaging

US may be needed in unclear cases to rule out patent urachus or omphalomesenteric fistula.

### DIFFERENTIAL DIAGNOSIS

- Umbilical polyp
- Omphalitis
- Umbilical hernia
- Patent urachus
- Omphalomesenteric fistula:
  - These final 2 have copious discharge.

## TREATMENT

### MEDICATION

Topical application of 75% silver nitrate:

- Apply once a week for 2–4 wk.
- Apply with great care to avoid surrounding skin burns or skin staining.
- Make sure the granuloma is dry before application.
- Surrounding skin may be protected by petroleum jelly.

### SURGERY/OTHER PROCEDURES

- Cryotherapy in form of liquid nitrogen has been used effectively.
- Double ligature of pedunculated granuloma has been used successfully.
- Rarely, surgical excision may be needed.

### DISPOSITION

#### Admission Criteria

- Omphalitis or other findings suggestive of severe infection
- Inpatient workup to rule out patent urachus or omphalomesenteric fistula

#### Discharge Criteria

The condition is managed on an outpatient basis.

#### Issues for Referral

If not improving after 3–4 applications of silver nitrate, refer to a dermatologist or pediatric surgeon.

**FOLLOW-UP**

**FOLLOW-UP RECOMMENDATIONS**

- The patient needs weekly follow-up to evaluate healing.
- The local area should be kept dry after silver nitrate application.

**Patient Monitoring**

If it is persistent despite treatment, particularly with significant discharge, investigation for patent urachus or fistula should be carried out.

**PROGNOSIS**

- Outcome is excellent.
- Most cases resolve with 1 or 2 applications of silver nitrate.

**COMPLICATIONS**

Secondary infection

**ADDITIONAL READING**

**See Also (Topic, Algorithm, Electronic Media Element)**

Omphalitis

**ICD9**  
771.4 Omphalitis of the newborn

**PEARLS AND PITFALLS**

- Omphalitis is a life-threatening infection that requires prompt treatment with parenteral antibiotics and inpatient therapy.

- Patent urachus and omphalomesenteric fistulas may be misdiagnosed as an umbilical granuloma:
  - This is likely due to the frequency with which umbilical granuloma occurs and the rarity of these other pathologies.
  - All umbilical lesions should be evaluated carefully to note history of copious discharge or presence of significant discharge, as umbilical granulomas typically have scant discharge.
- Severe burns may result from silver nitrate that contacts keratinized skin:
  - Care should always be taken to properly prepare for silver nitrate cauterization to ensure that only the granuloma is contacted by this caustic agent.

# UPPER RESPIRATORY INFECTION

Joseph F. Perno

## BASICS

### DESCRIPTION

- Upper respiratory infection (URI) is the most common illness in all individuals, regardless of age (1).
- Known as the “common cold”
- Multitude of symptoms: Rhinorrhea, coryza, sneezing, cough, fever, pharyngitis
- Viruses account for the vast majority of URIs:
  - Rhinovirus
  - Respiratory syncytial virus (RSV)
  - Influenza A and B
  - Parainfluenza 1, 2, 3
  - Coronaviruses
  - Adenovirus
  - Human metapneumovirus (HMPV)

### EPIDEMIOLOGY

#### Incidence

- Children experience 6–9 URIs per year.
- Adolescents and adults have 2–4 URIs per year (2).
- Seasonal variability of viral respiratory illness exists (3):
  - Rhinovirus: All year, with peaks in September and spring
  - Rhinovirus is responsible for 40–50% of colds
  - RSV: October–May
  - Influenza A: December–January
  - Influenza B: March–April
  - Parainfluenza 1 and 2: Alternating yearly pattern with peak in mid autumn
  - Parainfluenza 3: Yearly

### RISK FACTORS

- Exogenous:
  - Day care attendance outside the home
  - Increased number of household members
  - Passive smoke exposure
  - Polluted environment
  - Urban living with high population density

- Endogenous:
  - Gastroesophageal reflux
  - Primary ciliary dyskinesia
  - Short duration of breast-feeding
  - Adenoid hypertrophy
  - Eustachian tube dysfunction
  - Immune deficiency

### GENERAL PREVENTION

- Reduced exposure to ill contacts
- Good hand hygiene
- Cleaning surfaces of contaminated objects (eg, toys at a day care center) with disinfectant
- Influenza vaccination

### PATHOPHYSIOLOGY

- Direct contact and inoculation of virus into the upper respiratory tract
- Development of long-lasting antibody that is protective against reinfection with the same serotype (4)
- Most viruses spread via both aerosol and large droplet transmission.

### ETIOLOGY

- Rhinovirus
- RSV:
  - The majority of infants experience infection prior to the 1st birthday.
  - 40–50% involve the upper and lower respiratory tract (5).
- Influenza A and B (see the Influenza topic)
- Parainfluenza 1, 2, 3
- Coronaviruses
- Adenovirus:
  - Responsible for 7% of childhood respiratory infections
- Human metapneumovirus (HMPV):
  - Discovered in 2001
  - Spectrum of disease similar to RSV

### COMMONLY ASSOCIATED CONDITIONS

- Acute otitis media is a common complication of pediatric URI.
- Sinusitis may complicate pediatric URI.
- Lower respiratory infection (bronchiolitis or pneumonia) may be associated with an antecedent URI.

## DIAGNOSIS

### HISTORY

- Gradual onset for most viruses:
  - Influenza has a more rapid onset.
- Duration of symptoms is 9–10 days (4).
- Stuffy nose, nasal congestion
- Sneezing
- Sore throat
- Mild cough
- Fever:
  - Fever is common and severe with influenza.
- Myalgias and malaise are typically more severe with influenza.
- Headache

### PHYSICAL EXAM

- Rhinorrhea with inflamed turbinates
- Injected tonsils and posterior pharynx:
  - Usually without exudates
- Lung fields clear
- Fever may or may not be present.
- Pulse oximetry and respiratory rate should be normal.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

- Typically no testing is necessary.
- Rapid detection of influenza A and B, parainfluenza, RSV, and adenovirus can be done in most labs:
  - The positive predictive value is higher when there is a greater prevalence of disease and the virus is present in the community (4).

**Imaging**

Chest radiograph should be obtained only for concern of a concomitant lower respiratory tract process such as pneumonia.

**DIFFERENTIAL DIAGNOSIS**

- URIs typically are caused by respiratory viruses; must rule out a concomitant bacterial process.
- Must rule out lower respiratory tract involvement (bronchiolitis, viral pneumonitis, bacterial pneumonia)

**TREATMENT****PRE HOSPITAL**

Support airway, breathing, and circulation.

**INITIAL STABILIZATION/THERAPY**

- Assessment of airway, breathing, and circulation.
- A simple URI should have no life-threatening complications.

**MEDICATION****First Line**

- Antipyretics are the only routinely indicated therapy.
- Avoid the use of antibiotics unless a specific bacterial infection can be identified.

**ALERT**

- The FDA expressly recommends against the use of over-the-counter (OTC) cough and cold preparations in children <4 yr of age.
- Evaluation of safety and efficacy in children 4–11 yr of age is ongoing.
- Many parents are unaware of this or will disagree with the advice and seek such medications.

**Second Line**

Antiviral medication for confirmed influenza can be used for a select population (see the Influenza topic).

**COMPLEMENTARY & ALTERNATIVE THERAPIES**

- OTC cough and cold preparations should be avoided in those <6 yr of age, including:
  - Nasal decongestants (pseudoephedrine, phenylephrine)
  - Expectorants (guaifenesin)
- Homeopathic remedies (eg, *Echinacea*, zinc) fail to demonstrate therapeutic benefit in controlled studies.
- Honey may be useful as an antitussive. Do not use in infants <12 mo of age to avoid botulinum.

**DISPOSITION****Admission Criteria**

Respiratory distress or complication such as pneumonia or asthma exacerbation may require inpatient admission.

**Discharge Criteria**

A simple uncomplicated URI patient may be discharged with supportive therapy at home.

**FOLLOW-UP****FOLLOW-UP RECOMMENDATIONS**

Discharge instructions and medications:

- Ensure adequate fluid intake.
- Use acetaminophen or ibuprofen for fever and myalgias as needed.
- OTC cough and cold formulations for children >12 yr of age; use with caution in children 6–12 yr; avoid altogether in children <4 yr.

**PROGNOSIS**

Pediatric URIs are typically self-limited processes that resolve in <10 days.

**COMPLICATIONS**

- Otitis media
- Sinusitis
- Pneumonia
- Bronchiolitis
- Croup
- Asthma exacerbation

**REFERENCES**

**CODES****ICD9**

- 465.8 Acute upper respiratory infections of other multiple sites
- 465.9 Acute upper respiratory infections of unspecified site
- 487.1 Influenza with other respiratory manifestations

**PEARLS AND PITFALLS**

- Most URIs are caused by viruses; avoid antibiotics unless there is an identified bacterial infection.
- Avoid all use of OTC cough and cold formulations in those <4 yr of age.
- Good hygiene and hand washing is the best defense against URIs.
- Evaluate carefully for URI complications such as acute otitis media, sinusitis, and pneumonia.

# URETHRAL PROLAPSE

Sunil Sachdeva

## BASICS

### DESCRIPTION

- Urethral prolapse is a circular protrusion of distal urethral mucosa through the external urethral meatus seen in females.
- Classification of prolapse:
  - I: Minimal inflammation
  - II: Circumferential prolapsed with edema
  - III: Edematous mass protruding beyond labia minora
  - IV: Severe hemorrhagic inflammation or necrosis and ulceration of the prolapse

### EPIDEMIOLOGY

#### Prevalence

- 90% of cases occur in black girls.
- Predominantly seen in prepubertal girls <10 yr of age:
  - The youngest case reported was 5 days old.
- Most patients are above average height and weight.

### RISK FACTORS

- Race: Black females
- Prepubescence
- Genetic factors may be involved.
- Female circumcision

### PATHOPHYSIOLOGY

- Poor attachment between inner longitudinal and outer circular muscle of urethra
- Increased intra-abdominal pressure may play a role in separation of the muscular layers.
- Once the separation occurs, the urethral mucosa is not anchored to the inner muscle layer and may prolapse.

### ETIOLOGY

Exact etiology is unknown, but putative causes include:

- Relative estrogen deficiency
- Poor adherence between smooth muscle layers of the urethra
- Intrinsic abnormalities of the urethra:
  - Patulous urethra
  - Redundant mucosa

## DIAGNOSIS

### HISTORY

- Pain and/or dysuria
- Bleeding from genital area
- Underwear spotting
- Urinary symptoms including:
  - Dysuria
  - Urinary frequency
  - Urinary retention

### PHYSICAL EXAM

#### ALERT

Do not attempt manual reduction of the urethral prolapse.

- A reddish-purple mass is visible in the introital area.
- Circular and donutlike shape
- Urethral meatus lies in the center of the mass.
- Mass lies anterior to the hymeneal opening.
- It may cover the vaginal opening, which can be better seen in knee–chest position.
- Mass is sensitive to touch and may bleed if touched.
- Exam under anesthesia or sedation may be required.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

- Usually no lab tests are needed.
- If urinary symptoms are present:
  - Urine analysis
  - Urine culture

#### Imaging

Sonogram may be needed in some cases to rule out sarcoma botryoides.

**Diagnostic Procedures/Other**

- Observation during voiding is diagnostic.
- Catheterization of the central opening may prove the diagnosis.

**DIFFERENTIAL DIAGNOSIS**

- Urethral carbuncle
- Urethral polyp
- Condyloma
- Ureterocele
- Sarcoma botryoides
- Local trauma including that secondary to sexual abuse

**TREATMENT**

- Avoid local manipulation
- Sitz baths

**MEDICATION**

- Topical estrogen cream b.i.d. for at least 2 wk:  
– May be extended to 6 wk if initial response is inadequate
- Ibuprofen 10 mg/kg PO q6h is effective for analgesia and as an anti-inflammatory.

**COMPLEMENTARY & ALTERNATIVE THERAPIES**

Sitz bath

**SURGERY/OTHER PROCEDURES**

Referral for surgical intervention may be required in a small number of cases:

- After insertion of a Foley catheter, the prolapse is excised and the remaining ends re-anastomosed.

**DISPOSITION**

**Admission Criteria**

- Patients requiring surgery
- Patients with severe prolapse that must be followed out of concern for potential need for surgery
- Urinary retention requiring continued catheterization

**Discharge Criteria**

Most cases are managed on an outpatient basis.

**Issues for Referral**

As a general rule, cases should be followed by a surgeon capable of surgical excision, if this becomes necessary.

**FOLLOW-UP**

**FOLLOW-UP RECOMMENDATIONS**

- Weekly follow-up is needed in the 1st month.
- Avoid local manipulation.
- Avoid activities that may worsen irritation, such as bicycle riding, gymnastics, and horseback riding.

**PROGNOSIS**

- Generally, the prognosis is good.
- Most patients improve in 2–4 wk.

**COMPLICATIONS**

- Bleeding
- Necrosis

**ADDITIONAL READING**

**See Also (Topic, Algorithm, Electronic Media Element)**

- Dysuria
- Vaginal Bleeding, Prepubertal

**CODES**

- ICD9**
- 599.5 Prolapsed urethral mucosa
  - 618.03 Urethrocele

**PEARLS AND PITFALLS**

- Vaginal bleeding is the most common presenting complaint associated with urethral prolapse.
- Urethral prolapse should be considered in the differential for girls in the appropriate age range with urinary symptoms and normal urinalysis:  
– Failure to examine the urethra in such cases may result in missed diagnosis.

# URETHRITIS

Ravi Thamburaj  
Catherine Scarfi

## BASICS

### DESCRIPTION

- Urethritis is inflammation of the urethra caused by infection that presents as a urethral discharge, dysuria, or both.
- May be infectious or inflammatory, though most typically infectious etiologies are diagnosed:
  - Usually reserved to describe a syndrome of STIs
  - Divided into 2 etiologies: Gonococcal (GU) and nongonococcal (NGU) urethritis

### EPIDEMIOLOGY

- Incidence is significantly underreported.
- In the U.S., 700,000 new cases of GU and 3 million new cases of NGU per year
- Worldwide, 62 million new cases of GU and 89 million new cases of NGU

### RISK FACTORS

- May occur in any sexually active person: Highest incidence is in persons 15–24 yr of age.
- Occurs equally in males and females:
  - Underrecognized in females; may be asymptomatic or may present with cystitis, vaginitis, or cervicitis
- Highest incidence is in homosexual males.
- Increased risk in lower socioeconomic class

### PATHOPHYSIOLOGY

- Inflammatory condition that can be infectious or posttraumatic in nature
- Infectious causes:
  - Gonococcal urethritis: *Neisseria gonorrhoeae*, gram-negative diplococcus; short incubation period (2–7 days); abrupt dysuria and purulent discharge
  - Nongonococcal urethritis: 2 major causes are *Ureaplasma urealyticum* and *Chlamydia trachomatis*; subacute (7–21 days) development of dysuria and purulent discharge
- Posttraumatic causes: Usually secondary to intermittent catheterization, recent instrumentation, or foreign body insertion; latex catheters > silicone catheters
- Symptoms may occur in females after initiating sexual intercourse after a period of abstinence, colloquially termed *honeymoon cystitis*.

### ETIOLOGY

- Infectious causes: Typically STIs—2 major categories:
  - Gonococcal (80% of cases): *N. gonorrhoeae*
  - Nongonococcal (50% of cases): *U. urealyticum* (40–60%), *C. trachomatis* (30–40%), *Mycoplasma genitalium* (5–10%), *Trichomonas vaginalis* (<5%)
  - Minor causes: Herpes simplex virus (HSV), syphilis, mycobacteria, gram-negative rods associated with cystitis and urethral stricture
- Posttraumatic
- Chemical causes: Sensitivity to chemicals used in spermicides/contraceptive jellies, creams, foams

## COMMONLY ASSOCIATED CONDITIONS

- Urinary tract infection
- Other STIs are likely to be present in patients with urethritis.

## DIAGNOSIS

### HISTORY

- Sexual history:
  - Contraceptive use:
    - Using condoms decreases the chance of STI transmission.
    - Other birth control methods have no effect of transmission.
    - Spermicides may cause chemical urethritis, which may mimic infectious urethritis.
  - Age at 1st intercourse: Younger age of sexual debut is correlated with increased risk of contracting STIs.
  - Number of partners: Individuals with multiple partners have increased risk.
  - Sexual preference: Homosexual men have the highest rate of STIs.
  - Previous STIs: Patients with a prior history of STIs have higher likelihood of contracting another STI and may also have concurrent STIs (syphilis, HIV).
- May be asymptomatic
- Inquire about timing of symptoms: Symptoms begin 4 days to 2 wk after contact with an infected partner.
- Inquire about discharge and associated symptoms (dysuria, itching, orchalgia, menstrual cycle):
  - Dysuria: Usually localized to meatus/distal penis, worst during 1st morning void, and worsened with ETOH consumption:
    - Urinary frequency and urgency typically are absent (typically suggests cystitis/prostatitis), especially in men.
  - Hesitancy: At initiation of voiding attempt, delayed, interrupted, or intermittent voiding occurs.
  - Dribbling: Voiding is incomplete; after void, a small amount of urine is released from the urethra.
  - Pain with intercourse or ejaculation
  - Itching: Sensation between urinary voids
  - Orchalgia: Occasional complaint of heaviness in genitalia (pain suggests epididymitis/orchitis)
  - Menstrual cycle: Occasional complaint of worsening of menstrual symptoms. Inquire about foreign body or instrumentation.
- Inquire about systemic symptoms:
  - Fever, chills, nausea, low back pain, iritis, rash (may be signs of regional or disseminated infection)

### PHYSICAL EXAM

- Most patients do not appear ill/manifest signs of sepsis (fever, tachycardia, tachypnea, hypotension).
- Primary focus is on the genitalia exam. Should also evaluate vitals, presence of rash, joint pain, or conjunctivitis.

- Men:
  - Should examine the patient prior to micturition, as urinating may temporarily wash away discharge. Adequate specimen is needed for lab assay. Examine in a standing position.
  - Examine for skin lesions (including around anus) that may indicate other STIs.
  - Examine the lumen of the distal urethral meatus for lesions, strictures, or obvious urethral discharge.
  - Strip the urethra by gently milking from the base of the penis toward the glans, and evaluate for discharge.
  - Palpate along the urethra to evaluate for warmth, fluctuance, and tenderness to check for abscess or foreign body.
  - Examine the testes for mass/inflammation; palpate the spermatic cord for swelling, tenderness, or warmth to check for orchitis/epididymitis.
  - Check for inguinal adenopathy.
  - Palpate the prostate for tenderness or boggy suggestive of prostatitis.
- Women:
  - Should examine the patient prior to micturition, as urinating may temporarily wash away discharge. Adequate specimen is needed for lab assay. Examine in the lithotomy position.
  - Examine for skin lesions (including around anus) that may indicate other STIs.
  - Strip the urethra by inserting a finger into the anterior vagina and stroking forward along urethra, and evaluate for discharge.
  - Complete abdominal and pelvic exam including cervical cultures to evaluate for concomitant pelvic inflammatory disease (PID)

## DIAGNOSTIC TESTS & INTERPRETATION

### Initial Lab Tests

- All patients should be tested for *N. gonorrhoeae* and *C. trachomatis*.
- Multiple assays are available for gonorrhea and chlamydia, most commonly used or DNA probes:
  - Nucleic acid amplification tests:
    - Polymerase chain reaction assay on urine specimens for GC and chlamydia available and are the preferred test: Most sensitive
    - However, does not allow for antibiotic susceptibility testing that a culture provides, but culture is not routinely needed.
  - Culture/Gram stain is not necessarily indicated, but if taken, it should be an endourethral specimen; additional endocervical specimen should be obtained in women; may not be cost-effective or necessary, as results do not influence initial antibiotic therapy:
    - Urethral secretions: >5 WBCs/high-power field confirms diagnosis
- Urine: Urinalysis is not useful unless using to exclude cystitis/pyelonephritis if cases of dysuria without discharge
- KOH prep: Can be used to exclude fungal organisms if suspected

- Wet preparation: Secretions can detect movement of trichomonal organisms if present.
- The patient should be offered testing for other STIs (HIV, syphilis)
- Pregnancy testing in females
- Consider ESR or HLA B-27 testing in patients with clinical signs of Reiter syndrome.

### Imaging

- Retrograde urethrogram: Only needed in cases of trauma or possible foreign body insertion
- Pelvic US: Only needed if concerned about intrapelvic/abdominal abscess

### DIFFERENTIAL DIAGNOSIS

- Urinary tract infection
- Gonococcal infections: Arthritis, GU infections, disseminated
- Trauma: Instrumentation, other
- *Mycoplasma/Ureaplasma* infections
- Trichomoniasis
- *Escherichia coli/Bacteroides* infection
- HSV/Human papillomavirus infections
- Chancroid/*Gardnerella* infections
- Syphilis
- Prostatic disease: Prostatitis, abscess
- Epididymitis
- Urethral strictures
- Malignancies: Skin, urethral

### TREATMENT

#### THERAPY

- Antibiotics should cover GU and NGU.
- Antibiotic choice should be based on cost, adverse effects, effectiveness, and compliance.
- Optimal treatment is with single-dose therapy administered in the office/emergency department.

#### MEDICATION

- Azithromycin: Adult, 2 g PO single dose treats both GU and NGU, 1 g PO treats NGU only.
- Ceftriaxone (treats GU only): Adolescent, adult, 250 mg IM single dose; if <45 kg use 125 mg IM single dose
- Cefpodoxime (treats GU only): Adult/Adolescent, 400 mg PO single dose
- Cefixime (treats GU only): Adult/Adolescent, 400 mg PO single dose
- Ciprofloxacin (treats GU only): Adult/Adolescent, 500 mg PO single dose
- Ofloxacin (treats GU only): Adult, 400 mg PO single dose; adolescent, not recommended:
  - Contraindicated in pregnancy
- Levofloxacin (treats GU and NGU): Adult/Adolescent, 250 mg PO single dose for GU; adult/adolescent, 300 mg PO b.i.d. × 7 days for NGU:
  - Contraindicated in pregnancy
- Doxycycline (treats NGU only): Adult/Adolescent, 100 mg PO b.i.d. × 7 days:
  - Contraindicated in pregnancy
- Amoxicillin (treats NGU only): Adult/Adolescent, 500 mg PO t.i.d. × 7 days
- Spectinomycin (treats GU only): Adult/Adolescent, 2 g IM single dose

### DISPOSITION

#### Discharge Criteria

- All patients will have symptoms resolve over time regardless of treatment.
- Antibiotics should be given to prevent morbidity and to reduce transmission.
- Optimal treatment is with single-dose therapy administered in the office/emergency department.

### FOLLOW-UP

#### FOLLOW-UP RECOMMENDATIONS

- Further outpatient care:
  - Obtain follow-up cultures if patient remains symptomatic.
    - If remains symptomatic: Treat for NGU with 14–28-day course of erythromycin.
    - Most infections post treatment are reinfection by the same partner or a new partner.
- Prevention/Deterrence:
  - Instruct patients regarding abstinence × 1 wk post treatment.
  - Educate at-risk patients on how to prevent disease recurrence (use condoms, single partner, avoid partners with known infections).
  - Educate patients on other STIs.
  - Early diagnosis and treatment of infected individuals
  - Evaluate and treat sexual partners of known infected persons.

#### PROGNOSIS

All patients with uncomplicated urethritis spontaneously recover with or without treatment: Must treat to prevent complications and transmission.

#### COMPLICATIONS

- Women:
  - Morbidity: 10–40% secondary to development of PID, which can lead to infertility and ectopic pregnancy due to postinflammatory scarring in the fallopian tubes:
    - May develop cystitis, pyelonephritis, cervicitis, salpingitis
  - Also increased risk of congenital *Chlamydia* exposure to newborns if vaginal delivery (conjunctivitis, iritis, otitis media, pneumonia):
    - Rarely, disseminated gonococcal infection or Reiter syndrome
- Men:
  - Morbidity: 1–2% secondary to development of urethral stricture or stenosis due to postinflammatory scar formation:
    - May develop prostatitis, epididymitis, orchitis, abscess, proctitis, infertility, abnormal semen
    - Rarely, disseminated gonococcal infection or Reiter syndrome

- Gonorrhea
- Pelvic Inflammatory Disease
- Sexually Transmitted Infections

#### ICD9

- 098.0 Gonococcal infection (acute) of lower genitourinary tract
- 099.40 Other nongonococcal urethritis, unspecified
- 597.80 Urethritis, unspecified

### PEARLS AND PITFALLS

- Urethritis is inflammation of the urethra caused by infection that presents as a urethral discharge, dysuria, or both, usually caused by gonococcal or nongonococcal organisms.
- Obtain a detailed sexual history, and obtain appropriate specimen for lab testing.
- Treat for GU and NGU; optimal treatment is with single-dose therapy administered in the office/emergency department.
- HIV testing in the emergency department or referral for HIV testing is recommended.

# URINARY RETENTION

Jennifer H. Chao

## BASICS

### DESCRIPTION

- Urinary retention is the involuntary retention of urine in the bladder.
- Once the bladder is distended, it may be painful.
- Urinary retention may be acute or chronic. This topic focuses on acute urinary retention.

### RISK FACTORS

- Urinary tract infection
- Anticholinergic medication use
- Neurologic disease such as MS, myasthenia gravis, Guillain-Barré syndrome
- Constipation

### PATHOPHYSIOLOGY

- The expected capacity of the bladder is generally as such:  $(\text{Age in years} + 2) \times 30 \text{ cc}$ .
- If the volume exceeds this and the patient is unable to void spontaneously, or there is a palpable distended bladder and the patient cannot void voluntarily, this is considered urinary retention.

### ETIOLOGY

- Urinary tract infection
- Obstruction:
  - Labial fusion
  - Constipation
  - Pelvic/Abdominal neoplasm
  - Urolithiasis
  - Urethral stenosis
  - Phimosi
  - Paraphimosis
  - Periurethral abscess
  - Urethral prolapse

- Urethral irritation resulting in spasm (post instrumentation/catheterization)
- Ureteral pelvic junction obstruction
- Neurologic:
  - Multiple sclerosis
  - Myasthenia gravis
  - Guillain-Barré syndrome
  - Stroke
  - Neurogenic bladder
- Overdistended bladder
- Medications:
  - Anticholinergic
  - Opioid
  - Sympathomimetic

### COMMONLY ASSOCIATED CONDITIONS

Urinary tract infection

## DIAGNOSIS

### HISTORY

History is foremost in determining the cause of urinary retention. Seek a history of:

- Straining
- Frequency
- Urgency
- Fever
- Pain: Bladder/Abdominal/Genitourinary/Back
- Hematuria, discolored urine
- Medications
- Patient or family history of renal stones
- Surgery
- Radiation
- Trauma

### PHYSICAL EXAM

- A full bladder will be palpated as a smooth, firm suprapubic mass.
- BP may be elevated as a result of renal involvement or discomfort/pain.
- Close inspection must be performed for pelvic masses, spinal dysraphism, genitourinary stricture or malformation, mass, or trauma.
- Rectal exam to check for tone, stool, pelvic mass
- Pelvic exam in teenage girls to inspect for mass or imperforate hymen
- Neurologic exam with strength, sensation, sphincter tone, and reflexes

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

Obtain any of the following tests, depending on the history and physical exam:

- Urinalysis
- Urine culture
- BUN/Creatinine and serum electrolytes

#### Imaging

Sonogram may be performed to confirm distended bladder and potentially delineate obstructive pathology.

#### Diagnostic Procedures/Other

- CT scan: To delineate other abdominal pathology that may be contributing to retention
- Cystoscopy: Performed by urology to examine intrabladder pathology
- Urometry: Performed by urology for intrinsic bladder dysfunction

### DIFFERENTIAL DIAGNOSIS

See Etiology.

## TREATMENT

Gentle pressure/massage to the suprapubic/bladder region:

- Analgesics for known urethral irritation

### INITIAL STABILIZATION/THERAPY

- If the above methods do not result in drainage of the bladder, a urinary catheter may be used to drain the urine acutely.
- Identify and discontinue any medications that may be the cause for urinary retention.
- If a urinary tract infection and sphincter spasm is the cause of retention, treat the infection with antibiotics and consider a urinary analgesic (phenazopyridine).

### MEDICATION

- Antibiotics may be used to prevent infection in patients who have an indwelling urinary catheter:
  - Cephalexin 40 mg/kg/day PO divided b.i.d.–q.i.d.
  - Co-trimoxazole 5 mg/kg/dose PO b.i.d.
- Phenazopyridine: Children, 12 mg/kg/day divided t.i.d. for 2 days; adolescents or adults, 100–200 mg PO t.i.d.–q.i.d. for 2 days:
  - Suspension for children must be compounded by a pharmacist who can crush tablets and suspend in syrup.

### SURGERY/OTHER PROCEDURES

- Foley catheter placement or suprapubic ostomy to drain the bladder if simple drainage is not sufficient
- Further procedures by urology to resolve obstruction are based on the underlying pathology.

### DISPOSITION

#### Admission Criteria

Patients with acute urinary retention requiring continuous catheterization

### Discharge Criteria

- Urinary retention is relieved.
- The patient demonstrates ability to void independently; if the etiology involves urinary retention, such as meningocele, the caregivers are able to safely catheterize the child.
- There is no underlying pathology that requires hospitalization.

### Issues for Referral

If there is any obstructive pathology or the etiology is unknown, the patient should be referred to urology for definitive management.

## FOLLOW-UP

### FOLLOW-UP RECOMMENDATIONS

- Discharge instructions and medications:
  - Patients should be instructed to return if retention recurs.
- Further instructions should be aimed at:
  - Preventing a recurrence AND
  - Treatment of the underlying condition

### PROGNOSIS

Depends on the etiology

### COMPLICATIONS

- Urinary tract infection
- Bladder rupture
- Postobstructive diuresis:
  - Hypovolemia
  - Hypotension

## ADDITIONAL READING

### See Also (Topic, Algorithm, Electronic Media Element)

Urinary Tract Infection

## CODES

### ICD9

788.20 Retention of urine, unspecified

## PEARLS AND PITFALLS

- Once the retention has been resolved, a reasonable explanation should be sought.
- Urinary tract infection is the most common cause of urinary retention in children.
- If the primary cause is not identifiable in the emergency department, referral to primary care, urology, and/or neurology for further evaluation is necessary.

# URINARY TRACT INFECTION

Mercedes M. Blackstone

## BASICS

### DESCRIPTION

- Urinary tract infection (UTI) is defined as growth of pathogenic bacteria in the urine:
  - For suprapubic aspirate: Any growth is significant.
  - For urine obtained by catheterization:
    - ≥ 100,000 CFU/mL
  - For urine obtained by clean-catch technique:
    - ≥ 10,000 CFU/mL for males; ≥ 100,000 CFU/mL for females
- Upper tract infection or pyelonephritis: Infection of the renal parenchyma; the vast majority of febrile babies with a positive urine culture have upper tract infection.
- Lower tract infection or cystitis: Infection limited to the bladder and urethra that occurs more in older children and adolescents; usually no fever

### EPIDEMIOLOGY

Most common serious bacterial illness in infants and young children

#### Incidence

- Bimodal age distribution, with peak incidence in infants <1 yr of age (1)
- Second peak in adolescent females

#### Prevalence

Overall prevalence of ~7% in febrile infants and young children (2); varies by risk factors:

- Highest prevalence (up to 16%) in Caucasian girls <2 yr of age

### RISK FACTORS

- Sex/Age: Boys most at risk for UTI during 1st year of life; girls are at risk until school age and again in adolescence:
  - Among young febrile children, the prevalence among girls is about twice as high as boys (2).
- Race/Ethnicity: Caucasian children are 2–4 times more likely than blacks to have UTI (2–4):
  - May be due in part to differences in blood group antigens on the surfaces of uroepithelial cells, which affect bacterial adherence
- Circumcision status: Uncircumcised male infants have 10 times the prevalence of UTI compared with circumcised males (2).
- Abnormal urinary tract: Children with vesicoureteral reflux (VUR) and obstruction are at higher risk for UTI.
- Voiding dysfunction (eg, severe constipation)
- Requiring frequent catheterization
- Sexual activity
- Multiple recommended approaches to determining risk and need for evaluation:
  - If all of the following are present: Fever without apparent source of infection, temperature ≥39°C, age <1 yr, male or female
  - Temperature ≥39°C, fever ≥2 days, white race, age <1 yr, absence of another potential source of fever
  - If ≥2 of following risk factors are present (5): Temperature ≥39°C, fever ≥2 days, white race, age <1 yr, absence of another potential source of fever

### GENERAL PREVENTION

- Good diapering and toilet training habits: Wipe from front to back.
- Urinate after sexual intercourse.
- Avoid urinary stasis.
- Frequent voiding and treatment of constipation

### PATHOPHYSIOLOGY

- Bacterial invasion of the urinary tract from ascending skin or gut flora
- A shorter urethra in females puts them at increased risk.
- Poor bladder emptying (neurogenic bladder, obstructive uropathies) facilitates movement of pathogens into the upper tract.
- In young infants, UTI may result from hematogenous spread.

### ETIOLOGY

Bacterial urinary tract pathogens include:

- Common: *Escherichia coli* >> *Klebsiella* species, *Enterococcus*, *Proteus mirabilis*, and *Staphylococcus saprophyticus* (teenage girls)
- Less common: *Enterobacter cloacae*, group B hemolytic streptococci, *Citrobacter*, *Pseudomonas* species, *Staphylococcus aureus*, *Serratia* species

### COMMONLY ASSOCIATED CONDITIONS

- Bacteremia in <10% of patients (6)
- VUR or urinary abnormalities

## DIAGNOSIS

### HISTORY

- Infants:
  - Nonspecific symptoms, most often have fever alone
  - Can have vomiting, irritability, lethargy, poor feeding
  - Rarely have failure to thrive or jaundice
- Older children:
  - Lower tract infection symptoms typically include urgency, frequency, dysuria, hematuria, hesitancy, suprapubic pain, and malodorous urine.
  - Upper tract infection symptoms typically include nausea, vomiting, fever, chills, and flank pain.
  - May have a history of constipation
  - May also present with incontinence or secondary enuresis

### PHYSICAL EXAM

- Infants:
  - Often no physical findings or fever alone
  - Less commonly: Dehydration, abdominal pain or distention, poor weight gain, malodorous urine, jaundice
  - Possible associated physical findings: Labial adhesions, phimosis, vaginal discharge or foreign body, abdominal or flank mass
- Older children:
  - Lower tract: Suprapubic tenderness
  - Upper tract: Fever, costovertebral angle tenderness

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

- Initial lab tests include urinalysis (UA) and urine culture.
- Urine culture by sterile technique is the gold standard:
  - Bladder catheterization or suprapubic aspirate in young children
  - Midstream clean catch if possible
  - A specimen should not be obtained by applying a bag to the perineum, as this technique is associated with an unacceptably high rate of contamination (7).
- Cultures take 24–48 hr to grow, so several rapid screening tests are available.
- The following are suggestive of UTI:
  - Conventional UA: ≥5 WBC/high-power field centrifuged urine
  - Enhanced UA (combines microscopy on uncentrifuged urine with Gram stain):
    - ≥10 WBC/mm<sup>3</sup> and/or positive Gram stain
  - Enhanced UA has high sensitivity and specificity; helpful when diagnosis is crucial (neonates).
  - Urine dipstick: Leukocyte esterase (LE) and/or nitrites
    - Nitrites are highly specific but poorly sensitive: Urine must remain in bladder ≥4 hr for nitrites to be detectable
    - LE and nitrites are both suggestive of UTI; they are highly specific (8).
- Screening tests alone fail to detect 10–30% of UTIs; always send culture for fever without source of or with suspected UTI.
- Serum testing is not routinely indicated:
  - Blood culture: Not indicated in the well-appearing patient >2 mo of age
  - WBC count, C-reactive protein, and ESR may be elevated but are less specific screens than UA. They will not distinguish between upper and lower tract disease.
  - Serum creatinine is not necessary in routine UTIs; check if recurrent infections, renal anomalies, and known renal dysfunction.

#### Imaging

There is seldom a role for imaging in the emergency department:

- However, consider US if there is concern for obstructive uropathy or congenital or iatrogenic urinary tract anomalies.

### DIFFERENTIAL DIAGNOSIS

- Infants: Gastroenteritis, occult bacteremia, occult pneumonia, meningitis
- Older children and adolescents:
  - Common: Vaginal foreign body, vulvovaginitis/urethritis, epididymitis, gastroenteritis, STI, pelvic inflammatory disease, dehydration with concentrated urine
  - Less common: Excessive drinking, urinary calculi, diabetes mellitus or insipidus, appendicitis, Kawasaki disease, tubo-ovarian abscess, ovarian torsion
  - Rare: Mass adjacent to the bladder, spinal cord process (tumor, abscess), hypercalcemia

## TREATMENT

### INITIAL STABILIZATION/THERAPY

- Most patients with UTI are stable and need only antipyretics initially.
- Toxic-appearing patients with urosepsis require prompt attention to airway, breathing, and circulation:
  - Rapidly obtain IV access; isotonic fluids should be rapidly infused.
  - Initiate broad-spectrum parenteral antibiotics.

### MEDICATION

#### First Line

- Empiric inpatient therapy—IV therapy with a 3rd-generation cephalosporin: Cefotaxime (40 mg/kg/dose IV q8h); ceftioxone (50–75 mg/kg IV/IM per day; combination ampicillin (25 mg/kg/dose IV q6h) and gentamicin (5–7.5 mg/kg IV per day or divided t.i.d.):
  - Those who are high risk, immunocompromised, with indwelling catheters, or have recurrent UTIs should initially receive antibiotics that cover organisms involved in prior infections.
- Empiric outpatient therapy: Cefixime (8 mg/kg/day divided b.i.d.); cefdinir (14 mg/kg PO per day); amoxicillin/clavulanate or amoxicillin (45 mg/kg/day divided b.i.d.); cephalexin (50 mg/kg/day divided b.i.d.–t.i.d.); co-trimoxazole (5 mg/kg/day divided b.i.d.):
  - Some communities have high resistance to amoxicillin and co-trimoxazole; in these locations, they are poor initial choices.
  - Oral 3rd-generation cephalosporins are useful since many are dosed daily.
  - Initial use of single-dose parenteral ceftioxone followed by oral antibiotics is sometimes practiced, though evidence for benefit over oral antibiotic alone is lacking.
- Antibiotic duration (IV/PO):
  - Children  $\leq 2$  yr of age, with a febrile UTI, recurrent UTI, or urinary tract abnormalities should receive a total of 10–14 days of antibiotic.
  - Afebrile older children likely to have uncomplicated cystitis may receive 5–7 days.
- Analgesic for dysuria; phenazopyridine: Patient  $< 12$  yr of age, 4 mg/kg/dose t.i.d.  $\times 2$  days;  $> 12$  yr, 100 mg/kg/dose t.i.d.  $\times 2$  days

#### Second Line

Fluoroquinolones should not be used as a first-line agent in children with simple UTIs. Limit use to complicated UTIs with resistant pathogens when no alternative is feasible (9).

### SURGERY/OTHER PROCEDURES

Rarely, obstructive uropathy requires surgery.

### DISPOSITION

#### Admission Criteria

- Neonates require hospital admission.
- Age at which outpatient treatment is used varies by local practice pattern; often, patients  $< 2$ – $3$  mo of age are initially treated as inpatients with parenteral antibiotics.
- If ill appearing, dehydrated, unable to tolerate PO (10), or there is concern for compliance and follow-up
- Critical care admission criteria:
  - Urosepsis or unstable vital signs

### Discharge Criteria

- Patients should be nontoxic, well hydrated, and able to tolerate oral fluids and should have a good follow-up plan in place:
  - Administer the 1st dose of oral antibiotic in the emergency department to ensure that it is tolerated.
- Mounting evidence supports treatment of children  $> 1$  mo of age with parenteral antibiotics as outpatients or in ambulatory treatment centers (6,11):
  - This practice is relatively new and not extensively studied.

### Issues for Referral

Patients with recurrent UTIs or urinary tract anomalies should be referred to urology.

## FOLLOW-UP

### FOLLOW-UP RECOMMENDATIONS

Discharge instructions and medications:

- Patients should be instructed to complete the entire prescribed course of antibiotics and to return for worsening symptoms, ill appearance, or inability to tolerate oral fluids or antibiotics.
- Patients should follow up with their primary care provider within 2 days to ensure that symptoms are improving.
- Young patients with a 1st UTI will also need to follow up for consideration of further imaging (renal US and voiding cystourethrography).

### Patient Monitoring

- Repeat urine culture to demonstrate sterilization is unnecessary.
- If symptoms are not improving despite antibiotic treatment, a 2nd culture may be indicated.
- Consider UTI for all subsequent febrile illnesses once a child has a history of UTI.

### PROGNOSIS

UTI with timely treatment and an appropriate antibiotic course have a very good prognosis.

### COMPLICATIONS

- Urosepsis
- Bacteremia
- Meningitis
- Repeated febrile UTIs in young children may lead to renal scarring.
- Renal scarring can result in HTN, pre-eclampsia, and end-stage renal disease.

## CODES

### ICD9

- 599.0 Urinary tract infection, site not specified
- 771.82 Urinary tract infection of newborn

## PEARLS AND PITFALLS

- Screening tests are imperfect. Always send a culture if UTI is suspected.
- Contaminated cultures are difficult to interpret. Obtain urine by catheterization or suprapubic tap.
- Consider obtaining a urine specimen in febrile children with other sources of fever (bronchiolitis, upper respiratory infection, otitis media, gastroenteritis) since they may have concurrent UTIs.

# UROLITHIASIS

Lilit Minasyan

## BASICS

### DESCRIPTION

- Urolithiasis is a condition in which calculi form in the urinary tract, including the kidneys, ureters, or bladder:
  - Also referred to as kidney stones, renal stones, or renal calculi
- Classified based on their chemical derivatives:
  - Calcium with oxalate or phosphate
  - Uric acid
  - Struvite (magnesium ammonium phosphate) or infection related
  - Cysteine
  - Drug metabolites

### EPIDEMIOLOGY

- 1 in 1,000 to 1 in 7,600 pediatric hospital admissions in the U.S. due to urolithiasis
- Varies by region:
  - More common in the southeastern U.S.
- Male to female ratio is about 1.4:1–2.1:1:
  - Male preponderance is not as dramatic as in the adult population.

### RISK FACTORS

- 75% of cases will have identifiable predisposition to stone formation.
- Metabolic abnormalities that may change the urine composition
- Structural abnormalities of the urogenital tract
- Obesity
- Medications

### GENERAL PREVENTION

See Diet.

### PATHOPHYSIOLOGY

Stone formation occurs as a result of interplay of several factors:

- Increased concentration of stone-forming compounds such as calcium, oxalate, and uric acid resulting in crystallization
- Urinary stasis due to anatomic abnormalities or damaged uroepithelium
- Lack of stone inhibitors such as magnesium, citrate, and glycosaminoglycans

### ETIOLOGY

- Hypercalciuria:
  - 30–50% of children with nephrolithiasis
  - Calcium oxalate or calcium phosphate stones are seen in >50% of urolithiasis in pediatrics.
  - Idiopathic, familial, or sporadic
  - >4 mg/kg/day urinary calcium excretion
  - Calcium:creatinine >0.21
  - Dents disease: X-linked mutation of renal chloride channel gene
  - Renal tubular acidosis (RTA)
  - Medication use: Loop diuretics, adrenocorticotrophic hormone, corticosteroids
  - Most cases of hypercalciuria have normal serum calcium levels:
    - If serum calcium is elevated, consider hyperparathyroidism, hypo- or hyperthyroidism, immobility, adrenal insufficiency, or malignancy.

- Hyperoxaluria:
  - Found in up to 20% of children with stones
  - May be idiopathic, genetic, or due to excess dietary intake of oxalate-rich foods:
    - Excess vitamin C, beets, turnips, strawberries, rhubarb
  - Bowel disease/malabsorption
- Infection-associated (struvite) stones:
  - Urease-producing organisms: *Pseudomonas*, *Proteus*, *Klebsiella*
  - Nonstruvite stones may have infection as a complication of the stone rather than a cause of the stone.
- Cystinuria:
  - Up to 6% of pediatric urolithiasis
  - Autosomal recessive disorder of renal tubular transport
- Hyperuricosuria:
  - 2–10% of pediatric urolithiasis
  - Idiopathic hyperuricosuria, inborn error of purine metabolism
  - Associated with excessively acidic urine (diabetes and obesity)
  - Bowel disease/malabsorption

### COMMONLY ASSOCIATED CONDITIONS

- Familial idiopathic hypercalciuria
- Hyperparathyroidism
- Obesity
- Diabetes mellitus
- Ketogenic diet for refractory seizures

## DIAGNOSIS

### HISTORY

- Sudden onset of severe pain in the flank, costovertebral angle (CVA), or lateral abdomen:
  - Flank pain often radiates from the back to the lower abdomen, present in 50–63% of cases.
- Nausea and vomiting: ~50% of cases
- Hematuria: Gross hematuria or history of microscopic hematuria in 20–90%
- Prior history of urolithiasis
- Family history of urolithiasis, gout, arthritis, or renal disease
- Prior history of urinary tract infections
- Dietary, drug, and vitamin intake

### PHYSICAL EXAM

- Physical exam is often normal.
- Abdominal tenderness is atypical and should raise concern for other diagnoses.
- Evaluate vital signs and growth parameters:
  - Tachycardia or HTN due to pain
  - Fever is suggestive of infection.
  - Hypotension, particularly with altered mental status, is suggestive of urosepsis.
  - HTN despite adequate analgesia warrants evaluation for renal disease.
  - Impaired growth may be due to underlying disease: Inflammatory bowel disease, malabsorption, RTA
- Flank pain or CVA tenderness is typical.
- Exam of external genitalia in all patients and pelvic exam in sexually active females should be performed to rule out STIs and in males to diagnose epididymitis or testicular torsion.

## DIAGNOSTIC TESTS & INTERPRETATION

### Lab

#### Initial Lab Tests

- Urinalysis (UA) or urine dipstick to assess for hematuria and infection:
  - Hematuria (macroscopic or microscopic) occurs with urolithiasis in 20–90% of cases.
  - 15% of cases may have normal UA.
  - There is no correlation between the degree of hematuria and size of the stone.
- Electrolyte panel with BUN and creatinine levels to assess renal function
- Urine culture if infection suspected
- Urine pregnancy test for females

#### Imaging

- 90% of urinary stones are radiopaque:
  - Uric acid stones are radiolucent.
- Noncontrast helical CT scan:
  - Most sensitive and specific test for identifying stones and complications such as ureteral edema, hydroureter, and hydronephrosis
  - Higher sensitivity and specificity regardless of location in the genitourinary tract: 94–100%
  - Detects calculi as small as 1 mm
  - May be useful in identifying alternative diagnoses
  - Potential risks with radiation exposure
  - Indicated in patients without a previous diagnosis of urolithiasis
- Abdominal plain x-rays:
  - Sensitivity of about 40%
  - X-ray cannot differentiate urinary stones from phlebolith or radiopaque bowel contents.
  - X-ray does not allow a diagnosis of obstruction.
- Abdominal US:
  - US is useful with larger stones or calculi.
  - May miss stones <5 mm
  - Is highly operator dependent; wide range of sensitivity of 44–90%
  - May be more accurate for renal stones rather than ureteral stones (98% vs. 38%)
  - US can identify hydronephrosis and hydroureter.
  - US may still be useful as an initial study in suspected urolithiasis:
    - US is the modality of choice in pregnant patients.
    - Stones missed by US are likely to be smaller and will not significantly alter immediate management.
- IV pyelogram: Rarely used in children in the U.S., given improvement in US and CT techniques

#### Diagnostic Procedures/Other

Additional testing may be indicated to identify any underlying metabolic abnormality and determine stone composition:

- These may be done as an outpatient.
- 24-hr urine collection to test for urine sodium, calcium, oxalate, creatinine, uric acid, citrate
- Parathyroid hormone level

**DIFFERENTIAL DIAGNOSIS**

- Urinary tract infection or pyelonephritis
- Hematuria due to other causes:
  - Glomerulonephritis
  - Nephropathy
- Renal cortical necrosis or renal infarct
- Anatomic abnormalities causing obstruction
- Ectopic pregnancy
- Ovarian cyst/torsion
- Acute abdominal problems causing colicky pain, such as intussusception, appendicitis
- Musculoskeletal pain
- Lower lobe pneumonia

**TREATMENT**

**INITIAL STABILIZATION/THERAPY**

Initial emergency department therapy is aimed at adequate hydration and pain control.

**MEDICATION**

- Opioid analgesics:
  - Morphine 0.1 mg/kg IV/IM/SC q2h PRN:
    - Initial morphine dose of 0.1 mg/kg IV/SC may be repeated q15–20min until pain is controlled, then q2h PRN.
  - Hydromorphone 0.015 mg/kg/dose IV/SC q4–6h. Initial dosing may be repeated q30min until pain is adequately controlled.

**ALERT**

Avoid use of NSAIDs in pregnant patients to prevent premature closure of the ductus arteriosus and fetal injury.

- Ketorolac 0.5 mg/kg/dose IV/IM q6h
- Ondansetron 0.1 mg/kg IV q8h as needed for emesis
- Appropriate antibiotics for suspected urinary tract infection associated with stones
- Other medications will depend on the specific stone composition and metabolic abnormality:
  - Started as inpatient or outpatient
  - Furosemide 1–2 mg/kg IV q6–12h if hypercalciuria
  - Alkalinizing agent citrate or citric acid 2–3 mEq/kg/day in divided doses t.i.d.–q.i.d. for uric acid stones or cystinuria

**COMPLEMENTARY & ALTERNATIVE THERAPIES**

Various herbal therapies are thought to have diuretic effects, thus increasing urine flow and decreasing stone formation:

- Chocolate vine, Gotu kola, Kamala, cumin

**SURGERY/OTHER PROCEDURES**

- Obstruction in the presence of infection warrants immediate urologic/nephrologic intervention.
- Surgical management is otherwise reserved for cases where a stone does not pass spontaneously.
- Modality depends on the stone size, location, composition, and urinary tract anatomy/prior procedures.
- Extracorporeal shock wave lithotripsy:
  - May be done without sedation in older children and adults
  - Bruising and hematuria commonly are seen but transient; generally safe without serious complications.
- Ureteroscopic stone removal:
  - Allows for simultaneous stent placement if indicated
- Percutaneous nephrolithotomy
- Open lithotomy

**DISPOSITION**

**Admission Criteria**

- Dehydration requiring IV fluid hydration
- Inability to tolerate oral intake, intractable vomiting
- Urinary obstruction
- Renal insufficiency
- Pain requiring parenteral opioids

**Discharge Criteria**

- Able to tolerate oral intake
- Normal or baseline renal function
- Adequate pain control
- Provide a urine strainer to collect stones for future analysis.

**Issues for Referral**

- Generally, referral to a nephrologist is needed for further evaluation and/or follow-up of an underlying metabolic disorder.
- Urologic referral for urinary obstruction or further surgical therapy for stones that have not passed

**FOLLOW-UP**

**FOLLOW-UP RECOMMENDATIONS**

- Discharge instructions and medications:
- Encourage increased fluid intake and adequate hydration.
  - Pain medications including oral narcotic medications and NSAIDs
  - Other medications may be needed depending on the stone composition.

**Patient Monitoring**

- Monitor for adequate hydration and urine output.
- Outpatient monitoring of urine and plasma electrolytes under the guidance of a pediatric nephrologist
- Follow-up imaging to monitor for recurrence

**DIET**

- Increased water intake
- Dietary changes depend on the stone composition:
  - Limiting dietary calcium intake to recommended daily allowances in cases of calcium stones
  - Reducing oxalate-rich foods
  - Reducing dietary sodium intake

**PROGNOSIS**

- ~50% of stones will pass spontaneously, especially if <5 mm.
- Recurrence rates of 20–48% have been reported:
  - Most commonly occur in patients with a metabolic abnormality

**COMPLICATIONS**

- Obstruction of the urinary tract
- Superinfection
- Renal damage/failure

- Abdominal Pain
- Hematuria
- Urinary Tract Infection

- ICD9**
- 592.9 Urinary calculus, unspecified
  - 592.0 Calculus of kidney
  - 592.1 Calculus of ureter

**PEARLS AND PITFALLS**

- Oligoanalgesia is a common error in management of children with pain; generous opioid analgesia is indicated for urolithiasis.
- Children with urolithiasis are more likely to have underlying metabolic or structural abnormality than adults.
- Younger children are more likely to present with nonspecific complaints of nausea and vomiting rather than the classic adult presentation of acute flank pain with hematuria.

# VAGINAL BLEEDING DURING EARLY PREGNANCY (<20 WEEKS)

Ilene A. Claudius

## BASICS

### DESCRIPTION

- A number of reasons for vaginal bleeding during early pregnancy exist; these are listed in the Etiology section.
- Abortion: Any termination of pregnancy prior to potential viability (generally 20 wk):
  - Threatened abortion: Vaginal bleeding prior to 20 wk
  - Inevitable abortion: Bleeding or membrane rupture with cervical dilatation prior to 20 wk
  - Incomplete abortion: Loss of fetal tissue with placental retention
  - Missed abortion: Retention of nonviable products of conception (1)

### EPIDEMIOLOGY

#### Incidence

1–1.5 million women per year

#### Prevalence

- 20–25% of women have bleeding during the 1st 20 wk of pregnancy:
  - 50% will go on to miscarry.
- 12% of pregnant adolescents will miscarry in the 1st 20 wk (2).

### RISK FACTORS

- Maternal coagulation issues
- Fetal anomalies
- Uterine anomalies
- Smoking and environmental factors

### GENERAL PREVENTION

Early diagnosis of pregnancy and management of risk factors

### PATHOPHYSIOLOGY

Spontaneous abortion can occur at any time in the fetal development but usually occurs prior to 12 wk. A number of potential causes exist, including:

- Abnormal embryogenesis (blighted ovum)
- Hormonal abnormalities affecting implantation
- Fetal chromosomal anomalies
- Autoimmune disorder
- Coagulation disorders
- Structural abnormalities of the uterus may cause miscarriages, in particular 2nd trimester miscarriages

### ETIOLOGY

Though the primary concern with bleeding at <20 wk is for spontaneous abortion, other possibilities include:

- Implantation
- Trauma from coitus
- Cervicitis
- Placental abnormalities
- Ectopic pregnancy
- Cervical polyps

## DIAGNOSIS

### HISTORY

- If spontaneous abortion, bleeding is often accompanied by cramping abdominal, low back, or suprapubic pain.
- Recent coitus
- Trauma (maintain high suspicion for nonaccidental trauma during pregnancy)
- Cervical or uterine anomalies
- Risk factors or other symptoms of cervicitis
- History of ectopic pregnancy or pelvic inflammatory disease/tubal scarring

### PHYSICAL EXAM

- Both speculum and bimanual exam are safe to perform for vaginal bleeding within the 1st 20 wk.
- Blood from a closed cervical os indicates threatened abortion or completed abortion.
- An open cervical os indicates inevitable abortion.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

- Pregnancy test
- CBC, PT/PTT/INR
- Blood type and cross-match
- Quantitative beta-hCG levels are helpful in early pregnancy but should be used in conjunction with US:
  - A gestational sac should be seen by transvaginal sonography with a beta-hCG of 1,500–2,000 mIU/mL (5–6 wk from the last menstrual period) and 6,500 mIU/mL by transabdominal sonography (2):
    - If the beta-hCG is above these levels and a gestational sac is not visible, then an ectopic pregnancy must be considered.
- The Kleihauer-Betke test, which has been considered the standard of care for identifying fetomaternal hemorrhage, is of questionable utility and value in the emergency department.

### Imaging

- An empty gestational sac at 7 wk with a diameter of 15 mm or at 8 wk with a diameter of 22 mm is 90.8% specific for diagnosing miscarriage
- Absence of a gestational sac with beta-hCG >1,500 mIU/mL indicates possible ectopic pregnancy.

### Diagnostic Procedures/Other

Dilatation and curettage (D&C) can be diagnostic as well.

### Pathological Findings

Any sloughed or excreted tissue seen in the vaginal vault or extruding through the os should be sent to pathology for identification of products of conception.

### DIFFERENTIAL DIAGNOSIS

- Spontaneous abortion (miscarriage)
- Ectopic pregnancy (see Ectopic Pregnancy topic)
- Trauma
- Coitus
- Cervical, uterine, or placental abnormalities
- Cervicitis
- Bleeding beyond 20 wk has an expanded differential with different management. Due to the possibility of a placenta previa, bimanual pelvic exam is avoided in these cases:
  - Placental abruption (separation of the placenta from the uterine wall) can present with dark vaginal blood and uterine tenderness. Management requires CBC, disseminated intravascular coagulation (DIC) panel, type and cross, and transfer to an obstetric center for either monitoring or emergent delivery.
  - Placental abnormalities (placenta previa, circumvallate placenta, and vasa previa) can present with painless bright red vaginal blood. CBC, type and screen, US for confirmation, and emergent obstetric consultation are recommended.
  - Vaginal bleeding from trauma beyond 20 wk requires obstetric consultation and monitoring for contractions and fetal distress.
  - Bleeding may be the initial presentation of labor with passage of the “bloody show,” and preterm labor should be considered. These patients need obstetric consultation and monitoring for contractions and fetal distress.

## TREATMENT

### PRE HOSPITAL

- Assess and stabilize airway, breathing, and circulation.
- If hemodynamically unstable, place 2 large-bore IV catheters and administer a normal saline bolus of 20 mL/kg. Repeat as necessary.

### INITIAL STABILIZATION/THERAPY

Assess and stabilize airway, breathing, and circulation. The most critical action is fluid resuscitation to treat hypotension. Severe hypotension unresponsive to multiple fluid boluses may require blood transfusion.

### MEDICATION

#### First Line

Rho(D) immune globulin (RhoGAM) IM within 72 hr is required in spontaneous abortion or vaginal bleeding:

- For Rh-negative women.
- A 50- $\mu$ g dose in the 1st trimester (<13 wk)
- 300  $\mu$ g IM is used during the 2nd trimester (>13 wk)
- Need only be administered if the patient did not receive a prophylactic dose at 28 wk (3)

#### Second Line

- If an ectopic is diagnosed early and the patient is stable, medical treatment with methotrexate can be considered:
  - This should be done in consultation with an obstetrician.
- Misoprostol may be used by obstetrics to help expel remaining products in a patient with an incomplete abortion.

### SURGERY/OTHER PROCEDURES

Not emergent if bleeding is controlled and can be scheduled as an outpatient:

- Vacuum aspiration
- D&C

### DISPOSITION

#### Admission Criteria

- Floor admission if soaking through >1 pad per hour, follow-up unsure, ectopic pregnancy
- Critical care admission criteria:
  - Hemodynamic instability, including requirement of multiple fluid boluses, blood products, or pressors to maintain BP

### Discharge Criteria

- Hemodynamically stable
- Active bleeding <1 pad per hour
- Follow-up ensured
- Ectopic pregnancy ruled out or early ectopic follow-up ensured

### Issues for Referral

Should follow up promptly with an obstetrician:

- For possible miscarriage, within 3 days for consideration of D&C
- For potential ectopic pregnancy, in 48 hr for recheck of labs and US (see Ectopic Pregnancy topic)
- For cervicitis, 48-hr recheck

## FOLLOW-UP

### FOLLOW-UP RECOMMENDATIONS

- Discharge instructions and medications:
  - Return for increased bleeding or symptoms of hemodynamic instability.
  - If ectopic pregnancy has not been definitively ruled out, return for increased pain.
- Activity:
  - No intercourse or lifting >10 kg (20 pounds) for 6 wk

### Patient Monitoring

Return for increased bleeding, signs of significant anemia.

### PROGNOSIS

- 15–25% of pregnancies end in fetal loss.
- For pregnant patients with vaginal bleeding at <20 wk estimated gestational age, the risk of miscarriage is 50%.
- 14% of documented live pregnancies with 1st trimester maternal vaginal bleed end in fetal loss.

### COMPLICATIONS

Prolonged retention of nonviable products of conception can result in DIC and infection.

## CODES

### ICD9

- 640.00 Threatened abortion, unspecified as to episode of care
- 640.90 Unspecified hemorrhage in early pregnancy, unspecified as to episode of care
- 640.93 Unspecified hemorrhage in early pregnancy, antepartum

## PEARLS AND PITFALLS

Pitfalls are:

- Failure to diagnose ectopic pregnancy
- Failure to administer RhoGAM
- Failure to treat hemodynamic instability adequately

# VAGINAL BLEEDING DURING PREGNANCY (>20 WEEK GESTATION)

James M. Shen

## BASICS

### DESCRIPTION

- Vaginal bleeding is one of the most common presenting complaints associated with emergency department visits by pregnant patients.
- It carries the potential for significant mortality for the mother and fetus.
- Any bleeding during pregnancy must be considered abnormal.
- Complications can be divided into early pregnancy complications (<20 wk) and late pregnancy complications (>20 wk).
- This topic will focus on the more prevalent causes of vaginal bleeding during late pregnancy.

### EPIDEMIOLOGY

4% of patients will have vaginal bleeding after 20 wk (1):

- Placenta abruption accounts for 30% of these cases, and placenta previa accounts for 20%.

### RISK FACTORS

- For spontaneous abortion: Endocrine disorders, genetic (most common), uterine abnormalities, immunologic conditions, and infections
- For placenta previa: Chronic HTN, multiparity, multiple gestations, older age, prior cesarean delivery, tobacco use, and uterine curettage
- For placental abruption: Chronic HTN, maternal age, multiparity, pre-eclampsia, previous abruption, trauma, thrombophilia, cocaine use, and tobacco use

### PATHOPHYSIOLOGY

- Spontaneous abortion occurs when the death of an embryo causes a drop in hormone production and expulsion of the products of conception (POCs).
- In placenta previa, the placenta overlies or is adjacent to the os, and bleeding occurs when the placenta vessels are torn.
- Placenta abruption is due to abnormal separation of the placenta from the uterine wall:
  - Bleeding can be concealed and undetectable or overt and clinically apparent.

### ETIOLOGY

See Pathophysiology.

### COMMONLY ASSOCIATED CONDITIONS

- Placenta previa
- Placental abruption
- Ectopic pregnancy
- Miscarriage

## DIAGNOSIS

### HISTORY

- Quantify the amount and length of bleeding, especially the number of pads.
- Obtain a thorough menstrual history.
- Ask the patient about contraception methods.
- Obtain information about possible risk factors.

### PHYSICAL EXAM

- Monitor vital signs closely, and watch for signs of hemorrhagic shock (tachycardia and hypotension).
- Kerr sign: Referred pain to the shoulder due to diaphragmatic irritation
- If <20 wk, perform a bimanual and pelvic exam:
  - Threatened abortion: The cervical os is closed, and the patient has bleeding.
  - Inevitable abortion: The cervical os is open.
  - Incomplete abortion: POCs are present at the cervical os or in the vaginal canal.
  - Complete abortion: The cervix is closed, and the uterus is contracted.
- If >20 wk, bimanual and pelvic exam should not be performed and deferred to an obstetrician:
  - If the patient has placenta previa, exam can precipitate catastrophic hemorrhage.
- Ectopic pregnancy: Adnexal and uterine tenderness as well as a palpable adnexal mass
- Placental abruption: Vaginal bleeding (painful), uterine and abdominal tenderness, and fetal distress
- Placenta previa: Vaginal bleeding (painless)

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

- Pregnancy test
- CBC, PT/PTT/INR
- Blood type and cross-match
- Quantitative beta-hCG levels are helpful in early pregnancy but should be used in conjunction with US:
  - A gestational sac should be seen by transvaginal sonography with a beta-hCG of 1,500–2,000 mIU/mL (5–6 weeks from the last menstrual period) and 6,500 mIU/mL by transabdominal sonography (2):
    - If beta-hCG is above this level and a gestational sac is not visible, then an ectopic pregnancy must be considered.

- The Kleihauer-Betke test, which has been considered the standard of care for identifying fetomaternal hemorrhage, is of questionable utility and value in the emergency department.

### Imaging

- Start with a transabdominal US and progress to a transvaginal US if further imaging is needed (3).
- Transvaginal US in late pregnancy (>20 wk) has been shown to be safe but should be used with caution.
- US cannot rule out placenta abruption.

### Pathological Findings

If the patient has passed any tissue, it should be examined for POCs:

- Chorionic villi can be seen under microscopy as fronds and appear feathery in saline solution:
  - Can help differentiate a miscarriage from an ectopic pregnancy

### DIFFERENTIAL DIAGNOSIS

- Any gestation:
  - Vaginal trauma
  - Cervical lesions
  - Cervicitis, vulvovaginitis
  - Postcoital trauma
  - Bleeding dyscrasias
- Gestation >20 wk:
  - Molar pregnancy
  - Placenta previa
  - Vasa previa
  - Marginal separation of the placenta
  - Preterm labor

## TREATMENT

### PRE HOSPITAL

- Assess and stabilize airway, breathing, and circulation.
- Obtain large-bore vascular access, and administer fluid resuscitation as needed.
- For women with a gestation >20 wk, consider transport to a facility with labor and delivery services.
- If the patient is in the 3rd trimester and hypotensive, consider placing the patient in the left lateral decubitus position.

### INITIAL STABILIZATION/THERAPY

- Assess and stabilize airway, breathing, and circulation.
- Establish 2 large-bore IVs in any patient actively bleeding or hypotensive.
- If the pregnancy is >20 wk, continuous fetal monitoring is indicated, if available.
- Early consultation with an obstetrician is recommended.
- Consider focused abdominal sonograph for trauma (FAST) scans to identify hemoperitoneum.
- For patients who continue to have unstable vital signs, surgical exploration may be warranted.

### MEDICATION

- RhoGAM:
  - For RH-negative women.
  - A 300- $\mu$ g dose is used after the 2nd trimester.
  - Of questionable benefit in the 3rd trimester:
    - Need only be administered if the patient did not receive a prophylactic dose at 28 wk (4)
- If an ectopic pregnancy is diagnosed early and the patient is stable, medical treatment with methotrexate can be considered:
  - This should be done in consultation with an obstetrician.

### COMPLEMENTARY & ALTERNATIVE THERAPIES

Patients with a miscarriage experience a significant amount of grief and guilt and should be given counseling.

### SURGERY/OTHER PROCEDURES

- Patients who are hemodynamically unstable and unable to be resuscitated need operative care.
- Laparoscopy may be necessary to make the definitive diagnosis of an ectopic pregnancy.
- Patients with an inevitable or incomplete abortion will likely need dilatation and evacuation (D&E) or a dilatation and curettage (D&C).
- Patients with placenta abruption usually require early delivery.

### DISPOSITION

#### Admission Criteria

Any patient with suspected placental abruption and most patients with placenta previa will need hospital admission.

#### Discharge Criteria

- Stable patients with a threatened abortion and complete abortion can be safely discharged home.
- A subset of patients with placenta previa who are stable and who have rapid access to a hospital with labor and delivery can be discharged home in consultation with an obstetrician.

#### Issues for Referral

If a presumed completed abortion, the patient needs follow-up in 1–2 wk.

## FOLLOW-UP

### FOLLOW-UP RECOMMENDATIONS

- Discharge instructions and medications:
  - All patients should be advised to return to the emergency department for increased bleeding, abdominal pain, fever, weakness, dizziness, shortness of breath, and/or any other concerns.
- Activity:
  - Patients discharged with diagnoses of threatened abortion should be advised to avoid tampons, sexual intercourse, and other activities that can lead to uterine infection.

### PROGNOSIS

- 50% of women with threatened abortion will ultimately miscarry (5).
- Placenta previa may resolve spontaneously near term without any complications.

- Abruption Placenta
- Ectopic Pregnancy
- Vaginal Bleeding During Early Pregnancy (<20 Weeks)

## CODES

### ICD9

- 641.20 Premature separation of placenta, unspecified as to episode of care
- 641.90 Unspecified antepartum hemorrhage, unspecified as to episode of care
- 641.93 Unspecified antepartum hemorrhage

## PEARLS AND PITFALLS

- Use caution when interpreting beta-hCG levels.
- Do not rely on a normal US to rule out placenta abruption.
- Patients with a concealed placenta abruption will not present with vaginal bleeding.

# VAGINAL BLEEDING, PREPUBERTAL

John T. Kanegaye

## BASICS

### DESCRIPTION

Prepubertal vaginal bleeding is abnormal in most circumstances and warrants investigation of the possible underlying pathology:

- Physiologic vaginal bleeding in newborn females and expected menarche in normal girls subsequent to thelarche are exceptions.

### EPIDEMIOLOGY

- Maternal estrogen withdrawal causes vaginal bleeding in up to 10% of normal female newborns.
- In referral populations who require exam under anesthesia, genital malignancies and various forms of premature endometrial bleeding are common (each representing 21% of the population studied) (1).
- However, among patients presenting to clinics and the emergency department, the most common causes are trauma, foreign bodies, and infection:
  - Unintentional perineal injury in prepubescent patients represents 0.2% of all pediatric injuries presenting to emergency departments (2).
  - Intravaginal foreign bodies cause 18% of prepubertal bleeding and up to 50% of bleeding without discharge (3).
  - Vaginal bleeding is present with 93% of previously unsuspected prepubertal vaginal foreign bodies (3).

### PATHOPHYSIOLOGY

Vaginal bleeding arises from 2 possible sources:

- Vulva/Vagina/Cervix (external trauma or lesion)
- Endometrium (hormonal influence)

### ETIOLOGY

- Trauma: Though any injury mechanism may occur, blunt external trauma associated with straddle injury is most common:
  - Injuries range from ecchymoses, minor abrasions, and shallow lacerations to large hematomas and lacerations requiring repair.
  - Though minor anterior (especially labial) injuries predominate in accidental straddle injury, posterior injuries are common (16–34%) (2).
  - Hymeneal injury is rare in the absence of penetrating injury, but vaginal injury may result from high-pressure water mechanisms that may occur with water slides or water skiing.
  - Findings concerning for abuse include age <9 mo; perianal, vaginal, and hymeneal injuries without a plausible accidental penetrating mechanism; and associated extragenital trauma.
- Foreign body
- Vulvovaginitis may result in a bloody discharge, particularly if caused by a specific pathogen such as group A streptococcus or *Shigella* species.

- Lichen sclerosus et atrophicus is most common in postmenopausal women, but 5–15% of cases occur in prepubertal girls, occasionally raising concern for sexual abuse:
  - Symptoms include pruritis, pain, dysuria, and pain with defecation.
  - The individual lesions are ivory papules that coalesce to form a characteristic figure 8 of whitened, parchmentlike skin around the vulva and anus.
  - Hemorrhagic lesions and bleeding can occur with anatomic changes and scarring in more advanced cases.
- Excoriation (multiple causes including lichen sclerosus et atrophicus, pinworm infestation, or other conditions causing pruritis or local discomfort)
- Urethral prolapse typically presents with painless blood staining (a minority have urinary symptoms):
  - Black girls 2–10 yr of age are most commonly affected (4).
  - Because urethral prolapse is the only interlabial mass that completely encircles the urethra, recognition of the characteristic donut-shaped lesion is sufficient for the diagnosis.
  - If doubt remains, passage of a small urinary catheter through the central orifice into the bladder is diagnostic.
- Other anatomic lesions (hemangiomas)
- Neoplasms: Benign (polyps, condylomata) and malignant (sarcoma botryoides)
- Precocious puberty (secondary sexual characteristics before 8 yr of age and menarche before 10 yr)
- Other endocrine (neonatal pseudomenses, exogenous hormone exposure, hypothyroidism, syndrome-related premature menarche, estrogen-producing functional ovarian cysts or neoplasms)
- Vulvar Crohn disease
- Hematologic (before menarche, bleeding disorders rarely cause vaginal bleeding in the absence of other sites of bleeding).
- Nonvaginal sources of bleeding (urinary, rectal polyps, prolapse)

## DIAGNOSIS

### HISTORY

- Trauma:
  - Accidental trauma is common and is usually blunt, affecting external structures only.
  - However, hymeneal or vaginal injuries in the absence of a plausible penetrating mechanism should raise concern for abuse.
- Discharge:
  - A mucopurulent or purulent discharge suggests the presence of a specific bacterial pathogen.
  - Malodorous discharge suggests the presence of a foreign body.
- Antecedent respiratory or diarrheal illness may precede infection with a specific respiratory or enteric pathogen.
- Foreign body:
  - Accumulated toilet paper is the most common type of prepubertal intravaginal foreign body.
  - Prior history of foreign bodies in the vagina or other orifices raises the possibility even if none is reported with the current episode of bleeding.

- Parental observation of secondary sexual characteristics, body odor, mood changes
- Other sites of bleeding, bruising, or petechiae
- Exogenous hormone exposure, such as with topical estrogens prescribed for labial adhesions, inadvertent ingestion of hormone-containing medications (eg, contraceptive pills), and consumption of hormone-supplemented food products

### PHYSICAL EXAM

- General exam screening for extragenital trauma
- Pubic or axillary hair, breast development
- Abdominal and/or bimanual palpation to evaluate for the presence of ovarian masses
- Anogenital exam in the supine frog-leg and knee-chest positions with attention to:
  - Signs of trauma
  - Site(s) of bleeding
  - Presence of discharge, leukorrhea
  - Abnormal masses
  - Foreign bodies
  - Mucosal estrogenization (relatively enlarged clitoris and thickened labia minora, leukorrhea, thickened redundant hymeneal folds)
- Nonvaginal sources of bleeding: Vulvar, urethral, anal
- Rectal exam: Though possibly unnecessary if other portions of the exam yield the cause of bleeding, anal inspection and digital rectal exam may reveal fissures, polyps, and foreign bodies.
- Stigmata of syndromes or endocrinopathy:
  - McCune-Albright syndrome (polyostotic fibrous dysplasia): Bony lesions, limb deformity, café au lait spots with irregular borders, precocious puberty, and other endocrinopathies
  - Hypothyroidism: Growth failure, coarse facial features, constipation, cold intolerance

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

- In most cases, the diagnosis is established by clinical evaluation alone.
- In the rare event of major trauma or other serious hemorrhage, hemoglobin and possibly blood type and cross-match are indicated.
- If a specific infection (other than nonspecific vulvovaginitis) is suspected, cultures of vaginal discharge should be obtained:
  - Streptococcal antigen testing or culture may be useful if intense erythema suggests anogenital streptococcal infection. If culture is submitted, laboratory personnel will require knowledge of suspected streptococcal etiology.
  - Consider testing for gonorrhea and chlamydia if sexual abuse is possible.
- If hypothyroidism is suspected, tests of thyroid function may secure the diagnosis leading to appropriate therapy (5).
- Evaluation of precocious puberty may include estradiol levels, gonadotropin-releasing hormone stimulation tests, and imaging of the pelvis and brain:
  - These are usually unavailable and unnecessary in the emergency department setting and warrant outpatient referral to a pediatric endocrinologist.

**Imaging**

Radiologic procedures are occasionally useful in a detailed outpatient evaluation of vaginal bleeding (5) but have little role in emergency management.

**Diagnostic Procedures/Other**

- Colposcopy
- Saline irrigation of the vaginal vault (for removal of known or suspected foreign body)
- Catheterization of central orifice of urethral prolapse (confirms diagnosis by demonstrating location of urethral lumen)
- Exam under anesthesia or procedural sedation

**DIFFERENTIAL DIAGNOSIS**

See Etiology.

**TREATMENT****PRE HOSPITAL**

- For significant bleeding: Oxygen and IV access
- Volume expansion if perfusion is compromised
- Direct pressure to external bleeding sites (gauze dressing and adduction of thighs may suffice)

**INITIAL STABILIZATION/THERAPY**

- If bleeding is severe, respiratory and hemodynamic stability must be restored, providing oxygen, fluid resuscitation, and blood replacement as necessary.
- Trauma:
  - Suture repair of lacerations and drainage of hematomas are rarely necessary. Most minor wounds, including shallow lacerations, heal without sequelae with only local care measures such as sitz baths.
  - As a temporizing measure, insertion and inflation of a Foley catheter balloon will tamponade bleeding from an intravaginal laceration.
- Foreign body: Techniques for removal include irrigation or vaginoscopy. Rectal exam may assist in location and expression of the foreign body, though gentle irrigation may be better tolerated.
- Urethral prolapse: Treatment ranges from observation to surgical excision. Small, nonnecrotic prolapses benefit from sitz baths, warm compresses, and topical antiseptics.

**MEDICATION**

- Urethral prolapse: A common recommendation is for topical estrogen daily for 2 wk.
- Lichen sclerosus: Initial treatment is symptomatic, including removal of local irritants (as with vulvovaginitis), bland ointments, and antipruritics:
  - Low-potency corticosteroids may be beneficial in persistent cases.
  - Severe lichen sclerosus may require specialty referral and consideration of potent topical corticosteroids (eg, clobetasol propionate 0.05% ointment with gradual taper) (6) or calcineurin antagonists (tacrolimus 0.1% ointment) (7).
- Vulvovaginitis: Though most cases are nonspecific and respond to symptomatic treatment and measures to improve hygiene, a bloody discharge suggests a specific pathogen:
  - If rapid streptococcal antigen positive, treatment with penicillin, amoxicillin, or other medication identical in dose and duration of strep pharyngitis is appropriate, although perianal involvement may require repeated therapy.

- Antibiotic treatment can await the results of antigen detection tests or cultures. *Shigella* vaginitis (especially due to *Shigella flexneri*) may require prolonged treatment (2–4 wk), even when antibiotics are appropriate to the susceptibilities.
- Shigellae are now often resistant to ampicillin and trimethoprim/sulfamethoxazole; often, a 3rd-generation cephalosporin or a quinolone is required.

**SURGERY/OTHER PROCEDURES**

- Urethral prolapse: Complex or necrotic lesions warrant urologic consultation.
- Severe perineal trauma may require exam and repair under general anesthesia or procedural sedation.

**DISPOSITION****Admission Criteria**

- Management of serious genital and extragenital trauma and hemorrhage
- Inability to discharge to a safe outpatient environment in the care of a responsible adult
- Suspected malignancy
- Critical care admission criteria:
  - Cardiorespiratory instability
  - Severe refractory hemorrhage

**Discharge Criteria**

- Hemodynamically normal
- Medical follow-up assured even if a diagnosis not secured

**Issues for Referral**

- Pediatric endocrinology: Precocious puberty, hypothyroidism
- Dermatologic: Severe lichen sclerosus et atrophicus (may benefit from high-potency corticosteroids or calcineurin inhibitors)
- Child protection: If physical or sexual abuse cannot be excluded by the emergency physician
- Surgery/Urology: Complex laceration, refractory foreign body, other need for exam or treatment under anesthesia or procedural sedation

**FOLLOW-UP****FOLLOW-UP RECOMMENDATIONS**

- Discharge instructions and medications:
  - Most patients with external trauma, irritation, or inflammation will benefit from sitz baths, bland ointments, and perineal lavage in place of toilet paper.
  - Unless the patient is referred to a specialist, the primary care provider should monitor for resolution of the genitourinary findings.
- Activity:
  - Usually limited only by physical discomfort or by wound healing in the case of trauma

**ADDITIONAL READING**

Paradise JE. Vaginal bleeding. In Fleisher GR, Ludwig S, eds. *Textbook of Pediatric Emergency Medicine.* 6th ed. Philadelphia, PA: Lippincott Williams & Wilkins; 2010.

**CODES****ICD9**

- 623.8 Other specified noninflammatory disorders of vagina
- 772.8 Other specified hemorrhage of fetus or newborn
- 939.2 Foreign body in vulva and vagina

**PEARLS AND PITFALLS**

- A calm, unhurried approach with parental support will facilitate the genital exam in apprehensive girls.
- Neither the appearance or behavior of family members nor a normal exam can exclude the possibility of inflicted genital injury.
- Recognition of lichen sclerosus et atrophicus prevents unnecessary evaluation for sexual abuse.
- Urethral prolapse may be overlooked or mistaken for more serious conditions without a careful genital inspection.
- Though accidental blunt injury is common, hymeneal or vaginal injuries in the absence of a plausible explanation should raise concern for abuse.

# VAGINAL BLEEDING, PUBERTAL/DUB

Ilene A. Claudius

## BASICS

### DESCRIPTION

- Normal menstrual bleeding is ~30 mL/day:
  - About 6 mL of blood soaks a regular tampon.
  - Amount of blood absorbed by a pad is variable.
- Menorrhagia is heavy or prolonged bleeding characterized by:
  - >7 days of bleeding
  - >80 mL/day blood loss
- Metrorrhagia is bleeding at irregular intervals <21 days.
- Menometrorrhagia is heavy bleeding at irregular intervals.
- Dysfunctional uterine bleeding (DUB) implies irregular, frequent, or heavy bleeding not related to an underlying condition (2). This topic will discuss underlying causes of bleeding, as well as DUB, with an emphasis on treatment of DUB.

### EPIDEMIOLOGY

#### Prevalence

- 20% of women at some point in their life experience abnormal uterine bleeding.
- 20% of adolescent girls hospitalized for heavy bleeding (particularly at or near menarche) have a bleeding disorder (3).

### RISK FACTORS

DUB from anovulatory cycles is common within the 1st 3 yr following menarche.

### PATHOPHYSIOLOGY

- The normal menstrual cycle has 3 phases:
  - Follicular: Gonadotropin-releasing hormone release stimulates follicle-stimulating hormone (FSH) and luteinizing hormone.
  - Ovulatory: Ovary releases the oocyte.
  - Luteal: Deterioration of the progesterone-producing corpus luteum triggers menstrual sloughing.

- In DUB caused by anovulatory cycles, there is a lack of progesterone, and estrogen causes unopposed stimulation of the endometrium. Eventually, it outgrows its vascular supply, leading to unpredictable and heavy bleeding (4).

### ETIOLOGY

Usually, pediatric DUB occurs secondary to anovulatory cycles associated with an immature hypothalamic-pituitary-ovarian (HPO) axis.

### COMMONLY ASSOCIATED CONDITIONS

- Anemia
- Bleeding disorder

## DIAGNOSIS

### HISTORY

- Amount, appearance, and timing of bleeding:
  - Heavy cyclic bleeding can indicate a bleeding disorder.
  - Intramenstrual spotting can indicate cervical pathology such as cervicitis, polyps, cancer, or endometriosis.
  - Foul-smelling bloody discharge indicates retained foreign body (eg, tampon).
- Menstrual history:
  - Being within 3 yr of menarche is suspicious for anovulatory cycles from an immature HPO axis.
- Birth control use: Missed oral contraceptive doses or intrauterine device use can produce abnormal bleeding.
- Excess stress, weight loss, or dieting can cause result in missed menses (5).
- History of easy or other bleeding, or family history of bleeding disorders or heavy menses, may indicate a primary bleeding disorder as a cause of menorrhagia.
- Thyroid abnormalities or adrenal disorders can cause menstrual irregularity; therefore, symptoms such as weight changes, cold/heat intolerance, and fatigue should be elicited. Similarly, medications such as excess steroids, which can mimic these disorders, can cause excess menstrual bleeding.
- Polycystic ovarian syndrome can cause irregular menses and anovulatory cycles.

### PHYSICAL EXAM

- Vital sign abnormalities for evidence of hemodynamic instability or orthostatic hypotension
- Speculum exam of the pelvis for cervical friability (frequently due to cervicitis or malignancy), polyps, or evidence of trauma
- Bimanual exam of the pelvis for evidence of pelvic inflammatory disease if indicated based on history and physical exam
- Acne and hirsutism are suspicious for polycystic ovarian syndrome.
- Other sites of bleeding/bruising concerning for a bleeding disorder, such as von Willebrand disease

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

- Urine or serum pregnancy test
- If indicated by the history and physical exam, the following can be considered in the emergency department or by the primary care provider:
  - CBC to assess hematocrit and platelet count
  - STI testing
  - Von Willebrand evaluation: PT, PTT, ristocetin cofactor testing, von Willebrand factor antigen test, von Willebrand multimers, platelet count
  - Endocrine testing, particularly thyroid-stimulating hormone, free T4, and cortisol levels. Further hormonal workup, such as FSH, is at the discretion of the gynecologist.

#### Imaging

Pelvic US may be indicated nonemergently.

#### Diagnostic Procedures/Other

Pap smear or endometrial biopsy may be indicated nonemergently.

### DIFFERENTIAL DIAGNOSIS

- Miscarriage
- Pelvic or sexual trauma
- Bleeding disorder, either primary or secondary to renal or hepatic pathology
- Cervical disease
- Foreign body
- Endocrinopathy

## TREATMENT

### PRE HOSPITAL

IV fluid if hemodynamically unstable

### INITIAL STABILIZATION/THERAPY

- Normal saline IV boluses for patients with tachycardia and/or hypotension
- If the patient is anemic and hemodynamically unstable, blood transfusion may be necessary.

### MEDICATION

#### First Line

Medications include hormonal therapy options:

- If a specific disease, such as hypothyroidism, is identified, specific disease-directed therapy should be initiated as well as the following hormonal therapies:
  - IV estrogen for PO intolerance or severe bleeding (5–25 mg q4–12h)
  - Oral estrogen—use monophasic 25–30  $\mu$ g estradiol pill: 3 pills per day for 3 days, 2 pills per day for 6 days, then 1 pill daily for 21 days (skip placebo tablets). Ortho-Novum 1/35 and Lo/Ovral are appropriate choices.
  - Medroxyprogesterone 10 mg PO daily for 12–14 days for patients who cannot take estrogen. Expect a response to hormonal therapy within 6–12 hr.

#### Second Line

- For DUB, NSAIDs can help decrease blood loss.
- Iron or folic acid may be indicated if the patient is anemic.
- Antiemetics may be required to treat nausea caused by high doses of oral estrogen.
- Antifibrinolytic agents may be used in chronic refractory cases by subspecialist consultants.

### Pregnancy Considerations

Pregnancy should be ruled out before a diagnosis of dysfunctional uterine bleeding is given.

### COMPLEMENTARY & ALTERNATIVE THERAPIES

- Iron
- Vitamins A and C
- Cranesbill, witch hazel, shepherd's purse, and garrow: All are thought to be helpful for hemostasis.

### SURGERY/OTHER PROCEDURES

- Dilatation and curettage (D&C) is an option for uncontrolled bleeding.
- Some sources advocate use of a pediatric-sized Foley urinary catheter placed through the cervical os and the balloon inflated in the uterus to tamponade bleeding. This has some proven effectiveness, but also has reported complications, including uterine rupture.

### DISPOSITION

#### Admission Criteria

- Floor admission for:
  - Heavy active bleeding with moderate to severe anemia (hemoglobin <9 g/dL)
  - Inability to ensure adequate follow-up
  - Inability to tolerate oral medications
- Critical care admission criteria: Persistent hemodynamic instability

#### Discharge Criteria

- Vital sign stability
- Ability to take medication
- Follow-up ensured
- Pregnancy excluded

#### Issues for Referral

Patients must follow up with a gynecologist or primary care provider.

## FOLLOW-UP

### FOLLOW-UP RECOMMENDATIONS

Discharge instructions and medications:

- Return if bleeding exacerbates rather than improves and for severe abdominal pain, fever, or any general deterioration.
- Oral hormonal therapy and adjunctive medications should be continued on discharge.

### PROGNOSIS

Most girls with bleeding due to an immature HPO axis will establish ovulatory cycles within 2 yr of menarche.

### COMPLICATIONS

- Anemia
- Complications specific to the underlying cause

- Vaginal Bleeding During Pregnancy (>20 Weeks Gestation)
- Vaginal Bleeding, Prepubertal

## CODES

### ICD9

- 626.2 Excessive or frequent menstruation
- 626.6 Metrorrhagia
- 626.8 Other disorders of menstruation and other abnormal bleeding from female genital tract

## PEARLS AND PITFALLS

Pitfalls are:

- Failure to perform a pelvic exam when indicated
- Failure to recognize pregnancy, vaginal trauma, or STIs

# VAGINAL DISCHARGE, PREPUBERTAL

Tina S. Lee  
Hanan Sedik

## BASICS

### DESCRIPTION

- Normal physiologic vaginal discharge includes secretions or fluid produced by glands in the vaginal wall and cervix.
- Abnormal discharge may result from a variety of problems, primarily inflammation and infection.
- Vaginal discharge in the prepubertal age can be normal. However, any persistent and symptomatic vaginal discharge in this age group should be considered abnormal.

### PATHOPHYSIOLOGY

- Cervical and vaginal glands normally produce clear mucus dependent on estrogen levels:
  - This is called physiologic leukorrhea.
  - This mucus may turn yellow or white when exposed to air.
- In the neonate, vaginal discharge can be normal due to maternal estrogen effect. The levels of estrogen remain elevated after birth, and as they decrease, vaginal discharge is common:
  - Discharge can be thick, grayish-white, and mucoid.
  - It may also be blood tinged or grossly bloody, similar to menses.
- Discharge may be due to irritation and infection. These are more common in prepubertal girls for the following reasons:
  - Labial folds are smaller in prepubertal girls, and they lack pubic hair.
  - Distance between the vagina and anus in prepubertal girls is relatively shorter than in postpubertal girls.
  - Low levels of estrogen in prepubertal girls make the vaginal mucosa thin.
  - An alkaline pH (~7.0) of the vaginal secretions in prepubertal girls allows bacteria to flourish.

### ETIOLOGY

- Vulvovaginitis:
  - *Haemophilus influenzae*, *Staphylococcus* species, *Streptococcus* species:
    - Most common bacteria is *Streptococcus pyogenes* (1)
  - Enteric infections (*Escherichia coli*, *Shigella* species, *Yersinia* species)
  - Pinworms (*Enterobius vermicularis*)
  - Fungal (*Candida albicans*)
  - STIs: Strongly suspect sexual abuse in this age group:
    - *Neisseria gonorrhoeae*, *Chlamydia trachomatis*, *Trichomonas vaginalis*, *Gardnerella vaginalis*, condyloma acuminata

- Dermatitis:
  - Contact:
    - Bubble baths
    - Strong detergents
    - Sand
    - Nonabsorbent occlusive clothing
    - Poor hygiene
  - Eczematous
- Foreign bodies:
  - Toilet paper is the most common foreign body to cause vaginal discharge.
- Trauma, sexual abuse
- Malignancies, masses:
  - Rhabdomyosarcoma
  - Sarcoma botryoides
  - Endodermal sinus tumor
  - Polyps
- Associated systemic illnesses (group A streptococci, varicella, Stevens-Johnson syndrome, Crohn disease)
- Vulvar ulcers: May be caused by infection or irritation from vaginal foreign bodies
- Fistulas (rectovaginal/vesicovaginal)

## DIAGNOSIS

### HISTORY

- Describe the vaginal discharge (color, consistency, odor).
- Timing and duration of discharge
- Associated pain, itching, or burning
- Associated symptoms (abdominal pain, fever, bleeding, lesions, or urinary changes)
- Allergies or eczema
- Hygiene history:
  - Type of diapers and how often the patient is changed
  - Use of bubble baths or strong soaps
  - Use of strong detergents
  - Wiping from back to front after a bowel movement
  - Tight clothing around the genital area or nylon panties
- Recent or concomitant illness:
  - *S. pyogenes*
  - *Shigella flexneri* infection
  - Systemic illnesses (varicella)
  - Pinworms
- Immunocompromised
- Concern about possible sexual abuse

### PHYSICAL EXAM

- Evaluate the entire genital and anal area while the child is at rest and is calm:
  - Positioning options for examiner:
    - Lay the patient on her back in the supine frog-leg position with knees bent and soles of feet touching.
    - Lay face down in the prone knee–chest position.
    - While sitting in the parent's lap, with the legs hanging over the parent's legs, the parent's legs may be spread to spread the patient's legs.
  - Presence of bruises, lacerations, or abrasions suggest trauma or sexual abuse.
  - Excoriations around the anus/vagina suggest itching caused by pinworms.
  - Rashes that spare skin folds suggest irritative causes.
  - Rashes mainly within skin folds suggest candidiasis.
  - Look for foreign bodies within the vaginal vault.
- Evaluate the vaginal discharge:
  - Candida is thick and white, with a "cottage cheese–like" discharge.
  - Trichomonas is greenish-yellow, with purulent discharge.
  - Gardnerella is thin and fish smelling, with a gray discharge.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

- If vaginal discharge is present, obtain:
  - Routine vaginal culture and Gram stain:
    - The presence of leukocytes increases the likelihood of finding a bacterial pathogen (2).
  - Wet prep slide:
    - Motile trichomonads suggest *T. vaginalis*.
    - Clue cells suggest bacterial vaginosis.
  - KOH-prepped slide:
    - Hyphae on the slide suggest *C. albicans*.
  - Culture for *N. gonorrhoeae* and *C. trachomatis*
- If the patient has perianal itching: Apply cellophane tape to the perianal area and then place the tape onto a glass slide. This may reveal *E. vermicularis* eggs.

#### Imaging

US or referral for outpatient MRI may be useful in detecting foreign bodies.

#### Diagnostic Procedures/Other

- If the child has persistent vaginal discharge with negative culture results, an intravaginal exam under anesthesia or procedural sedation is indicated, especially if the child is <6 yr of age (3).
- Vaginoscopy may be indicated as well.

### DIFFERENTIAL DIAGNOSIS

- Contact dermatitis
- Psoriasis
- Lichen sclerosus et atrophicus
- See Etiology.

## TREATMENT

- In the neonate, no treatment is needed. The discharge usually resolves within 10 days of age.
- If the discharge is caused by an irritative origin:
  - Discontinue the offending agent.
  - Encourage the patient to wear cotton underpants and loose-fitting pants/skirts.
  - Reinforce wiping the genital area from front to back only.
  - Use sitz baths with mild soap for temporary relief.
  - Encourage air drying of the perineal area.
- Remove the foreign body:
  - If a foreign body is highly suspected but not visualized, irrigate the vagina with saline solution to flush out small objects.
- If discharge is caused by another infection, treat the underlying infection.
- If the infection is found to be sexually transmitted, it must be reported to child protective services. See the Child Abuse topic.

## MEDICATION

- Infectious causes:
  - *H. influenzae*, *Staphylococcus* species, *Streptococcus* species:
    - Amoxicillin 50 mg/kg/day PO divided b.i.d. × 10 days OR
    - Amoxicillin/Clavulanic acid (dose on amoxicillin component) 50 mg/kg/day PO divided b.i.d. × 10 days
  - Enteric infections (*E. coli*, *Shigella* species, *Yersinia* species):
    - Trimethoprim/Sulfamethoxazole: Trimethoprim component 6–10 mg/kg/day PO × 3 days
  - Pinworms (*E. vermicularis*):
    - Mebendazole 100 mg PO × 1, then repeat 2 wk later OR
    - Pyrantel pamoate 10 mg/kg PO × 1
  - Fungal (*C. albicans*):
    - Topical clotrimazole or miconazole b.i.d. or t.i.d. × 6 days
    - Fluconazole 20 mg/kg PO × 1
  - *N. gonorrhoeae*:
    - Ceftriaxone 125 mg IM × 1
    - Azithromycin 20 mg/kg PO × 1
  - *C. trachomatis*:
    - Erythromycin base or ethylsuccinate 50 mg/kg/day divided q.i.d. PO × 14 days, max 2 g/day
    - Azithromycin 1 g PO × 1 (if patient is >45 kg)
    - Doxycycline 100 mg PO b.i.d. × 7 days (if patient is >8 yr of age)

- *T. vaginalis*:
  - Metronidazole 15–20 mg/kg/day PO divided t.i.d. × 7 days, max 2 g/day
- *G. vaginalis*:
  - Metronidazole 15–20 mg/kg/day PO divided b.i.d. × 7 days, max 1 g/day
- Condyloma acuminata:
  - Imiquimod 5% cream qhs 3 times a week for up to 16 wk. Then, wash with soap and water 6–10 hr after application:
    - Topical immunomodulator proposed for off-label pediatric use in cutaneous warts
  - Herpes simplex virus—primary infection:
    - Acyclovir 80 mg/kg/day divided t.i.d.–q.i.d. PO × 7–10 days, max 1.2 g/day
    - Valacyclovir 1 g PO t.i.d. × 7–10 days
- If appropriate treatment is unsuccessful, an estrogen cream may be helpful to promote a transient increase in genital mucus that may enhance resistance to pathogenic microorganisms:
  - Promestriene 1% cream applied for 10 days

## SURGERY/OTHER PROCEDURES

If the patient has a foreign body that is difficult to observe or remove, this may require a referral to a gynecologist or surgeon for an exam under general anesthesia or under procedural sedation.

### Issues for Referral

- If the evaluation yields evidence of sexual abuse, immediate referral to child protective services, social work, and/or the police is warranted.
- If a tumor or polyps are present, referral for surgery for removal and/or oncology for further workup is indicated.

## FOLLOW-UP

### FOLLOW-UP RECOMMENDATIONS

- Vulvovaginitis is a disease with minor symptoms that usually responds to medications, good hygiene, or emollients.
- Be aware of the rare and unusual causes for persistent vaginal discharge.

## CODES

### ICD9

- 616.10 Vaginitis and vulvovaginitis, unspecified
- 623.5 Leukorrhea, not specified as infective

## PEARLS AND PITFALLS

- Nonspecific vulvovaginitis is very common, and obtaining appropriate hygiene history is important.
- If vaginal discharge is positive for a sexually transmitted organism, suspect sexual abuse and report it.
- Persistent vaginal discharge despite appropriate therapy as described above requires referral for exam under anesthesia or procedural sedation, with or without vaginoscopy.

# VAGINAL DISCHARGE, PUBERTAL

Hanan Sedik

## BASICS

### DESCRIPTION

- Normal physiologic vaginal discharge includes secretions or fluid produced by glands in the vaginal wall and cervix.
- Abnormal discharge may result from a variety of problems, primarily inflammation and infection.
- Vaginal discharge is a commonly encountered complaint in the pubertal population.
- Infectious vaginitis is a common cause of vaginal discharge:
  - Bacterial vaginosis: Accounts for 22–50% of infectious vaginitis
  - Vaginal candidiasis: 17–39%
  - *Trichomonas vaginalis* vaginitis: 4–35% (1,2)

### RISK FACTORS

- Use of feminine hygiene products, local contraceptives, vaginal medications
- Systemic antibiotics
- Sexual activity
- Stress

### PATHOPHYSIOLOGY

- Normal vaginal discharge is white or transparent and odorless.
- Normal vaginal discharge increases around the time of ovulation and during pregnancy.
- The pH of the normal vaginal secretions is 4.0–4.5, which inhibits the growth and adherence of pathogens to the vaginal wall.
- *Lactobacillus* species is the most abundant normal isolate from vaginal secretions. It produces hydrogen peroxide, and lactic acid maintains the acidity of vaginal pH.
- During reproductive years, estrogen helps cornify the vaginal epithelium and protects against pathogens.

### ETIOLOGY

- Vaginitis: *Candida albicans*, *Trichomonas vaginalis*, or a combination of multiple bacteria, especially *Gardnerella vaginalis* causing bacterial vaginosis
- Cervicitis: STIs and pelvic inflammatory disease (PID) may be caused by *Neisseria gonorrhoeae* and *Chlamydia trachomatis*.
- Chemical irritants, like vaginal douching
- Malignancy of the genital tract

- Hormonal deficiency
- Systemic disease: Collagen vascular diseases, pemphigus syndromes, and Behçet syndrome
- Trauma
- Urinary tract infection (UTI) or cystitis
- Vaginal foreign body
- Contact dermatitis
- Ulcerative vaginitis associated with *Staphylococcus aureus* and toxic shock syndrome
- Idiopathic vulvovaginal ulceration associated with HIV infection
- Desquamative inflammatory vaginitis
- Streptococcal vaginitis (group A)
- Erosive lichen planus
- Idiopathic vaginitis

### COMMONLY ASSOCIATED CONDITIONS

- Vulvitis
- Cervicitis

## DIAGNOSIS

### HISTORY

- Excessive vaginal discharge
- History should include quantity, duration, color, and odor.
- Pruritis
- Irritation or burning sensation
- Dyspareunia
- Dysuria
- Sexual activity: Whether sexually active or not, last encounter, single or multiple sexual partners, symptomatic partner(s), or new partner
- Last menstrual period and timing to the vaginal discharge:
  - Candida vulvovaginitis often occurs in the premenstrual period.
  - Trichomoniasis often occurs during or immediately after the menstrual period.
- Abdominal pain: With PID or cystitis
- Medications: Antibiotics and high-estrogen contraceptives may predispose to candida vulvovaginitis.

### PHYSICAL EXAM

- Vulvar erythema
- Presence of vaginal discharge
- Bacterial vaginosis: Thin, homogenous, malodorous, white-to-grey vaginal discharge
- Vaginal candidiasis: Thick, odorless, white vaginal discharge with “cottage cheese–like” appearance
- *T. vaginalis*: Vaginal discharge that can be white, gray, yellow, or green
- Pelvic exam, if sexually active:
  - Presence of cervical motion tenderness on bimanual exam suggests PID.
  - Erythematous and friable cervix in cervicitis
- Abdominal tenderness in PID
- Suprapubic tenderness in cystitis

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

- Bedside testing of vaginal discharge:
  - Vaginal pH using a litmus paper:
    - Bacterial vaginosis: pH of 5.0–6.0
    - Vaginal candidiasis: pH <4.5
    - *T. vaginalis*: pH of 5.0–7.0
- Saline wet mount: Vaginal discharge is placed on a slide with 1–2 drops of normal saline solution and examined under a high-power microscope:
  - Clue cells are vaginal epithelial cells covered with many rods and cocci bacteria, creating a stippled or granular appearance. This is characteristic of bacterial vaginosis.
  - Oval- or fusiform-shaped motile protozoan in *T. vaginalis*
  - KOH-prepped slide: Hyphae and budding yeast forms are noted in vaginal candidiasis.
- Vaginal culture for *Candida* or *Trichomonas* if negative microscopy
- Endocervical swabs or urine specimen for *N. gonorrhoeae* or *C. trachomatis*
- Pregnancy testing is generally indicated in the sexually active patient.
- Urinalysis and culture to evaluate for UTI

#### Imaging

Referral for outpatient pelvic US if PID or a malignancy is suspected

#### Diagnostic Procedures/Other

Referral for outpatient colposcopy and cervical biopsies for suspected malignancy

### DIFFERENTIAL DIAGNOSIS

- Normal physiologic discharge
- STI

## TREATMENT

### MEDICATION

- Depending on the diagnosis:
  - Bacterial vaginosis:
    - Metronidazole 500 mg PO b.i.d. for 7 days OR
    - Metronidazole gel 0.75%: 1 full applicator (5 g) intravaginally, once a day for 5 days
  - Vaginal candidiasis:
    - Clotrimazole 1% cream: 5 g intravaginally for 7–14 days OR
    - Butoconazole 2% cream: 5 g intravaginally for 3 days OR
    - Fluconazole 150 mg oral tablet in a single dose
  - *T. vaginalis*:
    - Metronidazole 2 g PO in a single dose OR
    - Tinidazole 2 g PO in a single dose
- Refer to the Sexually Transmitted Infections or Pelvic Inflammatory Disease topics for treatment.

### Pregnancy Considerations

- Pregnant women with trichomoniasis may be treated with 2 g of metronidazole in a single dose.
- Pregnant women should have a follow-up visit 1 mo after completion of treatment.

### COMPLEMENTARY & ALTERNATIVE THERAPIES

- A low-carbohydrate diet may help by decreasing the proliferation of candidiasis.
- Yogurt, garlic, and lactobacilli or acidophilus supplements may help by increasing the level of *Lactobacillus* species in the vagina, thereby decreasing the growth of other organisms.

### DISPOSITION

#### Admission Criteria

If associated with PID or other systemic illness

#### Discharge Criteria

Most patients can be discharged with primary care provider follow-up of lab/culture results.

#### Issues for Referral

Gynecologic referral for chronic/resistant vaginal discharge or suspicion of malignancy

## FOLLOW-UP

### FOLLOW-UP RECOMMENDATIONS

Discharge instructions and medications:

- Patients should be informed if the diagnosis is related to sexual transmission and made aware of the need to treat the partner.

### Patient Monitoring

- Frequency of discharge and response to treatment
- Screening of STIs

### DIET

- Regular
- Patients should be advised to avoid alcohol consumption during and 24 hr after treatment with metronidazole.

### PROGNOSIS

- Depends on the etiology
- Generally a good prognosis

### COMPLICATIONS

- Generally no complications
- Infertility can complicate long-standing PID.

## CODES

### ICD9

- 112.1 Candidiasis of vulva and vagina
- 616.10 Vaginitis and vulvovaginitis, unspecified
- 623.5 Leukorrhea, not specified as infective

## PEARLS AND PITFALLS

- Though vaginal discharge is a common complaint, many patients deny the presence of “abnormal vaginal discharge” or are unaware of it.
- Though the nature of the vaginal discharge on the history and physical exam can be diagnostic, it is unreliable.

# VAGINITIS

Jennifer H. Chao

## BASICS

### DESCRIPTION

- Vaginal irritation and inflammation can occur for a variety of reasons.
- Vulvovaginitis is inflammation of the vulva, as well as the vagina, that occurs in prepubescent girls.
- Vaginosis is overgrowth of vaginal flora, particularly anaerobic bacteria that produce a malodorous discharge.
- Vaginal pH and flora vary based on hormonal influences, medication use, and local factors.
- Pubertal causes differ from those that are postpubertal.

### RISK FACTORS

- Sexual activity
- Poor hygiene
- Obesity
- Bubble baths or other skin irritants
- Tight-fitting, occlusive clothing
- Recent antibiotic use
- Recent diarrheal illness

### PATHOPHYSIOLOGY

- Physiologic leukorrhea is a normally occurring vaginal discharge that is clear or white, nonirritating, and not malodorous.
- Prepubertal children:
  - Relatively alkaline vaginal pH in comparison to that in postpubertal patients
  - The vaginal mucosa is columnar epithelium.
  - Vaginal mucous glands are absent.
  - Normal vaginal flora is composed of gram-positive cocci and anaerobic gram-negative bacteria.
- Pubertal and postpubertal adolescents:
  - More acidic vaginal pH
  - Stratified squamous vaginal mucosa
  - Presence of vaginal mucous glands
  - Normal vaginal flora are lactobacilli.
  - Thick labia and hypertrophied hymens and vaginal walls
- Loss of vaginal lactobacilli appears to be the primary factor in the changes that lead to bacterial vaginosis (BV).
- Candidiasis may occur in patients of all ages but is more common in the presence of elevated serum glucose levels, such as with pregnancy or diabetes and with antibiotic use that may kill normal bacterial vaginal flora.

### ETIOLOGY

- Nonspecific vaginitis:
  - Scant or mucoid discharge with pruritus/irritation
  - Caused by local irritation and alteration of flora
- BV:
  - Occurs as a result of an overgrowth of normal *Lactobacillus* vaginal flora in the postpubertal adolescent, most commonly with *Gardnerella vaginalis*.
- Candidiasis (moniliasis):
  - An overgrowth of *Candida* generally in postpubertal adolescents and with antibiotic use
- *Streptococcus pyogenes* (group A streptococcus) and various species of gram-negative bacteria: *Shigella* species, *Escherichia coli*, *Salmonella* species, and *Haemophilus influenzae* are known causes of vaginitis in prepubertal children.
- *Enterobius vermicularis* (pinworms) and trichuriasis (*Trichuris trichiura*) may result in vaginitis.
- Numerous STIs may result in vaginitis:
  - Gonorrhea
  - Chlamydia
  - Herpes simplex
  - Human papillomavirus
  - Chancroid
  - Lymphogranuloma venarum
- Systemic disease:
  - Measles
  - Chickenpox
  - Scarlet fever
  - Epstein-Barr virus
  - Stevens-Johnson syndrome
  - Crohn disease
  - Kawasaki disease

### COMMONLY ASSOCIATED CONDITIONS

- Poor hygiene, such as retained toilet tissue in the vaginal vault or wiping from back to front
- Obesity
- Recent antibiotic use, diabetes, or immunosuppression for candida
- Recent or concurrent diarrheal illness due to *Shigella* or *Salmonella*

## DIAGNOSIS

### HISTORY

- Vaginal irritation, itching or burning, and/or discharge, bleeding, odor
- Dysuria
- Medication history
- Sexual activity

### PHYSICAL EXAM

- Exam of the vagina for redness, irritation, foreign body, and lesions
- Discharge: May be physiologic or pathologic
- Candida: Very red rash with satellite lesions and some scaling; thick, curdlike discharge
- BV: Thin, gray discharge, fishy odor
- Trichomonas: Frothy, greenish discharge, often with “strawberry cervix”
- Streptococcal infection: Beefy red cellulitis
- Other bacterial infections: Irritation and purulent discharge

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

- Pregnancy test in sexually mature females
- Potassium hydroxide (KOH) or “whiff test”: In BV, there is a fishy or amine odor released with application of KOH.
- Endocervical swab testing for gonorrhea and chlamydia.
- Microscopy:
  - In candidal vaginitis, branching hyphae should be seen. This may be aided by the addition of KOH to remove epithelial cells that may obscure the hyphae.
  - In BV, clue cells are diagnostic: These are epithelial cells stippled with bacteria.
  - With *Trichomonas* infection, the trichomonads are identified as flagellated protozoa that dart about the slide.
- pH testing should be performed by touching the vaginal walls/discharge with Nitrazine or pH paper:
  - The test is inaccurate if blood is present.
  - In normal postpubertal patients, the normal pH is <4.5.
  - In patients with either BV or *Trichomonas* infection, the pH is >4.5.
- Rapid streptococcal antigen assay and/or streptococcal culture may be obtained for suspected vaginal/perineal streptococcal infection.

**DIFFERENTIAL DIAGNOSIS**

- Vaginal foreign body
- Pinworms
- Vaginal foreign body
- Lichen sclerosis et atrophicus
- Urethral prolapse
- Abuse
- Rectovaginal fistula (Crohn disease)
- Chlamydia or gonorrhea cervicitis
- Herpes simplex

**TREATMENT**

- For mild cases of nonspecific vaginitis in prepubertal children, good hygiene is all that is required.
- Any foreign body should be removed.

**MEDICATION**

- Penicillin (<27 kg 250 mg b.i.d. >27 kg 500 mg b.i.d. × 10 days) or amoxicillin (50 mg/kg PO divided b.i.d. × 10 days) or azithromycin (12 mg/kg/day × 5 days) may be used for streptococcal disease.
- Amoxicillin dosing as above may be used for coliform bacteria.
- Candidal infection should be treated with either intravaginal imidazoles (various regimens 1, 3, or 7 days) or oral fluconazole 150 mg × 1.
- Trichomonas infection: Metronidazole 2 g PO × 1 or 500 mg PO b.i.d. × 7 days
- BV: Metronidazole (5 g intravaginally daily × 7 days or 500 mg b.i.d. × 7 days) or clindamycin (5 g per day × 7 days or 300 mg PO b.i.d. × 7 days):
  - Other bacterial infections should be treated with antibiotics appropriate for the bacteria isolated from culture.

**COMPLEMENTARY & ALTERNATIVE THERAPIES**

- Douching is discouraged because of an increased incidence of endometritis.
- There is limited evidence to support the administration of probiotics to prevent and/or treat candida and BV.

**DISPOSITION****Discharge Criteria**

Patients should be discharged home unless there is a specific reason for admission such as foreign body that must be removed operatively or admission for child protective purposes.

**Issues for Referral**

- If concern for abuse: Appropriate referral for counseling and police services should be made.
- For sexually active adolescents, appropriate follow-up for complete gynecologic care is imperative.

**FOLLOW-UP****FOLLOW-UP RECOMMENDATIONS**

- Discharge instructions and medications:
  - If the diagnosis is nonspecific vaginitis caused by poor hygiene, patients should be advised to wear loose-fitting clothes and cotton underwear and use sitz baths in plain water for 20 min/day. It is often helpful to advise flushable wipes or baby wipes to aid in cleaning after toilet use.
  - They should also only use unscented toilet paper and mild soaps and laundry detergents. If the child is self-cleaning after toileting, he or she should be instructed on proper cleaning technique (front to back).
  - If a particular organism is found to be the cause, antimicrobial prescription specific to the cause should be given.
  - For pain and discomfort, analgesic (ibuprofen and acetaminophen) may be prescribed. If needed, PRN topical lidocaine jelly may also be applied (sparingly and to older children to prevent toxicity).
  - Follow-up should be arranged to monitor response to therapy with the primary care physician in 1 wk.
- Activity:
  - Patients with STIs should not have sex without a condom until their partner is treated.

**DIET**

Patients prescribed metronidazole should be advised to avoid alcohol because of the “disulfiram reaction.”

**PROGNOSIS**

- The prognosis varies on etiology but is generally excellent.
- There are some cases of “nonspecific vaginitis” that are protracted and difficult to resolve, most likely due to patient factors including hygiene.

**ADDITIONAL READING**

- Abad C, Safdar N. The role of lactobacillus probiotics in the treatment or prevention of urogenital infections: A systematic review. *J Chemother.* 2009;21(3):243–252.

**See Also (Topic, Algorithm, Electronic Media Element)**

- Pelvic Inflammatory Disease
- Vaginal Bleeding, Prepubertal
- Vaginal Discharge, Prepubertal

**CODES****ICD9**

- 054.11 Herpetic vulvovaginitis
- 616.10 Vaginitis and vulvovaginitis, unspecified
- 616.11 Vaginitis and vulvovaginitis in diseases classified elsewhere

**PEARLS AND PITFALLS**

- In prepubertal children, pathogens associated with STIs should always prompt investigation for sexual abuse.
- If there is any concern for abuse, before treatment with any antibiotics, appropriate cultures should be obtained.

# VENTRICULOPERITONEAL SHUNT INFECTION

Toni K. Gross

## BASICS

### DESCRIPTION

- Ventricular shunts are the standard treatment for hydrocephalus and account for the most common neurosurgical procedure in children:
  - Shunt devices may also be used to drain CSF from arachnoid cysts, the subdural space, spinal syrinxes, and other fluid-filled intracranial or intraspinal compartments.
- The most common type of ventricular shunt is the ventriculoperitoneal shunt (VPS); a ventriculoatrial shunt may also be employed.
- Infection is the 2nd most common complication for shunted patients.

### EPIDEMIOLOGY

#### Incidence

- 7–12% of shunt procedures result in infection (1–3)
- 24-mo infection rate for uncomplicated initial shunt procedures: 12% of patients and 7% of procedures (4)

### RISK FACTORS

- CSF leak from the incision postoperatively
- Direct exposure of hardware due to skin breakdown
- Myelomeningocele
- Young age
- Insertion of a ventricular shunt into premature neonate
- Intra-abdominal infectious process
- Multiple ventricular shunt connections

### GENERAL PREVENTION

Aseptic techniques in the operating room:

- Specially trained operating room team
- Reducing the number of people in the operating room
- Doing ventricular shunt surgeries as the 1st case of the day
- Shortening the duration of surgery
- Keeping the ventricular shunt from touching the skin
- Use of prophylactic antibiotics

### PATHOPHYSIOLOGY

- Ventricular shunts become infected by 3 main routes. Organisms may:
  - Colonize the wound at the time of surgery
  - Reach the CSF by hematogenous spread
  - Travel retrograde through a contaminated distal catheter
- The majority of shunt infections appear to be acquired intraoperatively or in the immediate perioperative period:
  - 50% occur within 2 wk of surgery (2).
  - 70% occur within 2 mo of surgery (5).
  - 90% occur within 6 mo of surgery (1).
- Different locations along the track of the shunt are prone to infection:
  - Lumen of the shunt itself
  - Ventricles
  - Cranial and distal surgical sites
  - Peritoneal cavity

### ETIOLOGY

- The most common pathogen isolated is coagulase-negative *Staphylococcus* followed by *Staphylococcus aureus* (2):
  - Staphylococcal species make up >2/3 of all infections.
  - Coagulase-negative *Staphylococcus* organisms secrete a biofilm that enhances adherence to the device and protects them from the host immune response, namely pleocytosis and phagocytosis.
  - Infections presenting late after surgery are less likely to involve *S. aureus*.
- Other pathogens include skin flora such as *Propionibacterium acnes* (prevalent in adolescents), environmental bacteria such as *Haemophilus influenzae*, and enteric organisms such as *Enterococcus*.

### COMMONLY ASSOCIATED CONDITIONS

Infections presenting late after surgery are more likely to present with abdominal pseudocysts:

- An abdominal peritoneal pseudocyst is a pathologic collection of CSF at the distal end of the shunt with a wall consisting of granulation and/or fibrous tissue but without an epithelial layer.
- Pseudocysts are thought to form secondary to inflammation.
- Related to decreased peritoneal absorption of CSF
- Pseudocysts can be a direct consequence of ventricular shunt infection or may develop in the absence of infection and become secondarily infected.

## DIAGNOSIS

### HISTORY

- Fever is the most common sign but may be present in <1/2 of cases (5).
- Headache may occur because of infection itself or due to impaired CSF drainage.
- Symptoms of shunt malfunction may or may not be present.
- Meningismus (~30%)
- Abdominal pain (~15%)
- Seizure has been reported, but seizure without any other signs or symptoms would be an uncommon presentation.

### PHYSICAL EXAM

- Often, the child does not appear acutely ill.
- Though fever may be the only finding, some patients may also have:
  - Skin erythema, warmth, swelling, or tenderness over the ventricular shunt
  - Abdominal pain or tenderness or distension

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

- CBC:
  - Peripheral WBC count is of little predictive value.
- C-reactive protein:
  - Predictive value unclear; future studies needed
- Blood culture:
  - Positive in the minority of cases
- Urine culture to be considered:
  - Patients with myelomeningocele are prone to urinary tract infections.
  - Patients who self-catheterize are prone to bacterial colonization.

#### Imaging

- CT scan of the brain
- Plain x-rays of the ventricular shunt system to assess for disconnection or twisting of distal catheter
- In the presence of abdominal symptoms such as tenderness or distension, US to assess for abdominal pseudocyst

#### Diagnostic Procedures/Other

Ventricular shunt needle puncture:

- Procedure involves carefully cleansing the skin with an antiseptic solution, then inserting a small, hollow needle.
- Proceed with caution: Incidence of tap-related infection is unknown but has been reported to be as high as 32% in patients requiring multiple taps (1):
  - CSF is sent for cell count, glucose, protein, Gram stain, and culture.
  - Increased CSF WBC count, higher protein, and lower glucose are indicative of shunt infection.
  - CSF pleocytosis  $\geq 100,000$  WBC/mm<sup>3</sup> is associated with a 90% positive culture rate (5).
  - The causative organism is identified in 85% of infections (1).
  - False-negative cultures may occur when a ventricular shunt tap is done after antibiotics have been given or when patients are treated with chronic prophylactic antibiotics.
  - In the absence of positive CSF culture, diagnosis of infection is defined as CSF pleocytosis >50 WBC/mm<sup>3</sup> and  $\geq 1$  of the following: Fever, shunt malfunction, neurologic symptoms, or abdominal signs or symptoms.
  - Gram stain is negative in 50% of *Staphylococcus epidermidis* infections (5).
  - Absence of growth from a ventricular shunt tap does not eliminate the possibility of a contaminated distal catheter. The 1-way valve located distal to the reservoir in most shunts may prevent spread of the organism proximally.

**DIFFERENTIAL DIAGNOSIS**

Ventricular shunt puncture is not indicated in all patients with fever and a shunt:

- Other common sources of fever in children include viral illnesses, otitis media, pharyngitis, pneumonia, and urinary tract infection.
- Symptoms related to ventricular shunt malfunction frequently overlap those associated with infections. Consider ventricular shunt malfunction in patients with symptoms of increased intracranial pressure.
- Consider pseudocyst formation, with or without acute infection, in patients with abdominal pain and distention.

**TREATMENT**

**INITIAL STABILIZATION/THERAPY**

- Patients who appear septic should be treated accordingly, with early goal-directed therapy.
- Patients with signs or symptoms of impending brain herniation should be treated accordingly, with airway management, circulatory support, and emergent CSF drainage.

**MEDICATION**

**First Line**

- Vancomycin 15 mg/kg IV q6h
- Broad-spectrum cephalosporin such as ceftriaxone 50 mg/kg IV per day

**COMPLEMENTARY & ALTERNATIVE THERAPIES**

Intrathecal or intrashunt installation of antibiotics

**SURGERY/OTHER PROCEDURES**

- Externalization of shunt hardware until resolution of infection, followed by replacement of hardware
- If pseudocyst is present, evacuation of the cyst and repositioning of the catheter

**DISPOSITION**

**Admission Criteria**

- All patients with VPS infection that is strongly suspected based on exam or lab findings should be admitted with neurosurgical consultation.
- Critical care admission criteria:
  - Patients with severe illness, signs of increased intracranial pressure, intracranial infection, or vital sign instability

**Discharge Criteria**

Select patients who have a shunt and a fever may be managed as outpatients without the need for a ventricular shunt puncture, after consultation with neurosurgery. These include those who are:

- Stable and well appearing
- Lacking signs and symptoms of shunt malfunction
- Have an obvious source for the fever
- Have not had a ventricular shunt placed within the past 2 mo or recently revised

**Issues for Referral**

Discharged patients should be referred to a neurosurgeon for ongoing follow-up.

**FOLLOW-UP**

**FOLLOW-UP RECOMMENDATIONS**

Discharge instructions and medications:

- Continue home medications.
- Antibiotic prescription for home use should be limited to patients with focal infection on exam and no suspicion of ventricular shunt infection.

**PROGNOSIS**

Mortality related to shunt infection was 10% in 1 long-term follow-up study (6).

**COMPLICATIONS**

- Brain abscess formation
- Abdominal pseudocyst formation
- Peritonitis
- Multiloculated hydrocephalus
- Death

**CODES**

**ICD9**

996.63 Infection and inflammatory reaction due to nervous system device, implant, and graft

**PEARLS AND PITFALLS**

- Ventricular shunt infections are uncommon if surgery was performed > 6 mo previously.
- It is important to evaluate for other sources of fever in patients with ventricular shunts.
- Many patients with infection have subtle clinical findings.
- Physical exam findings of skin erythema, warmth, or swelling or signs of CSF leakage are highly predictive of shunt infection.

# VENTRICULOPERITONEAL SHUNT MALFUNCTION

Jeff Beecher  
Keith Blum

## BASICS

### DESCRIPTION

- A ventriculoperitoneal shunt (VPS) is placed for treatment of hydrocephalus by allowing CSF to be removed from the ventricular system of the brain to the peritoneum:
  - Less commonly used shunt systems exist:
    - Ventriculoatrial shunt, ventriculopleural shunt, or lumboperitoneal shunt
- The shunt involves 3 distinct parts, and each is subject to malfunction:
  - Proximal catheter: Inserted into the ventricular system of the brain
  - Valve: Controls the flow of CSF out of the ventricles:
    - Nonprogrammable valves set at low, medium, or high pressures
    - Programmable valves adjusted to a specific pressure using an external magnet
  - Distal catheter: Removes CSF from the valve to the peritoneum
- Shunt failure may result in cerebral herniation and sudden death.
- Neurosurgery should be consulted promptly in symptomatic patients with shunt malfunction.

### EPIDEMIOLOGY

#### Incidence

- Incidence of malfunction ranges from 25–80% of shunted patients (1–5).
- Malfunction occurs in 25–40% of children within 1 yr of initial insertion (3,6,7).
- 1 study demonstrated 56% of the 1,719 patients shunted experienced at least 1 episode of shunt block in a 12-yr period (1).

### RISK FACTORS

- Children born prematurely and children <6 mo of age or who weigh <3 kg at the time of insertion (2)
- Prior revision(s)

### PATHOPHYSIOLOGY

Infection is often associated with VPS malfunction and obstruction:

- Annual rate of shunt infection is 6.5–13.9% (8)

### ETIOLOGY

- Obstruction of the proximal catheter is the most common cause of VPS malfunction (2):
  - More common in early shunt failure
  - Often seen between the ages of 6 and 10 yr, when a child may outgrow the ventricular catheter initially placed as a neonate/infant, resulting in the tip becoming embedded in the brain parenchyma (7)
  - Obstruction of the catheter fenestrations with the choroid plexus

- Obstruction of the distal catheter (2):
  - The distal tip may become obstructed by omentum.
  - Pseudocysts formed by nonepithelial tissue encapsulating the distal tip, forming a collection of CSF and resulting in obstruction typically associated with infection (9)
  - Distal catheter fractures also result in malfunction:
    - More commonly seen in late shunt failure
- Valve malfunction:
  - Includes disconnections or an obstruction
- Overshunting:
  - May result in subdural hematomas/hygromas/slit ventricle syndrome and results from valve pressure being too low
- Undershunting:
  - Secondary to shunt malfunction or valve pressure being too high
  - May result in large ventricles, fluid fluctuance around the shunt path, and persistent symptoms

## DIAGNOSIS

### HISTORY

- Cause and type of hydrocephalus
- Date of last shunt revision
- Frequency of shunt revisions
- Type of shunt:
  - Programmable or nonprogrammable
  - If a programmable shunt, determine if the patient had a recent MRI:
    - The MRI magnet will likely change the setting of the shunt; this can easily be reset.
- Most common complaints:
  - Headache
  - Vomiting
  - Drowsiness
  - Irritability
  - Somnolence
  - Fever
- A family member may give history that the patient is “not him- or herself,” is “not acting normal,” or that a previous episode of VPS malfunction had a similar presentation:
  - The patient may be unable to provide a specific complaint because of age, developmental delays, or current symptoms.
  - A caregiver may be a valuable resource, especially if he or she has experienced a shunt malfunction in the past (1).

### PHYSICAL EXAM

- Evaluation of the shunt should be completed on all patients with suspected malfunction.
- There are a variety of valves that the patient may have, and each has its own properties:
  - The valve should be located, and if it appears to have a reservoir chamber, digital compression of the chamber may provide valuable information about the patency of the proximal catheter:
    - Not all valves have a depressible chamber.

- Digital compression allows assessment of emptying and, more importantly, refilling:
  - If the chamber does not easily refill, this may indicate a proximal partial or complete occlusion.
  - If the reservoir empties well, it does not exclude distal catheter malfunction.
- HEENT:
  - Head circumference
  - The fontanelle should be palpated, if present:
    - A bulging fontanelle may correlate with a shunt malfunction/obstruction.
    - A flat fontanelle usually correlates with a functioning shunt.
    - A sunken fontanelle may indicate overshunting.
  - The shunt site and its path should be evaluated for fluid or fluctuance, possibly indicating shunt malfunction or undershunting.
  - The shunt site and path should be inspected for erythema, edema, drainage, or skin breakdown.
  - Ooscopic evaluation should be done to assess for otitis media.
  - Eyes:
    - Funduscopic exam to evaluate for papilledema or optic nerve atrophy resulting from increased intracranial pressure (ICP)
    - Extraocular muscles should be evaluated, as increased ICP may result in cranial nerve palsies.
- Neck:
  - Palpation to elicit tenderness possibly from infection or disconnection/breakage
  - Evaluate for fluid fluctuance along the catheter.
  - Evaluate for meningismus.
- Abdomen:
  - Palpation to elicit tenderness possibly from infection or pseudocyst formation
  - The surgical incision should be inspected for infection, dehiscence, and adhesions.
- Neurologic:
  - Mental status
  - Irritability, drowsiness, or lethargy
  - Glasgow Coma Scale, cranial nerve evaluation, reflexes, and motor and sensory evaluation

### DIAGNOSTIC TESTS & INTERPRETATION

#### Imaging

- CT brain without contrast:
  - Evaluation for signs of increased ICP, shunt disconnection, misplacement, subdural hematomas/hygromas, and changes from prior CT studies (10):
    - Subtle changes may be indicative of shunt malfunction.
- US of the brain may be utilized in children with an open fontanelle.
- A shunt series:
  - A collection of x-rays visualizing the complete shunt path, evaluating for disconnection
- US/CT of the abdomen/pelvis:
  - Indicated in patients with abdominal distention or fluctuance of the shunt site to evaluate for pseudocyst, abscess, and other abdominal pathology

**Diagnostic Procedures/Other**

- Each of these procedures is most safely performed by a neurosurgical team.
- If necessary, they may be performed by other treating physicians in the emergency department, usually in emergent circumstances.
- Consultation with a neurosurgeon is strongly recommended.
- Procedures:
  - Shunt tap:
    - Performed by inserting a 25-gauge butterfly needle into the reservoir
  - Ventricular puncture:
    - Only used emergently in cases of cerebral herniation
    - Either through an open fontanelle or through an existing craniotomy hole where the VPS is placed using a 2.5–3-inch, 18–22-gauge spinal needle
  - Lumbar puncture:
    - If performed in a noncommunicating hydrocephalus with shunt malfunction, this may result in serious neurologic sequelae or cerebral herniation.

**DIFFERENTIAL DIAGNOSIS**

- Infection:
  - Upper respiratory infection, other viral illnesses, otitis media
- Increased abdominal pressure:
  - Constipation
- Intracranial mass or fluid collection
- Metabolic abnormalities

 **TREATMENT**

**INITIAL STABILIZATION/THERAPY**

- Patients presenting with signs and symptoms of VPS malfunction require prompt diagnosis and treatment to prevent serious sequelae:
  - In patients with whom there is a strong suspicion of VPS malfunction, consult the neurosurgeon promptly.
  - VPS “tap” removing CSF via the reservoir to decrease ICP as well as to evaluate for malfunction or infection:
    - In settings or scenarios where a neurosurgeon may not be accessible on site promptly, it may be recommended that the treating physician perform this. See Diagnostic Procedures/Other.
    - If the tap reveals good return of CSF, this indicates that the proximal catheter is patent and a distal malfunction should be considered.
    - The CSF should be sent for Gram stain, cell count, protein, glucose, and culture.
  - If the tap does not allow for good CSF removal, this indicates proximal catheter malfunction; these patients are typically urgently taken to the operating room for shunt revision.

**DISPOSITION**

**Admission Criteria**

- Critical care admission criteria:
- Patients suspected of VPS malfunction should be admitted to an ICU or other unit that provides close monitoring.

**FOLLOW-UP**

**FOLLOW-UP RECOMMENDATIONS**

If VPS malfunction has been evaluated and ruled out:

- Follow up with the patient’s primary care provider or neurosurgeon for reassessment after discharge.
- If the patient’s neurosurgeon is not within the same hospital system or does not have access to emergency department imaging, discharge the patient with a copy of his or her imaging studies.

**PROGNOSIS**

- Studies demonstrate a 1.4–4% mortality rate of shunted patients (11)
- With prompt diagnosis and intervention, the prognosis is fairly good.
- The overall prognosis is largely dependent on the underlying brain morphology and organic etiology of the initial hydrocephalus (7).

**COMPLICATIONS**

- Cerebral herniation
- Permanent central neurologic deficit
- Death

**See Also (Topic, Algorithm, Electronic Media Element)**

- Meningitis
- Ventriculoperitoneal Shunt Infection

 **CODES**

**ICD9**  
996.2 Mechanical complication of nervous system device, implant, and graft

**PEARLS AND PITFALLS**

- Pearls:
  - Early recognition and treatment are important factors for a favorable outcome.
  - Initiate early neurosurgery consultation.
  - Subtle changes on imaging studies may indicate increased ICP and shunt malfunction.
  - Caregivers are often extremely useful in detecting changes in patient behavior or recognizing similar presentation in a previous episode of VPS malfunction.
  - Proper family education and early medical evaluation when the child demonstrates worrisome symptoms are essential to prevent death.
- Pitfalls:
  - Not recognizing that prior films may have been equally abnormal to current films. Prior films may have indicated malfunction; therefore, no change from a prior exam may be seen with VPS malfunction.
  - Performing a lumbar puncture in the face of a shunt obstruction in a patient with obstructive hydrocephalus. This may result in cerebral herniation.
  - The majority patients who die from shunt malfunction usually have symptoms days or weeks prior to diagnosis (12).

# VOLVULUS

Sandy Saintonge  
Todd A. Mastrovitch

## BASICS

### DESCRIPTION

- Volvulus is abnormal twisting of the gut that may result in:
  - Bowel obstruction
  - Bowel ischemia
- Therefore, volvulus is a life-threatening surgical emergency
- It can occur at many sites along the GI tract:
  - Midgut volvulus is the most common type in children.
  - Segmental volvulus may occur at any age because of adhesions from previous abdominal surgery or abnormal intestinal contents.
- The most common reason for volvulus in pediatrics is congenital malrotation of the intestines.
- Most pediatric patients with volvulus present during infancy.

### EPIDEMIOLOGY

#### Prevalence

- Volvulus is estimated at 1/6,000.
- Intestinal malrotation is estimated at 1/600 births.
- Autopsy results reveal 0.2–1% prevalence of malrotation.

### RISK FACTORS

- Intestinal malrotation
- Gastroschisis
- Omphalocele
- Congenital diaphragmatic hernia
- Adhesions from previous abdominal surgery

### PATHOPHYSIOLOGY

During embryogenesis, the small and large bowel are malpositioned, which predisposes to twisting at points of abnormal fixation.

### ETIOLOGY

Malrotation results from the gut torsion upon itself or upon a small mesenteric pedicle.

### COMMONLY ASSOCIATED CONDITIONS

- Malrotation
- Obstructing (Ladd) bands
- Polysplenia, asplenia
- Abdominal wall defects

## DIAGNOSIS

### HISTORY

- Symptoms of acute or recurrent obstruction at birth or during the 1st year of life
- Acute onset of bilious vomiting and acute abdomen
- Though uncommon, the patient may present with a history of chronic feeding intolerance, episodic abdominal pain, or failure to thrive.
- Symptoms may be subtle, may include diarrhea and constipation, and may be intermittent.
- Frankly bloody stools are a late finding and indicate bowel necrosis.

### PHYSICAL EXAM

- Tachypnea and/or tachycardia may be present.
- Abdominal tenderness or fullness with or without distention
- Irritability or lethargy may be present.
- Brawny edema of the abdominal wall
- Drawing up of the legs
- The abdominal wall may have a blue hue if the bowel is ischemic or necrotic.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

- The diagnosis is primarily clinical, augmented by imaging studies.
- The following may be helpful to determine the degree of resuscitation required or preoperatively to correct abnormalities:
  - Serum chemistry to evaluate for metabolic acidemia
  - Serum lactate
  - CBC: Peripheral leukocytosis
  - PT/PTT, disseminated intravascular coagulation panel: Signs of coagulopathy

### Imaging

- Imaging studies are an essential component of the diagnostic process.
- Abdominal x-rays should be obtained, which should include an upright view as well as a flat plate view:
  - Findings on plain x-ray include:
    - Double bubble sign
    - Paucity of gas in lower intestines
    - Air-fluid levels OR
    - Normal gas pattern
  - A high index of suspicion with a normal x-rays should warrant further studies.
- An upper GI contrast series is the easiest and most confirmatory for diagnosis:
  - Findings may include:
    - Obstruction of contrast at the site of the volvulus
    - Bird's beak sign with proximal dilation of the bowel
    - Corkscrew or spiral configuration
  - If the initial upper GI series is normal and suspicion is high, the contrast should be followed through past the ligament of Treitz.
  - A barium enema should be performed if the lower GI system is suspected. It may also be indicated when the upper GI series is normal:
    - Barium enema may show abnormal position of the cecum.
- Abdominal CT with contrast and US may also be used to make the diagnosis but have lower sensitivity than a contrast GI study.

### DIFFERENTIAL DIAGNOSIS

- Duodenal atresia
- Pyloric stenosis
- Intussusception
- Necrotizing enterocolitis
- Appendicitis
- Intestinal obstruction
- Acute gastroenteritis
- Abdominal mass

## TREATMENT

### PRE HOSPITAL

- Address airway, breathing, and circulation.
- It is likely that IV fluid administration will be indicated.

### INITIAL STABILIZATION/THERAPY

- Fluid resuscitation
- NPO
- Placement of an NG tube to low wall suction
- Early involvement of the surgical service

### MEDICATION

- Morphine 0.1 mg/kg IV/IM/SC q2h PRN
  - Initial morphine dose 0.1 mg/kg IV/SC may be repeated q15–20min until pain is controlled then q2h PRN
- Administration of broad-spectrum antibiotics similar to therapy for appendicitis or bowel perforation:
  - Piperacillin/Tazobactam:
    - >9 mo of age, <40 kg: 300 mg piperacillin component/kg/day in divided doses q8h
    - >40 kg: 3 g piperacillin/0.375 g tazobactam q6h
  - Cefoxitin 100 mg/kg/day divided q6h, max dose 12 g/day
  - Cefotetan 40–80 mg/kg/day divided q12h, max dose 6 g/day
  - If penicillin allergic:
    - Gentamicin (2–2.5 mg/kg/dose q8h) and metronidazole (30 mg/kg/day in divided doses q6h, max dose 4 g/day)

### SURGERY/OTHER PROCEDURES

- Ladd procedure, in which the bowel is detorsed, peritoneal bands are divided, ischemic nonviable bowel is resected, and the small and large bowel is replaced in the correct anatomic position within the peritoneal cavity
- Bowel resection may be necessary for necrotic gut.

### DISPOSITION

#### Admission Criteria

Critical care admission criteria:

- Sepsis, shock, or significant hemorrhage
- Consider admitting more stable patients to the ICU while awaiting surgery, as the risk of rapid change in status or decompensation is possible.

### Discharge Criteria

- Patients with volvulus should be admitted from the emergency department.
- After surgery, patients may be discharged if they are afebrile, under adequate pain control, and tolerating an oral diet.

### Issues for Referral

Recurrent symptoms in a patient who has undergone primary repair of volvulus or bowel resection

## FOLLOW-UP

### FOLLOW-UP RECOMMENDATIONS

#### Patient Monitoring

Monitor for recurrent symptoms of bowel obstruction.

#### DIET

Patients may require IV parenteral nutrition if they have had a significant bowel resection.

#### PROGNOSIS

Mortality is estimated at 3–18% and depends on the extent of bowel ischemia at surgery.

#### COMPLICATIONS

- Bowel necrosis
- Rarely, recurrent volvulus
- Short gut syndrome
- Obstruction due to adhesion
- Death

- Vomiting

## CODES

### ICD9

- 560.2 Volvulus
- 751.4 Congenital anomalies of intestinal fixation
- 751.5 Other congenital anomalies of intestine

### PEARLS AND PITFALLS

- Volvulus is a life-threatening surgical emergency. Diagnosis and definitive therapy should occur as rapidly as possible.
- Consultation with a surgeon early in management, even prior to the definitive diagnosis, may be helpful.
- Since plain radiographs can be normal, x-rays are not adequate to exclude a diagnosis of volvulus
- Consider admission for observation and repeat upper GI series if the initial series is indeterminate.

# VOMITING

Miguel Glatstein  
Dennis Scolnik

## BASICS

### DESCRIPTION

- Although it often represents a transient response to a self-limited infectious, chemical, or psychological stimulus, vomiting can also be a symptom of serious or life-threatening illness.
- Vomiting is a common childhood condition that often causes dehydration.
- A complete history and physical exam reveals most causes of vomiting.
- Life-threatening causes related to the CNS, GI, and endocrine systems can present very subtly.
- If GI obstruction occurs below the 2nd part of the duodenum, vomitus is usually bile stained.
- Ileus is a functional obstruction resulting from a dynamic bowel and can be caused by any serious underlying disease or infection.

### EPIDEMIOLOGY

Vomiting is one of the most common causes of emergency department visits:

- The usual cause in children is gastroenteritis.

### GENERAL PREVENTION

- Vaccine use:
  - Rotavirus
  - Hepatitis A
  - Salmonella
- Appropriate hygiene to prevent gastroenteritis, especially in endemic areas

### PATHOPHYSIOLOGY

- Emesis is a complex process coordinated by the vomiting center in the lateral reticular formation of the medulla.
- This center receives input from the chemoreceptor trigger zone in the area postrema in the floor of the 4th ventricle, from the vestibular apparatus via the cerebellum, from higher brainstem and cortical structures, and from visceral afferents that originate in peripheral structures such as the heart, testes, and the GI tract.
- As a consequence, vomiting can be caused by many pediatric conditions.

### ETIOLOGY

- Causes of vomiting in newborn infants:
  - GI causes:
    - Gastroesophageal reflux (GER)
    - Milk allergy, obstructive conditions (eg, meconium ileus, duodenal atresia or web, volvulus, imperforate anus)
    - Hirschsprung disease
    - Necrotizing enterocolitis
  - Non-GI causes:
    - Neurologic (eg, hydrocephalus, cerebral edema, shaken baby syndrome)
    - Acute renal failure
    - Infection (eg, sepsis, meningitis, urinary tract infection [UTI])
    - Metabolic (eg, inborn errors of metabolism, congenital adrenal hyperplasia)

- Causes of vomiting in infants:
  - GI causes:
    - GER
    - Acute gastroenteritis (AGE)
    - Pyloric stenosis
    - Obstruction (eg, malrotation, intussusception, incarcerated hernia, Hirschsprung disease)
    - Peritonitis
    - Appendicitis
    - Esophageal foreign body
  - Non-GI causes:
    - Neurologic (eg, increased intracranial pressure from hydrocephalus, cerebral edema, tumor, head injury)
    - Renal (eg, acute renal failure and urinary tract obstruction)
    - Infection (eg, sepsis, meningitis, encephalitis, UTI, pneumonia)
    - Metabolic (eg, inborn errors of metabolism such as galactosemia, fructose intolerance, adrenal disease)
    - Posttussive vomiting
    - Intoxication
- Causes of vomiting in older children:
  - GI causes:
    - AGE
    - Obstruction (eg, esophageal stricture, malrotation, foreign body, intussusception)
    - Peptic ulcer
    - Peritonitis
    - Appendicitis
    - Pancreatitis
  - Non-GI causes:
    - Neurologic (eg, brain tumor, head injury)
    - Renal
    - Pregnancy
    - Infection (eg, UTI, meningitis, encephalitis)
    - Metabolic (eg, diabetic ketoacidosis, adrenal insufficiency, Reye syndrome)
    - Anorexia and bulimia
    - Psychogenic
    - Intoxication

### COMMONLY ASSOCIATED CONDITIONS

- Hypoglycemia
- Diarrhea
- Fever
- Dehydration

## DIAGNOSIS

### HISTORY

- Age
- Nature of the vomiting: Timing, color, presence of bile or blood, composition, relationship to eating, position, onset, progression, character (projectile)
- Assessment of hydration status: Intake since last vomit, tears, urine output, activity level
- Associated symptoms: Pain, fever, headache, activity level, weight loss, stooling patterns
- Family history, including congenital diseases
- Past medical history, including previous episodes of vomiting, perinatal and social history, history of intoxication, drug use, sexual and pregnancy history, trauma history

### PHYSICAL EXAM

- Vital signs
- Mental status, Glasgow Coma Scale score
- Assessment of general condition for toxicity and hydration status
- Neurologic exam including sensation, reflexes, tone, and power; pupils and fundoscopy (1)
- Abdominal and genitourinary exam including assessment of the need for a rectal exam

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

- Lab testing is not necessary in most patients.
- Consider serum glucose testing for any younger patient with protracted vomiting or any patient with depressed consciousness.
- Consider serum chemistry analysis in patients with severe vomiting or dehydration.
- For possible bacteremia, consider CBC, C-reactive protein, and blood culture
- For possible meningitis or encephalitis, consider a lumbar puncture for CSF studies.
- Stool culture should be sent in patients with bloody or prolonged diarrhea, or history of travel to tropical areas.
- Consider serum lactate and ammonia to rule out hypoglycemia and metabolic disease in patients with lethargy.
- Associated hematemesis should prompt LFTs and clotting studies.
- Urine or serum pregnancy test

#### Imaging

Imaging is not necessary for most cases but is typically necessary if vomiting is bilious. Consider the following tests as indicated:

- Plain abdominal x-rays (including upright or cross-table lateral)
- Abdominal US or contrast enema if concerned about intussusception
- CT scan of the head for patients with suspected increased intracranial pressure (2)
- Focused abdominal sonograph for trauma (FAST) or abdominal CT for patients with abdominal trauma
- US or abdominal CT for appendicitis
- Upper GI series for malrotation

#### Diagnostic Procedures/Other

- An ECG may be helpful with the management of certain intoxications associated with vomiting.
- The following tests may be ordered after stabilization in the emergency department:
  - Barium swallow and follow-through to evaluate intestinal integrity and swallowing mechanism
  - Endoscopy, manometry, and pH studies as indicated

### DIFFERENTIAL DIAGNOSIS

- “Spitting up” and/or regurgitation
- See Etiology.

## TREATMENT

### PRE HOSPITAL

- Address ABCs.
- In cases of severe dehydration, IV fluid normal saline (NS) boluses of 20 mL/kg may be given.
- Pain relief with parenteral narcotics if necessary
- Patients should be made NPO.

### INITIAL STABILIZATION/THERAPY

- Address ABCs.
- For most children with AGE and mild to moderate dehydration, small, frequent feedings should be given. As a guide for oral rehydration, 50 mL/kg of the oral rehydration solution should be given over 4 hr to patients with mild dehydration and 100 mL/kg over 4 hr to those with moderate dehydration.
- If there are signs of severe dehydration or shock, provide aggressive fluid resuscitation, beginning with 20 mL/kg of NS IV delivered rapidly.
- Delivery of fluids via NG tube is an alternative to IV fluid hydration if IV access has failed (3).
- Monitor urine output to ensure a volume of at least 1–2 mL/kg/hr.
- Frequent reassessment to decide on the need for additional IV fluids
- Keep the patient NPO if a surgical problem is suspected, and consider placing an NG tube to decompress the stomach.

### MEDICATION

- Before considering medications, the cause of the vomiting should be established.
- Appropriate use of rehydration fluids as described should be viewed as a medication.
- A serotonin receptor antagonist such as ondansetron has proven useful for most causes of vomiting (chemotherapy, radiotherapy, poisoning, and AGE) (4). >1 dose has been linked to diarrhea:
  - Ondansetron 0.15 mg/kg PO × 1 dose OR:
    - ≤15 kg: 2 mg PO × 1 dose
    - 15–30 kg: 4 mg PO × 1 dose
    - >30 kg: 8 mg PO × 1 dose
- Antibiotics for systemic infectious causes of vomiting
- Appropriate treatment of intoxications
- Specific treatment of metabolic diseases: As a first line, 150% of fluid requirement as 10% dextrose IV is effective.

### SURGERY/OTHER PROCEDURES

Consultation with the appropriate surgical service for specific causes of vomiting, such as appendicitis, malrotation, hydrocephalus, etc.

### DISPOSITION

#### Admission Criteria

- Ill appearance
- Abnormal vital signs with signs of dehydration despite adequate fluid resuscitation
- Severe dehydration
- Severe abnormal lab values (eg, hyperglycemia/diabetic ketoacidosis, metabolic alkalosis, hypochloremia, hyper- or hyponatremia)

### Discharge Criteria

- In cases of gastroenteritis: Well appearing, no or minimal signs of dehydration, even if still vomiting
- Return precautions understood
- Reliable follow-up
- Ability to maintain hydration

### Issues for Referral

Consultation in the emergency department may be necessary:

- Surgical subspecialties
- Social services or child protective services
- Gastroenterology or metabolism

## FOLLOW-UP

### FOLLOW-UP RECOMMENDATIONS

Discharge instructions and medications:

- Follow up with a primary care provider within 24 hr.
- Frequent PO fluids. See Diet.

### Patient Monitoring

Watch for increased irritability, decreased level of consciousness, poor interaction, excessive sleep, poor feeding, lethargy, decreased urine output, dry mouth, sunken eyes, green vomitus, not passing stool and gas, or a distended abdomen.

### DIET

- In the case of AGE, a normal diet can be given despite ongoing vomiting, as enough may be absorbed to prevent dehydration.
- If there is accompanying diarrhea, highly sweetened fluids such as carbonated beverages and juices should be avoided.
- If milk allergy is suspected, milk and milk products should be avoided and consideration should be given to partially or fully digested formulas.
- Soy products can lead to allergy in many patients allergic to milk products, thus it is not a first-line choice in milk allergy.

### PROGNOSIS

Depending on the underlying cause of the vomiting, the prognosis can range from poor when associated with a life-threatening diagnosis to good for self-limited diseases.

### COMPLICATIONS

- Dehydration can be a complication in any patient with vomiting; if severe, hypovolemic shock may occur.
- Depending on the underlying cause:
  - Metabolic alkalosis with hypochloremia
  - Other electrolyte disturbances
  - Metabolic acidosis
  - Seizures
  - Sepsis
  - Peritonitis
  - Renal failure
  - Complications of intoxications
  - Death

## CODES

### ICD9

- 779.32 Billious vomiting in newborn
- 779.33 Other vomiting in newborn
- 787.03 Vomiting alone

## PEARLS AND PITFALLS

- A fecal odor to the vomitus can occur with peritonitis or a lower intestinal obstruction.
- Inappropriate treatment of the symptom of vomiting without 1st establishing the cause can lead to extremely important diagnoses such as bowel obstruction, intracranial tumor, or meningitis being missed.
- Intermittent volvulus can masquerade as psychogenic illness.

# WARTS

Pinaki N. Patel

Christopher S. Amato

## BASICS

### DESCRIPTION

- Warts (*verrucae vulgaris*) are benign epithelial tumors that may occur on any epithelial surface of the body.
- Human papillomavirus (HPV) is the main causative virus.
- Inoculation period of 2–6 mo prior to the appearance of the wart
- Cutaneous warts, which are raised, round, or oval growths, occur in various types:
  - Common warts (*verruca vulgaris*)
  - Flat (juvenile)
  - Plantar warts (*myrmecia*)
- Epidermodysplasia verruciformis is a rare disease in which lesions manifest in childhood and undergo a malignant transformation during adulthood in 50% of patients.
- Refer to the Genital Warts topic for focused discussion of this disease.

### EPIDEMIOLOGY

- Seen more commonly in certain occupations such as handlers of meat, poultry, and fish
- Incidence of plantar warts is higher in people who share common bathing areas (dormitory students, gym members).
- 1/3 of primary schoolchildren have warts.
- Plantar warts occur most often in children between 12 and 16 yr of age and in young adults.
- Humans are the only reservoir for HPV.

### RISK FACTORS

- Chronic skin conditions such as eczema and psoriasis
- Immunocompromise

### GENERAL PREVENTION

- Do not touch or manipulate warts.
- Use slippers in public showers in order to minimize contact with public surfaces.
- Tools such as nail files and pumice stones that are used to pare down warts should not be shared with other people.
- Athletes engaging in contact sports such as wrestling or American football should cover warts completely or avoid play.
- Cut nails short to prevent school-age children and toddlers from scratching and autoinoculating other areas, such as the eye, mouth, or other body locations.

### PATHOPHYSIOLOGY

- HPV has an affinity for epidermal cells and cannot replicate in nonepithelial tissue.
- While replicating, the viruses induce rapid proliferation of epithelial cells.

### ETIOLOGY

HPV infects the epithelial tissues of skin and mucous membranes:

- > 150 distinct HPV subtypes:
  - HPV types 2 and 4 are the most common cause of common warts.
  - HPV type 1 causes plantar warts by infecting the soles of the feet.
  - HPV types 3, 10, and 28 cause flat warts.
  - HPV types 6 and 11 cause anogenital warts by infecting the anogenital area.

## DIAGNOSIS

### HISTORY

- Visualized change or growth noted
- Warts can develop anywhere on the body.
- They are found singly, in groups, or as plaques.

### PHYSICAL EXAM

- Thorough clinical exam
- Common warts: Appear as rough, hard nodules that are well demarcated or plaques with an irregular surface:
  - Common sites include:
    - Dorsum of the hand
    - Between the fingers
    - On the palms and soles
    - Adjacent to the nails
  - Rarely appear on mucous membranes
  - Are usually asymptomatic unless located on a pressure point
  - Rarely undergo malignant transformation
- Plantar warts: Appear as a thick, painful plaque:
  - Common sites include:
    - Palms
    - Soles
  - Often covered by a thick callus
  - Shaving can reveal punctuate bleeding vessels.
  - Lack dermatoglyphics: The whorls, ridges, and loops seen on the palm, digit, or sole
  - Affect mostly adolescents and young adults
- Flat warts: Appear as multiple papules with irregular contour and smooth surface:
  - Common sites include:
    - Face
    - Neck
    - Hand
  - Affect mostly children
- Epidermodysplasia verruciformis—flat wartlike appearance:
  - Common sites include:
    - Dorsum of the hands and extremities
  - Other sites include the trunk, pubic area, neck, and face, which include pityriasis versicolor–like lesions

### DIAGNOSTIC TESTS & INTERPRETATION

The diagnosis is typically made based on the characteristic appearance of the lesion.

#### Lab

- Histologic evaluation may be used to detect and confirm HPV infection.
- Molecular-based tests include nonamplification tests such as Southern blot and in-situ hybridization.
- Polymerase chain reaction: Technique that can be used to amplify target sequences with the use of primers specifically designed to detect a broad array of HPV

#### Diagnostic Procedures/Other

Bronchoscopy is indicated to evaluate laryngeal papillomatosis, a circumstance in which vertical transmission of HPV to the newborn during passage results in seeding of warts that grow in the airway and lungs.

#### Pathological Findings

Koilocytes with a characteristic halo noted on microscopy

### DIFFERENTIAL DIAGNOSIS

- Amelanotic melanoma
- Molluscum contagiosum
- Acrochordon: Skin tags
- Pedunculated, flesh-colored papules
- Seborrheic keratosis
- Clavus: Corns
- Callus
- Lichen planus: Flat-topped papules

## TREATMENT

### MEDICATION

- Therapy depends on the type, location, extent, patient's immune status, and cooperation.
- Most therapies work by destroying the tissue containing the virus, preserving healthy tissue.
- Use the least painful methods 1st:
  - Aggressive methods should be used on areas where scarring is not a consideration or for symptomatic lesions.
  - Salicylic acid for topical therapy comes in a variety of forms, including liquids and impregnated bandages.
  - Imiquimod 5% cream applied 3 times weekly for up to 16 wk
  - Podophyllin 25% topical solution applied to the head of the wart and washed off in 6 hr:
    - Highly toxic if ingested; a small ingestion may be lethal to a young child.
    - Can cause severe caustic burn if it contacts healthy skin.

**COMPLEMENTARY & ALTERNATIVE THERAPIES**

- Duct tape:
  - Cover the wart with duct tape for 6 days.
  - Remove the tape, soak the area in warm water for 10–20 min, and debride with an emery board or pumice stone.
  - Keep the wart uncovered on the 6th night. Repeat the cycle as needed.
  - The majority of warts will resolve within 28 days of such treatment.
  - Duct tape that has a rubber-based adhesive is more effective than clear duct tape with acrylic adhesive.
  - This treatment may result in severe skin irritation or necrosis in sensitive individuals and should be avoided in diabetics.
- Spontaneous regression may occur in up to 2/3 of warts and within 2 yr; as such, observation may also be used as a form of treatment.

**SURGERY/OTHER PROCEDURES**

- Cryotherapy
- Laser therapy
- Excision or debulking may be used for plantar warts or for large wart masses prior to other surgical or medical therapy.

**DISPOSITION**

**Discharge Criteria**

Patients should have follow-up with a clinician capable of ongoing treatment of warts if further treatment is necessary.

**Issues for Referral**

Warts that are extensive, in cosmetically sensitive locations, refractory to therapy, or for which the primary caregiver is uncomfortable treating may be referred to dermatology.

**FOLLOW-UP**

**FOLLOW-UP RECOMMENDATIONS**

Discharge instructions and medications:

- Use medication or therapy for the full course as indicated.

**PROGNOSIS**

- Warts typically resolve, though multiple treatments may be necessary.
- Some HPV types induce neoplastic transformation and may result in genital tract or oropharyngeal dysplasia or cancer.

**COMPLICATIONS**

- Recurrence
- Superinfection
- Transmission to others
- Dysplasia or cancer of the skin as well as the oropharyngeal or urogenital tract
- Recurrent respiratory laryngopapillomatosis

**See Also (Topic, Algorithm, Electronic Media Element)**

Genital Warts

- ICD9**
- 078.10 Viral warts, unspecified
  - 078.11 Condyloma acuminatum
  - 078.12 Plantar wart

**PEARLS AND PITFALLS**

- It may take several weeks or months of therapy for warts to resolve.
- Parents and older patients may find this frustrating:
  - The use of immediately effective therapies such as cryotherapy is helpful in such circumstances.
- Though the site may look healed, the virus is microscopic and is still present in remaining tissue. Parents and patients should be made aware of this.
- In older children and adolescents, warts in cosmetically significant locations or genital warts may result in significant psychological sequelae, including major depression or suicide.

# WEAKNESS

Steven Krebs

Faye E. Doerhoff

## BASICS

### DESCRIPTION

- Weakness refers to decreased strength or decreased ability to voluntarily move  $\geq 1$  body part against resistance.
- Weakness may be a general complaint or related to a specific body area or function.
- Symptoms may be broad, from mild disruption of function to frank paralysis.
- Weakness in infants may manifest as lethargy, poor feeding, decreased extremity or neck tone, or changes in urinary or bowel habits.
- Guillain-Barré syndrome (GBS) is the most common cause of acute flaccid paralysis in children (1).

### RISK FACTORS

- Family history (acute intermittent porphyria, familial periodic paralysis, muscular dystrophy)
- Environmental/Dietary toxin exposure

### PATHOPHYSIOLOGY

Weakness constitutes dysfunction anywhere along the axis of upper and lower motor units:

- The upper motor unit consists of the motor strip of the cerebral cortex extending through the corticospinal tracts of the spinal cord to the anterior horn cells:
  - Typically characterized by spasticity and hyperreflexia, or increased deep tendon reflexes (DTRs), though early flaccid paralysis may be present
- The lower motor unit consists of the anterior horn cells, peripheral nerves, neuromuscular junction (NMJ), and muscle fibers:
  - Typically characterized by hyporeflexia, fasciculations, hypotonia, and weakness
  - May result in muscle atrophy.

### ETIOLOGY

- Upper motor unit:
  - Cerebral cortex:
    - Stroke: Embolic, thrombotic
    - Cerebral hemorrhage: Traumatic, aneurysm/arteriovenous malformation rupture
    - Brain tumor hemorrhage
    - Todd paralysis
    - Amyotrophic lateral sclerosis (ALS)
  - Spinal cord:
    - Trauma: Cord concussion/spinal shock, epidural hematoma, fracture, dislocation, transection
    - Epidural abscess
    - Spinal cord tumor
    - Discitis
    - Transverse myelitis
    - ALS
    - Anatomic/Congenital: Tethered cord, Chiari malformation, atlantoaxial dislocation

- Lower motor unit:
  - Anterior horn cell: Poliomyelitis, spinal muscular atrophy (SMA), ALS
  - Cranial nerves (CNs): Bell palsy (CN VII palsy), Miller-Fisher syndrome (MFS)
  - Peripheral nerves: GBS/MFS, drug toxicity, Erb/Klumpke palsy (birth trauma), marine toxins, acute intermittent porphyria
  - NMJ: Myasthenia gravis (MG), botulism, tick paralysis, organophosphate toxicity
  - Muscle:
    - Muscular dystrophy (MD)
    - Myotonic dystrophy
    - Dermatomyositis
    - Infectious: Viral myositis, pyomyositis, trichinellosis
    - Metabolic disorders
    - Periodic paralysis, inherited or sporadic
    - Rhabdomyolysis
    - Endocrine disorders
    - Steroid myopathy
- Others: Acute hemiplegic migraine, electrolyte disturbance, hyper-/hypoparathyroidism, hyper-/hypothyroidism, hyper-/hypoadrenalism, heavy metal toxicity, conversion disorder, malingering

## DIAGNOSIS

### HISTORY

- Timing and pattern of symptoms:
  - Sudden severe symptoms without trauma: Stroke, intracranial hemorrhage, brain tumor hemorrhage
  - Subacute onset (days to months) is typical of neuropathies and myopathies.
  - Chronically progressive symptoms suggest congenital etiologies.
  - MG classically worsens through the day with activity and improves with rest.
- Associated injury with weakness suggests intracranial hemorrhage or spinal cord lesion.
- Presence/Description of headache:
  - Sudden onset of severe headache: “Worst headache of my life” raises concern for intracranial hemorrhage.
  - Progressive morning headache, vomiting, and weakness suggests intracranial mass.
  - Hemiplegia with aura phase of migraine (hemiplegic migraine: familial or sporadic)
- Neck or back pain is associated with GBS, transverse myelitis, epidural hematoma or abscess, and poliomyelitis.
- Myalgias suggest infectious, inflammatory (dermatomyositis), or myopathic (rhabdomyolysis) conditions.
- Fever may suggest infectious, autoimmune, or etiologies at any level from upper to lower motor units.
- Seizure activity may indicate stroke, intracranial hemorrhage, or Todd paralysis:
  - Todd paralysis lasts, on average, for 15 hr but may resolve within several hours or last up to 36 hr.
    - Most commonly follows generalized tonic-clonic seizures
    - Typically, there is prior history of seizures.

- Possible triggers or associated activity of chronic or recurrent symptoms:
    - Exercise inducing weakness occurs with MG, rhabdomyolysis, myotonic dystrophy, and periodic paralysis.
    - Fever may trigger exacerbation of acute intermittent porphyria.
  - Dietary history is relevant regardless of age:
    - Honey or home-canned foods (botulism)
    - Undercooked pork or contaminated meat (trichinellosis)
    - Reef fish such as grouper, red snapper, eel, barracuda, and sea bass (ciguatera poisoning)
    - Organic mercury and arsenic from fish, seafood, and seaweed products
  - Voiding/Stooling changes or complaints:
    - Red or brown urine suggest rhabdomyolysis.
    - Constipation for infantile botulism
    - Incontinence or retention may suggest a spinal cord lesion.
  - Medication/Toxin exposure:
    - Prescription medications: Metronidazole, phenytoin, nitrofurantoin, amiodarone:
      - Steroid myopathy may occur following corticosteroid administration:
        - Chronic (classic): Presents weeks to years after prolonged administration
        - Acute: Typically within days of high-dose administration
    - Herbal or dietary supplement use
    - Environmental exposure risk factors:
      - Heavy metal toxicity: Parental occupation, home/local environment, paints:
        - Acute exposures commonly are associated with nausea, vomiting, and abdominal pain.
      - Pesticides (organophosphates)
  - Recent illnesses:
    - *Campylobacter* infection precedes up to 30% of GBS cases:
      - Others: Cytomegalovirus, Epstein-Barr virus, herpes simplex virus, hepatitis A and B virus, *Mycoplasma*, enterovirus, and *Haemophilus influenzae*
    - Bell palsy
  - Family history
  - Developmental history (acquisition or loss of milestones)
- ### PHYSICAL EXAM
- 1st priority is assessment of respiratory status:
    - Concerning signs: Poor effort, weak cough
  - Detailed neurologic exam:
    - Assess quality/symmetry of muscle strength:
      - Widespread weakness occurs in MG, systemic disorders (poisoning, electrolyte disturbance), and periodic paralysis.
      - Asymmetric weakness occurs in CNS lesions (tumor, stroke, hemorrhage), spinal cord lesions, polio, and hemiplegic migraine.
      - Symmetric proximal weakness is more common with myopathies.
      - Distal weakness occurs with peripheral neuropathies.
      - Regional weakness may occur in tick paralysis near the tick bite site.

- Observe the patient walking, sitting, standing:
  - The Gower sign denotes proximal pelvic weakness: MD
- CN exam:
  - Commonly abnormal with GBS/MFS, MG, Bell palsy, SMA, botulism
  - Bilateral facial palsy should be thoroughly investigated, though Bell palsy is the leading cause.
  - Unilateral facial droop sparing the upper face distinguishes cortical stroke from the full facial paralysis seen in Bell palsy.
  - Ptosis is commonly associated with MG and infantile botulism.
- Sensory impairment more commonly is seen in GBS and transverse myelitis and usually is spared with botulism, MG, and MD.
- DTRs:
  - Increased in upper motor unit disease
  - Diminished in lower motor unit disease
  - Preserved in myasthenia syndromes
- Muscle assessment:
  - Hypertrophic “doughy” muscles suggest MDs (Duchenne and Becker).
  - Atrophic muscles and fasciculations suggest lower motor neuron disease.
  - Muscle tenderness suggests local infection or inflammation.
- Spinal tenderness may indicate epidural abscess or transverse myelitis.
- Nuchal rigidity/meningismus may indicate epidural abscess/hemorrhage/hematoma, transverse myelitis, increased intracranial pressure, or poliomyelitis.
- Skin exam for ticks (removal is curative within hours), rash, or infected wounds:
  - Findings with dermatomyositis include heliotrope rash, Gottron papules, and periungual capillary changes.

### DIAGNOSTIC TESTS & INTERPRETATION

Diagnostic testing should be guided by historical and physical findings.

#### Lab

- Blood gas (if respiratory involvement)
- CBC with differential, C-reactive protein
- Serum electrolytes, including calcium, magnesium, phosphate
- Creatine kinase (myopathy, rhabdomyolysis)
- Urinalysis, urine myoglobin (rhabdomyolysis)
- Lumbar puncture for CSF studies:
  - Gram stain and culture, cell count, glucose, protein
  - Elevated protein suggests GBS, though it may be normal in the 1st week of symptoms.

#### Imaging

- CT scan of the brain for any suspected intracranial process: Tumor, stroke, hemorrhage
- Imaging of the spine is indicated for any focal weakness, especially with history of neck or back trauma:
  - Radiographs may show compression, subluxation, or fracture.
  - Emergent spinal MRI if any concern for spinal cord lesion: Tumor, abscess, hematoma

### Diagnostic Procedures/Other

- Pulmonary function testing/assessment in patients with suspected respiratory muscle weakness:
  - Negative inspiratory force measurements
- Electromyography and nerve conduction studies in lower motor unit disease to differentiate neuropathy and myopathy
- Tensilon (edrophonium) test and serum anti-acetylcholine antibodies for MG
- ECG to evaluate for cardiomyopathy in MD
- Muscle biopsy for myopathic conditions

### TREATMENT

Treatment is dependent on the etiology; therefore, a comprehensive description of treatment is beyond the scope of this topic.

#### PRE HOSPITAL

- In the setting of trauma, spinal immobilization per Advanced Trauma Life Support (ATLS) protocols
- Assess and stabilize airway, breathing, and circulation.

#### INITIAL STABILIZATION/THERAPY

Assess and stabilize airway, breathing, and circulation.

#### MEDICATION

##### First Line

- Analgesics for myositis/myalgia:
  - Ibuprofen 10 mg/kg/dose PO/IV q6h PRN
  - Ketorolac 0.5 mg/kg IV/IM q6h PRN
  - Naproxen 5 mg/kg PO q8h PRN
  - Acetaminophen 15 mg/kg/dose PO/PR q4h PRN
- Hydration (PO or parenteral) for rhabdomyolysis:
  - Consider alkalization of urine.
- Antibiotics for abscess/pyomyositis:
  - See the Abscess topic for specific antibiotics.

##### Second Line

- IV immunoglobulin or plasmapheresis may be considered for severe cases of GBS.
- Acyclovir/steroids may be considered for Bell palsy (see the Facial Nerve Palsy topic).

#### DISPOSITION

##### Admission Criteria

- Any condition with potential to jeopardize respiratory status: GBS, toxin mediated, etc.
- Inability to perform routine activities of daily living or concern for progression of symptoms
- Critical care admission criteria:
  - Intracranial process with a need for invasive monitoring or high risk for sudden deterioration
  - Respiratory failure requiring intubation
  - Systemic illness with potential for cardiorespiratory collapse

##### Discharge Criteria

Low degree of disability and no concern for progression: Viral myositis, Bell palsy, Todd paralysis, etc.

##### Issues for Referral

- Neurosurgery consultation in the emergency department: Spinal cord trauma, epidural abscess, or CNS lesion that may require operative management/invasive monitoring
- Neurology consultation: Acute and/or focal weakness, other focal abnormalities on neurologic exam, or any patient being admitted for complaints related to weakness

### FOLLOW-UP

#### FOLLOW-UP RECOMMENDATIONS

Dependent on underlying etiology

#### PROGNOSIS

Based on etiology of symptoms

#### COMPLICATIONS

- Death from respiratory failure
- Secondary injury from falls
- Varies with etiology

#### REFERENCE

1. Jones HR Jr. Guillain-Barré syndrome: Perspectives with infants and children. *Semin Pediatr Neurol.* 2000;7(2):91–102.

#### ADDITIONAL READING

- Fenichel GM, ed. *Clinical Pediatric Neurology: A Signs and Symptoms Approach.* 6th ed. Philadelphia, PA: Saunders Elsevier; 2009.
- Fuchs S. Weakness. In Strange GR, Ahrens WR, Schafermeyer RW, et al., eds. *Pediatric Emergency Medicine.* 3rd ed. New York, NY: McGraw-Hill; 2009.
- Tsarouhas N, Decker JM. Weakness. In Fleisher GR, Ludwig S, eds. *Textbook of Pediatric Emergency Medicine.* 6th ed. Philadelphia, PA: Lippincott Williams & Wilkins; 2010.

### CODES

#### ICD9

- 728.87 Muscle weakness (generalized)
- 779.89 Other specified conditions originating in the perinatal period
- 780.79 Other malaise and fatigue

#### PEARLS AND PITFALLS

- Conditions causing acute weakness have the potential to be life threatening, resulting in respiratory failure or CNS damage.
- Botulism may be caused by ingestion of toxin, bacterial colonization (infantile), or contamination or infection of a wound.
- Weakness may be confused with ataxia, which may be differentiated by exam.

# WHEEZING

Vincent J. Wang  
Jaw J. Wang

## BASICS

### DESCRIPTION

- Wheezes are whistling or musical adventitious sounds that are the hallmark of lower airway constriction and/or obstruction:
  - Wheezes are continuous sounds most frequently heard during expiration.
  - Rales or crackles, in contrast, are intermittent or discontinuous popping noises.
- This topic will focus on the approach to wheezing. For more details on the causes of wheezing and the management of these causes, please see the respective topics (eg, Asthma, Bronchiolitis, Pneumonia topics, Pulmonary Edema, Angioedema, Congenital Heart Disease, Foreign Body Aspiration, Gastroesophageal Reflux, etc.).

### EPIDEMIOLOGY

#### Prevalence

- Almost 50% of children <6 yr of age will wheeze once (1).
- An episode of wheezing may occur at least once in 20% of infants <1 yr of age.
- <15% of children will develop asthma (1,2).
- Seasonal variation occurs, with peaks during the winter months.

### RISK FACTORS

- Particulate air pollution
- Smoking (primary and secondary)
- Pollen and other allergens

### GENERAL PREVENTION

Avoidance of precipitants

### PATHOPHYSIOLOGY

- Obstruction to air flow is the common factor in all conditions that produce wheezing.
- Wheezing usually results from obstruction of the intrathoracic lower airways (bronchioles):
  - Less commonly, wheezing occurs from narrowing of the trachea or bronchi.
- Obstruction of the lower airway passages may be anatomic or physiologic and is the result of extrinsic airway compression or intrinsic airway narrowing:
  - Intrinsic airway narrowing may be caused by bronchial or bronchiolar constriction, inflammation, and/or intraluminal airway blockage.
  - Wheezing may also be caused by a combination of these factors simultaneously, as in asthma.

### ETIOLOGY

- The most common causes of wheezing are bronchiolitis and asthma:
  - Bronchiolitis is an acute viral infection of the lower respiratory tract predominantly caused by respiratory syncytial virus. This typically affects children <2 yr of age.
  - Asthma is a chronic inflammatory disorder of the airways, characterized clinically by recurrent exacerbations involving symptoms of coughing and/or wheezing.

- Less common causes are:
  - Pneumonia, both bacterial and viral
  - Foreign body aspiration, which occurs more commonly in toddler-aged children but may be seen at any age
  - Recurrent aspiration of food or gastric contents: Gastroesophageal reflux, disorders of swallowing and esophageal motility, and structural abnormalities of the tracheolaryngeal complex
  - Allergic reaction or anaphylaxis: Wheezing is of sudden onset and may be accompanied by  $\geq 1$  other clinical findings that include urticaria, angioedema, stridor, and hypotension.
  - Smoking and air pollutant exposures may cause transient wheezing.
  - Bronchopulmonary dysplasia and chronic lung disease (CLD)
- Rare causes of wheezing:
  - Cardiovascular abnormalities and congenital heart disease
  - Cystic fibrosis, immotile cilia syndrome
  - Pulmonary edema
  - Children with various defects in host defense mechanisms often present with recurrent wheezing and bacterial pulmonary infections.
  - An enlarged lymph node or tumor may cause extrinsic tracheobronchial compression.
  - Congenital structural anomalies of the respiratory tract, including bronchogenic cysts, cystic malformations of the lung, congenital lobar emphysema, intrinsic stenosis, and webs
  - Psychogenic wheezing or malingering: These patients are typically adolescents who may generate wheezing noises in their larynx.
  - Parasitic infections, TB, sarcoidosis, vascular rings/slings, histoplasmosis, allergic bronchopulmonary aspergillosis, and carcinoid syndrome

## DIAGNOSIS

### HISTORY

- Age of onset
- Course of symptoms: Sudden vs. gradual
- Recurrence of symptoms
- Choking
- Cyanosis
- Cough and rhinorrhea
- Fever
- History of failure to thrive
- Ill contacts with similar symptoms
- Past medical history, including neonatal history and premature birth
- Family history of asthma or other conditions
- Travel history
- Time of year: Winter season may indicate infectious causes such as bronchiolitis or pneumonia.

### PHYSICAL EXAM

- Vital signs—temperature, heart rate, respiratory rate, and BP:
  - Increasing pulsus paradoxus occurs with worsening asthma.
- Degree of respiratory distress assessing for cyanosis, retractions, work of breathing, and respiratory fatigue
- Diffuse or unilateral wheezing
- Rales or crackles
- Other associated signs
- Bronchiolitis: Rhinorrhea, fever, staccato-like cough, and a variable degree of respiratory distress, often with rales on auscultation
- Asthma: Atopic skin, diffuse or unilateral wheezing, and a variable degree of respiratory distress
- Pneumonia and foreign body aspiration: Mild tachypnea, focal wheezes or rales on auscultation:
  - Presence of fever for pneumonia
- Gastroesophageal reflux: Vomiting or spitting up, arching of the back in infants (Sandifer syndrome)
- Cystic fibrosis: Peripheral clubbing, failure to thrive, diarrhea, steatorrhea
- Anaphylaxis: Urticaria, lip swelling, stridor, hypotension, emesis, diarrhea, angioedema
- Cardiovascular abnormalities and congenital heart disease: Heart murmur, abnormal heart sounds, cyanosis, hepatomegaly, diaphoresis

### DIAGNOSTIC TESTS & INTERPRETATION

- Pulse oximetry is the most helpful adjunctive measurement to assess degree of pulmonary insufficiency:
  - Normal pulse oximetry values are  $\geq 95\%$  but may be lower in higher altitudes.
  - Accepted pulse oximetry values for bronchiolitis are  $\geq 90\%$  (3).
- Most causes of wheezing can be determined by history, physical exam, and selective testing.
- The peak expiratory flow rate is useful in assessing the degree of resistance to airflow in asthma exacerbations.

### Lab

#### Initial Lab Tests

- Arterial blood gas or capillary blood gas for severe respiratory distress
- End-tidal  $\text{CO}_2$  monitoring may be useful in assessing carbon dioxide retention as an indicator of respiratory decompensation.

**Imaging**

- Patients with bronchiolitis or exacerbation of asthma typically do not need routine imaging.
- Chest radiograph: PA and lateral for pneumonia, CLD, suspected foreign body aspiration, cystic fibrosis:
  - Inspiratory and expiratory or decubitus films for suspected foreign body aspiration
- The following tests may be obtained during hospital admission or as an outpatient if stable:
  - Chest CT scan for suspected malignancies, congenital structural abnormalities
  - Upper GI series for suspected swallowing disorders
  - CT angiography for vascular rings/slings

**Diagnostic Procedures/Other**

- Laryngoscopy and bronchoscopy must be performed emergently for suspected foreign body aspiration.
- The following may be performed during hospital admission or as an outpatient if stable:
  - Sweat chloride testing for cystic fibrosis
  - PPD placement for suspected TB

**DIFFERENTIAL DIAGNOSIS**

See Etiology.

**TREATMENT****PRE HOSPITAL**

- Support ABCs.
- Oxygen
- Albuterol nebulized treatments PRN
- IV hydration PRN

**INITIAL STABILIZATION/THERAPY**

- Initial therapy focuses on supporting the patient's respiratory efforts, including providing oxygen and nebulized or aerosolized albuterol treatments if indicated.
- If concomitant dehydration is present, oral or IV hydration should be provided.

**MEDICATION**

- Oxygen should be administered to patients with hypoxemia. Consider oxygen administration in patients with respiratory distress or increased work of breathing.
- Bronchodilators, corticosteroids, or adjunctive medication may be indicated to treat asthma, bronchiolitis, or anaphylaxis. See associated topics on Asthma, Bronchiolitis, or Anaphylaxis for further information.
- Antibiotics as indicated for bacterial pneumonia. See the Pneumonia topic for drug choices and dosing regimens.

**DISPOSITION****Admission Criteria**

- Inpatient ward admission criteria:
  - Hypoxemia
  - Moderate respiratory distress
  - Dehydration
- Critical care admission criteria:
  - Respiratory failure or severe respiratory distress
  - Anaphylaxis with laryngoedema or hypotension
  - Tracheal foreign body aspiration requires immediate removal in the operating room.

**Discharge Criteria**

- Not hypoxic
- Well hydrated
- Minimal or no respiratory distress
- Adequate follow-up

**Issues for Referral**

Suspected new diagnosis of cystic fibrosis, congenital heart disease, severe asthma, immunodeficiency, swallowing disorder, etc.

**FOLLOW-UP****FOLLOW-UP RECOMMENDATIONS**

Discharge instructions and medications:

- Continue current respiratory regimen of bronchodilators or other pulmonary medications as directed.
- Ensure adequate hydration.
- Consider inhaled corticosteroid for moderate persistent asthmatic patients.

**DIET**

If anaphylaxis, avoidance of foods that precipitate anaphylaxis is necessary.

**PROGNOSIS**

The prognosis depends on the underlying condition.

**COMPLICATIONS**

- Depends on etiology and severity
- Dehydration
- Hypoxemia
- Respiratory failure and death may result from severe airway constriction.

**CODES**

ICD9

786.07 Wheezing

**PEARLS AND PITFALLS**

- Pearls:
  - Recognizing appropriate age groups for the different diagnoses
  - Well-appearing, well-hydrated patients with bronchiolitis and a pulse oximetry reading  $\geq 90\%$  may be considered for discharge home.
- Pitfalls:
  - Failure to appropriately treat asthma exacerbation may result in deterioration with severe morbidity and mortality.
  - Failure to recognize severe disease, such as foreign body aspiration, cardiogenic wheezing, or cardiac failure
  - Failure to recognize psychogenic wheeze or malingering, especially in an adolescent
  - Not ensuring adequate follow-up

# WILMS TUMOR

Kimberly A. Randell

## BASICS

### DESCRIPTION

- Wilms tumor is the most frequently occurring pediatric renal tumor.
- 5th most common solid tumor in children (1)
- Also called *nephroblastoma*

### EPIDEMIOLOGY

#### Incidence

- 7.6 cases per million children <15 yr of age annually in the U.S. (2):
  - 500 new cases annually in the U.S. (2)
- More common in boys than girls
- Accounts for 6% of all new cases of childhood cancer patients per year (2)
- Bilateral disease:
  - Incidence of 4.4–7% for synchronous disease (tumor in both kidneys at the same time) (2)
  - Incidence of 1–1.9% metachronous (tumor in both kidneys, presenting at different times) (2)
- 80% present by 5 yr of age, with peak at 3 yr of age (1,3).

### RISK FACTORS

- Overgrowth syndromes:
  - Hemihypertrophy
  - Beckwith-Wiedemann
  - Denys-Drash syndrome
  - Sotos syndrome
- WAGR syndrome:
  - Wilms tumor
  - Aniridia
  - Genitourinary malformations
  - Mental retardation
- Genitourinary anomalies
- Neurofibromatosis
- Family history of Wilms tumor

### PATHOPHYSIOLOGY

- Develops from pluripotent embryonic renal precursor cells
- 2-hit hypothesis: Tumor develops due to 2 mutational events in tumor suppressor genes.
- Evidence suggests tumor due to alterations in multiple genes:
  - Wilms tumor genes: WT1, WT2
  - Alterations of tumor suppressor gene p53
  - Multiple other genetic mutations potentially are involved.

### ETIOLOGY

- Sporadic
- Associated with genetic syndromes
- Familial (1–2%):
  - Autosomal dominant with incomplete penetrance

### COMMONLY ASSOCIATED CONDITIONS

See Risk Factors.

## DIAGNOSIS

### HISTORY

- Abdominal mass (often noted by caretaker)
- Abdominal distention:
  - May develop rapidly if hemorrhage into tumor
- Gross hematuria
- Abdominal pain (30%)
- Systemic symptoms:
  - Anorexia
  - Weight loss
  - Fever
  - Malaise
- Excessive bleeding (possible acquired von Willebrand syndrome)
- Family history of Wilms tumor

### PHYSICAL EXAM

- HTN (25%) (2):
  - Attributed to increased renin activity
- Abdominal distention
- Abdominal mass:
  - Extends from the flank toward the midline
  - Hard
  - Smooth
  - Typically does not move with respiration
- Varicocele when supine:
  - Suggests venous obstruction
- Signs of Wilms tumor–associated syndromes:
  - Hemihypertrophy
  - Genitourinary anomalies
  - Aniridia
  - Signs of neurofibromatosis
- Signs of hepatic veno-occlusive disease may include hepatomegaly, right upper quadrant tenderness, jaundice, ascites, or fever.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

- Urinalysis:
  - Hematuria (30%) (1)
- Basic metabolic panel:
  - Hypercalcemia (seen with rhabdoid tumor of kidney or congenital mesoblastic nephroma)
- CBC:
  - Anemia (possibly due to hemorrhage into tumor)
  - Polycythemia
- Hepatic enzyme tests
- Increased lactate dehydrogenase
- Consider coagulation studies:
  - Acquired von Willebrand disease is seen in 8% (2).

#### Imaging

- Abdominal x-ray:
  - Mass contour in flank
  - Displacement of bowel gas to the contralateral abdomen
- Abdominal US:
  - Differentiates solid (like Wilms) from cystic mass
  - May show origin of the mass
  - Doppler study to assess for tumor extension into the inferior vena cava (IVC)
- Abdominal CT:
  - Further delineation of extent of the tumor
  - May show small lesions in the contralateral kidney
- CXR:
  - May show metastases
- Chest CT scan:
  - More sensitive detection of metastatic disease, though not all nodules seen on CT are metastatic lesions.
  - A preoperative scan is more helpful, as postoperative atelectasis and/or pleural effusions may confuse the diagnostic picture.

#### Diagnostic Procedures/Other

- Biopsy or tumor excision with histologic exam
- Lung biopsy may be considered for pulmonary nodules.

**Pathological Findings**

- Stage I: Tumor confined to the kidney with complete resection
- Stage II: Tumor extends beyond the kidney but is completely resected
- Stage III: Incomplete resection, intraoperative tumor spillage, regional lymph node metastases, transected tumor thrombus
- Stage IV: Hematogenous metastases or lymph node metastases outside the abdomen
- Stage V: Bilateral tumors at diagnosis

**DIFFERENTIAL DIAGNOSIS**

- Benign abdominal masses:
  - Polycystic kidney
  - Renal abscess
  - Renal hematoma
  - Hydronephrosis
  - Teratoma
- Malignant abdominal masses:
  - Clear cell sarcoma of kidney
  - Rhabdoid tumor
  - Renal cell carcinoma
  - Congenital mesoblastic nephroma
  - Neuroblastoma

**TREATMENT****INITIAL STABILIZATION/THERAPY**

- Evaluation of vital signs and assessment of airway, breathing, and circulation
- Hemorrhage into the tumor may require administration of IV fluid boluses.
- Most patients are stable at presentation.

**MEDICATION**

## Chemotherapy:

- Indicated preoperatively in some patients: Tumor extension into the IVC above the hepatic veins, bilateral renal tumors, tumor found to be unresectable during surgery
- Results in loss of staging information
- The most commonly used agents are vincristine and dactinomycin, with or without doxorubicin, depending on staging.

**SURGERY/OTHER PROCEDURES**

- Initial treatment for most children with Wilms tumor:
  - Total resection or partial nephrectomy depending on disease
- Radiotherapy is indicated for stage III tumors, diffuse anaplastic tumors, and some metastatic disease.

**DISPOSITION****Admission Criteria**

All patients with presumptive diagnosis of Wilms tumor should be admitted for confirmation of diagnosis and initial care.

**Issues for Referral**

Consultation with an oncologist and a surgeon for coordination of hospital admission and confirmation of diagnosis.

**FOLLOW-UP****FOLLOW-UP RECOMMENDATIONS**

Discharge instructions and medications:

- Patients should follow up with an oncology specialist as recommended.

**PROGNOSIS**

- 85% overall survival rate (1):
  - Stages I, II: 95%
  - Stage III: 75–80%
  - Stage IV: 65–75%
- Recurrence rates (2):
  - Favorable histology: 15%
  - Anaplastic histology: 50%

**COMPLICATIONS**

- Tumor extension into renal veins and/or IVC (6%), right atrium (rare) (4)
- Metastatic disease (up to 5%) (4):
  - Common: Lung, lymph nodes
  - Uncommon: Liver, bone marrow, brain, bone
- Renal dysfunction
- Hemorrhage into tumor
- Hepatic dysfunction
- 2nd tumors (benign or malignant)
- Hepatic veno-occlusive disease:
  - Hepatomegaly
  - Right upper quadrant pain
  - Jaundice
  - Unexplained weight gain
  - Ascites
  - Fever
  - Elevated liver transaminases
  - Thrombocytopenia
  - Occurs within the 1st 10 wk of treatment

**REFERENCE**

**CODES****ICD9**

189.0 Malignant neoplasm of kidney, except pelvis

**PEARLS AND PITFALLS**

- If tumor growth is slow, caregivers may not notice progressive abdominal distention or a mass, which can be detected by physical exam.
- Children with a single kidney should wear a kidney guard during contact sports.

# WITHDRAWAL SYNDROMES

Robert J. Hoffman  
Adhi Sharma

## BASICS

### DESCRIPTION

- Drug withdrawal is a physiologic response to effectively lowered drug concentrations in a patient with tolerance to that drug.
- Causes a predictable pattern of symptoms that are reversible if the drug in question or another appropriate substitute is reintroduced
- Sedative-hypnotic withdrawal is most common life-threatening withdrawal syndrome in children:
  - Barbiturates, benzodiazepines, baclofen, and other medications are in this group.
- Other substances causing withdrawal syndromes are opioids, selective serotonin reuptake inhibitors (SSRIs), nicotine, and caffeine.

### EPIDEMIOLOGY

#### Incidence

Alcohol withdrawal, the most common life-threatening withdrawal syndrome, rarely occurs in neonates born to alcohol-dependent mothers.

### RISK FACTORS

Patients receiving sedatives or analgesics capable of causing tolerance are at risk:

- Particularly true with infusions or high doses

### GENERAL PREVENTION

- Clinician familiarity with tolerance and withdrawal associated with prescribed medications allows appropriate drug tapering.
- Drug abuse prevention is appropriate for all expectant mothers and children.

### PATHOPHYSIOLOGY

- Altered CNS neurochemistry is the most important and clinically relevant aspect of withdrawal pathophysiology.
- Pathophysiology varies with the class of drug involved, but the generally relevant physiology relates to the degree of agonism and/or antagonism between stimulatory and inhibitory mechanisms:
  - GABA receptors in cases of alcohol and sedative-hypnotic withdrawal
  - Opioid receptors in cases of opioid withdrawal
- The timing of withdrawal varies depending on the half-life of the substance involved.
- The shorter the half-life, the sooner the onset of withdrawal and typically the more severe the withdrawal symptoms.

### ETIOLOGY

- Neonates:
  - Maternal alcohol, caffeine, opioid, sedative-hypnotic, or SSRI use may result in a neonatal abstinence syndrome.
  - Treatment with caffeine, opioids, or sedative-hypnotics may result in an abstinence syndrome.

- Older children:
  - Subsequent to treatment with caffeine, opioids, or sedative-hypnotics, an abstinence syndrome may result.
  - Substance abuse such as gamma hydroxybutyrate or other sedative-hypnotics may result in an abstinence syndrome.
  - Frequent caffeine or nicotine use may lead to an abstinence syndrome.
  - The use of opioid antagonists such as naloxone, naltrexone, and nalmefene are associated with opioid withdrawal.

### COMMONLY ASSOCIATED CONDITIONS

- Small for gestational age
- Neurologic disease, such as cerebral palsy, seizure disorder

## DIAGNOSIS

### HISTORY

- Typically, a history of substance exposure, either directly or maternal use, will be elicited.
- Exposure may be to prescribed medication or abusable substances.
- Substance use might intentionally be concealed.
- Alcohol or sedative-hypnotics:
  - Withdrawal from these may result in tremulousness, diaphoresis, agitation, insomnia, altered mental status, or withdrawal seizures.
  - Baclofen withdrawal is more frequently severe or life-threatening relative to benzodiazepine withdrawal:
    - History of pump manipulation or malfunction should be sought.
- Caffeine: Withdrawal may result in dysphoria, headache, behavioral changes, or agitation.
- Opioids:
  - Nausea, vomiting, diarrhea, irritability, yawning, sleeplessness, diaphoresis, lacrimation, tremor, and hypertonicity may result.
  - Neonates can also have seizures, a high-pitch cry, skin mottling, and excoriation.
  - These latter signs and symptoms are more typical of opioid withdrawal and rarely occur with neonatal alcohol withdrawal.
- Nicotine: Dysphoria, agitation, behavioral changes, and increased appetite may all occur.
- SSRIs:
  - Neonatal withdrawal from SSRIs may result in jitteriness, agitation, crying, shivering, increased muscle tone, breathing and sucking problems, and seizure.
  - Children withdrawing from SSRIs may have jitteriness, agitation, dysphoria, behavioral changes, shivering, increased muscle tone, and seizure.

### PHYSICAL EXAM

- Vital signs including temperature should be evaluated regularly. For sedative-hypnotic withdrawal, frequent monitoring of vital signs is indicated.
- Technology-dependent patients, such as children with an intrathecal baclofen pump, should have an evaluation of the machine to determine if it is working properly.
- Most cases of substance withdrawal only result in behavioral changes.
- Opioid withdrawal may be accompanied by diaphoresis, mydriasis, yawning, and lacrimation.
- Sedative-hypnotic withdrawal may result in HTN, tachycardia, hyperthermia, agitation, hallucinations, and seizure.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

- No routine lab tests are indicated for patients with substance withdrawal.
- Tests necessary to rule out differential diagnoses should be obtained when appropriate.

#### Imaging

Neuroimaging to rule out intracranial pathology may rarely be indicated.

### DIFFERENTIAL DIAGNOSIS

- Hypoglycemia
- Intoxication with sympathomimetics, anticholinergics, theophylline, caffeine, aspirin, or lithium
- Thyroid storm
- Serotonin syndrome
- Neuroleptic malignant syndrome
- Encephalitis
- Meningitis
- Sepsis

## TREATMENT

### INITIAL STABILIZATION/THERAPY

- Assess and stabilize airway, breathing, and circulation:
  - If altered mental status, assess for and treat hypoglycemia.
- Supportive care is the most important principle:
  - Maintain vital signs within acceptable limits, and address issues if they arise.
- Maintenance IV fluid may be required in patients who are unable to take them PO.
- There is no fixed quantity of drug to use for any withdrawal syndrome. Each patient requires a unique quantity of drug.
- Sedative-hypnotic and alcohol withdrawal:
  - Sedative-hypnotic withdrawal with severe symptoms is best managed with initial cardiopulmonary monitoring until vital sign abnormalities are controlled with appropriate replacement therapy.
  - Patients should be monitored closely until vital signs are acceptable and stable.

- Vigilance for agitation or delirium in patients with sedative-hypnotic withdrawal
- Vigilance to detect oversedation and respiratory depression is necessary.
- Ideally, withdrawal is treated with the same class of substance, such as benzodiazepine or barbiturate, if not the precise same drug.
- Repeated dosing using an agent with rapid onset, such as diazepam, should continue until the symptoms are controlled, at which point maintenance and tapering can occur:
  - Maintenance may be with a longer-acting drug such as lorazepam or phenobarbital.
- Symptom-triggered treatment has been demonstrated to be superior to fixed-regimen treatment in terms of patient outcome as well as length of stay.
- Patients experiencing withdrawal from benzodiazepines or barbiturates after treatment in a chronic or intensive care setting may be treated by reinstating the drug and then tapering.
- Benzodiazepines are particularly useful due to the rapid onset of effect.
- Diazepam has active metabolites that assist in tapering the drug.
- Propofol is an outstanding medication for treatment of severe alcohol or sedative-hypnotic withdrawal in adults.
- Propofol may be used in pediatric cases refractory to benzodiazepines and barbiturates.
- Use is associated with respiratory depression. The administering clinician must be able to support the airway if needed.
- Propofol use is safe in children, but rare cases of metabolic acidemia have occurred when prolonged infusions are used. Prolonged use for > 24 hr of propofol infusion should be accompanied by close observation for acidemia.
- Opioid withdrawal:
  - Withdrawal is best treated with an opioid of similar potency and equal or longer duration of action as the opioid the patient was using.
  - Patients with opioid withdrawal in chronic care or intensive care may be treated by reinstating the infusion or dosing of the drug used before withdrawal symptoms began, then tapering by 10% daily.
  - Iatrogenic withdrawal induced by opioid antagonists are not treated by opioid administration.
    - Withdrawal due to naloxone should abate rapidly due to the brief half-life of naloxone.
    - Withdrawal induced by naltrexone or nalmefene will be much longer lasting. Symptomatic treatment may be indicated.
- Caffeine withdrawal: Caffeine replacement
- Nicotine withdrawal is not typically treated in children:
  - The nicotine patch, gum, etc., are used to increase the success rate of abstinence rather than withdrawal syndrome.

## MEDICATION

### First Line

- Refer to a local subspecialist for specific dosing.
- A general safe dosing method is administration of 75–100% of the dose of medication the patient was previously taking.
- Opioids: Withdrawal is treated with other opioids of similar potency and duration of effect:
  - Methadone:
    - Preferred treatment for withdrawal in children and adolescents. Most neonatologists have limited or no experience with this drug.
  - Paregoric, or tincture of opium: Refer to a neonatologist for dosing.
- Sedative-hypnotic or alcohol withdrawal:
  - Diazepam 0.2 mg/kg IV given q5min for 3 doses. If the patient is still exhibiting withdrawal symptoms, double the dose after 3 doses. For example, in a 10-kg patient, the initial dose is 2 mg. Repeat this q5–10min for 3 doses. If still symptomatic, double the dose to 4 mg. If symptomatic, give 4 mg dose total of 3 times, then if still symptomatic, double the dose to 8 mg, etc.
  - For sedative-hypnotic withdrawal, the use of clonidine or other medications to treat symptoms such as tachycardia and HTN without providing CNS effect are not recommended.

### Second Line

- SSRIs may be given for neonatal SSRI withdrawal. Refer to a local subspecialist for dosing.
- Caffeine withdrawal:
  - Caffeine in soft drink or tea treats headache or agitation in children and adolescents.
  - In neonates, reinstitute 75–100% of the caffeine dosage that was discontinued. This amount is then tapered by 10% daily.

## DISPOSITION

### Admission Criteria

- Inpatient treatment for alcohol or sedative-hypnotic withdrawal is mandatory.
- Though withdrawal from opioids and SSRIs is not life threatening, admission with initial management as an inpatient is preferable.
- Critical care admission criteria:
  - Unstable vital signs, seizure, or a requirement for large doses of medication to treat alcohol or sedative-hypnotic withdrawal

### Discharge Criteria

- If the disposition is discharge, it is crucial to ensure that the patient's condition is stable.
- If there is any question as to whether the patient can be appropriately managed as an outpatient, initial inpatient management is preferable.
- Inpatients controlled with oral medication after parenteral medications are stopped
- Patients who do not require parenteral therapy may be discharged with oral medication after consultation with the appropriate specialist.

### Issues for Referral

- Refer drug abusers to drug counseling.
- Most withdrawal is best handled by addiction specialists, medical toxicologists, intensivists, or others experienced in managing withdrawal.

## FOLLOW-UP

### FOLLOW-UP RECOMMENDATIONS

Discharge instructions and medications:

- Follow-up needs are based on the type and severity of withdrawal syndrome.

### PROGNOSIS

- Generally good prognosis
- Poor prognostic factors are primarily related to comorbidities.

### COMPLICATIONS

Complications of HTN, tachycardia, hyperthermia, and CNS agitation or seizure may occur with sedative-hypnotic withdrawal.

## CODES

### ICD9

- 291.81 Alcohol withdrawal
- 292.0 Drug withdrawal
- 779.5 Drug withdrawal syndrome in newborn

## PEARLS AND PITFALLS

- Sedative-hypnotic withdrawal may be life threatening. Treat with adequate amounts of GABA medication such as diazepam, barbiturates, or propofol. Large doses may be needed.
- There is no fixed quantity of drug to use for any withdrawal syndrome. Each patient requires a unique quantity of drug.

## APPENDIX A ■ CARDIAC EMERGENCIES

**TABLE A-1**

**EMERGENT MANAGEMENT OF DYSRHYTHMIAS IN CHILDREN (WITH INADEQUATE PERFUSION<sup>a</sup>)**

Dysrhythmia	Pharmacologic therapies	Definitive electrophysiologic
<b>Slow heart rate</b> Complete heart block Sinus bradycardia, sick sinus syndrome	Epinephrine bolus of 0.01 mg/kg IV of 1:10,000 dilution, followed by infusion of 0.1–2.0 μg/kg/min Atropine 0.02–0.04 mg/kg IV (0.1 mg/min)–(2 mg max)	Pacemaker
<b>Rapid heart rate</b> Supraventricular tachycardia	Adenosine (when perfusion deemed sufficient) Initial 0.1 mg/kg (max 6 mg/dose), subsequent 0.2–0.3 mg/kg (max 12 mg/dose) Amiodarone 5 mg/kg IV over 20–60 min (max 300 mg/dose) Procainamide 5 mg/kg (max 100 mg/dose over 5–10 min, can repeat q5–10min) max load 15 mg/kg total (500 mg)	Cardioversion, 0.25–2 J/kg, doubling wattage until 10 J/kg or successful
Junctional tachycardia	Amiodarone 5 mg/kg IV over 20–60 min (max 300 mg/dose), digoxin, procainamide	Cardioversion 24 J/kg
Ventricular tachycardia	Amiodarone 5 mg/kg IV over 20–60 min (max 300 mg/dose) Lidocaine 1 mg/kg Defibrillation 2 J/kg	
Ventricular fibrillation <b>Irregular heart rate</b> Premature ventricular contractions Second-degree heart block	Lidocaine 1 mg/kg Epinephrine, atropine	Lidocaine 1 mg/kg and defibrillation 4–10 J/kg Amiodarone, procainamide Pacemaker

IV, intravenous.

# APPENDIX B ■ RESPIRATORY EMERGENCIES

**TABLE B-1**

**CRITERIA FOR RESPIRATORY FAILURE<sup>a</sup>**

Clinical	Laboratory
Tachypnea, bradypnea, apnea, irregular respirations Pulsus paradoxus >30 mm Hg Decreased or absent breath sounds Stridor, wheeze, grunt Severe retractions and use of accessory muscles  Cyanosis on 40% inspired O <sub>2</sub> <sup>b</sup> Depressed level of consciousness, decreased response to pain Inability to spontaneously clear secretions Poor muscle tone	PaO <sub>2</sub> <60 mm Hg in 60% O <sub>2</sub> <sup>c</sup> PaCO <sub>2</sub> >60 mm Hg and rising pH <7.3 Vital capacity <15 mL/kg Maximum inspiratory pressure ± 25 cm H <sub>2</sub> O
<p><sup>a</sup>Respiratory failure is likely if two clinical findings and one laboratory finding exist.  <sup>b</sup>Excluding cyanotic heart disease.  <sup>c</sup>Without underlying pulmonary disease.                      (Modified with permission from Fleisher GR, Ludwig S, eds. <i>Textbook of Pediatric Emergency Medicine</i>, 6th ed. Philadelphia: Lippincott Williams &amp; Wilkins, 2010.)</p>	

TABLE B-2

## EMERGENCY DEPARTMENT ACUTE ASTHMA THERAPY

Therapy	Dose	Maximum	Comments
<b>Oxygen</b>	Maintain SaO <sub>2</sub> >90% (>93% in infants)		
<b>Adrenergic agents</b>			
Albuterol (0.5%) nebulizer solution	Intermittent: 0.15 mg/kg q15–20min in 2 mL NS × 3 and then 0.15–0.3 mg/kg q1–4h Continuous: 0.5 mg/kg/h (minimum 2.5 mg)	5 mg/dose  15 mg/h	
Albuterol MDI	2–8 puffs q20min × 3 and then q1–4h as needed		Use valved holding chamber for most children Face mask in children <4 yr
Levalbuterol nebulizer solution (0.63 mg/3 mL, 1.25 mg/3 mL)	Intermittent: 0.075 mg/kg (minimum 1.25 mg) q20 min × 3 and then 0.075–0.15 mg/kg q1–4h Continuous: 0.25 mg/kg/h	2.5–5 mg/h  5–7.5 mg/h	Use one-half the dose of racemic albuterol
Subcutaneous or intramuscular Epinephrine 1:1,000	0.01 mg/kg SQ/IM q15–20min	0.3–0.5 mg/dose	See the text for indications
Terbutaline (0.1%) Intravenous	0.01 mg/kg SQ q15–20min	0.25 mg/dose	See the text for indications
Terbutaline (0.1%)	Loading dose: 10 μg/kg over 10 min; initial maintenance: 0.4 μg/kg/min		Titrate up by 0.2 μg/kg/min Usual effective range: 3–6 μg/kg/min
<b>Anticholinergics</b>			
Ipratropium bromide <sup>b</sup> Nebulizer solution (0.25 mg/mL)	0.25 mg q20min × 3 <sup>a</sup> (child) 0.5 mg q20min × 3 <sup>a</sup> (adult)	0.5 mg/dose	May mix with same nebulizer as albuterol in moderate to severe exacerbations; should be added to β <sub>2</sub> -agonist
Metered-dose inhaler (18 μg/puff)	4–8 puffs q20min × 3 doses	8 puffs/dose	
<b>Corticosteroids</b>			
Methylprednisolone	1–2 mg/kg IV bolus	60 mg/day	
Prednisone	1–2 mg/kg PO	60 mg/day	
Dexamethasone	0.6 mg/kg PO or IM	16 mg/day	

NS, normal saline; SQ, subcutaneous; IV, intravenous; PO, orally; IM, intramuscular.  
<sup>a</sup>May give with second and third albuterol.  
<sup>b</sup>Contraindicated with MDI use in those with peanut or soy allergies.  
 (Modified with permission from Fleisher GR, Ludwig S, eds. *Textbook of Pediatric Emergency Medicine*, 6th ed. Philadelphia: Lippincott Williams & Wilkins, 2010.)

# APPENDIX C ■ OTHER EMERGENCIES

**TABLE C-1**

**PROCEDURAL SEDATION DRUG RECOMMENDATIONS<sup>a</sup>**

Drug	Clinical effect	Indications	Dose (mg/kg)	Onset (min)	Duration (min)	Reversible	Comments
<b>Sedative-Hypnotics</b>							
Dexmedetomidine	Sedation, light sleep	Imaging, painless diagnostic tests	IV 0.5–1 $\mu$ g/kg over 10 min; infusion of 0.2–1 $\mu$ g/kg/hr IN 1–2 $\mu$ g/kg Buccal 2–4 $\mu$ g/kg	IV 10 IN 30 Buccal 30–45	60–120	No	May cause BP instability especially with atropine; bradycardia or SA node conduction delay
Etomidate	Deep sedation	Brief imaging, painless or painful diagnostic tests	IV 0.2–0.3	1–2	5–10	No	Very rapid onset; minimal cardiorespiratory depression; injection pain, myoclonus common; transient adrenal suppression
Midazolam <sup>b</sup>	Sedation, anxiolysis	Shorter procedures, anxiolysis, mild sedation (not sleep) when used alone	IV 0.05–0.1 (may repeat q5–10min to a max of 0.5 mg/kg IV) IN 0.2–0.4 IM 0.1–0.2 PO/PR 0.5	IV 1–2 IN 2–5 IM 5–15 PO 15–20 PR 10–15	IV 45–60 IN 15–30 IM 60–120 PO/PR 60–90	Partially: Flumazenil	Lower doses in combination with narcotics; may produce paradoxical irritability; decrease dose for older children/adolescents
Pentobarbital	Sedation, sleep, immobility	Longer painless procedures (MRI, bone scan)	IV 2–6, titrated at 1–2 mg/kg q2–3min IM 2–6 PO/PR 3–6 mg/kg (max IV dose is 100 mg and max PR dose is 200 mg)	IV 3–5 IM 10–15 PO/PR 15–60	IV 30–90 IM 60–120 PO/PR 60–240	No	Younger children often restless before sleep induced; avoid in porphyria
Propofol	Sedation, deep sleep, immobility	Any procedure requiring deep sedation, consider adding narcotic for painful procedure	Induction bolus 2.5–3.5 IV q1–2min until asleep; infusion of 125–300 $\mu$ g/kg/min to maintain deep sedation	IV only; onset in seconds	Bolus dose: 5–10; or duration of infusion	No	Very rapid onset; high potential for apnea; injection pain ameliorated with 1% lidocaine (1 cc:9 cc propofol, or pre-treat vein with lidocaine)
<b>Analgesics</b>							
Fentanyl	Analgesia	Shorter mildly to moderately painful procedures	IV 1–2 $\mu$ g/kg, may increase by 1 $\mu$ g/kg q3–5min to desired effect	IV 1–2	IV 30–60	Yes: Naloxone	Chest wall rigidity with rapid IV push
Ketamine	Analgesia, dissociation, amnesia, motion control	Shorter moderately to severely painful procedures (fracture reduction)	IV 1.5–2 (max IV dose is 100 mg) IM 4–5 (use concentrated 100 mg/mL formulation) (max IM dose is 200 mg) PO 10 mg/kg	IV 1–2 IM 3–5 PO 10–30	IV 15–30 IM 30–90	No	Contraindicated with increased intraocular pressure, psychosis, thyroid disease. Laryngospasm a rare (1 in 250) complication.
Nitrous oxide	Mild analgesia, sedation, amnesia	Mildly painful procedures (IV, bladder cath)	Inhaled 30–70% nitrous mixed with oxygen	1–3	<5 after discontinuing flow	No	Contraindicated with trapped gas pockets
<b>Reversal agents</b>							
Naloxone	Narcotic reversal		IV/IM 0.1 (max 2 mg/dose) May repeat q2min	IV 2–3 IM 10–15	IV 20–40 IM 60–90		Sedative may outlast reversal agent
Flumazenil	Benzodiazepine reversal		IV 0.02 (max 1 mg/dose) May repeat q1min	IV 1–2	IV 30–60		Sedative may outlast reversal agent

<sup>a</sup>Doses are generalizations only; dosing must be individualized in all cases; dosing may be altered by age or degree of illness; neonatal dosing may differ; all PO/PR/IM dosing is difficult to titrate—use caution and monitor for oversedation.

<sup>b</sup>Consider co-administration with atropine 0.01 mg/kg (min 0.1 mg, max 0.5 mg) or glycopyrrolate 5  $\mu$ g/kg to blunt hypersalivation response; some believe that administration with midazolam may ameliorate dysphoria or lessen vomiting.

TABLE C-2

## SUMMARY OF ANTIDOTES

Poison	Antidote															
Acetaminophen	<i>N</i> -acetylcysteine; intravenous (IV)—150 mg/kg over 1 h, then 12.5 mg/kg/hr for 4 h, then 6.25 mg/kg/hr; enteral—140 mg/kg, then 70 mg/kg every 4 h.															
Anticholinergics	Physostigmine (adult, 0.5 to 2 mg; child, 0.02 mg/kg) slow IV; may repeat in 15 min until desired effect is achieved; subsequent doses every 2–3 h PRN ( <i>Caution: May cause seizures, asystole, cholinergic crisis; see text</i> )															
Anticholinesterases	Atropine, 2–5 mg (adults); 0.05–0.1 mg/kg (children) intramuscular (IM) or IV, repeated every 10–15 min until atropinization is evident															
Organophosphates	Pralidoxime chloride 1–2 g (adults); 25–50 mg/kg (children) IV; repeat dose in 1 h PRN, then every 6–8 h for 24–48 h (consider also constant infusion; see text)															
Carbamates	Atropine, as above; pralidoxime for severe cases (see text)															
$\beta$ -Adrenergic blockers	Glucagon, 0.1 mg/kg IV, followed by 0.05 mg/kg/h															
Calcium channel blockers	Calcium chloride 10%, 10 mL (adult); 0.2 mL/kg (pediatric) IV Or Calcium gluconate 10%, 30 mL (adult); 0.6 mL/kg (pediatric) IV															
Carbon monoxide	Oxygen 100% inhalation, consider hyperbaric for severe cases															
Cyanide—cyanide antidote kit	<i>Adult:</i> Amyl nitrite inhalation (inhale for 15–30 s every 60 s) pending administration of 300 mg sodium nitrite (10 mL of a 3% solution) IV slowly (over 2–4 min); follow immediately with 12.5 g sodium thiosulfate (2.5–5 mL/min of 25% solution) IV <i>Children</i> (Na nitrite should not exceed recommended dose because dangerous methemoglobinemia may result):															
	<table border="1"> <thead> <tr> <th>Hemoglobin</th> <th>Initial dose 3% Na nitrite</th> <th>Initial dose 25% Na thiosulfate IV</th> </tr> </thead> <tbody> <tr> <td>8 g</td> <td>0.22 mL (6.6 mg)/kg</td> <td>1.10 mL/kg</td> </tr> <tr> <td>10 g</td> <td>0.27 mL (8.7 mg)/kg</td> <td>1.35 mL/kg</td> </tr> <tr> <td>12 g (normal)</td> <td>0.33 mL (10 mg)/kg</td> <td>1.65 mL/kg</td> </tr> <tr> <td>14 g</td> <td>0.39 mL (11.6 mg)/kg</td> <td>1.95 mL/kg</td> </tr> </tbody> </table>	Hemoglobin	Initial dose 3% Na nitrite	Initial dose 25% Na thiosulfate IV	8 g	0.22 mL (6.6 mg)/kg	1.10 mL/kg	10 g	0.27 mL (8.7 mg)/kg	1.35 mL/kg	12 g (normal)	0.33 mL (10 mg)/kg	1.65 mL/kg	14 g	0.39 mL (11.6 mg)/kg	1.95 mL/kg
Hemoglobin	Initial dose 3% Na nitrite	Initial dose 25% Na thiosulfate IV														
8 g	0.22 mL (6.6 mg)/kg	1.10 mL/kg														
10 g	0.27 mL (8.7 mg)/kg	1.35 mL/kg														
12 g (normal)	0.33 mL (10 mg)/kg	1.65 mL/kg														
14 g	0.39 mL (11.6 mg)/kg	1.95 mL/kg														
Cyanide—hydroxocobalamin	<i>Adult:</i> 5g IV; <i>Child:</i> 70 mg/kg IV.															
Digitalis	Fab antibodies (Digibind): dose based on amount ingested and/or digoxin level (see text, package insert)															
Fluoride	Calcium gluconate 10%, 0.6 mL/kg IV slowly until symptoms abate, serum calcium normalizes; repeat PRN															
Heavy metals (usual chelators)	BAL (British Anti-Lewisite; dimercaprol): 3–5 mg/kg/dose deep IM every 4 h for 2 days, every 4–6 h for an additional 2 days, then every 4–12 h for up to 7 additional days															
Arsenic (BAL)	EDTA (ethylene diamine tetraacetic acid): 50–75 mg/kg/24 h deep IM or slow IV infusion given in 3–6 divided doses for up to 5 days; may be repeated for a second course after a minimum of 2 days; each course should not exceed a total of 500 mg/kg body weight (see text)															
Lead (BAL, EDTA, penicillamine, DMSA)	(see text)															
Mercury (BAL, DMSA)	Penicillamine: 100 mg/kg/d (max 1 g) by mouth (PO) in divided doses for up to 5 days; for long-term therapy, do not exceed 40 mg/kg/d DMSA (succimer): 350 mg/m <sup>2</sup> (10 mg/kg) PO every 8 h for 5 days, followed by 350 mg/m <sup>2</sup> (10 mg/kg) PO every 12 h for 14 days															
Iron	Deferoxamine: 5–15 mg/kg/h IV; use higher dosage for severe symptoms (see text) and decrease as patient recovers															
Isoniazid (INH)	Pyridoxine 5%–10%, 1 g per gram of INH ingested (70 mg/kg up to 5 g if dose unknown) IV slowly over 30–60 min															
Methanol/ethylene glycol	Fomepizole: load 15 mg/kg; maintenance 10 mg/kg q12h 4 doses, then 15 mg/kg q12h (dose should be adjusted during dialysis; ethanol may be used if fomepizole unavailable) Ethanol loading dose: 0.75 g/kg infused over 1 h (fomepizole is preferred) Ethanol maintenance: 0.1–0.2 g/kg/h infusion; adjust as needed with target level 100 mg/dL Folate 1 mg/kg IV every 6 h (methanol) Thiamine 0.5 mg/kg and pyridoxine 2 mg/kg (ethylene glycol)															

(continued)

**TABLE C-2****SUMMARY OF ANTIDOTES (CONTINUED)**

Poison	Antidote
Methemoglobinemic agents	Methylene blue 1%, 1–2 mg/kg (0.1–0.2 mL/kg) IV slowly over 5–10 min if cyanosis is severe or methemoglobin level >40%
Opioids	Naloxone 0.4–2 mg IV, IM, sublingual or by ETT; may repeat up to total 8–10 mg in adolescent/adult (see text)
Phenothiazines (dystonic reaction)	Diphenhydramine, 1–2 mg/kg IM or IV; or Benztropine, 1–2 mg IM or IV (adolescents)
Sulfonylureas	Octreotide 1–2 µg/kg/dose subcutaneous (SC) or IV every 6–12 h
Tricyclic antidepressants	Sodium bicarbonate, 1–2 mEq/kg IV
Warfarin (and “superwarfarin” rat poisons)	Vitamin K <sub>1</sub> 10 mg (adult); 1–5 mg (pediatric) IV, IM, SC, PO
Animals	Antivenin <sup>a</sup> for envenomation
Snake, Crotalidae (all North American rattlers and moccasins)	Crotalidae polyvalent immune Fab (Savage)
Snake, coral	Antivenin ( <i>Micrurus fulvius</i> ), monovalent (Wyeth)
Spider, black widow	Antivenin <i>Latrodectus mactans</i> (Merck, Sharp & Dohme)

<sup>a</sup>See package insert for dosage and administration.

TABLE C-4

## GUIDELINES FOR TRANSFUSION THERAPY

Blood component	Indication	Dose
Whole blood	Immediate restoration of blood volume and red blood cell mass after trauma or surgery; exchange transfusion	Calculation of red blood cell transfusion requirements <sup>a</sup>
Packed RBCs	For all nonemergency transfusions or emergency restoration of red blood cell mass (may be combined with saline or fresh-frozen plasma for volume expansion or exchange transfusion)	Calculation of red blood cell transfusion requirements <sup>a</sup>
Leukoreduced RBCs	Same indications as packed RBCs but contains few leukocytes; helpful in preventing febrile transfusion reactions and platelet alloimmunization	Calculation of red blood cell transfusion requirements <sup>a</sup>
White blood cells	Recommended only for some severely neutropenic patients with documented or strongly suspected sepsis	One unit daily (each unit should contain at least 10 <sup>10</sup> granulocytes)
Platelets	For hemorrhagic complications caused by thrombocytopenia or abnormal platelet function	5–10 mL/kg
Fresh-frozen plasma	To provide multiple coagulation factors	10–20 mL/kg/dose

RBC, red blood cell.  
<sup>a</sup>Calculation of RBC transfusion requirements:  
 Required volume of packed RBCs = blood volume × [(desired hematocrit – present hematocrit)/hematocrit of packed RBCs].  
 Blood volume (mL) = weight (kg) × 70 mL/kg.  
 Packed RBCs usually have a hematocrit of 60%–75%; whole blood has a hematocrit of 44%–48%.

TABLE C-5

MANAGEMENT OF HYPERBILIRUBINEMIA IN THE HEALTHY TERM INFANT ACCORDING TO TOTAL SERUM BILIRUBIN AND BABY'S AGE<sup>a</sup>

Age (h)	Initiate phototherapy <sup>b</sup> (mg/dL)	Exchange transfusion if intensive phototherapy fails <sup>c</sup> (mg/dL)
<25	8–10	17–20
25–48	12–15	19–22
49–72	17–19	22–25
>72	20–21	25

<sup>a</sup>These guidelines apply to well neonates of gestational age equal to or more than 35 weeks. The lower ends of the above total serum bilirubin ranges apply to the youngest in each age range.

<sup>b</sup>Lower bilirubin levels than the above would warrant initiation of phototherapy in infants who have any of the following risk factors: shorter gestation, isoimmune hemolytic disease, glucose-6-phosphate dehydrogenase deficiency, asphyxia, significant lethargy, respiratory distress, temperature instability, sepsis, acidosis, or albumin level higher than 3.0 g/dL. Consult neonatology and/or hematology regarding possible need for exchange transfusion or alternative therapy if levels significantly exceed these numbers or if the bilirubin is predominately conjugated (direct).

<sup>c</sup>Intensive phototherapy should produce a decline of total serum bilirubin of 1 to 2 mg/dL within 4 to 6 hours, and the total serum bilirubin level should continue to fall and remain below the threshold level for exchange transfusion. If this does not occur, it is considered a failure of phototherapy.

Adapted from American Academy of Pediatrics, Subcommittee on Neonatal Hyperbilirubinemia. Management of hyperbilirubinemia in the newborn infant 35 or more weeks of gestation. *Pediatrics* 2004;114:297–316.

Variola, rash in, 804–805  
Vascular defect  
petechiae in, 798–799  
purpura in, 800–801  
Vascular lesions, neck mass from, 650–651  
Vasculitis  
immune-mediated, 484–485  
petechiae in, 798–799  
purpura in, 800–801  
systemic  
Henoch-Schönlein purpura, 484–485  
Kawasaki disease, 578–579  
Vasodepressor syncope, 894–895  
Vaso-occlusive crisis, in sickle cell disease, 858–859  
Vasovagal syncope, 894–895  
Venom. *See* Envenomation  
Venous hum, 466, 932  
Venous thromboembolism, 236–237  
Ventricular dysrhythmia, 278–279  
Ventricular fibrillation, 278–279, 902–903, 1037  
Ventricular septal defect  
as congenital heart disease, 186  
cyanotic heart disease from, 222–223  
Ventricular shunt, 1018  
Ventricular tachycardia, 278–279, 902–903, 1037  
Ventriculoperitoneal, 1018, 1020  
Ventriculoperitoneal shunt, 1018, 1020  
Ventriculoperitoneal shunt infection, 1018–1019  
Ventriculoperitoneal shunt malfunction, 1020–1021  
Verapamil poisoning, 134–135  
Verrucae vulgaris, 1026–1027  
Vertigo, 270–271  
Vesicant burns, 128–129  
Vesicle, 804  
Vesicoureteral reflux, 504  
Vesiculobullous rash, 804–805  
Vesiculopapular lesions, neonatal, 796–797  
Vestibular system, 270  
Vestibule, 270  
*Vibrio cholera* diarrhea, 252–253  
Vincent stomatitis, 874  
Viral conjunctivitis, 192–193  
Viral hemorrhagic fevers, 240. *See also specific types*  
Viral hepatitis, 488–489  
Viscus organ irritation, abdominal, 700  
Vision loss, 112–113  
Visual disturbance, 336–337  
Visual images, abnormal, 336–337  
Visual loss, sudden, 336–337  
Vitamin D, abnormal production of, 526  
Vitamin K, 58

Vitamin K cycle, 58  
 Vitreous hemorrhage, 112  
 Volatile anesthetic poisoning, 562–563  
 Volvulus, 1022–1023  
 Vomiting  
   cyclic, 224–225  
   general discussion of, 1024–1025  
 Vulvar ulcers, sexually transmitted, 850–851  
 Vulvovaginitis, 1016  
   vaginal bleeding in, 1008  
   vaginal discharge in  
     prepubertal, 1012–1013  
     pubertal, 1014–1015

**W**

WAGR syndrome, 1032  
 Warfarin poisoning, 58–61, 1043  
 Warm calorimetric response testing, 270  
 Warts  
   common, 1026–1027  
   cutaneous, 1026–1027  
   flat, 1026–1027

  genital, 436–437  
   plantar, 1026–1027  
 Wasp stings, 300–301  
 Weakness, 1028–1029  
 Weber test, 462  
 Wedge fracture, cervical spine, 376  
 Wegener granulomatosis, 178–179  
 Weight loss, in failure to thrive, 340–341  
 Wenckebach heart block, 120, 464–465  
 West syndrome, 552  
 “Wet” drowning, 272–273  
 Wheezing, 1030–1031. *See also specific disorders*  
 Whippets, 562–563  
 White blood cell transfusion, 1044  
 White pulp, 868  
 Whitlow, herpetic, 494  
 Whole blood transfusion, 1044
