Care has been taken to confirm the accuracy of the information presented and to describe generally accepted practices. However, the authors, editors, and publisher are not responsible for errors or omissions or for any consequences from application of the information in this book and make no warranty, expressed or implied, with respect to the currency, completeness, or accuracy of the contents of the publication. Application of the information in a particular situation remains the professional responsibility of the practitioner.

The authors, editors, and publisher have exerted every effort to ensure that drug selection and dosage set forth in this text are in accordance with current recommendations and practice at the time of publication. However, in view of ongoing research, changes in government regulations, and the constant flow of information relating to drug therapy and drug reactions, the reader is urged to check the package insert for each drug for any change in indications and dosage and for added warnings and precautions. This is particularly important when the recommended agent is a new or infrequently employed drug.

Some drugs and medical devices presented in the publication have Food and Drug Administration (FDA) clearance for limited use in restricted research settings. It is the responsibility of the health care provider to ascertain the FDA status of each drug or device planned for use in their clinical practice.

## PREFACE

---

**W**e have produced this first edition of *The 5-Minute Pediatric Emergency Medicine Consult* with the specific goal of providing a concise, formatted resource for the clinical management of pediatric emergencies and common pediatric complaints encountered in emergency departments and other settings. As academic pediatric emergency physicians, our goal is to apply the best evidence, published clinical practice guidelines, and other information to optimize patient care. Numerous constraints may interfere with one's ability to stay apprised of the most current evidence and guidelines applicable to pediatric emergency medicine. We recognize this and present this book as a resource for those who also wish to practice evidence-based medicine but require the information distilled in a single, easily accessible reference. This *5-Minute Pediatric Emergency Medicine Consult* is exactly such a reference book. Honorifically named for the Fleisher and Ludwig *Textbook of Pediatric Emergency Medicine*, which is the seminal comprehensive textbook of pediatric emergency medicine, our text seeks to provide a rapid reference for use in the clinical workplace rather than thorough, extensive coverage of the subject matter. *The 5-Minute Pediatric Emergency Medicine Consult* is intended to be accurate, pointed, and readily integrated into practice rather than definitive.

Clinicians at all levels of training and all stages of career development need references to facilitate the provision of optimal patient management. Each chapter presents information in a thor-

ough but very concise, succinct manner so that all key points about clinical presentations, differential diagnoses, diagnostic investigations, therapeutic interventions including medications and doses, and admission or discharge criteria are presented. This text has been authored by selected pediatric emergency physicians from both emergency and pediatric medicine backgrounds to provide true subspecialty expertise.

*The 5-Minute Pediatric Emergency Medicine Consult* will be useful to trainees as well as to clinicians far beyond training. Though the editors and authors practice pediatric emergency medicine within the confines of emergency departments in academic medical centers, we recognize that most pediatric emergencies are not treated in such settings, and many pediatric emergencies are treated outside of an emergency department altogether. Thus, we have taken great strides to produce a reference that represents optimal management of emergent and urgent pediatric conditions as well as common pediatric complaints in all such locations. Clinicians practicing in a tertiary care academic medical center with extensive subspecialty support or those in the community setting in which little or no subspecialty support will find this text to be an invaluable resource.

We hope this book will serve as a useful and frequently used resource to assist in our common goal of providing the best possible pediatric emergency care to our patients.

---

## FOREWORD

---

**F**ive Minutes – What can you do in 5 minutes? Working in the pediatric emergency department for more than 35 years has often been a humbling experience. Along the way, we have learned many lessons. One of the most important has been the value of orientation and preparation. We have all provided care for children when they suddenly burst through the doors in the arms of a police officer or paramedic with major multisystem trauma or cardiac arrest. We have been in the same critical situation when we had just 5 minutes to prepare for the event. As many of the readers of this book know, that extra 5 minutes makes a world of difference to the outcome and perceived quality of care provided. Even when residents are assigned to the emergency department for a rotation it is our perception that those who get a brief orientation to the site perform much better than those who do not. And those who take a minute to prepare before going into a treatment room also evolve to be better physicians.

That brings us to this book, *The 5-Minute Pediatric Emergency Medicine Consult*. We know that using this book will provide physicians with the orientation and preparation needed to address a wide range of clinical problems. Sometimes it will be a new condition that the physician has not faced before, and the topic will give an im-

portant overview. At other points, it will be used for a familiar or common clinical situation but a 5-minute refresher will provide a reassuring double check to make sure nothing has been overlooked or forgotten. In either case, that initial orientation and preparation will prove most valuable.

We are honored to have our names as part of the title of this book. We view it as a perfect companion to the *Textbook of Pediatric Emergency Medicine, 6th Edition* where more in-depth information can be learned. We thank the editors and authors for allowing us to share in this work. We see it as yet another important step in improving the emergency care to ill and injured children, which has been the foundation of our life's work.

Five minutes can mean a lot, and 5 minutes of reading one of the topics that follow will set you on a pathway toward rewarding clinical care.

## ACKNOWLEDGMENTS

---

I thank my wife Miya for her understanding, support, and sacrifice during the production of this text.

I sincerely thank Lewis Goldfrank and Steve Davidson for giving me the most formative academic opportunities of my career, and Lewis Nelson and Bob Hoffman for serving as ideal models of academic emergency physicians and clinician educators. To the many emergency medicine residency classes and notably the chief residents of Beth Israel Medical Center, I extend thanks for years of rewarding interaction and inspiration to remain in academics.

I acknowledge friends across the globe past and present who have assisted my endeavors by helping me balance productive work with enjoyable recreation. Lastly, I thank the families and patients to whom I've provided emergency care for the privilege of treating them.

**R.J.H.**

With any significant work, there are inevitably numerous individuals who have contributed to bring this project to fruition. I would like to thank the authors and editors, who have spent enormous amounts of their own personal time to produce this book. Thanks to the patients and my colleagues: my co-attendings, the residents and fellows, and the nurses, who have inspired me to be a better clinician and teacher. I also want to acknowledge Gary Fleisher and the late Michael Shannon for their mentorship and guidance. Finally, I deeply appreciate my wife Esther, and my parents Jaw and Jean, for their continual support, patience, and sacrifice.

**V.J.W.**

I would like to thank my patients, colleagues, and mentors who have taught me so much in my career. Your collective inquisitiveness, selflessness, and support have inspired me to become a clinician worthy of your trust. I am grateful to the many authors of this book who have worked so hard to create an outstanding resource for patient care. Thank you to my wife, Karen, for your love and support, and thank you to my wonderful children Steven and Julia—I love you and I'm proud of the young people that you have become.

**R.J.S.**

This book is the result of the hard work of countless dedicated authors. It has been a pleasure to work with them and the editorial and publishing team of this book. I want to extend a special thanks to the many residents and fellows past and present whose questions and pursuit of knowledge have made me a better clinician–educator. I would also like to thank my many mentors throughout my training. Finally, many thanks to my loving family, especially my wife, Libby, and three children, Maya, Samir, and Riya, who have made sacrifices, yet have been there to support, entertain, and inspire me.

**S.A.G.**

I would first like to thank my wife, Leslie, my sons Noah, Ben and Logan, and my daughter Lia, for all of their support and love. Everything I am, I owe to them. I would also like to thank the authors that I have worked with, the editorial staff for their support, and my co-editors who had to put up with me. It has truly been a pleasure to work on this project, and I have learned a great deal from all.

**R.P.**

 Steven and Alexandra Cohen Children's  
 Medical Center of New York/Long  
 Island Jewish Medical Center  
 New Hyde Park, New York

**Teresa M. Romano, MD**

Fellow  
 Department of Emergency Medicine  
 St. Christopher's Hospital for Children  
 Philadelphia, Pennsylvania

**Emily Rose, MD**

Internist  
 Brigham and Women's Hospital  
 Boston, Massachusetts

**Michael D. Rosen, MD**

Clinical Assistant Professor of Emergency Medicine  
Department of Emergency Medicine  
New Jersey Medical School  
University of Medicine and Dentistry of New Jersey  
Medical and Fellowship Director  
Department of Pediatric Emergency Medicine  
Children's Hospital of New Jersey at Newark Beth Israel Medical Center  
Newark, New Jersey

**Michael G. Rosenberg, MD**

Department of Pediatrics  
Jacobi Medical Center  
Bronx, New York

**Cindy Ganis Roskind, MD**

Assistant Clinical Professor of Pediatrics  
Columbia University College of Physicians and Surgeons  
Attending Physician  
Department of Pediatrics, Division of Pediatric Emergency Medicine  
New York-Presbyterian Morgan Stanley Children's Hospital  
New York, New York

**Michael Rosselli, MD**

Sports Medicine Fellow  
Department of Emergency Medicine  
North Shore University Hospital  
Manhasset, New York

**Sudha A. Russell, MD**

Assistant Professor of Pediatrics  
Keck School of Medicine of the University of Southern California  
Attending Physician KidsCare  
Division of Emergency Medicine  
Children's Hospital Los Angeles  
Los Angeles, California

**Christopher J. Russo, MD**

Attending Physician  
Division of Emergency Medicine  
Nemours/A.I. duPont Hospital for Children  
Wilmington, Delaware

**Deirdre D. Ryan, MD**

Assistant Clinical Professor  
Department of Orthopaedic Surgery  
Keck School of Medicine of the University of Southern California  
Children's Hospital Los Angeles  
Los Angeles, California

**Mary T. Ryan, MD**

Clinical Instructor in Emergency Medicine  
Weill College of Medicine  
Cornell University  
New York, New York  
Attending Physician  
Department of Emergency Medicine  
Lincoln Medical and Mental Health Center  
Bronx, New York

**Heather R. Saavedra, MD**

Department of Emergency Medicine  
Children's Hospital of Wisconsin  
Milwaukee, Wisconsin

**Sunil Sachdeva, MD**

Clinical Assistant Professor  
Department of Emergency Medicine  
State University of New York, Downstate Medical Center  
Assistant Director  
Department of Emergency Medicine  
Long Island College Hospital  
Brooklyn, New York

**Nagela Sainte, MD**

Department of Pediatrics  
Robert Wood Johnson Medical School  
New Brunswick, New Jersey

**Sandy Saintonge, MD**

Department of Emergency Medicine  
Weill Cornell Medical College  
New York, New York  
Pediatric Emergency Medicine  
Attending  
Department of Emergency Medicine  
New York Hospital - Queens  
Flushing, New York

**Efren A. Salinero, MD**

**Esther Maria Sampayo, MD, MPH**  
Assistant Professor of Pediatrics  
University of Pennsylvania School of Medicine  
Attending Physician  
Children's Hospital of Philadelphia  
Philadelphia, Pennsylvania

**Kalyani Samudra, MD**

Adjunct Assistant Professor of Psychiatry  
University of Utah  
Salt Lake City, Utah  
Medical Director  
Department of Intensive Psychiatric Residential and DBT Day Treatment  
Valley Mental Health  
Midvale, Utah

**Marcelo Sandoval, MD**

Assistant Professor  
Department of Emergency Medicine  
Albert Einstein College of Medicine  
Beth Israel Medical Center  
New York, New York

**Genevieve Santillanes, MD**

Assistant Professor of Clinical Emergency Medicine  
Department of Emergency Medicine  
Keck School of Medicine of the University of Southern California  
LAC and USC Medical Center  
Los Angeles, California

**Masafumi Sato, MD**

Fellow  
Department of Emergency Medicine  
St. Christopher's Hospital for Children  
Philadelphia, Pennsylvania

**Rasha Dorothy Sawaya, MD**

Fellow  
Department of Pediatric Emergency Medicine  
Columbia University Medical Center  
New York, New York

**Catherine Scarfi, MD**

Physician  
Department of Pediatric Emergency Medicine  
Newark Beth Israel Medical Center  
Newark, New Jersey

**Richard J. Scarfone, MD**

Associate Professor of Pediatrics  
University of Pennsylvania School of Medicine  
Medical Director, Emergency Preparedness  
The Children's Hospital of Philadelphia  
Philadelphia, Pennsylvania

**Emily Schapiro, MD**

Professor of Clinical Pediatrics  
 Department of Pediatrics  
 University of Pennsylvania School of  
 Medicine  
 Director, Extended Care Unit  
 Attending Physician  
 Department of Emergency Medicine  
 The Children's Hospital of Philadelphia  
 Philadelphia, Pennsylvania

**Dana Aronson Schinasi, MD**

Department of Emergency Medicine  
 The Children's Hospital of Philadelphia  
 Philadelphia, Pennsylvania

**Suzanne Schmidt, MD**

Instructor  
 Department of Pediatrics  
 Northwestern University Feinberg School  
 of Medicine  
 Children's Memorial Hospital  
 Chicago, Illinois

**Suzanne Schuh, MD**

Professor  
 Department of Paediatrics  
 University of Toronto  
 Staff Emergency Physician  
 Department of Paediatrics  
 The Hospital for Sick Children  
 Toronto, Ontario, Canada

**Sandra H. Schwab, MD**

Attending Physician  
 Department of Emergency Medicine  
 Peyton Manning Children's Hospital -  
 St. Vincent's  
 Indianapolis, Indiana

**Dennis Scolnik, DCH, MSc, MB, ChB**

Associate Professor  
 Department of Pediatrics  
 University of Toronto  
 Staff Physician  
 Division of Pediatric Emergency Medicine  
 The Hospital for Sick Children  
 Toronto, Ontario, Canada

**Halden F. Scott, MD**

Instructor  
 Department of Pediatrics  
 University of Pennsylvania School of  
 Medicine  
 Attending Physician  
 Division of Emergency Medicine  
 Department of Pediatrics  
 Children's Hospital of Philadelphia  
 Philadelphia, Pennsylvania

**Hanan Sedik, MD**

Attending Physician  
 Division of Emergency Medicine  
 Children's Hospital Los Angeles  
 Los Angeles, California

**Désirée M. Seeyave, MBBS**

Clinical Assistant Professor  
 Department of Emergency Medicine  
 University of Michigan  
 Ann Arbor, Michigan  
 Clinical Assistant Professor  
 Department of Pediatric Emergency  
 Medicine  
 Hurley Medical Center  
 Flint, Michigan

**Jeffrey A. Seiden, MD**

Assistant Professor of Clinical Pediatrics  
 University of Pennsylvania School of  
 Medicine  
 Associate Medical Director CHOP at  
 Virtua Pediatric Emergency Care  
 Philadelphia, Pennsylvania

**Janet Semple-Hess, MD**

Assistant Professor of Pediatrics  
 Division of Emergency Medicine  
 Keck School of Medicine of the University  
 of Southern California  
 Children's Hospital Los Angeles  
 Los Angeles, California

**Usha Sethuraman, MD**

Children's Hospital of Michigan

**Ami P. Shah, MD, MPH**

Fellow  
 Department of Pediatric Emergency  
 Medicine  
 Children's Hospital of Pittsburgh of UPMC  
 Pittsburgh, Pennsylvania

**Manish I. Shah, MD**

Assistant Professor of Pediatrics  
 Department of Pediatrics, Section of  
 Emergency Medicine  
 Baylor College of Medicine  
 Attending Physician  
 Emergency Center  
 Texas Children's Hospital  
 Houston, Texas

**Nikhil B. Shah, MD, MS**

Assistant Professor  
 Department of Emergency Medicine  
 Weill Cornell Medical College  
 Attending Physician  
 Department of Emergency Medicine  
 New York Presbyterian Hospital - Cornell  
 New York, New York

**Adhi Sharma, MD**

Assistant Professor  
 Department of Emergency Medicine  
 Mount Sinai School of Medicine  
 Chairman  
 Department of Emergency Medicine  
 Good Samaritan Hospital Medical Center  
 New York, New York

**Sophia Sheikh, MD**

Instructor  
 Department of Emergency Medicine  
 Emory University  
 Atlanta, Georgia

**James M. Shen, MD**

Attending Physician  
 Emergency Department  
 Hoag Hospital  
 Newport Beach, California

**Cathy E. Shin, MD**

Assistant Professor  
 Department of Surgery  
 Keck School of Medicine of the University  
 of Southern California  
 Attending Physician  
 Department of Surgery  
 Children's Hospital Los Angeles  
 Los Angeles, California

**Victoria Shulman, MD**

Assistant Professor of Clinical Pediatrics  
 Albert Einstein College of Medicine  
 Attending Physician  
 Children's Emergency Service  
 Department of Pediatrics  
 Children's Hospital of Montefiore  
 Bronx, New York

**Lawrence Siew, MD**

Clinical  
 Department of Pediatric Emergency  
 Medicine  
 Yale New Haven Children's Hospital  
 New Haven, Connecticut

**Adam M. Silverman, MD, FAAP**

Assistant Professor  
 Department of Pediatrics  
 University of Connecticut School of  
 Medicine  
 Farmington, Connecticut  
 Attending Physician  
 Department of Pediatrics, Division of  
 Critical Care and Emergency Medicine  
 Connecticut Children's Medical Center  
 Hartford, Connecticut

**Donna M. Simmons, MD**

Department of Emergency Medicine  
Maimonides Medical Center  
Brooklyn, New York

**Sari Soghoian, MD**

Assistant Professor  
Department of Emergency Medicine  
NYU Langone Medical Center  
New York, New York

**Louis A. Spina, MD**

Assistant Professor  
Departments of Emergency Medicine and  
Pediatrics  
Mount Sinai Medical Center  
Attending Physician  
Department of Emergency Medicine  
Mount Sinai Medical Center  
New York, New York

**Curt Stankovic, MD**

Assistant Professor  
Department of Pediatric and Emergency  
Medicine  
Wayne State University  
Fellowship Director  
Department of Pediatrics  
Children's Hospital of Michigan  
Detroit, Michigan

**Danniel J. Stites, MD**

Weill Cornell Medical College  
New York, New York  
Department of Emergency Medicine  
New York Hospital Queens  
Flushing, New York

**David J. Story**

Fellow  
New York City Poison Control Center  
Bellevue Hospital Center  
New York, New York

**Christopher G. Strother, MD**

Assistant Professor  
Department of Emergency Medicine  
Mount Sinai School of Medicine  
Physician  
Department of Emergency Medicine  
Mount Sinai Hospital  
New York, New York

**Kristin S. Stukus, MD**

Fellow  
Department of Pediatric Emergency  
Medicine  
Children's Hospital of Pittsburgh of UPMC  
Pittsburgh, Pennsylvania

**Kai M. Stürmann, MD**

Chairman  
Department of Emergency Medicine  
Brookhaven Memorial Hospital  
Patchogue, New York

**Mark Su, MD**

Family Practitioner  
Holistic Family Practice, Inc.  
Newbury, Massachusetts

**Payal Sud, MD**

Department of Emergency Medicine  
North Shore University Hospital  
Manhasset, New York

**Srinivasan Suresh, MD, MBA**

Assistant Professor of Pediatrics  
and Emergency Medicine  
Wayne State University  
Medical Director, Emergency Department  
Chief Medical Information Officer  
Children's Hospital of Michigan  
Detroit, Michigan

**Linda Szema, MD**

Department of Emergency Medicine  
Albert Einstein College of Medicine  
Beth Israel Medical Center  
New York, New York

**Ee Tein Tay, MD**

Attending Physician  
Department of Emergency Medicine  
Mount Sinai School of Medicine  
Mount Sinai Hospital  
New York, New York

**Natasha A. Tejwani, MD**

Department of Pediatrics  
St. Barnabas Hospital  
Bronx, New York

**Ravi Thamburaj, DO**

Attending Physician  
Department of Emergency Medicine  
Newark Beth Israel Medical Center  
Newark, New Jersey

**Lindsay Thomas, MD**

Department of Emergency Medicine  
North Shore University Hospital  
Manhasset, New York

**Amy D. Thompson, MD**

Instructor  
Department of Pediatrics  
Jefferson Medical College  
Philadelphia, Pennsylvania  
Attending Physician  
Department of Emergency Medicine  
Alfred I duPont Hospital for Children  
Wilmington, Delaware

**Jennifer Thull-Freedman, MD, MSc**

Assistant Professor  
Department of Pediatrics  
University of Toronto  
Staff Physician  
Paediatric Emergency Medicine  
The Hospital for Sick Children  
Toronto, Ontario, Canada

**Helene Tigchelaar, MD**

Professor  
Departments of Pediatrics and  
Emergency Medicine  
Wayne State University  
Attending Physician  
Department of Pediatrics, Division of  
Emergency Medicine  
Children's Hospital of Michigan  
Detroit, Michigan

**Lindsey Tilt, MD**

Fellow  
Department of Pediatric Emergency  
Medicine  
Columbia University  
New York Presbyterian Hospital  
New York, New York

**Howard Topol, MD**

Department of Pediatrics  
Children's Hospital of Philadelphia  
Philadelphia, Pennsylvania

**Nicholas Tsarouhas, MD**

Professor of Clinical Pediatrics  
Department of Pediatrics  
University of Pennsylvania School of  
Medicine  
Associate Medical Director  
Emergency Department  
Medical Director  
Emergency Transport Team  
The Children's Hospital of Philadelphia  
Philadelphia, Pennsylvania

**Laura Umbrello, MD**

Fellow  
Division of Emergency Medicine  
Miami Children's Hospital  
Miami, Florida

**Neil G. Uspal, MD**

Fellow  
Department of Emergency Medicine  
Children's Hospital of Philadelphia  
Philadelphia, Pennsylvania

**Diana Valcich, MD**

Sports Medicine Fellow  
North Shore University Hospital  
Manhasset, New York

**Michael E. Valente, MD**

Fellow  
 Division of Emergency Medicine  
 Children's Hospital Los Angeles  
 Los Angeles, California

**Eugenio Vazquez, MD**

Department of Pediatrics  
 Children's Hospital of Orange County  
 Orange, California

**Adam Vella, MD**

Assistant Professor of Pediatrics and  
 Emergency Medicine  
 Director of Pediatric Emergency Medicine  
 Emergency Department  
 Mount Sinai Medical Center  
 New York, New York

**Rebecca L. Vieira, MD**

Instructor in Pediatrics  
 Harvard Medical School  
 Assistant in Medicine, Staff Physician  
 Department of Emergency Medicine  
 Children's Hospital Boston  
 Boston, Massachusetts

**Phillip Visser, MBCHB**

Fellow in Pediatric Emergency Medicine  
 Department of Emergency Medicine  
 Royal Children's Hospital  
 Parkville, Victoria, Australia

**David M. Walker, MD**

Assistant Professor  
 Department of Pediatric Emergency  
 Medicine  
 Yale University School of Medicine  
 Director of Quality and Safety/  
 Attending Physician  
 Department of Pediatric Emergency  
 Medicine  
 Yale-New Haven Hospital  
 New Haven, Connecticut

**Jaw J. Wang, MD**

Attending Physician  
 Montebello Pediatrics  
 Montebello, California

**Vincent J. Wang, MD, MHA**

Associate Professor of Pediatrics  
 Keck School of Medicine of the University  
 of Southern California  
 Associate Division Head  
 Division of Emergency Medicine  
 Children's Hospital Los Angeles  
 Los Angeles, California

**Marie Waterhouse, MD**

Fellow  
 Division of Emergency Medicine  
 Children's Hospital Los Angeles  
 Los Angeles, California

**Tara Webb, MD**

Fellow  
 Department of Pediatric Emergency  
 Medicine  
 Children's Hospital of Wisconsin  
 Wauwatosa, Wisconsin

**Kristin Welch, MD**

Assistant Professor  
 Department of Pediatrics  
 University of Connecticut School of  
 Medicine  
 Farmington, Connecticut  
 Attending Physician  
 Department of Pediatric Emergency  
 Medicine  
 Connecticut Children's Medical Center  
 Hartford, Connecticut

**Emily L. Willner, MD**

Assistant Professor of Pediatrics  
 Department of Pediatrics  
 Keck School of Medicine of the University  
 of Southern California  
 Associate Fellowship Director  
 Division of Emergency Medicine  
 Children's Hospital of Los Angeles  
 Los Angeles, California

**Derek A. Wong, MD**

Assistant Professor  
 Department of Pediatrics  
 David Geffen School of Medicine at UCLA  
 Los Angeles, California

**James M. Wu, MD**

Fellow  
 Department of Emergency Medicine  
 Children's Mercy Hospital  
 Kansas City, Missouri

**Shira Yahalom, MD**

Attending Physician  
 Department of Emergency Medicine  
 Beth Israel Medical Center  
 New York, New York

**Yuki Yasaka, MD**

Fellow  
 Department of Pediatric Critical Care  
 Children's Hospital Los Angeles  
 Los Angeles, California

**Sabina Zavolkovskaya, MD**

Attending  
 Department of Emergency Medicine,  
 Division of Pediatric Emergency  
 Medicine  
 Maimonides Medical Center  
 Brooklyn, New York

**Arezoo Zomorodi, MD**

Department of Pediatrics  
 Jefferson Medical College  
 Philadelphia, Pennsylvania  
 Attending Physician  
 Department of Pediatrics  
 Alfred I duPont Hospital for Children  
 Wilmington, Delaware

**Mark R. Zonfrillo, MD, MSCE**

Assistant Professor  
 Department of Pediatrics  
 University of Pennsylvania School of  
 Medicine  
 Attending Physician  
 Division of Emergency Medicine  
 Children's Hospital of Pennsylvania  
 Philadelphia, Pennsylvania

Preface	v	Apparent Life-Threatening Event	70
Foreword	vi	Appendicitis	72
Acknowledgments	vii	Arthritis, Rheumatoid	74
Contributors	ix	Arthritis, Septic	76
		Ascaris Lumbricoides	78
Abdominal Distention	2	Ascites	80
Abruptio Placenta	4	Asthma	82
Abscess, Bartholin Gland	6	Asystole	84
Abscess, Dentoalveolar	8	Ataxia	86
Abscess, Gluteal	10	Atlantoaxial Instability	88
Abscess, Intracranial	12	Atopic Dermatitis	90
Abscess, Ludwig Angina	14	Avascular Necrosis of the Femoral Head	92
Abscess, Perianal	16	Bacteremia	94
Abscess, Peritonsillar	18	Balanitis/Balanoposthitis	96
Abscess, Rectal	20	Barotrauma, Sinus	98
Abscess, Retropharyngeal	22	Beta-Blocker Poisoning	100
Acetaminophen Poisoning	24	Biliary Tract Disease	102
Acne	26	Bipolar Disorder/Mania	104
Acute Hemolytic Anemia	28	Bite, Animal	106
Acute Renal Failure	30	Bite, Human	108
Acute Respiratory Failure	32	Blepharitis	110
Adrenal Insufficiency	34	Blindness	112
Agitation	36	Body Packers (Ingested Drug Packages)	114
Altered Level of Consciousness/Coma	38	Botulism	116
Altitude Sickness	40	Brachial Plexus Injury	118
Amenorrhea	42	Bradycardia	120
Anal Fissure	44	Branchial Cleft Cyst	122
Anaphylaxis	46	Breast Lesions	124
Anemia	48	Bronchiolitis	126
Angioedema	50	Burn, Chemical	128
Ankle Sprain	52	Burn, Thermal	130
Anterior Uveitis (Iritis)	54	Caffeine/Theophylline Poisoning	132
Anticholinergic Poisoning	56	Calcium Channel Blocker Poisoning	134
Anticoagulant Poisoning	58	Candidiasis	136
Anticonvulsant Poisoning	62	Carbon Monoxide/Cyanide Poisoning and Smoke Inhalation	138
Aphthous Stomatitis	64	Cardiogenic Shock	140
Aplastic Anemia	66	Cardiomyopathy	142
Apnea	68		

Carpal Tunnel Syndrome	144	Cystic Hygroma	230
Cat Scratch Disease	146	Dacryocystitis/Dacryostenosis	232
Cauda Equina Syndrome	148	Decompression Sickness	234
Caustic Exposure	150	Deep Vein Thrombosis	236
Cavernous Sinus Thrombosis	152	Dehydration	238
Celiac Disease	154	Dengue Fever	240
Cellulitis	156	Depression	242
Cerebral Contusions	158	Dermatomyositis	244
Cervical Lymphadenitis	160	Diabetes Insipidus	246
Chalazion	162	Diabetic Ketoacidosis	248
Chancroid	164	Diaper Rash	250
Chickenpox/Shingles	166	Diarrhea	252
Child Abuse	168	Digoxin Toxicity	254
Cholelithiasis	170	Diphtheria	256
Cholinergic Poisoning	172	Discitis	258
Cocaine Poisoning	174	Dislocation, Knee	260
Colitis	176	Dislocation, Patella	262
Collagen Vascular Disease	178	Dislocation, Temporomandibular Joint	264
Compartment Syndrome	180	Disorders of Energy Metabolism (Mitochondrial Disease)	266
Concussion	182	Disseminated Intravascular Coagulation	268
Congenital Adrenal Hyperplasia	184	Dizziness/Vertigo	270
Congenital Heart Disease	186	Drowning	272
Congestive Heart Failure	188	Ductal-Dependent Cardiac Emergencies	274
Conjunctival Injury	190	Dysrhythmia, Atrial	276
Conjunctivitis	192	Dysrhythmia, Ventricular	278
Conjunctivitis, Neonatal	194	Dystonia	280
Constipation	196	Eating Disorders	282
Constricting Band/Tourniquet Syndrome	198	Ectopic Pregnancy	284
Contact Dermatitis	200	Eczema Herpeticum	286
Conversion Disorder	202	Edema	288
Corneal Abrasion	204	Electrical Injury	290
Costochondritis	206	Emergency Contraception	292
Cough	208	Empyema	294
Croup	210	Encephalitis	296
Crying/Colic	212	Endometriosis	298
Cryptorchidism	214	Envenomation, Insect Bites and Stings	300
Cushing Syndrome	216	Envenomation, Marine	302
Cutaneous Larva Migrans	218	Envenomation, Scorpion	304
Cyanosis	220	Envenomation, Snake	306
Cyanotic Heart Disease	222	Envenomation, Spider	308
Cyclic Vomiting	224	Epididymitis and Orchitis	310
Cystic Fibrosis: Exacerbation	226	Epidural Hematoma	312
Cystic Fibrosis: New Diagnosis	228		

Epiglottitis/Supraglottitis	314	Fracture, Pelvic Avulsion	400
Epistaxis	316	Fracture, Rib	402
Erythema Infectiosum	318	Fracture, Scaphoid	404
Erythema Multiforme	320	Fracture, Scapula	406
Erythema Nodosum	322	Fracture, Skull	408
Erythema Toxicum	324	Fracture, Supracondylar	410
Esophageal Varices	326	Fracture, Tibial Avulsion	412
Esophagitis	328	Fracture, Toddler's	414
Ethanol Poisoning	330	Fracture, Torus (Buckle)	416
Eye, Red	332	Fracture, Zygoma	418
Eye, Strabismus	334	Frostbite	420
Eye, Visual Disturbance	336	Ganglion Cyst	422
Facial Nerve Palsy	338	Gastritis	424
Failure to Thrive	340	Gastroenteritis	426
Fasciitis	342	Gastroesophageal Reflux	428
Febrile Seizure	344	Gastrointestinal Bleeding: Lower	430
Felon	346	Gastrointestinal Bleeding: Upper	432
Fever in Children Older than 3 Months	348	Gastrointestinal Polyps	434
Fever in Infants 0–3 Months of Age	350	Genital Warts	436
Fever of Unknown Origin	352	Giardiasis	438
Flail Chest	354	Globe Rupture	440
Food Poisoning	356	Glomerulonephritis	442
Foreign Body Aspiration	358	Gonorrhea	444
Foreign Body Ingestion	360	Groin Mass	446
Foreign Body, Cornea	362	Group B Streptococcal Infection	448
Foreign Body, Disc Battery	364	Guillain-Barré Syndrome	450
Foreign Body, Ear	366	Gynecomastia	452
Foreign Body, Esophagus	368	Hair-Thread Tourniquet	454
Foreign Body, Nose	370	Hallucinogen Poisoning	456
Foreign Body, Rectum	372	Hand-Foot-and-Mouth Disease	458
Foreign Body, Soft Tissue	374	Headache	460
Fracture, Cervical Spine	376	Hearing Loss	462
Fracture, Clavicle	378	Heart Block	464
Fracture, Coccyx	380	Heart Murmur	466
Fracture, Femur	382	Heat Illness	468
Fracture, Foot	384	Hemangioma	470
Fracture, Forearm/Wrist	386	Hematuria	472
Fractures, Greenstick/Bowing	388	Hemolytic Disease of the Newborn	474
Fracture, Humerus	390	Hemolytic Uremic Syndrome	476
Fracture, Mandibular	392	Hemophilia	478
Fracture, Nasal	394	Hemoptysis	480
Fracture, Orbital	396	Hemothorax	482
Fracture, Patella	398	Henoch-Schönlein Purpura	484

Hepatic Encephalopathy	486	Irritable Bowel Syndrome	572
Hepatitis, Acute	488	Jaundice, Conjugated Hyperbilirubinemia	574
Hepatomegaly	490	Jaundice, Unconjugated Hyperbilirubinemia	576
Hernia	492	Kawasaki Disease	578
Herpes Simplex	494	Labial Adhesions	580
Hirschsprung Disease	496	Laceration Repair	582
HIV/AIDS	498	Laryngitis	584
Hydrocarbon Poisoning	500	Laryngomalacia/Tracheomalacia	586
Hydrocephalus	502	Lead Poisoning	588
Hydronephrosis	504	Leukemia	590
Hypercalcemia	506	Lice (Pediculosis)	592
Hyperemesis Gravidarum	508	Limp	594
Hyperglycemia	510	Lyme Disease	596
Hyperkalemia	512	Lymphadenopathy	598
Hypernatremia	514	Lymphogranuloma Venereum	600
Hypertension	516	Malaria	602
Hyperthermia	518	Mallet Finger	604
Hyperthyroidism	520	Mastitis	606
Hyperventilation	522	Mastoiditis	608
Hyphema	524	Measles	610
Hypocalcemia	526	Meckel's Diverticulum	612
Hypoglycemia	528	Mediastinal Mass	614
Hypoglycemic Agents Poisoning	530	Meningitis	616
Hypokalemia	532	Meningococemia	618
Hyponatremia	534	Menses, Dysmenorrhea	620
Hypoparathyroidism	536	Menses, Oligomenorrhea	622
Hypotension	538	Mesenteric Adenitis	624
Hypothermia	540	Metabolic Acidosis	626
Idiopathic Thrombocytopenic Purpura	542	Methemoglobinemia	628
Immobile Arm	544	Migraine Headaches	630
Imperforate Hymen	546	Molluscum Contagiosum	632
Impetigo	548	Mumps	634
Inborn Errors of Metabolism	550	Munchausen Syndrome by Proxy	636
Infantile Spasm	552	Muscular Dystrophy	638
Infectious Mononucleosis	554	Myasthenia Gravis	640
Infective Endocarditis	556	Myocardial Contusion	642
Inflammatory Bowel Disease	558	Myocardial Infarction	644
Influenza	560	Myocarditis	646
Inhalant Abuse/Poisoning	562	Nail Bed Injuries	648
Intestinal Malrotation	564	Neck Mass	650
Intraosseous Infusions	566	Neck Stiffness	652
Intussusception	568	Necrotizing Enterocolitis	654
Iron Poisoning	570	Needle Stick	656

Neoplasm, Brain	658	Pertussis	742
Neoplasm, Lymphoma	660	Phimosis	744
Neoplasm, Neuroblastoma	662	Pilonidal Cyst	746
Nephrotic Syndrome	664	Pinworms	748
Neuroleptic Malignant Syndrome	666	Pityriasis Rosea	750
Nonsteroidal Anti-Inflammatory Drug (NSAID) Poisoning	668	Pleural Effusion	752
Nursemaid's Elbow	670	Pneumonia, Aspiration	754
Obstructive Sleep Apnea Syndrome	672	Pneumonia, Bacterial	756
Omphalitis	674	Pneumothorax/Pneumomediastinum	758
Opioid Poisoning	676	Poison Ivy/Oak/Sumac	760
Oral Lesions	678	Polycystic Kidney Disease	762
Orbital Cellulitis	680	Polycystic Ovarian Syndrome	764
Orchitis	682	Polycythemia	766
Osgood-Schlatter Disease	684	Polyuria	768
Osteogenesis Imperfecta	686	Pregnancy	770
Osteomyelitis	688	Priapism	772
Osteosarcoma	690	Procedural Sedation and Analgesia	774
Otitis Externa	692	Prolonged QT Interval	776
Otitis Media	694	Pseudotumor Cerebri	778

# TOPICAL TABLE OF CONTENTS

## Cardiovascular Emergencies

Bradycardia	120
Cardiogenic Shock	140
Cardiomyopathy	142
Congenital Heart Disease	186
Congestive Heart Failure	188
Cyanosis	220
Cyanotic Heart Disease	222
Ductal-Dependent Cardiac Emergencies	274
Dysrhythmia, Atrial	276
Dysrhythmia, Ventricular	278
Heart Block	464
Heart Murmur	466
Hypertension	516
Hypotension	538
Infective Endocarditis	556
Myocardial Contusion	642
Myocardial Infarction	644
Myocarditis	646
Palpitations	712
Patent Ductus Arteriosus	726
Pericardial Effusion/Tamponade	732
Pericarditis	734
Prolonged QT Interval	776
Pulmonary Edema	786
Pulmonary Embolism	788
Rheumatic Fever	818
Shock, Cardiogenic	852
Sudden Infant Death Syndrome (SIDS)	888
Syncope	894
Tachycardia	902
Tetralogy of Fallot	918

## Dermatology/Soft Tissue Emergencies

Abscess, Bartholin Gland	6
Abscess, Gluteal	10
Abscess, Ludwig Angina	14
Abscess, Perianal	16

Abscess, Rectal	20
Acne	26
Atopic Dermatitis	90
Avascular Necrosis of the Femoral Head	92
Branchial Cleft Cyst	122
Breast Lesions	124
Burn, Chemical	128
Burn, Thermal	130
Candidiasis	136
Cellulitis	156
Cervical Lymphadenitis	160
Constricting Band/Tourniquet Syndrome	198
Contact Dermatitis	200
Cutaneous Larva Migrans	218
Cystic Hygroma	230
Diaper Rash	250
Eczema Herpeticum	286
Erythema Infectiosum	318
Erythema Multiforme	320
Erythema Nodosum	322
Erythema Toxicum	324
Fasciitis	342
Felon	346
Foreign Body, Soft Tissue	374
Ganglion Cyst	422
Gynecomastia	452
Hair-Thread Tourniquet	454
Hemangioma	470
Impetigo	548
Lymphadenopathy	598
Mastitis	606
Molluscum Contagiosum	632
Neck Mass	650
Omphalitis	674
Panniculitis	718
Paronychia	722
Pilonidal Cyst	746
Pityriasis Rosea	750

Poison Ivy/Oak/Sumac	760	Drowning	272
Psoriasis	780	Electrical Injury	290
Pyogenic Granuloma	792	Envenomation, Insect Bites and Stings	300
Rash, Maculopapular	794	Envenomation, Marine	302
Rash, Neonatal	796	Envenomation, Scorpion	304
Rash, Petechiae	798	Envenomation, Snake	306
Rash, Purpura	800	Envenomation, Spider	308
Rash, Urticaria	802	Foreign Body, Soft Tissue	374
Rash, Vesiculobullous	804	Frostbite	420
Scabies	830	Hair-Thread Tourniquet	454
Seborrheic Dermatitis	840	Heat Illness	468
Staphylococcal Scalded Skin Syndrome	868	Hyperthermia	518
Stevens-Johnson Syndrome/TEN Spectrum	872	Hypothermia	540
Tendon Laceration	908	Poison Ivy/Oak/Sumac	760
Thyroglossal Duct Cyst	922	Tick Bite	924
Tinea Capitis	926		
Tinea Corporis	928	<b>Gastrointestinal Emergencies</b>	
Tinea Versicolor	930	Abdominal Distention	2
Umbilical Granuloma	990	Abscess, Perianal	16
Warts	1026	Abscess, Peritonsillar	18
		Abscess, Rectal	20
<b>Endocrine Emergencies</b>		Abscess, Retropharyngeal	22
Adrenal Insufficiency	34	Anal Fissure	44
Congenital Adrenal Hyperplasia	184	Appendicitis	72
Cushing Syndrome	216	Ascaris Lumbricoides	78
Diabetic Insipidus	246	Ascites	80
Diabetic Ketoacidosis	248	Biliary Tract Disease	102
Gynecomastia	452	Botulism	116
Hyperthyroidism	520	Celiac Disease	154
Hypoparathyroidism	536	Cholelithiasis	170
Inborn Errors of Metabolism	550	Colitis	176
Menses, Oligomenorrhea	622	Constipation	196
Polycystic Ovarian Syndrome	764	Cyclic Vomiting	224
Syndrome of Inappropriate Antidiuretic Hormone Secretion (SIADH)	896	Dehydration	238
		Diarrhea	252
<b>Environmental Emergencies</b>		Esophageal Varices	326
Altitude Sickness	40	Esophagitis	328
Barotrauma, Sinus	98	Food Poisoning	356
Bite, Animal	106	Foreign Body Ingestion	360
Bite, Human	108	Foreign Body, Disc Battery	364
Burn, Thermal	130	Foreign Body, Esophagus	368
Contact Dermatitis	200	Foreign Body, Rectum	372
Decompression Sickness	234	Gastritis	424

Gastroenteritis	426	Groin Mass	446
Gastroesophageal Reflux	428	Herpes Simplex	494
Gastrointestinal Bleeding: Lower	430	Lymphogranuloma Venereum	600
Gastrointestinal Bleeding: Upper	432	Orchitis	682
Gastrointestinal Polyps	434	Paraphimosis	720
Giardiasis	438	Patent Urachus	728
Hepatic Encephalopathy	486	Phimosis	744
Hepatitis, Acute	488	Priapism	772
Hepatomegaly	490	Scrotal Mass	834
Hernia	492	Scrotal Pain	836
Hirschsprung Disease	496	Scrotal Swelling	838
Inflammatory Bowel Disease	558	Sexually Transmitted Infections	850
Intestinal Malrotation	564	Syphilis	898
Intussusception	568	Testicular Torsion	912
Irritable Bowel Syndrome	572	Trauma, Perineal	972
Jaundice, Conjugated	574	Trauma, Scrotal and Penile	974
Jaundice, Unconjugated	576	Urethral Prolapse	994
Meckel's Diverticulum	612	Urethritis	996
Mesenteric Adenitis	624	Urinary Retention	998
Necrotizing Enterocolitis	654	Urinary Tract Infection	1000
Pain, Abdomen	700		
Pancreatitis	714	<b>Gynecologic/Obstetric Emergencies</b>	
Peritonitis	740	Abruptio Placenta	4
Pinworms	748	Abscess, Bartholin Gland	6
Pyloric Stenosis	790	Amenorrhea	42
Rectal Bleeding	806	Chancroid	164
Rectal Prolapse	808	Ectopic Pregnancy	284
Reye Syndrome	814	Emergency Contraception	292
Salmonella	826	Endometriosis	298
Splenomegaly	866	Genital Warts	436
Tapeworm and Cestode Infestations	904	Gonorrhea	444
Thrush	920	Herpes Simplex	494
Tracheoesophageal Fistula	940	Hyperemesis Gravidarum	508
Trauma, Abdominal	948	Imperforate Hymen	546
Volvulus	1022	Labial Adhesions	580
Vomiting	1024	Menses, Dysmenorrhea	620
		Menses, Oligomenorrhea	622
<b>Genitourinary Emergencies</b>		Ovarian Cyst	696
Balanitis/Balanoposthitis	96	Ovarian Torsion	698
Chancroid	164	Pelvic Inflammatory Disease	730
Cryptorchidism	214	Pregnancy	770
Epididymitis and Orchitis	310	Sexually Transmitted Infections	850
Genital Warts	436	Syphilis	898
Gonorrhea	444	Trauma, Perineal	972

Trauma, Vaginal	980	Stomatitis	874
Urethritis	996	Strangulation	878
Vaginal Bleeding During Early Pregnancy ( $<20$ Weeks)	1004	Stridor	880
Vaginal Bleeding During Pregnancy ( $>20$ Week Gestation)	1006	Teething	906
Vaginal Bleeding, Prepubertal	1008	Thyroglossal Duct Cyst	922
Vaginal Bleeding, Pubertal/DUB	1010	Tracheitis	938
Vaginal Discharge, Prepubertal	1012	Trauma, Dental	954
Vaginal Discharge, Pubertal	1014	Trauma, Facial	958
Vaginitis	1016	Trauma, Head	964
		Trauma, Neck	968
		Upper Respiratory Infection	992
<b>Head/Neck Emergencies</b>		<b>Hematologic/Oncologic Emergencies</b>	
Abscess, Dentoalveolar	8	Acute Hemolytic Anemia	28
Abscess, Intracranial	12	Anemia	48
Abscess, Ludwig Angina	14	Aplastic Anemia	66
Abscess, Peritonsillar	18	Cavernous Sinus Thrombosis	152
Abscess, Retropharyngeal	22	Disseminated Intravascular Coagulation	268
Aphthous Stomatitis	64	Epistaxis	316
Branchial Cleft Cyst	122	Fever of Unknown Origin	352
Cavernous Sinus Thrombosis	152	Hemolytic Disease of the Newborn	474
Cerebral Contusions	158	Hemolytic Uremic Syndrome	476
Cervical Lymphadenitis	160	Hemophilia	478
Cystic Hygroma	230	Idiopathic Thrombocytopenic Purpura	542
Dislocation, Temporomandibular Joint	264	Leukemia	590
Dizziness/Vertigo	270	Mediastinal Mass	614
Epistaxis	316	Methemoglobinemia	628
Facial Nerve Palsy	338	Neoplasm, Brain	658
Foreign Body, Ear	366	Neoplasm, Lymphoma	660
Foreign Body, Nose	370	Neoplasm, Neuroblastoma	662
Fracture, Mandibular	392	Osteosarcoma	690
Fracture, Nasal	394	Polycythemia	766
Fracture, Orbital	396	Renal Vein Thrombosis	810
Fracture, Skull	408	Sickle Cell Disease	858
Fracture, Zygoma	418	Spinal Cord Compression	864
Hand-Foot-and-Mouth Disease	458	Splenomegaly	866
Laryngitis	584	Transfusion Reaction	942
Mastoiditis	608	Wilms Tumor	1032
Oral Lesions	678	<b>Immunologic Emergencies</b>	
Otitis Externa	692	Anaphylaxis	46
Otitis Media	694	Angioedema	50
Parotitis	724	Arthritis, Rheumatoid	74
Perichondritis, Ear	736	Collagen Vascular Disease	178
Sinusitis	860		

Dermatomyositis	244	Epiglottitis/Supraglottitis	314
Erythema Multiforme	320	Erythema Infectiosum	318
Erythema Nodosum	322	Eye, Red	332
Hemolytic Disease of the Newborn	474	Fasciitis	342
Kawasaki Disease	578	Febrile Seizure	344
Lymphadenopathy	598	Felon	346
Serum Sickness	846	Fever in Children Older than 3 Months	348
Stevens-Johnson Syndrome/TEN Spectrum	872	Fever in Infants 0–3 Months of Age	350
Systemic Lupus Erythematosus	900	Fever of Unknown Origin	352
Transfusion Reaction	942	Food Poisoning	356
<b>Infectious Disease</b>		Gastroenteritis	426
Abscess, Bartholin Gland	6	Genital Warts	436
Abscess, Dentoalveolar	8	Giardiasis	438
Abscess, Gluteal	10	Gonorrhea	444
Abscess, Intracranial	12	Group B Streptococcal Infection	448
Abscess, Ludwig Angina	14	Hand-Foot-and-Mouth Disease	458
Abscess, Perianal	16	Hematuria	472
Abscess, Peritonsillar	18	Hepatitis, Acute	488
Abscess, Rectal	20	Herpes Simplex	494
Abscess, Retropharyngeal	22	HIV/AIDS	498
Arthritis, Septic	76	Impetigo	548
Ascaris Lumbricoides	78	Infectious Mononucleosis	554
Bacteremia	94	Infective Endocarditis	556
Biliary Tract Disease	102	Influenza	560
Botulism	116	Laryngitis	584
Bronchiolitis	126	Lice (Pediculosis)	592
Candidiasis	136	Lyme Disease	596
Cat Scratch Disease	146	Lymphogranuloma Venereum	600
Cellulitis	156	Malaria	602
Cervical Lymphadenitis	160	Mastitis	606
Chancroid	164	Mastoiditis	608
Chickenpox/Shingles	166	Measles	610
Conjunctivitis, Neonatal	194	Meningitis	616
Croup	210	Meningococcemia	618
Cutaneous Larva Migrans	218	Mesenteric Adenitis	624
Dengue Fever	240	Molluscum Contagiosum	632
Diphtheria	256	Mumps	634
Discitis	258	Myocarditis	646
Eczema Herpeticum	286	Neck Stiffness	652
Empyema	294	Needle Stick	656
Encephalitis	296	Omphalitis	674
Epididymitis and Orchitis	310	Orbital Cellulitis	680
		Orchitis	682

Osteomyelitis	688	Upper Respiratory Infection	992
Otitis Externa	692	Urethritis	996
Otitis Media	694	Urinary Retention	998

# ABDOMINAL DISTENTION

Besh Barcega

Eugenio Vazquez

## BASICS

### DESCRIPTION

- Abdominal distention is an increase in the volume of the abdominal cavity as the anterior abdominal wall is forced outwardly by rising internal pressure from either gas, fluid, stool, an enlarged organ, or a mass.
- Abdominal distention may be difficult to discern in infants and children, as they normally have protuberant bellies secondary to their immature abdominal musculature, relatively large internal organs, and physiologic lordosis.

### RISK FACTORS

- Prematurity is a risk factor for several abdominal emergencies that may present as abdominal distention.
- Previous abdominal surgeries may cause the formation of adhesions leading to bowel obstruction (1).
- Children with neuromuscular disease are more prone to abdominal distention from an ileus.

### PATHOPHYSIOLOGY

- Abdominal distention is a nonspecific sign that can be caused by a large number of pathologic and physiologic processes, most all of them falling into one of the following categories:
  - Increased intraluminal volume of the GI tract caused by oral intake of food, swallowed air, trapped air from obstruction, or production of gas from malabsorption or bacterial overgrowth
  - Increased extraluminal accumulation of gas or fluid:
    - Free peritoneal air after a perforation of the GI tract, pneumomediastinum infiltrating the abdominal cavity, or air introduced from surgery or trauma
    - Extraluminal fluid can originate from an effusion, an exudate (pus), a hemorrhagic process (blood), the disruption of the gallbladder (bile), the genitourinary tract (urine), or the lymphatic vessels (chyle).
  - Severe organomegaly:
    - Hepatomegaly and splenomegaly can develop from inflammation, venous congestion, an infiltrative processes, or trauma.
    - Enlarged kidneys can be seen from obstructive uropathies causing hydronephrosis or from polycystic kidney disease.
- Masses such as cysts, tumors, and even pregnancy
- Abdominal wall hypotonia from either weak musculature or fascia

### ETIOLOGY

- Neonates:
  - Bowel obstruction:
    - Malrotation with volvulus
    - Necrotizing enterocolitis
    - Hirschsprung disease with toxic megacolon
    - Inguinal hernia with incarceration
  - Intra-abdominal masses. Up to 2/3 originate from the kidneys or the urinary tract, with most being multicystic kidneys or hydronephrosis in this age group.
    - These neonatal abdominal masses usually do not present as medical emergencies but require urgent attention.
- Infants and children:
  - Bowel obstruction:
    - Intussusception is the most common etiology in children <2 yr old.
    - Adhesive bands from prior surgery (1)
  - Intra-abdominal masses: Hydronephrosis, Wilm's tumor, neuroblastoma, lymphoma
  - Trauma
  - Peritonitis: Ruptured appendicitis is a common etiology in children <2 yr old.
  - Ileus from infection or electrolyte abnormalities
  - Constipation
  - Nephrotic syndrome
- Adolescent females:
  - Hematoocolpos
  - Ovarian cyst(s)

## DIAGNOSIS

### HISTORY

- The history should be comprehensive due to the large number of processes that can cause abdominal distention but can be focused by age, risk factors, and duration of symptoms.
- In the neonate:
  - Bilious emesis suggests intestinal obstruction beyond the ampulla of Vater and can be seen with malrotation, intestinal atresias, or ileus.
  - Delayed passage of meconium can be seen in cystic fibrosis and Hirschsprung disease.
  - Fever may be from an infectious process such as sepsis causing ileus, a GI infection, or peritonitis due to perforation.
  - A weak urinary stream may be secondary to posterior urethral valves causing hydronephrosis.
- In the infant and older child:
  - Inquire about previous abdominal surgeries.
  - Inquire about the stooling pattern.
  - Pain should be thoroughly evaluated and differentiated, as it may render important clues to the etiology of the disease:
    - Acute onset of inconsolability or increased irritability should alert toward abdominal emergencies such as intussusception, obstruction, or infection.
    - Chronic irritability may point to infant colic, formula intolerance, malabsorption, or constipation.

- Chronic isolated abdominal distention in otherwise healthy children is suspicious for neoplasm, organomegaly, or ascites.
- A history of weight gain and edema can be seen in nephrotic syndrome.
- Gross hematuria may suggest kidney disease such as polycystic kidney disease or Wilm's tumor.
- Inquire about sexual history and menstruation in adolescent females.
- Inquire about direct trauma to the abdominal region.

### PHYSICAL EXAM

- Look for signs of toxicity including pallor, diaphoresis, hypotension, rapid pulse, shallow breathing, poor capillary refill, and lethargy.
- Conduct a detailed visual exam looking for generalized edema, bruises, pallor, jaundice, or surgical scars.
- Detailed abdominal exam:
  - Auscultate:
    - Hyperactive bowel sounds are heard with acute intestinal obstruction, malabsorption syndromes, or gastroenteritis.
    - Hypoactive bowel sounds suggest ileus.
  - Percuss:
    - Tympanic abdomen suggests gaseous distention.
    - Localized tympany may result from a proximal obstruction, while a generalized tympanic note suggests either a distal obstruction or free peritoneal air.
    - Generalized shifting dullness when the patient is placed on the lateral decubitus position is indicative of free peritoneal fluid.
  - Palpate:
    - Masses may consist of stool, enlarged organs, cysts, or tumors. Location, mobility, and contour of the mass should be noted.
    - Rebound tenderness and involuntary guarding suggest peritonitis.
- A pelvic exam on sexually active females and genital exam on males may be indicated.
- Rectal examination is recommended if a lower quadrant abdominal mass is found on exam.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

- Obstructive bowel process is common cause, and laboratory testing is of limited value for diagnosis but can be used as an adjunct for patient management:
- CBC with peripheral smear is recommended to evaluate for inflammatory or infectious process or malignancy.
  - Assess electrolytes if an ileus is suspected
  - Order BUN/creatinine if concerned for renal disease.
  - LFTs if hepatomegaly is found
  - Urinalysis if concerned for renal etiology or if generalized edema is found on exam

**Imaging**

- A 2- or 3-view abdominal radiograph is the most helpful initial diagnostic study to perform for a patient presenting with abdominal distention. The findings on the radiograph will aid to determine what additional lab and/or imaging studies will be needed (2,3). Look at the intraluminal gas pattern, presence of free air, calcifications, constipation, and some soft tissue masses:
  - An intestinal obstruction or a paralytic ileus can cause distended loops of bowel and air-fluid levels.
  - “Double bubble sign” is appearance of a gas-filled stomach and duodenum separated by the pylorus and is seen in neonates and infants with duodenal atresia or malrotation with volvulus.
- Abdominal US is useful for initial evaluation of an abdominal mass and can also be used to diagnose intussusception.
- Abdominal CT is the most sensitive imaging modality for detailed evaluation of intra-abdominal solid organ pathology, especially if US findings are inconclusive, but it does run the risk of radiation exposure (3).
- Upper GI series is indicated if malrotation or upper GI obstruction is suspected. Obtain only if the patient is clinically stable.
- Air or barium enema is indicated if intussusception is highly suspected. The pediatric surgeon should be involved due to the risk of bowel perforation.

**DIFFERENTIAL DIAGNOSIS**

- Extra-abdominal pathology such as pulmonary hyperinflation from bronchiolitis or an asthma exacerbation
- Unrecognized pregnancy

**TREATMENT**

**INITIAL STABILIZATION/THERAPY**

Assess and stabilize airway, breathing, and circulation.

**MEDICATION**

- Broad-spectrum IV antibiotics if suspicious for peritonitis or sepsis:
  - Gentamicin 2.5 mg/kg/dose PLUS ampicillin/sulbactam 50 mg/kg/dose of ampicillin component OR
  - Piperacillin/tazobactam 100 mg/kg/dose of piperacillin component OR
  - Ampicillin 50 mg/kg/dose PLUS gentamicin 2.5 mg/kg/dose PLUS metronidazole 7.5 mg/kg/dose
- Analgesic if patient is in pain:
  - Morphine 0.1 mg/kg IV/IM/SC q2h PRN:
    - Initial morphine dose 0.1 mg/kg IV/SC may be repeated q15–20min until pain is controlled then q2h PRN
- Antiemetic if patient has persistent nausea and/or vomiting: Ondansetron 0.15 mg/kg/dose IV/PO q6h PRN
- Maintenance IV fluids if patient is found to be dehydrated

**SURGERY/OTHER PROCEDURES**

- Immediate surgical consultation is required for any ill-appearing patient with suspected peritonitis from bowel perforation or malrotation with mid-gut volvulus.
- Nasogastric tube placement if intractable vomiting or if a bowel obstruction is suspected

**DISPOSITION**

**Admission Criteria**

- Newborns with fever or infants and children who are ill appearing
- Peritoneal signs and those who may also require urgent surgical intervention
- Poorly controlled pain and/or intractable vomiting without a specific diagnosis
- Intra-abdominal organ trauma
- Nephrotic syndrome with hypoalbuminemia refractory to oral corticosteroids

**Discharge Criteria**

- Patients who are well appearing and have a definitive nonemergent etiology of the abdominal distention
- Patients who are well appearing and do not have a definitive etiology of the abdominal distention but do have reliable follow-up
- Patients with abdominal pain and/or vomiting whose symptoms are relieved or improved

**FOLLOW-UP**

**FOLLOW-UP RECOMMENDATIONS**

- 24-hr follow-up with either the primary care provider or ED if etiology of abdominal distention has not been determined and symptoms persist
- 24–48-hr follow-up with primary care provider if etiology has been determined and additional evaluation is needed
- Discharge instructions and medications:
  - Return if patient develops vomiting, severe abdominal pain, or fever.
  - If pain is mild, provide an analgesic:
    - Acetaminophen 10–15 mg/kg/dose PO or PR q4–6h

**PROGNOSIS**

Dependent on the underlying etiology

**COMPLICATIONS**

- Bowel obstruction
- Bowel perforation
- Gut necrosis
- Sepsis
- Death

**CODES**

**ICD9**

787.3 Flatulence, eructation, and gas pain

**PEARLS AND PITFALLS**

- Necrotizing enterocolitis may occur in term infants and should be in the differential diagnosis of any newborn with feeding intolerance and abdominal distention.
- An obstructive bowel process is the most common cause of acute onset of abdominal distention with abdominal pain.
- Abdominal masses are usually an incidental finding on abdominal exam. Patients usually present with abdominal pain only when the mass is causing an obstruction.
- It is critical to rule out neoplasm in children with abdominal swelling.

# ABRUPTIO PLACENTA

Shira Yahalom

## BASICS

### DESCRIPTION

- Abruptio placenta refers to separation of the placenta from the uterus after 20 wk gestation and prior to delivery.
- The severity of separation can range from mild to fatal for both mother and fetus.

### EPIDEMIOLOGY

- Abruptio placenta complicates 1% of pregnancies.
- ~1/3 of all antepartum bleeding is attributed to abruptio placenta.

### RISK FACTORS

- Maternal HTN
- Multiple gestation
- Uterine malformations
- Tobacco or cocaine use
- Polyhydramnios with sudden uterine decompression
- Previous abruptio
- Thrombophilias
- Trauma

### PATHOPHYSIOLOGY

- Rupture of blood vessels in the placenta leads to hematoma formation and placental separation.
- Placental separation releases prostaglandins, and contractions occur worsening separation and bleeding.
- Dissection of blood into the decidua basalis may progressively increase the shearing force on placenta.

### ETIOLOGY

Bleeding may result from trauma, defective placental blood vessels, thrombophilias, drug abuse, or uterine malformations.

## DIAGNOSIS

### HISTORY

- Triad of severe abdominal/back pain, vaginal bleeding, and fetal distress should alert the clinician for the presence of abruptio placenta.
- Since the bleeding may be concealed, the absence of vaginal bleeding does not rule out the diagnosis of abruptio placenta.
- Abdominal/Back pain may persist between contractions.
- Decrease in fetal activity as sensed by the mother
- Obtain history regarding cocaine use or recent trauma.

### PHYSICAL EXAM

- Since blood loss may be severe, maternal tachycardia and hypotension can occur.
- Fundal tenderness may be palpated, and fundal height may increase due to an expanding hematoma.
- The amount of vaginal bleeding does not correlate with the degree of abruptio:
  - Avoid pelvic examination until location of the placenta is verified given the differential diagnosis of placenta previa.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

- CBC
- Serum electrolytes, LFTs, BUN, and creatinine
- PT/PTT/INR, fibrinogen
- Blood type and Rh status

### Imaging

- US demonstrates abruptio placenta in only 50% of cases:
  - US use to demonstrate hematoma is of limited value since most abruptions will not be detected.
  - US should be used to locate the placenta.
- MRI is sensitive in detecting small or posterior abruptions.

### DIFFERENTIAL DIAGNOSIS

- Placenta previa is associated with painless vaginal bleeding.
- Uterine rupture causes severe abdominal pain, bleeding, and fetal distress/demise.
- Vasa previa will result in massive fetal blood loss.
- Vaginal or cervical laceration
- Preterm labor

## TREATMENT

### INITIAL STABILIZATION/THERAPY

- Obtain large-bore IV access, and start fluid resuscitation with 20 mL/kg crystalloid; repeat as needed.
- Supplemental oxygen
- Continuous fetal heart rate and contractions monitoring
- Close monitoring of the mother for signs of hemodynamic instability
- Fetal age should be assessed and complications of prematurity anticipated.

**MEDICATION****First Line**

RhoGAM IM  $\times$  300  $\mu$ g:

- Given as soon as possible within 72 hr of event for Rh-negative mothers  $>$  12 wk gestation

**Second Line**

- Typed and crossed-matched packed RBCs or platelets may be indicated.
- Fresh frozen plasma if disseminated intravascular coagulation (DIC) occurs
- Tocolytics may be considered with obstetric consultation.

**SURGERY/OTHER PROCEDURES**

- Obtain immediate obstetric consultation.
- Anticipate prematurity of fetus and consult neonatal ICU if precipitous delivery of an infant  $>$  20 wk gestation may occur.

**DISPOSITION****Admission Criteria**

- All patients should be admitted.
- Decision to deliver should be made with obstetric consultation and consideration of prematurity risks versus fetal and maternal morbidity and mortality.
- Critical care admission criteria:
  - All hemodynamically unstable patients, either before or after delivery, should receive ICU care.

**Discharge Criteria**

- All patients presenting to the ED with suspected abruptio placenta require admission for monitoring.
- Transfer to a facility with a neonatal ICU should be considered for stable patients. Transfer should be done after delivery if delivery is required to stabilize the mother.
- Patients with no evidence of abruption or other significant injury may be discharged after 4–6 hr of normal maternal and fetal monitoring.

**FOLLOW-UP****FOLLOW-UP RECOMMENDATIONS**

Discharge instructions include pelvic rest, no intercourse, no heavy lifting, and no prolonged standing.

**COMPLICATIONS**

- Maternal: Hemorrhagic shock, transfusion-related complications, DIC
- Fetal: Complications of prematurity, perfusion compromise, anoxic insult

**ADDITIONAL READING**

- Abbrescia K, Sheridan B. Complications of second and third trimester pregnancies. *Emerg Med Clin North Am.* 2003;21:695–710.
- Ferentz KS, Nesbitt LS. Common problems and emergencies in the obstetric patient. *Prim Care.* 2006;33(3):727–750.
- Francois KE, Foley MR. Antepartum and postpartum hemorrhage. In Gabbe SG, Niebyl JR, Simpson JL, et al., eds. *Obstetrics: Normal and Problem Pregnancies.* 5th ed. Philadelphia, PA: Churchill Livingstone Elsevier; 2007.
- Sakornbut E, Leeman L, Fontaine P. Late pregnancy bleeding. *Am Fam Physician.* 2007;75(8):1199–1206.

**See Also (Topic, Algorithm, Electronic Media Element)**

Vaginal Bleeding in Pregnancy

**CODES****ICD9**

- 641.20 Premature separation of placenta, unspecified as to episode of care
- 641.21 Premature separation of placenta, with delivery
- 641.23 Premature separation of placenta, antepartum

**PEARLS AND PITFALLS**

- Patients may not present with the classic triad. Consider the diagnosis in all patients presenting with preterm labor.
- The presenting complaint may only be a decrease in fetal activity per the patient.
- Lack of vaginal bleeding does not exclude abruptio placenta.
- US should not be used to exclude the diagnosis given the low sensitivity of the test. Diagnosis of abruptio placenta remains clinical.
- Anticipate shock and DIC.
- Consult an obstetrician early in the course of suspected abruptio placenta.

# ABSCESS, BARTHOLIN GLAND

Carl P. Kaplan

## BASICS

### DESCRIPTION

- The Bartholin glands are the major mucus-secreting sites of the vulva, with ducts located at 5 and 7 o'clock on the mucosal aspect of introitus adjacent to the labia minora.
- Trauma or local inflammation leads to duct obstruction, cyst formation, and bacterial colonization leading to localized abscess sometimes with accompanying cellulitis.
- Diagnosis is clinical.
- Therapy focuses on surgical incision and drainage with fistulization as well as antimicrobial therapy aimed at common flora.

### EPIDEMIOLOGY

#### Incidence

~2% of postmenarchal females

### RISK FACTORS

- Vulvovaginitis
- Sexual activity/Trauma
- Sexually transmitted infections (STIs)
- Black and non-Hispanic white females

### PATHOPHYSIOLOGY

Inflammation at the site of the duct leads to obstruction, mucocele formation, and suppurative infection by local flora.

### ETIOLOGY

- Anaerobic vaginal species:
  - *Bacteroides*
  - *Peptostreptococcus*
  - *Prevotella*
  - *Escherichia coli*
- Gonorrhea
- *Staphylococcus* species (MSSA/MRSA)
- *Streptococcal* species

## DIAGNOSIS

### HISTORY

- Acute labial swelling, redness, and pain
- Dyspareunia
- Dysuria
- Pain with movement or sitting
- Spontaneous discharge of pus

### PHYSICAL EXAM

- Unilateral labia swelling, redness, and tenderness
- 2–5-cm tender unilateral fluctuant mass
- Surrounding cellulitis
- Rarely fever
- Spontaneous purulent discharge

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

- Lab testing is not necessary for diagnosis.
- Cultures may be sent to assess for specific diagnosis, including gonorrhea.

#### Imaging

Soft tissue US may be employed to aid in diagnosis or to guide drainage.

### DIFFERENTIAL DIAGNOSIS

- Labial abscess
- Enterocutaneous fistula (inflammatory bowel disease)
- Hematoma
- Mucocele
- Genital ulcers
- Chancroid
- Vulvovaginitis
- Endometriosis
- Malignancy

## TREATMENT

### INITIAL STABILIZATION/THERAPY

Analgesics:

- NSAIDs
- Opioids
- Topical viscous lidocaine
- Locally injected or regional anesthesia

### MEDICATION

- Antibiotics for empiric coverage of STIs:
  - Ceftriaxone 125 mg IM or cefixime 400 mg PO plus azithromycin 1 g PO or doxycycline 100 mg PO b.i.d. for 7–14 days (or azithromycin 2 g PO)
  - Or alternately, a single dose of azithromycin 2 g PO as sole therapy
- Antibiotics for common flora:
  - Given if abscess is complicated by cellulitis
  - Amoxicillin/clavulanate 875 mg PO b.i.d. for 7–10 days OR
  - Trimethoprim/sulfamethoxazole 160 mg PO b.i.d. for 7–10 days if suspected of MRSA
  - For sepsis, consider combined therapy with all of the following:
    - Vancomycin 500–100 mg IV q12h PLUS
    - Doxycycline 100 mg IV q12h PLUS
    - Metronidazole 500 mg IV q8h
- NSAIDs:
  - Consider NSAIDs in anticipation of prolonged pain and inflammation:
    - Ibuprofen 10 mg/kg/dose PO/IV q6h PRN
    - Ketorolac 0.5 mg/kg IV/IM q6h PRN
    - Naproxen 5 mg/kg PO q8h PRN
- Acetaminophen 15 mg/kg/dose PO/PR q4h PRN

- Local anesthetics:
  - Infiltration with a local anesthetic may achieve significant analgesia.
- Opioids:
  - Morphine 0.1 mg/kg IV/IM/SC q2h PRN:
    - Initial morphine dose of 0.1 mg/kg IV/SC may be repeated q15–20min until pain is controlled, then q2h PRN.
  - Fentanyl 1–2 μg/kg IV q2h PRN:
    - Initial dose of 1 μg/kg IV may be repeated q15–20min until pain is controlled, then q2h PRN.
  - Codeine or codeine/acetaminophen dosed as 0.5–1 mg/kg of codeine component PO q4h PRN
  - Hydrocodone or hydrocodone/acetaminophen dosed as 0.1 mg/kg of hydrocodone component PO q4–6h PRN

**Issues for Referral**

Recurrence

**COMPLEMENTARY & ALTERNATIVE THERAPIES**

- Warm compresses
- Sitz baths

**SURGERY/OTHER PROCEDURES**

- Incision and drainage is the mainstay of therapy.
- Analgesia should be administered prior to the procedure. This may be local infiltration or regional anesthesia.
- Various drainage approaches include:
  - Simple incision and drainage
  - Fistulization procedures (Word catheter, Jacobi ring, etc.)
  - Marsupialization

**DISPOSITION**

**Admission Criteria**

Patients typically are discharged, but consider admission for severe associated cellulitis, pelvic inflammatory disease, intractable pain requiring parenteral opioids, or immunocompromise.

**Discharge Criteria**

- Pain controlled
- Spontaneous urination
- Ability to obtain and tolerate antibiotics if prescribed
- Ability to follow up in 48–72 hr

**FOLLOW-UP**

**FOLLOW-UP RECOMMENDATIONS**

- Discharge instructions and medications:
  - Analgesics as needed. See Medication section.
  - It is unclear if antibiotics are necessary after successful incision and drainage.
  - If cellulitis is present, antibiotics are necessary.
  - Warm compresses or sitz baths t.i.d.–q.i.d. for 48–72 hr
  - Maintain placement of Word catheter port in vagina (if applicable).
- Activity:
  - Avoid vaginal intercourse for 2–4 wk.
  - Wear loose-fitting undergarments.
  - Avoid running during placement while devices are in place.

**Patient Monitoring**

Follow up in 48–72 hr in ED or with primary care provider.

**PROGNOSIS**

- Average healing time is 4.8 days to 2.2 wk.
- Recurrence after fistulization procedure is 4–17% at 6 mo compared to 0–38% recurrence after simple needle aspiration.

**COMPLICATIONS**

- Recurrence
- Cyst formation
- Cellulitis
- Sepsis
- Scarring

**See Also (Topic, Algorithm, Electronic Media Element)**

- Pelvic Inflammatory Disease
- Sexually Transmitted Infections

**ICD9**  
616.3 Abscess of Bartholin’s gland

**PEARLS AND PITFALLS**

- Incision and drainage alone is inferior to the addition of a fistulization procedure.
- Topical viscous lidocaine and systemic opioids prior to incision and drainage will facilitate some procedures, but consider procedural sedation.
- During any procedure, wear appropriate personal protective equipment since abscess contents are under pressure.
- Gonorrhea cultures from abscess contents must be ordered and collected with appropriate media, as routine wound culture will not detect *Gonococcus*.

# ABSCESS, DENTOALVEOLAR

Kristin S. Stukus  
Raymond Pitetti

## BASICS

### DESCRIPTION

- Untreated bacterial caries, gingivitis, and periodontitis may result in infection in the adjacent space surrounding the teeth.
- A dentoalveolar abscess is typically characterized by localization of pus in the structures that surround the teeth as well as infection of adjacent soft tissues.
- May progress to life-threatening infections of the deep spaces of the neck.

### EPIDEMIOLOGY

#### Incidence

- Decreasing over the last 30 years due to fluoridation of the water supply
- More common in lower socioeconomic groups
- Exact incidence is unknown, as most cases are not reported.

#### Prevalence

- Dental caries occur in 30–50% of at-risk children, including those from low-income homes and developing countries.
- Dental abscess accounts for 47% of all dental-related visits to pediatric emergency departments (1).

### RISK FACTORS

- Tooth morphology:
  - Abnormal crown anatomy
  - Abnormal structure of the dentin
- Pre-eruptive intracoronal resorption
- Mandibular infected buccal cyst
- Factors associated with caries:
  - Multiple tooth surfaces with caries increase the likelihood of additional teeth developing caries.
  - High carbohydrate consumption: Sucrose is the most cariogenic sugar because its by-product helps bacteria adhere to the tooth surface.
  - Use of nonfluoridated water
  - Poor oral hygiene
- Poor bone mineralization due to prematurity or medications
- Preceding dental trauma

### GENERAL PREVENTION

- Screening dental exams performed by pediatricians at well-child visits
- Early referral for dental exams
- Good general dental hygiene with daily brushing with fluoridated toothpaste
- Fluorine supplementation for those with unfluoridated water
- Limiting carbohydrate-containing beverages, especially drinking from bottles at bedtime

### PATHOPHYSIOLOGY

- Oral bacteria adhere to the tooth enamel.
- Remaining food particles ferment to form organic acids.
- Lower pH from organic acids and bacterial production causes tooth demineralization.
- If untreated, tooth demineralization may progress to form pits and fissures.
- Oral bacteria colonize the demineralized area and may invade the tooth.
- Deeper infections may involve the dental pulp or alveolar bone.
- If left untreated, localized dental infections may progress to cause facial swelling and tenderness.

### ETIOLOGY

- Polymicrobial, with an average of 4–6 different causative bacteria
- Most commonly:
  - Oral *Streptococcus* (viridans)
  - Oral anaerobes (*Bacteroides*)
  - *Prevotella* species
  - *Fusobacterium* species

### COMMONLY ASSOCIATED CONDITIONS

Dental caries

## DIAGNOSIS

### HISTORY

- Pain at the tooth that is the nidus for the infection is invariably present.
- Pain may radiate to the jaw or ear on the affected side.
- Preceding history suggestive of caries may be present: Dentalgia, temperature sensitivity
- Young children may not localize pain as well as older children and adolescents.
- Progressive swelling and tenderness of the gingival surface and of the adjacent buccal tissue is typical.
- Fever is often present.
- Decreased oral intake as a result of pain

### PHYSICAL EXAM

- Frank, severe erosive dental caries of the affected tooth is typically readily apparent.
- Localized swelling, warmth, and tenderness of the gingival surface and face:
  - May see a fluctuant mass that extends toward the buccal side of the gum
- Tenderness to percussion of the affected tooth, though it is usually unnecessary to perform as the infection is readily apparent
- Bimanual palpation of the adjacent buccal tissues is performed to detect any large abscess that could be drained for diagnostic and therapeutic purposes.
- Anterior cervical lymphadenopathy is present on the affected side.
- Trismus is infrequently present.
- Assess for neck or facial swelling.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

- In uncomplicated dentoalveolar abscess, lab testing is not warranted.
- Strongly consider CBC, C-reactive protein, and blood culture in toxic-appearing children.
- If needle aspiration of the abscess is performed, send aspirate for Gram stain and aerobic and anaerobic cultures:
  - Aspirate may be sent in blood culture bottles.

#### Imaging

The diagnosis is primarily clinical. However, the following imaging modalities may help with the diagnosis if indeterminate:

- Plain radiographs may be useful in diagnosing early infection.
- Maxillofacial CT scan with contrast:
  - May help rule out other problems such as sinusitis, lymphadenitis, and peritonsillar or retropharyngeal abscess
  - May also determine the location, size, extent, and relationship of the inflammatory process to the surrounding vital structures
  - Particularly important if there is concern for deep space neck abscess, such as Ludwig angina, or retropharyngeal, parapharyngeal, or lateral pharyngeal abscesses
- Parotitis may be seen on CT.

#### Diagnostic Procedures/Other

Needle aspiration:

- Warranted in complicated cases and is therapeutic and provides material for lab analysis
- Not routinely necessary and not used in uncomplicated cases

### DIFFERENTIAL DIAGNOSIS

- Parotitis
- Sialadenitis
- Facial cellulitis
- Lymphadenitis
- Sinusitis
- Ludwig angina
- Peritonsillar, retropharyngeal, parapharyngeal, or lateral pharyngeal abscess
- Osteomyelitis

## TREATMENT

### PRE HOSPITAL

Assess and stabilize airway, breathing, and circulation.

### INITIAL STABILIZATION/THERAPY

- Assess and stabilize airway, breathing, and circulation.
- Antibiotic therapy
- Pain control
- IV hydration, if warranted

### MEDICATION

#### First Line

- Oral or parenteral antibiotics:
  - Severe infections require parenteral therapy; mild infections with only moderate swelling without high fevers may be treated with oral antibiotics.
  - Ampicillin/sulbactam 50 mg/kg/dose IV q6h; adolescent/adult 1–2 g IV q6h
  - Penicillin 50 mg/kg PO divided b.i.d.–q.i.d. × 10 days; adolescent/adult 500 mg PO t.i.d.–q.i.d.:
    - Traditionally was first-line oral or parenteral medication used, but due to pathogen resistance, infections requiring parenteral antibiotics are not treated with penicillin alone.
    - Acceptable for treatment of mild oral infections, but not indicated for moderate to severe infections requiring parenteral antibiotics due to increased pathogen resistance.
- Opioids:
  - Morphine 0.1 mg/kg IV/IM/SC q2h PRN:
    - Initial morphine dose of 0.1 mg/kg IV/SC may be repeated q15–20min until pain is controlled, then q2h PRN.
  - Codeine or codeine/acetaminophen dosed as 0.5–1 mg/kg of codeine component PO q4h PRN
  - Hydrocodone or hydrocodone/acetaminophen dosed as 0.1 mg/kg of hydrocodone component PO q4–6h PRN
- NSAIDs:
  - Consider NSAID medication in anticipation of prolonged pain and inflammation:
    - Ibuprofen 10 mg/kg/dose PO/IV q6h PRN
    - Ketorolac 0.5 mg/kg IV/IM q6h PRN
    - Naproxen 5 mg/kg PO q8h PRN
- Acetaminophen 15 mg/kg/dose PO/PR q4h PRN
- Local anesthetic:
  - Lidocaine 1% or 2% with or without epinephrine, max 5 mg/kg used to infiltrate
  - Ropivacaine 1 mg/kg/dose, max 2 mg/kg:
    - Is optimal isomer of bupivacaine that lacks deadly cardiotoxicity of bupivacaine
    - Preferred agent due to duration of action and lack of cardiotoxicity

#### ALERT

- Inadvertent IV administration of bupivacaine may cause immediate cardiac arrest and death. Bupivacaine used for nerve block should be placed by clinicians with vast experience performing such a block. Ropivacaine is strongly recommended for this procedure due to lack of the severe cardiotoxicity of bupivacaine.

### Second Line

Clindamycin for penicillin-allergic patients, 10 mg/kg/dose PO/IV q6h:

- Considered second-line parenteral therapy
- Treatment of choice for penicillin-allergic patients

### SURGERY/OTHER PROCEDURES

- Incision and drainage of complicated dentoalveolar abscesses
- Following resolution of acute infection, pulpectomy is indicated.
- Nerve block:
  - Block of individual tooth is contraindicated due to local infection.
  - Regional blockage, such as alveolar or maxillary dental block, may be performed:
    - Only perform if trained and comfortable in the procedure

### DISPOSITION

#### Admission Criteria

- Complicated abscess
- Inability to handle secretions
- Airway compromise
- Involvement of facial spaces of the head and neck
- Systemic involvement
- Failure of outpatient therapy
- Need for IV hydration
- Critical care admission criteria:
  - Airway compromise: Present or pending

#### Discharge Criteria

Uncomplicated dentoalveolar abscess

#### Issues for Referral

Refer to a maxillofacial or oral surgeon or dentist.

## FOLLOW-UP

### FOLLOW-UP RECOMMENDATIONS

Discharge instructions and medications:

- Follow-up evaluation by a dentist
- Complete antibiotic course

#### Patient Monitoring

Monitor improvement of infection closely.

#### DIET

- As tolerated
- Soft diet for comfort

#### PROGNOSIS

Uncomplicated dental abscess typically resolves easily with proper treatment.

#### COMPLICATIONS

- Dentocutaneous fistulas
- Acute suppurative osteomyelitis
- Cavernous sinus thrombosis
- Suppurative complications:
  - Acute suppurative lymphadenitis
  - Peritonsillar or pharyngeal abscess
  - Ludwig angina
  - Maxillary sinusitis
- Necrotizing fasciitis

## CODES

#### ICD9

- 522.5 Periapical abscess without sinus
- 522.7 Periapical abscess with sinus

## PEARLS AND PITFALLS

- Most patients with uncomplicated dentoalveolar abscess can be treated as an outpatient.
- Failure to recognize a complicated abscess
- Failure to adequately assess or recognize airway compromise

# ABSCESS, GLUTEAL

David O. Kessler

## BASICS

### DESCRIPTION

- Gluteal abscess is a type of localized infection located beneath the skin:
  - “Gluteal” describes the location of the abscess being in close proximity to the gluteus muscles. It is otherwise similar to simple subcutaneous abscesses in other locations.
  - A boil, furuncle, or carbuncle refers to a type of abscess that is associated with a hair follicle and typically involves the skin.
  - Folliculitis refers to an infection at a hair follicle that is more superficial with inflammation and pus localized to the epidermal layer.
- A simple gluteal abscess may occur spontaneously in a healthy host as a result of localized infection with common skin flora.

### EPIDEMIOLOGY

- Abscesses or subcutaneous soft tissue infections are thought to be common but are poorly reported.
- There is a wide range of presentation and need for intervention; therefore, not all abscesses will present for medical care.
- Published rates vary between 2.5% and 21.5% in certain populations and appear to be on the rise (1).

### RISK FACTORS

- Subcutaneous abscesses may be seen in normal healthy hosts but are more commonly seen in those who are immunocompromised, have poor hygiene, or have close contact with others who have similar infections.
- Outbreaks have occurred in communities that become colonized with MRSA:
  - Athletes (wrestlers)
  - Military personnel
  - IV drug users
- Simple cysts may be secondarily infected.

### GENERAL PREVENTION

Good hygiene, antistaphylococcal soap, and proper care early in the disease course may help prevent development of larger abscesses.

### PATHOPHYSIOLOGY

- Subcutaneous abscesses form when the body's immune system walls off an infection that is often the result of an inoculum of skin flora that enters either through a break in the epidermis or a hair follicle.
- A fibrous capsule surrounds a core of liquefied necrotic tissue, inflammatory cells, and bacteria in the body's attempt to expel the foreign material.

### ETIOLOGY

Subcutaneous abscesses are often polymicrobial, including common skin flora such as *Staphylococcus* and *Streptococcus* (2):

- Enteric organisms may also be found in abscesses with close proximity to the anus.

### COMMONLY ASSOCIATED CONDITIONS

- Abscesses are more commonly seen in immunocompromised patients who are more susceptible to infection.
- Comorbid disease should be considered in those with recurrent or multiple abscesses:
  - HIV, diabetes mellitus, IV drug users
  - May also be associated with genetic immunodeficiency syndromes

## DIAGNOSIS

### HISTORY

- Many abscesses start off as a small pimple or folliculitis that expands over days to weeks.
- They are usually tender, swollen, red, and warm and may spontaneously express pus.
- Fever may be present.
- An abscess may be spontaneous or chronic/recurrent in nature:
  - There may be a history of previous abscesses.
- History of a cyst at the site of the lesion
- History of close contacts with similar lesions
- Recent hot tub use
- Comorbidities (Crohn disease, diabetes, etc.)

### PHYSICAL EXAM

- Abscesses exhibit the signs of an acute infection: Erythema, swelling, warmth, and tenderness.
- Induration may be present as a hardened mass of fibrous tissue that is often palpable in an abscess beneath the skin.
- Fluctuance may be present as a spongy softness indicative of pus or fluid.
- There may be overlying cellulitis or central extrusion of pus.
- Regional lymphadenopathy may be associated with an abscess.
- If an abscess is in close proximity to the anus, a rectal exam may help to evaluate for rectal involvement or communication.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

- A simple abscess does not require any lab confirmation.
- Basic labs may be considered with chronic infection or to evaluate or rule-out comorbid conditions:
  - Wound cultures, particularly to track rates and susceptibilities of MRSA infections or to help guide management in complicated chronic cases (1)

### Imaging

- Bedside US has been used to help distinguish between cellulitis and abscess when the clinical exam is inconclusive (3).
- Bedside US can also be used to help guide a drainage procedure.
- Abscesses are also well visualized with other modalities such as MRI and contrast-enhanced CT scans:
  - However, these imaging tests have been largely replaced by US.

### Diagnostic Procedures/Other

Depending on the size, location, and extent of a lesion, needle aspiration or incision and drainage may be used.

### DIFFERENTIAL DIAGNOSIS

- Hidradenitis suppurativa: Recurrent inflammatory disorder affecting the apocrine glands (typically seen in the axilla or buttocks)
- Pilonidal cyst or abscess
- Necrotizing fasciitis
- Pyomyositis
- Botfly myiasis
- Osteomyelitis: May also present with drainage to surface

## TREATMENT

### INITIAL STABILIZATION/THERAPY

- In the initial management of an abscess, warm, clean compresses (or sitz baths) may be used to help promote spontaneous drainage.
- Abscesses are usually extremely painful, so analgesia should be administered early, though full pain relief is often not achieved until pressure is relieved from the wound with a procedure.

### MEDICATION

- Recent literature suggests that antibiotics may not be necessary in the treatment of gluteal abscess following successful incision and drainage (4)
- Incision and drainage is thought to be efficacious regardless of the use of antibiotics
- The presence of overlying cellulitis or comorbidities requires the use of antibiotics, despite the performance of incision and drainage
- Debate does exist as to whether incision and drainage alone is enough to treat gluteal abscess. Many practitioners continue to use antibiotics.
- 1st-generation cephalosporins:
  - Cefazolin 50–100 mg/kg IV divided q8h, max dose
  - Cephalexin 50 mg/kg PO divided t.i.d., max dose 2 g/day
- MSSA:
  - Dicloxacillin: <40 kg, 50–100 mg/kg/24 hr PO divided q6h; >40 kg, 250–500 mg/dose PO q6h (max dose 4 g/24 hr)
  - Nafcillin: <40 kg, 50–200 mg/kg/24 hr PO/IV divided q6h; >40 kg, 500–2,000 mg PO/IV q6h (max daily dose 12 g).

- MRSA:
  - Clindamycin: <40 kg, PO 10–30 mg/kg/24 hr divided q6–8h, IV 25–40 mg/kg/24 hr divided q6–8h; >40 kg, PO 300 mg/dose q6–8h, IV 1,200–1,800 mg/24 hr divided q6–12h (max daily dose 4.8 g/24 hr)
  - Trimethoprim/sulfamethizole (dosing based on trimethoprim): <40 kg, 5 mg/kg/dose PO/IV q12h; >40 kg, 160 mg/dose PO/IV q12h
  - Vancomycin: <40 kg, 10 mg/kg/dose IV q8h (max 1 g/dose); >40 kg, 2 g/24 hr IV divided q6–12h (max dose 4 g/24 hr)
    - Drug of choice, first-line parenteral medication for MRSA
  - When antibiotics are used (such as in the case of secondary cellulitis), consideration should be made for whether coverage is warranted for community- or hospital-acquired MRSA.

**SURGERY/OTHER PROCEDURES**

- The definitive treatment for a gluteal abscess is incision and drainage of the abscess cavity. Technique varies widely and is only briefly described here:
  - Confirm location for incision and drainage. This may be done with US, if available, to help identify fluid pockets and avoid vascular structures.
  - Adequate analgesia is often difficult to achieve, but several strategies may be used. A local field block (1% or 2% lidocaine with or without epinephrine depending on the location) provides injections of anesthetic in a ring around the indurated space. Injecting into the wound itself is typically ineffective because of the acidity of the abscess space, and increased pressure from an injection may worsen pain.
  - For superficial abscess, topical anaesthetics such as ethyl chloride spray may help numb the skin immediately prior to incision.
  - Some patients may require sedation in order to obtain adequate pain control prior to the procedure.
  - A needle aspiration may be attempted 1st to confirm the location of the fluid pocket.
  - Fluctuance typically represents fluid immediately beneath the surface of the skin and may also be used to guide the initial incision.
  - After topical cleansing with povidone-iodine or an alcohol solution, incision is made using an 11-blade scalpel inserted 0.5–1 cm deep through the epidermis and dermal layer and in 1 continuous motion incising ~75% of the length of the wound.
  - The wound is then explored with a surgical clamp, and any loculations or fibrous strands should be broken apart to help release any additional fluid pockets.
  - If the wound is deep, a small amount of packing material may be used to help keep skin layer from healing prior to granulation of the inside of the wound.
- Needle aspiration is performed using a small syringe attached to an 18-gauge needle, withdrawing slightly on the plunger as the needle is inserted into the area of greatest fluctuance and aspirating fluid.

**DISPOSITION**

**Admission Criteria**

- A simple skin abscess does not typically require admission unless there is a comorbid condition, complication, or a social reason for admission.
- Large abscesses (>5 cm) may be more likely to require inpatient management.
- A rapidly spreading overlying cellulitis may require admission.

**Issues for Referral**

Subspecialist involvement should be strongly considered for abscesses in children <6 mo of age, recurrent abscesses, or abscesses also involving sensitive locations such as the genitals or perianal area, where concern for a fistula may exist:

- Depending on the institution, specific referrals may be handled by pediatric surgery, plastic surgery, or gynecology.

**FOLLOW-UP**

**FOLLOW-UP RECOMMENDATIONS**

- After uncomplicated incision and drainage, patients should follow up within 24–48 hr with a provider experienced in wound care.
- Warm compresses and/or sitz baths can help provide comfort and may promote healing.

**PROGNOSIS**

- Most abscesses resolve within 1–2 wk after incision and drainage.
- Recurrence is not uncommon and may be seen in up to 25% of cases.

**COMPLICATIONS**

- The most common complications include failure of the wound to heal and recurrence that often requires re-exploration or a 2nd incision and drainage procedure.
- Bleeding may also occur but is usually controlled spontaneously or with local pressure.
- Rare complications may be seen with the less frequent causes of an abscess:
  - Fistulas can occur in patients with inflammatory bowel disease or if the abscess is in communication with the bowels.
  - Recurrence is more common in a cyst that has become secondarily infected, such as a pilonidal cyst.
  - Severe bleeding can occur if a vessel is lacerated during the procedure.

**See Also (Topic, Algorithm, Electronic Media Element)**

- Abscess, Perianal
- Cellulitis
- Pilonidal Cyst

**ICD9**  
682.5 Cellulitis and abscess of buttock

**PEARLS AND PITFALLS**

- Distinguishing between cellulitis and deeper infection (eg, abscess) can sometimes be difficult on physical exam alone. Bedside US can be helpful in identifying fluid collections.
- Differentiate between gluteal and rectal abscess. If in doubt, consult a pediatric surgeon for evaluation.

# ABSCESS, INTRACRANIAL

Kerry Capere  
Raymond Pitetti

## BASICS

### DESCRIPTION

- An intracranial abscess is a bacterial, suppurative, life-threatening infection inside the cranial cavity.
- Most typically, this is an abscess involving the brain.
- Subdural empyemas and epidural abscesses are rare, clinically distinct entities that will not be discussed here.

### EPIDEMIOLOGY

#### Incidence

- Rare in developed countries
- 25% occur in children <15 yr old
- In children, the incidence is highest between ages 4 and 7 yr.
- Unusual in neonates except in the setting of gram-negative meningitis

### RISK FACTORS

- Cyanotic congenital heart disease
- Otitis media
- Mastoiditis
- Meningitis
- Penetrating head trauma
- Sinusitis
- Cystic fibrosis
- Ventriculoperitoneal shunt infection
- Post neurosurgery
- Endocarditis
- Lung infections
- Other infections in the head

### PATHOPHYSIOLOGY

- Brain abscesses are almost always caused by hematogenous spread of bacteria from distant sites.
- Can occur secondarily to infection from contiguous structures, such as from suppurative infection in the mastoid, in the sinuses, or from dentoalveolar abscesses
- Violation of the integrity of the skull and dura may result in abscess. This includes penetrating trauma as well as cranial surgery.

### ETIOLOGY

- Most intracranial abscesses are due to streptococcal species, both aerobic and anaerobic.
- *Staphylococcus aureus*, particularly after penetrating trauma or surgery, is common.
- Cysticercosis is relatively commonly seen in immigrants from Mexico and Central America.

- Other pathogens:
  - *Bacteroides*, *Prevotella*, *Propionibacterium*, *Fusobacterium*, *Eubacterium*, *Veillonella*, *Actinomyces*, *Klebsiella pneumoniae*, *Pseudomonas*, *Escherichia coli*, *Proteus*, *Haemophilus*, *Actinobacillus*, *Salmonella*, and *Enterobacter*
- Up to 30% of brain abscesses contain mixed flora.
- Gram-negative bacteria are an important cause in neonates.
- Immunocompromised patients have esoteric pathogens: *Toxoplasmosis*, *Listeria*, *Nocardia*, *Cryptococcus*, *Coccidioides*, *Candida*.

### COMMONLY ASSOCIATED CONDITIONS

- Cyanotic congenital heart disease
- Ventriculoperitoneal shunt
- Chronic suppurative otitis media
- Sinusitis
- Mastoiditis
- Dental infection
- Meningitis

## DIAGNOSIS

### HISTORY

- The classic triad of fever, headache, and focal neurologic deficit is present in <50% of children.
- Mean duration of signs and symptoms prior to diagnosis is 2 wk but can be as long as 4 mo.
- Most common symptoms are headache, fever, and vomiting.
- A unilateral headache is especially concerning.
- Mental status changes and seizures are less common.

### PHYSICAL EXAM

- Fever may or may not be present.
- Headache, seizure, or focal neurologic deficit, including cranial nerve deficit
- Papilledema
- Meningeal signs:
  - These signs are seen in <1/2 of all children with brain abscess.
- Signs of sepsis may be present, such as tachycardia, tachypnea, decreased perfusion, delayed capillary refill, and hypotension.
- Signs of raised intracranial pressure (ICP), such as Cushing triad: Irregular respirations, bradycardia, and HTN

## DIAGNOSTIC TESTS & INTERPRETATION

### Lab

#### Initial Lab Tests

- Laboratory studies such as CBC, ESR, and C-reactive protein (CRP) are not generally helpful in the acute setting but may be used to follow clinical response to therapy.
- Blood cultures are positive in only 10% of brain abscesses.
- Lumbar puncture is contraindicated until imaging has excluded increased ICP.
- CSF in 20% of cases is normal.
- Serologic test may assist in diagnosing toxoplasmosis or cysticercosis.
- If abscess aspirate is obtained, culture and Gram stain are key in identifying pathogen(s).

### Imaging

- Contrast-enhanced CT scan of the brain shows a ring-enhancing area:
  - Obtain both axial and coronal views that extend through the frontal bone and the sellar region.
  - This may be normal in the 1st few days of abscess formation.
- MRI is the test of choice:
  - Can detect smaller lesions
  - Can show greater soft tissue detail

### DIFFERENTIAL DIAGNOSIS

- Meningitis
- Encephalitis
- Space-occupying lesion or mass
- Stroke
- Migraine
- Venous sinus thrombosis
- Trauma
- Toxic/metabolic effects

## TREATMENT

### INITIAL STABILIZATION/THERAPY

- Manage airway and resuscitate as needed.
- Patients with depressed level of consciousness should be intubated immediately for controlled ventilation.
- Early neurosurgical consultation; emergent surgery may be needed
- IV access should be obtained immediately.
- Treatment with broad-spectrum antibiotics and surgical decompression is routine.

**MEDICATION**

**First Line**

- Antimicrobial therapy is the treatment of choice and should be broad spectrum until culture results are available.
- When the apparent source is otitis media, mastoiditis, sinusitis, or congenital heart disease, a 3rd-generation cephalosporin plus metronidazole is indicated:
  - Ceftriaxone or cefuroxime plus metronidazole
  - Ceftriaxone 100 mg/kg/dose IV q12h, max single dose 2 g/24 hr
  - Cefuroxime 50 mg/kg/dose IV q8h, max single dose 1 g/24 hr
  - Metronidazole 30 mg/kg/day IV q6h, max single dose 4 g/24 hr
- When the apparent source includes penetrating trauma, ventriculoperitoneal shunt, meningitis, or endocarditis, a 3rd-generation cephalosporin plus vancomycin is indicated:
  - Vancomycin 10 mg/kg/dose IV q6h, max individual dose 1 g
- In neonates, ampicillin should be added if *Listeria* is a possibility:
  - Ampicillin 100 mg/kg/dose IV q6h, max single dose 12 g/24 hr
- In immunosuppressed children, coverage for fungal organisms should be strongly considered.

**Second Line**

- Ampicillin/Sulbactam 100 mg/kg/dose IV q6h, max single dose 12 g ampicillin/24 hr
- Meropenem 40 mg/kg/dose IV q8h, max single dose 6 g/24 hr
- Ciprofloxacin 10 mg/kg/dose IV q12h, max single dose 1 g/24 hr
- Corticosteroids:
  - Dexamethasone 0.5 mg/kg/dose IV q24h
  - Methylprednisolone 30 mg/kg IV loading dose followed by 5.4 mg/kg/hr for 23 hr
  - This is same dose used in spinal trauma; another dosing regimen may be recommended by the neurosurgeon.
  - Glucocorticoids may lead to an improvement in signs and symptoms secondary to mass effect, but they should not be used if a well-defined capsule is not apparent on imaging.

**SURGERY/OTHER PROCEDURES**

- Guided surgical aspiration is indicated to obtain infected material for cultures to guide definitive antimicrobial therapy.
- Cultures should be sent for both aerobic and anaerobic pathogens.
- Surgical excision is occasionally necessary.

**DISPOSITION**

**Admission Criteria**

- All children with brain abscess should be admitted to the hospital.
- Many of these children will warrant admission to a pediatric ICU for monitoring, including ICP monitoring in select cases.

**Issues for Referral**

- Infectious disease consultation may be useful.
- Referral to a Critical care specialist is recommended.

**FOLLOW-UP**

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**

Most patients will initially require monitoring in the pediatric ICU.

**DIET**

Patients should be NPO given the likelihood for procedures requiring sedation/anesthesia.

**PROGNOSIS**

- Even with optimal treatment, mortality from brain abscess is as high as 15%.
- A more recent case series had a mortality rate of only 4%.
- Factors associated with increased morbidity and mortality include age < 1 yr, coma at diagnosis, rapidly progressive neurologic deterioration, and multiple foci of infection.

**COMPLICATIONS**

Up to 1/3 of surviving patients will have permanent neurologic disabilities.

**See Also (Topic, Algorithm, Electronic Media Element)**

- Abscess, Dentoalveolar
- Mastoiditis
- Meningitis

**ICD9**  
324.0 Intracranial abscess

**PEARLS AND PITFALLS**

- Routine lab tests, including CSF, are not generally helpful in ruling out brain abscess.
- Early imaging is warranted if brain abscess is suspected.
- Empiric antibiotic therapy should cover gram-positive, gram-negative, and anaerobic organisms.
- Specific populations may be at risk for unique pathogens, such as Mexican and Central American immigrants with a likelihood for cysticercosis or HIV/immunosuppressed patients at risk for toxoplasmosis, *Cryptococcus*, and *Candida*.

# ABSCESS, LUDWIG ANGINA

Michelle A. Alletag

Marc A. Auerbach

## BASICS

### DESCRIPTION

- Ludwig angina is a rapidly spreading deep cellulitis of the submandibular, submental, and sublingual space.
- Generally originates as an odontogenic infection
- Poses high risk for airway compromise and loss
- Untreated, has a high risk of mortality

### EPIDEMIOLOGY

- Incidence is rare, with 1 report citing 5 of 117 total pediatric head and neck infections treated in a 6-yr period.
- More common in adults:
  - Pediatric patients make up 25–30% of all cases.
- Accounts for 13% of all deep neck infections

### RISK FACTORS

- In adults and older children, poor dental hygiene is the primary risk factor (with spread of infection from the 2nd and 3rd molars being the most frequent cause).
- In children, oral lacerations, sialadenitis (submandibular), and mandibular trauma are other frequent causes.
- Piercings of the lingual frenulum
- Patients with systemic diseases, such as diabetes mellitus, and immunocompromised patients are at increased risk.
- Many pediatric cases of Ludwig angina have no identifiable preceding risk factor.

### GENERAL PREVENTION

Good oral and dental hygiene significantly decreases the risk of this rare but life-threatening infection.

### PATHOPHYSIOLOGY

- Caused by infection originating in the oropharynx, with contiguous (not lymphatic) spread through the submandibular and neck soft tissue spaces:
  - Polymicrobial nature of oropharyngeal infections predisposes to gangrenous cellulitis.
  - Anatomy of the submandibular space allows rapid spread of infection along fascial planes and for rapid airway impingement.

- Diagnostic criteria:
  - Occurs bilaterally, in > 1 space
  - Infiltrate is gangrenous or serosanguineous with little or no pus
  - Involves connective tissue, fascia, and muscle (rarely involves glandular structures)
  - Spreads by continuity (not hematogenous or lymphatic)

### ETIOLOGY

Most common microbes include *Staphylococcus aureus*, *Streptococcus viridans*, and beta-hemolytic streptococcus, with oral anaerobes (*Bacteroides*, *Fusobacterium*, *Enterobacter*, *Peptostreptococcus*) also frequently cultured.

- Majority of infections are polymicrobial, with a mix of aerobic and anaerobic organisms
- *Candida* may also be present in immunocompromised patients

### COMMONLY ASSOCIATED CONDITIONS

Dental caries

## DIAGNOSIS

### HISTORY

Patients often present with complaints of fever, throat or tongue pain, trismus, dysphagia, dysphonia, or drooling. Poor oral intake and decreased urine output are common occurrences among younger patients.

- Onset is generally acute, with patients presenting after 2–3 days of symptoms.
- Often, patients will have been initially managed with oral antibiotics.

### PHYSICAL EXAM

- Induration of the floor of the mouth with bilateral submandibular swelling and posterior and superior displacement of the tongue are considered pathognomonic signs:
  - Classically, the tongue protrudes from the oral cavity.
- Systemic findings may include fever, toxic appearance, and evidence of dehydration.
- Impending airway compromise may be heralded by stridor, drooling, dyspnea, or cyanosis:
  - Carefully evaluate patency of the airway.

## DIAGNOSTIC TESTS & INTERPRETATION

### Lab

#### Initial Lab Tests

- Aerobic and anaerobic blood cultures should be obtained (although they are positive in only 30% of cases).
- CBC will show elevated WBC count with left shift; C-reactive protein will be elevated.

#### Imaging

- Plain radiographs of the neck will show soft tissue swelling of the submandibular region.
- Contrast CT scan of the neck is not necessary for diagnosis but may be used to assess for extent of retropharyngeal involvement and abscess formation:
  - CT should be deferred until a stable airway is confirmed or established.

### DIFFERENTIAL DIAGNOSIS

- Retropharyngeal or parapharyngeal abscess
- Epiglottitis
- Sialadenitis
- Dental abscesses
- Infected congenital (eg, branchial cleft or thyroglossal duct) cyst

## TREATMENT

### PRE HOSPITAL

- Assess and stabilize airway, breathing, and circulation.
- Allow patients to maintain a position of comfort, as they may prefer to be upright or even leaning forward to keep the airway patent.

### INITIAL STABILIZATION/THERAPY

- Assess and stabilize airway, breathing, and circulation.
- Airway management is critical, with preparation for an emergent or surgical airway should it become necessary.
- Consult ENT or head/neck surgeon:
  - Most pediatric patients can be managed conservatively with antibiotics and steroids, but the airway should be actively monitored.

**MEDICATION**

**First Line**

Parenteral antibiotics should provide coverage for anaerobes and aerobes, with a penicillin and metronidazole, or ampicillin/sulbactam may be used alone or in combination with metronidazole considered first-line treatment.

- Oral antibiotic therapy is not appropriate.
- Ampicillin/Sulbactam 50 mg/kg/dose IV q6h, adult dose 1–2 g/dose, max single dose ampicillin 8 g/24 hr
- Metronidazole 30 mg/kg/day q6h, max single dose 4 g/24 hr

**Second Line**

- Clindamycin 40 mg/kg/day q6h, adult dose 900 mg IV q8h, max single dose 4.8 g/24 hr:
  - Used in patients with penicillin allergy
- Dexamethasone 1–2 mg/kg/24 hr divided q6h:
  - Decreases airway swelling and decreases length of illness

**SURGERY/OTHER PROCEDURES**

- Extraction of necrotic or abscessed teeth is important to remove the nidus for infection.
- Surgical drainage is reserved for patients with abscess formation and is generally deferred for 1–2 days after initiation of antibiotics:
  - Patients unresponsive to medical therapy may also require surgical exploration and drainage.
  - Unlike adults (most of whom require surgical drainage and surgical airways), most pediatric patients respond well to medical management alone.

**DISPOSITION**

**Admission Criteria**

- All patients should be admitted to the hospital with suspected Ludwig angina.
- Critical care admission criteria:
  - Any child with concern for potential airway compromise should be admitted to the critical care unit for observation.
  - The hospital’s airway team (anesthesia, ENT, or both) should be made aware of any patient being admitted with Ludwig angina.

**Discharge Criteria**

No patient with suspected Ludwig angina should be discharged from the ED given the high risk of airway compromise and death.

**FOLLOW-UP**

**PROGNOSIS**

- Mortality remains ~10% in both children and adults, primarily due to airway compromise:
- Mortality exceeded 50% in the 1800s when Ludwig angina was 1st described but decreased substantially with the advent of antibiotics.

**COMPLICATIONS**

- Spread of infection to lateral pharyngeal or retropharyngeal spaces is common and can cause retropharyngeal abscess, mediastinitis, empyema, or even pericarditis.
- Bacteremia
- Sepsis

**ADDITIONAL READING**

- Marcus BJ, Kaplan J, Collins KA. A case of Ludwig angina. A case report and review of the literature. *Am J Forensic Med Path.* 2008;23(3):255–259.

**See Also (Topic, Algorithm, Electronic Media Element)**

- Abscess, Dentoalveolar
- Abscess, Retropharyngeal
- Cystic Hygroma
- Epiglottitis

**ICD9**  
528.3 Cellulitis and abscess of oral soft tissues

**PEARLS AND PITFALLS**

- Prompt recognition and initiation of antibiotic therapy is lifesaving and may prevent significant morbidity by avoiding the need for surgical airway management.
- The rarity of this disease may lead to delays in diagnosis, and mortality rates remain high.

# ABSCESS, PERIANAL

Antonio Riera

David M. Walker

## BASICS

### DESCRIPTION

- A perianal abscess is a localized collection of pus at or near the anus or perianal skin.
- A perianal abscess often originates from occluded and infected anal glands.
- May be associated with underlying pathology

### EPIDEMIOLOGY

- Overall incidence is unknown.
- Incidence in infants is estimated at 0.5–4.3%.
- Strong male predominance

### RISK FACTORS

- Age <1 yr
- Immunodeficiency syndromes
- Local trauma
- In patients >2 yr of age, risk factors include Crohn disease, diabetes mellitus, and immunosuppression (from disease such as HIV/AIDS or medications including steroids and chemotherapy).

### PATHOPHYSIOLOGY

- Infection of the perianal skin and anal glands due to proliferation of local bacteria
- Congenital predisposition and abnormal hindgut migration may play a role.
- Other proposed pathogenesis includes:
  - Cryptoglandular involvement
  - Congenital sinus of perianal tissue
  - Abnormal widening of crypts of Morgagni
  - Androgen imbalance

### ETIOLOGY

- Bacterial microbiology similar to adults
- Anaerobes outnumber aerobes by 3 to 1 (1).
- Mixed flora predominate:
  - Generally mixed infections caused by enteric flora such as *Escherichia coli* and *Enterococcus* and *Bacteroides* species
  - Other isolated bacteria include group C streptococcus and *Staphylococcus aureus*.

### COMMONLY ASSOCIATED CONDITIONS

- Fistula-in-ano (anal fistula) present in 1/3 of cases
- Immunodeficiency syndromes
- Chronic granulomatous disease
- Inflammatory bowel disease
- Crohn disease
- Diabetes mellitus
- Hirschsprung disease
- Local trauma
- Neoplasm
- *Enterobius vermicularis* (pinworm) infection

## DIAGNOSIS

### HISTORY

- Fever
- Mass near anus:
  - May be noted by parent or during routine well child exam
- Pain with bowel movements
- Anal discharge

### PHYSICAL EXAM

- Fever may be present.
- Mass has typical inflammatory findings of abscess.
- Warmth
- Erythema
- Tender/Painful to touch
- Fluctuance may be present.
- It is crucial to examine surrounding gluteal and buttock area to note extension of abscess.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

- Local wound culture
- If fever present:
  - CBC
  - C-reactive protein
  - Blood culture
- Immunodeficiency workup as warranted; recommended if history of recurrence or other bacterial infections

### Imaging

- Endoscopic US:
  - 80–90% accurate for perianal disease when compared to surgical exam under anesthesia
  - Accuracy depends on proper technique
- MRI:
  - 80–90% accurate for perianal disease when compared to surgical exam under anesthesia

### Pathological Findings

Abscess wall can be examined histologically for evidence of Crohn disease.

### DIFFERENTIAL DIAGNOSIS

- Anal fissure
- Skin tags
- Hemorrhoids
- Pilonidal cyst/abscess
- Perianal cellulitis
- Diastasis ani

## TREATMENT

### MEDICATION

- Analgesics:
  - Topical anesthetic to abscess prior to incision and drainage
  - Morphine 0.1 mg/kg IV/IM/SC q2h PRN:
    - Initial morphine dose of 0.1 mg/kg IV/SC may be repeated q15–20min until pain is controlled, then q2h PRN.
  - Codeine or codeine/acetaminophen dosed as 0.5–1 mg/kg of codeine component PO q4h PRN
  - Hydrocodone or hydrocodone/acetaminophen dosed as 0.1 mg/kg of codeine component PO q4–6h PRN
- NSAIDs:
  - Consider NSAIDs in anticipation of prolonged pain and inflammation:
    - Ibuprofen 10 mg/kg/dose PO/IV q6h PRN
    - Ketorolac 0.5 mg/kg IV/IM q6h PRN
    - Naproxen 5 mg/kg PO q8h PRN

- Acetaminophen 15 mg/kg/dose PO/PR q4h PRN
- Stool-bulking agents and stool softeners to prevent constipation (post drainage):
  - Polyethylene glycol 3350: 17 g in 8 oz of water qhs; children >6 mos: 0.5–1.5 g/kg daily
- Antibiotics—universal use is debatable. Anaerobic and staphylococcal coverage is recommended if ill appearing, febrile, or immunocompromised:
  - Oral first line:
    - Amoxicillin/Clavulanate 20 mg/kg/dose PO q12h OR
    - Clindamycin 8–10 mg/kg/dose PO q8h
  - IV first line:
    - Ampicillin/Sulbactam 50 mg/kg/dose IV q6h OR
    - Clindamycin 10–12 mg/kg/dose IV q8h
  - Suspected MRSA:
    - Trimethoprim/Sulfamethoxazole (TMP/SMX) 5 mg/kg/dose PO q12h based on TMP component OR
    - Vancomycin 10–15 mg/kg/dose IV; determine interval by trough levels
  - Penicillin allergic (PO):
    - Clindamycin (for MSSA)
    - TMP/SMX plus metronidazole 10 mg/kg/dose PO q8h (for MRSA)
  - Penicillin allergic (IV):
    - Clindamycin (for MSSA)
    - Vancomycin plus metronidazole 10 mg/kg/dose IV q8h (for MRSA)

**SURGERY/OTHER PROCEDURES**

- Perianal abscess should be treated in a timely fashion by incision and drainage (2):
  - Lack of fluctuance should not delay timely drainage.
- In infants, medical management may be an acceptable alternative:
  - In a retrospective study of 140 children <1 yr of age for whom abscess size was not reported, medical management with local hygiene and systemic antibiotics had equivalent cure rates when compared to traditional surgical drainage (3):
    - Fistula formation was greater in the surgical drainage group (60%) vs. the medical management group (16%).
- Fistulotomy may be performed:
  - In a meta-analysis of adult patients, surgical drainage with fistulotomy reduced risk of recurrence by 83% but tended to increase rates of incontinence to flatus and stool (RR 2.46, 95% CI 0.75–8.06) when compared to surgical drainage alone (4).

**DISPOSITION**

**Admission Criteria**

- Toxic or ill appearing
- Suspected or confirmed fistula requiring surgical intervention
- Suspected child abuse
- Younger age of child
- Extensive lesions
- Pain not well controlled

**Discharge Criteria**

- Well appearing
- Small, uncomplicated abscess
- Pain well controlled
- Adequate wound care plan arranged
- Follow-up for wound check in 24 hr

**Issues for Referral**

Consider surgical consultation for initial management and/or follow-up.

**FOLLOW-UP**

**FOLLOW-UP RECOMMENDATIONS**

- 24-hr follow-up for wound check and repacking of abscess cavity
- Frequent daily sitz baths or warm soaks to promote further drainage
- Consider home nursing services.

**PROGNOSIS**

- Simple perianal abscesses have excellent outcomes after incision and drainage.
- Perianal abscesses with anal fistula have higher rates of complications.

**COMPLICATIONS**

- Fistula-in-ano
- Recurrence
- Stool incontinence (if sphincter-cutting procedure performed)

**REFERENCES**

**ICD9**  
566 Abscess of anal and rectal regions

**PEARLS AND PITFALLS**

- Unlike other skin abscesses, cultures grow a mixed population of bacteria with a predominance of gut anaerobic and aerobic species.
- Many cases are associated with underlying conditions.
- Incision and drainage remains the treatment of choice.
- Conservative medical management may be an option for children <1 yr of age.

# ABSCESS, PERITONSILLAR

Nikhil B. Shah

## BASICS

### DESCRIPTION

- Peritonsillar abscess (PTA), or quinsy, is the most common deep neck infection in children, accounting for at least 50% of cases (1).
- PTA develops when oropharyngeal bacteria invade the peritonsillar space, resulting in a pus collection.
- Prompt diagnosis and management is essential to ensure successful recovery and prevent complications.

### EPIDEMIOLOGY

#### Incidence

- PTA occurs most frequently in adolescents and young adults but can occur in younger children.
- Estimated incidence:
  - All children (<18 yr): 14 per 100,000
  - Adolescents: 40 per 100,000 (2)

### RISK FACTORS

- Chronic or recurrent tonsillitis
- Smoking may be a risk factor.

### PATHOPHYSIOLOGY

- Peritonsillar infection represents a spectrum ranging from cellulitis to phlegmon to abscess.
- Abscess formation occurs in the peritonsillar space, bound medially by the fibrous peritonsillar capsule and laterally by the superior pharyngeal constrictor muscle.
- PTA usually occurs as a well-defined pus collection in the superior pole of the tonsil but may also occur in the mid- or inferior pole of the tonsil or be less well circumscribed with multiple loculations within the peritonsillar space.

### ETIOLOGY

- Most cases are polymicrobial.
- PTA frequently includes both aerobic and anaerobic bacteria:
  - *Streptococcus pyogenes* (group A streptococcus [GAS])
  - *Staphylococcus aureus* (MRSA)
  - Anaerobes such as *Fusobacteria*, *Prevotella*, and *Veillonella* species
  - Occasionally *Haemophilus* species

### COMMONLY ASSOCIATED CONDITIONS

- PTA is generally preceded by pharyngitis or tonsillitis but may occasionally occur without antecedent infection (ie, obstruction of the Weber salivary glands in the soft palate)
- Infectious mononucleosis
- Kawasaki disease (rarely)

## DIAGNOSIS

### HISTORY

- Fever
- Severe sore throat, usually unilateral
- “Hot potato” or muffled voice
- Drooling or pooling of saliva may be present.
- Trismus (in >60% of patients) (1):
  - Related to irritation and reflex spasm of the internal pterygoid muscle
  - Helps to distinguish PTA from severe pharyngitis or tonsillitis
- Neck swelling
- Neck pain
- Ipsilateral ear pain
- Nonspecific symptoms such as fatigue, irritability, and decreased oral intake

### PHYSICAL EXAM

- Presence of trismus may limit the ability to perform an adequate exam.
- If severe airway compromise is present, exam in the operating room under anesthesia may be appropriate.
- Exam findings consistent with PTA include:
  - Unilateral, swollen, fluctuant tonsil seen as a convex mass protruding into the posterior pharynx and displacing the uvula to the opposite side
  - Alternatively, there may be a bulging, fluctuant mass or fullness of the posterior soft palate near the tonsil.
- PTA is usually unilateral; bilateral PTA is uncommon and can make diagnosis difficult.
- Clinical distinction between abscess and peritonsillar cellulitis (PTC) can be problematic, although uvular deviation and trismus are often absent in the latter (3).

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

PTA is diagnosed clinically and radiographically. Lab evidence is not routinely necessary for diagnosis but may assist in identifying organism or complications:

- Gram stain and culture from abscess aspirate may be performed.
- Rapid streptococcal antigen test and/or throat culture
- Mononucleosis screen
- CBC with differential
- C-reactive protein
- Serum electrolytes

#### Imaging

- Imaging studies are generally not required for diagnosis, but indications may include:
  - Distinguishing abscess from cellulitis
  - Determining extent of infection
  - Exclusion of other deep neck space infections such as retropharyngeal abscess
  - Inadequate exam secondary to trismus

- CT scan with IV contrast is the preferred imaging modality (4) for unclear cases:
  - Able to distinguish PTA from PTC
  - Can demonstrate extension of infection into contiguous deep neck spaces
  - PTA appears as a hypodense mass with ring enhancement; PTC findings include soft tissue swelling, loss of fat planes, and lack of ring enhancement.
  - CT should be deferred in children with moderate to severe distress, especially if sedation is required.
- Intraoral US:
  - Highly sensitive, cost-effective, nonradiation alternative modality (4)
  - Distinguishes PTA from PTC
  - Exam may be limited if trismus is present.
  - PTA findings include an echofree cavity with an irregular border; PTC appears as a homogeneous or striated area with no distinct fluid collection.
- Lateral neck radiographs:
  - Limited role
  - Useful to rule out other clinically similar conditions such as retropharyngeal abscess

### Diagnostic Procedures/Other

See Surgery/Other Procedures for information about abscess incision and drainage.

### DIFFERENTIAL DIAGNOSIS

Includes other causes of upper airway obstruction, sore throat, and pharyngeal swelling such as:

- Retropharyngeal abscess or cellulitis: Usually seen in younger children, neck stiffness more predominant than trismus
- Parapharyngeal abscess: Bulging behind tonsillar pillar rather than superior to tonsil
- Epiglottitis (now rare in post-*Haemophilus influenzae* type B vaccine era)
- Severe tonsillopharyngitis (Epstein-Barr virus, herpangina, diphtheria, gonorrhoea)

## TREATMENT

### INITIAL STABILIZATION/THERAPY

- Drainage, antibiotic therapy, and supportive care are the mainstays of management.
- Airway:
  - When severe airway compromise is suspected, all interventions should be deferred until the airway is secured.
- Supportive care:
  - Hydration
  - Analgesia
  - Monitoring for complications

### MEDICATION

#### First Line

- Early antibiotic therapy may prevent abscess formation in patients with PTC but must be combined with a drainage procedure once pus has formed.
- Empiric therapy should include coverage for GAS, *S. aureus*, and anaerobes and can then be modified according to culture and sensitivity results if drainage is performed.

- Potential parenteral regimens include:
  - Ampicillin/Sulbactam 200 mg/kg/day divided q6h IV OR
  - Clindamycin 40 mg/kg/day divided q8h IV, which has the benefit of community-acquired MRSA coverage
  - Vancomycin 40–60 mg/kg/day divided q6–8h IV may be added if no clinical response or in case of severe infection.
- IV antibiotic therapy should be continued until the patient is afebrile and clinically improved.
- An oral antibiotic regimen should then be continued to complete a 14-day course:
  - Amoxicillin/Clavulanate 80–90 mg/kg/day divided PO b.i.d. OR
  - Clindamycin 40 mg/kg/day divided PO q8h
  - Linezolid may be used when vancomycin has been added to the parenteral regimen (<12 yr: 30 mg/kg/day divided PO t.i.d.; ≥12 yr: 20 mg/kg/day divided PO b.i.d).

**Second Line**

**Corticosteroids:**

- Evidence is lacking to support routine use of steroids for PTA in children (2).
- Some studies demonstrate improvement in pain scores, symptom severity, and length of stay, while others find no clear difference between treatment and nontreatment groups.

**SURGERY/OTHER PROCEDURES**

- Drainage in combination with antibiotic therapy and hydration results in resolution in >90% of cases (5).
- Surgical drainage of PTA is performed by one of the following methods:
  - Needle aspiration
  - Incision and drainage
  - Tonsillectomy
- Choice of procedure depends upon clinician skill level, age and ability of the patient to cooperate, cost, and whether the patient has indications for tonsillectomy.
- Indications for tonsillectomy include:
  - Significant upper airway obstruction either acutely or at baseline (eg, snoring)
  - Recurrent pharyngitis or PTA
  - Treatment failure with other drainage techniques
- An older, cooperative child or adolescent who is clinically stable without trismus may undergo needle aspiration or incision and drainage with topical anesthesia or procedural sedation (5).
- If the child is young and unable to cooperate, the procedure should be performed in the operating room.
- Careful attention to maintaining the airway must be given if procedural sedation is undertaken.
- Prompt surgical intervention is indicated in the following circumstances:
  - Impending airway compromise (consider exam under anesthesia)
  - Enlarging masses
  - Significant comorbidities (eg, immunodeficiency)

**DISPOSITION**

- Hospitalization may be warranted, particularly in younger children.
- Older children with uncomplicated PTA who are well hydrated with adequate pain control may be managed as outpatients.

**Admission Criteria**

Critical care admission criteria:

- Toxicity
- Potentially life-threatening complications
- Significant airway compromise

**Discharge Criteria**

- Patients who are managed as outpatients must be observed post-procedure to ensure they can tolerate oral antibiotics, analgesics, and liquids.
- Patients who are managed as inpatients may be discharged home if there is response to treatment as defined by improvement in pain, fever, and/or tonsillar swelling within 24 hr of intervention.

**FOLLOW-UP**

**FOLLOW-UP RECOMMENDATIONS**

- Patients treated as outpatients should have follow-up within 24–36 hr, whereas admitted patients should be seen within several days of discharge.
- Discharge instructions and medications:
  - Continue appropriate oral antibiotic regimen.
  - Analgesics
  - Maintain hydration.

**Patient Monitoring**

Discharged patients should be instructed that prompt re-evaluation is necessary for:

- Dyspnea
- Worsening pain
- Worsening trismus
- Enlarging mass
- Fever
- Neck stiffness
- Bleeding (as a complication of drainage procedure)

**DIET**

Soft diet and liquids; advance as tolerated

**PROGNOSIS**

- PTA usually resolves without sequelae if recognized early and treated appropriately.
- Recurrence rate is 10–15%.
- Recurrence rate is higher (40%) in patients with a history of recurrent tonsillitis.

**COMPLICATIONS**

- Airway obstruction
- Aspiration pneumonia if the abscess ruptures into the airway
- Sepsis
- Internal jugular vein thrombosis
- Lemierre syndrome (a potentially fatal condition usually caused by *Fusobacterium necrophorum* and characterized by thrombophlebitis of head and neck veins and systemic dissemination of septic emboli)
- Carotid artery rupture
- Carotid artery pseudoaneurysm
- Mediastinitis
- Necrotizing fasciitis
- Sequelae of GAS infection (when GAS is isolated)

ICD9  
475 Peritonsillar abscess

**PEARLS AND PITFALLS**

- The diagnosis of PTA is clinical and does not require lab or imaging tests.
  - “Classic” presentation: Severe sore throat; fever; “hot potato” voice; drooling; trismus with a unilaterally enlarged, fluctuant tonsil that pushes the uvula to the opposite side
- Management of PTA includes antibiotic therapy in combination with a surgical drainage procedure:
  - Patients with PTC may be given a trial of antibiotics alone.

# ABSCESS, RECTAL

Danniel J. Stites

Todd Mastrovitch

## BASICS

### DESCRIPTION

- A perirectal (rectal) abscess is a collection of pus in the tissues surrounding the anus or within the wall of the rectum.
- Perirectal abscesses are classified based on their anatomic location.
- The most commonly described locations are perianal (most common, >50%), ischioanal, intersphincteric, and supralelevator.

### EPIDEMIOLOGY

- Overall incidence is unknown.
- Incidence is bimodal:
  - The 1st peak is in children <1 yr of age.
  - The greatest incidence in adults is during the 3rd and 4th decades of life.
- Males are affected more frequently than females, with estimated ratios of 2:1 to 3:1 (1).
- Incidence may be higher in warmer months (spring and summer).

### RISK FACTORS

- In children <2 yr of age, there are generally no identifiable risk factors.
- Perirectal abscesses in young children may be a result of abnormal anal crypt development, which may be related to hormonal imbalance of androgen and estrogen during crypt formation.
- In patients >2 yr of age, risk factors include Crohn disease, diabetes mellitus, and immunosuppression (from disease such as HIV/AIDS or medications including steroids and chemotherapy).

### GENERAL PREVENTION

- Unknown
- No direct relationship has been proven between bowel habits or personal hygiene and the development of perirectal abscesses.

### PATHOPHYSIOLOGY

- The vast majority of the perirectal abscesses result from infected anal crypt glands:
  - The infection may then penetrate the surrounding tissues.
- Perianal abscesses occur when the infection travels through the intersphincteric groove to the perianal skin.
- Ischioanal abscesses occur when the infection penetrates the external anal sphincter into the ischioanal space.
- Intersphincteric abscesses are a result of spread into the intersphincteric space between the internal and external sphincters.
- Supralelevator abscesses are the result of either superior spread from the intersphincteric space through the longitudinal muscles of the rectum or from primary disease of the pelvis or lower abdomen (appendicitis, diverticulitis, Crohn disease).

### ETIOLOGY

- Generally mixed infections caused by enteric flora such as *Escherichia coli* and *Enterococcus* and *Bacteroides* species
- Other isolated bacteria include group C streptococcus and *Staphylococcus aureus*.

### COMMONLY ASSOCIATED CONDITIONS

- Inflammatory bowel disease (Crohn disease >> ulcerative colitis)
- Leukemia
- HIV/AIDS
- Diabetes mellitus
- Hirschsprung disease or imperforate anus (postoperative sequelae)

## DIAGNOSIS

### HISTORY

- Perianal abscess: Complaints of dull perianal discomfort and pruritus exacerbated by movement, sitting, or defecation:
  - In children, the only historical evidence may be increased irritability, refusal to walk, or refusal to defecate.
- Alternatively, perianal disease may be a presenting symptom of Crohn disease, which often has a history of abdominal pain, weight loss, diarrhea, and failure to thrive.
- Ischioanal abscess: Fevers, chills, and severe perirectal pain
- Intersphincteric abscess: Present with rectal pain
- Supralelevator abscess: Fevers, chills, severe pelvic or anorectal pain, and occasionally urinary retention

### PHYSICAL EXAM

- Perianal abscess: Small, erythematous, well-defined, fluctuant, tender, subcutaneous mass near the anal orifice (usually lateral to anus)
- Ischioanal abscess: External signs may be minimal but may include erythema, induration, and fluctuance within the buttocks. On digital rectal exam (DRE), a fluctuant, indurated mass may be encountered. DRE may require procedural sedation.
- Intersphincteric abscess: Often no external signs. DRE reveals a tender fluctuant mass.
- Supralelevator abscess: Usually no external signs. DRE may reveal induration or fluctuance above the anorectal ring.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

- Culture of abscess contents may be useful for antibiotic optimization.
- CBC and blood culture may be useful adjuncts if bacteremia is suspected.

#### Imaging

- Imaging is generally not necessary for perianal or ischioanal abscesses.
- CT or MRI may be required for the diagnosis of intersphincteric or supralelevator abscesses.
- US may aid in the diagnosis of intersphincteric abscess.
- In patients suspected of having Crohn disease or with complex abscesses, CT scan or contrast enema may be useful.

#### Diagnostic Procedures/Other

- Biopsy of the abscess wall can aid in determination of etiology if unclear.
- Needle aspiration may be used as an adjunct to incision and drainage for confirming abscess location and obtaining culture material.
- Colonoscopy with biopsy may be needed to confirm Crohn disease.

#### Pathological Findings

Biopsy of the abscess wall may show granulomas that may indicate underlying Crohn disease.

### DIFFERENTIAL DIAGNOSIS

- Presacral epidermal inclusion cyst
- Hidradenitis suppurativa
- Pilonidal disease
- Bartholin abscess
- Inflammatory bowel disease

## TREATMENT

### INITIAL STABILIZATION/THERAPY

- The treatment of all perirectal abscesses is incision and drainage.
- Patient comfort and accessibility of the abscess determine how and where an abscess may be drained.
- Perianal abscesses may be drained in the office or ED.
- Incision and drainage should always be performed with appropriate anesthesia and analgesia, and the abscess should be incised over the area of maximal fluctuance. The cavity should then be probed with a finger or hemostat to disrupt any loculations that may exist.
- Ischioanal abscess drainage may be performed in the office or ED if possible; otherwise, intraoperative drainage may be necessary.

- Intersphincteric abscesses must be drained in the operating room.
- Supralelevator abscesses should be drained according to the site of origin:
  - If an ischioanal abscess, drainage should be performed via the skin through the overlying buttock.
  - Abscesses resulting from the extension of an intersphincteric abscess or from a pelvic process should be drained through the rectal wall to avoid extrasphincteric fistula formation.

**MEDICATION**

**First Line**

- Antibiotics may not be needed in the otherwise healthy child.
- Possible indications for antibiotics may include immunocompromised states, valvular heart disease, diabetes mellitus, underlying Crohn disease, extensive cellulites, or other significant comorbidities:
  - Clindamycin 10–30 mg/kg/day q8h IV/PO
  - Cefazolin 50–100 mg/kg/day qh IV
  - Trimethoprim/Sulfamethoxazole 10 mg/kg/day b.i.d. PO
- Tetanus booster if patient has not received one in the past 5–10 yr

**Second Line**

- Analgesics:
  - Morphine 0.1 mg/kg IV/IM/SC q2h PRN:
    - Initial morphine dose of 0.1 mg/kg IV/SC may be repeated q15–20min until pain is controlled, then q2h PRN.
  - Codeine or codeine/acetaminophen dosed as 0.5–1 mg/kg of codeine component PO q4h PRN
  - Hydrocodone or hydrocodone/acetaminophen dosed as 0.1 mg/kg of hydrocodone component PO q4–6h PRN
- NSAIDs:
  - Consider NSAIDs in anticipation of prolonged pain and inflammation:
    - Ibuprofen 10 mg/kg/dose PO/IV q6h PRN
    - Ketorolac 0.5 mg/kg IV/IM q6h PRN
    - Naproxen 5 mg/kg PO q8h PRN
- Acetaminophen 15 mg/kg/dose PO/PR q4h PRN
- Stool-bulking agents and stool softeners to prevent constipation (post drainage):
  - Polyethylene glycol 3350: 17 g in 8 oz of water qhs

**DISPOSITION**

**Admission Criteria**

Critical care admission criteria:

- Signs or symptoms of sepsis

**Discharge Criteria**

- No signs of systemic toxicity
- Uncomplicated incision and drainage of perianal or ischioanal abscess

**Issues for Referral**

- Complex abscesses involving the ischioanal space, supralelevator abscesses, or abscesses that also involve the contralateral side of the anus (horseshoe abscess) require further workup for the possibility of underlying Crohn disease and often require surgical consultation for intraoperative drainage.
- Nonhealing or recurrent abscesses and/or fistulas
- Chronic drainage or recurrent abscess may be the result of an underlying fistula, requiring further exploration and surgical consultation.

**FOLLOW-UP**

**FOLLOW-UP RECOMMENDATIONS**

- Discharge instructions and medications:
  - Maintain the area clean and dry.
  - Do not remove abscess packing.
  - Keep abscess covered until wound is re-evaluated by physician 2 days post drainage.
  - If antibiotics are prescribed, take medication as directed.
  - Wound check with packing removal or dressing change within 2 days after drainage.
  - Sitz baths (2–3 times/day) and warm compresses after packing removal until complete abscess resolution
  - Follow up in 2–3 wk of drainage for wound evaluation and inspection for possible fistula-in-ano.
- Activity:
  - Patients may perform daily activities without restriction, understanding that good perianal hygiene can minimize postprocedural complications such as reinfection.

**Patient Monitoring**

- No monitoring is generally required for local anesthesia and incision and drainage.
- Patients with complex disease should undergo further evaluation and possibly testing for associated underlying medical problems such as Crohn disease.

**DIET**

High-fiber diet or fiber supplementation

**PROGNOSIS**

- Prognosis of perianal abscesses is generally very good when treated appropriately with incision and drainage.
- Incision and drainage in infants works very well but in older children may be associated with recurrence or fistula formation.

**COMPLICATIONS**

- Patients with rectal abscesses may develop a chronic fistula, especially if they have a history of Crohn disease (1).
- Without appropriate management, up to 85% of children with perianal abscesses will have recurrent abscess or fistula formation.
- Fistulas generally do not heal spontaneously and may require fistulotomy.

- Abscess, Gluteal

**ICD9**  
566 Abscess of anal and rectal regions

**PEARLS AND PITFALLS**

- Perianal and ischioanal abscesses may be drained in the office or ED with appropriate analgesia and local anesthesia.
- Intersphincteric, supralelevator, and horseshoe abscesses generally require surgical consultation and intraoperative drainage.
- Antibiotics are generally not required and do not replace incision and drainage as the mainstay of treatment.
- Patients should be re-evaluated 2–3 wk after drainage to ensure abscess resolution and evaluation for fistula formation.

# ABSCESS, RETROPHARYNGEAL

Nikhil B. Shah

## BASICS

### DESCRIPTION

- Retropharyngeal abscess (RPA) is a deep tissue neck infection:
  - Specifically, it is a suppurative adenitis of the paramedial lymph node chain (1).
  - RPA develops in the potential space between the posterior pharyngeal wall and the prevertebral fascia.
- RPA is serious and occasionally life threatening, partly as a result of the anatomic location and the potential to obstruct the upper airway.
- RPA has been dubbed “the epiglottitis of the new millennium.”
- Causes:
  - Infectious
  - Traumatic
  - Idiopathic

### EPIDEMIOLOGY

- RPA due to infectious causes is noted most commonly in children <6 yr of age.
- Peak incidence occurs at 3 yr of age.
- Uncommon in older children, as the involved lymph node chain atrophies with increasing age

### RISK FACTORS

RPA in children tends to be preceded by infections of the nasopharynx, paranasal sinuses, and middle ear (2).

### PATHOPHYSIOLOGY

- Infection occurs as a result of contiguous spread along a lymphatic chain that originates from the nasopharynx, adenoids, and paranasal sinuses and extends to the adjacent pharyngeal tissues.
- The spectrum may range from cellulitis to frank abscess formation based on the extent of tissue involvement, accounting for the diverse clinical presentation.

### ETIOLOGY

- The pathogen varies depending on the originating source of infection.
- Multiple aerobic and anaerobic organisms are frequently implicated:
  - *Streptococcus viridans* and *Streptococcus pyogenes*
  - *Staphylococcus aureus*, including MRSA strains and *Staphylococcus epidermidis*
  - *Bacteroides*, *Peptostreptococcus*, *Fusobacterium*, *Haemophilus*, and *Klebsiella*

## COMMONLY ASSOCIATED CONDITIONS

RPA may also be associated with:

- Accidental trauma
- Foreign body ingestion
- Complication of medical procedures
- Immunocompromised states (1,2)

## DIAGNOSIS

### HISTORY

- Symptoms are often nonspecific, and diagnosis is based on clinical suspicion:
  - Fever
  - Neck pain, swelling, and/or stiffness
  - Sore throat
  - Odynophagia, dysphagia
  - Irritability
- Limitation of neck movement associated with decreased oral intake or drooling is an important diagnostic clue.
- Symptoms usually progress over several days in contrast to epiglottitis, which progresses more quickly.

### PHYSICAL EXAM

- Neck swelling/mass
- Neck in midline, neutral, or hyperextended position:
  - Neck stiffness in RPA may be confused with that seen in meningitis.
  - Refusal to turn neck laterally often distinguishes RPA from meningitis.
- Trismus (more commonly seen with peritonsillar abscess)
- Cervical lymphadenopathy
- The “classic” findings listed below are usually only seen in more advanced cases:
  - Muffled “hot potato” voice
  - Drooling
  - Torticollis
  - Respiratory distress
  - Stridor and/or wheeze

## DIAGNOSTIC TESTS & INTERPRETATION

### Lab

- CBC (leukocytosis with left shift +/- bands)
- Blood cultures, both aerobic and anaerobic (rarely positive)
- Throat culture for group A streptococci

## Imaging

- Lateral soft tissue neck radiography:
  - Simple screening tool
  - Prevertebral soft tissue swelling >7 mm at level of C2 vertebra or >14 mm at C6 is concerning for RPA but nondiagnostic:
    - False widening may occur with crying, swallowing, expiration, and neck flexion.
    - Attention to proper technique may yield more optimal results.
  - Additional findings include loss or reversal of normal cervical lordosis, radiopaque foreign body, soft tissue mass, air-fluid level, or gas in the prevertebral area.
  - Radiography is not useful in distinguishing cellulitis from abscess unless the presence of gas is noted.
- Neck CT with IV contrast:
  - Most commonly used diagnostic modality
  - Overcomes many of the limitations associated with radiography
  - Disadvantages:
    - High-dose ionizing radiation
    - Potential need for procedural sedation
  - Very helpful in delineating the location and extent of infection
  - Able to differentiate cellulitis from abscess, though studies correlating CT findings with intraoperative findings demonstrate that CT scan has a false-negative rate of 13% and a false-positive rate of 10%
  - Area of hypodensity >2 cm<sup>2</sup> may be more suggestive of abscess.
  - “Scalloping” or irregularity of abscess wall on CT may represent impending rupture and predict need for surgical intervention (64% sensitivity).
- Neck US:
  - Nonradiation alternative (3)
  - Useful for evaluation as well as monitoring progression
  - Able to detect infection in early nonsuppurative stage (when combined with color Doppler), thereby allowing for earlier initiation of antimicrobial therapy and a possible reduction in the number of surgeries
  - Able to differentiate between abscess and adenitis
  - May be used to guide intraoperative aspiration and drainage

## DIFFERENTIAL DIAGNOSIS

Other infectious conditions that may mimic RPA include:

- Epiglottitis (now rare in post *Haemophilus influenzae* type b vaccine era)
- Laryngotracheobronchitis (croup)
- Bacterial tracheitis
- Meningitis
- Cervical lymphadenitis

## TREATMENT

### INITIAL STABILIZATION/THERAPY

- Initial therapy depends on the severity of respiratory distress and likelihood of drainable fluid (based on CT findings, clinical features, and clinical course)
- Airway management:
  - If the child has significant stridor or respiratory distress, a clinician with advanced airway skills (eg, ENT, anesthesia) should be present for airway stabilization.
  - Diagnostic workup must be deferred until the airway is stabilized.
  - In cases of severe airway compromise, a management protocol similar to that previously used for epiglottitis should be considered (ie, emergent endoscopic airway exam by ENT with no interventions initiated until the child is under anesthesia in the operating room).
- IV fluid resuscitation

### MEDICATION

#### First Line

- The majority of patients may be managed with early administration of IV antibiotics alone (75–90% success rate):
  - Early institution of antibiotics may prevent progression to mature abscess (4).
- Selection of the antibiotic regimen should be based on regional bacterial sensitivity patterns and include coverage against multiple mixed aerobic and anaerobic pathogens:
  - Ampicillin/Sulbactam 200 mg/kg/day divided q6h IV OR
  - Clindamycin 40 mg/kg/day divided q8h IV:
    - Added benefit of MRSA coverage
- Parenteral treatment should be maintained until the patient is afebrile and clinical improvement is noted.
- Oral therapy should then be continued to complete a 14-day course and includes the following regimens:
  - Amoxicillin/Clavulanate 80–90 mg/kg/day divided q12h OR
  - Clindamycin 40 mg/kg/day divided q8h
- Analgesia:
  - Acetaminophen 15 mg/kg/dose PO q4–6h PRN
  - Ibuprofen 10 mg/kg/dose PO q6h PRN
  - Morphine 0.1 mg/kg IV/IM/SC q2h PRN
    - Initial morphine dose 0.1 mg/kg IV/SC may be repeated q15–20min until pain is controlled then q2h PRN

#### Second Line

In patients not responding to parenteral clindamycin or those with severe disease:

- Vancomycin 40–60 mg/kg/day divided q6–8h IV
- Linezolid:
  - <12 yr: 30 mg/kg/day divided q8h IV
  - ≥12 yr: 20 mg/kg/day divided q12h IV
  - Max daily dose 1,200 mg

### SURGERY/OTHER PROCEDURES

- Indications for surgical drainage (in combination with empiric antibiotic therapy) include:
  - Airway compromise or other life-threatening complications
  - Large (>2 cm<sup>2</sup>) hypodense area on CT scan
  - Failure to respond to IV antibiotic therapy
- Factors associated with drainable fluid at surgery include duration of symptoms >2 days and hypodense area >2 cm<sup>2</sup> on CT scan (5).
- If surgical drainage is performed, aerobic and anaerobic specimens for culture should be obtained.

### DISPOSITION

#### Admission Criteria

- Children with suspected or confirmed RPA should be hospitalized and managed in consultation with ENT.
- Critical care admission criteria:
  - Severe airway compromise
  - Toxicity
  - Development of potentially fatal complications (eg, sepsis, mediastinitis)

## FOLLOW-UP

### FOLLOW-UP RECOMMENDATIONS

- Discharge instructions and medications:
  - Children with RPA should be admitted from the emergency department.
- When discharged from the hospital after appropriate therapy:
  - Follow up within few days of discharge.
  - Patients should be advised to return for re-evaluation if the following symptoms develop:
    - Fever
    - Dyspnea
    - Worsening/Severe pain
    - Trismus
    - Enlarging mass
    - Neck stiffness

#### Patient Monitoring

Children with retropharyngeal infections should be monitored closely for persistence or progression of symptoms and development of complications.

### PROGNOSIS

- RPA seldom leads to long-term sequelae when detected early and appropriately treated.
- Relapse rate of 1–5%; may be associated with trauma or anatomic abnormality.

### COMPLICATIONS

- Infection may spread from the retropharyngeal space to other deep neck spaces, contiguous structures, and the bloodstream.
- Complications are rare but potentially fatal and include:
  - Airway obstruction
  - Sepsis
  - Aspiration pneumonia (if abscess ruptures into the airway)
  - Internal jugular vein thrombosis
  - Lemierre syndrome: A potentially fatal condition usually caused by *Fusobacterium necrophorum* and characterized by thrombophlebitis of head and neck veins and systemic dissemination of septic emboli
  - Carotid artery rupture
  - Mediastinitis (from extension into chest)
  - Atlantoaxial dislocation
  - Grisel's syndrome

## CODES

### ICD9

478.24 Retropharyngeal abscess

## PEARLS AND PITFALLS

- Consider the diagnosis of RPA in a child with fever, stiff neck, and dysphagia.
- When a critical airway is suspected, all interventions should be deferred until the airway is secured.
- CT with IV contrast provides an optimal image. However, if skilled operators are available, sonography may be used to confirm the diagnosis and assist in drainage.
- Hospitalize all children with RPA in consultation with ENT, with careful attention to maintenance of the airway.
- Initial therapy depends on severity of respiratory distress and likelihood of drainable fluid.
- Initiate empiric antibiotic therapy as soon as possible in all patients.

# ACETAMINOPHEN POISONING

Stephanie H. Hernandez

## BASICS

### DESCRIPTION

- Acetaminophen is used as an analgesic and antipyretic.
- Acetaminophen toxicity is the leading cause of hepatotoxicity and toxin-induced hepatic failure.
- Acetaminophen is one of the most commonly ingested toxins in the U.S.
- Acetaminophen ingestion may cause a spectrum of illness from minor symptoms and no hepatotoxicity to severe hepatotoxicity, liver failure, and death.
- Use of a nomogram to predict the likelihood of toxicity and the antidote N-acetylcysteine (NAC), used to prevent and treat acetaminophen toxicity, play a key role in management of acetaminophen ingestions.

- Toxic acetaminophen ingestions are typically initially "silent," and there is no way by physical exam to determine which patients will have hepatotoxicity.
- Single ingestions of  $<200$  mg/kg are typically considered nontoxic in children.

### EPIDEMIOLOGY

- Acetaminophen is among the most commonly ingested drugs reported to poison control centers in the U.S., with  $>90,000$  cases of exposure reported in 2008.
- Acetaminophen combination formulations were among the top 5 ingestions reported to poison centers associated with death in 2008:
  - Acetaminophen alone is among the top 10.
- Acetaminophen poisoning is the leading cause of fulminant hepatic failure in the U.S. and U.K.

- In patients with intentional suicidal gestures, 1 in 500 will fail to disclose an acetaminophen ingestion that warrants treatment.

### RISK FACTORS

- Increased NAPQI (N-acetyl-p-benzo-quinone) formation:
  - CYP2E1 induced
  - Decreased hepatic glutathione (GSH) stores
  - Poor nutritional status
- Decreased capacity for nontoxic metabolism
- Patients who receive antidote treatment more than after 8 hr after acute ingestion
- Chronic supratherapeutic ingestions

### GENERAL PREVENTION

- Appropriate parental weight-based dosing in pediatric patients
- Recognition of the difference in concentration between infant and children's formulation

### PATHOPHYSIOLOGY

- Acetaminophen generates the hepatotoxic metabolite NAPQI, which can be converted to less toxic compounds by endogenous glutathione.
- Toxicity occurs when excessive NAPQI is produced and glutathione stores are exhausted.

### ETIOLOGY

- Acetaminophen is commonly referred to as Tylenol in the U.S. However, depending on the manufacturer, it may be recognized by different names worldwide. Some of these common names include but are not limited to Panadol, paracetamol, Crocin, and Dolex.
- There are many over-the-counter and prescriptive products that contain acetaminophen.
- Examples include but are not limited to:
  - Vicodin (hydrocodone/acetaminophen)
  - Percocet (oxycodone/acetaminophen)
  - Darvocet (propoxyphene/acetaminophen)
  - Fioricet (butalbital/caffeine/acetaminophen)
- Over-the-counter cold and cough medications

### COMMONLY ASSOCIATED CONDITIONS

- Toddlers with febrile illnesses
- Chronic pain syndromes and tolerance to opiate analgesics
- Ignorance of the acetaminophen component in combination medications
- Suicidality and psychiatric illness
- Prescriptive drug abuse: Patients taking opioid/acetaminophen combinations may take toxic doses of acetaminophen in order to ingest the quantity of opioid they desire.

## DIAGNOSIS

### HISTORY

- Time of ingestion
- Single acute ingestion or multiple ingestions
- Acetaminophen formulation
- Combination products that may delay absorption; opiates or anticholinergic agents

### PHYSICAL EXAM

- Physical exam is usually unremarkable in acute ingestion.
- GI distress may be observed.
- In massive overdoses, early clinical signs may be seen (metabolic acidosis accompanied by tachypnea, altered mental status and, renal impairment) in the absence of hepatic impairment.

Rumack-Matthew nomogram. (Adapted from Rumack BH, Matthew H. Acetaminophen poisoning and toxicity. *Pediatrics*. 1975;55:871-876.)

- Hepatotoxicity occurs most commonly within 24 hr post-ingestion if not treated or if treatment is initiated >8 hr post-ingestion:
  - Clinical findings include jaundice, right upper quadrant pain, coagulopathy, and encephalopathy.

## DIAGNOSTIC TESTS & INTERPRETATION

### Lab

#### Initial Lab Tests

- Serum acetaminophen concentrations should be obtained:
  - These must be interpreted according to the circumstances of ingestion: Time from ingestion, coingestants, and LFTs.
  - In a single acute ingestion, a serum concentration should be obtained ideally no earlier than 4 hr post-ingestion, and results should be available no later than 8 hr post-ingestion in order to initiate treatment if needed.
  - In single acute ingestions, utilize the Rumack-Matthew nomogram to determine if treatment with NAC is warranted.
  - In chronic multiple ingestions, call your nearest poison center and/or consult a toxicologist to determine if treatment is warranted.
- LFTs should be routinely obtained if the acetaminophen concentration is in the toxic range or in cases of late presentation.
  - LFTs are usually within normal limits until ~24 hr post-ingestion with the exception of massive overdoses.
  - LFTs may be abnormal with relatively low or absent acetaminophen concentrations in chronic overdoses.
- Specific lab tests that indicate poor prognosis include PT >100, creatinine 3.3 mmol/L, lactate >3 mmol/L, phosphate >2.6 mmol/L on day 2, pH <7.3.

## TREATMENT

### PRE HOSPITAL

General supportive care should be provided.

### INITIAL STABILIZATION/THERAPY

- Maintain vital signs within normal limits; IV fluid administration is usually indicated.
- Assess the serum acetaminophen concentration at least 4 hr post-ingestion.
- If the patient has a toxic acetaminophen concentration as indicated by the Rumack-Matthew nomogram, administer NAC. In the U.S., toxicity is any value above the lower (dashed) line.
- If the patient reaches 8 hr post-ingestion and the serum acetaminophen level is not known, immediately administer NAC.
- NAC is most effective when given within 8 hr of ingestion. If a nontoxic serum acetaminophen concentration is subsequently noted, the NAC therapy may be discontinued.

### MEDICATION

#### First Line

- IV NAC is indicated in a single acute ingestion of acetaminophen when the acetaminophen concentration  $\geq$ 4 hr post-ingestion is above the treatment line on the Rumack-Matthew nomogram.
- NAC should be started in the setting of suspected chronic supratherapeutic acetaminophen dosing with low or nondetectable acetaminophen concentration and elevated LFTs.

- It is ideal to start NAC within 8 hr of ingestion in order to prevent significant hepatotoxicity and mortality.
- NAC IV dosing (21-hr NAC protocol): 150 mg/kg over 60 min, then 50 mg/kg over 4 hr, then 100 mg/kg over 16 hr:
  - It is usually mixed with 5% dextrose. For patients <40 kg, assure appropriate weight-based calculation and administration of NAC in IV fluid. See <http://www.acetadote.net> for a dose calculator.
  - Status epilepticus and death have been associated with medication errors with NAC in pediatric patients.
  - A loading bolus over 15 min is advocated by some, but we advise 60 min due to lower incidence of severe anaphylactoid reaction with the longer initial infusion.
- NAC oral dosing: 140 mg/kg PO loading dose followed by 70 mg/kg PO q4h for 72 hr.
- Oral dosing often causes vomiting.
- Due to vomiting and length of treatment (72 hr vs. 21 hr), oral administration is not typically the first-line therapy: IV NAC is preferable.
- Consult your poison control center and/or toxicologist in the setting of multiple or chronic ingestions in order to decide if NAC is indicated.
- An oral NAC regimen should be considered for patients with severe and/or active asthma or prior severe anaphylactoid reaction to NAC.

### Second Line

- Consider activated charcoal if the risk of aspiration is low and the airway is intact:
  - 1 g/kg orally if within 1 hr of ingestion
  - With ingestions of acetaminophen and other substances that may diminish GI motility, such as diphenhydramine or opioids, charcoal may be administered even after 1 hr of ingestion.
- Fresh frozen plasma if coagulopathic
- Vitamin K if coagulopathic
- Renal replacement therapy for persistent acidosis despite supportive care and/or renal failure

### SURGERY/OTHER PROCEDURES

Liver transplant may be necessary.

### DISPOSITION

#### Admission Criteria

- All patients who require treatment with NAC must be admitted.
- Critical care admission criteria:
  - Consider admission to a critical care unit if the patient has the following:
    - Altered mental status or encephalopathy
    - Metabolic acidosis
    - Coagulopathy
    - Renal failure
    - Rising LFTs

#### Discharge Criteria

Treatment with NAC may be terminated and the patient may be discharged after LFTs are assured to be within normal limits and acetaminophen concentration is less than the limits of detection.

#### Issues for Referral

- Patients with poor prognostic criteria should be referred for liver transplant: PT >100, creatinine 3.3 mmol/L, lactate >3 mmol/L, phosphate >2.65 mmol/L on day 2, pH <7.3.
- All cases should be reported to the local poison center.
- Unclear cases or cases of chronic supratherapeutic ingestion should be discussed with a poison specialist and/or toxicologist.

## FOLLOW-UP

### FOLLOW-UP RECOMMENDATIONS

#### Patient Monitoring

- Psychiatric consultation is required for all intentional overdoses.
- Patients who recover from hepatotoxicity do not require repeat liver function evaluations.

### PROGNOSIS

- If NAC is started within 8 hr from the time of ingestion in an acute single ingestion, morbidity and mortality is very low.
- Chronic overdoses and patients who present late for treatment with NAC have increased morbidity and mortality.
- Poor prognosis—the King's College criteria:
  - pH <7.3 at 2 days after overdose despite volume resuscitation and PT >100, serum creatinine >3.3 mmol/L, or severe hepatic encephalopathy
  - Other criteria predictive of poor prognosis:
    - Serum lactate >3 mmol/L after fluid resuscitation or phosphate >2.65 on day 2

### COMPLICATIONS

- Encephalopathy
- Coagulopathy
- Renal failure
- Fulminant hepatic failure
- Acidosis
- Death

### ADDITIONAL READING

### See Also (Topic, Algorithm, Electronic Media Element)

IV NAC administration information (including weight-based infusion): <http://www.acetadote.net>

### CODES

#### ICD9

965.4 Poisoning by aromatic analgesics, not elsewhere classified

### PEARLS AND PITFALLS

- Inappropriate utilization of the Rumack-Matthew nomogram and misinterpretation of acetaminophen concentrations
- Premature termination of NAC therapy or failure to continue therapy beyond 21 hr when indicated
- IV NAC administration should be given carefully; dosing errors are common due to the 3 different concentrations of infusion required.

## BASICS

### DESCRIPTION

- Acne is any cutaneous disease that begins with the formation of a microcomedo.
- Acne has the potential for scarring and invasive infection and may be associated with psychosocial disorders including depression, social isolation, and suicide.
- Severity ranges from mild comedones to extensive nodular acne, with usual distribution over the face, chest, and back.

### EPIDEMIOLOGY

- Acne occurs at some point in 80–85% of all adolescents/young adults:
  - It is the most common skin disease in this age group.
- Neonatal acne occurs in 20% of infants, with onset at 3 wk of age and resolution by 4 mo of age.
- Infantile acne, with a male predominance, presents at 3 mo of age with resolution by 2 yr of age.

### RISK FACTORS

- Genetic
- Medications:
  - Glucocorticoids, anabolic steroids, isoniazid, phenytoin, iodides, bromides, cyclosporine, azathioprine, and others
- Oily cosmetics, pomades, oil and coal tar exposure
- Hormonal changes related to androgen-producing tumors, menstrual periods, pregnancy, birth control pills, or stress

### GENERAL PREVENTION

- Avoid anabolic steroids, oily cosmetics, and excessive scrubbing of skin.
- Use powdered, water-based, or noncomedogenic cosmetics.
- An association between acne and milk ingestion may possibly be related to hormones present in milk.

### PATHOPHYSIOLOGY

- Initially begins due to follicular plugging caused by hyperkeratinization and abnormal desquamation of pilosebaceous follicles (microcomedo)
- Increased sebum production occurring in adolescence and in infancy leads to sebum trapping in follicles.
- Follicle colonized by *Propionibacterium acnes*
- *P. acnes* proliferate in an anaerobic setting, leading to follicular wall rupture as well as a neutrophilic inflammatory response.
- Stimulation of toll-like receptors and cell surface receptors lead to the release of inflammatory mediators, including cytokines, resulting in follicular rupture.

### ETIOLOGY

- Neonatal: Possibly related to sebaceous gland stimulation by maternal androgens. There is controversy regarding the relationship to cephalic pustulosis. Neither entity has comedonal lesions.
- Infantile acne: Hyperplasia of sebaceous glands due to androgenic stimulation with full spectrum of acne lesions
- Acne vulgaris: Precipitating events that lead to formation of the initial hyperkeratotic plug are multifactorial but in general are hormonally mediated:
  - Consider hyperandrogenism from polycystic ovary syndrome or ovarian or adrenal tumor if the onset is rapid and/or the patient has virilization.

## DIAGNOSIS

### HISTORY

- Age at onset
- Presence of fever, arthralgia, myalgia, or weight loss
- Family history of acne or endocrine disorders
- Menstrual history: Menarche and regularity, oligomenorrhea
- Medication history including medications used for acne (topical and systemic)
- Cosmetics/Pomades used
- Workplace exposures (eg, fryers in fast-food restaurants)

### PHYSICAL EXAM

- Type and distribution of lesions:
  - Open comedones (blackheads)
  - Closed comedones (whiteheads)
  - Inflammatory papules and pustules
  - Nodules and cysts:
    - Scarring and hyperpigmentation
- Fever or arthralgia
- Evidence of invasive infection (gram-negative folliculitis and staphylococcal infections)
- In infants, look for signs of virilization including body odor, axillary or pubic hair, and clitoromegaly.
- In adolescents, hyperandrogenism may manifest as late-onset or resistant acne, hirsutism, acanthosis nigricans, alopecia, and deepened voice.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

- Cultures are indicated only with suspicion of gram-negative folliculitis or staphylococcal or streptococcal infections.
- Consider obtaining free testosterone, serum dehydroepiandrosterone sulfate, luteinizing hormone, and follicular-stimulating hormone levels in children who present with severe persistent infantile acne or in acne vulgaris with virilization.

#### Imaging

Children who present with virilization may require a pelvic US or CT of the abdomen and pelvis.

### DIFFERENTIAL DIAGNOSIS

- Neonatal acne may be confused with:
  - Cephalic pustulosis, sometimes used synonymously with acne (lacks comedones and possibly related to *Malassezia* species overgrowth)
  - Miliaria rubra (heat rash): Obstruction of eccrine sweat ducts due to keratin (may have papules and pustules); caused by excessive warming of young infant
  - Milia: Keratin retention in pilaceous follicles; common areas of distribution include the nose and cheeks; occurs during 1st few weeks of life
- Infantile acne:
  - If all stages of lesions are in the typical facial distribution, diagnosis is straightforward.
  - For pustules, consider staphylococcal or candidal infections.
  - For papules, consider viral exanthem, Gianotti-Crosti syndrome, zinc deficiency, or irritant eczema.
  - For nodules, consider pilomatrixoma, insect bites, and idiopathic facial aseptic granuloma.
- Acne vulgaris, although generally a clinically apparent diagnosis, can be confused with:
  - Flat warts and molluscum contagiosum (both noninflammatory)
  - Rosacea, which is usually after extended steroid therapy but has no comedones
  - Sebaceous hyperplasia (neonates and older teens): Forehead and cheeks.
  - Bacterial folliculitis: No comedones, and lesions are usually all in the same stage
  - Pseudofolliculitis barbae (barber's itch): Related to secondary infection of ingrown hairs
  - Acnelike eruption of Apert syndrome: On arms, legs, and buttocks

## TREATMENT

### MEDICATION

#### First Line

- Neonatal acne will resolve without treatment:
  - Gentle washing with tepid water and cleanser b.i.d.
  - Avoidance of oils and lotions
  - May use a keratolytic shampoo or a 2.5% benzoyl peroxide lotion
  - A mild nonfluorinated steroid (hydrocortisone 1% b.i.d.) may decrease erythema.
- Infantile acne will resolve but has rare potential for scarring:
  - Mild to moderate: Benzoyl peroxide (2.5%), topical antibiotics (erythromycin or clindamycin), topical retinoids
  - Severe:
    - Erythromycin 30–50 mg/kg/day PO divided t.i.d.

- Acne vulgaris (adolescents and young adults): Mild to moderate acne (starting with 1st 2 and progressing through therapeutic armamentarium until there is improvement):
  - Gentle cleansing with tepid water and mild cleanser such as a glycolic/salicylic acid–based cleanser b.i.d.
  - Salicylic acid lotion: Thin layer applied to affected area b.i.d.
  - Benzoyl peroxide 2.5% daily to b.i.d. as tolerated to entire involved area (not just lesions). Alternative is salicylic acid:
    - Benzoyl peroxide bleaches fabrics and hair; in dark-skinned patients, it may cause some lightening at higher concentrations.
    - Benzoyl peroxide also may cause excessive dryness of skin.
  - May increase concentration of benzoyl peroxide to 5% if a lower concentration is tolerated
  - Topical antimicrobial (erythromycin or clindamycin) containing benzoyl peroxide daily
  - Topical retinoid (adapalene or tretinoin) are effective but not typically prescribed from the emergency department.
- Acne vulgaris (moderate to severe) or resistant inflammatory acne:
  - Add to the above regimen:
    - Tetracycline 500 mg PO b.i.d. OR
    - Doxycycline 100 mg PO b.i.d.
    - Doxycycline is more effective but can cause photosensitivity or nausea.
  - If failure of above, switch to:
    - Minocycline 50–100 mg PO b.i.d.
    - Minocycline can cause pseudotumor cerebri, autoimmune reactions, and blue pigmentation of skin and teeth.
  - Erythromycin base 30–50 mg/kg/day PO divided t.i.d.
  - Trimethoprim (TMP)/Sulfamethoxazole 6–12 mg TMP/kg/day PO divided b.i.d.

### Second Line

The following therapies should be instituted by a dermatologist:

- Isotretinoin:
  - Drug is teratogenic.
  - Other possible side effects include headaches, nosebleed, paronychia, depression, elevated liver enzymes, and possibly inflammatory bowel disease.
- Consider oral contraceptives [norgestimate with ethinyl estradiol (Ortho Tri-cyclin) or norethindrone acetate with ethinyl estradiol (Estrstep)].
- Class B (level II evidence) drugs: Spironolactone, antiandrogens, and oral corticosteroids

### Pregnancy Considerations

- Oral isotretinoin therapy is highly teratogenic. Use is restricted to prescription by dermatologists under the stringently regulated FDA program iPledge:
  - Available in unregulated countries
- Oral tetracyclines, topical retinoids, and hormonal therapy are all contraindicated during pregnancy.

### COMPLEMENTARY & ALTERNATIVE THERAPIES

Stress relief measures may be effective.

### DISPOSITION

#### Admission Criteria

Secondary gram-negative, staphylococcal, or streptococcal infections leading to cellulitis or abscess with fever and toxicity

#### Issues for Referral

- Referral to dermatology for treatment of:
  - Resistant and severe nodular acne
  - Severe pustular or cystic acne
  - Isotretinoin therapy
- Endocrinology: Rapid onset, atypical age, or persistence

### FOLLOW-UP

#### FOLLOW-UP RECOMMENDATIONS

Discharge instructions and medications:

- Specific primary care or dermatology follow-up in a timely manner will reinforce instructions and encourage compliance.
- Improvement in lesions with any therapy takes 4–8 wk.
- Avoid an excessively complex initial program, especially in boys.
- Application of topical medications should be done about 15 min after facial cleansing and drying to avoid excessive absorption with increased side effects.
- Warn about the possibility of initial worsening of symptoms, erythema, and scaling with therapy.

#### DIET

Dietary restrictions are ineffective.

#### PROGNOSIS

With optimal therapy and compliance, acne is a controllable disease.

#### COMPLICATIONS

- Acne fulminans:
  - Sudden flare in males of severe acne of the chest and back with associated fever, myalgia, and arthralgia
  - May occur during early isotretinoin therapy or with testosterone therapy
  - Treatment includes systemic steroids and oral antibiotics; after 4 wk, low-dose isotretinoin is used (see Medication section).
- Gram-negative folliculitis:
  - May develop after long-term antibiotic use
  - Suspect with flaring and worsening of acne on antibiotic therapy
  - Treatment with gram-negative antibiotics
- Staphylococcal (MRSA) secondary infections
- Excoriated acne: More common in females and consists of compulsive picking at lesions resulting in infection and scarring.

### See Also (Topic, Algorithm, Electronic Media Element)

<http://www.skincarephysicians.com/acnenet/>

ICD9  
706.1 Other acne

### PEARLS AND PITFALLS

- Pearls:
  - Time-honored dietary restrictions are not supported by best evidence.
- Pitfalls:
  - Failing to recognize the profound psychosocial implications of acne for the suffering teen
  - Missing signs of virilization or atypical presentation suggesting an androgen-producing tumor
  - Failure to counsel, prevent, and monitor for pregnancy in females on systemic medications or topical retinoids
  - Use of topical antibiotics not in combination with benzoyl peroxide can lead to bacterial resistance.

# ACUTE HEMOLYTIC ANEMIA

Angela M. Ellison

## BASICS

### DESCRIPTION

- Hemolysis is the destruction or removal of RBCs before their normal life span of 90–120 days.
- Hemolytic anemia occurs when the rate of hemolysis exceeds the ability of the bone marrow to adequately compensate for the loss of RBCs.
- This topic focuses on the identification and treatment of acute hemolytic anemia.

### EPIDEMIOLOGY

#### Incidence

- The incidence and prevalence of hemolytic anemia depends on the etiology.
- Autoimmune-mediated hemolytic anemia (AIHA) is rare, with an estimated annual incidence of 1 in 80,000 persons (1).

### RISK FACTORS

- AIHA is more likely to occur in females.
- G6PD deficiency is an X-linked recessive disorder:
  - Individuals with this disorder are at risk of developing acute hemolytic anemia when exposed to certain foods, drugs, and other substances.
- Individuals with inherited disorders that cause chronic hemolysis during steady-state conditions (eg, sickle cell anemia [SCA], hereditary spherocytosis) are also at risk of developing acute hemolytic episodes:
  - These acute episodes may be triggered by the onset of acute illness or infection.
- Transfusion of incompatible blood products may also trigger an acute hemolytic reaction:
  - May occur up to several weeks after the initial transfusion (delayed hemolytic reaction).

### GENERAL PREVENTION

- Medications and chemicals that are likely to trigger hemolysis in patients with G6PD deficiency should be avoided.
- Patients with chronic hemolytic diseases (eg, SCA, hereditary spherocytosis) should be provided anticipatory guidance regarding the signs and symptoms of acute hemolysis and worsening anemia.

### PATHOPHYSIOLOGY

There are 2 mechanisms of hemolysis:

- Intravascular: Destruction of RBCs in the circulation with release of cell contents into the plasma
- Extravascular: Removal and destruction of RBCs with membrane alterations by the macrophages of the spleen and liver

### ETIOLOGY

Hemolysis occurs secondary to either an acquired or inherited cause:

- Acquired:
  - AIHA occurs when the body forms antibodies against its own RBCs' surface antigens.
  - Primary AIHA: Autoantibodies are present, but there is no evidence of systemic disease. It can be categorized as warm-reactive AIHA (IgG autoantibodies maximally bind RBCs at 37°C) or cold-reactive AIHA (autoantibodies preferentially bind RBCs at 4°C) (2).
  - Cold-reactive AIHA includes cold agglutinin disease (IgM autoantibodies) and paroxysmal cold hemoglobinuria (IgG autoantibodies).
  - Secondary AIHA: Immune-mediated hemolytic anemia is only a manifestation of a broader systemic disorder. Teenagers who present with AIHA are more likely to have an underlying systemic illness (3).
  - Microangiopathic anemia results from the mechanical destruction of RBCs in circulation (eg, disseminated intravascular coagulation [DIC], hemolytic uremic syndrome [HUS], thrombotic thrombocytopenia purpura [TTP]).
- Inherited:
  - Enzymopathies (G6PD deficiency, pyruvate kinase deficiency)
  - Membranopathies (hereditary spherocytosis, hereditary elliptocytosis)
  - Hemoglobinopathies (thalassemia, SCA)

### COMMONLY ASSOCIATED CONDITIONS

- Idiopathic
- Malignancy
- Drugs
- Autoimmune disorders
- Infections (viral and bacterial)
- Transfusions
- SCA
- TTP
- HUS
- DIC
- Porphyria
- Eclampsia
- Malignant HTN
- Prosthetic valves

## DIAGNOSIS

### HISTORY

- Dyspnea, fatigue, weakness, or angina may occur in the presence of abrupt hemolysis and severe anemia.
- Acute onset of pallor may be reported in cases of brisk hemolysis:
  - Slow onset of pallor usually suggests diminished RBC production.
- Back pain and dark urine may be reported by patients with intravascular hemolysis.
- Jaundice may be present because of an increase in indirect bilirubin.
- Family history of anemia or autoimmune diseases should be elicited.
- Family history of splenectomy or cholecystectomy suggests an inherited hemolytic disorder such as hereditary spherocytosis or pyruvate kinase deficiency.
- Transfusion history should be obtained.
- Current and previous medication history should be documented.
- Exposure to other agents that may cause abrupt hemolysis in patients with G6PD deficiency (eg, naphthalene-containing mothballs, fava beans) should be explored.

### PHYSICAL EXAM

- Evidence of CHF (tachycardia, gallop rhythm, cardiomegaly, and hepatomegaly) may be present.
- Skin may appear jaundiced or pale:
  - Mucous membranes, conjunctivae, nail beds, palms, and soles should be closely examined.
- Lymphadenopathy suggests a malignancy.
- Splenomegaly suggests either malignancy or the presence of other underlying disorder (eg, hereditary spherocytosis, SCA, or systemic lupus erythematosus [SLE]).
- Leg ulcers may be found in the presence of SCA or other chronic hemolytic states.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

- Complete blood and reticulocyte counts should be obtained to determine degree of anemia and if bone marrow response is adequate:
  - Peripheral blood smear should be examined. Spherocytes and schistocytes are pathognomonic of hemolysis.
  - Platelets and WBCs should also be examined to evaluate for coexisting hematologic or malignant disorders.
  - Thrombocytopenia occurs in SLE and microangiopathic hemolytic anemia.
- Indirect bilirubin, lactate dehydrogenase (LDH), and haptoglobin levels should be obtained:
  - Indirect bilirubin and LDH levels are increased while haptoglobin levels are usually decreased in the presence of acute hemolysis.

- Direct antiglobulin test (direct Coombs test) should be performed to determine if hemolysis is immune mediated.
- Urinalysis will reveal the presence of hemoglobinuria in cases of intravascular hemolysis. The urine dipstick will identify the presence of blood in the absence of RBCs.

### Imaging

Chest radiograph may be useful in the evaluation of cardiopulmonary status.

### Diagnostic Procedures/Other

Bone marrow aspiration may be indicated for the evaluation of possible bone marrow failure or malignancy.

### DIFFERENTIAL DIAGNOSIS

- Refer to Commonly Associated Conditions.
- Other causes of anemia, including anemia secondary to decreased production of RBCs or blood loss, should be considered.

## TREATMENT

### INITIAL STABILIZATION/THERAPY

- Maintain the airway, and assure adequate ventilation. Supplemental oxygen should be administered to increase the oxygen-carrying capacity.
- Maintain adequate circulation.
- Transfusions should be avoided unless absolutely necessary:
  - Blood transfusion in patients with AIHA is extremely challenging because type matching and cross matching may be difficult and the risk of acute hemolysis of transfused blood is high.
- Patients with severely compromised cardiopulmonary status or life-threatening anemia should be transfused:
  - The least incompatible blood available should be used if transfusion is indicated.
  - Packed RBCs should be administered slowly in an effort to decrease cardiac stress and, in the case of AIHA, to decrease the rapid destruction of transfused blood.
- Children with suspected cold-reactive AIHA should be placed in a warm environment.
- Medications and other agents that may be contributing to acute hemolysis should be discontinued.

### MEDICATION

#### First Line

- Corticosteroids represent the best primary therapy for AIHA, particularly in children with IgG autoantibodies. Desirable dosing regimens are variable and should be discussed with the hematology consultant:
- Corticosteroids are not as effective in cold agglutinin disease (4).
  - Paroxysmal cold hemoglobinuria is usually self-limited, but some patients may require a short course of corticosteroids.

### Second Line

- Plasmapheresis or plasma exchange is another therapeutic option in cases of suspected AIHA. Patients with IgM autoantibodies respond better to plasmapheresis than do those with IgG autoantibodies (5).
- Although intravenous immunoglobulin (IVIG) is an attractive option for adults with AIHA, children with AIHA usually do not respond to IVIG therapy.

### SURGERY/OTHER PROCEDURES

Splenectomy may be necessary in patients with hereditary spherocytosis, hereditary elliptocytosis, or refractory AIHA.

### DISPOSITION

#### Admission Criteria

Critical care admission criteria:

- Patients with severe anemia and evidence of cardiopulmonary compromise require admission to an ICU setting.
- Patients who are severely anemic but stable should be admitted for diagnostic workup.

#### Issues for Referral

Hematology consultation should be obtained for all patients with suspected acute hemolytic anemia.

## FOLLOW-UP

### FOLLOW-UP RECOMMENDATIONS

Discharge instructions and medications:

- Immunizations against encapsulated organisms and prophylactic penicillin therapy should be administered to those with splenectomy or compromised splenic function.
- Anticipatory guidance regarding the need for immediate evaluation and treatment of fever should also be provided to patients with splenectomy or compromised splenic function.
- All patients should be educated about the signs and symptoms of recurrent acute hemolysis.
- Folic acid should be administered to children with chronic hemolysis.
- Iron therapy is indicated in patients with iron deficiency secondary to ongoing losses or low iron stores.

### Patient Monitoring

Hemoglobin level, reticulocyte count, indirect bilirubin, LDH, and haptoglobin should be monitored closely to determine response to therapy.

### DIET

Patients with G6PD deficiency should avoid foods containing fava beans.

### PROGNOSIS

- Prognosis depends on the underlying cause and baseline health status of affected individuals.
- In general, death rarely occurs with prompt diagnosis and appropriate treatment.

### COMPLICATIONS

If severe:

- Cardiopulmonary compromise
- Congestive cardiac failure
- Neurologic dysfunction
- Shock
- Multiorgan system failure

- Anemia
- Aplastic Anemia
- Hyperbilirubinemia, Direct
- Hyperbilirubinemia, Indirect
- Jaundice

### ICD9

- 282.2 Anemias due to disorders of glutathione metabolism
- 283.0 Autoimmune hemolytic anemias
- 283.9 Acquired hemolytic anemia, unspecified

### PEARLS AND PITFALLS

- Anemia associated with hemolysis is usually normocytic, but a marked reticulocytosis can lead to an elevated measurement of mean corpuscular volume.
- The concomitant presence of certain conditions (eg, infections, chronic hemolysis) may mask the diagnosis of acute hemolysis by elevating haptoglobin levels.
- The direct Coombs test may be falsely negative in some patients with autoimmune hemolytic anemia.
- Myoglobinuria can mimic hemoglobinuria on urine dipstick.

# ACUTE RENAL FAILURE

Rahul Kaila

Nirupama Kannikeswaran

## BASICS

### DESCRIPTION

- Acute renal failure is more appropriately referred to as acute kidney injury (AKI).
- Definition: Acute reduction in kidney function characterized by a rapid decrease in the glomerular function rate (GFR)
- Two types—oliguric and nonoliguric:
  - Oliguric/Anuric AKI:
    - Urine output <500 mL/24 hr in older children and 1 mL/kg in infants and children
  - Nonoliguric AKI: Normal urine output. It has less morbidity, and mortality is less than that found with oliguric AKI.
- Clinically, AKI is divided into categories of prerenal, renal, and postrenal.
- It manifests as impairments of nitrogenous waste excretion (increase in BUN, acid-base regulation [metabolic acidosis]), and water and electrolyte regulation (oliguria, anuria, hyperkalemia).

### EPIDEMIOLOGY

- Incidence in children is 0.8 per 100,000 population (1).
- Incidence in children is about 1/5 that of adults, although it is increasing due to an increase in the number of surgeries for congenital heart diseases, solid organ and bone marrow transplantation, and improved survival of very low birth weight babies.
- Estimated 20 cases/yr/100,000 neonates (2)
- Estimated 2 cases/yr/100,000 adolescents (2)

### RISK FACTORS

- Intrinsic kidney disease
- Stem cell transplant recipient
- Sepsis with and without multisystem organ failure
- Tumor lysis syndrome
- Hypoxic-ischemic injury
- Nephrotoxic insult
- Postoperative cardiac patients

### PATHOPHYSIOLOGY

- Prerenal: Volume depletion or decrease in effective circulating volume secondary to 3rd spacing of fluids leads to acute decline in renal perfusion, which in turn causes ischemia of renal cells leading to a decrease in GFR.
- Compensation by dilation of afferent arterioles through release of vasodilators such as prostaglandins

- Reversible in initial stages but if not treated can lead to hypoxic-ischemic acute tubular necrosis (ATN).
- Renal: Ischemia/toxic insult—parenchymal injury—cellular destruction; tubular injury leading to tubular obstruction or tubular backleak leading to decreased filtration pressure leading to decreased GFR
- Postrenal: Obstruction of the urethra, bladder, or ureter causes increase in fluid pressure proximally and hence tubular damage and decrease in renal function.

### ETIOLOGY

- Prerenal (most common):
  - GI losses (acute gastroenteritis)
  - Increased urinary loss (diabetes insipidus, diuretics)
  - Vasodilation (sepsis)
  - Blood loss (trauma, surgery)
  - Redistribution of extracellular fluid (heart failure, nephrotic syndrome, cirrhosis)
  - Skin losses (burns)
- Renal:
  - Acute glomerulonephritis (most commonly poststreptococcal)
  - Intrarenal vascular diseases (hemolytic uremic syndrome [HUS]), renal artery/vein thrombosis in newborns
  - Acute interstitial nephritis: Pyelonephritis, drug induced (methicillin and beta-lactam antibiotics), NSAIDs, quinolones
  - ATN secondary to nephrotoxic drugs (aminoglycosides, amphotericin B, contrast agents, ibuprofen, acyclovir) and uric acid in tumor lysis syndrome
- Postrenal:
  - Congenital (posterior urethral valves, ureteropelvic junction obstruction)
  - Acquired (urolithiasis, tumors such as abdominal lymphomas and rhabdomyosarcomas)
- In developed countries, renal ischemia and nephrotoxins are the leading cause of AKI as opposed to developing countries where primary renal disease is the most common cause.
- Factitious AKI: Use of creatine, a popular dietary supplement, causes dramatic elevations in serum and urinary creatinine that meet definitions of AKI:
  - Failure to recognize this in patients who are creatine users, typically young athletes, may result in misdiagnosis.

### COMMONLY ASSOCIATED CONDITIONS

- Hyperkalemia
- HTN

## DIAGNOSIS

### HISTORY

Volume losses such as vomiting, diarrhea, preceding sore throat or pyoderma, bloody diarrhea in HUS, fever, chills in patients with infection sepsis, history of previous surgery, nephrotoxic drugs, antibiotics, diuretics, oliguria, or anuria

### PHYSICAL EXAM

- Assess vital signs with attention to indications of shock.
- Signs of dehydration such as tachycardia, dry mucous membranes, shock, edema associated with 3rd spacing of fluids or secondary to renal failure itself
- Petechiae and bleeding in systemic vasculitis, suprapubic mass in postrenal causes, HTN, seizures, uremic pericarditis
- Distinguishing between de novo acute renal failure vs. acute renal failure superimposed on chronic renal failure by the presence of failure to thrive, anemia, evidence of renal rickets, and maintenance of urine output in acute renal failure superimposed on chronic renal failure

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

- CBC with differential and peripheral blood smear
- Electrolytes, BUN, creatinine, calcium, magnesium, phosphorus
- Urine analysis, urine electrolytes, urine protein, urine creatinine
- ASO titers, complement levels C3/C4, anti-DNase B titers
- Prerenal findings:
  - Normal urinary sediments
  - Increased BUN/creatinine ratio
  - Urine osmolality >400–500 mosmol/L, >350 mosmo/L in neonates (urine concentration in view of hypovolemia)
  - Urine sodium <10–20 mEq/L (sodium retention in view of hypovolemia)
  - FENa (fractional excretion of sodium):  $(U_{Na^+} \div U_{Cr}) : (P_{Na^+} \div P_{Cr}) \times 100 < 1\%$  (child)
  - FENa <2.5% (neonates)

- Renal pathology findings:
  - Urinary sediments—RBC casts and granular casts
  - Urine osmolality <350 mosmol/L (inability to concentrate the urine)
  - Urine sodium >30–40 mEq/L (ability to reabsorb the sodium)
  - FENa >2%, low C3 (systemic lupus erythematosus, membranoproliferative and poststreptococcal glomerulonephritis); low C4, ASO titers, anti-DNase B titers in patients with poststreptococcal glomerulonephritis

### Imaging

- Prerenal: Normal renal US and renal scan
- Renal: Renal scan—delay in accumulation and absence of excretion from collecting tubule of radioisotope in areas of parenchymal damage; identifies areas of normal or poor perfusion and poor renal function
- Postrenal: Renal US shows dilated renal pelvis. Use abdominal US in cases of suspected abdominal mass.
- Voiding cystourethrogram for suspected posterior urethral valves
- Renal scan shows isotopic collection at any level of ureter or bladder depending upon the obstruction and absence/delay of excretion of the isotope.

### DIFFERENTIAL DIAGNOSIS

Prerenal, renal, and postrenal acute renal failure are differentiated by using urinary indices, urine osmolality, and imaging studies.

## TREATMENT

### INITIAL STABILIZATION/THERAPY

- Fluid therapy: In an oliguric and hemodynamically unstable patient, give 20 cc/kg of isotonic fluid in repeated boluses as necessary.
- Correct electrolytes.
- Hyperkalemia: ECG—tall, peaked T waves:
  - See Hyperkalemia topic for detailed management instructions, including the use of calcium gluconate, sodium bicarbonate, insulin/glucose, or albuterol.

### MEDICATION

- Furosemide 2 mg/kg PO/IV q6h:
  - Indicated in edematous hypertensive child with signs of fluid overload needing immediate fluid removal
  - Use lower dose if patient is hypotensive—0.5 mg/kg initially; may repeat q2h until reaching 2 mg/kg q6h
- Sodium bicarbonate 0.5–1 mEq/kg IV given over 30 min; repeat PRN:
  - May also calculate dose using  $0.6 \times \text{Body weight (Desired HCO}_3^- - \text{Current HCO}_3^-) / 2$ . Monitor for hypocalcemia.
  - Use to treat severe metabolic acidosis; pH <7.2 with inadequate respiratory compensation and acidosis causing hyperkalemia

- Hypocalcemia/hyperphosphatemia: Treat with calcium gluconate (10%) 0.5–1 mL/kg up to 10 mL
- Antihypertensives:
  - If increased vascular tone is causing HTN, administer antihypertensives (2).
  - If volume overload is causing HTN, administer furosemide.
  - Nifedipine 0.25–1 mg/kg/dose PO/sublingual, max single dose 10 mg
  - Labetalol 0.2–1 mg/kg IV q10min, max single dose 20 mg
  - Hydralazine 0.1–0.2 mg/kg IV q4h, max single dose 40 mg
  - Sodium nitroprusside 0.05–0.1  $\mu\text{g/kg/min}$  IV, max single dose 10  $\mu\text{g/kg/min}$

### SURGERY/OTHER PROCEDURES

Renal replacement therapy: When medical management fails to restore kidney function, use dialysis. Indications for initiating dialysis include:

- Serum urea nitrogen >150 mg/dL
- Serum creatinine >10 mg/dL
- Potassium >6.5 mEq/L (6.5 mmol/L), with T-wave elevation not corrected by medical means
- Severe metabolic acidosis with serum bicarbonate persistently <10 mEq/L and not relieved by bicarbonate therapy
- CHF and fluid overload

### DISPOSITION

#### Admission Criteria

- Any patient requiring dialysis
- AKI patients who are hemodynamically unstable
- Electrolyte imbalances such as life-threatening hyperkalemia
- Hypertensive emergency or urgency
- Multisystem organ failure
- Critical care admission criteria:
  - Unstable vital signs

#### Discharge Criteria

- Follow up with nephrologist.
- Electrolyte abnormalities corrected within acceptable limits
- Vital signs within acceptable limits

#### Issues for Referral

Refer to nephrologist.

### COMPLEMENTARY & ALTERNATIVE THERAPIES

Use of mannitol or low-dose dopamine is still controversial and clinically not recommended.

## FOLLOW-UP

### FOLLOW-UP RECOMMENDATIONS

Discharge instructions and medications:

- Take medications as prescribed, and follow up with a nephrologist.

### DIET

- Infants with AKI: Formula low in phosphorus
- Older children: Protein with high biologic value

### PROGNOSIS

Depends on need for dialysis, age of the patient, and underlying condition. Those of young age with multisystem organ failure have a worse prognosis.

### COMPLICATIONS

- Seizures secondary to uremia
- CHF secondary to HTN
- Hypertensive encephalopathy
- Hyperkalemia, dysrhythmia

2. Bunchman TE. Treatment of acute kidney injury in children: From conservative management to renal replacement therapy. *Nat Clin Pract Nephrol.* 2008;4(9):510–514.

## ADDITIONAL READING

Whyte DA, Fine RN. Acute renal failure in children. *Pediatr Rev.* 2008;29(9):299–307.

## CODES

### ICD9

- 584.5 Acute kidney failure with lesion of tubular necrosis
- 584.9 Acute kidney failure, unspecified

## PEARLS AND PITFALLS

- Hyperkalemia is the most common life-threatening complication of AKI.
- Diagnosing and treating severe hyperkalemia is critical. Assess serum potassium and ECG.
- If there are elevations of serum and/or urinary creatinine in healthy persons, exclude use of creatine supplements as factious cause.

# ACUTE RESPIRATORY FAILURE

Sean E. Button  
Raymond Pitetti

## BASICS

### DESCRIPTION

Inability of the respiratory system to maintain appropriate gas exchange to meet the metabolic demands of the body:

- Arterial oxygen tension falls below 60mm Hg (acute hypoxemia)
- CO<sub>2</sub> tension rises above 50mm Hg (acute hypercarbia)
- With history of chronic respiratory failure – an acute respiratory failure is diagnosed by an increase in PCO<sub>2</sub> of 20 mm Hg from baseline
- Arterial pH drops below 7.35

### EPIDEMIOLOGY

Inversely related to age: 2/3 of cases occur during infancy—1/2 of which are in neonatal period.

### RISK FACTORS

- Young age:
  - Size of airway: Smaller in younger children
  - Infants and young children have a large tongue that can fill the oropharynx
  - Respiratory center is immature in infants and younger children
  - Greater compliance of thoracic cage relative to older children/adults leads to a lower functional residual capacity
  - Marginal energy stores in infants—diaphragm fatigues easily.
- Prematurity
- Chronic lung disease (eg, CF, myopathy, asthma, RSV)
- Cardiac disease

### GENERAL PREVENTION

Use of corticosteroids prior to delivery in preterm patients

### PATHOPHYSIOLOGY

- Inability of respiratory system to provide sufficient oxygen to meet metabolic needs or to excrete enough CO<sub>2</sub> produced by body.
- 3 basic abnormalities account for most cases of acute respiratory failure:
  - V/Q mismatch: determines adequacy of gas exchange in the lung. V/Q ratio <1 throughout the lung results in hypoxemia
  - Intrapulmonary shunt
  - Hypoventilation

### ETIOLOGY

- Chronic conditions that can lead to acute failure:
  - Poorly controlled asthma
  - CF
  - Myopathy
  - Cardiac
  - Muscular dystrophy
  - Acute conditions
- Failure of central nervous system drive:
  - Drug intoxication (eg opioids, alcohol)
  - Head trauma
  - Intracranial hemorrhage
- Pulmonary embolism
- Inborn errors of metabolism
- Airway obstruction:
  - Croup
  - Epiglottitis
  - Anaphylaxis
  - Bronchoconstriction
  - Foreign body aspiration
  - Airway burn
  - Drowning
- Lung/Alveolar injury:
  - Septic shock/Systemic Inflammatory Response Syndrome
  - Pulmonary contusion
  - Airway burn
  - Drowning
- Pulmonary embolism
- Mechanical:
  - Flail chest
  - Pneumothorax/Hemothorax

### COMMONLY ASSOCIATED CONDITIONS

- Prematurity
- Lower respiratory infections:
  - Pneumonia
  - Bronchiolitis
- Asthma

## DIAGNOSIS

### HISTORY

- Pre-existing conditions
- Onset of symptoms
- Events surrounding onset of symptoms:
- Sudden or progressive onset of symptoms
- Systemic signs such as fever, cough, respiratory distress, stridor, apnea, color changes, weakness, paralysis, headache
- Pain

### PHYSICAL EXAM

- Assess vital signs with particular attention to respiratory rate, oxygen saturation, and temperature
  - Measurement of oral temperature is not advised, patients have difficulty keeping mouth closed for duration of time necessary to obtain sublingual temperature reading
- General appearance—appears well or sick, work of breathing, GCS.
- Vitals: Respiratory rate, blood pressure, pulse oximetry.
- HEENT: Grunting, nasal flaring, stridor, head bobbing.
- Cardiac: Murmur, muffled heart sounds, gallop
- Lungs: Aeration, symmetry, stridor, stertor, wheeze, rales, rhonchi, work of breathing and accessory muscle use,
- Skin: Skin temperature, color, perfusion of skin, capillary refill.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

- Blood gas:
  - Venous or capillary blood gas is less invasive, but is only useful if parameters are within normal or acceptable limits; useful for negative predictive value of respiratory failure
  - Arterial blood gas- optimal measurement but invasive and greater risk of injury
- Hemoglobin cooximetry:
  - Carboxyhemoglobin
  - Methemoglobin
- CBC and differential
- CRP
- Basic chemistry assay
- Ammonia: Inborn error of metabolism
- Blood culture
- Respiratory viral Panel
- Sputum culture

#### Imaging

- CXR: Pneumonia, pulmonary edema, pleural effusion, pneumothorax, rib fractures
- CT chest: Empyema, pulmonary embolism,
- Airway CT scanning, MRI and angiography can be used to differentiate deep-tissue structures, bony lesions and vascular abnormalities

#### Diagnostic Procedures/Other

- Bronchoalveolar lavage: Identify specific infectious pathogen
- Lung biopsy
- Bronchoscopy
- Thoracentesis
- Pneumogram

### DIFFERENTIAL DIAGNOSIS

Extensive—see Etiology.

## TREATMENT

### PRE HOSPITAL

- Assess and stabilize airway, breathing, and circulation
- Administer supplemental oxygen
- Consider nasal or oral airway
- Administer necessary medications as per local protocol (eg, Albuterol for wheezing, nebulized epinephrine for croup, parenteral epinephrine for anaphylaxis or severe asthma)

### INITIAL STABILIZATION/THERAPY

- Assess and stabilize airway, breathing, and circulation
- Treatment partly determined by underlying diagnosis
- Close ongoing monitoring is necessary:
  - Pulse oximetry and capnography
  - Respiratory status, including respiratory rate and work of breathing
  - Cardiovascular status, including perfusion, heart rate and capillary refill rate
  - Neurologic status
  - Serial blood gas analysis

### MEDICATION

#### First Line

- Depends on working diagnosis—see specific algorithm.
- Bronchoconstriction:
  - Albuterol, ipratropium, racemic epinephrine, terbutaline, corticosteroid, magnesium as appropriate for condition
  - Asthma
  - Reactive airway disease
  - Bronchiolitis
  - Allergic reaction
- Stridor:
  - Racemic epinephrine, corticosteroid, parenteral epinephrine, heliox as appropriate for condition
  - Croup
  - Epiglottitis
  - Allergic reaction
- Pneumonia
- Parenteral antibiotic

### COMPLEMENTARY & ALTERNATIVE THERAPIES

- BiPAP
- Nasal CPAP

### SURGERY/OTHER PROCEDURES

- Arterial catheter placement for frequent arterial blood sampling
- Nasal suction (deep, bulb)
- Needle thoracostomy
- Chest Tube
- Cricothyroidotomy

### DISPOSITION

#### Admission Criteria

- Critical care admission criteria
- All patients with acute respiratory failure should be admitted to the intensive care unit

### Discharge Criteria

- Resolution of underlying illness to acceptable degree
- Ability for independent respirations or adequate respiratory status with mechanically assisted respiration as outpatient (home oxygen, nasal CPAP/BiPAP)

### Issues for Referral

- Patients with acute respiratory failure should be referred to an institution capable of the continuous management, ongoing evaluation, and level of expertise that will be necessary to care for such patients.
- The underlying diagnosis may necessitate subspecialist consultation (eg, neurology, cardiology, pulmonology, and ENT)

## FOLLOW-UP

### FOLLOW-UP RECOMMENDATIONS

Discharge instructions and medications

- Vary according to condition.
- Certain conditions will require continued use of medication:
  - Bronchodilators, corticosteroids for asthma exacerbations
  - Oral antibiotic therapy for pneumonia

### PROGNOSIS

Dependent on diagnosis and/or response to treatment

### COMPLICATIONS

- Shock
- Long-term need for ventilatory support
- Permanent neurologic injury
- Death

## CODES

### ICD9

- 518.81 Acute respiratory failure
- 770.84 Respiratory failure of newborn

## PEARLS AND PITFALLS

- Pearls:
  - Prompt recognition of acute respiratory failure and appropriate intervention can prevent the progression to cardiopulmonary arrest.
  - Always anticipate a difficult airway prior to intubation
  - Use of venous or capillary blood gas is less invasive and if normal or acceptable values, arterial blood gas sampling may be avoided
- Pitfalls:
  - Failing to recognize impending respiratory failure.
  - Failure to aggressively manage acute respiratory failure with assisted ventilations.
  - Failure to provide continuous evaluation, and treatment.
  - Failure to recognize reversible causes of acute respiratory failure.

# ADRENAL INSUFFICIENCY

Kevin Ching

## BASICS

### DESCRIPTION

- Adrenal insufficiency is characterized by a deficiency in the production and availability of adrenocortical hormones:
  - In primary adrenal insufficiency, adrenal dysfunction impairs glucocorticoid and mineralocorticoid production.
  - In secondary adrenal insufficiency, deficient corticotropin-releasing hormone (CRH) from the hypothalamus or adrenocorticotropic hormone (ACTH) from the pituitary impairs adrenal glucocorticoid production (mineralocorticoid production is preserved).
- Acute adrenal insufficiency (adrenal crisis) is a life-threatening emergency involving hypotensive shock that ensues primarily from mineralocorticoid deficiency:
  - Rare in children
  - Nonspecific presentation often leads to delay in diagnosis and treatment.

### EPIDEMIOLOGY

#### Incidence

- Incidence of primary adrenal insufficiency is unknown:
  - Congenital adrenal hyperplasia (CAH), the most common form of primary adrenal insufficiency, occurs in 1 of 15,000 births (1).
- Although the incidence of secondary adrenal insufficiency is also unknown, iatrogenic suppression of the hypothalamic-pituitary axis from corticosteroid therapy is more common.

### PATHOPHYSIOLOGY

- Adrenal cortex:
  - Aldosterone—primarily mediated by renin-angiotensin system:
    - Also stimulated by hyperkalemia
    - Aldosterone deficiency leads to hyponatremia, hyperkalemia, and acidosis.
  - Cortisol and androgens—mediated by ACTH and CRH:
    - Cortisol, in turn, inhibits both CRH and ACTH.
    - Glucocorticoid (cortisol) deficiency can lead to hypoglycemia, hypotension, and shock.
    - Upregulation of ACTH increases melanocyte-stimulating hormone.
    - Androgen deficiency leads to diminished axillary and pubic hair.

- Adrenal medulla:
  - Epinephrine and norepinephrine—mediated by sympathetic stimulation

### ETIOLOGY

- Primary adrenal insufficiency (2):
  - CAH:
    - 21-hydroxylase deficiency: Neonates often present with salt-wasting CAH (hyponatremia, hyperkalemia, acidosis, and hypotension, with ambiguous genitalia in females), while prepubertal children present with virilizing CAH.
    - Several other forms of CAH exist, including salt wasting and non-salt wasting.
  - Infection:
    - Tuberculosis (TB), HIV, cryptococcosis, or fungal infections (histoplasmosis, blastomycosis, or coccidiomycosis)
  - Autoimmune disease (Addison):
    - Comorbid autoimmune polyglandular syndromes (type 1 diabetes, hypothyroidism, etc.)
  - Adrenal hemorrhage or infarction:
    - Waterhouse-Friderichsen syndrome (*Neisseria meningitidis*, *Streptococcus pneumoniae*, *Staphylococcus aureus*, *Pseudomonas aeruginosa*)
    - Anticoagulant use
    - Antiphospholipid syndrome
  - Septic shock:
    - Critically ill patients may develop a relative adrenal insufficiency (3).
  - Etomidate:
    - Sedation agent used in rapid sequence induction and procedural sedation
    - Reversible inhibition of cortisol production
    - Unclear clinical significance in critically injured trauma patients and critically ill patients with septic shock (4,5)
- Secondary adrenal insufficiency:
  - Suppression by exogenous corticosteroid therapy or endogenous steroid production (tumor)
  - Hypothalamic-pituitary disease:
    - Trauma
    - Pituitary surgery
    - Neoplasm (eg, craniopharyngioma)
    - Congenital aplasia

## DIAGNOSIS

### HISTORY

- Chronic adrenal insufficiency:
  - Fatigue and weakness
  - Anorexia
  - Weight loss
  - Nausea and vomiting
  - Recurrent abdominal pain
  - Skin pigmentation
- Acute adrenal insufficiency (adrenal crisis):
  - Neonates:
    - Lethargy
    - Vomiting and diarrhea
    - Weight loss
    - Seizures
  - Children:
    - Altered mental status
    - Syncope
    - Seizures
    - Weakness
    - Fever
    - Severe abdominal pain
    - Vomiting and diarrhea
    - Weight loss
    - Skin pigmentation

### PHYSICAL EXAM

- Chronic adrenal insufficiency:
  - Often subtle and nonspecific
- Acute adrenal insufficiency (adrenal crisis):
  - Fever
  - Tachycardia
  - Dehydration
  - Hypotension
  - Shock
  - Altered mental status
  - Coma

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

- Serum chemistries:
  - Hyponatremia, hyperkalemia, metabolic acidosis, and hypoglycemia
- Cortisol level:
  - Obtain early morning sample, if possible.
  - Under conditions of severe stress, levels <20  $\mu\text{g/dL}$  indicate adrenal insufficiency.
- Serum ACTH
- Plasma renin activity
- Serum aldosterone
- Thyroid studies
- CBC
- Blood cultures as indicated

**Imaging**

- Consider abdominal CT scan:
  - Identify adrenal hemorrhage, calcifications, and infiltrative and metastatic diseases.
- Consider chest radiograph:
  - Identify TB, fungal pneumonias

**Diagnostic Procedures/Other**

- ECG:
  - Hyperkalemia may manifest as peaked T waves, shortened QTc.
- ACTH stimulation test:
  - Obtain baseline serum cortisol and ACTH levels.
  - Administer 250  $\mu$ g IV cosyntropin (synthetic ACTH).
  - Check serum cortisol levels every 30 min.
  - Failure of cortisol to rise appropriately indicates insufficiency.

**DIFFERENTIAL DIAGNOSIS**

- CAH
- Infectious adrenalitis
- Autoimmune polyglandular syndrome
- Adrenal hemorrhage
- Hypopituitarism
- Sepsis
- Differential for abdominal pain (eg, acute appendicitis)

**TREATMENT****INITIAL STABILIZATION/THERAPY**

- Assess and stabilize airway, breathing, and circulation.
- Aggressive volume resuscitation:
  - Bolus of 20 cc/kg of isotonic crystalloid; may repeat as needed
- Dextrose:
  - 0.5–1 g/kg IV (2 mL/kg of 25% dextrose or 5 mL/kg of 10% dextrose) if hypoglycemic
- Identify precipitant, and consider empiric antibiotics.

**MEDICATION****First Line**

- Correct hyperkalemia:
  - Calcium:
    - Calcium gluconate 100 mg/kg/dose IV of 10% solution over 3–5 min
    - Calcium chloride 20 mg/kg/dose IV of 10% solution over 5 min (requires central venous access)
  - Insulin and glucose:
    - Insulin 0.1 units/kg IV over 30 min
    - Dextrose 0.5 g/kg IV over 30 min
  - Sodium bicarbonate:
    - 1–2 mEq/kg IV

- Administer glucocorticoid:
  - Hydrocortisone:
    - If acute adrenal insufficiency suspected, administer stress dose immediately.
    - Provides both glucocorticoid and mineralocorticoid activity
    - Infants/toddlers (<3 yr): 25 mg IV/IM
    - Children: 50 mg IV/IM
    - Adolescents (>12 yr): 100 mg IV/IM
    - Follow with 150 mg/day divided q6–8h
    - Maintenance dosing in consultation with an endocrinologist
  - Dexamethasone:
    - May be administered without interfering with ACTH stimulation test
    - Negligible mineralocorticoid activity
    - 0.03–0.15 mg/kg/day IV divided q6–12h

**Pregnancy Considerations**

Crosses placenta and suppresses fetal adrenal function:

- Consider fludrocortisone at 0.1–0.2 mg PO.
- Necessary if dexamethasone is given
- Mineralocorticoid dose is NOT weight based.

**Second Line**

Vasopressors for refractory hypotension:

- Dopamine 1–20  $\mu$ g/kg/min IV
- Epinephrine 0.1–1  $\mu$ g/kg/min IV
- Norepinephrine 0.1–1  $\mu$ g/kg/min IV

**DISPOSITION****Admission Criteria**

Critical care admission criteria:

- Necessary for all presentations of acute adrenal insufficiency (adrenal crisis)

**Issues for Referral**

Manage in consultation with an endocrinologist.

**FOLLOW-UP****FOLLOW-UP RECOMMENDATIONS****Patient Monitoring**

- Monitor and correct hypoglycemia and electrolyte abnormalities.
- Ensure appropriate fluid replacement therapy.
- Monitor and adjust glucocorticoid maintenance dosing.

**COMPLICATIONS**

- Hypoglycemia
- Hypotension
- Shock
- Sepsis

**See Also (Topic, Algorithm, Electronic Media Element)**

Congenital Adrenal Hyperplasia

**CODES****ICD9**

- 255.2 Adrenogenital disorders
- 255.41 Glucocorticoid deficiency

**PEARLS AND PITFALLS**

- Immediate therapeutic intervention is frequently necessary prior to diagnostic confirmation.
- Presentation may be similar in sepsis or disseminated intravascular coagulation.
- Consider in critically ill patients with pressor-dependent or refractory shock.
- As little as 2 wk of exogenous corticosteroid therapy can suppress the hypothalamic-pituitary axis.

# AGITATION

Marsha Aizen Elkhunovich  
Emily L. Willner

## BASICS

### DESCRIPTION

- Agitation is restlessness, increased tension, and/or irritability that can present with psychomotor disturbances ranging from twitching or pacing to violent behavior, with or without altered level of awareness.
- It may occur in patients with an intoxication, a psychiatric condition, as a result of an organic cause, or, in the case of developmentally delayed/minimally verbal children, as a manifestation of pain or distress.

### PATHOPHYSIOLOGY

- The unifying pathophysiology corresponds to the precipitating etiology.
- The current understanding is that psychomotor agitation results from dysregulation of the dopaminergic, noradrenergic, GABAergic, and serotonergic systems, the combination of which causes these symptoms (1). However, sometimes an agitated state can result from an inability to communicate, as in the example of a developmentally delayed child.

### ETIOLOGY

- Toxicologic:
  - Alcohol
  - Cocaine, methamphetamines
  - Hallucinogens such as PCP, Ecstasy (MDMA), jimson weed, etc.
  - Postanesthesia emergence
  - Akathisia or paradoxical reaction (eg, to metoclopramide, benzodiazepines, diphenhydramine)
  - Ingestion/Overdose (eg, to psychoactive drugs, amphetamine derivatives, NSAIDs, amantadine, and many others)
  - Medication side effects (eg, antipsychotics)
  - Withdrawal (eg, opiates)
- Medical:
  - Encephalitis: Viral, autoimmune, paraneoplastic, or antibody mediated, such as anti-NMDA receptor
  - Meningitis
  - Seizure (especially frontal or temporal lobe)
  - Atypical migraine: Confusional
  - Acute disseminated encephalomyelitis (ADEM)
  - Hypoglycemia
  - Hypoxemia or hypercarbia
  - Carbon monoxide poisoning
  - Hyperthyroidism
  - Encephalopathy: Hypertensive, hepatic, systemic lupus erythematosus (SLE)
  - Poststreptococcal: Sydenham chorea, pediatric autoimmune neuropsychiatric disorders associated with streptococcus (PANDAS)
  - Traumatic brain injury

- Psychiatric:
  - Manic episode in patient with bipolar disorder
  - Severe depression (particularly if actively suicidal)
  - Acute psychosis in patient with schizophrenia; delusional disorder; or antisocial, paranoid, or borderline personality disorder
  - Severe anxiety
  - Posttraumatic stress disorder
  - Autism
  - ADHD
  - Conduct disorder or reaction to an acute stressor
  - Night terrors (common in normal children)
- In a developmentally delayed or preverbal child, all of the above etiologies are possible, but consider other disturbances that the child might be unable to communicate:
  - Pain due to fracture, corneal abrasion, hair tourniquet, testicular torsion, renal stone, etc.
  - Infection due to pharyngitis, otitis media, appendicitis, meningitis, urinary tract infection, etc.
  - Child abuse
  - Change in the home/school environment

## DIAGNOSIS

### HISTORY

- Acute or chronic/recurrent (duration of symptoms)
- Underlying conditions (eg, developmental delay, autism, psychiatric condition, diabetes, SLE)
- Possible ingestions/exposures
- Current medications
- Recent illness:
  - Streptococcal infection might suggest Sydenham chorea or PANDAS.
  - Sinusitis might raise concern for intracranial extension/infection.
  - Viral symptoms might suggest ADEM or viral encephalitis/meningitis.
- Systemic symptoms: Fevers, vomiting, rash, arthritis, respiratory distress
- Neurologic symptoms: Gait changes, headache, weakness
- Family history
- Allergies

### PHYSICAL EXAM

- During the initial evaluation, make sure to assess if the patient is a threat to himself or others.
- Vital signs:
  - Tachypnea is likely to be present in an agitated state, but frank respiratory distress and/or hypoxemia suggest an underlying cardiac or respiratory etiology.
  - Tachycardia is common in agitated patients but may be seen with a toxidrome or a physical illness:
    - Tachyarrhythmias may cause agitation in a preverbal or developmentally delayed child.
  - Fever may indicate febrile delirium or an infectious or autoimmune cause.
  - HTN is common in agitated patients. However, it can also be caused by pain, toxic exposures/ingestions, or increased intracranial pressure (ICP).

- Neurologic exam (as complete as patient cooperation allows). Important elements include:
  - Pupil size and reactivity
  - Gross neurologic abnormalities
  - Nuchal rigidity
  - Cognitive function
- Look for signs of physical injury/trauma (especially to the head).
- If possible, perform ophthalmologic and fundoscopic exams to assess vision and check for increased ICP.
- Thorough cardiac, respiratory, abdominal, and skin exams to look for signs of systemic illness
- Psychiatric evaluation to assess for suicidal/homicidal ideation, psychosis, and level of awareness
- Agitated children with developmental delay need an especially detailed physical exam, including extremities (for fracture, hair tourniquet), HEENT (ear or dental infection), abdomen (infection, constipation), and genitalia (hernia, torsion). See Crying/Colic topic.

## DIAGNOSTIC TESTS & INTERPRETATION

### Lab

The extent of lab evaluation will depend on the clinical presentation. Consider any of the following lab tests initially, depending on the clinical presentation.

#### Initial Lab Tests

- Dextrose stick
- Blood alcohol level
- Basic metabolic panel to look for electrolyte derangements associated with poisoning or SIADH/cerebral salt wasting associated with various neurologic conditions
- LFTs and ammonia level if suspicious for hepatic encephalopathy
- Rapid strep test, anti streptolysin-O titers
- Thyroid function tests
- Testing of carbon monoxide level
- CBC and blood culture if meningitis is suspected
- Lumbar puncture if febrile or suspicious for encephalitis/meningitis:
  - Bacterial cultures, Lyme titers, and viral PCR/cultures for potential causes of viral meningoencephalitis
  - See Meningitis, Lyme Disease, and Encephalitis topics for details.
- If performing a lumbar puncture, consider consulting a neurologist regarding specific tests to be sent from the spinal fluid.

### Imaging

Imaging may be indicated based on clinical presentation:

- Consider urgent head CT if concerned about increased ICP or intracranial mass, hemorrhage, or injury.
- Consider ordering an MRI if a brain lesion or autoimmune process is suspected.
- Nonverbal/Delayed children may need additional imaging to evaluate for painful or infectious conditions.

### Diagnostic Procedures/Other

Consider co-oximetry if carbon monoxide poisoning is suspected.

## TREATMENT

### PRE HOSPITAL

Advise EMS personnel to:

- Try to reassure the patient with calm voices and decrease stimulation if at all possible.
- Decrease risk of harm to the patient and others. EMS protocols may include IM sedation with benzodiazepines.

### INITIAL STABILIZATION/THERAPY

- ABCs: Ensure that the patient is adequately protecting his or her airway, and stabilize breathing and circulation abnormalities.
- Ensure physical safety of patient, caregiver, and medical staff.
- Verbal reassurance and redirection should be used for all patients.
- Chemical restraints can and should be used to protect the patient and health care staff and allow for patient exam and treatment when verbal redirection is not adequate.

### MEDICATION

- Consider options for chemical restraint as needed.
- Benzodiazepines, alone or in combination with antipsychotics (2):
  - Midazolam PO dosing 0.25–0.5 mg/kg, max single dose 10 mg, IM/IV dosing 0.1 mg/kg, max single dose 6 mg
  - Lorazepam PO/IM/IV 0.05 mg/kg/dose, max single dose 2 mg
- Atypical antipsychotics: Preferred over classical antipsychotics due to more favorable side effect profile
  - Risperidone (Risperdal):
    - PO dosing: 0.25 mg/dose in children 6–14 yr; 0.5 mg > 14 yr
- Classical antipsychotics: Haloperidol IM/IV/PO:
  - IM dosing: 6–12 yr, 1–3 mg IM/IV; > 12 yr, 2–5 mg IM/IV
  - PO dosing: 0.25 mg/dose
  - Ziprasidone (Geodon) IM (4):
    - IM dosing: Children > 12 yr, 10–20 mg, dose may be repeated q2h (max daily dose 40 mg)
  - Olanzapine (Zyprexa) PO/IM (4):
    - PO dosing: 2.5–5 mg in children > 12 yr
    - IM dosing: Children > 12 yr, 5 mg; consider using 2.5 mg dose in children < 40 kg
  - Olanzapine and risperidone are available in oral disintegrating wafers that can be administered to minimally cooperative patients without the need for IM or IV access

### ALERT

- Use with caution when chemically restraining patients with developmental delay and no prior psychiatric diagnoses.
- These patients need a thorough medical evaluation even if agitation improves with chemical restraint.

## DISPOSITION

### Admission Criteria

- Significant vital sign abnormalities
- Respiratory distress
- Risk of harm to self/others
- Inability of caretaker to care for patient
- Impaired neurologic state
- Need for further diagnostic or therapeutic procedures
- Critical care admission criteria:
  - Need for ventilator support because of inability to control airway or need for significant sedation
  - Deteriorating neurologic status
  - Risk of cardiovascular depression or arrhythmia from an ingestion

### Issues for Referral

- If an ingestion is suspected, consultation with a toxicologist or the poison control center is crucial for identifying optimal treatment.
- Consultation with a neurologist is indicated in instances of abnormal neurologic exams and when ADEM or encephalitis are suspected.
- Consultation with social work services and/or psychiatry is indicated for patients with ingestion, overdose, a psychiatric condition, or homicidal or suicidal ideation for further investigation and potential need for placement in protective care.

### COMPLEMENTARY & ALTERNATIVE THERAPIES

- Physical restraints can be used if alternate measures are ineffective:
  - 4-point physical restraint is optimal.
  - Subdue the patient with 4–5 staff members, with one restraining each extremity and one securing the head.
  - It is essential to continually reassess the need for restraints and frequently monitor restrained patients, as there are risks for further harm with their use.
- Further therapy depends on the etiology of the agitated state.

### Pregnancy Considerations

- Haloperidol (Haldol) is potentially embryotoxic in high doses, so this drug should be avoided in pregnancy if possible.
- There is little literature on the safety of atypical antipsychotics in those who are pregnant/lactating, but no evidence of teratogenicity has been found.

## FOLLOW-UP

### FOLLOW-UP RECOMMENDATIONS

Follow-up recommendations depend on the etiology of the patient's agitated state. Most patients who present to the emergency department with agitation due to psychiatric or behavioral causes will require follow-up with psychiatric or behavioral services.

## CODES

### ICD9

307.9 Other and unspecified special symptoms or syndromes, not elsewhere classified

## PEARLS AND PITFALLS

- Agitated behavior can be caused by a large number of organic and psychiatric etiologies, and a detailed history and physical exam is essential to limit the considerations and to direct evaluation and treatment.
- A developmentally delayed child with agitation needs broad consideration of medical etiologies that may be causing distress prior to diagnosing a primarily behavioral or psychiatric condition.
- All patients with acute agitation should be under close supervision. Proper documentation and use of institution-specific protocol for restraints is mandated by the Joint Commission.

# ALTERED LEVEL OF CONSCIOUSNESS/COMA

Vincent J. Wang

## BASICS

### DESCRIPTION

- Altered level of consciousness (ALOC):
  - Depressed level of consciousness (LOC) rather than increased alertness
  - See Crying/Colic and Agitation topics for other changes in behavior.
- ALOC is a spectrum:
  - Confusion: Disoriented with delayed or impaired thinking or responses, but awake
  - Lethargy/Somnolence: Mild depressed LOC, but the patient remains easily arousable
  - Obtundation: Increasing depression of LOC, significant difficulty to arouse
  - Coma: Alteration in LOC with no purposeful movement or awareness; not arousable
- Objective measures to describe LOC:
  - Glasgow Coma Scale (GCS): 15-point scale quantifying eye opening, verbal, and motor responses:
    - Modifications for preverbal children
  - AVPU: Alert, responsive to Verbal stimuli, responsive to Painful stimuli, Unresponsive

### GENERAL PREVENTION

- Wearing helmets and protective gear in appropriate physical activity
- Secure storage of medications

### PATHOPHYSIOLOGY

Neurons in the ascending reticular activating system mediate the state of wakefulness in the brainstem and pons, connecting to the cerebral cortex, which mediates awareness:

- Disruption in the normal function of these areas leads to ALOC and coma (see below).

### ETIOLOGY

- Trauma:
  - Intracranial hemorrhage: Subarachnoid hemorrhage, epidural hemorrhage, subdural hemorrhage, cerebral contusion:
    - Hemorrhage may be worse with underlying bleeding disorders such as von Willebrand disease, hemophilia, etc.
  - Diffuse cerebral edema
  - Concussion
  - Anoxic brain injury
  - Diffuse axonal injury
- Toxicologic:
  - Any agent causing hypoglycemia, such as beta-blockers, oral hypoglycemic agents, isoniazid, ethanol, salicylates
  - Ethanol and other alcohols
  - Narcotics
  - Substances of abuse, such as opioids, hallucinogens, marijuana, heroin, LSD
  - Psychotropic medications
  - Sedatives (eg, diazepam, chloral hydrate)
  - Others (eg, clonidine, cyanide, gamma-hydroxybutyrate, organophosphates, iron)

- Infectious:
  - Meningitis: Bacterial, viral, fungal, parasitic, and mycobacterial
  - Encephalitis: Bacterial and viral
  - Intracranial abscess or empyema
  - Tickborne illnesses (eg, Rocky Mountain spotted fever)
  - Meningococemia, disseminated intravascular coagulation
- Vascular/Cardiac:
  - Bradyarrhythmias may result in inadequate heart rate, leading to hypotension or shock.
  - Tachyarrhythmias may result in ineffective cardiac contractions and resultant shock.
  - Myocardial infarction
  - Hypotension
  - HTN
  - Vasculitis: Henoch-Schönlein purpura, systemic lupus erythematosus
- Metabolic:
  - Hyperglycemia: Diabetic ketoacidosis (DKA)
  - Hypoglycemia: Sepsis, toxicologic ingestion
  - Metabolic acidosis/alkalosis
  - Dehydration
  - Electrolyte abnormalities: Sodium, potassium, calcium, magnesium, and phosphorous
  - Hyperammonemia: Urea cycle defects
  - Renal failure
  - Hepatic failure: Toxic, drug induced, Reye syndrome, infectious, obstructive, inborn errors of metabolism, etc.
  - Hypertthyroidism/Hypothyroidism
- Respiratory:
  - Hypoxemia
  - Hypercarbia
- Environmental:
  - Carbon monoxide poisoning
  - Hypothermia
  - Hyperthermia
  - Envenomations (eg, snakes, spiders)
- Neurologic:
  - Seizures:
    - Generalized or complex
    - Postictal period following seizures
    - Nonconvulsive status epilepticus
  - Vascular:
    - Cerebrovascular accident (CVA): Thrombotic, hemorrhagic, embolic
    - Arteriovascular malformation: Bleeding
    - Aneurysm: Rupture
    - Hemangiomas
- Neoplastic:
  - Tumor growth
  - Hemorrhage from tumor
  - Seizures secondary to tumor
  - Increased intracranial pressure
- Psychiatric
- Other:
  - Ventriculoperitoneal shunt (VPS) malfunction
  - Methemoglobinemia
  - Severe anemia
  - Intussusception: Lethargy can be the sole presenting sign, rather than crying
  - Vitamin B<sub>12</sub> deficiency

- Mnemonic to remember the broad differential listed above—**MOVESTUPID** (adapted from adult version):
  - **M**etabolic—inborn errors of metabolism, Reye syndrome, etc.
  - **O**xygen insufficiency—pulmonary, cardiac, anemia; also, hypercarbia
  - **V**ascular/Cardiac causes—hypertensive emergency, ischemic/hemorrhagic CVA, Vasculitis; VPS malfunction; Vitamin deficiency
  - **E**ndocrine—hypo- or hyperglycemia, DKA; Electrolyte abnormalities; Envenomations
  - **S**eizures—active, postictal, and nonconvulsive status epilepticus
  - **T**umor; **T**rauma; **T**emperature; **T**oxins
  - **U**remia—renal or hepatic dysfunction with hepatic encephalopathy
  - **P**sychiatric; **P**orphyrin
  - **I**nfection; **I**ntussusception
  - **D**rugs, including withdrawal
- Other mnemonics: **DPT OPV HIB MMR (1) or AEIOU TIPS**

## DIAGNOSIS

### HISTORY

- Obtain history of the patient's baseline activity.
- Trauma time and mechanism if applicable
- Toxicologic exposure if applicable:
  - Time and exposure
  - History of unsupervised periods of time
- Environmental exposure:
  - Temperature extremes
  - Exposure to carbon monoxide
- General symptoms:
  - Fever and other constitutional symptoms
  - Neck pain
  - Photophobia
  - Vomiting and/or abdominal pain
  - Incontinence of bowel or bladder
  - Dietary history
- Neurologic:
  - Headache
  - Lethargy
  - Changes in gait
  - Seizure activity
- Cardiac:
  - Chest pain
  - Palpitations
  - Syncope
- Dermatologic exam

### PHYSICAL EXAM

- Vital signs including pulse oximetry
- A thorough but rapid physical exam should be performed but may be tailored to the suspected cause.
- Maintain cervical spine precautions during the physical exam for suspected traumatic injuries.
- Assess for odors (eg, DKA and some exposures or ingestions)
- Neurologic assessment including:
  - GCS
  - Presence of meningismus (Kernig or Brudzinski signs, photophobia)
  - Neurologic exam
  - Limb movement (eg, focal or generalized shaking, flexion/extension of extremities)

- HEENT:
  - Presence of hemotympanum, Battle sign, periorbital hematoma, CSF rhinorrhea or otorrhea, retinal hemorrhages
- Eyes:
  - Miosis or mydriasis
  - Anisocoria suggests focal intracranial lesion.
  - Eye movements
  - Oculocephalic reflexes
  - Corneal reflex
  - Presence of nystagmus
- Cyanosis of the lips
- Scalp deformities, lacerations
- Facial swelling
- Papilledema
- Cardiac:
  - Bradycardia or tachycardia
- Respiratory:
  - Respiratory rate (hyper- or hypoventilation)
  - Breathing pattern
- Abdominal:
  - Abdominal tenderness
  - Hepatomegaly
  - Presence of blood in the stool
- Dermatologic:
  - Presence of bruising
  - Vesicular lesions
  - Cherry red, blue, or pale-colored lips

## DIAGNOSTIC TESTS & INTERPRETATION

### Lab

#### Initial Lab Tests

- Bedside capillary glucose
- Consider any of the following, selectively:
  - Serum electrolyte panel
  - BUN, creatinine, AST, ALT, ammonia level
  - Serum osmolality
  - Serum ethanol level
  - Serum aspirin level
  - Blood gas measurement
  - Urine toxicologic screening: Positive results indicate either recent usage or usage within days to weeks of testing.

### Imaging

- Abdominal radiographs may reveal:
  - Signs of intussusception
  - Radiopaque pills (eg, iron ingestion)
- Noncontrast CT brain may reveal:
  - Intracranial hemorrhage
  - Intracranial mass, sulcular effacement, herniation, cerebral edema, hydrocephalus
- US, abdomen:
  - Intussusception
- MRI may be necessary for infarction or thromboses as well as for improved imaging of the posterior fossa.

### Diagnostic Procedures/Other

- ECG as indicated
- EEG as indicated

## DIFFERENTIAL DIAGNOSIS

- Munchausen syndrome
- Autism or other neuropsychiatric disorders
- Death

## TREATMENT

- Treatments for the diverse etiologies of ALOC are beyond the scope of this topic.
- The following sections emphasize the initial treatment and management. The reader is encouraged to refer elsewhere for further details.

### PRE HOSPITAL

- Address ABCs per Pediatric Advanced Life Support (PALS) or Advanced Trauma Life Support (ATLS) protocols.
- Maintain cervical spine alignment for suspected traumatic injury.

### INITIAL STABILIZATION/THERAPY

- Rapid assessment of ABCs:
  - Control airway as indicated:
    - Rapid sequence endotracheal intubation with GCS <8, significant hypoxemia, inability to control airway
    - Normalize PCO<sub>2</sub>
    - Supplemental oxygen as needed
  - Maintain perfusion:
    - Establish vascular access.
    - Administer isotonic solutions to avoid hypotension and treat dehydration.
- Maintain cervical spine precautions.
- Once stabilized, a methodical approach to the evaluation and treatment of the likely diagnosis should ensue.

### MEDICATION

- Dextrose 0.25–1 g/kg IV for suspected or proven hypoglycemia
- Consider naloxone 0.1 mg/kg IV/IM (max single dose 2 mg) for suspected narcotic ingestion.
- Activated charcoal 1 g/kg PO/NG (max single dose 50 g) for suspected toxic ingestions except alcohols, iron

### SURGERY/OTHER PROCEDURES

- Emergent neurosurgical intervention may be required for intracranial lesions or hematomas.
- Hemodialysis may be required for some toxic ingestions.

### DISPOSITION

#### Admission Criteria

- Persistence of ALOC with stable airway and circulatory status
- Admission for ALOC without a clear etiology
- Critical care admission criteria:
  - Coma
  - Respiratory failure or significant distress
  - Hemodynamic compromise requiring ongoing resuscitation

#### Discharge Criteria

- Resolved or self-limited changes in LOC
- Elimination of cause of symptoms
- Appropriate follow-up

#### Issues for Referral

Depends on the underlying cause: Surgery, toxicology, neurosurgery, neurology, social work, or psychiatry

## FOLLOW-UP

### FOLLOW-UP RECOMMENDATIONS

Discharge instructions and medications:

- Avoid cause of symptoms.
- Follow up closely with the primary care provider.

### Patient Monitoring

- If discharged: Recurrence of symptoms
- If admitted:
  - Cardiorespiratory status
  - Recurrence or worsening of symptoms

### PROGNOSIS

Depends on the underlying cause

### COMPLICATIONS

Depends on the underlying cause

- Trauma, Head

### ICD9

- 780.01 Coma
- 780.09 Alteration of consciousness, other

## PEARLS AND PITFALLS

- Pearls:
  - Avoid use of atropine in rapid sequence induction since atropine causes pupillary dilation, eliminating the ability to assess pupillary reactivity on physical exam.
- Pitfalls:
  - Not recognizing that intracranial injury may occur in association with other causes of ALOC
  - Not suspecting child abuse: Numerous etiologies may be secondary.
  - Assuming that a toxicologic ingestion has not occurred if “tox screen” is negative:
    - Many ingestions require specific assays for detection.
  - Assuming that a toxicologic ingestion is the etiology for ALOC if “tox screen” is positive:
    - The screen typically is positive for up to a week after ingestion and may be unrelated to ALOC.

# ALTITUDE SICKNESS

David O. Kessler

## BASICS

### DESCRIPTION

- Altitude sickness comprises several different altitude-related illnesses, all of which are preventable:
  - Acute mountain sickness
  - High altitude cerebral edema
  - High altitude pulmonary edema
- Though these illnesses probably represent a spectrum of similar pathophysiology, this topic will mainly focus on acute mountain sickness.
- Altitude sickness increases with altitude and may be seen in unacclimated people who climb to as low as 8,000 feet (2,400 meters).

### EPIDEMIOLOGY

#### Incidence

The incidence and severity of altitude sickness varies with altitude and the rate of ascent (1):

- 28% of children climbing to 2,835 meters from 1,600 meters will experience symptoms of altitude sickness:
  - 21% experience symptoms traveling from sea level (2).
- Adult tourists traveling to 2,500 meters have similar rates of symptoms (20–25%).
- This increases to 40–50% of people climbing to 4,000 meters.
- If the ascent is made in hours as opposed to days, the incidence rises to 90% (1).

### RISK FACTORS

- Rate of ascent and altitude itself are the biggest risk factors for developing disease. Other factors that may contribute to one's risk include:
  - Poor hypoxemic ventilatory response
  - Genetic predisposition
  - Degree of exertion
  - Altitude where one sleeps
  - Use of sedatives
- Infants are more susceptible to hypoxemia for multiple reasons, including:
  - Increased rib cage compliance
  - Smaller airway diameter
  - Reduced alveoli
  - Persistent fetal hemoglobin
  - Paradoxical inhibition of respiratory drive

### GENERAL PREVENTION

- Use of supplemental oxygen by tourists ascending to altitude may prevent altitude sickness. This is particularly helpful during rapid ascent or a brief visit to a high altitude.
- Controlling the rate of ascent over a period of days will help prevent symptoms of altitude sickness.
- Children <2 yr of age should sleep below 2,000 meters.
- Children <10 yr of age should sleep below 3,000 meters.

### PATHOPHYSIOLOGY

- The symptoms of acute mountain sickness are thought to occur secondary to cerebral swelling secondary to impaired cerebral autoregulation and hypoxia-induced vasodilation (3).
- Vasogenic cerebral edema causes the symptoms of acute mountain sickness.

### ETIOLOGY

- Normally, an increase in altitude will cause increased ventilation in response to relative hypoxemia. This leads temporarily to an alkalosis, but eventually the body will equilibrate to the new environment.
- Rapid increases in altitude do not allow the acid base and volume status of the cerebral circulation to acclimatize slowly, which subsequently leads to vasogenic edema.

## DIAGNOSIS

### HISTORY

- Acute mountain sickness is a clinical diagnosis:
  - Headache
  - Poor sleep
  - Nausea
  - Vomiting
  - Anorexia
  - Dizziness
  - Fatigue
- In preverbal children, this may manifest as crying or fussiness.
- Symptoms usually begin within 6–12 hr of a rapid ascent but may occur up to 4 days later.

### PHYSICAL EXAM

No physical signs are diagnostic of acute mountain sickness:

- Peripheral edema may be present in some cases.
- Rales may be heard with acute mountain sickness or high altitude pulmonary edema.
- Neurologic signs such as ataxia, altered mental status, paralysis, and paresthesia may suggest a more serious cause such as high altitude cerebral edema.
- Retinal hemorrhages are extremely common, seen in 33% of climbers who do not live at high altitude:
  - These are usually asymptomatic and are an incidental finding.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

Labs are not usually required as part of the workup for altitude sickness.

### DIFFERENTIAL DIAGNOSIS

The symptoms of acute mountain sickness are nonspecific, and other illnesses may cause a similar cluster of symptoms, including:

- Acute gastritis
- Labyrinthitis
- Migraine headache
- Meningitis
- Encephalitis
- Intoxication
- Psychiatric illness
- Dehydration

## TREATMENT

### PRE HOSPITAL

IV hydration should be initiated, which protects against symptoms and works to combat altitude-related diuresis.

### INITIAL STABILIZATION/THERAPY

- Assess and stabilize airway, breathing, and circulation.
- The immediate treatment for those experiencing altitude sickness is to bring them down to a lower elevation.
- For high altitude pulmonary edema, assisted ventilation by endotracheal intubation and mechanical ventilation or noninvasive ventilatory support by BiPAP may be necessary:
  - Hyperventilation may lower intracranial pressure, but excessive hyperventilation may paradoxically decrease cerebral perfusion.

**MEDICATION**

- Oxygen is the primary treatment for altitude sickness. Supplemental oxygen often dramatically improves symptoms:
  - Oxygen, including hyperbaric oxygen, is particularly useful for acute mountain sickness, high altitude cerebral edema, and high altitude pulmonary edema.
- Nifedipine 0.25–0.5 mg/kg/day PO in children <40 kg, 10 mg PO per day in children >40 kg:
  - Improves overall symptoms; particularly useful in improving pulmonary function in high altitude pulmonary edema
- Acetazolamide has been used successfully in adults to help mitigate symptoms of acute mountain sickness:
  - Acetazolamide 5–10 mg/kg/day divided t.i.d., or 250 mg PO b.i.d. in adults, is typically started 1 day before ascent and is continued until acclimatization is achieved.
  - Acetazolamide is used only to prevent altitude sickness, whereas dexamethasone is used to treat once illness occurs.
  - Side effects include diuresis, paresthesia, headache, nausea, and vomiting.
- Dexamethasone:
  - Treatment of altitude sickness:
    - 0.5–1.5 mg/kg IV/IM/SC/PO to a max of 4–8 mg loading dose followed by 0.5 mg/kg to a max of 4 mg q6h. This is continued for 48–72 hr.
    - Should be initiated at 1st suspicion or symptoms of altitude sickness
  - Prevention of altitude sickness: Lower dosage and frequency:
    - 0.05 mg/kg/dose PO q4–12h. Lesser frequency of q12h may be used in children being passively taken to altitude who are sedentary, such as infants.
  - Useful for acute mountain sickness, high altitude pulmonary edema, and high altitude cerebral edema
  - Dexamethasone is typically tolerated much better than acetazolamide.
  - Dexamethasone is used in both the prevention and treatment of altitude sickness.
- Ibuprofen 10 mg/kg/dose PO q6h may prevent or treat headache associated with altitude sickness.

**COMPLEMENTARY & ALTERNATIVE THERAPIES**

Ginkgo biloba has been found to be more effective than placebo for reducing acute mountain sickness in small studies (3).

**DISPOSITION**

**Admission Criteria**

- Patients who have altered mental status or neurologic signs should be evaluated for more serious etiologies, such as high altitude cerebral edema, and admitted for further management.
- Critical care admission criteria:
  - Patients requiring mechanical ventilation
  - Patients with severe symptoms, including pulmonary edema, should be admitted to a critical care unit.

**Discharge Criteria**

Patients with acute mountain sickness who return to a lower elevation will often return to baseline spontaneously and may be safely discharged.

**FOLLOW-UP**

**FOLLOW-UP RECOMMENDATIONS**

Patients with acute mountain sickness are at risk for future events and should be counseled regarding prophylaxis and preventative measures.

**PROGNOSIS**

- Patients with acute mountain sickness typically improve completely without sequelae within several days.
- High altitude pulmonary edema and high altitude cerebral edema vary with severity, duration, and appropriate medical therapy.

**COMPLICATIONS**

In more serious altitude-related illnesses, high altitude cerebral or pulmonary edema or even death may occur:

- Patients with comorbid pulmonary or cardiac risk factors are at greater risk from hypoxemia-related complications.

**REFERENCES**

2. Samuels MP. The effects of flight and altitude. *Arch Dis Child.* 2004;89:448–455.
3. Barry PW, Pollard AJ. Altitude Illness. *BMJ.* 2003; 326(7395):915–919.

**ICD9**  
993.2 Other and unspecified effects of high altitude

**PEARLS AND PITFALLS**

- Altitude sickness can be prevented by a slow rate of ascent or by avoiding very high altitudes.
- Children are more susceptible to hypoxemia-related illnesses, such as acute mountain sickness.
- Oxygen is useful for all forms of altitude sickness.
- Though acetazolamide has been traditionally used, patients tolerate it less than dexamethasone.

# AMENORRHEA

William I. Krief  
Cara Bornstein

## BASICS

### DESCRIPTION

- Primary amenorrhea is defined as the absence of menses by the age of 14 yr in patients with no secondary sexual characteristics (ie, breast development) or by the age of 16 yr in patients with development of secondary sexual characteristics.
- Secondary amenorrhea is the absence of menses for 3 consecutive months with previously normal menstruation or absence of menses for at least 6 mo in females with previous oligomenorrhea.
- Amenorrhea is a normal state prior to puberty and during pregnancy and lactation:
  - The most common cause of secondary amenorrhea is pregnancy.

### EPIDEMIOLOGY

- <1% of adolescent girls have primary amenorrhea.
- The prevalence of secondary amenorrhea in the general population has been reported to be as high as 5%:
  - May be as high as 80% in competitive athletes

### RISK FACTORS

- Eating disorder
- Excessive exercising
- Psychosocial stress

### GENERAL PREVENTION

Maintaining an appropriate body mass index (BMI)

### PATHOPHYSIOLOGY

Any disruption of the complex interaction between the hypothalamic-pituitary-ovarian axis as well as outflow tract obstruction can cause amenorrhea.

### ETIOLOGY

- Primary amenorrhea:
  - Müllerian agenesis (agenesis of the uterus and upper 2/3 of vagina)
  - Imperforate hymen
  - Turner syndrome
  - Constitutional delay of growth or puberty
  - Kallmann syndrome (facial abnormalities, anosmia)
  - All etiologies of secondary amenorrhea

- Secondary amenorrhea:
  - Pregnancy
  - Functional: Weight loss, exercise, stress, chronic illness
  - CNS tumors: Craniopharyngioma, pituitary adenomas
  - Medications: Antipsychotics, oral contraceptive pills, antihypertensives, steroids, chemotherapy
  - Polycystic ovarian syndrome (PCOS)
  - Endocrinopathies: Thyroid disease, diabetes mellitus
  - Premature ovarian failure: Autoimmune, genetic
  - Female athlete triad (eating disorder, amenorrhea, osteoporosis)

### COMMONLY ASSOCIATED CONDITIONS

- Pregnancy
- Eating disorders
- Stress, depression
- PCOS
- Lactation
- Chronic diseases
- Medication use

## DIAGNOSIS

### HISTORY

- In cases of primary amenorrhea, a thorough history of childhood growth and development, including growth charts and age of sexual development, is imperative:
  - Family history, including age of mother and sister pubertal development
- Details about menstrual cycle, including last menstrual period (if applicable), flow, amount of days of flow, and cycle time.
- Sexual activity
- Any history of trauma or chronic illness
- Substance abuse
- Dietary history, exercise
- Psychosocial stressors
- Review of symptoms should include history of vasomotor symptoms, palpitations, dizziness fatigue, hearing loss, visual changes, breast changes, and headache.

### PHYSICAL EXAM

- Vital signs, including height and weight
- BMI
- Evaluation for dysmorphic features (webbed neck, short stature, low hairline)
- Ophthalmologic exam looking for papilledema, visual field defects, and cranial nerve palsy in cases of CNS tumors.
- Skin exam: Acne, acanthosis nigricans
- Tanner staging
- Breast findings: Underdeveloped, galactorrhea
- Pubic hair development, facial hair: Too much or too little
- Genital exam: Clitoromegaly, virilization, imperforate hymen (bulging of external vagina), vaginal agenesis, pelvic fullness (pregnancy or tumor), cervical mucus production
- Thyroid exam

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

- Pregnancy test
- No other lab tests are required emergently, but they can be performed to be followed by the primary care physician or subspecialist:
  - Thyroid-stimulating hormone, follicle-stimulating hormone (FSH), luteinizing hormone (LH), and prolactin are performed as part of the initial evaluation if the exam is suggestive of an ovarian-axis problem.
  - If hirsutism is present, androgen testing should be performed (testosterone, DHEAS, androstenedione, 17-OH progesterone)
  - If the exam suggests chronic disease: CBC, BUN, creatinine, LFTs, ESR

##### Imaging

- Neuroimaging (CT/MRI) to evaluate the CNS for tumors:
  - MRI is preferred to visualize the sella turcica.
- US to evaluate the ovaries and uterus

**Diagnostic Procedures/Other**

Probing the introitus with a moist cotton-tipped swab or soft catheter to verify patency of the hymen and vagina

**Pathological Findings**

Depends on underlying cause

**DIFFERENTIAL DIAGNOSIS**

- Hyperprolactinemia-altered metabolism, ectopic production, breast-feeding, hypothyroidism, medications, pituitary adenoma
- Hypergonadotropic hypogonadism (elevated LH and FSH): Gonadal dysgenesis (Turner syndrome), premature ovarian failure
- Hypogonadotropic hypogonadism (normal or low LH and FSH): Eating disorders, constitutional delays of growth or puberty, CNS tumor, chronic illness, severe depression, cranial radiation, excessive exercise, Kallmann syndrome, Sheehan syndrome
- Normogonadotropic: Congenital, hyperandrogenic anovulation (PCOS, Cushing disease), outflow tract obstruction (imperforate hymen, transverse vaginal septum)
- Pregnancy
- Thyroid disease

**TREATMENT**

Treatment should be directed toward the underlying cause of amenorrhea.

**MEDICATION**

Medical treatment should be initiated following diagnostic workup in the outpatient setting.

**SURGERY/OTHER PROCEDURES**

Excision of the hymen for imperforate hymen under sedation

**DISPOSITION****Admission Criteria**

- CNS tumors requiring acute management
- Symptomatic eating disorder:
  - Bradycardia, orthostatic BP, hypothermia, altered mental status, syncope, electrolyte imbalance

**Discharge Criteria**

All patients who do not meet admission criteria can safely be discharged with appropriate outpatient follow-up.

**Issues for Referral**

- Patients should be referred to an endocrinologist and/or gynecologist for further evaluation.
- Patients with an eating disorder require a multidisciplinary approach with adolescent medicine, a nutritionist, and a psychologist.
- Counseling is important in adolescents whose diagnosis will make them unable to conceive.

**FOLLOW-UP****FOLLOW-UP RECOMMENDATIONS**

- Discharge instructions and medications:
  - Refer for follow-up to a specialist.
- Activity:
  - Reducing activity if amenorrhea is secondary to excessive exercising

**DIET**

Increasing caloric intake in patients with an eating disorder and exercise-induced amenorrhea

**PROGNOSIS**

In most instances, amenorrhea is not life threatening and patients do well with medical management.

**COMPLICATIONS**

- Wrist and hip fractures when older due to poor bone mineralization
- Infertility

**ADDITIONAL READING**

- Emans SJ. Amenorrhea in the adolescent. In Emans SJ, Laufer MR, Goldstein DP, et al., eds. *Pediatric and Adolescent Gynecology*. 5th ed. Philadelphia, PA: Lippincott Williams & Wilkins; 2005.
- Master-Hunter T, Heiman D. Amenorrhea: Evaluation and treatment. *Am Fam Physician*. 2006;73(8):1374–1382.

**See Also (Topic, Algorithm, Electronic Media Element)**

Pregnancy

**ICD9**

626.0 Absence of menstruation

**PEARLS AND PITFALLS**

- If secondary sexual characteristics are present, amenorrhea is due to pregnancy until proven otherwise.
- Important to remember the psychological effects of impaired body image and self-esteem issues.

# ANAL FISSURE

Gregory Garra

## BASICS

### DESCRIPTION

An anal fissure is a linear tear or tears in the lining of lower half of the anal canal.

### PATHOPHYSIOLOGY

- The pathogenesis is poorly understood:
  - Typically, the anoderm is resistant to abrasions and lacerations.
  - Commonly associated with the passage of hard stool
- History of constipation is elicited in only 25% of cases. However, diarrhea is a predisposing factor in 4–7%.
- Associated pain may promote stool retention, thus increasing constipation and establishing a cycle of worsening pain or chronic fissure.
- Most occur in the posterior midline:
  - Rarely in the anterior midline

### ETIOLOGY

- Anal fissures are the result of mechanical disruption of the anal mucosa or skin external to the anus.
- This is almost exclusively the result of hard stools abrading or lacerating the epidermis.

### COMMONLY ASSOCIATED CONDITIONS

- Anal fissures can be seen in association with inflammatory bowel disease, immunosuppression, and HIV infection.
- Anal fissures can result from sexual abuse.

## DIAGNOSIS

### HISTORY

- Anal pain during or after defecation accompanied by the passage of blood-streaked stools or bright red blood per the rectum
- Pain is typically severe and may last minutes to hours.
- Infants may present with inconsolable crying.
- Children may volitionally withhold stool to prevent the pain associated with stool passage.

### PHYSICAL EXAM

- Linear or pear-shaped split in the lining of the anal canal
- >90% of anal fissures are identified in the posterior midline.
- Spasm of the anal sphincter may obscure visualization.
- An anoscope or other clear plastic tubing, such as a chest tube, may be used to assist in dilating the anus for improved visualization.

### DIAGNOSTIC TESTS & INTERPRETATION

- Anal fissure is a clinical diagnosis.
- If causes other than constipation or hard stool are a possibility, consider the following:
  - CBC
  - C-reactive protein
  - Stool culture, Gram stain, and ova/parasite evaluation
  - Hepatic enzyme testing, total protein, and albumin

## DIFFERENTIAL DIAGNOSIS

- Multiple fissure or nonmidline fissures can be the result of perianal abscess.
- Hemorrhoid
- Inflammatory bowel disease
- HIV
- Immunosuppression
- Anal trauma:
  - Child sexual abuse

## TREATMENT

### INITIAL STABILIZATION/THERAPY

Most anal fissures resolve spontaneously with dietary modification and stool softeners.

### MEDICATION

#### First Line

- The primary treatment of anal fissures consists of anal hygiene, warm water sitz baths to relieve anal sphincter spasm, and a stool softener.
- Long-term care and resolution may require use of a stool-softening agent or lubricant, such as polyethylene glycol (eg, Miralax) or mineral oil to keep the stool soft.

#### Second Line

Topical anesthetics may be used but are associated with delayed healing and skin sensitization.

### DISPOSITION

Patients with uncomplicated midline fissures not suggestive of an alternate condition should be discharged home with appropriate management advice.

**COMPLEMENTARY & ALTERNATIVE THERAPIES**

Other methods to soften or bulk stool to relieve constipation include:

- Increasing water intake
- Use of a high-fiber or high-bran diet
- Psyllium seeds

**Issues for Referral**

- Children suspected of sexual abuse should be referred to the child protective services.
- Children with suspected inflammatory bowel disease should be referred to gastroenterology for evaluation.

**FOLLOW-UP****FOLLOW-UP RECOMMENDATIONS**

Discharge instructions and medications:

- All patients should be referred to their primary care provider for follow-up evaluation if the condition does not resolve.

**DIET**

Increased fluids and high-fiber diet

**PROGNOSIS**

>90% heal spontaneously or with simple measures within 1–2 wk.

**COMPLICATIONS**

Chronic fissure

**ADDITIONAL READING**

- Ayantunde AA, Debrah SA. Current concepts in anal fissures. *World J Surg.* 2006;30:2246–2260.
- Jonas MJ, Scholefield JH. Anal fissure. *Gastroenterol Clin North Am.* 2001;30:167–181.

**See Also (Topic, Algorithm, Electronic Media Element)**

- Gastrointestinal Bleeding: Lower
- Inflammatory Bowel Disease
- Rectal Bleeding

**CODES****ICD9**

565.0 Anal fissure

**PEARLS AND PITFALLS**

- Anal fissures in children typically result from hard stools. Education about dietary and, if necessary, medicinal/therapeutic stool softening can prevent recurrence.
- Consider the possibility of sexual abuse or an alternate condition.
- Patients with multiple fissures, fissures not in the midline, or other tissue abnormalities in the perineal or anal area should be evaluated for more serious disease.

# ANAPHYLAXIS

Christopher G. Strother

## BASICS

### DESCRIPTION

- Anaphylaxis is a severe, potentially lethal, allergic reaction involving multiple systems that results from the sudden release of mast cell- and basophil-derived mediators (1).
- Classic “immunologic anaphylaxis” refers to IgE- or IgG-mediated reactions. Anaphylaxis can also be “nonimmunologic” or “anaphylactoid.”

### EPIDEMIOLOGY

#### Incidence

- The rate of occurrence in children is difficult to precisely define but appears to be increasing (2).
- Allergy-related conditions account for 0.2–1% of emergency visits.
- Anaphylaxis causes death in 0.65–2% of patients (3).

### RISK FACTORS

- Previous allergic reactions to food
- Atopic dermatitis
- History of respiratory diseases such as asthma, bronchiolitis, and croup

### GENERAL PREVENTION

- Avoidance of known allergens is essential but can be difficult, especially with food allergens.
- Allergen testing for patients with previous severe reactions can help patients avoid triggers.

### PATHOPHYSIOLOGY

- Immunologic anaphylaxis is an immunoglobulin-mediated severe allergic reaction.
- An allergen reacts with IgE or IgG, which stimulates B and T cells, which in turn signal mast cells, basophils, and eosinophils to degranulate.
- Mediators such as histamine, tryptase, histamine-releasing factor, and other cytokines are released.
- Mediators have either direct effects on the cardiovascular, GI, respiratory, or skin systems, creating symptoms or further promoting the release of mediators from other cells.
- Type I hypersensitivity reactions that are mild or moderate without developing fully to anaphylaxis are common.

### ETIOLOGY

- Most anaphylactic reactions in children occur as a result of food allergy.
- Other common triggers include:
  - Insect bites
  - Drugs
  - Exercise
  - Latex
  - Immunotherapy
  - Environmental allergens such as pollen

### COMMONLY ASSOCIATED CONDITIONS

Urticaria

## DIAGNOSIS

### HISTORY

- Anaphylaxis is a clinical diagnosis, but no single finding is always present.
- Always inquire about possible allergen exposures and history of previous reactions.
- Symptom progression and time from exposure are important historical details.
- Symptomatology can include the following:
  - Sense of impending doom
  - Hives
  - Generalized itching
  - Cough
  - Nasal congestion
  - Shortness of breath
  - Wheezing
  - Sore throat
  - Laryngitis
  - Nausea
  - Vomiting
  - Diarrhea
  - Eye itching
  - Eye tearing
  - Eye redness
  - Increased salivation
  - Diaphoresis
  - Seizures

### PHYSICAL EXAM

- Vital signs: Hypotension, tachycardia
- HEENT:
  - Stridor, dysphonia, aphonia, tearing, eye itching or redness, nasal congestion, salivation
- GI:
  - Vomiting, diarrhea
- Respiratory:
  - Stridor, cough, wheezing, dyspnea, hypotension
- Dermatologic:
  - Urticaria, pruritus, flushing, diaphoresis
- 10–20% of patients with anaphylaxis will not have skin findings.
- 1 criteria set created by experts for diagnosing anaphylaxis includes any one of the following (1):
  - 1. Acute onset of an illness (minutes to several hours) with involvement of the skin, mucosal tissue, or both (eg, hives, pruritus, or flushing) and at least one of the following:
    - Respiratory compromise (eg, dyspnea, bronchospasm, stridor, hypoxemia)
    - Reduced BP or associated symptoms of end-organ dysfunction (eg, hypotonia, syncope, incontinence)

- 2. Two or more of the following that occur rapidly after exposure to a likely allergen for that patient:
  - Involvement of the skin or mucosal tissue
  - Respiratory compromise
  - Reduced BP or associated symptoms
  - Persistent GI symptoms (eg, crampy abdominal pain, vomiting)
- 3. Reduced BP following exposure to a known allergen for that patient:
  - Infants and children: Low systolic BP (age specific) or >30% decrease from baseline systolic BP
  - Adults: Systolic BP <90 mm Hg or >30% decreases from baseline

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

- Lab testing and imaging is not generally helpful in diagnosis nor prognosis for acute anaphylactic reactions.
- Plasma histamine can be measured and peaks 5–15 min following a reaction but returns to normal within 60 min.
- Serum tryptase can be elevated in the first few hours and may aid an unclear diagnosis but is not helpful in most cases.
- Radioallergen sorbent (RAST) testing or other allergy tests are essential in patients after recovery in order to identify allergens and prevent future reactions.

#### Initial Lab Tests

- The diagnosis of anaphylaxis is clinical. Laboratory testing is generally not helpful in the emergency department for diagnosing anaphylaxis.
- Laboratory testing may help in the management of the complications of anaphylaxis. Such testing might include:
  - Arterial or venous blood gas
  - CBC
  - Basic metabolic panel

### DIFFERENTIAL DIAGNOSIS

- Allergic reaction that is a type I hypersensitivity but does not fully meet diagnostic criteria for anaphylaxis
- Vasovagal syncope, urticaria, angioedema, asthma, anxiety, and other forms of shock can all mimic aspects of anaphylaxis.
- Medications that cause flushing, such as vancomycin, can mimic skin findings.
- Overdose of medications such as anticholinergics can cause skin findings and cardiovascular changes.
- Food syndromes like scombroid that involve nonimmunoglobulin-mediated histamine release can appear very similar in clinical appearance though are usually not life threatening.
- Serum sickness (transfusion reactions) is another type of serious immune-mediated reaction (immune complex or type III reaction).

## TREATMENT

### PRE HOSPITAL

- Assess and stabilize airway, breathing, and circulation.
- Administer high-flow oxygen.
- Obtain IV access and administer IV fluid.
- Administer epinephrine, albuterol, and/or diphenhydramine as per local protocol.
- Cardiac and pulse oximetry monitoring

### INITIAL STABILIZATION/THERAPY

- Assess and stabilize airway, breathing, and circulation.
- Consider early intubation if loss of airway access from swelling is a possibility.
- Epinephrine is a key part of management.
- Volume resuscitation with crystalloids or colloids

### MEDICATION

#### First Line

- Epinephrine is the mainstay of treatment:
  - 0.01 mg/kg up to 0.5 mg IM/SC q3–5min:
    - Epinephrine IM has the therapeutic advantage of SC, and is the preferred route.
  - May give as an infusion (0.1  $\mu$ g/kg/min up to 1  $\mu$ g/kg/min) if needed for persistent hypotension or severe respiratory symptoms:
    - IV use is recommended only when absolutely necessary to maintain BP. Adverse events such as stroke and MI resulting from IV administration are well reported.
- Albuterol for wheezing: Adjunct to epinephrine for relief of bronchospasm (2.5–5 mg by nebulizer)
- IV fluids for hypotension: 20 mL/kg normal saline per bolus

#### Second Line

- Steroids:
  - Not helpful in acute management but do help to prevent progression of symptoms as well as rebound or biphasic symptoms
  - Methylprednisolone 1–2 mg/kg q6h, max single dose 125 mg IV
  - Dexamethasone 0.3 mg/kg IV/IM q12h, max single dose 10 mg IV/IM q12h
  - Prednisone 1 mg/kg/dose PO q12h, max single dose 30 mg PO q12h
- Diphenhydramine:
  - Relieves itching and flushing but does NOT improve cardiovascular or respiratory effects of anaphylaxis and should not take priority over epinephrine
  - 1–2 mg/kg/dose IV/IM/PO q6h, max single dose 50 mg IV/IM/PO q6h
- H2 blockers:
  - Can be used as supplement to diphenhydramine
  - Ranitidine 1 mg/kg/dose q6h, max single dose 50 mg IV q6h
  - Famotidine 1 mg/kg/dose q12h, max single dose 40 mg IV q12h
- Vasopressors: Can be used for persistent hypotension despite epinephrine and fluids. Dopamine, norepinephrine, or phenylephrine can be used.

### DISPOSITION

#### Admission Criteria

- Intubated patients
- Patients in respiratory distress
- Significant generalized reactions and/or persistence of symptoms
- Persistent abnormal vital signs
- Critical care admission criteria:
  - Intubated patients
  - Persistent hypotension or respiratory distress despite adequate therapy requires continuous monitoring.

#### Discharge Criteria

- Patients with complete resolution of symptoms may be discharged following a period of observation in the emergency department (generally 4–8 hr)
- Patients who receive epinephrine should be observed 4–8 hr for biphasic reactions, which usually occur within 8 hr but can occur as late as 72 hr.

#### Issues for Referral

- Patients without previous evaluation by an allergist should be referred as soon as possible for skin testing.
- Consultation with an allergist or immunologist can be considered for desensitization therapy.

## FOLLOW-UP

### FOLLOW-UP RECOMMENDATIONS

- Discharge instructions and medications:
  - Typically, patients are discharged with prescribed corticosteroid burst dose, diphenhydramine, and an EpiPen.
  - Follow-up allergy testing should be arranged.
  - Consider steroids for up to 72 hr to prevent biphasic reactions.
  - Consider symptomatic treatment with diphenhydramine with or without an H2 blocker for up to 72 hr.
- Activity:
  - As tolerated
  - Avoid activities that might bring a patient into contact with potential triggers (ie, bees and bee stings)

#### Patient Monitoring

Cardiovascular monitoring is essential in anyone with respiratory distress or abnormal vital signs.

#### DIET

- Patients should be kept NPO during observation.
- Avoid foods allergens.

#### PROGNOSIS

- Prognosis is generally good if anaphylaxis is recognized and treated early.
- Development of shock is a poor prognostic indicator.
- Delay in the administration of epinephrine has been associated with poor outcomes.

### COMPLICATIONS

- Respiratory failure
- Shock
- Multisystem organ failure
- Disseminated intravascular coagulation

Rash, Urticaria

### CODES

#### ICD9

- 989.5 Toxic effect of venom
- 995.0 Other anaphylactic shock, not elsewhere classified
- 995.60 Anaphylactic shock due to unspecified food

### PEARLS AND PITFALLS

- IM-administered epinephrine is the mainstay and drug of choice for treating anaphylaxis.
- Up to 20% of patients will not have skin findings.
- Diphenhydramine will not treat the cardiovascular effects of anaphylaxis.
- Failing to recognize the possibility of a biphasic reaction and discharging too soon after stabilization can be dangerous (most biphasic reactions occur within 8 hr).

# ANEMIA

Eyal Ben-Isaac  
Vincent J. Wang

## BASICS

### DESCRIPTION

- Anemia is defined by an abnormally low hemoglobin (Hgb), hematocrit (Hct), or number of RBCs per  $\text{mm}^3$ .
- A significant drop in Hgb may be important even if the current value is normal.
- Black children have Hgb levels  $\sim 0.3$  g/dL lower than those of white or Asian children of comparable age and socioeconomic status.
- Normal (and lower limit) Hgb values by age:
  - Cord blood, 16.8 (13.7) g/dL
  - 2 wk, 16.5 (13.0) g/dL
  - 3 mo, 12.0 (9.5) g/dL
  - 6 mo to 6 yr, 12.0 (10.5) g/dL
  - 7–12 yr, 13.0 (11.0) g/dL
  - Adult female, 14.0 (12.0) g/dL
  - Adult male, 16.0 (14.0) g/dL
- This topic focuses on nontraumatic anemia.

### EPIDEMIOLOGY

#### Incidence

Iron deficiency:  $\sim 1$  in 24, or 11.2 million per year in the U.S.

#### Prevalence

- Up to 20% of American children and 80% of children in developing countries become anemic at some point during their childhood.
- Iron deficiency is the most common etiology of anemia: Toddlers 7%, adolescent and adult women 9–16%.

### RISK FACTORS

- Nutritional deficiencies:
  - Iron deficiency (eg, excessive milk intake)
  - Vitamin B<sub>12</sub> (eg, exclusively breast-fed by vegetarian mother)
  - Folic acid (eg, impaired absorption)
- Age:
  - Congenital or early onset (eg, Diamond-Blackfan, enzyme deficiencies)
  - Late infancy (eg, hemoglobinopathies)
  - Late infancy/Toddlers (eg, iron deficiency, lead poisoning)
- Sex:
  - Males more likely to have G6PD deficiency
  - Immune hemolytic anemias are more common in adolescent females.
- Ethnicity:
  - Thalassemias: Much of Africa, the Middle East, the Indian subcontinent, Southeast Asia, areas bordering the Mediterranean Sea
  - Hemoglobinopathies:
    - Hgb S syndromes in Central African origin
    - Hgb E syndromes in Southeast Asia
  - G6PD deficiency in Mediterranean or Southeast Asian origin

### GENERAL PREVENTION

- Appropriate nutrition and iron intake
- Screening hemoglobin at well-child visits
- Possible supplementation with iron and vitamins if at risk

### PATHOPHYSIOLOGY

- Physiologic anemia:
  - Relative polycythemia in utero stimulates erythropoietin; PaO<sub>2</sub> rise after birth leads to decreased erythropoiesis.
  - Neonates have an increased rate of destruction of RBCs and a shortened RBC life span.
  - Hgb and Hct values decrease during the 1st 6–8 wk of life; may be low until 3 mo.
  - In premature infants, the decline in Hgb is more extreme and more rapid.
- Iron deficiency: Insufficient iron leads to depleted RBC mass, decreased Hgb.
- Vitamin B<sub>12</sub> and folate deficiencies lead to inhibited cell growth.
- Lead interferes with heme synthesis.
- Reticulocytes:
  - Elevated in response to acute blood loss, hemolysis, or with initial iron replacement
  - Calculate the reticulocyte index (RI; or corrected reticulocyte count) as follows:  $\text{RI} = \text{reticulocyte} \times (\text{patient Hct} \div \text{normal Hct})$ .
  - RI should typically be between 1.0 and 2.0.
  - RI  $< 2$  with anemia indicates decreased production of reticulocytes and therefore RBCs:
    - May indicate bone marrow's inability to produce new blood cells

### ETIOLOGY

- Blood loss:
  - Trauma
  - GI losses (ulcer, Meckel diverticulum, polyp, hemangioma, inflammatory bowel disease)
  - Menorrhagia/Dysfunctional uterine bleeding
- Increased RBC destruction
- Decreased RBC production
- Nutritional deficiencies:
  - Iron, vitamin B<sub>12</sub>, folate
  - Chronic illnesses involving deficiencies of vitamin B<sub>6</sub>, copper
  - Malabsorptive conditions
- Congenital:
  - Inherited bone marrow failure disorders (eg, Diamond-Blackfan, Fanconi anemia)
  - Hemolytic processes
  - Infections (eg, cytomegalovirus, toxoplasmosis, syphilis, rubella, herpes, group B streptococcus, parvovirus)
- RBC defects: Membrane, enzymes, and hemoglobinopathies (eg, sickle cell disease [SCD])
- Anemia in the immediate newborn period: Consider hemorrhagic and isoimmune causes, congenital infections, sepsis, and congenital disorders of the RBC.

- Diagnosis based on mean corpuscular volume (MCV):
  - Microcytic:
    - Iron deficiency
    - Thalassemias
    - Sideroblastic (eg, lead poisoning)
    - Acute and chronic inflammation (can be normocytic)
  - Normocytic with low reticulocyte count:
    - Pancytopenias
    - Bacterial or viral suppression
    - Pure RBC aplasia: Diamond-Blackfan, transient erythroblastopenia of childhood (TEC)
  - Normocytic with normal or high reticulocyte count:
    - Antibody mediated (Coombs positive): Isoimmune (ABO/Rh incompatibility) or autoimmune etiologies such as infections (eg, mycoplasma, Epstein-Barr virus, HIV), lymphomas, disorders of immune regulation (eg, systemic lupus erythematosus), drugs (eg, methyldopa or other drugs such as antihistamines, sulfonamides, insulin, penicillin, etc., that can cause immune hemolysis that is not autoimmune)
    - Hemorrhagic disorder (blood loss)
    - Microangiopathic hemolytic anemia (eg, artificial heart valves, hemolytic uremic syndrome [HUS; see Hemolytic Uremic Syndrome topic], disseminated intravascular coagulation [DIC], Kasabach-Merritt syndrome)
    - Membrane defects (eg, spherocytosis, elliptocytosis, paroxysmal nocturnal hemoglobinuria)
    - Hemoglobinopathies
    - Enzyme defects (eg, G6PD deficiency, pyruvate kinase deficiency)
  - Macrocytic:
    - Megaloblastic: Folate deficiency, vitamin B<sub>12</sub> deficiency, hereditary orotic aciduria
    - Nonmegaloblastic: Liver disease, hypothyroidism, myelodysplasia, preleukemia, Diamond-Blackfan, Fanconi anemia

## DIAGNOSIS

### HISTORY

- Symptoms: Pallor, fatigue, exercise intolerance
- Sudden onset may represent an acute event.
- Syncope or palpitations
- Bone pain (eg, SCD, infiltrative disorders)
- Blood loss (eg, trauma, menstrual history, hematochezia, melena)
- Ethnic origin
- Diet: Initiation and current intake of milk
- Jaundice: Timing, recurrence
- Exposures:
  - Toxins: Insecticides, benzene, nitrogen mustards
  - Medications:
    - Immune mediated (eg, penicillin, quinidine, methyldopa)
    - Aplastic crises due to chemotherapeutic agents, chloramphenicol, sulfonamides, anticonvulsants, cimetidine, and others

- Lead (old paint, pica, foreign medications/foods/pottery)
- G6PD deficiency: May be precipitated by antimalarials, sulfonamides, nitrofurantoin, naphthalene (moth balls), fava beans
- Family history of anemia, splenectomy, gallstones

### PHYSICAL EXAM

- Vital signs (including orthostatics): Tachycardia, hypotension, tachypnea
- Pallor, heart murmur, hepatosplenomegaly
- Lymphadenopathy: Neoplastic process
- Glossitis: B<sub>12</sub> deficiency
- Dactylitis: SCD
- Purpura: Infections, DIC
- Petechiae: HUS, DIC, pancytopenia
- Signs of extramedullary hematopoiesis (eg, frontal bossing)
- Syndromic features: Limb anomalies in Fanconi, Diamond-Blackfan

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

- CBC with differential and smear:
  - Mentzer index (MCV/RBC) may suggest iron deficiency (ratio > 13) vs. thalassemia (< 13).
  - Clues on the smear:
    - Acanthocytes: Vitamin E deficiency, liver disease
    - Bizarre shapes: RBC membrane defects, thalassemia syndromes
    - Blister or bite cells: G6PD deficiency
    - Helmet cells (fragmented cells): Microangiopathic anemia
    - Rouleaux: Inflammation or immune hemolytic anemia
    - Stomatocytes: Liver disease, stomatocytosis
    - Target cells: Iron deficiency, hemoglobinopathy, liver disease
    - Tear drop cells: Bone marrow failure, burns
    - Basophilic stippling: Lead toxicity, thalassemia
- Reticulocyte count
- Consider type and cross-matching blood
- Consider heme testing the stool
- Other tests depending on initial labs and possible etiologies:
  - Coombs/Direct antibody test
  - Iron studies (iron, ferritin, total iron-binding capacity, % saturation)
  - Hemoglobin electrophoresis
  - DIC panel
  - Tumor lysis labs

#### Diagnostic Procedures/Other

Bone marrow aspirate or biopsy may be indicated to evaluate for an infiltrative process and/or marrow arrest:

- Persistent severe normocytic anemia (evaluate for TEC, Diamond-Blackfan)
- Macrocytic anemia without obvious etiology (evaluate for myeloproliferative syndromes, Diamond-Blackfan)
- Blasts on smear (evaluate for leukemia)
- Pancytopenias

### DIFFERENTIAL DIAGNOSIS

See Etiology section.

## TREATMENT

### PRE HOSPITAL

- Assess and stabilize airway, breathing, and circulation.
- Assessment for trauma:
  - IV fluid resuscitation if tachycardic or hypotensive
  - Supplemental oxygen usually appropriate

### INITIAL STABILIZATION/THERAPY

- Assess and stabilize airway, breathing, and circulation.
- Exclude traumatic etiologies.
- Evaluate nature of anemia, estimate of blood loss, and presence of other illnesses.
- Supplemental oxygen usually is appropriate.
- Transfusion criteria: Severe hypoxemia, significant ongoing losses, significant tachycardia, and/or hypotension:
  - 10 cc/kg packed RBCs over 3–4 hr (faster if active hemorrhage)
  - 1 cc/kg per Hgb level over 3–4 hr if severely anemic or any signs/suspicion of CHF on history or exam
  - Use caution if suspecting a hemolytic process.
  - Discuss with the hematologist first if suspecting an oncologic process.
- See Aplastic Anemia topic for aplastic crises and Sickle Cell Disease and Acute Hemolytic Anemia topics for specifics on these diseases.

### MEDICATION

- Oral iron supplementation for deficiency:
  - Prophylaxis: 1–2 mg of elemental iron/kg/day
  - Mild to moderate anemia: 3 mg of elemental iron/kg/day
  - Severe anemia: 4–6 mg of elemental iron/kg/day. Parenteral iron may be indicated for specific etiologies: Iron deficiency with inflammatory bowel disease and dialysis and oncology patients. Consultation with the hematologist is recommended before such administration.
- Autoimmune causes: See specific topics.

### DISPOSITION

#### Admission Criteria

- Admit for anemia requiring inpatient evaluation or for severe symptomatic anemia.
- Critical care admission criteria:
  - Unstable vital signs despite resuscitation
  - Ongoing blood loss with unstable vital signs

#### Discharge Criteria

- Stable vital signs
- Asymptomatic
- Able to tolerate oral therapy if needed
- Close follow-up is assured

#### Issues for Referral

Hematology referral for:

- Aplastic anemia and disorders of RBCs, including autoimmune hemolytic anemia, heredity spherocytosis, hemoglobinopathies, thalassemia, and G6PD deficiency
- CBC suggestive of leukocyte disorders and/or thrombocytopenia
- Evidence of bone marrow failure

## FOLLOW-UP

### FOLLOW-UP RECOMMENDATIONS

Discharge instructions and medications:

- Return for increased pallor, fatigue, or blood loss
- Iron supplementation (see Medication)
- Timing of follow-up CBC depending on etiology and severity

### DIET

Iron deficiency: Increase dietary iron such as red meat, beans, green leafy vegetables, blackstrap molasses, enriched breakfast cereals, and some sea foods.

### PROGNOSIS

- The prognosis generally is good but overall depends on underlying cause and severity.
- Iron-deficiency anemia resolves with treatment.

### COMPLICATIONS

Chronic anemia can lead to cardiac problems (arrhythmia, high output failure) and poor growth.

### ADDITIONAL READING

### CODES

#### ICD9

- 280.9 Iron deficiency anemia, unspecified
- 283.0 Autoimmune hemolytic anemias
- 285.9 Anemia, unspecified

### PEARLS AND PITFALLS

- In the immediate newborn period, consider hemorrhagic and isoimmune causes, congenital infections, sepsis, and disorders of RBCs.
- Iron deficiency is the most common childhood anemia.
- CBC and smear typically allow definitive diagnosis of the etiology of anemia.

# ANGIOEDEMA

Rahul Kaila

Nirupama Kannikeswaran

## BASICS

### DESCRIPTION

- Angioedema is self-limited localized swelling resulting from extravasation of fluid into interstitial tissues.
- Nonpitting edema involves the deeper layers of the dermis and subcutaneous tissues.
- Most commonly involves head, neck, hand and GI tract:
  - Involvement of the larynx is life threatening.
- As compared to other forms of edema, which are symmetric, angioedema is:
  - Asymmetric
  - Has a rapid onset
  - Occurs in nondependent areas

### EPIDEMIOLOGY

- 2nd most common allergic disease leading to hospitalization, next only to asthma
- The exact incidence is unknown.
- Prevalence is higher in children with atopic dermatitis.
- Hereditary angioedema (C1 esterase inhibitor deficiency) occurs 1 in 50,000 (1).

### RISK FACTORS

Angioedema occurs with higher frequency in children with history of food allergy, allergic rhinitis, asthma, or atopic dermatitis.

### GENERAL PREVENTION

Avoidance of trigger agents

### PATHOPHYSIOLOGY

- Mast cell activation following contact with IgE cross-linking antigen leads to release of histamine, which in turn increases the vascular permeability, and leakage of fluid into the skin:
  - IgE cross-linking with the mast cell also releases prostaglandin D2 and leukotrienes, activates the complement system, and releases several other vasodilators.
- Non-IgE: Kinin-mediated pathway:
  - Kallikrein enzyme converts kininogen to bradykinin, a potent vasodilator, which increases vascular permeability and causes edema.
  - Andioedema caused by the use of angiotensin-converting enzyme (ACE) inhibitors is a typical example using this mechanism (2).
- Mast cell angioedema (IgE mediated):
  - 90% associated with urticaria
  - In kinin pathway activation (non-IgE mediated), urticaria usually is absent (1).
- Direct, nonimmunologic mechanisms include radio contrast dyes, physical stimuli like thermal and mechanical, medications like vancomycin and opioids, and foods like strawberries and shellfish.

### ETIOLOGY

- Idiopathic: Most common
- Food induced: Eggs, peanuts, cow's milk, shellfish
- Medication induced:
  - Trimethoprim/sulfamethoxazole, other sulfa derivatives, penicillins, cephalosporins, and NSAIDs
- Insects causing angioedema: Fire ants, venomous insects
- Latex allergy: Especially in children with myelomeningocele and in children with multiple surgical procedures
- Physically induced: Heat, cold, vibration, ultraviolet radiation, and pressure
- Infection induced:
  - Viral most common: Herpes simplex virus, coxsackievirus, Epstein-Barr virus, and viral upper respiratory tract infection can cause angioedema and urticaria.
  - Bacterial infections such as otitis media, sinusitis, and tonsillitis and urinary tract infection are associated with angioedema.
- Hereditary angioedema: C1 esterase inhibitor deficiency is a rare autosomal dominant condition, which occurs result of kinin pathway activation:
  - Type 1 occurs in 85% of patients with C1 esterase inhibitor deficiency.
  - Type 2 occurs in 15% (3).
- Acquired angioedema:
  - Increased destruction or metabolism of C1 esterase inhibitor
  - Clinically apparent after 40–50 yr of age
  - Associated with rheumatologic conditions and lymphomas
  - Resembles hereditary angioedema but distinguished by low C1q levels

## DIAGNOSIS

### HISTORY

- Focus on agents likely to cause angioedema (eg, foods such as shellfish, peanuts, wheat, eggs):
  - If history of new food/exposure time, note when the consumption or contact occurred.
- All medications including over-the-counter medications
- Family history of angioedema, autoimmune problems
- Swelling:
  - Onset
  - Location
  - Associated symptoms:
    - Pruritus
    - Dyspnea
    - Dysphagia
    - Vomiting
    - Diarrhea
    - Nausea
  - Edema of the GI tract can present with acute abdominal pain, nausea, and vomiting without cutaneous features.

### PHYSICAL EXAM

- Nonpitting edema of the face, lip, hands, feet, GI tract, or any part of the skin:
  - Nonpitting edema has ill-defined margins.
  - Edema of the GI tract can present with acute abdominal pain, nausea, and vomiting without cutaneous features.
- Associated urticaria and flushing may be seen.
- Skin may be warm and tender.
- Angioedema of the throat can cause airway obstruction.
- Hereditary angioedema—3 common forms:
  - Subcutaneous edema:
    - Nonerythematous, nonpruritic, and circumscribed
    - Not associated with urticaria
  - Abdominal edema:
    - Attack can mimic a surgical abdomen.
    - Present with vomiting, diarrhea, ileus, and diffuse abdominal pain
    - It can be the 1st and only presenting sign (4)
  - Laryngeal edema:
    - Life-threatening presentation
    - Present with stridor, dyspnea, hoarseness, and dysphagia

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

- No lab test is recommended routinely, and no test is diagnostic.
- Avoid challenging a patient with a specific food or drug to confirm suspected allergy.
- Elevated tryptase level: Marker of mast cell degranulation can be elevated for few hours after the reaction, but normal values do not exclude angioedema.
- Patients with chronic, recurrent, unexplained episodes of angioedema should undergo evaluation to rule out connective tissue disorders as well as autoimmune and thyroid problems.
- It is not necessary to perform this in the emergency department setting:
  - Workup should include CBC, ESR, antinuclear antibody, thyroid function testing, and antithyroglobulin and antimicrosomal antibody.
- Hereditary angioedema:
  - Complement C4 level is usually low during the attack as well as between acute episodes.
  - C1 esterase inhibitor levels help distinguish between various types of hereditary angioedema:
    - In type 1, there is quantitative deficiency of C1 esterase inhibitor.
    - In type 2, there is a functional defect in C1 inhibitor.

#### Imaging

- Imaging is usually not indicated.
- US of the abdomen is helpful to differentiate surgical abdomen from abdominal angioedema:
  - In angioedema, 80% have ascites and edema of intestinal wall (5).

**Diagnostic Procedures/Other**

Radioallergosorbent testing (RAST) if food allergy is suspected in an outpatient setting

**DIFFERENTIAL DIAGNOSIS**

Myxedema, facial cellulitis, superior vena cava syndrome, dermatomyositis, facial lymphedema, allergic contact dermatitis, and idiopathic edema

**TREATMENT****PRE HOSPITAL**

- Assess and stabilize airway, breathing, and circulation.
- In children with angioedema of the larynx, administration of epinephrine IM is of utmost importance.
- Discontinue exposure to any triggering agent.

**INITIAL STABILIZATION/THERAPY**

- Assess and stabilize airway, breathing, and circulation.
- Epinephrine is the drug of choice for patients with anaphylaxis or angioedema with upper airway involvement.

**MEDICATION**

- Medication will depend on whether or not the patient has hereditary angioedema.
- For hereditary angioedema, standard therapies of epinephrine, steroids, and antihistamines are ineffective and not recommended.
- See treatment of hereditary angioedema below.
- Epinephrine is the drug of choice for patients with anaphylaxis or angioedema with upper airway involvement:
  - Dose = 1:1,000 concentration: 0.01 mg/kg IM, max single dose 0.5 mg
  - Dose can be repeated in 5–15 min intervals as needed.
- Antihistamines:
  - Typically, both an H1 blocker and H2 blocker are used.
  - H1 blockers:
    - Diphenhydramine 1 mg/kg IM/IV/PO q6h, max 50 mg
    - Hydroxyzine 0.5–1 mg/kg IM/IV/PO q6h, max 50 mg
  - H2 blockers:
    - Theoretically may be beneficial and are commonly used
    - Famotidine 0.5 mg/kg IV, max single dose 40 mg
    - Ranitidine 2–4 mg IV, max single dose 100 mg
- Steroids:
  - Indicated if airway involvement or extensive cutaneous involvement
  - Dexamethasone 0.2 mg/kg IV/IM/PO (max single dose 10 mg) may be repeated q6–12h if necessary.
  - Methylprednisolone 1–2 mg/kg IV q6h
  - Prednisone 2 mg/kg PO (max single 60 mg) loading dose can be used, followed by 1 mg/kg/dose b.i.d. for 5 days (max 60 mg/day)

- Hereditary angioedema: During an acute attack, patients should be treated with fresh frozen plasma (FFP) or C1 inhibitor concentrate:
  - Plasma: 2 units of FFP given IV, may be repeated in 2 hr
  - Kallikrein inhibitor (Ecallantide):
    - 30 mg IM given in 3 different injection sites, usually both arms and 1 thigh
    - Only approved in patients > 16 yr
  - C1 inhibitor concentrates 10–20 U/kg (alternatively: <50 kg, 500 U; 50–100 kg, 1000 U; > 100 kg, 1500 U) (4)

**DISPOSITION****Admission Criteria**

- Patients with no systemic symptoms and localized angioedema without progression of symptoms may be discharged home.
- Patients with systemic symptoms, diffuse angioedema, and/or progression of symptoms should be admitted to the hospital for close monitoring and follow up.
- Critical care admission criteria:
  - Patients with laryngeal edema or impending airway compromise
  - Patients with signs and symptoms of anaphylaxis

**Discharge Criteria**

- Patients with no sign of airway compromise can be managed on an outpatient basis.
- Patients should be discharged home on a short course of antihistamines and oral steroids.

**FOLLOW-UP****FOLLOW-UP RECOMMENDATIONS**

- Discharge instructions and medications
  - All patients should be discharged with an epinephrine autoinjector:
    - Patients with a weight <30 kg require an EpiPen Jr.
  - Avoid medications, food, physical agents and allergens that cause angioedema.
- For hereditary angioedema:
  - Follow up with an experienced allergist.
  - Register at the hereditary angioedema international database at [www.haeregister.org](http://www.haeregister.org).

**DIET**

Avoid triggers (food products) that cause angioedema.

**PROGNOSIS**

Hereditary angioedema is incurable, but acute attacks can be treated, and prophylaxis is available.

**ADDITIONAL READING****See Also (Topic, Algorithm, Electronic Media Element)**

- Anaphylaxis
- Asthma
- Atopic Dermatitis
- Rash, Urticaria

**CODES****ICD9**

- 277.6 Other deficiencies of circulating enzymes
- 995.1 Angioneurotic edema, not elsewhere classified

**PEARLS AND PITFALLS**

- Pearls:
  - Early recognition of laryngeal edema to prevent impending airway obstruction
  - Early administration of epinephrine in life-threatening angioedema
  - Patients with hereditary angioedema require different therapy than anaphylaxis, including plasma, Ecallantide, or C1 inhibitor concentrate.
  - Discharge patients with a prescription for an EpiPen.
- Pitfalls:
  - Missing hoarseness as a sign of impending airway obstruction
  - Failure to recognize the potentially progressive nature of angioedema
  - For hereditary angioedema, epinephrine, steroids, and antihistamines are not useful.
  - Administering epinephrine solution of 1:10,000 instead of 1:1,000

# ANKLE SPRAIN

Megan E. Lavoie  
Marc Gorelick

## BASICS

### DESCRIPTION

- Ankle injury is a musculoskeletal injury where ligaments of ankle are injured due to stretching or tearing, typically from inversion injury.
- The major concern is differentiating sprain from fracture.

### EPIDEMIOLOGY

- The ankle is the most commonly injured joint among athletes (1):
  - 30–40% of all athletic injuries
- Most frequently seen musculoskeletal injury in the emergency department or primary care setting:
  - 75% of all ankle injuries are sprains.
  - 85% of sprains are inversion injuries.
- Incidence is equal in males and females.

### RISK FACTORS

Previous ankle sprain or injury

### PATHOPHYSIOLOGY

- The ankle is a hinge joint composed of the tibia, fibula, and talus, which in turn are stabilized by ligaments medially and laterally:
  - Lateral ligaments: Anterior talofibular ligament (ATFL), calcaneofibular ligament (CFL), posterior talofibular ligament (PTFL):
    - The ATFL is the most commonly injured.
    - The PTFL is the strongest of the lateral ligaments and is rarely injured with inversion injury.
  - Medial support is from the deltoid complex:
    - Medial ligament sprain with eversion injury, which is commonly associated with lateral malleolus fracture
- Several types of ligamentous injuries:
  - Grade I (mild)—ligament stretch:
    - Mild pain
    - Minimal if any swelling
    - Can bear weight or ambulate with minimal pain
    - No joint instability on testing

- Grade II (moderate)—partial ligament tear:
  - Moderate pain
  - Swelling with possible ecchymosis
  - Pain with weight bearing or ambulation
  - Some joint instability on testing
- Grade III (severe)—complete ligament tear or rupture:
  - Severe pain or occasionally painless
  - Significant swelling (>4 cm about fibula)
  - Unable to bear weight or ambulate
  - Mechanically unstable ankle on testing

### ETIOLOGY

Trauma to ankle, typically by inversion or eversion

### COMMONLY ASSOCIATED CONDITIONS

Fracture

## DIAGNOSIS

### HISTORY

- Mechanism of injury
- Activity at time of injury
- Previous injury to ankle
- Location, duration, and quality of pain
- Bearing weight or ambulatory after injury
- Presence of swelling or bruising
- “Pop” or “snap” in ankle at time of injury

### PHYSICAL EXAM

- Inspect for swelling, bruising, and deformity.
  - Compare with contralateral ankle.
- Assess passive and active range of motion.
- Palpate for tenderness along entire length of fibula, tibia, and base of 5th metatarsal.
- Palpate for tenderness along ligaments.
- Anterior drawer test (for integrity of ATFL):
  - Hold ankle in slight plantar flexion, grasping heel with one hand, holding tibia/fibula above joint line, trying to pull foot forward with anterior force on heel. Compare laxity relative to uninjured side.

- Inversion stress test (for integrity of CFL):
  - Hold foot in neutral, stabilize tibia/fibula above ankle joint, invert ankle with other hand to assess talar tilt and inversion of midfoot. Compare relative to uninjured side.
- Squeeze test (assessing for syndesmosis injury):
  - Compress the tibia and fibula at the level of the midcalf. The test is positive if there is pain distally over tibia and fibula with calf squeezing.
- External rotation test (assessing for syndesmosis injury):
  - Stabilize leg proximal to ankle joint, grasp plantar aspect of foot, and rotate it externally. The test is positive if there is pain with external rotation.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Imaging

- If there is concern for fracture, obtain ankle x-rays.
- Ottawa ankle rules (2,3):
  - Obtain AP, lateral, and mortise x-rays of ankle if patient presents within 10 days of injury with any of the following:
    - Bony tenderness in posterior aspect of distal 6 cm of malleolus of tibia or fibula
    - Unable to walk for 4 steps immediately after injury or in emergency department
  - If there is bony tenderness over the navicular bone or base of the 5th metatarsal, obtain foot x-rays.
  - Ottawa ankle rules were not developed for use in children; if there is concern for fracture involving the growth plate, obtain x-rays.
- If the sprain is symptomatic >6 wk, or if there is crepitus, catching, or locking of the joint, obtain CT or MRI.

### DIFFERENTIAL DIAGNOSIS

- Fracture of lateral, medial, or posterior malleolus
- Fracture of proximal fibula:
  - Maisonneuve fracture involves a syndesmosis injury to the interosseus membrane, which results in a proximal fibular fracture.

- Fracture of lateral process of talus
- Fracture of anterior process of calcaneus
- Fracture of base of 5th metatarsal
- Navicular or midtarsal fracture
- Salter I distal fibula fracture
- Hindfoot sprain
- Tear of peroneal brevis or longus tendon
- Superficial peroneal nerve injury
- Osteochondral talar dome injury
- Syndesmosis (“high”) sprain
- Ankle impingement syndrome

## TREATMENT

### PRE HOSPITAL

- Rest, ice, compression, and elevation of affected extremity (RICE)
- Avoid weight bearing if painful.
- Pain control

### INITIAL STABILIZATION/THERAPY

- RICE
- Adequate pain control
- Crutches during initial period, with weight bearing as tolerating
- Plastic ankle-foot orthotic, walking boot, or posterior splint if severe sprain; air or gel-filled ankle brace if mild or moderate sprain
- Early mobilization and range-of-motion exercises
- Return to athletics only when jogging is pain free and the affected ankle has full range of motion.

### MEDICATION

- NSAIDs:
  - Consider NSAID medication in anticipation of prolonged pain and inflammation:
    - Ibuprofen 10 mg/kg/dose PO/IV q6h PRN
    - Naproxen 5 mg/kg PO q8h PRN
  - Some clinicians prefer to avoid NSAIDs due to theoretical concern over influence of callus formation if fracture is present.

- Acetaminophen 15 mg/kg/dose PO/PR q4h PRN
- Opioids:
  - Morphine 0.1 mg/kg IV/IM/SC q2h PRN:
    - Initial morphine dose of 0.1 mg/kg IV/SC may be repeated q15–20min until pain is controlled, then q2h PRN.
  - Codeine or codeine/acetaminophen dosed as 0.5–1 mg/kg of codeine component PO q4h PRN
  - Hydrocodone or hydrocodone/acetaminophen dosed as 0.1 mg/kg of hydrocodone component PO q4–6h PRN

### SURGERY/OTHER PROCEDURES

Surgery is not needed in the acute setting but may ultimately be indicated by the consulting orthopedic surgeons for grade III sprains.

#### Issues for Referral

- Follow up with primary physician, sports medicine, or orthopedics if pain is not improving in 4–7 days.
- Refer to orthopedics from the emergency department if:
  - Fracture or dislocation
  - Neurovascular compromise
  - Tendon rupture or subluxation
  - Wound penetrating joint space
  - Locking of joint
  - Syndesmosis sprain
  - Symptoms out of proportion to degree of trauma

## FOLLOW-UP

### FOLLOW-UP RECOMMENDATIONS

- Discharge instructions and medications:
  - RICE
  - Analgesic medication
- Activity:
  - Weight bearing when pain free
  - No return to athletics until pain free

### PROGNOSIS

Most patients will be back to playing sports by 6 wk, but up to 50% will have symptomatic complaints for up to a year after injury (4).

## CODES

### ICD9

- 845.00 Unspecified site of ankle sprain
- 845.01 Deltoid (ligament), ankle sprain
- 845.02 Calcaneofibular (ligament) ankle sprain

## PEARLS AND PITFALLS

- If growth plates are open, the clinician must consider a possible Salter-Harris type I fracture.
- Premature return to activity can cause chronic ankle instability and pain. Patients should be counseled not to return to activity until their injured ankle has full range of motion and can tolerate weight bearing without pain.

# ANTERIOR UVEITIS (IRITIS)

Maria Carmen G. Diaz

## BASICS

### DESCRIPTION

- The uveal tract is comprised of the iris, ciliary body, and choroid. The iris and ciliary body are found in the anterior portion of the uveal tract, and the choroid is in the posterior portion.
- Uveitis is an inflammation of the uveal tract.
- Anterior uveitis is an inflammation of the iris and/or ciliary body. It is often referred to as iridocyclitis or iritis depending on the part of the uveal tract that is inflamed.
- Posterior uveitis includes choroiditis and retinitis.
- Uveitis may be classified by location, chronicity, or etiology. When classified by etiology, it is generally identified as traumatic, infectious, inflammatory, or idiopathic.

### EPIDEMIOLOGY

#### Incidence

- The annual incidence of uveitis is 17 in 100,000 people (1).
- Anterior uveitis occurs most commonly in patients between the ages of 20 and 50 yr (1).
- 29–50% of cases of pediatric anterior uveitis are idiopathic.
- 16% of cases of anterior uveitis in children are related to the human leukocyte antigen B27 (HLA-B27).

#### Prevalence

- Pediatric uveitis comprises 5–10% of all cases of uveitis (2).
- 1 study from the United Kingdom described a prevalence of 4.9 in 100,000 children (3).
- Iritis is seen in 25% of pediatric patients with ankylosing spondylitis.
- Iritis is seen in 3–12% of patients with Reiter syndrome.
- Iridocyclitis occurs in 2–11% of patients with inflammatory bowel disease.
- Uveitis occurs in 20% of patients with juvenile rheumatoid arthritis (JRA) (2).

### RISK FACTORS

JRA is the most common condition associated with anterior uveitis in the pediatric population:

- Uveitis is most prevalent in the pauciarticular form of JRA.
- Females who are antinuclear antibody positive and Rh negative are at the highest risk for developing uveitis (2).

### PATHOPHYSIOLOGY

Inflammation of the uveal tract

### ETIOLOGY

- Traumatic:
  - Direct blow from blunt object
- Infectious:
  - Herpes
  - Syphilis
- Inflammatory:
  - HLA-B27
  - Sarcoidosis
  - JRA
- Idiopathic

### COMMONLY ASSOCIATED CONDITIONS

- JRA
- HLA-B27
- Sarcoidosis
- Herpes

## DIAGNOSIS

### HISTORY

- Always ask about history of trauma.
- Acute anterior uveitis: Sudden onset of photophobia, pain, redness, decreased vision, and tearing (2). Deep aching pain that may radiate to the periorbital or temporal area. Pain is worse with eye movement and accommodation (4).
- Traumatic iritis: Photophobia, redness, and pain of the affected eye 1–3 days after injury, usually a direct blow to the eye
- Chronic anterior uveitis: May have minimal symptoms. Will often have other symptoms of underlying disease.

### PHYSICAL EXAM

- Assess visual acuity.
- Perilimbal or circumcorneal injection (ciliary flush)
- Tearing but no purulent discharge
- Pupil is constricted and may be irregular.
- Pupillary response to light is sluggish compared to unaffected eye.
- May have direct photophobia
- May have consensual photophobia (photophobia of affected eye when light shines in unaffected eye) (4)

- Slit lamp exam:
  - Inflammatory cells
  - Proteinaceous flare
  - In cases of severe inflammation, leukocytes may settle in the anterior chamber, forming a hypopyon—a white or yellowish accumulation of purulent material
  - Keratic precipitates: WBCs on endothelium. Small precipitates are nongranulomatous. Large ones are granulomatous and often seen in sarcoidosis.
- Traumatic iritis: Aqueous cells and flare with normal, low, or elevated intraocular pressure. Assess carefully for hyphema.
- Chronic anterior uveitis: May have minimal symptoms but may have severe inflammation on exam
- Specific physical exam findings may help to uncover an underlying etiology or associated condition:
  - HLA-B27 associated uveitis:
    - Ankylosing spondylitis
    - Iritis with hypopyon in anterior chamber
    - Lower extremity pain
    - Back pain
  - Reiter syndrome:
    - Iritis
    - Associated arthritis and urethritis
  - Inflammatory bowel disease:
    - Iridocyclitis
    - GI symptoms
    - Joint inflammation
  - Psoriasis:
    - Chronic anterior uveitis
    - Pauciarticular or polyarticular arthritis of distal joints of hands/feet and sacroiliac joints
    - Rash
  - Sarcoidosis-associated uveitis:
    - Chronic anterior uveitis
    - Large keratic precipitates
    - Iris nodules
    - Aqueous cells
    - Patients with onset at 8 and 15 yr of age will often have pulmonary involvement, lymphadenopathy/hepatosplenomegaly.
    - Those with onset of disease at <5 yr of age will also have arthritis and skin rash.

- Herpes-associated uveitis:
  - Iridocyclitis
  - Aqueous cells
  - Posterior synechia
  - Keratitic precipitates
  - Hypopyon
  - Hyphema
  - May have elevated intraocular pressures
  - May have associated keratitis
  - Skin vesicles
- JRA-associated uveitis:
  - Pauciarticular or polyarticular arthritis (usually precedes the onset of uveitis)

**DIAGNOSTIC TESTS & INTERPRETATION**

**Lab**

**Initial Lab Tests**

- Lab work is often not indicated in the emergent setting.
- Infectious uveitis can be difficult to diagnose and may require specific serology testing if the patient does not respond to conventional therapy.
- Patients with a suspected systemic condition will require further testing. This may often be done as an outpatient.

**Imaging**

- Consider CXR or CT of the chest if there is suspicion for sarcoidosis.
- Consider obtaining images of the sacroiliac joints if there is suspicion of HLA-B27 disease.

**DIFFERENTIAL DIAGNOSIS**

- Retinoblastoma:
  - May cause intraocular inflammation in a patient <5 yr of age
  - May occasionally present with red, painful eye
  - May see pseudohypopyon—layering of tumor cells in anterior chamber
- Leukemia:
  - Also causes ocular inflammation
  - Will see heterochromia, iris infiltrates, spontaneous hyphema, leukemic cells in the aqueous, or pseudohypopyon in the anterior segment
- Juvenile xanthogranuloma:
  - Nonneoplastic histiocytic proliferation that usually develops in children <2 yr of age
  - Present with anterior chamber cells or spontaneous hyphema. There also may be iris heterochromia.
  - The condition is self-limited and remits by 5 yr of age (2).

**TREATMENT**

**INITIAL STABILIZATION/THERAPY**

In cases of traumatic iritis, careful primary and secondary surveys should be conducted to rule out other concomitant traumatic injuries.

**MEDICATION**

**First Line**

Cycloplegics and topical corticosteroids:

- Corticosteroid therapy should only be initiated after consultation with ophthalmology.
- Prednisone: 2 drops in affected eye q.i.d.:
  - Patients with idiopathic anterior uveitis may require a corticosteroid taper lasting several weeks.
  - Corticosteroids may worsen symptoms in certain infectious etiologies of anterior uveitis (4).
- Tropicamide 1%: 1–2 drops in affected eye t.i.d.:
  - Good cycloplegic choice because of its short (4–6 hr) duration of action. In contrast, atropine lasts 5–7 days.

**Second Line**

Treat underlying disorder in nontraumatic cases.

**SURGERY/OTHER PROCEDURES**

Surgery is generally only indicated if complications develop.

**DISPOSITION**

**Admission Criteria**

Systemic illness or trauma requiring inpatient therapy

**Discharge Criteria**

Most patients may be discharged home with close outpatient follow-up.

**Issues for Referral**

- All patients with anterior uveitis should be referred to an ophthalmologist.
- Consider referral to a rheumatologist if an associated rheumatologic disease is suspected.

**FOLLOW-UP**

**FOLLOW-UP RECOMMENDATIONS**

- Discharge instructions and medications:
  - Follow-up with an ophthalmologist.
  - Use medication as prescribed.
  - Traumatic iritis:
    - Avoid bright lights.
    - Use sunglasses (5).
- Activity:
  - Traumatic iritis: Avoid strenuous activity and contact sports until cleared by an ophthalmologist.

**PROGNOSIS**

Idiopathic cases of anterior uveitis usually resolve in 6 wk. Most cases will not recur (1).

**COMPLICATIONS**

- Synechia: Adhesions of the posterior iris to the anterior capsule of the lens
- Angle closure glaucoma
- Cataract formation (6)
- Band keratopathy
- Visual loss (2)

**REFERENCES**

**CODES**

**ICD9**

364.3 Unspecified iridocyclitis

**PEARLS AND PITFALLS**

- Patients with anterior uveitis will have hyperemia adjacent to the limbus. In contrast, hyperemia in those with conjunctivitis is maximal on the periphery, farther from the limbus.
- Consensual photophobia is another distinguishing feature of anterior uveitis. This is not seen in other superficial causes of photophobia.
- “Floaters” and decreased visual acuity are symptoms of posterior uveitis.
- All patients with anterior uveitis require referral to an ophthalmologist.

# ANTICHOLINERGIC POISONING

David H. Jang  
Lewis S. Nelson

## BASICS

### DESCRIPTION

- Anticholinergic poisoning occurs with the inhibition of muscarinic cholinergic transmission at muscarinic receptors that often manifest as an “anticholinergic syndrome.”
- Overdose from anticholinergic agents often occur secondary to prescription medications, nonprescription medications, and plants.
- Severe problems include seizures and agitated delirium.

### RISK FACTORS

- Use of multiple anticholinergic medications simultaneously, such as over-the-counter (OTC) cough/cold preparations
- Repeated high-dose anticholinergic use, such as diphenhydramine for allergy or ipratropium for status asthmaticus
- Adolescents who use substances like cough syrups or hallucinogenic plants recreationally

### PATHOPHYSIOLOGY

- Anticholinergic symptoms result from muscarinic receptor antagonism.
- Atropine is the prototypical muscarinic receptor antagonist.
- Antagonism of central and peripheral muscarinic cholinergic receptors
- Antagonism of central muscarinic receptors often will produce delirium, agitation, or seizures.
- Antagonism of peripheral muscarinic receptors will often produce tachycardia, decreased GI motility, and flushed skin.

### ETIOLOGY

- Anticholinergics:
  - Atropine
  - Benztropine
  - Scopolamine
- Antihistamines:
  - Chlorpheniramine
  - Diphenhydramine
  - Doxylamine

- Tricyclic antidepressants (TCAs):
  - Amitriptyline
  - Doxepin
  - Imipramine
- Neuroleptics:
  - Chlorpromazine
  - Clozapine
  - Olanzapine
  - Quetiapine
- Plants:
  - *Atropa belladonna* (deadly nightshade)
  - *Datura stramonium* (jimson weed)

### COMMONLY ASSOCIATED CONDITIONS

Ingestion of other drugs or alcohol

## DIAGNOSIS

### HISTORY

- A history of exposure may be helpful but may not be available or forthcoming.
- The use of OTC medicines, such as multisymptom cold preparations or dietary supplements, may be obtained.
- Onset of symptoms is usually within 1 hr.
- Anticholinergic toxicity following ingestion typically peaks in 1–4 hr and lasts 4–8 hr, but this largely depends on the agent and dose.
- Symptoms include altered mental status:
  - Confusion
  - Garbled, pressured, nonsensical speech
  - Classically will display “picking behavior” where patients will pick at imaginary objects near them.
  - “Lilliputian” hallucinations in which patients have distortion of sense of scale, perceiving that objects or persons are extremely small or extremely large relative to themselves

### PHYSICAL EXAM

- Anticholinergic syndrome is a clinical diagnosis.
- Vital sign abnormalities are common:
  - Tachycardia is typical, and mild hyperthermia may occur.

- Mental status changes are common:
  - Patients are often confused and may also display agitated delirium.
  - Seizure may rarely occur.
- Inability for eyes to accommodate and mydriasis (often does not respond to light as opposed to mydriasis that occurs with sympathomimetics)
- Skin is dry and flushed.
- Often will have accompanying decreased GI motility as well as urinary retention

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

- Anticholinergic syndrome is a clinical diagnosis, and assays are only adjunctive.
- Acetaminophen level:
  - The serum acetaminophen level should be considered in patients with intentional ingestion.
  - OTC products often contain acetaminophen.
- The measurement of electrolytes, BUN, creatinine, and blood sugar may be useful to differentiate from other etiologies.
- Measurement of creatine phosphokinase for suspected rhabdomyolysis that can occur with agitation, seizures, or certain overdoses (doxylamine can cause rhabdomyolysis in overdose)

#### Imaging

A noncontrast head CT should be obtained in unresponsive patients or those with focal neurologic deficits.

#### Diagnostic Procedures/Other

- Obtain ECG.
- Strongly consider lumbar puncture in patients who have signs and symptoms of meningitis or encephalitis (more likely; seizure, fever, altered mental status, etc.) where a history of an overdose may not be forthcoming.

### DIFFERENTIAL DIAGNOSIS

- Sympathomimetic poisoning
- Malignant hyperthermia
- Neuroleptic malignant syndrome
- Hyperthyroidism/Thyroid storm
- Subarachnoid hemorrhage
- Serotonin syndrome
- Withdrawal syndromes
- Encephalitis
- Sepsis

## TREATMENT

### INITIAL STABILIZATION/THERAPY

- Assess and stabilize airway, breathing, and circulation.
- Maintaining vital signs within acceptable limits and controlling patient agitation are commonly required.
- Patients who are hyperthermic may require cooling and sedation with a benzodiazepine.
- Use of antipsychotics, such as haloperidol, is relatively contraindicated, as these medications may increase risk of cardiac dysrhythmia, lower seizure threshold, impair heat dissipation, and also have anticholinergic effects.

### MEDICATION

- Activated charcoal:
  - 1 g/kg may be administered in cooperative patients to bind drug in the GI tract.
  - Typically, charcoal is used only if ingestion occurred < 1 hr previously, but anticholinergic medications slowing GI motility and charcoal may be administered later than 1 hr after ingestion.
- Benzodiazepines:
  - Used to control agitation and delirium
  - Extremely favorable safety profile and clinician familiarity usually indicate benzodiazepines as a first-line medication
  - Diazepam:
    - 0.1 mg/kg IV, max single dose 10 mg q5–20min titrated to effect
    - First line for agitation; faster and more predictable as a sedative
  - Lorazepam in doses of 0.05 mg/kg IV q15min titrated to effect is the preferred treatment for seizures.
- Physostigmine:
  - Dose 0.02 mg/kg, max single dose 0.5 mg in children < 10 yr of age, 1–2 mg total dose in adults, given IV over 5 min
  - Physostigmine is a cholinergic antidote used to reverse central anticholinergic effects:
    - As such, physostigmine is the preferred medication since it normalizes anticholinergic symptoms and benzodiazepines only provide sedation.
    - Physostigmine may allow restoration of normal mental status and avert the need for additional evaluation such as lumbar puncture or head CT.
  - Indications for physostigmine include the presence of anticholinergic toxicity without any evidence of QRS or QTc prolongation.
  - Half-life is approximately 15 min, but duration of action may be over an hour. Redosing may be required as indicated.

- When administered, the patient should be on a cardiopulmonary monitor, with atropine at the bedside to give for immediate.
- Should not be used in patients with suspected TCA overdose
- Relative contraindications include reactive airway disease, atrioventricular block, and intraventricular conduction delays.
- Adverse reactions often include increased cholinergic symptoms, such as bradycardia, bronchorrhea, vomiting, and diaphoresis:
  - Monitoring for bradycardia and airway secretions is especially important.
- Physostigmine when compared to benzodiazepines showed shorter time to recovery from agitation, but length of stay was unchanged.
- As a pure antidote, physostigmine is superior to benzodiazepines, but clinician comfort and familiarity should determine whether physostigmine or benzodiazepines are used for treating anticholinergic symptoms.

### DISPOSITION

#### Admission Criteria

- Unstable vital signs, abnormal mental status, patient being a danger to self or others, end-organ toxicity
- If antidotal physostigmine or benzodiazepines are needed to reverse anticholinergic symptoms, admission should be strongly considered.
- Critical care admission criteria:
  - Unstable vital signs, seizures, end-organ toxicity

#### Discharge Criteria

Any patient with vital signs within normal limits, normal mental status, and no evidence of end-organ damage may be discharged from the emergency department.

#### Issues for Referral

- Refer patients with intent of self harm to psychiatry.
- Refer patients with substance abuse for drug counseling.

## FOLLOW-UP

### PROGNOSIS

Patients who are anticholinergic typically do well with good supportive care, with special attention to other medication effects such as sodium channel blockade.

### COMPLICATIONS

Complications of anticholinergic toxicity often can include seizures and injury to self.

## CODES

### ICD9

971.1 Poisoning by parasympholytics (anticholinergics and antimuscarinics) and spasmolytics

## PEARLS AND PITFALLS

- Anticholinergic syndrome can be clinically diagnosed with a good physical exam and history.
- It is important to be wary of medications that are anticholinergic and also have other associated toxicity, such as TCAs.
- Use of benzodiazepines or physostigmine to control agitation or other neurologic symptoms assists in management.
- Physostigmine is the preferred antidote because it results in normalization of mental status and reversal of other anticholinergic symptoms.
- Although benzodiazepines only result in sedation and do not improve other anticholinergic symptoms, clinician familiarity with benzodiazepines and their excellent safety profile may warrant use.

# ANTICOAGULANT POISONING

Beth Y. Ginsburg

## BASICS

### DESCRIPTION

- Warfarin and heparin are the main anticoagulants available for medicinal use:
  - Warfarin is an oral anticoagulant.
  - Unfractionated heparin is administered IV or SC. Low-molecular-weight heparins (LMWH; eg, dalteparin, enoxaparin) are administered SC.
- Indications for use include coronary artery disease, cerebrovascular events, venous thromboses, and pulmonary embolisms. Heparin is also used for prevention of thrombosis after surgery and during periods of immobilization (eg, hospitalization).
- Long-acting oral anticoagulants, or superwarfarins, are manufactured for use as rodenticides and typically contain only a small concentration of anticoagulant.
- Exposure to superwarfarin rodenticides are the most common pediatric anticoagulation issue seen in the pediatric emergency department. Most of these fortunately do not result in anticoagulation.
- Superwarfarin exposures should be evaluated by lab assay due to fact that if anticoagulation occurs, it will be present for weeks to months and may result in death from minor trauma, such as intracranial hemorrhage after minor head injury.

### EPIDEMIOLOGY

#### Incidence

- There are many reported cases of intentional and unintentional overdoses of warfarin and superwarfarins:
  - In children, these are typically exposure to superwarfarin rodenticides used in the home.
  - Most unintentional single ingestions of superwarfarins are not associated with a large enough dose to cause toxicity.
  - Toxicity may potentially develop with repeated ingestions over time, even if small.
  - Intentional overdoses of superwarfarins are associated with significant toxicity.
- Unfractionated heparin typically is administered to hospitalized patients. Most overdoses involve unintentional poisoning due to medication error.
- There is potential for intentional overdose with self-administered LMWH.

### PATHOPHYSIOLOGY

- The mechanism of action of warfarin as an anticoagulant involves its role in the inhibition of the vitamin K cycle:
  - Vitamin K is a cofactor in the synthesis of clotting factors II, VII, IX, and X and proteins C and S. It is required for transforming clotting factor from their inactive to active forms.
  - Warfarin leads to inactivation of vitamin K.
  - Vitamin K must be enzymatically reduced back to its active form in order to resume function as a cofactor.
  - Warfarin inhibits this enzymatic reaction, thereby interfering with coagulation.
- Toxicity is characterized by coagulopathy:
  - The risk of hemorrhage depends on the intensity of anticoagulation as well as the patient's comorbidities.
  - The most common sites of bleeding are the GI and genitourinary tract. Patients may also present with bruising and menorrhagia.
  - The most serious complication is an intracranial hemorrhage, which is associated with a high mortality rate.
- Anticoagulant effects can be potentiated by coingestion of other drugs that inhibit warfarin metabolism or lead to increased free warfarin levels by competing for binding to albumin:
  - Allopurinol, anabolic steroids, cephalosporins, cimetidine, clofibrate, cyclic antidepressants, erythromycin, ethanol, NSAIDs, sulfonyleureas
- Anticoagulant effects are delayed until existing stores of active vitamin K and coagulation factors are depleted. In most patients, effects are not apparent until at least 15 hr.
- Duration of action is several days for warfarin.
- Superwarfarins have a duration of action of weeks to months depending on which agent is ingested. They are also more potent than warfarin:
  - They are designed as such to be lethal rodenticides when ingested in a single, small dose by a rodent.

- Warfarin is also associated with nonhemorrhagic dermatologic complications:
  - Urticaria
  - Purple toe syndrome, which is due to small atheroemboli that are no longer adherent to plaque by clot
  - Warfarin skin necrosis, which is due to microvascular thrombosis in dermal vessels as a result of falling protein C levels with the onset of warfarin therapy
  - Treatment involves cessation of warfarin and initiation of heparin.
- Heparin functions as an anticoagulant by accelerating the binding to antithrombin III to thrombin. As a result, clotting factors IX to XII and thrombin are inhibited.
- Duration of action is usually 1–3 hr.
- LMWHs have a similar mechanism of action with some pharmacologic differences:
  - Patients with renal insufficiency or failure are at increased risk of toxicity.
- Toxicity is characterized by coagulopathy that can result in various forms of bleeding.
- Heparin is also associated with a mild thrombocytopenia referred to as heparin-induced thrombocytopenia (HIT) as well as a more severe form referred to as heparin-induced thrombocytopenia and thrombosis syndrome (HITS):
  - HIT and HITS occur less frequently with LMWHs.

### ETIOLOGY

- Heparin
- Warfarin (Coumadin)
- Rodenticides (superwarfarins):
  - Brodifacoum
  - Difenacoum
  - Chlorophacinone
  - Diphacinone

## DIAGNOSIS

### HISTORY

- In absence of a history of exposure, complaints of bleeding and/or bruising in conjunction with abnormal laboratory values may be suggestive of an exposure to an anticoagulant.
- Children with exposure to rodenticide anticoagulants typically have an exposure history of possible ingestion of a small quantity of rodenticide.

### PHYSICAL EXAM

The physical exam should focus on uncovering evidence of coagulopathy and bleeding:

- Vital sign abnormalities may include tachycardia and hypotension depending on the degree of blood loss.
- Evaluation of the mouth may reveal gingival bleeding.
- Rectal exam may uncover bright red blood or melena. Stool may be tested for occult blood.
- A urine sample may reveal gross hematuria and may be tested for microscopic hematuria.
- Dermatologic examination may reveal bruising.
- Altered mental status, seizures, or any other neurologic deficits should elicit concern for intracerebral hemorrhage.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

- Prolongation of the PT and elevation of the INR are indicative of coagulopathy secondary to warfarin or a superwarfarin:
  - Onset of PT prolongation and INR elevation is between 12 and 24 hr post ingestion.
  - It is not routinely necessary to obtain a PT or INR prior to this time frame.
  - If there is a concern for chronic or repeated exposures to a superwarfarin rodenticide
  - For the purpose of obtaining the baseline, PT and INR are not required.

- Elevated PTT is indicative of coagulopathy secondary to heparin toxicity. LMWHs do not have an effect on the PTT, and this test cannot be used to monitor for LMWH toxicity.
- Hemoglobin and hematocrit should be monitored in cases of bleeding.
- Platelets should be monitored for development of HIT or HITTS.
- Urine and stool may be checked for occult blood.

### ALERT

- In children, lab error resulting from inadequately filled blood vials to assay coagulation times commonly results from underfilling these tubes.
- When filling vacuum tubes, allow the tube to aspirate precisely the quantity of blood taken by its vacuum.
- Even a slightly decreased amount may errantly result in falsely prolonged coagulation times due to inappropriate anticoagulant/blood ratio in the tube.

### Imaging

- Neuroimaging should be performed if there is concern for an intracranial hemorrhage.
- Imaging with CT and/or US may be used for diagnosing hemorrhage into other tissues or compartments.

## TREATMENT

### INITIAL STABILIZATION/THERAPY

- Assess and stabilize airway, breathing, and circulation.
- Blood transfusion should be initiated in patients with significant blood loss who are, or are expected to become, hemodynamically unstable:
  - Packed RBCs are useful in replacing lost blood but cannot easily or fully correct coagulopathy.

- In cases of life-threatening hemorrhage secondary to warfarin or superwarfarins, coagulopathy should be reversed with a transfusion of fresh frozen plasma (FFP), prothrombin complex concentrate, or recombinant factor VIIa.
- Exchange transfusion may be used in neonates following a heparin overdose.
- Oral activated charcoal (1 g/kg) may be administered to patients with a recent (1 hr) potentially significant ingestion of oral anticoagulant as long as there are no contraindications such as altered mental status.

### MEDICATION

- Vitamin K in the form of vitamin K<sub>1</sub> (phytonadione) is used to reverse coagulopathy in the setting of oral anticoagulant toxicity.
  - Vitamin K<sub>3</sub> (menadiolone) is not appropriate for use; only vitamin K<sub>1</sub> (phytonadione) is used.
  - It should be administered in any case of serious bleeding regardless of the degree of elevation of the PT or INR.
- Chronic warfarin exposure:
  - For patients with an elevated INR who require chronic anticoagulation, the use of vitamin K and transfusion depends on the degree of elevation of INR and whether or not there is bleeding:
    - INR <5.0; no significant bleeding: Lower the warfarin dose, or omit next dose, of warfarin; monitor INR frequently; resume anticoagulation when INR reaches therapeutic range.
    - INR ≥5.0–9.0; no significant bleeding: Omit next 1–2 doses of warfarin; monitor INR frequently; resume anticoagulation when INR reaches therapeutic range. May administer vitamin K 1–2.5 mg PO, especially if patient is at increased risk for bleeding.
    - INR ≥9.0; no significant bleeding: Hold warfarin; administer vitamin K<sub>1</sub> 2.5–5.0 mg PO; monitor INR frequently; administer additional vitamin K<sub>1</sub> as needed; resume anticoagulation when INR reaches therapeutic range.
    - Serious or life-threatening bleeding and elevated INR: Hold warfarin; administer vitamin K<sub>1</sub> 10-mg slow IV infusion; supplement with FFP, prothrombin complex concentrate, or recombinant factor VIIa; administer additional vitamin K<sub>1</sub> as needed q12h.

- Warfarin (not superwarfarin) exposure: Following exposure in asymptomatic patients not requiring anticoagulation, PT and INR should be monitored at 24 and 48 hr post ingestion:
  - Vitamin K<sub>1</sub> 0.6 mg/kg/dose PO b.i.d.–q.i.d., typically 5–10 mg PO b.i.d.–q.i.d. × 3 days in children; max single dose 10–50 mg PO b.i.d.–q.i.d. × 3 days in adolescents
  - Given if coagulation results reveal prolongation secondary to anticoagulant effects
  - 3 days of therapy is dosing for warfarin (medicinal).
- Vitamin K<sub>1</sub> may be administered prophylactically (without serial measurements of PT and INR) for 3 days. Treatment for this time period will likely cover the expected duration of action of warfarin:
  - This is not recommended following large ingestions since the duration of anticoagulation is unpredictable.
  - Treatment for prolonged coagulation due to a rodenticide such as brodifacoum or difenacoum, etc., is a min of 4 wk and longer in some cases.
- Vitamin K<sub>1</sub> should not be given prophylactically following suspected ingestion of a superwarfarin.
- The duration of action is expected to be several weeks to months. The administration of vitamin K for several days will merely delay the onset of an INR abnormality and coagulopathy in cases in which a significant amount of superwarfarin was ingested:
  - In addition, most exposures to superwarfarins do not result in anticoagulation since the amount ingested, if any, is not enough to cause toxicity. In these cases, PT and INR will remain within normal range and treatment with vitamin K is not needed.
- Superwarfarin exposure: After exposure, PT and INR should be monitored at 24 and 48 hr post exposure:
  - Patients who develop coagulopathy will require high doses of vitamin K several times a day for weeks to months.
  - Vitamin K<sub>1</sub>: Starting dose is typically 25–50 mg PO b.i.d.–q.i.d. in adolescents/adults and 0.6 mg/kg/dose PO b.i.d.–q.i.d. in children taken for an initial 4-wk period.
  - INR should be monitored frequently and the dose titrated up or down according to the INR.
  - Upon completion of treatment with vitamin K, INR should continue to be monitored frequently for several days to determine if it is safe to discontinue vitamin K<sub>1</sub> therapy.
- Parenteral vitamin K<sub>1</sub>:
  - Given SC or IV for severe warfarin or superwarfarin toxicity
  - Children 1–5 mg IV/SC, adults 10–25 mg IV/SC; max volume 5 mL/50 mg per dose at SQ injection site
  - IV: Given rarely due to risk of anaphylactoid reaction. Children dosed as 0.6 mg/kg/dose; max single dose 10–25 mg in older children/adolescents. Infuse at a rate of 1 mg/min or 5% of total dose/min, whichever is slower. Slow infusion immediately if there are anaphylactoid symptoms.
  - SC administration is reserved for cases in which oral administration is unlikely to be effective, such as significant GI hemorrhage.
  - IM administration should always be avoided in patients with coagulopathy due to risk of developing hematomas.
  - IV administration is associated with a risk of anaphylactoid reaction and even death. Slow IV infusion of vitamin K<sub>1</sub> should be limited to cases of life-threatening bleeding.
- Blood products:
  - Vitamin K<sub>1</sub> will not begin to affect clotting for 6 hr. Patients with active hemorrhage will require FFP or whole blood. Recombinant factor VII (NovoSeven) may be used as an alternative to FFP:
    - FFP 15–25 mL/kg IV; adult dose 2–4 units IV. Based on serial PR/INR, repeated doses may be necessary.
    - NovoSeven 35–120 μg/kg IV
- Heparin has a relatively short duration of action. Following an overdose, observation alone may be sufficient if significant bleeding has not occurred:
  - Heparin infusion should be held. It may be resumed when serial PTT levels reach the therapeutic range.
- Protamine:
  - Used to reverse coagulopathy due to heparin toxicity. It has a greater affinity for heparin than antithrombin III, thereby causing dissociation of the heparin-antithrombin III complex
  - 1 mg of protamine neutralizes 100 U of heparin.
  - The dose of protamine given should not exceed the amount of heparin expected to be found intravascularly at the time of protamine infusion. Excess protamine administration may result in paradoxical anticoagulation.
  - The dose needed should be calculated from the dose of heparin administered and assuming a heparin half-life of 60–90 min:
    - If 30–60 min after heparin injection, give 0.5 mg of protamine per 100 U of heparin initially given.
    - If ≥ 2 hr after heparin injection, give 0.25 mg of protamine per 100 U of heparin initially given.

- Protamine use should be limited to cases of life-threatening hemorrhage.
- Protamine is associated with significant adverse effects, including anaphylactic and anaphylactoid reactions, bradycardia, acute lung injury, and thrombocytopenia.
- Diabetic patients receiving protamine-containing insulin (NPH) are at increased risk of having an adverse reaction.
- Protamine is not recommended for use in cases of bleeding secondary to LMWHs.

## DISPOSITION

### Admission Criteria

- Patients requiring ongoing care for hemorrhage or at risk for significant hemorrhage, including patients with intentional ingestions of superwarfarins
- Critical care admission criteria:
  - Unstable vital signs, life-threatening hemorrhage (eg, intracranial hemorrhage)

### Discharge Criteria

- Patients usually may be safely discharged if they have a reliable history of an unintentional overdose, are asymptomatic, and are not considered to be at risk for hemorrhage.
- For children with unintentional exposures to rodenticides, the chance of toxicity is small, but it is recommended that they follow up for repeat PT/INR:
  - These patients may complete their 24- and 48-hr PT and INR testing as outpatients.

## Issues for Referral

Patients who present following an intentional overdose require a psychiatric evaluation.

## FOLLOW-UP

### PROGNOSIS

- There is potential for significant morbidity due to hemorrhage, particularly in cases of large intentional overdoses of superwarfarins.
- Due to its short duration of action, development of significant morbidity secondary to heparin overdose is rare.

### COMPLICATIONS

- Hemorrhage, particularly intracranial hemorrhage with permanent neurologic injury
- Death

## CODES

### ICD9

964.2 Poisoning by anticoagulants

## PEARLS AND PITFALLS

- Superwarfarin rodenticide exposure is the most common anticoagulant issue in pediatric patients.
- Usually, this is a single small exposure with low likelihood to result in anticoagulation. Due to length of anticoagulation (weeks to months) and potential for fatality, evaluation of PT/INR at 24–48 hr is recommended.
- Do not initially give prophylactically vitamin K<sub>1</sub>, as this may mask prolonged coagulation that will occur and be present for months.
- Only vitamin K<sub>1</sub> (phytonadione), not vitamin K<sub>3</sub> is useful.
- Failure to thoroughly fill Vacutainer tubes sent for coagulation profile is a common lab error.
- Failure to aggressively reverse anticoagulated patients with significant active bleeding may result in severe morbidity and mortality.
- Protamine has anticoagulant properties itself.

# ANTICONVULSANT POISONING

Beth Y. Ginsburg

## BASICS

### DESCRIPTION

- Anticonvulsant toxicity falls broadly into several categories.
- Classically used anticonvulsants, such as phenytoin, phenobarbital, and carbamazepine, cause ataxia and nystagmus.
- Anticonvulsants working by GABA mechanism, such as phenobarbital, valproic acid, and topiramate, cause dose-dependent CNS depression similar to sedative-hypnotic medications.
- Unique toxicities, such as cardiotoxicity from carbamazepine and metabolic toxicity from valproic acid or topiramate, also occur. These are more common with newer anticonvulsants.
- The search for an effective anticonvulsant has led to the use of a variety of agents since the mid-1800s with several new anticonvulsants having been introduced starting in the 1990s.

### RISK FACTORS

Anticonvulsant use as antiepileptic drug

### GENERAL PREVENTION

General poison prevention methods, such as keeping medications inaccessible to children

### PATHOPHYSIOLOGY

- Seizures result from one of several cellular mechanisms:
  - The mechanism of action of anticonvulsants relates to one or more of the cellular mechanisms responsible for seizures:
    - Phenytoin and carbamazepine prolong inactivation of sodium channels.
    - Lamotrigine inhibits glutamic acid activity.
    - Phenobarbital, valproic acid, gabapentin, and tiagabine enhance GABA activity.
    - Topiramate blocks sodium channels, modulates glutamic acid activity, and enhances GABA activity.
    - The mechanism of action of levetiracetam is not well defined.
- Adverse effects and toxicity associated with anticonvulsant exposure depend on the particular agent involved.
- Phenytoin:
  - Toxicity is seen at levels above the therapeutic level of 10–20 mg/L.
  - Toxicity primarily affects the cerebellar and vestibular systems and may be concentration dependent:
    - Nystagmus may occur at a concentration > 15 mg/L.
    - Ataxia may occur at a concentration > 30 mg/L.
  - Lethargy, slurred speech, and pyramidal and extrapyramidal effects may occur at a concentration > 50 mg/L.
  - Seizures rarely may occur in the setting of an acute overdose of phenytoin, typically in patients with a prior seizure disorder.

- Children with phenytoin toxicity may have atypical presentations such as opisthotonos.
- An overdose or rapid infusion of IV phenytoin may result in cardiovascular toxicity (ie, impaired myocardial contractility and conduction, decreased peripheral vascular resistance). Dysrhythmias may include asystole, ventricular tachycardia, and ventricular fibrillation. ECG manifestations may include increased PR interval, widened QRS interval, and alteration of ST segments and T waves.
  - These effects are partially due to the presence of propylene glycol and ethanol in the diluent used in IV preparations and are therefore not associated with overdoses of oral preparations.
  - IV phenytoin also is associated with local skin irritation, and extravasation may cause necrosis. This also is due to the presence of propylene glycol.
- Chronic phenytoin toxicity may be associated with behavioral changes such as hyperactivity, confusion, lethargy, and hallucinations as well as gingival hyperplasia, cerebellar effects, and encephalopathy.
- Phenobarbital
  - Toxicity is seen at levels >40  $\mu\text{g}/\text{mL}$  but may occur at lower levels with co-ingestants.
  - Toxicity is typically dose dependent, similar to that of other sedative hypnotic agents.
  - Typically is characterized by slurred speech, ataxia, and incoordination. Severe toxicity may lead to coma with respiratory depression, hypothermia, and loss of neurologic responses.
  - Phenobarbital toxicity also is associated with development of cutaneous bullae over pressure-point areas.
- Carbamazepine:
  - Toxicity is seen at levels >6–12  $\mu\text{g}/\text{dL}$ .
  - Overdose is associated with neurologic effects such as nystagmus, ataxia, and dysarthria. Large overdoses may be associated with a decreased level of consciousness and even coma. Seizures may occur in patients both with and without underlying seizure disorders.
  - Carbamazepine also is associated with cardiovascular toxicity due to anticholinergic activity. Effects may include sinus tachycardia, hypotension as a result of myocardial depression, and conduction abnormalities such as QRS and QT. Other manifestations of anticholinergic toxicity may occur, such as decreased GI motility and urinary retention.
  - Children are more likely to present with dystonic reactions, choreoathetosis, and seizures but are less likely to have cardiotoxicity. Children are at risk for toxicity at lower serum drug concentrations.
  - SIADH may occur with high concentrations.
  - Chronic toxicity may result in headaches, diplopia, and ataxia.

- Valproic acid:
  - Acute toxicity is seen at levels >100  $\mu\text{g}/\text{mL}$ , the upper range of therapeutic.
  - Associated with neurotoxicity characterized by lethargy. Coma with cerebral edema may develop in cases of severe toxicity. GI effects may include nausea and vomiting.
  - Associated with various metabolic effects: Metabolic acidosis, hyperammonemia, hypocarnitinemia, hypernatremia, and hypocalcemia
  - Pancreatitis, hepatotoxicity, and renal insufficiency rarely occur after acute overdose of valproic acid. Bone marrow suppression resulting in pancytopenia may occur following very large overdoses.
  - Chronic toxicity may result in hepatotoxicity due to altered fatty acid metabolism.
- Gabapentin: Overdose is characterized by lethargy, slurred speech, ataxia, and movement disorders. GI symptoms may occur.
- Lamotrigine:
  - Toxicity is associated with lethargy, nystagmus, and ataxia. Seizures have been reported in the setting of overdose.
  - Associated cardiotoxicity may include QRS prolongation. GI symptoms may occur.
  - Chronic lamotrigine toxicity may lead to rashes, rhabdomyolysis, and hepatotoxicity.
- Topiramate:
  - Lethargy, nystagmus, ataxia, and myoclonus. Seizures have been reported in the setting of overdose.
  - Metabolic acidosis also has been reported in the setting of topiramate toxicity.
- Tiagabine: Toxicity is associated with lethargy, nystagmus, facial myoclonus, and posturing. Seizures have been reported in cases with high serum concentrations.
- Levetiracetam: Lethargy, coma, and respiratory depression were described in 1 case of overdose.

### ETIOLOGY

See Pathophysiology.

## DIAGNOSIS

### HISTORY

- A history of exposure is usually available.
- History of ataxia may be given.

### PHYSICAL EXAM

- Vital sign abnormalities are rare:
  - Bradycardia and/or hypotension may occur with IV phenytoin or carbamazepine toxicity.
  - Respiratory depression may develop with CNS depression.
  - Hypothermia has been described in cases of phenobarbital toxicity.
  - Fever occurs with anticonvulsant hypersensitivity syndrome.

- Ophthalmologic findings often include nystagmus.
- Cardiac dysrhythmias may occur with carbamazepine toxicity or IV phenytoin toxicity.
- Nausea and vomiting are associated with phenytoin, carbamazepine, gabapentin, valproic acid, and lamotrigine toxicity.
- Dermatologic findings include cutaneous bullae in the setting of phenobarbital toxicity. Local skin irritation may develop in cases of IV phenytoin extravasation. Rash occurs with anticonvulsant hypersensitivity syndrome.
- Neurologic findings are common. Ataxia, usually with accompanying nystagmus, is typical with phenytoin, carbamazepine, and phenobarbital. Altered mental status, confusion, lethargy, coma, slurred speech, myoclonus, posturing, ataxia, incoordination, and seizures may also result from anticonvulsants generally.

## DIAGNOSTIC TESTS & INTERPRETATION

### Lab

#### Initial Lab Tests

- Assess bedside fingerstick blood glucose in all patients with altered mental status.
- CBC is generally recommended.
- Serum electrolytes are generally recommended.
- Serum drug concentration for phenytoin, phenobarbital, carbamazepine, or valproic acid:
  - An elevated serum drug concentration may help confirm toxicity and in some cases may help guide management.
  - Serial drug concentrations should be obtained in cases of overdose of phenytoin and carbamazepine since there may be prolonged or delayed absorption.
  - Serial drug concentrations also should be obtained in cases of overdose of extended-release preparations of valproic acid.
- Carbamazepine: Assay serum electrolytes.
- Valproic acid:
  - Specific lab assays are indicated. In addition to CBC and serum electrolytes, assay LFTs and ammonia concentration, lipase, and venous blood gas.
- Lamotrigine: LFTs and serum creatine phosphokinase
- Topiramate: Electrolytes, serum bicarbonate, and blood gas analysis should be obtained in cases of topiramate toxicity.

#### Diagnostic Procedures/Other

- ECGs in cases of carbamazepine toxicity may demonstrate QRS widening, QT prolongation, atrioventricular block, and ventricular dysrhythmias.
- Lamotrigine toxicity may also be associated with QRS widening.

## DIFFERENTIAL DIAGNOSIS

- Hypoglycemia
- Sedative-hypnotic intoxication
- Ethanol intoxication
- Acute cerebellar ataxia
- Vertigo
- Encephalopathy of other etiology

## TREATMENT

### INITIAL STABILIZATION/THERAPY

- Assess and stabilize airway, breathing, and circulation.
- Assess bedside fingerstick blood glucose concentration for altered mental status.
- Discontinue further dosing of anticonvulsant.
- GI decontamination:
  - Activated charcoal may be considered in recent (<1 hr) ingestions.
  - Multiple-dose activated charcoal may be considered for phenytoin, phenobarbital, carbamazepine, and valproic acid toxicity.
- Phenytoin:
  - Cardiac dysrhythmias and hypotension from IV phenytoin toxicity usually resolve within an hour. Hypotension generally responds to an IV fluid. The phenytoin infusion should be stopped for a few minutes and may be restarted at half the initial rate.
  - Use of multiple-dose activated charcoal 1 mg/kg orally q2–4h may be indicated.
- Phenobarbital:
  - In toxicity, alkalization with a sodium bicarbonate infusion is an effective means of elimination of phenobarbital.
  - Multiple-dose activated charcoal is more effective and safer (recommended).
  - Use of multiple-dose activated charcoal 1 mg/kg orally q2–4h may be indicated.
- Carbamazepine:
  - Assess for cardiac dysrhythmia, which may require treatment with sodium bicarbonate.
  - Use of multiple-dose activated charcoal 1 mg/kg orally q2–4h may be indicated.
- Valproic acid: Use of L-carnitine, possible hemodialysis or hemoperfusion

### MEDICATION

- Activated charcoal:
  - 1 mg/kg PO, may be repeated q2–4h if multidose activated charcoal is needed.
  - Do not give multiple doses of charcoal with sorbitol; severe abdominal bloating and pain may occur
  - Multidose charcoal; useful for phenytoin, phenobarbital, carbamazepine, and possibly valproic acid
- Sodium bicarbonate:
  - If cardiotoxicity is due to carbamazepine, sodium bicarbonate bolus and infusion should be administered for widening of the QRS interval >100 msec.
  - If wide QRS >100 msec, give 1 mEq/kg IV push, then repeat ECG 10 min later to assess response.
  - If QRS narrowing resulted, bicarbonate infusion of 2 ampules of sodium bicarbonate in 1 L of D5W may be infused.
- L-carnitine:
  - The loading dose is 100 mg/kg IV (max single dose 6 g) over 30 min, followed by 15 mg/kg IV over 10–30 min q4h until clinical improvement is evident.
  - Oral dosing of 100 mg/kg/day (up to 3 g/day) divided q6h may be given following an acute overdose without hepatotoxicity or symptomatic hyperammonemia.
  - Should be administered in cases of hyperammonemia or hepatotoxicity.

## SURGERY/OTHER PROCEDURES

Hemodialysis/hemoperfusion:

- Valproic acid; hemodialysis/hemoperfusion; for rapid clinical deterioration, hepatic dysfunction, continued drug absorption, and/or serum valproic acid concentration >1,000 mg/L
- Indications for phenobarbital toxicity are persistent severe hypotension.

## DISPOSITION

### Admission Criteria

- Abnormal vital signs, metabolic derangements, neurologic symptoms, or end-organ dysfunction
- Ataxia resulting from phenytoin or carbamazepine toxicity. If only ataxia, cardiac monitoring is not required.
- Admission for extended-release valproic acid. Peak concentrations may take 24 hr to occur.
- Critical care admission criteria:
  - Cardiac dysrhythmia, unstable vital signs

### Discharge Criteria

Asymptomatic after a period of observation or if signs and symptoms of toxicity resolve

## FOLLOW-UP

### PROGNOSIS

- Significant toxicity associated with anticonvulsant exposure is rare.
- Potential for significant morbidity and mortality with severe toxicity exists.

## ADDITIONAL READING

- Craig S. Phenytoin poisoning. *Neurocrit Care*. 2005;3:161–170.

- Spiller HA. Management of carbamazepine overdose. *Pediatr Emerg Care*. 2001;17:452–456.

## CODES

### ICD9

966.3 Poisoning by other and unspecified anticonvulsants

## PEARLS AND PITFALLS

- Common presenting problems are ataxia and nystagmus as well as impaired consciousness or neurologic function.
- Newer anticonvulsants have unique toxicities that may require specific treatment.
- Multiple-dose activated charcoal may be useful for phenytoin, phenobarbital, carbamazepine, and possibly valproic acid.
- Phenobarbital coma can mimic brain death.

# APHTHOUS STOMATITIS

Helene Tigchelaar

## BASICS

### DESCRIPTION

- Aphthous stomatitis (canker sores) are:
  - Recurrent
  - Painful
  - Solitary or occasionally multiple
  - Limited to the nonkeratinized mucous membranes of the mouth (ventral tongue, buccal mucosa, labial mucosa, floor of the mouth)
  - Yellow or gray, shallow, round or oval ulcers, sharply demarcated, with an erythematous border
- Discussed are minor recurrent aphthous stomatitis (RAS), major RAS (10%), and herpetiform aphthous ulceration:
  - Minor aphthous stomatitis:
    - Lesions are <1 cm in diameter.
    - Lesions heal in 1 wk without scarring.
    - Usually starts in adolescence and improves with age
  - Major aphthous stomatitis is more severe (<10%):
    - Ulcers are larger, deeper, more frequent, and associated with severe pain.
    - Lesions can last weeks to months.
    - Lesions scar.
    - Presents at puberty and does not remit
  - Herpetiform ulceration:
    - More frequent in females
    - Clusters of small lesions (up to 100) throughout the mouth
    - Herpesvirus is not isolated from these lesions, and there is no initial vesicle.
    - Onset in adulthood

### EPIDEMIOLOGY

#### Incidence

- Lifetime risk of a single episode up to 50%
- 20% of the population has RAS:
  - Female preponderance

### RISK FACTORS

- Genetics: 30–40% of patients with RAS have a family history of aphthous ulcers:
  - Multiple gene inheritance pattern, penetrance affected by multiple factors
- Dental appliances (braces) can cause mouth trauma, increasing the frequency of ulcers
- See Commonly Associated Conditions.

### GENERAL PREVENTION

- Prevention of mouth trauma:
  - Dental wax on braces
  - Avoid toothbrush abrasions.
  - Avoid abrasive foods and citrus fruits.
  - Avoid chemical irritants, including toothpaste containing sodium lauryl sulfate.
- Decreasing physical and emotional stress and improving rest may decrease the frequency of episodes.
- Consider treating deficiencies in iron, zinc, folate, and B vitamins.

### PATHOPHYSIOLOGY

- Conflicting theories increasingly support immune dysregulation.
- Cells in an area of diminished mucosal barrier may become the targets of a cell-mediated immune reaction:
  - Targeted by lymphocytes and Langerhans cells
- Antibody formation and complement fixation induced by L-forms of streptococci may play a role in pathophysiology.

### ETIOLOGY

- Current evidence suggests a genetic and immunologic predisposition.
- Most cases are idiopathic:
  - No proven viral associations

### COMMONLY ASSOCIATED CONDITIONS

- Behçet disease:
  - Vasculitis:
    - Diagnostic criteria include a min of 3 oral outbreaks per year plus 2 additional extraoral areas of involvement.
    - Findings may not be present simultaneously but may be elicited by history.
  - Oral and genital lesions similar to all 3 types of RAS
  - Cutaneous lesions
  - Uveitis, retinal vasculitis, optic neuritis, and vascular occlusion may lead to blindness.
  - Arthralgia
  - Progressive neurologic involvement in 20% of patients
- Inflammatory bowel disease (IBD):
  - Crohn disease can involve any portion of the GI tract, including the mouth.
- HIV and AIDS:
  - Gingival involvement is a differentiating feature.
  - May have severe debilitating RAS
- Periodic fever with aphthous stomatitis, pharyngitis, and adenitis (PFAPA syndrome):
  - Onset 2–5 yr with slight male predominance
  - Cyclic event of 3–6-wk intervals with fever lasting ≤5 days
  - Otherwise healthy child
  - Dramatic defervescence and symptomatic relief with 1 dose of prednisone
  - Mouth lesions are small and few and involve the lips and buccal mucosa
  - Pharyngitis and cervical adenopathy
  - Syndrome generally resolves within 5 yr
- Celiac disease:
  - Adherence to a glutenfree diet may promote resolution.
- Cyclic neutropenia
- Iron and possibly zinc deficiency

## DIAGNOSIS

### HISTORY

- History of lesions:
  - Prodrome of tingling or burning at site
  - Erythematous papule forms
  - Develops into a painful ulcer
  - Length of healing stage depends on severity
- Age at onset of lesions
- Apparent provocative and relieving factors including emotional stressors and menstrual cycle
- Frequency of episodes
- Impact on quality of life
- Known underlying health conditions
- Associated symptoms: Fever, malaise, genital ulcers, ocular and musculoskeletal involvement

### PHYSICAL EXAM

- Vital signs
- Toxicity
- Hydration and nutrition
- Location, size, number and appearance of lesions:
  - Minor RAS: Lesions limited to the floor of mouth, tongue, soft palate, and buccal and labial mucosa
- Submental adenopathy is common.
- Facial edema:
  - Seen with major RAS
- Findings outside the oral mucosa suggest the possibility of other associated diseases.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

May occasionally be indicated to look for etiology for RAS:

- CBC with differential to rule out cyclic neutropenia
- Consider serum ferritin, folate, and B vitamin levels
- Biopsy for recalcitrant atypical lesions
- Tzanck smear to rule out herpes simplex

#### Pathological Findings

- Biopsy rarely is required and is not diagnostic:
  - May be required if suspicion of granulomatous infection or inflammatory disease
- Lesions have an ulcer base covered by a fibrinopurulent pseudomembrane:
  - Lymphocytosis and mononuclear cells at the margins of the lesion
  - Superficial tissue necrosis
  - Neutrophils and debris cover the area of necrosis.
  - Dilated blood vessels

### DIFFERENTIAL DIAGNOSIS

- Geographic tongue:
  - Migratory glossitis in a maplike pattern
  - Rarely painful
- Trauma:
  - Burns from hot foods or caustics
  - Biting or sucking injuries to the buccal mucosa and palate

- Herpes simplex gingivostomatitis:
  - Fever (primary herpes infection)
  - Initial lesions are vesicular.
  - Lesions may be extraoral.
  - Lesions occur on keratinized mucosa such as the hard palate and gingiva in addition to distribution of aphthous ulcers.
- Herpangina (coxsackie A virus):
  - Fever
  - Multiple lesions
  - Initially vesicular and then ulcerative with an erythematous base, limited to the posterior pharynx, uvula, and soft palate
- Hand-foot-and-mouth disease (HFMD; coxsackie A 16):
  - Fever
  - Vesicles that progress to ulcers on an erythematous base limited to the anterior buccal mucosa, tongue, and hard palate
  - Papules and vesicles on hands, feet, knees, elbows, and buttocks
  - Other enteroviruses can cause both herpangina and HFMD
- Oral lichen planus:
  - White patches on buccal mucosa, plaque on tip of the tongue, erosions of gingiva
  - May be associated with cutaneous or genital involvement
  - Oral lesions are rare in children.

**TREATMENT**

**MEDICATION**

**First Line**

- Antimicrobial mouth rinses
- Topical anesthetics:
  - Topical benzocaine available in gel, liquid (Anbesol or Orajel), or adhesive disc (Orajel protective discs) 4 times a day
- Topical steroids:
  - For symptomatic relief of severe or recurrent outbreaks
  - Topical triamcinolone acetonide or hydrocortisone hemisuccinate cream or ointment applied sparingly b.i.d.
  - Steroid rinses can be used for posterior lesions, prednisolone 1 mg/kg/day swish and spit 2 times a day
  - May predispose to candidal overgrowth
- Menthol:
  - Short-acting local anesthetic:
    - Lozenges
    - Over-the-counter Canker Cover is menthol in an adhesive disc.

**Second Line**

- Intra- and perilesional glucocorticoids for deep or prolonged major lesions as a single intramuscular injection
- Oral steroids:
  - Prednisone 1 mg/kg/day tapered over 2 wk
  - May also use rinse and swallow prednisolone 1 mg/kg/day b.i.d. for combined topical and systemic treatment

**COMPLEMENTARY & ALTERNATIVE THERAPIES**

- Topical and systemic tetracycline is a traditional therapy with questionable efficacy.
- No support for use of antivirals
- Levamisole, colchicine, gamma globulin, dapsone, estrogen replacement, empirical zinc replacement, and monoamine oxidase inhibitors are all therapies with limited data to support their use.
- Vitamin B<sub>12</sub>: Empirical or with documented deficiency
- Licorice root extract (eg, paste or CankerMelts discs, OTC patches) may heal or reduce extension of existing lesions.
- Barrier-protective gels like cyanoacrylate (Orabase Sooth-N-Seal) protect ulcers from acidic foods and trauma.
- Debacterol, a topic sulfuric acid/phenolic solution (cauterizing agent) that is not FDA approved
- Thalidomide:
  - Inhibits the production of cytokines
  - Found to be effective in numerous studies of HIV with severe RAS as well as Behçet disease and major RAS
  - Teratogenic:
    - May only be prescribed under FDA-mandated System for Thalidomide Education and Prescribing Safety (STEPS)
  - Additional side effects of rash and somnolence

**SURGERY/OTHER PROCEDURES**

Silver nitrate cautery improves pain but not healing time.

**DISPOSITION**

- The vast majority of patients with RAS can be managed as outpatients.
- Severe outbreaks of major RAS and associated conditions may rarely require hospitalization for IV hydration and parenteral analgesia.

**Discharge Criteria**

Ability to remain hydrated and nourished

**Issues for Referral**

- Severe RAS requires referral to a dermatologist or oral maxillofacial surgeon.
- Suspicion for Behçet disease or HIV disease may require referral to an immunologist.
- Suspicion for IBD may require referral to a gastroenterologist.

**FOLLOW-UP**

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**

Pregnancy monitoring for females on systemic medications

**DIET**

Avoid acidic, spicy, salty, or abrasive foods.

**PROGNOSIS**

- Episodes of minor RAS become less frequent as the patient ages.
- Major RAS and herpetiform RAS are chronic health problems that may be controllable with appropriate medications but do not remit.

**COMPLICATIONS**

Major RAS and associated conditions:

- Scarring
- Dehydration and weight loss secondary to decreased oral intake
- Chronic pain with decreased quality of life

**ADDITIONAL READING**

- Hand-Foot-and-Mouth Disease
- Herpes Simplex
- Inflammatory Bowel Disease
- Oral Lesions
- Stomatitis

**CODES**

ICD9  
528.2 Oral aphthae

**PEARLS AND PITFALLS**

- Pearls:
  - Recent alternative therapies provide the potential for control of RAS symptoms.
- Pitfalls:
  - Failure to obtain an adequate history and perform an adequate physical exam to identify associated conditions such as Behçet disease and predisposing conditions such as AIDS and IBD
  - Failure to recognize the impact on quality of life for patients with major RAS

# APLASTIC ANEMIA

Dana Aronson Schinasi

## BASICS

### DESCRIPTION

- Aplastic anemia is characterized by pancytopenia and a hypocellular bone marrow.
- May be inherited (congenital) or acquired:
  - >80% of cases are acquired.

### EPIDEMIOLOGY

#### Incidence

- Incidence is ~2 per million people per year in the U.S. (1).
- Incidence is triphasic, with peaks at (2):
  - 2–5 yr of age, due to inherited causes
  - 20–25 yr
  - >60 yr

### RISK FACTORS

- No age, sex, or racial predominance
- Risk for acquired aplastic anemia is higher in the setting of:
  - Viral infection (Epstein-Barr virus, parvovirus B19, hepatitis, HIV)
  - Drugs (NSAIDs, chloramphenicol, sulfonamides, carbamazepine, cimetidine, nifedipine)
  - Toxins (nitrous oxide, radiation, benzene)
  - Autoimmune disease (systemic lupus erythematosus)
  - Pregnancy
  - Graft vs. host disease (GVHD)

### GENERAL PREVENTION

Avoidance of risk factors, if known

### PATHOPHYSIOLOGY

- Mostly unknown, although immune dysfunction has been implicated in the pathogenesis (3)
- Involves loss of, or injury to, pluripotent hematopoietic stem cells (4):
  - In absence of infiltrative bone marrow process

### ETIOLOGY

- Inherited (congenital):
  - See Commonly Associated Conditions.
  - Familial aplastic anemia
- Acquired:
  - Idiopathic: No clear etiology is identified in the majority of children with acquired aplastic anemia.
  - Following orthotopic liver transplantation

### COMMONLY ASSOCIATED CONDITIONS

- Fanconi anemia
- Shwachman-Diamond syndrome
- Dyskeratosis congenita
- Amegakaryocytic thrombocytopenia (thrombocytopenia-absent radius syndrome)
- Diamond-Blackfan syndrome
- Cartilage-hair hypoplasia
- Pearson syndrome
- Dubowitz syndrome
- Paroxysmal nocturnal hemoglobinuria

## DIAGNOSIS

### HISTORY

- Clinical presentation is variable and is based on the degree of pancytopenia, and specific cell lines that are depleted:
  - Progressive anemia: Suggested by history of fatigue, pallor, dyspnea, headache
  - Neutropenia: Suggested by history of fever, mucosal ulcerations, recurrent bacterial infections
  - Thrombocytopenia: Suggested by easy bruising, petechiae, jaundice, mucous membrane bleeding
- Recent infection, medication use, radiation treatment or exposure
- History of failure to thrive, short stature, and nail, skin, or hair anomalies may point to an underlying inherited syndrome.
- Family history of anemia

### PHYSICAL EXAM

- Pallor is usually the first sign of aplastic anemia:
  - May be accompanied on skin exam by bruising, petechiae, purpura
- Findings on cardiovascular exam range from tachycardia and systolic flow murmur to overt signs of heart failure such as weak pulses, prolonged capillary refill, pulmonary congestion, and hepatomegaly.
- Jaundice and tender hepatomegaly may be seen in some patients.
- Splenomegaly may be present.
- Specific findings of certain inherited syndromes (5):
  - Fanconi anemia: Microcephaly, strabismus, short stature, mental retardation, hyperpigmentation, hypopigmentation, thumb anomalies, skeletal anomalies
  - Shwachman-Diamond syndrome: Eczema, skeletal anomalies
  - Dyskeratosis congenita: Oral leukoplakia, dysmorphic nails, dental anomalies, exudative retinopathy
  - Amegakaryocytic thrombocytopenia: Absent radii
  - Diamond-Blackfan syndrome: Cleft palate, micrognathia, thumb anomalies

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

- CBC:
  - Anemia: Usually normocytic, may be macrocytic
  - Neutropenia, with toxic granulation
  - Absence of blast cells
  - Thrombocytopenia
  - Normal morphology on peripheral smear; no suggestion of leukemia
  - Reticulocyte count <1%
- Coombs test, lactate dehydrogenase, renal and hepatic function tests may be useful in evaluating the etiology
- Serologic viral testing for Epstein-Barr virus, parvovirus, hepatitis, and HIV, as indicated

### Imaging

No imaging is needed to establish the diagnosis of aplastic anemia.

### Diagnostic Procedures/Other

Bone marrow aspiration and biopsy:

- Staging is based on exam of peripheral blood and marrow and has implications for treatment and outcome.

### Pathological Findings

Bone marrow aspiration and biopsy:

- Hypocellular marrow with fatty replacement
- Absence of abnormal infiltrates or fibrosis

### DIFFERENTIAL DIAGNOSIS

- Acute lymphoblastic leukemia
- Acute myelogenous leukemia
- Bone marrow infiltration
- Chemotherapy effects
- Human herpesvirus 6
- Megaloblastic anemia
- Multiple myeloma
- Myelodysplastic syndrome
- Non-Hodgkin lymphoma
- Osteopetrosis
- Splenic sequestration

## TREATMENT

### PRE HOSPITAL

- Assess and stabilize airway, breathing, and circulation.
- Stop exposure to possible offending agent, if known.

### INITIAL STABILIZATION/THERAPY

- Support hemodynamics:
  - Crystalloid IV fluids are the initial fluids of choice to support circulation.
  - Since aplastic anemia is usually of gradual onset, most patients are well compensated and can tolerate moderate levels of anemia.
  - Blood and platelet transfusions: Goal is relief of symptoms of poor tissue oxygenation or CHF, not restoration of normal hemoglobin levels.
  - Exposure to HLA may adversely affect future engraftment of transplanted bone marrow; therefore, transfusions should be used judiciously.
  - Irradiated, cytomegalovirus-negative blood products should be used to minimize alloimmunization
- Spontaneous bleeding may occur with platelet counts <10,000/ $\mu$ L; consider transfusion at these levels.

**MEDICATION****First Line**

Broad-spectrum antibiotics to cover potentially life-threatening infections in the setting of fever with neutropenia:

- Vancomycin 10 mg/kg/dose IV q6h
- Ceftriaxone 50–75 mg/kg/dose IV q24h
- No role for prophylactic antibiotics with neutropenia in the absence of fever

**Second Line**

- Immunosuppressive therapy (when no HLA-matched sibling is available):
  - Antithymocyte globulin 40 mg/kg/day for 4 days
  - Cyclosporine 12 mg/kg/day IV starting on day 5 for 3–6 mo
  - Prednisone 40 mg/m<sup>2</sup>/day (max single dose 60 mg/day) PO for 2 wk
  - Recombinant human granulocyte colony-stimulating factor 5 μg/kg/day SC for 28 days
- HLA-matched unrelated donor hematopoietic cell transplantation

**SURGERY/OTHER PROCEDURES**

A central venous catheter is required for the administration of immunosuppressive therapy and hematopoietic cell transplantation.

**DISPOSITION****Admission Criteria**

Critical care admission criteria:

- Hemodynamic instability, persistent or uncontrolled bleeding, septic shock
- All patients with neutropenia and fever require admission for broad-spectrum antibiotics, while awaiting culture and sensitivity results.
- All patients with a new diagnosis require admission for further diagnostic testing and for initiation of therapy.

**Discharge Criteria**

- Patients should not be discharged from the emergency department without consultation with a pediatric hematologist.
- Patients deemed eligible for discharge by a pediatric hematologist must have normal vital signs, be afebrile, and be without signs of CHF or bleeding.

**Issues for Referral**

Diagnostic and management decisions should always be made in consultation with a pediatric hematologist.

**COMPLEMENTARY & ALTERNATIVE THERAPIES**

HLA-matched sibling donor hematopoietic cell transplantation is the treatment of choice for children with severe or very severe disease (6):

- Survival rates are better than using immunosuppression alone.

**FOLLOW-UP****FOLLOW-UP RECOMMENDATIONS**

- Discharge instructions and medications:
  - Patients should return to the emergency department if they develop fever, prolonged bleeding, or signs of heart failure.
  - Medications vary based on severity and should be prescribed in conjunction with a pediatric hematologist.
- Activity:
  - Patients with splenomegaly or thrombocytopenia should avoid contact sports.
  - Dental work should be postponed until the patient is no longer neutropenic.

**Patient Monitoring**

- Blood counts should be monitored on a regular basis.
- Patients should be monitored for adverse effects of immunosuppressive therapies.

**DIET**

- Avoid potential causative agents.
- Neutropenic patients should avoid raw meats, dairy products, and certain fruits and vegetables.
- Salt restriction is recommended while on cyclosporine or steroid therapy.

**PROGNOSIS**

Depends on severity of pancytopenia (7):

- The spontaneous recovery rate is not well established (1).
- Estimated 5-yr survival rate for patients receiving an HLA-matched sibling donor hematopoietic stem cell transplant is >90% (6).
- Estimated 5-yr survival rate for patients receiving immunosuppression is 75% (1).

**COMPLICATIONS**

- Complications of aplastic anemia include infections and bleeding.
- Complications related to immunosuppressive therapies and conditioning regimens for stem cell transplantation include GVHD and graft failure.

**ADDITIONAL READING****See Also (Topic, Algorithm, Electronic Media Element)**

- Acute Hemolytic Anemia
- Anemia
- Leukemia
- Lymphoma

**ICD9**

- 284.01 Constitutional red blood cell aplasia
- 284.89 Other specified aplastic anemias
- 284.9 Aplastic anemia, unspecified

**PEARLS AND PITFALLS**

- In contrast to those with leukemia, children with aplastic anemia should have WBCs of normal morphology on the peripheral smear.
- Patients with fever and neutropenia require broad-spectrum antibiotics and admission.

# APNEA

Robin L. Altman  
Ilene A. Claudius

## BASICS

### DESCRIPTION

- Apnea of infancy is an unexplained episode of cessation of breathing either  $\geq 20$  sec duration or accompanied by bradycardia, cyanosis, pallor, or marked hypotonia (1).
- Apnea of prematurity is the cessation of breathing for  $\geq 20$  sec or accompanied by a decrease in heart rate of at least 30 bpm or oxygen desaturation below 85% in an infant  $< 37$  wks PCA. Apnea of prematurity usually resolves by 43 wks postconceptual age (2,3).
- Periodic breathing is a normal immature respiratory pattern in which infants pause in breathing for several seconds without cyanosis. Parents may easily mistake this for true apnea (4).
- Apnea can be part of an apparent life-threatening event (ALTE). (See Apparent Life-Threatening Event topic.)
- 3 categories of apnea:
  - Central: Absence of respiratory effort
  - Obstructive: Breaths associated with no air movement or with paradoxical inverse movements of the chest wall and abdomen
  - Mixed: Features of both

### EPIDEMIOLOGY

#### Incidence

2,000–10,000 episodes of acute infantile apnea per year in the U.S.

#### Prevalence

- 0.2–0.9% of infants have apnea leading to admission.
- Up to 5.3% of all parents report periods of infantile apnea  $> 20$  sec when questioned.
- 2–10% of the pediatric population has obstructive sleep apnea in the U.S. (See Obstructive Sleep Apnea topic.)
- 70% of infants born at  $< 34$  wk estimated gestational age experience apnea of prematurity.

### RISK FACTORS

- Infants  $< 1$  yr, especially between 1 and 3 mo of age
- Prematurity
- Respiratory infection, especially respiratory syncytial virus (RSV)
- GERD or other feeding difficulties
- Congenital upper airway compromise
- Neuromuscular disorder
- Head trauma
- Sepsis
- Risk of apnea of prematurity increases with decreasing gestational age at birth.

### GENERAL PREVENTION

- Risk factors identified to decrease the incidence of sudden infant death syndrome (SIDS) do not seem to impact infantile apnea (5).
- Measures to decrease premature delivery

### PATHOPHYSIOLOGY

- Central apnea: Disruption of respiratory signals from the CNS
- Obstructive apnea: Attempt at breathing through an occluded airway
- Cyanosis: Hemoglobin desaturation from impaired oxygen exchange or distribution
- Altered muscle tone can be CNS or vasovagally mediated processes.
- Apnea of prematurity: Immaturity of breathing responses to hypoxia, hypercarbia, and inhibition of airway receptors (6)

### COMMONLY ASSOCIATED CONDITIONS

See Differential Diagnosis.

## DIAGNOSIS

### HISTORY

- Birth history
- Central vs. obstructive
- Thorough description of the apnea, including who witnessed it
- Feeding and growth history
- Fever
- Respiratory symptoms
- Seizure activity
- History of previous ALTEs
- Family history of SIDS
- Medication use (including over the counter)
- Trauma (accidental or suspected nonaccidental)
- Degree of resuscitation required
- Proximity to feeds

### PHYSICAL EXAM

- Toxic or ill appearing
- Vital signs
- Signs of distress
- Cyanosis
- Pallor
- Respiratory findings
- Cardiac findings
- Mental status
- Muscle tone (limpness or stiffness)
- Focal neurologic findings
- Skin lesions
- Any evidence of trauma, including retinal hemorrhages
- Blood in nares
- Recurrent episodes

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

- Oxygen saturation or arterial blood gas, especially if suspecting acidosis
- Consider complete sepsis evaluation if ill appearing or  $< 60$  days old with history of prematurity (7).
- Consider urinalysis and urine culture in all-aged patients (8,9).
- RSV, influenza, or pertussis testing if clinically indicated
- Consider urine toxicology testing if poisoning, either intentional or unintentional, is suspected (10), though urine toxicology testing is center dependent and usually limited to drugs of abuse.
- Consider glucose and electrolytes if the history is suggestive (acute gastroenteritis, dehydration, underlying medical problem, inappropriate formula mixing, seizures, medication use).
- Additional labs if clinically indicated only

#### Imaging

- Chest radiograph
- Head neuroimaging as indicated based on the history and suspicion of injury (including nonaccidental trauma)

#### Diagnostic Procedures/Other

- Workup for GERD or seizures (if clinically indicated) can be performed on either an inpatient or outpatient basis.
- Pneumocardiogram may be performed for patients without a clear etiology felt to be at high risk of recurrent apnea (eg, premature infants, patients with recurrent apneas or subsequent apneas in the emergency department, significant apneic event requiring substantial resuscitation).
- Consider ECG or Holter testing for suspicion of arrhythmia, QT prolongation, or cardiac history.

### DIFFERENTIAL DIAGNOSIS

- Seizure
- GERD
- Lower respiratory tract infection
- Bronchiolitis
- Pertussis
- Upper respiratory tract infection
- Nonaccidental head injury, intentional poisoning, intentional suffocation
- Coughing or gagging on mucus
- Breath-holding or other vasovagal episode
- Acute hypoglycemia or electrolyte abnormality
- Sepsis or serious bacterial infection, including urinary tract infection
- Arrhythmia

## TREATMENT

### PRE HOSPITAL

Assess and stabilize airway, breathing, and circulation.

### INITIAL STABILIZATION/THERAPY

- Assess and stabilize airway, breathing, and circulation.
- For recurring apneas or an ill-appearing patient, rapid stabilization and initial therapies focus on airway control, respiratory support as needed, and consideration of sepsis or other life-threatening conditions such as head injury.
- For the child with recurrent apneas, consider a targeted workup of the potential underlying cause.

### MEDICATION

#### First Line

- Oxygen may be needed with significant apnea and/or cyanosis.
- If a cause is identified or suspected, targeted therapy should be initiated (eg, anticonvulsant for suspected seizure or bronchodilator for bronchoconstriction).
- Further therapy should be determined based on the suspected etiology.

#### Second Line

- For apnea of prematurity, methylxanthines and CPAP are the mainstays of therapy:
  - Aminophylline:
    - Loading dose: 5 mg/kg PO/IV
    - Maintenance dose: 1–2 mg/kg/dose q6–8h
  - Caffeine:
    - Loading dose: 10 mg/kg PO/IV
    - Maintenance dose: 5–10 mg/kg PO/IV per day
  - Theophylline:
    - Loading dose: 5 mg/kg PO
    - Maintenance dose: 3–6 mg/kg/day PO divided q6–8h
- Further therapy should be determined based on the suspected etiology.

### DISPOSITION

#### Admission Criteria

- Floor admission:
  - Ill appearance
  - Condition (eg, sepsis) requiring admission
  - Age <43–48 wk postconceptual age
  - Consider admission for high-risk apneic event (eg, multiple apneas, bradycardia, significant and prolonged change in tone and color)
  - Respiratory acidosis
  - Risk for child abuse
  - Physical exam findings, lab testing, or medical or family history that is concerning enough to the health care provider to necessitate admission
  - Marked obstructive apnea with associated hypoxia or hypercarbia
  - Physician or parental concern regarding severity of event, degree of resuscitation needed, medical history
  - Apnea of prematurity requiring initiation of methylxanthines
- Critical care admission criteria:
  - Need for intubation or recurrent apneic episodes that might portend the need for intubation
  - Identification of underlying disease requiring critical care monitoring

### Discharge Criteria

- Well appearing
- Normal physical exam
- Single episode of apnea without high-risk features
- >43–48 wk postconceptual age
- Abuse is not suspected.
- Follow-up is ensured.
- Family is comfortable with discharge.

### Issues for Referral

- Patients diagnosed with or suspected to have seizures should be referred to neurology.
- Patients with GERD should be referred to their primary care provider or gastroenterology.
- Patients with recurrent apneas or apnea of prematurity should be referred to pulmonology.

## FOLLOW-UP

### FOLLOW-UP RECOMMENDATIONS

- Discharge instructions and medications are guided by the cause and use of xanthine therapy.
- No activity restrictions
- Parents should be taught infant CPR

### Patient Monitoring

- Close primary care provider follow-up is required.
- Consider consultation by pulmonology for home monitoring of preterm infants with extreme apnea, infants with anatomic abnormalities susceptible to airway compromise, infants with neurologic or metabolic disorders affecting respiratory control, and infants with chronic lung disease (1).

### PROGNOSIS

- Apnea of prematurity typically resolves by 43 wk postconceptual age.
- Risk of SIDS after an uncomplicated ALTE is 0–3%. Children with recurrent ALTEs or those requiring significant resuscitation may have an increased risk of future SIDS. This data can be applied to apnea as well.

### See Also (Topic, Algorithm, Electronic Media Element)

Obstructive Sleep Apnea

### ICD9

- 770.81 Primary apnea of newborn
- 770.82 Other apnea of newborn

## PEARLS AND PITFALLS

- A good history is key to determining the cause.
- Consider occult child abuse.
- It is essential to address parental concerns. If apneic events are recurrent, ensure that parents have been trained in infant CPR.

# APPARENT LIFE-THREATENING EVENT

Kevin Ching

## BASICS

### DESCRIPTION

- According to the NIH, an infant apparent life-threatening event (ALTE) is an unexpected, frightening episode that is characterized by some combination of (1):
  - Apnea (central, obstructive, or mixed)
  - Color change (cyanosis, pallor, redness, or plethora)
  - Marked change in muscle tone (limpness or rigidity)
  - Choking or gagging
  - Fear (in some cases) that the infant has died
- An ALTE may prompt the caregiver to stimulate or resuscitate the infant before recovery.

### EPIDEMIOLOGY

#### Incidence

Unknown, though estimates range from 0.5–6% (2):

- Most occur in infants <1 yr of age, peaking at 1 wk to 2 mo of age (3).

### RISK FACTORS

- Prematurity
- Infection with respiratory syncytial virus (RSV)
- Male gender
- Prone sleeping position
- Feeding difficulties
- History of apnea, cyanosis, or pallor

### PATHOPHYSIOLOGY

- The pathophysiology of ALTE in infants is unclear.
- Apnea (1):
  - Cessation of respiratory airflow for any reason:
    - In central apnea, respiratory pauses may be caused by CNS immaturity, seizures, or tumors.
    - In obstructive apnea, breathing may be obstructed by a laryngeal web, vascular ring, tracheoesophageal fistula, or foreign body.
  - In pathologic apnea, there is a respiratory pause >20 sec accompanied by bradycardia, cyanosis, pallor, hypotonia, or other signs of compromise.
  - In apnea of infancy, there is an unexplained respiratory pause >20 sec, or <20 sec when accompanied by bradycardia, cyanosis, pallor, hypotonia, or other signs of compromise.
  - Periodic breathing is a normal respiratory pattern involving  $\geq 3$  brief pauses interrupted by <20 sec of normal respirations in between (no bradycardia, cyanosis, or hypotonia).

### ETIOLOGY

An underlying diagnosis is identified in only 50% of cases (~50% are idiopathic):

- GI:
  - Gastroesophageal reflux
  - Intussusception
  - Volvulus
  - Swallowing incoordination
- Neurologic:
  - Seizure
  - CNS hemorrhage
  - Hydrocephalus
  - Chiari malformation
  - Central hypoventilation syndrome
  - Vasovagal syncope
- Respiratory:
  - Laryngotracheomalacia
  - Vocal cord dysfunction
  - Vascular ring
  - Obstructive sleep apnea
  - Foreign body aspiration
  - Congenital airway anomalies
  - Stimulation of laryngeal chemoreceptors
  - Breath-holding spell
- Cardiac:
  - Congenital heart disease (eg, ductal-dependent lesion)
  - Dysrhythmia (eg, long QT, Wolff-Parkinson-White syndrome)
  - Cardiomyopathy
  - Myocarditis
- Metabolic/Endocrine:
  - Inborn error of metabolism
  - Endocrine disorder
- Infection:
  - Sepsis or meningitis
  - RSV
  - Pertussis
  - Croup
  - Pneumonia
- Child abuse:
  - Physical abuse
  - Munchausen by proxy (eg, suffocation, intentional poisoning, head trauma)
- Normal:
  - Respiratory pauses
  - Periodic breathing

## DIAGNOSIS

### HISTORY

Detailed accounts from witnesses (caretaker) and emergency prehospital personnel may provide important insight on nature of event:

- Condition:
  - Awake, asleep, crying, position (prone vs. supine)
- Activity during event:
  - Coughing, feeding, vomiting, gagging
- Respiratory effort:
  - Fast, slow, shallow, stridor, gasping, choking, none
- Color:
  - Red, blue, purple, pale
- Tone and movement:
  - Limp, rigid, convulsions
- Duration:
  - Time to recovery (eg, normal respiratory pattern or tone)
- Interventions (and duration):
  - None, gentle or vigorous stimulation, artificial respirations, CPR
- Recent illnesses
- Past medical history:
  - Prenatal care
  - Prematurity
  - Developmental history
  - Feeding history
  - Sleep habits
  - Prior events
- Family/Social history:
  - Siblings with sudden infant death syndrome (SIDS)
  - Dysrhythmias
  - Medications in home
  - Smoking, alcohol, or substance abuse

### PHYSICAL EXAM

- Infants may appear well without any signs or symptoms of pathology:
  - In 1 study, 83% of infants evaluated by paramedics had unremarkable physical exams after an ALTE (4).

- Thorough exam:
  - General:
    - Height, weight, head circumference (compared to norms)
    - Dysmorphisms
    - Vital signs
  - Neurologic assessment:
    - Muscle tone, posture
  - Developmental assessment:
    - Age-appropriate milestones
  - Respiratory and cardiac:
    - Stridor, wheezes, rales
    - Murmurs
    - BP differential
  - Signs of trauma:
    - Consider dilated funduscopy.

## DIAGNOSTIC TESTS & INTERPRETATION

### Lab

- Lab testing should be guided by the history and physical exam findings.
- No standard for the minimum lab and radiographic testing exists (5).

### Initial Lab Tests

- High-yield studies include:
  - Bedside glucometry
  - CBC
  - Urinalysis
  - Electrolytes, BUN, calcium, magnesium
  - Serum bicarbonate
  - Serum lactate
- Other tests to consider:
  - Toxicology screen
  - Metabolic screening (eg, ammonia)
  - Respiratory virus screens (eg, RSV, pertussis)
  - CSF analysis
  - Blood and urine cultures

### Imaging

- CXR: High yield
- Neuroimaging
- Skeletal survey

### Diagnostic Procedures/Other

- ECG
- Screen for gastroesophageal reflux (eg, esophageal pH probe or upper GI series)
- Echo
- Multichannel polysomnography

## DIFFERENTIAL DIAGNOSIS

See Etiology.

## TREATMENT

### INITIAL STABILIZATION/THERAPY

- Assess and stabilize airway, breathing, and circulation.
- Management is dependent on presentation and condition.
- Most infants appear well on presentation, and minimal stabilization and therapy will be required.

### DISPOSITION

#### Admission Criteria

- Admission criteria vary: Some institutions routinely admit patients with ALTE and perform extensive workup; others do not admit patients and do not routinely conduct lab testing or imaging:
  - It is unclear if there is any superiority of routine admission or routine discharge.
- Any infant who has required resuscitation or whose history, exam, or diagnostic studies suggest any potential abnormalities should be hospitalized for further workup and monitoring.

#### Discharge Criteria

Patients with normal physical exam and no apparent underlying medical problem requiring treatment are potential candidates for discharge:

- In particular, children >30 days old with a single ALTE may be discharged safely from the hospital.

#### Issues for Referral

Subspecialty referral is determined by historical and physical exam findings as well as lab and radiographic findings.

## FOLLOW-UP

### FOLLOW-UP RECOMMENDATIONS

Discharge instructions and medications:

- If there is any problem for which medication prescription is required, take the prescription compliantly.
- Use a supine sleep position.
- Discourage cosleeping.
- Avoid overheating (overbundling).
- Encourage breast-feeding.
- Avoid overfeeding.
- Ensure timely vaccinations.
- Eliminate any exposure to tobacco smoke.
- Seek training in CPR.

#### Patient Monitoring

- Cardiopulmonary monitoring, such as an apnea alarm, is of no proven benefit.
- Parents should monitor for recurrent episodes of ALTE or other illness.

## PROGNOSIS

- Highly variable: Dependent on underlying condition
- The recurrence rate for severe ALTE is as high as 68%.
- Overall risk of death is <1% (2).

## CODES

### ICD9

799.82 Apparent life threatening event in infant

## PEARLS AND PITFALLS

- Infants typically are well appearing with a normal physical exam after ALTE.
- There is a lack of evidence supporting or refuting management styles. The range of appropriate management is a spectrum from no lab or imaging evaluation and routine discharge to routine admission and lab investigations.
- Children >30 days old with a single ALTE and normal exam are particular candidates for safe home discharge.
- Child abuse can present as an ALTE.
- Studies have not confirmed a link between ALTE and SIDS.

# APPENDICITIS

Lindsey Tilt

Anupam Kharbanda

## BASICS

### DESCRIPTION

- Appendicitis is an inflammation of the appendix, a blind-ending structure that arises from the cecum.
- Occurs in 1 in 15 individuals (7%)
- Males > females (3:2)
- Familial predisposition
- Seasonal peak: Spring and fall
- Diet may influence frequency of appendicitis:
  - Countries with high-fiber diets have a lower incidence of appendicitis as compared to those with lower-fiber diets (1).
- Mortality is low (<1%), but morbidity is high and mostly associated with perforation.
- Perforation occurs in 15–30% of patients but is not evenly distributed through age groups:
  - Greatest in children <4 yr; this is thought to be, in part, due to patients' inability to communicate their symptoms.
  - Perforation usually occurs within 36–48 hr of onset of symptoms.
  - Prevalence of perforation with symptoms >36 hr is as high as 65% (2).

### EPIDEMIOLOGY

#### Incidence

- 1–2 in 10,000 children per year <4 yr of age
- 25 in 10,000 children per year in 10–17 yr olds (1)
- Most common in the 2nd decade of life (2)

### GENERAL PREVENTION

In any child having abdominal surgery, elective appendectomy should be considered to obviate the future risk of appendicitis.

### PATHOPHYSIOLOGY

- The 2 leading hypotheses are:
  - Luminal obstruction:
    - Obstruction trapping mucus in the appendix, leading to elevated intraluminal pressure
    - Increased pressure leading to impaired perfusion and venous drainage and thus ischemia of the appendix
    - Bacteria entering the compromised tissue, leading to inflammatory infiltrate and eventually necrosis
  - Direct invasion:
    - Direct bacterial invasion of the ulcerated mucosa of the appendix after enteric infections
    - May explain why appendicitis is more common in the spring and fall, when enteric infections are at a peak (1,3)
- Appendicitis and perforation represent a continuum of disease.
- Patient signs and symptoms correlate with degree and timing of inflammation:
  - Initially, isolated inflammation within the appendix causes edema and inflammatory infiltration of the appendiceal wall. Early distention of the appendix triggers visceral pain, which is transmitted primarily through sympathetic fibers traveling to the spinal cord along T10, so pain is appreciated as periumbilical and vague.

- Progression to suppurative appendicitis occurs when bacteria and inflammation spread transmurally to the serosa of the appendix and inflammatory exudate irritates neighboring tissues. This surrounding tissue is innervated by the T12 and L1 spinal nerves, which causes somatic pain that the patient localizes in the right lower quadrant (RLQ).
- Ultimately, gangrenous appendicitis may occur, which involves necrosis of the appendiceal wall and can rapidly progress to perforation if untreated.

### ETIOLOGY

- Luminal obstruction: Lymphoid follicle hyperplasia, fecalith, foreign bodies, parasites
- Direct invasion:
  - Enteric infection leads to ulceration of the mucosa.
  - Superinfection leads to inflammation and necrosis. The most common bacteria responsible are *Escherichia coli*, *Bacteroides fragilis*, and *Peptostreptococcus* and *Pseudomonas* species.

## DIAGNOSIS

### HISTORY

- Classic presentation:
  - Abdominal pain:
    - Vague, periumbilical pain develops first.
    - Colicky
    - Unrelated to activity or position
  - Nausea and/or anorexia:
    - Follows the abdominal pain
    - Food refusal is a useful surrogate in children.
  - Migration of pain to the RLQ:
    - Occurs 6–12 hr following onset of pain
    - Pain is exacerbated by movement.
  - Vomiting:
    - Often occurs as the infection progresses
    - Nausea/Vomiting is present in more than half of patients with appendicitis.
    - Classically follows the onset of pain
  - Fever:
    - Common but nonspecific finding in children presenting with appendicitis
- <50% of pediatric patients will present with the classic presentation. Women and toddlers are most likely to have atypical presentations (1), including diffuse abdominal pain, vomiting, or fever.

### PHYSICAL EXAM

- Observe the patient.
- Begin with a component of the physical exam that is not painful (cardiac/pulmonary).
- Assess for difficulty with walking, jumping, or positioning.
- Auscultate bowel sounds, which may be normal, hyperactive, or hypoactive depending on stage of disease.
- Palpate at McBurney point: 1/3 the distance from the right anterior superior iliac spine to the umbilicus
- Assess for specific signs for appendicitis:
  - Rebound tenderness: Pain that is elicited on release of pressure after deep palpation of the abdomen

- Rovsing sign: Pushing on the abdomen in the left lower quadrant elicits pain in the RLQ
- Obturator sign: Pain on passive internal rotation of the flexed right thigh
- Psoas sign: Pain on passive extension of the right thigh with the patient lying on the left side
- Since these maneuvers can be painful to an already uncomfortable child, less forceful alternatives include asking the child to walk or hop and whether that causes pain.
- A pelvic exam should be considered in teenage female patients due to the overlap in presentation of many gynecologic processes.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

- WBC: The likelihood of appendicitis is greatly decreased if the WBC is <10,000/ $\mu$ L (2).
- C-reactive protein (CRP): Combining use of WBC and CRP increases sensitivity of laboratory evaluation of possible appendicitis.
- Urinalysis:
  - May be useful in differentiating appendicitis from a urinary tract infection
  - Sterile pyuria may occur with appendicitis due to the proximity of the inflamed appendix to the bladder. Bacteria and nitrates should be absent in the urine.
- Urine pregnancy test: Useful in ruling out pregnancy as a cause as well as recognition in the event a CT scan is considered
- Serum chemistry: If local practice involves documentation of renal function prior to use of IV contrast with CT scan, obtaining these lab values early may decrease time to CT imaging.

#### Imaging

- X-rays are not routinely useful in the diagnosis of appendicitis, but recognition of a fecalith or free air under the diaphragm may quickly provide radiologic evidence necessary for the decision to undergo surgery.
- US:
  - Findings of appendicitis include a nonperistalsing, noncompressible, blind-ending tubular structure >6 mm in diameter
  - Strengths:
    - Low cost, no radiation, and requires little preparation time
    - Provides dynamic images
    - Especially useful in females, where acute gynecologic disease can often be confused with appendicitis
  - Limitations:
    - Operator dependent, low negative predictive value

- CT scan:
  - Findings of appendicitis include a fluid-filled tubular structure >6 mm in diameter with periappendiceal inflammation.
  - Choice of contrast:
    - Rectal contrast alone is sufficient for the diagnosis of appendicitis (4) but is difficult to administer in young children.
    - Recent literature suggests that CT with IV contrast alone is useful and sufficient (5).
  - Strengths:
    - Not operator dependent
    - No decrease in quality of image with obesity
    - Provides a better view of the extent of disease, which can guide drainage of fluid collections or alternative diagnoses
  - Limitations: Radiation exposure, contrast exposure, higher cost
- A negative or equivocal result on US should be followed with the more sensitive CT scan to reliably exclude appendicitis or to identify those patients with appendicitis missed by US (4).

### DIFFERENTIAL DIAGNOSIS

- General:
  - Gastroenteritis, mesenteric adenitis, constipation, acute pancreatitis, peptic ulcer, Henoch-Schönlein purpura, cholecystitis, inflammatory bowel disease, septic arthritis
  - Meckel diverticulitis, volvulus, referred pain from pneumonia/pleuritis
- Genitourinary:
  - Pregnancy/Ectopic pregnancy, pelvic inflammatory disease, ovarian torsion, follicular rupture, endometriosis
  - Urinary tract infection, nephrolithiasis
  - Testicular torsion, orchitis, hernia

### TREATMENT

#### INITIAL STABILIZATION/THERAPY

- NPO, provide IV fluids, correct any electrolyte abnormalities
- NG tube if there is concern for obstruction or ileus

#### MEDICATION

##### First Line

- Early analgesia is recommended. There is no increase in missed appendicitis or in negative appendectomies after analgesia (6):
  - Morphine 0.1 mg/kg IV/IM/SC q2h PRN
    - Initial morphine dose 0.1 mg/kg IV/SC may be repeated q15–20min until pain is controlled then q2h PRN
- For acute appendicitis, antibiotics are usually given preoperatively to decrease the risk of abscess formation and wound infection:
  - Ampicillin/Sulbactam 100–200 mg ampicillin/kg/day divided q6h to a max of 1–2 g q6h

- Complicated/Advanced appendicitis:
  - Select antibiotics that cover Gram-negative rods and anaerobes. Length of treatment is often influenced by normalization of inflammatory markers and temperature (typically ~1 wk).
  - Piperacillin/Tazobactam:
    - >9 mo of age, <40 kg: 300 mg piperacillin component/kg/day in divided doses q8h
    - >40 kg: 3 g piperacillin/0.375 g tazobactam q6h

#### Second Line

- 2nd-generation cephalosporin:
  - Cefoxitin 100 mg/kg/day divided q6h, max single dose 12 g/day
  - Cefotetan 40–80 mg/kg/day divided q12h, max single dose 6 g/day
- If penicillin allergic: Gentamicin (2–2.5 mg/kg/dose q8h or 5 mg/kg/dose per day) and metronidazole (30 mg/kg/day in divided doses q6h, max single dose 4 g/day)

#### SURGERY/OTHER PROCEDURES

- Acute appendicitis:
  - Surgical treatment is indicated for acute appendicitis.
  - Surgical timing: The choice of when to go to the operating room is variable among individual surgeons/institutions. Debate exists over the risks of delaying surgery in patients who are candidates for appendectomy (eg, delays >8 hr).
- Complicated/Advanced appendicitis (appendicitis with gangrene or perforation of the appendix):
  - Acute presentation of advanced appendicitis (ie, perforation with signs and symptoms <96 hr, without a well-organized abscess on CT) and patients who remain unstable despite resuscitation will go to the operating room for an appendectomy.
  - Patients with stable perforations such as with a well-formed abscess or phlegmons may be observed initially on antibiotics.
  - Some surgeons elect for 10–14 days of outpatient antibiotics followed by an interval appendectomy in 6–8 wk.
  - Interval appendectomy is an increasingly common practice despite the lack of randomized clinical trials comparing this with standard appendectomy.

#### DISPOSITION

All patients with acute appendicitis should be admitted from the emergency department.

### FOLLOW-UP

#### FOLLOW-UP RECOMMENDATIONS

Postoperatively, patients should return if they develop any symptoms of an abdominal abscess, such as abdominal pain, vomiting, or fever.

#### PROGNOSIS

Patients do well after an appendectomy, with most children going home in 24–48 hr. In comparison, in cases of complicated appendicitis, one case study reported a mean hospital length of stay of 6½ days (7).

#### COMPLICATIONS

- Abscess, phlegmon, diffuse peritonitis, cellulitis, small bowel obstruction, ileus, wound infections, fistulas, sepsis, death
- Complications are more common in perforated appendicitis.
- Decreased fertility in females with appendicitis is recognized.

#### CODES

##### ICD9

- 540.0 Acute appendicitis with generalized peritonitis
- 540.1 Acute appendicitis with peritoneal abscess
- 541 Appendicitis, unqualified

#### PEARLS AND PITFALLS

- Failure to diagnose appendicitis is one of the most common causes for malpractice lawsuits in pediatric emergency medicine.
- Younger children, particularly of toddler age, are at increased risk for perforated appendicitis, probably due to inability to communicate pain sensation.

# ARTHRITIS, RHEUMATOID

Helene Tigchelaar  
Usha Sethuraman

## BASICS

### DESCRIPTION

- Juvenile rheumatoid arthritis, or juvenile idiopathic arthritis (JIA), is the most common rheumatic disease of childhood.
- Definition:
  - Arthritis in at least 1 joint for >6 wk in a child <16 yr of age after other causes have been excluded
- Has a highly variable disease course
- Persists into adulthood in many children
- International League of Associations for Rheumatology (ILAR) classification system:
  - 7 clinical subtypes defined
  - Subtypes are different diseases with different genetics, presentations, and clinical features.
- Systemic arthritis JIA (10% of JIA):
  - Peak onset between 1 and 6 yr of age
  - Affects boys and girls equally
  - Arthritis plus daily spiking (intermittent) fevers for >2 wk with toxicity plus  $\geq 1$  of the following:
    - Macular pink rash with fever
    - Serositis, lymphadenopathy, anemia
    - Hepatosplenomegaly, pericarditis
  - Extra-articular symptoms precede arthritis by weeks or months and are self-limiting.
  - Laboratory findings:
    - Antinuclear antibody (ANA) negative
    - Rheumatoid factor (RF) negative
    - Elevated ferritin may occur.
  - In persistent disease, short stature, brachydactyly, and micrognathia can occur.
  - Life-threatening complications like tamponade, vasculitis, and macrophage-activating syndrome (MAS) may occur.
- Oligoarthritis JIA (50% of all cases):
  - <5 joints in 1st 6 mo
  - Large lower joints but rarely hips
  - 2 additional types after 6 mo:
    - Persistent:  $\leq 4$  joints always
    - Extended: >4 joints always
  - Females > males
  - Disease onset between 1 and 5 yr of age
  - Uveitis only systemic symptom (20–25%)
  - ANA positive in 75–85%
  - High risk of uveitis when ANA is positive
- Polyarticular JIA (25% of all cases):
  - $\geq 5$  joints within 1st 6 mo
  - Females > males
  - Morning stiffness, joint swelling
  - Systemic findings are less
- RF negative polyarticular JIA:
  - <10 yr of age, fewer joints
  - No systemic features
  - Asymmetric joint arthritis
  - Often ANA positive (uveitis)
- Polyarticular JIA (RF positive):
  - >8 yr of age
  - Females, more severe disease
  - Symmetric small joint polyarthritis
  - Usually HLA DR4 positive:
    - Progressive, unremitting, adult counterpart
    - Early, aggressive treatment required

- Enthesitis-related JIA:
  - Pain at tendon insertion and joints
  - In addition, two of the following:
    - Sacroiliac tenderness
    - Inflammatory spinal pain
    - Anterior uveitis
    - Positive family history
    - Onset >8 yr of age
    - Positive HLA-B27 (85–92% of cases)
- Psoriatic arthritis:
  - Arthritis and definite psoriasis or two of the following:
    - Dactylitis, nail pitting, onycholysis PLUS
    - Family history
    - Clinically similar to early-onset oligoarticular
  - HLA-B27 positive: Axial arthritis with psoriasis
- Undifferentiated:
  - Arthritis that does not fit current classifications

### EPIDEMIOLOGY

- Studies suggest that JIA is underreported.
- Prevalence is 0.07–4.01 per 1,000 children.
- Lower (26/100,00) in urban African Americans
- Incidence is 0.008–0.226 per 1,000 children.
- Distribution of subtypes varies with population.

### RISK FACTORS

- Genetic predisposition
- Female (in most types)

### PATHOPHYSIOLOGY

- Synovium infiltrated by lymphocytes, plasma cells, macrophages, and dendritic cells
- Fibroblast and synoviocytes proliferate.
- Different autoantigens are targeted.
- Fibrin deposits on/in the synovium
- Joint effusions, erosion, and destruction
- Ends in deformity, subluxation, and ankylosis

### ETIOLOGY

- Poorly understood
- Abnormal autoimmunity involved
- Genetic factors play a strong role
- Specific HLAs identified

## DIAGNOSIS

### HISTORY

- History is key to proper diagnosis.
- Family history (including siblings):
  - Psoriasis, hypermobility syndromes, inflammatory bowel disease (IBD), uveitis, other autoimmune diseases
- Patient history (as above)
- Precipitating factors:
  - Trauma
  - Recent illness (upper respiratory infection, sore throat, enteritis)
  - Medications, activity
- Alleviating factors: Medications, heat, cold
- Review of systems: Patterns of fever, rash, loss of weight, abdominal pain, eye symptoms

- Pattern of pain:
  - Onset, duration; frequency; severity; timing; migration; spinal, muscle, or jaw pain
  - Location and number of joints, symmetry, swelling, warmth or redness
- Stiffness in morning or with immobility

### PHYSICAL EXAM

- Vital signs, general appearance, gait
- Examine heart, lungs, eyes, and skin.
- Examine all joints for symmetry, swelling, redness, tenderness, warmth, pain to palpation or movement, and full range of motion and mobility.
- Muscle strength

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

- Perform limited, focused diagnostic studies.
- CBC with differential, ESR, C-reactive protein:
  - Nonspecific and frequently normal in JIA
- Urinalysis, LFTs, BUN, and serum creatinine:
  - Alternative diagnosis of systemic lupus erythematosus (SLE) or vasculitis
- Ferritin levels for systemic JIA
- Acute joint pain: Consider:
  - Cultures of throat, blood, stool, joint aspirate
  - Inflammatory joint aspirate: 500–75,000 WBC/mm<sup>3</sup>; glucose >50% of serum
  - Septic arthritis: >50,000 WBC/mm<sup>3</sup>; glucose <50% of serum; Gram stain and/or culture positive
  - Serologic testing for Lyme disease and antistreptolysin O (ASO) titer
- Chronic joint pain: ANA and RF:
  - Often negative in JIA and false positive in general population
  - HLA-B27 (associated with IBD, reactive arthritis, psoriatic arthritis, juvenile ankylosing spondylitis)

#### Imaging

- X-ray for arthritis of single joint:
  - Consider x-ray of contralateral joint
  - Early findings:
    - Effusion
    - Soft tissue swelling
    - Osteoporosis, periostitis, new bone formation
  - Late findings:
    - Subchondral erosions
    - Narrowing of cartilage space
    - Bony destruction and fusion
- US for effusion if isolated hip pain or knee pain and swelling

### DIFFERENTIAL DIAGNOSIS

- Trauma
- Infection:
  - Sepsis, bacterial endocarditis, septic arthritis, osteomyelitis, Lyme disease, postinfectious and viral arthritis (Parvovirus), malaria
- Reactive arthritis:
  - Neisseria and streptococcal infections
  - Rapid onset of multiple joint involvement more typical of reactive than JIA

- Rheumatic fever
- Other immune-mediated diseases:
  - Henoch-Schönlein purpura, SLE, Kawasaki disease, polyarteritis
  - Drug reaction, serum sickness
- Hematologic/Oncologic:
  - Leukemia, lymphoma, neuroblastoma, bone tumor, hemoglobinopathies, and hemophilia
- IBD

## TREATMENT

### MEDICATION

#### First Line

##### NSAIDs:

- Inhibit COX-1 and COX-2 in the inflammatory response
- For mild cases, response in 6 wk
- 50% respond to the 1st NSAID
- Another 50% respond to a 2nd NSAID
- Ibuprofen 10 mg/kg/dose PO/IV q6h PRN
- Ketorolac 0.5 mg/kg IV/IM q6h PRN
- Naproxen 5 mg/kg PO q8h PRN

#### Second Line

- Disease-modifying antirheumatic drugs
- Required in 2/3 of persistent joint disease
- Retards progression of disease:
  - Methotrexate (MTX) 5–15 mg/m<sup>2</sup> once weekly PO, IM or SC:
    - Used for systemic/polyarticular forms
    - Requires folic acid supplementation
    - Requires lab monitoring
    - Improvement after 6–12 wk
    - Combination therapy with leflunomide has better outcome when monotherapy fails.
  - Sulfasalazine, hydroxychloroquine
- Biologic agent: Tumor necrosis factor (TNF) receptor antagonists:
  - Rapid improvement in MTX resistance cases
  - Etanercept 0.4 mg/kg SC biweekly or 0.8 mg/kg SC once weekly
  - Other TNF-alpha antagonists used are infliximab and adalimumab.
- Oral or IV steroids 0.5–2.0 mg/kg/day PO:
  - Systemic JIA, rarely used for other subtypes
  - Not for long-term therapy
  - Early use of MTX to allow weaning of steroids
- Corticosteroid joint injection:
  - Most commonly used in pauciarticular
  - Prevents use of systemic drugs
  - Triamcinolone hexacetonide
- Treatment of uveitis:
  - Frequent eye exams
  - Topical corticosteroids and mydriatics
  - Systemic steroids and sub-Tenon injections

### SURGERY/OTHER PROCEDURES

- Release of joint contractures
- Joint replacement
- Autologous stem cell transplants

### DISPOSITION

#### Admission Criteria

- Pericarditis/Symptomatic pericardial effusion
- MAS or toxic appearing

#### Issues for Referral

- Rheumatology referral for suspected JIA
- Ophthalmology for suspicion of uveitis
- Hematology/Oncology referral for suspected malignancy
- Orthopedic/Infectious disease for septic joint

### COMPLEMENTARY & ALTERNATIVE THERAPIES

- Physical and occupational therapy, splinting
- Emotional support with counseling or therapy

### FOLLOW-UP

#### FOLLOW-UP RECOMMENDATIONS

##### Patient Monitoring

- Patients on MTX and biologic agents require close monitoring of CBC and LFTs.
- Patients on etanercept require monitoring for neurologic complications including neuropathy.
- All patients with JIA require monitoring for ophthalmic complications.

### PROGNOSIS

- Mortality reported is 0.29–1.1%.
- 60% of deaths are due to systemic type.
- Spontaneous remission varies by subtype:
  - Systemic onset:
    - 50% remit in 1 yr, 25% joint destruction
  - Oligoarticular: Best prognosis of all:
    - 35–50% remission rates
    - Chronic uveitis has high morbidity; extended type has worse prognosis.
  - RF-positive polyarticular disease has a 6% 10-yr remission rate:
    - Generally chronic and progressive
  - Psoriatic arthritis is chronic and destructive.
- Biologic agents are continuing to improve functional outcome.
- Predictors of progressive disability: Female sex, early-onset symmetric disease, hip involvement, positive RF, and prolonged elevation of ESR

### COMPLICATIONS

- Uveitis (may be presenting complaint):
  - Common in pauciarticular with positive ANA
  - Red eye, tearing, pain, decreased vision
  - Permanent damage may have occurred.
- All patients with JIA require emergent ophthalmology exam for eye complaints:
  - Regular slit lamp exam on a set schedule:
    - Frequency based on duration, age at onset, and ANA status of disease
- Macrophage activation syndrome (5–8%):
  - Systemic onset highest risk
  - Fever, hepatosplenomegaly, anemia, lymphadenopathy, thrombocytopenia and leukopenia, neurologic abnormalities
  - May follow infection or due to drugs (MTX, sulfasalazine, NSAIDs)
  - Treatment:
    - High-dose IV corticosteroids
    - Cyclosporin

- Pericarditis:
  - Presenting symptom or accompany systemic JIA
  - Subclinical pericardial effusion or pericarditis
  - Chest pain, tachycardia, dyspnea, cardiomegaly, friction rubs
  - CXR, ECG, echo
  - Treatment:
    - ABCs
    - Systemic steroids
  - Quality-of-life issues include depression, lower rate of marriage, increased unemployment as patients enter adulthood, and limited socialization.

### CODES

#### ICD9

- 714.30 Chronic or unspecified polyarticular juvenile rheumatoid arthritis
- 714.31 Acute polyarticular juvenile rheumatoid arthritis
- 714.32 Pauciarticular juvenile rheumatoid arthritis

### PEARLS AND PITFALLS

- Pearls:
  - Increased use of disease-modifying antirheumatic drugs and biologic agents is dramatically improving outcome.
- Pitfalls:
  - Severe pain, refusal to bear weight, or a red hot severely painful joint suggests infection or malignancy rather than JIA.
  - Normal laboratory studies including negative ANA and acute phase reactants do not rule out JIA.
  - Patients on immunosuppressive therapy may not demonstrate normal serologic or clinical response to infection.
  - Failure to entertain the diagnosis of uveitis in any child with a red, painful, or tearing eye

# ARTHRITIS, SEPTIC

Rebecca L. Vieira  
Nikhil B. Shah

## BASICS

### DESCRIPTION

- Septic arthritis refers to inflammation of a joint caused by a bacterial infection
- Most commonly bacterial in origin
- 90% are monoarticular
- Hip and knee joints affected most frequently
- Early recognition and treatment are critical to prevent joint damage and permanent disability
- Septic arthritis of the hip is a surgical emergency and requires immediate drainage
- Septic arthritis is distinct from joint infections caused by viral or fungal pathogens (referred to as “aseptic arthritis”)
- Septic arthritis includes suppurative arthritis, bacterial arthritis, pyogenic arthritis, purulent arthritis and pyarthrosis

### EPIDEMIOLOGY

- Reported incidence: 5–37 per 100,000 (1,2)
- Most frequently affects children <3 years old
- Males affected more than females (1.2-2 to 1)
- Hip and knee joints most frequently involved
- Majority are monoarticular

### RISK FACTORS

- Neonates: umbilical vessel catheterization; central venous catheter, femoral venipuncture, osteomyelitis
- Older children: immunodeficiency, joint surgery, hemoglobinopathy, underlying arthritis, diabetes, sexual activity
- Preexisting arthropathy (which may delay the diagnosis) (3)
- Most patients have no underlying medical conditions

### PATHOPHYSIOLOGY

- Most cases result from hematogenous dissemination of an organism into either the joint or metaphysis
- Rarely can occur from direct inoculation (i.e., penetrating injury) or contiguous extension (eg, joint involvement during osteomyelitis)
- Bacteria spread through metaphyseal capillaries to epiphyseal plate, allowing invasion into joint space
  - Inflammatory response with neutrophilic infiltration occurs
  - Pus accumulation leads to distension of joint capsule producing the characteristic clinical and radiographic findings

### ETIOLOGY

- Bacterial etiology confirmed by appropriate culture (blood, synovial fluid, and/or other sites) in 50–70% of cases
- *Staphylococcus aureus*
  - Most common cause across all age groups
  - Increasing prevalence of community-acquired methicillin-resistant *S. aureus* (CA-MRSA)
- Streptococci
  - Includes Group A and B streptococci (GAS and GBS, respectively) and pneumococcus
    - GAS seen primarily in children >5 years
    - GBS in infants <3 months
    - Pneumococcus in children <2 years

- *Kingella kingae*
  - Increasingly recognized causative agent (2)
- *N. gonorrhoeae* and meningitidis
- *H. influenzae* type B (Hib)
  - More common in under- or nonimmunized children
- *Salmonella*
  - Seen in children with hemoglobinopathy such as sickle-cell disease
- Other:
  - *Pseudomonas aeruginosa* (from puncture wounds or injectable drug use)
  - Nonsalmonella gram negative rods (*Serratia*, *Enterobacter*, *Campylobacter*)
  - Anaerobes (*Bacteroides*, *Fusobacterium* spp., etc.)

## DIAGNOSIS

### HISTORY

- Fever, joint pain, restricted range of motion
- Pain is progressive, does not wax and wane
- Decreased limb use, particularly limping, is the most common manifestation
- Findings are nonspecific in neonates and young infants (<2–3 months):
  - Presents similar to sepsis, i.e., irritability, poor feeding, or fever without a focus
  - Subtle findings include:
    - Positional preference (eg, leg abducted and externally rotated in septic hip)
    - Lack of use of the involved extremity (“pseudoparalysis”)
    - Evidence of discomfort when handled (paradoxical irritability) or having the diaper changed
- Findings in older children and adolescents:
  - Fever and other constitutional symptoms (eg, malaise, poor appetite)
  - Swelling of affected joint
  - Pain with movement
  - Limp, refusal to walk or bear weight
- Hip involvement may cause referred pain in adjacent structures such as the knee or abdomen (may mimic an acute abdomen or UTI)
- Unusual worsening of one joint in patients with underlying arthropathy (eg, juvenile idiopathic arthritis [JIA, formerly JRA]) should arouse suspicion for septic arthritis

### PHYSICAL EXAM

- Patients with septic arthritis often appear ill
- Fever may or may not be present
- Joint may be warm, erythematous, swollen and tender (swelling rare in hip & shoulder)
- Active & passive range of motion elicit pain
- Range of motion may be decreased
- Patients with septic arthritis of the hip will preferentially hold leg flexed & externally rotated
- In adolescent, perform GU exam to evaluate for GC infection.

## DIAGNOSTIC TESTS & INTERPRETATION

### Lab

#### Initial Lab Tests

- WBC, ESR, and C-reactive protein typically reveal elevations consistent with infection.
  - Elevations are not always present
- Blood cultures are positive in 30–40% of patients with septic arthritis
- Blood culture (aerobic and anaerobic)
- Kocher’s criteria (4) can be used to clinically predict septic arthritis in a child with painful hip:
  - Non-weight bearing on affected side
  - ESR >40
  - Fever
  - WBC count >12,000
- When 4/4 criteria are met, there is a 99% probability of septic arthritis
  - 3/4 = 93%; 2/4 = 40%; 1/4 = 3%; 0/4 = 0.2%
- CRP and ESR can be used to monitor disease course and response to treatment
- Additional tests may be necessary when specific pathogens are suspected:
  - Throat culture (GAS, *N. gonorrhoeae*)
  - Eye and CSF (neonatal gonococcal infection)
  - ASO (GAS)
  - Lyme titer
  - Stool and/or urine (for septic or reactive arthritis secondary to gastrointestinal infection)
- Arthrocentesis fluid
  - Synovial WBC >50,000 with >90% PMN suggests septic arthritis
  - Pathologic organisms in the synovial fluid on Gram stain or culture confirms diagnosis
  - Gram stain and culture are negative in 40–50% of patients with other findings suggestive of septic arthritis

### Imaging

- X-rays are rarely diagnostic, can be used to rule out osteomyelitis or other causes of pain and swelling, sometimes show evidence of joint effusion
  - Findings suggestive of septic arthritis include displacement of muscle surrounding the joint, distension of joint capsule, joint space widening, subluxation or dislocation (rarely), and bony erosion (late finding)
- Ultrasound
  - Can identify and quantify joint effusion
  - High negative predictive value for septic hip
  - Joint aspiration should be performed if ultrasound demonstrates an effusion
  - Can be used to guide diagnostic aspiration
- CT scan
  - Not routinely used in diagnostic evaluation
- Bone scan/scintigraphy
  - Generally only used if concomitant osteomyelitis suspected or if a deep joint (eg, hip or sacroiliac) is affected
- MRI
  - More sensitive imaging modality
  - Also evaluates concomitant osteomyelitis or osteomyelitis-associated abscess

**Diagnostic Procedures/Other**

- Arthrocentesis is necessary
- Orthopedic consultation if uncomfortable or inexperienced performing arthrocentesis

**DIFFERENTIAL DIAGNOSIS**

- Fracture, sprain, soft tissue traumatic injury
- Other orthopedic conditions (eg, slipped capital femoral epiphysis, Legg-Calve-Perthes disease)
- Oncologic processes (eg, leukemia, osteosarcoma, osteoid osteoma)
- Aseptic arthritis
- Reactive arthritis
- Lyme disease
- Cellulitis
- Osteomyelitis
- Transient synovitis

**TREATMENT****MEDICATION****First Line**

- Analgesics, antipyretics, and antibiotics are the mainstay pharmacologic agents.
- Opioids
  - Morphine 0.1 mg/kg IV/IM/SC q2h PRN:
    - Initial morphine dose 0.1 mg/kg IV/SC may be repeated q15–20min until pain is controlled then q2h PRN
  - Codeine codeine/acetaminophen dosed as 0.5–1 mg/kg of codeine component PO q4h PRN
  - Hydrocodone or hydrocodone/acetaminophen dosed as 0.1 mg/kg of hydrocodone component PO q4–6 h PRN
- NSAIDs
  - Consider NSAID medication in anticipation of prolonged pain and inflammation
  - Ibuprofen 10 mg/kg/dose PO/IV q6h PRN.
  - Ketorolac 0.5 mg/kg IV/IM q6h PRN
  - Naproxen 5 mg/kg PO q8h PRN
- Acetaminophen 15 mg/kg/dose PO/PR q4h PRN
- Septic arthritis is a surgical emergency that requires prompt joint irrigation by an orthopedic surgeon. Systemic antibiotics should be started immediately after synovial fluid analysis, awaiting surgical irrigation.
- Antibiotics should be chosen to cover the most likely causative organisms based on age and risk factors.
- Birth–3 mo: Combination of anti-staphylococcal agent (eg, oxacillin or vancomycin) plus gentamicin or cefotaxime
  - Oxacillin 50 mg/kg/dose IV q6h
  - Gentamicin 5–7 mg/kg IV q24h or divided q8h
  - Cefotaxime 50 mg/kg/dose IV q6h
  - Ceftriaxone 50 mg/kg/dose IV daily
- Older than 3 mo: Antistaphylococcal and streptococcal agent (nafcillin, clindamycin, or vancomycin, depending on prevalence and susceptibilities of CA-MRSA) in combination with gram-negative coverage if clinical situation suggests possible gram-negative organism (eg, direct inoculation, gram negatives seen on Gram stain)
  - Cefotaxime 50 mg/kg/dose q6–8h up to max dose 1 g IV q8h
- Ceftriaxone 50 mg/kg/dose IV daily, up to max dose 2 g IV daily

- Ciprofloxacin 10 mg/kg/dose q12h up to max 400 mg IV q12h
  - For use if suspected GC arthritis, only appropriate in areas without GC quinolone resistance
- Oxacillin 50 mg/kg/dose IV q6–8h up to max 1 g/dose IV q6h
- Nafcillin 25 mg/kg/dose IV q4–6h up to max 2 g IV q4–6h
- Clindamycin 10 mg/kg/dose IV q8h
- Vancomycin 10 mg/kg/dose IV q12h up to max single dose 1 g IV q12h
- Sexually active adolescents: Anti-staph and strep agent plus coverage for *N. gonorrhoeae* (3rd-generation cephalosporin or quinolone if in nonquinolone-resistant geographic area)

**SURGERY/OTHER PROCEDURES**

Septic hip usually mandates surgical irrigation:

- Arthroscopy and needle aspiration may be considered in certain circumstances, but this decision is made by orthopedic surgeon.

**DISPOSITION****Admission Criteria**

- All patients are admitted
- If findings are equivocal, arthrocentesis or orthopedic consultation cannot occur in ED, admit patient for inpatient therapy and observation.

**Discharge Criteria**

- Well-appearing
- No fever, normal WBC, normal ESR and CRP, able to bear weight (if lower limb joint)
- Synovial fluid analysis with WBC <50,000 cells/microL and negative Gram stain in well-appearing child with good follow-up

**Issues for Referral**

- Refer to orthopedic surgeon
- Refer to infectious disease specialist for unusual pathogens or therapy failure

**FOLLOW-UP****FOLLOW-UP RECOMMENDATIONS**

Follow up at 1-wk intervals

**Patient Monitoring**

- Monitoring response to therapy (serial examination, WBC count, ESR and/or CRP, and synovial fluid WBC and culture)
- Radiographs 2–3 wk into the course to look for evidence of osteomyelitis
- Drug monitoring (antibiotic levels, serum bactericidal titers, adverse effects) has been suggested
- Long-term monitoring for joint dysfunction and limb-length discrepancy

**PROGNOSIS**

- Varies by pathogen, joint involvement, and time to diagnosis
- Factors related to poor outcome include:
  - Greater duration before treatment
  - Involvement of the hip joint
  - Age less than one year old
  - *S. aureus* or Enterobacteriaceae

**COMPLICATIONS**

- Osteomyelitis
- Bacteremia or sepsis
- 10–40% will have the following:
  - Decreased joint function (restriction, increased laxity)
  - Limb length discrepancy
  - Avascular necrosis
  - Enlargement of the femoral head (in septic arthritis of the hip)

**REFERENCES**

1. Riise OR, Handeland KS, Cvancarova M, et al. Incidence and characteristics of arthritis in Norwegian children: A population-based study. *Pediatrics*. 2008;121(2):e299–306.
2. Yagupsky P, Bar-Ziv Y, Howard CB, et al. Epidemiology, etiology, and clinical features of septic arthritis in children younger than 24 months. *Arch Pediatr Adolesc Med*. 1995;149(5):537–40.

**CODES****ICD9**

- 711.40 Arthropathy, site unspecified, associated with other bacterial diseases
- 711.45 Arthropathy involving pelvic region and thigh associated with other bacterial diseases
- 711.46 Arthropathy involving lower leg associated with other bacterial diseases

**PEARLS AND PITFALLS**

- Early diagnosis and treatment is critical for best outcome
- Initiation of antibiotics prior to synovial fluid analysis confounds diagnosis
- Goals of treatment are to sterilize and decompress the joint
- Failure to perform synovial fluid analysis in a timely manner can delay diagnosis and treatment, leading to worse outcomes

# ASCARIS LUMBRICOIDES

Ami P. Shah  
Raymond Pitetti

## BASICS

### DESCRIPTION

- *Ascaris lumbricoides* is the largest small intestinal parasite, growing up to 40 cm.
- It is a roundworm (nematode) that is the most common cause of helminth infections in humans.

### EPIDEMIOLOGY

- > 1 billion people are infected with this worm annually.
- Most common in tropical and subtropical areas
- Uncommon in the U.S., found predominantly in rural southeastern parts of the U.S.
- Global distribution
- ~1/4–1/3 of the world's population is infected with this worm.
- School-aged children have highest incidence.

### RISK FACTORS

- Poor hygiene and sanitation
- Unwashed vegetables and fruits
- Children playing in soil

### GENERAL PREVENTION

- Routine sanitary hygiene, especially good hand washing
- Washing vegetables and fruits well, especially if grown in soil that uses human feces as a fertilizer

### PATHOPHYSIOLOGY

- Infection starts with ingestion of fertilized eggs. Unfertilized eggs are not infective:
  - Ingestion of eggs is typically from unwashed fruits or vegetables that contain eggs.
  - Children may become infected directly from their hands when playing in soil or sand containing the parasite.
- The larvae then hatch in the small intestine, from where they enter the portal circulation and reach the lungs via systemic circulation.

- They further mature in the lungs for 10–14 days.
- Larvae then penetrate the alveolar walls and enter the tracheobronchial tree. From this site, they are coughed up, swallowed, and reach the small intestine:
  - Löffler syndrome: Acute transient pneumonitis may occur during the larval migratory phase, presenting with fever, cough, and marked eosinophilia.
- In the small intestine, they mature into adult worms, where they then reside.
- Adult female worms lay ~200,000 eggs per day.
- Eggs are passed in the feces. They need to incubate for 2–3 wk in the soil to become infectious.

### ETIOLOGY

*A. lumbricoides*, or roundworm: A small intestinal parasite

### COMMONLY ASSOCIATED CONDITIONS

Malnutrition

## DIAGNOSIS

### HISTORY

- Patients may present with nonspecific GI and pulmonary symptoms, such as:
  - Nausea
  - Vomiting
  - Abdominal pain
  - Diarrhea
  - Cough
  - Nasal congestion
- Patients may cough up round “white strings” or “noodlelike” material.
- Travel to tropical areas or living on a farm are crucial components of the history.

### PHYSICAL EXAM

- Most patients are asymptomatic.
- The patient may be malnourished.
- Nonspecific GI symptoms, including abdominal pain
- Heavy worm load may present as intestinal obstruction.
- May present with signs of biliary obstruction and peritonitis, including:
  - Abdominal distention
  - Decreased bowel sounds
  - Scleral icterus
  - Jaundice
  - Pallor

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

- Stool for ova and parasites:
  - Infection is confirmed by identification of eggs in the stool sample.
- Peripheral blood can be tested to look for eosinophilia in severe cases or suspected case of Löffler syndrome.

#### Imaging

- Not routinely required
- X-ray, US, and CT scan of the abdomen may be required based on the clinical presentation.

### DIFFERENTIAL DIAGNOSIS

- Acute appendicitis
- Cholangitis
- Hepatitis
- Pancreatitis
- Other helminth or tropical parasitic infections, such as strongyloides and hookworm

## TREATMENT

### INITIAL STABILIZATION/THERAPY

- Assess and stabilize airway, breathing, and circulation.
- Symptomatic care unless signs of intestinal obstruction are present
- Emergent surgical consultation if intestinal obstruction

### MEDICATION

#### First Line

- Treatment should be instituted for all cases, both asymptomatic.
- Benzimidazoles (albendazole and mebendazole) are wormicidal. These agents act by blocking the energy/adenosine triphosphate production of the worms, leading to their death:
  - Albendazole: <2 yr of age, 200 mg PO as a single dose; >2 yr of age, 400 mg PO as a single dose
  - Mebendazole: >2 yr of age 100 mg PO b.i.d. × 3 days:
    - Used in children >2 yr
- Ivermectin 150–200 µg/kg PO once, max single dose 400 mg:
  - Used in children >15 kg
  - Do not use during lactation.

#### ALERT

For all medications above, safety not established in children <2 yr of age.

#### Pregnancy Considerations

Safety not established in pregnant patients.

#### Second Line

For cases of partial or complete intestinal and biliary tract obstruction:

- Piperazine is a helminth paralytic. It causes flaccid paralysis of the worms and thus facilitates their passage from the small intestine (75 mg/kg PO per day × 2 days).
- Pyrantel pamoate is a neuromuscular depolarizing agent that can be used alternatively (11 mg/kg/dose PO as a single dose).

### SURGERY/OTHER PROCEDURES

- May be required to relieve obstruction caused by a heavy worm load
- Endoscopic retrograde cholangiopancreatography may help relieve biliary obstruction.

### DISPOSITION

#### Admission Criteria

- Secondary intestinal obstruction, peritonitis, bowel perforation, or biliary tract obstruction
- Critical care admission criteria:
  - If unstable vital signs, particularly due to pulmonary compromise

#### Discharge Criteria

Appropriate antihelminth therapy has been initiated

#### Issues for Referral

Infectious disease referral may be required in the U.S. since the infection is infrequent.

## FOLLOW-UP

### FOLLOW-UP RECOMMENDATIONS

Discharge instructions and medications:

- Emphasize personal hygiene and hand washing.
- Although not necessary, it is recommended to repeat the stool sample for ova and parasites 2–3 wk after antihelminth therapy.
  - A 2nd course of antihelminth therapy may be necessary if the sample is positive.

#### Patient Monitoring

- Inspect stools every day for worm passage.
- If coughing, inspect the sputum for worms.

### PROGNOSIS

Unless there are rare complications such as bowel obstruction or Löffler syndrome, the prognosis with treatment is excellent.

### COMPLICATIONS

- Löffler syndrome
- Small bowel obstruction
- Small bowel perforation and peritonitis
- Biliary tract obstruction

## CODES

#### ICD9

127.0 Ascariasis

### PEARLS AND PITFALLS

- Pearls:
  - Though rarely encountered in the U.S., *Ascaris* should be considered in any child with suggestive signs or symptoms.
  - Antihelminth therapy is generally effective and safe.
- Pitfalls:
  - Delay in diagnosis can lead to serious complications, including intestinal obstruction, peritonitis, bowel perforation, or biliary tract obstruction.

# ASCITES

Nirupama Kannikeswaran

## BASICS

### DESCRIPTION

- Ascites is the pathologic accumulation of fluid in the peritoneal cavity.
- Liver, kidney, and cardiac diseases are common causes of ascites in children.
- Can be classified as (1):
  - Grade 1: Detected only by US exam
  - Grade 2: Moderate ascites manifested by moderate symmetrical distension of abdomen
  - Grade 3: Gross ascites with marked abdominal distension

### EPIDEMIOLOGY

- 44% of children with cirrhosis have ascites (2).
- 16.5–55% of patients with subacute hepatic failure, acute hepatitis, or fulminant hepatic failure have ascites.

### RISK FACTORS

- Children with liver disease, heart failure, nephrotic syndrome, ventriculoperitoneal shunt
- IV drug use, unprotected sex, recurrent transfusion of blood or blood products

### PATHOPHYSIOLOGY

- Underfilling theory: Portal HTN leads to inappropriate sequestration of fluid in the splanchnic vasculature:
  - This leads to decreased effective circulating volume causing activation of renin-angiotensin and aldosterone pathways, leading to sodium and water retention
- Overfill theory: Primary abnormality is inappropriate sodium and water retention, leading to hypervolemia rather than hypovolemia.
- Peripheral arterial vasodilation theory: Cirrhosis causes distortion of liver architecture and hepatic fibrosis:
  - This leads to increased intrahepatic resistance to blood flow causing portal HTN, which leads to shunting of blood to systemic circulation.
  - Vasodilators like nitric oxide are produced, leading to splanchnic arterial vasodilation, which decreases effective circulating volume.
  - This theory is the most widely accepted.

### ETIOLOGY

- Liver disease: Cirrhosis, fulminant hepatic failure, congenital hepatic fibrosis, portal vein obstruction, lysosomal storage disorders
- Kidney disease: Nephrotic syndrome, obstructive uropathy, peritoneal dialysis, perforated urinary tract
- Cardiac: CHF, constrictive pericarditis

- Infectious: TB, schistosomiasis, chlamydia
- Neoplastic: Neuroblastoma, lymphoma, ovarian tumors
- GI: Infarcted bowel, perforation, pancreatitis
- Others: Ventriculoperitoneal shunt, chylous ascites, systemic lupus erythematosus (SLE)

## DIAGNOSIS

### HISTORY

- Increase in belt or clothing size, inappropriate weight gain
- Abdominal pain or sensation of fullness
- Yellow discoloration of eyes
- Easy fatigability
- Shortness of breath
- History of pre-existing liver disease, heart disease, and kidney disease
- Risk factors: History of IV drug use or repeated blood transfusions

### PHYSICAL EXAM

- Abdominal distension with or without an everted umbilicus
- Evaluate for hepatosplenomegaly, consistency of liver (soft vs. firm vs. hard), abdominal masses
- Presence of shifting dullness, flank dullness, fluid wave
- Stigmata of liver disease and cirrhosis: Jaundice, palmar erythema, abdominal wall collaterals
- Presence of venous hum at umbilicus in portal HTN
- Sister Mary Joseph nodule: A hard periumbilical nodule indicative of metastatic disease from a pelvic or GI primary tumor
- Presence of cardiac disease: Jugular venous distension, gallop, rales in chest
- Extremity edema, anasarca in nonhepatic causes of ascites

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

- CBC with platelet count
- Evaluation of liver disease: AST, ALT, alkaline phosphatase, serum total and direct bilirubin, total protein, albumin, PT, hepatitis profile
- Evaluation of renal disease: Electrolytes, BUN and creatinine, urinalysis, urine protein creatinine ratio
- Ascitic fluid analysis: Cell count, total protein, albumin, glucose, lactate dehydrogenase (LDH), amylase, triglycerides, bacterial culture, and cytology:
  - Normal ascitic fluid is transparent, yellow, and contains  $<500$  WBC/mm<sup>3</sup> with polymorphonuclear count  $<250$ /mm<sup>3</sup>.

- Ascitic fluid polymorphonuclear count  $\geq 250$ /mm<sup>3</sup> indicates infection.
- Ascitic fluid is classified as an exudate if the total protein concentration is  $\geq 2.5$  or 3 g/dL, but this has low sensitivity of 59%.
- Serum to ascites albumin gradient (SAAG): This is calculated as the difference between serum albumin value and ascitic fluid albumin:
  - The presence of SAAG  $\geq 1.1$  g/dL indicates that the patient has portal HTN with 97% sensitivity (3).
  - A high SAAG ( $> 1.1$  g/dL) is associated with diffuse parenchymal liver disease and occlusive portal and hepatic venous disease, liver metastasis, and hypothyroidism.
- Milky fluid indicates chylous ascites, usually having a triglyceride concentration  $>200$  mg/dL.
- Ascitic fluid glucose concentration is similar to that of serum:
  - Low levels indicate infection.
  - Levels are undetectable in gut perforation.
- The ascitic fluid/serum ratio of LDH is 0.4 in uncomplicated ascites. The ratio:
  - Approaches 1 in cases of spontaneous bacterial peritonitis (SBP)
  - $> 1$  in cases of tumor
- Ascitic fluid amylase concentration is 40 IU/L in uncomplicated ascites and is increased in the setting of ascites secondary to pancreatitis or gut perforation.

### Imaging

- US of the abdomen is the diagnostic modality of choice to confirm ascites, determining the presence of a mass, and evaluating the size of the liver and spleen.
- CT scan is helpful if a focal lesion such as malignancy is visualized on the US.
- Upright and supine films of the abdomen may demonstrate diffuse abdominal haziness and loss of psoas margins.
- Consider CXR and/or echo to evaluate for cardiac causes of ascites.

### Diagnostic Procedures/Other

- Abdominal paracentesis may be performed to confirm the presence of ascites, diagnose its cause, or determine the nature of the fluid (and if it is infected):
- Left lower quadrant paracentesis site may be preferred over midline location since the abdominal wall is relatively thinner and the depth of fluid is greater.
  - Tap 2 fingerbreadths cephalad and 2 fingerbreadths medial to the anterior superior iliac spine.

- US-guided paracentesis is preferred to reduce the incidence of complications.
- Removal of > 100 mL/kg of ascitic fluid is considered “large-volume” paracentesis, and albumin replacement in addition to IV fluid replacement typically accompanies such paracentesis.

#### DIFFERENTIAL DIAGNOSIS

- Obesity
- Abdominal masses (eg, neuroblastoma, hepatoblastoma, Wilms tumor)
- Pregnancy
- Urine and fecal retention

### TREATMENT

#### PRE HOSPITAL

Assess and stabilize airway, breathing, and circulation.

#### INITIAL STABILIZATION/THERAPY

- Assess and stabilize airway, breathing, and circulation.
- Ascites with respiratory compromise should be treated with paracentesis.
- Dietary sodium restriction to 1–2 mEq/kg/day:
  - Effective in reducing the dose of diuretics and leads to shorter hospital stay; effective only if urinary sodium > 15 mEq/24 hr
- Water restriction is not recommended unless there is associated hyponatremia (serum sodium < 130 mmol/L).

#### MEDICATION

- Diuretics are used to produce a negative fluid balance of 10 mL/kg/day. Spironolactone and furosemide are preferred diuretics. Steady gradual loss is preferred. Oral diuretics are preferred compared to IV diuretics:
  - Spironolactone 1.5–3.3 mg/kg/day PO/IV in divided doses b.i.d.–q.i.d.
  - Furosemide 0.5–1 mg/kg/dose PO/IV q8h PRN
- For suspected or culture proven SBP:
  - Cefotaxime 50 mg/kg/dose IV q8h, max single dose 2 g/day
  - Ceftriaxone 50 mg/kg IV per day
- To prevent SBP:
  - Penicillin 50 mg/kg/day PO divided b.i.d.–q.i.d. may be used to prevent SBP in patients with ascites. This practice is losing prevalence due to poor penicillin sensitivity of streptococcal bacteria.

#### SURGERY/OTHER PROCEDURES

- Large-volume paracentesis with albumin infusion: For diuretic resistant ascites, tense ascites, or those with respiratory distress secondary to ascites
- Definitive therapy may involve:
  - Transjugular intrahepatic portasystemic shunts (TIPS) and peritoneovenous shunts for refractory ascites
  - Liver transplantation

#### DISPOSITION

##### Admission Criteria

- Ascites resistant to oral diuretic therapy
- If SBP is suspected
- Critical care admission criteria:
  - Ascites causing significant respiratory distress
  - Complications of underlying disease: Liver failure, variceal hemorrhage, hepatic encephalopathy

##### Discharge Criteria

- Uncomplicated, small-volume ascites
- Stable vital signs
- No airway or hemodynamic compromise

##### Issues for Referral

- All patients with ascites require referral to a subspecialist for determination of the extent of underlying disease and its management.
- Referral to dietician to set caloric goal and sodium-restricted diet

### FOLLOW-UP

#### FOLLOW-UP RECOMMENDATIONS

- Discharge instructions and medications:
  - Sodium restricted diet:
    - 1–2 mEq/kg/day for infants and children
    - 1–2 g/day (44–88 mEq of sodium per day) in adolescents
- Consider combination oral diuretic therapy:
  - Single morning dose of spironolactone (0.3–3 mg/kg) along with furosemide (0.5 mg/kg) in the ratio of 5:2
- Follow up with an appropriate specialist based on the etiology of ascites.
- Activity:
  - Bed rest is not recommended in children with uncomplicated ascites.

#### Patient Monitoring

- Strict intake and output
- Weight

#### DIET

- Salt-restricted diet
- Maintain calorie intake at goal.
- Protein intake (1 g/kg/day) unless patient is severely catabolic

#### PROGNOSIS

Variable depending on the cause and extent of underlying disease

#### COMPLICATIONS

- Respiratory distress
- SBP
- Complications of portal HTN: Variceal hemorrhage, hepatorenal syndrome, liver failure

#### REFERENCES

#### CODES

##### ICD9

789.59 Other ascites

#### PEARLS AND PITFALLS

- Paracentesis is the gold standard to detect the underlying cause of ascites.
- Urgent paracentesis is indicated in patients with ascites and fever or those with acute decompensation or significant respiratory distress secondary to ascites.
- Prompt initiation of broad-spectrum antibiotic therapy is indicated if SBP is suspected.

## BASICS

### DESCRIPTION

- Asthma is a chronic, reversible, recurrent inflammatory disease of the airways resulting in airway obstruction, bronchial hyperresponsiveness, and inflammation.
- Acute exacerbations result from inflammation, typically due to viral infection.
- Common environmental triggers include cigarette smoke, house dust mites, and animal dander.

### EPIDEMIOLOGY

- Most prevalent chronic disease in childhood
- ~9% (6 million) of children in the U.S. have asthma.
- Male prevalence higher than females (10% vs. 7.8%)
- Black and Hispanic children have higher prevalence rates.
- Prevalence has doubled from 1980–1990.
- In 2004, asthma was responsible for 760,000 emergency department visits.

### RISK FACTORS

- Atopy
- Low birth weight
- Frequent respiratory infections
- Obesity
- Race: Black and Hispanic populations, due to either genetic and/or environmental factors:
  - In teenage years, these patients have a high risk of mortality of acute asphyxial asthma.

### GENERAL PREVENTION

Avoidance of triggers:

- Common triggers: Upper respiratory infections, tobacco smoke, weather changes, dust mites, air pollution, cockroaches, animal dander, mold
- Less common triggers: Cold, foods, emotional stress, exercise

### PATHOPHYSIOLOGY

- A multifactorial and complex disease involving the immunologic response of airways to infectious and/or environmental triggers
- Cause of airway hyperresponsiveness is unknown in most patients.
- Numerous environmental exposures may cause asthma to develop: Cigarette smoke, lacquer, isocyanates, acrylates, varied wood dusts, ivory dust, aldehydes, metals, preservatives, plastic and rubber dust, fungicides, and numerous other chemicals:
  - Low-molecular-weight agents act as haptens.
  - Higher-molecular-weight products are directly immunogenic.
  - Exposure to these may cause permanent injury and sensitize the patient and induce asthma in a previously nonasthmatic patient.
  - This is distinct from allergens that trigger an exacerbation of asthma in asthmatic patients.
- Three components of asthma:
  - Airway edema: Regulated by mast cells, eosinophils, macrophages, epithelial cells and activated T lymphocytes causing inflammation, mucus production, and edema

- Airway hyperresponsiveness: IgE-mediated response leading to bronchoconstriction
- Bronchial constriction: Stimulation of smooth muscle and endogenous stimulation of mast cells
- Results in progressive air trapping, poor oxygenation, poor ventilation, and ventilation/perfusion mismatch.
- After recurrent episodes, sensory nerves may become hypersensitive with hyperreactivity.
- Progressively over the years, patients may lose the perception of dyspnea, increasing the chance of inadequate self-treatment of exacerbations.

### ETIOLOGY

Genetic and environmental components:

- Genetic: Multiple genetic defects have been linked to asthma, and twin studies have found high concordance rates.
- Environment: Common triggers (ie, dust, pollen, dander, smoke, viral infections) often result in increased IgE-specific response.

### COMMONLY ASSOCIATED CONDITIONS

- Atopy (allergies, eczema) in patient or family
- Upper respiratory infections

## DIAGNOSIS

### HISTORY

- Focus on onset, duration, progression, and severity of symptoms:
  - How does the severity of this attack compare to other exacerbations?
- Exposure to triggers
- Recent febrile respiratory illnesses
- Ask about medication dose, route, frequency and time since last dose.
- Inquire about compliance with controller medication.
- Frequency, severity, and management of past exacerbations: Number of emergency department visits, hospitalizations, ICU admissions, and previous intubations
- Smoking or drug use
- Comorbid conditions such as cardiac, chronic lung, or psychiatric disease

### PHYSICAL EXAM

- Vital signs: Tachypnea, hypoxia
- Focus on general appearance, mental status, color, and accessory muscle use and work of breathing
- Lack of wheeze may be due to poor aeration:
  - Cough-variant asthma will present with cough but no or minimal wheeze.
- Degree of respiratory distress is determined by assessing lung auscultation for aeration, symmetry, wheeze in inspiratory/expiratory phase, ability to speak, accessory muscle use, and oxygen requirement.
- Estimation of severity:
  - Mild: Normal alertness, color, and speech; normal to 30% increase in respiratory rate; absent to mild dyspnea; no to mild intercostal retractions; end-expiratory wheeze; >95% oxygen saturation in room air, PaCO<sub>2</sub> <42 mm Hg

- Moderate: Normal or slightly agitated alertness, pale color, speaks in short phrases, 30–50% increase in respiratory rate, moderate dyspnea, moderate intercostal retractions with suprasternal retractions/chest hyperinflation, wheeze throughout expiration, 91–95% oxygen saturation in room air, PaCO<sub>2</sub> <42 mm Hg
- Severe: Agitated or somnolent; cyanotic; difficulty speaking; respiratory rate >50% increase; severe dyspnea, deep intercostal and tracheosternal retractions; chest hyperinflation; wheeze throughout inhalation/exhalation; poor aeration; <91% oxygen saturation in room air; PaCO<sub>2</sub> ≥42 mm Hg
- Associated conditions such as rhinitis, eczema, or sinusitis may be found on physical exam.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

- Venous or arterial blood gas may be useful in severe exacerbations to objectively measure oxygenation and ventilation.
- Initial use of venous blood gas is preferable. If further information is required, arterial sampling may be performed.

#### Imaging

Chest radiograph rarely uncovers an unsuspected alternative diagnosis:

- CXR should not be routinely performed on patients presenting with 1st episode of wheezing.
- Most films will show hyperinflation and flattened diaphragms from air trapping, increased bronchial wall markings from inflammation, and/or atelectasis.
- CXR may be useful if alternate problems such as pneumonia, pneumothorax, etc. are suspected.

#### Diagnostic Procedures/Other

- Asthma is a clinical diagnosis; however, spirometry may be used to help establish the diagnosis:
  - Spirometry, also known as pulmonary function testing, evaluates for signs of reversible obstruction.
  - Difficult to perform before 5 yr of age
  - If clinical suspicion is high in a child with normal or near normal spirometry, bronchoprovocation with methacholine, histamine, cold air, or exercise may show airway hyperresponsiveness.
- Allergy testing to identify potential allergens

### DIFFERENTIAL DIAGNOSIS

- Acute wheezing: Bronchiolitis, foreign body aspiration, pneumonia, anaphylaxis, tracheitis, laryngotracheobronchitis, bronchitis, cholinergic toxicity, pulmonary edema, cardiac failure
- Chronic or recurrent wheezing: Gastroesophageal reflux, recurrent aspiration, cystic fibrosis, immunodeficiency, primary ciliary dyskinesia, bronchopulmonary dysplasia, foreign body aspiration, bronchiolitis obliterans, pulmonary edema, vocal cord dysfunction, interstitial lung disease, tracheobronchomalacia, vascular rings/compression, tracheal stenosis/webs, cystic lesions/masses, cardiac disease, tumors/lymphadenopathy

## TREATMENT

### PRE HOSPITAL

- Assess and stabilize airway, breathing, and circulation.
- Administer supplemental oxygen.
- Administer bronchodilators as appropriate protocol.

### MEDICATION

#### First Line

- Mild to moderate exacerbations:
  - Oxygen to achieve oxygen saturation >90%
  - Inhaled beta<sub>2</sub>-agonist, with or without ipratropium, up to 3 treatments in 1st hr
  - Inhaled beta<sub>2</sub>-agonist may be either albuterol or levalbuterol:
    - Albuterol 0.15 mg/kg/dose by intermittent or continuous nebulization (0.5 mg/kg/hr)
    - Continuous nebulization has similar efficacy and side effects as intermittent dosing.
    - Levalbuterol (0.075 mg/kg) by intermittent or continuous nebulization
  - Ipratropium bromide (0.25–0.5 mg), up to 3 treatments in 1st hr, given concurrently with inhaled beta<sub>2</sub>-agonist
  - Systemic corticosteroids if no immediate improvement or prolonged symptoms prior to arrival:
    - Prednisone or prednisolone 1–2 mg/kg PO, max single dose 60 mg
    - Methylprednisolone 2 mg/kg
    - Dexamethasone 0.6 mg/kg IV/IM/PO, max single dose 12 mg
    - Single-dose dexamethasone equivalent to burst dose of prednisone; may be used without subsequent steroid treatment
- Severe exacerbations:
  - As outlined for mild to moderate exacerbations, plus consider:
    - Nonrebreathing mask to deliver supplemental oxygen
    - Epinephrine 1:1000, 0.01 cc/kg/dose (max single dose 0.5 cc) SC or IM
  - Indicated for those with very tight wheezing with impaired delivery of inhaled beta-agonists.
  - IV magnesium sulfate 50–75 mg/kg over 20 min, max single dose 2.5 g
  - Terbutaline 10 μg/kg SC/IV bolus:
    - May follow with infusion of 0.4 μg/kg/min; increase by increments of 0.3–0.5 μg/kg/min q30min as needed for respiratory distress

#### Second Line

Adjunctive therapies, with largely unproven benefit, may be considered for severely ill children who are unresponsive to more conventional treatment:

- Heliox (mixture of oxygen and helium) to reduce turbulent airflow and resistance

- Ketamine 0.25–2 mg/kg IV/IM loading dose:
  - May be followed with infusion
  - Ketamine may be used in an attempt to avert intubation or as sedation prior to endotracheal intubation.
- Noninvasive positive pressure ventilation: BiPAP/CPAP:
  - Use in an attempt to avert endotracheal intubation

### DISPOSITION

#### Admission Criteria

Critical care admission criteria:

- Altered mental status, need for ventilation support (BiPAP/CPAP, mechanical ventilation), need for adrenergic infusion, need for very frequent (eg, q60min) nebulization, significant respiratory acidosis, severe hypoxia, hypercarbia, respiratory failure, complications (pneumothorax, dysrhythmias), or comorbidities (pneumonia, cystic fibrosis)
- Admit less severely ill patients to the general inpatient unit.

#### Discharge Criteria

- Good clinical response to treatment that is sustained 60 min after last treatment
- Peak flowmeter >80% predicated
- Caregiver and patient competence in proper use of inhaler
- Reliable caregivers to provide continual observation and management of medication

#### Issues for Referral

Refer to an allergist or pulmonologist if:

- Atypical symptoms or questionable diagnosis
- Comorbid conditions (sinusitis, nasal polyps, severe rhinitis, vocal cord dysfunction)
- Specialized treatment for immunotherapy
- Poor control of asthma symptoms
- Patient requires additional education and guidance on complications of therapy, medication adherence, or allergen avoidance
- Life-threatening asthma exacerbation
- >2 oral corticosteroid courses per year

## FOLLOW-UP

- Discharge instructions and medications:
  - Provide an asthma action plan detailing when and how to escalate therapy.
  - Patients with persistent asthma should be started on a daily inhaled corticosteroid.
- Activity:
  - Avoid exercise or pollen if these are triggers.
  - Patient monitoring
    - Use peak flowmeter to monitor lung function.
    - Provide asthma action plan to clarify medication plan and warning signs.

### PROGNOSIS

- Improvement of an asthma exacerbation can be expected in 24–48 hr.
- Long-term control of asthma symptoms can be expected in 2–4 wk.
- 50% of children with asthma will be asymptomatic as adults.

### COMPLICATIONS

- Cardiorespiratory arrest
- Pneumothorax
- Pneumomediastinum
- Pneumonia
- Cardiac dysrhythmias

### See Also (Topic, Algorithm, Electronic Media Element)

- Bronchiolitis
- Wheezing

## CODES

### ICD9

- 493.00 Extrinsic asthma, unspecified
- 493.02 Extrinsic asthma, with (acute) exacerbation
- 493.81 Exercise induced bronchospasm

### PEARLS AND PITFALLS

- Albuterol and levalbuterol, at equipotent doses, have similar efficacy and safety profiles.
- In severe asthma with very poor aeration, wheezing may not be heard.
- Ketamine is the sedative of choice for endotracheal intubation due to bronchodilatory properties.

# ASYSTOLE

Mioara D. Manole  
Robert W. Hickey

## BASICS

### DESCRIPTION

- Asystole is characterized by:
  - Cessation of cardiac mechanical activity
  - Absence of perfusion to vital organs
  - Absence of central pulses, loss of consciousness, and apnea or gasping respirations
- ECG shows flat line, pulseless electrical activity (PEA), ventricular tachycardia, or ventricular fibrillation (VF).
- This topic covers asystolic cardiac arrest (CA). VF CA is covered in a separate topic.
- 4 phases of CA are described: Prearrest, no flow, low flow (CPR), and post return of spontaneous circulation (ROSC) (1).
- 2 categories of CA exist, with different etiology, pathophysiology, and outcome (2):
  - Out-of-hospital CA
  - In-hospital CA (occurs in the hospital setting: Emergency department, pediatric ICU, operating room, pediatric wards)

### EPIDEMIOLOGY

#### Incidence

- Out-of-hospital CA occurs in 8.04/100,000 persons per year (72.71 in infants, 3.73 in children, 6.37 in adolescents) (3).
- In-hospital CA occurs in ~3% of the children admitted to the hospital (4).

### RISK FACTORS

Congenital abnormalities, ex-premature children, birth asphyxia, chronic illness, cancer treatment, transplant patients (1)

### GENERAL PREVENTION

- Trauma prevention: Car seats, seat belts, drowning prevention
- Infants: "Back to sleep" program
- Chronic conditions: Early treatment of shock and respiratory failure
- CPR training for parents of high-risk children

### PATHOPHYSIOLOGY

- Prearrest phase:
  - Asphyxial CA: Hypoxemia, followed by arterial hypotension, bradycardia, PEA, and asystole
  - VF CA: VF, followed by asystole
  - Asystole is the common terminal rhythm for both VF and PEA.
- No flow phase:
  - Oxygen delivery ceases.
  - Tissue hypoxia results in anaerobic metabolism, lactate production, and acidosis.
- Low flow (CPR) phase

- Post ROSC phase:
  - Oxygen delivery is restored.
  - Reactive oxygen species are produced.
  - Inflammatory mediators are released.
  - Pathologies include:
    - Myocardial dysfunction (hypotension, bradycardia, tachycardia, or tachyarrhythmia)
    - Hypoxic-ischemic encephalopathy (cerebral edema, seizures)
    - Metabolic acidosis and electrolyte abnormalities (hyperkalemia, hypocalcemia, hypomagnesemia)
    - Coagulation abnormalities
    - Renal failure
    - Adrenal insufficiency
- 1st monitored rhythm (2):
  - Out-of-hospital CA:
    - Asystole (46%)
    - Bradycardia (10%)
    - PEA (10%)
    - VF (7%)
  - In-hospital CA:
    - Bradycardia (49%)
    - Asystole (16%)
    - VF (10%)
    - PEA (9%)

### ETIOLOGY

- Out-of-hospital CA (2):
  - Respiratory (asphyxia, respiratory failure)
  - Cardiac (arrhythmias, shock)
  - Trauma
- In-hospital CA:
  - Cardiac (arrhythmias, shock, congenital heart disease)
  - Respiratory (respiratory failure, tracheal tube displacement, airway obstruction)
  - Trauma
- Potential treatable causes of CA: 6Hs and 5Ts
  - Hypoxia, Hypovolemia, Hypo-/Hyperkalemia, Metabolic acidosis (Hydrogen ions), Hypoglycemia, Hypothermia
  - Trauma, Toxins, Tamponade (cardiac), Tension pneumothorax, Thromboembolism

## DIAGNOSIS

### HISTORY

- Events leading to CA: Sudden collapse vs. progressive deterioration, trauma
- Past medical history: Chronic condition, medications
- ROSC: Obtained in the field, hospital, no ROSC
- Bystander CPR
- Family history of sudden death (inheritable cardiac disease)

### PHYSICAL EXAM

- Primary survey: ABCDE
- Secondary survey:
  - Identify signs of:
    - Treatable potential causes: 6Hs, 5Ts, trauma (accidental and nonaccidental)
    - Signs of futile resuscitation efforts (dependent cyanosis, rigidity)
- Airway:
  - If artificial airway is established, check:
    - Tracheal tube position: End-tidal CO<sub>2</sub>, lung sounds, or direct visualization of tube between vocal cords (End-tidal CO<sub>2</sub> can be absent due to absence of CO<sub>2</sub> production during CA.)
    - Tracheal tube patency and size
  - If artificial airway is not established:
    - Assess for airway patency.
- Breathing:
  - Check for adequacy and symmetry of ventilation (identify pneumothorax, tracheal tube malposition).
- Circulation:
  - Assess quality of pulse after ROSC.
- Disability:
  - Assess for spontaneous movement after ROSC.
- Exposure:
  - Signs of physical abuse (bruises, petechiae)
- Secondary survey
  - Glasgow Coma Score
  - Neck: Check for venous distention (identify cardiac tamponade).
  - Chest: Respiratory disease, pulmonary edema
  - Cardiovascular: Perfusion, heart sounds, rhythm
  - Extremities: Intraosseous (IO) access—note sites of previous IO attempts, and check patency of IO and signs of infiltration.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

- During CA:
  - Check for treatable causes of CA: 6Hs, 5Ts.
  - Obtain bedside capillary glucose level, ABG, electrolytes, and hemoglobin level. Consider obtaining a specimen for toxicology screen.
- Post ROSC: CBC, electrolytes, lactate, glucose, toxicology screen, ABG

#### Imaging

- CXR: Confirm tracheal tube placement.
- Consider head CT for suspicion of trauma.
- Consider skeletal survey if suspicious for nonaccidental trauma.

#### Diagnostic Procedures/Other

- ECG
- Consider echo post ROSC to evaluate cardiac contractility and pericardial effusion.

### DIFFERENTIAL DIAGNOSIS

- Asystole, VF, PEA
- Determine rhythm in 2 different leads to assure no faulty lead placement.

## TREATMENT

### PRE HOSPITAL

- Activate EMS (5).
- Get automated defibrillation (automatic external defibrillator) (5).
- Start CPR (5).
- Airway management (5):
  - Short transport time: Bag-mask ventilation
  - Long transport time: Placement of advanced airway depends on the level of training, experience, and availability of end-tidal CO<sub>2</sub> detector.
  - If airway is obstructed, reposition (jaw thrust, head tilt chin lift) and look for foreign body in the oropharynx.

### INITIAL STABILIZATION/THERAPY

- Airway and breathing (5):
  - Tracheal intubation
  - Use capnography or an end-tidal CO<sub>2</sub> detector.
  - Resuscitation with 100% O<sub>2</sub>.
  - After ROSC: Titration of FiO<sub>2</sub> to ensure adequate oxygenation while avoiding hyperoxia
- Compression technique: Push hard, push fast, minimize interruptions (5):
  - Push hard: 1/3 of the depth of the chest
  - Infant: Chest compressions with 2 thumbs encircling hands technique (2 rescuers), or 2-finger technique (1 rescuer)
  - Children: 1- or 2-hand technique
- Compression/Ventilation ratio (5):
  - Lay rescuers 30:2 for single responder
  - Health care providers 15:2
  - After advanced airway is placed (eg, endotracheal tube, laryngeal mask airway, Combitube, etc.), ventilations are given without interrupting chest compressions at a rate of 8–10/min (compressions give at 100/min).
- Treatment algorithm (5):
  - CPR
  - Epinephrine every 3–5 min
  - Check pulse and cardiac rhythm every 2 min.
  - Rotate compressors every 2 min.
  - Check for potential causes (6Hs and 5Ts).
- Postresuscitation care (5):
  - Ventilation:
    - Target normocapnia:
    - Hyperventilation can cause hypocapnia and cerebral vasoconstriction, causing secondary brain insult.
    - Hyperventilate only for impending herniation.
  - Temperature:
    - Avoid hyperthermia.
    - Therapeutic hypothermia may be beneficial for neurologic outcome.
    - Consider inducing therapeutic hypothermia for 12–24 hr for comatose patients.
  - Hemodynamic support:
    - Vasoactive drugs to improve hemodynamics and maintain normotension: Epinephrine, norepinephrine, dopamine
  - Glucose control:
    - Avoid hyperglycemia or hypoglycemia.
    - Glucose-containing fluids are not recommended during resuscitation unless hypoglycemia is present.

### MEDICATION

Administration routes:

- IV or IO is preferable.
- Absorption of medication through a tracheal tube is uncertain.
- Epinephrine:
  - 0.01 mg/kg of 1:10 000 for the 1st and subsequent doses IV or IO:
    - Higher doses (IV or IO) are no longer recommended and may be harmful.
    - If administered via tracheal tube, use a dose of 0.1 mg/kg to compensate for lower absorption.
- Magnesium sulfate for hypomagnesemia or torsades de pointes:
  - 25–50 mg/kg, max 2 g IV or IO
- Dextrose if glucose is <50 mg/dL:
  - 0.25 g/kg rapid IV infusion (2.5 cc/kg D10)

### SURGERY/OTHER PROCEDURES

Extracorporeal membrane oxygenation (ECMO):

- Consider ECMO-CPR (E-CPR) for selected patients in which ROSC cannot be achieved (eg, in-hospital CA, witnessed arrests with bystander CPR and short transport time, in select patients with reversible pathologic processes).
- Consider ECMO for patients with hemodynamic instability after ROSC.

### DISPOSITION

#### Admission Criteria

Critical care admission criteria:

- All patients who have sustained CA

## FOLLOW-UP

### FOLLOW-UP RECOMMENDATIONS

#### PROGNOSIS

- Survival is lower for the following categories:
  - Infants
  - Congenital abnormalities (cardiac, chromosomal abnormalities)
  - Chronic conditions (malignancy, transplant, pulmonary, renal)
- Survival is higher for the following categories:
  - Bystander CPR was administered.
  - ROSC was obtained in the field or before arrival to the hospital.
  - Hospitals staffed with pediatric physicians
  - In-hospital CA vs. out-of-hospital CA (2)
  - Children compared with adolescents
- Survival to hospital discharge for all cases of pediatric CA:
  - Out-of-hospital CA: 12%
  - In-hospital CA: 27%
- Good neurologic outcome in children who gain ROSC (2):
  - Out-of-hospital CA: 24%
  - In-hospital CA: 47%

### COMPLICATIONS

- Hypoxic-ischemic encephalopathy
- Seizures
- Death

## CODES

ICD9

427.5 Cardiac arrest

## PEARLS AND PITFALLS

- Pearls:
  - ECMO-CPR should be considered for selected patients.
  - Check for potential causes of CA (6Hs, 5Ts).
- Pitfalls:
  - Inadvertent hyperventilation during CPR is common and harmful.

# ATAXIA

Steven Krebs  
Faye Doerhoff

## BASICS

### DESCRIPTION

- Ataxia is a disturbance in making coordinated movements.
- Ataxias may be generalized, affecting gait or affecting extremities alone.
- Acquired ataxia is commonly differentiated into acute, recurrent, or chronic:
  - Acute ataxia in children is uncommon, and life-threatening causes of pure ataxia are rare:
    - The most common cause is acute cerebellar ataxia (40% of all cases) (1).
      - Most common in younger children (2–4 yr of age) but may affect older children
      - 70% have a history of antecedent infection 1–3 wk prior to ataxia.
    - Toxic exposures account for ~30% of acute cases.
      - Most commonly, it is a poisoning in children ≤6 yr of age.
      - 2nd peak in adolescence, associated with intentional ingestion or drug abuse
  - Chronic ataxias can be further classified as progressive or nonprogressive:
    - Episodic and chronically progressive ataxias are uncommon and usually are caused by inherited metabolic or genetic disorders.

### RISK FACTORS

Access or exposure to toxic substances that may cause ataxia

### GENERAL PREVENTION

Poison prevention education is the most effective way to prevent toxic exposures:

- Emphasize childproof containers and safe storage of prescription medications so that they are inaccessible to children.

### PATHOPHYSIOLOGY

- Complex movements and activities are coordinated by the cerebellum:
  - The cerebellum lies in the posterior cranial fossa beneath the tentorium.
  - Lesions in the cerebellum, its afferent, and/or efferent pathways can cause ataxia:
    - Midline lesions affect truncal gait with swaying during walking, sitting or standing, or head/neck bobbing (titubations)
    - Unilateral hemisphere lesions cause movement disturbance in the ipsilateral side
  - Acute cerebellar ataxia usually results from postinfectious cerebellar demyelination.
- Hydrocephalus and increased intracranial pressure (ICP) from space-occupying lesions (posterior fossa tumors, cerebellar hemorrhage) may cause ataxia.
- Pathology of the inner ear or proprioceptive sensory dysfunction may also cause ataxia.

### ETIOLOGY

- Acute ataxia:
  - Acute cerebellar ataxia:
    - Historically, primary varicella was the most common etiology of acute cerebellar ataxia, preceding as many as 26% of cases (2).
    - Generally considered postinfectious; commonly occurs 2 wk following viral illness
  - Infectious/immune-mediated conditions for which directed therapy may be required:
    - Brainstem encephalitis; pneumococcal or meningococcal meningitis; herpes simplex virus (HSV)-1; acute demyelinating encephalomyelitis (ADEM); mycoplasma pneumonia; legionella; malaria; MS; systemic infections such as typhoid, scarlet fever, diphtheria, leptospirosis, and coxiella (Q fever)
    - Infectious/immune-mediated conditions for which supportive care is primary treatment:
      - Direct infection by echovirus, coxsackie B; post- or parainfectious cerebellitis by Epstein-Barr virus, hepatitis A, influenza A and B, coxsackie A, parvovirus B19, measles, mumps, enterovirus
  - Toxic exposure/ingestion: Alcohol, ethylene glycol, anticonvulsants, dextromethorphan, antihistamines, risperidone, phenothiazines
  - Mass lesions: Tumor, vascular malformation, abscess (cerebellar, cerebral, epidural)
  - Head or neck trauma: Cerebellar contusion/hemorrhage, posterior fossa hematoma, postconcussion syndrome, vertebralbasilar dissection
  - Vertigo or vestibular pathology
  - Postictal
  - Stroke
  - Paraneoplastic syndrome: Opsoclonus-myoclonus syndrome (neuroblastoma)
  - Sensory ataxia: Guillian-Barré syndrome (GBS), Miller-Fisher syndrome (MFS)
  - Other: Nonconvulsive seizures/epilepsy, central pontine myelinolysis, conversion disorder, parietic ataxia of upper or lower motor neurons
- Recurrent ataxia:
  - Recurrence of acute cerebellar ataxia
  - Migraine or equivalents: Basilar migraine, benign paroxysmal positional vertigo (BPPV)
  - Metabolic disorders: Mitochondrial disorders, urea cycle defects, amino/organic acidopathies, Hartnup disease
  - Genetic: Episodic ataxia types 1–4
- Chronic ataxia:
  - Progressive ataxia:
    - Brain tumor: Astrocytoma, pontine glioma, medulloblastoma, ependymoma
    - Genetic: Friedrich ataxia, ataxia telangiectasia, spinocerebellar degeneration, Refsum disease
    - Metabolic: Abetalipoproteinemia, liposomal storage disease, mitochondrial defects
  - Nonprogressive ataxia:
    - Head trauma, cerebral palsy, kernicterus
    - Congenital malformations: Arnold-Chiari, cerebellar agenesis/hypoplasia, Dandy-Walker

## DIAGNOSIS

### HISTORY

- Duration/progression of symptoms
- Identify any previous similar or related episodes.
- Identify recent illnesses (weeks to months).
- Associated vertigo or otalgia
- Recent head or neck trauma
- Recent immunizations
- Constitutional symptoms
- Access or exposure (witnessed or suspected) to medication, alcohol, or household chemicals
- Changes in gait, speech, general coordination
- Changes in cognitive function (in conjunction with motor findings may suggest toxic/acquired pathology)
- Changes in personality or behavior
- Recurrent or persistent headache, vomiting, and/or diplopia suggest intracranial mass lesion and possible elevated ICP
- Delay or loss of developmental milestones in infants and toddlers
- Repeated bronchopulmonary infections (ataxia-telangiectasia)
- Family history of ataxia (episodic ataxia)

### PHYSICAL EXAM

- Signs of increased ICP must be evaluated: Bulging fontanelle in infants, papilledema, Cushing triad (bradycardia, HTN, abnormal or irregular respirations)
- Meningismus including nuchal rigidity, Brudzinski and Kernig signs
- Neurologic exam may be difficult depending on age/cooperation of the child: Include general consciousness, cranial nerve function, strength, tone, deep tendon reflexes (hyper- or areflexia), proprioception, noting symmetry with all:
  - Patients with chronic lesions usually have normal tone and reflexes.
  - In infants, check for decreased truncal and/or extremity tone, areflexia, decreased deep tendon reflexes
- Detailed cerebellar examination: Difficult to impossible in younger children:
  - Observe posture and gait for wide base, staggering, zig-zag course, short unequal steps, inability to sit/stand unsupported
  - Swaying provoked with eye closure (Romberg sign) may or may not be present depending on the site of the lesion (lower vermis lesions cause postural tremor not enhanced with eye closure)
  - Limb ataxia more marked in:
    - Upper than lower extremities
    - Complex than simple movements
    - Fast then slow movements (finger-to-nose, heel-to-shin, rapid alternating movements)
  - Distal movements are typically more affected than proximal movements.
  - Oculomotor signs such as rebound nystagmus, opsoclonus

**DIAGNOSTIC TESTS & INTERPRETATION**

**Lab**

- Bedside serum glucose testing
- Lumbar puncture (LP) if febrile, toxic appearing, or meningitic:
  - CSF studies including culture with Gram stain, protein, glucose, cell count, and viral studies: HSV, enterovirus, etc.
  - Obtain opening pressures when possible.
  - CSF examination is routinely normal in postinfectious acute cerebellar ataxia.
- Urine/serum toxicology screens:
  - Drug level should be obtained where a specific intoxicant is identified.
- Urinary catecholamine metabolites for suspicion of neuroblastoma
- Serologic evaluation for suspected inborn error of metabolism includes CBC, transaminases, ammonia, lactate, pyruvate, and ketone levels.

**Imaging**

- Urgent head/brain imaging (usually CT) in any patient with acute presentation of unknown etiology, focal neurologic deficits, altered consciousness, recent head trauma, signs of increased ICP, or persistent ataxia for > 1 wk:
  - Any patient having LP performed should first have head imaging to rule out obstruction or cerebellar herniation.
  - MRI can detect inflammation/encephalitis, and is better at posterior fossa imaging but is slower than CT; need for stat MRI may be discussed with neurologist and/or radiologist.
- If nuchal rigidity or pain or headache, consider urgent CT or MRI; cerebellar herniation may cause these symptoms.

**Diagnostic Procedures/Other**

Further diagnostic testing may be indicated after consultation with neurology:

- EEG in patients with altered consciousness and fluctuating clinical signs
- Electromyography in patients with sensory ataxia may help diagnose or confirm GBS or MFS.

**DIFFERENTIAL DIAGNOSIS**

See Etiology.

**TREATMENT**

**PRE HOSPITAL**

In the setting of recent trauma, cervical spine stabilization and evaluation of ABCs

**INITIAL STABILIZATION/THERAPY**

- Prompt evaluation of ABCs
- Appropriate immobilization in cases of trauma

**MEDICATION**

**First Line**

- Suspicion of active infectious etiology (meningitis, encephalitis) warrants coverage with broad-spectrum antibiotics pending identification of a causative organism. Consider acyclovir as well:
  - Ceftriaxone 50 mg/kg IV (max single dose 2 g) q12h (meningitic dosing)

- Acyclovir IV q8h: 20 mg/kg <12 yr old; 10 mg/kg ≥ 12 yr old
- If immunocompromised, cover for *Listeria monocytogenes*
  - Ampicillin 50 mg/kg IV q6h plus aminoglycoside
- Consider mannitol or hypertonic saline for increased ICP:
  - Neurosurgery consultation is necessary for any patient with evidence of increased ICP.

**Second Line**

- GBS and MFS may be treated with intravenous immunoglobulin (IVIG) and/or plasmapheresis.
- ADEM/inflammatory conditions may be treated with methylprednisolone or IVIG (specialty consultation recommended).

**DISPOSITION**

**Admission Criteria**

- Inpatient admission criteria:
  - Any acute ataxia without established etiology
  - Concern for active infectious etiology requiring IV antibiotic/antiviral treatment
  - Suspicion of GBS/MFS
  - Known or suspected ingestion of toxic substance requiring prolonged monitoring for clearance
- Critical care admission criteria:
  - Cases requiring advanced airway support
  - Evidence of increased ICP, for neurosurgical intervention, or for monitoring of treatment

**Discharge Criteria**

- Well-appearing patients with acute cerebellar ataxia
- Toxic substance ingestions with short half-life and return to baseline function

**Issues for Referral**

- Consider emergency department or inpatient neurology consultation especially when no clear etiology is readily identified.
- Consider infectious disease consultation for inpatients with suspected infectious etiology.
- Local or regional poison control center and/or toxicology consultation for management recommendations of known or suspected ingestion
- Inpatient cardiology evaluation if suspicion or diagnosis of Friedrich ataxia
- Inpatient genetics evaluation if suspicion of inborn error of metabolism

**FOLLOW-UP**

**FOLLOW-UP RECOMMENDATIONS**

- Discharge instructions and medications:
  - Supportive care and reassurance are the mainstays in the majority of cases.
  - For significant ataxia, head protection may be indicated due to risk of fall.
- Activity:
  - Strenuous activities such as sports or those requiring complex coordination (eg, bicycling) should be avoided until all symptoms resolve.

**PROGNOSIS**

- Outcome is largely determined by etiology.
- Acute cerebellar ataxia has an excellent prognosis, with most patients recovering completely without intervention within 2 wk to 3 mo.
- With or without specific treatment, >90% of GBS and MFS patients recover fully within 6–12 mo.

**COMPLICATIONS**

Tumors, stroke, traumatic brain injury, and brainstem encephalitis are commonly complicated by significant neurologic sequelae.

**REFERENCES**

- Johnston MV. Movement disorders. In Kleigman RM, Behrman RE, Jenson HB, et al., eds. *Nelson Textbook of Pediatrics.* 8th ed. Philadelphia, PA: Saunders; 2007.
- Ryan MM, Engle EC. Acute ataxia in childhood. *J Child Neurol.* 2003;18(5):308–316.

- 334.3 Other cerebellar ataxia
- 781.2 Abnormality of gait
- 781.3 Lack of coordination

**PEARLS AND PITFALLS**

- Failure to recognize signs of increased ICP may result in worse neurologic outcomes or delay of lifesaving intervention.
- Acute cerebellar ataxia generally has no other symptoms outside of incoordination, unsteady gait, or tremor—any other findings require investigation of alternate etiologies.
- MFS is characterized by triad of ataxia, areflexia, and ophthalmoplegia (usually diplopia).

# ATLANTOAXIAL INSTABILITY

Joni E. Rabiner  
Jeffrey R. Avner

## BASICS

### DESCRIPTION

- Atlantoaxial instability (AAI) is characterized by excessive mobility at the articulation between C1 (atlas) and C2 (axis):
  - AAI is due to bony abnormality and/or ligamentous laxity or defect.
  - Considered symptomatic if there are neurologic symptoms consistent with spinal cord compression
  - The atlantodens interval (ADI) is the predental space between the anterior aspect of the dens and the posterior border of the anterior arch of C1.
  - AAI may be defined as an ADI on lateral cervical spine x-ray of greater than:
    - 4–5 mm in children <8 yr of age
    - 3 mm in older children and adults
- Atlantoaxial rotary subluxation:
  - A form of AAI that results in forced rotation of the neck with lateral tilt (torticollis)
  - Usually due to laxity or disruption of the alar ligaments
  - May occur spontaneously or in association with trauma or neck infection

### EPIDEMIOLOGY

- Rare in absence of risk factors such as trauma or Down syndrome:
  - Trauma: 10% of cervical spine fractures involve C1-2
  - Down syndrome:
    - Asymptomatic AAI in 10–20%
    - Symptomatic AAI in 1–2%
- There is no evidence that asymptomatic AAI increases the risk of developing symptomatic AAI (1).

### RISK FACTORS

- Trauma: Flexion with axial load displaces the odontoid process posteriorly and injures the transverse ligament.
- Down syndrome: Associated with laxity of the transverse ligament
- Odontoid process abnormalities: Aplasia, hypoplasia, fracture:
  - Os odontoideum (failure of the odontoid process to fuse with the body of C2)
- Congenital syndromes affecting bones and/or soft tissues of the neck: Congenital scoliosis, osteogenesis imperfecta, neurofibromatosis, spondyloepiphyseal dysplasia congenita (40% risk of AAI), Morquio syndrome (due to odontoid hypoplasia/aplasia), Larsen syndrome, Klippel-Feil syndrome, chondrodysplasia punctata
- Infections or surgery of the head/neck:
  - Grisel syndrome: A form of AAI due to ligamentous laxity as result of an infectious or inflammatory process of the head and neck region
- Rheumatoid arthritis
- Degenerative spinal disease

### GENERAL PREVENTION

- Recommendations vary and should be individualized.
- The Special Olympics requires radiologic screening for all athletes with Down syndrome prior to sports participation.
- The American Academy of Pediatrics recommends the use of history and physical examination to screen for symptomatic AAI in patients with Down syndrome but does not support routine radiologic screening for asymptomatic AAI (1).

### PATHOPHYSIOLOGY

- The atlantoaxial articulation depends on the stability of the odontoid process and the surrounding ligaments:
  - Any laxity, injury, and/or disruption of the spinal ligaments or bony structures may cause AAI.
- Spinal ligaments:
  - The transverse ligament is a strong ligament that keeps the odontoid process in contact with C1 and prevents AP displacement.
  - The paired alar “check” ligaments attach the odontoid process to the occipital condyles and prevent rotary displacement.
- The Steele rule of 3rds: Spinal cord, odontoid process, and empty space each account for 1/3 of the diameter of the C1 ring:
  - With AAI, the odontoid process loses contact with C1, moves posteriorly, and approaches the spinal cord (especially with neck flexion).
  - The presence of empty space within the ring of C1 allows for some pathologic displacement of the odontoid process posteriorly without impinging on the spinal cord.
- In the skeletally mature spine, the atlantoaxial joint has 10 degrees of flexion and extension and 50 degrees of rotation with minimal lateral bending (2).

### ETIOLOGY

- Trauma
- Rotary subluxation can occur following an upper respiratory infection, head/neck surgery, or minor trauma.
- Occurs primarily in children

### COMMONLY ASSOCIATED CONDITIONS

See Risk Factors.

## DIAGNOSIS

### HISTORY

- Trauma:
  - Head or facial injury associated with neck flexion and axial load (eg, head hitting a car windshield or a diving accident)
- Down syndrome
- Other congenital syndromes (see Risk Factors)
- Recent infection or surgery
- Neurologic symptoms: Easily fatigued, changes in gait, changes in bowel or bladder function, clumsiness
- Neck: Pain, decreased range of motion, head tilt, or torticollis

### PHYSICAL EXAM

- Vital signs
- Thorough neurologic exam for:
  - Upper motor neuron signs: Hyperreflexia, clonus, Babinski
  - Posterior column signs: Diminished touch, proprioception
- Neck exam for tenderness over the cervical spinous processes
- Torticollis or “cock-robin” deformity of the neck (seen in rotary subluxation):
  - Sudeck sign in rotary subluxation: Chin and spinous process of C2 point to the same side.
  - Complete physical exam looking for evidence of congenital syndromes.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

Consider CBC, ESR/C-reactive protein, and rapid strep test for Grisel syndrome.

#### Imaging

- Radiographic imaging is indicated for patients with neck pain and/or neurologic symptoms in the setting of trauma or other risk factors for AAI.
- X-rays of the cervical spine:
  - AP, lateral, and open-mouth odontoid views (or Waters view for children unable to cooperate with open mouth view)
  - ADI should be measured on the lateral view:
    - Maximal ADI occurs in flexion.
    - Posterior ADI, the distance between the posterior aspect of the dens and anterior aspect of the posterior portion of C1, correlates with neurologic deficits.
      - In young children, the posterior ADI should be greater than the transverse diameter of the dens.
      - In teenagers, the posterior ADI should be > 13–14 mm.
      - Shortening of the posterior ADI reflects narrowing of the spinal canal with likely impingement of the spinal cord.
  - Flexion and extension views if cervical spine is stable:
    - Do not attempt flexion and extension views if there are neurologic symptoms.
    - Flexion and extension views should never be forced, as pain will limit flexion of the neck to prevent the odontoid process from impinging on the spinal cord.
    - Widening of the ADI in flexion is a sign of occult instability.
- Radiographic results are often poorly reproducible and can change over time from abnormal to normal or from normal to abnormal.
- Further diagnostic imaging (CT or MRI) is indicated:
  - If the initial cervical spine x-ray is abnormal
  - If the initial cervical spine x-ray is normal, consider further imaging for persistent torticollis, neck pain, limitation of neck movement (especially if associated with trauma or a recent head/neck infection), or neurologic symptoms.
  - CT: Dynamic CT scanning with flexion and extension
  - MRI to evaluate ligaments, spinal cord

**DIFFERENTIAL DIAGNOSIS**

- Atlantoaxial dislocation
- Os odontoideum

**TREATMENT****PRE HOSPITAL**

Cervical spine immobilization if:

- Trauma with the presence of neck pain, limitation of neck movement, neurologic symptoms, distracting injury
- Known AAI with neurologic symptoms

**INITIAL STABILIZATION/THERAPY**

- Maintain cervical spine stabilization with a hard cervical collar until a thorough neurologic exam is completed and appropriate imaging, if indicated, is obtained and reviewed.
- Asymptomatic AAI: No treatment
- Symptomatic AAI: Cervical spine stabilization maintaining the spine in a neutral position
- Rotary subluxation: Most resolve spontaneously; antibiotics to treat associated infections as needed:
  - <1 wk of symptoms: Soft collar, rest for a week, physical therapy
  - >1 wk of symptoms: Halo traction

**MEDICATION****First Line**

Consider NSAIDs to reduce inflammation in rotary subluxation:

- Ibuprofen 10 mg/kg/dose PO/IV q6h PRN, max dose 800 mg PO, 2.4 g/24 hr
- Ketorolac 0.5 mg/kg IV/IM q6h PRN, max dose 30 mg/dose, 120 mg/24 hr
- Naproxen 5 mg/kg PO q8h PRN, max dose 500 mg/dose, 1,250 mg/24 hr

**Second Line**

- Methylprednisolone 30 mg/kg IV over 15 min followed by an infusion of 5.4 mg/kg over the next 23 hr:
  - Indicated for neoplastic or inflammatory etiology of spinal cord compression
  - Dosage derived from adult guidelines due to lack of high-level evidence in pediatrics
  - Steroids are no longer routinely used for spinal cord trauma, as current data has led to its withdrawal from Advanced Trauma Life Support (ATLS) guidelines.
- Dexamethasone may be used for spinal cord compression:
  - Numerous dosing regimens exist, with no very definitive benefit of a specific regimen. Refer to the consulting neurologist and/or neurosurgeon for dosing recommendations.

**SURGERY/OTHER PROCEDURES**

Posterior C1-2 fusion for unstable displacement, neurologic involvement, or transverse ligament injuries, as they are unlikely to heal

**DISPOSITION****Admission Criteria**

- Admit patients with suspected AAI.
- Critical care admission criteria:
  - Symptoms of spinal cord compression

**Discharge Criteria**

Stable cervical spine without neurologic symptoms

**Issues for Referral**

Consult neurosurgery and/or orthopedic surgery for symptomatic AAI.

**FOLLOW-UP****FOLLOW-UP RECOMMENDATIONS**

- Discharge instructions and medications:
  - Follow-up for repeat imaging as directed
  - Neurologic consultation and close follow-up should be assured if there is any radiographic abnormality or if there is high suspicion of injury (eg, persistent neck pain, neurologic symptoms) regardless of radiographic results.
- Activity:
  - Activity recommendations are made on an individual basis.
  - In general, avoid contact sports or sports with high risk of neck flexion in patients with:
    - Postsurgical stabilization
    - Down syndrome with ADI >5 mm
  - High-risk sports include gymnastics, diving, pentathlon, butterfly stroke, high jump, and soccer.

**Patient Monitoring**

Observe for neurologic symptoms.

**PROGNOSIS**

Depends on cause of AAI and neurologic involvement:

- Good prognosis for those with symptomatic AAI treated with surgery

**COMPLICATIONS**

- Subluxation
- Spinal cord compression with excessive range of motion in AAI

**See Also (Topic, Algorithm, Electronic Media Element)**

- Fracture, Cervical spine
- Spinal Cord Compression
- Trauma, Neck

**CODES****ICD9**

718.88 Other joint derangement, not elsewhere classified, involving other specified sites

**PEARLS AND PITFALLS**

- Pearls:
  - Down syndrome is an important associated condition that increases the risk of AAI and resultant spinal cord compression.
  - Any patient with an increased predental space on lateral cervical spine x-ray should have additional radiographic imaging (CT or MRI) to delineate the presence and/or extent of injury, regardless of the presence or absence of neurologic symptoms.
  - Persistent torticollis, neck pain, or limitation of neck movement (especially if associated with trauma or a recent head/neck infection) may be a sign of atlantoaxial rotary subluxation.
- Pitfalls:
  - Forcing the neck into a neutral position during clinical evaluation if there is resistance to movement, increased pain, or torticollis
  - Inaccurate measurement of the predental space on a lateral cervical spine x-ray
  - Attempting and/or forcing flexion and extension views of the cervical spine if there are neurologic symptoms

# ATOPIC DERMATITIS

Désirée M. Seeyave

## BASICS

### DESCRIPTION

- Atopic dermatitis, also known as eczema, is a chronic, pruritic, relapsing skin eruption that is worse in infants and toddlers and generally improves with age.
- Inflammation causes itching, scratching, and scarring.
- Variants include:
  - Infantile eczema
  - Nummular eczema
  - Dyshidrotic eczema
  - Eczema herpeticum
  - Exfoliative erythroderma

### EPIDEMIOLOGY

#### Incidence

- ~60% of children with atopic dermatitis develop it before 1 yr and 80% develop it by 5 yr of age.
- Rarely, it can appear 1st at puberty or later.

#### Prevalence

Occurs in 10–20% of children

### RISK FACTORS

- Personal or family history of atopy: Asthma, allergic rhinitis, atopic dermatitis
- Excessive dryness of skin, exacerbated by winter, dry air, and prolonged or frequent hot baths
- Stress
- Sweating
- Environmental allergens (eg, pollens or dust mite antigen)
- Food allergen exposure (eg, milk protein, peanuts, eggs)

### GENERAL PREVENTION

Strategies to minimize rash in patients with eczema:

- Keep skin lubricated often, and prevent excessive stripping of natural oils from skin.
- Shorten bath times, use lukewarm instead of hot water, and apply lubricant immediately after washing.
- Use humidifiers during winter to prevent excessive drying of skin.
- Avoid use of harsh soaps, cleansers, and other chemicals.

### ETIOLOGY

- Multifactorial etiology, with genetic, environmental, physiologic, and immunologic factors influencing acute and chronic flares
- Increased IgE levels and response to triggering agents lead to release of histamine, prostaglandins, and cytokines.
- Decreased cell-mediated immunity and impaired neutrophil chemotaxis

### COMMONLY ASSOCIATED CONDITIONS

- Asthma, allergic rhinitis
- Food allergies
- Early growth delay

## DIAGNOSIS

### HISTORY

- History of atopy or atopic dermatitis
- Symptoms of:
  - Acute waxing and waning of itchy, dry patches of skin
  - Weeping of skin
  - Hyper- or hypopigmentation

### PHYSICAL EXAM

- Acute flares: Poorly demarcated erythema, with weeping, crusting, edema, exudation, papulovesicles, scaling, or crusting
- Chronic disease: Poorly defined hyper- or hypopigmentation, lichenification (thickened skin), scaling, and excoriation
- Age-dependent distribution:
  - Infantile eczema:
    - Widespread disease involving cheeks, forehead, scalp, diaper area, and extensor surfaces
  - Children 3–11 yr:
    - Flexural surfaces (neck, antecubital and popliteal fossae) with lichenification
    - Hands and feet may be involved.
  - Adolescence to adulthood: Flexures, hands, feet, occasionally face, eyelids, and neck
- Exfoliative erythroderma with diffuse scaling and erythema in severe cases
- Nummular eczema: Single or multiple coin-shaped plaques on extensor surfaces of hands, arms, and legs:
  - May have central clearing and round lesions similar to dermatophyte infections, impetigo, or granuloma annulare
- Eczema herpeticum or Kaposi varicelliform eruption:
  - Disseminated herpes simplex virus 1 or 2 infection; also can be due to coxsackievirus A16 or vaccinia virus
  - Umbilicated vesiculopustular eruption usually is disseminated and widespread in areas of skin affected by atopic dermatitis.
  - Vesicles may become hemorrhagic and crusted, painful punched-out erosions.
- Other associated findings:
  - Xerosis (dry skin)
  - Geographic tongue
  - Dennie-Morgan folds (infraorbital eyelid folds)
  - Pityriasis alba (dry, scaly, hypopigmented patches)
  - Ichthyosis vulgaris (inherited fishlike scaling)
  - Keratosis pilaris (chicken-skin appearance due to cornified plugs in upper hair follicles)
  - Hyperlinear palms
  - Facial pallor/infraorbital darkening
  - Keratosis pilaris (follicular accentuation on extensor surfaces of upper arms and thighs)

## DIAGNOSTIC TESTS & INTERPRETATION

### Lab

- No diagnostic tests are available.
  - Elevated IgE levels are common.
- Bacterial or viral cultures when lesions are superinfected during acute flares
- Tzanck smear and viral culture to confirm eczema herpeticum

### Diagnostic Procedures/Other

- Biopsy can be done to rule out other skin conditions.
- Patch testing to differentiate atopic from contact or allergic dermatitis

### Pathological Findings

Biopsy may reveal:

- Nonspecific lymphocytic infiltration of epidermis and intercellular edema in acute flares
- Hyperplasia and hyperkeratosis in chronic disease

## DIFFERENTIAL DIAGNOSIS

- Seborrheic and contact dermatitis
- Psoriasis
- Scabies
- Xerosis
- Wiskott-Aldrich syndrome
- Histiocytosis X
- Acrodermatitis enteropathica
- Hyper-IgE syndrome

## TREATMENT

### INITIAL STABILIZATION/THERAPY

- If ill appearing, address ABCs per Pediatric Advanced Life Support (PALS) algorithm.
- Infections of the skin, such as eczema herpeticum, are the most common emergencies associated with atopic dermatitis.
- Hydration status is especially important in severe cases:
  - May need fluid resuscitation similar to burn management
- Topical steroids to control inflammation. Begin with mid- to high-potency steroids per day–b.i.d. for acute flares (no longer than 7 days) and taper to low-potency steroid.

### MEDICATION

#### First Line

- High potency steroids:
  - Halcinonide (Halog) 0.1% cream/ointment per day or b.i.d.
  - Fluocinonide (Lidex) 0.05% cream/ointment per day or b.i.d.
  - Desoximetasone (Topicort) per day or b.i.d.
  - Betamethasone dipropionate (Diprosone) 0.05% per day or b.i.d.

- Mid-potency steroids:
  - Betamethasone valerate (Valisone) 0.1% cream/ointment b.i.d.
  - Fluticasone (Cutivate) 0.05% cream/ointment b.i.d.
  - Mometasone (Elocon) 0.1% cream/ointment/lotion b.i.d.
  - Prednicarbate (Dermatop) 0.1% b.i.d.
  - Triamcinolone acetonide (Aristocort) 0.1% cream/ointment b.i.d.
- Low-potency steroids:
  - Hydrocortisone 1–2.5% cream/ointment/lotion b.i.d.–t.i.d.
  - Desonide (DesOwen) 0.05% cream b.i.d.
  - Fluocinolone acetonide (Synalar) 0.01% cream, apply sparingly b.i.d.
- Low-cost generic steroids:
  - Betamethasone dipropionate 0.05% ointment/cream
  - Mometasone 0.1% cream/ointment/lotion
  - Triamcinolone acetonide 0.1% ointment/cream
  - Fluocinolone acetonide 0.01%
  - Hydrocortisone 1% cream/ointment/lotion
- Bland emollients (eg, Aquaphor, Vaseline®), apply liberally several times a day
- Antihistamines to control itching:
  - Diphenhydramine 1.25 mg/kg/dose q6h PO/IM/IV (max 300 mg/day)
  - Hydroxyzine 2 mg/kg/day divided q6–8h PO; 0.5–1 mg/kg/dose q4–6h IM PRN
- Calcineurin phosphatase inhibitors:
  - Suppresses T-cell function
  - Safe and effective in children >2 yr of age with severe atopic dermatitis (1)
  - Tacrolimus 0.03% or 0.1% cream or pimecrolimus 1% cream: Apply a thin layer to the skin b.i.d. and continue for 1 wk after skin clearance.
- Antivirals for eczema herpeticum:
  - Acyclovir 15 mg/kg/day IV divided q8h or 1,200 mg/day PO (max 80 mg/kg/day) divided q6–8h × 7–10 days
  - Valacyclovir 20 mg/kg PO t.i.d. for 5 days (max 3 g/day) in children >2 yr

**ALERT**

- Use of corticosteroids on the face may produce permanent change in cosmetic appearance. Limit corticosteroid use on the face to <3–5 days of continuous use.
- Calcineurin phosphate inhibitors should not be used with occlusive dressings, and sun exposure should be avoided. Side effects include burning, pruritus, flulike symptoms, allergic reaction, erythema, and headache.

**Second Line**

- Prednisone 1–2 mg/kg PO divided per day–b.i.d.:
- A short course may be given in disease that is difficult to control or hospitalized patients.
  - Never use in any case of eczema herpeticum.

**DISPOSITION**

**Admission Criteria**

- Ill appearing
- Extensive skin involvement with weeping, secondary bacterial or viral superinfection
- Dehydration from excessive loss of fluids from the skin
- Disseminated eczema herpeticum for IV antivirals

**Discharge Criteria**

- Well appearing
- Mild-moderate involvement of skin
- Reliable follow-up

**Issues for Referral**

Refer to dermatologist in severe cases, unresponsive to topical steroids, extensive lichenification, eczema herpeticum

**COMPLEMENTARY & ALTERNATIVE THERAPIES**

- Phototherapy with ultraviolet B for extensive and resistant disease (2)
- Probiotic-supplemented formula: *Bifidobacterium lactis* Bb-12 and *Lactobacillus* strain GG decrease severity of atopic dermatitis in babies being weaned off breast milk (3).
- Trim nails to prevent scratching.
- Protective clothing while sleeping.
- Cold compresses q.i.d. for acute flares with oozing, crusting, and superinfection

**FOLLOW-UP**

**FOLLOW-UP RECOMMENDATIONS**

Discharge instructions and medications:

- Frequent application of emollients for skin
- Limit length, frequency, and temperature of bathing.
- Topical steroids for active lesions: Mild, mid-, high potency
- Primary care provider follow-up in 1–2 wk, sooner if culture of lesions was performed
- Return for pain or swelling, increasing discharge, fever, worsening of skin condition

**DIET**

Avoid known food allergies; in severe disease, avoid common food allergens (eg, milk protein, peanuts, eggs).

**PROGNOSIS**

- Up to 50% of patients outgrow atopic dermatitis after 5 yr of age.
- Can be a lifelong condition; tends to improve with age

**COMPLICATIONS**

- Hyper- or hypopigmentation of affected areas
- Sepsis from bacterial or viral superinfection
- Localized abscess formation
- Flexion contractures in severe cases
- Overuse of potent topical steroids can result in hypopigmentation, telangiectasias, atrophy, striae, and systemic absorption leading to hypothalamic-pituitary axis suppression and growth retardation.

**REFERENCES**

1. Paller A, Eichenfield LF, Leung DY, et al. A 12-week study of tacrolimus ointment for the treatment of atopic dermatitis in pediatric patients. *J Am Acad Dermatol.* 2001;44(1 Suppl):S47–S57.
2. Hoare C, Li Wan Po A, Williams H. Systematic review of treatments for atopic eczema. *Health Technol Assess.* 2000;4(37):1–191.
3. Isolauri E, Arvola T, Tas YS, et al. Probiotics in the management of atopic eczema. *Clin Exp Allergy.* 2000;30(11):1604–1610.

**CODES**

**ICD9**

- 690.12 Seborrheic infantile dermatitis
- 691.8 Other atopic dermatitis and related conditions
- 705.81 Dyshidrosis

**PEARLS AND PITFALLS**

- Good skin care and lubrication are essential for control of disease.
- Topical steroid overuse can lead to chronic skin changes and adrenal suppression.
- Eczema herpeticum and severe disease can lead to severe fluid loss from lack of a protective skin barrier.

# AVASCULAR NECROSIS OF THE FEMORAL HEAD

Louis A. Spina

## BASICS

### DESCRIPTION

- Avascular necrosis (AVN) is an aseptic necrosis resulting from disrupted blood supply:
  - The areas of dead bone are weakened and can lead to collapse.
- AVN may occur in any joint or bone and in any age group but is most common in the hip joint:
  - In pediatrics, Legg-Calvé-Perthes disease (LCPD), which is the main focus of this topic, is the most common cause of AVN of the femoral head (hip joint).
  - AVN may also occur as complications of:
    - Slipped capital femoral epiphysis (SCFE)
    - Developmental dysplasia of the hip (DDH)
- A high index of suspicion is usually necessary for accurate early diagnosis.

### EPIDEMIOLOGY

- Usually occurs in children between 3 and 12 yr of age
- Most commonly seen between 5 and 7 yr of age
- Boys are affected 3–5 times as often as girls.
- 10–20% of cases are bilateral.
- Uncommon in black and Hispanic populations

### Incidence

Occurs in ~6 out of 100,000 children

### RISK FACTORS

- Low birth weight
- 2nd-hand smoke exposure as well as maternal smoking during pregnancy (1)
- Steroid exposure
- Birth via C-section (1)
- Delayed growth maturation
- Other hip conditions:
  - SCFE
  - DDH
- HTN
- HIV infection:
  - Unclear if increased risk is from HIV infection itself, HIV-associated complications, or complications of HIV-directed therapy (2)

### GENERAL PREVENTION

- Avoidance of known risk factors
- Successful diagnosis and management of conditions such as DDH and SCFE
- Identification and treatment of antithrombin factor deficiencies, hypofibrinolysis, and thrombophilia:
  - Protein-C deficiency
  - Protein-S deficiency
  - Antithrombin factor C or S deficiency
  - Resistance to activated protein-C

### PATHOPHYSIOLOGY

Circulation to the femoral head is interrupted due to traumatic or nontraumatic causes:

- This leads to death of the bone marrow and osteocytes, which leads to collapse of the involved segment.

### ETIOLOGY

- The cause of LCPD is unknown:
  - Mechanical obstruction of extraosseous vessels has not been demonstrated.
  - There is suggestion that LCPD is a local manifestation of a generalized transient disorder of the epiphyseal cartilage, rendering it avascular.
- When associated with acquired abnormalities such as SCFE and DDH, the etiology is better understood:
  - In DDH, AVN is usually iatrogenic, secondary to cartilaginous compression during reduction of the joint.
  - In SCFE, AVN may result from injury to the retinacular vessels, compression from an intrascapular hematoma, direct injury from operative repair, or due to forced manipulation of an unstable or acute slippage.

### COMMONLY ASSOCIATED CONDITIONS

- Sickle cell disease/hemoglobinopathies:
  - Sickling of RBCs leads to hyperviscosity and vascular occlusion in the intramedullary capillaries and veins.
- HIV infection
- Chronic renal disease/dialysis:
  - Increased parathyroid hormone leads to increased bone turnover, disorganized bone matrix, and microfractures.
- Systemic lupus erythematosus:
  - With high-dose corticosteroid therapy
- HTN
- Alcoholism

## DIAGNOSIS

### HISTORY

- The presenting complaint is usually a limp.
- There may or may not be associated pain:
  - If pain is present, it may be in the affected hip, the anterior ipsilateral thigh, or the ipsilateral knee (referred pain).
  - Pain is usually mild and/or intermittent.
- Parents sometimes report what they feel is an associated injury.
- Parents or child may report complaints of “growing pains.”

- Review of systems is pertinent for:
  - No isolated fever
  - Symptoms isolated to 1 or both lower extremities
  - No constitutional symptoms, such as weight loss, myalgias, etc.
  - No significant medical problems, such as leukemia, juvenile rheumatoid arthritis, etc.

### PHYSICAL EXAM

- Patients are generally well appearing (nontoxic) and afebrile.
- An antalgic gait is usually present:
  - In delayed presentation, a Trendelenburg gait may be present.
- Limitations in abduction and internal rotation of the affected hip are usually present with the hip positioned in both flexion and extension.
- Shortening of the affected limb may be present.
- Atrophy of the proximal thigh on the affected limb may be present.
- Pertinent negatives on physical exam:
  - Normal range of motion of the knee(s)
  - No swelling or bruising

### DIAGNOSTIC TESTS & INTERPRETATION

#### Imaging

- Radiographic evaluation of bilateral hips with both AP and Lauenstein (frog) lateral views should be the initial imaging modality:
  - Often normal in early stages of the disease
  - In later stages, increased density of necrotic bone will be seen.
  - Can show a flattened, fragmented, and small femoral head
  - Mottled density may be present in areas of osteoclastic activity with new bone formation.
  - The modified lateral pillar classification of the femoral head seen on x-ray has been developed to help determine the extent of disease (3):
    - Group A: The height of the lateral pillar is normal.
    - Group B: There is reduction between 50% and 100% of the original height of the lateral pillar.
    - Group B/C: There is reduction of exactly 50% of the original height of the lateral pillar with a thin and poorly ossified lateral pillar.
    - Group C: There is reduction of >50% of the original height of the lateral pillar.
- MRI is the most accurate modality and is the study of choice in those with normal radiographs and suspected AVN:
  - Double line sign in T2 images are classic:
    - 2 concentric low- and high-signal bands
  - Useful for picking up bilateral cases of AVN
  - Smaller lesions (<1/4th the diameter of the radial head) and more medial lesions predict better outcomes.

- A bone scan may be obtained if radiography is indeterminate with high index of suspicion and MRI is either unavailable or contraindicated:
  - This will show decreased uptake/perfusion to the femoral head.
  - Photopenic area surrounded by increased tracer uptake is typical.
  - Less sensitive and less specific than MRI

**DIFFERENTIAL DIAGNOSIS**

- Trauma, fracture
- Soft tissue injury
- Transient synovitis
- Septic arthritis
- Osteomyelitis
- Rheumatic disease, arthritis
- Malignancy, tumor
- Appendicitis
- Testicular torsion
- Pelvic inflammatory disease

**TREATMENT**

**INITIAL STABILIZATION/THERAPY**

- Treatment is focused on removing pressure from the joint and allowing the disease to run its course:
  - Cannot “cure” the disease, but the goal is to minimize damage to and allow for remodeling of the femoral head.
- Crutches and/or a cane may be useful in those old enough to use appropriately.
- Avoidance of activities and sports that put pressure on the hip joint

**COMPLEMENTARY & ALTERNATIVE THERAPIES**

- IV bisphosphonate therapy has been associated with preserving the integrity of the femoral head in children with traumatic AVN.
- IV zoledronic acid has been shown in a small study to reduce bone remodeling and turnover, especially in the LCPD group:
  - Zoledronic acid requires further study to confirm patient safety and efficacy before its use can be widely recommended.

**SURGERY/OTHER PROCEDURES**

- An operative vs. nonoperative approach (with bracing) is still controversial.
- Surgery may involve a pelvic osteotomy, a femoral osteotomy, or a combination of the two.
- Indication for surgical repair is based on disease category and age at presentation of disease:
  - Children  $\leq 8$  yr of age with group B classification have been found to do equally as well with both operative and nonoperative treatment (4).
  - Children  $\geq 8$  yr of age with group B or B/C disease classification have been found to do significantly better with surgical treatment (4).
  - Children with group C classification have the poorest outcome regardless of the treatment route (4).

**DISPOSITION**

**Admission Criteria**

- Admission is not usually necessary for LCPD.
- Operative therapy can be scheduled electively as an outpatient.

**Discharge Criteria**

LCPD is managed as an outpatient provided that:

- Orthopedic consultation has been obtained or close follow-up with a pediatric orthopedist has been arranged.
- Pain, if present, is well controlled.

**Issues for Referral**

All patients with the diagnosis of AVN of the femoral head should have urgent referral to a pediatric orthopedist.

**FOLLOW-UP**

**FOLLOW-UP RECOMMENDATIONS**

Activity:

- Recommended activity may vary dependent on severity of the disease; treatment is still somewhat controversial.
- Nonoperative treatment ranges from non-weight bearing with a brace, weight bearing with a brace allowing for limited movement, and weight bearing with a brace that allows full movement of the hip.
- Physical therapy is sometimes used to improve range of motion of the hip.

**PROGNOSIS**

- 2 factors that are of long-term prognostic value (5):
  - Age of the patient at the onset of disease
  - Shape of the femoral head at skeletal maturity
- Age at which long-term results are felt to worsen is 8–9 yr.
- Lateral pillar classification has been shown to correlate with prognosis:
  - Classifications B/C and C have been directly correlated with poor prognosis (4,6).
- Most patients clinically do well in early adulthood.
- Radiographic osteoarthritis is increased in 20- and 40-yr follow-ups.
- Most patients who had poor results at skeletal maturity develop osteoarthritis over 50 yr of life.

**CODES**

**ICD9**  
733.42 Aseptic necrosis of head and neck of femur

**PEARLS AND PITFALLS**

- Pearls:
  - Requires high index of suspicion and should still be considered even if radiographic investigation is normal
  - MRI is the most sensitive and specific diagnostic modality for AVN.
- Pitfalls:
  - Not recognizing those at increased risk for AVN (such as those with sickle cell disease, HIV, and others)

# BACTEREMIA

Joni E. Rabiner  
Jeffrey R. Avner

## BASICS

### DESCRIPTION

- Bacteremia is defined as the presence of bacteria in the blood.
- Bacteremia may be transient and resolve spontaneously or may lead to complications including focal infections, meningitis, sepsis, or septic shock.
- Occult (or unsuspected) bacteremia is a term used to describe bacteremia in a well-appearing, previously healthy child (usually 3–36 mo of age) without a source of infection on history or physical exam.

### EPIDEMIOLOGY

#### Incidence

- The incidence of bacteremia varies with a variety of factors including:
  - Exposure to a particular organism (ie, local epidemiology)
  - The host immune status (eg, HIV, sickle cell disease, cancer)
  - Clinical appearance (well vs. ill)
  - Risk factors (eg, dental work, indwelling catheters)
- Declining incidence of occult bacteremia:
  - Routine *Haemophilus influenzae* type b (Hib) and heptavalent pneumococcal conjugate (PCV7) vaccines have significantly decreased the prevalence of occult bacteremia from 3–5% to 0.25–0.7% in vaccinated, nontoxic febrile children (1–3).
  - The risk of bacteremia in incompletely vaccinated febrile children is likely <3–5% due to herd immunity.
  - For vaccinated febrile children, the risk of serious complications is <0.05% (4).
- The rate of contaminant isolation from blood cultures is 1.8% (2):
  - For example, with a bacteremia rate of 0.25%, there would be 7 contaminated blood culture results for every 1 true positive blood culture (3).

### RISK FACTORS

- Chronic underlying medical conditions
- Immunodeficiency: HIV, chemotherapy
- Incomplete immunization: <6 mo of age or incomplete primary series of 3 vaccinations for both Hib and PCV7, although there may be effect with as few as 1 dose of vaccine (1)
- Recent or current antibiotic use

### GENERAL PREVENTION

Routine vaccination with Hib, PCV7, and meningococcal conjugate vaccine as per the Advisory Committee on Immunization Practices (ACIP)

### PATHOPHYSIOLOGY

- Bacteria enter bloodstream:
  - Directly (eg, dental work, laceration, catheter placement)
  - Indirectly through disruption of normal mucosal barriers, usually following viral infection or other focal infection:
    - Often associated with nasopharyngeal colonization or exposure (eg, meningococemia, invasive pneumococcal disease)
- Bacteria in bloodstream are either cleared spontaneously or cause focal infection or septicemia

### ETIOLOGY

- Bacteremia in well-appearing children 3–36 mo:
  - Prevacination: *Streptococcus pneumoniae* (80%) and Hib (20%) were the primary causes of bacteremia (5).
  - Postvaccination: *Escherichia coli* (1/3), nonvaccine serotypes of *S. pneumoniae* (1/3), *Staphylococcus aureus*, *Neisseria meningitidis*, group A streptococcus, *Salmonella* species (2)
- Bacteremia in children with sickle cell disease:
  - Bacteremia/Sepsis: *S. pneumoniae* (most common), Hib (if incomplete immunization)
  - Bacteremia/Osteomyelitis: *S. aureus*, *Salmonella*
- Bacteremia in children who are immunosuppressed:
  - *S. aureus*, *Staphylococcus epidermidis* (associated with cellulitis, abrasion, indwelling catheters)
  - *Streptococcus viridans* (associated with mucosal tenderness, mouth sores)
  - Gram-negative organisms (*E. coli*, *Klebsiella*, *Pseudomonas*)
  - *S. pneumoniae*
  - *Salmonella*

### COMMONLY ASSOCIATED CONDITIONS

Complications include focal infections, meningitis, sepsis, septic shock, pneumonia, and septic arthritis.

## DIAGNOSIS

### HISTORY

- Fever:
  - >38°C (100.4°F) for infants <3 mo of age or children with immunodeficiency
  - >39°C (102.2°F) for children 3–36 mo of age who are well appearing and at risk for occult bacteremia
- Risk factors: Chronic underlying illness, immunodeficiency, recent antibiotic use
- Immunization status

### PHYSICAL EXAM

- Vital signs
- General appearance:
  - Well appearing in occult bacteremia
  - Ill appearance suggests a serious bacterial illness associated with the bacteremia.
- Complete physical exam looking for source of infection:
  - Petechiae, especially below the nipple line, suggest the diagnosis of meningococemia.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

- If bacteremia is known from a prior blood culture result:
  - Repeat blood culture
  - Additional lab tests vary depending on:
    - Age of the patient
    - Specific bacteria identified
    - Host risk factors
    - Appearance of the patient
    - Persistence of fever
    - Other symptoms (nuchal rigidity, joint swelling, respiratory distress, etc.)

- If occult bacteremia is suspected:
  - Child with up-to-date immunizations (>6 mo of age): No lab tests indicated due to low rate of bacteremia and complications
  - Incompletely immunized child (ages 3–36 mo):
    - CBC: Some sources suggest sending a blood culture if screening WBC count >15,000/mm<sup>3</sup>
      - WBC has a low positive predictive value for occult bacteremia (2).
    - Blood culture:
      - Time to positive culture for pathogens: Mean 15 hr (5)
      - Time to positive culture for contaminants: Mean 31 hr (5)
      - Contaminants: Slow growth, gram-positive rods, coagulase-negative gram-positive cocci
    - C-reactive protein and ESR are nonspecific inflammatory markers.

### Imaging

Consider CXR for occult pneumonia.

### Diagnostic Procedures/Other

Consider procedures related to complications of bacteremia:

- Bladder catheterization to evaluate for urinary tract infection (UTI)
- Lumbar puncture to evaluate for meningitis
- Joint aspiration to evaluate for septic arthritis

### DIFFERENTIAL DIAGNOSIS

- Viral illness
- UTI
- Occult pneumonia
- Sepsis
- Contaminated blood culture (false positive)

## TREATMENT

### INITIAL STABILIZATION/THERAPY

- Assess and manage ABCs per Pediatric Advanced Life Support (PALS) protocol.
- Patients with organisms other than *S. pneumoniae* (such as *S. aureus*, *N. meningitidis*, *H. influenzae*) typically require hospital admission and parenteral antibiotic therapy.
- If penicillin-susceptible bacterial growth, clinical signs and symptoms in the child guide management:
  - These patients may be appropriate candidates for outpatient therapy with amoxicillin, particularly if pathogen is *S. pneumoniae*.
- Suspected occult bacteremia:
  - Completely immunized child, no severe illness other than fever, normal vital signs: No empiric antibiotics are required.

- For incompletely immunized children with elevated WBC  $> 15,000/\text{mm}^3$ :
  - Consider ceftriaxone.
- For immunocompromised patients or patients with systemic symptoms, particularly unstable vital signs:
  - Consider ceftriaxone and vancomycin.
- In specific circumstances, such as leukopenic oncology patients, additional antibiotic coverage for *Pseudomonas* may be indicated.
- Known bacteremia from a prior blood culture result:
  - If bacteremia is thought to represent a true pathogen (ie, not a contaminant), antibiotic administration should be determined on the basis of known or epidemiologically determined bacterial sensitivities.

## MEDICATION

### First Line

- Ceftriaxone 50–100 mg/kg/day IV/IM divided q12–24h
  - Vancomycin 40–60 mg/kg/day divided q6h
  - May be added based on local susceptibility patterns of *S. pneumoniae* and severity of illness if present, and immune status of patient
- Amoxicillin 80 mg/kg PO divided b.i.d.–t.i.d.:
  - Used for patient with penicillin-sensitive pathogens, particularly *S. pneumoniae*
- Antipyretics as needed:
  - Ibuprofen 10 mg/kg/dose PO/IV q6h PRN
  - Acetaminophen 15 mg/kg/dose PO/PR q4h PRN

### Second Line

- Clindamycin 10 mg/kg IV/PO q8h:
  - May be appropriate as parenteral or oral therapy in penicillin-allergic patients

## DISPOSITION

### Admission Criteria

- Neonates  $< 28$  days
- Outpatient follow-up cannot be assured
- Dehydration, lethargy, ill appearance
- Immunocompromised patient with known or suspected bacteremia
- Bacteremia with persistent fever
- Critical care admission criteria:
  - Sepsis
  - Meningitis with neurologic symptoms

### Discharge Criteria

- Children with occult bacteremia who return for follow-up due to a positive blood culture for *S. pneumoniae* can be discharged home if the child remains afebrile, well appearing, and has no evidence of serious bacterial infection (eg, meningitis):
- Patients with organisms other than *S. pneumoniae* (such as *S. aureus*, *N. meningitidis*, *H. influenzae*) typically require hospital admission and parenteral antibiotic therapy.

## Issues for Referral

Any child with persistent or recurrent bacteremia should be referred to, or have consultation with, an infectious disease specialist.

## FOLLOW-UP

### FOLLOW-UP RECOMMENDATIONS

Discharge instructions and medications:

- If the child is treated with antibiotics, follow-up within 24 hr.
- If the child is not treated with antibiotics, follow-up for persistent fever in 48 hr.
- If the child looks sicker, or if new signs or symptoms develop, the patient should follow-up sooner.

### Patient Monitoring

Clinical symptoms:

- Fever
- Appearance

### PROGNOSIS

- Depends on age, severity, etiology, past medical history, and immunization status
- For occult bacteremia, spontaneous resolution of bacteremia occurs in  $> 90\%$  without antibiotic treatment.

### COMPLICATIONS

Pneumonia, septic arthritis, osteomyelitis, meningitis, sepsis, septic shock, death

## CODES

### ICD9

- 771.83 Bacteremia of newborn
- 790.7 Bacteremia

## PEARLS AND PITFALLS

- Pearls:
  - Occult (unsuspected) bacteremia occurs in well-appearing febrile children.
  - As the incidence of occult bacteremia has declined below 0.5% (with universal PCV7 and Hib vaccination), routine CBC and blood culture management strategies for febrile young children should be abandoned.
- Pitfalls:
  - Not assuring appropriate follow-up for a child with suspected or documented bacteremia within 24–48 hr

# BALANITIS/BALANOPOSTHITIS

Kerry Caperell  
Raymond Pitetti

## BASICS

### DESCRIPTION

- Balanitis is defined as inflammation of the glans penis.
- Balanoposthitis is defined as inflammation of the glans penis and foreskin.

### EPIDEMIOLOGY

#### Incidence

- 2.9–7.6% in circumcised boys (1)
- 5.9–14.4% in uncircumcised boys (1)
- More common in black and Hispanic boys
- Peak age in children is 2–5 yr but can occur at any age (2).

### RISK FACTORS

- Uncircumcised male
- Poor hygiene
- Excessive washing
- Not yet toilet trained
- Recent antibiotics

### GENERAL PREVENTION

- Good hygiene to the area
- Practicing gentle foreskin retraction (avoiding excessive force)

### PATHOPHYSIOLOGY

- Infections:
  - In uncircumcised boys, the potential space between the foreskin and glans may retain moisture as well as bacteria.
  - Particularly when the foreskin begins separating from the glans around the 2nd and 3rd yr of life, collection of moisture and bacteria may result in an infection that is often suppurative.
  - Typically, local cellulitis as well as collection of pus in the potential space between the glans and foreskin occurs.
  - Since the potential space is not all contiguously open to the meatus of the foreskin, pus collection may act as an abscess in this area, which is often near the coronal sulcus.
- Irritant dermatitis due to soap or other cleaning agent
- Trauma due to forceful foreskin retraction

### ETIOLOGY

- Infectious:
  - Group A streptococcus
  - *Escherichia coli* and fungi are common in diaper-wearing children.
  - Enterococci and *Staphylococcus aureus* are more common in older children.
  - *Neisseria gonorrhoeae* and *Chlamydia trachomatis* are possibilities in sexually active children.
  - Viruses
- Noninfectious inflammation:
  - Irritant dermatitis
  - Drug eruption
  - Local trauma

### COMMONLY ASSOCIATED CONDITIONS

- Immunodeficient states, including AIDS
- Diabetes mellitus

## DIAGNOSIS

### HISTORY

- Dysuria is a common complaint.
- Penile itching or pain
- Penile discharge
- Swelling or redness of the glans penis

### PHYSICAL EXAM

- Erythema and swelling of the glans penis
- Occasionally, foul-smelling exudate is seen.
- Inguinal lymphadenopathy
- Phimosis
- The triad of pain, fiery erythema, and a thin transudate/exudate under the prepuce may indicate a group A streptococcus as the causative agent.
- Carefully evaluate the scrotum to determine if any evidence of testicular torsion is present: Scrotal appearance, cremasteric reflex, testicular position, testicular tenderness.
- Evaluate for epididymitis by palpation of the epididymis.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

- Typically, no lab testing is necessary.
- A culture for group A streptococcus from the genital area may be performed in children with recent pharyngitis, impetigo, or other signs of possible strep infection.
- Rapid antigen testing for group A streptococcus has not been validated in this setting.
- Patients suspected of having an STI should have swabs sent for chlamydia, gonorrhea, and herpes simplex.
- For patients without obvious balanitis, urinalysis and possibly urine culture to detect urinary tract infection may be necessary.

### DIFFERENTIAL DIAGNOSIS

- Smegma
- Psoriasis
- Eczema
- Paraphimosis
- Lichen planus
- Human papillomavirus
- Balanitis xerotica obliterans
- Herpes simplex

## TREATMENT

### INITIAL STABILIZATION/THERAPY

- Patients who are unable to void may require emergent bladder drainage.
- Provide analgesia to patients with severe pain.

### MEDICATION

#### First Line

- Oral antibiotic
- Amoxicillin 40 mg/kg/day PO divided b.i.d.–t.i.d., max 500 mg/dose for 7–10 days
- Cephalexin 50 mg/kg/day PO divided b.i.d.–q.i.d., max 500 mg/dose for 7–10 days

- Most irritant and bacterial cases can be treated with topical mupirocin b.i.d. for 1 wk
- If group A streptococcus is suspected, amoxicillin b.i.d. for 10 days is necessary.
- Cases due to STIs are treated in the same manner as the respective STI.
- Fungal infection can be treated with topical nystatin q.i.d. for 1 wk.

### Second Line

For group A streptococcal infections, any of the regimens for strep pharyngitis is adequate.

### SURGERY/OTHER PROCEDURES

- Forced retraction of the foreskin to release pus followed by cleaning with chlorhexidine or Betadine may be performed:
  - This procedure is typically very painful and may be preceded with topical anesthetic such as EMLA or another analgesic.
  - If this is performed, instruct the parent to continue retracting the foreskin multiple times daily to ensure it remains retractible.
- A dorsal slit through the phimotic area performed emergently if bladder drainage by catheterization or suprapubic aspiration is necessary but cannot be carried out. This procedure would usually be performed by a urologist.

### DISPOSITION

#### Admission Criteria

Patients with urinary obstruction requiring catheterization or surgery should be admitted.

#### Discharge Criteria

Uncomplicated cases can be discharged from the emergency department.

#### Issues for Referral

- Patients with urinary retention who cannot be catheterized should be seen by a urologist emergently.
- Those who have urinary retention, phimosis, or disease that is refractory to treatment should be seen by a urologist.
- Suspicion of a sexually transmitted etiology in a young child should be further investigated for the possibility of sexual abuse.

## FOLLOW-UP

### FOLLOW-UP RECOMMENDATIONS

Discharge instructions and medications:

- Sitz baths 3 times daily until signs of inflammation disappear
- Good hygiene
- Only use gentle force to retract the foreskin.
- Antibiotics as indicated
- Follow up with the primary care physician as needed.

### PROGNOSIS

- Most patients have an uneventful course.
- Up to 10% of patients will have a recurrence.

### COMPLICATIONS

Balanitis xerotica obliterans, a chronic inflammatory disease, is a separate entity that should be considered in cases of balanitis that are refractory to conventional treatment (3).

### See Also (Topic, Algorithm, Electronic Media Element)

- Epididymitis/Orchitis
- Scrotal Pain
- Testicular Torsion
- Urinary Tract Infection

ICD9  
607.1 Balanoposthitis

### PEARLS AND PITFALLS

- Most cases resolve with only local care and antibiotics.
- If there is significant swelling between the foreskin and glans, forced retraction of the foreskin to release pus may be highly beneficial.
- Balanitis suspected of being secondary to sexually transmitted pathogens should raise the possibility of sexual abuse.

# BAROTRAUMA, SINUS

Curt Stankovic

## BASICS

### DESCRIPTION

Barosinusitis is also known as aerosinusitis or sinus squeeze:

- It results in pain and occasionally bleeding into the sinus cavities as a result of exposure to pressure gradients.

### EPIDEMIOLOGY

- Barotrauma is much less common in children than adults.
- 3–4 episodes per 100,000 adult exposures (1)
- Middle ear barotrauma is 6–10 times more prevalent than barosinusitis (1).

### RISK FACTORS

- Flying, scuba diving, skydiving, mountain climbing
- Hyperbaric oxygen chamber
- Presence of anatomic abnormalities of the nose and paranasal sinuses including polyps (2)

### GENERAL PREVENTION

Avoid exposure to potential pressure gradients, especially when suffering from upper respiratory tract infections or seasonal allergies.

### PATHOPHYSIOLOGY

- Barosinusitis is typically preceded by an upper respiratory tract infection or seasonal allergies.
- In this setting, it occurs when the facial sinuses are unable to drain due to obstruction of ostia by mucus secretions or edema. This prevents the sinus to equalize if exposed to a pressure gradient.
- The Boyle law ( $P1V1 = P2V2$ ) can predict sinus barotrauma. The volume of gas is inversely related to the amount of pressure on it.
- There are 2 types of barotrauma—squeeze and reverse squeeze:
  - Squeeze occurs when pressure is applied to air that is trapped in a sinus. The volume of gas reduces, resulting in negative pressure and the influx of fluid and blood.
  - Reverse squeeze occurs when the pressure outside of the sinus is low, resulting in the air within the sinus to expand. If the sinus is obstructed, preventing pressure equalization, pain, and bleeding may occur.

### ETIOLOGY

Any situation that will expose someone to a pressure gradient, such as ascent or descent in an airplane or scuba diving, skydiving, mountain climbing:

- The frontal sinus is most commonly affected, followed by the maxillary sinus.

### COMMONLY ASSOCIATED CONDITIONS

- Barodontalgia
- Barotitis
- Pulmonary barotrauma

## DIAGNOSIS

### HISTORY

- Exposure to pressure gradients without pressure equalization, such as diving, air travel
- Preceding upper respiratory tract infection or seasonal allergies
- Feeling of pressure in the affected sinus, worsening congestion, sudden sharp facial pain, or frontal headache
- Epistaxis, vertigo, nausea may be present.

### PHYSICAL EXAM

- Inspect nasal mucosa for evidence of infection, polyp, allergies, or epistaxis.
- Tenderness over the sinus may be present, and sinus transillumination may reveal fluid.
- 5th cranial nerve or infraorbital nerve palsy may be present in severe barosinusitis.
- Percuss maxillary teeth with tongue depressor to inspect for tenderness.
- Rule out other injuries associated with barotrauma:
  - Pulmonary barotrauma: Look for signs of a pneumothorax or subcutaneous emphysema. Patient may complain of shortness of breath, hemoptysis, and dysphagia.
  - Barotitis media: Which is associated with otalgia, blood/fluid in the middle ear, ruptured tympanic membrane.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Imaging

- Barosinus is a clinical diagnosis, so no imaging is required (3).
- However, sinus plain radiographs may reveal mucosal thickening and fluid in the sinus.
- CT scan of the sinuses with coronal and axial views is recommended for patients with severe barosinusitis (1).

#### Diagnostic Procedures/Other

Barosinusitis can be classified into 3 grades:

- Grade 1: Mild transient discomfort without radiologic findings
- Grade 2: Severe pain for <24 hr with mucosal thickening on radiograph
- Grade 3: Severe pain for >24 hr, severe mucosal thickening, opacification on radiograph. Epistaxis may be present. Sinusitis may occur.

### DIFFERENTIAL DIAGNOSIS

- Barodontalgia
- Sinusitis
- Seasonal allergies
- Cerebrovascular accident
- Malignant tumors of nasal cavity and sinuses

## TREATMENT

### PRE HOSPITAL

- Remove patient from the source of barotrauma.
- Attempt to equalize pressure by swallowing or performing the Valsalva maneuver.

### INITIAL STABILIZATION/THERAPY

- Assess and stabilize airway, breathing, and circulation.
- Apply local pressure if epistaxis is present.
- Use analgesics and nasal decongestants to relieve pain and pressure.

**MEDICATION****First Line**

- Nasal decongestants:
  - Oxymetazoline 0.05%, 2 sprays in each nostril b.i.d. for 3–5 days (1)
  - Phenylephrine
- Analgesics (NSAIDs) at age-appropriate doses
- Opioids:
  - Morphine 0.1 mg/kg IV/IM/SC q2h PRN:
    - Initial morphine dose of 0.1 mg/kg IV/SC may be repeated q15–20min until pain is controlled, then q2h PRN.
  - Codeine or codeine/acetaminophen dosed as 0.5–1 mg/kg of codeine component PO q4h PRN
  - Hydrocodone or hydrocodone/acetaminophen dosed as 0.1 mg/kg of hydrocodone component PO q4–6h PRN
- NSAIDs:
  - Consider NSAID medication in anticipation of prolonged pain and inflammation.
  - Ibuprofen 10 mg/kg/dose PO/IV q6h PRN
  - Ketorolac 0.5 mg/kg IV/IM q6h PRN
  - Naproxen 5 mg/kg PO q8h PRN
- Acetaminophen 15 mg/kg/dose PO/PR q4h PRN
- Aspirin should be avoided due to the potential for hematoma formation.
- If bleeding or sinus effusion is present, antibiotics are indicated (1):
  - Amoxicillin 40–80 mg/kg/day PO divided b.i.d.–t.i.d., max daily dose 2 g
  - Clindamycin 30 mg/kg PO divided t.i.d., max daily dose 1.8 g
  - Trimethoprim/Sulfamethoxazole (TMP/SMZ) 10 mg/kg/day PO divided b.i.d., max single dose 320 mg TMP/1,600 mg SMZ

**Second Line**

Pseudoephedrine 1 mg/kg/dose PO given b.i.d.–q.i.d.; adult dose 60–120 mg PO (1)

**SURGERY/OTHER PROCEDURES**

- Surgery is used to restore sinus ventilation.
- May be necessary if traditional medications fail and symptoms persist
- Endoscopic sinus surgery has improved efficacy when compared to conventional surgical options (4)

**DISPOSITION****Admission Criteria**

Uncontrollable pain

**Discharge Criteria**

Ability to manage pain with oral analgesics or opioids

**Issues for Referral**

- Otorhinolaryngologist referral may be necessary for severe or persistent symptoms.
- Otorhinolaryngology or neurosurgery referral may be necessary if the sphenoid sinus is involved and does not respond to first-line treatment.
- Dental referral may be necessary if barodontalgia is present. Barodontalgia may result in referred pain to face.

**FOLLOW-UP****FOLLOW-UP RECOMMENDATIONS**

- Discharge instructions and medications:
  - Nasal decongestants and oral analgesics
  - Oral antibiotics if fluid is seen in the sinus cavity
- Activity:
  - Avoid activities that may result in barotrauma until fully recovered.
  - If undergoing endoscopic sinus surgery, the patient may return to full activity in 1–3 wk.

**PROGNOSIS**

Generally considered good. Patients typically respond to first-line medications:

- Recurrent barosinusitis may be secondary to anatomic pathology. These patients are more likely to need surgical drainage of the affected sinus.
- Patients with uncontrolled or chronic sinusitis as well as seasonal allergies may find more difficulty returning to normal activities.

**COMPLICATIONS**

- Rarely, a sinus may rupture and result in pneumocephalus causing vertigo, vomiting, headache, and pain.
- Other complications include orbital cellulitis, abscess, and hematoma formation.

**See Also (Topic, Algorithm, Electronic Media Element)**

- Barotrauma, Ear
- Sinusitis

**ICD9**  
993.1 Barotrauma, sinus

**PEARLS AND PITFALLS**

- Treat patients who have blood or fluid in the sinus cavity with antibiotics to prevent infectious complications.
- Refer patients with severe or unresponsive symptoms to otorhinolaryngology.
- Recognize life-threatening complications of barotrauma.

# BETA-BLOCKER POISONING

Amit K. Gupta  
Mark Su

## BASICS

### DESCRIPTION

- There are 3 subtypes of beta receptors:
  - Beta<sub>1</sub> receptors located primarily on cardiac cells:
    - Blockade leads to bradycardia, hypotension, decreased myocardial contractility, and reduced myocardial oxygen consumption.
  - Beta<sub>2</sub> receptors located primarily on smooth muscle; blockade leads to relaxation in arteries and pulmonary bronchi; also found on beta islet cells of the pancreas, promoting insulin release
  - Beta<sub>3</sub> receptors located on adipose tissue cause lipolysis. It is unclear if beta-blocker poisoning has any significant effect on these functions.
- Consequential overdoses of beta-blockers can cause severe hypotension and bradycardia and potentially death.

### EPIDEMIOLOGY

#### Incidence

- Exposures to beta-blockers accounts for a large number of emergency department visits.
- Pediatric deaths are exceedingly rare.
- Propranolol is the most toxic beta-blocker and the most frequently reported beta-blocker used in suicide attempts worldwide.

### RISK FACTORS

- Exposure to sustained-release preparations can lead to delayed toxicity.
- Coingestants with other cardiotoxic agents such as calcium channel blockers, cyclic antidepressants, and neuroleptics may exacerbate toxicity.

### GENERAL PREVENTION

Poison proofing homes and giving parents poison prevention education is the most effective way to prevent exposure in children.

### PATHOPHYSIOLOGY

- Blockade of beta-adrenergic receptors results in decreased production of intracellular cyclic adenosine monophosphate (cAMP) with a resultant blunting of multiple metabolic and cardiovascular effects of circulating catecholamines.
- Bradycardia occurs due to blockade at the sinoatrial node.
- Direct decrease in myocardial contractility (inotropy) leads to hypotension.
- Conduction abnormalities may occur due to blockade at the atrioventricular node.
- Toxicity may also occur from myocyte sodium channel blockade (propranolol) leading to a prolonged QRS duration and impairing cardiac conduction.
- Toxicity may also arise from potassium channel blockade (sotalol) leading to a prolonged QTc interval and placing patients at risk for developing torsade de pointes.

- Lipid-soluble agents (propranolol) may cause a depressed mental status by crossing the blood-brain barrier and penetrating the CNS.
- Hypoglycemia may occur due to increased insulin release from the beta islet cell of the pancreas.
- A slight rise in serum potassium may occur due to impaired uptake by skeletal muscle.

### ETIOLOGY

- Numerous brands of beta-blockers are available.
- Understanding the different characteristics of each class may be helpful in evaluating the clinical outcome and guiding therapy.

### COMMONLY ASSOCIATED CONDITIONS

Congenital heart disease, CHF, cardiac dysrhythmia, essential tremor

## DIAGNOSIS

### HISTORY

- Obtain history of exposure, other possible coingestants, and events that led to exposure.
- Ask parents to bring in pill bottles if possible.

### PHYSICAL EXAM

- Absorption of beta-blockers is rapid and occurs within 30 min.
- Depressed mental status may be due to hypoglycemia or to lipid-soluble agents crossing the blood-brain barrier.
- Cardiovascular effects may include bradycardia.
- Pulmonary effects may include bronchospasm or pulmonary edema.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

- Immediate assessment of capillary blood glucose
- Hypoglycemia may result from beta-blocker overdose.
- Electrolytes, BUN, creatinine, glucose
- Measure acetaminophen and salicylate levels if suicidal ingestion.
- Urine drug screen usually is not indicated unless for forensic purposes such as suspected malicious intent or child abuse.

#### Imaging

- CXR should be performed to assess for pulmonary edema.
- A CT of the brain should be considered in individuals with altered mentation.

#### Diagnostic Procedures/Other

ECG should be performed to look for signs of bradycardia and/or other conduction abnormalities.

### DIFFERENTIAL DIAGNOSIS

- Calcium channel blocker toxicity
- Digoxin toxicity
- Clonidine toxicity
- Cardiogenic shock
- Hemorrhagic shock
- Septic shock
- Acute myocardial infarction

## TREATMENT

### PRE HOSPITAL

- Assess and stabilize airway, breathing, and circulation.
- Supplemental oxygen
- Establishment of an IV line with cardiac monitoring

### INITIAL STABILIZATION/THERAPY

- Assess and stabilize airway, breathing, and circulation.
- Assess blood glucose level.
- Consultation with a medical toxicologist or poison control center is recommended.
- Activated charcoal (1 g/kg) may be given if the patient is protecting the airway.
- Syrup of ipecac is contraindicated.
- Orogastric lavage may be considered if the patient presents shortly after a potentially life-threatening overdose (usually within 1 hr) and the airway is protected:
  - This is predicated on having a clinician with experience performing orogastric lavage; NG lavage is not indicated and not helpful.

### MEDICATION

#### First Line

- Dextrose 0.25 g/kg (2.5 mL/kg of 10% dextrose or 1 mL/kg of 25% dextrose) IV bolus for hypoglycemia
- 0.9% saline bolus (20 cc/kg) for hypotension
- Atropine 0.02 mg/kg (min dose 0.1 mg and max 2 mg) for bradycardia; may not be effective
- Glucagon 150 µg/kg over 1 min (max 5 mg) IV bolus:
  - Glucagon bypasses the beta receptor and increases cAMP levels leading to an increase in inotropy and BP
  - Also administer a continuous infusion in 5% dextrose in water (D5W) if effective (2–5 mg/hr).
  - May cause vomiting due to decrease of lower esophageal sphincter tone

- Lorazepam 0.05 mg/kg IV, max dose 2 mg:
  - First-line agent for seizures
- Sodium bicarbonate (1–2 mEq/kg) IV bolus for signs of sodium channel blockade on ECG followed by IV infusion of 3 ampules of sodium bicarbonate in 1 L of D5W at twice maintenance. Carefully monitor serum pH.

### Second Line

- A variety of inotropes are available if above treatments fail.
- Norepinephrine infusion (0.1–2  $\mu$ g/kg/min) IV and titrate to maintain adequate cardiac output:
  - Directly stimulates alpha- and beta<sub>1</sub>-adrenergic receptors, thus increasing inotropic and vasopressor effects
- Epinephrine infusion (0.1  $\mu$ g/kg/min) IV and titrate to maintain adequate cardiac output:
  - Directly stimulates alpha- and beta-adrenergic receptors
- Dopamine 5–20  $\mu$ g/kg/min IV and titrate to maintain adequate cardiac output:
  - Indirectly stimulates alpha- and beta<sub>1</sub>-adrenergic dopaminergic receptors to produce inotropic, chronotropic, renal/splanchnic vasodilatory (at low doses), and vasopressor (at high doses) effects
- Amrinone 50  $\mu$ g/kg IV loading dose with maintenance infusion of 0.50  $\mu$ g/kg/min IV and titrate to desired effect:
  - Inhibits myocardial phosphodiesterase, leading to increased cAMP levels
- High-dose insulin/glucose infusion:
  - Insulin (1 unit/kg bolus followed by 1 unit/kg/hr)
  - Glucose must be coadministered, initially 1 g/kg bolus followed by infusion of 0.5 g/kg/hr.
  - Frequent blood glucose monitoring, initially q10–15min for the 1st few hours, is necessary.
  - This therapy has been shown to be effective in case reports and in animal models.
  - The theorized mechanism is via positive inotropic effects of insulin and cardiac utilization of glucose as an energy source.
  - Frequent monitoring of serum glucose and potassium levels is necessary.

### COMPLEMENTARY & ALTERNATIVE THERAPIES

- Enhanced elimination with hemodialysis is only effective for beta-blockers with low volumes of distribution and high water solubility (ie, atenolol, naldol, and sotalol).
- Cardiac pacing may be effective in increasing the rate of myocardial contractions, but electrical capture is not always successful and BP is not always restored.

- IV fat emulsion therapy (Intralipid 20% 1 mL/kg) has been shown in animal models and case reports to be beneficial in lipid-soluble drug overdoses (propranolol).
- The proposed mechanism of action is the “lipid sink” theory, where drugs may become trapped in an expanded plasma lipid compartment. Another proposed theory is that the emulsion acts as additional fuel source for the heart due to the energy from fatty acids.

### SURGERY/OTHER PROCEDURES

- Extracorporeal membrane oxygenation has also been attempted in patients who have hypotension refractory to all pharmacologic therapies.
- Intra-aortic balloon counterpulsation is another invasive supportive option in refractory cases and has been used successfully to improve cardiac output and BP.

### DISPOSITION

#### Admission Criteria

- All patients with exposure to sustained-preparation beta-blockers should be admitted to a monitored setting due to the potential of delayed toxicity.
- Admit all symptomatic patients.
- Critical care admission criteria:
  - Patients with signs of hemodynamic instability should be admitted to an ICU setting.

#### Discharge Criteria

May discharge if the patient remains asymptomatic after observation for 6 hr for immediate-release preparations

### FOLLOW-UP

#### FOLLOW-UP RECOMMENDATIONS

- Discharge instructions and medications:
  - Follow up with the primary pediatrician.
  - Return to the emergency department for change in behavior, alteration in mental status, or if ill appearing.
- Activity:
  - Normal activity after discharge

#### Patient Monitoring

Patients with intentional overdoses should be monitored for acts of self-harm.

### PROGNOSIS

The prognosis is generally good for isolated beta-blocker overdose.

### COMPLICATIONS

- Cardiovascular collapse
- Shock
- Death

### ADDITIONAL READING

### See Also (Topic, Algorithm, Electronic Media Element)

- Calcium Channel Blocker Poisoning
- Digoxin Poisoning
- Shock, Cardiogenic

### CODES

#### ICD9

- 971.3 Poisoning by sympatholytics (antiadrenergics)
- 972.0 Poisoning by cardiac rhythm regulators

### PEARLS AND PITFALLS

- Hypotension and bradycardia can occur as consequences of beta-blocker overdose.
- Glucagon is the first-line agent for beta-blocker toxicity.
- Admission and observation are indicated for any sustained-release beta-blocker ingestion.
- Certain beta-blockers such as propranolol and acebutolol may cause myocyte sodium channel blockade leading to QRS prolongation.

# BILIARY TRACT DISEASE

Gregory Garra

## BASICS

### DESCRIPTION

Biliary tract disease is a broad category of diseases that can affect children of all ages and includes the biliary ducts, gallbladder, and liver.

### EPIDEMIOLOGY

#### Incidence

- Biliary atresia is relatively uncommon, occurring in 1:10,000–1:15,000 live births.
- Choledochal cysts occur in ~1:15,000 births.
- Caroli disease is very rare, with 1 case per 1,000,000 people.

### RISK FACTORS

- Females are more commonly afflicted with biliary atresia and choledochal cysts.
- A temporal relationship between acute gallbladder hydrops and scarlet fever, leptospirosis, and Kawasaki disease has been suggested.

### PATHOPHYSIOLOGY

- Extrahepatic biliary atresia is an inflammatory condition of the bile ducts resulting in progressive obliteration of the extrahepatic biliary tract. It is the most frequent cause of death from liver disease and indication for liver transplantation in children.
- Primary sclerosing cholangitis (PSC) is an uncommon, slowly progressing disorder of the biliary tract resulting from inflammation and fibrosis of intra- and extrahepatic biliary ductal systems.
- Choledochal cysts are congenital saccular or fusiform dilatations of the extrahepatic biliary tract.
- Caroli disease is a congenital disorder resulting in segmental, saccular dilatation of intrahepatic biliary ducts.
- Cholelithiasis is described elsewhere.
- Cholecystitis is an acute or chronic inflammatory condition of the gallbladder.
- Acute cholangitis is a clinical syndrome resulting from stasis and infection of the biliary tract.
- Acute gallbladder hydrops is a noninflammatory acute distention of the gallbladder without gallstones.

### ETIOLOGY

- The exact mechanism accounting for the progressive obliteration of the biliary tree in biliary atresia is uncertain, although numerous etiologies are proposed.
- The etiologies of PSC and choledochal cysts are unknown. However, PSC is thought to result from an immunologic mechanism.

### COMMONLY ASSOCIATED CONDITIONS

- Symptomatic liver disease in patients with cystic fibrosis (CF) ranges from 2–18%.
- PSC is commonly associated with inflammatory bowel disease, histiocytosis X, and immunodeficiency.
- Caroli disease is associated with congenital hepatic fibrosis and autosomal recessive polycystic kidney disease.
- Failure to thrive is common in patients with chronic biliary disease.

## DIAGNOSIS

### HISTORY

- Most biliary tract diseases will present with jaundice. A detailed description of the evaluation of jaundice is described in the Jaundice, Unconjugated and Jaundice, Conjugated topics.
- Patients with biliary atresia and choledochal cysts typically present with jaundice during the 1st few months of life.
- Stools are typically acholic in patients with biliary atresia or choledochal cysts.
- Urine is typically dark in patients with conjugated hyperbilirubinemia.
- Ascending cholangitis is suggested by the presence of fever, jaundice, and abdominal pain.

### PHYSICAL EXAM

- Exam of the skin for cutaneous manifestations of liver disease; jaundice, bruising
- Abdominal exam for tenderness, distention, hepatomegaly, splenomegaly, or ascites. An abdominal mass may be palpated in patients with choledochal cysts.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

- LFTs such as bilirubin, serum transaminase, alkaline phosphatase, and gamma-glutamyl aminotransferase are often elevated:
  - However, lab studies are not fully diagnostic, as there is much overlap with each of the aforementioned conditions.
- Conjugated (direct) hyperbilirubinemia is defined as:
  - Serum conjugated bilirubin > 1.0 mg/dL if total bilirubin is < 5 mg/dL OR
  - Fractional conjugated bilirubin > 20% in cases where total bilirubin is > 5 mg/dL
  - Biliary atresia results in conjugated hyperbilirubinemia.
- Alkaline phosphatase is commonly elevated in cases of PSC.

#### Imaging

- US is an excellent screening tool for anatomic abnormalities of the biliary tract:
  - Choledochal cysts appear as dilated portions of the biliary tree (choledochal cysts).
  - A small or absent gallbladder on US suggests biliary atresia.
  - US will demonstrate multiple intrahepatic bile lakes in patients with Caroli disease.
  - US is the diagnostic modality of choice for suspected cholecystitis or acute gallbladder hydrops.
- Hepatobiliary scanning is nearly 100% sensitive for biliary atresia: Confirmed gut excretion excludes the diagnosis.

#### Diagnostic Procedures/Other

- The diagnosis of PSC is based upon cholangiography: Alternating strictures and areas of dilation imparting a beaded appearance of the biliary ducts.
- Endoscopic retrograde cholangiopancreatography or magnetic resonance cholangiopancreatography is useful for the workup of several biliary tract diseases.
- Percutaneous liver biopsy is frequently used to assist in establishing a definitive diagnosis.

**DIFFERENTIAL DIAGNOSIS**

- Sepsis
- Inborn errors of metabolism
- CF
- Hypothyroidism
- Alpha-1 antitrypsin deficiency
- Progressive familial intrahepatic cholestasis
- Ascariasis
- Infectious hepatitis

**TREATMENT****INITIAL STABILIZATION/THERAPY**

The treatment of acute gallbladder hydrops is supportive and typically subsides spontaneously.

**MEDICATION**

Broad-spectrum antibiotics should be administered in cases of suspected acute cholangitis:

- Beta-lactam/beta-lactamase inhibitor monotherapy:
  - Ampicillin-sulbactam (3 g q6h) OR
  - Piperacillin/Tazobactam (3.375 g q6h) OR
  - Ticarcillin/Clavulanate (3.1 g q4h)
- Metronidazole (500 mg IV q8h) PLUS ceftriaxone (100 mg/kg IV q24h)
- Monotherapy with a carbapenem:
  - Imipenem (500 mg q6h) OR
  - Meropenem (1 g q8h) OR
  - Ertapenem (1 g daily)
- Metronidazole (10 mg/kg/dose IV q8h) PLUS a fluoroquinolone (ciprofloxacin 15 mg/kg IV q12h) or levofloxacin 10 mg/kg/dose q24h)

**SURGERY/OTHER PROCEDURES**

- Diversion of bile flow, usually by Kasai procedure (hepatopertoenterostomy) is essential for survival in biliary atresia.
- Surgical excision of choledochal cysts provides excellent long-term results.
- Liver transplantation is frequently required for patients with end-stage liver disease resulting from biliary atresia or PSC.

**DISPOSITION****Admission Criteria**

- Patients with complications related to biliary tract disease such as ascending bacterial cholangitis require admission for treatment.
- Critical care admission criteria:
  - Intensive supportive care may be required for infants with conjugated hyperbilirubinemia.

**Discharge Criteria**

Patients who are stable with LFTs and electrolytes within acceptable limits and a known diagnosis may be discharged to the care of their appropriate subspecialist.

**Issues for Referral**

These patients should be managed in conjunction with a pediatric gastroenterologist or hepatologist and surgeon.

**FOLLOW-UP****FOLLOW-UP RECOMMENDATIONS**

Discharge instructions and medications:

- Close follow-up with the appropriate subspecialists is critical.

**PROGNOSIS**

- Untreated biliary atresia has an extremely poor prognosis.
- The most important predictor for success in a patient with biliary atresia is early operative therapy (before 60 days of age).
- The course of PSC is variable but typically progressive.

**COMPLICATIONS**

- Choledochal cysts and biliary atresia can be complicated by ascending cholangitis, hepatic cirrhosis, and portal HTN.
- Choledochal cysts are associated with an increased incidence of biliary carcinoma.
- Caroli disease is a risk factor for malignancy and recurrent cholangitis.

- Lee CK, Jonas MM. Pediatric hepatobiliary disease. *Curr Opin Gastroenterol.* 2007;23:306–309.
- McEvoy CF, Suchy FJ. Biliary tract disease in children. *Pediatr Clin North Am.* 1996;43:75–98.

**See Also (Topic, Algorithm, Electronic Media Element)**

- Jaundice, Conjugated
- Jaundice, Unconjugated

**CODES****ICD9**

- 576.9 Unspecified disorder of biliary tract
- 751.61 Biliary atresia, congenital
- 751.69 Other congenital anomalies of gallbladder, bile ducts, and liver

**PEARLS AND PITFALLS**

- The possibility of hepatobiliary disease must be considered in any neonate with jaundice beyond 2 wk of age.
- Evaluation for cholestatic jaundice may be delayed to 3 wk of age in breast-fed infants if the exam is normal.
- Biliary atresia be differentiated from other causes of neonatal cholestasis because early intervention is associated with more favorable outcome.
- An elevated conjugated bilirubin level should prompt a structured and rapid evaluation of biliary tract disorders.

# BIPOLAR DISORDER/MANIA

Todd A. Mastrovitch

## BASICS

### DESCRIPTION

- Bipolar disorder is an illness characterized by cycles of mania and depression. It is commonly referred to as manic depression.
- Recognition and treatment of manic and hypomanic episodes or episodes of depression are relevant for emergency medical clinicians.
- Benzodiazepines, lithium, carbamazepine, and valproic acid may be used to treat manic or hypomanic episodes.

### EPIDEMIOLOGY

- 1% of the population  $\geq 18$  yr of age in any given year
- Lifetime prevalence is 1%.
- Bipolar disorder affects men and women equally.
- Age of onset is usually between 15 and 30 yr of age.

### RISK FACTORS

- Genetics play a role in the development of bipolar disorder in children and young adults.
- Use of drugs, caffeine, and alcohol increase chances of manic, hypomanic, and depressive episodes.

### GENERAL PREVENTION

Teens with mood disorder symptoms should be screened with the Mood Disorder Questionnaire (MDQ) to aid in diagnosis, further screening, and eventual treatment.

### PATHOPHYSIOLOGY

- Genetics are important in the pathogenesis of bipolar disorder.
- $>2/3$  of people with bipolar disorder have at least 1 close relative with the disorder.
- Children with 1 affected parent have a 25% chance of developing bipolar disorder. For children with 2 affected parents, chances of bipolar disorder climb to 50%.
- Patients may engage in substance use, which may be an attempt at self-medication and also may precipitate manic, hypomanic, and depressive episodes.

### ETIOLOGY

- Most likely a combination of genetic and environmental factors
- Linkage studies suggest a role for the tryptophan hydroxylase 2 (TPH2) gene.
- Genome wide association studies point to CACNA1C to be the most consistent locus, associated with calcium channel gating.

### COMMONLY ASSOCIATED CONDITIONS

- Unipolar depression
- Substance abuse

## DIAGNOSIS

### HISTORY

Diagnostic criteria for mania include the following:

- 1 wk of persistently elevated, expansive, or irritable mood
- During the period of mood disturbance, at least three of the following symptoms are present:
  - Inflated self-esteem or grandiosity
  - Decreased need for sleep
  - More talkative than usual
  - Racing thoughts or flight of ideas
  - Distractibility
  - Increase in goal-directed activity
  - Excessive involvement in pleasurable activities (spending money or sexual indiscretion)
- The mood disturbance leads to significant impairment in social or occupational functioning.
- Symptoms are not due to medical illness or substance abuse.

### PHYSICAL EXAM

May show reduced psychomotor activity, low muscle tone, weight loss, slowed gait, and constipation

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

- Baseline CBC and serum blood chemistry
- Thyroid function tests
- Urine toxicology for stimulants

##### Imaging

EEG or CT scan of the brain based on specific historical or physical exam findings

### DIFFERENTIAL DIAGNOSIS

- ADD or ADHD
- Unipolar depression
- Borderline personality disorder
- Major depression
- Schizophrenia
- Drug abuse
- Thyrotoxicosis

## TREATMENT

### INITIAL STABILIZATION/THERAPY

- Providing a safe environment for the patient to be evaluated in while in the emergency department.
- Activation of crisis team or psychiatric service to screen the patient for psychiatric needs and to provide initial determination of need for acute hospitalization and treatment

**MEDICATION****First Line**

- Manic or hypomanic episodes:
  - Benzodiazepines:
    - Severe mania may require sedation with benzodiazepines.
    - Lorazepam 0.05–0.1 mg/kg IV q15–30min titrated to effect
  - Lithium: Children 15–60 mg/kg/day PO divided t.i.d. or q.i.d.; adolescents 600–1,800 mg t.i.d. or q.i.d.
  - Valproic acid: Initial dose 10–15 mg/kg/day PO divided q.d.–t.d.; dosing schedule must be adjusted weekly to achieve therapeutic levels.
- Depressive episodes: Discuss medication with consulting psychiatrist.

**Second Line**

Lamotrigine: Dosing schedule should be reviewed with a neurologist or psychiatrist.

**DISPOSITION****Admission Criteria**

- Risk of harm to themselves or others
- Unstable mood or severe depression requiring hospitalization to start medication and psychiatric stabilization
- Severe alteration of mood or level of consciousness due to overdose on drugs or alcohol

**Discharge Criteria**

Maintenance of stable mood for daily functioning

**Issues for Referral**

Persistence of symptoms of mania or depression despite treatment with medication and close follow-up may require repeat hospitalization.

**COMPLEMENTARY & ALTERNATIVE THERAPIES**

- St. John's Wort, an herb commonly marketed as a natural antidepressant, may cause a patient with bipolar disorder to have a manic attack.
- Omega-3 fatty acids (most commonly found in fish oil) may have some effect on patients with bipolar disorder.

**FOLLOW-UP****FOLLOW-UP RECOMMENDATIONS**

- Discharge instructions and medications:
  - Strict follow-up with psychiatrist or mental health care professional
  - Ensuring the patient is taking the medication as prescribed
- Activity:
  - As tolerated, with daily exercise

**Patient Monitoring**

Close follow-up in the outpatient mental health system

**DIET**

- As tolerated with focus on a varied, well-balanced diet
- Avoid caffeine and alcohol.

**PROGNOSIS**

- After the diagnosis of bipolar disorder is made, it is common that the disorder relapses.
- Patients may alternate between manic and depressive symptoms.
- 90% of patients with bipolar disorder have had at least 1 psychiatric hospital admission.

**COMPLICATIONS**

- Life expectancy for patients with bipolar disorder is reduced. Between 25 and 50% of patients attempt suicide, and 15% are successful.
- 2/3 of patients with bipolar disorder also have an addictive disorder.
- Anxiety disorder can also be seen in patients with bipolar disorder.

**ADDITIONAL READING**

- American Psychiatric Association. Mood disorders. In: *Diagnostic and Statistical Manual of Mental Disorders*. 4th ed, Text Revision. Washington, DC: Author; 2000:345–428.
- Baroni A, Lunsford JR, Luckenbaugh DA, et al. Practitioner review: The assessment of bipolar disorder in children and adolescents. *J Child Psychol Psychiatry*. 2009;50(3):203–215.
- Malhi GS, Adams D, Cahill CM, et al. The management of individuals with bipolar disorder: A review of the evidence and its integration into clinical practice. *Drugs*. 2009;69(15):2063–2101.
- Staton D, Volness LJ, Beatty WW. Diagnosis and classification of pediatric bipolar disorder. *J Affect Disord*. 2008;105(1–3):205–212.

**CODES****ICD9**

- 296.00 Manic affective disorder, single episode, unspecified degree
- 296.10 Manic affective disorder, recurrent episode, unspecified degree
- 296.80 Bipolar disorder, unspecified

**PEARLS AND PITFALLS**

- Children with bipolar disorder frequently have an ongoing, continuous mood disturbance that is a mix of mania and depression.
- Bipolar children typically have 4–5 severe mood swings per day and are more irritable than euphoric.
- Many teens with untreated bipolar disorder abuse alcohol and drugs, which may be attempts at self-medication. Any child or adolescent who abuses substances should be evaluated for a mood disorder.

# BITE, ANIMAL

Michael L. Epter

## BASICS

### DESCRIPTION

- This topic focuses on mammalian bites, which are the most common animal bites children experience.
- Polymicrobial wounds:
  - Mixed aerobic/anaerobic predominance on culture with multiple isolates
  - Anaerobes account for 3/4 of isolates from wound infections (especially abscesses).
- Most common animal bites (descending order):
  - Dog (85–90%):
    - 1/3 upper extremity; 1/3 lower extremity; 20% face and neck
    - Children <6 yr old have a higher percentage of face, neck, and scalp injuries.
    - Lacerations, 31–45%
    - Abrasions, 30–43%
    - Puncture wounds, 13–34%
  - Cat (5–10%):
    - 2/3 upper extremity (cat scratches also affect periorbital region)
    - More commonly puncture
  - Rodents
  - Domestic/Wild animals

### EPIDEMIOLOGY

#### Incidence

- 1% of emergency department visits annually
- 2–5 million cases annually (U.S.):
  - Children constitute >50% of reported cases.

### RISK FACTORS

Boys >> girls

### GENERAL PREVENTION

Supervision of young children when around animals

### PATHOPHYSIOLOGY

Bites typically may involve crushing and shearing force as well as deep tissue penetration:

- Dog bites may result in localized crush injuries (shearing force) → stretch lacerations and devitalized tissue
- Cat bites do not involve the amount of crushing or shearing force as dog bites: Puncture wounds → deep tissue penetration

### ETIOLOGY

- *Pasteurella* species is most often associated with animal bites (cats > dogs):
  - *Pasteurella canis* with dog bites
  - *Pasteurella multocida/septica* with cat bites
- Common aerobic isolates:
  - *Streptococcus*
  - *Staphylococcus*
  - *Moraxella*
  - *Corynebacterium*

- Common anaerobic isolates (more commonly associated with abscess formation):
  - *Streptococcus*
  - *Fusobacterium*
  - *Bacteroides*
  - *Porphyromonas*
  - *Prevotella*
- *Eikenella corrodens* (human >> animal)
- Catscratch agent: *Bartonella henselae* (can be transmitted by cat/flea bite)
- Marine bites: *Vibrio* and *Pseudomonas* species, *Plesiomonas shigelloides*, *Aeromonas hydrophila*
- Monkey bites: Herpes virus simiae (B virus)
- Rabies: For full information, see Rabies topic:
  - Any break in the skin can transmit rabies.
  - Higher risk of transmission: Unprovoked attack, ill-appearing or stray animal, raccoons/skunks/bats

## DIAGNOSIS

### HISTORY

- History of bite:
  - Provoked/Unprovoked attack
  - Time bite occurred
  - Place of bite (eg, outside of U.S.)
- Tetanus and rabies status of patient and rabies status of animal
- Pertinent medical history and allergies

### PHYSICAL EXAM

- Wound assessment—evaluate and document the following:
  - Type of injury (eg, laceration, crush, avulsion)
  - Signs of infection (swelling/erythema/pain/discharge)
  - Degree of penetration
- Involvement of vasculature/nerves
- Involvement of joints/tendons
- Range of motion
- Lymphadenopathy
- Eschariform lesion, malar purpura, sepsis with purpura fulminans → *Capnocytophaga canimorsus* infection
- Crusted, erythematous papule plus tender regional lymphadenopathy → catscratch disease (2 wk after primary lesion)

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

- Gram stain/culture (aerobic plus anaerobic):
  - If soil/vegetative debris contamination, add mycobacteria plus fungal cultures
  - Obtain viral cultures for monkey bites.
- ESR, C-reactive protein if suspected septic arthritis/osteomyelitis

### Imaging

X-ray for suspected crush injury to bone/fracture

### DIFFERENTIAL DIAGNOSIS

- Human bite
- Cellulitis
- Lymphadenitis
- Osteomyelitis
- Laceration from trauma

## TREATMENT

### PRE HOSPITAL

Local wound care:

- Irrigation
- Dressing
- Splint application if necessary

### INITIAL STABILIZATION/THERAPY

- Assess ABCs and provide hemostasis.
- Wash the wound to reduce inoculum cell count:
  - Soap and water if grossly dirty
  - Normal saline irrigation
  - Quaternary ammonium compound (benzalkonium chloride) plus water
- Irrigate:
  - Normal saline through 18-gauge catheter > 150 mL/cm under high pressure (>7 PSI)
  - Monkey bite wounds → 15 min of irrigation
- Debride devitalized tissue.
- Excise margins of wounds.
- Primary closure:
  - <12 hr old
  - Dog bites
  - Facial bites (up 24 hr):
    - Loose closure by suture
- Delayed primary closure:
  - Crush injuries
  - Hand/Feet injuries
  - Pre-existing infection
  - Cat bites
  - Puncture wounds
  - Wounds >12–24 hr old
  - Wounds in immunocompromised patients
- Immobilization (if indicated)

### ALERT

If the wound is infected and fluctuant, open/incise and drain.

**MEDICATION****ALERT**

- Prophylactic antibiotics should be given in the following high-risk clinical situations:
  - Deep bite wounds
  - Puncture wounds
  - Facial bites
  - Hand/Foot bites
  - Involvement of tendon/bone/muscle/joint
  - Crush injuries
  - Immunocompromised patients, prosthesis, and/or high risk of endocarditis
- Treatment guidelines:
  - Prophylaxis → 3–5 days
  - Infected → 7–14 days
  - Tendon/Bone/Joint involvement → 3–6 wk (depending on location)
- For cat bites, administer the 1st dose of antibiotics parenterally to increase tissue levels; consider for other bites as well.
- Patients presenting ≥72 hr after injury with no clinical signs of infection, those sustaining only a cat scratch, or uncomplicated dog bite to head/neck do not require antibiotics.

**First Line**

For prophylaxis and infected wounds:  
Ampicillin/Sulbactam 50 mg/kg IV, max single dose 3 g, then:

- >40 kg: Amoxicillin/Clavulanic acid 875/125 mg PO q12h (30–50 mg/kg/day)
- ≥3 mo and ≤40 kg: Amoxicillin/Clavulanic acid 45 mg/kg/d PO divided q12h or 40 mg/kg/d PO divided q8h

**Second Line**

- For prophylaxis: Clindamycin 5–10 mg/kg IV, max single dose 600 mg, then:
  - Clindamycin 10–30 mg/kg/d PO divided q6–8h, max single dose 300 mg plus trimethoprim/sulfamethoxazole 8–10 mg/kg of trimethoprim per day PO divided q12h
- For infected wounds requiring admission: Piperacillin/Tazobactam:
  - >6 m: 300–400 mg/kg/day IV divided q6–8h
  - <6 m: 150–300 mg/kg/d IV divided q6–8h
  - >40 mg: 3.375–4.5 g IV q6h
- Tetanus administration (if indicated):
  - Contaminated/Minor wound plus 3 previous doses (last dose >5 yr) → booster
  - Unknown tetanus status/contaminated/major wound → tetanus toxoid plus immunoglobulin (250–500 U IM)
- Rabies prevention (if indicated):
  - Postexposure prophylaxis: 20 IU/kg human rabies immunoglobulin (1/2 at bite site plus 1/2 IM) plus diploid vaccine (1 mL IM days 0, 3, 7, 14, 28)
  - New evidence has resulted in multiple public health authorities to recommend a 4-dose rabies prophylaxis regimen at days 0, 3, 7, 14 only, without a 5th dose.
- Antiviral therapy for moderate- to high-risk monkey bite wounds

**DISPOSITION****Admission Criteria**

- Critical care admission criteria:
  - Moderate to severe hand infections
  - Severe trauma (eg, penetrating wounds to head/neck)
  - Septic
- Consider inpatient admission for the following:
  - Functional/Cosmetic morbidity
  - Secondary infection requiring IV antibiotics (eg, cellulitis/septic arthritis)
  - Tendon/Bone/Joint/Nerve involvement
  - Immunocompromised patients, especially corticosteroid use, leukemia, lupus, asplenia

**Discharge Criteria**

Patients not meeting the above admission criteria may be discharged home with appropriate follow-up.

**Issues for Referral**

- All patients require follow-up with their pediatrician within 24–48 hr to assess for wound infection/dehiscence and failure to respond to initial antibiotic regimen:
- Facial injuries must be assessed daily for a min of 5 days.
  - Consider plastic/general surgery consultation for cosmetic wounds or those requiring extensive debridement.
  - Orthopedic/Hand consultation should be obtained in all cases involving joints/bony structures/tendons.

**FOLLOW-UP****FOLLOW-UP RECOMMENDATIONS**

Patients should seek further medical care for new or worsening symptoms (eg, secondary infection, no improvement within 72 hr of antimicrobial treatment, fever)

**PROGNOSIS**

- 1–2% require hospitalization
- 10–20 deaths annually with 2° mammalian bites:
  - The major cause of death in children <10 yr from dog bites is exsanguination following carotid trauma.
  - *Pasteurella* septicemia has >30% mortality.
  - *C. canimorsus* has >40% mortality.
- Infection rate 5–13%:
  - Dog bites: 2–10%
  - Cat bites: ≤50%
  - Hand wounds: ≥30%

**COMPLICATIONS**

- Abscess
- Septic arthritis
- Tenosynovitis
- Osteomyelitis
- Lymphangitis
- Cellulitis

- Secondary infections:
  - Tularemia (cats)
  - Herpes B (monkey)
  - Rat-bite fever (rats)
  - Leptospirosis (dogs/rodents)
  - Rabies (dogs/bats/raccoon)
- Less commonly: Endocarditis, brain abscess, meningitis, sepsis (with disseminated intravascular coagulation), encephalomyelitis (B virus)

**See Also (Topic, Algorithm, Electronic Media Element)**

- Bite, Human
- Cellulitis

**CODES****ICD9**

- 879.8 Open wound(s) (multiple) of unspecified site(s), without mention of complication
- 879.9 Open wound(s) (multiple) of unspecified site(s), complicated
- 924.9 Contusion of unspecified site

**PEARLS AND PITFALLS**

- Bites can have serious complications despite a relatively benign appearance.
- Obtaining cultures is critical in all patients with infected wounds since no single antibiotic will cover all infecting pathogens.
- If an infection develops within 12 hr of a bite, there is a high likelihood of *P. multocida*.
- Corneal abrasions should be ruled out on bites/scratches to the periorbital region.
- Consider photography of wounds for forensic purposes.

# BITE, HUMAN

Michael L. Epter

## BASICS

### DESCRIPTION

- Human bites are the 3rd most common mammalian bite.
- Polymicrobial wounds:
  - Average of 5 different microorganisms (60% anaerobic)
  - Bacteria that cause infection are much more likely to be normal oral flora than skin flora.
- May be more likely to be infected than other mammalian bites
- Younger children sustain bites to face, upper extremities, and trunk:
  - 1–3% secondary to child abuse
- Clenched fist injury (“fight bite”) and/or occlusional bites seen in older children:
  - 75% involve the hand (especially 4th metacarpal/phalangeal joint of dominant hand)
  - Clenched fist bites have the highest incidence of infection.
  - Potential penetration of tendon sheaths/mid palmar space

### EPIDEMIOLOGY

#### Incidence

2–3% of all bites

### PATHOPHYSIOLOGY

- Clenched fist injury:
  - Inoculation of joint capsules/dorsal tendons through skin over the knuckles with spread/seeding to avascular fascia
  - Could also result in cellulitis, osteomyelitis, tenosynovitis
- Occlusional bite:
  - Crush injury to soft tissue → lacerations, avulsion, amputation

### ETIOLOGY

- *Eikenella corrodens* (25% of human bites)
- Aerobes:
  - *Streptococcus (pyogenes, viridans)*
  - *Staphylococcus aureus*
- Anaerobes:
  - *Porphyromonas*
  - *Bacteroides*
  - *Prevotella*
- Occlusional bites (higher predominance):
  - *Fusobacterium*
  - *Peptostreptococcus*
  - *Candida*

## DIAGNOSIS

### HISTORY

- History of bite:
  - Time bite occurred
- Tetanus status
- Pertinent medical history and allergies
- Source of patient medical history (if possible):
  - HIV/Hepatitis

### PHYSICAL EXAM

Wound assessment: Evaluate and document the following:

- Type of injury (eg, laceration, crush, avulsion)
- Signs of infection (swelling/erythema/pain/discharge)
- Degree of penetration
- Involvement of vasculature/nerves
- Involvement of joints/tendons
- Range of motion (pain with active/passive range → tendinitis, compartment infection)
- Lymphadenopathy

### ALERT

All suspected clenched fist injuries should undergo local exploration with the hand in the clenched fist position to avoid missing an injury to the tendon, joint capsule, and/or metacarpal head.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

- Lab testing is not needed for most patients.
- If signs of infection are present:
  - Gram stain/culture (aerobic plus anaerobic)
  - If there is soil/vegetative debris contamination, add mycobacteria plus fungal cultures.
  - ESR and/or C-reactive protein if suspected septic arthritis/osteomyelitis

#### Imaging

Consider x-ray(s) of affected area (eg, hand/scalp):

- Retained tooth fragment(s)
- Fracture

### DIFFERENTIAL DIAGNOSIS

- Animal bite
- Cellulitis
- Septic arthritis
- Osteomyelitis
- Nonbite laceration

## TREATMENT

### PRE HOSPITAL

- Local wound care:
  - Dressing
  - Splint application (if necessary)
- Assess ABCs and provide hemostasis.

### INITIAL STABILIZATION/THERAPY

- Assess ABCs and provide hemostasis.
- Wash the wound to reduce inoculum cell count:
  - Soap and water
  - Quaternary ammonium compound (benzalkonium chloride) plus water
- Irrigate:
  - 18-gauge catheter plus normal saline (> 150 mL per cm of laceration) under high pressure (> 7 PSI)
- Debride devitalized tissue.
- Primary closure (including tendon/nerve repair) should be delayed in all human bites unless there is an overriding need for cosmetic purposes, such as a gaping facial wound.
- Immobilization (if indicated)
- Avoid irrigation with betadine/alcohol/peroxide (impair healing/damage wound surface).
- If the wound is infected/fluctuant, open/incise and drain.

### MEDICATION

- Antibiotics should be administered in all cases of human bite wounds except patients presenting  $\geq 72$  hr after injury with no clinical signs of infection or bites not penetrating the dermis.
- Treatment guidelines:
  - Prophylaxis → 3–5 days
  - Infected → 7–14 days
  - Tendon/Bone/Joint involvement → 3–6 wk (depending on location)
- Consider giving the 1st dose of antibiotics parenterally to increase tissue levels.

#### First Line

For prophylaxis and infected wounds:  
Ampicillin/Sulbactam 50 mg/kg IV, max single dose 3 g, then:

- $> 40$  kg: Amoxicillin/Clavulanic acid 875/125 mg PO q12h (30–50 mg/kg/day)
- $\geq 3$  mo and  $\leq 40$  kg: Amoxicillin/Clavulanic acid 45 mg/kg/day PO divided q12h or 40 mg/kg/day PO divided q8h

**Second Line**

- For prophylaxis: Clindamycin 5–10 mg/kg IV, max single dose 600 mg, then:
  - Clindamycin 10–30 mg/kg/day PO divided q6–8h, max single dose 300 mg, plus trimethoprim/sulfamethoxazole 8–10 mg/kg of trimethoprim per day PO divided q12h
- For infected wounds: Cefoxitin 80–160 mg/kg/day IV, max 2 g divided q4–8h

**DISPOSITION****Admission Criteria**

- Moderate to severe hand infections
- Functional/cosmetic morbidity
- Secondary infection requiring IV antibiotics (eg, cellulitis/septic arthritis)
- Tendon/Bone/Joint/Nerve involvement
- Sepsis
- Immunocompromised patients, especially corticosteroid use, leukemia, lupus, asplenia

**Discharge Criteria**

Patients not meeting the above admission criteria can be discharged home with appropriate follow-up.

**Issues for Referral**

- All patients require follow-up with their primary care provider within 24–48 hr to assess for wound infection and failure to respond to initial antibiotic regimen.
- Significant clenched fist injuries should be referred to and evaluated by a hand surgeon.

**COMPLEMENTARY & ALTERNATIVE THERAPIES**

- Tetanus administration (if indicated):
  - Clean/Minor wound plus 3 previous doses (last dose > 10 yr) → booster
  - Contaminated/Minor wound plus 3 previous doses (last dose > 5 yr) → booster
  - Unknown tetanus status/contaminated/major wound → tetanus toxoid plus immunoglobulin (250–500 U IM)
- Postexposure prophylaxis for HIV is not recommended in human bites.
- In a patient with a negative anti-hepatitis B surface antibody, administer hepatitis B immunoglobulin plus hepatitis B vaccine if source patient positive hepatitis B surface antigen or unknown status.

**FOLLOW-UP****FOLLOW-UP RECOMMENDATIONS**

Patients should seek further immediate care for new or worsening symptoms (eg, secondary infection, no improvement within 72 hr of antimicrobial treatment, fever).

**Patient Monitoring**

All patients are at risk of transmission for hepatitis/HIV from human bites and should receive baseline screening from their pediatrician with interval testing based upon initial results.

**PROGNOSIS**

- Overall rate of infection rate up to 18% (hand wounds  $\geq$ 30%):
  - Dependent on structures involved/depth of penetration
- Risk of transmission of HIV is 0.015%.

**COMPLICATIONS**

- Abscess
- Septic arthritis
- Tenosynovitis
- Osteomyelitis
- Lymphangitis
- Cellulitis
- Less common: Endocarditis, brain abscess, meningitis, sepsis (with disseminated intravascular coagulation)

**See Also (Topic, Algorithm, Electronic Media Element)**

- Bite, Animal
- Cellulitis
- Tetanus

**CODES****ICD9**

- 879.8 Open wound(s) (multiple) of unspecified site(s), without mention of complication
- 879.9 Open wound(s) (multiple) of unspecified site(s), complicated
- 924.9 Contusion of unspecified site

**PEARLS AND PITFALLS**

- Human bites can have serious complications despite a relatively benign appearance.
- Always consider the risk of transmittable diseases (hepatitis B virus/hepatitis C virus, herpes simplex, HIV, syphilis).
- Obtaining cultures is critical in all patients with infected wounds since no single antibiotic will cover all infecting pathogens.
- Child abuse should be considered in bite marks with an intercanine distance >3 cm.
- Consider photographing wounds for forensic purposes.

# BLEPHARITIS

Ruby F. Rivera

## BASICS

### DESCRIPTION

- Blepharitis is an inflammation of the eyelid often associated with conjunctivitis and keratitis.
- Blepharitis is usually chronic, intermittent, and bilateral.
- Blepharitis is classified by anatomic location (1):
  - Anterior blepharitis:
    - Affects the base of the eyelashes and eyelash follicles
    - Usually caused by *Staphylococcus* species and seborrhea
  - Posterior blepharitis:
    - Affects the meibomian glands and gland orifices
    - Usually caused by meibomian gland dysfunction

### EPIDEMIOLOGY

- Epidemiologic data on the incidence and prevalence of blepharitis is lacking.
- Common but underdiagnosed in children (2,3)

### PATHOPHYSIOLOGY

The pathophysiology of blepharitis is complex and results from interaction of various factors including lid margin secretion, lid margin organisms, and a dysfunctional tear film (4).

### ETIOLOGY

- Bacterial:
  - *Staphylococcus aureus*
  - *Staphylococcus epidermidis*
  - *Propionibacterium acnes*
- Parasitic:
  - *Demodex folliculorum*
  - Pediculosis palpebrarum caused by *Pediculus humanus corporis* or *capitis*
  - Demodex infestation of the facial skin has been implicated in rosacea and blepharitis (4).

- Isotretinoin use can cause blepharitis and corneal irritation.

### COMMONLY ASSOCIATED CONDITIONS

- Seborrheic dermatitis
- Atopic dermatitis
- Meibomian gland dysfunction usually associated with rosacea and seborrhea

## DIAGNOSIS

### HISTORY

- Burning, itching, eye discharge, contact lens discomfort, photophobia, loss of eyelashes
- Eyelashes sticking together in the morning usually common in staphylococcal blepharitis
- Recent exposure to an infected person (eg, pediculosis palpebrarum)
- Current and previous use of systemic or topical medications (eg, isotretinoin)

### PHYSICAL EXAM

- Staphylococcal blepharitis is characterized by:
  - Scaling, crusting, and erythema of the eyelid margin
  - Loss of eyelashes and corneal involvement may occur.
- Seborrheic blepharitis is characterized by:
  - Greasy scaling of the eyelid margin
  - There is often seborrhea of the scalp and eyebrows.
- Meibomian gland dysfunction is characterized by:
  - Frothy discharge
  - Prominent blood vessels
  - Thickening of the eyelid margin
  - Expression of meibomian secretions

## DIAGNOSTIC TESTS & INTERPRETATION

### Lab

- Lab testing is not always indicated.
- Culture of the eyelid margins should be obtained in patients with recurrent anterior blepharitis and those not responding to therapy.

### Diagnostic Procedures/Other

Microscopic exam of epilated eyelash to reveal Demodex mite

### DIFFERENTIAL DIAGNOSIS

- Conjunctivitis
- Discoid lupus erythematosus
- Lacrimal duct obstruction

## TREATMENT

- Eyelid hygiene is the mainstay of treatment.
  - Warm compress 1–2 times daily followed by eyelid massage
- Cleaning the eyelid margin with a cotton ball soaked in diluted baby shampoo

### MEDICATION

#### First Line

Bacitracin or erythromycin ophthalmic ointment:

- Apply 1/4–1/2-inch ribbon 1–2 times daily for  $\geq 1$  wk
- Duration should be guided by severity of symptoms and response to therapy.

#### Second Line

- Selenium sulfide/tar shampoo, as seborrheic blepharitis is often associated with seborrheic dermatitis of the scalp and eyebrows
- Topical corticosteroids may be helpful in those with severe inflammation:
  - Hydrocortisone ophthalmic cream (1%) applied b.i.d. to affected area

- Patients unresponsive to eyelid hygiene and topical antibiotics can be given oral antibiotics:
  - Tetracycline: >8 yr of age, 25–50 mg/kg/day divided q6h; adult dose, 1–2 g PO divided b.i.d.–q.i.d.
  - Doxycycline: >8 yr of age, 2–4 mg/kg/day divided b.i.d.; adult dose 100 mg PO b.i.d.
  - Erythromycin ethylsuccinate: 30–50 mg/kg/day divided q8h
  - Azithromycin: 10 mg/kg PO on day 1, then 5 mg/kg PO days 2–5; adult dose, 500 mg PO day 1, then 250 mg PO days 2–5

## DISPOSITION

### Admission Criteria

Admission is generally not required. Rarely, in cases of visual loss, intractable pain, corneal loss, or unclear diagnosis, admission may be indicated.

### Discharge Criteria

Patients with blepharitis should almost universally be discharged.

### Issues for Referral

- Patients with blepharitis with the following symptoms should be emergently referred to an ophthalmologist:
  - Visual loss
  - Moderate to severe pain
- Patients with blepharitis with the following symptoms may be referred to an ophthalmologist for follow-up within 1–2 days:
  - Chronic or severe redness
  - Unresponsiveness to therapy
  - Corneal involvement

## FOLLOW-UP

### FOLLOW-UP RECOMMENDATIONS

Discharge instructions and medications:

- Warm compresses applied 1–2 times daily followed by eyelid massage
- Cleaning the eyelid margin with a cotton ball soaked in diluted baby shampoo
- Bacitracin or erythromycin ophthalmic ointment:  $\frac{1}{4}$ – $\frac{1}{2}$ -inch ribbon 1–2 times daily for  $\geq 2$  wk. Duration of therapy should be guided by severity of symptoms and response to therapy.
- Artificial tears applied twice daily for dry eyes

### Patient Monitoring

Close follow-up and monitoring with the patient's primary care physician to ensure resolution

### PROGNOSIS

- Blepharitis is usually a chronic, intermittent condition.
- Patients should be advised that symptoms may improve with treatment but that there will be recurrences.
- Patients should continue eyelid hygiene even after symptoms improve.

### COMPLICATIONS

- Hordeolum
- Chalazion
- Dry eyes secondary to aqueous tear deficiency

- Hordeolum

### CODES

#### ICD9

- 373.00 Blepharitis, unspecified
- 373.01 Ulcerative blepharitis
- 373.02 Squamous blepharitis

## PEARLS AND PITFALLS

- Blepharitis is usually a chronic condition caused by inflammation due to bacterial infection, parasitic infection, seborrheic dermatitis, or chemical irritation.
- Blepharitis may result from pediculosis pubis. Pediculosis pubis is an STI; if present in a young patient, the possibility of sexual abuse must be considered.

# BLINDNESS

Désirée M. Seeyave

## BASICS

### DESCRIPTION

- Blindness is defined as the loss of vision.
- Blindness can be bilateral, unilateral, transient, or permanent.
- Vision loss can occur for many reasons and can involve many systems.

### EPIDEMIOLOGY

#### Incidence

- The true incidence is unknown. The World Health Organization estimates 1.494 million children 0–15 yr of age are born blind or become severely visually impaired (1):
  - Mostly due to vitamin A deficiency, severe protein-energy malnutrition, measles, or use of traditional eye medicines
- Pediatric blindness accounts for 5% of all blindness.
- U.S. prevalence: 0.3 per 1,000 children (1)

### RISK FACTORS

- Males are more likely to suffer from direct trauma to the eye.
- Contact lens use predisposes to keratitis (corneal inflammation) caused by *Staphylococcus aureus*, *Pseudomonas aeruginosa*, herpes simplex virus (HSV), and adenovirus.
- Acute sinusitis, ophthalmic surgery, and trauma predispose to orbital cellulitis.
- Sickle cell disease predisposes to stroke, central retinal artery occlusion, and glaucoma.
- Prothrombotic disorders predispose to cavernous sinus thrombosis and central retinal vein occlusion.

### GENERAL PREVENTION

- Eye protection during sports
- Appropriate safety equipment
- Proper sterile techniques when wearing contact lens

### ETIOLOGY

- Infection, such as keratitis and orbital cellulitis
- Vitamin A deficiency
- Severe protein-energy malnutrition
- Traumatic injury
- Use of traditional eye medicines
- Retinopathy of prematurity
- Optic nerve hypoplasia
- Structural problems along the visual pathway, including:
  - Visual media: Cornea, lens, anterior chamber, aqueous or vitreous humor
  - Retina: Vascular occlusion, retinal detachment, tumors
  - Neurovisual pathway: Optic nerve, visual pathways, occipital lobes

## DIAGNOSIS

### HISTORY

- Problems with visual media due to history of blunt trauma to eye, chemical burns, keratitis, iritis, glaucoma, lens abnormalities, and endophthalmitis:
  - Decreased vision
  - Pain
  - Blepharospasm
  - Conjunctival injection
  - Photophobia
  - Excessive tearing
- Problems with the retina due to retinoblastoma, central retinal artery occlusion, and central retinal vein occlusion:
  - Vision loss
  - Complaints of floaters and flashes of light (photopsias), with partial or complete painless loss of vision in the affected eye
  - Sudden, painless monocular vision loss
- Problems with the neurovisual pathway due to orbital cellulitis, orbital compartment syndrome, orbital neoplasms, idiopathic intracranial HTN, optic neuritis, optic pathway tumors, optic nerve avulsion:
  - Can have rapid or gradual loss of vision

### PHYSICAL EXAM

- Trauma:
  - Foreign bodies may be visible on sclera and should be removed carefully.
  - Fluorescein staining of the eye for corneal abrasion
  - Hyphema: Crescentic line of blood seen by shining a tangential light into the anterior chamber; slit lamp to see microhyphema
  - Globe rupture: May be occult or obvious on inspection, with obvious corneal/sclera laceration, volume loss of eye, iris abnormalities, foreign body protruding or visible on funduscopy, decreased visual acuity
  - Orbital fracture: Impaired extraocular movements if orbital muscles entrapped; tenderness on palpation of orbital bones
- Chemical burn: Corneal scarring, ulceration, and vision loss (2)
- Ischemia to scleral vessels may cause the eye to appear white (alkali burn) (3)
- Keratitis: Corneal opacity (round white spot), red eye; HSV causes dendritic pattern on fluorescein stain
- Iritis: Slit lamp needed to see inflammatory cells in the anterior chamber
- Glaucoma: Painful red eye, cloudy cornea, enlarged eye (buphthalmos) in children <3 yr of age, vision loss, increased intraocular pressure

- Ectopic lens: Lens dislocation visible on inspection or with slit lamp
- Vitreous hemorrhage: Dome-shaped hemorrhage in front of retina, decreased red reflex
- Endophthalmitis: Red eye, hypopyon
- Retinoblastoma: Leukocoria when attempting to see red reflex; dilated eye exam visualizes chalky, white-gray retinal mass
- Retinal detachment: Dull red reflex, retina appears elevated with folds, relative afferent papillary defect if severe
- Central retinal artery occlusion:
  - Early (minutes to hours): Vascular narrowing; 20% patients may have visible embolus.
  - Late (hours): White retina except cherry-red fovea; afferent pupillary defect
- Central retinal vein thrombosis: Dilated and tortuous retinal veins, disc swelling, diffuse nerve fiber layer and preretinal hemorrhage, “cotton wool” spots on retina
- Orbital cellulitis: Proptosis, ophthalmoplegia, diplopia, vision loss if orbital apex and optic nerve involved (orbital apex syndrome)
- Orbital compartment syndrome: Proptosis, ecchymosis of eyelids, chemosis, ophthalmoplegia, papilledema, increased intraocular pressure
- Neuroblastoma: Proptosis and periorbital ecchymosis occur with metastasis.
- Optic neuritis: Photopsias, papillitis on funduscopy
- Optic pathway tumors: Visual field defects

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

- CBC, C-reactive protein, blood culture, inflammatory markers if infectious or rheumatologic cause suspected
- Lyme titers, toxicology screen, lumbar puncture, if indicated
- Culture of lesions if keratoconjunctivitis suspected
- Lumbar puncture for meningitis, opening pressure measurement for idiopathic intracranial HTN (<200 mm H<sub>2</sub>O normal, >250 mm H<sub>2</sub>O high, 200–250 mm H<sub>2</sub>O equivocal) measured with patient in lateral decubitus position with legs extended

#### Imaging

- US for orbital cellulitis, retinoblastoma, optic nerve diameter as indirect measure of intracranial pressure in idiopathic intracranial HTN
- CT: High-resolution, thin-slice, orbital CT with coronal images for orbital trauma or intraocular foreign bodies (noncontrast), orbital cellulitis (with contrast)
- MRI: For evaluation of optic nerve tumors, optic neuritis, white matter lesions with MS, soft tissue abnormalities. Do not perform if metallic intraocular foreign body is suspected.

**Diagnostic Procedures/Other**

- Slit lamp exam for visualization of the cornea and anterior chamber (eg, for keratitis, iritis, hyphema, lens dislocation)
- Tonometry for glaucoma, orbital compartment syndrome
- Sinus radiographs
- Electroencephalogram to diagnose seizures as the cause of blindness
- Optokinetic drum for nystagmus

**DIFFERENTIAL DIAGNOSIS**

- Conversion disorder: Vision loss may be monocular or binocular, total or partial.
- Typically seen in female teens who are not concerned about their lack of vision (La Belle indifférence)
- Nystagmus with an optokinetic drum demonstrates an intact visual pathway.
- Toxins, the metabolite of methanol, formate, causes optic nerve and retinal epithelial cell destruction, can occur 72 hr after ingestion. Any toxin that decreases occipital blood flow can cause cortical blindness (eg, CO, nifedipine, amphetamines, etc.).
- Migraine: Causes transient vision loss
- Head trauma: Minor head injury may be associated with transient visual loss due to occipital concussion or vascular hyperreactivity.
- Seizures: Blindness and visual hallucinations are seen in benign occipital epilepsy of childhood.

**TREATMENT****PRE HOSPITAL**

- Trauma: Do not force the eye open if an open globe is suspected. Leave foreign bodies in place. Use a hard shield that does not place pressure on the eye. Elevate head of bed 30 degrees. Give antiemetics and pain medication.
- Chemical burns: Immediate irrigation with sterile normal saline or water

**INITIAL STABILIZATION/THERAPY**

- Chemical burns: Topical analgesia such as 0.5% tetracaine, IV morphine (0.1 mg/kg/dose), irrigation for at least 30 min using a polymethylmethacrylate scleral lens (eg, Morgan lens):
  - Irrigate until fornix pH is 6.5–7.5. When pH is normal, recheck at 5 and 30 min after irrigation. May need passive restraints and eyelid retraction.
- Central retinal artery occlusion: Emergent ophthalmology consult is needed to restore circulation—ocular massage, anterior chamber paracentesis, local arterial thrombolytics, hyperbaric O<sub>2</sub>, and surgical revascularization are all treatments that may be required emergently.
- Emergent lateral canthotomy for orbital compartment syndrome to restore blood flow and prevent permanent blindness.

**MEDICATION****First Line**

- Corneal abrasion: Topical antibiotics (trimethoprim polymyxin B, 1–2 drops in affected eye q4–6hr for 2–3 days)
- Keratitis: Prompt initiation of topical antibiotics if bacterial and topical +/- oral antiviral if HSV, in consultation with ophthalmology
- Traumatic iritis: Cycloplegics and topical steroid drops in consultation with ophthalmology
- Globe rupture: Empiric broad-spectrum antibiotics:
  - Vancomycin 15 mg/kg IV, max dose 1 g
  - Ceftazidime 50 mg/kg (max dose 2 g); if penicillin allergic, ciprofloxacin 10 mg/kg (max dose 400 mg)
- Endophthalmitis: Vancomycin or ceftazidime, +/- antifungals (eg, oral fluconazole, IV amphotericin B); emergent consultation for intravitreal antibiotics or vitrectomy
- Orbital cellulitis: Broad-spectrum antibiotics to cover *Haemophilus influenzae* and *Streptococcus pneumoniae*, which are common causes of sinusitis in children—ampicillin/sulbactam 50 mg/kg/dose q6h
- Idiopathic intracranial HTN: Acetazolamide 25 mg/kg/day, max dose 2 g/day

**Second Line**

Update tetanus status for eye injuries.

**COMPLEMENTARY & ALTERNATIVE THERAPIES**

- Chemical burns: Topical collagenase inhibitor to reduce inflammation (human data limited)
- Idiopathic intracranial HTN: Weight loss, topiramate 3

**SURGERY/OTHER PROCEDURES**

- Orbital cellulitis and abscesses require emergent surgical drainage to prevent intracranial spread via a valveless venous system leading to intracranial abscesses, meningitis, or cavernous sinus thrombosis
- Globe rupture repair
- Endophthalmitis: Intravitreal antibiotics or vitrectomy

**DISPOSITION****Admission Criteria**

- In general, all patients with acute vision loss should be admitted to the hospital.
- Critical care admission criteria:
  - Admission for management of serious, associated conditions (eg, hemorrhagic shock, stroke, meningitis, and cavernous sinus thrombosis)

**Discharge Criteria**

- Patients with restored vision after chemical burn and normal eye pH 30 min after irrigation
- Patients with corneal abrasions and microhyphema may be discharged with close follow-up.

**Issues for Referral**

- Refer to ophthalmologist for:
  - Keratitis, iritis, glaucoma: Confirmation of diagnosis, visual monitoring, and treatment
  - Hyphema: Size correlates with visual outcome; rebleeding or acute glaucoma predisposes to permanent visual loss, especially in patients with sickle cell or bleeding disorders.
  - Ectopic lens to be replaced/monitored
- Refer to an oncologist/neurosurgeon for management of tumors.

**FOLLOW-UP****FOLLOW-UP RECOMMENDATIONS**

- Discharge instructions and medications:
  - Follow up with an ophthalmologist within 24–48 hr to ensure healing and preservation of vision.
- Activity:
  - Bed rest for microhyphema to prevent rebleeding

**PROGNOSIS**

Permanent blindness is a complication of all major forms of eye trauma, infections, and tumors.

**REFERENCES**

1. Steinkuller PG, Lee D, Clare G, et al. Childhood blindness. *J AAPOS*. 1999;3(1):26–32.
2. Berry M, Jeffreys D. Ocular injuries from household chemicals: Early signs as predictors of recovery. *In Vitro Mol Toxicol*. 2001;14(1):5–13.
3. Ambati BK, Ambati J, Azar N, et al. Periorbital and orbital cellulitis before and after the advent of *Haemophilus influenzae* type B vaccination. *Ophthalmology*. 2000;107(8):1450–1453.

**CODES****ICD9**

- 369.00 Blindness of both eyes, impairment level not further specified
- 369.60 Blindness, one eye, not otherwise specified
- 369.61 One eye: total vision impairment; other eye: not specified

**PEARLS AND PITFALLS**

- Loss of vision should be managed as an emergency.
- There are many causes of acquired blindness in children.
- The visual structure involved can be determined from the history and physical.
- Ophthalmology referral is essential to monitor vision.

# BODY PACKERS (INGESTED DRUG PACKAGES)

John Kashani

## BASICS

### DESCRIPTION

- A body packer is an individual who smuggles a large amount of drugs in well-sealed packets.
- Known as “mules,” they either swallow or insert the drugs into body cavities. Usually, the drugs are smuggled across international borders.
- Body packers typically carry cocaine or heroin:
  - Rare cases of body packing other drugs, such as methamphetamine, Ecstasy (MDMA), and marijuana have been reported.
- A body stuffer is an individual who hurriedly ingests drugs or inserts drugs into a body cavity in an attempt to conceal them from the authorities.
- These may involve any type of illicit drug:
  - The drugs are usually poorly packaged and are intended for sale or individual use. The risk of drug leakage from these drug packages is high.
  - Additionally, body stuffing carries the risk of aspiration of drug packets.

### EPIDEMIOLOGY

#### Incidence

- The incidence of body packers and stuffers is not known.
- Body packing in children is likely rare, though it has been reported.

### PATHOPHYSIOLOGY

- Illness occurs when drug packages leak their contents or cause intestinal obstruction.
- Body stuffing involves a small quantity of packs, and this never results in intestinal obstruction.
- Rarely, attempts to quickly swallow packs may result in aspiration or airway obstruction.
- Body packing is performed with ingestion of large quantities of packs prepared with the intent that they may transit the gut:
  - Packs may leak their contents. If so, they contain much larger quantities of drugs and are more likely to cause severe illness.
  - Packs may also result in intestinal obstruction.
- The drugs most commonly packed or stuffed are cocaine and heroin. To a lesser extent, amphetamines and marijuana may be packed or stuffed. Patients may present with signs and symptoms of cocaine, heroin, or amphetamine toxicity.
- Additionally, a packer or stuffer may present with GI disturbances secondary to the mechanical effects of the drug packets. Abdominal obstruction may occur.

### ETIOLOGY

- Cocaine
- Heroin
- Methamphetamine
- Other drugs may also be ingested by body stuffers
- Other drugs are rarely ingested by body packers

### COMMONLY ASSOCIATED CONDITIONS

Substance abuse/use may be associated with body stuffers, who are often drug abusers, as opposed to body packers, who typically transport the drugs for profit but are not drug abusers.

## DIAGNOSIS

### HISTORY

- Usually, the patient is brought by law enforcement authorities after being apprehended.
- Body packers are typically apprehended at international airports and borders, while body stuffers are typically apprehended by local law enforcement officers who witnessed the patient swallow drugs in order to conceal them.
- Less commonly, the patient may present after developing symptoms or failing to pass the drug packages rectally.

### PHYSICAL EXAM

- If the drugs involved are leaking and being systemically absorbed, it is likely that the physical exam will make the class of drug involved readily apparent.
- Opioids will typically cause an opioid toxidrome consisting of miotic pupils, CNS depression or coma, and respiratory depression.
- Cocaine or methamphetamine will typically cause a sympathomimetic toxidrome consisting of agitation, diaphoresis, mydriasis, HTN, and tachycardia.
- If a person is believed to be a body stuffer or packer, the physical exam should include a vaginal and rectal exam.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

- No lab testing is routinely necessary.
- Body packing involves one of the only times in which urine drug of abuse screening may be useful for clinical management:
  - On rare occasions, drug of abuse screening may assist in managing scenarios involving rupture of packages in a body packer.
  - A drug screening assay in this circumstance is not sensitive or specific to identify the drugs ingested.

- A positive test cannot differentiate between remote exposure to the drug and current exposure from a ruptured package.
- Ingested packets by both body stuffers and body packers often contain enough residue to result in a positive drug screening.
- Basic chemistry profile to assess for dehydration and hyperkalemia
- Creatine phosphokinase and/or urinalysis to evaluate for rhabdomyolysis
- Troponin should be ordered in any patient with chest pain or findings consistent with myocardial ischemia.

### Imaging

- An abdominal radiograph may show oblong packets outlined in bowel gas, or the packets themselves may be made of a radiopaque material.
- Body packers:
  - Typically, imaging plays a key role in management.
  - Sensitivity of abdominal radiography is up to 90% in body packers.
  - CT may be more sensitive than plain radiography in detecting drug packets, though sensitivity is not 100%.
  - CT is the most appropriate for suspected body packing. Body stuffers do not usually require imaging by CT, though it is not always able to detect drug packets.
  - US appears to be very sensitive in detecting drug packages in body packers:
    - In 1 study, 40 of 42 body packers who were airport detainees had ingested drug packs detected by US. 7 of 8 suspects without any ingested drugs were correctly identified as not containing drug packages (1).
  - Detecting drug packets in body packers by radiography is unreliable and cannot be used to absolutely confirm or exclude the diagnosis.
- Body stuffers: Radiographs may be used in management. They may be specific, showing such x-ray findings as nonsurgical staples, but they are poorly sensitive.

### DIFFERENTIAL DIAGNOSIS

- Sympathomimetic poisoning
- Cocaine or heroin abuse without ingesting drug packs

## TREATMENT

### PRE HOSPITAL

- Assess and stabilize airway, breathing, and circulation.
- If signs of opioid toxicity are present, administer naloxone as per local protocol.
- If there are signs of psychomotor agitation or seizures that may be the result of cocaine, administer diazepam as per local protocol.

### INITIAL STABILIZATION/THERAPY

- Assess and stabilize airway, breathing, and circulation.
- Use continuous cardiac monitoring and pulse oximetry.
- These patients should be reassessed often because they may decompensate quickly.

- Supportive care is the mainstay of therapy:
  - Toxicity from ingested drug, most commonly heroin or cocaine must be treated
  - If opioids are ingested, administration of naloxone, sometimes in large doses, is adequate to treat toxicity.
  - Intestinal obstruction may require surgery.
  - Rupture of cocaine packages may result in severe HTN and tachycardia as well as intestinal ischemia and necrosis:
    - This usually requires intensive management of cardiovascular stimulation with diazepam and medications to control BP such as phentolamine
    - This may require immediate surgical removal to preserve the ischemic gut as well as to prevent death.

**ALERT**

- Obtain rectal temperature immediately in patients with possible hyperthermia.
- Significant hyperthermia ( $\geq 39.0$ – $40.0^{\circ}\text{C}$  or  $102.2$ – $104.0^{\circ}\text{F}$ ) requires passive cooling or mild active cooling and medications:
  - Life-threatening hyperthermia ( $> 41.5$ – $42.0^{\circ}\text{C}$  [ $< 106.7$ – $107.6^{\circ}\text{F}$ ]) should be treated by immersion in an ice bath. Other cooling measures are inadequate:
    - Wrapping the patient in sheets with ice or placing the patient in a body bag with ice are reasonable approaches.

**MEDICATION**

**First Line**

- Diazepam:
  - First-line medication for any cocaine-intoxicated patient
  - Administer for agitation, chest pain, or HTN/tachycardia
  - Initial dose 0.2 mg/kg IV; dose may be repeated q5min
  - After administering a given dosage 3 times, increase the dose by doubling:
    - If 10 mg IV has been given 3 times without adequate effect, increase dose to 20 mg. If 20 mg IV has been given 3 times without effect, double dose to 40 mg IV.
    - Although these doses are higher than typical, tolerance of multiple doses without sedation provides reassurance to increase the dose.
- Naloxone:
  - Treatment for opioid toxicity
  - Very large doses or infusion may be necessary.
  - Initial dose 0.4 mg/kg or empiric 2-mg dose
  - Use a smaller dose (0.05 mg) for a body stuffer who has swallowed heroin, as the person may be tolerant and naloxone may cause opioid withdrawal that is difficult to manage.
  - In nontolerant patients, repeat the 2-mg dose 3 times if there is a suspected opioid toxidrome.
  - If arousal recurs, redose using the cumulative dose that initially worked or administer 2/3 (66%) of that dose hourly as an infusion.

**Second Line**

See Cocaine topic for information about treatment of cocaine toxicity.

**SURGERY/OTHER PROCEDURES**

- Endoscopic removal of packets may be indicated in both body packers and stuffers.
- If cocaine body packing is suspected, surgical consultation and surgical removal may be necessary due to the high risk of mortality associated with package leakage.

**DISPOSITION**

**Admission Criteria**

- Critical care admission criteria:
- All symptomatic body packers or body stuffers require critical care admission.
  - All body packers should be admitted to a critical care unit.

**Discharge Criteria**

- Body packers are never discharged from the emergency department.
- Body stuffers who are stable after a period of observation can be considered for discharge.
- The period of observation will vary with the type of agent swallowed, reliability of the history, and discharge destination (home vs. correctional institution):
  - 4–10 hr depending on how many packs are believed to have been swallowed based on history or visualized on the x-ray

**Issues for Referral**

- There is debate about whether body packers who present independently should be reported to police:
  - For public health, patient, and staff safety, the authors strongly urge in doing so.
- Refer all drug abusers for drug counseling.

**COMPLEMENTARY & ALTERNATIVE THERAPIES**

Whole bowel irrigation for packers and stuffers:

- Administer 1 L/hr of polyethylene glycol (Go Lytely) solution via an NG tube:
  - The goal is to assist the patient in passing all packs rectally.

**FOLLOW-UP**

**PROGNOSIS**

- Prognosis varies with drug ingested, quantity, and leakage of packs.
- Body stuffers tend to have less severe morbidity and less mortality.
- Cocaine body packing is most dangerous. Ruptured packs may result in death even if the patient reaches medical care.

**COMPLICATIONS**

- End-organ damage from cocaine toxicity: Stroke, myocardial infarction, or cardiac dysrhythmia
- Respiratory depression, apnea, and asphyxiation from heroin toxicity

**REFERENCE**

**See Also (Topic, Algorithm, Electronic Media Element)**

Cocaine Poisoning

**CODES**

**ICD9**

- 965.01 Poisoning by heroin
- 969.72 Poisoning by amphetamines
- 970.81 Poisoning by cocaine

**PEARLS AND PITFALLS**

- The mainstay of therapy is supportive care, maintaining vital signs within acceptable limits, and treating cardiovascular stimulation or respiratory depression.
- GI decontamination to get patients to excrete packs more quickly is typical part of therapy.
- Diazepam is typically the only medication needed to treat cocaine toxicity.
- Naloxone is typically the only medication needed to treat heroin toxicity.
- Obtain emergent surgical consultation in cocaine body packers with overt toxicity.
- Body packers should be treated until all packs have passed. They typically know the exact number of packs they are transporting, as this is the number they are expected to excrete once across the border in the country of drug delivery.

## BASICS

### DESCRIPTION

- *Clostridium botulinum* is an anaerobic, spore-forming, gram-positive bacillus. The spores are ubiquitous and can be found in soil, water, and air.
- Botulinum toxin is considered the most lethal substance known, with an estimated oral LD<sub>50</sub> of 1 µg/kg in humans.
- There are 3 main types of botulism:
  - Foodborne botulism occurs when a person ingests preformed toxin.
  - Infant botulism occurs in a small number of susceptible infants who harbor *C. botulinum* in their intestinal tract (intestinal toxemia).
  - Wound botulism occurs when wounds are infected with *C. botulinum* that secretes toxin.
- 2 less common forms of botulism are also defined:
  - Iatrogenic botulism occurs from treatment with botulinum toxin for cosmetic or therapeutic reasons.
  - Intestinal colonization by *C. botulinum* in patients > 1 yr of age with subsequent toxin formation and botulism (infant-type botulism in an adult)
- 7 different serotypes of botulinum toxin have been identified (types A–G):
  - The vast majority of cases are due to 3 serotypes: A, B, and E
  - Type A predominantly is found west of the Mississippi.
  - Type B predominantly is found east of the Mississippi.
  - Type E is found in the Pacific Northwest, especially in Alaska.

### EPIDEMIOLOGY

- Wound botulism is not a disease of children.
- Foodborne botulism rarely affects children:
  - Outbreaks typically occur in clusters.
- Infant botulism:
  - Most common form of botulism, representing 70% of all new cases of botulism reported annually
  - In the U.S., 1.9/100,000 live births yield ~77 cases annually.

### RISK FACTORS

Infant botulism is associated with:

- Higher birth weights
- Older, Caucasian mothers
- Breast-fed infants
- Equal male:female distribution
- >50% of infantile botulism cases reported over last 30 years have been in California.

### GENERAL PREVENTION

- Food and dust seem to be possible spore sources in infant botulism:
  - Honey has been implicated in 20% of cases.
  - Corn syrup has also been implicated.
  - Infants should not be fed these foods, though the vehicle for transmission remains unclear.
  - Vacuum cleaner dust has also been implicated, as have nearby construction sites.
- Foodborne botulism has been associated with improperly canned foods, the majority are home canned:
  - Use of proper canning technique and refrigeration or boiling canned foods in a pressure cooker prior to consumption can reduce both the botulinum toxin load and the spore load.

### PATHOPHYSIOLOGY

Botulism is a neuroparalytic illness resulting from the action of the botulinum toxin:

- The active form of the toxin is composed of heavy and light polypeptide chains connected by disulfide bonds.
- Botulinum toxin enters presynaptic nerve terminals via endocytosis, where it irreversibly prevents the release of acetylcholine by inhibiting calcium-dependent exocytosis.
- The net result is a decrease in the acetylcholine concentration within the synaptic cleft within the autonomic nervous system and at neuromuscular junctions resulting in anticholinergic (muscarinic and nicotinic) effects and flaccid paralysis.

### ETIOLOGY

- Botulism is the result of the presence of toxin-secreting *C. botulinum* in the body, ingestion of preformed toxins contained in food, or rarely iatrogenic.
- Botulinum toxin serotypes A and B are found in near 50/50 distribution in cases of infant botulism.

### COMMONLY ASSOCIATED CONDITIONS

Wound botulism is associated with IV heroin use, especially black tar heroin.

## DIAGNOSIS

### HISTORY

- Foodborne botulism results in predominantly GI symptoms, including nausea, vomiting, abdominal pain, and distention:
  - Symptoms usually develop within 12–36 hr but may develop as early as 4 hr or as late as 10 days.
  - Other initial symptoms are often mild and include fatigue, weakness, vertigo, dry mouth, and sore throat.
  - Severe cases can develop symmetric, descending flaccid paralysis with prominent bulbar palsies such as diplopia, dysarthria, dysphonia, and dysphagia.

- Infant botulism is characterized by constipation followed by neuromuscular paralysis or “floppiness”:
  - A history of poor feeding, lethargy, and diminished crying is also common.
  - Breast-feeding mothers will specifically note that the child is taking less milk.
- In both types, a history of descending paralysis and bulbar palsies should increase the level of suspicion.

### PHYSICAL EXAM

- Patients with foodborne botulism may demonstrate weakness or paralysis of the upper extremities; dilated, nonreactive pupils; and ophthalmoplegia:
  - May see drooling or difficulty phonating
  - Deep tendon reflexes may be preserved, and ataxia is absent.
  - Paralysis of the respiratory muscles can occur.
  - Deep tendon reflexes and mental status are typically normal.
  - Autonomic instability, such as orthostatic hypotension, may also occur.
- Infant botulism results in bulbar palsies and hypotonia, which can be severe or include respiratory insufficiency:
  - Classic finding is of a “floppy infant”

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

- Routine lab tests are not helpful in making the diagnosis, as most will be normal:
  - Serum electrolytes can help exclude several of the differential diagnoses.
- Evaluation of the stool by culture and toxin assays can help confirm what is largely a clinical diagnosis:
  - Neurotoxin may be identified in the serum, feces, vomitus, or gastric contents.

#### Imaging

No specific imaging study will confirm the diagnosis of botulism.

#### Diagnostic Procedures/Other

- Electromyography may be helpful in distinguishing botulism from Guillain-Barré syndrome or myasthenia gravis:
  - This is only helpful for foodborne botulism in an adolescent patient.
- Testing of food specimens can help identify toxins, but results are often delayed.
- Rapid testing techniques are currently under development and include optical immunoassays and polymerase chain reactions.

**DIFFERENTIAL DIAGNOSIS**

- Infant botulism:
  - Sepsis
  - Electrolyte imbalance
  - Metabolic encephalopathy
  - Congenital myopathy
  - Leigh disease
- Foodborne botulism:
  - Myasthenia gravis
  - Guillain-Barré syndrome
  - Tick paralysis
  - Diphtheria
  - Poliomyelitis

**TREATMENT**

**PRE HOSPITAL**

Assess and stabilize airway, breathing and circulation.

**INITIAL STABILIZATION/THERAPY**

Patients with respiratory compromise require careful monitoring of respiratory vital capacity and aggressive respiratory care for those with respiratory insufficiency.

**MEDICATION**

**First Line**

- Human-derived botulism immune globulin has been FDA approved for treatment of infant botulism since 2003 (BabyBIG).
- BabyBIG is maintained by the California Department of Public Health via their Infant Botulism Treatment and Prevention Program. Contact and drug information is available at <http://www.infantbotulism.org>:
  - BabyBIG has been shown to reduce the overall hospital length of stay (LOS), the ICU LOS, and duration of mechanical ventilation.
- Patients with foodborne botulism with more than mild symptoms should receive an equine derived trivalent (A, B, E) botulinum antitoxin:
  - This antitoxin is maintained by the CDC and requires contacting local state health departments who in turn contact the CDC for release.
  - The CDC can be contacted directly 24 hr/day when local health departments are unavailable.
  - The usual dose is a 10 mL vial IV; however, dosing regimens will be included with the antitoxin.
  - There is no role for equine antitoxin in infant botulism due to associated risks of anaphylaxis and serum sickness.

**Second Line**

Antibiotic therapy has a defined role in wound botulism; however, it has no benefit in foodborne botulism, which is the result of the ingestion of preformed toxin:

- Antibiotics are not indicated in infant botulism, as lysis of intestinal *C. botulinum* could result in the release of large quantities of toxin, worsening the patient’s condition.

**COMPLEMENTARY & ALTERNATIVE THERAPIES**

Supportive care is essential, including ventilatory support, nutritional support, skin care, positioning, and so forth, to reduce associated complications.

**DISPOSITION**

**Admission Criteria**

Critical care admission criteria:

- All patients with diagnosed or suspected foodborne or infant botulism should be admitted to a critical care setting.
- While there are some cases of mild botulism, many require mechanical ventilation.
- In 1 study, 83% of infants diagnosed with infant botulism required mechanical ventilation.

**FOLLOW-UP**

**FOLLOW-UP RECOMMENDATIONS**

After discharge from the hospital, patients should be referred to a neurologist for follow-up.

**PROGNOSIS**

- Prognosis is generally good with early supportive care and antitoxin as indicated:
  - Recovery can be prolonged, lasting from several months to 1 year.
- Infant botulism usually results in complete recovery.

**COMPLICATIONS**

Complications are usually minimal and are those associated with prolonged ventilatory dependence:

- Neurologic sequelae of foodborne botulism are not uncommon and can range from fatigue to persistent muscle weakness to dyspnea.

**See Also (Topic, Algorithm, Electronic Media Element)**

- <http://www.infantbotulism.org>
- <http://www.cdc.gov>

**CODES**

**ICD9**

- 005.1 Botulism food poisoning
- 040.41 Infant botulism
- 040.42 Wound botulism

**PEARLS AND PITFALLS**

- Early consultation of infectious disease, toxicology, and neurology are critical for establishing what is largely a clinical diagnosis.
- Suspect botulism in any patient with neuromuscular weakness, especially bulbar palsies.
- Early diagnosis can result in early administration of antitoxin, which is associated with shorter LOS and reduced morbidity and mortality.
- Mortality for foodborne botulism is currently 5–10% and often related to complications of prolonged ventilator dependence.
- Pitfalls include waiting for lab analysis to make the diagnosis and delayed consultation.

# BRACHIAL PLEXUS INJURY

Nina Lightdale

## BASICS

### DESCRIPTION

- The brachial plexus is the network of peripheral nerves that originate from the spinal cord at cervical and thoracic roots C5, C6, C7, C8, and T1:
  - These nerves control the sensory and motor function of the hand, wrist, elbow, and shoulder.
- Brachial plexus injury (BPI) can be transient with full recovery or result in long-term disability with partial or complete motor and sensory functional loss of the upper limb.

### EPIDEMIOLOGY

#### Incidence

- Traumatic BPI:
  - Motorcycle or fall from height injury
  - Transient BPI:
    - Often called “stingers” or “burners”
    - Occur in ~30–50% of football players over the course of a high school, college, or professional career
- Brachial plexus birth palsy (BPBP) occurs in ~0.4–4 of 1,000 live births.

#### Prevalence

- Males > females
- Upper C5-6 Erb-Duchenne palsy is most common.
- Lower C8-T1 Klumpke palsy is less common.
- Global C5-T1, or total plexus injury, is rare.
- In a 30-yr case series of 1,000 BPIs (1):
  - Traumatic:
    - Stretch/Contusion injuries (49%)
    - Gunshot wound (12%)
    - Lacerations (7%)
  - Nontraumatic:
    - Thoracic outlet syndrome (16%)
    - Tumors (% of all BP tumors reported):
      - Neural sheath origin (16%)
      - Solitary neurofibromas (34%)
      - Neurofibromas associated with von Recklinghausen disease (20%)
      - Schwannomas (34%)
      - Malignant nerve sheath (20%)

### RISK FACTORS

- High-velocity traction injury
- Sharp laceration in the neck or axilla
- Birth risk factors: Shoulder dystocia, gestational diabetes or macrosomia, breech presentation, vacuum or forceps use during prolonged labor, or traumatic delivery (2)

### GENERAL PREVENTION

- Safe helmet and cervical padding/support use for motorcycle riders and high-contact sport athletes (3)
- Careful instruction, training, and regulations designed to eliminate headfirst contact.
- Prenatal screening

### PATHOPHYSIOLOGY

Sedon and Sunderland classification (4):

- Neurapraxia: Motor paralysis, intact axons
- Axonotmesis: Loss of axonal continuity, intact nerve sheath
- Neurotmesis: Complete transection

### ETIOLOGY

- Traction or avulsion:
  - Motorcycle accident, fall from height, or sports injury in which the angle between the shoulder and the neck, or the angle between the axilla and the body, is increased acutely causing stretch, rupture, or avulsion injury to the brachial plexus
  - If the arm is down, the shoulder is forced inferiorly and/or posteriorly while the neck moves in the opposite direction:
    - Damage is first to the upper roots and superior trunk, affecting shoulder and elbow function.
  - If the arm is overhead, damage is first to the lower roots and inferior trunk, affecting wrist and hand function and often involving the sympathetic chain with resulting facial paralysis.
  - If the impact is extreme, all levels will sustain damage and the arm will be flaccid.
- Compression by tumor or local or metastasized masses involving neurovascular structures, lung, muscle, or bone
- Parsonage Turner syndrome (5):
  - Brachial plexus neuritis of unknown etiology, possibly postviral, with variable onset of shoulder pain
  - Paralysis of the shoulder and arm, wrist, or hand may be delayed.
  - The syndrome can vary greatly in presentation and nerve involvement.

### COMMONLY ASSOCIATED CONDITIONS

- Associated with head injury, thoracic trauma, and fractures/dislocation of the cervical spine or upper extremity
- 20% associated with vascular trauma

## DIAGNOSIS

### HISTORY

- Birth history:
  - Shoulder dystocia
  - Gestational diabetes or macrosomia
  - Breech presentation
  - Vacuum or forceps use during delivery
  - Prolonged labor or traumatic delivery
- Timing and onset of symptoms:
  - Since birth
  - Acutely with injury
- Mechanism of injury:
  - Type of trauma: Blunt vs. penetrating
  - Position of arm during injury
  - Use of protective gear
- Recent viral illness
- Recent trauma

### PHYSICAL EXAM

- Skin: Stab wound or viral rash
- Musculoskeletal exam:
  - Fractures: Presence of swelling, tenderness, or decreased range of motion of the arm
  - Thoracic outlet syndrome signs or symptoms of the involved upper extremity:
    - Loss of radial pulse with arm over head
    - Pain
    - Paresthesias
    - Weakness
    - Cold intolerance
    - Raynaud phenomena
  - Glenohumeral stability:
    - Full range of motion
    - Sulcus sign or apprehension test demonstrating dislocation
    - Dislocation is most commonly inferior or posterior and may cause direct injury to the axillary nerve.
- Neurologic exam:
  - Motor: Examine the patient’s upper back, shoulder, arm and hands.
    - Look for muscle wasting or fasciculations and scapular winging (weakness of the rhomboids or serratus muscles).
    - Pronator drift test: Associated with upper extremity weakness.
    - C5 and C6: Biceps muscle for elbow flexion; rotator cuff muscles for external/internal shoulder rotation
    - C6 and C7: Triceps muscle for elbow extension
    - C6 and C7: Wrist extension
    - C8: Finger flexion
    - T1: Finger abduction or “fanning”
    - C8 and T1: Thumb opposition
  - Sensation:
    - Sharp-dull discrimination
    - Light touch in C5-T1 distributions
  - Horner sign: Ipsilateral facial palsy indicates lower plexus involvement.
  - Pain in an anesthetic extremity suggests deafferentation and correlates with root avulsion and poor prognosis.
  - Resting shift of the head away from the injured side is evidence of denervation of paraspinal muscles.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Imaging

- X-rays of the cervical spine, chest, shoulder girdle, and humerus should be obtained to assess for associated injuries.
- CXRs could include inspiration and expiration PA views to determine activity of the diaphragm:
  - An elevated hemidiaphragm suggests denervation of the phrenic nerve.
- Follow-up imaging after stabilization:
  - CT myelogram
  - MRI (6)

**Diagnostic Procedures/Other**

Electromyogram or nerve conduction studies are not routinely utilized in the acute setting and may be performed at follow-up visits.

**Pathological Findings**

- Avulsion of the nerve roots from the spinal cord or neuromas in continuity
- Prominent 1st rib
- Pleural, nerve, muscle, or bone tumor or other mass causing compression of the plexus

**DIFFERENTIAL DIAGNOSIS**

- Infection
- Mass
- Transient quadriparesis

**TREATMENT****PRE HOSPITAL**

- Cervical spine stabilization and immobilization
- Angel wings for removal of face mask

**INITIAL STABILIZATION/THERAPY**

- Assess and stabilize airway, breathing, and circulation.
- Supportive therapy, analgesia, and management of associated traumatic injuries

**MEDICATION**

No clear indications for IV or oral steroids, antivirals, or treatment with hypothermia. Reports of efficacy are anecdotal.

**SURGERY/OTHER PROCEDURES**

- Early repair of sharp lacerations is indicated.
- Traction injuries are monitored for recovery with fracture stabilization as indicated.
- Mass resection or debulking as indicated

**DISPOSITION****Admission Criteria**

- Monitoring for secondary survey due to mechanism of injury
- Any evidence of respiratory distress due to phrenic nerve injury
- Surgical indications

**Discharge Criteria**

Stabilized by trauma criteria

**Issues for Referral**

- Trauma surgery for mechanism and associated injuries
- Primary care provider for monitoring of transient “stingers” or postviral neuritis
- Neurology, neurosurgery, oncology, orthopaedic surgery for relevant issues
- Refer to a pediatric BPBP specialist for the possible need for surgical brachial plexus reconstruction.

**COMPLEMENTARY & ALTERNATIVE THERAPIES**

Physical therapy:

- Restoring neck, shoulder, elbow, wrist, and digital strength
- Restoring range of motion

**FOLLOW-UP****FOLLOW-UP RECOMMENDATIONS**

Discharge instructions and medications:

- Use of arm sling for comfort
- Close monitoring until return of protective sensation

**Patient Monitoring**

- After blunt or traction injury, follow neurologic exam:
  - Obtain MRI or CT myelogram with electromyogram/nerve conduction velocity test if no return of nerve function
- Immediate outpatient referral to a surgeon for indications for acute and late reconstructive procedures

**PROGNOSIS**

- 92% newborns with BPBP have mild injury and spontaneous recovery within the 1st 2 mo of life.
- 75% of persons with Parsonage Turner syndrome experience complete recovery within 2 yr.

**COMPLICATIONS**

- Long-term disability from incomplete or partial recovery and decreased upper extremity function
- Glenohumeral joint chronic instability

**REFERENCES**

**ADDITIONAL READING**

Newton EJ, Love J. Emergency department management of selected orthopedic injuries. *Emerg Med Clin North Am*. 2007;25(3):763–793, ix–x.

**CODES****ICD9**

- 353.0 Brachial plexus lesions
- 767.6 Injury to brachial plexus due to birth trauma
- 953.4 Injury to brachial plexus

**PEARLS AND PITFALLS**

- Most BPIs are transient, unilateral, and require supportive care and outpatient follow-up only:
  - Nearly 50% of football players will experience a “burner” or “stinger” within their career.
- Consider Parsonage Turner syndrome or compression from local or metastasized mass and full evaluation if there is no relevant mechanism of injury.
- A careful history for mechanism of injury guides treatment, as evaluation based on sensory and motor exam can be difficult in the pediatric patient.

# BRADYCARDIA

Adam Vella

Karen Goodman

## BASICS

### DESCRIPTION

- Bradycardia is a heart rate below the normal range for age.
- Sinus bradycardia, in which a P wave precedes each QRS complex, may be seen in normal asymptomatic children with a benign course and without any underlying pathology, or it may be due to an abnormality of the sinus node.
- Bradycardia may be symptomatic or asymptomatic.
- In athletic adolescents, normal heart rates may be <60 bpm.
- Common causes of bradycardia in children are from corrective surgery of congenital heart disease, vagal stimulation, drugs, and hypoxemia.

### EPIDEMIOLOGY

#### Incidence

- The incidence and prevalence of asymptomatic bradycardia is unknown, as most young patients are asymptomatic.
- Congenital complete atrioventricular (AV) heart block is found in 1/22,000 live births.

### RISK FACTORS

- Congenital heart disease (CHD)
- Cardiac surgery
- Thyroid disease
- Cardiac disease
- Inflammatory processes

### PATHOPHYSIOLOGY

- Bradycardia may originate from the sinus node, AV node, or bundle of His.
- Bradycardia is caused by intrinsic dysfunction or injury to the heart's conduction system or by extrinsic factors acting on a normal heart and its conduction system.
- Conduction abnormalities may also cause bradycardia:
  - 1st-degree AV block: Abnormal delay of conduction through the AV node is associated with prolonged PR intervals and no dropped beats.
  - 2nd-degree AV block:
    - In Mobitz type I, PR intervals progressively prolong until a QRS complex is dropped. This is caused by an increased refractory period at the AV node.
    - Mobitz type II is an "all or none" phenomenon. There is either a normal PR interval with normal conduction or a complete conduction block. The failure of conduction is at the level of the bundle of His with a prolonged refractory period at the level of the His-Purkinje system.

– 3rd-degree AV block occurs when there is no conduction from the atrial pacemaker to the ventricles. P waves are completely dissociated from the QRS waves.

- Sick sinus syndrome manifests with sinus node function depression that does not increase the heart rate in response to stress.

### ETIOLOGY

- Intrinsic causes:
  - Infarction or ischemia
  - Infiltrative diseases: Sarcoidosis, amyloidosis, hemochromatosis
  - Collagen vascular diseases: Systemic lupus erythematosus, rheumatoid arthritis, scleroderma
  - Myotonic muscular dystrophy
  - Surgical trauma: Valve replacement, correction of CHD, heart transplantation. Postsurgical heart block may resolve by day 8 postoperatively or may recur years after the surgery.
  - Familial diseases: Carnitine deficiency, genetic mutations, and familial patterns of inheritance causing rhythm disturbances
  - Infectious diseases: Chagas disease, endocarditis
- Extrinsic causes:
  - Autonomically mediated syndromes: Vasovagal syncope, carotid-sinus hypersensitivity, situational changes (coughing, micturition, defecation, vomiting)
  - Drugs: Beta-adrenergic blockers; calcium channel blockers; clonidine; digoxin; antiarrhythmic drugs; cholinergic or muscarinic agents such as carbamates, some mushrooms, organophosphates, physostigmine, pilocarpine, and pyridostigmine
  - Hypothyroidism
  - Neurologic disorders: Traumatic conditions such as spinal cord injuries or head trauma as well as nontraumatic causes such as epilepsy and Guillain-Barré syndrome
  - Metabolic disturbances: Hypokalemia, hyperkalemia, hypoglycemia, hypoxia

### COMMONLY ASSOCIATED CONDITIONS

- Complete heart block may be an isolated finding.
- It may be congenital and is associated with specific types of CHD defects and maternal collagen disease.
- Acquired heart block may be idiopathic or associated with CHD, infectious diseases, endocarditis, cardiomyopathy, inflammatory processes, muscle diseases, trauma, cardiac tumors, cardiac sclerosis, hypocalcemia, and drug overdoses.
- Acquired heart block may be found after cardiac surgery as a transient or a permanent condition.

## DIAGNOSIS

### HISTORY

- History of medications
- Family history of syncope or sudden death
- History of cardiac disease
- Past episodes of syncope, dizziness, or unexplained seizures
- Time of episodes
- Association with precipitating factors
- Symptoms such as fatigue, exercise intolerance, dizziness, shortness of breath, and syncope
- Infants and young children may have nonspecific symptoms such as poor feeding and lethargy.

### PHYSICAL EXAM

- Many patients with sinus bradycardia will remain asymptomatic with a normal physical exam.
- Infants in complete heart block may show signs of CHF.
- Severe bradycardia may present with poor systemic perfusion and shock.
- Tachypnea
- Heart murmur
- Jugular venous distension
- Hepatomegaly
- Edema
- Rales

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

- Many cases of bradycardia in children are asymptomatic and do not require lab work.
- Specific cases may suggest electrolyte or hormone abnormalities that should be evaluated:
  - Electrolytes including calcium
  - Thyroid function tests including thyroid-stimulating hormone, serum thyroxine (total T4), free thyroxine (free T4), serum triiodothyronine (T3)
  - In cases of suspected cardiac ischemia, cardiac enzymes (creatinine phosphokinase, creatine kinase/myoglobin) and troponin levels may be tested.

#### Imaging

- Echo (cardiac US) may be used to evaluate the contractility of the heart and any structural abnormalities that may be causing or resulting from the bradycardia.
- CXR is an adjunct to visualize heart size and possible effects from bradycardia.

**Diagnostic Procedures/Other**

- The single most important test is a 12-lead ECG, which may reveal conduction abnormalities such as sinus bradycardia and 1st-, 2nd-, and 3rd-degree AV block (complete heart block).
- Other testing may be helpful, as indicated:
  - 24-hr ambulatory (Holter) monitoring may have greater yield if the initial ECG is normal and the index of suspicion is high for arrhythmias.
  - Exercise testing and ambulatory monitoring may diagnose chronotropic abnormalities.
  - Tilt table testing, or evaluation of orthostatic BP, may help define indeterminate cases of vasovagal bradycardia.
  - Invasive electrophysiologic testing may be helpful in the unusual circumstances in which the mechanism of the bradycardia remains uncertain, attempts to monitor the heart rate have been unsuccessful, or symptoms suggest a potentially life-threatening arrhythmia.

**DIFFERENTIAL DIAGNOSIS**

See Etiology for further details.

**TREATMENT****PRE HOSPITAL**

- Assess and address the ABCs, and follow the Pediatric Advanced Life Support (PALS) or Advanced Cardiac Life Support (ACLS) protocol.
- Administer oxygen via face mask if symptomatic from bradycardia.

**INITIAL STABILIZATION/THERAPY**

- Stabilize the airway and provide oxygen.
- Chest compressions are indicated for patients with bradycardia and hemodynamic compromise.
- Among symptomatic patients with bradycardia, the cause of the bradycardia must be ascertained in order to potentially reverse these factors, especially with regard to extrinsic factors.
- Volume expansion with IV fluids

**MEDICATION****First Line**

- Epinephrine 0.01 mg/kg (1:10,000) IV/IO with a max single dose of 1 mg:
  - May repeat the dose q3–5min to a max dose of 10 mg
- Atropine 0.02 mg/kg IV/IO (min dose of 0.1 mg):
  - May repeat dose once during the resuscitation

**Second Line**

- Epinephrine infusions may be started at 0.1–1  $\mu$ g/kg/min, particularly if a response to single doses of epinephrine is noted but the patient has failed to achieve hemodynamic stability.
- Isoproterenol infusion may be started at 0.05–2  $\mu$ g/kg/min as a second-line agent when epinephrine has failed.
- Specific antidotal therapy may be indicated for cardiovascular medication toxicity. (Refer to Beta-Blocker Poisoning, Calcium Channel Blocker Poisoning, and Digoxin Poisoning topics.)

**SURGERY/OTHER PROCEDURES**

- Follow current PALS protocol with regard to chest compression and endotracheal intubation.
- Consider cardiac pacing, especially if a conduction defect is suggested.

**DISPOSITION****Admission Criteria**

- Stable, symptomatic patients may be admitted to inpatient units that are capable of cardiac monitoring or Holter devices.
- Critical care admission criteria:
  - A patient who remains unstable requires admission to the ICU for further monitoring and intervention.
  - A patient who has converted from an unstable rhythm should be admitted to the ICU for monitoring.

**Discharge Criteria**

- Asymptomatic and chronic bradycardia may be managed on an outpatient basis in stable patients.
- If a reversible cause of the patient's bradycardia is recognized and treatment or management is under way, the patient may be discharged to follow up with the primary care provider (PCP) or cardiologist.

**Issues for Referral**

- Unstable patients who require transcutaneous or transvenous pacing or other more advanced modes of treating symptomatic bradycardia should have cardiology involved as soon as possible.
- Patients with a history of cardiac disease and cardiac surgery may benefit from involvement of cardiology to further clarify potential causes of their arrhythmia and ways to manage them.
- Asymptomatic or stable patients with cardiac etiologies for their symptoms should have scheduled follow-up with cardiology.

**FOLLOW-UP****FOLLOW-UP RECOMMENDATIONS**

- Discharge instructions and medications:
  - Patients should follow up with their PCP or cardiologist as recommended.
  - Depending on the need for a further workup, patients may be instructed to schedule appointments for Holter monitoring, repeat ECGs, or blood work.
- Activity:
  - Activity that may have precipitated an event of bradycardia should be avoided until a thorough evaluation and clearance have been made.

**Patient Monitoring**

Depending on the need for a further workup, patients may be instructed to obtain Holter monitoring or repeat ECGs.

**PROGNOSIS**

Depending on the etiology and severity of the bradycardia, the prognosis may range from an asymptomatic and resolvable arrhythmia to a severely symptomatic bradycardia that can result in cardiac arrest and sudden death.

**COMPLICATIONS**

Symptomatic bradycardia may lead to cardiovascular collapse and death.

**ICD-9 CODES**

- 426.10 Atrioventricular block, unspecified
- 427.89 Other specified cardiac dysrhythmias
- 746.86 Congenital heart block

**PEARLS AND PITFALLS**

- Hypoxia is a common cause of bradycardia. If present, hypoxia should be corrected before progressing to use of medications.
- Bradycardia is an arrhythmia in which symptoms may range from asymptomatic to life threatening.
- The etiology of the abnormal rhythm may aid in the management and treatment of the bradycardia.
- Treatment protocols are aimed at stabilizing the patient, searching for the etiology, and treating the underlying pathology.

# BRANCHIAL CLEFT CYST

Michelle J. Alletag

Marc A. Auerbach

## BASICS

### DESCRIPTION

- A branchial cleft cyst is a lateral neck mass or sinus tract that arises when a branchial arch fails to close (most commonly the 2nd arch) following the 4th or 5th wk of gestation (1–3).
- They may occur anywhere along the anterior border of the sternocleidomastoid muscle or the mandibular ramus.

### EPIDEMIOLOGY

- Most common congenital anomaly of the lateral neck
- Comprise about 30% of congenital neck masses
- Equal incidence among males and females

### GENERAL PREVENTION

Prevention of branchial cleft cyst complications is best accomplished by early diagnosis and excision.

### PATHOPHYSIOLOGY

- Branchial cleft anomalies are lined with various types of epithelium and will rarely develop into squamous cell carcinoma in adults (1–3).
- Cysts have no external opening.
- Sinuses may open to the exterior neck.
- Fistulas open into the pharynx (or both the neck and pharynx).
- Approximately 2/3 of cysts have associated sinuses or fistulas.
- Up to 10% of patients have bilateral branchial anomalies, which is more commonly associated with craniofacial syndromes.

### ETIOLOGY

Result from failure of obliteration of branchial clefts (primitive gills) during embryologic development

### COMMONLY ASSOCIATED CONDITIONS

Branchio-oto-renal syndrome is an autosomal dominant disorder consisting of branchial arch anomalies (usually bilateral), profound deafness, and varying degrees of renal anomalies.

## DIAGNOSIS

### HISTORY

- May present as an asymptomatic neck mass or as an acute infection, with a painful, red, acutely enlarging mass.
- Up to 40% initially present during upper respiratory tract infections (because of lymphatic tissue that is present within the cyst):
  - Occasionally noted at birth when a pit or sinus is seen on the neck

### PHYSICAL EXAM

- Mobile, nontender, fluctuant mass located along the anterior border of the sternocleidomastoid muscle
- When infected:
  - Erythema overlying the cyst
  - Tenderness to palpation
  - May be draining if a sinus is present

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

Inflammatory markers are nonspecific for infected branchial cleft cysts:

- Elevation of WBC count or C-reactive protein are typical with infected cysts.

#### Imaging

- CT neck, with contrast, is the diagnostic study of choice.
- Sonography or MRI may also be used.

#### Diagnostic Procedures/Other

Fine-needle aspiration should NOT be performed, as it may make resection more difficult and may lead to infectious complications.

#### Pathological Findings

Excised lesions consist of epithelium and may also include lymphoid, salivary, or sebaceous tissue.

## DIFFERENTIAL DIAGNOSIS

- Abscess
- Lymphadenopathy
- Lymphadenitis
- Parotitis
- Vascular malformation
- Scrofula
- Ectopic thyroid
- Neoplasm (eg, rhabdomyosarcoma)
- Neurofibroma
- Lipoma
- Torticollis with sternocleidomastoid muscle knot may be incorrectly presumed to be a “tumor”.
- Thyroglossal duct cysts (midline)
- Cystic hygromas

## TREATMENT

Ideally, cysts or sinuses are noted prior to infection and referred to an otolaryngologist or pediatric surgeon for surgical excision.

### INITIAL STABILIZATION/THERAPY

If infected, the cysts must be treated with antibiotics prior to surgical intervention, as operating on infected lesions results in a significantly higher risk of recurrence and complications.

### MEDICATION

#### First Line

- Antibiotics:
  - Antimicrobial agents that treat both typical oral flora and gram-negative bacteria:
    - Ampicillin/Sulbactam 50 mg/kg/dose IV q6h
    - Amoxicillin/Clavulanate 45 mg/kg/day PO b.i.d.
- Analgesics:
  - Ibuprofen 10 mg/kg/dose PO/IV q6h PRN
  - Acetaminophen 15 mg/kg/dose PO/PR q4h PRN
  - Codeine/Acetaminophen dosed as 0.5–1 mg/kg of codeine component PO q4h PRN
  - Hydrocodone or hydrocodone/acetaminophen dosed as 0.1 mg/kg of hydrocodone component PO q4–6h PRN

**Second Line**

Clindamycin (may be used for patients with penicillin allergies) 10 mg/kg/dose IV q6h or 10 mg/kg/dose PO t.i.d.

**SURGERY/OTHER PROCEDURES**

Elective surgical excision/resection is considered the definitive therapy:

- Surgical excision should take place during infancy or early childhood.
- Surgical excision should be delayed 4–6 wk if the cyst is considered infected.

**DISPOSITION****Admission Criteria**

- Infected cysts are notoriously difficult to treat and generally require admission for IV antibiotics.
- Critical care admission criteria:
  - Swelling, resulting in airway compromise, may necessitate ICU admission.

**Discharge Criteria**

- Children with infected cysts may be discharged if:
  - Infection controlled or patient minimally symptomatic
  - Patient able to tolerate oral antibiotics
  - Follow-up ensured
- Uncomplicated cysts may be removed as an outpatient procedure.

**Issues for Referral**

All branchial cleft cysts require otolaryngology or pediatric surgery referral for definitive management.

**FOLLOW-UP****FOLLOW-UP RECOMMENDATIONS**

Discharge instructions and medications:

- Antibiotics with follow-up for drainage
- Analgesics as noted in the Medication section
- Return for swelling, drainage, or worsening pain at the surgical site or for fever  $> 101^{\circ}\text{F}$ .

**Patient Monitoring**

Any patient with branchial cleft anomalies (both repaired and unrepaired) should be monitored for signs of infection or recurrence, including swelling, drainage, pain, or erythema at the site of the lesion.

**DIET**

A soft diet is recommended if fistulous tract was closed; otherwise, normal diet.

**PROGNOSIS**

The majority of patients recover fully, with excellent functional and cosmetic outcome postoperatively.

**COMPLICATIONS**

- Branchial cleft anomalies are notoriously difficult to resect fully and may require multiple surgeries, with an average of 1–2 recurrences after initial resection.
- Damage to nearby cranial nerves (most often the facial nerve) is also a risk during surgical resection.

**REFERENCES**

2. Rosa PA, Hirsch DL, Dierks EJ. Congenital neck masses. *Oral Maxillofacial Surg Clin North Am.* 2008;20:339–352.
3. Mandell DL. Head and neck anomalies related to the branchial apparatus. *Otolaryngol Clin North Am.* 2000;33:1309–1332.

**CODES****ICD9**

- 744.41 Branchial cleft sinus or fistula
- 744.42 Branchial cleft cyst

**PEARLS AND PITFALLS**

- Early diagnosis and excision before infection develops can prevent significant morbidity.
- Attempts at probing or incision and drainage of an infected cyst can lead to fistula formation and serious cosmetic morbidity.
- Airway compromise is possible from expanding cysts. Careful initial and ongoing evaluation of airway patency is critical.

# BREAST LESIONS

Alyssa Abo

Atima Chumpa Delaney

## BASICS

### DESCRIPTION

- Pediatric breast lesions are usually benign and self-limited. The most common causes are variations of thelarche, gynecomastia, neonatal hypertrophy, and infection. Malignant lesions are rare.
- Lesions are differentiated by several factors, including age, gender, location of the lesion, puberty, nipple discharge, relation to menses, presence and absence of fever, and pain.

### EPIDEMIOLOGY

#### Incidence

Mastitis:

- Peaks: Neonates and postpubertal females
- Frequency of female to male:
  - Neonatal (1st 2 wk) 1:1
  - All other ages 2:1

#### Prevalence

- Neonatal hypertrophy in ~60%
- Premature thelarche in 2% (1)

### RISK FACTORS

For breast infection:

- Trauma, foreign body, obesity, poor hygiene
- Breast manipulation (neonates)

### PATHOPHYSIOLOGY

- Breasts are composed of ducts and glands surrounded by connective and adipose tissue.
- Neonatal breasts are influenced by maternal hormones, which may cause hypertrophy or discharge.
- During childhood and puberty, breast development occurs in response to hormones.
- Thelarche occurs between 6 and 14 yr of age.
- Masses may involve the skin, ducts, or glands.

### ETIOLOGY

- Infection (mastitis and abscess):
  - Females and males, all ages
  - Unilateral
  - Warm, swollen, tender, indurated
  - Abscesses are fluctuant, +/- purulent drainage.
  - Systemic symptoms are rare.
  - *Staphylococcus aureus* (most common), MRSA, *Streptococcus* species. In neonates, also consider *Escherichia coli*.
- Neonatal breast hypertrophy:
  - Benign, occurring in females and males
  - 1st weeks of life, from maternal hormones
  - Self-resolving, females have longer duration
  - May be associated with white nipple discharge
- Thelarche and precocious puberty:
  - Premature thelarche:
    - Benign
    - Prepubertal females, <6–8 yr of age (1)
    - No other signs of puberty
  - Unilateral thelarche:
    - Asymmetric pubertal breast development, generally a normal variant
    - Firm area of tissue below areola
    - May be onset of puberty
  - Precocious puberty:
    - Females <6–8 yr of age
    - Other signs of puberty are present.

- Gynecomastia:
  - Males, mostly adolescents, usually benign
  - Unilateral or bilateral
  - Discrete lesions to enlarged breasts
  - Can be painful
  - Causes: Physiologic; tumors; metabolic disturbance; medications such as phenytoin, metronidazole, spironolactone, cimetidine
  - Needs evaluation if prepubertal patient
- Fibroadenoma:
  - Benign; most common lesion in adolescents (1)
  - Adolescent females, generally asymptomatic
  - May be larger or tender before menses
  - Smooth, round, mobile, usually 2–3 cm
  - Any quadrant, usually upper outer
  - If there is rapid growth to >5 cm, consider juvenile fibroadenoma.
- Fibrocystic disease:
  - Benign, common
  - Hormonal, cystic breast changes
  - Upper outer quadrants
  - Nipple discharge (nonbloody) brown or green
  - Tender before menses, improves with menses
- Phyllodes tumor (Cystosarcoma phyllodes):
  - Usually benign but may be malignant
  - Painless large mass
  - Shiny, thin skin, +/- bloody nipple discharge
- Fat necrosis:
  - Trauma to breast (eg, sports, seat belt)
  - Well circumscribed, firm, may be tender
  - May mimic carcinoma
  - May become scar tissue
- Malignant lesion:
  - Very rare
  - Primary, secondary, or metastasis
  - Hodgkin, rhabdomyosarcoma
  - Solitary, hard, irregular borders
  - Nontender, nonmobile
  - Skin changes: Dimpling, edema (peau d'orange), warm, nipple changes
  - Lymphadenopathy
  - Hepatosplenomegaly (metastasis)

### COMMONLY ASSOCIATED CONDITIONS

Conditions associated with mastitis: Obesity, steroid therapy, trauma, diabetes mellitus, rheumatoid arthritis

## DIAGNOSIS

### HISTORY

- General history:
  - Onset of symptoms: Acute, chronic, recurring:
    - Acute: Mastitis, abscess, trauma
    - Chronic: Fibrocystic change, fibroadenoma, thelarche
  - Location of lesion
  - 1 or multiple lesions
  - Associated nipple discharge:
    - White: Neonatal hypertrophy, galactorrhoea
    - Bloody: Phyllodes tumor, nipple irritation/trauma, breast cancer (rare)
    - Serous/Serosanguineous: Fibrocystic disease, breast cancer (rare)
    - Purulent: Infection

- Associated pain: Mastitis, abscess, trauma
- History of trauma: Sports, piercings
- Fever: Mastitis, abscess
- Menstrual history (if applicable):
  - Last menstrual period
  - Relation of breast lesion to menses:
    - Fibrocystic change: Pain before menses and improves with menses
- Pregnancy history (if applicable)

### PHYSICAL EXAM

- General:
  - Full exam, including lymph node exam
- Breast:
  - Technique: Lay the patient supine with the ipsilateral arm over the head. Use tips of fingers to palpate the lesion.
  - Inspection
    - Tanner stage
    - Skin
  - Erythema: Mastitis, abscess, trauma:
    - Assess symmetry:
      - Asymmetry: Unilateral thelarche, gynecomastia, neonatal hypertrophy
    - Breast lesion size:
      - >5 cm: Consider phyllodes tumor and juvenile fibroadenoma.
    - Breast lesion location:
      - Upper outer quadrants: Consider fibroadenoma or fibrocystic change.
    - Palpation:
      - Tenderness: Trauma, infection, fibrocystic change
      - Warm: Mastitis, abscess
      - Characterize lesion: Nodular (fibrocystic change), solid (fat necrosis, fibroadenoma, breast cancer), fluctuant (abscess)
      - Mobility: Mobile (fibroadenoma), nonmobile (breast cancer, fat necrosis)
      - Nipple discharge (as above)

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

- Routine lab tests are not generally necessary, especially for afebrile breast lesions.
- Consider a fever evaluation for neonatal mastitis or abscess.
- Consider CBC, C-reactive protein, and blood culture for patients with mastitis or abscess.
- Gram stain and culture of purulent nipple discharge or fluid from abscess

#### Imaging

- US is the imaging modality of choice when considering conditions that need to be diagnosed urgently (2), such as breast abscesses:
  - Preferred for immature breast
  - Differentiates solid mass, cyst, and infection
  - Cysts: Avascular, anechoic (black)
  - Abscess: Heterogeneous echoes, peripheral flow increased
- Mammography:
  - Less frequently indicated in pediatrics because immature breast has more glandular than adipose tissue.

**Diagnostic Procedures/Other**

Aspiration or incision/drainage of abscess

**DIFFERENTIAL DIAGNOSIS**

- Neonatal mastitis vs. hypertrophy:
  - Hypertrophy:
    - Not erythematous
    - Resolves spontaneously
    - White nipple discharge
- Differential diagnosis of mastitis:
  - Mammary duct ectasia, trauma, malignancy
- Tumor
- Fibroadenoma can be differentiated from phyllodes tumor by histology; may be difficult with US.
- Fibrocystic disease
- Thelarche
- Gynecomastia
- Fat necrosis can be differentiated from malignancy by biopsy, possibly with US.

**TREATMENT****INITIAL STABILIZATION/THERAPY**

- Neonatal mastitis or abscess:
  - Admit patient for parenteral antibiotics.
  - Consider surgical consultation for abscess aspiration or incision/drainage.
- Mastitis or abscess in children and adolescents:
  - Warm compresses
  - Oral antibiotics for mastitis
  - Incision/drainage for abscess (3,4)
- Premature thelarche:
  - If other signs of puberty are present, evaluate for precocious puberty (in emergency department or outpatient).
- Unilateral thelarche:
  - Reassure that asymmetry should lessen over time.
- Gynecomastia:
  - Reassurance
  - Medication is not indicated (1).
- Fibroadenoma:
  - Reassurance
  - If lesion is >5 cm, refer for biopsy.
- Fibrocystic change:
  - Analgesia: NSAIDs
  - Consider oral contraceptives.
  - Eliminate caffeine.
  - Persistent lesions: Refer for fine-needle aspiration and US.

**MEDICATION**

- Neonatal mastitis and abscess:
  - Broad-spectrum antibiotics for 7–14 days; consider MRSA coverage.
  - Use penicillinase-resistant antibiotic in combination with aminoglycoside or a 3rd-generation cephalosporin:
    - Nafcillin or oxacillin:
      - <7 postnatal days or weight <1,200 g: 50 mg/kg/day IV divided q12h
      - >7 postnatal days and weight >2,000 g: 100 mg/kg/day divided q6h AND
    - Gentamicin:
      - <7 postnatal days: 5 mg/kg/day IV divided q12h
      - >7 postnatal days and weight >2,000 g: 7.5 mg/kg/day IV divided q8h
    - Cefotaxime:

- <7 postnatal days or weight <1,200 g: 100 mg/kg/day IV divided q12h
- >7 postnatal days and >1,200 g: 150 mg/kg/day divided q8h
- Mastitis and abscess in children, adolescents:
  - Antibiotic coverage for gram-positive organisms for 7–14 days; consider MRSA
  - Oral therapy (if no systemic symptoms):
    - Cephalexin 25–50 mg/kg/day PO divided q6–8h
    - MRSA coverage (follow local recommendations):
      - Clindamycin 150–450 mg/dose IV/IM q6–8h (max 1.8 g/day) OR
      - Trimethoprim (TMP)/Sulfamethoxazole, dose 6–12 mg TMP/kg/day PO divided q12h:
  - Parenteral therapy:
    - Cefazolin 25–100 mg/kg/day IV divided q6–8h (max 6 g/day)
    - MRSA coverage
      - Clindamycin 1.2–2.7 g/day IV/IM in 2–4 divided doses (max 4.8 g/day) OR
      - Vancomycin 40–60 mg/kg/day IV divided q6–8h

**DISPOSITION****Admission Criteria**

- Neonatal mastitis or abscess
- Infections that fail outpatient management
- Worsening mastitis, systemic symptoms
- Abscess that requires operation by surgeons

**Discharge Criteria**

- No evidence of systemic symptoms
- Tolerating oral therapy

**Issues for Referral**

- Surgical:
  - Lesions that require biopsy (core needle, excisional) or fine-needle aspiration
  - Suspicious solid lesions:
    - Nonmobile, hard, enlarging
    - Skin changes, adenopathy
  - Recurring cystic lesions after aspiration
  - Rapidly growing lesions
  - Gynecomastia requiring cosmetic surgery
- Endocrinology for precocious puberty, prepubertal gynecomastia
- Oncology for malignant lesions

**COMPLEMENTARY & ALTERNATIVE THERAPIES**

Fibrocystic change:

- Primrose oil (1 tablespoon at bedtime)

**FOLLOW-UP****FOLLOW-UP RECOMMENDATIONS**

Discharge instructions and medications:

- Mastitis and abscess requires close follow-up with the patient's primary care provider.
- Benign lesions can be monitored every few months.

**ADDITIONAL READING**

Baren JM. Breast lesion. In Fleisher GR, Ludwig S, eds. *Textbook of Pediatric Emergency Medicine.* 6th ed. Philadelphia, PA: Lippincott Williams & Wilkins; 2010.

**ICD9**

- 611.0 Inflammatory disease of breast
- 611.89 Other specified disorders of breast
- 778.7 Breast engorgement in newborn

**PEARLS AND PITFALLS**

- Pearls:
  - Breast lesions in children are usually benign.
  - Differentiate thelarche from abnormal lesions
  - Prepubertal breast development with other pubertal signs requires further evaluation.
  - Prepubertal gynecomastia requires evaluation.
- Pitfalls:
  - Failure to recognize and adequately treat MRSA in patients with mastitis and breast abscess where MRSA is prevalent
  - Failure to treat neonatal mastitis with parenteral, broad-spectrum antibiotics
  - Improper incision and drainage of a breast abscess can damage the breast bud and may result in later cosmetic deformity.

# BRONCHIOLITIS

Suzanne Schuh

## BASICS

### DESCRIPTION

- Bronchiolitis is a lower respiratory tract infection with airway inflammation and bronchoconstriction.
- It is characterized by upper respiratory prodrome followed by wheezing/crepitations.
- Bronchiolitis may include tachypnea, hypoxemia, and respiratory distress.

### EPIDEMIOLOGY

#### Incidence

- The most common lower respiratory tract infection in the 1st yr of life with a rate of 10–20 episodes per 100 children
- Responsible for 16% of all hospital admissions in the 1st yr of life (1,2)

#### Prevalence

Accounts for up to 60% of all lower respiratory tract illness during the 1st yr of life and for up to 32% of hospitalizations for lower respiratory tract infection in this age group

### RISK FACTORS

- Risk factors for bronchiolitis:
  - Exposure to tobacco smoke, lack of breastfeeding
- Predictors of need for airway intervention/ICU care:
  - Age <7 wk
  - Weight <4 kg
  - Respiratory rate >80/min
  - Heart rate >180 bpm
  - Prematurity
  - Comorbidity: Cardiac/Pulmonary disease, immunodeficiency, neuromuscular disease

### GENERAL PREVENTION

- Palivizumab prophylaxis:
  - Indicated at  $\leq 32$  wk gestation if  $\leq 6$  mo old at start of respiratory syncytial virus (RSV) season and  $\leq 28$  wk gestation if  $\leq 12$  mo old at start RSV season (3)
- Hand washing to limit viral transmission

### PATHOPHYSIOLOGY

Viral-induced necrosis of small airway epithelium, acute neutrophilic inflammation and edema, profuse mucus and bronchospasm

### ETIOLOGY

- RSV in 85–90%
- Human meta pneumovirus, coinfections with RSV common (4)
- Parainfluenza
- Influenza
- Adenovirus

### COMMONLY ASSOCIATED CONDITIONS

Otitis media

## DIAGNOSIS

### HISTORY

- Upper respiratory prodrome of coryza, cough, and fever
- Fever usually  $<39^{\circ}\text{C}$
- Decreased fluid intake
- Increased work of breathing, usually 1st episode
- Sleep disruption

### PHYSICAL EXAM

- Vital signs, including respiratory rate, temperature, and pulse oximetry:
  - Mild hypoxemia common
  - No evidence that mild hypoxemia predicts progress of disease
- Respiratory distress with chest retractions, tracheal tug, nasal flare/grunting (severe disease)
- Tachypnea, tachycardia
- Lethargy (hypoxemia or severe disease)
- Frank dehydration uncommon
- Wheezing; may be absent in mild or severe disease
- Crepitations

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

- Most cases need no investigations (3).
- Most blood assays are not useful.
- Blood gas analysis may be useful in severe disease to detect respiratory failure.
- Virologic testing (ELISA, fluorescent antibody testing, PCR, culture) in critically ill, neonates, comorbidities, atypical presentation
- Not necessary for diagnosis but may be used for cohorting during hospital admission
- Consider urinalysis and urine culture in febrile children  $<3$  mo of age.
- Consider sepsis workup in febrile bronchiolitis in those  $<28$  days of age if respiratory status permits: Bacterial coinfections are rare (5).

#### Imaging

- Chest radiographs:
  - Not indicated in typical presentation (6)
  - May demonstrate airway disease, atelectasis, hyperinflation
  - The minority have airway and airspace disease
  - Pneumonia is viral.
- Consider chest radiograph when:
  - Need to exclude another diagnosis
  - Chronic course with lack of resolution over 3 wk
  - Critically ill with impending respiratory failure
  - Atypical presentation in toxic or deteriorating child

### DIFFERENTIAL DIAGNOSIS

- Asthma/Recurrent virus-induced wheezing
- Possible mechanisms with later viral-induced wheeze: Subnormal lung function prior to bronchiolitis, genetic factors, bronchiolitis-induced lung changes
- Pertussis: Usually no respiratory distress between coughs, no wheezing
- Bacterial pneumonia: Focal wheezing, often toxic appearance, isolated consolidation without airway disease on radiograph
- Foreign body: Typically sudden onset, afebrile
- CHF: Chronic feeding problems, failure to thrive
- Congenital abnormalities: Protracted clinical course, recurrent “pneumonias”

## TREATMENT

### PRE HOSPITAL

- Cardiorespiratory and oxygenation monitoring is essential.
- Young infants have limited respiratory reserve and may decompensate suddenly.

### INITIAL STABILIZATION/THERAPY

- Assess and stabilize airway, breathing, and circulation.
- Bag-mask ventilation with apnea
- Intubation if persistent apnea, impending respiratory failure
- Supplemental oxygen if oxygen saturation  $<90\%$  (3)
- IV hydration if dehydrated or severe respiratory distress

### MEDICATION

#### First Line

- Ibuprofen 10 mg/kg/dose PO/IV q6h PRN
- Acetaminophen 15 mg/kg/dose PO/PR q4h PRN
- Most patients require no pharmacotherapy beyond antipyretics.
- Bronchodilators (albuterol, epinephrine): Not routinely indicated; do not change hospitalization rates or clinical course (7):
  - Therapeutic trial of albuterol 2.5 mg via nebulizer or 500  $\mu\text{g}$  via metered-dose inhaler/spacer an option:
    - Continue only if major decrease in work of breathing
    - Response usually mild and transient
  - Should not be routinely used (3)

- Epinephrine:
  - Has a theoretical advantage over albuterol due to its alpha effects
  - Does not decrease hospitalization on its own (8)
  - Very temporary benefit
- Bronchodilators not effective after discharge

### Second Line

- Corticosteroids: Controversial; of questionable benefit (8–10):
  - Not recommended by most widely accepted practice guideline (3)
- Antibiotics:
  - Not indicated
  - Consider if associated bacterial disease (otitis media), toxic appearance, sepsis syndrome

### DISPOSITION

#### Admission Criteria

- Hospitalize if:
  - Hypoxemia <90% on room air
    - Home oxygen is an option in otherwise healthy infants with mild bronchiolitis and room air saturations in the upper 80s.
  - Dehydration with inability to maintain hydration
  - Major comorbidity
  - Need to rule out alternative diagnosis
  - Severe increase in the work of breathing
  - Strongly consider in infants with high-risk criteria: Weight <4 kg, age <7 wk, respiratory rate >80/min, heart rate >180 bpm
  - Significant social concerns
- Critical care admission criteria:
  - Recurrent apneas
  - Concern regarding impending respiratory failure, increasing oxygen requirements

#### Discharge Criteria

- Mild respiratory distress:
  - Consider for moderate respiratory distress if the patient is meeting other discharge criteria.
- Acceptable oxygen saturation in room air  $\geq 90\%$
- Well hydrated
- Follow-up available

### FOLLOW-UP

#### FOLLOW-UP RECOMMENDATIONS

Discharge instructions and medications:

- Close, frequent follow-up and reassurance are often helpful.
- Warn parents that symptoms may persist for 2–3 wk.
- Frequent small feeds usually are required.
- Nasal suctioning may be helpful.
- Instruct parents that pharmacotherapy after discharge generally is not beneficial.
- Bronchodilators after discharge do not change the subsequent clinical course.
- Daily oral corticosteroids such as prednisolone 1 mg/kg after a trial of dexamethasone 1.0 mg/kg and 2 treatments of epinephrine 1:1,000 3 mL by nebulization 30 min apart in the emergency department may be considered:
  - Not routinely recommended (3)

### PROGNOSIS

- Generally excellent
- 20% still symptomatic at 3 wk
- Severe bronchiolitis with need for airway support rare (~2%):
  - Patients at risk if very young or premature, if there is marked tachycardia/tachypnea (above), and if there are comorbidities.

### COMPLICATIONS

- Otitis media
- Dehydration (poor feeding common but frank dehydration rare)
- Pneumonia
- Apnea
- Respiratory failure

- Wheezing

### ICD9

- 466.11 Acute bronchiolitis due to respiratory syncytial virus (rsv)
- 466.19 Acute bronchiolitis due to other infectious organisms

### PEARLS AND PITFALLS

- Pay close attention to vital signs.
- Very young infants and patients with comorbidities or highly abnormal vital signs have the greatest risk of decompensation.
- The majority of infants with bronchiolitis require no investigations and no pharmacotherapy,

# BURN, CHEMICAL

Mark X. Cicero

## BASICS

### DESCRIPTION

- Chemical burns are caused by caustics, which include acids, bases, and other agents that cause tissue destruction on contacts.
- Cutaneous burns to the face and extremities are most common.
- More serious or life-threatening burns involve the face, airway, alimentary tract, and/or eyes.
- An estimated 25,000 chemicals are known to cause burns.

### EPIDEMIOLOGY

In the U.S., >121,000 burns of all kinds occur each year in those <20 yr of age:

- 9% of these burns result from chemical burns.
- Incidence has remained similar from 1990–2006.

### RISK FACTORS

- Male gender
- Age <6 yr
- Poor home supervision

### GENERAL PREVENTION

Anticipatory guidance to maintain household chemicals out of reach of children may be helpful to prevent many chemical burns.

### PATHOPHYSIOLOGY

- Acids cause coagulative necrosis, which is coagulation of tissue proteins. When this occurs, an eschar forms, limiting the depth of burning.
- The lower the pH or the higher the titratable reserve, the more hydrogen ions are donated.
- Acids with lower pH (0.0–2.0) cause worse burns more quickly:
  - Specific acids to consider include:
    - Hydrochloric acid, found in toilet bowl cleaners and metal cleaners
    - Phosphoric acid, found in metal cleaners and agricultural settings
    - Sulfuric acid, noteworthy for exothermic reactions when exposed to water
    - Hydrofluoric acid, a relatively high pH acid found in swimming pool “shock” and etching and industrial cleaning products. The fluorine ion increases tissue penetration, increasing damage to muscle and other underlying structures.
    - Phenols, such as carbolic acid, are weak organic acids used in plastic manufacturing and found in nail polish.
- Alkali (bases) cause liquefaction necrosis and cause deeper injuries.
- Proteins are denatured, and fats are saponified. Neither denatured proteins nor saponified fats stop alkali penetration of tissue.
- Bases with higher pH (12.0–14.0) cause more liquefaction necrosis more quickly than bases with pH closer to 7.0:
  - Bases of clinical interest in pediatrics include:
    - Sodium hydroxide and potassium hydroxide, which are found in drain cleaners and oven cleaners. These are among the most caustic products found in homes. These cause exothermic reactions and significant liquefaction necrosis.

- Lye is the common name for sodium hydroxide. Historically, this agent has been used to attempt suicide and is sometimes thrown in the face of an adversary as a form of assault.
- Sodium hypochlorite, the active ingredient of household bleach and swimming pool chlorinator, is itself a weaker base (pH 11) and not very corrosive. Concentrated pool chlorinator, especially in solid form, is more dangerous.
- Wet cement includes calcium hydroxide and is moderately caustic.
- Ammonia in household cleaners is not corrosive enough to cause burns to the skin. It can cause respiratory distress and pulmonary edema if aspirated.
- Other agents cause burns, not by donating (as with acids) or accepting (as with bases) a proton but by reactions with moisture on the skin or direct tissue toxicity. These include:
  - Vesicants, such as nitrogen mustard. These agents were used in World War I and may potentially be used in chemical terrorism.
  - Hair-coloring agents, which are occasionally ingested by toddlers, may cause airway edema or esophageal injuries. Additionally, the persulfates and peroxides in hair coloring may cause scalp and skin burns if not removed promptly.
  - Elemental metals, such as lithium and potassium
- Factors that influence burn severity include:
  - Duration of contact
  - Volume of chemical in contact with the body
  - Thickness of the epithelium at the burn site
  - pH and other chemical properties of the agent (eg, exothermic reactions)
  - Concentration (molarity) of the agent
- In contrast to thermal burns, the chemical agent is in contact with the skin longer.

### ETIOLOGY

- At home, children may expose themselves to improperly stored cleaning agents, fuels, and other preparations.
- Chemical exposures may occur from chemical production plants and from release of chemicals from vehicles transporting chemicals.
- Chemicals may be used as agents of terrorism.
- Nonaccidental trauma

### COMMONLY ASSOCIATED CONDITIONS

- Ophthalmic burns
- Ingestion of chemical
- Aspiration of chemical

## DIAGNOSIS

### HISTORY

- Ideally, the agent in its container or its material safety data sheet will travel to the emergency department with the patient. Several questions can help guide diagnosis and treatment, including:
  - Time of exposure
  - Duration of exposure
  - Type of agent and its pH and concentration
  - Volume of agent
  - Whether irrigation and decontamination have occurred
- Eye irritation and respiratory irritation are commonly associated with chemical burns.

### PHYSICAL EXAM

- Assess the patient’s airway 1st, looking for signs of inhalation or ingestion. If stridor, respiratory distress, or oral burns are present, endotracheal intubation may be necessary.
- Dribble marks on the face or chest may be seen with caustic ingestion.
- The eyes are assessed for signs of corneal injury and globe perforation:
  - Visual acuity should be assessed for suspected eye injury.
- Assess abdomen for signs of ingestion injury:
  - Tenderness
  - Guarding
  - Rigidity
- The percent total body surface area (%TBSA) burned is assessed, as is the location and depth of burns:
  - Edema of underlying tissue can cause difficulty assessing burn depth.
  - Chemical burns evolve in the hours after the injury, and burns should be re-evaluated frequently. Special situations include:
    - Burns to the hands, face, or genitals
    - Circumferential burns due to risk of compartment syndrome and neurovascular compromise

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

- Localized burns, such as to the hands, require no lab studies.
- Patients with severe burns (>5–10% TBSA), those with a suspected inhalation injury or ingestion, or who may require surgical intervention may require an extensive lab evaluation, including:
  - Metabolic profile, including renal function
  - Blood gas analysis with lactate to assess oxygenation, ventilation, and perfusion
  - CBC
  - Urinalysis
  - Creatine phosphokinase to assess tissue destruction and risk to the kidneys
  - Coagulation profile

##### Imaging

- Chest radiography, when inhalation is suspected, to assess pulmonary edema
- Abdominal radiography to assess for free air in cases of ingestion
- CT of the chest and abdomen may be indicated with caustic ingestion.

##### Diagnostic Procedures/Other

- Endoscopy may be performed by gastroenterology.
- May be indicated with any suspected esophageal burn or with severe burns of lower GI system
- Otorhinolaryngology may be consulted to directly visualize the airway.

##### Pathological Findings

Airway, esophageal, and gastric ulcers are classified by depth and extent: Superficial, transmucosal, transmural, and circumferential.

**DIFFERENTIAL DIAGNOSIS**

- Thermal burns
- Pemphigus
- Stevens-Johnson syndrome
- Epidermolysis bullosa
- Phytophotodermatitis

**TREATMENT****PRE HOSPITAL**

- Decontamination, including disrobing the patient and irrigation:
  - During irrigation, protect unburned skin from the effluent.
  - Irrigation with water is adequate for the majority of caustics and corrosives, with these exceptions:
    - Elemental metals, such as lithium and sodium, react violently with water. They should be irrigated with mineral oil.
    - Vesicants, such as mustard, require irrigation with a 0.5% chloride solution after removal of clothes and contaminated hair. Soap and water are a less effective alternative. Rescuers must don masks and rubber (not latex) gloves.
- Protection of prehospital care providers to prevent further injuries

**INITIAL STABILIZATION/THERAPY**

- Dilution with copious amounts of water is the key to stopping the burning process. Attempts to neutralize the pH of the caustic agent are generally not helpful. Dilution continues until the pH of the irrigation effluent is neutral:
  - Phenols specifically are best irrigated with polyethylene glycol (PEG)-containing liquids.
- After decontamination, burns should be dressed with nonadhesive bandages, such as petroleum jelly gauze, then bandaged loosely.
- IV normal saline or lactated Ringer solution should be given. Use Parkland formula to determine the amount of fluid resuscitation to be given in the 1st 24 hr:
  - Parkland: 4 mL/kg per %TBSA. Add maintenance fluid for children <5 yr.
  - Administer 1/2 of the fluids over the 1st 8 hr and the remainder over the next 16 hr.
  - Ringer lactate is the fluid of choice.
  - No colloid in the 1st 24 hr
- Burn center treatment is indicated for a smaller %TBSA than with thermal burns due to the depth of burns and tissue disruption.
- Chemical burns to eye require irrigation with a Morgan lens and ophthalmologic consultation.
- pH paper placed in the palpebral space can assess pH; the goal is a pH of 7.4:
  - Decontaminate phenols with polyethylene glycol.
- Agents specifically used for hydrofluoric acid:
  - Calcium or magnesium to neutralize the fluoride ion
  - Applied topically for small burns and SC for larger areas

**MEDICATION**

- Topical antibiotics are applied to superficial or small burns to limit the risk of superinfection. Options include bacitracin, erythromycin, and silver sulfadiazine (the latter is used in children >2 mo of age due to the risk of hyperbilirubinemia).
- Analgesics are usually needed.
- Opioids:
  - Morphine 0.1 mg/kg IV/IM/SC q2h PRN:
    - Initial morphine dose of 0.1 mg/kg IV/SC may be repeated q15–20min until pain is controlled, then q2h PRN.
  - Hydrocodone or hydrocodone/acetaminophen dosed as 0.1 mg/kg of hydrocodone component PO q4–6h PRN
- NSAIDs:
  - Consider NSAID medication in anticipation of prolonged pain and inflammation:
    - Ibuprofen 10 mg/kg/dose PO/IV q6h PRN
    - Ketorolac 0.5 mg/kg IV/SC q6h PRN
    - Naproxen 5 mg/kg PO q8h PRN

**SURGERY/OTHER PROCEDURES**

Laparotomy may be required to locate and treat GI perforation.

**DISPOSITION****Admission Criteria**

- The decision to admit the patient is based on the %TBSA burned, the age of the patient, and the quality of the likely outpatient follow-up. It is impossible to note a definitive TBSA at which admission is mandatory.
- Smaller burns for which admission is more strongly indicated include burns to the hands, face, feet, and genitals.
- Burn center admission should be considered based on local protocols, the pediatric burn expertise of the referring institution, and the severity of the burn.
- Critical care admission criteria:
  - Need for endotracheal intubation or respiratory compromise
  - Unstable vital signs or shock

**Discharge Criteria**

Small burns to the skin and minor burns to the eyes may be followed in the outpatient setting.

**Issues for Referral**

Appropriate services, including hand, face, plastic surgery, ophthalmology, GI, ENT, and pediatric surgery, may need to be consulted in the emergency department, inpatient, or after discharge.

**FOLLOW-UP****FOLLOW-UP RECOMMENDATIONS**

Discharge instructions and medications:

- Follow-up is needed within 24 hr to assess progression of the burn, signs of infection, and adequacy of pain control.

**COMPLICATIONS**

- General complications include infection, pain, scarring, and loss of function.
- Complications of chemical ingestions include mediastinitis, esophageal perforation, peritonitis, and strictures.
- Complications of ocular burns include blindness, globe perforation, and corneal scarring.
- Complications of chemical aspiration include airway burns, edema, respiratory distress, respiratory failure, and pulmonary edema.

**ADDITIONAL READING**

- D'Souza A, Nelson N, McKenzie L. Pediatric burn injuries treated in US emergency departments between 1990 and 2006. *Pediatrics*. 2009;124(5):1–7.
- Turner A, Robinson P. Respiratory and gastrointestinal complications of caustic ingestion in children. *Emerg Med J*. 2005;22(5):359–361.

**CODES****ICD9**

- 949.0 Burn of unspecified site, unspecified degree
- 949.1 Erythema due to burn (first degree), unspecified site
- 949.2 Blisters with epidermal loss due to burn (second degree), unspecified site

**PEARLS AND PITFALLS**

- Proper early decontamination and irrigation of burns with an irrigant appropriate to the agent is key:
  - Water is usually the irrigant of choice.
  - Mineral oil should be used for hygroscopic metals.
  - PEG should be used for phenols.
- With ingestion, vomiting, drooling, stridor, or inability to take PO are suggestive of significant GI burn.
- When aspiration or ingestion is suspected, early intubation is prudent.
- Stridor, dysphonia, or aphonia are indications for intubation. Delay may result in the inability to secure the airway.
- Hydrofluoric acid burns require calcium or magnesium applied to the burn or calcium gluconate intra-arterially or SC.
- Consider non-accidental trauma and self-injurious behavior as factors leading to the burn.

# BURN, THERMAL

Nikhil B. Shah

## BASICS

### DESCRIPTION

- Burn-related injuries are a leading cause of morbidity and mortality in children.
- Thermal burns are the most common type of burn in childhood.
- Prompt referral to a burn center for children with major burns improves outcomes.
- Children with burns require long-term follow-up with special attention to prevention of disability.
- Most burns are potentially preventable.

### EPIDEMIOLOGY

- Burns are the 3rd leading cause of death resulting from unintentional injury in children (1).
- 80% of pediatric burns are scald injuries (2).
- House fires account for the majority of deaths due to pediatric burns.
- Nonaccidental burns account for 20% of burn unit admissions.

### GENERAL PREVENTION

- Pay careful attention to the water heater set point (49°C or 120°F) and bath water temperature.
- Maintain kitchen/cooking safety (eg, keeping hot objects away from edge of the counter).
- Appliance safety: Cords should be stowed, and the child's activity monitored while an appliance (eg, radiator, iron, etc.) is on.
- Fire safety (eg, candles and cigarettes should never burn unattended)
- Never heat infant bottles in microwave ovens.
- Keep flammable substances out of reach.

### PATHOPHYSIOLOGY

- Thermal energy results in local injury:
  - Intensity and duration of thermal exposure determines depth of the burn.
- In major thermal burns, a systemic inflammatory response will follow in which increased capillary permeability and 3rd spacing of fluid into the interstitium will occur:
  - Hypotension (burn shock) and edema may result.
- A hypermetabolic state (dramatic increase in energy expenditure and protein metabolism) develops following resuscitation for major burns.

### ETIOLOGY

- Scald injuries result most commonly from hot bath water but can occur when a child pulls hot substances off a stove.
- Contact burns may result from irons, ovens, treadmill belts (friction), and other hot objects; this type of injury is most frequently seen in toddlers.
- Flame burns may result from house fires, candles, matches, lighters, and fireworks:
  - Occur more commonly in children and adolescents
- Burn injuries can be a manifestation of child abuse.

## DIAGNOSIS

### HISTORY

- Interview prehospital personnel, patient, and/or family.
- Note any inconsistencies or implausible history that may suggest abuse.
- Determine the mechanism of injury.
- History of closed space exposure (suggests smoke inhalation or carbon monoxide)
- Extrication time
- Identify delays in seeking attention or discrepancies in the history (may indicate inflicted injury).
- Fluids given during transport
- Past medical history
- Tetanus status
- Allergies

### PHYSICAL EXAM

- Vital signs with pulse oximetry
- Accurate weight in kilograms
- Primary survey: Assess airway, breathing, and circulation:
  - Evaluate for signs/symptoms of upper airway burns (eg, stridor, drooling) or inhalational injury (eg, carbonaceous material in mouth/nares).
    - Respiratory compromise may result from circumferential chest burns or carbon monoxide exposure.
    - Children with impaired perfusion at initial presentation may have other underlying injuries; later onset suggests burn shock.
- Secondary survey: Evaluate for other injuries.
- Evaluate the burn for total body surface area (TBSA) affected:
  - TBSA is estimated using an age-specific chart.
  - Alternatively, use the palmar surface of the patient's hand, which represents 1% of TBSA (3):
    - Major burns involve >10% of TBSA.
- Evaluate the burn for depth:
  - Superficial (1st degree):
    - Confined to epidermis only; red and painful; blanches with pressure; not included in TBSA estimation for major burns
  - Superficial partial thickness (2nd degree):
    - Involves epidermis and superficial dermis; painful, red, weeping, usually blisters; blanches
  - Deep partial thickness (2nd degree):
    - Involves epidermis and deep dermis; less painful; blisters; white to red; wet or waxy dry; nonblanching; difficult to distinguish from full-thickness burns
  - Full thickness (3rd degree):
    - Extends through and destroys epidermis and dermis; usually insensate; waxy white to leathery gray to charred and black; dry and inelastic; nonblanching
  - 4th-degree burns:
    - Life threatening; extend into deeper tissues such as muscle, fascia, or bone

- Circumferential burns should be noted:
  - May lead to compartment syndrome or interfere with respiratory mechanics
- Evaluate the burn pattern:
  - Symmetric stocking distribution or branding may suggest inflicted burn injury.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

- Baseline CBC and serum electrolytes in anticipation of major fluid and electrolyte shifts in serious burns:
  - Lab testing is not necessary for minor burns.
- Urinalysis to detect myoglobin in patients with muscle injury
- Blood gas with lactate concentration to assess oxygenation, ventilation, perfusion, and tissue injury
- Carboxyhemoglobin levels in suspected carbon monoxide exposure

#### Imaging

Need for imaging is dictated by mechanism of injury and physical exam:

- Radiographs can be performed for suspected upper airway obstruction or smoke inhalation but should never delay definitive airway management.
- CT scan or US may be performed to identify associated injuries.

## TREATMENT

### PRE HOSPITAL

- Provide basic life support and oxygen.
- Intubation may be required for airway burns.
- Stop the burning process by removing offending clothing/jewelry (unless stuck to the patient).
- Cover the burn area with a clean sheet or blanket.
- Fluid therapy (for major burns/long transports)
- Analgesia
- Rapid transport

### INITIAL STABILIZATION/THERAPY

- Airway:
  - Anticipate difficult airway; intubate early for suspected upper airway burns or significant inhalational injury
- Breathing:
  - Supplemental oxygen for fire-related burns
- Circulation:
  - Fluid resuscitation in major burns (1st 24 hr):
    - Parkland: 4 mL/kg per %TBSA. Add maintenance fluid for children <5 yr.
    - Galveston: 5,000 mL/m<sup>2</sup> per %TBSA. Add 2,000 mL/m<sup>2</sup>/day for maintenance fluid.
    - Administer 1/2 over the 1st 8 hr, and the other 1/2 over the next 16 hr.
    - Ringer lactate is the fluid of choice.
    - No colloid in the 1st 24 hr.
- Pain control
- Monitor fluid status:
  - Place bladder catheter.
  - Maintain urine output at 1 mL/kg/hr.

**MEDICATION**

- Pain control is essential.
- Opioid analgesia is often required:
  - Morphine 0.1 mg/kg IV/IM/SC q2h PRN:
    - Initial morphine dose of 0.1 mg/kg IV/SC may be repeated q15–20min until pain is controlled, then q2h PRN.
  - Hydrocodone or hydrocodone/acetaminophen dosed as 0.1 mg/kg of hydrocodone component PO q4–6h PRN
  - Codeine 0.5–1 mg/kg/dose PO q4–6h
- NSAIDs:
  - Consider NSAID medication in anticipation of prolonged pain and inflammation:
    - Ibuprofen 10 mg/kg/dose PO/IV q6h PRN
    - Ketorolac 0.5 mg/kg IV/IM q6h PRN
    - Naproxen 5 mg/kg PO q8h PRN
- Acetaminophen 15 mg/kg/dose PO/PR q4h PRN
- Tetanus prophylaxis as indicated:
  - Tetanus toxoid 0.5 mL IM
- Superficial burns are managed with moisturizers and over-the-counter analgesics:
  - Silver sulfadiazine: Apply b.i.d. to the burn area until healed; should not be used on the face.
  - Neosporin cream: Apply q.i.d. to burn area until healed.

**SURGERY/OTHER PROCEDURES**

- Partial- and full-thickness burn wound management:
  - Clean burns with mild soap and water.
  - Debride devitalized tissue.
  - Leave blisters intact unless large, painful, or if rupture is imminent (4).
  - Apply a topical antibiotic, such as 1% silver sulfadiazine (avoid in sulfa allergy and neonates); mafenide to cartilaginous areas; or bacitracin to the face.
  - Synthetic occlusive dressings (eg, Acticoat) are an alternative to topical antimicrobials for burns <2% TBSA and <24 hr old
  - Cover with a sterile nonadherent dressing, then wrap with gauze or a woven gauze bandage roll.
- Emergent escharotomy may be indicated to relieve restriction of the chest wall or to reduce compartment pressure in an extremity.

**DISPOSITION**

The majority of burns are small and may be managed in the outpatient setting (ie, partial thickness <10% TBSA or full thickness <2%) (5).

**Admission Criteria**

- Criteria for transfer to a burn center (6):
  - Partial-thickness burns >20% TBSA at any age or >10% TBSA in those <10 yr of age
  - Full-thickness burns >5% TBSA
  - Any significant burn to the face, hands, major joints, genitalia, or perineum
  - Inhalation, chemical, or electrical injury
  - Significant associated injuries
- Patients with significant burns not fulfilling the above criteria should be admitted to the hospital for observation, IV fluids, and pain control.
- Critical care admission criteria:
  - Unstable vital signs; need for mechanical ventilation

**Discharge Criteria**

- No airway compromise
- Burns <10% TBSA
- Tolerating adequate fluids by mouth
- No suspicion for inflicted burn injury
- Family must have the resources to support an outpatient care plan that includes the following:
  - Teaching proper wound care and dressing techniques to the patient and family
  - Pain control
  - Clearly defined early return conditions (eg, signs of infection)
  - Immediate and long-term follow-up with scar management

**Issues for Referral**

Follow-up is essential to a successful outcome:

- Re-evaluate every 1–2 wk for wound healing and infection until epithelialization occurs, then every 6 wk thereafter for scarring.
- Long-term rehabilitation, including physical and occupational therapy
- Pressure therapy (application of pressure garments), massage, and/or splints may be needed to treat wound contracture sites as the scar matures.
- Requires a multidisciplinary approach

**FOLLOW-UP****FOLLOW-UP RECOMMENDATIONS**

Discharge instructions and medications:

- Maintain proper wound care, and change the dressing twice a day.
- Pain control with over-the-counter or narcotic analgesics as indicated

**Patient Monitoring**

Monitor for infection, hypertrophic scar formation, and development of contractures.

**PROGNOSIS**

Mortality from burn injury is related to young age, burn extent, and the presence of inhalational injury.

**COMPLICATIONS**

- Delayed respiratory failure (inhalation injury)
- Wound infection
- Sepsis
- Hypertrophic scar formation
- Contractures

**ADDITIONAL READING**

- Kassira W, Namias N. Outpatient management of pediatric burns. *J Craniofac Surg*. 2008;19(4):1007–1009.
- Reed JL, Pomerantz WJ. Emergency management of pediatric burns. *Pediatr Emerg Care*. 2005;21(2):118–129.

**CODES****ICD9**

- 949.0 Burn of unspecified site, unspecified degree
- 949.1 Erythema due to burn (first degree), unspecified site
- 949.2 Blisters with epidermal loss due to burn (second degree), unspecified site

**PEARLS AND PITFALLS**

- Most burns are small and can be managed as an outpatient.
- Major burns require aggressive attention to airway management, adequate fluid resuscitation, and wound care.
- Long-term follow-up and rehabilitation are essential to a successful outcome.

# CAFFEINE/THEOPHYLLINE POISONING

David H. Jang  
Lewis S. Nelson

## BASICS

### DESCRIPTION

- Caffeine is found in tea, coffee, and soft drinks. It is the most widely used psychoactive substance in the world.
- Caffeine is contained in combination with aspirin, ibuprofen, and other medications marketed for headache therapy.
- Caffeine is contained in high concentrations in many “energy” and sports drinks.
- Caffeine is used as a proconvulsant in conjunction with electroconvulsive therapy.
- Caffeine is also used for neonatal apnea as well as adjunctive treatment for headaches.
- Theophylline and its IV formulation, aminophylline, were once commonly used in the treatment of asthma, bronchitis, and COPD.
- Theophylline is used to treat neonatal apnea.
- Caffeine and theophylline are extremely similar structurally and pharmacologically.
- Caffeine has an additional methyl group that allows it greater CNS penetration and effect.

### RISK FACTORS

- Therapeutic use of caffeine or theophylline
- Use of highly caffeinated energy and sports drinks or dietary supplements containing caffeine
- Patients at extremes of age are more susceptible to toxicity.

### PATHOPHYSIOLOGY

- Caffeine and theophylline are adenosine receptor antagonists and phosphodiesterase inhibitors. They also increase intracellular cyclic AMP.
- Caffeine and theophylline result in the release of endogenous catecholamines, which stimulate beta receptors and result in a therapeutic effect previously sought in asthma treatment:
  - In overdose of caffeine or theophylline, extremely elevated levels of epinephrine and norepinephrine result.
- Caffeine toxicity develops in children at doses >35 mg/kg and in adults at a dose of 1 g.
  - Theophylline toxicity develops acutely at similar doses.
- Both caffeine and theophylline may result in severe or even fatal status epilepticus if they result in seizure:
  - Due to their adenosine antagonist activity, the natural mechanism by which the brain terminates seizures is prevented.
  - These are the only toxins for which exposure alone may be an indication to give prophylactic anticonvulsant due to severe morbidity and mortality resulting if seizures occur.

### ETIOLOGY

- Caffeine:
  - Iatrogenic: Give for neonatal apnea or headache
  - Medicinal use in combination with analgesics and headache medications and stimulants used to increase alertness and prevent sleep
  - In beverages such as sports or energy drinks
  - In other beverages and foods
- Theophylline:
  - Iatrogenic: Used to treat neonatal apnea, COPD, bronchitis, and asthma

### COMMONLY ASSOCIATED CONDITIONS

- Vomiting occurs with any acute poisoning.
- Hyperventilation may occur.

## DIAGNOSIS

### HISTORY

- Typically, a history of ingestion is readily given.
- Prominent nausea and vomiting is a characteristic feature of significant acute toxicity.
- Chronic toxicity often manifests subtle symptoms such as anorexia or palpitations.
- Patients with chronic toxicity may present with a seizure as their 1st sign of toxicity.
- Acute-on-chronic toxicity is often very similar to an acute ingestion.

### PHYSICAL EXAM

- Vital signs: Tachycardia is invariably present, tachypnea is usually present, BP may be elevated, and wide pulse pressure is common. Hyperthermia is often present with accompanying diaphoresis.
- CNS: Mydriasis, anxiousness, agitation, insomnia, headache, agitation. Delirium, psychosis or hallucination may rarely occur.
- GI: Nausea and vomiting are present and usually severe.
- Diaphoresis is typical.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

- Blood glucose level to detect hypoglycemia; caffeine and theophylline toxicity result in extreme hyperglycemia, but symptoms are clinically similar to those of hypoglycemia.
- Serum electrolytes: Hypokalemia is expected; rarely, anion gap metabolic acidosis may occur.
- Urinalysis to assess for rhabdomyolysis
- Assay creatine phosphokinase in any symptomatic patient.
- Troponin is rarely indicated with dysrhythmia, ECG changes, or severe toxicity. Slight elevations may be seen as a result of toxicity without any myocardial ischemia or infarction.

- Serum caffeine or theophylline level: Measure initially and then q2h until levels are falling and patient improves clinically.
- In cases of caffeine toxicity, some caffeine metabolism will result in a small detectable theophylline level:
  - Neonates are able to metabolize caffeine to theophylline and vice versa.

### Imaging

- Brain CT may rarely be indicated to assess for intracranial hemorrhage.
- CXR may be indicated to evaluate hyperventilation, tachypnea, or hyperpnea.

### DIFFERENTIAL DIAGNOSIS

- Sympathomimetic toxicity:
  - Amphetamines, cocaine, pseudoephedrine, etc.
- Salicylate toxicity
- Serotonin syndrome
- Neuroleptic malignant syndrome
- Infection and sepsis

## TREATMENT

### PRE HOSPITAL

Assess and stabilize airway, breathing, and circulation.

### INITIAL STABILIZATION/THERAPY

- Assess and stabilize airway, breathing, and circulation.
- Supportive care is the mainstay of care with special attention to neurovascular and cardiovascular function.
- GI decontamination:
  - Orogastric lavage may be of limited use, as pills may be too large.
  - Ipecac should not be used and is potentially dangerous in patients who present with seizures or decreased mental status.
  - Activated charcoal can be given if there are no contraindications (eg, seizures).
  - Multiple-dose activated charcoal enhances systemic elimination of theophylline by GI dialysis.
  - Whole-bowel irrigation may be used in patients who ingest sustained-release pills.
- Vomiting typically occurs and is severe. Use of potent antiemetics such as ondansetron or granisetron are indicated to treat vomiting.
- Although hypokalemia occurs, it is rarely consequential. If serum potassium is <2.4 mEq/L, supplemental potassium may be given:
  - Typically, such administration is futile. Due to intense beta-adrenergic agonism, potassium is continuously driven intracellularly. Excessively supplementing potassium may result in hyperkalemia when the beta-agonist effect abates and supplemental potassium moves to the extracellular space.

**MEDICATION****First Line**

- Antiemetics are the most commonly needed medication:
  - Dose 0.2 mg/kg IV, max single dose 8 mg, may repeat dose q45–60min to max of 0.6 mg/kg total dose
- Agitation:
  - Lorazepam 0.05–0.1 mg/kg IV, repeat q15min and titrate to effect

**Second Line**

- Anticonvulsant to prophylax seizure:
  - Severe morbidity and mortality result if seizures occur. Acute theophylline toxicity—and by extrapolation, caffeine toxicity—with an elevated level  $>90 \mu\text{g/dL}$  should receive a loading dose of barbiturate or possibly a benzodiazepine.
  - Evidence exists for phenobarbital use due to the fact that this was the predominant GABAergic medication decades ago when theophylline toxicity was prevalent.
  - Lorazepam 0.1 mg/kg IV (max single dose 5 mg) may be used instead of phenobarbital.
  - Phenobarbital 10–20 mg/kg IV administered over 30 min may also be used.
- Anticonvulsant to treat seizure:
  - Due to severe nature of seizure and likelihood of developing status epilepticus, rapid escalation to powerful anticonvulsants is indicated.
  - Lorazepam 0.05 mg/kg IV q5–10min may be attempted for 3 doses.
  - Propofol 1 mg/kg IV. May follow with infusion 0.1 mg/kg/min, escalating to 0.3 mg/kg/min as necessary.
  - If benzodiazepine therapy fails, immediately escalate to propofol.
  - May result in respiratory depression necessitating endotracheal intubation.
  - Effectively the most powerful anticonvulsant available for emergency department use, this medication has not come to prominence in the U.S. though in other countries is a routine second-line medication for disruption of status epilepticus.
  - Valproic acid, midazolam, or pentobarbital administered by infusion may be used if propofol is unavailable:
    - These take longer to administer and are less effective.

**ALERT**

Do not use phenytoin under any circumstance in cases of theophylline or caffeine toxicity. Phenytoin is completely contraindicated for use. Due to its mechanism of action, it will potentiate seizures and cardiac dysrhythmias. Use of phenytoin is not beneficial and is highly detrimental.

- Esmolol 100–500  $\mu\text{g/kg}$  loading dose, then infusion of 50–300  $\mu\text{g/kg/min}$ :
  - To treat tachydysrhythmia or other adverse cardiovascular effects of caffeine or theophylline
  - Esmolol is preferred due to titratable effect.
  - Do not use long-acting beta-blockers.
  - Esmolol may improve tachycardia as well as hypotension.
  - Beta-blockade also improves metabolic derangement such as hyperglycemia and hypokalemia but is never administered for this purpose.

**SURGERY/OTHER PROCEDURES**

Hemodialysis or charcoal hemoperfusion may be indicated:

- Acute toxicity with caffeine or theophylline level  $>90 \mu\text{g/dL}$
- Chronic toxicity with caffeine or theophylline level  $>45 \mu\text{g/dL}$
- Any toxicity with severe systemic toxicity such as ventricular dysrhythmia or seizure

**DISPOSITION****Admission Criteria**

- Patients with significant toxicity, such as intractable vomiting or toxicity requiring inpatient observation but not requiring ICU care
- Any patient who displays suicidal ideation.
- Critical care admission criteria:
  - Patients with hypotension or other unstable vital signs, severe toxicity that requires seizure precautions, cardiac dysrhythmia
  - Treatment for cardiac dysrhythmia or seizure in emergency department

**Discharge Criteria**

- Patients who are asymptomatic after 6–8 hr of observation can safely be discharged.
- Patients who display suicidal ideation should also be evaluated by psychiatry.

**Issues for Referral**

Consult a medical toxicologist, intensivist, or other clinician experienced and familiar with caffeine and/or theophylline toxicity.

**FOLLOW-UP****PROGNOSIS**

- Varies with degree of toxicity, adequacy of supportive care
- Most cases resolve with only occurrence of vomiting.
- If seizures occur, they may be difficult to control. Permanent neurologic injury may result.

**COMPLICATIONS**

- Hypokalemia
- Seizure
- Rhabdomyolysis
- Cardiac dysrhythmia
- Permanent neurologic injury
- Death

**ADDITIONAL READING**

**See Also (Topic, Algorithm, Electronic Media Element)**

Sympathomimetic Poisoning

**ICD9**

- 969.71 Poisoning by caffeine
- 974.1 Poisoning by purine derivative diuretics

**PEARLS AND PITFALLS**

- Caffeine and theophylline toxicity may result in permanent neurologic injury or death if seizures occur.
- Severe vomiting is expected with any significant ingestion. Use of potent antiemetics such as ondansetron are indicated for this.
- Due to adenosine antagonist activity of these medications, the brain's natural ability to terminate a seizure is disrupted. If a seizure begins, it is likely to be long lasting or result in status epilepticus.
- The clinical presentation and management are significantly different between patients with acute toxicity vs. chronic toxicity.
- The mainstay for treatment remains primarily supportive with careful attention to the neurologic and cardiovascular status.

# CALCIUM CHANNEL BLOCKER POISONING

Amit K. Gupta  
Mark Su

## BASICS

### DESCRIPTION

- There are 3 classes of calcium channel blockers (CCBs) in clinical use:
  - Dihydropyridine (nifedipine, amlodipine, nicardipine): Causes smooth muscle relaxation in the peripheral vascular system, lowering BP:
    - Little direct cardiac negative inotropic effect: Reflex tachycardia may occur.
    - Loses selectivity in large overdoses
  - Phenylalkylamine (verapamil): Direct negative inotropic and chronotropic effects that lead to bradycardia and hypotension with toxicity
  - Benzothiazepines (diltiazem): Have less profound effects compared to verapamil, but toxicity also leads to bradycardia and hypotension
- Diltiazem and verapamil are most clinically consequential in overdose.

### EPIDEMIOLOGY

#### Incidence

Of the 2.4 million exposure logged by the American Association of Poison Control Centers (AAPCC) in 2007, 10,084 of these were due to various CCBs:

- ~13% were in children <6 yr, and 2.3% occurred in children 6–19 yr.
- 4.5% of adolescent exposures were fatal, whereas 2.3% of cases in children <3 yr were fatal. This likely reflects that difference between intentional vs. unintentional ingestion.

### RISK FACTORS

- Exposure to sustained-release preparations can lead to delayed toxicity.
- Coingestants with other cardiotoxic agents such as beta-blockers, cyclic antidepressants, and neuroleptics may exacerbate toxicity.

### GENERAL PREVENTION

Poison-proofing homes and giving parents poison prevention advice is the most effective way to prevent exposure in children.

### PATHOPHYSIOLOGY

- Absorption of CCBs is rapid and occurs within 30 min.
- Calcium plays an important role in excitation-contraction coupling and myocardial contraction.
- Calcium influx also plays an important role in the spontaneous depolarization of the sinoatrial (SA) node.

- Influx also allows normal propagation of myocardial electrical impulses in the atrioventricular (AV) node.
- Calcium is driven intracellularly down a concentration gradient via a voltage-sensitive L-type calcium channel.
- CCBs function by binding and inhibiting this L-type calcium channels on the cell membrane, thereby decreasing the flow of calcium into the cell.
- In the myocardium, this blockade decrease myocardial contraction force and causes hypotension.
- In the vasculature, this blockade results in arterial vasodilation and relaxation.
- Calcium inhibition at the SA node leads to bradycardia.
- Calcium inhibition at the AV node can lead to conduction abnormalities.
- Hyperglycemia may occur due to prevention of insulin release from pancreatic beta islet cells.

### ETIOLOGY

- Numerous brands of CCBs are available.
- Understanding of the different characteristics of each class may be helpful in evaluating clinical outcome and guiding therapy.

### COMMONLY ASSOCIATED CONDITIONS

- Cardiac dysrhythmia
- Congenital heart disease
- CHF

## DIAGNOSIS

### HISTORY

- Obtain history of exposure, other possible coingestants, and events that led to exposure.
- Ask parents to bring in pill bottles if possible.

### PHYSICAL EXAM

- Cardiovascular effects may include bradycardia and hypotension, both which may be severe.
- Mental status is often preserved, unless the patient has hemodynamic instability.
- Cardiovascular effects may include bradycardia.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

- Electrolytes, BUN, creatinine, glucose, calcium
- Measure acetaminophen and salicylate levels if suicidal ingestion.
- Obtain serum digoxin level if the patient is also taking it chronically.
- Urine drug screen usually is not indicated unless for forensic purposes such as suspected malicious intent or child abuse.

### Imaging

- CXR should be performed to assess for pulmonary edema.
- CT of the brain should be considered in individuals with altered mentation.

### Diagnostic Procedures/Other

ECG should be performed to look for signs of bradycardia and/or other conduction abnormalities.

### DIFFERENTIAL DIAGNOSIS

- Beta-blocker toxicity
- Digoxin toxicity
- Clonidine toxicity
- Cardiogenic shock
- Hemorrhagic shock
- Septic shock
- Acute MI

## TREATMENT

### PRE HOSPITAL

- Assess and stabilize airway, breathing, and circulation.
- Supplemental oxygen
- Establishment of an IV line with cardiac monitoring
- Assess blood glucose level if any alteration of mental status.

### INITIAL STABILIZATION/THERAPY

- Assess and stabilize airway, breathing, and circulation.
- Assess blood glucose level if any alteration of mental status.
- Consultation with a medical toxicologist or poison control center is recommended.
- Activated charcoal (1 g/kg) may be given if the patient is protecting the airway.
- Syrup of ipecac is contraindicated.
- Orogastric lavage may be considered if the patient presents shortly after a potentially life-threatening overdose (usually within 1 hr) and the airway is protected:
  - This is predicated on having a clinician with experience performing orogastric lavage; NG lavage is not indicated and not helpful.

**MEDICATION****First Line**

- 0.9% saline bolus (20 cc/kg) for hypotension
- Atropine 0.02 mg/kg (min dose 0.1 mg and max 2 mg) for bradycardia; usually ineffective
- Lorazepam 0.05 mg/kg IV, max dose 2 mg:
  - First-line agents for seizures
- IV calcium administration creates a concentration gradient large enough to partially overcome the channel blockade, driving calcium into the cells:
  - A single 10-mL ampule of calcium chloride has 3 times the calcium concentration than that of calcium gluconate (13.4 mEq vs. 4.3 mEq).
  - Calcium chloride is sclerosing to veins and should only be given via a central line. Infusion through an intraosseous line is acceptable.
  - Calcium chloride dosing is 15–25 mg/kg (0.1–0.25 mL/kg of 10% solution), not to exceed 1 g slow IV bolus; may repeat q10–20min for a total of 3–4 doses.
  - Calcium gluconate dosing is 50–100 mg/kg (0.3–1 mL/kg of 10% solution), not to exceed 1 g slow IV bolus; may repeat q10–20min for a total of 3–4 doses.
- Continuous infusion of calcium can be given, if effective (0.5 mEq/kg/hr). Carefully monitor serum calcium levels.

**Second Line**

- A variety of inotropes are available if the above treatments fail.
- Norepinephrine infusion (0.1–2  $\mu$ g/kg/min) IV and titrate to maintain adequate cardiac output:
  - Directly stimulates alpha- and beta<sub>1</sub>-adrenergic receptors, thus increasing inotropic and vasopressor effects
- Epinephrine infusion (0.1  $\mu$ g/kg/min) IV and titrate to maintain adequate cardiac output:
  - Directly stimulates alpha- and beta-adrenergic receptors
- Dopamine 5–20  $\mu$ g/kg/min IV and titrate to maintain adequate cardiac output:
  - Indirectly stimulates alpha and beta<sub>1</sub>-adrenergic dopaminergic receptors to produce inotropic, chronotropic, renal/splanchnic vasodilatory (at low doses), and vasopressor (at high doses) effects
- Amrinone 50  $\mu$ g/kg IV loading dose with maintenance infusion of 0.50  $\mu$ g/kg/min IV and titrate to desired effect:
  - Inhibits myocardial phosphodiesterase leading to increased cyclic adenosine monophosphate levels
- High-dose insulin/glucose infusion:
  - Insulin (1 unit/kg bolus followed by 1 unit/kg/hr)
  - Glucose must be coadministered, initially 1 g/kg bolus followed by infusion of 0.5 g/kg/hr.
  - Frequent blood glucose monitoring, initially q10–15min for the 1st few hours, is necessary.
  - This therapy has been shown to be effective in case reports and in animal models.
  - The theorized mechanism is via positive inotropic effects of insulin and cardiac utilization of glucose as an energy source.
  - Frequent monitoring of serum glucose and potassium levels is necessary.

**COMPLEMENTARY & ALTERNATIVE THERAPIES**

- Cardiac pacing may be effective in increasing the rate of myocardial contraction, but electrical capture is not always successful and BP is not always restored.
- IV fat emulsion therapy (Intralipid 20% 1 mL/kg) has been shown in animal models and case reports to be beneficial in lipid-soluble drug overdoses (verapamil).
- The proposed mechanism of action is the “lipid sink” theory, where drugs may become trapped in an expanded plasma lipid compartment. Another proposed theory is that the emulsion acts as an additional fuel source for the heart due to the energy from fatty acids.

**SURGERY/OTHER PROCEDURES**

- Extracorporeal membrane oxygenation (EMCO) has also been attempted in patients who have hypotension refractory to all pharmacologic therapies.
- Cases of survival after complete prolonged asystole/cardiac standstill in which EMCO has been used therapeutically have been reported in children with CCB toxicity.
- Intra-aortic balloon counterpulsation is another invasive supportive option in refractory cases and has been used successfully to improve cardiac output and BP.

**DISPOSITION****Admission Criteria**

- All patients with exposure to sustained-preparation CCBs should be admitted to a monitored setting due to the potential of delayed toxicity.
- Admit all symptomatic patients.
- Critical care admission criteria:
  - Patients with signs of hemodynamic instability should be admitted to an ICU setting.

**Discharge Criteria**

May discharge if the patient remains asymptomatic after observation for 6 hr for immediate-release preparations

**FOLLOW-UP****FOLLOW-UP RECOMMENDATIONS**

- Discharge instructions and medications:
  - Follow up with the primary pediatrician.
  - Return to the emergency department for change in behavior, alteration in mental status, or if ill appearing.
- Activity:
  - Normal activity after discharge

**Patient Monitoring**

Patients with intentional overdoses should be monitored for acts of self-harm.

**PROGNOSIS**

- The prognosis is generally good with dihydropyridine overdoses.
- Patients with verapamil or diltiazem overdoses have a variable prognosis depending on the severity of ingestion.

**COMPLICATIONS**

- Cardiovascular collapse
- Shock
- Death

**ADDITIONAL READING**

- DeRoss F. Calcium channel blockers. In Goldfrank LR, Flomenbaum NE, Lewin NA, et al., eds. *Goldfrank's Toxicologic Emergencies*. 8th ed. Stamford, CT: Appleton & Lange; 2006:911–923.

**See Also (Topic, Algorithm, Electronic Media Element)**

- Beta-Blocker Poisoning
- Digoxin Poisoning
- Shock, Cardiogenic

**ICD9**

972.9 Poisoning by other and unspecified agents primarily affecting the cardiovascular system

**PEARLS AND PITFALLS**

- There are 3 classes of CCBs, with verapamil and diltiazem being the most consequential in overdose.
- Dihydropyridine overdoses are the least concerning, usually without serious sequelae.
- An ingestion of 1 tablet of verapamil or diltiazem could result in fatality in small children.
- Admission and observation are indicated for any sustained-release verapamil or diltiazem ingestion.
- Calcium administration is the first-line agent for CCB overdose.

# CANDIDIASIS

Désirée M. Seeyave

## BASICS

### DESCRIPTION

- Candidiasis is an opportunistic fungal infection caused by *Candida* species, most commonly *Candida albicans*.
- *Candida* species are part of the normal flora of the skin, mouth, intestinal tract, and vagina.
- Disease can occur at any site, including mucosally, cutaneously, vaginally, and systemically.
- Oropharyngeal candidiasis, also known as pseudomembranous candidiasis or thrush, is the most common human fungal infection.
- Systemic candidiasis or candidemia may occur in immunocompromised patients and is potentially life threatening.

### EPIDEMIOLOGY

#### Prevalence

- Candida is in the oral cavity in 40–60% of the population (1).
- Thrush occurs in 40% of healthy neonates.
- Oral candidiasis is the most common infection in patients with HIV and occurs in up to 90% of patients with AIDS (2).
- Relapse rates of 30–50% after completion of antifungal treatment in severe immunosuppression (2)
- Candidemia is rare in immunocompetent hosts.

### RISK FACTORS

- Local risk factors:
  - Steroid aerosol inhalers
  - Impaired salivary gland function: radiotherapy, chemotherapy, Sjogren
  - Dentures or implants
  - High-carbohydrate diet
  - Smoking
  - Indwelling vascular access devices and catheters
- Systemic risk factors:
  - Age: Neonates, advanced age
  - Malignancy
  - Immunodeficiency (eg, HIV)
  - Immunosuppression (eg, patients on chemotherapy, organ transplantation)
  - Recent broad-spectrum antibiotic use
  - Diabetes mellitus
  - Parenteral nutrition
  - Nutritional deficiencies (eg, vitamin B)

### GENERAL PREVENTION

- Good oral and vaginal hygiene
- Avoid overuse of antibiotics to prevent normal flora disruption and candidal overgrowth.
- Avoid douching and prolonged moisture in the vaginal area by using loose-fitting cotton underwear.
- Antifungal prophylaxis in immunocompromised patients

### PATHOPHYSIOLOGY

- Conditions associated with a decrease in normal flora lead to overgrowth of *Candida* species (eg, dry mouth, broad-spectrum antibiotic use).
- Impaired cellular immunity, T-cell function, and phagocytic activity allow *Candida* species to proliferate.
- Neonatal infection is acquired during birth from infected vaginal mucosa and usually manifests within the 1st wk of life; also is acquired from mother's breast and infected bottle nipples or pacifiers.
- Opportunistic candidal overgrowth on mucosal surfaces of the GI, respiratory tract, vagina, and skin, with hematogenous spread leading to systemic disease

### COMMONLY ASSOCIATED CONDITIONS

Immunodeficiency/immunosuppression:

- Oral lesions are common in newborns and infants, whose immune systems are immature.
- After infancy, immunodeficiency should be suspected in patients with candidiasis.

## DIAGNOSIS

### HISTORY

- Oropharyngeal candidiasis:
  - Local discomfort, poor feeding, white plaques in mouth
  - Neonates and young infants are typically asymptomatic.
- Esophageal candidiasis:
  - Odynophagia, poor feeding, weight loss
  - In immunocompromised patients, a history and physical are adequate for diagnosis and empiric treatment should be initiated.
- Cutaneous and diaper candidiasis:
  - Red, itchy rash with satellite lesions, especially in folds of skin; may occur anywhere on body
- Vaginal candidiasis:
  - Curdlike or mucoid white-yellow discharge, with pruritus, vulvar pain or burning, dysuria and dyspareunia
- Systemic candidiasis:
  - Fever, lethargy, oliguria, respiratory distress
  - Symptoms depend on organ system involved.

### PHYSICAL EXAM

- Oropharyngeal candidiasis (thrush):
  - Friable white pseudomembranous patches:
    - On buccal mucosa, gingivae, palate, tongue, and oropharynx
    - Plaques do not rub off easily with a tongue blade or swab.
    - If scraped off, red, ulcerated mucosa is exposed.
- Diaper dermatitis:
  - Erythematous papular rash that spreads into the inguinal folds, with a scaling border and satellite lesions
- Intertrigo:
  - Candidal infection in skin folds, often in neck
  - Erythematous, macerated skin; unlike diaper dermatitis, characteristic satellite lesions not typical

- Vaginal candidiasis:
  - Erythema of introitus with white-yellow curdlike discharge, white plaques on cervix or vaginal walls
- Systemic candidiasis:
  - Ill appearance, fever, shock, dehydration, presence of indwelling vascular access device

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

- Oral, vaginal, and esophageal candidiasis do not require lab assay for diagnosis.
- Test of scrapings from oropharyngeal and cutaneous lesions if initial treatment fails
- Direct light microscopy of scrapings from the mouth, skin, or vagina using potassium hydroxide preparation reveals long, branching hyphae of *C. albicans*.
- Vaginal pH remains normal (<4.5).
- Neutropenia in patients with candidemia
- Fungal culture and susceptibility testing of mucosal or skin scrapings, blood, urine, CSF, bone marrow, tissue biopsy, abscess aspirate, bronchoalveolar lavage fluid
- Blood culture growing fungus in patients with suspected candidemia

##### Diagnostic Procedures/Other

- Endoscopy for direct visualization of esophageal lesions
- Dilated retinal exam for endophthalmitis, which is sight threatening, should be done in patients with candidemia.
- CT, US, echo to identify deep organ lesions in lung, liver, kidney, brain, spleen, eye, heart (3)

### DIFFERENTIAL DIAGNOSIS

- Oral/mucosal lesions: Formula stuck to mucosa, aphthous stomatitis, acute necrotizing gingivitis, herpes gingivostomatitis or other viral stomatitis, lichen planus, squamous cell carcinoma, leukoplakia
- Diaper lesions: Atopic, seborrheic, bacterial, or occlusional dermatitis
- Cutaneous lesions: Seborrheic and atopic dermatitis
- Esophageal: Foreign body, GERD, pharyngitis
- Vaginitis: *Neisseria gonorrhoeae*, *Trichomonas vaginalis*, *Chlamydia trachomatis*, *Gardnerella vaginalis*, *Bacteroides* species, *Mycoplasma hominis*, *Peptostreptococcus*, chemical or mechanical irritants
- Systemic: Sepsis from other organisms

## TREATMENT

### INITIAL STABILIZATION/THERAPY

Systemic candidiasis:

- If ill appearing, address ABCs per the Pediatric Advanced Life Support (PALS) algorithm.

### MEDICATION

- Oropharyngeal candidiasis
- Oral hygiene: Gentle cleaning of teeth and oral cavity daily with a soft brush:
  - Nystatin suspension (100,000 units/mL): Use for 2 days after lesions have cleared (usually 7 days):
    - Preterm newborns: 0.5 mL in each cheek q.i.d.
    - Term infants: 1 mL in each cheek q.i.d.
    - Children: 4–6 mL swish and swallow q.i.d.
    - Side effects: Nausea, vomiting, diarrhea

- Fluconazole and ketoconazole for persistent infections (see below)
- Esophageal candidiasis:
  - Trial of fluconazole: 10 mg/kg IV/PO (max single dose 400 mg) × 1 day, then 3–6 mg/kg IV/PO (max single dose 200 mg) qd × 14–21 days
  - Itraconazole and amphotericin B may also be used.
- Diaper and cutaneous candidiasis:
  - Keep area dry.
  - Nystatin cream (100,000 units/g): Use with each diaper change until the rash has cleared.
  - Nystatin powder (100,000 units/g): May be used for intertrigo or very moist diaper rash
  - Topical clotrimazole 1%, miconazole 1%, ketoconazole 2%, or econazole 1% b.i.d. × 2–6 wk
  - Amphotericin B: 3% cream, 3% lotion, 3% ointment—apply b.i.d.–q.i.d.
- Vaginal candidiasis:
  - Topical:
    - Clotrimazole: 100 mg/dose QHS × 7 days or 200 mg/dose qhs × 3 days or 2% applicator dose qhs × 3 day
    - Miconazole: 100-mg applicator qhs × 7 days or 200 mg qhs × 3 days
  - Oral agents:
    - Fluconazole: 10 mg/kg PO (max single dose 150 mg) × 1
    - Ketoconazole (> 2 yr of age): 3.3–6.6 mg/kg/day (max single dose 400 mg) qd × 5 days OR
    - Itraconazole: 3–5 mg/kg/day (max single dose 200 mg) divided b.i.d. × 1 or 200 mg qd × 3 days
  - Recurrent vaginal candidiasis (>4 episodes of infection/1 yr):
    - Induction with 2 wk of topical or oral azole, then maintenance for 6 mo with fluconazole 150 mg every week, ketoconazole 100 mg qd, or itraconazole 100 mg qod, or daily topical azole

**ALERT**

- Monitor hepatic function in long-term use of azoles. May cause nausea, vomiting, rash, headache, pruritus, and fever.
- Systemic candidiasis:
  - Amphotericin B: 0.25–0.5 mg/kg/day IV qd
  - Amphotericin B cholesterol sulfate: Start at 3–4 mg/kg/day IV qd, infused at 1 mg/kg/hr; if tolerated, increase infusion rate.
  - Amphotericin B lipid complex: 2.5–5 mg/kg/day IV qd, infused at 2.5 mg/kg/hr
  - Amphotericin B, liposomal: 3–5 mg/kg/day IV qd
  - Fluconazole: 12 mg/kg/day PO/IV (max 600 mg/day)
  - Itraconazole: 10 mg/kg/day PO/IV
  - No antifungal is shown to be superior to any other in eradicating systemic disease (4).
  - Flucytosine is synergistic with amphotericin for candidal meningitis.
  - The need for IV medication and severity of illness necessitates hospitalization.
  - Remove indwelling catheters, as these are most common source of infection in children (4).
  - Continue topical medication if mucosal infection is the primary source to decrease the dose or duration of systemic therapy.

**ALERT**

- Mix all amphotericin formulations in D5W. Monitor electrolytes and renal, hepatic, and hematologic status closely, as side effects include hypercalciuria, hypokalemia, hypomagnesemia, renal tubular acidosis, renal and hepatic failure, hypotension, and phlebitis.
- Infusion-related reactions include fever, chills, headache, hypotension, nausea, and vomiting. Premedicate 30 min before and 4 hr after with acetaminophen and diphenhydramine; add hydrocortisone to the infusion (1 mg/mg amphotericin, max single dose 25 mg).
- Prior to each dose of amphotericin, load with 10–15 mL/kg of normal saline to minimize nephrotoxicity.

**SURGERY/OTHER PROCEDURES**

- Removal of infected foreign bodies (eg, indwelling catheters and central lines)
- Incision and drainage of abscesses

**DISPOSITION****Admission Criteria**

- Ill appearing
- Suspected systemic infection
- Patients with candidemia usually require management in the ICU.

**Discharge Criteria**

- Well appearing
- Adequate oral intake (oral or esophageal candidiasis)

**Issues for Referral**

- Immunology/hematology referral for suspected immunodeficiency or impaired cellular immunity
- Dermatology, gynecology, or gastroenterology referral for recurrent or refractory cutaneous, vaginal, or esophageal candidiasis, respectively

**COMPLEMENTARY & ALTERNATIVE THERAPIES**

Chlorhexidine rinses for bone marrow transplant patients

**FOLLOW-UP****FOLLOW-UP RECOMMENDATIONS**

Discharge instructions and medications:

- Follow up with primary care provider within 1 wk for oropharyngeal, cutaneous, and vaginal infections.

**PROGNOSIS**

- Good prognosis for oral candidiasis, diaper dermatitis, and vaginal candidiasis
- Treatment failures usually due to poor compliance with therapy, poor oral hygiene, or inability to resolve underlying predisposing factors
- Treatment failures due to resistance to systemic agents are increasing in frequency.
- Systemic candidiasis has a mortality rate of 19–31% (4).

**COMPLICATIONS**

- Persistent or recurrent candidiasis, especially in immunocompromised patients
- Systemic dissemination

**REFERENCES**

1. Epstein JB, Polsky B. Oropharyngeal candidiasis: A review of its clinical spectrum and current therapies. *Postgrad Med J.* 1998;20(1):40–57.
2. Akpan A, Morgan R. Oral candidiasis. *Postgrad Med J.* 2002;78:455–459.

4. Blyth CB, Palasanthiran P, O'Brien TA. Antifungal therapy in children with invasive fungal infections: A systematic review. *Pediatrics.* 2007;119(4):772–784.

**CODES****ICD9**

- 112.0 Candidiasis of mouth
- 112.1 Candidiasis of vulva and vagina
- 112.9 Candidiasis of unspecified site

**PEARLS AND PITFALLS**

- Neonates and young infants may commonly develop thrush, intertrigo, or candidal diaper rash despite being otherwise healthy with no systemic illness.
- Candidiasis is becoming more common because of increased numbers of patients who are immunocompromised.
- Systemic candidiasis is serious and potentially life threatening and should be considered in the immunocompromised child with fever and neutropenia.

# CARBON MONOXIDE/CYANIDE POISONING AND SMOKE INHALATION

David H. Jang  
Lewis S. Nelson

## BASICS

### DESCRIPTION

- Smoke inhalation is a major cause of death from fires. Significant fire exposures can also lead to carbon monoxide (CO) and cyanide (CN) poisoning, which causes cellular hypoxia.
- CO is leading cause of mortality from poisoning in the U.S.
- There is substantial morbidity in CO poisoning survivors by delayed neurologic sequelae (DNS).
- Combustion of organic nitrogen-containing products like plastics, polyurethanes, wool, silk, nylon, and synthetic rubber can produce CN.

### EPIDEMIOLOGY

- CO is the leading cause of poisoning death in children and adults in the U.S.
- There are > 1.5 million fire incidents in the U.S. with > 3,000 fire deaths per year.
- There are > 2,000 nonfire CO deaths yearly in the U.S.
- CO poisoning contributes to > 5,000 smoke inhalation deaths per year.
- After Hurricane Katrina in Louisiana and Hurricane Ike in Texas, it was recognized that a significant number of pediatric exposures to CO result with use of gasoline-powered generators during electrical outages.
- A significant number of closed-space or indoor fires result in CN exposure due to combustion of certain materials in fires.
- The majority of CO and CN exposure is unintentional. Either can occur in suicidal attempts but this is far less common.

### RISK FACTORS

- Vehicular, such as riding in the back of a pickup truck
- Use of propane-powered equipment (ie, ice rink resurfacers or forklifts in enclosed spaces)
- Gas furnaces during the winter months
- Smoke inhalation
- Use of combustion engines in a location without proper ventilation, such as using a gasoline-powered generator indoors or leaving an automobile running inside a closed garage

### GENERAL PREVENTION

- Use smoke and CO detectors, especially during the winter, and learn to recognize symptoms of CO poisoning (ie, flulike symptoms).
- Use of an indoor detector that senses both smoke and CO is recommended.

### PATHOPHYSIOLOGY

- Toxic combustion products from fires include chemical asphyxiants (CO and CN), simple asphyxiants (such as carbon dioxide), and irritants.
- CO is a by-product of hemoglobin (Hb) degradation.
- CO binds with Hb with 200 times greater affinity than oxygen, which renders it incapable of delivering oxygen. CO also binds with cytochrome oxidase and inhibits cellular respiration.

- CO causes a leftward shift of the oxyhemoglobin dissociation curve, which decreases off-loading of oxygen from Hb.
- A series of immune-mediated damage in the CNS as well as oxidative damage can lead to lipid peroxidation.
- CN is an inhibitor of multiple enzymes, including cytochrome oxidase. This leads to cellular hypoxia with an elevated lactate and often has multiorgan effects.
- CN is also a very potent neurotoxin that affects areas of the brain with high metabolic activity, such as the basal ganglia and cerebellum.

### ETIOLOGY

- Smoke from closed-space fires
- Exhaust from furnaces, combustion engines such as generators, automobiles, furnaces

### COMMONLY ASSOCIATED CONDITIONS

- Burns:
  - Airway
  - Lung injury
  - Skin
- Smoke inhalation

## DIAGNOSIS

### HISTORY

- The primary complaint from smoke inhalation is respiratory, ranging from cough to respiratory distress and coma.
- Early symptoms of CO exposure are often nonspecific and can mimic a viral syndrome, especially during winter months when an indoor heater may be in use.
- A headache that is described as diffuse and aching is the most common complaint.
- Heavy CO poisoning can manifest as syncope, coma, or seizure.
- Children often manifest atypical symptoms of CO poisoning, presenting with vomiting or an isolated seizure.
- Patients with long-term exposure to low levels of CO often will complain of a persistent headache and nonspecific cognitive problems such as memory loss.
- Patients with smoke inhalation and severe metabolic acidosis should also be evaluated for possible CN toxicity.
- The persistent or delayed effects of CO poisoning can include apraxia and agnosias, dementia, amnesic syndromes, parkinsonism, and cortical blindness.

### PHYSICAL EXAM

- Assess vital signs and pulse oximetry.
- Tachycardia and hypotension are common in toxicity. Tachypnea and hyperpnea may also occur.
- Respiratory:
  - Head and neck findings include burns, soot in nares, copious oral secretions, and oropharyngeal edema.
  - May also exhibit drooling, stridor, and inability to handle secretions
  - Pulmonary symptoms include rhonchi, crackles, and wheezing.

- Neurologic symptoms can include agitation, seizure, confusion, and coma.
- Dermatologic:
  - Burns may be present on skin as well as in nares.
  - Skin findings can include cherry-red colorations as a result of CN exposure and lack of oxygen extraction across capillary bed.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

- CO testing should occur with patients who present with CO-related complaints such as headache or flulike symptoms.
- The carboxyhemoglobin (COHb) level is important to obtain with smoke inhalation:
  - Normal levels range between 0 and 5% with neonates; patients with hemolytic anemia may have higher levels.
  - Levels > 5% are considered abnormal, levels > 25% are considered very elevated, and levels > 45% are extremely elevated:
    - Heavy smokers can have levels as high as 10%.
    - High levels may confirm CO exposure but do not correlate with clinical symptoms or outcome.
    - It is important to consider testing cohabitants of the patient for CO exposure.
- Blood gas analysis, lactate and methemoglobin concentrations:
  - Metabolic acidemia is indicative of CN toxicity.
- Lactate can be elevated in the setting of hypoxia, serious CO poisoning, and CN toxicity. Rapidly obtain a lactate level:
  - Lactate elevation is extremely sensitive and usually is specific for CN exposure in the setting of closed-space fires.
  - Levels > 10 mmol/L suggest CN poisoning and should trigger CN antidote use.
  - CN concentrations can be obtained but often are not readily available to be meaningful. Blood CN concentration > 1.0 ug/mL is considered toxic.
- Troponin can be elevated due to diffuse myocardial damage.
- Elevations of creatine phosphokinase (CPK) are typically mild, but rhabdomyolysis may occur, so assay CPK as indicated.

##### Imaging

- Chest radiograph should be obtained in most cases of smoke inhalation, which can show interstitial changes and diffuse alveolar involvement.
- A noncontrast head CT should be obtained in unresponsive patients or those with focal neurologic deficits.

##### Diagnostic Procedures/Other

ECG should be obtained to evaluate for dysrhythmias and ischemia with severe exposure.

##### Pathological Findings

Autopsies from severe CO poisoning can show necrosis of the cerebellum, globus pallidus, and hippocampus.

**DIFFERENTIAL DIAGNOSIS**

- Acute lung injury
- Stroke
- Sepsis
- Shock
- Food poisoning
- Viral syndrome
- Gastroenteritis

 **TREATMENT**

**PRE HOSPITAL**

- Assess and stabilize airway, breathing, and circulation.
- Administer high-flow oxygen.
- Consider transport to a facility with an hyperbaric oxygen (HBO) chamber.

**INITIAL STABILIZATION/THERAPY**

Assess and stabilize airway, breathing, and circulation.

**ALERT**

- CO toxicity results in erroneously elevated pulse oximetry readings. Administer high-flow oxygen regardless of the pulse oximetry measurement obtained by a finger probe.
- Hydroxocobalamin use may interfere with pulse oximetry readings in various manners, potentially making it impossible to use pulse oximetry measurements after administration.

- Administer high-flow oxygen.
- Assess serum glucose rapidly.
- Maintain a very low index of suspicion for CO exposure. Early diagnosis is crucial to prevent morbidity and mortality.
- Early control of the airway is crucial, especially in the context of serious smoke inhalation injury.
- Treatment of CO poisoning consists of high-flow oxygen therapy, mechanical ventilation, or HBO therapy, depending on the circumstances.
- Treatment of suspected CN poisoning should be based on clinical presentation in conjunction with lab values.
- Metabolic acidemia, particularly with an elevated lactate level, or loss of consciousness, severe altered mental status, shock, or cardiac dysrhythmia are indications for treatment for presumed CN poisoning.

**MEDICATION**

- Hydroxocobalamin:
  - Recently approved for use in CN poisoning
  - Combines with CN to form cyanocobalamin, which is nontoxic.
  - Dose 70 mg/kg (not to exceed 5 g initially) administered IV over 30 min
  - Can be administered as an IV push in cases of CN-induced cardiac arrest
  - The dose can be repeated (not to exceed a total dose of 15 g) as necessary.
  - Recommended in patients with metabolic acidemia, particularly with elevated lactate level, and clinically for loss of consciousness, severe altered mental status, shock, or cardiac dysrhythmia

- The CN antidote kit should be administered in suspected CN toxicity:
  - Three components in the kit are amyl nitrite, sodium nitrite, and sodium thiosulfate.
  - Nitrites, which induce methemoglobinemia, are contraindicated in the setting of smoke inhalation.
  - Sodium thiosulfate dose 400 mg/kg or 1.65 mL/kg of 25% solution, to max of 12.6 g. Adolescent/Adult dose is 12.5 g:
    - Administered IV either as a bolus or infused over 10–30 min
    - Sodium thiosulfate is relatively free of significant adverse side effects and is completely safe for use in patients with concomitant CO toxicity.
    - Recommended in patients with metabolic acidemia, particularly with an elevated lactate level, clinically for loss of consciousness, severe altered mental status, shock, or cardiac dysrhythmia

**DISPOSITION**

**Admission Criteria**

- Any patients with significant smoke inhalation, CO toxicity, or CN toxicity
- Critical care admission criteria:
  - Dysrhythmia, unstable vital signs

**Discharge Criteria**

No significant elevation of CO level; asymptomatic after 6–8 hr of observation

**Issues for Referral**

- Refer to a poison center and/or medical toxicologist.
- The decision whether to initiate HBO can also be made with consultation.

**COMPLEMENTARY & ALTERNATIVE THERAPIES**

HBO:

- The primary benefits of HBO include clearing COHb, but more importantly preventing brain lipid peroxidation.
- Indications for HBO therapy include syncope, abnormal cerebellar findings, seizures, COHb >25%, and fetal distress in pregnancy.

 **FOLLOW-UP**

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**

If there is significant CO or CN toxicity, ongoing neurologic testing for sequelae is indicated.

**PROGNOSIS**

- Varies with severity of exposure and ranges from excellent prognosis to certain death
- The most important morbidity of CO poisoning is DNS. Patients with history of syncope or an abnormal neurologic exam are at increased risk of developing DNS.

**COMPLICATIONS**

Complications of serious CO and CN poisoning can be permanent and include apraxia and agnosias, dementia, amnesic syndromes, parkinsonism, paralysis, and cortical blindness.

 **CODES**

ICD9

- 986 Toxic effect of carbon monoxide
- 987.9 Toxic effect of unspecified gas, fume, or vapor
- 989.0 Toxic effect of hydrocyanic acid and cyanides

**PEARLS AND PITFALLS**

- Flu-like symptoms such as headache, especially during winter months are a common presentation of patients with CO poisoning.
- Patients who present with a coma and severe metabolic acidosis from a fire should also be empirically treated for suspected CN poisoning.
- The biggest pitfall in managing patients with smoke inhalation injury is failing to realize that they may suddenly deteriorate.

# CARDIOGENIC SHOCK

Marsha Ayzon Elkhunovich  
Vincent J. Wang

## BASICS

### DESCRIPTION

- Cardiogenic shock is a state of tissue hypoperfusion as a result of primary cardiac failure, despite normal or increased left ventricular filling pressures.
- Cardiac preload remains normal to increased, which distinguishes cardiogenic shock from hypovolemic shock (decreased effective blood volume) and distributive shock (blood vessel dilation causing relative hypovolemia). All 3 types of shock are defined by decreased cardiac output and tissue hypoperfusion:
  - Obstructive shock is usually caused by cardiac or cardiothoracic etiologies and is managed similarly as cardiogenic shock:
    - Because of this, obstructive shock will be considered a variant of cardiogenic shock in this topic.
    - Septic shock is similar to distributive shock.
- Pediatric cardiogenic shock occurs primarily in neonates with congenital heart disease and in children with myocarditis.
- In adults, MI is the most common cause.

### RISK FACTORS

Risk factors for specific conditions that cause cardiogenic shock:

- Infants of diabetic mothers have an increased incidence of congenital heart defects and cardiomyopathy.
- Asphyxia during birth predisposes infants to heart failure early in life.
- Infants of mothers with autoimmune disease, especially systemic lupus erythematosus, have an increased incidence of congenital heart block.
- Infants and children with a family history of cardiomyopathy and arrhythmias have a higher incidence of such conditions.

### GENERAL PREVENTION

Pulse oximetry screening in the newborn nursery helps to identify infants with cyanotic congenital heart disease. Done early and prior to discharge, this may identify conditions that may cause cardiogenic shock upon closing of the ductus arteriosus (1).

### PATHOPHYSIOLOGY

- Cardiogenic shock occurs when cardiac output is inadequate because of:
  - Increased cardiac demand (eg, large ventricular septal defect [VSD])
  - Decreased/ineffective contractility (eg, arrhythmia or myocarditis) OR
  - Obstruction (eg, hypertrophic obstructive cardiomyopathy [HOCM])
- This leads to CHF and inadequate perfusion and oxygenation of all vital organs, including the heart muscle itself.
- Tissue hypoperfusion in turn leads to acidosis and electrolyte abnormalities, which have adverse effects on myocardial function and causes further myocardial depression and ischemia.

### ETIOLOGY

The etiology of cardiogenic shock stems from primary cardiac dysfunction. They may be categorized as follows:

- Structural heart disease (eg, single ventricle physiology, transposition of the great arteries, large VSD) (Refer to the Congenital Heart Disease topic.)
- Obstruction (eg, severe aortic stenosis, coarctation of the aorta, obstructive intracardiac mass, HOCM, postsurgical valvular or vascular restenosis)
- Dysrhythmias:
  - Heart block: Congenital or from toxic ingestion
  - Supraventricular tachycardia
  - Ventricular tachyarrhythmias (associated with long QT syndrome or other dysrhythmias, trauma, etc.)
- Impaired contractility:
  - Myocarditis
  - Cardiomyopathy
  - Metabolic disease (eg, Pompe disease, pyruvate dehydrogenase deficiency, myotonic dystrophy, carnitine deficiency, propionic acidemia)
  - Severe hypoglycemia
  - Adrenal insufficiency
  - Ischemia caused by:
    - Coronary artery aneurysms
    - Anomalous left coronary artery from the pulmonary artery (ALCAPA)
    - Acute MI
- Other:
  - Pulmonary HTN
  - Cardiogenic shock following intrapartum asphyxia (2):
    - Tricuspid insufficiency +/- mitral valve dysfunction (2° to papillary muscle infarct)
    - Right ventricle failure (2° to impaired coronary perfusion)
    - Left ventricle failure (with HTN initially, then hypotension)
  - Cardiac tamponade
  - Tension pneumothorax
  - Trauma (can induce tamponade, ruptured septum, pneumothorax, arrhythmia, etc.)
  - Ingestion/Overdose (eg, cocaine, calcium channel blockers, beta-blockers, tricyclic antidepressants)
  - Postsurgical complications:
    - Thrombosis (eg, obstructed pulmonary blood flow in Blalock-Taussig shunt)
    - Dysrhythmia (see above)

## DIAGNOSIS

### HISTORY

- The etiology of cardiogenic shock will differ greatly in the neonate and older infant/child.
- Birth history (gestational age, delivery problems, neonatal ICU stay, mechanical ventilation, etc.)
- Antecedent symptoms (acute vs. insidious onset, failure to thrive, etc.)
- History of underlying conditions or surgeries (cardiac disease, metabolic conditions, etc.)

- Problems feeding, sweating with feeds, respiratory distress with or without feeding
- History of possible ingestions or exposures
- Current medications
- History of recent infections
- Systemic symptoms: Fevers, fatigue, decreased urine output, etc.
- Family history
- Allergies to rule out distributive shock secondary to anaphylaxis

### PHYSICAL EXAM

- General appearance:
  - A neonate or child in cardiogenic shock will appear ill with decreased responsiveness, gray/clammy extremities, and respiratory distress or may be in complete cardiovascular collapse.
- Vital signs:
  - Tachycardia (except in heart block or late stages of shock)
  - Tachypnea:
    - If not present, assess for apnea and impending respiratory failure.
  - Fever (or even hypothermia) is also possible, especially in an infant.
  - Variable BP: Usually hypotension, but normal BP or even elevated BP in the initial stages of shock
  - Widened pulse pressure is common.
- Skin and extremity:
  - Capillary refill time may be delayed.
  - Cool/Clammy extremities may be present.
  - Bounding pulses may be felt in early stages of shock, followed by poor, thready pulses in late stages.
  - In a child with unknown history, chest wall scars suggest previous cardiac surgery.
- Respiratory:
  - Increased respiratory effort including grunting, flaring, or retractions
  - Agonal or irregular breathing
  - Patients most often have crackles on exam from pulmonary edema.
- Cardiac:
  - Jugular venous distension
  - Evidence of heave, lift, or thrill
  - Evaluation of heart sounds with splitting
  - Presence of murmur
- Other:
  - Hepatomegaly
  - Check for pulses and presence of radiofemoral delay

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

- Capillary glucose measurement is necessary, as hypoglycemia should be rapidly corrected.
- Arterial blood gas analysis to check for acidosis, oxygenation, and ventilatory status
- Serum lactate for degree of acidosis
- Comprehensive metabolic panel and ionized calcium level should be checked for electrolyte disturbances, which may be corrected:
  - High potassium and low sodium in an infant may suggest adrenal insufficiency.
  - Elevated BUN, creatinine, and LFTs may be a sign of end-organ damage.

- Coagulation studies and platelets to check for evidence of disseminated intravascular coagulation (DIC)
- Hemoglobin level to determine if blood should be given to maximize oxygenation
- Type and cross match in case of need for blood product transfusion

**Imaging**

- Chest radiograph to evaluate for cardiomegaly, pulmonary edema, pneumothorax
- Focused abdominal sonograph for trauma (FAST) exam if trauma or for evaluation of pericardial effusion or pneumothorax
- Echo to evaluate for obstructive lesions, shortening fraction, and volume status if suspecting structural or functional heart disease

**Diagnostic Procedures/Other**

ECG to look for evidence of dysrhythmias, ST changes, and low voltages

**DIFFERENTIAL DIAGNOSIS**

- Hypovolemic shock
- Distributive (septic) shock
- Anaphylaxis
- Inborn error of metabolism

**TREATMENT**

**PRE HOSPITAL**

- Assess and continuously reassess ABCs.
- Ensure airway patency, and administer supplemental oxygen as necessary.
- Bag-mask ventilation and sometimes endotracheal intubation may be necessary.
- Obtain access with an IV or intraosseous line.
- Administer fluid boluses with guidance from the base station.
- Administer CPR if necessary.
- Capillary glucose assessment and glucose supplementation as necessary

**ALERT**

In patients with cardiogenic shock, endotracheal intubation may lead to complete cardiovascular collapse. Intubate only if necessary, and be prepared to administer CPR if needed.

**INITIAL STABILIZATION/THERAPY**

- ABCs: See Pediatric Advanced Life Support (PALS) or Advanced Cardiac Life Support (ACLS) protocols for initial stabilization steps. The goal of initial treatment is to restore tissue perfusion both directly and by correcting the underlying etiology.
- General:
  - Provide optimal ventilation and oxygenation.
  - Connect the defibrillator, and administer CPR if needed.
  - Obtain venous access, preferably peripheral and central venous.
  - Obtain arterial access for more accurate continuous BP measurements.
- Improve preload:
  - Begin fluid resuscitation (cautiously if there is known heart disease or evidence of CHF).

- Improve contractility:
  - Correct hypoglycemia with a dextrose bolus.
  - Replace electrolytes as needed (specifically, calcium and potassium) to maximize myocardial function.
  - Correct acidosis with sodium bicarbonate or tromethamine (THAM).
  - Inotropic agents if needed
- Decrease afterload:
  - Administer vasodilators, avoiding hypotension.

**ALERT**

- In infants in whom heart disease is suspected, avoid administration of 100% oxygen during the resuscitation, as it can induce closure of the patent ductus arteriosus in neonates and cause overcirculation in the lungs of older infants.
- Use only enough supplemental oxygen delivery to achieve adequate oxygenation (3). See the Patent Ductus Arteriosus and Ductal Dependent Cardiac Emergencies topics.

**MEDICATION**

**First Line**

- Inotropic agents to increase cardiac output:
  - Dobutamine
  - Dopamine
  - Epinephrine
  - Isoproterenol (if heart rate is low)
- Antidysrhythmic agents for dysrhythmias:
  - Lidocaine
  - Digoxin
  - Adenosine
  - Esmolol
  - Amiodarone

**Second Line**

- Corticosteroids: First line if suspecting adrenal insufficiency
- Nitric oxide if pulmonary HTN
- Amrinone or milrinone should be used to decrease afterload in appropriate patients who have structural heart disease and/or poor contractility if the patients have an adequate BP.

**SURGERY/OTHER PROCEDURES**

- Pericardiocentesis may be necessary in cardiac tamponade.
- Thoracentesis if large pulmonary effusions are present or to resolve a pneumothorax or hemothorax

**DISPOSITION**

**Admission Criteria**

- Any patient who presents to the emergency department in cardiogenic shock warrants admission.
- Telemetry monitoring is necessary for any patient with a recent history of cardiogenic shock.
- Critical care admission criteria:
  - Need for ventilatory support
  - Need for inotropic support
  - Prostaglandin E2 infusion in an infant
  - High risk for cardiovascular collapse/dysrhythmia

**Issues for Referral**

Consultation from the emergency department as necessary:

- Cardiology for most cardiogenic shock cases
- Toxicology for ingestions or drug overdoses
- Metabolism if known metabolic disease
- Trauma surgery if traumatic etiology

**FOLLOW-UP**

**PROGNOSIS**

- Depends on the extent of tissue damage and the timing of intervention
- Some patients may require extracorporeal membrane oxygenation or a left ventricular assist device and may need cardiac transplantation in the future.

**COMPLICATIONS**

If there is prolonged tissue hypoperfusion and hypoxia, end-organ damage, such as to the kidney, liver, lung, and/or brain, may occur.

**REFERENCES**

1. De-Wahl Graneli A, Wennergren M, Sandberg K, et al. Impact of pulse oximetry screening on the detection of duct dependent congenital heart disease: A Swedish prospective screening study in 39,821 newborns. *BMJ*. 2009;338:a3037.
2. Lees MH, King DH. Cardiogenic shock in the neonate. *Pediatr Rev*. 1988;9(8):258–266.
3. Steinhorn RH. Evaluation and management of the cyanotic neonate. *Clin Pediatr Emerg Med*. 2008; 9(3):169–175.

**CODES**

ICD9  
785.51 Cardiogenic shock

**PEARLS AND PITFALLS**

- Pearls:
  - Initial treatment of shock should generally be the same regardless of etiology.
  - It is more important initially to start treatment and decrease further tissue injury than to determine the exact etiology.
- Pitfalls:
  - Performing invasive procedures on patients with cardiogenic shock (eg, intubation, line placement) may bring about complete cardiovascular collapse.
  - Not being prepared to administer CPR

# CARDIOMYOPATHY

Heather R. Saavedra  
Marc Gorelick

## BASICS

### DESCRIPTION

- Cardiomyopathy (CM) is a group of disorders of the myocardium associated with a decrease in cardiac function.
- 3 main types:
  - Dilated cardiomyopathy (DCM): Characterized by left ventricular (LV) dilation and reduced contractility
  - Hypertrophic cardiomyopathy (HCM): Characterized by a nondilated left ventricle with disproportionate thickening of the ventricular septum. Systolic function is normal or increased.
  - Restrictive cardiomyopathy (RCM): Characterized by abnormal diastolic filling with normal or decreased diastolic volume of the ventricle

### EPIDEMIOLOGY

- 1/100,000 children in the U.S. has diagnosed CM.
- 1,000–5,000 new cases per year
- Most new diagnoses are in infants and children <12 yr of age.

### RISK FACTORS

- Family history:
  - DCM: 20–30% have a family history of DCM.
  - HCM: 50–60% have a family history of HCM.
- Sudden death risk factors occur in 10–20% of all patients with HCM:
  - A history of cardiac arrest or spontaneous, sustained ventricular tachycardia
  - A family history of early sudden death (<45 yr in age) related to the disease
  - Syncopal episodes, especially during exercise, when repeated, or associated with arrhythmia on Holter monitor
  - Multiple, repeated episodes of nonsustained ventricular tachycardia
  - A drop in BP, or inability to increase it and maintain it at high levels (>25 mm Hg above resting level) during exercise testing
  - Extreme LV hypertrophy, especially interventricular septum thickness >30 mm

### PATHOPHYSIOLOGY

- Familial DCM is due to defects in the cytoskeleton genes.
- Inheritance: X-linked, autosomal dominant, or autosomal recessive
- Familial HCM is a disease of the sarcomere, involving mutations in at least 7 different genes encoding proteins of the myofibrillar apparatus.

### ETIOLOGY

- The majority of cases of DCM are idiopathic.
- Known causes of DCM include LV outflow tract obstruction, genetic conditions such as X-linked, neuromuscular abnormalities, exposure to anthracyclines, connective tissue disorders, immunologic abnormalities, Kawasaki-related coronary disease, and myocarditis.
- 1/3 of childhood HCM cases are associated with Noonan syndrome.

- HCM may result from genetic or metabolic disorders and contractile protein abnormalities.
- Most RCM are idiopathic, but known causes include sarcoidosis, amyloidosis, Hurler syndrome, Gaucher syndrome, hypereosinophilic syndromes, radiation exposure, and anthracycline toxicity.

## DIAGNOSIS

### HISTORY

- Symptoms may be absent, mild, or severe.
- In infants, common presenting symptoms include poor weight gain, difficulty feeding, diaphoresis, excessive fussiness, or lethargy.
- In older children or adolescents, symptoms may also include shortness of breath, orthopnea, paroxysmal nocturnal dyspnea, dizziness, fatigue, weakness, chest pain, exercise intolerance, syncope or presyncope, and palpitations.
- Patients with predominantly right-sided failure may present with abdominal pain and/or vomiting.
- Inquire about family history of CM, sudden cardiac events, or unexplained deaths.

### PHYSICAL EXAM

- Presentation ranges from asymptomatic to cardiovascular collapse.
- Presenting signs may include tachycardia, tachypnea, hypotension, cool and poorly perfused extremities, thready pulses, heart murmur, rales, hepatomegaly, jugular venous distention, 3rd and 4th heart sounds, peripheral edema, and ascites.
- In patients with LV outflow tract obstruction, there may be a significant murmur noted on exam.
- In patients without obstruction, there may be no murmur when the patient is at rest, but the patient may have an increased LV apical impulse or 4th heart sound.
- Murmur in HCM may increase with Valsalva maneuver or rising from squatting position:
  - The same murmur may be decreased with squatting from a standing position and with passive leg elevation.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

- Initial lab evaluation should include CBC, electrolytes, transaminases, basic natriuretic peptide (BNP), and blood gas:
  - Heart disease that causes significant volume or pressure overload of either ventricle has elevated BNP and NT-pro BNP levels.
  - BNP can help to differentiate cardiac from pulmonary causes in infants with respiratory distress.
  - Blood gas analysis allows evaluation of oxygenation, ventilation, and perfusion.
- With initial presentation in infants, it is important to investigate the etiology of the CM by obtaining serum amino acids, urine organic acids and amino acids, lactate, and pyruvate.
- Other tests to evaluate the etiology include creatine kinase, carnitine, and acylcarnitine levels.

### Imaging

- CXR may reveal cardiomegaly, pulmonary venous congestion, or pulmonary edema in HCM.
- In HCM, CXR may reveal cardiomegaly with LV contour.
- In RCM, CXR may reveal cardiomegaly with atrial enlargement and pulmonary venous congestion.
- CT or MRI may be done to provide a 3D image of the heart structures.

### Diagnostic Procedures/Other

- ECG may demonstrate atrial or ventricular enlargement, dysrhythmia, or ischemic changes.
- Echo with Doppler to evaluate cardiac structure and function:
  - DCM: Echo may reveal the dilated and poorly functional LV and help to evaluate structural abnormalities.
  - HCM: Echo will evaluate the form of hypertrophy present—diffuse and symmetric, asymmetric septal, or apical:
    - Echo in HCM will also estimate the degree of LV outflow tract obstruction and the integrity of the mitral valve.
  - RCM: Echo usually reveals marked atrial enlargement with normal LV end diastolic dimensions as well as atrioventricular valve dysfunction, ventricular hypertrophy, and occasionally atrial thrombi.
- Cardiac catheterization may be necessary to further evaluate LV outflow tract gradients and hemodynamics and to facilitate endomyocardial biopsy.
- Electrophysiology studies may be done to determine susceptibility to arrhythmias and the need for a pacemaker or defibrillator.
- A 24-hr Holter monitor may provide additional information regarding dysrhythmias.

### Pathological Findings

- In RCM, endomyocardial biopsy may reveal a specific cause such as myocyte hypertrophy, interstitial fibrosis, myocytolysis, and infiltrative processes.
- Biopsy is more useful in adults than children.

### DIFFERENTIAL DIAGNOSIS

- In patients who present in extremis, the differential includes sepsis, ingestion, pericarditis, myocarditis, cardiac tamponade, respiratory failure, and trauma.
- Other differentials may include aortic stenosis, chronic anemia, endocarditis, stimulant toxicity, hypothyroidism, and hyperthyroidism.

## TREATMENT

### PRE HOSPITAL

Assess and stabilize airway, breathing, and circulation.

### INITIAL STABILIZATION/THERAPY

- Assess and stabilize airway, breathing, and circulation.
- Immediate aggressive therapy for those who present with severe symptoms or in cardiovascular collapse

**MEDICATION**

- Cardiovascular support:
  - IV inotropes that do not increase afterload, titrating to effect:
    - Milrinone 50–75  $\mu\text{g}/\text{kg}$  loading dose over 15–60 min followed by a continuous infusion of 0.25–0.75  $\mu\text{g}/\text{kg}/\text{min}$
    - Dobutamine 5–15  $\mu\text{g}/\text{kg}/\text{min}$
  - If hypotensive, the patient may require alpha-adrenergic support, titrating to effect:
    - Epinephrine 0.1–1  $\mu\text{g}/\text{kg}/\text{min}$
    - Dopamine 10–15  $\mu\text{g}/\text{kg}/\text{min}$
- Treatment for DCM:
  - Angiotensin-converting enzyme inhibitors: Enalapril or captopril
  - Diuretics: Furosemide or spironolactone is used to reduce afterload and to relieve venous congestion.
  - Warfarin for anticoagulation due to diminished risk of thrombus
  - Digoxin or amiodarone to prevent arrhythmias
- Treatment for HCM with obstruction:
  - Beta-blockers and calcium channel blockers are used in the setting of moderate to severe obstruction:
    - Beta-blockers decrease outflow obstruction and increase ventricular compliance.
    - Calcium channel blockers improve diastolic filling by improving diastolic relaxation and decreasing outflow gradient due to depression of cardiac contractility.
  - Diuretics and digoxin are not used, as they can worsen the obstruction of blood flow out of the heart.
  - Amiodarone: Children, 5 mg/kg IV load over 30 min followed by 5  $\mu\text{g}/\text{kg}/\text{min}$  (max dose 15  $\mu\text{g}/\text{kg}/\text{min}$ ); adults, 150 mg IV load over 10 min followed by infusion 0.5 mg/min:
    - Used to prevent ventricular arrhythmias
- Treatment of RCM:
  - Patients are at high risk for blood clots and often need heparin or warfarin for anticoagulation.
  - Diuretics to relieve venous congestion
  - Beta-blockers for their negative inotropic and chronotropic effects

**SURGERY/OTHER PROCEDURES**

- Extracorporeal membrane oxygenation may be required for patients who cannot be stabilized with maximal pharmacologic support.
- In HCM, surgical septal myectomy is recommended in some cases of symptomatic children with obstruction to relieve the symptoms of heart failure:
  - Myectomy does not prevent arrhythmia or sudden death.
- HCM patients may also benefit from mitral valve replacement.
- Pacemakers may be necessary to monitor and stabilize slow heart rates in patients with CM.
- An automatic implantable cardioverter defibrillator may benefit patients with a history of severe syncope and aborted cardiac arrest.
- Radiofrequency ablation of conduction defects may be needed to prevent dysrhythmias.
- ~20% of symptomatic DCM patients require cardiac transplant within 2 yr of diagnosis:
  - 1–2-yr survival rate of 80% after transplant

**DISPOSITION**

- Patients who are hemodynamically stable and without signs of heart failure or rhythm disturbance may be admitted to an inpatient ward with cardiac monitoring.
- Critical care admission criteria:
  - Hemodynamic instability, significant symptoms, signs of heart failure, or dysrhythmia

**Discharge Criteria**

Patients may be discharged home with close follow-up with a pediatric cardiologist if the following conditions are met:

- After stabilization and improvement of the signs/symptoms of failure
- Following a complete evaluation of arrhythmic potential
- After initiation of drugs for long-term management

**Issues for Referral**

- Cardiology consultation as early as possible
- Other specialists such as geneticists, endocrinologists, neurologists, and immunologists may be helpful in determining the etiology and for guiding treatment of underlying disease.

**FOLLOW-UP****FOLLOW-UP RECOMMENDATIONS**

Activity:

- In patients with HCM: Strenuous activity should be avoided as well as anaerobic exercise such as weightlifting and high-level competitive sports.
- Competitive-level sports are not advised if any of the following are present:
  - Significant outflow gradient
  - Significant ventricular or supraventricular arrhythmia
  - Marked LV hypertrophy OR
  - History of sudden death in relatives with HCM

**Patient Monitoring**

- Initially after discharge, patients will be followed closely by a pediatric cardiologist weekly to biweekly to monitor medications and symptoms.
- After stabilization, follow-up should be every 3–12 mo by a pediatric cardiologist.

**PROGNOSIS**

- Mortality for children with HCM is 1% per year.
- Pediatric 5-yr survival with HCM is 85–95%.
- Pediatric 5-yr survival with DCM is 40–50%.
- The 2-yr survival rate after presentation of RCM is 44–50%.
- Prognosis is poor for infants who present with symptomatic HCM. Many of these patients do not survive to adolescence.

**COMPLICATIONS**

- In DCM and RCM, blood clots may form in the heart due to abnormal blood flow.
- 10% of HCM patients will have an arrhythmia.
- Patients with CM are more susceptible to endocarditis, which typically occurs after a dental procedure or surgical procedure involving the GI or urinary tracts:
  - These patients generally require prophylactic antibiotics prior to those procedures.

- <http://www.pcmregistry.org>

**CODES****ICD9**

- 425.4 Other primary cardiomyopathies
- 425.3 Endocardial fibroelastosis

**PEARLS AND PITFALLS**

- Do not forget to ask about the family history, as there is a strong familial component.
- The majority of cases associated with genetic syndromes present in infancy and fall into 4 categories:
  - Inborn errors of metabolism
  - Malformations
  - Neuromuscular disorders
  - Familial isolated cardiomyopathic disorders

# CARPAL TUNNEL SYNDROME

Jennifer Eng Lunt  
Justin LaCorte

## BASICS

### DESCRIPTION

- Carpal tunnel syndrome (CTS) is a common nerve entrapment disorder of adults but is uncommon in childhood.
- The carpal tunnel is bound by the carpal bones dorsally, the transverse carpal ligament on the palmar surface, and encased by the flexor retinaculum.
- The tunnel contains the median nerve, flexor digitorum profundus, flexor digitorum superficialis, and flexor pollicis longus.
- Compression of the median nerve causes symptoms of numbness, tingling, pain, and weakness.

### EPIDEMIOLOGY

#### Incidence

- CTS is rarely seen in children.
- Most cases are seen with injuries of the wrist or in lysosomal storage disorders.

#### Prevalence

- <200 pediatric cases have been reported in the literature since 1989.
- Women are found to be twice as likely to be affected as men.

### RISK FACTORS

- In children, genetic predisposition and history of lysosomal storage disease may increase risk.
- In older children, overuse, sports, or wrist-related injuries may also increase risk.

### GENERAL PREVENTION

- Avoidance of exacerbating symptoms dependent on the individual's causative factors
- Cessation of repetitive wrist movements
- Wrist support

### PATHOPHYSIOLOGY

- The exact pathophysiology is unclear.
- Symptoms may occur due to pressure within the carpal tunnel during flexion and extension along with demyelination, edema, venous congestion, or vascular sclerosis leading to compression of the median nerve.

### ETIOLOGY

- Considerations in children:
  - Trauma
  - Lysosomal storage disorders (eg, mucopolysaccharidosis)
  - Hamartoma of the median nerve
  - Anomalous flexor digitorum superficialis
  - Hemophilia with hematoma
  - Hereditary
  - Idiopathic

- Considerations in older children:
  - Repetitive motion
  - Sports-related motions or injuries
  - Video games
  - Trauma
  - Pregnancy or use of oral contraceptives
  - Mass lesions that compress the median nerve
  - Bony abnormalities (osteophytes)
  - Rheumatoid arthritis
  - Endocrine disorders: Hypothyroidism, diabetes mellitus, acromegaly
  - Chronic hemodialysis
  - Idiopathic

### COMMONLY ASSOCIATED CONDITIONS

- Mucopolysaccharidosis
- In adolescents, associated conditions that have been reported include:
  - Colles fracture or other wrist trauma
  - Rheumatoid arthritis or other inflammatory rheumatic disease
  - Diabetes mellitus
  - Osteoarthritis of the wrist
  - Pregnancy
  - Myxedema
  - Acromegaly
  - Amyloidosis
  - Hepatic disease
  - Fibromyalgia
  - Tumors

## DIAGNOSIS

### HISTORY

- In children, a history may be difficult to obtain due to the lack of ability to communicate symptoms.
- Children often present differently than adults or adolescents.
- Children may present with difficulty with fine motor tasks.
- Children present more often with bilateral disease.
- Common symptoms include:
  - Numbness/Paresthesia in median nerve distribution: Thumb, index, middle, and radial aspect of the ring finger
  - Pain that is exacerbated by:
    - Repetitive wrist movement
    - Activities in which the wrist is flexed or extended
  - Pain in the wrist or hand, sometimes radiating to the elbow, forearm, or shoulder
- Often worse at night, relieved by "shaking out" the hand:
  - Flick sign: Shaking or flicking one's hands for relief during maximal symptoms:
    - Sensitivity 47% and specificity 62%

### PHYSICAL EXAM

- Children may have:
  - Thenar atrophy
  - Decreased sweating
  - Weakness
  - Claw hand deformity
- Adolescents and adults may present more commonly with thumb weakness manifested by difficulty with writing, pincer grasp, or holding small utensils.
- Specific physical exam tests:
  - Phalen sign: Hyperflexion of the wrist for 60 sec may elicit paresthesia in the median nerve distribution:
    - Sensitivity 68% and specificity 73%
  - Tinel sign: Gentle tapping over the median nerve at the wrist produces tingling in the fingers in the median nerve distribution:
    - Sensitivity 50% and specificity 77%
  - Manual carpal compression test: Applying pressure over the transverse carpal ligament leads to paresthesias within 30 sec of applying pressure:
    - Sensitivity 64% and specificity 83%
  - Sensory testing with 2-point discrimination or tactile testing

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

- Not indicated in most pediatric cases
- There are no known lab studies specific for the diagnosis.
- In older children and adolescents, lab tests to rule out diseases or conditions causing CTS may be helpful such as rheumatoid factor, antinuclear antibody, pregnancy tests, and genetic testing.

#### Imaging

- Conventional radiology may be useful if suspicious of fracture or bony abnormality.
- MRI is helpful to confirm the diagnosis and to examine the anatomy within the canal.
- US may be useful in evaluating for synovitis.

#### Diagnostic Procedures/Other

Electromyographic and nerve conduction studies help to confirm the diagnosis of CTS:

- Sensitivity 85% and specificity 95%

### DIFFERENTIAL DIAGNOSIS

- See Commonly Associated Conditions.
- Tendinitis
- Tenosynovitis
- Median nerve neuropathy
- Brachial plexus injuries
- Arthritis

## TREATMENT

### INITIAL STABILIZATION/THERAPY

- Splint the wrist in neutral position (0 degrees).
- Avoidance of repetitive wrist movement
- Wrist splint to be worn at night until follow-up
- Apply heat to involved wrists:
  - Heating pad
  - Hot water bottle
  - Low-level heat wraps
- Motion and tendon-gliding or nerve-gliding exercises

### MEDICATION

#### First Line

- NSAIDs:
  - No significant long-term benefit to using NSAIDs
  - Ibuprofen 10 mg/kg/dose PO/IV q6h PRN
  - Ketorolac 0.5 mg/kg IV/IM q6h PRN
  - Naproxen 5 mg/kg PO q8h PRN
- Acetaminophen 15 mg/kg/dose PO/PR q4h PRN

#### Second Line

- Prednisone 1 mg/kg/dose PO b.i.d. if conservative measures fail
- Referral to a hand surgeon for methylprednisone injections

### COMPLEMENTARY & ALTERNATIVE THERAPIES

- Conservative therapy for mild to moderate symptoms
- Application of a customized or prefabricated wrist splint
- Combined therapy found to be better than any single modality:
  - Splinting
  - Stretching exercises
  - Steroid injections
- Complementary CTS treatments:
  - Yoga
  - Occupational therapy
  - Nerve-gliding maneuvers
  - Magnetic therapy
  - Myofascial massage
- US

### SURGERY/OTHER PROCEDURES

- May need referral to a hand surgeon for consideration of surgical release of the transverse carpal ligament:
  - Definitive therapy for patients with moderate to severe symptoms
  - Surgery may be open or endoscopic with similar efficacy:
    - Endoscopic surgery has been shown to result in earlier return to daily activities and fewer wound problems.
    - Possible disadvantages may include higher complication rates and cost.
- Surgery for CTS has a long-term success rate >75%.
- Surgery for children with CTS and associated mucopolysaccharidosis is definitive and shown to be effective.

### DISPOSITION

#### Admission Criteria

Patients are almost always discharged.

#### Discharge Criteria

Patients and families should have an understanding of the etiology, management options, and proper follow-up with a primary care physician prior to discharge from the emergency department.

#### Issues for Referral

- Cases refractory to conservative management should be referred to hand surgery or a rehabilitation medicine specialist.
- Referral to occupational medicine for ergometric testing if caused by repetitive motion
- Typical emergency department management does not consist of steroid injections:
  - Such practices should be referred to hand surgery or a rehabilitation medicine specialist.

## FOLLOW-UP

### FOLLOW-UP RECOMMENDATIONS

- Discharge instructions and medications:
  - Discharge home with appropriate referral to either the patient's primary care provider or a specialist in hand surgery or to occupational or rehabilitation medicine.
- Activity:
  - Avoid activity that may worsen symptoms.

### PROGNOSIS

- Prognosis usually is excellent.
- Refractory cases may require surgery:
  - Prognosis following surgery has been found to be good.

### COMPLICATIONS

- Postoperative complications or infections after surgery
- Chronic hand pain
- Chronic hand weakness and numbness

### ADDITIONAL READING

- Yuen A, Dowling G, Johnstone B, et al. Carpal tunnel syndrome in children with mucopolysaccharidosis. *J Child Neurol*. 2007;22(3):260–263.

### ICD-9 CODES

354.0 Carpal tunnel syndrome

### PEARLS AND PITFALLS

- Uncommon in young children
- Most likely associated in children with history of mucopolysaccharidosis, trauma, or repetitive use injuries
- Emergency department treatment includes conservative therapy and splinting:
  - Refer to hand surgery or an occupational or rehabilitation medicine specialist for refractory cases.

# CAT SCRATCH DISEASE

Kerry Caperell  
Raymond Pitetti

## BASICS

### DESCRIPTION

- Cat scratch disease is caused by infection from the intracellular bacteria *Bartonella henselae*.
- Usually seen after kitten or cat bite or scratch
- Causes lymphadenopathy that is most often localized or regional

### EPIDEMIOLOGY

#### Incidence

- Estimated 9.3 U.S. cases per 100,000 people per year (1)
- 55% of these are in children <18 yr of age.
- In the U.S., cat scratch disease is the most common cause of chronic unilateral regional lymphadenitis in children.

### RISK FACTORS

- Exposure to cats, particularly kittens infested with fleas
- More common in the fall and winter
- More common in warm and humid climates

### GENERAL PREVENTION

- Immunocompromised children should avoid contact with cats known to scratch or bite.
- Immunocompromised children should immediately wash all cat bites and scratches with soap and water.

### PATHOPHYSIOLOGY

- Infection causes the formation of a papule at the site of the bite or scratch.
- Hyperplasia and infection of the lymph nodes occurs; microabscesses form and may become confluent leading to pus-filled sinuses. These may drain.
- The liver, spleen, eyes, and CNS can also be affected via hematologic transmission.

### ETIOLOGY

Caused by the inoculation of *B. henselae* bacteria via a cat bite or scratch

## DIAGNOSIS

### HISTORY

- Children usually present with axillary or cervical lymphadenopathy (2).
- Systemic symptoms:
  - Up to 50% of children will be febrile.
  - Malaise or anorexia
- There is often no history of a cat bite or scratch, but history of cat exposure is almost always present.
- History of a papular lesion forming 1–2 wk following a cat bite or scratch
- History of lymphadenopathy occurring up to several weeks later

### PHYSICAL EXAM

- A brown to red papule can be seen at the site of the bite or scratch.
- Affected lymph nodes are usually axillary or cervical, but submandibular, auricular, epitrochlear, as well as lower limb nodes, may be inflamed:
  - The arm and neck are usually involved, as the site of inoculation is usually the hand.
  - Other inoculation sites will have lymphadenopathy in the area of regional lymph node drainage.
  - These nodes are enlarged (1–5 cm or more) and nearly always tender.
  - Most nodes are warm and erythematous.
  - 10–15% of nodes suppurate.
- Children with visceral involvement (bacillary peliosis) may have hepatosplenomegaly.
- Children with vascular involvement (bacillary angiomatosis) have vascular proliferative skin or subcutaneous nodules.
- Can rarely see ocular manifestations such as conjunctivitis or neuroretinitis.
- Children very rarely can have CNS involvement including encephalopathy, ataxia, or transverse myelitis.

## DIAGNOSTIC TESTS & INTERPRETATION

### Lab

- Serologic tests for *B. henselae* are commercially available and are diagnostic in the appropriate clinical setting:
  - These may be indirect fluorescence antibody, enzyme immunoassay, or PCR tests.
- An elevated neutrophil count, ESR, or C-reactive protein may indicate disseminated disease.
- Cultures for *B. henselae* are of limited value because the organism can take several weeks to grow.

### Imaging

Abdominal US, contrast CT scan, or MRI are rarely indicated but can be used to evaluate the liver or spleen for microabscesses.

### Diagnostic Procedures/Other

Biopsy of an affected lymph node is only rarely indicated in cases where the diagnosis is in question.

### Pathological Findings

- Biopsied tissue will show stellate granulomas and microabscesses.
- Warthin-Starry stain will tint the bacteria.

## DIFFERENTIAL DIAGNOSIS

- Lymphadenopathy
- Lymphadenitis due to typical suppurative bacteria, such as *Streptococcus* and *Staphylococcus*
- Mycobacterial lymph node infection
- Malignancy
- Toxoplasmosis
- HIV, Epstein-Barr virus, cytomegalovirus
- Other bacterial causes: *Nocardia* infection, tularemia, cutaneous anthrax, brucellosis, sarcoidosis, and bubonic plague

## TREATMENT

### MEDICATION

#### First Line

- In uncomplicated cases in immunocompetent hosts, cat scratch disease is a self-limited illness requiring only supportive care.
  - In uncomplicated cases, there is controversy over the utility of treatment with azithromycin (3).
- Azithromycin:
  - Dose 10 mg/kg/dose on day 1 followed by 5 mg/kg/dose on days 2–5; adult dose 500 mg day 1 followed by 250 mg PO days 2–5
  - Patients with more disseminated disease may benefit from treatment with azithromycin.
- Immunocompromised patients always require antimicrobial therapy.
- In the immunocompromised child, erythromycin, rifampin, doxycycline, or gentamicin should be used alone or in combination.
- Analgesics are indicated for pain due to lymphadenopathy.
- NSAIDs:
  - Ibuprofen 10 mg/kg/dose PO/IV q6h PRN
  - Ketorolac 0.5 mg/kg IV/IM q6h PRN
  - Naproxen 5 mg/kg PO q8h PRN
- Acetaminophen 15 mg/kg/dose PO/PR q4h PRN

#### Second Line

Trimethoprim/sulfamethoxazole (TMP/SMZ) or ciprofloxacin may also be effective:

- TMP/SMZ: 6–12 mg TMP/kg/day PO q12h; adult dose 160 mg TMP/800 mg SMZ b.i.d. × 7 days

## DISPOSITION

### Admission Criteria

- Immunocompromised children usually need to be hospitalized for observation and therapy.
- Children with bacillary peliosis, bacillary angiomatosis, or complicated or disseminated disease often need to be hospitalized and receive parenteral antibiotics.

### Discharge Criteria

- Most immunocompetent patients with suspected cat scratch disease can be safely discharged.
- Patients with disseminated disease and immunocompromised patients should be admitted for antibiotic therapy.

## FOLLOW-UP

### FOLLOW-UP RECOMMENDATIONS

Discharge instructions and medications:

- Patients should be followed closely by their primary care provider.
- Many clinicians elect to treat with a 5-day course of azithromycin.

### PROGNOSIS

- Uncomplicated cases gradually resolve over several months without treatment.
- Even in immunocompromised hosts, the prognosis is good if the disease is treated adequately.

### COMPLICATIONS

- Visceral organ involvement:
  - Hepatic
  - Splenic
  - Mesenteric adenitis
- Rare complications:
  - Encephalopathy
  - Optic neuritis
  - Erythema nodosum
  - Osteolytic bone lesions
  - Osteomyelitis
  - Transverse myelitis
  - Guillain-Barré syndrome

Fever of Unknown Origin

## CODES

### ICD9

078.3 Cat-scratch disease

## PEARLS AND PITFALLS

- Children with catscratch disease often give no history of a cat scratch or bite.
- Regional lymphadenitis is the most common sign.
- Cat scratch disease is usually a self-limited illness requiring no antibiotic therapy.
- Cat scratch disease can be an etiology for fever of unknown origin.

# CAUDA EQUINA SYNDROME

Kerry Caperell  
Raymond Pitetti

## BASICS

### DESCRIPTION

- Cauda equina syndrome is a rare condition that results from the compression of the nerve roots of the spinal cord distal to L1.
  - The cauda equina, or “horsetail,” represents the lower end of the spinal cord and contains the nerve roots from L1–L5 and S1–S5.
- Compression of these nerve roots manifests as one or more of the following:
  - Weakness of the lower extremities
  - Saddle anesthesia
  - Bowel or bladder dysfunction
  - Sexual dysfunction

### EPIDEMIOLOGY

- Uncommon with unclear incidence
- Usually reported as a case report

### RISK FACTORS

- History of cancer
- History of low back trauma

### PATHOPHYSIOLOGY

- Compression of some or all of the nerve roots from L1–S5 by any lesion (see below)
- These nerve roots are particularly susceptible to injury since they have a poorly developed epineurium.

### ETIOLOGY

- Midline lumbar disc herniation
- Meningitis
- Space-occupying lesions in the spinal cord:
  - Epidural hematoma
  - Abscess
  - Tumor
- Ankylosing spondylitis
- Paget disease
- Inferior vena cava thrombosis
- Lymphoma
- Sarcoidosis
- Trauma (blunt or penetrating):
  - Can rarely be related to spinal anesthesia or lumbar puncture

### COMMONLY ASSOCIATED CONDITIONS

- Meningocele
- Lumbar vertebral subluxation
- Neoplasia in the lumbosacral area:
  - Can be primary or metastatic
  - Often Ewing’s sarcoma or neuroblastoma
- Epidural hematoma or abscess

## DIAGNOSIS

### HISTORY

- Pain in the lumbar region
- Pain that radiates down both legs in the sciatic distribution
- Numbness or weakness in both legs that is often progressive
- Urinary retention
- Rectal sphincter dysfunction
- Altered urinary sensation
- Altered perineal sensation
- Urinary frequency
- Urinary incontinence
- Sexual dysfunction

### PHYSICAL EXAM

- Sensory deficit in a saddle distribution
- Sensory deficit in the perineal area
- Often asymmetric flaccid paralysis of the lower extremities
- Decreased rectal sphincter tone
- Positive straight leg raise test
- Reflex abnormalities: Loss or diminution

### DIAGNOSTIC TESTS & INTERPRETATION

#### Imaging

- MRI is the preferred imaging modality.
- If concerned, MRI should be performed emergently.
- CT scan is inferior for diagnosing cauda equina syndrome:
  - However, it is the modality of choice if fracture is a concern.

**Diagnostic Procedures/Other**

Catheterization of bladder: Post-void residual bladder volume is usually high.

**DIFFERENTIAL DIAGNOSIS**

- Musculoskeletal back pain
- Herniated disc
- Fractured vertebra
- Spondylolisthesis
- Conus medullaris syndrome
- Functional back pain
- Severe constipation

**TREATMENT****PRE HOSPITAL**

- If due to a traumatic injury, immobilize the spine.
- Stabilize acute life-threatening conditions.

**INITIAL STABILIZATION/THERAPY**

- No proven medical treatment exists.
- Therapy is directed at underlying cause.
- Appropriate pain management
- If sudden in onset, surgical decompression is required emergently (see below).

**MEDICATION****First Line**

Analgesia should be given as appropriate:

- Morphine 0.1 mg/kg IV/IM/SC q2h PRN:
  - Initial morphine dose of 0.1 mg/kg IV/SC may be repeated q15–20min until pain is controlled, then q2h PRN.

**Second Line**

The use of steroid is considered controversial and should be administered only under the guidance of appropriate consultants.

**SURGERY/OTHER PROCEDURES**

- In cases of mechanical compression, immediate transfer to the operating room for emergent surgical decompression of the area is indicated.
- Earlier decompression maximizes preservation of neurologic function.

**DISPOSITION****Admission Criteria**

All patients with cauda equina syndrome should be admitted to a medical center that can provide definitive care.

**Discharge Criteria**

Not applicable

**Issues for Referral**

- As soon as the diagnosis of cauda equina syndrome is suspected, the patient should be transferred to a center with pediatric MRI capability.
- When the diagnosis is confirmed, the patient should be transferred to a center with pediatric spine surgeons capable of performing decompression surgery.
- Early neurosurgical, neurologic, and/or orthopedic consultations are recommended.

**FOLLOW-UP****PROGNOSIS**

- Early diagnosis and surgical decompression are the factors most identified with a favorable outcome:
  - In general, the longer the interval of time before treatment, the greater the damage caused to the nerve(s).
- Morbidity is variable and dependent on the etiology of the syndrome.
- Long-term sequelae include:
  - Bladder dysfunction
  - Leg weakness
  - Decubitus ulcers
  - Venous thromboemboli

**COMPLICATIONS**

If decompression is delayed, residual weakness, sensory deficits, bladder/bowel dysfunction, and sexual dysfunction can be seen.

**ADDITIONAL READING**

- Fraser S, Roberts L, Murphy E. Cauda equina syndrome: A literature review of its definition and clinical presentation. *Arch Phys Med Rehabil.* 2009;90:1964–1968.
- Mauffrey C, Randhawa K, Lewis C, et al. Cauda equina syndrome: An anatomically driven review. *Br J Hosp Med.* 2008;69:344–347.
- Podnar S, Trsinar B, Vodusek DB. Bladder dysfunction in patients with cauda equina lesions. *NeuroUrol Urodyn.* 2006;25:23–31.

**CODES****ICD9**

- 344.60 Cauda equina syndrome without mention of neurogenic bladder
- 344.61 Cauda equina syndrome with neurogenic bladder

**PEARLS AND PITFALLS**

- Bladder retention is one of the hallmarks of cauda equina syndrome, and the syndrome is rare in the absence of bladder retention.
- MRI is the diagnostic test of choice.
- When suspected, patients with cauda equina syndrome should be transferred to a center that can provide a definitive diagnosis and care.

# CAUSTIC EXPOSURE

Kristopher Hunt

Robert J. Hoffman

## BASICS

### DESCRIPTION

- Caustic exposures cause histologic damage on contact with tissue.
- The most familiar types are acids and alkali:
  - Others are desiccants, vesicants, and protoplasmic poisons.
- Caustics are often found in cleaning products.
- Acids include hydrochloric acid, sulfuric acid, and hydrofluoric acid (HF).
- Alkali include ammonia, calcium hydroxide, sodium hydroxide, and household bleach.
- HF poses a specific problem because it is a weak acid, allowing it to remain in an undissociated state and penetrate skin:
  - Contact with a body surface area as small as 2% with concentrated HF may be fatal.

### EPIDEMIOLOGY

#### Incidence

There are > 100,000 reported exposures to caustic agents annually in the U.S.:

- Household bleach is the most common.

### GENERAL PREVENTION

Keep poisons inaccessible to children.

### PATHOPHYSIOLOGY

- Acids and alkali exert damage as a result of proton donation or acceptance, respectively.
- Acids cause coagulation necrosis; the upper layer of damaged tissue forms a leathery eschar, preventing deeper tissue penetration:
  - HF is a unique caustic capable of causing severe systemic toxicity and dysrhythmias due to both depletion of calcium and magnesium and hyperkalemia.
  - Acids may cause damage to other organs, such as the spleen, liver, and biliary tree after being absorbed and distributed systemically.
- Alkalis cause liquefaction necrosis, which is more extensive and severe because saponification and protein disruption allow the caustic to penetrate through layers of tissue.
- Extent of injury after caustic exposure is mostly determined by pH, particularly if the substance is below pH 2 or > 12:
  - Concentration is also a determinant of injury, with more severe injuries resulting from more concentrated solutions.
  - Food in the stomach as well as vomiting may diminish the effect of the caustic ingestion.
  - Tissue penetration, duration of contact, and volume of caustic are other factors of injury.
  - For ocular exposures, alkaline agents have a potential to injure the eye to a greater extent at a lower concentration largely due to the inability of tears to buffer alkaline substances.

### ETIOLOGY

The following routes of exposure:

- Inhalational
- Dermal
- Ocular
- Oral
- GI

## DIAGNOSIS

### HISTORY

- Dermal:
  - Patients may or may not know of a specific caustic that has been exposed on skin.
  - HF exposure will present with a complaint of severe pain, discordant with physical exam findings. Burns with a benign skin appearance may be life threatening.
  - Onset of pain is directly related to concentration of HF:
    - Very concentrated HF > 40–50% causes immediate symptoms, weak HF < 10% solution typically causes symptoms only many hours (6–14) after exposure.
- Ocular:
  - Patients typically have severe pain.
  - Lack of pain may be the result of a severe burn.
- Inhalational:
  - Upper airway irritation, chest pain, or dyspnea after aerosolized caustic exposure
- Ingested:
  - Suicidal intent, more prevalent in adolescent ingestions, may predict significant injury.
  - Patients may complain of a variety of symptoms following caustic ingestion, and there may be a great disparity between symptomatology and severity of injury.
  - Pain complaints may be referred to the oropharynx, chest, or abdomen. These may include dysphagia, odynophagia, drooling, abdominal pain, chest pain, or vomiting.
  - Ominous symptoms: Constitutional symptoms or systemic complaints such as dizziness, listlessness, fever, chills, HA, or syncope
  - Weeks after ingestion, dysphagia and vomiting may result from stricture formation.

### PHYSICAL EXAM

- Dermal:
  - Patients will have localized pain and apparent burns.
  - HF exposure may have minimal or no apparent skin lesions:
    - Severe pain out of proportion related to the physical exam is very common with HF.
- Ocular:
  - Diminished visual acuity and clouding of the cornea are poor prognostic signs.
- Inhalational:
  - Patients may present with relative degrees of tachypnea, stridor, dysphonia, aphonia, bronchospasm, hypoxia, hypercarbia, or respiratory arrest depending on the involved caustic exposure.

- Ingested:
  - Typical findings include burns to the lips and oropharynx.
  - Patients may exhibit “dribble marks”—burns to the chin or chest from dribbled or spilled caustic liquid.
  - Dysphonia, aphonia, and stridor are ominous signs of airway injury and should trigger immediate action to stabilize and secure the airway.
  - Ominous signs include evidence of viscous perforation, hemodynamic instability, peritoneal signs, and signs of airway compromise.
  - Except in peritonitis, the abdominal exam correlates poorly with extent of damage.
  - Suicidal intent in the adolescent may be an independent risk factor for severity of injury.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

Serum chemistry, a venous or arterial blood gas analysis:

- Screening acetaminophen and salicylate should be done if there was intent of self-harm.

#### Imaging

- Radiographs of the chest and abdomen may aid in demonstrating pneumothorax, pneumomediastinum, pleural effusion, or intraperitoneal air:
  - Radiographs are not routinely indicated but are used in symptomatic patients.
- CT of the chest, abdomen, and/or pelvis may further delineate injuries; use only in symptomatic patients:
  - In the case of an ingested button battery, radiographs of the neck, chest, and abdomen should be obtained to locate the battery as well as obtain an estimate of size.

#### Diagnostic Procedures/Other

- Obtain a 12-lead ECG.
- Endoscopy:
  - Gold standard for assessment of GI damage
  - Endoscopy after a caustic ingestion will not result in damage to the endoscope.
  - Do not delay endoscopy to allow the injury to develop; delay increases the risk of perforation.
  - No evidence supports the idea that viscous perforation is more likely with endoscopies performed for caustic ingestions relative to those performed for any other reason.
  - The presence of vomiting, drooling, stridor, and the inability to voluntarily take oral liquids are reliable factors in young children to predict esophageal or gastric injury:
    - Children with none of these signs and symptoms can be presumed to not have severe GI involvement and do not require endoscopy.
  - Presence of  $\geq 2$  of these findings are indications for endoscopy. These criteria are only applicable to children and may not be applicable to adolescents.
  - Other indications include any patient or circumstance that is considered to be unreliable surrounding an ingestion (particularly suicidal intent) and any patient with 2nd- or 3rd-degree orofacial burns.

- The presence of a button battery located in the esophagus on CXR necessitates endoscopic removal secondary to the high associated risk of esophageal perforation or necrosis.

### Pathological Findings

Ingested:

- GI lesions are graded by the depth of penetration and appearance of mucosa.
  - Grade 0: Normal mucosa
  - Grade I: Hyperemia and edema of mucosa
  - Grade IIa: Friability, ulcers, hemorrhages, erosions, or exudates
  - Grade IIb: Similar to IIa with deep discrete or circumferential ulceration
  - Grade IIIa: Small scattered necrosis
  - Grade IIIb: Extensive necrosis

### DIFFERENTIAL DIAGNOSIS

The cornerstone of caustic exposure differential hinges upon whether the substance was known to be ingested or not:

- A broad differential must be maintained to determine if other substances are involved.

## TREATMENT

### PRE HOSPITAL

Ingestion:

- Decontamination by dilution is recommended.
- Drinking 2 mL/kg of water is a reasonable 1st step at attempting GI dilution:
  - Drinking more may result in vomiting.
- Induced vomiting is contraindicated.

### INITIAL STABILIZATION/THERAPY

- Assess and stabilize airway, breathing, and circulation.
- Obtain vascular access in the event of rapid decline.
- Dermal:
  - Remove clothing and perform copious irrigation.
  - All affected body areas should be irrigated until there is no remaining caustic agent.
  - Neutralizing agents are not recommended.
  - Water is not the diluent of choice with solid metals, which react in a highly exothermic reaction, and phenols, which form a glue-like adhesive that is difficult to remove:
    - These may be removed with a nonreactive diluent like polyethylene glycol (Go-Lytely).
- Ocular:
  - Decontamination of an ocular exposure may be a sight-saving intervention.
  - Irrigation is best facilitated with the use of ocular anesthetic and irrigation with a Morgan lens.
  - After irrigation, assess visual acuity, ocular integrity, funduscopy, cul-de-sacs for residual caustic material, and pH testing.
  - Continue irrigation with 2 L of fluid per eye or until the pH returns to 7.4.
  - Assessment of pH should be delayed several minutes after irrigation stops to ensure that the litmus paper reflects the pH of the eye surface and not the irrigation fluid.
- Inhalational:
  - Airway management is paramount.
- If there is any stridor, drooling, or hypoxemia, have a low threshold for endotracheal intubation.

- Ingested:
  - Airway compromise is the most urgent problem arising after caustic ingestion.
  - Edema or burns of the airway may rapidly progress to loss of airway patency.
  - Blind nasotracheal intubation is contraindicated.
  - Aspiration of stomach contents using an NG tube may be considered for ingestion of large volumes of acids to prevent systemic absorption of the agent.
  - Ingestion of HF is frequently fatal, and few patients survive such exposures.

### MEDICATION

- Dermal:
  - HF exposures may be treated by soaking in calcium gluconate gel:
    - Plain calcium chloride solution may be used or may be combined with large amounts of Surgilube to create a slurry.
    - Every 30 min, this slurry should be replaced, and the treatment should be continued until the patient is painfree.
    - Intra-dermal injections or intra-arterial 5% calcium gluconate may be rarely needed if the gel does not adequately control pain.
    - For phenol or solid metals, irrigate with polyethylene glycol (Go-Lytely).
    - Water may worsen injury due phenol and metals due to reactivity with water.
- Inhalational:
  - Inhalational acid exposures may safely be treated with neutralizing agents.
  - These involve minute amounts of caustic spread over a large surface area; therefore, caustic acids may be treated with nebulized aerosols of neutralizing sodium bicarbonate. A 2% sodium bicarbonate solution if made by diluting standard sodium bicarbonate 1:3 with normal saline.
  - Nebulized calcium gluconate may give symptomatic relief of HF inhalation.
- Ingested:
  - Steroid therapy for grade IIb lesions has been demonstrated to prevent stricture formation.
  - Methylprednisolone 2 mg/kg IV up to 120 mg/day divided in 3 equal doses.
  - Dexamethasone 0.5 mg/kg IV/IM initial dose in the emergency department
  - If grade III lesions, do not administer steroids due to an increased likelihood of perforation.
  - If administering corticosteroids, concomitantly give broad-spectrum antibiotics.

### SURGERY/OTHER PROCEDURES

- Inhalational:
  - Urgent bronchoscopy is indicated to remove a button battery lodged in the airway.
- Ingested:
  - Fiberoptic visualization of airway is advised in patients with symptoms of airway injury who do not undergo endotracheal intubation:
    - Best accomplished with the assistance of an otolaryngologist
  - Endoscopy criteria must be communicated appropriately to a gastroenterologist.
  - If there is evidence of perforation, early surgical intervention is needed.
  - Operative treatment allows perforation repair, debridement of necrotic tissue, and placement of a G or J tube for enteral feeds.

### DISPOSITION

#### Admission Criteria

- Dermal:
  - Significant burn that would otherwise meet admission criteria for a burn will require admission for similar management.
  - Diligent hemodynamic monitoring is required for any serious HF exposure or ingestion. HF has the ability to cause electrolyte abnormalities including hypocalcemia, hypomagnesemia, and hyperkalemia.
- Ingested:
  - Caustic ingestion with signs or symptoms of airway or GI compromise
  - Patients unable to tolerate liquids PO
  - Grade IIa or greater esophageal lesions; placed on either a soft diet or NG tube feeds. Stricture formation is typical.

#### Discharge Criteria

Ingestion:

- Grade 0–I injuries by endoscopy
- Ingestion of a button battery that is located past the pylorus
- A patient with a non-button battery in the stomach may be discharged to return within 48 hr for a repeat radiograph.
- If battery remains in the stomach, endoscopy should be performed to remove the battery.

### ADDITIONAL READING

- Arevalo-Silva C, Eliashar R, Wohlgeernter J, et al. Ingestion of caustic substances: A 15-year experience. *Laryngoscope*. 2006;116:1422–1426.
- Previtera C, Giusti F, Guglielmi M. Predictive value of visible lesions (cheeks, lips, oropharynx) in suspected caustic ingestion: May endoscopy reasonably be omitted in completely negative pediatric patients? *Pediatr Emerg Care*. 1990;6:176–178.
- Tekant G, Eroglu E, Erdogan E, et al. Corrosive injury-induced gastric outlet obstruction: A changing spectrum of agents and treatment. *J Pediatr Surg*. 2001;36:1004–1007.

### CODES

#### ICD9

- 983.1 Toxic effect of acids
- 983.2 Toxic effect of caustic alkalis
- 983.9 Toxic effect of caustic, unspecified

### PEARLS AND PITFALLS

- Vomiting, drooling, stridor and/or inability to take PO are predictive of significant injury.
- Induced vomiting is contraindicated.
- Consider endotracheal intubation for any symptoms of airway compromise.

# CAVERNOUS SINUS THROMBOSIS

Joseph B. House  
Michele M. Nypaver

## BASICS

### DESCRIPTION

- Cavernous sinus (CVS) thrombosis is the occurrence of a blood clot within the CVS.
- Common etiologies are infectious; less commonly, there is a predisposition to thrombosis of other causes:
  - Critical anatomy: The CVS lies within the cerebral sinus (CS) venous drainage system, located at the skull base:
    - Valveless sinus surrounded by dura mater encircling sella turcica
    - Without valves, venous blood may flow antegrade or retrograde depending on the hydrostatic pressure gradient.
    - Receives blood from superior and inferior ophthalmic veins, superficial middle cerebral vein, and sphenoparietal sinus
    - Connects with facial vein via superior ophthalmic vein
    - Drains posteroinferiorly via superior and inferior petrosal sinuses and emissary veins to pterygoid plexuses
  - Critical structures within the CVS include the internal carotid artery and surrounding sympathetic nerve plexus and cranial nerves (CNs) III (oculomotor), IV (trochlear), V (trigeminal division 1 ophthalmic and division 2 maxillary), and VI (abducens).
  - Any/All of these structures may be affected by thrombosis in the CVS.

### EPIDEMIOLOGY

#### Incidence

- Overall incidence of cerebral vein/sinus thrombosis in children is estimated at 7 cases per 1 million per year (1).
- More common in neonates/young children/young adults (especially women) than older adults

### RISK FACTORS

- Risk factors are age and gender related (neonatal, older children, young women) (2–4).
- Patients often have multiple risk factors.
- Neonatal CVS risk factors:
  - Perinatal complications (hypoxemia, premature rupture of membranes, placental abruption, gestational diabetes, infection)
  - Genetic hypercoagulable states
  - Dehydration
- Risk factors for nonneonates/children/young adults:
  - Head and neck infections (sinusitis, otitis media, mastoiditis, odontogenic infection)
  - Dehydration
  - Trauma (direct head/neck trauma, neurosurgical procedures, lumbar puncture)

- Hypercoagulable states:
  - Protein C and S deficiencies
  - Antithrombin deficiency
  - Fibrinogen deficiency
  - Plasminogen deficiency
  - Factor V Leiden
  - Presence of lupus anticoagulant
  - Presence of anticardiolipin, antiphospholipid antibodies
  - Prothrombin gene mutation
  - Homocysteinemia/Homocystinuria
  - Use/Administration of procoagulation drugs (chemotherapeutic agents, oral contraceptives)
  - Pregnancy/Postpartum state
  - Malignancy: Leukemia, lymphoma
- Acute systemic illness: Sepsis
- Chronic systemic disease: Inflammatory bowel disease, systemic lupus erythematosus, diabetes mellitus, sickle cell disease

### PATHOPHYSIOLOGY

Two primary processes: Venous obstruction (local edema effects) and thrombosis of sinuses (intracranial HTN):

- Results in cerebral edema (cytotoxic and vasogenic) and impaired absorption of CSF
- Not associated with ventricular dilatation (terminal phase of CSF flow does not result in pressure gradient change)

### ETIOLOGY

- Most causes of CVS are caused by head/neck infections; most children have an identifiable cause (2):
  - *Staphylococcus* species account for ~70% of all infections.
  - *Streptococcus pneumoniae* is the 2nd most common.
  - Gram-negative bacilli and anaerobes are also seen.
  - Fungi are rare pathogens.
- Noninfectious etiologies: Thrombosis from hypercoagulable state, infiltrative malignancy, mechanical factors (trauma, surgery), acute or chronic systemic illnesses, or mass effect (aneurysms)

## DIAGNOSIS

### HISTORY

- Highly variable (acute, subacute, or indolent) and requires high index of suspicion:
  - Children may present with nonspecific complaints such as fatigue, vomiting, headache, and fever.
- Most common complaint is headache:
  - Gradual, can be unilateral with bilateral involvement
- History of sinusitis, midface or odontogenic infection
- Eye complaints: Pain, swelling, tearing, visual changes, or diplopia
- Mental status changes: Lethargy, somnolence, confusion, coma
- Seizure (common neonatal presentation)
- Fever may be present.

### PHYSICAL EXAM

- Need to identify source of primary infection
- Eye:
  - Periorbital edema
  - Chemosis from ophthalmic vein obstruction
  - Ptosis
  - Signs of increased retrobulbar pressure
  - Exophthalmos
  - Ophthalmoplegia
  - Mydriasis
  - Signs of increased intraocular pressure:
    - Decreased visual acuity
    - Papilledema
    - Retinal hemorrhage
- Other findings consistent with intracranial pathology:
  - CN palsy, which may affect:
    - Some or all of CN III, IV, V, or VI
    - Sensory deficit of ophthalmic and maxillary branches of CN V
  - Hemiparesis
  - Meningeal signs if condition has progressed
  - In neonates: Seizure and diffuse neurologic signs are the most common presentation.
  - Alteration in mental status: Confusion, lethargy, somnolence, or coma
- Persistent fever and/or tachycardia (signs of sepsis) are late findings.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

Lab tests are nonspecific:

- Tests are done to identify underlying cause or etiology:
  - CBC
  - Blood culture
  - Coagulation profile, specific coagulation studies
  - Inflammatory markers: ESR, C-reactive protein

#### Imaging

- An MRI with contrast in combination with a magnetic resonance venogram (MRV) is the most sensitive imaging (4).
- MRV may show absence of flow in the CVS.
- CT is less sensitive than MRI:
  - May show increased density in the CVS suggesting the presence of a thrombus
  - Use of contrast may show filling defect in the CVS in addition to sinus infection.
  - Findings may be subtle.
  - Negative scan does not fully exclude CVS thrombosis.
- Sinus radiography:
  - May show sinus opacification
- Carotid angiography:
  - May show narrowing and/or obstruction of the carotid sinus as it passes through the CVS

**Diagnostic Procedures/Other**

- Lumbar puncture:
  - Consider only in patients without evidence of increased intracranial pressure due to risk of cerebral herniation.
  - Consider checking opening pressure
- Sinus puncture and drainage:
  - Requires acute surgical consultation
  - May identify causative agent

**Pathological Findings**

Thrombosis/Thrombophlebitis of the CVS or CS

**DIFFERENTIAL DIAGNOSIS**

Differential is large due to nonspecific presentations of CVS thrombosis:

- Cellulitis
- Sinusitis
- Periorbital or orbital infection
- Meningitis/Encephalitis
- Intracranial abscess:
  - Mucormycosis
- Migraine
- Stroke
- Allergic blepharitis
- Thyroid exophthalmos
- Brain or orbital neoplasm
- Epidural or subdural hematoma
- Subarachnoid hemorrhage
- Glaucoma
- Internal carotid artery aneurysm

**TREATMENT****PRE HOSPITAL**

Assess and stabilize airway, breathing, and circulation.

**INITIAL STABILIZATION/THERAPY**

- If ill appearing, follow the Pediatric Advanced Life Support (PALS) algorithm:
  - Careful assessment of mental status with possible need to secure airway as needed
- IV antibiotics if infectious etiology is suspected
- Focus of therapy is to reverse the underlying cause, manage intracranial HTN if apparent or suspected, control seizures, and consider antithrombotic therapy with expert consultation:
  - Anticoagulation is controversial (2,5):
    - There are limited data in children.
  - Thrombolytics have not been well studied in the pediatric population and are not routinely recommended. However, these may be considered in centers where expertise is available.

**MEDICATION**

- Antibiotic regimen is aimed at most likely infectious etiology:
  - Penicillin/Beta-lactamase inhibitor combination or carbapenem:
    - Piperacillin/Tazobactam 150–300 mg/kg/day IV q6–8h (max 16 g of piperacillin per day)
    - Ticarcillin/Clavulanate 200–300 mg/kg/day IV q12h (max 18–24 g/day of ticarcillin per day)
  - Meropenem 10–40 mg/kg/dose IV q12h (max single dose 2 g)
  - Imipenem 100 mg/kg/day IV q6h (max 4 g/day) OR

- Antistaphylococcal coverage:
  - Vancomycin 40–60 mg/kg/day IV q6–8h (max 1 g/dose) plus metronidazole 15–50 mg/kg/day IV/PO divided t.i.d., max single dose 750 mg plus 3rd- or 4th-generation cephalosporin:
    - Cefotaxime 100–200 mg/kg/day IV q6–12h (max 12 g/day) OR
    - Ceftriaxone 50–100 mg/kg/day IV or IM q12–24h (max 4 g/day)
- Consider antifungal agents in patients at risk (immunocompromised).
- Intracranial HTN:
  - Mannitol 0.5–1 g/kg IV q4–6h
  - Acetazolamide 5 mg/kg/day or 150 mg/m<sup>2</sup>/dose IV daily
- Anticoagulation:
  - Heparin 50–100 units/kg IV load, then either 50–100 units/kg q4h or 20 units/kg/hr drip to maintain APTT 60–85 sec

**SURGERY/OTHER PROCEDURES**

Surgical (neurosurgery, otolaryngology, oral maxillofacial surgery) subspecialists may be required acutely and should be involved early in the medical decision-making process so as to contribute to critical (anticoagulation) actions that may impact surgical options.

**DISPOSITION****Admission Criteria**

Critical care admission criteria:

- All patients with CVS thrombosis should be admitted to the pediatric ICU.

**Discharge Criteria**

These patients should not be discharged.

**Issues for Referral**

Pediatric neurology, infectious disease, and hematology consultation/referral may be required acutely in addition to the acute surgical consults mentioned previously.

**FOLLOW-UP****FOLLOW-UP RECOMMENDATIONS**

Discharge instructions and medications:

- All patients should be admitted to the hospital.

**Patient Monitoring**

- Cardiovascular monitoring
- Neurologic observation and repeated assessment

**DIET**

Patients should remain NPO until evaluation is complete.

**PROGNOSIS**

- Poor prognostic factors:
  - Evidence of cerebral infarct at presentation
  - Seizure at presentation (nonneonates)
  - Coma
- Better prognoses:
  - Young adult women with gender-specific risk factors may have better prognoses (4).

**COMPLICATIONS**

- Cerebral herniation
- Cerebral infarction (stroke)
- Death
- Intracranial abscess
- Pulmonary (septic) emboli (Lemierre syndrome):
  - Permanent neurologic sequelae
  - Persistent neurologic deficits in ~30% of neonates

325 Phlebitis and thrombophlebitis of intracranial venous sinuses

**PEARLS AND PITFALLS**

Due to the variable nature of presentation, timely diagnosis of CVS thrombosis requires a high degree of suspicion.

# CELIAC DISEASE

Nina Gold

Todd A. Mastrovitch

## BASICS

### DESCRIPTION

- Celiac disease (CD), or gluten-sensitive enteropathy, is an autoimmune enteropathy.
- CD is triggered by ingestion of gliadin-containing grains:
  - Grains that contain triggering proteins include wheat, barley, and rye.

### EPIDEMIOLOGY

- The number of diagnosed cases has been increasing with increased awareness.
- True incidence is unknown.
- 1% of the worldwide population
- Affects twice as many females as males
- In the U.S., it has been estimated that for every celiac patient, there are many undiagnosed subjects due to poor recognition of the variable clinical manifestations of the disease.

### RISK FACTORS

- CD is not confined to the Caucasian population as previously described, although whites and whites of European descent are more commonly affected.
- 2–5% of 1st-degree relatives of CD patients have symptomatic gluten-sensitive enteropathies.
- 10% of 1st-degree relatives have asymptomatic damage to small bowel mucosa consistent with CD.

### PATHOPHYSIOLOGY

- In CD, there is an intramucosal enzyme defect that leads to an inability to digest gluten.
- This causes rapid mucosal cell turnover and an increase in epithelial lymphocytes.
- The resulting toxic environment leads to damage to the surface epithelium, atrophy of the villi of the small bowel, and malabsorption of nutrients and vitamins.
- CD mainly targets the intestinal mucosa but can affect any organ or tissue.

### ETIOLOGY

- Autoimmune in nature
- More commonly associated with HLA haplotypes DR3 and DQw2.

### COMMONLY ASSOCIATED CONDITIONS

- Insulin-dependent diabetes mellitus
- Down syndrome (20-fold increase in risk over the general population)
- Autoimmune thyroid disease
- Addison disease
- Osteomalacia
- Secondary hyperparathyroidism
- Vitamin D or iron deficiency
- Fertility problems
- Hypogonadism in men
- Autoimmune hypopituitarism
- Turner and Williams syndrome (3- to 10-fold increase in risk over the general population)

## DIAGNOSIS

### HISTORY

- Children usually present with nonspecific or mild symptoms.
- Diarrhea is the most common symptom:
  - Acute or insidious in onset
  - Characteristically pale, loose, and offensive
- Poor weight gain and/or poor linear growth may occur due to malabsorption or decreased appetite.
- The typical presentation of a toddler with diarrhea, abdominal distention, and failure to thrive is becoming less common.
- GI symptoms in older children and teens are similar but usually less dramatic:
  - CD can cause either constipation or diarrhea.
  - When diarrhea is present, the stools are often bulky and foul smelling.
  - May float because of steatorrhea
  - Flatulence and abdominal distension are common in older children.
- Numerous non-GI manifestations of CD have been described:
  - Neurologic: Ataxia, peripheral neuropathy, epilepsy
  - Skin: Dermatitis herpetiformis
  - Dental: Enamel defects
  - Bone: Decrease in bone mass
  - Joint: Arthritis

### PHYSICAL EXAM

- Diffuse abdominal tenderness without rebound
- Abdominal distention
- Growth disturbance
- Signs of anemia such as pallor
- Often, children may only have nonspecific or mild exam findings.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

- In the emergency department, only serum electrolytes may be necessary. All other lab testing can be performed as an outpatient.
- Measuring antibodies against tissue transglutaminase (anti-tag).
- In patients <3–7 yr old, antigliadin antibody may be measured due to minimal amounts of detectable anti-tag.
- The diagnostic accuracy of the IgA anti-tag immunoassays is >96%.
- The anti-endomysium IgA antibody test is more expensive and operator dependant and has been replaced by anti-tag.
- There can be false negatives in IgA deficiency, so measurement of serum IgA should occur.
- Elevated alkaline phosphatase levels can indicate bone loss.
- Low cholesterol and albumin can reflect malabsorption.
- Mildly abnormal liver enzymes and abnormal blood clotting may also be noted with anemia.

#### Diagnostic Procedures/Other

Patients may be referred for upper GI endoscopy and small bowel biopsy.

#### Pathological Findings

Histologic changes can be seen in small bowel biopsies: A mosaic pattern of alternating flat and bumpy areas on the bowel surface due to an almost absence of villi and an irregular disorganized network of blood vessels.

### DIFFERENTIAL DIAGNOSIS

- Inflammatory bowel disease/Irritable bowel syndrome
- Infectious gastroenteritis
- Parasitic bowel infection
- Juvenile rheumatoid arthritis
- Thyroid disease
- Any cause of failure to thrive, growth delay, and short stature

## TREATMENT

- The majority of patients with CD are stable and will require little in the way of emergent treatment.
- Patients who are dehydrated should receive IV fluids.

### PRE HOSPITAL

- The majority of patients with CD will be stable and will require little in the way of emergent treatment.
- Patients who are dehydrated or have a history of poor oral intake should be given IV fluids.

### INITIAL STABILIZATION/THERAPY

- Fluid management to treat dehydration
- Avoidance of trigger proteins and a glutenfree diet
- Reinstitution of caloric requirements for energy and growth

### MEDICATION

#### First Line

- Total parenteral nutrition may be required to re-establish adequate nutrition.
- In general, medications are not required in the acute management of CD.

#### Second Line

Occasionally, oral/IV steroids may be prescribed for short-term use for severe symptoms:

- Prednisone 1 mg/kg/dose PO b.i.d.
- Methylprednisolone 1 mg/kg/dose IV q6h

### COMPLEMENTARY & ALTERNATIVE THERAPIES

- Adherence to a glutenfree diet and glutenfree vitamins
- Vitamin supplementation in children who have malnutrition due to long-standing GI damage

### DISPOSITION

#### Admission Criteria

- Dehydration
- Electrolyte abnormalities
- Clotting derangements
- Neurologic complications

#### Discharge Criteria

Re-establishment of adequate fluid intake and nutrition and a glutenfree diet

### Issues for Referral

- Clinical suspicion and positive screening tests with referral to pediatric GI and clinical nutritionist with experience treating CD patients
- Refractory symptoms not responding well to a glutenfree diet

## FOLLOW-UP

### FOLLOW-UP RECOMMENDATIONS

- Discharge instructions and medications:
  - Adherence to the glutenfree diet in those known to have the disease
- Activity:
  - Normal activity to promote health

### Patient Monitoring

Parental and patient involvement and monitoring of the glutenfree diet and avoidance of triggers that cause increased symptoms

### DIET

Glutenfree diet (no wheat, barley, and rye)

### PROGNOSIS

With proper nutrition and adherence to a glutenfree diet, prognosis is good.

### COMPLICATIONS

- Growth failure
- Weight loss
- Severe anemia
- Neurologic disorders from deficiencies of B vitamins
- Osteopenia from deficiency of vitamin D and calcium
- Delaying diagnosis or not following the glutenfree diet puts patients at risk for:
  - Autoimmune disorders
  - GI cancers and lymphoma (usually outside adolescence)
  - Fractures
  - Infertility
  - Miscarriage

## ADDITIONAL READING

## CODES

### ICD9

579.0 Celiac disease

## PEARLS AND PITFALLS

- A glutenfree diet should not be initiated before the diagnosis is made. Doing so will affect testing for CD.
- IgA deficiency has an increased incidence in CD and can cause screening tests to be falsely negative.
- Noncompliance with the glutenfree diet, either intentional or unintentional, can lead to exacerbation of symptoms.
- In children <2 yr of age, milk protein-sensitive enteropathy can produce symptoms similar to CD.

# CELLULITIS

Louis A. Spina

## BASICS

### DESCRIPTION

- Cellulitis is an infection of the skin and subcutaneous tissues. It involves the dermis but generally does not involve the epidermis.
- Any part of the body may be involved.
- The most common organisms that cause cellulitis are group A streptococcus (GAS) and *Staphylococcus aureus*, including MRSA.
- Less commonly, *Haemophilus influenzae* and pneumococcus are found as causes of cellulitis:
  - These are more commonly found with facial cellulitis.

### EPIDEMIOLOGY

- Cellulitis is a common infection in children.
- Overall incidence (including adult population) is about 200 cases per 100,000 patient-years.
- Emergency visits for soft tissue infections, including cellulitis, are increasing.
- Often seen during the warmer months and in warmer climates
- Facial cellulitis is more common in children <5 yr of age:
  - Facial cellulitis is more likely to be associated with fever and systemic toxicity.

### RISK FACTORS

- Diabetes mellitus
- Lymphatic stasis
- Immunosuppressive states
- Eczema and other inflammatory states
- Pre-existing skin infection:
  - Tinea pedis
  - Impetigo
- Recent surgical procedure
- Recent laceration or other injury causing a break in the skin

### PATHOPHYSIOLOGY

- Cellulitis is generally caused by local invasion of a pathogenic organism or by hematogenous spread. This is typical for staphylococcal and streptococcal infections.
- A break in the skin due to previous trauma can predispose to cellulitis.
- A cut or a scrape, as well as excoriated insect bites or rashes, can be the cause.
- Surgical sites can be areas for bacterial colonization.
- Underlying skin lesions may also predispose to cellulitis.

- At times there is no discernible predisposing condition, and cellulitis can occur spontaneously.
- *Streptococcus pneumoniae* and *H. influenzae* are thought to be more commonly spread via the hematogenous route:
  - *H. influenzae* cellulitis is more commonly associated with complications and meningitis, whereas pneumococcal cellulitis is less likely to be associated with complications or meningitis (1).

### ETIOLOGY

- The most common organisms to cause cellulitis are GAS and *S. aureus*, including MRSA.
- *H. influenzae* was once a common cause of facial and buccal cellulitis, but as a result of the Hib vaccine, this is now rare.
- Oral flora such as *Streptococcus viridans*, *Streptococcus mutans*, *Prevotella* species, and *Fusobacterium* are common causes of facial soft tissue infections associated with dental abscesses.
- Pneumococcus is an uncommon cause of cellulitis.
- *S. aureus* and GAS are usually spread via direct invasion of a wound.

## DIAGNOSIS

### HISTORY

- Patients will usually present with a recent insect bite, abrasion, laceration, or other insult to the skin, with a new area of redness and tenderness.
- Particularly in areas capable of significant swelling, such as the periorbital area, scrotum, penis, or earlobe, inflammation resulting from histamine or allergy, such as from an insect bite or sting, may be difficult to distinguish from cellulitis:
  - Both are erythematous, warm, and swollen.
  - One aspect of history helpful to differentiate between infection from allergic reaction is pain and pruritus. Cellulitis may be painful but is not pruritic. Insect bites or other similar allergic reactions are described as “itchy” but not painful.
- Patients or their families are often concerned that an area has “become infected.”
- Fever is usually not an accompanying symptom, although it can be seen in some cases of simple cellulitis as well as in facial cellulitis or in those with systemic toxicity.

### PHYSICAL EXAM

- Patients are often afebrile and generally well appearing.
- The infection is usually erythematous, warm, and tender to the touch. Edema may also be present.
- Fluctuance and drainage are not commonly associated with cellulitis and would signify a concurrent abscess.
- Local lymphadenopathy may be present.
- Examine the entire affected area as well as underlying muscle and other deeper tissues to detect more severe disease such as necrotizing fasciitis or pyomyositis.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

- Cultures of blood, needle aspirations, or punch biopsies are not routine in cases of mild cellulitis.
- Blood cultures have been shown to be positive in <5% of cases (2,3).
- Infection with *H. influenzae* or pneumococcus have been associated with higher rates of positive blood cultures:
  - Infection with these organisms is infrequent due to vaccination, and routine cultures are not warranted in healthy children.
  - In patients with systemic toxicity and/or facial cellulitis, blood cultures may be useful.
- Cultures or swabs from intact skin are rarely helpful and should not be performed:
  - An exception to this is a swab to detect *Streptococcus pyogenes* in cases of perianal cellulitis in young children.

### DIFFERENTIAL DIAGNOSIS

- Erysipelas
- Impetigo
- Necrotizing fasciitis
- Pyomyositis
- Pyoderma gangrenosum
- Gas gangrene
- Toxic shock syndrome
- Herpes zoster
- Osteomyelitis
- Erythema migrans
- Allergic reaction
- Contact dermatitis

## TREATMENT

### INITIAL STABILIZATION/THERAPY

- Most children who present with a nonfacial cellulitis that is not extensive may be treated with oral antibiotics as an outpatient.
- Those who present with a facial cellulitis, are afebrile, and have no risk factors for bacteremia can be treated as an outpatient with oral antibiotics.
- Often, it is useful to outline the area of cellulitis with a marker or a pen to be able to monitor the progression or resolution of the infection.

### MEDICATION

- Oral antibiotics:
  - In most cases of cellulitis, treatment is managed as an outpatient and first-line therapy should be directed at the most likely causative organism. If there is not a concern for possible MRSA infection, the following are acceptable initial treatment regimens:
    - Cephalexin 50–100 mg/kg/day PO divided b.i.d.–q.i.d.
    - Dicloxacillin 12.5–25 mg/kg/day PO divided q6h
    - Amoxicillin/Clavulanic acid 50 mg/kg/day of amoxicillin PO divided b.i.d.
  - Length of treatment with oral antibiotics can be as long as 14 days. A typical length of treatment will range between 7 and 10 days, although there is some evidence that a 5-day course may be sufficient.
  - Given the increasing frequency of MRSA infections, alternative or additional agents may be used if this is a concern:
    - Trimethoprim/Sulfamethoxazole (TMP/SMX) 8–12 mg/kg/day of TMP component PO divided b.i.d. may be added in combination with any of the above regimens to cover for MRSA.
    - Alternatively, it may be used as a sole agent if *S. aureus* is known to be the infectious agent.
    - Clindamycin 10–30 mg/kg/day PO in 3 divided doses (q8h) may be used as an alternative therapy.
    - However, in areas that clindamycin is used, MRSA resistance to this medication develops.
- Parenteral antibiotics:
  - For cases that fail outpatient treatment or are deemed necessary for admission and inpatient therapy, IV antibiotics are usually used.
  - In cases of cellulitis where *S. aureus* or streptococcus are likely organisms and MRSA is not a possibility:
    - Cefazolin 50–100 mg/kg/day q8h IV
    - Oxacillin 100–200 mg/kg/day q6h IV
    - Clindamycin 25–40 mg/kg/day q8h IV can be used for penicillin-allergic patients.

- If MRSA is a serious consideration (or a known causative agent), the parenteral antibiotic of choice is vancomycin 40 mg/kg/day given q6–8h IV.
- In cases of facial cellulitis, where other less common bacterial organisms (such as *H. influenzae*) are considered, ampicillin/sulbactam (200 mg/kg/day of ampicillin component) given q6h IV is an appropriate choice:
  - However, ampicillin/sulbactam does not provide coverage for MRSA.

### Additional Therapies

- The affected area should remain elevated to aid in reduction of edema and drainage of inflammatory substances.
- If an underlying condition is a predisposing factor for the cellulitis, therapy should be aimed at this condition as well as the infection.

### DISPOSITION

#### Admission Criteria

- Lymphangitis (red streaking extending proximally along the course of lymphatic drainage)
- Worsening cellulitis despite being treated with oral antibiotics for 24–48 hr
- Ill appearance or concern for bacteremia
- Facial cellulitis
- Critical care admission criteria:
  - Unstable vital signs or severe illness such as requirement of pressor to maintain BP

#### Discharge Criteria

- Well-appearing children without signs or symptoms of systemic toxicity may be discharged home on a course of oral antibiotics.
- Ability to follow up within 24–72 hr

## FOLLOW-UP

### FOLLOW-UP RECOMMENDATIONS

- Discharge instructions and medications:
  - Complete entire course of antibiotics.
  - Monitor progression of disease.
  - Follow up with primary care provider in 24–72 hr.
- Activity:
  - Elevate affected area when possible to help reduce swelling and inflammation.

### Patient Monitoring

- Follow-up should be arranged within 24–72 hr to monitor progression of disease.
- Outlining the extent of cellulitis with a pen or marker, or having parent take picture on cell phone or camera, may be useful to gauge regression or progression of cellulitis
- Patients should be instructed to return earlier than their scheduled follow-up if they feel they are worsening with increasing areas of erythema, fever, or signs of lymphangitis.

### PROGNOSIS

- With timely treatment and compliant antibiotic use, outcome is usually excellent.
- Underlying conditions hindering resolution of infection may worsen the prognosis.
- Colonization with MRSA, unless eradicated, may lead to recurrence in the future.
  - Recurrent cellulitis may lead to lymphedema.

### COMPLICATIONS

- Infections can worsen, requiring admission.
- Cellulitis can be associated with lymphangitis, which would require admission and IV antibiotics.
- Abscess

### CODES

#### ICD9

- 682.0 Cellulitis and abscess of face
- 682.1 Cellulitis and abscess of neck
- 682.9 Cellulitis and abscess of unspecified sites

### PEARLS AND PITFALLS

- Occasionally, an area of cellulitis is actually due to an infection originating in deeper structures.
- Facial cellulitis is more often associated with fever, rapid progression, and systemic toxicity.
- Given the increasing incidence, infection with MRSA should always be considered when choosing antibiotic therapy.
- Caregivers should follow up immediately if infection is progressing despite oral antibiotic use.

# CEREBRAL CONTUSIONS

Lynn Babcock Cimpello

## BASICS

### DESCRIPTION

- Cerebral contusion is bruising of the cerebral parenchyma and consists of brain tissue damage and vascular injury:
  - Resultant findings include edema and microhemorrhages.
  - Can range from focal to diffuse
- About 2% of the population in the U.S. live with disabilities from traumatic brain injuries (TBIs) (1).

### EPIDEMIOLOGY

#### Incidence

- TBIs are the leading cause of death and disability for children >1 yr of age (1).
- About half a million children sustain TBIs per year (1).
- Cerebral contusions occur in 20–30% of children with severe TBI.
- Presence of a contusion is a strong predictor of poor outcomes in those with TBI.

### RISK FACTORS

- Male
- Minority groups
- Lower socioeconomic status
- Alcohol use
- Child abuse
- Coagulation abnormalities increase the risk of progression of cerebral contusions.

### GENERAL PREVENTION

- Primary prevention measures, such as wearing helmets and seat belts, as well as use of airbags and stair gates, can decrease the incidence and severity of the injury.
- Controlling secondary insults from hypoxemia, hypotension, and intracranial HTN are critical since these lead to poor outcomes.

### PATHOPHYSIOLOGY

- Primary injury of cerebral contusions occurs from direct trauma when the head is stationary or from acceleration/deceleration forces when the head is in motion:
  - Coup contusions occur directly under the site of impact from the resultant deformation of the skull.
  - Contrecoup contusions occur on the opposite side from the impact site from the deceleration forces.
  - Contusions from acceleration/deceleration forces occur when the brain strikes the bony skull.
- Areas of the brain in close contact with the skull are most commonly affected: Orbitofrontal cortex, anterior temporal lobe, and posterior portion of the superior temporal gyrus area with the adjacent parietal opercular area.

- Secondary injury to surrounding brain tissue can occur from:
  - Mass effect that decreases cerebral blood flow to surrounding tissue and increases intracranial pressure (ICP) from cerebral autoregulation
  - A release of toxic metabolites from a cascade of biochemical and physiologic responses
- There are 3 phases of brain swelling due to contusions (2–4):
  - 1st 24 hr:
    - Life threatening
    - Formation of idiogenic osmoles draws fluid into the core of the contusion.
  - Next 24–72 hr:
    - 30% of hemorrhages will expand during this time frame.
    - Edema expands to adjacent uninjured tissue.
  - Slow, delayed swelling can continue for up to 10 days after injury.

### ETIOLOGY

Depends on age:

- <4 yr: Falls, child abuse, and motor vehicle collisions
- >4 yr: Motor vehicle collisions, sports, and assaults

### COMMONLY ASSOCIATED CONDITIONS

- Skull fractures
- Other intracranial injuries
- Child abuse in younger children

## DIAGNOSIS

### HISTORY

- Mechanism with direct blow to head or acceleration/deceleration forces
- Loss of consciousness, alteration of mental status, headache, amnesia, nausea, vomiting, irritability, or seizures
- Focal neurologic symptoms related directly to the contused area may be present, such as behavioral changes with frontal contusions or memory disturbances with temporal contusions.
- Inconsistent history or mechanism should raise suspicions of child abuse.

### PHYSICAL EXAM

- Vital signs
- Glasgow Coma Scale (GCS)
- Signs of increasing ICP include:
  - Worsening of mental status
  - Bradycardia, irregular respirations, and HTN (Cushing triad)
  - Changes in pupillary responses starting with ipsilateral dilation and progressing to ptosis and loss of medial gaze
  - Decorticate or decerebrate posturing
- Signs of head trauma such as scalp laceration, scalp hematoma, signs of basilar skull fractures (raccoon eyes or Battle sign), hemotympanum, or CSF rhinorrhea or otorrhea

## DIAGNOSTIC TESTS & INTERPRETATION

### Lab

- CBC:
  - Anemia (hemoglobin <9 mg/dL) increases the likelihood of cerebral injury (5).
  - Thrombocytopenia is a risk factor for progression of hemorrhage (3,4).
- Coagulation studies:
  - Progression of contusion is associated with coagulation abnormalities (INR >1.3) (3).
- Serum glucose:
  - Admission serum glucose  $\geq 300$  mg/dL is associated with death (6).
- Electrolytes and serum osmolality are useful if initiating hyperosmolar therapy.

### Imaging

- Image findings in contusions vary with their stages of evolution.
- Head CT is the most common acute imaging modality:
  - Edema appears as hypodense areas.
  - Microhemorrhages appear as hyperdense areas.
  - Up to 25% of initial CT findings may be normal due to partial volume averaging between edema and hemorrhages.
  - Up to 50% of contusions can progress, thus:
    - Follow-up CT should be considered if neurologic deterioration or rises in ICP occur.
- After stabilization, MRI is the criterion standard for defining contusions:
  - Predicts neurocognitive impairments
  - Can demonstrate hemorrhage earlier than CT

### DIFFERENTIAL DIAGNOSIS

- Other intracranial injuries
- Other causes of alteration of mental status such as ingestions, infections, or hemorrhage

## TREATMENT

### PRE HOSPITAL

- Assess and stabilize airway, breathing, and circulation.
- Cervical spine precautions
- Transport to a trauma center with pediatric expertise, if possible.

### INITIAL STABILIZATION/THERAPY

- Management depends on severity of injury.
- Primary goal is to prevent or ameliorate secondary brain injury (7).
- Assess and stabilize airway, breathing, and circulation:
  - Control airway as needed:
    - Rapid sequence endotracheal intubation if GCS <8, significant hypoxemia, inability to control airway, or hemodynamic instability exists
    - Normalize PCO<sub>2</sub> (PCO<sub>2</sub> of 35–38 mm Hg).
  - Maintain perfusion:
    - Establish vascular access.
    - Administer isotonic solutions to avoid hypotension (systolic BP <5th percentile for age).

- Maintain cervical spine precautions.
- Maintain euthermia:
  - Hyperthermia is associated with worse outcomes.
- Correct abnormalities in glucose, electrolytes, blood counts, and coagulation studies.
- Early consultation with neurosurgery
- ICP monitoring is recommended for children with GCS  $\leq 8$ .

## MEDICATION

### First Line

- Provide IV analgesia and sedation with one or more of the following agents:
  - Midazolam/lorazepam  $\sim 0.1$  mg/kg
  - Fentanyl  $1\text{--}2$   $\mu\text{g/kg}$
  - Propofol  $1\text{--}2$  mg/kg
- Control seizures with IV benzodiazepine:
  - Lorazepam/diazepam  $\sim 0.1$  mg/kg
- For signs of increasing ICP/acute brain herniation:
  - Elevate head of bed to  $30^\circ$  to decrease venous obstruction.
  - Mild hyperventilation (PCO<sub>2</sub> 30–35 mm Hg)
  - Consider initiating hyperosmolar therapy (7):
    - Mannitol can acutely decrease ICP:
      - Recommended dose is 0.5 mg/kg of 20% solution to raise serum osmolality to 320 mOsm/L.
      - Complications include hypovolemia and electrolyte disturbances.
    - Hypertonic saline can also reduce ICP (8):
      - Less osmotic diuresis than mannitol
      - Optimal dosing has not been clearly established; however, 3% saline at 2–6 mL/kg boluses over 5–10 min is commonly used to raise serum osmolality to 360 mOsm/L.
      - May cause reversible renal insufficiency

### Second Line

- Prophylactic use of antiseizure medication, usually fosphenytoin/phenytoin, to decrease the incidence of posttraumatic seizures is controversial (9,10):
  - Short-term use may decrease early posttraumatic seizures in young children.
  - Loading dose 15–20 mg of phenytoin equivalents/kg IV.
- IV barbiturate therapy with pentobarbital (10 mg/kg) or thiopental (3 mg/kg) can be used for increased ICP resistant to conventional therapy.

## SURGERY/OTHER PROCEDURES

Conservative surgical evacuation of contusions may be done to remove:

- Edema to reduce mass effect
- Necrotic tissue and blood to limit the production of toxic metabolites from ongoing biochemical cascades

## DISPOSITION

### Admission Criteria

- All children with cerebral contusions should be hospitalized.
- Children with persistent alteration of mental status or an abnormal neurologic exam should be hospitalized even if the head CT is normal because many contusions do not show up on the initial CT.

- Children with small contusions ( $<10$  mm) and a normal neurologic exam can be admitted to a regular pediatric floor:
  - Monitor for neurologic signs of progression
- Critical care admission criteria:
  - Children with moderate/severe contusions ( $>10$  mm) or alteration of mental status should be admitted to the ICU for monitoring.

### Issues for Referral

- Neurosurgical consultation
- Criteria for transfer to a pediatric trauma center after stabilization include:
  - GCS  $\leq 12$  in the field
  - Pediatric trauma score  $\leq 8$
  - Moderate and severe TBI

## COMPLEMENTARY & ALTERNATIVE THERAPIES

Induced moderate hypothermia on the outcomes of children with severe TBI is being investigated.

## FOLLOW-UP

### FOLLOW-UP RECOMMENDATIONS

Not applicable from the emergency department

### Patient Monitoring

- Frequent mental status assessments
- Cardiopulmonary monitoring is required initially.
- ICP monitoring for children with GCS  $\leq 8$

### DIET

- NPO initially
- Parenteral nutrition as needed

### PROGNOSIS

- A detailed prognosis of children following cerebral contusions is not known.
- Most children with mild and moderate TBI have few long-term sequelae.
- $\sim 50\%$  of children with severe TBI have long-term sequelae.

### COMPLICATIONS

- Seizures in 10–20%
- Cognitive, language, and sensory impairments
- Postconcussive syndrome symptoms including headaches, difficulty concentrating, difficulty sleeping, and mood changes
- Personality changes

## ADDITIONAL READING

Greenes D. Neurotrauma. In Fleisher GR, Ludwig S, eds. *Textbook of Pediatric Emergency Medicine.* 6th ed. Philadelphia, PA: Lippincott Williams & Wilkins; 2010:1432–1433.

### ICD9

- 851.80 Other and unspecified cerebral laceration and contusion, without mention of open intracranial wound, with state of consciousness unspecified
- 854.00 Intracranial injury of other and unspecified nature, without mention of open intracranial wound, with state of consciousness unspecified

## PEARLS AND PITFALLS

- The goal is to prevent secondary injury: Ventilate, oxygenate, and perfuse.
- The initial CT may be negative, so maintain a high level of suspicion of brain injury in a child with a traumatic mechanism and alteration of mental status.
- Up to 50% of cerebral contusions progress in the 1st 72 hr, so careful monitoring is necessary.

# CERVICAL LYMPHADENITIS

Marc A. Auerbach  
Lawrence Siew

## BASICS

### DESCRIPTION

- Lymphadenitis is inflammation of one or more lymph nodes of the neck as a result of infection.
- Lymphadenopathy, a term sometimes inappropriately used interchangeably, refers to enlargement, which may occur from etiologies other than infection, and does not necessarily involve inflammation.
- 80% of affected nodes involve the submaxillary, submandibular, and deep cervical lymph nodes.
- Cervical lymphadenitis is categorized into 3 broad categories:
  - Acute bilateral cervical lymphadenitis
  - Acute unilateral pyogenic cervical lymphadenitis
  - Chronic cervical lymphadenitis
- Most commonly, acute bilateral lymphadenitis occurs following upper respiratory tract infections.

### EPIDEMIOLOGY

- Extremely common in children
- Tuberculous lymphadenitis is seen in developing countries.

### RISK FACTORS

- Upper respiratory infection
- Pharyngitis
- Conjunctivitis
- Impetigo
- Mononucleosis
- Dental caries or abscess

### PATHOPHYSIOLOGY

- Microorganisms penetrate mucosa of head and neck and infiltrate surrounding tissue.
- Transport via afferent lymph vessels to lymph nodes.
- Immunologic response is generated.
- Pyogenic organisms result in sudden onset of swelling, erythema, and tenderness.

### ETIOLOGY

- Acute bilateral cervical lymphadenitis:
  - Most common presentation
  - Commonly due to self-limited upper respiratory viral infections (enterovirus, adenovirus, influenza)
  - Other causes may include Epstein-Barr virus (EBV), cytomegalovirus (CMV), or group A streptococcus.
- Acute unilateral cervical lymphadenitis:
  - Commonly due to pyogenic bacteria
  - *Staphylococcus aureus* and group A streptococcus account for 80%.
  - Group B streptococcus (infants), anaerobes (history of periodontal disease), tularemia, brucellosis
- Chronic cervical lymphadenopathy (> 2 wk):
  - Bilateral nodal involvement: EBV, CMV
  - Unilateral nodal involvement: Nontuberculosis mycobacteria (NTM), *Bartonella henselae* (cat scratch disease), TB, toxoplasmosis
  - Noninfectious considerations include connective tissue disorders, neoplasm, Kawasaki disease, and PFAPA syndrome (periodic fevers, aphthous stomatitis, pharyngitis, adenitis).

### COMMONLY ASSOCIATED CONDITIONS

- Fever
- Malaise

## DIAGNOSIS

### HISTORY

- Duration of symptoms (acute is < 2 wk)
- Unilateral or bilateral nodal involvement
- Change in size
- Associated symptoms (fever, cough, rhinorrhea, sore throat, rash, weight loss)
- Ill contacts (TB, EBV)
- History of dental caries or periodontal disease
- Unusual exposures (animal exposures, unpasteurized milk, uncooked meats)
- Medications and recent travel

### PHYSICAL EXAM

- Adenopathy: Location, consistency (solid or fluctuant, fixed or mobile), number, and size
- Systemic lymph nodes, hepatomegaly, splenomegaly
- Pharynx and dentition
- Conjunctival injection with preauricular or submandibular adenopathy (Parinaud oculoglandular syndrome) is seen in cat scratch disease, tularemia, and adenovirus.
- Skin erythema or cellulitis

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

- Rapid streptococcal antigen test and/or bacterial culture of pharynx if suspected group A streptococcal pharyngitis.
  - This assay may provide rapid diagnosis and give clear indication of optimal antibiotic treatment.
- If ill appearing and suspecting systemic infection, send CBC, C-reactive protein, ESR, LFTs, and blood cultures.
- Tuberculin skin test for chronic lymphadenopathy
- Consider serologic studies for EBV, CMV, HIV, *Treponema pallidum*, *Toxoplasma gondii*, or *Brucella* in selected cases.

#### Imaging

- US is performed when a neck mass is large, increasing in size, or unresponsive to antibiotic therapy.
- Contrast-enhanced CT and MRI are reserved for more severe cases.
- Consider CXR for systemic disease or suspicion of possible malignancy.

#### Diagnostic Procedures/Other

- Needle aspiration:
  - Generally reserved for lymphadenitis caused by pyogenic bacteria that has failed initial antibiotic therapy (after 48–72 hr of treatment)
  - Incision and drainage is contraindicated in suspected mycobacterial infections due to risk of creating a persistently draining sinus tract.
- Excisional biopsy:
  - Preferred for suspected mycobacterial infections.
  - Used to diagnose malignancy

**DIFFERENTIAL DIAGNOSIS**

- Lymphadenopathy
- Midline neck lesions: Thyroglossal duct cysts, epidermoid cysts, and lipomas
- Cystic hygroma, branchial cleft cyst, thyroid tumors, laryngocele

**TREATMENT****INITIAL STABILIZATION/THERAPY**

- Acute bilateral lymphadenitis is usually due to self-limited viral infections. Observation with no treatment is usually appropriate.
- Acute unilateral lymphadenitis:
  - In a well-appearing child with a minimally enlarged and tender lymph node, measuring initial dimensions and monitoring over time is recommended.
  - For warm and tender lymph nodes, without evidence of fluctuance, a course of oral antibiotics is recommended.
  - If ill appearing or abscess is suspected, IV antibiotics are indicated.

**MEDICATION****First Line**

- Empiric oral regimens including amoxicillin, penicillin, cephalexin, or clindamycin are appropriate for most infections.
- Infections with severe illness should be treated with parenteral antibiotics.
- Duration of treatment is 10–14 days.
- Oral therapy:
  - Cephalexin 50 mg/kg/day PO divided b.i.d.–q.i.d., max dose 2 g/day
  - Amoxicillin 40 mg/kg/day PO divided b.i.d.–q.i.d., max dose 2 g/day
  - Penicillin 50 mg/kg/day PO divided b.i.d.–q.i.d., max dose 2 g/day
  - Clindamycin 30 mg/kg/day PO divided t.i.d.–q.i.d., max dose 1.8 g/day:
    - Optimal for polymicrobial infections, suspected MRSA
- Parenteral therapy:
  - Cefazolin 50–100 mg/kg/day IV divided q8h, max dose 6 g/day
  - Nafcillin or oxacillin 150 mg/kg/day IV divided q6h, max dose 6 g/day

**Second Line**

- Amoxicillin/Clavulanate 45 mg/kg/day PO divided b.i.d.–t.i.d., max dose 2 g/day × 10–14 days:
  - If periodontal disease is present, consider clindamycin or amoxicillin/clavulanate.
- Trimethoprim/Sulfamethoxazole (TMP/SMZ) 10 mg/kg/day PO divided q12h, max daily dose 320 mg TMP/1,600 mg SMZ daily
- Azithromycin 10 mg/kg day 1, then 5 mg/kg PO days 2–5:
  - Used specifically for cat scratch disease

**DISPOSITION****Admission Criteria**

- Failure of outpatient management
- Pain requires IV medications
- Requires IV fluids
- For further workup

**Discharge Criteria**

- Other more serious diagnoses have been ruled out.
- No airway compromise
- Ability to take PO

**Issues for Referral**

Nonresponse to antibiotics: Consider ENT and/or infectious disease consult.

**FOLLOW-UP****FOLLOW-UP RECOMMENDATIONS**

Discharge instructions and medications:

- Take medications as prescribed. Return to primary care provider to evaluate for improvement on antibiotics.

**Patient Monitoring**

Monitor clinical response to treatment to note improvement or lack thereof.

**PROGNOSIS**

- Cervical lymphadenitis spontaneously regresses in most children over the course of several weeks.
- Mycobacterial infections may take a long time to resolve.

**COMPLICATIONS**

- Persistent or recurrent lymphadenitis is the most frequent complication.
- Development of a sinus tract or disseminated disease associated with mycobacterial disease
- Abscess formation, cellulitis, bacteremia

**ADDITIONAL READING**

Cat scratch Disease

**CODES****ICD9**

- 017.20 Tuberculosis of peripheral lymph nodes, unspecified examination
- 289.1 Chronic lymphadenitis
- 289.3 Lymphadenitis, unspecified, except mesenteric

**PEARLS AND PITFALLS**

- Cervical lymphadenitis is inflammation of  $\geq 1$  cervical lymph nodes.
- Most commonly, acute bilateral lymphadenitis is due to upper respiratory infections.
- Unilateral lymphadenitis may require treatment: PO antibiotics in moderate illness and IV antibiotics for severe illness.
- 80% of acute unilateral lymphadenitis is due to pyogenic infection by group A streptococcus or *S. aureus*.
- Suspect NTM or TB with chronic lymphadenopathy.

# CHALAZION

Nicole D. Porti  
Karen Franco

## BASICS

### DESCRIPTION

A chalazion is an inflammatory lesion of the eyelid that usually arises as a result of obstruction of a sebaceous gland duct:

- Meibomian gland lipogranuloma is another name for a chalazion.
- In contrast, a hordeolum or sty is a localized infection or inflammation of the eyelid margin involving hair follicles.
- Chalazia are typically nontender, while hordeolum are tender and erythematous.

### EPIDEMIOLOGY

- Chalazia, as well as hordeola, are the most common acquired lid lesions in childhood (1).
- The exact incidence or prevalence of chalazia in the U.S. is not known.

### RISK FACTORS

- Poor lid hygiene
- Blepharitis
- Seborrhea
- Acne rosacea
- Atopy
- Viral infection
- Immunodeficiency

### PATHOPHYSIOLOGY

- The sebaceous glands of the eyes include the meibomian glands and the glands of Zeis:
  - Meibomian glands are embedded in the tarsal plate of the eyelid.
  - Glands of Zeis are located at the base of the eyelash follicles.
  - Both glands produce sebum that is incorporated into the eye's tear film.
- Blockage of  $\geq 1$  gland leads to accumulation of sebaceous material and a resulting inflammatory reaction.

### ETIOLOGY

Blockage can occur due to:

- Blepharitis
- Acne rosacea
- Hordeolum

## DIAGNOSIS

### HISTORY

- A chalazion usually presents as a chronic, painless swelling on the eyelid.
- Obtain pertinent information about location, onset, duration, aggravating and/or alleviating factors, and previous treatment.
- Note if chalazion is recurrent and in same location, which may indicate possible malignant origin (2).
- Symptoms not consistent with chalazion include:
  - Eye pain
  - Eye redness
  - Fever
  - Visual changes
  - Discharge
  - Fever
  - Diffuse swelling

### PHYSICAL EXAM

- A palpable nodule on the eyelid or lid margin, depending on location of obstructed gland:
  - May have significant inflammation with lid edema
  - Nontender to mild tenderness
  - Nonerythematous
  - Nonfluctuant
  - No intraocular pathology
  - Note any associated skin findings.
- Document visual acuity (should be normal).

### DIAGNOSTIC TESTS & INTERPRETATION

No diagnostic tests are needed, as the diagnosis is made clinically.

### DIFFERENTIAL DIAGNOSIS

- Hordeolum
- Molluscum contagiosum
- Nasolacrimal duct obstruction
- Dacryocystitis
- Atopic dermatitis
- Preseptal/Periorbital cellulitis
- Orbital cellulitis
- Skin swelling secondary to other inflammation, such as insect bite or sting
- Eyelid papilloma
- Xanthelasma
- Sebaceous gland carcinoma
- Basal cell carcinoma
- Tuberculosis
- Orbital tumor

## TREATMENT

### INITIAL STABILIZATION/THERAPY

- Usually resolves spontaneously over several weeks with conservative management
- Warm compress to area 10–15 min q.i.d. to soften the plug of material, allowing gland's contents to drain

### MEDICATION

#### First Line

Baby shampoo applied daily to affected eyelid to reduce clogging of ducts

#### Second Line

Consider oral tetracyclines to reduce inflammation in older children with significant blepharitis:

- Tetracycline:  $>8$  yr of age, 25–50 mg/kg/day PO q6h

**DISPOSITION****Discharge Criteria**

- All patients with chalazion may be discharged and managed as outpatients.
- Patients can be safely discharged home if they have:
  - No changes in visual acuity
  - No signs of intraocular pathology

**Issues for Referral**

- Most chalazia can be managed at home without consultation of an ophthalmologist, with conservative treatment alone.
- Consider ophthalmologic referral if the diagnosis is in question, especially if the chalazion is recurrent (histopathologic diagnosis) (3).
- Referral to ophthalmology if:
  - Failed conservative management
  - Recurrent chalazia
  - Any visual disturbance (4)
- Treatment by an ophthalmologist after failed therapy may include either of the following:
  - Incision and curettage is preferred treatment.
  - Intralesional steroids may also be considered (5).

**FOLLOW-UP****FOLLOW-UP RECOMMENDATIONS**

Discharge instructions and medications:

- Lid hygiene should be discussed.
- Advise patients to follow up with ophthalmology if symptoms are not improving as expected.

**PROGNOSIS**

- Most chalazia resolve on their own.
- Recurrences do occur, especially in those with predisposing skin disorders.

- Dacryocystitis
- Hordeolum
- Orbital Cellulitis
- Periorbital Cellulitis

**CODES****ICD9**

373.2 Chalazion

**PEARLS AND PITFALLS**

- Chalazion is a localized inflammatory reaction of the eyelid.
- Differentiation between a chalazion, which is nonpainful and nonerythematous, and a hordeolum or sty, which is typically painful and erythematous, is important as management differs.
- Conservative management with warm compresses is usually the only treatment required:
  - Consider ophthalmologic referral if conservative management fails, the chalazion is recurrent, or the diagnosis is in question.

# CHANCROID

Marcelo Sandoval

## BASICS

### DESCRIPTION

- Chancroid is also referred to as “soft chancre.”
- It is an STI causing painful genital ulceration and painful inguinal adenopathy.
- Symptoms are almost always local, not systemic.
- Painful regional lymphadenopathy
- Fluctuant lymph abscesses (buboes)
- Risk factor for HIV coinfection (1–5)

### EPIDEMIOLOGY

#### Incidence

- Very common worldwide, especially Africa, southeast Asia, and Latin America (1–5)
- Declining in U.S.: 23 cases reported to the CDC in 2007, down from 5,191 in 1989 and 67 in 2002 (4–6)
- Probably underdiagnosed due to expense and unavailability of culture and PCR testing
- 10% of chancroid patients are coinfecting with HSV or syphilis (3,4).
- Male to female ratio is 3:1 (4).
- Prevalence in the pediatric/adolescent population is unknown.

### RISK FACTORS

- Unprotected sexual intercourse
- Sex workers and persons engaging in sexual activity with them
- Illicit drug use
- Immigration from, or travel to, endemic areas such as Asia and Africa
- Low socioeconomic status (1–5)

### GENERAL PREVENTION

- Condom use
- Counseling of high-risk groups

### PATHOPHYSIOLOGY

- *Haemophilus ducreyi*, a highly infectious bacterium, enters a skin break.
- Attracts neutrophils and macrophages to form the initial pustule
- Toxin causes local necrosis and ulceration (7).

- Lesion begins as a single erythematous papule or pustule.
- This quickly erodes into  $\geq 1$  painful chancres (1–20 mm).
- Occurs on average 4–7 days after exposure
- Incubation period average 3–10 days.
- Usually, there is associated painful inguinal adenopathy.

### ETIOLOGY

See Pathophysiology.

### COMMONLY ASSOCIATED CONDITIONS

- HIV
- Herpes simplex virus (HSV)
- Syphilis (3,4)

## DIAGNOSIS

### HISTORY

- Ask about above risk factors.
- Stress confidentiality with adolescents afraid of parental disapproval.
- Ask about abuse/coercion if appropriate.
- History of tender genital papule, then pustule, then ulcer (1)
- Dysuria
- Dyspareunia
- Painful inguinal lymphadenopathy 1–2 wk later in 50% (1,3)
- Buboes: Suppurative adenopathy in 25% (5)

### PHYSICAL EXAM

- Males:
  - Lesions on foreskin, frenulum, glans shaft
  - Painful, necrotic, yellow-grey exudates
  - Soft, not indurated, unlike syphilis
  - Jagged, undermined edges that stand up off the ulcer base
  - Erythematous border (1,4,5)
  - Unilateral lymphadenopathy (1,3–5)
- Females:
  - Similar lesions
  - Vulva, cervix, perianal areas, thighs
  - Unilateral lymphadenopathy (1,4,5)

### DIAGNOSTIC TESTS & INTERPRETATION

#### Diagnostic Procedures/Other

- Clinical diagnosis based on lesion appearance is often inaccurate, and lab testing is difficult or often unavailable by the local health department.
- Diagnosis is based primarily on the clinical findings in conjunction with excluding syphilis and HSV as the cause.
- The main necessary lab testing is that which excludes syphilis:
  - This may be by darkfield microscopic evaluation of ulcer exudates.
  - Also may be by serologic evaluation for syphilis if  $\geq 7$  days since ulcer formation
- Culture for HSV or Tzanck smear may be sent, though these are not highly sensitive.
- Gram stain: Chancroid may demonstrate “schools of fish” parallel linear clusters of gram-negative bacilli:
  - Poor sensitivity/specificity (4,5)
- Culture: Proper medium and qualified technicians are not readily available in most labs (1–5).
- PCR: Still not practical for emergency department use and is not widely available in hospitals (1–5)
- Refer for HIV testing, or perform testing in the emergency department if available (2).

### DIFFERENTIAL DIAGNOSIS

- HSV: Most common genital ulcer in the U.S. (1–5)
- Syphilis: Second most common genital ulcer in the U.S. (1–5)
- Lymphogranuloma venereum (LGV): Seen in travelers to Asia, Africa, the Caribbean, and South America (4,5)
- Granuloma inguinale (GI): South Pacific, Australia, India, the Caribbean (5)
- Helpful syndromic management points:
  - Grouped vesicles prior to ulcer: Suggestive but not diagnostic of HSV (2,3)
  - Painful: HSV, chancroid (4,5)
  - Painless: Syphilis, LGV, GI (4,5)
  - Lymphadenopathy seen in all but GI, but buboes only with chancroid and LGV (4,5)
  - Physical exam has poor predictive value, especially with concomitant HIV.
  - Syndromic management decisions use history, exam, testing with darkfield and Tzanck preparations, direct HSV immunofluorescence, and viral culture (1,2).
  - CDC diagnostic criteria: Probable diagnosis of chancroid if painful ulcers with lymphadenopathy do not have darkfield or serologic evidence of syphilis, nor Tzanck or culture evidence of HSV (2).
  - Treat for LGV if buboes are present (3 wk of treatment) (1).

## TREATMENT

### MEDICATION

#### First Line

- Azithromycin 1 g PO × 1 dose
- Ceftriaxone 250 mg IM × 1 dose
- Single-dose regimens assure compliance but may fail in HIV or in uncircumcised patients (1–5).

#### Second Line

- Ciprofloxacin 500 mg PO b.i.d. × 3 days
- Erythromycin base 500 mg PO t.i.d. × 7 days (1–5)

#### Pregnancy Considerations

- Safety of azithromycin in pregnancy and lactation has not been established (2).
- Ciprofloxacin is contraindicated in pregnancy (2).

### SURGERY/OTHER PROCEDURES

- Buboec <5 cm in size usually resolve with treatment. Size >5 cm usually requires drainage (5).
- Incision and drainage of buboes is preferred over aspiration, as there is less need to repeat the procedure (2,5).

### DISPOSITION

#### Admission Criteria

- Rarely necessary
- Admission is warranted in rare cases of extensive tissue necrosis or severe systemic illness. Refer to complications below.

#### Issues for Referral

- Sexual partners need evaluation and treatment if exposed within 10 days of lesion or symptom onset (2).
- Some states require notification of child protection authorities if the patient is below the age of consent. Know your local reporting requirements and call social services as needed.

## FOLLOW-UP

### FOLLOW-UP RECOMMENDATIONS

- Follow-up in 3–7 days with the primary care provider (2).
- Incision and drainage packing removal in 24–48 hr if applicable
- Discharge instructions and medications:
  - Analgesics as needed
  - Avoid sexual activity until lesions are healed.
  - Safe sex education

### Patient Monitoring

- 3-day symptomatic improvement and 7-day subjective appearance improvement are typical of successful treatment (3,5).
- Incision and drainage may need to be done later if bubo develops or recurs despite primary ulcer healing (2,3,5).
- Repeat syphilis and HIV testing at 3 mo is recommended (2).

### PROGNOSIS

- Generally excellent with improvement by 3 days and healing by 7–14 days (2,3,5)
- Longer healing times and treatment failures are seen in uncircumcised men, larger ulcers, and HIV-positive patients (1–5).
- Erythromycin regimen for 7 days may be preferred for HIV patients (2).
- Any treatment failure should also prompt a search for a different or coinfecting STI, drug resistance, noncompliance, and/or HIV-positive status (2).

### COMPLICATIONS

- Scarring (1,3)
- Balanoposthitis (4)
- Phimosis (4)
- Bubo rupture and superinfection (1,4,5)
- Phagendic variant with widespread necrosis and tissue destruction (5)
- Systemic fever/illness (rare)
- Fistula formation (4)

### See Also (Topic, Algorithm, Electronic Media Element)

- Herpes Simplex
- Sexually Transmitted Infections
- Syphilis

### CODES

#### ICD9

099.0 Chancroid

## PEARLS AND PITFALLS

- Pearls:
  - HSV and syphilis are the most common source of anogenital ulcers, followed by chancroid.
  - Clinical impression is often unreliable in differentiating syphilis, HSV, and chancroid.
  - Emergency department testing with darkfield and Tzanck smears, direct immunofluorescence, and viral cultures and syphilis serologies should be done if available to enhance correct diagnosis and treatment.
  - Buboes may persist or even grow after ulcer resolution, but this does not necessarily mean treatment failure.
  - Buboes often resolve with treatment, but if >5 cm in size, incision and drainage, rather than aspiration, is preferred.
  - Treatment failure is associated with coinfection with another STI or HIV.
- Pitfalls:
  - If a purely clinical approach without testing in the emergency department is the only practical option, failing to ensure that the patient understands follow-up is crucial due to the potential for error in diagnosis.
  - Not arranging follow-up syphilis and HIV serologies at 3 mo
  - Failing to recommend that sexual partners seek evaluation for STI

# CHICKENPOX/SHINGLES

Keri Cohn  
Sarita Chung

## BASICS

### DESCRIPTION

Varicella zoster virus (VZV), a herpes virus, results in two common clinical entities:

- Varicella (Chickenpox), is a result of primary infection, and is characterized by fever and disseminated rash
- Herpes Zoster (Shingles), is reactivation disease of latent virus residing in the dorsal root ganglion from previous infection (or immunization). It is characterized by a painful, vesicular rash of dermatomal distribution

### EPIDEMIOLOGY

#### Incidence

- Peaks during late winter and early spring
- Pre-vaccine era incidence in the U.S.:
  - Chickenpox: 4 million cases
    - >90% patients are <15 yr of age
  - Zoster: 1.2 million cases
- Postvaccine decline of ~95% in varicella incidence (including decline in <12-mo-old group, suggesting herd immunity)
  - Decrease in varicella-related hospitalizations and costs of ~85%
  - Decrease in mortality by 75%

#### Prevalence

- VZV is highly contagious, affecting >90% of seronegative exposed persons, with a prevalence of ~75,000 cases occurring at any one time in the U.S.
- >95% of adults have antibodies to VZV, suggesting an almost universal lifetime infection rate.

### RISK FACTORS

- Immunocompromised hosts, particularly T-cell defects or HIV/AIDS, are at high risk for severe or disseminated disease.
- Increased risk of vaccine failure: <12 mo or >5 yr of age at time of vaccination, history of asthma/eczema, patients receiving steroids (>2 mg/kg of prednisone or 20 mg/day)

### GENERAL PREVENTION

The 2-dose live-attenuated varicella vaccine series is 95% effective in preventing severe disease. 10–30% of vaccinated children develop mild to moderate disease upon exposure.

### PATHOPHYSIOLOGY

- Spread by direct contact with fluid from vesicles/zoster lesions or by airborne spread from respiratory tract secretions (varicella or disseminated zoster in immunocompromised host)
- VZV inoculates respiratory epithelial cells and spreads to regional nodes, thereafter causing primary viremia and subsequent infection of liver reticuloendothelial cells.

- After replication in the reticuloendothelial system, a secondary viremia occurs.
- Skin lesions (a source of continued replication) form 10–21 days after exposure.
- Respiratory mucosal sites are infected in late incubation, so respiratory droplets are infectious 1–2 days prior to rash.
- Primary VZV results in latent infection in the dorsal root ganglion.
- Reactivation (zoster) occurs in a sensory dermatomal distribution; it does not infect respiratory cells in the immunocompetent host.
- Intact cellular immunity is important for control of viremia and localized replication.

### ETIOLOGY

VZV is a double-stranded DNA herpesvirus that infects only humans and is responsible for varicella disease and reactivation zoster.

## DIAGNOSIS

### HISTORY

- Varicella:
  - Prodrome of fever and malaise 1–3 days prior to rash
  - Resolution of fever within 24 hr of rash
  - Universally pruritic centripetal rash starting on trunk/neck/face and progressing outward
- Zoster:
  - Sudden onset of vesicular lesions in dermatomal distribution (often T3–L3)
  - Pain, sometimes severe, may precede lesions by 48–72 hr
  - Typical course: Few lesions that form for 3–5 days and last for 7–10 days
  - Immunocompromised host: More lesions, longer course, risk for dissemination

### PHYSICAL EXAM

- Primary varicella infection:
  - Rash: Erythematous papules (2–4 mm) evolving to vesicles, then pustules over 6–8 hr, then crusting within days
  - Successive crops appear over 2–4 days, so lesions (250–500) are in various stages of evolution.
  - Mucosal exanthem (oropharynx; less commonly, the vagina)
  - Secondary family cases have more lesions than the index case.
- Herpes zoster:
  - Painful grouped vesicular lesions on erythematous base distributed in 1–3 sensory dermatomes
  - 15–20% of patients have extradermatomal dissemination.

### DIAGNOSTIC TESTS & INTERPRETATION

Visual diagnosis is sufficient in most cases.

#### Lab

##### Initial Lab Tests

Lab testing is not necessary:

- CBC may show leukocytosis
- Mild transaminitis may be present.

#### Imaging

Imaging is generally not necessary. CXR may show interstitial infiltrates in 10–15% of adolescents (even without respiratory symptoms).

#### Diagnostic Procedures/Other

- Vesicular base scraping for direct fluorescent antibody or VZV PCR
- Vesicular fluid/scab for VZV PCR
- VZV IgM is not reliable for routine confirmation of acute infection (though if positive, this is suggestive of recent infection).
- Acute and convalescent VZV IgG levels can retrospectively confirm the diagnosis.
- Tissue/vesicular fluid viral culture (may take  $\geq 7$  days)

#### Pathological Findings

Tzanck smear of vesicular scrapings shows multinucleated giant cells with inclusions (not specific for VZV). Sensitivity is only 60%.

### DIFFERENTIAL DIAGNOSIS

- Disseminated herpes simplex virus (HSV)
- Eczema herpeticum
- Disseminated enterovirus
- Atypical measles
- Rickettsial pox
- Smallpox
- Both HSV and coxsackievirus can cause dermatomal vesicular lesions similar to zoster.

## TREATMENT

### PRE HOSPITAL

Identification of cases, isolation from public places to contain infection

### INITIAL STABILIZATION/THERAPY

- Assess and stabilize airway, breathing, and circulation.
- Mainstay of initial treatment in stable patients is infection control:
  - Varicella (including vaccine breakthrough): Contact and airborne precautions (negative pressure rooms if possible) in patients with lesions, unless all lesions have crusted over (min of 5 days after onset)
  - All disseminated zoster and immunocompromised hosts with local zoster: Contact and airborne precautions for duration of illness
  - Local zoster in normal hosts: Contact precautions until lesions crust over
  - Nonimmune exposed patients: Strict contact and airborne precautions from 8–21 days after exposure
  - Nonimmune exposed patients who have received VariZIG/intravenous immunoglobulin (IVIG) should have strict contact and airborne precautions for 28 days.

**MEDICATION**

- **Varicella:**
  - Diphenhydramine or hydroxyzine for pruritis
  - Antivirals are not indicated for uncomplicated disease in the healthy host.
  - Consider acyclovir if increased risk for complications (> 12 yr of age, chronic skin conditions, chronic lung diseases, patients receiving long-term salicylate or steroid [oral/inhaled] therapy, secondary household cases, pregnant women):
    - Oral acyclovir, if given within 24 hr of onset of rash, will reduce the duration of fever and the number/duration of lesions (80 mg/kg/day divided q6h × 5 days).
    - Acyclovir for any hospitalized child with ongoing vesicle formation (1,500 mg/m<sup>2</sup>/day IV divided q8h × 7–10 days)
    - Immunocompromised hosts require IV acyclovir (prevents visceral dissemination)
  - IVIG/VariZIG does not alter the disease course once symptomatic.
- **Zoster:**
  - Famciclovir and valacyclovir are licensed to treat zoster in adults; no data for children.
  - For adults: Famciclovir 500 mg or valacyclovir 1 g t.i.d. × 7 days, or acyclovir 800 mg 5 times daily × 7–10 days
  - Severely immunocompromised (transplants, malignancy) hosts require IV acyclovir.
  - May consider PO therapy in well, lower-risk immunocompromised hosts.
- Acyclovir resistance is rare; consider IV foscarnet.
- **Postexposure prophylaxis:**
  - Postexposure prophylaxis for nonimmune persons: Vaccine within 120 hr of exposure (ideally <72 hr) may prevent or modify disease.
  - VariZIG/acyclovir is indicated ASAP and within 96 hr of significant exposure in susceptible patients:
    - VariZIG dose: 12.5 units/kg (max single dose 625 units) IM or, if not available, IVIG 400 mg/kg
    - Acyclovir dose: 80 mg/kg/day divided q6h for 7 days (max 800 mg)
  - Significant exposure is:
    - Varicella: Household contact, indoor face-to-face play, newborns with mothers whose varicella lesions began between 5 days before and 2 days after delivery
    - Zoster: Intimate tactile contact
  - Candidates for postexposure prophylaxis if significant exposure: Immunocompromised (including HIV); unvaccinated pregnant patients without history of varicella, newborns with above perinatal exposure, hospitalized preterm infants
- Analgesic may be needed, particularly for varicella zoster:
  - Acetaminophen 15 mg/kg/dose PO/PR q4h PRN
  - NSAIDs:
    - Ibuprofen 10 mg/kg/dose PO/IV q6h PRN
    - Ketorolac 0.5 mg/kg IV/IM q6h PRN
    - Naproxen 5 mg/kg PO q8h PRN
    - Some clinicians prefer to avoid due to theoretical concern over bacterial superinfection.
  - Opioids:
    - Morphine 0.1 mg/kg IV/IM/SC q2h PRN:
      - Initial morphine dose of 0.1 mg/kg IV/SC may be repeated q15–20min until pain is controlled, then q2h PRN.

- Codeine or codeine/acetaminophen dosed as 0.5–1 mg/kg of codeine component PO q4h PRN
- Hydrocodone or hydrocodone/acetaminophen dosed as 0.1 mg/kg of hydrocodone component PO q4–6h PRN

**DISPOSITION****Admission Criteria**

- Immunocompromised hosts with varicella
- VZV pneumonia
- Bacterial superinfection requiring IV therapy
- Pain refractory to outpatient management
- Critical care admission criteria:
  - Respiratory failure
  - Sepsis
  - Consider ICU admission for varicella complicated by necrotizing fasciitis.

**Discharge Criteria**

Clinical stability, immunocompetent host

**Issues for Referral**

- High-risk patients should have close follow-up.
- Zoster ophthalmicus requires immediate ophthalmology referral.
- Infectious disease consultation for immunocompromised hosts

**COMPLEMENTARY & ALTERNATIVE THERAPIES**

- Aluminum acetate soaks for zoster
- Postherpetic neuralgia pain management (consider narcotics, gabapentin). Prednisone therapy may be beneficial in healthy patients with severe pain.

**FOLLOW-UP****FOLLOW-UP RECOMMENDATIONS**

- Discharge instructions and medications:
  - Supportive care with acetaminophen and antipruritics. Avoid aspirin and NSAIDs.
  - Acyclovir for high-risk patients
- Activity:
  - Exclusion of children from school until varicella lesions have crusted over
  - Zoster lesions may be covered for return to school.

**Patient Monitoring**

Primary care follow-up as needed

**PROGNOSIS**

- Healthy children tend to have benign disease lasting ~1 wk with an excellent prognosis.
- U.S. post-vaccine era mortality of varicella has decreased from 100 to 4 deaths per year.
- Perinatal varicella (~30% mortality) is severe disseminated disease due to lack of maternal protective antibodies.

**COMPLICATIONS**

- Bacterial superinfection of skin lesions
- Group A streptococcal sepsis/necrotizing fasciitis
- CNS complications (acute cerebellar ataxia, encephalitis) occur ~21 days post rash. CSF WBC up to 300; CSF protein 40–80 mg/dL.

- Pneumonia (adults or immunocompromised) occurs 3–5 days into illness; may have hemoptysis.
- Hemorrhagic varicella (mostly immunocompromised hosts)
- Less common: Thrombocytopenia, glomerulonephritis, arthritis, hepatitis, visceral VZV, transverse myelitis, Guillain-Barré syndrome, myocarditis, corneal lesions (zoster ophthalmicus), Ramsey Hunt syndrome, Reye syndrome (associated with salicylate use)

**ADDITIONAL READING**

- American Academy of Pediatrics Committee on Infectious Diseases. Prevention of varicella: Recommendations for use of varicella vaccines in children, including a recommendation for a routine 2-dose varicella immunization schedule. *Pediatrics*. 2007;120(1):221–231.
- Harper MB, Fleisher GR. Infectious disease emergencies. In Fleisher GR, Ludwig S, eds. *Textbook of Pediatric Emergency Medicine*. 6th ed. Philadelphia, PA: Lippincott Williams & Wilkins; 2010:887.

**ICD9**

- 052.9 Varicella without mention of complication
- 053.9 Herpes zoster without mention of complication

**PEARLS AND PITFALLS**

- Postvaccine varicella occurs in 3–5% of children at 5–26 days after immunization (typically 2–5 lesions, rash may be maculopapular).
- Immunosuppressed individuals, pregnant women, and infants <12 mo old should not be vaccinated.
- Vaccine-related immunity is >10–20 yr.
- VariZIG is not indicated for healthy term infants with postnatal varicella exposure (including those whose mother's rash developed >48 hr post delivery).
- Avoid salicylates due to increased risk of Reye syndrome.

# CHILD ABUSE

Lili Moran

## BASICS

### DESCRIPTION

- Child abuse may be subclassified:
- Physical abuse: An injury inflicted on a child by a caregiver via various nonaccidental means
- Sexual abuse: The involvement of children in sexual activities that they do not understand, for which they are not developmentally prepared, to which they cannot give consent, and that violate societal taboos
- Emotional abuse: Also called psychological maltreatment; includes intentional verbal or behavioral acts or omissions that result in adverse emotional consequences
- Neglect: The failure of caregivers to meet the needs of a child resulting in harm:
  - Can be physical, medical, emotional, educational, etc.
  - May result in failure to thrive, developmental delay, and poor health

### EPIDEMIOLOGY

- According to the National Incidence Studies of Child Abuse and Neglect (NIS-4) data from 2005–2006, ~1.25 million children experience maltreatment in the U.S. each year, corresponding to roughly 1 in 58 children.
- 44% of the cases included abuse:
  - 58% physical abuse
  - 27% emotional abuse
  - 24% sexual abuse
- 61% of the cases involved neglect.
- 1,760 cases of death reported in 2007 secondary to abuse
- Ranges from 5–35% at any given time in the U.S.

### RISK FACTORS

- Violence, including domestic violence
- Parental stress factors, including:
  - Financial problems, socioeconomic status
  - Mental illness
  - Substance abuse
  - Isolation
- Child with developmental delay or medical problems

### GENERAL PREVENTION

- Screening for signs of abuse on all patient interactions
- Early intervention in high-risk families
- Universal parenting education, home visitations

### PATHOPHYSIOLOGY

- The mechanisms of abuse may vary by type
- The common pathophysiology involves a caretaker causing intentional harm to a child either by inflicting injuries or abuse or by failure to meet the needs of the child.

### ETIOLOGY

- A complex dynamic including a parent who is capable of abuse, a child who actively or passively becomes the target, and a crisis that triggers the angry response
- Family stress and lack of specific child-rearing information play important roles.

### COMMONLY ASSOCIATED CONDITIONS

Munchausen by proxy

## DIAGNOSIS

### HISTORY

- The history provided by a caretaker may not be consistent with a plausible explanation for the injury.
- History provided may change or be inconsistent with the caregiver providing different accounts of the accident or injury to different health care providers or explanation or account of accident or injury changes over time.
- Multiple previous injuries or visits may have occurred, though this is not necessary for diagnosis.
- Delay in seeking care after injury, particularly with no explanation given
- Parents may seek care at a facility distant from their home rather than a facility at which they typically would seek care.
- Child's developmental level may not be compatible with the mechanism described.
- Parent blames the child or another child for the injury.

### PHYSICAL EXAM

- Evidence of major injuries with history of minor trauma
- Specific injuries for inflicted trauma:
  - Bruises: Patterns, symmetry, nonbony prominences
  - Burns: Patterns, symmetry, location
  - Retinal hemorrhages
  - Oral injuries, particularly frenulum tears
  - Fractures: Classic metaphyseal lesions (bucket handle), complex skull fractures, posterior rib fractures, scapular fractures
  - Abdominal injuries: Often occult
  - Genital injuries can represent physical or sexual abuse: Some injuries may be highly suggestive of sexual abuse

- Injuries in different stages of healing when history is only of 1 episode of trauma
- Evidence of healed lesions/scars from previous trauma
- Growth failure
- Inflicted head trauma, also known as shaken baby syndrome or shaken impact syndrome: Hallmark is subdural hemorrhage, a marker for diffuse acceleration-deceleration brain injury, often found with retinal hemorrhages and posterior rib fractures.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

- Lab values may occasionally be useful but are not routinely necessary.
- To look for occult abdominal trauma, screening labs may be sent.
- CBC to evaluate for blood loss
- PT/PTT if bruising or hemorrhage
- LFTs, lipase if concern for severe abdominal injury
- Urinalysis: Screen for genitourinary injury or myoglobinuria, hematuria.
- Lumbar puncture: Evaluate for intracranial hemorrhage.
- Toxicology screens if suspicion for malicious poisoning
- STI screening

#### Imaging

- Radiographs may be indicated if suspicion for injury or abuse
- CT and MRI for suspected head, thoracic, or abdominal trauma
- US can be used to scan for abdominal trauma, fractures, pneumothorax, etc.
- Skeletal surveys may be useful in children who lack ability to give verbal history, especially children <2 yr old.
- Radionuclide bone scan: Can be an adjunct to a skeletal survey, particularly if detecting an early occult fracture is of significant importance.

#### Diagnostic Procedures/Other

- It is important to clearly document all findings in the chart, using quotation marks for quotes.
- Avoid using terminology like "alleged" and "rule out abuse." Simply document the stated complaint and physical findings, including who is with the patient for the exam, etc.
- Avoid giving highly specific dates, times, and person identifiers:
  - Precise time, date, and identification of persons is not necessary in the medical record.
  - This avoids potential problems with inconsistency between the medical record and police record.

- A body diagram is important in documenting location and size of injuries; measurements should be included.
- Visible injuries should be photographed with a ruler present in the photo along with a card with the child's name, the date, and the signature of the photographer visible in the picture. Consent should be obtained for the photographs.

### Pathological Findings

- Physical abuse:
  - Subdural hematomas: Hallmark of inflicted head injury
  - Retinal hemorrhages
  - Burns: Classic patterns, such as glove and stocking distribution, dunking burns. Other patterned burns, such as cigarette burns, irons, etc., are also highly suspicious.
  - Bruises: Patterned bruises (ie, belt mark loop or lashes, handprints) are suspicious for abuse. Symmetrical bruises over nonbony prominences are also very suspicious.
- Neglect:
  - Failure to thrive, growth failure, noncompliance with medical treatments
- Sexual abuse:
  - Hymenal tears, vaginal lacerations
  - Anal lacerations
  - Perineal bruising
  - Bite marks to breasts, genitals
  - Precocious sexual behavior in young children

### DIFFERENTIAL DIAGNOSIS

- Accidental injury
- Infection: Sepsis, meningitis, congenital syphilis, osteomyelitis, impetigo, staph scalded-skin syndrome, purpura fulminans
- Phytophotodermatitis
- Cultural practices: Coining, cupping, moxibustion
- Metabolic: Copper deficiency, rickets, scurvy, vitamin K deficiency
- Congenital: Osteogenesis imperfecta, Ehlers-Danlos syndrome, familial dysautonomia with congenital indifference to pain, Mongolian spots, minor skeletal anomalies
- Immunologic: Henoch-Schönlein purpura, immune thrombocytopenic purpura
- Hematologic: Leukemia, hemophilia, von Willebrand disease, disseminated intravascular coagulation
- Miscellaneous: Apparent life-threatening event (ALTE), epidermolysis bullosa, erythema multiforme

### TREATMENT

#### PRE HOSPITAL

Trauma patients should be stabilized in the same manner they otherwise would be.

#### INITIAL STABILIZATION/THERAPY

- Management is dependent on injuries (ie, ABCs, head and visceral injuries managed accordingly).
- Medical caregivers in all states are mandated to report suspected child abuse.

### MEDICATION

Varies by injury

### DISPOSITION

#### Admission Criteria

- Children may require admission to care for their medical concerns (ie, burns, head injuries, etc.).
- Children may also be admitted when no suitable environment is available until a safe residence is secured.
- Critical care admission criteria:
  - Patients who have injuries that are life threatening may require critical care admission.

#### Discharge Criteria

- The child must be medically stable and prepared for discharge.
- It must be ensured that the child is being discharged to a safe environment with adequate follow-up.

#### Issues for Referral

Health care workers are mandated reporters and are protected by law when they refer a case to child protective services or the police in good faith.

### FOLLOW-UP

#### FOLLOW-UP RECOMMENDATIONS

Discharge instructions and medications:

- Family therapy may be indicated.
- In cases of neglect, additional measures may be needed to ensure compliance.
- Physical injuries should be treated in the same methods for noninflicted injuries.

#### Patient Monitoring

Cases must be investigated by child welfare agents and/or the police, who will determine the need for foster care placement or ongoing supervision.

#### PROGNOSIS

Varies depending on the injuries sustained, the degree of neglect, the family dynamic, and available support system

#### COMPLICATIONS

- Death
- Mental retardation
- Cerebral palsy
- Seizures
- Learning disabilities
- Emotional problems
- Posttraumatic stress disorder
- Neglect may lead to growth failure, developmental delay, and complications from poor nutrition, medical neglect, or other forms of neglect.
- Substance abuse and psychological sequelae are common in victims of sexual abuse.

### ADDITIONAL READING

#### See Also (Topic, Algorithm, Electronic Media Element)

Sexual Assault

### CODES

#### ICD9

- 995.50 Unspecified child abuse
- 995.51 Child emotional/psychological abuse
- 995.52 Child neglect (nutritional)

### PEARLS AND PITFALLS

- Always maintain a high suspicion of abuse, particularly when the history does not match the physical exam findings.
- Health care workers are mandated reporters: Failure to report suspicion could result in legal action.

# CHOLELITHIASIS

Lauren S. Chernick  
Anupam Kharbanda

## BASICS

### DESCRIPTION

- Gallstones are crystalline structures formed from both normal and abnormal bile components.
- Symptoms develop when stones migrate out of the gallbladder into the biliary canals:
  - 40% of children with gallstones are asymptomatic.
  - Gallstone complications occur when stones:
    - Obstruct the cystic duct (cholecystitis)
    - Obstruct the common bile duct (choledolithiasis)
    - Cause an infection of the common bile duct (cholangitis)

### EPIDEMIOLOGY

#### Prevalence

- In children, gallstones are rare (0.1–0.2%) but are recently thought to be increasing (1.9%) (1):
  - Most common type of stone in children is black pigment stones (2).
  - Females = males until puberty, when females > males
- In adults, gallstones are common with >20 million cases/year in the U.S. (3):
  - Most common type of stone in adults is cholesterol stones.
  - Females > males
- The prevalence of gallstones is higher in children with certain chronic diseases like hemolytic anemia:
  - The prevalence of gallstones in children with sickle cell disease (SCD) is double the general population.
  - ~50% of all children with SCD will develop gallstones.
- Of all ethnic groups in the U.S., Native Americans have the highest prevalence.

### RISK FACTORS

- Black pigment stones have been associated with hemolytic diseases such as SCD and beta-thalassemia, cystic fibrosis, ileal resection, and prolonged total parenteral nutrition (4).
- Cholesterol stones have been associated with female gender, obesity, pregnancy, rapid weight loss, and a family history of gallstones.

### PATHOPHYSIOLOGY

- Stones form when 1 normal component of bile increases in quantity and supersaturates, thus forming a nidus for stone formation.
- Stones are typically classified as black pigment, cholesterol, brown pigment, or mixed.
- Black pigment stones form when there is excess bilirubin in the bile:
  - Abnormal production or destruction of RBCs leads to increased levels of bilirubin.

- Cholesterol stones form when there is excess cholesterol in the bile:
  - Cholesterol supersaturates the bile and crystallizes.
  - Stone growth is accentuated in those with abnormal/decreased motility of the gallbladder.
- Brown pigment stones, although rare, often develop in the presence of obstruction and infection. They often contain bacteria, calcium bilirubinate, cholesterol, and fatty acids.

### ETIOLOGY

- Hemolytic disease
- Prematurity
- Inflammatory bowel disease
- Obesity
- Oral contraceptive use
- Pregnancy

## DIAGNOSIS

### HISTORY

- No single sign or symptom is highly sensitive or specific for cholelithiasis.
- Biliary colic results from gallbladder contraction and presents with the following characteristics:
  - Pain in right upper quadrant (RUQ) and/or epigastrium
  - Persistent or episodic pain, but the pain should last less than a few hours
  - Pain that may radiate to right shoulder, back, or flank
  - Possible association with nausea, vomiting, or eating fatty foods
- Incidental gallstones can be asymptomatic.
- Pain lasting longer than 4–6 hr suggests biliary obstruction.

### PHYSICAL EXAM

- Asymptomatic or mildly symptomatic gallstones should accompany normal vital signs.
- Certain components of the physical exam may suggest complications such as obstruction of the biliary tree or biliary infection:
  - Tachycardia or fever
  - Bradypnea due to splinting
  - RUQ and/or epigastric pain
  - Jaundice
  - A hard, rigid, or distended abdomen
  - Murphy sign:
    - Worsening pain or inspiration arrest when RUQ is palpated
    - Highly sensitive in adults for cholecystitis

## DIAGNOSTIC TESTS & INTERPRETATION

### Lab

#### Initial Lab Tests

- No lab testing is necessary when stones are confined to the gallbladder (all will be normal).
- The following are reasonable tests to evaluate other causes of abdominal pain:
  - AST, ALT, direct and indirect bilirubin, and GGT (liver involvement)
  - Amylase and lipase (pancreatitis)
  - CBC (hemolytic anemia or leukocytosis)
  - C-reactive protein (elevated in cholecystitis)
  - Urine pregnancy and urinalysis
  - Leukocytosis suggests cholecystitis.
  - Elevated GGT or direct bilirubin suggests cholangitis.

### Imaging

- US is the modality of choice (5):
  - Strengths:
    - Sensitivity and specificity >95%
    - Visualizes stones as small as 2 mm
    - Inexpensive and noninvasive
    - Gallbladder distention, wall thickening, or pericholecystic fluid suggests cholecystitis.
  - Weaknesses:
    - Poor visualization of common bile duct
- Plain radiographs:
  - Low sensitivity for stone visualization
  - A poor choice to rule in or out cholelithiasis
- CT: Rarely used as the test of choice due to its poor visualization of stones:
  - Strengths:
    - Helps to define gallbladder anatomy and adjacent organs
  - Weaknesses:
    - Associated with a lower sensitivity than US for visualizing stones
- Magnetic resonance cholangiopancreatography (MRCP) and endoscopic retrograde cholangiopancreatography (ERCP) help to delineate the anatomy of the extrahepatic and intrahepatic biliary tract and identify the location of stones:
  - MRCP:
    - Strengths: Useful diagnostic mechanism for localizing stones, has a sensitivity between 90 and 96%, and can better visualize the common bile duct (6)
    - Weaknesses: Does not provide a method for stone removal, not available at all institutions, and requires sedation
  - ERCP:
    - Strengths: Provides a diagnostic and therapeutic mechanism for localizing and removing the stone
    - Weaknesses: Invasive and may offer no advantage for clearance of the bile duct over surgical approaches

**DIFFERENTIAL DIAGNOSIS**

- RUQ/Epigastric pain: GERD, gastritis, pancreatitis, peptic ulcer disease, hepatitis, appendicitis, acute acalculous cholecystitis, inflammatory bowel disease, acute gastroenteritis
- Gallstone complications: Cholecystitis, choledolithiasis, cholangitis, pancreatitis

 **TREATMENT**

**PRE HOSPITAL**

- Uncomplicated cholelithiasis or biliary colic requires no intervention by EMS.
- If the patient has abnormal vital signs, secure IV access and administer IV fluids.

**INITIAL STABILIZATION/THERAPY**

Ill-appearing patients, likely suffering from biliary stone complications, should be stabilized:

- Assess and support the airway, if necessary.
- Assess circulatory needs:
  - Place 2 large-bore IV catheters.
  - Give IV fluids for volume deficiency (20 cc/kg boluses of normal saline).
  - Provide pain control.
- Assess for signs of peritonitis.

**MEDICATION**

**First Line**

- Analgesics:
  - Merperidine 1 mg/kg IV q4h, max single dose 100 mg
  - Ketorolac 0.5 mg/kg q8h IV/IM, max single dose 30 mg
- Antiemetics for nausea: Ondansetron 0.1 mg/kg IV, max single dose 4 mg
- Antibiotics if suspicious for acute cholecystitis or cholangitis, covering *Escherichia coli* and *Klebsiella* species:
  - 2nd-generation cephalosporin with anaerobic coverage such as:
    - Cefoxitin 80–160 mg/kg/24 hr divided q4–6h IM/IV OR
    - Cefotetan 40–80 mg/kg/24 hr divided q12h IV/IM
  - Piperacillin/Tazobactam: Infants <6 mo, 150–300 (piperacillin component) mg/kg/24 hr IV divided q6–8h; infants >6 mo and children, 300–400 mg/kg/24 hr IV divided q6–8h

**Second Line**

- Cholesterol stones are more likely to respond to nonsurgical management than other stones.
- Bile salt dissolvents such as ursodiol (Actigal) 10–15 mg/kg/24 hr daily PO:
  - Usually prescribed as outpatient medication
  - Stone must be noncalcified, small, and with a low likelihood of causing complications.
  - Good for patients when surgery is too high of a risk to perform (eg, cardiac disease)
  - May not work and stones can recur (4)

**SURGERY/OTHER PROCEDURES**

Laparoscopic cholecystectomy is the treatment of choice for symptomatic cholelithiasis.

- Patients with mild intermittent biliary colic can be scheduled for outpatient elective laparoscopic cholecystectomy.

- Patients with a clinical picture suggestive of cholecystitis should be admitted; the timing of cholecystectomy and/or ERCP is surgeon/GI specialist dependent but often occurs before discharge.
- Cholecystectomy is not recommended for incidental or asymptomatic gallstones.

**DISPOSITION**

**Admission Criteria**

- Patients with unresolved biliary colic or any suspicion of cholecystitis, choledolithiasis, cholangitis, or pancreatitis should be admitted.
- Critical care admission criteria:
  - Patients who are ill with unstable vital signs despite fluid resuscitation and antibiotics should be considered for ICU admission.

**Discharge Criteria**

- Patients with incidental gallstones or asymptomatic gallstones can be discharged home with primary care physician follow-up.
- Patients with resolved biliary colic can be discharged with timely outpatient surgical follow-up (within 1 wk).

 **FOLLOW-UP**

**FOLLOW-UP RECOMMENDATIONS**

Discharge instructions and medications:

- Return to the emergency department if the pain is severe, pain is not resolved with NSAIDs, or jaundice develops.

**PROGNOSIS**

- Some gallstones will resolve without any medical intervention.
- Patients with recurrent biliary colic without cholecystectomy have a high likelihood of experiencing a biliary obstruction.

**COMPLICATIONS**

- Gallbladder perforation
- Peritonitis
- Bacterial overgrowth
- Choledocholithiasis: Stone obstructing the common biliary duct
- Ascending cholangitis
- Pancreatitis

**See Also (Topic, Algorithm, Electronic Media Element)**

- Hepatitis
- Pain, Abdomen

 **CODES**

- ICD9**
- 574.20 Calculus of gallbladder without mention of cholecystitis, without mention of obstruction
  - 574.21 Calculus of gallbladder without mention of cholecystitis, with obstruction
  - 575.10 Cholecystitis, unspecified

**PEARLS AND PITFALLS**

- Gallstones are relatively uncommon in children. Children with hemolytic or ileal diseases are more at risk.
- Diagnostic modality of choice is US.
- Patients with asymptomatic gallstones can be followed as outpatients.
- Patients complaining of uncomplicated cholelithiasis should not appear ill.
- Resolved biliary colic can be followed up in the surgery clinic.
- Do not discharge home patients with sustained biliary colic, possible cholecystitis, choledolithiasis, or cholangitis. Patients should be admitted, given antibiotics, and have a surgical evaluation.

# CHOLINERGIC POISONING

Robert J. Hoffman

## BASICS

### DESCRIPTION

- Cholinergic poisoning results from agonism at muscarinic and/or nicotinic cholinergic receptors.
- This poisoning mimics the action of acetylcholine.
- Cholinergic poisoning results from exposure to pesticides as well as some medications.
- Organophosphate and carbamate pesticides cause severe cholinergic poisoning.
- Nerve gas agents are organophosphates that are extremely potent and capable of causing death rapidly.

### EPIDEMIOLOGY

#### Incidence

- In the U.S., cholinergic poisoning in children occurs predominantly due to pesticide exposure.
- This is more common in rural areas with agricultural industry but also occurs in urban areas.

### RISK FACTORS

- Use of pesticides without protective gear or use of pesticides in areas where unprotected persons are located
- Organophosphate and carbamate pesticides should not be used indoors:
  - Inappropriate indoor use places children at great risk.

### GENERAL PREVENTION

- Avoid exposure to pesticides and medications by storing these safely out of reach of children.
- Wear protective clothing when working with pesticides.

### PATHOPHYSIOLOGY

- Cholinergic agonism excites postganglionic cholinergic receptors:
  - Classic symptoms result from activity at muscarinic receptors, but nicotinic receptors may also be affected.
- Organophosphate agents bind irreversibly at the cholinergic receptor:
  - Initially, a weak electrostatic bond is formed.
  - Later, this becomes a permanent covalent bond:
    - This process is called “aging,” and treatment with pralidoxime is aimed at preventing this.
  - Nerve agents such as sarin and soman are particularly feared due to quick aging time.
- **DUMBELS** mnemonic describes most toxicity:
  - *Diarrhea, Diaphoresis, Urinary incontinence, Miosis, Bronchorrhea, Bronchospasm, Bradycardia, Emesis, Lacrimation, Salivation, Seizures*
- **MTWTF** mnemonic for nicotinic toxicity:
  - *Mydriasis, Muscle cramps, Tachycardia, Weakness, Twitching, Flaccid paralysis*

- “Intermediate syndrome” is a neurologic phenomenon that occurs 1–3 days after acute pesticide exposure that includes neck weakness, decreased deep tendon reflexes, cranial nerve abnormalities, proximal muscle weakness, and respiratory insufficiency:
  - This weakness may exacerbate and last several weeks.
- Delayed neuropathy with severe pain in a stocking/glove distribution may occur 1–3 wk after exposure:
  - This may persist for months or cause permanent injury.

### ETIOLOGY

- Medications:
  - Acetylcholine
  - Bethanechol
  - Carbachol
  - Pilocarpine
- Pesticides
- Nicotine
- Weaponized organophosphate agents:
  - Sarin
  - Soman
  - VX

### COMMONLY ASSOCIATED CONDITIONS

- Vomiting
- Diaphoresis
- Dyspnea
- Miosis

## DIAGNOSIS

### HISTORY

- See Pathophysiology for **DUMBELS** and **MTWTF** pneumonics.
- Typically, a history of exposure is readily available.
- Symptoms of vomiting, diaphoresis, altered mental status or coma, and weakness may be present.

### PHYSICAL EXAM

- See Pathophysiology for **DUMBELS** and **MTWTF** pneumonics.
- Assess vital signs and pulse oximetry:
  - Tachypnea may be present in response to bronchorrhea or bronchospasm.
  - Respiratory depression secondary to weakness or paralysis may be present.
  - Bradycardia if muscarinic excess, sometimes with hypotension
  - Tachycardia and HTN is nicotinic excess.

- HEENT: Miosis or mydriasis, salivation, eyelid twitching
- GI: Nausea, vomiting, diarrhea
- Respiratory: Dyspnea, cough, bronchospasm, respiratory depression
- Musculoskeletal: Muscle cramps, twitching, fasciculations, weakness, paralysis
- Neurologic: Vertigo, tremor, seizures, coma, paralysis

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

- Assess bedside glucose measurement in patients with altered mental status.
- Obtain acetaminophen concentration in patients with intentional exposure and intent of self-harm.
- Blood gas analysis to assess oxygenation, ventilation, and perfusion
- Lactate concentration to assess perfusion
- Serum electrolytes
- Creatine phosphokinase if prolonged seizures
- RBC cholinesterase and serum cholinesterase levels may be obtained:
  - These are not routinely used in acute management.

#### Imaging

- CXR may be indicated for patients with hypoxemia or symptoms of bronchorrhea/bronchospasm.
- CT of the head may be indicated for seizures or depressed mental status.

#### Diagnostic Procedures/Other

Obtain ECG.

### DIFFERENTIAL DIAGNOSIS

- Nicotine toxicity
- Mixed-drug or polypharmacy ingestion
- Other causes of paralysis or weakness:
  - Botulism
  - Myasthenia gravis
  - Eaton-Lambert syndrome

**TREATMENT**

**PRE HOSPITAL**

- Assess and stabilize airway, breathing, and circulation.
- Administer atropine and pralidoxime if indicated by local protocol.
- If topical exposure, decontaminate as per local protocol.

**INITIAL STABILIZATION/THERAPY**

- Decontamination of any patient exposed to topical cholinergic agents such as pesticides or nerve gas is critical. This action must be taken prior to treatment in the emergency department:
  - This is a particular instance when “airway, breathing, circulation” is not priority. Even compromised patients do not receive attention to ABCs in the emergency department until they are decontaminated.
  - Failure to decontaminate the patient may result in ongoing toxicity of the patient and may result in staff falling ill due to direct contact or from fumes emanating from an inadequately decontaminated patient.
- Assess and stabilize airway, breathing, and circulation.
- Administer high-flow oxygen.
- Supportive care by management of respiratory compromise, bradycardia or dysrhythmia, bronchospasm, and severe toxicity

**MEDICATION**

**First Line**

- In addition to doses of atropine and pralidoxime below, autoinjectors may be used:
  - DuoDote (2.1 mg atropine/600 mg pralidoxime): 1 IM injection initially:
    - If there are no severe symptoms, give no additional medication.
    - If severe symptoms persist, give 2 additional IM autoinjection doses.
- Although initially only adult doses adapted from military antidote kits were available, pediatric kits, as well as combination atropine/pralidoxime (DuoDote), are available.

- Atropine:
  - 0.05 mg/kg IV, max initial dose 2 mg, IV over 5 min
  - If still symptomatic 5 min later, double the dose and administer IV.
  - Continue dosing q5min, doubling the dose and titrating to effect.
  - Use of autoinjector (AtroPen) is acceptable:
    - 15–40 lb (7–18 kg), 0.5 mg IM
    - 40–90 lb (19–41 kg), 1.0 mg IM
    - >90 lb and adults (>41 kg), 2.0 mg
  - Give initial autoinjector dose:
    - If no symptoms discontinue
    - If severe symptoms persist, immediately give 2 additional doses.
  - End point of treatment is drying of pulmonary secretions/pulmonary edema.
  - Reversal of miosis gives a good approximation for adequate quantity of atropine administration.
  - If “wet,” treatment is atropine.
- Pralidoxime:
  - 25 mg/kg, max single dose 1 g, IV over 15–30 min, followed by 25–50 mg/kg/hr, to max infusion of 500 mg/hr
  - 600-mg dose autoinjector may be used.
  - Indicated for fasciculations, weakness, or paralysis
  - If “weak,” treatment is pralidoxime.
- Benzodiazepine for seizure:
  - Diazepam 0.1 mg/kg IV, 0.5 mg/kg PR. When given IV, may repeat dose q5–10min PRN.
  - Lorazepam 0.05 mg/kg IV, may repeat dose q10min PRN.

**Second Line**

Albuterol:

- 0.15 mg/kg nebulized q15min as needed for wheezing

**DISPOSITION**

**Admission Criteria**

- Any treatment with medication warrants hospital admission for observation and possibly further treatment.
- Critical care admission criteria:
  - Unstable vital signs, seizure, or severe toxicity

**Discharge Criteria**

Asymptomatic for 4–6 hr without any treatment given during hospital stay

**Issues for Referral**

- Consider toxicology consultation to manage poisoning.
- Consult psychiatry if the patient has attempted self-harm.

**FOLLOW-UP**

**PROGNOSIS**

- Varies with specific poison and quantity ingested
- With appropriate supportive care and antidote use, most patients recover fully.
- Prolonged paralysis or neurologic sequelae are possible.

**COMPLICATIONS**

- Neurologic sequelae including intermediate syndrome or organophosphate-induced delayed neuropathy
- End-organ injury due to hypoperfusion
- Pulmonary insufficiency due to bronchospasm or pulmonary edema
- Shock
- Death

**ADDITIONAL READING**

- Eddleston M, Phillips MR. Self poisoning with pesticides. *BMJ*. 2004;328:42.

**CODES**

**ICD9**

971.0 Poisoning by parasympathomimetics (cholinergics)

**PEARLS AND PITFALLS**

- Appropriate decontamination of the patient is critical to treat the patient and to protect staff in cases of exposure to pesticides or other organophosphate agents.
- Copious quantities of atropine may be needed.
- Control of seizures is critical.
- After pesticide poisoning, prolonged treatment for several days may be required.

# COCAINE POISONING

John Kashani

## BASICS

### DESCRIPTION

- Cocaine is a naturally occurring alkaloid derived from the leaves of the *Erythroxylum coca* shrub.
- The shrub grows indigenously in Colombia, Peru, Bolivia, the West Indies, and Indonesia.
- Recreational use of cocaine was legal in the U.S. until 1914.

### EPIDEMIOLOGY

- Recent estimates suggest that ~34 million Americans have used cocaine and that 2 million people are regular users.
- In addition to morbidity and mortality directly from drug use, cocaine users are at significantly higher risk of injury or death by trauma.

### PATHOPHYSIOLOGY

- Cocaine binds to proteins transporting biogenic amines blocking their reuptake.
- As a result, the synaptic concentrations of dopamine, serotonin, norepinephrine, and epinephrine are increased.
- In addition, cocaine also has indirect actions that affect various other neuromodulatory systems, including the opioidergic, glutamatergic, and GABAergic systems.
- The route of administration, as well as coingestants, can affect the metabolism.
- The coingestion of ethanol with cocaine results in the formation of cocaethylene, which is a more potent and longer-acting metabolite.
- Cocaine has the potential to affect numerous body systems:
  - At low doses, pleasurable effects such as euphoria, hyperalertness, and hypersexuality may be experienced.
  - As the dose is increased, untoward effects such as agitation, confusion, and hallucinations can occur.
  - Seizures, strokes (hemorrhagic and embolic), and vasculitis may occur.
  - Choreoathetosis, secondary to dopamine excess, may occur, called “crack dancing.”
  - Cocaine may cause multiple GI complications: Intestinal infarction, perforated ulcers, and liver and kidney infarctions have all been reported.
  - Body packers, also called mules, who swallow packaged cocaine for international smuggling, may present with various abdominal complaints, especially obstruction or ischemia/infarction.
  - Vasoconstriction caused by cocaine in combination with an increased heart rate causes an imbalance in myocardial oxygen supply and demand. Additionally, cocaine is thought to accelerate atherosclerosis. Cocaine is also capable of blocking sodium and potassium channels on myocardial cells, resulting in a prolonged QRS and QTc, respectively.
  - Pulmonary: Pneumothoraces and pneumomediastinum have been reported, presumably by using the Valsalva maneuver during smoking. Cocaine can induce bronchospasm and exacerbate lung disease. Thermal injury can occur through the inhalation of superheated smoke. Hemorrhagic alveolitis (crack lung) consisting of eosinophilia, pruritus, and increased IgE levels has been described.

- Injury to the musculoskeletal system with cocaine use is usually secondary to trauma. Cocaine may cause muscle injury or rhabdomyolysis elevation in creatine phosphokinase (CPK), even without trauma or vigorous body activity.

### ETIOLOGY

Cocaine comes in several forms, all derived from the *Erythroxylum coca* plant:

- Cocaine hydrochloride, or cocaine powder
- Freebase (crack) cocaine

## DIAGNOSIS

### HISTORY

- Patients or parents may provide a history of cocaine exposure.
- Some patients may not be forthcoming about their cocaine use; however, it is incumbent upon a physician to inquire about the use of drugs, as it may alter the patient’s management.
- In patients forthcoming about cocaine use, chest pain is the most common presenting complaint.
- If a patient is brought to medical care by others, a history of altered mental status, psychomotor agitation, sympathomimetic symptoms, and seizures may be elicited.

### PHYSICAL EXAM

- Patients typically present in a sympathomimetic state of adrenergic stimulation.
- Cardiovascular: HTN, tachycardia
- Dermatologic: Warm or diaphoretic
- Psychiatric: Hyperalert, talkative with pressured speech, agitated, and sometimes with paranoia similar to schizophrenia. Occasionally, severe somnolence may be present if the patient presents after a prolonged cocaine binge.
- Neurologic: Pupillary dilation is typical, and focal neurologic deficits may be present if stroke of CNS ischemia.
- Stigmata of drug use such as track marks and defects in the nasal septum should be investigated.
- If body packing or body stuffing is suspected, exams of body cavities and imaging may be warranted.
- To distinguish from anticholinergic syndrome, evaluate for absence/presence of sweating, bowel sounds, and pupil reactivity to light:
  - Diminished bowel sounds, dry skin, and pupils sluggishly reactive to light suggest exposure to an anticholinergic agent.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

- No lab testing is routinely indicated, but consider as indicated:
  - Basic chemistry profile to assess for dehydration and hyperkalemia
  - CPK and/or urinalysis to evaluate for rhabdomyolysis
  - Troponin should be ordered in any patient with chest pain or findings consistent with myocardial ischemia.

- Drug of abuse screening:
  - It is critical for the treating clinician to understand the limitations of lab screening for cocaine or other drugs.
  - Clinicians should not use results of drug screening to guide management of a suspected intoxication with cocaine or other drugs of abuse but rather should rely on physical exam, clinical findings, and close attention to hemodynamic parameters:
    - A positive screen suggests exposure but cannot distinguish current intoxication from remote use.
    - Negative screen may occur in patients with toxicity in whom the urine is too dilute or the metabolite assayed, benzoylecgonine, is not yet present in urine.
  - Urine testing is the most widely used test to detect exposure to cocaine:
    - With respect to the drugs detected by typical drug of abuse screening panels, cocaine is the most specific test, with virtually no false-positive assays.
    - For forensic purposes, such as in cases of children too young to use drugs volitionally, drug of abuse screening may be of value to police and/or child protective services.
    - Metabolites of cocaine can be found in blood, hair, saliva, and meconium:
      - These assays are not readily available, are costly, and typically take at least several days to weeks to attain results.
      - These special tests are warranted only in specific circumstances, such as where they are used commonly, with meconium in certain nurseries or neonatal ICU, or when specific circumstances require forensic evidence.

#### Imaging

Radiographic imaging is used if pulmonary complications of cocaine use are suspected and when body packing or stuffing is suspected.

#### Diagnostic Procedures/Other

ECG should be obtained in all patients with cocaine exposure. Serial ECG may be needed.

#### DIFFERENTIAL DIAGNOSIS

Other states of sympathomimetic or adrenergic stimulation:

- Toxins:
  - Amphetamine toxicity, anticholinergic poisoning, sedative/hypnotic withdrawal (eg, benzodiazepines, barbiturates, alcohol), PCP intoxication, pheochromocytoma, monoamine oxidase inhibitor toxicity, serotonin syndrome, and neuroleptic malignant syndrome
- Encephalitis

## TREATMENT

### PRE HOSPITAL

- Assess and stabilize airway, breathing, and circulation.
- Administer supplemental oxygen and IV fluid if these can be done easily.
- Restrain patients with psychomotor agitation.
- If local policy permits, judicious use of diazepam 0.2 mg/kg IV may be attempted. If there is no effect, the dose may be repeated in 5 min.

### INITIAL STABILIZATION/THERAPY

- Assess and stabilize airway, breathing, and circulation.
- Supportive care is the main management.
- Administer IV fluid, normal saline bolus 20 mg/kg; may repeat 3 times in 1st hr.
- Administer high-flow oxygen to any patient with cardiovascular stimulation, chest pain, or suspected acute coronary syndrome.
- Common issues to manage include:
  - Psychomotor agitation, managed by administration of benzodiazepines
  - Chest pain and cardiovascular stimulation, managed by administration of benzodiazepines, phentolamine, and possibly additional cardiovascular medications
  - Hyperthermia, managed by active cooling, including possible need for ice immersion
- Although cocaine is bound by activated charcoal, the role of charcoal is limited to the patient having swallowed packets of cocaine.
- Avoid mechanical restraints to prevent the potential for heat generation and muscle injury/rhabdomyolysis if the patient struggles.
- Use of benzodiazepines, sometimes in massive doses, is recommended.

### ALERT

- Obtain a rectal temperature immediately in patients with possible hyperthermia.
- Significant hyperthermia ( $\geq 39.0$ – $40.0^\circ\text{C}$ , or  $102.2$ – $104.0^\circ\text{F}$ ) requires passive cooling or mild active cooling and medications:
  - Life-threatening hyperthermia ( $> 41.5$ – $42.0^\circ\text{C}$ , or  $< 106.7$ – $107.6^\circ\text{F}$ ) should be treated by immersion in an ice bath. Other cooling measures are inadequate:
    - Wrapping the patient in sheets with ice or placing patient in a body bag with ice are reasonable approaches.

### MEDICATION

#### First Line

Diazepam:

- First-line medication for any cocaine intoxicated patient
- Administer for agitation, chest pain, or HTN/tachycardia
- Initial dose 0.2 mg/kg IV. This dose may be repeated q5min.
- After administering a given dosage 3 times, increase the dose by doubling:
  - If 10 mg IV has been given 3 times without adequate effect, increase the dose to 20 mg.
  - If 20 mg IV has been given 3 times without effect, double the dose to 40 mg IV.

– Although these doses are higher than typical, the tolerance of multiple doses without sedation provides reassurance to increase the dose.

### Second Line

- Consider the following in rare cases that adequate diazepam dosing has not controlled chest pain, cardiovascular stimulation, or acute coronary syndrome.
- Phentolamine for HTN:
  - Initial dose 0.1 mg/kg IV; adolescent/adult, 10 mg IV. Reassess HTN and give additional dose PRN after 15–20 min.
  - Phentolamine administration should occur after initial diazepam administration.
- Nitroglycerine 0.3–0.6 mg SL for chest pain or acute coronary syndrome. Use after diazepam, as diazepam is superior in relieving chest pain.
- Nitrates, calcium channel blockers, and aspirin may be indicated for HTN/tachycardia or acute coronary syndrome.
- The authors strongly advocate against use of beta-blockers in the management of cocaine toxicity:
  - Potential for paradoxical increase in HTN and injury or death.
  - If using a beta-blocker, we recommend titration of esmolol after phentolamine.
  - No beta-blocker is clearly safe to use without a concomitant vasodilating agent, but labetalol has both beta- and alpha-blocking activity. It is used in centers that do not adhere to the admonition against use of beta-blockers.
- Sodium bicarbonate: For severe acidemia or widened QRS complex:
  - For acidemia, 1 mEq/kg IV; repeat PRN
  - If wide QRS  $> 100$  msec, 1 mEq/kg IV push, then repeat ECG 10 min later to assess response
  - If QRS narrowing results, a bicarbonate infusion of 2 ampules of sodium bicarbonate in 1 L of D5W may be infused.

### SURGERY/OTHER PROCEDURES

Surgery or endoscopic retrieval of drug packets for body packers and body stuffers

### DISPOSITION

#### Admission Criteria

Critical care admission criteria:

- If patients are medically ill, admit to the ICU.
- Cardiovascular stimulation requiring ongoing medication and monitoring to detect dysrhythmia, hyperthermia, rhabdomyolysis, disseminated intravascular coagulation (DIC), and end-organ injury such as stroke or MI are typical causes for ICU admission.

#### Discharge Criteria

Normal vital signs, normal mental status, and no end-organ damage

#### Issues for Referral

Refer all patients for drug counseling.

## FOLLOW-UP

### FOLLOW-UP RECOMMENDATIONS

Discharge instructions and medications:

- Avoid further drug use, and seek drug counseling.

### PROGNOSIS

Depends on severity of cocaine toxicity, development of end-organ injury:

- Cocaine users are likely to continue using cocaine despite injury.

### COMPLICATIONS

- MI
- Stroke
- Hepatic injury
- DIC
- Shock
- Death

### CODES

ICD9

970.81 Poisoning by cocaine

### PEARLS AND PITFALLS

- Main therapy is supportive care, maintaining vital signs within acceptable limits, and treating cardiovascular stimulation.
- Diazepam is typically the only medication needed to treat cocaine toxicity.
- Diagnosing cocaine toxicity based on a positive urine drug assay is a major pitfall resulting in misdiagnosis. Do not base clinical management on urine drug screening.
- Haloperidol or domperidone is contraindicated for sedating because of risk of seizure and cardiac death.

# COLITIS

Andrew Heggland  
Barbara M. Garcia Peña

## BASICS

### DESCRIPTION

- Colitis is inflammation of the large intestine due to various etiologies. It is often associated with diarrhea and abdominal pain (1–3).
- Diarrheal diseases are leading causes of morbidity and mortality in children worldwide: 1 billion ill and 2.5 million deaths annually (4).
- Infectious causes: Secondary to fecal–oral contamination or “food poisoning” (5)
- Inflammatory bowel disease (IBD):
  - Crohn disease (CD) or regional enteritis
  - Ulcerative colitis (UC)
  - Indeterminate colitis: Features of CD and UC
- Allergic colitis: Immune mediated (eg, milk protein intolerance or gluten sensitivity)
- Other causes: Radiation, immunosuppression, antibiotics, toxic megacolon, necrotizing enterocolitis (NEC), etc.

### EPIDEMIOLOGY

#### Incidence

- Infectious: 1 in 3 persons per year
- CD: 1–4/100,000 per year
- UC: 10–12/100,000 per year

#### Prevalence

- CD: 24–48/100,000
- UC: 50–75/100,000
- Allergic: 1 in 200 infants

### RISK FACTORS

- Infectious: Poor hygiene, travel to developing nations, immune suppression (4)
- IBD: Smoking, Judeo-European ancestry, isotretinoin use, family history (1–3)
- NEC: Premature birth, ischemic event, aggressive oral feeding

### GENERAL PREVENTION

- Fiber-based, well-rounded diet
- Stress reduction
- Improving hygiene
- Appendectomy is protective against UC.

### PATHOPHYSIOLOGY

- Infectious: Intracellular invasion, mucosal inflammation, toxin release
- CD: Transmural inflammation, cryptitis/crypt abscesses, fistula formation, giant cell granulomas
- UC: Mucosal inflammation, basal plasmacytosis, cryptitis/crypt abscesses, epithelial dysplasia, pseudopolyps
- Allergic: Protein triggering an immune response
- Significant diarrhea can cause acid–base disturbance and/or significant blood loss with hemodynamic instability, progressing to systemic inflammation, sepsis, and death.

### ETIOLOGY

- Infectious—bacterial (4):
  - *Salmonella* species
  - *Shigella* species
  - *Campylobacter jejuni*
  - *Yersinia enterocolitica*
  - *Escherichia coli*
  - *Clostridium difficile*
  - *Vibrio* species
- Infectious—viral:
  - Rotavirus
  - Norovirus
  - Adenovirus
  - Cytomegalovirus
- Infectious—parasitic:
  - *Microsporidia* species
  - *Cryptosporidia* species
  - Helminths/Worms
- Infectious—protozoal:
  - *Giardia intestinalis*
  - *Entamoeba histolytica*
  - *Coccidia* species
- IBD: Multifactorial, requiring genetic susceptibility and environmental triggering (3)
- Allergic: Dietary protein and associated immunologic response

### COMMONLY ASSOCIATED CONDITIONS

- Infectious: Hemolytic uremic syndrome (HUS), sepsis, immunosuppression
- CD: Pancreatitis, amyloidosis, renal stones, thromboembolic disease
- UC: Primary sclerosing cholangitis (3%), sacroiliitis, ankylosing spondylitis

## DIAGNOSIS

### HISTORY

- Weight loss
- Stool: Thin, liquid; frequency >3 stools per day
- Bleeding per the rectum
- Abdominal pain: Location, onset, duration, and character:
  - CD: Often right lower quadrant (RLQ) pain
  - UC: Often diffuse
  - Any colitis: Crampy, relapsing/remitting pain
- Medical history: Growth failure (IBD)
- Family history (IBD)
- Social/Travel history (infectious)
- Depression/Fatigue (IBD)
- Diet/Medication: Ingested food may resemble blood.

### PHYSICAL EXAM

- Fever, tachycardia, pallor
- Abdominal tenderness (peritonitis)
- Oral ulcerations (IBD)
- Perirectal fistula (CD)
- Arthritis (IBD)
- Rash: Erythema nodosum/pyoderma gangrenosum (CD)
- Eyes: Episcleritis/Uveitis (IBD)

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

- CBC (hemoglobin/platelets in acute bleeding, WBC/platelets as inflammatory reactants)
- Electrolytes (especially HCO<sub>3</sub> in large-volume diarrhea, acid–base status)
- LFTs (elevated transaminases indicate infectious/inflammatory liver dysfunction; albumin indicates nutritional and protein synthetic status)
- ESR and/or C-reactive protein (measures of inflammation)
- Blood type and screen (preparation for transfusion during acute blood loss)
- Stool assays (specific infectious diagnoses):
  - Stool culture
  - Ova and parasites
  - WBCs/Eosinophils
  - *C. difficile* toxin A/B

#### Imaging

- Abdominal upright film or cross-table lateral to exclude bowel perforation
- Upper GI series with small bowel follow-through (small intestinal disease—CD)
- Abdominal CT (delineates extent of disease and other abdominal organ involvement and is useful in differentiating CD RLQ pain from appendicitis)

#### Diagnostic Procedures/Other

Not emergently performed:

- Colonoscopy with biopsy
- Wireless capsule endoscopy to visualize small bowel disease in CD
- Esophagogastroduodenoscopy (with biopsy):
  - May be emergent if upper GI bleeding

### DIFFERENTIAL DIAGNOSIS

- Appendicitis
- Malrotation/Volvulus
- Intussusception
- Henoch-Schönlein purpura
- Upper GI bleeding
- Meckel diverticulitis
- GI/Abdominal neoplasm
- Vascular malformation
- Nonaccidental trauma/occult trauma
- Irritable bowel syndrome

## TREATMENT

### INITIAL STABILIZATION/THERAPY

- Assess and stabilize airway, breathing, and circulation.
- IV access and fluid resuscitation
- Pain management
- NPO
- Withdrawal of offending agent (eg, dietary protein/antibiotic)

**MEDICATION**

- Infectious colitis (6):
  - Most are self-limited and do NOT require directed antimicrobial therapy.
  - *Shigella* species:
    - Ceftriaxone 50 mg/kg/day IV/IM × 5 days, max 1–2 g/dose OR
    - Ciprofloxacin 20 mg/kg/day IV/PO divided b.i.d. × 5 days, max 500 mg/dose
  - Enterotoxigenic or enteroinvasive *E. coli*:
    - Trimethoprim/Sulfamethoxazole (TMP/SMX) 8 mg TMP/kg/day PO × 14 days, max dose 160 mg TMP/800 mg SMX
    - Azithromycin 10 mg/kg on day 1, then 5 mg/kg days 2–5; max single dose 500 mg
    - Ciprofloxacin 20 mg/kg/day PO divided b.i.d. × 1–3 days, max dose 500 mg
  - *Vibrio cholerae*: Doxycycline 5 mg/kg/day PO divided b.i.d. × 14 days, max single dose 100 mg
  - *C. difficile*: Metronidazole 30 mg/kg/day PO divided b.i.d. × 10 days, max single dose 500 mg
  - *Salmonella* species in vulnerable populations:
    - Ceftriaxone 50 mg/kg/day IV/IM initially, then convert to oral antibiotics
    - TMP/SMX 8 mg TMP/kg/day PO × 14 days, max single dose 160 mg TMP/800 mg SMX
    - Amoxicillin 50 mg/kg/day PO divided b.i.d.–t.i.d. × 14 days, max single dose 500 mg
  - *Campylobacter* species in vulnerable populations: Erythromycin 50 mg/kg/day PO divided t.i.d.–q.i.d. × 5–7 days, max dose 800 mg. Other macrolides such as azithromycin may be substituted for fewer side effects and improved compliance.
  - *G. intestinalis*: Metronidazole 30 mg/kg/day PO divided b.i.d. × 10 days, max single dose 500 mg
  - *E. histolytica*: Metronidazole 30 mg/kg/day PO divided b.i.d. × 10 days, max dose 500 mg, WITH paromomycin 35 mg/kg/day PO divided q.i.d., max single dose 250 mg
  - *Cryptosporidium* species: Nitazoxanide 200–500 mg/day (3 days) WITH paromomycin 35 mg/kg/day (7 days)
  - *Microsporidia* species: Albendazole 15 mg/kg/day PO 14–21 days, max dose 400 mg; metronidazole 30 mg/kg/day PO divided b.i.d. × 10 days, max single dose 500 mg:
    - *Coccidia* species: TMP/SMX 8 mg TMP/kg/day PO × 24 days, max single dose 160 mg TMP/800 mg SMX
- Inflammatory colitis (3):
  - Start meds in the emergency department and prescribe until a GI consultation within 1–2 wk.
    - Corticosteroids: Prednisone 1–2 mg/kg/day PO per day or methylprednisolone up to 30 mg/kg/dose
    - Salicylates: Mesalamine 50 mg/kg/day divided b.i.d.–q.i.d.
    - Antibiotic therapy: Ciprofloxacin 20 mg/kg/day IV/PO divided b.i.d. × 5 days, max 500 mg/dose, OR metronidazole 30 mg/kg/day PO divided b.i.d. × 10 days, max single dose 500 mg
    - Immunomodulators: For example, infliximab prescribed by gastroenterologists (NOT usually in the emergency department)

**SURGERY/OTHER PROCEDURES**

- Total colectomy in UC can be curative.
- Regional resection in CD usually is avoided if possible due to complication and recurrence rates.

**DISPOSITION****Admission Criteria**

- ICU: Sepsis/Systemic inflammatory response syndrome, hemodynamic instability, respiratory insufficiency
- Inpatient wards:
  - Need for IV pain management
  - Need for IV antibiotics
  - Inability to tolerate PO

**Discharge Criteria**

- Pain adequately controlled
- Tolerating PO
- Adequately hydrated

**Issues for Referral**

- Outpatient:
  - Gastroenterology referral for all new diagnoses of IBD if stable for discharge
  - Infectious disease referral may be indicated in refractory infectious colitis.
- Inpatient:
  - Surgical consultation should be obtained in suspected toxic megacolon, NEC, etc.
  - Infectious disease consult in refractory infectious colitis

**COMPLEMENTARY & ALTERNATIVE THERAPIES**

- Probiotics do not improve irritable bowel symptoms (7).
- In infectious and antibiotic-associated diarrhea, probiotics (lactobacillus GG 0.5–1 capsule per day until 2 days after symptom resolution) decreases abdominal pain, shortens diarrhea by 1–2 days, and increases stool firmness (7).

**FOLLOW-UP****FOLLOW-UP RECOMMENDATIONS****Patient Monitoring**

- Infectious: Symptom resolution; eradication of infectious agent upon subsequent stool culture
- IBD: Symptom resolution, improvement in markers of inflammation; GI neoplasm surveillance; growth monitoring
- Allergic: Symptom resolution with diet change

**DIET**

- High-fiber, bland solids; clear liquids
- Avoid inciting foods.
- Hydrolyzed protein formula for allergic colitis

**PROGNOSIS**

- Infectious: Most are self-limited. Can be remitting/relapsing or more indolent. Highest risk of death is severe dehydration.
- IBD: High morbidity; most patients experience recurring disease. Death is a rare complication.

**Pregnancy Considerations**

- Active CD is likely to progress while pregnant.
- Fertility is decreased by inflammation in colitis.
- Some anti-inflammatory medications (methotrexate, thalidomide, diphenoxylate) are contraindicated in pregnancy. Some (6-MP, azathioprine, olsalazine, infliximab) have limited data concerning safety during pregnancy.
- Some antimicrobials (ciprofloxacin, metronidazole, doxycycline, albendazole) also have limited safety data in pregnancy.

**ICD9**

- 009.0 Infectious colitis, enteritis, and gastroenteritis
- 555.9 Regional enteritis of unspecified site
- 558.9 Other and unspecified noninfectious gastroenteritis and colitis

**PEARLS AND PITFALLS**

- Perianal disease, small intestine disease, and/or skip lesions all strongly suggest CD.
- *C. difficile* colitis can strongly mimic IBD and must be ruled out.

# COLLAGEN VASCULAR DISEASE

Sudha A. Russell

## BASICS

### DESCRIPTION

- Collagen vascular diseases (CVDs) are a complex group of multisystem disorders resulting from autoimmune processes causing inflammation of the target organs. They are also defined as rheumatic and connective tissue diseases.
- CVDs affect many different organs, so they must be considered for a wide range of syndromes and therefore present diagnostic and therapeutic dilemmas in children (1,2).
- Because specific diagnostic tests for CVDs are unavailable emergently, the emergency department evaluation is often focused on excluding diagnoses that cause similar symptoms (eg, malignancy and infection).
- An immature skeleton, variable hormonal influences, immature immune system, and genetic expression modify expression of rheumatic disease in children.
- Specific diagnosis may take months, and rarely years, after the initial presentation.
- Juvenile idiopathic arthritis (JIA), systemic lupus erythematosus (SLE), Kawasaki disease (KD), Lyme disease, Henoch-Schönlein purpura (HSP), dermatomyositis, and inflammatory bowel disease (IBD) are discussed in specific topics.
- Diagnoses described in this topic are:
  - Systemic sclerosis (SS) causes a hardening of the skin and subcutaneous tissues.
  - Polyarteritis nodosa (PAN) causes necrotizing inflammation of small- and medium-sized arteries.
  - Sjögren's syndrome is associated with lymphocytic infiltration of exocrine glands.
  - Mixed connective tissue disease (MCTD) is a generalized disorder with overlapping clinical features of other CVD.
  - Behçet disease and Wegener granulomatosis (WG) are vasculitides that are rare in children.
- CVD is a complicated topic, and the reader is encouraged to peruse the Additional Readings section for more information on these diseases.

### EPIDEMIOLOGY

#### Prevalence

- Pediatric rheumatic conditions are relatively rare, affecting <0.5% of children in the U.S.
- Conditions that must be distinguished from CVDs, however, are prevalent: 20% of urgent pediatric visits involve musculoskeletal complaints.
- 300,000 children in the U.S. have CVD:
  - 85,000 have arthritis: Systemic JIA, psoriatic arthritis, polyarthritis, oligoarthritis, and enthesitis-related including ankylosing spondylitis (AS)
  - 25,000 have SLE (3).
  - The rest have the other CVDs.

### RISK FACTORS

- Genetic predisposition, in association with the presence of certain multiple HLA and other genetic alleles, has been noted.
- Family history of CVD
- Environmental factors such as blood transfusions, smoking, and ultraviolet light exposure (4)
- Female gender

### PATHOPHYSIOLOGY

- CVDs are characterized by autoimmune responses. Normally, the immune system does not respond to components of the body, only to nonself molecules such as viruses, bacteria, and other foreign tissue.
  - In CVDs, the tolerance to self molecules is lost, and the immune response is directed at self molecules.
- Disease susceptibility and severity are influenced by certain genetic factors and cellular recognition (especially T lymphocytes) (2).
- Cells release inflammatory cytokines including tumor necrosis factor alpha, interleukin (IL)-1, and IL-6, causing tissue damage. B lymphocytes produce excessive antibody. Normal cells in target organs can be destroyed by complement-mediated cytotoxicity.
- Cytokines appear to induce cortisol production, suppressing cellular and humoral immunity. Defects in these pathways may amplify the immune response (2).
- Female sex hormones augment cellular immune responses, which may increase the incidence of rheumatic diseases in females.

### ETIOLOGY

The etiology is unknown.

## DIAGNOSIS

### HISTORY

- Fevers, arthralgias, weakness, facial rash, dry skin, Raynaud phenomenon, mucocutaneous inflammation, chest pain, muscle weakness, and back pain
- Duration of symptoms at the time of diagnosis is quite variable (5).
- Fever, malaise, and myalgias may be complaints in PAN.
- Dry eyes and mouth can indicate Sjögren syndrome.
- Recurrent buccal aphthous and genital ulcers and uveitis with hypopyon suggest Behçet disease.
- A persistent dry cough may be the earliest symptom of SS.
- Raynaud phenomenon may be a primary disorder or due to SS, SLE, MCTD, and overlapping rheumatoid syndromes (1,6).
- Abnormal gait may indicate JIA, SLE, other arthritis, dermatomyositis, or orthopedic problems.
- Inability to walk is an emergent condition and may be a sign of acute decompensation due to SS or PAN.

### PHYSICAL EXAM

- General appearance:
  - Depressed affect suggesting psychiatric disease rather than CVD
  - Lack of, or abnormal, movement may be due to muscle weakness, arthritis, CNS disease, or skeletal abnormality.
- ~90% of patients with PAN will have a mild to moderate elevation of BP.

- Isolated findings may be important clues to the diagnosis:
  - A pericardial friction rub with orthopnea indicates JIA, SLE, or PAN.
  - Persistent oral mucosal lesions are found in Behçet disease and SLE.
  - Conjunctival injection could be episcleritis of SLE, conjunctivitis of KD, or uveitis of JIA.
  - Joint complaints suggest arthritis, but SLE, dermatomyositis, and MCTD (with muscle weakness) can also present with arthritis.
  - Focal neurologic deficits, muscle weakness, and seizures are seen in SS and PAN.
  - Rashes are common; erythema nodosum may indicate IBD, sarcoidosis, and Sjögren syndrome (7).
  - Tortuous nailfold capillaries or distal fingertip pitting is very suggestive of an underlying CVD, particularly SS.
  - Raynaud phenomenon is noted in diseases such as SS, SLE, overlap syndrome, undifferentiated connective tissue disorders, or MCTD.

### DIAGNOSTIC TESTS & INTERPRETATION

Emergency department diagnosis of CVD may not be possible, as specific findings may take months or even years to develop. The following tests may be done selectively.

#### Lab

Lab workup in the emergency department should be aimed at differentiating the far more common urgent and emergent traumatic and infectious complaints from CVD or malignancy.

#### Initial Lab Tests

- Serial inflammation labs: CBC, ESR, and C-reactive protein are useful in the emergency department to screen for infection vs. CVD. Infections typically cause transiently high ESR, but CVDs cause persistently high values.
  - A normal ESR does not exclude a CVD diagnosis (5).
- Urinalysis to detect proteinuria and hematuria, associated with SLE and vasculitis
- The antinuclear antibody (ANA) test is positive in certain syndromes:
  - All patients with MCTD, ≤90% of patients with SS, 67% with Sjögren syndrome, and >90% with SLE (2,6,7)
  - However, a positive ANA can be found in nonrheumatic diseases and with certain drugs (eg, phenytoin and procainamide).

#### Follow-Up Lab Tests

- Most of the evaluation may be done in the outpatient setting by the primary care provider. Early diagnosis is now more likely due to new tests:
  - Immunologic labs such as CH<sub>50</sub>, C3, and C4 are low in SLE and vasculitis syndromes.
  - Lactate dehydrogenase may be elevated in CVD, but marked elevations indicate malignancy.
  - The presence of anti-Scl 70 antibodies is more commonly associated with SS.
  - The presence of specific antibodies to Sjögren syndrome-related antigens (7)
  - Antineutrophilic cytoplasmic antibody in WG (8)
  - A high titer of anti-U1-RNP antibodies is critical in the diagnosis of MCTD.
  - An association with HLA-B5, and HLA-B51 is clear in Behçet disease.
- Consider appropriate tests to rule out the other causes of symptoms.

**Imaging**

- Chest radiographs may show:
  - Increased reticulation or a “honeycombed” appearance in SS
  - Globular enlargement of the cardiac silhouette is seen in PAN.
- Bone scan and MRI with gadolinium may reveal joint findings and may be done in the inpatient or outpatient setting.

**Diagnostic Procedures/Other**

ECG is necessary in patients with SS and PAN:

- Pulmonary HTN may cause ventricular hypertrophy.
- Cardiac involvement in PAN may show ST depression and inverted T waves (6).

**DIFFERENTIAL DIAGNOSIS**

Malignancy, infection, muscular dystrophies, viral myositis, school phobias, postinfectious reactive arthritis, traumatic arthritis, torn meniscus, hemarthrosis, osteochondritis, Legg-Calvé-Perthes, osteomyelitis, neuropathy, and periodic fever syndromes

**TREATMENT****INITIAL STABILIZATION/THERAPY**

- The complexity and the systemic nature of CVD should be kept in mind when such patients present to the emergency department.
- If the patient is unstable, support the ABCs.
- An integrated multisystem approach (eg, rheumatology, immunology, and orthopedics) is recommended for patients with CVD.

**MEDICATION**

- Arthralgia and myalgia are generally treated with salicylates or NSAIDs (2).
- Corticosteroids (oral and/or IV) used early in the course of these diseases may help attenuate inflammation (2,6).
- Artificial tears, oral lozenges, and fluids in patients with Sjögren syndrome may be used to limit damage from decreased secretions (7).
- In PAN, mild to moderate HTN is treated with diuretics, hydralazine, and beta-blockers.
- Cyclophosphamide and methotrexate are needed for life-threatening illness; cyclosporin can also be used.

**DISPOSITION****Admission Criteria**

- Inpatient admission should be considered when immediate subspecialty care is needed.
- Unstable patients (eg, hypertensive encephalopathy or CHF in PAN)
- Critical care admission criteria:
  - Unstable patients (eg, severe HTN with encephalopathy or CHF in PAN) should be admitted to the ICU.

**Discharge Criteria**

- Well appearing and in no distress
- Acute symptoms controlled in the emergency department
- Reliable follow-up

**Issues for Referral**

- Stable patients can be given a referral for outpatient rheumatology but should have prompt follow-up by a primary care provider and/or subspecialist.
- Refer patients to a center with:
  - Pediatric rheumatology
  - Other subspecialists as needed for anticipated complications of the disease
  - Physical therapy and nutritionists

**COMPLEMENTARY & ALTERNATIVE THERAPIES**

- Sun avoidance and protection
- Physical therapy
- Psychosocial therapy
- Keep hands warm with polyester, plastic, or sheepskin gloves during cold exposure for Raynaud phenomenon (1).
- Biofeedback training may help decrease the frequency of Raynaud syndrome attacks (2).
- Nutritional evaluation and guidance

**FOLLOW-UP****FOLLOW-UP RECOMMENDATIONS**

Discharge instructions and medications:

- 1–2 day follow-up for patient reassessment and to make appropriate referrals

**PROGNOSIS**

- CVDs have a variable course, and findings at presentation are usually not predictive.
- The course of CVD varies from mild disease with few complications to multiorgan disease leading to death (eg, PAN, SS).
- Sjögren syndrome develops and progresses slowly but has an increased risk of lymphoma.
- Patients with MCTD have milder symptoms and fewer complications than other CVDs.

**COMPLICATIONS**

- Raynaud phenomenon can be severe enough to lead to gangrenous changes that can lead to autoamputation or osteomyelitis of the digits.
- Pulmonary HTN and fibrosis is seen in SS with respiratory decompensation.
- Pulmonary hemorrhage and upper airway obstruction is seen in PAN.
- Cutaneous nodules in PAN may ulcerate and are at risk of infection.
- Enlarging granulomas in WG can disrupt local anatomy, causing orbital invasion or deafness.
- Pericarditis is seen in PAN and SS.
- Blindness is seen in Behçet disease due to posterior uveitis.
- Renal complications may gradually lead to chronic renal failure in SS, PAN, and Behçet.

**CODES****ICD9**

- 446.0 Polyarteritis nodosa
- 446.20 Hypersensitivity angiitis, unspecified
- 710.1 Systemic sclerosis
- 710.9 MCTD
- 714.0 Rheumatoid disease

**PEARLS AND PITFALLS**

- Sjögren syndrome patients have greater problems with corticosteroids, including acceleration of periodontal disease and thrush (7).
- PAN may present with acute scrotal pain and purpura with dysuria.
- Behçet disease may mimic numerous other conditions seen commonly in the emergency department and should be considered when appropriate.
- WG may present as an orbital pseudotumor or severe sinusitis (8).

# COMPARTMENT SYNDROME

Michael L. Epter

## BASICS

### DESCRIPTION

- Compartment syndrome is a surgical emergency.
- Most commonly associated with trauma, specifically fractures:
  - Tibia
  - Supracondylar
  - Forearm
  - Wrist
- The anterior compartment of the lower leg is most commonly affected.
- Diagnosis is challenging in the pediatric population because of difficulty in assessing compartment pressures, communication, cooperation, and poor reliability of physical exam (eg, 2-pt discrimination).
- Keys to ensuring good outcome:
  - High clinical suspicion
  - Early surgical/orthopedic consultation
  - Measurement of compartment pressures
  - Prompt surgical decompression

### RISK FACTORS

- Fractures
- Crush injuries +/- fractures (hand/foot)
- Excessive exercise
- Hypotension, especially low diastolic BP

### GENERAL PREVENTION

Avoid compressive casts in fracture management.

### PATHOPHYSIOLOGY

- Increased intracompartmental pressure → impaired perfusion → disruption of skeletal muscle metabolism → cytolysis → increase in fluid from plasma to interstitium → further increase in pressure → compromised blood supply/nerve conduction:
  - Sensory nerves: C fibers (most susceptible) > motor nerves/muscles > fat > skin (least susceptible)
- Muscle injury (can be irreversible) → rhabdomyolysis → myoglobinuria → renal failure

### ETIOLOGY

- Extrinsic (exert pressure on the compartment):
  - Pressure dressing
  - Casts (circumferential)
  - Burn eschar
  - Intramuscular hematoma
  - Limb compression
- Intrinsic (increased volume of compartment space):
  - Fracture (open is more common than closed)
  - Reperfusion after ischemia
  - Vascular injury
  - Thrombosis
  - Burns
  - Hereditary bleeding disorders
  - Snake and spider bite/envenomation
  - Viral infection (influenza, enterovirus)
  - Sepsis (arthritis, meningococemia)
  - Allergic reaction
  - Iatrogenic:
    - Intraosseous infusion
    - IV infiltration (especially in ICU patients)

### COMMONLY ASSOCIATED CONDITIONS

Trauma

## DIAGNOSIS

### HISTORY

History of any of the following:

- Trauma
- Fever/Infection
- Coagulopathy
- IV/IM medications
- Suspected abuse
- Persistent pain with increasing analgesic requirement
- Apprehension, crying, agitation, inability to console

### PHYSICAL EXAM

- May be unreliable due to confounding factors:
  - If equivocal → measure compartment pressures
- 6 P's:
  - Pain:
    - Disproportionate to physical exam
  - Pressure (pain on palpation):
    - Pain with passive stretch
    - Compartment may or may not be tense.
  - Paresthesias:
    - Loss of 2-point discrimination (early)
  - Paresis
  - Pallor
  - Pulselessness (late and not reliable):
    - Shiny, erythematous skin
    - Swelling (may or may not be present)
    - Consider measuring circumference of extremity

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

- No lab investigation is required to diagnose compartment syndrome.
- Complications resulting from muscle necrosis may warrant the following:
  - Creatine phosphokinase
  - Urinalysis
  - Electrolytes
  - Renal function

#### Imaging

Indicated for suspected fracture

#### Diagnostic Procedures/Other

- Measurement of compartment pressures:
  - Consider analgesia or sedation
  - Options available: Slit catheter, wick catheter, needle manometer, arterial line, intracompartmental pressure monitor (eg, Stryker, Stryker Instruments, Kalamazoo, MI)
- Stryker technique (used most often):
  - Aseptic preparation
  - Local anesthetic (eg, lidocaine): Only SC (IM will cause false positive)
  - 18-gauge needle attached to the monitor
  - Enter into compartment adjacent to area of greatest pressure.
  - Ensure placement into the compartment by squeezing the muscle and/or passively stretch the muscle (causes transient increase in pressure).
  - Inject <1 cc saline.
  - Take multiple pressures.
  - Record the highest pressure for determining the need for fasciotomy.

#### ALERT

- Tissue pressure should be measured within 5 cm of the zone of maximum pressure (injury site) to avoid false negatives.
- Intracompartmental pressures:
  - Fixed values are more applicable for unconscious patients:
    - <10–12 mm Hg: Normal pressure
    - >20 mm Hg: Compromised capillary flow
    - 30–40 mm Hg: Risk of ischemic necrosis of muscles/nerves

**Pathological Findings**

Muscle necrosis

**DIFFERENTIAL DIAGNOSIS**

- Arterial insufficiency/occlusion
- Thrombophlebitis
- Myositis/Fasciitis
- Lymphangitis
- Cellulitis
- Osteomyelitis

**TREATMENT**

**INITIAL STABILIZATION/THERAPY**

- Correct extrinsic factors, if applicable (eg, cast/dressing removal).
- Elevate affected limb to the level of the heart.
- Correct underlying hypotension.
- Application of ice or raising the affected limb above the heart will compromise circulation.

**MEDICATION**

- Pain control (eg, morphine 0.1 mg/kg IV/IM/SC PRN)
- Steroids/vasodilators have no proven benefit.

**SURGERY/OTHER PROCEDURES**

- Emergent fasciotomy is the treatment of choice:
  - Indications:
    - Clinical signs of compartment syndrome (most important)
    - Pressure measurements (controversial):
      - Absolute pressure >30 mm Hg
      - Delta pressure (diastolic BP—compartment pressure) ≤30
      - Differential pressure (mean arterial pressure—compartment pressure) ≤30
- Prompt consultation with orthopedics/surgery should be initiated once the diagnosis is suspected.

**DISPOSITION**

**Admission Criteria**

Clinical signs/symptoms of compartment syndrome with elevated pressure

**Discharge Criteria**

- No clinical signs/symptoms of compartment syndrome
- Normal pressures as determined by intracompartmental measuring device

**Issues for Referral**

All patients who are sent home with fractures and/or soft tissue injuries (eg, crush) should be referred to their primary care provider within 24 hr to assess for development of compartment syndrome.

**FOLLOW-UP**

**FOLLOW-UP RECOMMENDATIONS**

- Discharge instructions and medications:
  - Patients who sustain traumatic/soft tissue injury must be given strict instructions to return to the emergency department for any new or worsening symptoms (eg, increasing pain, paresthesias, swelling).
  - Pain control as appropriate. Use caution with opioids, as these may mask signs of compartment syndrome.
- Activity:
  - Restrict activity that may increase pain/swelling.

**Patient Monitoring**

All patients with suspected compartment syndrome with elevated pressures should be admitted for observation:

- Serial physical exams +/- compartment pressures should be performed given the evolving nature of this syndrome.
- Lab evaluation for rhabdomyolysis should occur.

**PROGNOSIS**

Functional loss and complication rate are directly proportional to the time to diagnosis and decompression:

- Fasciotomy at ≤6 hr of establishing the diagnosis is associated with a good recovery.
- Poor clinical outcomes are expected if fasciotomies are delayed >12 hr.
- 1–10% of patients with compartment syndrome develop Volkmann ischemic contracture.

**COMPLICATIONS**

- Tissue necrosis
- Infection
- Neurologic deficit
- Delayed fracture healing (if applicable)
- Ischemic contracture
- Amputation
- Rhabdomyolysis
- Hyperkalemia
- Acidosis
- Renal failure

**ADDITIONAL READING**

**See Also (Topic, Algorithm, Electronic Media Element)**

- Deep Vein Thrombosis
- Rhabdomyolysis

**CODES**

**ICD9**

- 958.8 Other early complications of trauma
- 958.91 Traumatic compartment syndrome of upper extremity
- 958.92 Traumatic compartment syndrome of lower extremity

**PEARLS AND PITFALLS**

- Delayed diagnosis is more common when the cause of compartment syndrome is not related to fracture and/or is complicated by altered mental status.
- Increasing analgesia/sedation requirement may be the only indicator of compartment syndrome.
- Lack of assessment of compartment pressures is the most common factor associated with a missed diagnosis.

# CONCUSSION

Emily Schapiro

## BASICS

### DESCRIPTION

- Concussion is any alteration in neurologic or cognitive function after head trauma, with or without loss of consciousness (LOC).
- The term *concussion* is most frequently used to refer to mild head injuries with little alteration in level of consciousness.
- LOC, if present, is usually brief. There are usually no focal deficits on neurologic exam.
- Grading of concussion is no longer recommended (1,2). Rather, an individualized approach to the patient's clinical presentation and needs is appropriate.
- Children who suffer a concussion may develop a postconcussive syndrome in which symptoms of varying severity may persist for several months and may affect school performance:
  - Symptoms may include headaches, confusion, difficulty concentrating, irritability, and mood changes.

### EPIDEMIOLOGY

#### Incidence

- It is estimated that there are >600,000 emergency department visits for traumatic brain injuries in children <18 yr of age annually in the U.S. (3).
- About 62,000 high school athletes experience concussions yearly, with 63% of these being associated with football (4).

### RISK FACTORS

- Impact sports, motor vehicle accidents, biking accidents
- Age at time of injury (younger brains are more susceptible, and high school athletes are at greater risk than college athletes)
- History of previous concussion
- Alcohol or drug intoxication
- Shaking impact syndrome

### GENERAL PREVENTION

- Safety equipment, such as helmets, during impact sports and biking
- Safety education

### PATHOPHYSIOLOGY

- Concussion is on the continuum of traumatic brain injury ranging from mild to severe.
- Rotational and shearing forces cause axonal injury and disruption of the electrophysiologic activities of neurons.
- Cerebrovascular autoregulation and alterations in cerebral metabolism have been shown in concussed animal models.
- MRI may show evidence of brain contusion or diffuse axonal injury even in the presence of normal CT imaging.
- Neuropsychological testing may reveal abnormalities in cognition for up to a week even in minor concussions:
  - These abnormalities persist for longer periods with more severe injury.
  - Younger children have a higher risk for persistent symptoms.
  - Amnesia for the event at the time of presentation is also a risk factor for persistent symptoms.

### ETIOLOGY

- Usually involves blunt force trauma to the head:
- Primarily associated with falls in younger children and contact sports in older children and teenagers
  - Other causes include motor vehicle accidents, pedestrian/auto accidents, biking accidents, assaults, and child abuse.

## DIAGNOSIS

### HISTORY

- A Sports Concussion Assessment Tool (2) may be useful in detecting common and uncommon symptoms:
  - Confusion
  - Headache
  - Nausea, vomiting
  - Dizziness
  - Blurred vision
  - Fatigue
  - Delayed verbal response
  - Poor coordination
  - Repetitive questioning
  - Sensitivity to light and noise
  - Drowsiness
  - Difficulty falling asleep
  - More emotional
  - Irritability
  - Sadness
  - Nervous or anxious
- There may be retrograde and anterograde amnesia.
- There may or may not be a period of LOC.
- Brief seizure activity may be noted at the time of injury.

### PHYSICAL EXAM

- Altered cognition is frequently present, even in seemingly minor injuries.
- There are usually no focal neurologic findings.
- Search for signs of a basilar skull fracture such as mastoid or periorbital ecchymoses or hemotympanum.
- Determine if the child has cervical spine tenderness or ligamentous laxity.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

No routine lab testing is recommended in most concussive injuries.

#### Imaging

- The decision to image the brain is multifactorial:
  - The mechanism of injury, patient's signs and symptoms, physician experience, parent comfort level, and patient age are all factors used in making the decision to obtain a head CT.
- Patients with altered mental status and signs of skull fracture have an increased risk of abnormal findings on head CT.
- If the patient has a normal mental status, no evidence of skull fracture, and a nonfocal exam, CT is not recommended in the absence of persistent vomiting, severe mechanism of injury, persistent severe headache, or worsening symptoms (4).

### DIFFERENTIAL DIAGNOSIS

- Brain contusion
- Epidural and subdural hemorrhage
- Skull fracture
- Cerebral edema/increased intracranial pressure
- The differential for children with altered mental status includes:
  - Seizure with postictal state
  - Intoxication
  - Hypoglycemia
  - Central nervous system infection

## TREATMENT

### PRE HOSPITAL

Attention to stabilizing airway, breathing, and circulation and cervical immobilization prior to transport

### INITIAL STABILIZATION/THERAPY

- Every effort should be focused on minimizing the possibility of secondary brain injury.
- Attention to vital signs, perfusion, and oxygenation, as necessary
- If there is persistent vomiting, IV hydration and administration of antiemetics, as needed
- Analgesics may be indicated.
- A search should be done for other injuries.
- Evaluation of the cervical spine should be performed:
  - If the patient is alert and there are no distracting injuries, the cervical spine may be cleared clinically.
  - Otherwise, plain radiographs should be obtained.

### MEDICATION

- Ondansetron 0.1 mg/kg may be used for nausea and vomiting.
- Acetaminophen 10–15 mg/kg up to 650 mg for headache
- Try to avoid analgesics, such as opioids, that will alter the mental status.

### DISPOSITION

#### Admission Criteria

Critical care admission criteria:

- Any patient with focal neurologic findings, unstable vital signs, or significantly abnormal findings on CT should be admitted to the ICU for close observation.
- Children with persistently severe headaches or intractable vomiting should be admitted to the general ward.

#### Discharge Criteria

- Most children with a concussion do not require hospitalization.
- Patients with a relatively minor mechanism can be safely discharged home.
- Obtaining a head CT is not necessary prior to discharge if the child does not meet criteria for having a head CT.

**Issues for Referral**

- Anticipatory guidance and education concerning concussion and postconcussion syndrome
- Follow-up with a neurologist for neuropsychological testing is indicated if symptoms persist beyond 7 days.

**COMPLEMENTARY & ALTERNATIVE THERAPIES**

- Neuropsychological testing should be performed for those with persistent symptoms:
  - Ideally, young athletes should have baseline, preconcussion testing performed before the sports season begins (5).
- The optimal timing of testing is unknown, as neurocognitive findings may be worse a week after the injury.

**FOLLOW-UP****FOLLOW-UP RECOMMENDATIONS**

- Discharge instructions and medications:
  - Discharge instructions should include signs and symptoms of progressing injury and specific instructions for when to return to the emergency department.
  - Anticipatory guidance is important, as many patients with even mild concussions may have persistent symptoms for days to months (postconcussive syndrome).
- Activity:
  - Rest and gradual return to activity are essential in patients who have been concussed because of the concern that the concussed brain is more susceptible to repeat injury. This may be particularly true in younger patients.
  - A number of guidelines have been developed to help determine the timing of the return of athletes to their sports activities safely.
  - Return to activity must be individualized, but in general the patient should be asymptomatic for at least 1 wk before return to sports (2). Response to exercise should be monitored closely.
  - Cognitive rest may be necessary for some children. Activities such as attending school, watching television, or using computers may cause symptoms may need to be avoided for days or weeks after a concussion.

**COMPLICATIONS**

- Some patients develop postconcussive syndrome with symptoms of confusion, poor concentration, headaches, depression, and poor school performance that may persist for weeks to months.
- Second impact syndrome is a rare and poorly understood phenomenon that has been observed in some athletes who have suffered a second injury soon after an initial concussion (6):
  - Presumably, altered cerebrovascular autoregulation from the initial event leads to a catastrophic response with the 2nd insult, which can lead to sudden death (4,6).

**CODES**
**ICD9**

- 850.0 Concussion with no loss of consciousness
- 850.11 Concussion, with loss of consciousness of 30 minutes or less
- 850.12 Concussion, with loss of consciousness from 31 to 59 minutes

**PEARLS AND PITFALLS**

- Most children who sustain a concussion do not have an associated LOC.
- Grading of concussion as simple or complex is no longer recommended.
- Most children will have resolution of concussive symptoms within 7 days of the injury.
- Most children with a concussion do not have an associated intracranial hemorrhage.
- After a concussion, a postconcussive syndrome involving neuropsychiatric changes may result.
- Recommendations to avoid contact sports after concussion are used to prevent morbidity and mortality due to second impact syndrome.

# CONGENITAL ADRENAL HYPERPLASIA

Shilpa Patel

Dewesh Agrawal

## BASICS

### DESCRIPTION

- Congenital adrenal hyperplasia (CAH) represents a group of autosomal recessive disorders resulting in a deficiency of 1 of 5 enzymes necessary for cortisol synthesis:
  - 90–95% are 21-hydroxylase deficiency (21OHD)
  - 5% are 11 $\beta$ -hydroxylase deficiency (11 $\beta$ -OHD)
  - <5% are 3 $\beta$ -hydroxysteroid dehydrogenase deficiency (3 $\beta$ -HSD), 17 $\beta$ -hydroxylase deficiency, and 20,22-desmolase deficiency.
- This topic focuses on 21OHD because it makes up 90–95% of CAH.
- CAH caused by 21OHD is characterized by cortisol deficiency, with or without aldosterone deficiency and androgen excess:
  - There are three typical presentations of 21OHD (see History section):
    - Classic severe salt wasting
    - Classic simple virilizing
    - Nonclassic

### EPIDEMIOLOGY

#### Incidence

- Classic 21OHD occurs in 1:15,000 of live births worldwide, but incidence varies according to geographic area and ethnicity:
  - 75% is classic severe salt wasting.
  - 25% is classic simple virilizing.
- Data on the incidence of nonclassic 21OHD is lacking because neonatal screening does not accurately detect it.

#### Prevalence

- Nonclassic 21OHD occurs in ~1:1,000 of the general Caucasian population. Prevalence varies according to ethnicity with a rate as high as 3% in those of Ashkenazi Jewish descent and people of Yugoslavian heritage.
- Nonclassic 21OHD is much more common than classic 21OHD and is thought to be the most common autosomal recessive disorder.

### GENERAL PREVENTION

- Genetic counseling for parents who have CAH may result in an early prenatal diagnosis.
- Obstetricians may consider prenatal treatment with dexamethasone during the 1st trimester for fetuses at a high risk of having CAH in order to minimize the degree of virilization.
- Screening:
  - Neonatal screening is present in all U.S. states and territories for classic 21OHD (1).
  - There is a high rate of false positives, especially in sick or preterm infants.

### PATHOPHYSIOLOGY

- Endocrinology:
  - 21OH is a cytochrome p450 enzyme that is responsible for converting 17-hydroxyprogesterone (17-OHP) to 11-deoxycortisol, a precursor of cortisol, as well as progesterone to 11-deoxycorticosterone, a precursor of aldosterone.
  - Cortisol deficiency leads to hypoglycemia and hypotension.
  - At the pituitary gland, there is a lack of negative feedback normally provided by cortisol, resulting in increased adrenocorticotropic hormone (ACTH) production, secondary adrenal hyperplasia, and shunting of adrenal hormone enzymatology to produce excess androgens.
- Genitourinary: Androgen excess causes virilization of the external genitalia beginning in utero.
- Nephrology: Aldosterone deficiency results in the inability to reabsorb sodium and excrete potassium in the renal tubules, thus leading to hyponatremia, hyperkalemia, and hyperreninemia (lack of negative feedback to the renin-angiotensin-aldosterone system).

### ETIOLOGY

A family of autosomal recessive disorders of adrenal steroidogenesis leading to a deficiency of cortisol production

## DIAGNOSIS

### HISTORY

- Classic severe salt-wasting 21OHD presents within the 1st 4 wk of life with:
  - Lethargy, decreased activity, or fatigue
  - Unresponsiveness
  - Poor feeding/weak suck
  - Vomiting
  - Dehydration
  - Failure to thrive
  - Seizures
- Classic simple virilizing 21OHD presents in childhood with:
  - Precocious pubarche
  - Rapid growth acceleration and adult short stature secondary to early skeletal maturation
  - Virilization in females
- Nonclassic 21OHD presents in adolescence or adulthood:
  - Females usually present with acne, menstrual irregularities (oligomenorrhea or infertility), and hirsutism.
  - In males, acne may be the only presenting symptom.

### ALERT

Failure to maintain a high index of suspicion for CAH in any ill-appearing vomiting infant can lead to a delay in treatment with a subsequent increase in morbidity and mortality.

### PHYSICAL EXAM

- Classic severe salt-wasting 21OHD presents with:
  - Hypotension
  - Shock
  - Hyponatremia
  - Hyperkalemia
  - Hypoglycemia
  - Metabolic acidosis
  - Hypothermia
  - Altered sensorium
  - Dehydration
  - Abnormal genitalia:
    - Ambiguous genitalia in a genotypic female with a large clitoris, rugated and partly fused labia majora, and common urogenital sinus in place of a separate vagina and urethra
    - A severely virilized female may have been incorrectly classified as male and therefore could have what appears to be a normal phenotypic male appearance without palpable gonads.
    - A genotypic male may have a large penis and subtle hyperpigmentation.
- Classic simple virilizing 21OHD presents with:
  - Premature puberty: Pubic hair, body odor, acne, and rapid linear growth
  - Hirsutism, clitoromegaly, and virilization are noted in females.
  - Premature isosexual development is noted in males with hyperpigmentation and phallic enlargement, usually with small testes.
- Nonclassic 21OHD usually presents with:
  - Females: Acne, hirsutism
  - Males: Acne, large penis with small testes

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

Typical findings of classic severe salt-wasting 21OHD include hyponatremia, hyperkalemia, hypoglycemia, and/or metabolic acidosis.

#### Initial Lab Tests

- Stat tests:
  - Serum glucose
  - Serum sodium
  - Serum potassium
  - Serum bicarbonate
  - pH
  - If there is a known diagnosis of CAH, no further diagnostic labs are necessary.
- Emergent labs in order of importance (before treatment with steroids if possible) to accurately diagnose the cause if diagnosis is unknown:
  - Serum cortisol level, 17-OHP, and ACTH
  - Plasma renin and aldosterone
  - Urine sodium and potassium

#### Imaging

Pelvic US to visualize internal reproductive organs and adrenal glands can be done at a later time and is not necessary emergently.

**Diagnostic Procedures/Other**

- Classic 21OHD is characterized by markedly elevated 17-OHP and low basal cortisol (<10 µg/dL). In infants with classic 21OHD, basal levels of 17-OHP are often >10,000 ng/dL (normal levels <100 ng/dL).
- In consultation with an endocrinologist, an ACTH stimulation test may be done as an outpatient or inpatient once the patient has been stabilized in the emergency department.
- Karyotype to determine genotypic sex can be sent once the patient is stable.

**DIFFERENTIAL DIAGNOSIS**

- Classic severe salt-wasting 21OHD:
  - Formula intolerance
  - Gastroenteritis/Dehydration
  - Pyloric stenosis
  - Sepsis and septic shock
  - CHF
  - Inborn error of metabolism
  - Methemoglobinemia
  - Infantile botulism
  - Nonaccidental head trauma
  - Acquired adrenal insufficiency
  - CAH: 3β-HSD
  - Poisoning
- Classic simple virilizing 21OHD:
  - Precocious puberty
  - Virilizing tumor
  - CAH: 11β-OHD
- Nonclassic 21OHD:
  - Polycystic ovarian syndrome

**TREATMENT**

**PRE HOSPITAL**

Rapid clinical recognition and correction of hypotension and hypoglycemia:

- IV fluid bolus for hypotension
- Check glucose level, and treat if hypoglycemic.

**INITIAL STABILIZATION/THERAPY**

- Rapid fluid resuscitation with isotonic saline to treat hypotension and hypovolemia
- Administration of glucose as necessary to correct hypoglycemia

**MEDICATION**

**First Line**

- Administration of high-dose stress steroids after obtaining the aforementioned labs:
  - Hydrocortisone 50–75 µg/m<sup>2</sup> IV once followed by hydrocortisone 100 µg/m<sup>2</sup> IV divided q.i.d. for 24–48 hr until the acute stressed phase has passed
  - Treatment should not be withheld if the diagnosis is known or suspected.

- Electrolyte correction is usually not necessary, as electrolytes should normalize with steroid administration. However, if hyperkalemia is severe, there are ECG changes, or there is renal insufficiency:
  - Patient should be placed on a continuous cardiac monitor.
  - Treat hyperkalemia. (See Hyperkalemia topic.)
- In a patient previously diagnosed with 21OHD, stress dosing is required for an acute illness or procedure (severe illness such as fever ≥38°C, vomiting, diarrhea, lethargy, surgery, trauma, dental work):
  - Give 2 to 3 times the regular dose per day IV divided t.i.d. or per the consensus guidelines (3):
    - <3 yr: 25 mg followed by 25–30 mg/day
    - 3–12 yr: 50 mg followed by 50–60 mg/day
    - >12 yr: 100 mg followed by 100 mg/day
- For an infant presenting in acute adrenal (addisonian) crisis, it is important to monitor BP, electrolytes, and response to therapy.

**Second Line**

The goal of maintenance therapy for classic severe salt-wasting 21OHD is to suppress adrenal androgen secretion enough to prevent virilization; optimize growth; and protect potential fertility by the administration of daily glucocorticoid, mineralocorticoid, and salt supplementation.

**SURGERY/OTHER PROCEDURES**

- Bilateral adrenalectomy may be indicated for individuals with classic 21OHD who have a history of poor control with hormonal replacement therapy (4).
- Genotypic females who are virilized at birth may require feminizing genitoplasty, if the family decides to raise the infant as a female. This surgery is controversial, and there is much debate regarding the timing of the procedure, though historically it was recommended between 2 and 6 mo of age (2).

**Issues for Referral**

- Patients should be followed by pediatric endocrinology.
- Those with ambiguous genitalia will likely need a surgical/urologic and psychological evaluation.
- Parents should be referred for genetic counseling.

**FOLLOW-UP**

**FOLLOW-UP RECOMMENDATIONS**

Patients should be instructed to wear a bracelet stating they have adrenal insufficiency with their normal required stress steroid dose determined by their endocrinologist.

**Patient Monitoring**

In treated individuals, 17-OHP levels will remain higher than normal, though renin levels should return to normal for age.

**PROGNOSIS**

Most individuals live relatively normal lives on lifelong steroid replacement.

**COMPLICATIONS**

- Refractory shock
- Hypoglycemic/Hyponatremic seizures
- Intractable hyperkalemia and arrhythmias

**CODES**

ICD9  
255.2 Adrenogenital disorders

**PEARLS AND PITFALLS**

- Consider CAH in any infant who presents with severe vomiting or shock in the 1st few weeks of life.
- CAH may be missed if newborn screen results are still pending or if genitalia are not noticeably ambiguous (male infants).
- The 4 rare causes of CAH (see Description section) are not routinely tested in every state as part of neonatal screening and thus may be missed.
- Severe hyponatremia may be delayed in the classic severe salt-wasting form and therefore not as apparent on presentation in the 1st 2 wk of life.

# CONGENITAL HEART DISEASE

Calvin G. Lowe

## BASICS

### DESCRIPTION

- Patients with congenital heart disease (CHD) present with symptoms in 2 typical age groups:
  - Ductal dependent lesions will present within the 1st mo of life (see Ductal Dependent Cardiac Emergencies topic).
  - Left (L) to right (R) shunting lesions will present in the 2–6 mo age range.
- Undiagnosed CHD patients can present to the emergency department in extremis at any age.
- There are 35 types of CHD.

### EPIDEMIOLOGY

#### Incidence

- CHD occurs in 8 per 1,000 live births within the 1st yr of life.
- Incidence is the same among premature and term infants.
- Premature infants have a greater incidence of patent ductus arteriosus (PDA).
- Parental or sibling history of CHD increases incidence to 16 per 1,000 live births.

#### Prevalence

- The prevalence of CHD at birth ranges from 1–5 per 1,000 live births.
- In North America, the observed prevalence of CHD in children rose from 6.88 per 1,000 people in 1985 to 11.89 per 1,000 in 2000.

### RISK FACTORS

Maternal risk factors:

- Infection (rubella)
- Medication use (anticonvulsants, lithium)
- Drug abuse (ethanol)
- Disease states (phenylketonuria, insulin-dependent diabetes mellitus, systemic lupus erythematosus)

### PATHOPHYSIOLOGY

- CHD can be classified as either acyanotic or cyanotic lesions.
- Acyanotic lesions can be further classified as L to R shunts or obstructive lesions:
  - L to R shunt lesions: Oxygenated blood from the L side of the heart or aorta is shunted to the R heart via an intra-arterial or intraventricular septal defect or a PDA.
    - The additional blood in the R side of the heart can increase the pulmonary blood flow and pulmonary BP.
    - The higher the degree of shunting, the greater the degree of symptoms.
    - Lesions in this category include atrial septal defect, ventricular septal defect (VSD), and PDA.
  - Obstructive lesions result in blood flow obstruction without shunting. A pressure gradient evolves resulting in pressure overload proximal to the obstruction, resulting in ventricular hypertrophy and CHF.
- Cyanotic lesions cause varying degrees of R to L shunting of deoxygenated venous blood:
  - Pulmonary blood flow may be ↑, normal, or ↓.
  - >5 g/dL of deoxygenated hemoglobin in blood will result in clinical cyanosis.
  - Examples of cyanotic heart lesions include: Tetralogy of Fallot (TOF), transposition of the great arteries (TGA), tricuspid atresia, total anomalous pulmonary venous return (TAVPR), and truncus arteriosus.

### ETIOLOGY

- The exact cause of CHD is unknown.
- Some factors are associated with an increased risk of CHD: Maternal risk factors, chromosomal abnormalities, and single gene defects
- A multifactorial etiology is a theoretical basis for most forms of CHD.

### COMMONLY ASSOCIATED CONDITIONS

- 5–8% of children with CHD have an association with a chromosomal abnormality.
- Examples include trisomy 21 (Down syndrome), trisomy 18, trisomy 13, Turner syndrome, cri-du-chat syndrome, Wolf-Hirschhorn syndrome, velocardiofacial syndrome, and/or DiGeorge sequence and Williams syndrome.
- Single gene defects such as Marfan syndrome, Smith-Lemli-Opitz syndrome, Ellis-van Creveld, Holt-Oram syndrome, Noonan syndrome, and the mucopolysaccharidoses are associated with CHD.

## DIAGNOSIS

### HISTORY

- Depending on the cardiac lesion, the age at presentation will vary greatly:
  - PDA-dependent lesions will clinically manifest within the 1st days of life.
  - Lesions that have a VSD may not become evident until 4–6 wk of age.
- Symptoms can vary from benign to CHF to shock.
- The most common presentations are acute respiratory distress and cyanotic episodes.
- CHF (fatigue, poor appetite, and diaphoresis during feeding, tachypnea, tachycardia, S3 heart sound, hepatomegaly, pallor), failure to thrive (FTT), irritability, dehydration, and recurrent lung infections are common signs and symptoms.

### PHYSICAL EXAM

- General appearance and color is the most important part of the exam:
  - Blue color indicates a cyanotic heart lesion and a R to L shunt.
  - Grey color indicates outflow obstruction, systemic hypoperfusion, and shock.
- BP should be measured with an appropriate-sized cuff:
  - BPs should be measured in both upper and lower extremities.
  - Lower extremity BP > upper extremity BP suggests aortic coarctation.
- Tachycardia and tachypnea may be out of proportion to the patient's general appearance.
- Cool skin and delayed capillary refill indicates shock from severe cardiac disease.
- Absent or ↓ distal pulses suggest aortic arch obstruction.
- Assessment of hydration status, mucosal color, auscultation of the heart and lungs, palpation of the precordium, and a survey for organomegaly should be performed.
- Heart murmurs with or without thrills can suggest CHD.
- Gallop rhythms may also be heard.
- CHF is a common presentation: Tachypnea, hyperactive precordium, chest congestion, and hepatomegaly.
- Recognition of dysmorphic features consistent with a genetic abnormality

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

- Serum electrolytes, calcium, glucose, and CBC:
  - Electrolyte abnormalities (hyponatremia and hypochloremia) can occur.
  - ↓ calcium can present as prolongation of the QT interval, CHF, hypotension.
  - Hypoglycemia may also cause weakness and fatigue.
  - Depending on the heart lesion, polycythemia (from chronic hypoxemia) or anemia (dilutional effects) can be present.
- A blood gas sample should be obtained to determine the degree of hypoxemia and metabolic acidosis.
- Cardiac enzymes, such as creatine phosphokinase (CPK), the cardiac fraction (CPK-MB) as well as the troponins, specifically troponin T (cTnT) and troponin I (cTnI) may be helpful.

#### Imaging

Chest radiographic imaging is essential:

- The heart size in CHD can be small, normal, or large.
- Some types of CHD will show characteristic findings on chest radiography:
  - The classic “boot-shaped” heart of TOF
  - The “3 sign” secondary to a prominent aortic knob and poststenotic dilation of the descending aorta is indicative of aortic coarctation.
  - The “snowman” or “figure of 8” sign is seen in supracardiac anomalous return.
  - The “egg on a string” is seen in TGA.
  - Various degrees of ventricular hypertrophy and pulmonary congestion will depend on the type of CHD.

#### Diagnostic Procedures/Other

- Any suspected CHD should have a pediatric cardiology consult.
- An echo should be performed on patients suspected of having CHD.
- A 12-lead ECG should be obtained. Depending on the lesion, the ECG may show various arrhythmias, hypertrophy, R or L axis deviations, and bundle branch blocks.
- A hyperoxia test can differentiate between cyanotic cardiac and pulmonary disease. For a description of the hyperoxia test, see the Cyanotic Heart Disease topic under Diagnostic Procedures/Other.

### DIFFERENTIAL DIAGNOSIS

- In neonates, sepsis must be suspected prior to a definitive diagnosis of CHD.
- Dilated cardiomyopathy
- Myocarditis
- Supraventricular tachycardia
- Arrhythmias
- Hypoglycemia
- Structural heart disease
- Persistent pulmonary HTN
- Apparent life-threatening event
- Pneumonia
- Inborn errors of metabolism

## TREATMENT

### INITIAL STABILIZATION/THERAPY

- Immediate evaluation and treatment of the ABCs and continuous pulse oximetry are crucial.
  - Administer oxygen (O<sub>2</sub>) judiciously.
  - Establish IV access: > 1 site is recommended.
- Obtain blood and urine samples.
- Small, frequent IV boluses of normal saline or lactated Ringer solution of 10 cc/kg are indicated to treat hypotension.
- 4 extremity BPs should be measured.
- A full sepsis evaluation should be initiated and antibiotics empirically started after the appropriate cultures are obtained in infants <2–3 mo of age who are exhibiting signs and symptoms of sepsis: Fever >38.0°C, irritability, respiratory distress, lethargy.
- Caution must be used if a lumbar puncture is indicated, especially in an unstable cyanotic child.

### MEDICATION

#### First Line

In a cyanotic patient who may have ductal-dependent CHD, a prostaglandin (PGE<sub>1</sub>) infusion should be initiated.

- Infusion rates should be started at 0.05–0.1 μg/kg/min with a max rate of 0.4 μg/kg/min.
- A common side effect of PGE<sub>1</sub> is apnea; prompt intubation may be necessary.
- Elective intubation of patients on PGE<sub>1</sub> for transport may increase the risk of transport complications (1).
- Other occurrences associated with PGE<sub>1</sub> include hyperthermia, flushing, arrhythmias, hypotension, and seizures.

#### Second Line

- A child with CHF may benefit from a dose of furosemide at 0.5–1 mg/kg.
- If a urine output of 3–5 cc/kg/hr is not achieved within 1–2 hr after the 1st dose of furosemide, repeat doses of 1 mg/kg can be given at hourly intervals to a max of 3–5 mg/kg.
- If hypotension persists after IV fluid boluses, dopamine should be initiated at 5 μg/kg/min and titrated up to a max of 20 μg/kg/min.
- For further inotropic support, dobutamine can be added with an initial rate of 5 μg/kg/min with titration to a max rate of 20 μg/mg/min.

## DISPOSITION

### Admission Criteria

- Any CHD patient with an ↑ O<sub>2</sub> requirement over baseline, acute respiratory distress, or worsening CHF not responsive to emergency department therapy should be admitted.
- Patients with confirmed or symptomatic respiratory syncytial virus should be admitted for observation.
- Critical care admission criteria:
  - Any patient who is intubated and/or requiring vasopressor support should be promptly admitted to a pediatric ICU (neonatal, pediatric, or cardiothoracic).
  - The decision to admit should be made in conjunction with a pediatric cardiologist.

### Discharge Criteria

A patient who has been evaluated by a pediatric cardiologist and deemed to be stable may be discharged home with outpatient cardiology follow-up.

### Issues for Referral

- If a patient requires a higher level of care at a tertiary pediatric center, then arrangements for transport should be made.
- A specialized pediatric critical care transport team may be necessary to facilitate the transport.

## FOLLOW-UP

### FOLLOW-UP RECOMMENDATIONS

Discharge instructions and medications:

- Parents should be instructed to look for worsening signs and symptoms of the patient's CHD.
- Discharge medications should be based upon the recommendations of the consulting pediatric cardiologist.
- A follow-up appointment with a pediatric cardiologist should be made.

### PROGNOSIS

Prognosis is based on the patient's initial acuity, CHD type, and need for surgical treatment.

### COMPLICATIONS

- Hypoxic brain injury
- FTT
- Severe metabolic acidosis
- Multiple organ failure
- Cardiopulmonary arrest

## ICD-9 CODES

### ICD9

- 745.5 Ostium secundum type atrial septal defect
- 746.9 Unspecified congenital anomaly of heart
- 747.0 Patent ductus arteriosus

## PEARLS AND PITFALLS

- A combination of cyanosis, murmur, and abnormal pulses is associated with a PGE<sub>1</sub>-sensitive CHD lesion.
- Routine intubation of patients on PGE<sub>1</sub> is not necessary.
- Administration of high levels of O<sub>2</sub> may worsen a patient with cyanotic CHD:
  - O<sub>2</sub> can act as a pulmonary vasodilator; hence, caution is warranted when administering O<sub>2</sub> in a suspected CHD patient.
- Caution should be used with higher doses of dobutamine because of its vasodilator effects that may lead to precipitous drops in BP, especially in the hypovolemic CHD patient.

# CONGESTIVE HEART FAILURE

Travis K. F. Hong  
Calvin G. Lowe

## BASICS

### DESCRIPTION

CHF is the inability of the heart to provide an adequate level of tissue perfusion to meet metabolic requirements.

### EPIDEMIOLOGY

#### Incidence

- ~12,000 cases of pediatric heart failure occur in the U.S. each year (1):
  - 61% of cases were associated with congenital heart disease (CHD) or cardiac surgery.
  - 82% of cases occur in infants.
- For primary cardiomyopathies in structurally normal hearts, the incidence is 0.87 per 100,000 infants (2).

### RISK FACTORS

- CHD, especially conditions with left-to-right shunting or left-sided obstruction
- Dilated or hypertrophic cardiomyopathy
- Previous cardiac surgery
- Metabolic or renal disorders

### PATHOPHYSIOLOGY

- CHF physiology is due to volume overload, pressure overload, inadequate inotropic state, alteration in chronotropic state, or a combination.
- Cardiac output (CO) equals heart rate (HR) multiplied by stroke volume (SV):
  - HR is controlled by neurologic and intrinsic cardiac conduction input.
  - SV depends on cardiac muscle contractility, preload, and afterload.
- Preload is the volume that must be ejected from the left ventricle (LV) at the end of diastole, which depends on venous return. A larger filling volume causes increased contractility via the Frank-Starling mechanism.
- Afterload is the pressure required to eject preload volume from the LV, typically measured as systolic aortic pressure.
- Clinical manifestations of CHF are primarily caused by alterations in fluid retention and adrenergic activity:
  - Inadequate systemic perfusion results in fluid retention via the kidneys and renin-angiotensin system.
  - After initial brief improvement in preload, dilated cardiomyopathy occurs and increases ventricular wall stress, pressure, and myocardial oxygen demand.
  - Compensatory cardiac hypertrophy then reduces contractility and thus CO.
- Increased  $\beta$ -adrenergic tone augments HR and contractility but causes many of the typical signs and symptoms of CHF due to an increased sympathetic state.

### ETIOLOGY

- Varies by age of presenting symptoms and functional classification
- 1st day of life:
  - Cardiac dysfunction: Hypoglycemia, sepsis, hypocalcemia, myocarditis, birth asphyxia
  - Structural: Valvular regurgitation, extracardiac arteriovenous malformation
  - Conductional: Supraventricular tachycardia, congenital heart block
  - Hematologic: Hyperviscosity states (eg, polycythemia), anemia
- 1st wk of life:
  - Structural: Persistent pulmonary HTN of the newborn, aortic coarctation, critical aortic stenosis (AS), hypoplastic left heart syndrome (HLHS), critical pulmonary stenosis (PS), interrupted aortic arch (IAA), transposition of the great arteries (TGA), obstructed total anomalous venous return (TAPVR), pulmonary atresia, patent ductus arteriosus (PDA)
  - Metabolic: Adrenal insufficiency, hyperthyroidism
  - Renal: Systemic HTN, renal failure
  - Cardiac dysfunction and conductional abnormalities
- 1st 2 mo of life:
  - Structural: Ventricular septal defect (VSD), atrioventricular canal, single ventricle, atrial septal defect, PDA, nonobstructed TAPVR, truncus arteriosus, AS, IAA, anomalous coronary artery, HLHS
  - Myocardial: Cardiomyopathy, myocarditis, Pompe disease
  - Pulmonary: Pulmonary HTN, central hypoventilation syndromes, upper airway obstruction (eg, tracheomalacia), bronchopulmonary dysplasia
  - Other: Hypothyroidism, renal and metabolic causes as above
- Childhood and beyond:
  - Acquired causes: Sepsis, infective endocarditis, rheumatic heart disease, cocaine toxicity
  - Genetic: Noonan syndrome, Marfan syndrome, Hurler syndrome, Duchenne muscular dystrophy, Friedreich ataxia
  - Unrepaired CHD: Valvular insufficiency, Eisenmenger syndrome, Ebstein anomaly, severe PS
  - Repaired CHD: Fontan procedure may cause protein-losing enteropathy and CHF.
  - Failure of surgical palliation: Large systemic to pulmonary artery shunt, pulmonary atresia with large VSD, prosthetic valve failure, ventricular failure following TGA arterial switch operation, reopened VSD, aortic insufficiency following valvotomy or truncus arteriosus repair, mitral insufficiency after endocardial cushion repair, myocardial ischemia following operative arrest, PS or outflow tract obstruction, pulmonary insufficiency
  - Collagen vascular disease: Systemic lupus erythematosus, juvenile idiopathic arthritis
  - Other: Kawasaki disease, neuromuscular weakness, hypo/hyperthyroidism, renal disease, end-stage cystic fibrosis, systemic HTN

## DIAGNOSIS

### HISTORY

- Presentation is usually related to the increased metabolic energy requirement in CHF.
- Changes in infant feeding habits:
  - Increase in feeding time, >30–60 min for a bottle (regardless of amount)
  - Caloric intake <75 kcal/kg/day
  - Increased work of breathing
  - Early fatigue, agitation, or irritability
  - Diaphoresis, especially with feeds
- Prolonged general fatigue and malaise
- Weight loss, anorexia, or nausea
- Decreased exercise tolerance or activity
- Tachypnea, orthopnea, or paroxysmal nocturnal orthopnea
- Chronic cough
- Frequent lower respiratory tract infections
- Above symptoms associated with excessive salt or fluid intake

### PHYSICAL EXAM

- Sinus tachycardia
- Systemic hypotension
- Murmurs may be present depending on location and size of defect or lesion (see Heart Murmur topic).
- Increased precordial activity in shunt lesions
- S3 or ventricular gallop
- S4 or atrial kick due to ventricular hypertrophy
- Cool or mottled extremities
- Decreased peripheral pulses or capillary refill
- Pulsus paradoxus
- Jugular venous distension
- Tachypnea
- Cyanosis, central or peripheral
- Persistent hacking cough
- Grunting, retractions, or nasal flaring
- Wheezing, and less commonly rales
- Hepatomegaly or liver tenderness
- Jaundice in infants
- Peripheral edema or ascites in older children

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

- Diagnosis is primarily clinical, but certain lab assays may be useful.
- Glucose and ionized calcium levels should be measured and monitored.
- Hyponatremia, hypochloremia, or anemia may be present during volume overload.
- Blood gas measurement may demonstrate metabolic acidosis and hypoxemia.
- Elevated troponin or creatine phosphokinase levels may be seen in myocardial inflammation or ischemia.
- The role of brain natriuretic peptide (BNP) levels is unclear in children:
  - Elevation may aid in distinguishing respiratory distress as cardiac or respiratory.
  - BNP >300 pg/mL is strongly correlated with poor outcome (3).

**Imaging**

- Chest radiograph is essential and may show the following:
  - Cardiomegaly is nearly always present.
  - Increased pulmonary vascular markings
  - Pleural effusion, especially in right-sided CHF
  - Pericardial effusion
- Echo provides a quick, noninvasive, and relatively inexpensive method to gather anatomic and physiologic data:
  - Provides essential details of cardiac anatomy
  - Color Doppler echo can detect and quantify valvular insufficiency, stenosis, or intracardiac shunting.
  - Ejection fraction is used to estimate left ventricular function by measuring the ratio of blood volume during diastole and systole.
- Cardiac MRI is helpful for 3D imaging and assessment of right ventricle and single ventricle function:
  - Limited use in emergent or acute situations

**Diagnostic Procedures/Other**

- ECG:
  - Nonspecific indicator of cardiac abnormality
  - Useful when an arrhythmia or myocardial ischemia is present.
  - Increased QRS amplitude in precordial leads may indicate ventricular wall hypertrophy.
  - Decreased QRS amplitude in precordial leads may indicate myocarditis.
  - In anomalous left coronary artery from the pulmonary artery (ALCAPA), an anterolateral infarct pattern is seen.
- Cardiac catheterization:
  - Used when interventional procedures are required (eg, biopsy, balloon septostomy)
  - Provides detailed hemodynamic and anatomic data
  - Emergent utility has decreased with advent of color Doppler echo.

**DIFFERENTIAL DIAGNOSIS**

- Myocardial infarction
- Sepsis
- Malnutrition
- Cardiac tamponade
- Thyrotoxicosis
- Pulmonary thromboembolism
- Intracardiac thrombus
- Pulmonary HTN
- Cardiac neoplasm
- Kawasaki disease
- Pregnancy
- Cardiotoxic drugs (eg, doxorubicin, daunorubicin, cyclophosphamide, 5-fluorouracil)

**TREATMENT**

**INITIAL STABILIZATION/THERAPY**

- Assess and stabilize airway, breathing, and circulation:
  - Judicious IV fluid resuscitation as needed to maintain adequate BP
  - 5 mL/kg boluses of isotonic fluid as needed with frequent reassessment of intravascular volume status

- Inotropic agents as indicated for hypotension:
  - Caution with high-dose dopamine (> 10 µg/kg/min) due to an increase in myocardial oxygen consumption
- Correct electrolyte and laboratory abnormalities.
- Consultation with a pediatric cardiologist and/or critical care specialist is recommended.

**MEDICATION**

**First Line**

- Furosemide 1 mg/kg IV, repeat q6–12h PRN:
- No pediatric data exist for thiazide diuretic monotherapy.

**Second Line**

- Digoxin, initial total digitalizing dose (IV):
  - 3-dose regimen: Give 50% of total digitalizing dose (TDD), then 25% of TDD × 2 q6–12h
  - Preterm infants: 20 µg/kg
  - Term infants: 25 µg/kg
  - 1 mo to 2 yr: 30 µg/kg
  - 2–10 yr: 25 µg/kg
  - 10 yr to adult: 0.5–1 mg
- Digoxin, maintenance dose (IV):
  - Preterm infant: 2.5 µg/kg b.i.d.
  - Term infants: 2.5–4 µg/kg b.i.d.
  - 1 mo to 2 yr: 4–6 µg/kg b.i.d.
  - 2–10 yr: 2.5–4.5 µg/kg b.i.d.
  - 10 yr to adult: 125–500 µg per day
- Digoxin: Dosages for CHF management only. Equivalent oral dose is 125% of IV form.
- Consultation with a pediatric cardiologist is strongly recommended prior to initiating therapy.

**SURGERY/OTHER PROCEDURES**

- Indications for surgical intervention are varied depending on the specific etiology of CHF.
- Pacemaker therapy in CHD is indicated for symptomatic bradycardia, atrioventricular asynchrony, or intra-atrial reentrant tachyarrhythmias.
- Implanted defibrillator in CHD is indicated for ventricular tachycardia or syncope.
- Mechanical ventricular assist devices may be used in end-stage CHF as a bridge to heart transplantation.
- Heart transplantation is indicated in refractory end-stage CHF:
  - 1-yr posttransplant survival is 85% (4).
  - 20-yr posttransplant survival is 40% (4).

**DISPOSITION**

**Admission Criteria**

- All patients with either new-onset CHF or an acute worsening of chronic CHF should be admitted for diuretic therapy and supportive care.
- Consider admission in the newly presenting neonate or infant for further workup and treatment of possible undiagnosed CHD.
- Critical care admission criteria:
  - Consider critical care admission in patients with hemodynamic instability or pulmonary compromise.

**FOLLOW-UP**

**FOLLOW-UP RECOMMENDATIONS**

- Consultation with a pediatric cardiologist is recommended.
- If the patient is stable for discharge home, an urgent follow-up with a pediatric cardiologist is strongly recommended.

**COMPLICATIONS**

- Cardiac arrhythmias, especially ventricular tachycardia or fibrillation
- MI
- Cardiac arrest
- Hypoxemic brain injury
- Pulmonary edema and respiratory failure
- Respiratory or metabolic acidemia
- Renal insufficiency or failure
- Hepatic dysfunction, including coagulopathies and delayed pharmacologic metabolism and clearance
- Digoxin toxicity
- Loop diuretic–induced hypokalemia, hyponatremia, contraction alkalosis, and ototoxicity (usually in chronic use)

**CODES**

ICD9  
428.0 Congestive heart failure, unspecified

**PEARLS AND PITFALLS**

- CHF in neonates or infants is often due to an undiagnosed congenital heart defect.
- As in most cases of cardiogenic shock, exercise caution during fluid resuscitation in order to avoid volume overload.

# CONJUNCTIVAL INJURY

Donald T. Ellis, II  
Sandip A. Godambe

## BASICS

### DESCRIPTION

- The conjunctival membranes represent the thin, translucent covering of the white sclera of the globe (bulbar conjunctiva) and the inside of the eyelids (palpebral conjunctiva).
- The most common conjunctival injuries include direct trauma and burns from chemical irritants or radiant energy, as with ultraviolet (UV) light.

### EPIDEMIOLOGY

#### Incidence

- The annual incidence of all forms of eye injury has been reported at ~1% (1).
- Conjunctival and corneal abrasions comprised 16.5% of the ocular injuries in the same study (1).

### RISK FACTORS

As with trauma in general, conjunctival injury is more common in males than females.

### GENERAL PREVENTION

- Eye protection is critical to reducing the risk of any eye injury.
- It has been postulated that 90% of eye injuries are preventable.

### PATHOPHYSIOLOGY

- Traumatic injury occurs from direct trauma from an object or foreign body.
- Alkaline substances induce liquefactive necrosis, which can allow the chemical to reach into the deeper tissues in the anterior chamber (2).
- Acids are typically responsible for superficial injury, as they cause coagulation of the tissues, which prevents them from reaching deeper layers in the eye (2):
  - Substances with a pH of  $\leq 2.5$  cause penetrating injury similar to that seen with alkalis.
  - Hydrofluoric acid, in particular, has been known to cause deep, “alkalilike” eye injuries.

### ETIOLOGY

- Trauma:
  - Play or sports activity
  - Motor vehicle accidents
  - Foreign body (dirt, sand, glass, etc.)
  - Self-inflicted (rubbing eye, scratching eye)
- Alkali: Oven cleaners, fireworks, dishwashing detergent
- Acid: Battery acid, bathroom cleaners, rust-removal agents, automotive wheel cleaners
- UV: Welding light, tanning beds, outdoor activities at increased elevation
- Thermal: Fire, steam, hot liquids

### COMMONLY ASSOCIATED CONDITIONS

- Conjunctival injury may also be associated with corneal abrasion, hyphema, open globe injury, facial/airway burns, and facial injury, including fractures.
- See respective topics on Fracture, Orbital; Corneal Abrasion; Hyphema; Foreign Body, Cornea; and Burn, Chemical.

## DIAGNOSIS

### HISTORY

- Most cases are readily identifiable from the history; however, burns from UV light may present with severe pain hours after the event.
- Pain
- Photophobia
- Foreign body sensation
- Conjunctival redness and tearing

### PHYSICAL EXAM

- Epiphora
- Chemosis
- Hyperemia
- Corneal clouding
- Scleral pallor
- Teardrop pupil (as seen with ruptured globe)
- Foreign body (Eyelid eversion is critical when evaluating for potential presence of foreign bodies.)
- UV keratitis may present with punctuate lesions over the corneal surface (seen on fluorescein staining) (3).

### ALERT

Strong acids may be associated with pale conjunctiva and corneal clouding, which may be followed by desquamation. The absence of hyperemia may then obscure the degree of tissue injury.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

Other lab testing is usually not indicated in conjunctival injury.

##### Imaging

Imaging is generally not helpful unless orbital or other facial fractures are suspected.

##### Diagnostic Procedures/Other

- Fluorescein staining is strongly encouraged when the differential diagnosis includes entities such as corneal abrasion, retained foreign body, herpetic keratitis, and UV burns.
- pH testing may be used in chemical burns, but irrigation should never be delayed.
- pH testing of the lacrimal fluid should be 6.5–7.5. Wait several minutes after discontinuing irrigation of the eye before testing to obtain an accurate result.
- Visual acuity should also be determined at baseline, but as with pH testing, it should not delay irrigation.
- Must consider performing slit lamp exam with fluorescein staining and measurement of intraocular pressure

### Pathological Findings

- Pronounced conjunctival chemosis
- Epithelial loss
- Corneal edema and opacification

### DIFFERENTIAL DIAGNOSIS

- Corneal abrasion
- Infectious conjunctivitis
- Allergic conjunctivitis
- Foreign body
- Glaucoma
- Scleritis/Episcleritis (such as in systemic lupus erythematosus, Wegener granulomatosis, rheumatoid arthritis, and inflammatory bowel disease)

## TREATMENT

### PRE HOSPITAL

- Trauma: An eye shield (not eye patch) should be placed if there is concern for a ruptured globe or if accommodation is painful.
- Thermal: Copious irrigation and rapid cooling of the ocular structures
- Chemical (alkali, acid): Copious irrigation with buffered solution (such as Diphoterine or lactated Ringer):
  - However, if none is available, use any sterile, nontoxic solution (such as normal saline).
  - Tap water is a preferable alternative to delayed irrigation and may be utilized immediately following the injury:
    - However, hypotonic solutions are associated with a risk of increasing the depth of penetration.

### INITIAL STABILIZATION/THERAPY

- All conjunctival injuries:
  - Administer topical anesthetic drops to provide comfort and to facilitate examination (once ruptured globe has been ruled out).
- Chemical burns:
  - Irrigate (see above) until pH has normalized for 30 min. Normal pH should be 6.5–7.5.
  - Irrigation using a Morgan lens is recommended to achieve adequate reaching of areas under the eyelids.
  - Never attempt to neutralize alkali burns with acidic solutions and vice versa.
  - Do not remove contact lenses during irrigation, as these may serve as physical barriers to block deeper penetration of the corrosive substance. Remove after completion of irrigation.
  - Evert the lids to ensure that no foreign material remains.
- Thermal burns:
  - As with chemical burns, irrigate liberally (see above) and remove any foreign matter.
  - Remove contact lenses.
  - May need to remove eschar from eyelids
  - Ensure that any perioral or airway burns are addressed.

**MEDICATION****First Line**

- Topical anesthetic (such as 0.5% proparacaine or tetracaine) in the emergency department. Do not use repeated doses upon discharge, as this may impair corneal healing.
- Parenteral analgesics (such as morphine 0.1 mg/kg/dose, up to 4–6 mg) to adequately control pain initially. Oral narcotics may be necessary for patients if discharged.
- Topical antibiotics (eg, erythromycin ointment or trimethoprim/polymyxin drops q.i.d.) should be a consideration. See Corneal Abrasion topic.
- For chemical and thermal burns, assess tetanus immunization status and update if appropriate.

**Second Line**

- Both systemic and topical steroids (such as oral prednisone 2 mg/kg/day, up to 60 mg) remain controversial but may be used after consultation with ophthalmology.
- After consultation with ophthalmology, medications to lower intraocular pressure (such as acetazolamide, dose not established for pediatrics) may be needed if glaucoma develops.
- Cycloplegics (such as homatropine 2% 1–2 drops; may use every 15–20 min as needed) have been used with chemical, thermal, and UV injuries, but evidence supporting this practice is limited.

**DISPOSITION****Admission Criteria**

Hospital admission is not needed unless there are severe burns (such as with hydrofluoric acid or alkaline substances), concurrent facial (or significant systemic) injuries, or social concerns.

**Discharge Criteria**

- Minor burns (most 1st-degree burns by thermal injury)
- UV injuries

**Issues for Referral**

Transfer to a regional burn center may be required for those with severe burns or with extraorbital injuries.

**COMPLEMENTARY & ALTERNATIVE THERAPIES**

- Cool compresses may provide a measure of relief for thermal burns.
- Eye patches remain controversial.

**FOLLOW-UP****FOLLOW-UP RECOMMENDATIONS**

Discharge instructions and medications:

- Follow up with the primary care provider for repeat fluorescein testing within 24 hr.
- Follow up with an ophthalmologist in the next 24–48 hr for significant injuries.
- Ophthalmic lubricant to reduce the risk of symblepharon
- Topical ophthalmic antibiotic ointment or drops as noted in the Medication section.

**Patient Monitoring**

Outpatient monitoring of healing and assessing for secondary complications should be done by the primary care provider.

**PROGNOSIS**

- Most patients with conjunctival injury from trauma do well if injuries are isolated to the conjunctiva.
- Both thermal and UV light–associated injuries are relatively self-limited problems when compared to those burns from chemical exposures (3).

**COMPLICATIONS**

- Dry eyes
- Infection
- Glaucoma
- Conjunctival adhesions
- Scarring

**REFERENCES**

- Xiang H, Stallones L, Chen G, et al. Work-related eye injuries treated in hospital emergency departments in the US. *Am J Ind Med*. 2005;48(1):57–62.

**CODES****ICD9**

- 918.2 Superficial injury of conjunctiva
- 921.1 Contusion of eyelids and periorcular area
- 940.3 Acid chemical burn of cornea and conjunctival sac

**PEARLS AND PITFALLS**

- Alkali burns tend to be the most severe; however, hydrofluoric acid burns may also cause sight-threatening injury.
- Assessment and documentation of visual acuity and deficit are critical.
- Use a Morgan lens to achieve adequate irrigation for caustic or thermal burns.
- Pinhole refraction may be used in visual acuity testing in patients whose corrective lenses are unavailable at the time of the emergency department evaluation.

# CONJUNCTIVITIS

Audrey H. Le

Sandip A. Godambe

## BASICS

### DESCRIPTION

Conjunctivitis denotes inflammation of the conjunctiva, a membrane that overlies the outer globe, or bulbar surface, and reflects back to cover the inner eyelids, the palpebral surface.

### EPIDEMIOLOGY

#### Incidence

Conjunctivitis occurs in 1.6–12% of newborns.

#### Prevalence

- Bacterial conjunctivitis is more prevalent during the winter season, while viruses predominate during the fall.
- Bacterial conjunctivitis is more common in children <6 yr of age, whereas adenovirus accounts for more infections in those >6 yr.

### GENERAL PREVENTION

- Frequent hand washing
- Wearing gloves for health care workers

### PATHOPHYSIOLOGY

- The conjunctiva, as the outer covering of the globe, is subject to environmental irritants and infectious agents, which trigger an inflammatory response, causing redness and edema.
- Allergic conjunctivitis is an IgE-mediated reaction in which exposure to environmental allergens triggers an allergic cascade, including mast cells and histamine release.

### ETIOLOGY

- The most common etiologies for acute conjunctivitis are allergic, bacterial, and viral.
- Bacterial conjunctivitis is most commonly caused by *Streptococcus pneumoniae*, *Staphylococcus aureus*, *Haemophilus influenzae*, and *Pseudomonas aeruginosa*.
- A number of different organisms have been implicated in viral conjunctivitis, among them adenovirus and herpesvirus.

## DIAGNOSIS

### HISTORY

- Common symptoms seen include itching, burning, “red eye” (redness), foreign body sensation, discharge, or sticky eyelids.
- Patients with allergic conjunctivitis will almost invariably present with itching with or without associated rhinorrhea or watery eyes. The predominant symptom in allergic conjunctivitis is itching. Watery eyes are also common. A personal or family history of atopy or the absence of sick contacts in patients with symptoms suggests allergic conjunctivitis.
- Bacterial and viral conjunctivitis generally starts abruptly in 1 eye and spreads to the contralateral side within 2 days.

- Bacterial conjunctivitis is suggested by a history of sticky eyelashes or eyelids in the morning and the presence of purulent eye discharge or crusting of the eyelashes or eyelid on exam.
- In neonates, *Neisseria gonorrhoeae* infection acquired by vertical transmission typically presents between 2 and 5 days of age, and *Chlamydia trachomatis* between 5 and 14 days of age. Other pathogens acquired perinatally or postnatally may present at 5–7 days. In contrast, chemical conjunctivitis may be seen 1–2 days after birth as a result of perinatal ocular prophylaxis, particularly with silver nitrate.
- Outside the neonatal period, *N. gonorrhoeae* and *C. trachomatis* infections occur mostly in young, sexually active individuals, spread from the genital area to the eye via hand contact.
- Viral conjunctivitis is usually hailed by irritation beginning in 1 eye and spreading to the other within a few days via hand-eye contact. Some patients may have concurrent upper respiratory tract symptoms.
- Viral conjunctivitis has symptoms that overlap both allergic and bacterial conjunctivitis, although itching is not as prevalent as in allergic conjunctivitis, and mucoid production is less common than in bacterial conjunctivitis.
- Pharyngoconjunctival fever caused by some adenovirus species presents abruptly with fever, pharyngitis, and bilateral conjunctivitis.
- Herpes simplex virus (HSV) conjunctivitis is usually unilateral, painful, and associated with a foreign body sensation.

### PHYSICAL EXAM

- Symptoms of allergic conjunctivitis are expectedly mild, and chemosis may be more impressive than redness.
- Bacterial infections will cause bulbar conjunctival injection that may be more pronounced at the fornices. A mucopurulent discharge is usually seen:
  - *N. gonorrhoeae* causes hyperacute conjunctivitis: Marked conjunctival injection, chemosis, lid swelling, globe tenderness, and profuse purulent discharge.
  - Pseudomembranes are associated with chlamydial infection, but this is not specific.
- Viral conjunctivitis may include injection, nonpurulent watery discharge, follicular reaction of the palpebral conjunctiva, and preauricular lymphadenopathy:
  - Epidemic keratoconjunctivitis caused by adenovirus species presents with conjunctival edema, petechial hemorrhages, a pseudomembrane, and corneal subepithelial infiltrates causing decreased visual acuity.
  - HSV conjunctivitis may have associated corneal ulceration or vesicular lesions on an erythematous base involving the eyelid and surrounding skin.

## DIAGNOSTIC TESTS & INTERPRETATION

### Lab

#### Initial Lab Tests

- Except in neonatal infections, lab tests are limited to those cases that are particularly severe or refractory to treatment.
- Neonates should have cultures:
  - Consider full sepsis workup with gonococcal infections.
  - Chlamydia infection mandates evaluation for pulmonary infection.

#### Diagnostic Procedures/Other

In herpetic infections, fluorescein staining of the eye and exam with a cobalt blue light may reveal the classic dendritic pattern.

#### Pathological Findings

- Staining scrapings of the conjunctival surface with Hansel or Giemsa stains reveals eosinophils in 20–80% of patients with allergic conjunctivitis.
- Chlamydial infections may be diagnosed via Giemsa stain, direct fluorescent antibody, ELISA testing, or PCR. Culture is the preferred method.

## DIFFERENTIAL DIAGNOSIS

- Nasolacrimal duct obstruction
- Glaucoma
- Intraocular tumors
- Subconjunctival hemorrhage
- Episcleritis
- Scleritis
- Uveitis
- Periorbital cellulitis
- Orbital cellulitis
- Eye irritation

## TREATMENT

Patients with contact lenses should be advised to stop wearing them until symptoms have resolved.

### MEDICATION

- Allergic conjunctivitis may be treated with comfort measures including cool compresses, artificial tears, and avoidance of triggers. Topical medications may provide relief (1):
  - First line: Naphcon-A, Occuhist (naphazoline hydrochloride/pheniramine maleate) 1–2 gtt q.i.d.: Over-the-counter combination decongestant and antihistamine for children >6 yr
  - Second line:
    - Azelastine 0.05% (Optivar) 1 gtt b.i.d.: H1 receptor antagonist for children ≥3 yr
    - Lodoxamide tromethamine 0.1% (Alomide) 1–2 gtt q.i.d.: Mast cell stabilizer

- Simple bacterial conjunctivitis can be treated with topical antibiotics (2):
  - First line:
    - Trimethoprim/Polymixin B (Polytrim) 1–2 gtt q.i.d. for 1 wk: Broad spectrum, inexpensive, minimal side effects
    - Aminoglycosides (gentamicin, tobramycin, erythromycin) 0.5-inch ribbon q.i.d. for 1 wk. The 1st 2 have good gram-negative coverage but are ineffective for *Chlamydia*. Erythromycin has good activity against *Chlamydia* but poor activity against gram-negative organisms and *Staphylococcus* species.
    - Sodium sulfacetamide 10% (Bleph-10) 1–3 gtt q2–3h while awake for 1 wk: Good coverage of gram-positive organisms but may cause significant local irritation
  - Second line:
    - Fluoroquinolones (ciprofloxacin 0.3%, ofloxacin) 1–2 gtt q.i.d. for 1 wk: Broad spectrum but more expensive
    - 4th-generation fluoroquinolones (gatifloxacin 0.3% 1–2 gtt q2h (max 8 times per day) while awake for 2 days, then q.i.d. for 5 days; moxifloxacin 0.5% 1 gtt t.i.d. for 1 wk): Broad spectrum with increased efficacy against gram-positive organisms; expensive
- Conjunctivitis-otitis syndrome is most often attributable to nontypeable *H. influenzae*, and may be treated with antibiotics alone (3):
  - Amoxicillin/Clavulanate: High dose (dosed as amoxicillin) 80–90 mg/kg/day PO divided b.i.d. or t.i.d.
  - Cefdinir 14 mg/kg/day given once daily or divided b.i.d., max 600 mg/day
  - Cefpodixime 10 mg/kg/day divided b.i.d., max 800 mg/day
- Gonococcal conjunctivitis is treated with a single dose of parenteral ceftriaxone (25–50 mg/kg, max 125 mg) and saline eye lavage (4).
- Chlamydial infection can be treated with:
  - Erythromycin ophthalmic ointment and oral erythromycin 50 mg/kg/day divided q.i.d. for 14 days in neonates:
    - A 2nd course is occasionally required.
  - Adolescents and adults may be treated with topical antibiotics for conjunctivitis, along with systemic antibiotics (eg, azithromycin 1 g PO, erythromycin base 500 mg q.i.d. for 7 days, or doxycycline 100 mg b.i.d. for 7 days) for genital disease (4).
- Most cases of viral conjunctivitis can be treated with supportive care including cold compresses and artificial tears.
- Treatment of HSV includes cool compresses and topical antiviral medications (eg, trifluridine 1% drops, vidarabine ointment). Severe cases may require oral antiviral medications and/or topical cycloplegic medications (5), given in cooperation with an ophthalmologist.

**DISPOSITION**

**Admission Criteria**

- Consider sepsis evaluation and/or hospitalization of neonates with gonococcal, chlamydial, or HSV infections.
- Consider admission for any patient with gonococcal conjunctivitis.

**Discharge Criteria**

- Simple bacterial infections in immunocompetent children may be managed on an outpatient basis with appropriate treatment.
- Close follow-up with an ophthalmologist for HSV infection

**Issues for Referral**

- Epidemic keratoconjunctivitis requires follow-up within 7 days with an ophthalmologist since keratitis is a potential complication.
- Patients with viral infections who do not show improvement within 7–10 days should be referred to an ophthalmologist.

**FOLLOW-UP**

**FOLLOW-UP RECOMMENDATIONS**

Discharge instructions:

- Allergic conjunctivitis should have follow-up within weeks depending on the response to treatment.
- Simple bacterial conjunctivitis should follow up within 3–4 days if symptoms do not improve.
- Patients with HSV, chlamydia, or gonococcal infection should follow up within 2 days.
- Hand washing and other hygiene is critical to prevent spread of infection.

**PROGNOSIS**

Most cases of conjunctivitis resolve without complications.

**COMPLICATIONS**

- Corneal ulcers
- Scarring
- Keratitis

**CODES**

**ICD9**

- 077.3 Other adenoviral conjunctivitis
- 372.14 Other chronic allergic conjunctivitis
- 372.30 Conjunctivitis, unspecified

**PEARLS AND PITFALLS**

- Treating HSV conjunctivitis with steroids can cause uncontrolled viral proliferation and increase the risk of secondary infection.
- Patients with allergic conjunctivitis treated with topical steroids require close supervision, and treatment should be limited to 2 wk to decrease the risk for complications.
- Gonococcal and chlamydial infections should be considered in every neonate presenting with eye discharge.
- Patients should discontinue use of contact lenses while being treated for any conjunctivitis.

# CONJUNCTIVITIS, NEONATAL

Emily Schapiro

## BASICS

### DESCRIPTION

- Ophthalmia neonatorum (ON) is any inflammatory (infectious or noninfectious) process affecting the conjunctiva that occurs within the 1st month of life.
- This includes those causes that have potential for serious and permanent damage to the eye and for systemic complications.

### EPIDEMIOLOGY

#### Incidence

- In the U.S. and Europe, the incidence of ON has fallen dramatically due to screening pregnant women for STIs and instilling antibiotics into infants' eyes shortly after birth (1).
- In the U.S., chlamydia ON occurs in 8.2/1,000 births, while gonococcal ON has an incidence of 0.3/1,000 live births (2).
- However, ON remains a more significant problem in developing countries where prenatal health care, STI screening, and newborn prophylaxis are less commonly available.

### RISK FACTORS

- Infectious ON is most commonly acquired as the infant is exposed to organisms in an infected mother during passage through the birth canal.
- Premature or prolonged rupture of membranes and prolonged labor increase the chance of transmission; postdelivery exposures to microorganisms may also occur.

### GENERAL PREVENTION

Prenatal screening and treatment for maternal STIs and prophylaxis by administering antibiotic agents dramatically decrease the incidence of ON.

### PATHOPHYSIOLOGY

- Gonococcal infection has the propensity to spread and become vision threatening:
  - Corneal involvement may occur with progression to perforation, leading to blindness.
  - There is also potential for development of systemic disease, including meningitis and sepsis.
- Untreated chlamydial infection may lead to eyelid scarring and pannus formation and may result in blindness, though it is generally less invasive than gonococcal disease.

### ETIOLOGY

- ON may arise from both infectious and noninfectious causes.
- The most common etiology of noninfectious ON is chemical irritation from 1% silver nitrate solution instilled in the eyes at birth to prevent infectious causes (3).

- The substitution of erythromycin or tetracycline ointment in place of silver nitrate has resulted in a decreased incidence of chemical conjunctivitis (3).
- Dacryostenosis may also present with conjunctivitis:
  - Stenosis may lead to dacryocystitis, a bacterial infection of the nasolacrimal duct.
- STIs such as *Chlamydia trachomatis*, *Neisseria gonorrhoeae*, and herpesvirus are the most common organisms causing infectious ON.
- Skin flora such as *Staphylococcus* or *Pseudomonas* species may also cause ON.

### COMMONLY ASSOCIATED CONDITIONS

Chlamydial ON may be associated with chlamydia pneumoniae.

## DIAGNOSIS

### HISTORY

- A history of STIs in the mother should raise the concern for infectious ON.
- Inquire about fever.
- Inquire about excessive tearing.
- The time from birth to symptom onset can be helpful in diagnosis, though presumptive treatment should not be based on this alone:
  - Chemical conjunctivitis from silver nitrate usually presents within the 1st day after instillation of the solution and spontaneously remits within 24–48 hr.
  - Gonococcal infection usually becomes symptomatic within 3–5 days after birth but can present later.
  - The incubation period for chlamydia is 5–14 days, so this infection tends to become symptomatic later with milder symptoms than gonorrheal disease.
- A history of marked lid swelling, chemosis, and copious amounts of purulent discharge is indicative of gonococcal disease.

### PHYSICAL EXAM

- Conjunctival injection
- Gonorrheal disease presents with marked eyelid swelling, chemosis, and copious amounts of purulent eye discharge. Corneal involvement may occur.
- Chlamydial disease usually presents with mild discharge, but chemosis and pseudomembrane formation may occur. Untreated infection may lead to eyelid scarring and pannus formation.
- Herpetic conjunctivitis usually presents as part of a more generalized infection. There may be vesicles surrounding the eye and corneal epithelial involvement. More seriously, life-threatening CNS infection may present in a septic-appearing infant.

## DIAGNOSTIC TESTS & INTERPRETATION

### Lab

#### Initial Lab Tests

- Diagnosis is made by sending a swab or scraping from the conjunctiva for Gram stain and bacterial and viral culture.
- The presence of gram-negative, intracellular diplococci is highly indicative of gonococcal infection.
- *Chlamydia trachomatis* may be diagnosed using a direct immunofluorescence test or polymerase chain reaction analysis. Also, Giemsa staining of epithelial cells scraped from the tarsal conjunctivae may show typical intracytoplasmic inclusions.
- In the ill-appearing or septic infant or one with a clinical picture suggestive of gonococcal disease, clinicians should order a CBC, blood culture, and CSF for analysis and culture.

#### Imaging

- Imaging is not necessary in uncomplicated ON and should be performed only as indicated for a given clinical situation.
- A CXR should be performed if chlamydial disease is suspected and the infant presents with cough.
- A CT of the head may be indicated in a septic-appearing child in whom herpetic disease is suspected.

#### Diagnostic Procedures/Other

- Gram stain and culture
- Lumbar puncture as indicated by the clinical picture

### DIFFERENTIAL DIAGNOSIS

- Noninfectious causes for ON including chemical irritation
- Dacryostenosis
- Dacryocystitis
- Infectious ON including gonococcal, chlamydial, and herpes viruses
- Other bacterial causes including *Staphylococcus* or *Pseudomonas* species

## TREATMENT

### INITIAL STABILIZATION/THERAPY

- Fluid stabilization in a septic-appearing infant as indicated
- ON is an ocular emergency requiring systemic treatment.

### MEDICATION

- Treatment of suspected gonococcal ON should not be delayed pending culture results.
- In cases where neither disease can be conclusively excluded on clinical grounds, the World Health Organization (WHO) guidelines call for treating infants with ON for both gonococcal and chlamydial infection since the coinfection rates are estimated to be ~2% (4).
- Treatment of chlamydial ON is oral erythromycin 50 mg/kg/day in 4 divided doses for 14 days. Topical erythromycin or tetracycline can be used as adjunctive therapy (4).
- In areas with endemic penicillinase-producing strains of gonorrhea, a 3rd-generation cephalosporin should be used. The WHO recommends a single dose of ceftriaxone 50 mg/kg IM/IV (max 125 mg) (4,5).
- In areas where most gonococcal disease is penicillin sensitive, treatment can consist of penicillin G, 100,000 U/kg/day IV for 7 days.
- The infant's eyes should be frequently irrigated with normal saline to clear discharge.
- Herpetic ON should be treated with systemic acyclovir 30 mg/kg/day PO in divided doses for at least 2 wk.

### DISPOSITION

#### Admission Criteria

- All infants with suspected gonococcal ON should receive a full evaluation for sepsis and be admitted for systemic treatment. Included would be those with any of the following features:
  - In the 1st week of life
  - Febrile
  - Mucopurulent eye discharge
  - Gram stain revealing gram-negative, intracellular diplococci
  - Maternal history of gonorrhea
- Critical care admission criteria:
  - Infants with signs of sepsis may require admission to a critical care unit.
  - Infants with severe *chlamydia* pneumonia may require management in a critical care unit.

### Discharge Criteria

A subset of newborns with conjunctivitis may be considered for outpatient therapy:

- This would include any newborns not meeting admission criteria above.
- These infants should be started on presumptive therapy for chlamydial infection, which may often be safely managed on an outpatient basis.

### Issues for Referral

- Referral to a neonatologist may be appropriate in most cases.
- Patients with *chlamydia* pneumonia should be referred to a neonatologist or pulmonologist with experience in managing this disease.

## FOLLOW-UP

### FOLLOW-UP RECOMMENDATIONS

#### COMPLICATIONS

- Corneal ulcer
- Glaucoma
- Blindness
- Meningitis
- Pneumonia
- Arthritis
- Osteomyelitis
- Bacteremia
- Sepsis

#### PROGNOSIS

- ON typically responds well to antibiotic therapy and usually resolves without sequelae.
- Pneumonia associated with *chlamydia* typically responds more slowly to antibiotic therapy than other bacterial pneumonias, whether IV or PO antibiotics are used.

## CODES

### ICD9

- 098.40 Gonococcal conjunctivitis (neonatorum)
- 771.6 Neonatal conjunctivitis and dacryocystitis

## PEARLS AND PITFALLS

- Infants at risk for gonococcal ON include those in the 1st week of life, with fever or mucopurulent eye discharge, or a maternal history of gonorrhea.
- If gonococcal disease is suspected, do not delay treatment awaiting culture results.
- *Chlamydia* ON may result in pneumonia; therefore, systemic rather than topical therapy is indicated.
- Response to treatment for pneumonia associated with *chlamydia* ON often takes several days to a week to begin demonstrable improvement.

# CONSTIPATION

Besh Barcega

Mary Jane Piroutek

## BASICS

### DESCRIPTION

- Constipation can be broadly defined as infrequent bowel movements with at least one of the following: Painful defecation, hard stools, purposeful fecal retention, fecal soiling, or encopresis.
- The normal frequency of stools varies with age and diet (1):
  - Newborns may pass stool with every feed, but the frequency varies with an average of 4 stools/day during the 1st wk of life.
  - 1.7 stools/day by age 2 yr
  - 1.2 stools/day by age 4 yr, which remains unchanged throughout adulthood
- Functional constipation is constipation without any evidence of an organic cause:
  - It is also known as idiopathic constipation, fecal withholding, nonorganic constipation, and functional fecal retention.
- Fecal impaction is characterized as a palpable hard mass in the lower abdomen, a dilated rectum filled with stool, or excessive stool in the colon seen on an abdominal radiograph.
- Constipation accounts for ~3% or all general pediatric outpatient visits and 25% of all pediatric gastroenterology referrals.

### EPIDEMIOLOGY

#### Incidence

- Peak incidence is between 2 and 4 yr of age.
- This is coincident with the typical age of toilet training.

#### Prevalence

- ~3% in the 1st yr of life (2)
- ~10% in the 2nd yr of life (2)
- Most studies report similar prevalence rates in boys and girls.

### RISK FACTORS

- Patients with anorectal anomalies such as imperforate anus and patients with neuromuscular diseases such as spina bifida tend to have constipation despite corrective surgery.
- Patients with metabolic abnormalities and patients taking medications, such as narcotics, tend to have constipation.

### GENERAL PREVENTION

Anticipatory guidance regarding diet, toilet training, and toileting behaviors may prevent or ameliorate functional constipation.

### PATHOPHYSIOLOGY

- Withholding stool leads to incomplete rectal emptying and stool impaction. Impacted stool becomes firm and dry as fluid reabsorption continues in the colon.
- Retained stool in the rectum causes distention and dilation of the rectum. This results in a higher threshold of stimulation to signal the need for defecation and also leads to weakening of the sphincter muscle, which further impedes stool evacuation and leads to soiling and encopresis.
- When the child does finally defecate, painful large, hard stool is passed, reinforcing further withholding behavior.

### ETIOLOGY

- The majority of children with constipation beyond the neonatal period have functional constipation:
  - Most commonly an acquired behavior, resulting from the child purposefully withholding stool in order to prevent further painful defecation
  - Common triggers include changes in routine or diet, toilet training, starting school, stressful events, and postponing defecation because the child is too busy or does not want to use a public toilet.
- Delayed passage of meconium or constipation in a newborn is organic in nature until proven otherwise:
  - Organic constipation: Varies due to underlying cause

### COMMONLY ASSOCIATED CONDITIONS

See the Differential Diagnosis below of organic causes of constipation.

## DIAGNOSIS

### HISTORY

- The child typically presents with a chief complaint of hard pelletlike stools, difficulty or pain with defecating, abdominal pain, abdominal distention, vomiting, or anorexia.
- Parents often describe previous similar episodes of central abdominal pain that improve with a large bowel movement.
- Parents often know when the child is resisting the urge to defecate, describing behavior such as squatting, standing on toes, or squeezing buttocks.
- Inquire about the child's:
  - Previous stooling pattern
  - Current pattern, consistency, and caliber of stools
  - Presence of blood on stools
  - Associated abdominal pain, vomiting, change in appetite, and weight loss
  - Recent dietary or social changes
- Delayed passage of meconium, constipation since birth, significant abdominal distention, bloody stools (unless an anal fissure is present), abnormal development, weight loss, and failure to thrive are red flags for an underlying organic cause.
- In the neonate or young infant, include questions about strength of suckle, feeding, and muscle tone.

### PHYSICAL EXAM

- Look for abdominal distention; palpate for abdominal masses and tenderness
- Assess the location of the anus, and examine the sacral area to look for anatomic malformations.
- Look for the presence of anal fissures if there is a history of bloody stools.
- Check for the presence of an anal wink and cremasteric reflexes. Also check extremity tone, strength, and deep tendon reflexes. Absence or diminished presence of these are suggestive of a neuromuscular abnormality.
- At least 1 digital anorectal exam is recommended (1):
  - If a rectal exam is done, an empty rectum on physical exam is concerning for an organic cause.
  - In the neonate, focus on suckle, bulbar findings, and muscle tone.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

- No other specific lab tests are recommended unless particular organic causes are suspected:
  - Thyroid-stimulating hormone and free T4 if concerned about hypothyroidism
  - Stool for botulinum toxin if concerned for botulism
- Stool for occult blood may be useful if history and exam are suggestive for an organic etiology such as failure to thrive (1).

#### Imaging

- Routine abdominal radiographs are not recommended for initial evaluation but may be useful to determine the extent of fecal impaction (1).
- Abdominal radiographs should be obtained if a sacral dimple is found on exam to look for spinal abnormalities.

### DIFFERENTIAL DIAGNOSIS

- Infant dyschezia: Immature coordination of contraction of abdominal musculature and relaxation of the pelvic floor muscles during defecation:
  - Typically presents with infant crying, grunting, and straining prior to having a soft normal bowel movement. Infants should have a stooling pattern within the limits of normal.
  - Reassure parents that symptoms will resolve with time as the infant's neuromuscular system becomes more developed.
- Functional causes of constipation: Dietary transitions, toilet training, acquired behavior secondary to painful defecation, fecal retention/withholding behavior, or sexual abuse
- Organic causes of constipation:
  - Anatomic: Anal fissures, strictures, or stenosis; imperforate or anteriorly displaced anus; abdominal or pelvic mass; rectal polyps, abscess, or foreign body
  - Endocrine/Metabolic: Meconium ileus, cystic fibrosis, hypothyroidism, dehydration, or cow's milk protein intolerance
  - Neuromuscular: Spina bifida, cerebral palsy, Hirschsprung disease, infantile botulism, or spinal cord lesion
  - Drugs: Antacids, anticholinergics, opiates, antidepressants, antiepileptics, antihypertensives, iron, or lead poisoning

## TREATMENT

- Treatment typically involves acute disimpaction and then maintenance therapy in order to keep the rectum empty and allow the rectum to return to its normal size:
  - Maintenance therapy is often needed for several months.
- Parental education, behavior modification, and close follow-up are essential to prevent recurrence.
- If an organic cause is found, treatment involves addressing the underlying problem.

**MEDICATION**

Disimpaction by either the oral or rectal route is effective:

- Oral route is preferred but may be limited by compliance issues.
- Rectal route yields results more quickly but is invasive.

**First Line**

Polyethylene glycol (PEG) 3350:

- Disimpaction: 1–1.5 g/kg/day for 3 days
- Maintenance: 1 g/kg/day

**Second Line**

- Osmotic agents:

- Lactulose or sorbitol 70% solution:
  - 1–3 mL/kg/day in divided doses
  - May cause abdominal cramping and flatulence
- Magnesium hydroxide 400 mg/5 mL liquid:
  - 1–3 mL/kg/day
  - Potential for acute magnesium toxicity
- Magnesium citrate:
  - <6 yr old: 1–3 mL/kg/day; 6–12 yr old: 100–150 mL/day; >12 yr old: 150–300 mL/day in single or divided doses
  - Potential for acute magnesium toxicity
- Phosphate enema:
  - Disimpaction:  $\geq 2$  yr old: 6 mL/kg up to 135 mL
  - Use with caution in children with kidney problems because of cases of lethal hyperphosphatemia and hypocalcemia.

- Lubricant:

- Mineral oil:
  - Disimpaction: 15–30 mL per year of age orally to max of 240 mL/day
  - Maintenance: 1–3 mL/kg/day
  - Not recommended <1 yr old; causes lipid pneumonia if aspirated

- Stimulants: Use for acute disimpaction for 3–5 days:

- Senna (8.8 mg sennosides/5 mL):
  - 2–6 yr old: 2.5–7.5 mL/day; 6–12 yr old: 5–15 mL/day
  - May cause abdominal pain. Side effects include idiosyncratic hepatitis, melanosis coli, hypertrophic osteoarthropathy, and analgesic nephropathy.

- Bisacodyl:

- $\geq 2$  yr old: 1–3 tablets (5-mg tablet) or 0.5–1 suppository (10-mg suppository) per dose
- Side effects include abdominal pain, diarrhea, hypokalemia, and proctitis.

- Glycerin suppository:

- Rarely of value in children >6 mo old

- PEG-electrolyte solution:

- Disimpaction: 25 mL/kg/hr (up to 1 L/hr) by NG tube until effluent is clear or 20 mL/kg/hr for 4 hr/day
- Maintenance: 5–10 mL/kg/day
- Usually requires hospital admission

**DISPOSITION****Admission Criteria**

- Children with abdominal pain and colons full of stool requiring whole bowel irrigation
- Failed disimpaction
- Concern for an undiagnosed organic cause of constipation necessitating further workup

**Discharge Criteria**

- Sufficient amount of stool evacuated
- Child able to tolerate food orally

**Issues for Referral**

Referral to pediatric gastroenterology when management is complex, therapy fails, or there is concern for an undiagnosed organic disease.

**COMPLEMENTARY & ALTERNATIVE THERAPIES**

- For infants, dietary changes:
  - Up to 4 ounces of sorbitol-containing juice (pear, prune, white grape, or apple) daily. May dilute 1:1 with water.
- Behavior modification
- Biofeedback therapy

**FOLLOW-UP****FOLLOW-UP RECOMMENDATIONS**

- Follow up with pediatrician in 2–3 days.
- Discharge instructions and medications:
  - For children eating table food, increase water and fiber content of diet. Bran, psyllium, or methylcellulose supplementation may help.
  - Encourage scheduled time to sit on the toilet for 10 min after each meal.
  - Return promptly to medical care for vomiting, fever, severe abdominal pain, anorexia, or any other concerns.

**PROGNOSIS**

- Months of treatment are usually required.
- Roughly 50% recurrence rate:
  - 1 yr recovery rate ~30–60% regardless of laxative chosen (4)

**COMPLICATIONS**

Chronic abdominal pain, rectal fissures, enuresis, encopresis, urinary tract infection, rectal prolapse, and social stigmata

**CODES**

- ICD9
- 560.32 Fecal impaction
- 564.00 Constipation, unspecified
- 564.09 Other constipation

**PEARLS AND PITFALLS**

- Constipation should be a diagnosis of exclusion in patients with acute abdominal pain.
- A “normal” stooling history per the patient should not be taken at face value, and appropriate historical questions may reveal abnormal stooling patterns that the patient has accepted as normal.

# CONSTRICTING BAND/TOURNIQUET SYNDROME

Carl K. Hsu  
Bradley Pecker

## BASICS

### DESCRIPTION

- Primary constricting band: A band of any type of material such as metal, fabric, or hair tightened around an appendage that causes swelling and pain (eg, a hair knotted around a toddler's toe).
- Secondary constricting band: Injury or disease process that causes the swelling and edema resulting in tightness against the band (eg, an impacted ring with an underlying fracture of the finger)
- If left untreated, the constricting band may become embedded and interrupt skin integrity and circulation to the affected appendage.

### RISK FACTORS

- Poor hygiene
- Long hair
- Child abuse

### GENERAL PREVENTION

- Good hygiene
- Short hair
- Avoidance of tight-fitting rings or small objects that can be potentially be slipped onto an appendage

### PATHOPHYSIOLOGY

- Primary constricting band: Constricting band or ring impedes return of lymphatic and venous fluid, resulting in edema
- Secondary constricting band: Underlying injury, typically traumatic but sometimes infectious, causes swelling and edema

### ETIOLOGY

Tourniquet syndrome may result from underlying allergic, dermatologic, iatrogenic, endocrinologic, infectious, malignant, metabolic, physiologic, or traumatic conditions or be related to pregnancy.

### COMMONLY ASSOCIATED CONDITIONS

- Trauma
- Any process causing edema and swelling

## DIAGNOSIS

### HISTORY

- A crying, inconsolable infant without obvious cause
- Pain and swelling, most commonly a finger or toe, with or without visualization of a constricting band (eg, a knotted hair that may be buried within the edema)
- Other locations: Wrist, ankle, toe, umbilicus, ear lobe, nipple, septum or nares of nose, uvula, penis, scrotum, vaginal labia, or tongue
- In older children and adolescents, inquire about duration of constriction, any associated trauma, and attempts at removal prior to the emergency department visit.
- For rings, inquire as to the type of metal, since new styles of rings made of ultrahard metals such as titanium or tungsten or ceramic cannot be removed using standard ring cutters and must be removed by cracking.

### PHYSICAL EXAM

Perform a thorough visual and neuromuscular exam of the swollen affected appendage, with high suspicion of a hair tourniquet if no constricting band is seen.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

Usually not indicated for acute treatment:

- Occasionally, CBC and C-reactive protein may be used to differentiate between edema and cellulitis of an involved digit or appendage.

#### Imaging

X-ray may be needed to assess for underlying fracture or foreign body after band removal.

#### Diagnostic Procedures/Other

Measurement of electrolytes, BUN and creatinine, thyroid function tests, and Tzanck smear of vesicular lesions may be useful in the diagnosis of secondary constricting band.

#### Pathological Findings

Pain, swelling, edema, cyanosis, prolonged capillary refill, neuropathia, or necrosis

### DIFFERENTIAL DIAGNOSIS

- Primary vs. secondary constricting band
- Cellulitis
- Tenosynovitis

## TREATMENT

### PRE HOSPITAL

Remove rings and other potential constricting bands, if possible, before the development of tourniquet syndrome.

### INITIAL STABILIZATION/THERAPY

- Pain management and conscious sedation may be necessary.
- Removal of ring or constricting band

### MEDICATION

- Local anesthetic:
  - Nerve blockade with local anesthetic is preferred.
  - Lidocaine 1% or 2%, max 5 mg/kg (without epinephrine)
- Opioids:
  - Removal of ring or constricting band usually results in significant immediate reduction in pain, and systemic analgesics are typically unnecessary.
  - Morphine 0.1 mg/kg IV/IM/SC q2h PRN:
    - Initial morphine dose of 0.1 mg/kg IV/IM may be repeated q15–20min until pain is controlled, then q2h PRN
  - Codeine/Acetaminophen dosed as 0.5–1 mg/kg of codeine component PO q4h PRN
- NSAIDs:
  - Consider NSAID medication in anticipation of prolonged pain and inflammation.
  - Ibuprofen 10 mg/kg/dose PO/IV q6h PRN
  - Ketorolac 0.5 mg/kg IV/IM q6h PRN
  - Naproxen 5 mg/kg PO q8h PRN
- Acetaminophen 15 mg/kg/dose PO/PR q4h PRN
- Administer tetanus prophylaxis if indicated.

### SURGERY/OTHER PROCEDURES

- The distal swollen finger, especially the proximal interphalangeal joint, presents an important obstacle in constricting band removal.
- Distal to proximal edema reduction by these sequential compression methods:
  - Self-adherent tape is wrapped distal to proximal to form a smooth and compressed area over which the band is advanced.
  - A Penrose surgical drain or a finger cut from a small glove is stretched to fit over the distal swelling before the attempted removal:
    - With lubrication, the proximal end of the drain is pulled under the ring to form a cuff around the ring; the cuff with distal traction applied advances the band over the decompressed area.
  - Suture material (no. 0 silk, dental floss, or umbilical tape) is wrapped under tension in a tight layer advancing over the edema in a distal to proximal direction; the proximal tail of the suture material (or floss) is tucked under the ring; with lubrication, the tail under tension is pulled distally and unwound, forcing the ring over the layered suture material and decompressed area.

- Constricting band removal by manual division:
  - Scissors may be used to lift and then cut the offending fibrous band constricting a toddler’s toe or penis.
  - A no. 11 scalpel blade with the cutting surface up may be sufficient to cut constricting bands formed by hair, fibers, or plastic ties.
  - A topical commercially available depilatory agent may be used to divide a tourniquet formed by a suspected hair obscured by local edema.
  - A handheld wire cutter/stripper may readily divide small-girth metallic rings with minimum discomfort:
    - This type of removal may impart a crush defect to the ring, making repair difficult.
  - A long-handled bolt cutter available in most operating rooms or in the hospital engineering department may be used to divide large-girth, broad-sized rings:
    - Longer handles provide significant mechanical advantage needed to cut large rings.
    - The reinforced cutting blades may not fit through a constricting band with adjacent swollen tissue and skin.
  - A standard hand-powered, medically approved ring cutter (Steinmann pin cutter with a MacDonald elevator) may be used to divide small-girth metallic constricting bands made of soft metals such as gold or silver:
    - This method has the advantage of a cleaner cut for subsequent repair of the ring.
    - The disadvantage is that the handheld ring cutter is labor intensive and may aggravate the pain of an underlying injury.
  - Constricting band removal by motorized cutting:
    - A motorized high revolution per minute (RPM) cutting device may be used to rapidly divide constricting bands irrespective of girth and size of the ring: It may be battery-powered, AC-powered, or pneumatically driven in the operating suite.
  - Motorized cutting procedure:
    - Protective eyewear should be worn by all persons present, including the patient.
    - Place a thin aluminum splint (shaped to the curvature of the ring) between the patient’s skin and the ring as a shield to protect underlying tissue from heat and debris.
    - Cool the splint and cutting surface with ice water irrigations before and during the cutting procedure.
    - The high-RPM cutting wheel is then used to cut through the band over the volar aspect of the finger.
    - Because of heat generation, limit cutting with the motorized device to 5-sec intervals with 60-sec intervals of ice water cooling.
    - A tenaculum may be used to spread the band made of softer metals after the 1st cut.
    - A 2nd cut may be made by rotating the ring 180 degrees and again cutting on the volar aspect.
    - This method may fail when used for ultrahard metal rings such as titanium.
    - Tungsten rings cannot be cut using a ring cutter.

- Cracking ring:
  - Rings made of ceramic or tungsten are removed by cracking them.
  - Tungsten is the hardest metal used in jewelry and cannot be cut but can be cracked due to poor malleability.
  - To do so, a vice or vice pliers is needed.
  - Tighten the vice pliers/grip onto the ring, remove and then tighten the vice by a turn of the tightening screw.
  - Clamp onto the ring, and repeat this process of slightly narrowing the width of the vice until when the vice is closed onto the ring, cracking occurs.
  - More than 1 crack may be required, and cracking in more than 1 location may be required.
  - Use this same technique for ceramic rings, taking care that no portion of the ring may fly out and strike the patient or staff.

**DISPOSITION**

**Admission Criteria**

- Loss of function, tissue ischemia or necrosis, or neurovascular compromise
- Suspected child abuse

**Discharge Criteria**

- Successful removal with restoration of circulation and function
- Decreased pain and edema

**Issues for Referral**

- Underlying fractures: Orthopedics, hand, or podiatry
- Ischemia of appendage: Hand surgery, urology

**COMPLEMENTARY & ALTERNATIVE THERAPIES**

- Treatment is directed at removal of the constricting band either by advancing the constricting band distally or by division.
- These adjuvant methods may be used alone or in combination:
  - Elevation of the affected extremity may help decrease vascular congestion.
  - Cooling the extremity with ice or cold water to reduce edema and erythema
  - Lubrication with soap or mineral oil to allow for slippage of tourniquet over an inflamed or edematous area

**FOLLOW-UP**

**FOLLOW-UP RECOMMENDATIONS**

- Discharge instructions and medications:
  - Wound check if skin disruption
  - Acetaminophen, ibuprofen, or opiates for pain
  - Appropriate medications for underlying medical causes
- Activity:
  - As tolerated

**Patient Monitoring**

- Social work referral
- Report for suspected child abuse

**PROGNOSIS**

- Varies with duration and degree of constriction and/or tourniquet syndrome
- Generally well tolerated if constricting band did not cause prolonged ischemia of the affected appendage

**COMPLICATIONS**

- Loss of function, neuroparaxia, or necrosis.
- Associated injury from attempts at removal

**ADDITIONAL READING**

- Hsu CK, Neblett M, Mansur M, et al. Hair tourniquet syndrome: Division by a topical depilatory agent. Unpublished data.

**See Also (Topic, Algorithm, Electronic Media Element)**

Tungsten and titanium ring removal instruction can be found at <http://www.titaniumstyle.com>

**CODES**

ICD9  
782.3 Edema

**PEARLS AND PITFALLS**

- Crying or inconsolable infants should be carefully evaluated for a hair tourniquet.
- Constricting bands or rings may result in tourniquet syndrome and permanent injury.
- Administration of local anesthesia or analgesic is appropriate.
- Rings made of titanium may take a long time to cut using a ring cutter, or a ring cutter may fail.
- Tungsten cannot be removed using a ring cutter and must be cracked using a vice.

# CONTACT DERMATITIS

Solomon Behar

## BASICS

### DESCRIPTION

- Contact dermatitis is an inflammatory condition of the skin leading to an eczematous rash.
- Two major types:
  - Irritant contact dermatitis (ICD), which accounts for 80% of cases
  - Allergic contact dermatitis (ACD)

### EPIDEMIOLOGY

#### Incidence

- Allergy sensitization rates:
  - 13–20% of all children (1,2)
  - 24.5% in children 6 mo to 5 yr of age (3)
  - More common in infants and younger children
- Prevalence increases with age due to cumulative exposure to allergens and sensitizations.

### RISK FACTORS

Previous exposure to antigen primes the immune system to react to re-exposures.

### GENERAL PREVENTION

Avoiding known allergens or irritating substances

### PATHOPHYSIOLOGY

- ICD: Nonimmunologic inflammatory reaction to any substance irritating the skin
- ACD: Type IV T-cell–mediated hypersensitivity reaction:
  - Allergen penetrates skin and activates Langerhans cell within skin, which presents the antigen to T cells (sensitization)
  - Upon re-exposure to allergen, memory T cells activate the allergic response.

### ETIOLOGY

- ICD: Saliva, feces, urine, foods, detergents, soaps, wipes, bubble baths, nickel, cobalt
- ACD: Certain plants (poison ivy, sumac, oak); nickel; thimerosal; and a wide variety of synthetic chemicals in rubber, metals, dyes, and preservatives

### COMMONLY ASSOCIATED CONDITIONS

Atopic dermatitis (associated with ACD)

## DIAGNOSIS

### HISTORY

- Ask about the following exposures:
  - Hygiene products
  - Clothing/Diapers
  - Footwear
  - Jewelry
  - Cosmetics
  - Fragrances
  - Deodorants
  - Medicines (systemic and topical)
  - Nonprescription medicinal supplements
  - Home remedies
- Past medical history
- Elicit history of known allergies
- Ask about:
  - Sporting and other extracurricular activities
  - Hobbies
  - Timing and distribution of rash
  - Pain and/or itching
  - Prior history of allergic reactions
  - Lip licking
  - Prior history of rashes
  - Respiratory symptoms

### PHYSICAL EXAM

- ICD: Large red patches in discrete patterns matching distribution of causative agent exposure
- ACD: Red, edematous areas usually in the same distribution as ICD but can have vesicles and papules present
- Generalized rash may occur in ACD (called *id* reaction)
- Special conditions:
  - Lip-licker's dermatitis: Perioral ICD after excessive licking around lips
  - Rhus dermatitis: ACD appearing as a vesicobullous eruption after exposure to poison ivy, sumac, or oak
  - Shoe dermatitis: ACD affecting dorsa of feet, sparing the skin between the toes
  - Juvenile plantar dermatosis: ICD usually affecting prepubertal children; dermatitis on plantar surface with painful fissuring

## DIAGNOSTIC TESTS & INTERPRETATION

### Lab

Usually a clinical diagnosis

### Diagnostic Procedures/Other

Refractory cases of ACD or those involving the face/hands should have patch testing against various allergens by a dermatologist or allergist.

### DIFFERENTIAL DIAGNOSIS

- Atopic dermatitis
- Acrodermatitis enteropathica
- Cutaneous mycosis
- Impetigo
- Scabies
- Photodermatitis
- Psoriasis
- Herpes simplex virus infection
- Chemical burn
- Nummular eczema
- Seborrheic dermatitis

## TREATMENT

### INITIAL STABILIZATION/THERAPY

Allergen avoidance is the single most important treatment in ICD/ACD. All other therapies are adjuvant and not for chronic use.

### MEDICATION

#### First Line

- Topical moisturizers (petroleum jellies, lotions)
- Barrier creams (in diaper ICD), such as zinc oxide, applied each diaper change to affected area
- Topical steroids:
  - Low potency: Hydrocortisone 1% cream applied to affected areas b.i.d. until improved
  - Moderate potency: Mometasone 1% cream or ointment applied to affected area per day until improved. Do not use >7 days on the face.
- Antihistamines:
  - Generally not necessary but may be used for severe pruritis
  - Diphenhydramine 1 mg/kg/dose PO q6h PRN for itching OR
  - Hydroxyzine 1 mg/kg/dose PO q6h PRN for itching (ACD has been described with this medicine in case reports, so use with caution.) OR
  - Loratadine: Age 2–5 yr, 5 mg PO per day >5 yr, 10 mg OR
  - Cetirizine: Age 6–12 mo, 2.5 mg PO per day 1–5 yr, 2.5–5 mg PO per day >6 yr, 5–10 mg PO per day

**Second Line**

- Topical calcineurin inhibitors: Tacrolimus 0.03% or pimecrolimus 1% applied to affected area b.i.d. PRN:
  - Should be short-term use
  - Only for children >2 yr of age
  - Avoid in immune-suppressed patients (4)
- Oral steroids for severe flares:
  - A 5-day burst of 1 mg/kg/day per day or divided b.i.d
  - In rhus dermatitis, a 14-day course (7 days at 1 mg/kg/day followed by 7-day taper) is sometimes used.

**DISPOSITION****Discharge Criteria**

Unless complicated by severe infection, all contact dermatitis patients may safely be discharged home.

**Issues for Referral**

Refer refractory cases to dermatology or allergy specialists.

**FOLLOW-UP****FOLLOW-UP RECOMMENDATIONS**

Discharge instructions and medications:

- Keep fingernails clean and short.
- Avoid known allergens/irritants.
- Follow up with primary care provider in 1–2 wk.

**DIET**

Exclude foods thought to be associated with outbreaks of dermatitis.

**PROGNOSIS**

Contact dermatitis is a chronic condition that has a good prognosis as long as avoidance of exacerbating substances is practiced.

**COMPLICATIONS**

Secondary skin infections from itching can occur.

**REFERENCES**

4. Fonacier L, Spergel J, Leung DYM, et al. Report of the Topical Calcineurin Inhibitor Task Force of the American College of Allergy, Asthma and Immunology and the American Academy of Allergy, Asthma and Immunology. *J Allergy Clin Immunol*. 2005;115:1249–1253.

**ADDITIONAL READING**

- Eczema. In Behrman RE, Kliegman RM, Jenson HB, eds. *Nelson Textbook of Pediatrics*. 16th ed. Philadelphia, PA: WB Saunders; 2000.
- Militello G, Jacob SE, Crawford GH. Allergic contact dermatitis in children. *Curr Opin Pediatr*. 2006;18(4):385–390.
- Nijhawan RI, Matiz C, Jacob SE. Contact dermatitis: From basics to allergodromes. *Pediatr Ann*. 2009;38(2):99–108.

**CODES****ICD9**

- 692.4 Contact dermatitis and other eczema due to other chemical products
- 692.5 Contact dermatitis and other eczema due to food in contact with skin
- 692.9 Contact dermatitis and other eczema, unspecified cause

**PEARLS AND PITFALLS**

- The location of the rash may give clues as to what the offending substance may be that is causing the rash (eg, rash on the lower abdomen under the jeans button leads one to consider a nickel contact allergic dermatitis).
- Palmar and plantar surfaces of the hands and feet are generally not affected by ACD.
- Ask about products used by parents and siblings. Children often will experiment with these substances on their own skin, leading to ICD/ACD.
- Nickel is the most common allergen in ACD. Topical neomycin is the second most common allergen.
- Make sure parents send instructions on allergen avoidance to daycare providers and teachers.

# CONVERSION DISORDER

Allison A. Keller

D. Richard Martini

Charles W. Pruitt

## BASICS

### DESCRIPTION

Conversion disorder is a type of somatoform disorder that typically affects voluntary motor or sensory functions. The symptom or deficit:

- Is not intentionally produced or feigned
- Cannot be fully explained by:
  - A general medical condition
  - The direct effects of a substance
  - A culturally sanctioned behavior
- Causes clinically significant distress or impairment in social or occupational functioning, or warrants medical evaluation
- Is not limited to pain symptoms
- Is not better accounted for by another cause
- Is a mental disorder (1)

### EPIDEMIOLOGY

#### Incidence

Annual incidence rate for all ages is 5–22/100,000 (2).

#### Prevalence

- Child psychiatrists report a prevalence of 1–3% of their patients (3).
- 1% of patients admitted for neurologic problems have conversion symptoms (2).

### RISK FACTORS

- More common in females than males across all age groups
- The onset of conversion disorder is from late childhood to early adulthood and is rare before age 10 yr or after age 35 yr.
- Children who have been exposed to violence or sexual abuse are more likely to experience conversion symptoms.
- High frequency of recent familial stress, family communication problems, unresolved grief reactions, and school-related and social disturbances (4)
- May have coexisting medical and neurologic disorders:
  - May be modeled after previous or current illness, or the illness of a family member

### PATHOPHYSIOLOGY

- Conversion reactions usually mimic lesions in the voluntary motor or sensory pathways.
- Some data implicate biologic and neuropsychological factors in the development of conversion symptoms:
  - Functional MRI studies have shown different activation patterns in patients with conversion symptoms vs. healthy control subjects.
  - These imaging findings are thought to be consistent with the “involuntary” nature of conversion symptoms (5).

### ETIOLOGY

- Psychodynamic theory:
  - An unconscious process by which psychosocial needs conflict or stresses are expressed as somatic symptoms
  - Conversion symptoms develop to defend against unacceptable impulses.
  - The conversion symptom binds anxiety and keeps a conflict internal.
- Learning theory:
  - Conversion symptom is seen as a classically conditioned learned behavior: Symptoms of illness are used as a means of coping with an otherwise perceived impossible situation.
  - Secondary gain may be an important factor:
    - Children with illness and disability become the focus for family attention.

### COMMONLY ASSOCIATED CONDITIONS

Occurs in the presence of other psychiatric illness including depression, anxiety, and personality disorders (6)

## DIAGNOSIS

- Conversion disorder is not a diagnosis of exclusion.
- The diagnosis should be made on the basis of negative organic findings and positive evidence of conversion reaction. See positive signs of conversion reactions in the Physical Exam section.

### HISTORY

- The physical impairment interferes with daily life.
- Symptoms often mimic those of a close friend or relative.
- A medical illness may have occurred prior to the development of the unexplained symptom.
- Psychological stressor within hours to weeks of symptom onset
- Symptoms may cause more distress to the parents than to the patient.
  - “La belle indifference” is lack of concern or indifference to physical disability that would cause great psychological distress to others with the same new-onset disability.
- Frequently reported symptoms:
  - Weakness or paralysis
  - Paresthesias
  - Gait disturbances
  - Pseudoseizures
  - Visual disturbance
- Conversion reaction vs. organic etiology:
  - Sleep or other vital functions often are not interrupted.
  - Occurs more during or preceding school hours
  - Occurs more around other people rather than in isolation
  - Brought on by emotional stresses rather than specific events or physical actions (7)

### PHYSICAL EXAM

- A detailed neurologic exam is necessary to evaluate for organic disease.
- Positive signs of conversion disorder in motor disturbances:
  - Movement during sleep
  - Movement after noxious stimuli
  - “Automatic” behaviors such as dressing oneself are preserved.
  - Avoidance of hurting oneself (when dropping the “paralyzed” arm over the child’s face)
  - Hoover test: If a patient in supine position is truly making an effort to lift a weak or paralyzed leg, the examiner will note pressure under the contralateral heel.
  - Giveaway weakness: A patient’s motor strength demonstrates resistance followed by a sudden loss of resistance (in contrast to true weakness, where the patient exerts constant resistance).
- Positive signs of conversion disorder in gait disturbances:
  - May walk normally when not being observed
  - May attempt to fall vs. attempt to support self
  - Atasia-abisia: Inability to stand despite normal ability to move legs when sitting
- Positive signs of conversion reaction with sensory deficits:
  - Sensory loss does not conform to dermatomal distribution.
  - Sharply demarcated boundaries that involve all localized sensory modalities (pain, temperature, light touch, proprioception, and vibration)
  - Reaction to sensation while asleep
  - Inconsistent findings on repeated sensory exams
- Pseudoseizure characteristics:
  - Thrashing about with trunk rather than tonic-clonic movement
  - Absence of incontinence, tongue biting, or postictal state
  - Resistance toward examiner opening eyelids during the event
  - Avoidance of noxious stimuli, such as sternal rub, or other painful stimuli
- Positive signs of conversion reaction with severe bilateral blindness:
  - Intact pupillary responses
  - Sudden flash of bright light results in patient flinching
  - Instruction to “Look at your hand” and the patient does not look there (Blindness does not affect looking in the appropriate direction.)
  - Instruction to “Touch your index fingers” and the patient is unable to perform (Blind people can do this via proprioception.)

**DIAGNOSTIC TESTS & INTERPRETATION****Lab**

- In all cases, consider the possibility of organic disease processes.
- Consider lab evaluation to exclude:
  - Electrolyte disturbances
  - Hypoglycemia
  - Renal dysfunction
  - Systemic infection
  - Toxicologic exposures/ingestions
- Consider CSF analysis to evaluate for infection.

**Imaging**

- CT scan or MRI may rule out lesions of the brain or spinal cord.
- EEG may help distinguish true seizures from pseudoseizures.

**DIFFERENTIAL DIAGNOSIS**

- Neurologic disorders:
  - Toxins, dystonic reaction, neuroleptic agents
  - Intracranial hemorrhage
  - Brain or spinal cord tumor or abscess
  - Encephalitis
  - Degenerative disease
  - Guillain-Barré syndrome
  - MS
  - Myasthenia gravis
  - Myopathy
  - Optic neuritis
  - Polymyositis
  - Vestibular neuronitis
  - Creutzfeldt-Jakob disease
- Psychologic disorders:
  - Factitious disorder or malingering
  - Munchausen syndrome or Munchausen by proxy
  - Hypochondriasis
  - Pain disorder or other somatoform disorder

**TREATMENT****PRE HOSPITAL**

Treat patients as if the symptoms are resulting from organic disease.

**INITIAL STABILIZATION/THERAPY**

- The emergency physician must initially evaluate the patient as if the symptoms are resulting from organic disease.
- However, consider both physiologic and psychosocial contributions to presenting symptoms (8).
- Emergency physicians should:
  - Accept that patients can have distressing physical symptoms without feigning symptoms.
  - Avoid telling patients that their symptoms are imaginary but empathize with the stress of their condition.
  - Avoid focusing on organic diagnosis or psychologic diagnosis alone but rather emphasize a concurrent physiopsychologic approach to evaluation (8).
- Suggestive therapy: Symptoms remit spontaneously with simple suggestion that “symptoms should resolve soon.”

**DISPOSITION****Admission Criteria**

Consider admission for patients when further evaluation is required to exclude organic etiology.

**Discharge Criteria**

- No evidence of acute medical or neurologic disorder requiring inpatient treatment
- Appropriate follow-up established

**Issues for Referral**

- Neurologic consultation may be helpful if the neurologic findings are equivocal:
  - May be necessary in the emergency department
  - If an emergency medical condition has been excluded, consider a neurology referral for further evaluation of a possible seizure disorder or for an equivocal neurologic exam.
- Psychiatric consultation may be helpful if an organic cause is largely excluded.
- Referrals may be made to behavioral pediatricians or child psychiatrists.

**FOLLOW-UP****FOLLOW-UP RECOMMENDATIONS**

- Close follow-up with the primary care physician and psychiatrist, if the patient is undergoing psychiatric care, is recommended to assess for persistence of symptoms, missed organic etiologies, or continued psychosocial stressors.
- The patient should be encouraged to return to age-appropriate levels of functioning as soon as possible.

**PROGNOSIS**

- Many children with conversion reactions have spontaneous remission or require only brief psychotherapy.
- Full recovery occurs in >85% of children.
- Favorable prognostic features include a recent onset of symptoms, a single symptom manifestation, and no other comorbidities.
- Early recognition is associated with a quicker recovery.

**COMPLICATIONS**

- Disuse atrophy and contractures are rare but reported in cases of prolonged conversion disorder with limb disuse.
- Unnecessary diagnostic tests and unsuccessful medical interventions
- School absence

**ADDITIONAL READING**

- Dula DJ, DeNaples L. Emergency department presentation of patients with conversion disorder. *Acad Emerg Med*. 1995;2:120–123.
- Glick TH, Workman TP, Gaufer SV. Suspected conversion disorder: Foreseeable risks and avoidable errors. *Acad Emerg Med*. 2000;7:1272–1277.

**CODES****ICD9**

300.11 Conversion disorder

**PEARLS AND PITFALLS**

- Conversion disorder is not simply a diagnosis of exclusion:
  - Rather, it requires a negative workup for organic etiologies as well as positive signs of conversion reaction.
- Anxiety, depression, exposure to violence or sexual abuse, and social/familial stress all predispose to conversion disorder.
- Children with conversion disorder may have coexisting medical or neurologic illness:
  - Children presenting with pseudoseizures often have an underlying seizure disorder.
  - Patients with chronic illnesses or recovering from illness may develop conversion symptoms.
- Limited time available in the emergency department makes the diagnosis of conversion disorder difficult. Consider early neurologic or psychiatric consultation.
- Ensure adequate follow-up to assess missed organic etiologies or continued psychosocial stressors.

# CORNEAL ABRASION

Nicole D. Porti  
Karen Franco

## BASICS

### DESCRIPTION

- The cornea is the transparent cover of the anterior portion of the eye that functions to protect the eye and provide refraction.
- A corneal abrasion is an acquired defect in the cornea, specifically the corneal epithelium.

### EPIDEMIOLOGY

#### Incidence

Corneal abrasions are common, but the exact incidence is unknown:

- In a survey of ophthalmic emergencies in a general hospital emergency department in the U.K., 66% presented with trauma, with 80% of those patients having minor trauma, mainly abrasions or foreign bodies (FBs) (1).
- In a pediatric study, nonpenetrating anterior globe injuries were the most frequent injury encountered (93%). 83% of those were corneal abrasions (2).

### RISK FACTORS

Not wearing protective eyewear when appropriate (eg, during sports activities)

### PATHOPHYSIOLOGY

The cornea is composed of 5 layers (anterior to posterior): The corneal epithelium, Bowman layer, corneal stroma, Descemet membrane, and the corneal endothelium:

- A corneal abrasion is a violation of the most superficial layer.

### ETIOLOGY

- Traumatic:
  - Sports-related injury
  - Blowing dust, sand, or debris
  - Mechanical injury:
    - Direct injury (eg, from a finger or tree branch)
    - May be occult, as in a 1-mo-old infant who presents with crying (inadvertent)
  - FB related
  - Contact lens trauma

- Trachoma
- Lid surgery
- Anesthesia
- UV keratitis
- Chemical exposures
- Spontaneous
- Iatrogenic factors

## DIAGNOSIS

### HISTORY

- Symptoms usually include:
  - Eye pain
  - FB sensation
  - Tearing
  - Comfort increased with eye closing
  - Blurred vision
  - Isolated crying in the infant
- Details of antecedent trauma or FB often given:
  - Injury: Finger or fingernail, paper, tree branch, sand
  - Exposure: Chemical, makeup application
- Obtain history of contact lens use

### PHYSICAL EXAM

- Exclude penetrating trauma. If unable to open the eye, gently retract the lids without applying pressure to the globe:
  - Confirm the pupil is central and round.
  - Confirm the anterior chamber is grossly clear with normal contour.
  - Elicit pupillary response to light:
    - Assess for an irregular pupil, large nonreactive pupil, extruded ocular contents, loss of normal contour, hyphema (blood), or hypopyon (pus).
    - The pupil may be small from a reactive miosis.
- Assess extraocular movement.
- Assess visual acuity:
  - Use an age-appropriate eye chart.
  - Visual acuity may be affected if the abrasion is over the visual axis.
- Inspect for FB. Make sure the eyelids are flipped in order to look for the object (see Foreign Body, Cornea topic).

- If the exam is limited by pain, a topical anesthetic should be used (tetracaine or proparacaine: See Medications).
- Slit lamp exam:
  - Reveals defect in the corneal epithelium
  - Reveals depth of corneal defect
  - Identifies associated injuries
  - Utility limited by age (ability to cooperate) and size of patient (ability to adjust slit lamp to size of patient)
  - Should be used in conjunction with the fluorescein exam (see Diagnostic Procedures/Other)

### DIAGNOSTIC TESTS & INTERPRETATION

#### Imaging

If there is concern about a retained FB, ocular CT or MRI may be needed:

- Metallic FBs are a contraindication to MRI.

#### Diagnostic Procedures/Other

Fluorescein exam confirms the diagnosis of corneal abrasion. This dye stains the basement membrane, which is exposed in the area of the epithelial defect:

- Techniques:
  - Place a fluorescein paper strip over the inferior cul-de-sac of eye, and use saline or a topical anesthetic to moisten the strip and allow dropping into the eye. Once the patient blinks, the dye is spread. Do not touch the cornea with the fluorescein paper strip. OR
  - Moisten the fluorescein strip with saline. Touch the strip to the palpebral conjunctivae, avoiding the bulbar conjunctivae. Once the patient blinks, the dye is spread.
- When using either the cobalt blue filter on an ophthalmoscope, slit lamp, or a Wood lamp, an abrasion will appear as yellow-green.
- If there is penetrating trauma, then leaking aqueous humor may be seen (Seidel sign).

**DIFFERENTIAL DIAGNOSIS**

- Corneal ulceration
- Conjunctivitis
- Keratitis
- Corneal perforation
- Ruptured globe
- Recurrent corneal erosion
- Corneal foreign body
- Chemical burn
- Iritis

**TREATMENT****INITIAL STABILIZATION/THERAPY**

- Cover the globe with a protective shield if penetrating trauma is suspected.
- Apply a topical anesthetic for patient comfort and to facilitate the exam.

**MEDICATION****First Line**

- Topical antibiotics are the mainstay of treatment. Ointment is better than drops since it acts as a lubricant and is administered less often. Duration of treatment is typically 3–5 days:
  - Bacitracin ointment 0.5" ribbon to lower eyelid q4–8h
  - Erythromycin ointment: 0.5" ribbon to the lower eyelid q4–8h
  - Sulfacetamide ointment: 0.5" ribbon to the lower eyelid q4–8h
- Topical NSAIDs have been found to be useful in reducing pain:
  - Ketorolac tromethamine 0.5%: 1 gtt q.i.d. for up to 2 wk
- Topical anesthetics:
  - Use a minimal amount in the emergency department, and do not let the patient take drops home. These agents can compromise wound healing (3) and blunt normal corneal reflex and sensation.
  - Tetracaine 0.5% ophthalmic solution:
    - Apply 1–2 gtt x 1; may repeat once
  - Proparacaine 0.5% ophthalmic solution:
    - Apply 1–2 gtt x 1; may repeat up to 5–7 times

**Second Line**

- Topical antibiotics:
  - Sulfacetamide 10% solution: 1–2 gtt q2h
  - Polymyxin/Trimethoprim solution: 1–2 gtt q2h
  - Ciprofloxacin solution: 1–2 gtt q2h
- Ibuprofen 10 mg/kg/dose PO q6h
- Acetaminophen/Oxycodone 0.1 mg/kg/dose q6h

**SURGERY/OTHER PROCEDURES**

- None
- Treating simple corneal abrasions by patching does not improve healing or reduce pain (4).

**DISPOSITION**

Corneal abrasions are managed on an outpatient basis.

**FOLLOW-UP****FOLLOW-UP RECOMMENDATIONS**

Discharge instructions:

- Instruct the patient to use antibiotics as prescribed or until asymptomatic (may be shorter duration than 3–5 days).
- Repeat eye exam in 24 hr.
- If symptoms persist >4 hr, re-exam by an ophthalmologist is warranted.
- Advise eye rest. Significant eye movement may interfere with healing.

**Patient Monitoring**

Follow up for fluorescein testing in 24–48 hr to ensure healing. May be done by optometry, ophthalmology, a primary care provider, or the emergency department

**PROGNOSIS**

Healing within 24–48 hr is to be expected. The prognosis is excellent in most cases.

**COMPLICATIONS**

- Deeper abrasions involving the visual axis may heal with a scar, leading to loss of visual acuity.
- Allergic conjunctivitis secondary to ophthalmic medications
- Recurrent corneal erosions may occur in area of healed abrasion if reinjured.

**REFERENCES**

**ADDITIONAL READING****See Also (Topic, Algorithm, Electronic Media Element)**

- Conjunctivitis
- Foreign Body, Cornea

**CODES****ICD9**

918.1 Superficial injury of cornea

**PEARLS AND PITFALLS**

- A patient with eye pain, FB sensation, and tearing with preceding trauma or FB likely has a corneal abrasion or more significant injury.
- Rule out penetrating trauma 1st:
  - Emergent referral to ophthalmology is warranted if penetrating trauma exists.
- Topical antibiotics are the treatment of choice, with resolution of abrasion expected in 1–2 days.
- Follow-up for fluorescein testing in 24–48 hr should be ensured to assess for healing.

# COSTOCHONDRITIS

Abu N.G.A. Khan  
Faiz Ahmad

## BASICS

### DESCRIPTION

- Costochondritis is an inflammatory process of the costochondral or costosternal joints that causes localized pain and tenderness.
- It is a benign cause of chest pain and is an important consideration in the differential diagnosis of chest pain:
  - Although the term *costochondritis* often is used interchangeably with fibrositis and Tietze syndrome, these are distinct diagnoses.

### EPIDEMIOLOGY

#### Incidence

The exact prevalence of a musculoskeletal etiology for chest pain is not known, although overall prevalence of a musculoskeletal etiology for chest pain was ~10–30%.

### RISK FACTORS

- Girls are affected more often than boys.
- Peak age for chest pain in children is 12–14 yr of age.

### GENERAL PREVENTION

Modify improper posture or ergonomics at home, school, or the workplace.

### PATHOPHYSIOLOGY

- Costochondritis is an inflammatory process of the costochondral or costosternal joints.
- The 2nd to 5th costochondral junctions most commonly are involved.
- > 1 site is affected in 90% of cases.

### ETIOLOGY

- The etiology of costochondritis is not well defined.
- Costochondritis is often preceded by an upper respiratory infection or exercise.
- Repetitive minor trauma has been proposed as the most likely cause.
- Bacterial or fungal infections of these joints occur uncommonly, usually in patients who are IV drug users or those who have had thoracic surgery.
- Costochondritis, among others, is a common noncardiac cause of chest pain in athletes.

## DIAGNOSIS

### HISTORY

The onset of costochondritis is often insidious. Chest wall pain with a history of repeated minor trauma or unaccustomed activity (eg, painting, moving furniture) is common. Pain may be described as follows:

- Sharp, nagging, aching, or pressure-like
- Affects the anterior chest wall
- Usually unilateral (left side more frequent than the right side)
- Usually localized but may extend or radiate extensively
- Exacerbated by trunk movement, deep inspiration, and/or exertion
- Lessens with decreased movement, quiet breathing, or change of position
- May be severe
- May wax and wane

### PHYSICAL EXAM

- Pain with palpation of affected costochondral joints is a consistent finding in costochondritis.
- Typically, the 2nd to 5th costochondral junctions are involved; in 90% of patients, >1 junction is involved.
- Surprisingly, patients may not be aware of the chest wall tenderness until exam.
- The diagnosis should be reconsidered in the absence of local tenderness to palpation:
  - Tietze syndrome is characterized by nonsuppurative edema.
  - Costochondritis has no palpable edema.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

No specific diagnostic studies exist for costochondritis. The clinical scenario and the most likely differential diagnoses should guide which laboratory tests are to be obtained:

- An ECG may be helpful to rule out cardiac pathology.

#### Imaging

- Chest radiograph is not routinely warranted but is sometimes obtained to rule out differential diagnoses for chest pain.
- Some case reports exist where bone (gallium) scans have been used to confirm the clinical diagnosis.

### DIFFERENTIAL DIAGNOSIS

- Tietze syndrome is similar to costochondritis, except for the presence of significant swelling, frequently at the right sternoclavicular or costochondral junction. It is usually due to minor trauma and responds to NSAIDs.
- Muscle strain is common, especially if there is a history of sports participation or exertion, although quite often there is no known precipitating event. Blunt trauma may cause recurrent pain long after the event. Chronic or paroxysmal coughing can cause muscle strain or even rib fractures.
- Precordial “catch,” or “Texidor twinge,” is a relatively frequent cause of sharp pain of short duration in healthy teenagers and young adults. It is often related to exercise and is characterized by a brief, sharp, shooting pain that pinpoints to the left substernal border or apex. The onset is sudden, with a momentary hesitation on inspiration, then shallow breathing resumes until the pain subsides, usually within a minute. The pain may recur frequently or remain absent for months.
- Chest wall pain from herpes zoster follows a dermatomal pattern and may precede the rash by 1–2 days. This is rare in adolescents and children.
- Bornholm disease: Also known as epidemic pleurodynia or “Devil’s grip.” It’s usually caused by some strains of coxsackievirus or echovirus and is due to inflammation of pleural lining or intercostal muscles. Pain is spasmodic, lasting 15–30 min. Symptoms may last from 2–6 days. Complications are rare but may include orchitis, pericarditis, myocarditis, and aseptic meningitis. Treatment is pain control with NSAIDs.
- Other diagnoses:
  - Cardiovascular: Myocardial ischemia, pericarditis, supraventricular tachycardia
  - Pulmonary: Asthma/Bronchospasm, pneumonia, pneumothorax, pneumomediastinum
  - GI: Reflux, esophagitis
  - Rheumatologic: Fibromyalgia, rheumatoid arthritis
  - Oncologic: Leukemia, sarcoma, etc.
  - Miscellaneous: Psychogenic chest pain (stress, anxiety), breast development (both sexes)

## TREATMENT

### INITIAL STABILIZATION/THERAPY

Assess and address any compromise of airway, breathing, or circulation.

### MEDICATION

#### First Line

Ibuprofen 10 mg/kg PO q6h, drug of choice for initial therapy.

#### Second Line

- Other NSAID options include flurbiprofen, mefenamic acid, ketoprofen, and naproxen.
- Narcotic analgesics generally are not required but may be used if necessary, such as morphine 0.1 mg/kg IV/SC/IM, repeated as necessary.
- Local infiltration of local anesthetic, steroid, or intercostal nerve block (reserved for refractory cases)

### COMPLEMENTARY & ALTERNATIVE THERAPIES

- Local heat
- Stretching of the pectoralis muscles 2–3 times a day may be beneficial.
- Avoid repetitive misuse of muscles.
- Modify improper posture or ergonomics at home, school, or the workplace.

### DISPOSITION

#### Admission Criteria

An isolated costochondritis patient does not need to be admitted unless there is an underlying systemic illness that requires hospitalization.

## FOLLOW-UP

- NSAIDs for pain control
- Reassure patients of the benign nature of the problem, and instruct them regarding avoidance of provoking activities.
- Provide patients with a good understanding of the proper use and potential adverse effects of NSAIDs.
- Primary care follow-up with persistent symptoms

### PROGNOSIS

- The prognosis for patients with costochondritis is excellent.
- After 1 yr, ~1/2 of patients still may have discomfort and ~1/3 report tenderness with palpation.

ICD9  
733.6 Tietze's disease

## PEARLS AND PITFALLS

- Always consider serious causes of chest pain in the differential diagnosis (myocardial ischemia or infarction, pulmonary embolism, pericarditis, pneumonia, etc.).
- Parents and patients often have significant anxiety and concern that the cause of chest pain is cardiac in nature. It is essential to assuage such concerns.
- Consider costochondral infection in IV drug abusers.
- Costochondritis is an important cause of school absence.
- Adolescents tend to limit physical activity unnecessarily for long periods.
- Restriction of activities is usually not required.

# COUGH

Eileen Murtagh Kurowski  
Lynn Babcock Cimpello

## BASICS

### DESCRIPTION

- Cough is forced expiration that can be stimulated by multiple receptors in the airways' mucosa or may be produced voluntarily.
- Cough can be divided into:
  - Acute: <4 wk
  - Chronic: >4 wk

### EPIDEMIOLOGY

#### Incidence

- According to the 2006 National Hospital Ambulatory Medical Care Survey, 6.6% (~1.4 million) of emergency department visits among children <15 yr of age were for the chief complaint of cough (1).
- School-aged children typically have 4–6 symptomatic upper respiratory tract infections (URTIs) per year (2). 50% recover by 10 days, 90% by 25 days, and 10% will have persistent symptoms into the 3rd and 4th wk (3).

#### Prevalence

- The exact prevalence is unknown.
- According to 1 community-based survey, reported cough without colds has a prevalence of 28% in boys and 30% in girls (4).

### GENERAL PREVENTION

Use measures to prevent spread of infections:

- Hand washing
- "Cover your cough," coughing into your elbow.

### PATHOPHYSIOLOGY

- Cough can be divided into 3 phases:
  - Inspiratory: Inhaling lengthens expiratory muscles.
  - Compressive: Very brief closure of the glottis to maintain lung volumes as intrathoracic pressure builds due to isometric contraction of expiratory muscles
  - Expiratory: Opening of glottis, releasing brief supramaximal expiratory flow followed by lower expiratory flows
- Dynamic collapse of airways occurs:
  - Can be voluntary or involuntary
  - May be triggered as part of a laryngeal expiratory reflex when the larynx is stimulated by foreign material. Laryngeal cough is thought to protect the airways from aspiration.
  - Chemo- or mechanical receptors in the lower airways may also act as a trigger for cough and function primarily in airway clearance and maintenance of the mucociliary apparatus.

### ETIOLOGY

- Most commonly due to URTIs:
  - Usually caused by viruses: Respiratory syncytial virus, human metapneumovirus, parainfluenza, influenza, adenovirus
  - Bacterial: *Streptococcus*, *Haemophilus*, *Moraxella*, *Chlamydia* (infants), pertussis, *Mycobacterium*
- Fungal
- TB

- Other focal infections: Sinusitis, tonsillitis, laryngitis, laryngotracheitis, tracheitis, pneumonia, bronchiolitis, pleuritis, bronchiectasis, airway or pulmonary abscess
- Structural: Pneumothorax, atelectasis due to mucus plugging, usually from infectious etiologies
- Congenital: Laryngotracheomalacia, tracheoesophageal fistula
- Suppurative lung disease: Cystic fibrosis, chronic aspiration, immunodeficiency
- Asthma, allergy, or vasomotor rhinitis
- Aspiration, including foreign body (FB)
- Physical/Chemical irritation: Tobacco/Wood smoke, dry/dusty environment, volatile chemicals
- Iatrogenic: Angiotensin-converting enzyme (ACE) inhibitors
- Other:
  - Habit or psychogenic
  - CHF
  - Mediastinal mass
  - GERD
  - Relentlessly progressive cough (increasing frequency and severity >2–3 wk) is concerning for pertussis, retained inhaled FB, expanding mediastinal neoplasm, or lobar collapse secondary to mucous plug or TB.

## DIAGNOSIS

The combination of the history and physical exam defines the etiology of cough in most cases.

### HISTORY

- Obtaining a detailed history will help elucidate the etiology of the cough.
- Chronicity:
  - Most children will present with acute onset of cough, especially with URTI and most infections
  - Chronic cough (>4 wk) is concerning for asthma, postnasal drip due to allergic rhinitis, GERD, retained FB, pertussis, TB, or mediastinal mass.
- Nature/Quality:
  - Barky: Croup
  - Brassy: Tracheomalacia, habit, or viral
  - Paroxysmal: Pertussis
  - Productive cough, especially with hemoptysis, concerning for bronchiectasis
- Absence of cough during sleep is suggestive of habit cough.
- Triggers: Smoke, cold, pets, plants
- Family history: Respiratory diseases, atopy
- Medication use: ACE inhibitors can cause cough.
- Red flags:
  - Neonatal onset: Congenital malformation, aspiration, or perinatal infection
  - Cough with feeding: Aspiration
  - Chronic moist cough: Bronchiectasis
  - Associated night sweats/weight loss: Malignancy or TB
  - Signs of chronic lung disease: Failure to thrive, finger clubbing, overinflated chest, or chest deformity

### PHYSICAL EXAM

- Vital signs including pulse oximetry (SpO<sub>2</sub>)
- Perform a full physical exam with particular focus on lung, cardiac, and ENT exams
- Lungs:
  - Asymmetric breath sounds suggest pneumonia, atelectasis, FB, or mass.
  - Rales (crackles) or rhonchi indicate atelectasis or infiltrate.
  - Increased work of breathing including grunting, nasal flaring, retractions, or abdominal breathing is found in children with respiratory compromise.
  - Wheezing can be found in asthma, bronchiolitis, or FB aspiration.
  - Stridor occurs in upper airway obstruction from edema, mass, infection, or FB.
  - Paroxysmal cough suggests pertussis or atypical pneumonia.
- Cardiac: Assess for signs of CHF and/or hemodynamic compromise including:
  - Tachycardia
  - Prolonged capillary refill
  - Presence of S3, S4, or gallop
  - Diminished or unequal central and distal pulses (especially important in infants with concern of congenital heart disease)
- ENT: Assess for signs of URTI, allergies, irritants, or FB:
  - Nasal congestion or rhinorrhea
  - Erythema of posterior pharynx, which may indicate postnasal drip
  - Inspection of the ear for matter in the external canal or fluid within the middle ear
  - Lymphadenopathy

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

- None routinely indicated
- Tests to consider include:
  - Pertussis culture or PCR if spasmodic or whooping cough.
  - CBC may show a lymphocytosis.
  - Sputum Gram stain/culture if productive cough to aid in diagnosis of pneumonia
  - PPD and/or acid fast bacilli (AFB) culture if there is clinical concern for TB. Consider referral for early-morning gastric aspirate samples for diagnosis.

#### Imaging

- Obtain a CXR if:
  - Red flags on history are present
  - Hemoptysis
  - Concern for FB aspiration
  - Uncertain about the diagnosis of pneumonia
- Consider CXR for occult pneumonia for children <5 yr of age, with temperature >39°C, and WBC >20,000/mcL (5).

#### Diagnostic Procedures/Other

- Urgent bronchoscopy is indicated if there is concern for aspirated FB.
- Consider spirometry in children ≥6 yr of age with chronic cough that is concerning for asthma.

## TREATMENT

### PRE HOSPITAL

Assess and support ABCs.

### INITIAL STABILIZATION/THERAPY

- Assess and stabilize airway, breathing, and circulation.
- Treat the underlying cause of cough.
- Consider symptomatic treatment such as a cool-mist humidifier and/or increased fluid intake.

### MEDICATION

The U.S. FDA Nonprescription Drugs and Pediatric Advisory Committees recommend against the use of over-the-counter (OTC) cough and cold medications in infants and children <6 yr, citing a lack of safety and efficacy data in these children (6).

#### First Line

- Treat the underlying cause of cough:
  - See the Asthma topic for dosing of bronchodilators.
  - See the Pneumonia topic for dosing of antibiotics.
- Dextromethorphan:
  - Not recommended for children <6 yr
  - Children 6–12 yr: 5–10 mg PO q4h or 15 mg PO q6–8h PRN
  - >12 yr: 10–30 mg PO q8h PRN

#### Second Line

- Codeine:
  - Not recommended for children <6 yr
  - Children 6–12 yr: 2.5–5 mg PO q4–6h PRN
  - >12 yr: 10–20 mg PO q4–6h PRN
- No strong evidence of efficacy of dextromethorphan or codeine in acute cough in children (7).
- For pertussis, macrolides should be initiated within 1–2 wk of the onset of symptoms to reduce the period of infectivity.
- A small study showed that nebulized lidocaine (0.25% solution given q4–6h, preceded by a bronchodilator) was able to decrease persistent cough in adults (8).

### SURGERY/OTHER PROCEDURES

Emergent laryngoscopy and bronchoscopy if concern for aspirated FB

### DISPOSITION

#### Admission Criteria

- Significant increased work of breathing
- Frequent albuterol treatment requirement
- Hypoxemia with increased oxygen requirement from baseline
- Significant dehydration and/or inability to maintain hydration status
- Critical care admission criteria:
  - Intubation for respiratory failure
  - Severe asthma with need for continuous albuterol and concern for decompensation

#### Discharge Criteria

- Well appearing without respiratory distress
- At baseline oxygenation level:
  - For young, previously healthy children with bronchiolitis, SpO<sub>2</sub> ≥90% is acceptable for discharge (9).
  - For children with other lung processes (eg, asthma or pneumonia), many clinicians use SpO<sub>2</sub> ≥92–93% as discharge criteria.
- Well hydrated and able to tolerate oral fluids

### COMPLEMENTARY & ALTERNATIVE THERAPIES

Honey (between 1/2 and 2 teaspoons/dose depending on the age of the child) has been shown to decrease symptoms in children 2–18 yr of age with acute URIs when given prior to bedtime, as compared to placebo (10).

#### Issues for Referral

Outpatient referral to pulmonology, allergy/immunology, cardiology, psychiatry, surgery, and others, as is appropriate to the patient

## FOLLOW-UP

### FOLLOW-UP RECOMMENDATIONS

- If a definitive diagnosis is not obtained in the emergency department, follow-up with the primary care provider is recommended.
- If an empiric trial of asthma therapy is started for cough, follow-up must be scheduled and medication stopped if no improvement is seen.
- Other discharge instructions, medications, and follow-up is disease specific.

### PROGNOSIS

- Most coughs resolve spontaneously or with treatment of the underlying cause.
- 10% of children will have persistent cough after viral illness for up to 1 mo.

### COMPLICATIONS

- Interference with sleep, school function, and play
- Parental anxiety
- Other complications are dependent upon the underlying etiology.

ICD9  
786.2 Cough

## PEARLS AND PITFALLS

- Appropriate treatment of cough depends on identification of the underlying etiology.
- OTC cough and cold remedies are not recommended for children <6 yr of age.

# CROUP

Mary Jane Piroutek  
Lilit Minasyan

## BASICS

### DESCRIPTION

- The term *croup* is used to describe laryngotracheobronchitis, or infectious croup, as well as spasmodic croup.
- Infectious croup is an acute respiratory illness characterized by barking, "seal-like" cough, fever, sometimes with inspiratory stridor, and mild to severe respiratory distress due to obstruction of the larynx.

### EPIDEMIOLOGY

- Peak incidence is between 6 mo and 3 yr of age (1).
- Occurs in ~5% of children in 2nd yr of life
- Typically seen in fall and winter seasons
- 85% of children seen in emergency departments have mild croup, and <1% have severe croup (2).

### GENERAL PREVENTION

Hand washing and routine personal protective equipment can help control transmission.

### PATHOPHYSIOLOGY

- Acute laryngotracheobronchitis: Erythema and edema of walls and inflammatory cells within respiratory lumen
- Edema of vocal cords and luminal narrowing leads to characteristic cough, hoarseness, and stridor.
- Spasmodic croup: Noninflammatory edema of subglottic trachea

### ETIOLOGY

Viral croup:

- Parainfluenza type 1 is the most common causative organism (1).
- Other viruses have also been implicated, including parainfluenza types 2 and 3, respiratory syncytial virus, adenovirus, influenza, and measles (1):
  - Influenza has been associated with more severe cases.

## DIAGNOSIS

### HISTORY

- Acute onset of barking cough, shortness of breath, fever, stridor or "noisy breathing"
- Symptoms are typically worse at night.
- Prodrome of fever, rhinorrhea, and cough may be present.

### PHYSICAL EXAM

- Stridor may be present at rest or with agitation:
  - Stridor may be inspiratory or biphasic in severe cases.
- Barking cough, hoarse voice
- Fever
- Varying degrees of tachypnea or respiratory distress
- Minimal to no pharyngitis, normal epiglottis
- Impending respiratory failure marked by severe retractions, significant hypoxemia, cyanosis, fatigue, or decreased level of consciousness
- A croup severity score has been developed (2):
  - Mild:
    - Occasional barking cough, no stridor at rest, mild or no retractions
  - Moderate:
    - Frequent barking cough, stridor at rest, retractions
  - Severe:
    - Frequent cough, prominent stridor, marked distress and retractions

### DIAGNOSTIC TESTS & INTERPRETATION

- Lab or imaging studies are generally not indicated in mild or moderate cases of croup.
- The diagnosis can be made based on historical and exam findings.

### Lab

- No routine lab testing is necessary, as croup is a clinical diagnosis.
- Viral studies are generally not useful, as disease is self-limited:
  - May be helpful in cohorting admitted patients or in severe cases, especially if the patient does not respond to routine management

### Imaging

- Radiographs are not routinely indicated.
- X-rays of the neck may show narrowing of the subglottic space (steeple sign) on AP or lateral views.

### Diagnostic Procedures/Other

Pulse oximetry should be obtained:

- May have hypoxemia in severe cases

### DIFFERENTIAL DIAGNOSIS

Other causes of stridor should be considered:

- Epiglottitis:
  - Lower incidence since the *Haemophilus influenzae* type b vaccine
  - Toxic appearing, severe distress, drooling, dysphagia, "sniffing" or "tripod" position
- Laryngomalacia or tracheomalacia
- Retropharyngeal or peritonsillar abscess
- Foreign body aspiration
- Angioedema or allergic reaction
- Anatomic abnormality of airway:
  - Subglottic stenosis
  - Respiratory laryngeal papillomatosis (human papillomavirus verrucae growth in airway)
  - Atrioventricular malformation
- Bacterial tracheitis:
  - Should be considered in severe cases that do not respond to routine treatment
  - Toxic-appearing patient
  - Drooling or dysphagia

## TREATMENT

### PRE HOSPITAL

Attention to airway patency and oxygenation

### INITIAL STABILIZATION/THERAPY

- Assess airway patency, oxygenation, and degree of respiratory distress.
- Take care not to upset or agitate the patient, as this may worsen stridor and respiratory distress.
- Oxygen as necessary
- Prompt treatment with appropriate medications
- Careful airway management with consideration for need of endotracheal intubation as indicated

### MEDICATION

#### First Line

- Nebulized epinephrine:
  - Recommended in patient with stridor at rest
  - Temporary relief of symptoms of airway obstruction
  - Repeat treatments may be needed in severe cases.
  - Recommended dose: 2.25% 0.5 mL in 2.5 mL of saline

- Corticosteroids:
  - Recommended for moderate or greater severity, typically patients with increased work of breathing or stridor at rest
  - Shown to decrease emergency department length of stay, rates of admission, and return visits
  - Associated with decreased need for intubation in severe cases
  - Oral or IM route of corticosteroids is equal or more effective than an inhaled route (3).
  - Recommended dose:
    - Dexamethasone 0.6 mg/kg single dose PO or IM (4)
    - Nebulized budesonide 2 mg in 4 mL saline
    - Nebulized L-epinephrine (1:1,000) solution diluted in 5 mL saline

**ALERT**

Humidified air or cool mist has repeatedly been demonstrated to be ineffective as a therapy for croup (5):

- Evidence-based practice clearly does not warrant use of this therapy on an inpatient or outpatient basis.

**Second Line**

Heliox (helium/oxygen mixture):

- May be equally effective but more expensive than treatment with racemic epinephrine (6)
- Caution should be used when using heliox, as it allows a greater quantity of epinephrine to be delivered to the alveoli.

**SURGERY/OTHER PROCEDURES**

Intubation and mechanical ventilation in cases of severe respiratory compromise or failure:

- May need smaller endotracheal tube due to edema around the glottic and subglottic structures

**DISPOSITION****Admission Criteria**

- Minimal or no improvement 2–4 hr after steroids given
- Recurrence of respiratory distress during observation period
- Persistent stridor at rest
- Requiring multiple nebulized epinephrine treatments
- Critical care admission criteria:
  - Severe symptoms with poor response to treatment
  - Suspected bacterial croup or tracheitis
  - Impending respiratory failure or need for mechanical ventilation

**Discharge Criteria**

- No stridor at rest
- No respiratory distress
- Normal color/perfusion or pulse oximetry
- Reliable follow-up
- Moderate cases may be discharged after treatment and 2–4 hr of observation:
  - Observation time after racemic epinephrine is not well studied or defined.

**Issues for Referral**

May need pediatric ENT consultation for suspected abscess or for congenital or anatomic abnormalities

**FOLLOW-UP****FOLLOW-UP RECOMMENDATIONS**

Discharge instructions and medications:

- For children who present early with croup that is mild and does not warrant corticosteroid therapy, a prescription for a burst dose of steroid (prednisone 1–2 mg/kg/day for 2–4 days) may be given to the parent with instructions to use if the child develops stridor at rest.
- Return for worsening dyspnea, stridor at rest, excessive drooling, dysphagia, fatigue, or cyanosis
- Generally, no further home medications, other than antipyretics, are indicated unless there is a comorbid condition such as:
  - Otitis media requiring antibiotics
  - Asthma exacerbation may need additional corticosteroids.

**Patient Monitoring**

The croup severity scale may be used to monitor response to treatment.

**PROGNOSIS**

- Self-limited illness usually lasting <1 wk, peaking on day 2–3 of illness
- <5% require hospitalization; of these, 1–2% require intubation.

**COMPLICATIONS**

Complications are uncommon but may include:

- Hypoxemia
- Respiratory failure
- Dehydration
- Secondary bacterial infections:
  - Otitis media
  - Sinusitis
  - Pneumonia

**See Also (Topic, Algorithm, Electronic Media Element)**

Tracheitis

**ICD9**

- 464.4 Croup
- 478.75 Laryngeal spasm
- 490 Bronchitis, not specified as acute or chronic

**PEARLS AND PITFALLS**

- Most cases of croup are mild to moderate cases and self-limited.
- Rapid administration of corticosteroids and use of racemic epinephrine are mainstays of therapy.
- If intubation is needed, be prepared to use an endotracheal tube that is 0.5–1.0 size smaller than would normally be used due to tracheal edema.
- Dexamethasone may be given orally with equal efficacy as IM administration.

# CRYING/COLIC

Seth L. Brindis

Marianne Gausche-Hill

## BASICS

### DESCRIPTION

- “Rule of 3”: Colic is defined as crying in an infant who is well fed and healthy that is:
  - >3 hr per day
  - >3 days a week
  - For >3 wk
- 10–30% of infants are affected.
- Begins at 2–4 wk, peaks at 6 wk, and resolves typically by 4 mo of age
- Diurnal pattern, with increased crying late afternoon and early evening
- Most common in 1st-born infants

### PATHOPHYSIOLOGY

The unifying pathophysiology of colic is largely unknown, though it has been attributed to:

- GI disorders
- Normal variances in temperament
- Psychosocial and neurodevelopmental disorders

### ETIOLOGY

- <5% of excessive crying is due to an organic cause, but this must be ruled out.
- Infection:
  - Meningitis
  - Sepsis
  - Otitis media/externa
  - Urinary tract infection
  - Viral illness
  - Thrush
  - Gingivostomatitis
- GI:
  - Constipation
  - Cow’s milk protein intolerance
  - GERD
  - Lactose intolerance
  - Anal fissure
  - Intussusception
  - Hernia
- Neurologic:
  - CNS abnormality (Chiari type 1)
  - Infantile migraine
  - Subdural hematoma
  - Seizure
- Trauma:
  - Fractures
  - Nonaccidental trauma
  - Corneal abrasions
- Other causes:
  - Diaper rash
  - Tight phimosis
  - Teething
  - Hair tourniquet (extremities, penis, clitoris)
  - Torsion (testicular, ovarian, appendix testis)
  - Supraventricular tachycardia

## DIAGNOSIS

### HISTORY

- Suggestive of colic:
  - 1st born
  - Late afternoon and evening crying
  - Increasing after 3–4 wk of age
  - Peak crying at 6 wk of age
  - Periods of “normal/happy” behavior
  - No fever
  - Able to be soothed
  - Mother’s mood, symptoms of postnatal depression
- Suggestive of organic cause:
  - Preterm
  - Complications in the perinatal period
  - History of underlying conditions
  - History of possible ingestions/exposures
  - Fever
  - Apnea
  - Cyanosis
  - Respiratory distress
  - Rash
  - Forceful vomiting
  - Recent illness
- Other important history points:
  - Allergies
  - Attempted medical treatments
  - Homeopathic, natural, cultural treatments
  - Stooling pattern
  - Family history
  - Sibling temperament

### PHYSICAL EXAM

- Plot child on growth chart: Height, weight, and head circumference. Failure to gain weight and poor growth are likely to point to an organic/infectious cause.
- Vital signs: With a temperature >38°C, consider infectious etiologies.
- Observation of the child being held by a parent gives clues to parent bonding and also consolability of the infant.
- Remove all clothing.
- Thorough cardiac, respiratory, abdominal, and skin exams to look for signs of systemic illness:
  - Lethargy, tachypnea, or poor perfusion are signs of serious illness.
  - Rashes
  - Orifices: Tight phimosis, fissure, white patches in oropharynx, erythematous ear canal or tympanic membrane, scleral injection
  - Neurologic exam: Normal baby reflexes

- Look for signs of physical injury/trauma:
  - Inspect for bruising.
  - Palpate for tenderness along the long bones.
  - Hair tourniquets:
    - Fingers: Swollen and edematous finger or toe distal to the tourniquet
    - Genitals (penis or clitoris) swollen or erythematous distal to the tourniquet
  - Fluorescein-aided corneal exam to detect abrasion
  - Retinal exam in suspected child abuse
- Observe feeding.
- Assess the emotional state of the parents: Presence of fatigue, depression, anger, or agitation.

### DIAGNOSTIC TESTS & INTERPRETATION

Lab tests and radiographic examinations usually are unnecessary if the patient is growing well and has a normal exam.

#### Lab

The extent of lab evaluation will depend on the clinical presentation and suspicion for illness or injury.

#### Imaging

Imaging may be indicated based on clinical presentation:

- Consider CXR in children with respiratory distress.
- Consider appropriate plain x-rays of deformed or tender long bones.
- Consider urgent head CT if concerned about child abuse or if there is a history of trauma.

## TREATMENT

### PRE HOSPITAL

Advise EMS personnel to reassure the parents, allowing the parents to ride with the child to the hospital.

### INITIAL STABILIZATION/THERAPY

- ABCs: Ensure that the patient is adequately protecting his or her airway, and stabilize breathing and circulation abnormalities.
- Reassure the parents, allowing them to watch your exam and explaining what you are examining. Discuss reassuring findings (eg, “Your baby is growing well.”).
- Once organic causes are excluded:
  - Acknowledge the difficulties the parents are facing.
  - Inquire how they are doing.
  - Ensure that they have some emotional support.
  - Encourage parents to take “breaks” away from the crying baby:
    - Division of labor: Alternate caretakers, allow one to leave the home
    - Single parent: Put the baby in the crib (back to sleep) and close a door.

- Reassure parents that colic is a benign process that will improve with infant growth and maturation.
- Encourage breast-feeding.
- Change to hypoallergenic formulas in infants with signs of cow's milk intolerance, such as loose or bloody stools, and dermatitis.
- Instruct parents on infant calming techniques using the 5 S's:
  - Nonnutritive Sucking/pacifier
  - Swinging or bouncing baby
  - Shushing or hushing baby
  - Singing to baby
  - Swaddling
- Encourage a stable emotional environment.
- Holding the infant for >3 hr a day has been shown to decrease intensity but not the duration of cry.

### MEDICATION

There are no proven medications.

### ALERT

Colic is a diagnosis of exclusion in well-appearing patients in which organic causes have been excluded.

### DISPOSITION

#### Admission Criteria

- Significant vital sign abnormalities
- Respiratory distress
- Inability of caretaker to care for patient

#### Issues for Referral

- Consultation with social work services for referral to parenting support groups or classes
- Psychiatry referral if the mother is exhibiting symptoms of severe postnatal depression
- Primary care referral for all patients who do not already have a pediatrician. They need follow-up checks, well-baby care, and immunizations.

### COMPLEMENTARY & ALTERNATIVE THERAPIES

- Simethicone (Mylicon, Gas-X): An oral agent that reduces surface tension and purportedly reduces "gas" but has not been shown to be more effective than placebo (1)
- Dicyclomine (Bentyl): An anticholinergic medication shown to be more effective than placebo in reducing crying. However, it is associated with apnea, seizures, and coma and is contraindicated in infants (2).
- Herbal tea of fennel, chamomile, vervain, licorice, and lemon has been shown to reduce crying when compared to placebo (3).
- Probiotics: *Lactobacillus reuteri* has been shown to be more effective than simethicone in reducing infant crying. 95% in a treatment group were treatment responders. However, it cannot be safely recommended for immunocompromised or severely debilitated patients (4).

- Hydrolyzed formula (hypoallergenic formula) has been shown to be effective in reducing crying times in a small randomized controlled trial. However, hypoallergenic-labeled formulas cost up to 3 times more than standard formulas (5).
- Infant massage is equal to the use of a crib vibrator in decreasing crying 47–48%. It has also been shown to have benefits on mother–infant interaction, infant sleeping, and crying (6).
- 12% sucrose solution has been shown to reduce symptoms by 63% compared to water. The effect is short lived (<30 min), so frequent redosing would be needed if crying persists (7).

### FOLLOW-UP

#### FOLLOW-UP RECOMMENDATIONS

Follow up with primary care provider in 2–3 days:

- Recheck crying symptoms.
- Evaluate for evolving organic etiology.
- Assess parental state of mind.

#### COMPLICATIONS

There is a high correlation between colic and excessive crying with postpartum depression. Infantile colic at 2 mo of age has been associated with high maternal depression scores 4 mo later (8).

### CODES

ICD9  
789.7 Colic

### PEARLS AND PITFALLS

- Gas does not cause colic. Excessive crying that accompanies colic usually leads to aerophagia.
- Excessive crying has been linked to parental distress and in rare instances infant abuse.
- Simple maneuvers and soothing techniques can help relieve symptoms. (See the 5 S's in the Initial Stabilization/Therapy section.)
- Medications are not routinely recommended for colic.
- Sucrose solutions may help relieve symptoms, but the effects are short lived.
- Parental reassurance and support remain the mainstay of treatment of infantile colic. The majority of colic symptoms eases by the 4th mo of life without treatment.

# CRYPTORCHIDISM

Marie Waterhouse  
Deborah R. Liu

## BASICS

### DESCRIPTION

- Cryptorchidism is failure of the testis to descend to its normal anatomic location at the base of the scrotum.
- Unilateral (90%) or bilateral (10%)
- Testis may be palpable (80%):
  - High in scrotum
  - Inguinal canal (“peeping”)
  - Ectopic (eg, perineal, anterior to symphysis pubis)
- Testis may be nonpalpable (20%):
  - Truly “cryptorchid” or “hidden” testis
  - Located in the abdomen

### EPIDEMIOLOGY

#### Incidence

- Most common genitourinary anomaly in boys
- 3–4% of term newborn males (1,2)
- 15–30% of preterm infants (3)

#### Prevalence

Falls to 1% by age 3 mo, indicating that most undescended testes (UDT) will self-resolve by this age (1)

### RISK FACTORS

- Birth factors:
  - Low birth weight
  - Small for gestational age
  - Intrauterine growth retardation
  - Twin gestation
  - Preterm birth
- Family history: 23% of cryptorchid patients will have a male relative with the disorder
- Maternal tobacco exposure
- Gestational diabetes
- Conditions of impaired androgen synthesis or effect
- Disorders affecting hypothalamic-pituitary-adrenal axis
- Disorders of abdominal musculature:
  - Prune-belly syndrome
  - Gastroschisis
  - Omphalocele
  - Down syndrome
  - Prader-Willi syndrome
- Caudal developmental defects:
  - Spina bifida
- Other chemical exposures:
  - Organochlorine compounds
  - Pesticides
  - Diethylstilbestrol

### PATHOPHYSIOLOGY

Normal testicular migration proceeds in 2 phases:

- Abdominal phase (8–15 wk gestation): Androgens mediate regression of the cranial suspensory ligament. This, in addition to firm caudal attachment of the testis to the inguinal ring by the gubernaculum, allows the testis to descend into the lower abdomen.
- Inguinoscrotal phase (usually complete by 28–34 wk gestation): Testosterone causes the gubernaculum to enlarge and widen within the inguinal canal. This facilitates passage of testis, aided by abdominal pressure, into the scrotum.

### ETIOLOGY

- Complex combination of genetic and environmental factors
- Disruption of normal testicular migration by interference with androgen sensitive pathways
- Preterm birth (prior to completion of testicular migration) will result in a temporary lack of descent.
- Identifiable genetic mutation in only a small subset of patients

## DIAGNOSIS

### HISTORY

- Pregnancy history: Gestational age, birth weight, maternal diabetes, smoking, estrogen or other steroid use
- Results of the scrotal exam at birth
- Family history: Other relatives with cryptorchid testis, hypospadias, other genitourinary anomalies
- History of endocrinopathy or intracranial pathology affecting hypothalamic-pituitary function

### PHYSICAL EXAM

- Best accomplished with relaxed patient, in seated frog-legged position
- With warm hands, examine the contralateral testicle first for size and consistency.
- Sweep the nondominant hand from the anterior superior iliac spine medially across the groin to push testis into the inguinal canal.
- Once the testis is palpated, grasp gently with the dominant hand and bring the testis into the scrotum.
- Hold this position for 1 min to fatigue the cremaster muscle, then release and observe.
- If the testis stays in the scrotum, it is retractile.
- If the testis reassumes a high position, it is undescended.
- Exam under anesthesia may locate the nonpalpable testis in 20% of cases.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

- Generally not necessary in the emergency department
- If bilateral UDT, karyotype and hormonal stimulation testing is recommended on an outpatient basis to confirm the presence of testicular tissue.

#### Imaging

- In general, imaging is not recommended due to poor sensitivity and reliability. It does not replace the diagnostic and therapeutic ability of laparoscopy.
- US is limited by intestinal gas and obesity.
- MRI is poorly sensitive and requires sedation in young children.
- Small studies suggest that gadolinium-enhanced MRA may be more reliable (4).
- May consider imaging in obese patients (where a normal exam is difficult) or if a history of multiple intrabdominal surgeries or adhesions make laparoscopy difficult or dangerous

#### Diagnostic Procedures/Other

Diagnostic laparoscopy is the gold standard.

#### Pathological Findings

Cryptorchid testes exhibit multiple histopathologic changes including:

- Germ cell loss
- Leydig cell loss
- Testicular fibrosis

### DIFFERENTIAL DIAGNOSIS

All of the following carry histopathologic changes and require urologic evaluation:

- Retractable testis:
  - Can be manipulated into normal anatomic position during exam and stays there after being released
  - Possibly due to hyperactive cremaster muscle (eg, cerebral palsy)
- Acquired UDT:
  - Normal testicular position at birth but “reascends” in early childhood due to failure of spermatic cord to elongate as child grows
  - Acquired UDT cannot be placed into the correct anatomic position during the exam. If forced, pain results and the testis immediately reassumes the prior position when released.
- Atrophic or “vanishing” testis:
  - Testicular tissue damaged by spermatic cord torsion or other cause of ischemic injury
  - Atrophic testicular remnant remains in either anatomic or ectopic location
- Absent testis (monorchia or anorchia):
  - Due to congenital defect or chromosomally female patient
  - Consider the virilized female in congenital adrenal hyperplasia.

## TREATMENT

Most pediatric urologists consider surgery to be first-line treatment for simple cryptorchidism.

### MEDICATION

Human chorionic gonadotropin or gonadotropin-releasing hormone therapies:

- Overall success rates are extremely variable (6–75%) but comparable for the 2 hormones.
- Higher success rates in older patients (>5 yr), bilateral UDT, and retractile testis
- Adverse effects include impaired spermatogenesis and/or precocious puberty.

### SURGERY/OTHER PROCEDURES

- Laparoscopic or open orchiopexy to secure the testis in the scrotum
- Orchiopexy: Recommended age of operation at 3–12 mo:
  - Orchiopexy allows better routine self-exams for malignancy monitoring.
  - The surgical plan must balance the anesthesia risk against the potential malignancy risk.
- Orchiectomy for selected patients, particularly those with atrophic or hypertrophic testis, in which the malignancy risk is higher
- The decision to observe, remove, or repair a UDT in the postpubertal male is complex, since the malignancy and fertility benefit from surgery may be limited.

### DISPOSITION

#### Admission Criteria

- Cryptorchidism not associated with underlying medical conditions rarely requires admission to the hospital.
- Cryptorchidism as a sign of an undiagnosed medical condition (eg, congenital adrenal hyperplasia or prune-belly syndrome) may require admission for further evaluation.

#### Discharge Criteria

Patients not experiencing pain, in whom torsion is not suspected, can generally be discharged with appropriate follow-up.

#### Issues for Referral

All patients with a testis located outside of normal anatomic position should be referred to a pediatric urologist or surgeon upon diagnosis.

## FOLLOW-UP

### FOLLOW-UP RECOMMENDATIONS

- Follow up with a pediatric urologist or surgeon.
- No limitations on physical activity

### Patient Monitoring

Encourage routine self-exams by the patient or primary caretaker for testicular malignancy.

### PROGNOSIS

- Dependent on multiple factors, including location of testis, uni- or bilateral, and age at discovery
- Correction before 2 yr of age may lower future infertility risks.
- Correction before puberty lowers future malignancy risk.

### COMPLICATIONS

- Testicular malignancy:
  - It is unclear whether lack of descent itself increases the malignancy risk or underlying intrinsic pathology is responsible for both.
  - Relative risk of malignancy is 2.75–8 (if uncorrected) (2):
    - Falls to 2–3 if surgically corrected before puberty (2)
  - Higher risk if bilateral UDT, abdominal location, abnormal karyotype, or coexistent endocrinopathy
  - Seminoma is the most common (70% of malignancies in uncorrected patients, 30% in corrected patients) malignancy.
  - Embryonal carcinoma, teratocarcinoma, and choriocarcinoma are also seen.
- Infertility:
  - Germ cell development in UDT begins to deteriorate after 1 yr of age.
  - Infertility risk increases with age.
  - Early surgical correction (between 3 and 12 mo of age) is important.
  - There is a lack of paternity in 10% of formerly cryptorchid males compared to 5% of controls (5).
- Surgical complications include postoperative edema, inflammation, and tension of the spermatic cord:
  - These can lead to ischemic injury and testicular atrophy.
- Testicular torsion is rare in cryptorchid patients but should be suspected in any male with acute abdominal pain and an empty ipsilateral hemiscrotum:
  - If suspicious for torsion, obtain an immediate US and/or urological or surgical consultation.

ICD9  
752.51 Undescended testis

## PEARLS AND PITFALLS

- Cryptorchidism is a very common developmental anomaly that may be found in the process of exam for unrelated complaints.
- Proper clinical exam with a relaxed patient is the key to diagnosis with an appropriate referral to pediatric urology or surgery.
- Imaging has little role in the diagnosis.
- Though rare, torsion of UDT constitutes a surgical emergency.

# CUSHING SYNDROME

Todd P. Chang

## BASICS

### DESCRIPTION

- Cushing syndrome (CS) is a constellation of signs and symptoms from excessive glucocorticoids, with typical cushingoid features, cardiovascular, hematologic, and endocrine effects.
- Cushingoid features include:
  - Facial fat deposition (moon facies)
  - Posterior neck fat deposition (buffalo hump)
  - Abdominal striae (stretch marks)
  - Truncal obesity with thin extremities
- Cushing disease refers to CS caused by a pituitary adenoma that produces excess adrenocorticotropic hormone (ACTH), which is the most common cause of CS in children  $\geq 5$  yr.

### EPIDEMIOLOGY

#### Incidence

- Pediatric CS is significantly more rare than adult-onset CS.
- Occurs in females more often than males
- Adrenocortical tumors account for most cases of CS in children  $< 7$  yr.
- Incidence has been reported to be 1–5% in patients of all ages with diabetes mellitus (DM) or HTN (1).

### RISK FACTORS

Chronic oral or IV glucocorticoid use for other underlying inflammatory conditions

### PATHOPHYSIOLOGY

- Excess hypercortisolemia causes characteristic changes to adipose tissue, hair follicles, and skin.
- Hypercortisolemia can come from abnormalities in any portion of the hypothalamus-pituitary-adrenal axis or from a purely exogenous source.

### ETIOLOGY

- Causes of CS are divided into ACTH dependent or ACTH independent:
- ACTH dependent:
  - Pituitary adenoma (Cushing disease)
  - Ectopic ACTH-producing tumor
- ACTH independent:
  - Exogenous glucocorticoid use or abuse is the most common cause of pediatric CS.
  - Adrenal adenoma or carcinoma: Beckwith-Weidemann syndrome
  - Primary adrenocortical hyperplasia:
    - Carney complex
    - Multiple endocrine neoplasia type 1
    - Primary pigmented adrenocortical disease, also known as micronodular adrenal disease
    - McCune-Albright syndrome
    - Macronodular adrenal hyperplasia

## DIAGNOSIS

### HISTORY

- Inquire about medication use.
- Weight gain and growth failure can occur insidiously over time and are more prevalent in infants and younger children.
- Facial and body fat changes
- Disproportionate skin pigmentation, increased sweating, or acne
- Headache, depression, emotional lability, or psychosis
- Muscle pain, frequent fractures
- Hirsutism, amenorrhea, virilization, and other pubertal disturbances may have occurred.

### PHYSICAL EXAM

- Elevated body mass index and poor growth: Children with CS are shorter than regular obese children (2).
- HTN
- Cushingoid features are almost always present in older children.
- Skin findings include acanthosis nigrans, generalized hyperpigmentation, hyperhidrosis, and striae:
  - Café-au-lait spots with distinct, jagged edges
  - “coast of Maine” are found with McCune-Albright syndrome
- Focal neurologic signs are rare but can suggest ischemia or infarct:
  - Papilledema may be present with associated pseudotumor cerebri.
- Evidence of inappropriate androgen activity, such as hirsutism, acne, body odor, and virilization may be seen in prepubertal children.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

- Lab tests are needed if the patient appears ill or toxic.
- With suspected sepsis, shock, or Addisonian crisis:
  - CBC may show lymphopenia despite elevated WBCs.
  - Chemistries may show hypernatremia and hypokalemia from mineralocorticoid effects.
  - Blood culture
  - Free cortisol level will be low or undetectable in crisis.
- Recommended nonemergent labs for CS include a workup for pituitary involvement:
  - Free  $T_4$
  - Thyroid-stimulating hormone
  - Prolactin
  - Luteinizing hormone
  - Follicle-stimulating hormone
  - Free testosterone
  - Androstenedione
  - Dehydroepiandrosterone sulfate (DHEA-S)
  - Beta-hCG

### Imaging

- Imaging is typically not done emergently.
- On plain films, bone age is typically delayed.
- CT or MRI of the abdomen can locate and differentiate an adrenocortical tumor or adrenal hyperplasia.
- MRI of the sella turcica can confirm a pituitary adenoma, though only half of microadenomas are visible by MRI (3).

### Diagnostic Procedures/Other

- ECG to evaluate for myocardial ischemia chest pain or if other suggestive symptoms exist
- An endocrinologist can confirm CS through a 24-hr urine cortisol screen, serial circadian cortisol levels, and/or dexamethasone suppression testing.

### DIFFERENTIAL DIAGNOSIS

- Obesity
- DM
- Hypothyroidism
- Polycystic ovarian syndrome

## TREATMENT

### PRE HOSPITAL

Assess the patient, and support airway, breathing, and circulation until hospital arrival.

### INITIAL STABILIZATION/THERAPY

- Check for signs of acute Addisonian crisis if a patient is under stress (infection, trauma, etc.).
- In a patient with CS who appears ill or toxic:
  - Crystalloid or colloid IV resuscitation as needed to maintain perfusion
  - Broad-spectrum antibiotic therapy
  - Vasopressors as necessary

### MEDICATION

#### First Line

- Hydrocortisone for Addisonian crisis: 1–2 mg/kg IV bolus, then 100 mg/m<sup>2</sup>/day divided or as an infusion. See Adrenal Insufficiency topic.
- Broad-spectrum antibiotic therapy:
  - Ceftriaxone 50 mg/kg IV q12h, adult max single dose 2,000 mg OR
  - Meropenem 20 mg/kg IV q8h, adult max single dose 1,000 mg OR
  - Piperacillin/Tazobactam 100 mg/kg IV q8h, adult max single dose 3,000 mg
  - Consider adding vancomycin 10 mg/kg IV q6h (adult max single dose 1,000 mg) if MRSA or if local antibiotic resistance of *Streptococcus pneumoniae* warrants.

**Second Line**

- Antihypertensive agents for uncontrolled hypertension (see Hypertension topic): Nicardipine (5 mg/kg/min IV, then titrated 1–3 mg/kg/min) has minimal risk of hypotension.
- Medications to lower serum cortisol levels such as bromocriptine or ketoconazole should be administered only under the guidance of a pediatric endocrinologist.

**SURGERY/OTHER PROCEDURES**

- Transphenoidal resection for pituitary adenoma
- Adrenalectomy(-ies) for adrenal causes
- Radiation may be useful for certain neoplasms.

**DISPOSITION****Admission Criteria**

- Admission should be considered in children with symptomatic HTN, toxic or septic appearance, or high suspicion of neoplasm.
- Critical care admission criteria:
  - Septic shock requiring significant fluid resuscitation (>60 mL/kg), pressors, or positive pressure ventilation

**Discharge Criteria**

- No evidence of acute addisonian crisis
- No symptomatic HTN

**Issues for Referral**

- Because pediatric CS differs in etiology and workup from adult CS, a pediatric endocrinologist is preferred to an adult endocrinologist.
- Most lab testing for CS takes a significant time to process; it may be beneficial to patient care to begin the lab workup in the emergency department for the endocrinologist follow-up.

**FOLLOW-UP****FOLLOW-UP RECOMMENDATIONS**

Discharge instructions and medications:

- Taper steroids as soon as possible.

**PROGNOSIS**

Untreated CS can lead to DM, HTN, dyslipidemia, and hypercoagulability in adults (4).

**COMPLICATIONS**

- Acute addisonian crisis
- Obesity
- Growth arrest
- Pubertal arrest
- Osteoporosis
- MI
- Cerebrovascular ischemia
- Sepsis and septic shock
- Pathologic and stress fractures
- DM and hyperosmolar coma

**CODES****ICD9**

255.0 Cushing's syndrome

**PEARLS AND PITFALLS**

- Consider corticosteroid use or abuse—either intentional or unintentional
- Consider a relative acute addisonian crisis in a patient who appears cushingoid
- CS in infancy is almost always associated with McCune-Albright syndrome.
- Obesity with growth failure warrants endocrinologic evaluation.

# CUTANEOUS LARVA MIGRANS

Craig A. McElderry

## BASICS

### DESCRIPTION

Cutaneous larva migrans (CLM) is an acquired dermatosis caused by infection with the infective larvae of various nematode parasites. It is one of the most common helminth (hookworm) infections acquired from subtropical and tropical regions of the world.

### EPIDEMIOLOGY

#### Incidence

- These small, round, blood-sucking worms infest ~700 million people worldwide each year.
- Rated 2nd to pinworms among helminth infections in developed countries
- The CLM parasite can be found in the southeastern and Gulf states of the U.S. and in the tropical countries of the Caribbean, South America, and Southeast Asia.

#### Prevalence

- Hookworm-related CLM is significantly more prevalent during rainy seasons (1).
- In 1 study of CLM in Brazil, the prevalence varied from 4.4% in the rainy season to 1.7% in the dry season (2).
- Most patients with hookworm-related CLM seen by health workers in developed countries are travelers returning from the tropics and subtropics (1).
- One study including 17,000 travelers who returned ill showed that hookworm-related CLM occurred in 2–3% of them, with the highest prevalence of the condition in those returning from Caribbean destinations, followed by Southeast Asia and Central America (1).

### RISK FACTORS

More common in children, gardeners, farmers, sunbathers, carpenters, and those whose hobbies or occupations involve contact with warm, moist, sandy soil contaminated with cat or dog feces

### GENERAL PREVENTION

- Avoid skin contact with moist soil contaminated with animal feces.
- Protective footwear should be worn at all times while walking on the beach.
- When lying on beaches frequented by cats and dogs, areas of sand washed by the tide are preferable to dry areas.
- Mattresses are preferable to towels.

### PATHOPHYSIOLOGY

- The life cycle of the parasites begins when eggs are passed from animal feces into warm, moist, sandy soil, where the larvae hatch. After two molts in the soil, larvae become infective. By using their proteases, larvae penetrate through follicles, fissures, or intact skin of the new host.
- In their natural animal hosts, the larvae are able to penetrate into the dermis and are transported via the lymphatic and venous systems to the lungs. They break through into the alveoli and migrate to the trachea, where they are swallowed. In the intestine, they mature sexually, and the cycle begins again as their eggs are excreted.
- Humans are accidental hosts. The larvae lack the collagenase enzymes required to penetrate the basement membrane to invade the dermis and thus are confined to the skin. There, they are unable to complete their life cycle, as they would do in cats and dogs.
- Rarely, in infections with a large burden of parasites, pneumonitis (Löeffler syndrome) and myositis may follow skin lesions.
- Occasionally, the larvae reach the intestine and may cause an eosinophilic enteritis.

### ETIOLOGY

- Infective larvae of cat and dog hookworms:
  - *Ancylostoma braziliense*, found in the central and southern U.S., Central America, South America, and the Caribbean
  - *Ancylostoma caninum*, found in Australia
  - *Uncinaria stenocephala*, found in Europe
- Other skin-penetrating nematodes are less common causes.

## DIAGNOSIS

### HISTORY

- Tingling/prickling at the site of exposure within 30 min of penetration of larvae
- Intense pruritis (98–100% of patients) (3)
- Erythematous, slightly elevated, linear track that moves forward in an irregular pattern
- Often associated with a history of sunbathing, walking barefoot on the beach, or similar activity in a tropical location

### PHYSICAL EXAM

- Pruritic, erythematous, edematous papules and/or vesicles with serous fluid
- Serpiginous (snakelike), slightly elevated, erythematous tunnels that are 2–3 mm wide and track 3–4 cm from the penetration site
- “Creeping dermatitis”
- Bullae
- Secondary impetiginization
- Most frequent anatomic locations of CLM lesions are on the feet in >50% of individuals, followed by buttock and thigh (3).
- Tract advancement of several millimeters to a few centimeters a day

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

- Labs are generally not necessary.
- Some patients may develop a peripheral eosinophilia and elevated levels of IgE.

#### Diagnostic Procedures/Other

Biopsy may be considered, but this rarely identifies the parasites since the anterior end of the track does not necessarily indicate the location of the larvae (1).

#### Pathological Findings

May show a larva (periodic acid-Schiff positive) in a suprabasilar burrow, basal layer tracts, spongiosis with intraepidermal vesicles, necrotic keratinocytes, and an epidermal and upper dermal chronic inflammatory infiltrate with many eosinophils

### DIFFERENTIAL DIAGNOSIS

Most of the following can be ruled out with a good clinical history of recent exposure to moist sand frequented by cats or dogs and physical exam findings of intensely pruritic, serpiginous lesions that advance:

- Impetigo
- Tinea pedis
- Photoallergic dermatitis
- Scabies
- Cercarial dermatitis (schistosomiasis)
- Allergic contact dermatitis
- Epidermal dermatophytosis
- Migratory myiasis
- Larva currens caused by *Strongyloides stercoralis*
- Erythema migrans of Lyme borreliosis

## TREATMENT

The condition is benign and self-limited but can cause severe pruritus. The intense pruritus and risk for infection often mandate treatment.

### MEDICATION

#### First Line

- The drug of choice is ivermectin. A single dose (200  $\mu$ g per kg of body weight) kills the migrating larva effectively and relieves itching quickly (2–4).
- Cure rates after a single dosage range from 77–100%.
- Contraindicated in children who weigh <15 kg (or <5 yr of age) and in pregnant and breast-feeding women
- Off-label use in children has been shown to be safe.

#### Second Line

- Albendazole 400–800 mg/day (according to weight) for 3 days (1,3,4); for children <2 yr, 200 mg/day for 3 days and repeat in 3 wk, if necessary
- Topical thiabendazole (thiabendazole) in a concentration of 10–15% t.i.d. for 5–7 days is as effective as oral treatment with ivermectin (1).
- Antistaphylococcal/Streptococcal antibiotics for secondary bacterial infections/impetiginization:
  - Cephalexin 25–100 mg/kg/day divided q6–8h, max dose 4 g/day
  - Clindamycin 10–30 mg/kg/day divided q6–8h, max dose 1.8 g/day

#### Additional Therapies

As an alternative therapy, liquid nitrogen cryotherapy can be applied to the progressive end of the larval burrow. This is considered obsolete by some since it is painful, ineffective, and may cause ulcerations (1).

### DISPOSITION

Generally treated on an outpatient basis

#### Admission Criteria

Consider admission for severe secondary infections not adequately treated with oral antibiotics.

## FOLLOW-UP

### PROGNOSIS

The prognosis is excellent. Hookworm-related CLM is a self-limiting disease. Human beings are accidental hosts, with the larva dying and the lesions resolving within 4–8 wk. Rarely, the disease can last for years.

### COMPLICATIONS

- Secondary infections
- Allergic reactions
- Erythema multiforme

### CODES

#### ICD9

126.9 Ancylostomiasis and necatoriasis, unspecified

## PEARLS AND PITFALLS

- Clinical diagnosis based on history of contact with warm, moist sand and physical findings of pruritic, serpiginous erythematous tunnels that advance
- Though a self-limited disease, the intense pruritus often mandates treatment.
- The best way to prevent CLM is to wear protective footwear at all times while on the beach.

# CYANOSIS

Marsha Ayzen Elkhunovich  
Joshua Nagler

## BASICS

### DESCRIPTION

- Cyanosis is a blue tint of the skin and mucous membranes that appears to be due to deoxygenated blood near the skin surface.
- Cyanosis becomes apparent when the amount of deoxygenated hemoglobin (Hgb) is  $>5$  g/dL.
- Central cyanosis is defined by blue discoloration of the skin and mucous membranes (particularly lips, mouth, head, and torso).
- Peripheral or acrocyanosis is a bluish tint of the skin of the distal extremities and around the lips, which may be a normal finding in neonates.
- Causes of cyanosis range from benign and transient (eg, breath-holding spell) to severe and life threatening (eg, congenital heart disease [CHD]). For specific details of the various etiologies, please see the respective topics in this textbook.
- Cyanosis can be acute or long-standing, transient or persistent, depending on its etiology.

### EPIDEMIOLOGY

#### Incidence

The incidence of cyanotic CHD is 0.1%, though with current prenatal screening, few of these children initially present in the emergency department (1).

### RISK FACTORS

- There are risk factors for specific conditions that cause cyanosis. Some of these include:
  - Advanced maternal age and gestational diabetes for CHD
  - Prematurity for chronic lung disease (CLD), apnea and asthma
  - Cerebral palsy/developmental delay for aspiration pneumonias, seizures, and central apnea
- Polycythemia will make patients appear cyanotic at a normal oxygen saturation even though they are not hypoxemic.

### PATHOPHYSIOLOGY

- Central cyanosis is usually a manifestation of hypoxemia, which appears when the amount of unsaturated Hgb is  $>5$  g/dL, which at normal Hgb levels corresponds to 73–78% (2).
  - Such hypoxemia may result from:
    - Inadequate oxygen intake
    - Poor oxygen absorption from the lungs to the circulation
    - Intracardiac or intrapulmonary shunting, which causes some blood to bypass oxygenation in the lungs
- Methemoglobinemia may manifest as central cyanosis but is not a result of hypoxemia. See Methemoglobinemia topic. Sulfhemoglobinemia is very rare dyshemoglobinemia that results in cyanosis without hypoxemia.

### ETIOLOGY

- Respiratory:
  - High altitude or any other reason for decreased amount of inspired oxygen
  - Neurologic causes of respiratory depression:
    - Apnea of prematurity, central apnea, seizure, breath-holding, respiratory depression due to medication or toxin (eg, morphine, alcohol, etc.), increased intracranial pressure
  - Restrictive lung process:
    - External compression, pneumothorax, hemothorax, pleural effusion or empyema, mediastinal or lung mass, flail chest, congenital diaphragmatic hernia, diaphragmatic paralysis, congenital cystic adenomatoid malformation, pulmonary sequestration, congenital lobar emphysema
    - Neuromuscular disease such as spinal muscular atrophy, botulism, Guillain-Barré syndrome, transient myelitis, muscular dystrophy
  - Obstructive lung process:
    - Asthma, bronchiolitis, croup, pertussis, foreign body aspiration, epiglottitis, tracheitis, laryngomalacia, tracheomalacia, anaphylaxis
    - Congenital obstruction secondary to a mass, choanal atresia, Pierre Robin and other structural abnormalities
    - Vocal cord paralysis, tracheostomy obstruction, hemorrhage
  - Diffusion abnormalities across the alveolar-capillary wall:
    - CLD or bronchopulmonary dysplasia
    - Surfactant deficiency, acute respiratory distress syndrome, cystic fibrosis, pneumonia, acute chest syndrome in sickle cell anemia, pulmonary hemorrhage/edema
- Cardiovascular:
  - Cardiac:
    - Cardiogenic shock, CHF, pulmonary HTN, persistent pulmonary HTN of the newborn
    - Congenital cyanotic heart disease:
      - Atrioventricular canal defect, Ebstein anomaly, hypoplastic left heart syndrome, pulmonary atresia/severe stenosis, tetralogy of Fallot, total anomalous pulmonary venous return, transposition of the great arteries, tricuspid atresia, truncus arteriosus, severe aortic coarctation may cause cyanosis in the lower extremities
  - Vascular:
    - Acrocyanosis of the newborn, cold exposure, Raynaud syndrome (if only affecting fingers and toes), pulmonary embolism (PE), septic shock
- Other:
  - Methemoglobinemia:
    - Congenital hemoglobin M or abnormalities in methemoglobin reductase
    - Exposure to toxins/drugs such as quinines, benzocaine, sulfonamide antibiotics

## DIAGNOSIS

### HISTORY

- Acute or chronic/recurrent (duration of symptoms)
- Birth history (eg, gestational age, problems with delivery, neonatal ICU stay, group B streptococcus status, mechanical ventilation, etc.)
- History of underlying conditions/surgeries
- History of aspiration
- Respiratory distress
- Problems feeding, sweating with feeds
- History of possible ingestions/exposures
- Current medications
- Systemic symptoms: Fevers, rash, etc.
- Neurologic symptoms: Weakness, difficulty with movements
- Family history
- Allergies

### PHYSICAL EXAM

- Vital signs:
  - Tachypnea will be most commonly present:
    - If tachypnea is not present and the patient is hypoxemic, assess for apnea or fatigue and impending respiratory failure.
    - Patients with long-standing cyanosis may not appear in distress but will have a mild baseline tachypnea.
  - Tachycardia will be commonly present.
  - Fever can point to infectious causes such as pneumonia, epiglottitis, etc.
  - Hypotension can be present with septic or cardiogenic shock.
- Skin exam: Distinguish between central and peripheral cyanosis:
  - If peripheral, is it distributed equally on the upper and lower extremities? (Infants with coarctation of the aorta and an open patent ductus arteriosus [PDA] may have cyanosis in just the lower extremities.)
- HEENT exam looking for evidence of choanal atresia, features of craniofacial abnormalities
- Respiratory exam:
  - Tracheal deviation
  - Diaphragmatic excursion
  - Stridor
  - Increased respiratory effort including grunting, flaring, or retractions
  - Wheezing, crackles, or rales
  - Egophony
  - Assessment of tracheostomy, if present
- Cardiac exam:
  - Evidence of heave, lift, or thrill
  - Evaluation of heart sounds with splitting
  - Presence of murmur
  - Check for pulses and presence of radiofemoral delay
- Neurologic exam: Thorough exam including an assessment for decreased strength or tone and deep tendon reflexes

**DIAGNOSTIC TESTS & INTERPRETATION**

- The most important initial test is a pulse oximetry (SpO<sub>2</sub>) reading, which serves as a noninvasive surrogate of blood gas oxygenation:
  - SpO<sub>2</sub> may be falsely high when forms of Hgb are present other than oxyhemoglobin and deoxyhemoglobin.
  - SpO<sub>2</sub> may be falsely low when the patient's circulation to the extremities is inadequate because of cold, shock, etc.
- Transient cyanosis that has resolved, with a normal SpO<sub>2</sub> reading, may not require further evaluation.

**Lab**

**Initial Lab Tests**

- A blood gas analysis should be obtained. In many cases, venous blood gas sampling will be adequate, but arterial blood gas provides more information about both oxygenation and ventilation:
  - PaO<sub>2</sub> <80 mm Hg on room air confirms hypoxemia.
- The following tests are indicated selectively:
  - Hgb level if concerned about anemia or polycythemia
  - In infants and patients with lethargy or sepsis, consider a capillary blood glucose measurement.
  - If concerned about sepsis, obtain CBC, disseminated intravascular coagulation panel, and appropriate cultures.
  - If methemoglobinemia, consider blood co-oximetry.
  - If drug ingestion, consider basic metabolic panel and toxicology screen.

**Imaging**

- Chest radiograph to assess for pneumonia, lung parenchymal abnormality, effusion, foreign body aspiration, pneumothorax, widened mediastinum, or enlarged cardiac silhouette
- Chest CT if concerned for a lung mass, pulmonary hemorrhage, or PE (CT angiography).
- Consider echo for concern of CHD.

**Diagnostic Procedures/Other**

- ECG
- Consider a hyperoxia test to distinguish between cardiac and respiratory causes. See Cyanotic Heart Disease topic, Diagnostic Procedures/Other.

**DIFFERENTIAL DIAGNOSIS**

- See Etiology.
- Some conditions can be confused with cyanosis:
  - Polycythemia can be mistaken for cyanosis.
  - The blue dye of clothing can cause an appearance of cyanosis.
  - Large pigmentary lesions such as Mongolian spots may be confused for cyanosis.
  - Amiodarone therapy or silver ingestion can cause a bluish tint to the upper body.

**TREATMENT**

**PRE HOSPITAL**

- Assess and stabilize airway, breathing, and circulation.
- Regularly reassess ABCs.
- Administer supplemental oxygen unless contraindicated.

**INITIAL STABILIZATION/THERAPY**

- Assess and stabilize airway, breathing, and circulation.
- Administer supplemental oxygen as needed to correct low oxygen saturation and improve cyanosis.
- If the ABCs are secure, the SpO<sub>2</sub> reading is normal, and the patient is in no distress, further treatment may proceed judiciously.

**ALERT**

In infants in whom heart disease is suspected, avoid administration of 100% oxygen during the resuscitation, as it can induce closure of the PDA in neonates and cause overcirculation in the lungs in older infants. These patients require only enough supplemental oxygen delivery to achieve adequate oxygenation (3). Examples of ductal-dependent lesions are (see Patent Ductus Arteriosus):

- Tricuspid atresia
- Pulmonary atresia
- Transposition of the great arteries
- Mitral valve atresia with hypoplastic left ventricle
- Aortic valve atresia
- Pulmonary artery hypoplasia
- Severe coarctation of the aorta

**MEDICATION**

- Choice of medications will depend on the etiology of cyanosis, for example:
  - Status asthmaticus requires bronchodilator therapy such as albuterol.
  - Seizures require antiepileptic medications, often benzodiazepines acutely.
  - If cyanotic CHD is suspected in a neonate, an IV infusion of prostaglandin E2 may be required emergently.
- See specific topics for recommended treatment for other diagnoses.

**SURGERY/OTHER PROCEDURES**

- Dependent on the etiology of cyanosis:
  - Intubation or even an emergent tracheostomy may be necessary for respiratory failure.
  - Tracheostomy management: Suctioning or changing the tube if necessary
  - Thoracentesis or thoracostomy for pleural effusion or pneumothorax
  - Laryngoscopy and bronchoscopy for foreign body aspiration
- See specific topics for recommended treatment for other diagnoses.

**DISPOSITION**

**Admission Criteria**

- Any patient who presents with acute, unresolved cyanosis will require admission to the hospital.
- Critical care admission criteria:
  - Any patient requiring ventilatory support
  - Impending cardiac or respiratory failure
  - Any infant requiring prostaglandin E2 infusion

**Issues for Referral**

Consultation from the emergency department should be done as necessary. Outpatient follow-up may be scheduled after consultation:

- Cardiology for CHD
- Pulmonology for chronic lung conditions
- Toxicology for ingestions or drug overdoses
- Neurosurgery for cases of suspected increased intracranial pressure
- Otorhinolaryngology for airway obstruction
- Surgery for thoracic masses, flail chest, etc.
- Neurology for seizures, suspected central apnea, and severe breath-holding spells. The latter two may be manifestations of seizures and may require EEG testing.

**FOLLOW-UP**

**FOLLOW-UP RECOMMENDATIONS**

As noted in the Issues for Referral section

**COMPLICATIONS**

Patients who experience a prolonged episode of hypoxemia may have end-organ damage including the kidney, liver, and/or brain.

**CODES**

**ICD9**

- 770.83 Cyanotic attacks of newborn
- 782.5 Cyanosis

**PEARLS AND PITFALLS**

- Pearls:
  - Cyanosis is not a direct correlate of oxygen saturation and depends on the absolute Hgb level.
  - In patients with anemia, cyanosis will be apparent at much lower oxygen saturation levels than with a normal or high Hgb concentration.
- Pitfalls:
  - Overoxygenation of neonatal patients with ductal-dependent lesions and older patients with heart disease

# CYANOTIC HEART DISEASE

Calvin G. Lowe

## BASICS

### DESCRIPTION

- Varying degrees of deoxygenated venous blood shunting from the right (R) to left (L) side of the heart or circulation occurs in cyanotic heart disease (CyHD).
- Cyanosis occurs when  $>5$  mg/dL of deoxygenated blood is in the capillary beds.

### EPIDEMIOLOGY

#### Incidence

In 2005, the CDC reported that CyHD occurred in 56.9 per 100,000 live births in the U.S.

#### Prevalence

CyHD accounts for  $\sim 25\%$  of all congenital heart disease (CHD).

### RISK FACTORS

Maternal risk factors:

- Infection (rubella)
- Medication use (eg, anticonvulsants, lithium)
- Drug abuse (ethanol)
- Disease states (phenylketonuria, systemic lupus erythematosus, diabetes mellitus)

### GENERAL PREVENTION

Adequate prenatal care: Prenatal US can diagnose CyHD in utero. After delivery, transport to an appropriate tertiary care center is warranted.

### PATHOPHYSIOLOGY

- Tetralogy of Fallot (TOF):
  - 4 basic lesions:
    - Ventricular septal defect (VSD)
    - R ventricular outflow obstruction from pulmonary stenosis (PS)
    - Overriding aorta
    - R ventricular hypertrophy =  $\downarrow$  pulmonary flow resulting in R to L shunting.
  - “Pink” TOF: Mild PS and L to R shunting
  - TOF hypercyanotic spells or “Tet spells”:
    - Agitated patient has extreme cyanosis in situations with  $\uparrow$  sympathetic activity.
    - R ventricular outflow tract obstruction worsens with infundibular septum spasms.
    - Tet spells may cause end-organ damage, are unpredictable, and potentially are lethal.
- Transposition of the great arteries (TGA):
  - The aorta originates from the R ventricle, and the main pulmonary artery (PA) arises from the L ventricle.
  - A patent ductus arteriosus (PDA), atrial septal defect (ASD), or VSD is critical for survival and allows mixing of the 2 systems to move oxygenated blood to the systemic system.
- Total anomalous pulmonary venous return (TAPVR):
  - Pulmonary veins return oxygenated blood from the lungs to the right atrium (RA).
  - An ASD or patent foramen ovale is needed to cause mixing and shunting of blood to the L side of the heart for survival.
- Tricuspid atresia (TA):
  - Atresia of the tricuspid valve causes the R ventricle to be hypoplastic or absent.
  - The RA will become hypertrophied.
  - An ASD, VSD, or PDA is critical to survival.
  - R to L shunting occurs to drain the RA.
- Truncus arteriosus (TrA): Failure of separation of the aorta and PA leads to a single arterial trunk arising from both ventricles:

- The lone arterial trunk sits over a large VSD.
- $\downarrow$  Pulmonary vascular resistance (PVR) and  $\uparrow$  blood flow indicate pulmonary HTN.
- Hypoplastic left heart syndrome (HLHS):
  - Hypoplasia of the L ventricle
  - Hypoplastic aortic arch
  - Aortic and mitral valvular stenosis
- Ebstein anomaly:
  - Tricuspid valve leaflets are abnormally attached to its annulus.
  - An enlarged RA and smaller R ventricle = R to L shunting and  $\downarrow$  pulmonary blood flow.

### ETIOLOGY

- Exact cause of CyHD is unknown.
- Factors associated with an increased risk of CyHD: Maternal risk factors, chromosomal abnormalities, and single gene defects
- A multifactorial etiology is the theoretical basis for most forms of CyHD.

### COMMONLY ASSOCIATED CONDITIONS

- DiGeorge syndrome: TA, TOF
- Noonan syndrome: Supravalvular (SV) PS
- Williams syndrome: SV aortic stenosis, pulmonary artery stenosis

## DIAGNOSIS

### HISTORY

- Not all CyHD is clinically evident at birth.
- Presence of a PDA can mask severe pulmonary or systemic flow obstruction.
- Presentation in 1st 2 wk of life: AS, HLHS, TGA, TAPVR, TA, and TrA
- Presentation within the 1st mo: TrA
- Presentation within 6 wk to 6 mo: TrA
- Patients can be stable, in CHF, or in shock.
- The most common presentations are acute respiratory distress and cyanotic episodes.
- Signs of CHF (fatigue, poor appetite and diaphoresis during feeding, pallor, tachypnea, tachycardia), failure to thrive, irritability, dehydration, and recurrent lung infections are common signs and symptoms.
- CHF is due to lesions that cause  $\uparrow$  pulmonary flow: TGA, TOF, TA, HLHS, and TAPVR.

### PHYSICAL EXAM

- Evaluation of general appearance and color is the most important part of the exam.
- Pink color = CyHD (“pink Tet”), L to R shunt.
- Blue color typically = CyHD with R to L shunt.
- Grey color indicates outflow obstruction, systemic hypoperfusion, and shock.
- Tachycardia and tachypnea may be out of proportion to the patient’s general appearance.
- Cool skin and delayed capillary refill indicates shock associated with severe cardiac disease.
- $\downarrow$  Distal pulses imply aortic arch obstruction.
- Hydration status, mucosal color, and lung/heart sounds should be assessed along with palpation of the precordium and a survey for organomegaly.
- Heart murmurs with or without thrills and gallop rhythms suggest CyHD.
- CHF: Tachypnea, hyperactive precordium, S3 heart sound, chest congestion, and hepatomegaly

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

- Serum electrolytes, calcium, glucose, and CBC:
  - Electrolyte abnormalities ( $\downarrow$  sodium, chloride) can occur.
  - $\downarrow$  Calcium can present as prolongation of the QT interval, CHF, hypotension.
  - Hypoglycemia can cause weakness and fatigue.
  - Depending on the heart lesion, polycythemia (from chronic hypoxemia) or anemia (dilutional effects) can be present.
- An arterial blood gas sample can determine the degree of hypoxemia and metabolic acidosis.

#### Imaging

- Chest radiographic imaging is essential.
- Various degrees of ventricular hypertrophy and pulmonary congestion depend on CyHD type:
  - A “boot-shaped” heart is seen in TOF.
  - “Snowman or “figure of 8” sign = TAPVR.
  - “Egg on a string” sign = TGA.

#### Diagnostic Procedures/Other

- An echo should be performed on patients suspected of having CyHD.
- A 12-lead ECG should be obtained. Depending on the lesion, the ECG may show various arrhythmias, hypertrophy, R or L axis deviations, and bundle branch blocks.
- A hyperoxia test can differentiate between cyanotic cardiac and pulmonary disease:
  - A baseline R radial artery (preductal) blood gas sample is obtained on room air.
  - A 2nd blood gas is obtained after a 10-min administration of 100% oxygen ( $O_2$ ).
  - A  $PaO_2 > 200$  mm Hg on 100%  $O_2$  makes cyanotic CHD unlikely.
  - A  $PaO_2 < 150$  mm Hg on 100%  $O_2$  suggests CyHD with complete mixing without pulmonary blood flow restriction.
  - A  $PaO_2 < 50$  mm Hg indicates a mixing lesion with restrictive pulmonary blood flow.

### DIFFERENTIAL DIAGNOSIS

- In neonates, sepsis must be suspected prior to a definitive diagnosis of CyHD.
- Tracheal or bronchial foreign body
- Congenital anomalies: Vascular malformations, hypoplastic mandible
- Apparent life-threatening event
- Pneumonia/Empyema/Effusion
- Pulmonary edema
- Diaphragmatic hernia
- Congenital pulmonary hypoplasia
- Breath-holding
- Methemoglobinemia

## TREATMENT

A pediatric cardiologist should be consulted for evaluation and treatment recommendations.

### INITIAL STABILIZATION/THERAPY

- Immediate evaluation and treatment of the ABCs and continuous pulse oximetry is crucial:
  - Administer O<sub>2</sub> judiciously.
  - Establish IV access: > 1 site is suggested.
- Small, frequent IV boluses of normal saline or lactated Ringer solution of 10 cc/kg are indicated to treat hypotension.
- A full sepsis evaluation should be initiated and antibiotics administered empirically in infants <2–3 mo of age who are exhibiting signs and symptoms of sepsis: Fever >38.0°C, irritability, respiratory distress, lethargy:
  - Caution must be used when considering lumbar puncture in a cyanotic child.

### MEDICATION

#### First Line

Prostaglandin (PGE<sub>1</sub>) should be initiated on patients with a ductal-dependent CyHD:

- 0.05–0.1 μg/kg/min should be initiated with a max rate of 0.4 μg/kg/min.
- A common side effect of PGE<sub>1</sub> is apnea; prompt intubation may be necessary.
- Elective intubation of patients on PGE<sub>1</sub> for transport may increase the risk of transport complications (1).
- Other occurrences associated with PGE<sub>1</sub> include hyperthermia, flushing, arrhythmias, hypotension, and seizures.

#### Second Line

- A child with signs or symptoms of CHF may benefit from furosemide at 0.5–1 mg/kg. If a urine output of 3–5 cc/kg/hr is not achieved within 1–2 hr after the 1st dose of furosemide, repeat doses of 1 mg/kg can be given at hourly intervals to a max of 3–5 mg/kg.
- If hypotension persists after IV fluid boluses, dopamine should be initiated at 5 μg/kg/min and titrated up to a max rate of 20 μg/kg/min.
- Dobutamine can be added for inotropic support with an initial rate of 5 μg/kg/min with titration to a max rate of 20 μg/mg/min.
- Tet spell treatment includes several options:
  - O<sub>2</sub> reduces hypoxemia and decreases PVR.
  - Calming the child decreases PVR.
  - IV fluids provides volume resuscitation.
  - Knee-chest position: ↓ Venous return, ↑ systemic vasculature resistance (SVR)
  - Morphine sulfate 0.1–0.2 mg/kg SC/IM/IV ↓ venous return, ↓ PVR, relaxes infundibulum
  - Phenylephrine 0.02 mg/kg IV increases SVR
  - Propranolol 0.15–0.25 mg/kg, slow IV push decreases inotropic effect and may ↓ SVR.
  - Sodium bicarbonate (1 mEq/kg IV) reduces metabolic acidosis.

### SURGERY/OTHER PROCEDURES

- Surgical options are lesion specific for CyHD.
- Atrial septostomy creates intra-atrial mixing between atria in TGA and TA.
- Modified Blalock-Taussig (BT) shunt: Artificial tubing sewn between the subclavian or carotid artery to the corresponding side branch PA.
- Similarly, the Sano shunt redirects blood directly from the R ventricle to the PA.
- The Glenn shunt: Superior vena cava (SVC) to PA shunt for infants with ↓ pulmonary resistance
- The Fontan procedure used in HLHS and TA: Anastomosis of SVC to R PA along with the anastomosis of the RA and/or IVC to the PAs
- Norwood procedure: 2-stage HLHS repair:
  - Stage 1: Proximal main PA to the aorta and a modified right BT shunt or Sano shunt to ↑ pulmonary blood flow.
  - An ASD is also created to allow L to R flow.
  - Stage 2: Bidirectional Glenn to reduce the volume overload of the single R ventricle.
  - Fontan procedure follows to correct cyanosis.
- Arterial switch of Jantene: TGA repair

### DISPOSITION

#### Admission Criteria

- Inpatient floor admission criteria:
  - ↑ O<sub>2</sub> requirement, acute respiratory distress, worsening CHF unresponsive to emergency department therapy or confirmed/symptomatic respiratory syncytial virus
- Critical care admission criteria:
  - Any patient who is intubated and/or requiring vasopressor support should be admitted to a pediatric ICU.
  - The decision to admit should be made in conjunction with a pediatric cardiologist.

#### Discharge Criteria

- Patients may be discharged home with follow-up if deemed stable by pediatric cardiology.
- A TOF patient with a Tet spell that is corrected without pharmacologic intervention may be considered for discharge directly from the emergency department.

#### Issues for Referral

- Transfer to a tertiary care center if needed.
- A specialized pediatric critical care transport team may be necessary to facilitate the transport.

## FOLLOW-UP

### FOLLOW-UP RECOMMENDATIONS

Discharge instructions and medications:

- Parents must be instructed to look for any worsening signs and symptoms of the CyHD.
- Discharge medications should be based upon pediatric cardiology recommendations.
- Cardiology follow-up should be arranged.

### DIET

Diet may include fluid and salt restrictions based upon pediatric cardiology suggestions.

### PROGNOSIS

Prognosis is based on the patient's initial acuity, CyHD type, and need for surgical treatment.

### COMPLICATIONS

- Without immediate treatment, anoxic brain injury, severe metabolic acidosis, multiple organ failure, and cardiopulmonary arrest may ensue.
- CyHD is associated with brain abscesses.

### ICD9

- 745.2 Tetralogy of fallot
- 745.4 Ventricular septal defect
- 746.9 Unspecified congenital anomaly of heart

### PEARLS AND PITFALLS

- HLHS patients can present with ↑ pulmonary blood flow at the expense of systemic blood flow.
- Therefore, the O<sub>2</sub> saturation will be >90%, but peripheral perfusion and pulses will be decreased.
- These patients should not be given supplemental O<sub>2</sub> but should be on room air since hypoxemia is a potent pulmonary vasoconstrictor.
- Hyperoxia testing requires blood sampling; an attempt to use a pulse oximetry reading on the right hand may give a falsely reassuring reading.

# CYCLIC VOMITING

Richard G. Boles

## BASICS

### DESCRIPTION

- A cyclic vomiting pattern is defined as the presence of multiple stereotypical episodes of nausea and vomiting separated by intervals without these symptoms:
  - Some patients, particularly adolescents and adults, have lesser degrees of nausea between episodes.
- ~90% of patients with a cyclic vomiting pattern do not have an alternative definable diagnosis (see Differential Diagnosis) and are given the diagnosis of cyclic vomiting syndrome (CVS) (1).

### EPIDEMIOLOGY

#### Prevalence

CVS was present in 2% of school-age children in 2 studies conducted in Australia (2) and Scotland (3):

- CVS is likely less common in non-European-derived populations.

### PATHOPHYSIOLOGY

- CVS is a “functional” disorder of multifactorial pathogenesis, related to migraine and irritable bowel syndrome (4,5):
  - Many consider CVS to be a migraine variant.
- CVS and the associated functional disorders are associated with abnormal autonomic nervous system function.
- In many cases, these same disorders are associated with mitochondrial dysfunction (4–6):
  - Some cases have frank mitochondrial disease.
  - Clinical manifestations are generally intermittent and typically occur at times of high-energy demand, including fasting, viral infection, overexercise, psychological stress, and environmental temperature extremes.

### ETIOLOGY

- Unknown in most cases but presumably multifactorial
- Many cases have mutations in the maternally inherited mitochondrial DNA (mtDNA), usually mutations not assayed by standard mtDNA screening tests (5,6):
  - In many cases, maternal-side relatives who share the same mtDNA sequence are affected with a variety of dysautonomic, functional, and psychiatric conditions (4,5).

## DIAGNOSIS

### HISTORY

- Within each patient, episodes are stereotypical (similar).
- Associated findings during episodes include:
  - Nausea
  - Vomiting
  - Lethargy
- Other findings that may be present include:
  - Abdominal pain
  - Diarrhea
  - Fever
  - Headache
  - Photophobia and/or phonophobia

- ~50% of patients have “cyclical” episodes at regular intervals, and the others have episodes triggered by stressors, or apparently at random.
- The duration of episodes varies from a few hours to several days, with a median of 2 days.
- The frequency of episodes varies from every several months to twice a week, with a median of 1 mo.
- The age of onset varies from neonates into adulthood, with a median of 4 yr for those presenting to pediatricians.
- CVS is frequently associated with other functional disorders such as:
  - Migraine headache
  - Irritable bowel syndrome
  - Other chronic pain syndromes
  - Chronic fatigue syndrome
  - GERD
  - Postural orthostatic tachycardia syndrome
  - Depression (unipolar or bipolar)
  - Anxiety disorder
- ~1/3 of cases have chronic neuromuscular disease (termed as CVS+), including:
  - Mental retardation
  - Seizure disorders
  - Hypotonia
  - Autistic spectrum disorders

### PHYSICAL EXAM

- Between episodes:
  - Usually normal
  - May have subtle signs of a skeletal myopathy
  - A minority of cases have findings related to  $\geq 1$  comorbid disorders listed in the History section.
- During episodes:
  - Acute distress with lethargy
  - Often with abdominal pain, with or without tenderness
  - Occasionally with fever, diarrhea, photophobia and/or phonophobia

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

- If done, standard lab testing will be normal between episodes in almost all cases.
- Lab abnormalities are common during vomiting episodes, as reflected below.

#### Initial Lab Tests

- Chemistry panel: Anion gap metabolic acidosis
- Urine dipstick: Ketosis (at onset of episode)
- ALT, GGT, lipase: Rule out potential non-CVS etiologies:
  - Mild elevations, up to about twice the upper limit of the normal range, in transaminases are common in CVS.
  - Pancreatitis can coexist with CVS.
- Beta-hCG in the appropriate setting
- Quantitative urine organic acids should be performed at least once early in an episode for potential mitochondrial disease and organic acidemias.
- Quantitative plasma amino acids should be performed at least once early in an episode for potential urea cycle defects.

### Imaging

Imaging is not helpful to diagnose CVS but is used to exclude other emergent diagnoses, if indicated:

- Upper GI series with small bowel follow-through to rule out etiologies such as malrotation should be performed at least once (5).
- Abdominal/Renal US to rule out non-CVS etiologies should be performed at least once.
- Brain imaging to rule out non-CVS etiology in cases with altered mental status or abnormal neurologic findings (5)

### DIFFERENTIAL DIAGNOSIS

- The differential includes the broad differential diagnoses of vomiting, which can be found in the Vomiting topic.
- Malrotation
- Unilateral ureteral obstruction
- Pancreatitis (but can be comorbid with CVS)
- Intracranial mass
- Ornithine transcarbamylase deficiency:
  - Other urea cycle disorders
- Organic acidemias
- Fatty acid oxidation disorders
- Congenital defects of glycosylation
- Pregnancy
- Marijuana cyclical emesis
- Fictitious disorder (unlikely)

### ALERT

- New neurologic findings should prompt additional workup for a metabolic disorder and/or intracranial mass (7).
- Acute abdomen or abdominal pain worse than usual for that patient should prompt workup for a surgical cause, especially malrotation (7).

## TREATMENT

Avoid fasting by administration of calories, including fruit juices, chocolate milk, etc.

### INITIAL STABILIZATION/THERAPY

- IV normal saline bolus if dehydrated
- IV fluids with 10% dextrose 0.45% normal saline at a high rate of 1.5–2 times maintenance:
  - Reduce glucose content if glucose  $>250$ – $300$  mg/dL; hyperglycemia triggers insulin, resulting in mitochondrial anabolism.
- Darkened and quiet room

**MEDICATION**

Acute treatment (7):

- Ondansetron for nausea/vomiting at 0.3–0.4 mg/kg/dose (adult dose 12–16 mg) given by standard routes (IV or oral dissolving tablet):
  - Patients do not generally respond to the lower doses but usually respond to higher doses.
- Some cases respond to triptan therapy if caught early:
  - Sumatriptan (Imitrex):
    - Intranasal: 5-, 10-, or 20-mg spray in 1 nostril for adolescents; may repeat in 2 hr, max dose 40 mg/day
    - SC: <30 kg, 3 mg; >30 kg, 6 mg; may be repeated once in 1 hr
- Sedation with lorazepam or diphenhydramine (possibly with a phenothiazine) for comfort in cases not responding to D10-containing IV fluids and ondansetron:
  - Start with lower dosages and observe, as patients with CVS have a high incidence of side effects from sedation.
  - Lorazepam 0.05 mg/kg/dose PO/IV q6h PRN
  - Diphenhydramine 1 mg/kg/dose q6h PRN
- Acute nausea and pain may improve with acid-reducing agents, such as proton pump inhibitors:
  - Lansoprazole 0.8–1.5 mg/kg/day up to 30 mg b.i.d.
  - Omeprazole 0.8–1 mg/kg/day up to 20 mg b.i.d.
- Abdominal pain—moderate:
  - Ketorolac 1 mg/kg/dose (max single dose 30 mg) q6h PRN
  - Ibuprofen 10 mg/kg/dose PO/IV q6h PRN
  - Naproxen 5 mg/kg PO q8h PRN
  - Acetaminophen 15 mg/kg/dose PO/PR q4h PRN

Prophylaxis:

- First line (7)
  - Amitriptyline is the first-line drug used for prophylaxis in patients  $\geq 5$  yr:
    - 0.5–1 mg/kg/day qhs
    - Higher dosages are often needed; check blood level.
    - Consider ECG prior to and 1–2 wk after starting to detect prolonged QTc.
    - Other tricyclic antidepressants may not be as effective.
  - Cyproheptadine is the first-line drug used for prophylaxis in patients  $\leq 4$  yr:
    - 0.25–0.5 mg/kg/day qhs
  - Co-enzyme Q10 was found to be as effective as amitriptyline with fewer side effects in 1 retrospective study (8) and is effective in all ages:
    - 10 mg/kg/day b.i.d. (adult dose 200 mg b.i.d.)
- Second line:
  - Propranolol 0.25–1.0 mg/kg/day b.i.d. (adult dose generally 10 mg b.i.d. or t.i.d.) (7)
  - L-carnitine 50–100 mg/kg/dose (adult dose 1 g/dose) b.i.d.
  - Oral contraceptives may improve catamenial CVS but may exacerbate vomiting episodes in some:
    - “Low dose” types are better tolerated.
  - Chronic nausea is often secondary to GERD and responds to proton pump inhibitors.

**COMPLEMENTARY AND ALTERNATIVE MEDICINE**

- Riboflavin:
  - 100 mg/day, or one B100 tablet/day
- Food allergen elimination diets (in selected cases with suspected food triggers) (7)

**DISPOSITION****Admission Criteria**

- Inability to stop emesis
- Significant dehydration, no urine output
- Failure to maintain adequate hydration
- Sodium <130 mEq/L
- Serum anion gap  $\geq 20$  mM (sodium minus chloride minus  $\text{HCO}_3^-$ ):
  - Serum anion gap 18–19 is borderline.
- Large urine ketones (>40 mg/dL):
  - Moderate ketones (40 mg/dL) is borderline.
- Loss of abilities, altered mental status (relative to baseline), or new neurologic finding
- Acute abdomen
- Pancreatitis

**Discharge Criteria**

- Ability to tolerate adequate enteral intake
- Patients know when the episode is over and can resume a regular diet.

**FOLLOW-UP****FOLLOW-UP RECOMMENDATIONS**

- Follow the management plan recommended by the specialist.
- Return for:
  - Signs of dehydration
  - New neurologic findings
  - Abdominal pain more severe than usual
  - Other worrisome findings
- Counsel patient to avoid other identifiable triggering factors as much as feasible:
  - Viral illnesses
  - Allergy and sinusitis
  - Anticipatory “positive” stress

**Patient Monitoring**

- Mental status
- Abdominal pain
- Urine ketones
- Serum anion gap, if very ill

**PROGNOSIS**

In most cases, episodes can be substantially reduced in frequency and severity on the appropriate therapeutic regimen.

**COMPLICATIONS**

- SIADH
- Urinary obstruction
- HTN
- Bowel obstruction (especially in opiate use):
- Complications of mitochondrial disease in the subpopulation with that etiology.

- <http://www.umdf.org>
- <http://www.curemito.org>

ICD9  
536.2 Persistent vomiting

**PEARLS AND PITFALLS**

- Pearls:
  - CVS is treatable in most cases. Referral to a CVS specialist is often appropriate.
  - Simple measures like frequent snacking and cofactor/vitamin therapy are often helpful.
- Pitfalls:
  - Drug therapy often appears to fail because only low dosages were tried.
  - Episodes can coalesce together into status CVS, which requires expert intervention.
  - Many adolescents and adults self-treat nausea with marijuana. While of apparent efficacy in some, cannabis abuse can precipitate cyclic vomiting in others.

# CYSTIC FIBROSIS: EXACERBATION

Craig A. McElderry

## BASICS

### DESCRIPTION

- Cystic fibrosis (CF) is an autosomal recessive disease caused by mutations in the cystic fibrosis transmembrane conductance regulator (CFTR) gene that results in abnormal viscous mucoid secretions in multiple organs.
- Exacerbations of pulmonary symptoms (eg, cough, wheeze, sputum production) in patients with CF must be recognized early and treated vigorously in order to maintain pulmonary function and relieve symptoms.
- Pulmonary exacerbations in patients with CF have an important negative impact on quality of life and survival.
- Pulmonary insufficiency is responsible for at least 80% of CF-related deaths (1).

### EPIDEMIOLOGY

See Cystic Fibrosis: New Diagnosis topic.

### RISK FACTORS

Factors shown to have an adverse effect on patients with CF include:

- Exposure to tobacco smoke
- Poor socioeconomic status

### GENERAL PREVENTION

- Adherence to maintenance treatment
- Good nutrition

### PATHOPHYSIOLOGY

- See Cystic Fibrosis: New Diagnosis topic.
- Patients with CF typically become chronically infected soon after birth.
- The presence of lower respiratory infection is associated with:
  - More frequent symptoms (eg, wheeze)
  - Increased levels of inflammatory mediators
  - Increased air trapping
- 1 study showed that 98% of a cohort of 40 infants with CF had serologic or culture evidence of *Pseudomonas aeruginosa* by 3 yr of age (2).
- Chronic infection leads to:
  - Generation and secretion of chemotactic cytokines
  - Cytokines recruit large numbers of polymorphonuclear cells into the airways.
- *P. aeruginosa* amplifies the cycle of infection and inflammation.
- *P. aeruginosa* has the ability to establish chronic infection through biofilm formation on damaged respiratory epithelium.
- Symptoms of an exacerbation may be secondary to release of organisms from this biofilm.
- This chronic infection/inflammation makes the patient with CF especially vulnerable to other factors, which may trigger an exacerbation. (See Etiology.)

### ETIOLOGY

- Many patients with CF will experience an exacerbation with no obvious new organism or obvious precipitant.
- Some known precipitating factors for pulmonary exacerbations include (3):
  - Nonadherence to maintenance treatment
  - New bacterial infection
  - Viral infection:
    - Respiratory syncytial virus (RSV)
    - Influenza A
  - Fungal infection/allergic bronchopulmonary aspergillosis (ABPA)—seen in 2–15% of patients with CF
  - Mucus plugging
  - Lobar/Segmental collapse
  - Atypical mycobacteria:
    - *Mycobacterium avium complex*
    - *Mycobacterium abscessus* or *Mycobacterium fortuitum*
    - *Mycobacterium kansasii*

## DIAGNOSIS

This section will focus on the diagnosis of pulmonary exacerbations in patients with CF.

### HISTORY

The most reliable indicators for a pulmonary exacerbation include (3):

- Decreased exercise tolerance
- Shortness of breath
- Difficulty breathing
- Increased wheeze or cough
- Increased sputum
- Absence from school or work
- Decreased appetite

### PHYSICAL EXAM

- Increased work of breathing manifested by tachypnea, retractions, dyspnea, etc.
- Increased adventitious sounds on lung examination (eg, crackles, rhonchi)
- Hypoxemia

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

- Respiratory tract culture (oropharyngeal or sputum):
  - Sample should be labeled as a CF culture, as many microbiology labs handle CF samples differently from routine samples in order to ascertain the presence of CF-specific organisms.
  - Consider viral, fungal, and mycobacterial cultures.
- Diagnosis of ABPA is likely if:
  - One can demonstrate a 4-fold rise in the level of IgE, accompanied by positive aspergillus precipitins
  - Clinical and radiologic deterioration despite appropriate antibiotics

- Periodic screening for pancreatic dysfunction should be done in all patients with CF:
  - Random glucose concentration
  - A yearly oral glucose tolerance test is thought to be the best screening method for those  $\geq 10$  yr of age.

### Imaging

- Chest radiography:
  - Remains the primary imaging modality used in the follow-up of patients with CF
  - Used to evaluate for new infiltrate or lobar or segmental collapse
  - Not sensitive in detecting bronchiectasis
- CT of the chest:
  - CT typically is used as a supplemental modality when specific, fine anatomic detail is necessary.
  - Detects even mild bronchiectasis
  - Serial CT scans allow assessment of the evolution of pulmonary abnormalities in patients with CF.
  - CT has advantages over pulmonary function tests and clinical scoring in the depiction of pulmonary changes over time.

### Diagnostic Procedures/Other

Bronchoalveolar lavage, though unlikely to become part of routine clinical monitoring, can be used to identify lower respiratory tract infections when sputum is unavailable.

### DIFFERENTIAL DIAGNOSIS

See Cystic Fibrosis: New Diagnosis topic.

## TREATMENT

- Treatment of CF includes therapies for maintenance of lung (including suppression of chronic infection), pancreatic, and nutritional health and management of pulmonary exacerbations.
- See Cystic Fibrosis: New Diagnosis topic for maintenance of lung and management of pancreatic and nutritional health.
- This section will focus on exacerbations:
  - Many patients with CF will develop pulmonary exacerbations in the presence of chronic lower respiratory infection, often with *P. aeruginosa*.
  - Determining which factor(s) may have triggered an exacerbation is essential for effective management of the exacerbation.

### INITIAL STABILIZATION/THERAPY

- Consider advanced airway management such as positive pressure ventilation for patients with respiratory failure.
- Treatment for pulmonary exacerbations often includes:
  - Antibiotics (PO, inhaled, or IV)
  - Increased used of airway clearance techniques
  - Improved nutrition

**MEDICATION**

Antibiotic treatment of pulmonary exacerbations is guided by identification of specific organisms from the airways.

**First Line**

- Antibiotics: Combination antibiotic treatment (generally with antipseudomonal activity) with agents that have different modes of action is preferred to single-agent treatment to avoid emergence of resistant strains, with treatment lasting about 14 days.
- Consider a beta-lactam–based antibiotic and an aminoglycoside.
- Antipseudomonal:
  - Ceftazadime (IV) 50 mg/kg/dose IV q8h
  - Tobramycin (IV) 4–6.6 mg/kg/dose IV per day
  - Meropenem (IV) (also has activity against *Staphylococcus aureus* and *Burkholderia cepacia*) 40 mg/kg/dose IV q8h
  - Ciprofloxacin (PO): May be sufficient for milder exacerbations in combination with inhaled antibiotics:
    - 1 mo to 5 yr: 15 mg/kg/dose PO q12h
    - 5–18 yr: 20 mg/kg/dose PO q12h
  - Tobramycin (inhaled):
    - Infant/Toddler: 10–20 mg in 2–4 mL normal saline nebulized b.i.d.
    - Children: 20–40 mg in 2–3 mL normal saline nebulized b.i.d.
- Antistaphylococcal:
  - Oxacillin (IV) 100–200 mg/kg/day in divided doses IV q6h
  - Linezolid (IV or oral) for MRSA: 10 mg/kg/dose q8h
- Anti-*Stenotrophomonas maltophilia*: Trimethoprim/Sulfamethoxazole (TMP/SMX) (PO): > 2 mo: 15–20 mg/kg/day (based on TMP) PO t.i.d.–q.i.d. for 14 days

**Second Line**

- Antifungal agents: Consider in patients with indwelling access devices who develop high, spiking fevers while on appropriate IV antibiotics:
  - Amphotericin B liposome IV (better tolerated than conventional amphotericin B):
    - Start: 1 mg/kg/day IV as a once-daily infusion
    - Increase by: 1 mg/kg/day IV to a max dose of 5 mg/kg/day as a once-daily infusion
  - Prednisone or prednisolone PO (treatment of ABPA) 0.5–1 mg/kg once daily for 2–3 wk, followed by the same dose alternating daily for 2–3 mo if there is improvement in clinical and radiologic features
- Antimycobacterium: Treatment guided by specific organism. At least 3 drugs started sequentially. Treatment is required for at least 12 mo.

**COMPLEMENTARY & ALTERNATIVE THERAPIES**

- Airway clearance techniques (should be augmented with inhaled dornase alfa, if the patient is not already receiving this):
  - Postural drainage and clapping
  - Vibrating mechanical vests
  - Forced expiratory technique and autogenic drainage: A technique characterized by breathing control, in which the individual adjusts the rate, depth, and location of respiration in order to clear the chest of secretions independently
- Supplemental oxygen

**SURGERY/OTHER PROCEDURES**

- For management of mucus plugging when physiotherapy and IV antibiotics have been unsuccessful, consider flexible bronchoscopy with suction.
- Percutaneous drainage may be necessary for pulmonary abscesses complicating severe bronchiectasis.

**DISPOSITION****Admission Criteria**

- Critical care admission criteria:
  - Endotracheal intubation
  - Positive pressure ventilation
- Inpatient admission criteria:
  - Failure of outpatient antibiotic therapy
  - Dyspnea
  - Deteriorating pulmonary exam
  - Deteriorating pulmonary function tests (including blood gas values)
  - Deteriorating chest radiograph appearance
  - Anorexia or weight loss
  - Need to initiate and teach home IV treatment
  - Lobar or segmental atelectasis
  - Right heart failure
  - Massive hemoptysis
  - Hypoxemia or initiation of home oxygen therapy
  - Pneumothorax
  - Respiratory failure
  - SIADH
  - Superimposed respiratory illness:
    - Influenza
    - RSV
    - Aspergillosis
    - Legionnaire disease
    - Status asthmaticus
  - New onset *P. aeruginosa* colonization
  - Initiation of treatment for MRSA
  - Initiation of comprehensive pulmonary treatment in a newly diagnosed patient

**Discharge Criteria**

Use of IV antibiotics does not require hospitalization. Similar results can be achieved with home IV treatment provided that appropriate patients are selected and adequate community support for patients and families is available.

**FOLLOW-UP****FOLLOW-UP RECOMMENDATIONS**

Follow-up in CF clinic should be arranged within several weeks of an exacerbation to assure that lung function has improved.

**Patient Monitoring**

Close attention to respiratory status as well as use of pulse oximetry should be considered in patients with CF exacerbations.

**DIET**

See Cystic Fibrosis: New Diagnosis topic.

**COMPLICATIONS**

- Respiratory failure
- Death

**REFERENCES**

1. O'Sullivan BP, Freedman SD. Cystic fibrosis. *Lancet*. 2009;373:1891–1904.
2. Burns J, Gibson R, McNamara S, et al. Longitudinal assessment of *Pseudomonas aeruginosa* in young children with cystic fibrosis. *J Infect Dis*. 2001;183:444–452.
3. Smyth A, Elborn JS. Exacerbations in cystic fibrosis: 3—management. *Thorax*. 2008;63(2):180–184.

**CODES****ICD9**

- 277.00 Cystic fibrosis without mention of meconium ileus
- 277.02 Cystic fibrosis with pulmonary manifestations

**PEARLS AND PITFALLS**

- Early recognition and vigorous management of pulmonary exacerbations in the patient with CF is vital to the maintenance of lung function, good quality of life, and survival.
- One should consider the etiology of an exacerbation in each patient.
- Appropriate antibiotic therapy, as well as attention to airway clearance and nutrition, is essential.

# CYSTIC FIBROSIS: NEW DIAGNOSIS

Craig A. McElderry

## BASICS

### DESCRIPTION

- Cystic fibrosis (CF) is an autosomal recessive disease caused by mutations in the cystic fibrosis transmembrane conductance regulator (CFTR) gene that results in abnormal viscous mucoid secretions in multiple organs.
- The main clinical features characteristic of CF are pancreatic insufficiency and chronic endobronchial infection.

### EPIDEMIOLOGY

#### Incidence

- CF is the most common life-threatening genetic condition in the Caucasian population.
- It is most common in populations of northern European descent.
- Birth incidence (affected/number of live births):
  - Non-Hispanic, Caucasian: 1/2,500–3,500
  - Hispanic: 1/4,000–10,000
  - African: 1/15,000–20,000
  - Asian: 1/100,000

#### Prevalence

- ~1 in 31,000, or 0.0000322%
- According to the Cystic Fibrosis Foundation, 30,000 children and adults in the U.S. (70,000 worldwide) are affected.

### PATHOPHYSIOLOGY

There are several hypotheses regarding how the CFTR gene mutation leads to the phenotypic disease known as CF. It is possible that all four of the following contribute to the pathogenesis of the disease.

- Low volume hypothesis:
  - Inhibition of epithelial sodium channels leads to excess sodium and water reabsorption
  - Results in dehydration of airway surface materials
  - Results in loss of lubricating layer between epithelium and mucus
  - Results in compression of cilia by mucus
  - Inhibition of normal ciliary and cough clearance of mucus
  - Mucus forms plaques with hypoxic niches that harbor bacteria, particularly *Pseudomonas aeruginosa*.
- High-salt hypothesis:
  - Excess sodium and chloride are retained in airway surface liquid.
  - The increased concentration of chloride in the periciliary layer disrupts the function of innate antibiotic molecules, allowing bacteria to persist.
- Dysregulation of the host inflammatory response hypothesis:
  - Abnormally high concentrations of inflammatory mediators are seen in CF cell cultures and uninfected ex vivo tissue samples.
- Primary predisposition to infection hypothesis:
  - An increase in asialo-GM1 in apical cell membranes allows increased binding of *P. aeruginosa* and *Staphylococcus aureus* to airway epithelium (1).

### ETIOLOGY

- Mutation in a gene that encodes CFTR protein, which is expressed in many epithelial cells and blood cells
- Autosomal recessive

### COMMONLY ASSOCIATED CONDITIONS

See History.

## DIAGNOSIS

Current diagnostic criteria for CF (2) are:

- $\geq 1$  characteristic phenotypic features (see History) OR
- A history of CF in a sibling OR
- A positive newborn screening test PLUS
- Evidence of abnormal CFTR function as demonstrated by one of the following:
  - Elevated sweat chloride  $\geq 60$  mmol/L
  - Abnormal nasal transepithelial ion transport
  - Identification of 2 disease-causing CFTR gene mutations

### HISTORY

The diagnosis of CF should be considered in any child or adult who presents with signs or symptoms of (1):

- Salty-tasting skin
- Clubbing of fingers or toes
- Mucoid *P. aeruginosa* isolated from airway secretions
- Hypochloremic metabolic alkalosis
- Meconium ileus
- Prolonged jaundice
- Abdominal or scrotal calcifications
- Intestinal atresia
- Persistent infiltrates on chest radiographs
- Failure to thrive
- Anasarca or hypoproteinemia
- Chronic diarrhea
- Abdominal distention
- Cholestasis
- *S. aureus* pneumonia
- Idiopathic intracranial HTN (vitamin A deficiency)
- Hemolytic anemia (Vitamin E deficiency can cause RBC fragility.)
- Chronic pansinusitis or nasal polyposis
- Steatorrhea
- Rectal prolapse
- Distal intestinal obstruction
- Idiopathic recurrent or chronic pancreatitis
- Liver disease
- Allergic bronchopulmonary aspergillosis
- Bronchiectasis
- Hemoptysis
- Pneumothorax
- Portal HTN
- Delayed puberty
- Azoospermia secondary to congenital bilateral absence of the vas deferens

### PHYSICAL EXAM

- While most patients with CF present with classic features of malabsorption, malnutrition, and chronic respiratory symptoms, some patients may have only a few or even just 1 clinical sign.
- Clinical features seen in CF patients include:
  - Salty taste to skin
  - Wheezing
  - Signs of pulmonary infection (eg, crackles, decreased aeration)
  - Nasal polyps
  - Digital clubbing
  - Rectal prolapse
  - Failure to thrive
  - Edema (secondary to hypoproteinemia and fat-soluble vitamin deficiency)

### DIAGNOSTIC TESTS & INTERPRETATION

The following tests would be performed as an inpatient in the ill child or as an outpatient in the clinically stable child. Consider consultation with a pulmonologist.

#### Lab

##### Initial Lab Tests

- Sweat chloride testing should be performed by experienced personnel:
  - Quantitative pilocarpine iontophoresis testing (QPIT) is the only acceptable method of sweat testing—determines concentration of chloride in the sweat:
    - $<40$  mmol/L: Unaffected
    - $\geq 40$  and  $59$  mmol/L: Indeterminate
    - $\geq 60$  mmol/L: Elevated/diagnostic of CF
  - Indeterminate test results require evaluation for other clinical features of CF:
    - Consider respiratory tract cultures, fecal elastase.
    - Because men with CF have obstructive azoospermia, a semen analysis can be helpful.
- Nasal potential difference measurements—can be helpful in cases where sweat chloride levels are indeterminate and genetic analysis unrevealing.
- Genetics testing:
  - Mutations in CFTR gene were identified in 1989 as the genetic basis of CF.
  - Over 1,400 mutations may cause CF.
  - Clinical relevance of some of the more rare mutations and polymorphisms is not known.
  - Complexity between CF genotype and phenotype limits diagnostic utility but may be helpful in some cases of indeterminate sweat tests.
- Newborn screening:
  - Not diagnostic/not available everywhere
  - Sweat testing or other appropriate diagnostic tests should always be performed in patients where CF is suspected regardless of newborn screening results.

#### Imaging

- Chest/Sinus radiographs: Limited value for diagnosis but often first line in evaluation of exacerbations
- Chest CT: To evaluate for bronchiectasis and to assess evolution of pulmonary abnormalities

**Pathological Findings**

- Lungs are normal at birth but progressively become infected and inflamed.
- Polymorphonuclear cells are seen in bronchoalveolar lavage specimens.
- Bronchiectasis
- *Haemophilus influenzae* or *S. aureus*, or both, rapidly colonize infants with CF.
- Within a short time, *P. aeruginosa* becomes the predominant organism.
- Other organisms commonly seen in patients with CF include *Burkholderia cepacia*, *Stenotrophomonas maltophilia*, and atypical mycobacteria.

**DIFFERENTIAL DIAGNOSIS**

- Malnutrition
- Hypogammaglobulinemia
- Immotile cilia syndrome
- Asthma
- Celiac disease
- Shwachman-Diamond syndrome
- Adrenal insufficiency
- Anorexia nervosa
- Hypothyroidism
- Congenital metabolic diseases

**TREATMENT****MEDICATION**

This section will focus on chronic medications used for maintenance of lung health in patients with CF. See Cystic Fibrosis: Exacerbation topic for therapies used for treatment of new infections/exacerbations of CF.

**First Line**

- Inhaled tobramycin (high dose):
  - Especially for patients  $\geq 6$  yr old who have moderate to severe lung disease and with *P. aeruginosa* persistently in airway cultures
  - Children  $\geq 6$  yr and adults: 300 mg every 12 hr; administered in repeated cycles of 28 days on drug, followed by 28 days off drug (3)
  - Lower dosages can be used in infants and children  $< 6$  yr of age.
- Inhaled recombinant human DNase (dornase alfa or Pulmozyme):
  - Especially for patients  $\geq 6$  yr with moderate to severe lung disease (3)
  - Children  $\geq 6$  yr and adults: 2.5 mg once daily using a recommended nebulizer
  - Recommended also for patients who are asymptomatic or those with mild disease (3)

**Second Line**

- Inhaled  $\beta_2$ -adrenergic receptor agonists (3)
- Inhaled hypertonic saline:
  - Used to increase hydration of airway surface liquid, improving mucociliary clearance
  - Improves quality of life and reduces pulmonary exacerbations
  - Dosage: 7% solution, 10 mL nebulized twice daily (3)

- Oral ibuprofen:
  - For patients  $\geq 6$  yr, with FEV<sub>1</sub>  $> 60\%$  predicted (3)
  - 20–30 mg/kg/dose: Consider risks of bleeding and potential adverse effects on renal function.
- Oral azithromycin (3):
  - For patients  $\geq 6$  yr and with *P. aeruginosa* persistently present in airway cultures

**SURGERY/OTHER PROCEDURES**

- Liver biopsy to look for evidence of biliary cirrhosis (highly suggestive of CF)
- Gastrostomy tube placement as needed for supplemental nutrition
- Lung transplantation for end-stage lung disease

**DISPOSITION****Admission Criteria**

- Consider for patients with:
  - Failure to thrive
  - Metabolic disturbances
  - Pancreatitis
  - Meconium ileus
  - Significant respiratory distress
  - Failure of outpatient antibiotic and respiratory therapy
- Critical care admission criteria:
  - See Cystic Fibrosis: Exacerbation topic.

**Issues for Referral**

As a complex and multisystemic disease, CF is best managed by a specialty center with multidisciplinary care teams (i.e., CF centers).

**COMPLEMENTARY & ALTERNATIVE THERAPIES**

Airway clearance techniques:

- Postural drainage and clapping
- Vibrating mechanical vests
- Forced expiratory technique
- Autogenic drainage: A technique characterized by breathing control, in which the individual adjusts the rate, depth, and location of respiration in order to clear the chest of secretions independently

**FOLLOW-UP****FOLLOW-UP RECOMMENDATIONS****Patient Monitoring**

Patients should be monitored in the CF clinic every 2–3 mo with the following goals:

- Maintenance of growth and development
- Maintenance of as nearly normal lung function as possible
- Intervention and retardation of the progression of lung disease via suitable use of antibiotics, bronchodilators, and airway clearance techniques
- Clinical evaluation to monitor GI tract involvement and presence of malabsorption and to provide enzyme and nutrition supplementation
- Monitoring for complications
- Addressing psychosocial issues

**DIET**

- Good nutrition is mandatory for CF patients.
- Pancreatic enzyme supplementation should be used in patients with pancreatic insufficiency.
- Fat-soluble vitamin supplementation is necessary in all patients with pancreatic insufficiency.
- Breast-feeding should be encouraged for infants with CF.
- Supplemental nutrition should be strongly considered (orally or by gastrostomy tube) in any patient with suboptimal growth.

**PROGNOSIS**

- The U.S. Cystic Fibrosis Foundation's projected life expectancy for patients has increased from 31 yr to 37 yr over the past decade.
- For children born with CF today, a U.K. model predicts their life span to be  $\geq 50$  yr (1).

**COMPLICATIONS**

See History section and Cystic Fibrosis: Exacerbation topic.

**REFERENCES**

1. O'Sullivan BP, Freedman SD. Cystic fibrosis. *Lancet*. 2009;373:1891–1904.

3. Flume PA, O'Sullivan BP, Robinson, et al. Cystic Fibrosis Foundation, Pulmonary Therapies Committee. Cystic fibrosis pulmonary guidelines: Chronic medications for maintenance of lung health. *Am J Respir Crit Care Med*. 2007;176(10):957–969.

**ADDITIONAL READING**

Voter KZ, Ren CL. Diagnosis of cystic fibrosis. *Clin Rev Allergy Immunol*. 2008;35:100–106.

**ICD9**

- 277.00 Cystic fibrosis without mention of meconium ileus
- 277.01 Cystic fibrosis with meconium ileus
- 277.02 Cystic fibrosis with pulmonary manifestations

**PEARLS AND PITFALLS**

- Common clinical features characteristic of CF are chronic endobronchial infection and pancreatic insufficiency.
- Presence of mucoid *P. aeruginosa* in airway secretions is strongly suggestive of CF.
- Refer to CF center.

# CYSTIC HYGROMA

Joseph B. House  
Stuart A. Bradin

## BASICS

### DESCRIPTION

- A cystic hygroma is a congenital malformation of the lymphatic system with dilated lymphatic channels.
- Synonymous with macrocystic lymphatic malformation and cystic lymphangioma
- Not a neoplasm
- Usually found in the posterior triangle of the neck, but can be in other neck locations as well as axillae, groin, popliteal fossae, or torso
- Can grow rapidly within the first few weeks
- Categorized as unilateral or bilateral and suprahyoid or infrahyoid (1):
  - Stage I: Unilateral infrahyoid
  - Stage II: Unilateral suprahyoid
  - Stage III: Unilateral supra- and infrahyoid
  - Stage IV: Bilateral suprahyoid
  - Stage V: Bilateral supra- and infrahyoid
- Classification based on size (1):
  - Microcystic or capillary lymphangiomas: < 1 cm
  - Macrocystic: > 1 cm

### EPIDEMIOLOGY

#### Incidence

- 1 case per 6,000–16,000 live births (2)
- 50–65% evident at birth, with 90% detected at < 2 yr of age
- Equal frequency in males and females
- Equal frequency in ethnic groups
- Most commonly occurs in head and neck (75%)
- About 20% of cystic hygromas occur in the axilla
  - In neck, most commonly in posterior triangle
    - 50% of fetuses with cystic hygroma have an abnormal karyotype, and chromosomal abnormalities are more frequent in septated cystic hygroma (4):
      - Karyotypes include Klinefelter syndrome, Turner syndrome, Down syndrome, trisomy 13 and 18, Noonan syndrome, Fryns syndrome, multiple pterygium syndrome, and achondroplasia.
- Those that develop in the third trimester or postnatally usually are not associated with a chromosomal abnormality (3).
- 33% of fetuses with cystic hygroma have a structural abnormality (4).

#### Prevalence

- In 1st trimester, overall about 1 in 100 fetuses:
  - Septated cystic hygroma occurs in 1 in 285 fetuses.
- Some authors believe all cystic hygromas are present at birth (2).

### RISK FACTORS

- Intrauterine substance exposure, including alcohol (2)
- Maternal viral infections, including parvovirus (3)

### PATHOPHYSIOLOGY

- Maldeveloped localized lymphatic network
- Combination of:
  - Failure of lymphatics to connect to venous system
  - Abnormal budding of lymphatic tissue
  - Sequestered lymphatic rests that retain embryonic growth potential

### ETIOLOGY

Unknown

### COMMONLY ASSOCIATED CONDITIONS

- Infection of cyst
- Hypertrophy of both bone and soft tissue:
  - Frequently seen as progressive distortion of mandibular body, can cause underbite and open-bite deformity (5)
- First trimester often associated with trisomies 13, 18, and 21; second trimesters often associated with monosomy X

## DIAGNOSIS

### HISTORY

- Symptoms vary based on lesion location.
- May present after sudden appearance of neck swelling secondary to infection or intralesional bleeding
- Rarely, new-onset obstructive sleep apnea or stridor or cyanosis
- Feeding difficulties or failure to thrive:
  - May be early sign of impending airway obstruction
- Pelvic lesions cause bladder outlet obstruction, constipation, or recurrent infection.

### PHYSICAL EXAM

- Often, overlying skin is normal or has bluish hue.
- Less common, puckering or deep cutaneous dimpling
- Soft, painless compressible mass
- In contrast to thyroid cysts, does not move with swallowing
- Typically transilluminates
- Microcystic form appears as clusters of clear, black, or red vesicles on buccal mucosa or tongue.
- Macrocystic lesions usually are found above level of mylohyoid muscle and involve oral cavity, lip, and tongue.
- Life-threatening airway compromise may present as noisy breathing, cyanosis, or tracheal deviation.
- Inspect the tongue and oral cavity for lesions that may lead to airway compromise.
- Lesions in the forehead and orbit can cause proptosis.
- Diffuse thoracic lymphatic anomalies or abnormalities of thoracic duct can manifest as recurrent pleural or pericardial chylous effusion or ascites.
- Lesions in an extremity may cause diffuse or localized swelling or gigantism with soft tissue and skeletal overgrowth.
- Diffuse soft tissue and skeletal lesions may cause progressive osteolysis, called *Gorham-Stout syndrome*, or disappearing bone or phantom bone disease.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

- No initial lab testing is routinely required.
- Check white blood cell count and/or C-reactive protein, and check blood culture if infection of cyst is suspected.

### Imaging

- MRI is study of choice:
  - Best soft tissue detail
  - Delineate relationship to underlying structures
  - Differentiates hemangiomas from lymphangiomas
  - Hyperintense signal in T2-weighted images
  - Ring enhancement with contrast use
- CT scanning:
  - Faster than MRI
  - Detail is lost if surrounding tissue of similar attenuation
  - Contrast helps to enhance cyst wall
- US:
  - Least invasive
  - No radiation exposure
  - Useful demonstrating relationship with surrounding structures
  - Limited in assessing mediastinal and retropharyngeal lesions
  - Can be used in utero in the late 1st trimester: May appear as excess nuchal fluid, largest in the nuchal region, and may extend along entire length of the fetus
- Plain radiography: Generally unhelpful but may delineate gross airway compromise

### Pathological Findings

- Large irregular sinuses with single layer of flattened epithelial lining and fibrous adventitial coats:
  - Hemorrhage within the cystic spaces is common after trauma or with spontaneous intralesional bleeding.
- Thickness of vessel wall varies with striated and smooth muscle components.

### DIFFERENTIAL DIAGNOSIS

- Teratoma
- Germ cell tumor
- Branchial cleft cyst
- Thyroglossal duct cyst
- Goiter
- Soft tissue tumor
- Neck abscess
- Lymphadenopathy
- Lymphadenitis
- Parotitis

## TREATMENT

### INITIAL STABILIZATION/THERAPY

- If airway compromise, consider aspiration:
  - Prepare for a difficult airway if compromise is suspected.
  - Emergent otolaryngology or anesthesiology consult may be needed for airway evaluation.
  - Aspiration with large-bore (18- to 20-gauge) needle may temporarily alleviate immediate airway compromise.
  - Save aspirate for culture if necessary.
- If signs of infection, treat with antibiotics:
  - IV antibiotic indicated
  - Treat with antibiotics for oral pathogens in head and neck lesions.
  - Treat with antibiotics for enteric pathogens in the trunk and perineum.
- Bleeding may be treated with analgesics:
  - Prophylactic antibiotics should be prescribed if there is a large collection of intraluminal blood.

### MEDICATION

#### Sclerotherapy:

- OK-432: Inactive strain of group A *Streptococcus pyogenes*
  - Mechanism: Inflammatory response
  - Option for large unilocular cysts
- Alcohol: Works well in vascular malformations with low flow; often painful and may need general anesthesia and postprocedural pain medication; can result in local necrosis blistering and neuropathy; systemic absorption may lead to cardiac arrest, pulmonary vasoconstriction, or systemic hypotension (6)
- Fibrin sealant:
  - Edema post-injection associated with prolonged recovery and increased therapeutic effect
  - Better results with macrocystic type lesions as compared to poor or absent results in microcystic type (7)

### SURGERY/OTHER PROCEDURES

#### Surgical resection:<sup>1</sup>

- Primary treatment
- Macrocystic lesions: Ideally removed in 1 procedure, repeated excisions complicated by fibrosis and anatomic distortions
- Microcystic lesions: Most difficult to resect, no distinct tissue planes between malformed and normal structures
- Exception to excision at diagnosis includes close proximity to crucial neurovascular structures; may need to wait until child is older.
- Since not a neoplasm, removal of surrounding blood vessels and nerves is not indicated.

### DISPOSITION

#### Admission Criteria

- Airway obstruction
- Superinfection of lesion
- Pericardial or pulmonary chylous effusions or ascites
- Observation of rapidly expanding cyst

#### Issues for Referral

Referral to surgeon or surgical subspecialist depending on anatomic location

### COMPLEMENTARY & ALTERNATIVE THERAPIES

- Observation: 15% spontaneous regress (1)
- Laser resection:
  - CO<sub>2</sub> laser or Neodymium:yttrium-aluminum-garnet laser
  - May be MRI controlled
  - Oral cavity, tongue, and airway most amenable

## FOLLOW-UP

### FOLLOW-UP RECOMMENDATIONS

Discharge instructions and medications:

- Follow up with a surgical consult.

#### Patient Monitoring

- Airway compromise
- Signs of cyst infection

### PROGNOSIS

- Spontaneous resolution is uncommon.
- Recurrence is rare when gross disease is removed.
- If residual tissue is left behind after surgery, the recurrence rate is about 15%.

### COMPLICATIONS

- Intralesional bleeding
- Cyst infection
- Cellulitis
- Airway compromise
- Deformation of surrounding bony structures or teeth if left untreated
- Adverse psychosocial effects may result from social stigmatization in cysts resulting in deformation.

### CODES

#### ICD9

228.1 Lymphangioma, any site

## PEARLS AND PITFALLS

- Rapid enlargement may cause respiratory distress.
- Early administration of antibiotics is indicated for superinfection.

# DACRYOCYSTITIS/DACRYOSTENOSIS

Donald T. Ellis II

Sandip A. Godambe

Kimberly A. Randell

## BASICS

### DESCRIPTION

- Dacryocystitis describes inflammation of either the lacrimal duct or sac.
- Infection occurs as the stasis of tears promotes bacterial overgrowth.
- Classifications:
  - Congenital dacryocystitis is associated with infection.
  - Acquired:
    - Acute dacryocystitis is commonly associated with pain, erythema and swelling of the lower eyelid, excessive tearing, eye discharge, and fever.
    - Chronic dacryocystitis is not normally associated with infection; however, it may develop tearing and discharge.
- Dacryostenosis: Blocked tear duct (also called nasolacrimal duct (NLD) impotency or stenosis)

### EPIDEMIOLOGY

#### Incidence

Bimodal, most often diagnosed in neonates and adults >40 yr

#### Prevalence

- A recent study of 15,398 neonates found the prevalence for congenital dacryocystitis to be 0.146% (1).
- Congenital dacryostenosis is found in 6–20% of all neonates (2,3)
- Dacryocystitis found in 2.9% of infants with dacryostenosis, 60% of infants with dacryocystocele (4,5)

### RISK FACTORS

- Brachycephaly, narrow facial structure, flattened nose, and dacryoceles are recognized as risk factors for the development of dacryocystitis.
- Caucasians are thought to be at an increased risk relative to blacks.

### GENERAL PREVENTION

Warm compresses and lacrimal massage have been suggested as possible techniques to decrease the rate of infection in the setting of nasolacrimal duct dysfunction.

### PATHOPHYSIOLOGY

- All forms of dacryocystitis are caused by the stagnation of tears, which promotes bacterial overgrowth:
  - Can see secondary conjunctivitis.
- Congenital obstruction results from failed atrophy of adhesion between the ductal epithelium and nasal mucosa:
  - Most common site of obstruction is at the valve of Hasner (the opening of the lacrimal duct into the inferior meatus of the nose)
- Acquired cases frequently involve obstruction of the inferior nasolacrimal system.

### ETIOLOGY

- Bacteria most often associated with dacryocystitis include *Staphylococcus* (especially *aureus* and *epidermidis*) and *Streptococcus pneumoniae*. However, other organisms such as diptherioids, *Escherichia coli*, *Pseudomonas* species, *Actinomyces* species, and TB have been implicated as well.
- Viruses (eg, Epstein-Barr virus and human papillomavirus) and fungi (eg, *Candida* species) have also been reported as causative agents.
- Acquired dacryocystitis is caused by a variety of conditions including the following:
  - Nearby infection (eg, sinusitis or rhinitis)
  - Structural defects (eg, deviated septum)
  - Trauma
  - Nasal foreign body
  - Neoplasm
  - Dacryolithiasis
  - Iatrogenic (eg, postoperative complication)

### COMMONLY ASSOCIATED CONDITIONS

- Conjunctivitis is frequently seen in conjunction with dacryocystitis with both acute and chronic forms.
- Orbital cellulitis is uncommon but may occur with congenital and acute dacryocystitis.
- A dacryocystocele or amniotocele is a bluish mass, which represents a collection of amniotic fluid from fetal development and may be seen with dacryocystitis:
  - Dacryocystoceles may cause nasal obstruction and subsequent respiratory distress in the newborn.
- Acute dacryocystitis may be associated with fistula formation from the lacrimal sac to the overlying skin.
- Autoimmune disease
- Sjögren syndrome

## DIAGNOSIS

### HISTORY

- In acute and congenital dacryocystitis, there is usually a history of tenderness, swelling, and erythema over the lacrimal sac, located medial to the medial canthus (1,6).
- Chronic dacryocystitis is characterized by a more indolent course (7).
- Elicit history of previous episodes, systemic illness, or other HEENT infections
- Dacryostenosis: Onset of tearing or mucoid eye discharge days-weeks after birth, 1/3 are bilateral, the conjunctiva are usually clear

### PHYSICAL EXAM

- Apply gentle pressure to bilateral lacrimal sacs to attempt to express discharge from lacrimal punctum.
- Assess for impairment of extraocular movements and for proptosis.
- Assess for any facial tenderness, especially sinus or nasal problems.
- Epiphoria is present in most cases.
- Fever and decreased activity may be seen in some patients.
- Mattering is due to the inability to effectively drain the mucoid portion of tears.
- Conjunctivitis can also be seen.
- Tenderness and erythema near the medial canthus indicate acute dacryocystitis.
- Chronic dacryocystitis may present with merely mucoid or purulent discharge from the upper and/or lower puncta.
- Photophobia suggests other etiologies (in neonates, consider congenital glaucoma).

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

- The diagnosis of dacryocystitis is most frequently determined on clinical grounds.
- The presence of peripheral leukocytosis may provide further evidence for dacryocystitis.
- Cultures of the lacrimal discharge should preferably be collected prior to the administration of antibiotics; blood cultures are rarely indicated.
- Nasal and/or conjunctival cultures may provide additional assistance in determining bacterial susceptibility.
- In febrile neonates, obtain blood, urine and cerebrospinal fluid cultures prior to initiating antibiotics (strongly consider in afebrile neonates).

#### Imaging

- If facial deformity or posttraumatic obstruction of tear outflow is suspected, plain radiographs may be obtained.
- CT scan (with axial and coronal views) of the orbit and paranasal sinuses may be necessary in atypical or severe cases of dacryocystitis, in patients with orbital cellulitis, or when concern for neoplasm.
- CT scans are generally preferred over MRIs when investigating the possibility of neoplasm resulting in obstruction.
- CT scans may also assist in differentiating preseptal from orbital cellulitis due to dacryocystitis.

#### Diagnostic Procedures/Other

Flourescein disappearance test can confirm diagnosis – place dye in lower conjunctival fornix, blotting excess solution/tears away. Examination after 5 min with cobalt blue filter identifies residual flourescein in children with dacryostenosis (90% sensitive, 100% specific).

**DIFFERENTIAL DIAGNOSIS**

- Dacryocystitis:
  - Conjunctivitis
  - Preseptal or orbital cellulitis
  - Dacryocystocele
  - Blepharitis
  - Ethmoid or maxillary sinusitis
  - Insect bite
  - Neoplasm
- Dacryostenosis:
  - Lacrimal fistula
  - Impatient/absent puncta
  - Congenital glaucoma
  - Corneal abrasion
  - Foreign body

 **TREATMENT**

**INITIAL STABILIZATION/THERAPY**

Especially in the newborn, airway, breathing, and circulation should be assessed and stabilized due to the potential for respiratory distress (eg, with obstruction as with a dacryocystocele) or sepsis.

**MEDICATION**

**First Line**

- For dacryostenosis, caregivers should provide nasolacrimal massage several times daily (gentle downward pressure along lacrimal duct, beginning just below the medial canthus). No antibiotics are indicated.
- For acute dacryocystitis, systemic antibiotics should be initiated (following acquisition of blood and lacrimal fluid cultures).
- Parenteral antibiotics should be used in any patient with systemic signs (8). Antibiotics with antistaphylococcal activity are preferred:
  - Clindamycin 25–40 mg/kg/day divided q6–8h; max daily dose 4.8 g/day
  - Vancomycin 40–60 mg/kg/day IV divided q6–8h; max daily dose 4 g/day
- Although antibiotics are indicated for congenital and acute forms, they are somewhat controversial in chronic dacryocystitis.

**Second Line**

- Naphazoline 0.05%: 6–12 yr, 1 gtt q6h PRN; > 12 yr, 2 gtt q6h PRN; do not use in children under 6 yr:
  - May be used for a max of 5 days but should be discontinued thereafter due to the risk of atrophic rhinitis
- Antihistamines have been used to decrease the amount of lacrimal secretions.

**SURGERY/OTHER PROCEDURES**

- Dacryocystorhinostomy (DCR) remains the definitive treatment.
- Nasolacrimal duct probing, incision and drainage, and DCR have historically been performed following clinical improvement with systemic antibiotics. However, DCR has been suggested as an alternative treatment even in the acute phase (9).
- Dacryostenosis: Probing of the NLD is not needed unless stenosis persists beyond 6–12 mo; in the majority of infants, adhesions within the NLD undergo spontaneous atrophy

**DISPOSITION**

**Admission Criteria**

- Inpatient treatment should be strongly considered for all infants and children who present with systemic signs (eg, fever), preseptal cellulitis, orbital cellulitis, meningitis, or ill appearance.
- Disposition should be planned in conjunction with input from ophthalmology, who will likely admit most congenital and acute cases for IV antibiotics and DCR.
- Critical care admission criteria:
  - Patients with ill appearance, especially with abnormal vital signs or change in mental status, may need intensive care services.

**Discharge Criteria**

- Well-appearing, afebrile patients with dacryocystitis can be discharged if they do not meet the aforementioned admission criteria.
- All patients with dacryostenosis may be treated as outpatients.

**Issues for Referral**

- Since dacryocystitis is definitively treated by DCR, consider referral to ophthalmology.
- Ophthalmology referral if congenital dacryostenosis persists beyond 6 mo

 **FOLLOW-UP**

**FOLLOW-UP RECOMMENDATIONS**

Discharge instructions and medications:

- Afebrile well-appearing patients with dacryocystitis can be discharged:
  - If being discharged, patients should have a clear plan for follow-up with ophthalmology (ideally within 24–48 hr).
  - Patients should return for fever; clear discharge (as seen with CSF leak after DCR); or increased pain, erythema, or swelling.
- Patients with dacryostenosis can follow up with their primary physician without specialist referral.

**PROGNOSIS**

- Following an initial episode of acute dacryocystitis, ~2/3 of patients may experience recurrence.
- DCR has a success rate of ≥90%.
- Congenital dacryostenosis: 90% will spontaneously resolve by 8–12 mo of age when treated with lacrimal sac massage (10)

**COMPLICATIONS**

- Orbital cellulitis
- Periorbital cellulitis
- Brain abscess
- Meningitis
- Cavernous sinus thrombosis
- Sepsis
- Cutaneous fistula

- Conjunctivitis
- Orbital cellulitis
- Periorbital cellulitis

 **CODES**

- ICD9**
- 375.30 Dacryocystitis, unspecified
  - 375.32 Acute dacryocystitis
  - 771.6 Neonatal conjunctivitis and dacryocystitis

**PEARLS AND PITFALLS**

- Uncomplicated dacryostenosis may be associated with scant mucoid drainage; the absence of conjunctival injection distinguishes this from conjunctivitis. If photophobia is present, evaluate for congenital glaucoma.
- Be aware of the uncommon, yet potentially devastating, complications of dacryocystitis (eg, orbital cellulitis, brain abscess, meningitis, cavernous sinus thrombosis, and sepsis). Hospitalize any patient with systemic signs or toxicity.

# DECOMPRESSION SICKNESS

Carl P. Kaplan

## BASICS

### DESCRIPTION

- Decompression sickness (DCS) primarily affects scuba divers and is referred to as “the bends.”
- It may also present in caisson workers or high-altitude aviators.
- It derives from a complex interaction of physical gas properties and physiologic processes.
- The pressure of a gas is inversely proportional to its volume (Boyle law). When inert nitrogen (the predominant gas in compressed air) is rapidly exposed to a lower pressure (during ascent), bubbles may form in tissue capillary beds as its volume expands, resulting in microvascular ischemia and local inflammatory response.
- Type I DCS: Also termed *pain only*, primarily affects periarticular areas and tendons (the bends), lymphatics, and the skin
- Type II DCS: Consists of vestibular, cardiopulmonary, CNS, or peripheral nervous system (PNS) manifestations
- Arterial gas embolism (AGE), or cerebral arterial gas embolism (CAGE), is the most severe form of DCS.

### EPIDEMIOLOGY

#### Incidence

- Male to female ratio: 3–4:1
- Around 16 cases per year in patients < 19 yr.
- Sport diving—associated DCS (all ages):
  - Warm water: 13.4:100,000 dives
  - Cold water: 10.5:100,000 dives
- 2.7/100,000 in healthy divers with strict adherence to published dive tables

### RISK FACTORS

- Caisson work
- High-altitude aviation
- Pre-existing cardiovascular disease
- Intracardiac shunts
- Dehydration

### GENERAL PREVENTION

- Avoidance of rapid ascents during diving
- Adherence to published dive tables
- Maintenance of cabin pressure in airplanes and caissons
- Scheduled maintenance of equipment

### PATHOPHYSIOLOGY

- The main component of compressed air is nitrogen, which, unlike oxygen, poorly and slowly diffuses into tissues and remains in the circulation.
- Decompression with rapid ascent allows the formation of nitrogen bubbles in the microcirculation leading to right to left shunting and local inflammatory response.
- Larger amounts of gas may enter the circulation mechanically through pulmonary barotrauma.
- Larger gas emboli may form in severe cases.
- Intracardiac shunts may allow CAGE (most commonly in the middle cerebral artery and vertebralbasilar artery).

### ETIOLOGY

- Inexperience or inebriation of divers
- Diving-related trauma
- Equipment failure
- Breath-holding on ascent (panic)
- Dangerous conditions necessitating rapid ascent
- Air travel following diving

### COMMONLY ASSOCIATED CONDITIONS

- Major trauma
- Near drowning
- Barotrauma (paranasal sinuses, pneumothorax, pneumomediastinum, tympanic membrane rupture)
- Nitrogen narcosis
- Dehydration
- Headache
- Vertigo

## DIAGNOSIS

### HISTORY

- Recent diving (depth, length of dive, time of each dive, use of dive tables or dive computers, number of dives)
- Air travel
- Difficulty breathing, chest pain
- Loss of consciousness
- Headache
- Weakness or paresthesias
- Vertigo
- Extremity pain or swelling
- Recent meals containing reef fish
- Associated dive trauma, such as coral abrasions, envenomations, blunt trauma

### PHYSICAL EXAM

- Musculoskeletal pain, often at joints, is typical.
- Dermal findings may include lymphedema, cutis marmorata.
- GI findings may include abdominal pain, nausea, and vomiting.
- Pulmonary findings may include dyspnea, cough, or substernal pressure.
- CNS findings:
  - Altered mental status
  - Focal neurologic deficits
  - Motor weakness or sensory loss
- PNS findings

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

No lab assays are required, but consider:

- CBC
- Basic metabolic profile, creatine phosphokinase, troponin I
- Urinalysis
- Venous blood gas analysis:
  - Arterial analysis is typically unnecessary.

#### Imaging

- CXR
- Consider brain CT +/- angiography for CNS pathology.
- Consider chest CT +/- angiography for suspected pulmonary embolism.

#### Diagnostic Procedures/Other

EKG

### DIFFERENTIAL DIAGNOSIS

- Cerebrovascular accident
- Traumatic brain or spinal cord injury
- Near drowning
- Dehydration
- Hypothermia
- Ciguatera poisoning from consumption of reef fish
- Envenomation: Jellyfish, corals, stingrays

## TREATMENT

### PRE HOSPITAL

- Assess and stabilize airway, breathing, and circulation.
- Recompression dive to 60-foot seawater depth with slow ascent (only feasible with stable divers and experienced oversight)
- Administer 100% oxygen.
- Maintain supine position.
- Administer isotonic fluids.
- Avoid hypothermia.

### ALERT

- Diver's Alert Network (DAN)
- Emergency Hotline (800) 446-2671
- Transport assistance (800) DAN-EVAC (326-3822)

### INITIAL STABILIZATION/THERAPY

- Assess and stabilize airway, breathing, and circulation.
- Administer 100% oxygen.
- Identify and treat associated trauma.
- Isotonic volume resuscitation
- Rewarming as necessary

### MEDICATION

#### First Line

- Hyperbaric oxygen (HBO) should be administered to all patients with DCS. U.S. Navy Treatment Table 6 is the standard first-line therapy and may be modified as needed.
- Multiple treatments with HBO or different tables may be employed by experts in refractory cases.

#### Second Line

- NSAIDs:
  - Consider NSAID medication in anticipation of prolonged pain and inflammation.
  - NSAIDs may reduce the duration of hyperbaric therapy by modifying inflammation in the CNS or PNS.
  - Ibuprofen 10 mg/kg/dose PO/IV q6h PRN
  - Ketorolac 0.5 mg/kg IV/IM q6h PRN
  - Naproxen 5 mg/kg PO q8h PRN
- Acetaminophen 15 mg/kg/dose PO/PR q4h PRN
- Opioids:
  - Morphine 0.1 mg/kg IV/SC/IM q2h PRN:
    - Initial morphine dose of 0.1 mg/kg IV/SC may be repeated q15–20min until pain is controlled, then q2h PRN.
  - Codeine or codeine/acetaminophen dosed as 0.5–1 mg/kg of codeine component PO q4h PRN
  - Hydrocodone or hydrocodone/acetaminophen dosed as 0.1 mg/kg of hydrocodone component PO q4–6h PRN
- Local anesthetic:
  - Lidocaine 1.5–2 mg/kg IV bolus followed by infusion 1 mg/min
  - May alleviate inflammatory response associated with severe CNS or PNS involvement, improve nerve conduction, decrease intracranial HTN, and improve spinal cord blood flow

### SURGERY/OTHER PROCEDURES

- Tube thoracostomy for associated pneumothorax
- Myringotomy tube placement for patients with altered mental status undergoing HBO. (Others are able to use maneuvers to equilibrate eustachian tube pressure.)

### DISPOSITION

#### Admission Criteria

Critical care admission criteria:

- Pulmonary complications such as pneumothorax, acute respiratory distress syndrome, or endotracheal intubation
- All patients requiring HBO should be considered for admission as an inpatient.

#### Discharge Criteria

- Resolution of symptoms within 4–6 hr following prehospital 100% oxygen
- Stable patients with mild symptoms may be discharged after HBO therapy.

#### Issues for Referral

- Availability of HBO therapy
- Air transport should only occur if cabin altitude can be maintained below 500 feet (152 meters) above the extraction point.

## FOLLOW-UP

### FOLLOW-UP RECOMMENDATIONS

- Discharge instructions and medications:
  - Keep well hydrated.
- Activity:
  - Avoid further diving for 4–6 wk. (Consider cessation of diving with severe disease.)
  - Avoid air travel for  $\geq 48$ –72 hr.

### PROGNOSIS

- 50–70% of patients achieve total resolution of symptoms.
- 30% achieve temporary relief of symptoms that may wax and wane.
- 1.3 deaths per 100,000 warm water dives
- 2.9 deaths per 100,000 cold water dives

### COMPLICATIONS

- Neurocognitive deficits
- Focal neurologic deficits
- Hearing loss
- Dysbaric osteonecrosis
- Chronic pain

## CODES

### ICD9

993.3 Caisson disease

## PEARLS AND PITFALLS

- Traumatic brain injury, anoxic brain injury, and DCS can present similarly or simultaneously in divers.
- Marine envenomations or ciguatera toxin may cause neurologic symptoms mimicking DCS.

# DEEP VEIN THROMBOSIS

Kevin D. Buckley

## BASICS

### DESCRIPTION

- Thrombotic events in deep veins are relatively rare in children, typically occurring in children with associated comorbidities and risk factors.
- Healthy children appear to be at a significantly lower risk than adults, and there may even be some protective mechanisms. Adults have at least a 7-fold increase in relative risk for deep vein thrombosis (DVT) compared to children (1).
- Health and cost burdens of DVT and its long-term complications are disproportionately higher in children since children live 60–80 yr following DVT, and postthrombotic syndrome (PTS) limits aerobic activities necessary for normal healthy development.

### EPIDEMIOLOGY

#### Incidence

- Peaks in newborn/infants and adolescents
- Newborn 5.1/10,000
- Childhood venous thrombosis 0.07–0.14/10,000 in the general population
- 5.3/10,000 child hospitalizations
- 0.51/10,000 births
- 0.24/10,000 neonatal admissions

### RISK FACTORS

- Previous thrombosis
- Children with DVT likely have multiple thrombophilia traits. In a recent study of those with thrombosis, 19% had no abnormality, 27% had a single trait, and 54% had multiple traits (3).
- Obesity and sedentary lifestyle or prolonged immobilization, such as from a cast or even long air travel
- Ongoing risk factors: Genetic thrombophilia, protein S, C and antithrombin III deficiency, factor V Leiden, primary or secondary antiphospholipid antibodies, inflammatory diseases such as ulcerative colitis or systemic lupus erythematosus, prosthetic cardiac valves, sickle cell disease, malignancy, central venous lines (CVLs)
- Age-specific risk factors in adolescents include smoking and the use of oral contraception.
- Nephrotic syndrome
- Pregnancy is a risk factor.

### PATHOPHYSIOLOGY

- Venous thrombi (VT) are composed mainly of fibrin and RBCs.
- Formation, growth, and breakdown of venous thromboemboli (VTE) reflect a balance between thrombogenic stimuli and protective mechanisms.
- Thrombogenic stimuli are:
  - Venous stasis
  - Activation of blood coagulation
  - Vein damage
- Protective mechanisms are:
  - Inactivation of activated coagulation factors by circulating inhibitors (eg, antithrombin III, activated protein C)
  - Clearance of activated coagulation factors and soluble fibrin polymer complexes by the liver and reticuloendothelial system
  - Lysis of fibrin by the fibrinolytic system
- Inflammation in the most common risk factor.

### ETIOLOGY

- Congenital:
  - Deficiencies of the regulatory proteins: Protein C, protein S, antithrombin III, and plasminogen
  - Synthesis of a procoagulant protein unable to be inhibited by regulatory protein (eg, factor V Leiden)
  - Elevated levels of procoagulant protein; prothrombin mutation (G20210A), elevated factor VIII levels
  - Elevated levels of a toxic organic acid (eg, homocystinemia)
- Acquired conditions that increase risk:
  - Obstruction to flow from indwelling lines, pregnancy, polycythemia, dehydration
  - Immobilization, injury, trauma, surgery
  - Inflammation: Inflammatory bowel disease (IBD), vasculitis, infection, Behçet syndrome
  - Hypercoagulability: Pregnancy, malignancy, antiphospholipid syndrome, nephrotic syndrome, oral contraceptives, L-asparaginase, elevated factor VIII levels
- Rare other entities:
  - Congenital: Dysfibrinogenemia blocks clot lysis
  - Acquired: Paroxysmal nocturnal hemoglobinuria, thrombocytopenia, grafts

### COMMONLY ASSOCIATED CONDITIONS

- CVLs are the most common risk factor for VTE, with 3.5/10,000 pediatric admissions:
  - CVL is the sole reason for increased frequency of VTE in the upper venous system of children (80% of DVT in newborns, and 60% in older children).
- Umbilical vein catheters are associated with thrombi in the inferior vena cava and portal vein.
- Common risk factors for inflammation: Lupus anticoagulant, CVLs, acute infection, chronic inflammation, and IBD
- Activated protein C resistance is the most common hereditary abnormality predisposing to VT.
- Factor V Leiden autosomal dominant inheritance is 5% in the Caucasian population but 16% in patients with their 1st episode of DVT.

## DIAGNOSIS

### HISTORY

- Classic signs and symptoms of DVT are associated with obstruction to venous drainage, including extremity pain and swelling.
- Clinical diagnosis of DVT is difficult.
- 50% of those with DVT have no symptoms, and DVT cannot be excluded or diagnosed based upon clinical findings.

### PHYSICAL EXAM

- Clinical features of VT include leg tenderness, warmth, swelling, a palpable cord, discoloration, venous distention, prominence of superficial veins, and cyanosis.
- Clinical diagnosis of DVT is nonspecific, since symptoms may also be from nonthrombotic disorders.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

- CBC, PT, PTT, and type and cross-match should be monitored prior to initiation of therapy.
- D-dimer may be useful as an exclusionary test, but a positive result is highly nonspecific.
- There are no screening tests for hereditary predisposition to thrombosis. Specific testing is required for protein C, protein S, antithrombin III, factor V Leiden, prothrombin 20210, and plasma homocysteine levels.

#### Imaging

- Real time US is noninvasive and is effective in demonstrating the presence or absence of residual blood flow in DVTs in extremities, particularly the jugular and subclavian veins but not in the intrathoracic veins:
  - Venous duplex US has now replaced venography as the diagnostic study of choice.
- Impedance plethysmography (IPG) is valuable for patients with suspected recurrent DVT because the test returns to normal earlier in patients with proximal VT than compression US.
- Less-used imaging modalities include CT and MRI, but the cost and use of IV contrast limits its use.
- If suspicious for pulmonary emboli, a spiral CT is recommended.

### DIFFERENTIAL DIAGNOSIS

- Muscle strain or tear
- Direct twisting injury of the leg
- Lymphangitis or lymphatic obstruction
- Venous reflux
- Popliteal cyst
- Cellulitis
- Pyomyositis
- Necrotizing fasciitis
- Leg swelling in a paralyzed limb
- Abnormality of the knee joint

## TREATMENT

### INITIAL STABILIZATION/THERAPY

Management should be directed at anticoagulation and/or antithrombotics.

### MEDICATION

#### First Line

- Standard unfractionated heparin or low-molecular-weight heparin (LMWH) is indicated for DVTs that are neither massive nor complicated or if thrombolytics are contraindicated:
  - Both are metabolized more rapidly in newborn infants.
  - Heparin, standard unfractionated:
    - 50–75 U/kg by IV bolus FOLLOWED BY:
    - 20–30 U/kg/hr in newborns OR 15–25 U/kg/hr in older children and adults
  - LMWH:
    - 1.5 mg/kg q12h SC for newborns
    - 1 mg/kg q12h SC for older children/adults
  - LMWH needs less monitoring.
- Warfarin (Coumadin):
  - 0.3 mg/kg/day PO for newborns
  - 0.15 mg/kg/day PO for older children

**Second Line**

- Thrombolytics (ie, tissue plasminogen activator [T-PA]) are indicated for (4):
  - Extensive DVT
  - Massive pulmonary embolism (PE), with respiratory compromise
  - Free-floating thrombi on the outer surface of indwelling central venous catheters
  - Consider first line in patients with all of the following: Acute DVT (<14 days), occlusive iliofemoral thrombi, significant pain, swelling, and no contraindications.
- Contraindications:
  - Active bleeding
  - Surgery or organ biopsy within 10 days
  - Neurosurgery within the previous 3 wk
  - Underlying bleeding diathesis
- Dosing of T-PA: No consensus exists. Either low-dose or high-dose TPA (4,5) can be used:
  - Children >3 mo, start 0.03 mg/kg/hr, max 2 mg/hr; no loading dose
  - Monitor labs every 12 hr and radiographic evidence of fibrinolysis every 24 hr. If there is no evidence of improvement in blood flow, adjust the infusion rate upward to 0.06 mg/kg/hr.
  - Neonates may require higher starting doses (0.06 mg/kg/hr), if there is no improvement in 24 hr, double to 0.12 mg/kg/hr.
  - A low dose can be used 6 hr to 4 days. Monitor blood flow every 24 hr, discontinuing T-PA as soon as clot lysis has been achieved.
  - High-dose T-PA may be given for a shorter duration at 0.5–0.6 mg/kg/hr for 6 hr and has higher bleeding complications. There is controversy over a 2nd 6-hr treatment.
- Unfractionated heparin has been shown to be helpful in adults with T-PA but is not well studied in children. T-PA should be accompanied by low-dose standard unfractionated heparin at 5–10 U/kg/hr without a loading dose:
  - If renal function is impaired, the infusion rate of heparin should be lowered to 2.5–5 U/kg/hr because of the greater bioavailability of heparin.
  - Both dosing strategies are associated with similar levels of efficacy.
- When T-PA therapy is discontinued, start immediately on LMWH, with b.i.d. dosing, as noted above.
- Monitor platelet counts because of a small risk for thrombocytopenia.
- On day 3 of LMWH, convert to oral warfarin.
- For fibrinogen levels <80 mg/dL, consider cryoprecipitate 0.2 bags/kg.
- Monitor platelet levels: Platelet transfusion may be required if platelets are <50,000/ $\mu$ L and bleeding occurs.

**SURGERY/OTHER PROCEDURES**

- Inferior vena cava filters are indicated for patients with acute DVT and:
  - An absolute contraindication to anticoagulant therapy
  - Rare for a patient with massive PE who survives but in whom a recurring PE may be fatal
  - Rare for a patient with objectively recurrent DVT during adequate anticoagulant therapy
  - Patient with recent (<6 wk) proximal VT who requires emergency surgery
- Filter increases incidence of recurrent DVT
- Thrombectomy has little role in children.
- Bleeding concerns:
  - Local or minor bleeding: Compress; topical thrombin, topical collagen, or combination
  - Major or life-threatening bleeding on T-PA: Stop T-PA and heparin, and give cryoprecipitate. Reversal of the thrombolytic process is by E-aminocaproic acid (Amicar) at a dose of 100 mg/kg IV or orally (max single dose 4 g).
  - If only heparin, stop heparin and give protamine: Dose is 1 mg per 100 units of heparin given in the past 2 hr.
  - If on warfarin, stop and give fresh frozen plasma.

**DISPOSITION**

- Inpatient admission criteria:
  - All newly diagnosed DVT patients should be admitted to the inpatient ward for anticoagulation with heparin.
- Critical care admission criteria:
  - Patients on T-PA will need ICU monitoring.
  - Patients who are hypoxemic with a PE need ICU admission.

**Discharge Criteria**

- Patients should be transitioned after 3 days of anticoagulation to oral warfarin with a goal INR of 2–3 for DVT, or 3–4 for PE or massive DVT.
- LMWH may be discontinued when INR is 2–3.

**Issues for Referral**

Consider hematology referral for congenital risk factors.

**FOLLOW-UP****FOLLOW-UP RECOMMENDATIONS**

Discharge instructions and medications:

- Patients should be on oral warfarin for 3–6 months, maintaining an INR of 2–3.
- Longer or indefinite therapy should be considered for the presence of congenital risk factors.
- Refrain from contact sports or high-risk physical activity because of the bleeding risk.
- Counsel the patient on the use of other medications, including over-the-counter medications, that may change the effectiveness of warfarin.
- If there is a negative US with risk factors, recommend a repeat US in 3–7 days to confirm there is no DVT.

**Patient Monitoring**

- Maintain INR between 2 and 3.
- IPG returns to normal in 65% of patients in 3 mo, 85% by 6 mo, and 95% in 1 yr compared to US, which has returns of 30%, 45%, and 60%.

**DIET**

Adjust warfarin if increasing intake of vitamin K.

**PROGNOSIS**

8% recur in 1 yr, and up to 18% recur within 7 yr.

**COMPLICATIONS**

- DVT has high risk for PE: 80/466, or 17%.
- 2.2% chance of death
- Being overweight predisposes to PTS (88%).

**CODES**
**ICD9**

- 453.40 Acute venous embolism and thrombosis of unspecified deep vessels of lower extremity
- 453.41 Acute venous embolism and thrombosis of deep vessels of proximal lower extremity
- 453.42 Acute venous embolism and thrombosis of deep vessels of distal lower extremity

**PEARLS AND PITFALLS**

- VT of the lower extremities, which occurs at an early age and peaks in the 2nd decade of life, is the most common symptom in antithrombin deficiency.
- Negative US of lower extremities and negative D-dimer does not require repeat US in 7 days.
- Poor outcome is defined as recurrent DVT within 2 yr, presence of residual thrombosis, or development of PTS.

# DEHYDRATION

Alan L. Nager

## BASICS

### DESCRIPTION

- Dehydration is a physiologic response to many diseases and conditions.
- It is the result of a negative fluid balance resulting from:
  - Decreased and/or inadequate intake AND/OR
  - Increased output, such as GI, renal, or insensible losses from systemic responses to specific disease states, such as burns or sepsis
- A spectrum of signs and symptoms can be seen in dehydration, with categorization ranging from asymptomatic or mild to severe dehydration with or without hypovolemic shock.
- In the U.S., acute gastroenteritis remains the most significant cause of dehydration.

### EPIDEMIOLOGY

#### Prevalence

- In the U.S., > 1.5 million outpatient visits occur annually for gastroenteritis, resulting in 200,000 hospitalizations and 300 deaths per year.
- Worldwide, diarrheal disease remains the leading cause of morbidity and mortality, with 1.5 billion episodes and 1.5–2.5 million deaths occurring annually in patients <5 yr (1).

### RISK FACTORS

- Sun exposure, humidity, insensible losses, exercise, young age
- Excessive losses
- Insufficient intake (voluntary or involuntary)

### GENERAL PREVENTION

- Fluid intake on a regular and adequate basis
- Protection against risk factors
- Monitoring input and output

### PATHOPHYSIOLOGY

- Dehydration causes total body water and electrolyte losses in the intracellular fluid and extracellular fluid compartments.
- Dehydration is often referred to in relation to serum sodium concentrations:
  - Isonatremic: Sodium 130–150 mEq/L
  - Hyponatremic: Sodium <130 mEq/L
  - Hypernatremic: Sodium >150 mEq/L
- Isonatremic dehydration is the most common form of dehydration, with hyponatremic or hypernatremic dehydration occurring much less frequently.

### ETIOLOGY

- Decreased intake (voluntary or involuntary):
  - Anatomic or pathologic diseases (pharyngitis, stomatitis, cleft lip/palate, facial dysmorphism, airway obstruction)
  - Neurologic diseases (meningitis, encephalitis, brain tumor, seizures)
  - Febrile illnesses
- Increased output:
  - GI losses (vomiting and/or diarrhea)
  - Renal losses:
    - Osmotic (diabetic ketoacidosis, acute tubular necrosis)
    - Nonosmotic (renal diseases, electrolyte disturbance, diabetes insipidus, adrenal disease, diuretics, kidney disease, pseudohypoaldosteronism)
  - Insensible losses (fever, heat, respiratory diseases, diaphoresis, thyroid disease, cystic fibrosis):
    - Moderate to severe burns
    - Secondary ascites
    - Respiratory disease, peritonitis (medical or surgical)
    - Anaphylaxis

### COMMONLY ASSOCIATED CONDITIONS

Some patients have underlying disease for which fluid requirements and losses are unique, such as diabetes, cystic fibrosis, thyroid disease, neurologic diseases (tumor, pituitary dysfunction, or diabetes insipidus), adrenal diseases affecting electrolytes, metabolic diseases, heat-related illnesses, moderate or major burns, or chronic GI illnesses.

## DIAGNOSIS

### HISTORY

- The history should include the environment in which symptoms developed the manifestation of the disease and prior treatment.
- Intake and output should be ascertained:
  - Intake history should include quantifying questions related to oral intake, such as types and amounts.
  - Output history should include such questions as the amount and frequency of urination, presence or absence of vomiting and/or stooling (description, amounts, frequency), tear production (none, minimal, streaming), and the presence or absence of sweating.
- Other questions that should be asked include the level of activity; evidence of a sunken fontanel; fever; presence of saliva; difficulty swallowing, drooling; respiratory symptoms; pallor, cyanosis or changes in skin warmth, texture, or integrity; hematemesis, melena, or hematochezia; penile swelling or changes in urinary stream pattern; changes in mental status, neurologic function, or seizure; appetite or thirst changes; antibiotic/medication use; possible toxic ingestion; travel history; and change in weight.

### PHYSICAL EXAM

- The physical exam should be performed looking at signs that may reflect dehydration.
- Vital signs may show evidence of tachycardia or tachypnea, which are signs characteristic of moderate dehydration.
- Hypotension may be present, which is a classic finding in hypovolemic shock.
- Further evidence of the degree of dehydration may be discovered by finding evidence of lethargy or listlessness; a sunken fontanel; sunken eyes or absent or diminished tears; dry or sticky mucous membranes; tachypnea; a scaphoid or distended abdomen; skin that is cool and/or mottled with delayed capillary refill time, diminished pulses; or evidence of neurologic dysfunction such as seizures (2).

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

- Utility of routine lab testing for patients thought to be mildly or moderately dehydrated is unclear.
- Different underlying mechanisms may result in varying lab abnormalities.
- No specific lab test is consistently predictive of dehydration severity in lieu of a clinical assessment for the mildly and moderately dehydrated patient.
- Obtain electrolytes, BUN, creatine, and glucose for:
  - Severe illness
  - Severe dehydration
  - Patients with chronic diseases
  - Patients whose diet may cause electrolyte changes (eg, rice water or improperly mixed formula)
  - Adjunct means to assess bicarbonate level or acidemia such as blood gas analysis or capnography are of potential value.

### DIFFERENTIAL DIAGNOSIS

See Etiology.

## TREATMENT

### PRE HOSPITAL

In most cases, normal saline or lactated Ringer solution should be used for IV fluid resuscitation as needed.

### INITIAL STABILIZATION/THERAPY

- Fluid administration can be given PO, IV, or NG:
  - Decision to rehydrate orally or parenterally is based on severity of dehydration; ability to tolerate oral fluid; and preference of clinician, patient, and parent:
    - Severe rehydration is typically treated with IV fluid.
    - Mild dehydration is typically treated with PO fluid.
  - Oral rehydration solution should be given in small, frequent amounts.
  - IV fluid can be given in 20–50 mL/kg boluses over  $\geq 1$  hr (clinician preference).
  - NG fluid should be given 20 mL/kg over 1 hr, which can be repeated to a max of 50 mL/kg (3).

- Maintenance hydration can be given based on the “4-2-1” rule:
  - For patients <10 kg, administer 4 mL/kg/hr.
  - For patients between 10 and 20 kg, administer  $[40 + 2 \times (\text{weight} - 10)]$  mL/hr.
  - For patients >20 kg, administer  $[60 + 1 \times (\text{weight} - 20)]$  mL/hr.
  - Additional fluid requirements (eg, 11/2 x maintenance) can also be given.

## MEDICATION

### First Line

Antiemetics such as ondansetron (Zofran) may be attempted:

- <4 yr: 0.15 mg/kg/dose IV/PO q6–8h
- 4–12 yr: 4 mg 2–3 times/day IV/PO, max dose 12 mg/day
- >12 yr: 8 mg 2–3 times/day IV/PO, max dose 24 mg/day

### Second Line

- Hyaluronic acid (Hylenex) 150 U single dose SC several minutes prior to SC fluid administration (4):
  - In preliminary stages of clinical use without clearly defined role in therapy
  - Facilitates rehydration without IV use in children
  - For use with difficult or expected difficult vascular access or based on clinician or patient/parent preference
- Other antiemetics such as diphenhydramine or metoclopramide have limited use in nononcologic patients.

## DISPOSITION

### Admission Criteria

- Persistent moderate dehydration despite treatment, usually related to ongoing losses (eg, vomiting and/or diarrhea)
- Electrolyte abnormalities requiring ongoing treatment
- Moderate or severe dehydration necessitating further treatment, including the need for additional fluid and electrolyte replacement and monitoring
- Critical care admission criteria:
  - Unstable vital signs despite IV hydration
  - Severe hypo- or hypernatremia

### Discharge Criteria

Baseline or near-baseline vital signs and clinical evidence of adequate hydration (3,5)

### Issues for Referral

Refer to a subspecialist if the dehydration is caused by a subspecialty disease requiring additional evaluation.

## FOLLOW-UP

### FOLLOW-UP RECOMMENDATIONS

- Discharge instructions and medications:
  - Follow-up should occur when additional guidance is needed or if a “hydration check” is deemed appropriate.
  - Instruct the patient and caregivers about hand hygiene and contagiousness.
- Activity:
  - As tolerated

### Patient Monitoring

Parent instructions should include watching for diminished tears, decreased urine output including concentrated or bright yellow urine, diminished alertness, lethargy, and seizures.

### DIET

- Encourage small amounts of oral rehydration fluids, such as Pedialyte, Gatorade, or other sport drinks.
- Give bland, nonspicy foods and avoid food or liquids known to cause diarrhea, such as beans, high-fructose-containing juices, and caffeinated drinks (6).
- BRAT (bananas, rice, applesauce, toast) diet may be helpful.

### PROGNOSIS

- Most patients will recover within 3–5 days, although recovery time may vary depending on the cause of the dehydration.
- Infectious agents causing diarrhea and dehydration may require antibiotics (see Diarrhea topic).
- The vast majority of patients recover without complications.

### COMPLICATIONS

- Hypernatremia
- Hyponatremia
- Shock
- Cerebrovascular accident
- Shock

## ADDITIONAL READING

World Health Organization. The treatment of diarrhea. WHO CDD/SER/80.2. Geneva, Switzerland: Author; 1995.

### ICD9

- 276.51 Dehydration
- 775.5 Other transitory neonatal electrolyte disturbances

## PEARLS AND PITFALLS

- Dehydration can cause significant morbidity and mortality.
- Clinicians must understand diseases that cause dehydration.
- Categorize the severity of dehydration so that treatment will be appropriate.
- Lab testing is clinically indicated based on dietary history or disease or in patients severely dehydrated or in shock.
- Consider PO, IV, or NG treatment modalities, as each may be used for specific circumstances.

# DENGUE FEVER

Linda Szema

## BASICS

### DESCRIPTION

- Dengue infection is caused by an RNA virus transmitted to humans by infected mosquitoes.
- Symptoms vary widely, from subclinical infection to dengue fever (DF) or dengue shock syndrome (DSS).
- Severe infection is categorized as dengue hemorrhagic fever (DHF) or DSS.
- Dengue is one of the viral hemorrhagic fevers (VHFs), others of which include infections such as hantavirus, Lassa fever, yellow fever, and Ebola and Marburg viruses

### EPIDEMIOLOGY

#### Incidence

- 50–100 million cases of dengue worldwide each year; this includes:
  - 500,000 DHF cases
  - 22,000 deaths, mostly among children
- Incidence over the last 50 yr has increased 30-fold.
- Following diarrheal diseases and respiratory infections, DF/DHF has become a leading cause of hospitalization and death among children in Southeast Asia.
- An increasing number of cases in the Caribbean, Central America, and Mexico:
  - Areas of the U.S. that border these locations as well as cities that receive travelers from these locations have an increasing incidence.

### RISK FACTORS

- Traveling to or living in tropical and subtropical environments
- Most U.S. citizens acquire the infection in Puerto Rico, the U.S. Virgin Islands, Samoa, and Guam, which are endemic for the virus.
- Dengue is present in urban and suburban areas in the Americas, Southeast Asia, Eastern Mediterranean, and Western Pacific and in rural areas in Africa.
- Children <15 yr have increased severe and fatal disease.

### GENERAL PREVENTION

- Avoid mosquito bites by using repellent, wearing clothing to reduce areas of exposed skin, and staying inside air-conditioned or well-screened buildings.
- Public health efforts include mosquito population control.

### PATHOPHYSIOLOGY

- Dengue virus is a single-stranded RNA virus belonging to the genus *Flavivirus*.
- It is transmitted by infected *Aedes* mosquitoes, primarily *Aedes aegypti*.
- Incubation is followed by viremia, causing the acute phase of the illness.
- Dengue cannot be spread directly from person to person.
- Viral clearance occurs with defervescence and is accomplished through the generation of antibodies and the activation of CD4+ and CD8+ T lymphocytes.

- In severe dengue, an imbalance of inflammatory mediators, cytokines, and chemokines occurs, which is thought to cause dysfunction of vascular endothelial cells and impaired progenitor cell growth:
  - This causes plasma leakage, hemoconcentration, and thrombocytopenia.
- Hemorrhage may be secondary to thrombocytopenia, platelet dysfunction, or disseminated intravascular coagulation (DIC).

### ETIOLOGY

Dengue virus (DENV)-1, DENV-2, DENV-3, and DENV-4, of the genus *Flavivirus*

## DIAGNOSIS

### HISTORY

- Abrupt high-grade fever
- Incubation ranges from 3–14 days.
- DF, the acute phase of the illness, is characterized by high fever for 2–7 days and two or more of the following:
  - Headache
  - Retro-orbital pain
  - Myalgia/Arthralgia
  - Rash
  - Leukopenia
  - Mild hemorrhagic manifestations
  - Bleeding of mucous membranes
  - Petechiae
- Associated symptoms not meeting the definition for DF include:
  - Fatigue
  - Irritability
  - Anorexia
  - Nausea
  - Abdominal pain
  - Persistent vomiting
- If the temperature drops to  $\leq 38^{\circ}\text{C}$  and the symptoms improve on days 3–7, then the patient is said to have nonsevere dengue.
- If capillary permeability and hematocrit increase, this marks the start of the critical phase and severe dengue:
  - New symptoms at the critical phase may include persistent vomiting, severe abdominal pain, and difficulty breathing.
  - The critical phase lasts for 24–48 hr.
- DHF characterized by:
  - Presence of resolving fever or recent history of fever lasting 2–7 days
  - Any hemorrhagic manifestation
  - Thrombocytopenia (platelet count  $< 100 \times 10^9/\text{L}$ )
  - Increased vascular permeability evidenced by:
    - $> 20\%$  rise in hematocrit for age and sex
    - $> 20\%$  drop in hematocrit following treatment with fluids as compared to baseline
  - Signs of plasma leakage: Hypoproteinemia, ascites, or pleural effusion
- DSS includes all criteria for DHF plus circulatory failure, evidenced by:
  - Rapid and weak pulse and narrow pulse pressure ( $> 20$  mm Hg)
  - Age-specific hypotension and cold, clammy skin and restlessness

### PHYSICAL EXAM

- Fever
- Rash, typically macular or maculopapular
- Petechiae, ecchymosis, purpura
- Mucosal membrane bleeding
- Hepatomegaly within a few days of fever onset
- In DHF, ascites or pleural effusion
- In DSS, evidence of shock

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

- CBC:
  - Leukopenia
  - Thrombocytopenia
  - Elevated hematocrit
  - Blood smear may show atypical lymphocytes.
- Basic metabolic panel:
  - Electrolyte/Acid-base abnormalities or hypo- or hyperglycemia may occur.
- LFTs: AST and ALT may be mildly elevated:
  - Normal AST is an extremely strong negative predictor of DF.
- Stool guaiac
- Urinalysis
- Additionally, DIC panel, type and cross-match, blood gas, and blood, urine, and CSF cultures as necessary
- Providers should report cases of patients with dengue-like illness and recent travel to affected areas to the local or state health department and send specimens for lab testing:
  - Specimens may be submitted directly to CDC laboratories in San Juan, Puerto Rico.
  - 2 serum specimens should be sent:
    - Acute (drawn prior to day 5 of illness) for RT-PCR for dengue virus
    - Convalescent (drawn on days 6–30) for ELISA for dengue IgM

#### Imaging

- CXR to assess for pleural effusion
- Abdominal sonography as needed to diagnose ascites

#### Diagnostic Procedures/Other

Tourniquet test: Positive tourniquet test—BP cuff is inflated to midway between systolic and diastolic pressure for 5 min, then petechiae are counted

- If  $> 10$  square inches, the test is positive.

### DIFFERENTIAL DIAGNOSIS

Depends on the geographic origin of the patient; includes:

- Influenza
- Chikungunya
- Infectious mononucleosis
- HIV
- Measles
- Enteroviral infections
- Malaria
- Leptospirosis
- Typhoid
- Rickettsial diseases
- VHFs
- Other *Flavivirus* infections: Yellow fever, St. Louis encephalitis, Japanese encephalitis, West Nile

## TREATMENT

### PRE HOSPITAL

Assess and stabilize airway, breathing, and circulation.

### INITIAL STABILIZATION/THERAPY

- Assess and stabilize airway, breathing, and circulation.
- Supportive treatment is the mainstay of care:
  - No antiviral therapy is available.
- Based on extensive experience treating children in dengue epidemics in Southeast Asia, the World Health Organization (WHO) advocates a specific protocol to treat hypotensive shock:
  - Initial bolus of D5 normal saline or Ringer lactate (20 mL/kg of body weight) infused over 15 min, followed by continuous infusion (10–20 mL/kg/hr depending on the clinical response) until vital signs and urine output normalize
  - As the patient has clinical improvement, the infusion rate should be slowly reduced until it matches plasma fluid losses.
  - Adequacy of treatment is assessed by BP, pulse, hematocrit, and urine output.
  - If shock persists, use WHO-recommended therapy; blood or platelet transfusion may also be necessary.
- If no warning signs (see below) are present, oral hydration should be encouraged; if not tolerated, give IV fluid therapy for rehydration and then reassess for PO tolerance.
- If warning signs (see below) are present, fluid therapy with isotonic solution should be initiated with reassessment of hematocrit and clinical status.
- If signs of severe dengue are present, judicious IV fluid resuscitation is necessary, with the goal to improve central and peripheral circulation and end-organ perfusion.
- Warning signs:
  - Abdominal pain or tenderness
  - Persistent vomiting
  - Clinical fluid accumulation
  - Bleeding
  - Lethargy, altered mental status, restlessness
  - Liver enlargement >2 cm
  - Increase in hematocrit concurrent with rapid decrease in platelet count

### MEDICATION

#### First Line

- Acetaminophen 15 mg/kg/dose PO/PR q4h PRN
- Threshold for blood or platelet transfusion varies with institution:
  - In the setting of hemorrhage, platelet transfusion if  $<25 \times 10^9/L$
  - If asymptomatic, platelet transfusion if  $<10 \times 10^9/L$

### Second Line

NSAIDs are relatively contraindicated due to the theoretical potential to exacerbate hemorrhage.

### DISPOSITION

#### Admission Criteria

- Abdominal pain or tenderness
- Persistent vomiting
- Ascites
- Hemorrhage, spontaneous bleeding
- Lethargy, altered mental status, or restlessness
- Rising hematocrit
- Coexisting conditions: Pregnancy, infancy, immunocompromise, diabetes, renal failure
- Critical care admission criteria:
  - Signs of shock
  - Severe bleeding
  - Fluid overload
  - Signs of organ impairment such as hepatic injury, encephalitis, myocarditis

#### Discharge Criteria

All of the following should be satisfied:

- Vital signs normal or with minimal elevation of heart rate, though fever is not a contraindication for discharge
- Ability to tolerate adequate oral fluids
- Passing of urine at least once q6h
- No spontaneous bleeding or a rising hematocrit

#### Issues for Referral

Consider transfer to a critical care setting capable of managing severe shock.

## FOLLOW-UP

### FOLLOW-UP RECOMMENDATIONS

Discharge instructions and medications:

- Take acetaminophen for fever or analgesia.
- Instructions for immediate return to care if deterioration or hemorrhage are critical

#### Patient Monitoring

Caregivers may monitor for petechiae or hemorrhage.

### PROGNOSIS

- Varies with severity of illness, particularly degree of thrombocytopenia, hemorrhage, and shock
- Permanent end-organ damage and death may result from hemorrhage and/or shock.

### COMPLICATIONS

- Rare but can include:
  - Hepatic injury
  - Encephalopathy
  - Myocarditis
- Death much more frequently occurs in cases outside of the U.S.

### ADDITIONAL READING

Idiopathic Thrombocytopenic Purpura

## CODES

### ICD9

- 061 Dengue
- 065.4 Mosquito-borne hemorrhagic fever

### PEARLS AND PITFALLS

- The clinical presentation of dengue infection varies widely.
- A history of recent travel to endemic areas and dengue-like illness should prompt providers to report to local or state authorities.
- DF can progress to DHF or DSS with severe hypoperfusion; this will last for 24–48 hr.
- Vital signs and CBC must be monitored, with assessment for bleeding, hypoperfusion, and dehydration.
- Give acetaminophen for fever, and avoid NSAIDs and aspirin.
- Overhydration to point of pulmonary edema is a risk of therapy.
- When patients have stable vital signs, normal hematocrit, and are able to take PO, discontinue IV fluid therapy.

# DEPRESSION

David Chao

Richard J. Scarfone

## BASICS

### DESCRIPTION

- Depression can refer to sadness but also describes a syndrome with cognitive, physiologic, and affective components (1).
- Childhood depressive disorders include sadness variation, bereavement, sadness problem, adjustment disorder with depressed mood, major depressive disorder (MDD), dysthymic disorder, and bipolar disorder (2).

### EPIDEMIOLOGY

- In the U.S., the prevalence of MDD is about 1% of preschoolers, 2% of school-age children, and 5–8% of adolescents (2):
  - 1 in 5 teens has a history of depression at some point during adolescence (2).
  - The prevalence of depression appears to be increasing, with onset at earlier ages (2).
  - Gender ratio is equal in prepubertal children and but there is a 2:1 female predominance in adolescents (2).
- Only 20–35% of youth who meet full criteria for depression currently receive treatment (2).

### RISK FACTORS

- Family history of depression
- Previous depressive episodes
- Family conflict
- Sexuality conflict
- Poor academic performance
- Dysthymia, anxiety disorders
- Substance abuse disorders (3)

### PATHOPHYSIOLOGY

- A multifactorial theory of depression is widely held, with biologic, environmental, psychological, and social inputs.
- Monoamine hypothesis: Depression results from deficiency or abnormal functioning of serotonin, epinephrine, and norepinephrine in the CNS:
  - Medical therapy is based on this theory (eg, selective serotonin reuptake inhibitors).

### ETIOLOGY

- It is important to consider organic (nonpsychiatric) causes of depression, which include the following:
- Neurologic: Stroke, subdural hematoma, postconcussive syndrome, brain tumors (especially frontal), Huntington disease, seizure disorder, syphilis
- Metabolic: Vitamin B<sub>12</sub> deficiency, pellagra (niacin deficiency), hypercalcemia, hyponatremia, hypokalemia, Wilson disease
- Endocrinologic: Thyroid disease (hypo- or hyperthyroid), adrenal disease (Addison disease, Cushing syndrome), diabetes mellitus
- Medications and toxins: Beta-blockers, anticonvulsants, antipsychotics, corticosteroids, estrogens/oral contraceptives, amphetamines, stimulants (cocaine, crack), marijuana, alcohol, heavy metals
- Other: Various infections (hepatitis, HIV, Epstein-Barr virus), malignancy, anemia, systemic lupus erythematosus

### COMMONLY ASSOCIATED CONDITIONS

See Risk Factors and Etiology.

## DIAGNOSIS

### HISTORY

- *Diagnostic and Statistical Manual of Mental Disorders* (DSM) diagnosis of MDD: Presence of 5 of 9 of the following, occurring almost daily for 2 wk: Depressed/Irritable mood (must be present), diminished interest or pleasure (must be present), psychomotor agitation/retardation, recurrent thoughts of death/suicidality, fatigue/energy loss, weight change, feelings of worthlessness, poor concentration (4):
  - DSM criteria were established for adults. Children and adolescents with depression may not present with these classic symptoms.
  - It is critical to ascertain degree of functional impairment rather than attempting to fit symptoms into a set of diagnostic criteria.
  - The *Diagnostic and Statistical Manual for Primary Care* (DSM-PC), *Child and Adolescent Version*, provides a concise guide for diagnosis of pediatric mental health disorders (5).
- *SIG E CAPS* mnemonic (“give energy capsules”): Sleep, Interest, Guilt, Energy, Concentration, Appetite, Psychomotor changes, Suicidality
- The *SHADSSSS* mnemonic can also be used to help address a complete inventory of psychosocial functioning, including School, Home, Activities, Depression, Drugs/Alcohol, Sexuality, Suicide, Safety, Strengths (1).
- Children and adolescents often present to the emergency department setting when symptoms have reached a crisis point (eg, suicide attempt).
- Most children present with nonpsychiatric chief complaints (eg, somatic symptoms, school problems, behavior problems, irritability).
- Diagnosis is challenging because many psychiatric illnesses (including psychotic disorders, ADHD, anxiety disorders, disruptive behavior disorders including oppositional defiant disorder and conduct disorder, and substance abuse disorders) present with similar symptoms:
  - Patients may lack insight into their problems with mood.
- The clinician cannot rule out depression based on patient’s rejection of this diagnosis.
- A comprehensive history to determine suicidality should include method and timing, lethality, circumstances, history of prior attempt(s), level of planning, current affect and psychological status, family consistency/dynamics, pharmaceuticals available to patient, history of interpersonal conflict/loss, history of substance abuse, history of psychological disorder or medical problem, history of abuse/neglect/incest, social supports and coping strategies, feelings of regret, or continued desire for self-harm (6).
- The presentation of depression differs based on stages of development (2).
- Infants and preschool-age children:
  - Manifestations of depression in infancy is typically the result of loss of the mother and lack of nurturance.
  - Symptoms include apathy, listlessness, staring, hypoactivity, poor feeding/failure to thrive, and increased rate of infections.

- School-age children:
  - Depressed school-age children are cognitively able to internalize environmental stressors (including family conflict) and display low self-esteem and guilt.
  - This inner turmoil is expressed through somatic complaints, anxiety, and irritability.
  - Key features of childhood depression are dysphoric mood (looking or feeling sad, moodiness/irritability, and crying easily) and self-deprecating ideation (low self-esteem, feelings of worthlessness, and suicidality).
  - Depressed children often present with somatization (eg, stomach aches, headaches), school problems (including school phobia), temper tantrums, runaway behavior, phobias, separation anxiety, and fire setting.
  - Because many of these symptoms can be observed in the school setting, teachers should be included in the evaluation process.
- Adolescents:
  - Adolescents undergo a period of biopsychosocial maturation that is fertile for the development of depressive symptoms in predisposed individuals.
  - Adolescent depression is similar to adult-onset depression.
  - Red flags include somatization, academic problems, promiscuity, drug/alcohol use, aggressive behavior, and stealing.
  - Because of their developmental struggle with autonomy from authority figures, it is particularly important to establish a good rapport with adolescent patients.

### PHYSICAL EXAM

- Evaluation of the child’s mental status takes place throughout the emergency department visit:
  - Features of the mental status examination include orientation, appearance, memory, cognition, behavior, relatedness, speech, affect, thought content, and insight/judgment.
- A depressed patient may appear withdrawn, lack spontaneous speech, express negativistic thoughts, and demonstrate psychomotor retardation and a limited range of affect.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

- Pregnancy test
- An initial presentation of depression may prompt an evaluation for organic causes:
  - CBC
  - Electrolytes and LFTs
  - Thyroid function tests
  - Vitamin B<sub>12</sub> level
  - Acetaminophen level if intentional ingestion and possibly other toxicologic screening (2)

#### Imaging

Consider CT or MRI of brain

#### Diagnostic Procedures/Other

The Pediatric Symptom Checklist and the Beck Depression Inventory are widely accepted screening tools used to detect psychopathology in the pediatric population (2).

**DIFFERENTIAL DIAGNOSIS**

- See Etiology.
- Consider factitious disorders.

**TREATMENT**
**INITIAL STABILIZATION/THERAPY**

- The 3 major goals are determining suicidal potential, uncovering acute precipitants, and making the appropriate disposition (1).
- Ascertain suicidal intent (eg, “When you took those pills, what did you expect to happen? What did you hope would happen?”) (1).
- Patient should be asked to change into a hospital gown, belongings should be secured out of the patient’s reach, the patient should be under constant supervision by emergency department personnel, and the exam room should be free of objects with which the patient can use to harm him- or herself.

**MEDICATION**

- Agitation:
  - Agitation or combativeness are less common in children than adults and infrequently require chemical restraint/sedation.
  - Lorazepam 0.05 mg/kg IV, with a max single dose of 2 mg in adolescents
  - Haloperidol 0.025–0.05 mg/kg IV/IM; use a 5-mg dose in adolescents.
- Antidepressants are typically not initiated in the emergency setting:
  - These medications take weeks to months to begin working and should be initiated and monitored by the patient’s long-term mental health provider.

**ALERT**

Selective serotonin reuptake inhibitors are associated with increased suicidality in some patients. These medications should only be prescribed in coordination with a mental health professional as part of a comprehensive treatment plan.

**DISPOSITION****Admission Criteria**

- Any patient who is at risk of harm to self or others but who is medically stable requires inpatient psychiatric hospitalization.
- Any patient who is unable to attend to self-care and whose family is unable to adequately provide care requires inpatient psychiatric hospitalization.
- An actively suicidal patient should *never* be discharged to home.

**Discharge Criteria**

A patient may be discharged to home in the care of family members if team members feel that he or she is not at risk for harm to self or others and adequate outpatient follow-up is arranged.

**Issues for Referral**

Patients who are determined to have a primary depressive disorder and/or suicidality should receive follow-up outpatient psychiatric care.

**Additional Therapies**

St. John’s Wort, omega-3 fatty acids, thyroid extract, and combination herbal preparations are sometimes used to treat depressive symptoms.

**FOLLOW-UP****FOLLOW-UP RECOMMENDATIONS****Patient Monitoring**

Outpatients must be monitored closely by family members and primary care physicians for suicidal ideation or self-injurious behavior.

**PROGNOSIS**

- Early recognition and treatment of depressive disorders improves functioning and prognosis.
- Efficacy of pharmacotherapy and psychotherapy varies (3).

**COMPLICATIONS**

- Suicide
- Self-injury
- Poor social functioning

**ICD9**

- 296.20 Major depressive affective disorder, single episode, unspecified degree
- 309.0 Adjustment disorder with depressed mood
- 311 Depressive disorder, not elsewhere classified

**PEARLS AND PITFALLS**

- Depression may be secondary to a primary psychiatric disorder or organic pathology.
- Most children with depression present with nonpsychiatric chief complaints (eg, somatic symptoms, school problems, behavior problems).
- The mnemonic *SIG E CAPS* (Sleep, Interest, Guilt, Energy, Concentration, Appetite, Psychomotor changes, Suicidality) is helpful in assessing the key features of MDD.
- The *SHADSSSS* mnemonic can be used to help address a complete inventory of psychosocial functioning. The components of the history should include School, Home, Activities, Depression, Drugs/Alcohol, Sexuality, Suicide, Safety, and Strengths.
- The 3 major goals of managing depression are determining suicidal potential, uncovering acute precipitants, and making an appropriate disposition.

# DERMATOMYOSITIS

Vincenzo Maniaci  
Barbara M. Garcia Peña

## BASICS

### DESCRIPTION

- Dermatomyositis is a systemic autoimmune vasculopathy primarily affecting the skeletal muscles and skin, causing symmetric muscle weakness and a characteristic skin rash.
- Characteristic skin rash plus three of the following criteria are necessary for a definitive diagnosis (1,2):
  - Symmetric proximal muscle weakness
  - Elevated muscle enzymes
  - Electromyographic changes of myositis
  - Muscle biopsy evidence of myositis and muscle necrosis

### EPIDEMIOLOGY

#### Incidence

- Peak age is 5–10 yr.
- Girls are affected more than boys (ratio 2.3:1).
- 2.5–4.1 cases per million children per year
- Rates by race (3):
  - 3.4 cases per million white non-Hispanic
  - 3.3 cases per million African American non-Hispanic
  - 2.7 cases per million Hispanic

### RISK FACTORS

- Strong association with HLA antigens B8/DR3, DQA1\*0501 (4), HLA-DRB\*0301, and DQA1\*0301 allele (5)
- Polymorphism of the tumor necrosis factor alpha and interleukin-1 receptor antagonist (6)

### PATHOPHYSIOLOGY

- Involves activation of the cell-mediated and humoral immune system, resulting in endothelial cell damage. The activation of cytotoxic CD8+ T cells, macrophages, and autoantibodies against an unknown endothelial antigen leads to upregulation of the expression of major histocompatibility complex class I and II (7).
- Immune complexes are deposited, leading to complement activation and subsequent vascular injury and muscle inflammation.

### ETIOLOGY

Unclear but proposed autoimmune vasculopathy provoked by a possible environmental trigger (group A beta-hemolytic streptococci, coxsackievirus, ECHO virus, ultraviolet light) in a genetically susceptible person

## DIAGNOSIS

### HISTORY

- Insidious vs. acute onset of muscle weakness and rash
- Muscle weakness may lead to limitations in performing activities of daily living such as brushing hair, getting out of bed, rising from a chair, or climbing stairs.
- May also complain of:
  - Low-grade fever
  - Weight loss
  - General weakness
  - Arthralgia
  - Dysphagia
  - Abdominal pain
  - Melena

### PHYSICAL EXAM

- Muscle: Symmetric, proximal muscle (deltoid, quadriceps) weakness
- Dermatologic:
  - Heliotrope dermatitis: Reddish-purple rash of the upper eyelids, usually accompanied with periorbital edema
  - Gottron papules: Erythematous, violaceous plaques located over the bony prominences of the finger joints, elbows, knees, and ankles
  - Nailfold changes: Capillary dilatation and tortuosity
  - Calcinosis:
    - Superficial plaques or nodules on the extremities
    - Deep muscle calcification potentially limiting joint mobility
    - Linear calcification along myofascial planes
    - Subcutaneous calcium deposition of the torso
  - Skin ulceration is generally a sign of significant vasculopathy.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

- Elevated muscle enzymes:
  - Aspartate aminotransferase
  - Aldolase
  - Creatine phosphokinase
  - Lactate dehydrogenase
- Myositis-specific antibodies seen in about 10% of patients:
  - Antisynthetase autoantibodies
  - Anti-Mi-2 autoantibodies
  - Antisignal recognition autoantibodies
- Antinuclear antibody, mainly speckled pattern, elevated in about half of patients
- Nonspecific lab findings:
  - ESR may be normal or elevated
  - Elevated Von Willebrand factor

### Imaging

- No imaging is necessary in the emergency department.
- As an outpatient or inpatient, MRI is useful in detecting areas of disease activity and localization for muscle biopsy (8).

### Diagnostic Procedures/Other

- Outpatient referral for electromyography of the muscles
- Outpatient referral for muscle biopsy of a clinically affected but not atrophied muscle
- Outpatient referral for pulmonary function testing to evaluate the progression of interstitial lung disease

### Pathological Findings

Lymphocytic vasculitis of small arteries and veins of muscle, skin, subcutaneous tissue, and GI tract

### DIFFERENTIAL DIAGNOSIS

- Mixed connective tissue disease, scleroderma, systemic lupus erythematosus
- Muscular dystrophy, Becker muscular dystrophy, limb-girdle muscular dystrophy, facioscapulohumeral dystrophy, spinal muscle atrophy
- Myasthenia gravis, amyotrophic lateral sclerosis, poliomyelitis, Guillain-Barré syndrome
- Drug-induced myositis: Chloroquine, azathioprine, penicillamine, ipecac, ethanol, corticosteroids
- Hypothyroidism, hyperthyroidism, Cushing syndrome

## TREATMENT

### PRE HOSPITAL

- Assess and stabilize airway, breathing, and circulation.
- Suctioning of secretions from oral cavity if necessary

### INITIAL STABILIZATION/THERAPY

- Assess and stabilize airway, breathing, and circulation.
- Intubation and mechanical ventilation for patients with respiratory failure or inability to protect upper airway
- Suctioning of the oral cavity in those patients with dysphagia
- Placement of an NG tube for gastric decompression
- Intubation and mechanical ventilation for patients with respiratory failure or inability to protect upper airway

**MEDICATION**

Institution of medications is usually done in conjunction with consultation with a rheumatologist.

**First Line**

Corticosteroids are the mainstay for muscle involvement:

- Prednisone 1–2 mg/kg/day PO

**Second Line**

Methotrexate 10–25 mg/m<sup>2</sup>/wk PO or SC, max 40 mg/wk

**SURGERY/OTHER PROCEDURES**

Surgical excision of areas of calcinosis causing pain or physical impairment may be done as an outpatient referral.

**DISPOSITION****Admission Criteria**

- Critical care admission criteria:
  - Myocarditis, CHF
  - Dysphagia with inability to handle secretions
  - Respiratory failure secondary to pulmonary fibrosis or weakness of the diaphragm and intercostal muscles
  - Hemodynamic instability from mucosal ulcerations resulting in GI bleeding and bowel wall perforations
  - Septic shock
- Inpatient admission criteria:
  - Progressive muscle weakness
  - Velopalatine weakness leading to pooling of oral secretions, nasal voice, and aspiration pneumonia

**Discharge Criteria**

Ability to handle oral secretions and resolution of respiratory dysfunction

**Issues for Referral**

Multidisciplinary outpatient approach: Rheumatologist, dermatologist, physical therapist, occupational therapist, speech therapist

**Additional Therapies**

Physical, occupational, and speech therapy

**FOLLOW-UP****FOLLOW-UP RECOMMENDATIONS**

Activity:

- Physical activity is encouraged to maintain range of motion and prevent contractures.
- Avoid ultraviolet exposure with protective clothing and sunscreen.

**Patient Monitoring**

Outpatient monitoring of muscle enzymes and muscle strength every 3–6 mo

**DIET**

Supplemental calcium and vitamin D if taking corticosteroids

**PROGNOSIS**

- Variable disease progression with 3 distinct clinical courses:
  - Monocyclic
  - Polycyclic
  - Chronic continuous (50% developing chronic disease within 24 mo of diagnosis) (9)
- 2–3% mortality

**COMPLICATIONS**

- Calcinosis cutis with secondary bacterial infection
- Joint contractures from calcinosis or prolonged immobility

Weakness

ICD9  
710.3 Dermatomyositis

**PEARLS AND PITFALLS**

- Dermatomyositis should be considered in patients presenting with rash and muscle weakness.
- Delayed recognition and treatment with corticosteroids results in disease progression and poor outcome.

# DIABETES INSIPIDUS

Phillip Visser

Peter L. J. Barnett

## BASICS

### DESCRIPTION

- Diabetes insipidus (DI) is defined as the inability to concentrate urine, leading to polyuria and compensatory polydipsia.
- It can result in severe fluid and electrolyte imbalance.
- Central DI is the failure of adequate antidiuretic hormone (ADH) release.
- Nephrogenic DI occurs when the distal tubules of the nephron do not respond to ADH.

### EPIDEMIOLOGY

- It is a rare condition with onset in childhood and early adult years.
- Development of the condition depends on the underlying pathologic process.

### PATHOPHYSIOLOGY

- ADH concentrates urine by binding to the vasopressin V2 receptor in the distal collecting tubule of the kidney. It inserts aquaporin 2, a water-channel protein, into the cell membrane. This allows passage of water from the lumen of the nephron, along an osmotic gradient, into the cells of the collecting duct.
- Inadequate levels of ADH or decreased effect on collecting tubules result in loss of water in urine.
- An intact thirst mechanism results in polydipsia to compensate for increased water losses.
- If access to water is unavailable or thirst mechanism is absent, severe dehydration ensues.

### ETIOLOGY

- Cranial DI:
  - Head trauma and neurosurgical procedures
  - Genetic causes include autosomal dominant, autosomal recessive (very rare), X-linked recessive (very rare), and DIDMOAD (**D**iabetes **I**nsipidus **D**iabetes **M**ellitus **O**ptic **A**trophy **D**eafness) syndrome.
  - Midline brain developmental defects (eg, septo-optic dysplasia)
  - Craniopharyngioma, pituitary adenoma, germinoma, and optic glioma are common causes.
  - Meningoencephalitis, tuberculous granulomas, congenital cytomegalovirus, and toxoplasmosis are infective conditions responsible for DI.
  - Langerhans cell histiocytosis is a common inflammatory cause for DI and less commonly sarcoid and lymphocytic neurohypophysitis.
  - Hypoxic/ischemic brain damage can cause transient or permanent DI.
  - Very commonly, no apparent cause is found.

- Nephrogenic DI:
  - X-linked recessive inheritance (vasopressin V2 receptor gene defect) and autosomal recessive inheritance (aquaporin-2 gene defect)
  - Chronic renal disease
  - Obstructive uropathy
  - Renal dysplasia
  - Polycystic kidney disease
  - Sickle cell disease
  - Electrolyte disturbances such as hypercalcemia and hypokalemia
  - Diabetes mellitus is often responsible for secondary ADH resistance.
  - Various drug associations exist: Amphotericin B, chlorpromazine, cisplatin, diphenylhydantoin, diuretics, ethanol, foscarnet, lithium, reserpine, rifampicin, and volatile anesthetics.

## DIAGNOSIS

### HISTORY

- Patients with complete DI do not voluntarily stop drinking for >2 hr, even at night.
- Water is the preferred fluid, and children may drink it from any available source.
- Estimate the daily volume of urine and frequency of micturition.
- New-onset enuresis may be a presenting complaint.
- Infants may present with polyuria, irritability, and failure to thrive.
- Breast-feeding infants can present later due to lower solute load in feeds, and the need for additional water feeds is often reported in infants.
- Previous episodes of dehydration requiring medical treatment would suggest previously unrecognized illness.
- Signs and symptoms of cranial tumor:
  - Headache
  - Visual disturbance
  - Abnormal weight gain or loss
  - Hyperpyrexia
  - Precocious puberty
- Family history will be important in directing the investigation and to provide genetic counseling.

### PHYSICAL EXAM

- Look for signs of dehydration, deficient nutritional status, and trauma.
- Midline anomalies can predispose to DI.
- Visual field defects and papilledema are early signs of intracranial tumors; very young patients will require an ophthalmology consultation.
- Abdominal mass can be present with hydronephrosis or bladder distension associated with DIDMOAD syndrome.

## DIAGNOSTIC TESTS & INTERPRETATION

### Lab

#### Initial Lab Tests

- Blood:
  - Random plasma osmolality
  - Renal function and electrolytes, calcium, phosphate
  - Random glucose
- Urine:
  - Random urine osmolality
  - Urinalysis and microscopy
- Pregnancy test in females
- These tests help to establish the diagnosis and unmasking possible differential diagnosis.
- Low serum sodium and osmolality suggest primary polydipsia; in untreated cranial or nephrogenic DI, serum sodium and osmolality are typically in the normal to high-normal range. Concomitant urine osmolality aids interpretation.
- Renal impairment and hypercalcemia can identify the underlying causes of nephrogenic DI.
- Elevated random glucose will identify underlying diabetes mellitus, a cause of polyuria on its own, but it can also be responsible for secondary nephrogenic DI.
- Tumor markers:
  - Alpha-fetoprotein and hCG levels should be measured if underlying malignancy is suspected.

### Imaging

- Brain MRI may show the loss of hyperintense signal on T1-weighted images of the posterior pituitary in both cranial and nephrogenic DI and identify tumors:
  - Serial MRI should be done in idiopathic cranial DI to screen for evolving disease.
- Skeletal survey should be done to identify or rule out Langerhans cell histiocytosis as the cause of cranial DI.

### Diagnostic Procedures/Other

A water deprivation test can be used to assess the patient's ability to produce ADH in the CNS and the renal response to it:

- Requires inpatient admission under close supervision

### DIFFERENTIAL DIAGNOSIS

- Psychogenic polydipsia
- Diabetes mellitus
- Hypernatremic dehydration
- Primary polydipsia
- Polyuric renal failure
- Hypercalcemia
- Adrenal insufficiency
- Cerebral salt wasting

## TREATMENT

### PRE HOSPITAL

- Assess and stabilize airway, breathing, and circulation.
- Manage trauma, if present.

### INITIAL STABILIZATION/THERAPY

- Assess and stabilize airway, breathing, and circulation.
- Manage trauma, if present.
- Assess the degree of dehydration and hypovolemia; sodium > 150 mmol/L should be corrected over 48 hr.

### ALERT

Correction of hyponatremia that occurs too rapidly may result in central pontine myelinolysis and permanent neurologic injury.

- Unless a patient is having seizures as a result of hyponatremia, it is advised to limit hyponatremia sodium correction to not more than 10 mmol/L/24 hr.
- Hypotension should be corrected using normal saline in 20 mL/kg boluses.
- Symptomatic or severe hypertonicity should be corrected to:
  - Serum osmolality of 330 mOsm/L
  - Serum sodium 155 mmol/L or until asymptomatic

### MEDICATION

Cranial DI:

- Desmopressin, given as IV, SC, intranasal, or oral form
- Synthetic analogue of ADH (DDAVP) with prolonged antidiuretic action; available in intranasal, tablet, and parenteral forms
- Initiation should typically be on inpatient basis under specialist supervision.

### DISPOSITION

#### Admission Criteria

- Patients with newly diagnosed DI, as well as any with dehydration or electrolyte imbalance requiring correction, should be admitted:
  - In the presence of severe intercurrent illness such as respiratory infections and GI conditions affecting the administration and absorption of medication, admit for management of fluid balance.
- Inability to cope with management at home warrants admission.
- Critical care admission criteria:
  - Sodium level < 110 or > 170 mmol/L
  - Hyponatremic seizure

### Discharge Criteria

An educated patient and caregiver with clear understanding of follow-up instructions, the ability to maintain fluid balance with medication, and with free access to water can safely be discharged.

## FOLLOW-UP

### FOLLOW-UP RECOMMENDATIONS

- DI is a complex condition that is usually lifelong and will require ongoing follow-up by an endocrinologist.
- Anterior pituitary hormone deficiency commonly occurs in patients with cranial DI and should be actively investigated if suspected.
- Discharge instructions and medications:
  - Families and patients should be educated in the correct use of DDAVP and instructed to present for assessment if the following develops:
    - Any sign of dehydration
    - Irritability
    - Lethargy
    - Reduced urine output
    - Sudden increase in weight
    - Seizures
    - Symptoms of urinary tract infections

### Patient Monitoring

Weight should be used as a measure of fluid balance at home, and abrupt changes should prompt reassessment.

### DIET

- Patients on treatment should drink only when thirsty, provided they have an intact thirst mechanism.
- Infants and patients without a thirst mechanism should only be given a carefully calculated fluid volume per day.

### PROGNOSIS

- Usually has a good prognosis
- It depends on the primary cause whether the condition is transient or lifelong and if management is going to be easy or difficult.

### COMPLICATIONS

- Dehydration
- Hypernatremia
- Hyponatremia
- Cerebral edema
- Seizure

### See Also (Topic, Algorithm, Electronic Media Element)

- Hyponatremia
- Polyuria

### ICD9

- 253.5 Diabetes insipidus
- 588.1 Nephrogenic diabetes insipidus

## PEARLS AND PITFALLS

- Pearls:
  - Hyponatremia and fluid overload can be avoided in patients on treatment by allowing a period of permissible polyuria, during which free fluid is cleared before the next dose of DDAVP is given.
- Pitfalls:
  - Patients with psychogenic polydipsia (habitual drinking) may fail a water deprivation test because:
    - Prolonged excessive water intake can wash out renal medullary gradient required for concentrating the urine.
    - There may have been surreptitious intake of water during the test.
  - Idiopathic DI may be due to a slow-growing tumor that was not evident on the first MRI, thus further imaging may be indicated later.

# DIABETIC KETOACIDOSIS

Mia L. Karamatsu  
Lilit Minasyan

## BASICS

### DESCRIPTION

- Diabetic ketoacidosis (DKA) results from a relative or absolute insulin deficiency associated with hyperglycemia, acidosis, and ketosis:
  - Glucose >11 mmol/L (>200 mg/dL)
  - Venous pH <7.3 and/or bicarbonate  $\leq$ 15 mmol/L
  - Moderate to large ketones in the urine
- Severity of DKA is determined by the degree of acidosis (1):
  - Mild: pH <7.3; bicarbonate <15 mmol/L
  - Moderate: pH <7.2; bicarbonate <10 mmol/L
  - Severe: pH <7.1; bicarbonate <5 mmol/L

### EPIDEMIOLOGY

#### Incidence

- The overall incidence of type 1 diabetes mellitus (T1DM) is 15 per 100,000 annually.
- In the U.S., ~25–30% patients newly diagnosed with DM present with DKA:
  - Prevalence of DKA decreases with age.
- In established T1DM, the risk of DKA is 1–10% per patient-year.
- Up to 9.7% of patients with type 2 diabetes mellitus (T2DM) may present in DKA.

### RISK FACTORS

- New-onset diabetes:
  - Younger age (<4 yr old)
  - Low socioeconomic status
  - Limited access to health care
  - Lower parental education level
- Established T1DM:
  - Insulin omission:
    - More common in adolescent girls
    - Psychosocial reason or psychiatric disorder, including eating disorders
  - Low socioeconomic status, poor metabolic control: Higher hemoglobin A1c (HbA1c), previous episodes of DKA
  - Patients with insulin pumps may develop DKA if they do not administer additional insulin.

### GENERAL PREVENTION

- Early recognition and diagnosis of T1DM via screening tests and awareness campaigns, comprehensive diabetes education programs
- Close follow-up care by a diabetes care team and a 24-hr helpline
- Evaluate and treat the psychosocial reason for insulin omission, educate about recognition and treatment of impending DKA, and have a responsible adult supervise insulin administration.

### PATHOPHYSIOLOGY

Insulin deficiency due to *b*-cell failure, omission of insulin, or ineffective insulin due to antagonistic effect of counterregulatory hormones and/or physiologic stress (eg, sepsis):

- The counterregulatory hormones include glucagon, catecholamines, growth hormone, and cortisol. They help promote glycogenolysis and gluconeogenesis and limit glucose utilization.

- Increased glucose production and limited glucose utilization results in hyperglycemia, osmotic diuresis, electrolyte loss, dehydration, decreased glomerular filtration rate, and hyperosmolarity.
- Lipolysis aids in gluconeogenesis and ketoacidosis, generating beta-hydroxybutyrate and acetoacetate.
- Ketoacidosis, along with lactic acidosis from poor perfusion, results in metabolic acidosis.

### ETIOLOGY

- T1DM:
  - Autoimmune destruction of *b*-cells
- T2DM:
  - Heterogeneous glucose disorder associated with a family history and obesity

## DIAGNOSIS

### HISTORY

- Polyuria (including nocturia), polydipsia, polyphagia, weight loss
- Nausea, abdominal pain, and vomiting
- Possible precipitating event such as concurrent febrile illness

### PHYSICAL EXAM

- Vital signs:
  - Tachycardia
  - Hypotension
  - Kussmaul respirations (rapid, deep breaths)
- Mental status/CNS:
  - Fatigue/Lethargy
  - Headache
  - Altered mental status
  - Irritability/Restlessness
  - Focal neurologic deficit
  - Coma
- Signs and symptoms of clinical dehydration:
  - Dry mucous membranes
  - Delayed capillary refill
  - Poor skin turgor
  - Most patients have a 5–10% deficit.
- Cerebral edema may be suggested by lethargy/coma/depressed level of consciousness or irritability/restlessness, focal neurologic signs, headache, recurrent emesis, elevation of BP, and inappropriate decrease in heart rate.
- Acanthosis nigricans suggests T2DM.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

- Bedside serum glucose, urinalysis, and venous blood gas
- CBC, serum electrolytes, BUN, creatinine, magnesium, phosphorus, calcium, urinalysis, HgA1c, and beta-hydroxybutyrate:
  - Most patients have a total body sodium, potassium, chloride, phosphorus, and magnesium depletion.
  - Leukocytosis is common but does not necessarily indicate a bacterial infection.

- Useful calculations:
  - Anion gap =  $\text{Na} - (\text{Cl} + \text{HCO}_3)$ :
    - Normal is 12 +/- 2
  - Corrected sodium = measured Na + [(glucose (mg/dL) – 100)  $\times$  0.016]
  - Effective osmolality =  $2[\text{Na} + \text{K}] + \text{glucose (mg/dL)}/18$ :
    - Frequently between 300 and 350 mOsm/L
- If febrile, send appropriate lab specimens for analysis or culture.

### Imaging

- A CT scan of the head should be ordered for the patient with altered level of consciousness and suspected cerebral edema:
  - It may show focal or diffuse cerebral edema.
  - However, in patients with cerebral edema, 40% of scans are initially normal.
- CXR if clinically indicated (for pulmonary edema, acute respiratory distress syndrome [ARDS])

### Diagnostic Procedures/Other

EKG, if indicated

### DIFFERENTIAL DIAGNOSIS

- Hyperglycemic hyperosmolar nonketotic coma
- Infection: Sepsis, acute gastroenteritis
- Ingestion or poisonings: Methanol, ethylene glycol, propylene glycol, iron, isoniazid, salicylate, carbon monoxide, cyanide, uremia
- Acute appendicitis, chronic renal failure

## TREATMENT

### INITIAL STABILIZATION/THERAPY

- Address airway, breathing, circulation, and mental status promptly.
- Obtain serum glucose and venous blood gas.
- Volume expansion with normal saline or lactated Ringer solution 10–20 cc/kg over 1 hr.

### MEDICATION

#### First Line

- After the initial fluid bolus, start 0.45% saline or higher tonicity fluid with potassium chloride, potassium acetate, and/or potassium phosphate (total potassium concentration equals 40 mmol/L) at 1.5–2 times the maintenance rate:
  - Rehydrate evenly over 48 hr. Slow correction with isotonic or near-isotonic fluids results in earlier resolution of acidosis.
- Insulin 0.1 U/kg/hr is the standard:
  - Insulin is started after the initial volume expansion and concurrently with the IV rehydration therapy.
  - A bolus of insulin is not routinely recommended, but it is acceptable therapy.
  - Some evidence suggests that bolus insulin may be associated with increased risk of cerebral edema.
  - Patients without previous diagnosis of DM may be very sensitive to exogenous insulin. Lower initial insulin dosing and careful blood glucose monitoring are warranted in these patients.
- If continuous IV insulin is unavailable, administer fast-acting insulin q1–2h SC or IM.

- Dextrose is added to the IV fluid when serum glucose drops to  $\sim 17$  mmol/L (300 mg/dL):
  - Usually, 5% dextrose can be added to the IV fluid to maintain a steady plasma glucose level (100–200 mg/dL). However, if the glucose falls too rapidly ( $> 100$  mg/dL/hr), 10% or 12.5% dextrose may be necessary.
- Transition to SC fast-acting insulin and taper off IV fluids when the patient can tolerate oral intake, serum glucose is  $< 200$  mg/dL, and the ketoacidosis has resolved (pH  $> 7.3$ , bicarbonate  $\geq 18$  mmol/L).

### Second Line

- Potassium replacement:
  - Boluses are not recommended unless the patient has an arrhythmia secondary to hypokalemia. Otherwise, give with the start of insulin therapy.
  - Patients with hyperkalemia should not receive potassium until urine output has been documented.
- Phosphate replacement:
  - Give in the form of potassium phosphate if the level is  $< 1$  mg/dL. However, clinical benefit has not been shown in prospective trials. If given, monitor for hypocalcemia.
- Bicarbonate has not been proven to be beneficial in controlled trials:
  - The use of bicarbonate may cause paradoxical CNS acidosis.
  - Bicarbonate use has been associated with the development of cerebral edema.
  - Rapid correction of acidosis results in hypokalemia and an increased sodium load and hypertonicity.
  - Only give if the patient is severely acidotic, has cardiac dysfunction, and has life-threatening hyperkalemia. Administer 1–2 mmol/kg cautiously over 60 min.
- Antibiotics as needed

### SURGERY/OTHER PROCEDURES

- Once cerebral edema is recognized, it must be treated promptly:
  - Mannitol 0.25–1 g/kg IV over 20 min or 3% normal saline 5–10 mL/kg over 30 min
- Intubation to protect the airway and provide adequate ventilation:
  - Hyperventilation is associated with poorer neurologic outcomes.

### DISPOSITION

#### Admission Criteria

- Admit all patients with new-onset T1DM and patients with previously diagnosed DM presenting in DKA.
- Critical care admission criteria:
  - Altered mental status
  - Moderate to severe dehydration and acidosis (pH  $< 7.2$  or bicarbonate  $< 10$  mmol/L)
  - Specific criteria may be institution dependent, including age  $< 5$  and the need for insulin infusion.

#### Discharge Criteria

Patient with known T1DM:

- Ketoacidosis is minimal or resolved, patient is tolerating oral intake, serum glucose is stable on SC insulin, patient has adequate supplies, and close follow-up is arranged

## FOLLOW-UP

### FOLLOW-UP RECOMMENDATIONS

- Follow up with a pediatric endocrinologist.
- Fast-acting insulin SC as previously instructed by the endocrinologist and/or diabetes team

### Patient Monitoring

- Continuous cardiopulmonary monitoring
- Hourly vital signs, fluid input and output, neurologic exam for signs and symptoms of cerebral edema, serum glucose, and venous blood gas, especially while receiving continuous insulin therapy
- Repeat serum electrolytes, magnesium, phosphorus, and calcium q2–4h for the 1st 8 hr, then q4h.
- The goals are to restore adequate perfusion to tissues and organs, correct dehydration and electrolyte imbalances, improve the glomerular filtration rate, clear glucose and ketones from the blood, and avoid complications of treatment such as cerebral edema.

### DIET

- NPO during the initial resuscitation
- Diabetic diet (including counting calories):
  - PO intake should coincide with transition from IV to SC insulin.

### PROGNOSIS

Mortality rate of DKA is 0.15–0.31%.

### COMPLICATIONS

- Cerebral edema:
  - Symptomatic cerebral edema occurs in  $\sim 0.3$ –1% of all episodes of DKA.
  - Typically occurs 4–12 hr after the initiation of therapy but can present prior to treatment or develop at any time during treatment
  - The leading cause of DKA-related deaths
  - Associated with a 20–25% mortality rate
  - Significant morbidity such as pituitary insufficiency in 10–26% of patients
  - Pathophysiology may be thought to be due to cellular swelling; however, it may also be due to vasogenic (or extracellular) edema.
  - Risk factors include young age, new-onset T1DM, longer duration of symptoms, and more profound acidosis.
  - Other factors include higher BUN on initial presentation, more severe hypocalcemia, and administration of bicarbonate.
  - Hyponatremia or the lack of a progressive increase in sodium with a concomitant fall in glucose increases the risk of cerebral edema.
- Hypo- or hyperkalemia, arrhythmia, hypoglycemia, infection, sepsis, ARDS, pulmonary edema, pneumomediastinum, CNS hematoma or thrombosis, and rhabdomyolysis

## CODES

### ICD9

- 250.10 Diabetes mellitus with ketoacidosis type ii or unspecified type, not stated as uncontrolled
- 250.11 Diabetes mellitus with ketoacidosis, type I (juvenile type) not stated as uncontrolled

## PEARLS AND PITFALLS

- Misdiagnosis of gastroenteritis is a risk in children not known to be diabetic whose presentation of DKA includes vomiting.
- Cerebral edema is the leading cause of death in DKA.
- The cause of cerebral edema is unknown, but it may be associated with extreme acidosis, extreme hypocalcemia, extreme BUN elevation or dehydration, and overly rapid correction of hyperglycemia. There may also be an association with the administration of bicarbonate and the development of cerebral edema.
- Patients with T2DM can present in DKA.

# DIAPER RASH

Solomon Behar

## BASICS

### DESCRIPTION

- The most common dermatologic problem in infancy, diaper rash is a group of inflammatory conditions leading to red, macerated skin in the groin region.
- It is most commonly due to irritation or infection.
- Location of erythema, presence of bullae, scales, or satellite lesions aid with distinguishing the underlying cause.
- Rarely, diaper rash can be a symptom of more serious illness.

### EPIDEMIOLOGY

#### Incidence

Variable due to regional differences in hygiene, diaper use, and toilet training

#### Prevalence

Unknown, but widely acknowledged to be the most common dermatologic problem of infancy

### RISK FACTORS

- Infrequent diaper changing
- Poor hygiene
- Diarrhea
- Recent antibiotic use
- Thrush
- Urinary tract abnormalities

### GENERAL PREVENTION

- Changing diapers frequently (q3–4h or ASAP when stool or urine is present)
- Using barrier cream for skin protection (eg, zinc oxide, petrolatum)
- Using nonocclusive diapers
- Using superabsorbent diapers
- Avoiding cloth diapers
- Avoiding scented wipes

### PATHOPHYSIOLOGY

- Enzymes in stool break down skin
- Alterations in pH from stool and urine
- Once skin integrity is interrupted from irritation, fungi and bacteria may invade skin, leading to infection

### ETIOLOGY

- Overhydration of skin
- Friction
- Urine and feces
- Microorganisms

### COMMONLY ASSOCIATED CONDITIONS

- Diarrhea
- Thrush

## DIAGNOSIS

### HISTORY

Presence of erythema, pain, or itching in the diaper region

### PHYSICAL EXAM

- Irritant diaper dermatitis:
  - Redness, scaling of convex areas of skin (“mountain peaks”) that come into contact with the diaper
  - Usually spares skin folds
- Candida diaper dermatitis:
  - Beefy erythema in intertriginous areas (“valleys”) with papular “satellite” lesions
  - May have oral thrush present
- Bacterial diaper dermatitis: Bullae or impetiginous lesions (honeycrust)
- Folliculitis: Small red papules and pustules on buttocks, thighs, and low abdomen
- Herpes simplex virus (HSV): Vesicles or bullae during 1st few weeks of life progressing to punched-out blisters
- Jacquet dermatitis: Severe erosions with punched-out lesions

### DIAGNOSTIC TESTS & INTERPRETATION

#### Diagnostic Procedures/Other

- If the diagnosis is in question, a skin scraping may be performed, which will show pseudohyphae when KOH prep is done in cases of *Candida* diaper dermatitis.
- Culture of bullae or lesions may yield a definitive diagnosis.
- In rare cases of refractory dermatitis with other systemic symptoms (eg, chronic otorrhea, hepatosplenomegaly), biopsy is needed (eg, histiocytosis).

### DIFFERENTIAL DIAGNOSIS

- Inflammatory conditions:
  - Irritant contact dermatitis
  - Allergic contact dermatitis
  - Seborrheic dermatitis
  - Psoriasis
  - Granuloma gluteale infantum (associated with the use of high-potency topical steroids)
- Infectious conditions:
  - Candidiasis
  - Folliculitis
  - Impetigo
  - Perianal streptococcal infection
  - HSV infection
  - Scabies
  - Congenital syphilis
- Nutritional (associated with failure to thrive):
  - Acrodermatitis enteropathica (zinc deficiency)
  - Biotin deficiency
  - Kwashiorkor
  - Cystic fibrosis
- Malignancy:
  - Langerhans cell histiocytosis (associated hepatosplenomegaly, lymphadenopathy, petechiae, erosions, vesicopustules, otorrhea)
- Miscellaneous:
  - Child abuse (immersion burn)
  - Kawasaki disease (fever, cervical lymphadenopathy, conjunctivitis, strawberry tongue, extremity peeling or swelling)

## TREATMENT

### INITIAL STABILIZATION/THERAPY

- Remove stool/urine-containing diapers.
- Cleanse gently with warm water and mild soap with a cotton ball or rinse with a squeeze bottle.
- Remove adherent feces with cotton balls and mineral oil.

**MEDICATION****First Line**

- For fungal dermatitis:
  - Topical antifungal:
    - Nystatin 100,000 U/g topical b.i.d. 7–14 days:
      - Cream used for most candidal rashes
      - Powder may be used for rashes that are very moist and macerated.
    - Miconazole 2% cream or lotion topical b.i.d. 7–14 days
      - Apply directly to skin every diaper change until clear for up to 7 days.
      - May add a layer of a barrier cream
  - For contact dermatitis:
    - Topical barrier paste, ointment or cream (eg, zinc oxide, petrolatum, lanolin); liberally apply every diaper change.
    - Low-potency steroid cream (hydrocortisone 1%) applied topically b.i.d. for max of 2 wk
    - Stomahesive powder (for severe cases refractory to steroids/antifungals and barrier creams)
  - For bacterial infections:
    - Topical mupirocin 2% cream t.i.d. until clear for up to 7 days

**Second Line**

For contact dermatitis, may apply all of the following topically until rash is improved:

- Topical sucralfate
- 2% eosin (aqueous)
- Topical cholestyramine ointment (in high stool output states)

**DISPOSITION****Admission Criteria**

Diaper rashes generally do not result in hospital admission.

- Signs of Kawasaki disease or histiocytosis may warrant admission.
- Systemic illness from bacterial or fungal sepsis in premature or low-birth-weight infants may require admission.

**Discharge Criteria**

Most diaper rash cases can be discharged safely to home.

**Issues for Referral**

Refractory cases of diaper rash not responding to usual therapy should be referred to a dermatologist.

**Additional Therapies**

Cornstarch powder applied topically to the diaper area daily:

- Helps reduce friction on skin
- Useful for contact dermatitis associated with prolonged wetness

**FOLLOW-UP****FOLLOW-UP RECOMMENDATIONS**

Discharge instructions and medications:

- Change diapers q3–4h, including 1 overnight diaper change.
- Apply topical medication every diaper change until the rash resolves as noted above.

**Patient Monitoring**

Follow up with the primary care provider in 1–2 days to check healing of lesions.

**COMPLICATIONS**

Bacterial superinfection, scarring from delayed therapy

**ADDITIONAL READING**

- Spraker MK. Update: Diapers and diaper dermatitis. *Pediatr Dermatol*. 2000;17:75–83.

**ICD9**

- 112.3 Candidiasis of skin and nails
- 691.0 Diaper or napkin rash

**PEARLS AND PITFALLS**

- Avoid use of clotrimazole/betamethasone dipropionate (Lotrisone), a combination high-potency steroid and antifungal cream. The steroid component is too strong for use in infants and may lead to systemic symptoms of steroid toxicity.
- Irritant diaper dermatitis present for >3 days usually has a component of *Candida* infection, even if the typical candidal appearance is not yet present. Treat these cases with an antifungal cream.
- Mupirocin has antifungal properties, so if treating a presumed bacterial infection, it may alleviate the patient needing to apply an antifungal cream.
- Avoid use of talcum or other powders near an infant's face, as it is an aspiration risk.
- Do not use allylamine (terbenafine, naftifine) or thiocarbamates (tolnaftate) topical antifungals, as their activity against *Candida albicans* is limited.

# DIARRHEA

Caroline Altergott

## BASICS

### DESCRIPTION

- Diarrhea is an alteration in the normal bowel pattern characterized by increase in water content, volume, or frequency of stools.
- Can be acute ( $\leq 14$  days), persistent ( $> 14$  and  $< 30$  days) or chronic ( $> 30$  days)

### EPIDEMIOLOGY

#### Incidence

- 2.6 episodes of diarrhea per year per child  $< 5$  yr
- Increased rate in children attending day care

### RISK FACTORS

Infectious diarrhea:

- Travel to developing area
- Ingestion of unsafe foods (raw meats, eggs, shellfish, unpasteurized milk or juices)
- Swimming/Drinking untreated fresh water
- Contact with animals known to be carriers
- Day care or residential facility
- Recent antibiotic use
- Contact with other infected individuals

### GENERAL PREVENTION

- Hand washing: The most important preventative measure
- Rotavirus vaccine
- Typhoid vaccine: If traveling to endemic areas

### PATHOPHYSIOLOGY

- Fluid output overwhelms the absorptive capacity of the intestines.
- Multifactorial:
  - Secretory: Enterotoxins increase the secretion of fluids and electrolytes from the mucosa.
  - Osmotic: Increase in osmotic load to the bowel lumen causes increased influx of water to the bowel lumen.
  - Inflammatory: Decreased absorption in the colon from direct injury of the mucosa

### ETIOLOGY

- Acute Infectious: Viral (70–80% of all infectious diarrhea):
  - Rotavirus: Vomiting and low-grade fever precedes watery diarrhea; usually affects children 3–15 mo; 2–6 day duration; more prevalent in winter
  - Norwalk: 1–2 day illness with explosive vomiting, watery diarrhea, abdominal pain, and fever; school age; more prevalent in winter
  - Enterovirus: Fever and vomiting with diarrhea lasting days to weeks; more prevalent in summer

- Acute infectious—bacterial:
  - *Salmonella*: Initially fever ( $< 48$  hr), abdominal pain, and green mucoid stool may have blood. Associated with poultry, livestock, and reptiles or ingestion of unsafe food. Increased invasive disease in children with hemoglobinopathies/immune deficiency
  - *Shigella*: 40 serotypes, *Shigella sonnei* most common in the U.S. Range: Mild to severe. Abdominal cramps; high fever; and watery, green diarrhea. 40% with bloody stools. Usually resolves in 72 hr. Occasionally is associated with seizures and hemolytic uremic syndrome (HUS).
  - *Campylobacter*: Watery diarrhea with abdominal pain and fever; 2/3 with gross blood in stool; sometimes confused with appendicitis; immunoreactive complications (arthritis, erythema nodosum, Guillain-Barré).
  - *Yersinia enterocolitica*: Watery diarrhea usually mild and self-limited but can also be bloody. Older children can have mesenteric adenitis or pseudoappendicitis syndrome.
  - *Clostridium difficile*: Pseudomembranous colitis. Bloody diarrhea is associated with antibiotic use.
  - *Escherichia coli*:
    - Enteropathogenic (EPEC): Infantile diarrhea
    - Enterotoxigenic (ETEC): Traveler's diarrhea
    - Enteroinvasive (EIEC): Similar to *Shigella*
    - Enterohemorrhagic (EHEC 0157:H7): Bloody diarrhea associated with HUS
  - *Vibrio cholera*: Painless, voluminous diarrhea without abdominal cramps or fever. It is associated with travel to or ingestion of food from Latin America or Asia or eating raw or uncooked shellfish in Gulf Coast states.
- Parasitic:
  - *Entamoeba histolytica*: Chronic episodic diarrhea; may have constipation episodes
  - *Giardia*: Explosive, watery, foul-smelling stool
  - Cryptosporidiosis: Immune-deficient patients with nonbloody diarrhea and abdominal pain
- Malabsorption:
  - Food allergy: Milk and soy most common
  - Lactose deficiency: Congenital or acquired (usually after acute enteritis)
  - Antibiotic use
  - Celiac disease: Intolerance to wheat gluten; failure to thrive with intermittent diarrhea
  - Cystic fibrosis: Foamy, bulky, foul-smelling stools
  - Inflammatory bowel disease (IBD): Ulcerative colitis or Crohn disease
- Structural:
  - Intussusception
  - Hirschsprung disease
  - Encopresis: Overflow stool past obstruction
  - Short bowel syndrome
  - Overfeeding: Common in neonates
- Miscellaneous:
  - Toxins: Laxative abuse in adolescence
  - HUS: Several days of diarrhea followed by bloody stools, hemolysis, and renal insufficiency

## DIAGNOSIS

### HISTORY

- Focus on signs of dehydration and symptoms of diarrhea.
- Dehydration:  $\downarrow$  Tears,  $\downarrow$  urine output, sticky saliva,  $\downarrow$  activity level
- Stool symptoms:
  - Color, consistency, volume, and number
  - Quantity of associated blood or mucus
  - Onset (acute, persistent, chronic)
- Travel history
- Medications
- Changes in diet or food intake
- Associated symptoms:
  - Vomiting (onset, frequency, quantity, quality)
  - Abdominal pain (onset, location, degree, consistency)
  - Systemic signs:
    - Rashes, arthralgias with chronic diarrhea: Consider IBD.
    - Dysuria, frequency, urgency: Consider urinary tract infection.
    - Altered sensorium: Severe dehydration or intussusception

### PHYSICAL EXAM

- Current and previous weight
- Elevated temperature: Suspect infectious
- Assess perfusion: Capillary refill, skin color, and warm vs. cold extremities may be helpful.
- Tachycardia, poor skin turgor and dry mucous membranes indicate severe dehydration:
  - Skin turgor may be doughy with hypernatremia and therefore a poor marker of degree of dehydration.
- Abdominal exam:
  - Mass in the right upper quadrant: Intussusception
  - Right lower quadrant pain: Appendicitis
  - Distension, rebound, and guarding: Peritonitis
  - Rectal exam for acute diarrhea:
    - Presence of blood: Food allergy or infection
    - Current jelly stools: Intussusception
    - Mucus in stools: Infection
  - Rectal exam for chronic diarrhea:
    - Anal fistulas: Crohn disease
    - Hard stool in vault: Overflow encopresis
    - Empty vault: Hirschsprung disease

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

Most patients with acute, nonbloody diarrhea, who are well appearing and not dehydrated do not require any lab testing.

**Initial Lab Tests**

- Severe dehydration: Serum electrolytes
- Suspected bacteremia/immune-compromised patients: CBC and blood culture
- Consider selectively:
  - Standard stool cultures (*Salmonella*, *Shigella*, *Campylobacter*, and *Yersinia* species) for acute inflammatory diarrhea, for food handlers, for institutionalized patients, and for those in day care
  - *E. coli* O157:H7 for acute grossly bloody diarrhea or HUS
- *C. difficile* toxin for diarrhea associated with antibiotic use
- *Vibrio parahaemolyticus* for those with recent shellfish ingestion
- Testing stool for WBCs in young infants at risk for *Salmonella*:
  - If positive, send standard stool culture.
- Testing for ova and parasites, and *Giardia lamblia* antigen testing for chronic diarrhea, travelers, and those in endemic areas

**Imaging**

- Usually not necessary for diarrhea
- For intussusception, consider a contrast enema (may therapeutically reduce) or US if indeterminate.

**DIFFERENTIAL DIAGNOSIS**

See Etiology.

**TREATMENT****PRE HOSPITAL**

- Assess and address the airway, breathing, and circulation.
- Supplement with a balanced commercially available electrolyte solution.
- IV fluid resuscitation for those with severe dehydration

**INITIAL STABILIZATION/THERAPY**

- Treat dehydration appropriately. Refer to Dehydration topic for specific therapy.
- Other than treatment of dehydration or electrolyte imbalance, no specific therapy is initially required.

**MEDICATION**

Use antibiotics, if indicated. However, most infectious diarrhea resolves without intervention, and antibiotic treatment may be harmful. See the Gastroenteritis topic for specific antibiotic therapy recommendations.

**DISPOSITION****Admission Criteria**

- Critical care admission criteria:
  - Shock refractory to 60 cc/kg IV fluids over 1 hr
  - Altered mental status
- Inpatient admission criteria:
  - > 10–15% dehydration or inability to replace ongoing losses while in the emergency department
  - Significant electrolyte abnormalities (↑ sodium, ↓ sodium, ↑ potassium)
  - Severe anemia (secondary to hematochezia)
  - Acute abdomen: Intussusception, appendicitis

**Discharge Criteria**

- Corrected dehydration (eg, moist mucous membranes, adequate urine output)
- Normal mental status
- Minimal to absent electrolyte abnormalities
- Minimal to absent ongoing blood loss
- Caregiver can follow through on appropriate oral rehydration therapy

**Issues for Referral**

Chronic diarrhea

**Additional Therapies**

- Controversial efficacy:
  - Lactobacillus
  - Absorbents
  - Zinc supplements
- Not recommended because of significant side effects:
  - Loperamide
  - Bismuth sulfate

**FOLLOW-UP****FOLLOW-UP RECOMMENDATIONS**

Discharge instructions and medications:

- Follow-up within 24 hr for moderate to severe dehydration with patients who meet discharge criteria.
- Return for worsening dehydration (↓ urine output, ↓ tears, dry mucous membranes, lethargy), ↑ blood to stool, and ↑ abdominal pain.

**DIET**

- Commercially available balanced oral rehydration solution for ongoing losses
- Homemade solutions (rice water) are often improperly balanced.
- Restricting to clear liquids alone has no benefit.
- Breast-fed infants should continue feeding; formula-fed infants should resume their usual formula upon rehydration.
- Older children should receive semisolid or solid foods low in simple sugars.

**COMPLICATIONS**

- Dehydration
- Electrolyte abnormalities
- Shock from hypovolemia or sepsis
- HUS

**ADDITIONAL READING**

- Fleisher GR. Diarrhea. In Fleisher GR, Ludwig S, eds. *Textbook of Pediatric Emergency Medicine*. 6th ed. Philadelphia, PA: Lippincott Williams & Wilkins; 2010.
- Guerrant RL, Van Gilder T, Steiner TS, et al. Infectious Diseases Society of America. Practice guidelines for the management of infectious diarrhea. *Clin Infect Dis*. 2001;32:331–351.
- King CK, Glass R, Bresee JS, et al. Managing acute gastroenteritis among children. *MMWR Recomm Rep*. 2003;52(RR-16):1–16.
- Mann CH. Vomiting and diarrhea. In Barren J, Rothrock S, Brennan JA, Brown L, eds. *Pediatric Emergency Medicine*. Philadelphia, PA: Saunders; 2008:567–575.
- Ramaswamy K, Jacobson K. Infectious diarrhea in children. *Gastroenterol Clin North Am*. 2001;30:611–624.

**CODES****ICD9**

- 008.8 Intestinal infection due to other organism, not elsewhere classified
- 009.2 Infectious diarrhea
- 787.91 Diarrhea

**PEARLS AND PITFALLS**

- Changes in BP are a late sign of significant dehydration.
- Assess serum glucose immediately in children with depressed mental status and diarrhea.
- Consider intussusception in a child with diarrhea and lethargy.

# DIGOXIN TOXICITY

Amit K. Gupta  
Mark Su

## BASICS

### DESCRIPTION

- Digoxin is the most commonly prescribed cardioactive steroid in the U.S.
- Other internationally available preparations include digitoxin, ouabain, lanatoside C, deslanoside, and gitalin.
- Most cases of digoxin toxicity are seen in adults; however, there is still a concern in children due to the narrow therapeutic index and wide availability.
- Toxicity can be acute or chronic.
- Plant sources of cardioactive steroids include oleander (*Nerium oleander*), yellow oleander (*Thevetin peruviana*), foxglove (*Digitalis* species), lily of the valley (*Convallaria maritima*), dogbane (*Apocynum cannabinum*), and red squill (*Urginea maritima*).
- Animal sources of cardioactive steroids include the cane toad (*Bufo marinus*); toxicity from ingestion, instead of intended topical application, of a purported aphrodisiac derived from the dried secretion of this toad has been reported.

### EPIDEMIOLOGY

#### Incidence

- Ingestion of digoxin is often difficult to establish, and precise numbers of exposure are unknown.
- The overall mortality rate and rate of response to Fab therapy in children are similar to those in adults. The mortality rate as a direct result of cardiac toxicity is 3–21%.

### RISK FACTORS

Coingestants with other cardiotoxic agents such as calcium channel blockers, beta-blockers, cyclic antidepressants, and neuroleptics may exacerbate toxicity.

### GENERAL PREVENTION

Poison-proofing homes and giving parents poison prevention advice is the most effective way to prevent exposure in children.

### PATHOPHYSIOLOGY

- Digoxin inhibits sodium-activated and potassium-activated adenosine triphosphatase ( $\text{Na}^+\text{K}^+$  ATPase) pump during repolarization. The result is an increase in the intracellular sodium and calcium concentrations and a decrease in the intracellular potassium concentration.
- Improved inotropy is due to an increased concentration of cytosolic calcium ions during systole, which increases the force of contraction of the cardiac muscle.
- Hyperkalemia can occur with acute toxicity due to increased extracellular concentration.
- Digitalis also has a negative chronotropic action, which is due to the vagal effect on the sinoatrial node.

- Digoxin increases automaticity and shortens the repolarization intervals of the atria and ventricles.
- Virtually any type of dysrhythmia can occur with toxicity, with the exception of the rapidly conducted supraventricular tachydysrhythmias.
- Hypokalemia inhibits  $\text{Na}^+\text{K}^+$  ATPase activity and contributes to the toxicity induced by digoxin.
- Hypomagnesemia also inhibits  $\text{Na}^+\text{K}^+$  ATPase activity and may result in refractory hypokalemia.

### ETIOLOGY

The main causes of digoxin toxicity in the pediatric population are:

- Erroneous dosing in infants, which is usually parenteral and frequently severe
- Unintentional ingestion in younger children
- Intentional ingestion in older children and young adults, which may be the result of a suicidal attempt

### COMMONLY ASSOCIATED CONDITIONS

Congenital heart disease, CHF, cardiac dysrhythmia

## DIAGNOSIS

### HISTORY

- Obtain history of exposure, other possible coingestants, and events that led to exposure.
- The peak effect with PO dosing is 2–6 hr, and that with IV dosing is 5–30 min.
- Ask parents to bring in pill bottles if possible.
- Nausea and vomiting are common.
- Lethargy or weakness may occur.
- Visual disturbances can occur: Aberrations of color vision, such as yellow halos around lights, scotoma, blurry vision, or decreased visual acuity.

### PHYSICAL EXAM

- Assess vital signs, with attention to cardiovascular stability.
- GI symptoms include anorexia, nausea, vomiting, and nonspecific abdominal pain.
- Lethargy, confusion, and weakness may occur with acute or chronic toxicity.
- Cardiovascular effects may include bradycardia.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

- Immediately assess capillary blood glucose.
- Digoxin level: Normal therapeutic range is 0.5–2.0 ng/mL. Always assure units reported are correct:
  - A 6-hr level postingestion is also recommended and is more representative of a postdistribution concentration.
  - A digoxin level may be falsely elevated after digoxin Fab fragment administration.

- Serum electrolytes, magnesium, BUN, creatinine, glucose
- Serum potassium is prognostic for dysrhythmia (potassium  $>5.0$  mEq/L).
- Assess acetaminophen and salicylate levels if suicidal ingestion.
- Urine drug screen usually is not indicated unless for forensic purposes such as suspected malicious intent or child abuse.

### Imaging

- A CT of the brain should be considered in individuals with altered mentation.
- CXR may be performed to assess for pulmonary edema.

### Diagnostic Procedures/Other

- ECG should be performed. Sinus bradycardia and 1st-degree or 2nd-degree atrioventricular blocks are more common in pediatric patients than in adults, whereas ventricular ectopy is more common in adults.
- Bidirectional ventricular tachycardia is virtually pathognomonic for digoxin toxicity.
- Suspect digoxin toxicity with increased automaticity and depressed conduction.

### DIFFERENTIAL DIAGNOSIS

- Calcium channel blocker toxicity
- Beta-blocker toxicity
- Clonidine toxicity
- Cardiogenic shock
- Hemorrhagic shock
- Septic shock
- Gastroenteritis
- Acute MI

## TREATMENT

### PRE HOSPITAL

- Assess and stabilize airway, breathing, and circulation.
- Supplemental oxygen
- Establishment of an IV line with cardiac monitoring

### INITIAL STABILIZATION/THERAPY

- Activated charcoal (1 g/kg) may be given if the patient is protecting the airway.
- Because of the enterohepatic circulation of digoxin, multiple-dose charcoal (1 g/kg/day) may be beneficial.
- Syrup of ipecac is contraindicated.

**MEDICATION****First Line**

- Atropine 0.02 mg/kg IV (min dose 0.1 mg and max 2 mg) for bradycardia:
  - Atropine may be effective due to enhanced vagal tone with digoxin.
- Digoxin immune Fab fragments are the treatment of choice for digoxin toxicity:
  - Indications for administration are any potential digoxin-related life-threatening dysrhythmia, renal failure, potassium concentration  $>5.0$  mEq/L in the setting of acute overdose, digoxin serum concentration  $\geq 15$  ng/mL at any time or  $>10$  ng/mL 6 hr post-ingestion.
  - Digoxin immune Fab fragments may also be beneficial in poisoning by nondigoxin cardioactive steroid (plant or animal sources).
    - 1 vial of Digibind neutralizes 0.5 mg of digoxin.
    - Number of vials for digoxin Fab dosing is calculated using the following equation:
      - No. of vials = [serum digoxin level (ng/mL)  $\times$  patient's weight (kg)]  $\div$  100
    - Empiric therapy for acute poisoning is 10–20 vials.
    - Empiric therapy for chronic poisoning is 2–4 vials.
  - Magnesium and potassium should be supplemented if serum concentrations are low.
  - Calcium administration is contraindicated since this may lead to excessive intracellular calcium and cardiac tetany (“stone heart”). It is safe to administer after digoxin Fab fragments have been given.

**Second Line**

In the event that digoxin Fab fragments are not available, the secondary drugs for the management of ventricular irritability include IV phenytoin (15–20 mg/kg, rate  $<50$  mg/min) or IV lidocaine (1.5 mg/kg).

**COMPLEMENTARY & ALTERNATIVE THERAPIES**

- External or transvenous pacing has a limited role for digoxin toxicity since digoxin-specific Fab antibodies are widely available.
- Transvenous pacing may increase the risk of initiating cardiac dysrhythmias and should be avoided.
- Cardiac defibrillation should be reserved for hemodynamically unstable ventricular tachycardia or ventricular fibrillation.

**DISPOSITION****Admission Criteria**

- Consider hospital admission of any patient with a history of a large ingested dose, especially if coexisting risk factors increase the patient's susceptibility to digoxin toxicity.
- Critical care admission criteria:
  - Patients with signs of hemodynamic instability should be admitted to an ICU setting.

**Discharge Criteria**

May discharge if the patient remains asymptomatic after observation for 12 hr

**FOLLOW-UP****FOLLOW-UP RECOMMENDATIONS**

- Discharge instructions and medications:
  - Follow up with the primary pediatrician.
  - Return to the emergency department for change in behavior, alteration in mental status, or if ill appearing.
- Activity:
  - Normal activity after discharge

**Patient Monitoring**

Patients with intentional overdoses should be monitored for acts of self-harm.

**PROGNOSIS**

The prognosis is usually good if the diagnosis is recognized and digoxin Fab fragments are administered.

**COMPLICATIONS**

- Hyperkalemia
- Dysrhythmia
- Cardiogenic shock
- Death

**ADDITIONAL READING**

- Antman EM, Wenger TL, Butler VP, et al. Treatment of 150 cases of life-threatening digitalis intoxication with digoxin-specific Fab antibody fragments. Final report of a multicenter study. *Circulation*. 1990;81:1744–1752.

**See Also (Topic, Algorithm, Electronic Media Element)**

- Beta-Blocker Poisoning
- Calcium Channel Blocker Poisoning
- Cardiogenic Shock
- Dysrhythmia, Atrial
- Dysrhythmia, Ventricular

**CODES****ICD9**

972.1 Poisoning by cardiotonic glycosides and drugs of similar action

**PEARLS AND PITFALLS**

- Digoxin exerts its inotropic effects by inhibiting the  $\text{Na}^+\text{K}^+$  ATPase pump during repolarization.
- Suspect digoxin toxicity with increased cardiac automaticity and depressed conduction.
- A 6-hr post-ingestion digoxin level is more indicative of a post-distribution concentration.
- The most clinically useful indication for digoxin immune FAB fragments is any potentially life-threatening digoxin-related dysrhythmia.

# DIPHTHERIA

James M. Wu

Craig A. McElderry

## BASICS

### DESCRIPTION

- Diphtheria is an upper respiratory tract illness characterized by sore throat, low-grade fever, and an adherent pseudomembrane of the nasopharynx, oropharynx, and/or larynx.
- Diphtheria can also present as primary cutaneous disease and, less commonly, vaginal, conjunctival, and otic disease.
- Disease is caused by *Corynebacterium diphtheriae*, a gram-positive, aerobic, pleomorphic bacillus.

### EPIDEMIOLOGY

#### Incidence

- 0–5 cases per year in the U.S.
- 0.001 cases per 100,000 in the U.S. since 1980 (1):
  - No data on cutaneous diphtheria, as it is not reportable
- Endemic in other countries where the population is not completely immunized:
  - Recent epidemics in independent nations of the former Soviet Union

### RISK FACTORS

Unimmunized or incompletely immunized children or adults

### GENERAL PREVENTION

- Maintain up-to-date immunizations:
  - Immunization estimated efficacy is 97%.
  - Immunized patients have milder disease, but immunization does not prevent asymptomatic carriage of *C. diphtheriae*.
- Avoid skin contact with cutaneous lesions.
- Avoid contact with respiratory secretions.
- Avoid travel to endemic areas.
- Prevention may be difficult due to asymptomatic carriers.

### PATHOPHYSIOLOGY

- Humans are the sole reservoir of *C. diphtheriae*.
- Organisms are spread via respiratory droplets, direct contact, and occasionally fomites.
- Incubation period is 2–7 days (2).
- *C. diphtheriae* colonizes, proliferates, and invades superficial local tissues of the throat and produces exotoxins in low iron conditions.
- Exotoxin causes local necrotic injury of epithelial cells by irreversibly inhibiting protein synthesis.
- Pseudomembranes—white to gray-brown adherent membranes consisting of blood plasma, fibrin, epithelial cells, leukocytes, erythrocytes and *C. diphtheriae* cells—form at the areas of injury.
- Toxin is absorbed and disseminated via lymph and blood, causing degenerative changes to tissues including heart muscle, nerves, liver, kidneys, and adrenals.
- Organisms are present in nasopharyngeal and oropharyngeal secretions and skin lesions for 2–6 wk after infection (3).

### ETIOLOGY

- *C. diphtheriae*: Gram-positive, aerobic pleomorphic bacillus
- 4 main toxin-producing strains with slight differences in growth characteristics and toxin production:
  - *C. diphtheriae gravis*:
    - Most rapid growth rate
    - Most rapid and copious toxin production
  - *C. diphtheriae intermedium*
  - *C. diphtheriae mitis*
  - *C. diphtheriae belfanti*

## DIAGNOSIS

### HISTORY

- Respiratory diphtheria:
  - Low-grade fever
  - Sore throat
  - Malaise
  - Serosanguinous nasal discharge
  - Difficulty swallowing
  - Respiratory distress
- Cutaneous diphtheria:
  - Generally lower extremity lesions
  - History of skin lesions (eg, eczema, dermatitis), trauma, or bruising
  - Pain, tenderness with subsequent anesthesia (2–5 wk after infection)
  - Erythema
  - Initial vesicle or pustule with subsequent ulceration and membrane formation

### PHYSICAL EXAM

- Respiratory diphtheria:
  - White to gray-brown membrane in nasopharynx, oropharynx, tonsils, and/or larynx
  - Scraping of membrane causes bleeding.
  - Serosanguineous nasal discharge
  - Cervical lymphadenitis, soft tissue swelling (bull neck)
  - Low-grade fever
  - Tachycardia
  - Airway obstruction
- Cutaneous diphtheria:
  - Ulceration with sharply demarcated borders
  - Peripheral edema, erythema
  - White to gray-brown membrane

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

- Culture and PCR of specimens from nose, throat, or other mucosal or cutaneous lesions
- Culture on cystine-tellurite blood agar or modified Tinsdale agar
- If *C. diphtheriae* recovered, test for toxigenicity (Elek test).
- May measure serum antibodies to diphtheria toxin
- Other, if positive test results:
  - Refer close patient contacts for culture and treatment with empiric antibiotics.

### Imaging

Consider chest radiograph to evaluate for diphtheria pneumonia, if indicated depending on the clinical assessment.

### Pathological Findings

Microscopy of the pseudomembrane will reveal fibrin exudates, neutrophils, and colonies of *C. diphtheriae*.

### DIFFERENTIAL DIAGNOSIS

- Respiratory diphtheria: Most of the following can be ruled out with a good clinical history of incomplete immunizations and physical exam findings of gray-brown adherent membrane in nasopharynx or oropharynx:
  - Exudative pharyngitis (group A beta-hemolytic streptococcus, Epstein-Barr virus)
  - Acute necrotizing ulcerative gingivitis (Trench mouth, Vincent angina)
  - Epiglottitis
  - Herpes simplex virus (HSV)
  - Mucositis
  - Thrush
- Cutaneous diphtheria: Lesions are relatively nonspecific, and thus the differential diagnosis may include a broad range of dermatologic diseases:
  - Streptococcal or staphylococcal impetigo
  - Ecthyma
  - Cutaneous TB
  - Pyoderma gangrenosum
  - Insect bites

## TREATMENT

### MEDICATION

Diphtheria is best treated using a 2-pronged approach with antitoxin and antimicrobials (3).

#### First Line

- Antitoxin—neutralization of toxins and prevention of secondary effects:
  - Available via the CDC
  - Administer as early as possible without waiting for bacteriologic confirmation.
  - Test for sensitivity to horse serum via cutaneous and then intradermal testing prior to administration.
  - Desensitize if patient reacts.
  - Dosage is severity dependent:
    - Cutaneous disease: 20–40,000 units IV/IM  $\times$  1
    - Pharyngeal/Laryngeal disease <48 hr: 20–40,000 units IV/IM  $\times$  1
    - Nasopharyngeal disease: 40–60,000 units IV/IM  $\times$  1
    - Extensive disease  $\geq$ 3 days or diffuse neck swelling: 80–120,000 units IV  $\times$  1

- Antimicrobial—destruction of organisms:
  - Erythromycin 40–50 mg/kg/day PO or IV divided t.i.d. or q.i.d.:
    - For 14 days for respiratory
    - For 10 days for cutaneous
  - Penicillin G 100,000–150,000 units/kg/day q6h IM or IV:
    - For 14 days for respiratory
    - For 10 days for cutaneous
- Referral for prophylaxis of close contacts:
  - Erythromycin PO 40–50 mg/kg per day for 10 days OR
  - Penicillin G benzathine IM 600,000 units (<30 kg) and 1.2 million units (>30 kg)

### Second Line

#### Immunization:

- Immunize with diphtheria toxoid containing vaccine after resolution of disease, as disease does not necessarily confer immunity.
- Refer close contacts for immunization if not fully immunized or if no booster has been received within 5 yr.

### DISPOSITION

#### Admission Criteria

- Admit all patients with suspected diphtheria for antitoxin treatment, antimicrobial treatment, and observation for secondary complications.
- Observe contact and respiratory precautions.

### FOLLOW-UP

#### FOLLOW-UP RECOMMENDATIONS

The test of cure 24 hr after antibiotic treatment has been completed is having 2 negative cultures collected 24 hr apart.

### PROGNOSIS

- Majority of cases resolve with treatment.
- Respiratory diphtheria has a 5–10% case fatality rate (2).
- Primary causes of death are airway obstruction and asphyxiation secondary to pseudomembrane detachment and myocarditis.

### COMPLICATIONS

Most commonly seen complications are cardiac and neurologic:

- Myocarditis, dysrhythmias, cardiac failure:
  - 2–40 days after onset of pharyngitis
  - Poorer prognosis with earlier onset of myocarditis
- Polyneuropathy:
  - Paralysis of soft palate, eye muscles, limbs, diaphragm
  - 1–8 wk after onset of pharyngitis
  - Usually resolves completely
- Renal failure
- Pneumonia

### CODES

#### ICD9

- 032.1 Nasopharyngeal diphtheria
- 032.2 Anterior nasal diphtheria
- 032.9 Diphtheria, unspecified

### PEARLS AND PITFALLS

- Clinical diagnosis based on:
  - History of incomplete immunization
  - Travel to or contact with travelers from endemic areas
  - Physical findings of nasopharyngeal, oropharyngeal, and laryngeal pseudomembrane
- Antitoxin should be given as early as possible.
- The best way to prevent diphtheria is to maintain proper and complete immunization of patients.

# DISCITIS

Katherine Remick  
Marianne Gausche-Hill

## BASICS

### DESCRIPTION

- Discitis is infection or inflammation of the intervertebral disc leading to narrowing of the disc space (1–5).
- Infection may extend to or from the adjacent vertebral end plates.
- It is usually localized to the lumbar region but may affect any disc in the thoracic, lumbar, or sacral spine (1,2).
- Discitis is uncommon, and in some cases it may be a self-resolving low-grade infection that is underdiagnosed.
- Most commonly affects children <5 yr with a 2nd smaller peak in early adolescence (2,3)

### RISK FACTORS

- Bacteremia
- Recent sore throat or upper respiratory tract infection
- Spinal surgery
- Trauma
- Vertebral osteomyelitis

### PATHOPHYSIOLOGY

- Trauma, inflammation, and infection have all been attributed as the etiology of the disease process. Most authors, however, attribute discitis to infectious causes (1–3).
- Disc space infections are caused most commonly by hematogenous spread and rarely result from direct extension (eg, vertebral osteomyelitis) or direct inoculation (eg, postoperative discitis).
- Pediatric patients are at higher risk of developing disc space infections due to the large network of blood vessels that traverse the vertebral end plate between the vertebral body and the intervertebral disc (3,4).
- These blood vessels terminate at the intervertebral disc. Thus, relative to the adjacent vertebral body, the disc is an avascular space with a limited immune response creating a safe haven for bacteria (4,6).
- Proliferation of bacteria within the disc space leads to degradation of the annulus fibrosus and, subsequently, narrowing of the disc space, as is evident on plain radiographs (4).
- In addition, the hyaline cartilage covering the end plates may become eroded, resulting in destruction and the characteristic “saw tooth” appearance of the vertebral end plates (4).
- Such erosion eventually leads to increased blood flow to the site of infection, which results in either resolution of the infection secondary to increased host defense or progression of the infection to adjacent areas (eg, vertebral osteomyelitis or paraspinal abscess) (4).
- In contrast to adults, infants and young children have a large network of anastomoses between the intraosseous arteries of the vertebral bodies. These enhance bacterial clearance and decrease the risk of pyogenic vertebral body infections (4).
- Such anastomoses significantly decrease by 15 yr of age and disappear by adulthood, likely leading to the increased risk of vertebral osteomyelitis, rather than discitis, in older patients (4).

### ETIOLOGY

- Etiology in children is controversial, although infectious etiologies must be considered.
- Discitis may be due to *Staphylococcus aureus* in up to 60% of cases, but a number of bacteria have been implicated (1,4).
- Cultures from disc space biopsies are positive in <40% of samples (1).
- Rare etiologies may include malignancy and nonstaphylococcal pyogenic infections from *Streptococcus pneumoniae* and *Salmonella* species as well as TB, fungal infections, and brucellosis (4,6,8).

### COMMONLY ASSOCIATED CONDITIONS

- Preceding or concomitant infections such as respiratory illness, urinary tract infection, or otitis media (5)
- History of trauma or surgery
- Vertebral osteomyelitis

## DIAGNOSIS

### HISTORY

- The onset of discitis is usually insidious, with subtle findings often leading to delay in diagnosis from the onset of symptoms.
- Diagnosis is often delayed until 4–6 wk after the onset of symptoms (5,7).
- Children present with a variety of symptoms that often mimic other disease processes such as meningitis, abdominal pathology, or septic arthritis.
- Diagnosis can be challenging, especially in younger children who are unable to provide an accurate history.
- Symptoms in toddlers often differ from those in older children (6):
  - The most common symptoms in toddlers include refusal to walk, limp, refusal to bear weight, abdominal pain, neck pain, irritability, nausea, and vomiting.
- The most common symptoms in older children include back pain and neck pain or neck stiffness.
- It is important to remember that children may present with nonspecific symptoms such as excessive crying, irritability, or fever.

### PHYSICAL EXAM

- Afebrile or low-grade to moderate fever.
- Refusal to bear weight sometimes including refusal to sit or pain on crawling
- Inability or refusal to flex spine
- Loss of lumbar lordosis
- Gibbus deformity (sharp structural kyphosis in an area of vertebral body collapse)
- Tenderness to palpation upon palpation of adjacent spinous processes
- Toddlers may be unable to localize the spinal level.
- Limp
- Poorly localized hip or leg pain

### DIAGNOSTIC TESTS & INTERPRETATION

Diagnosis of discitis requires a high index of suspicion.

#### Lab

##### Initial Lab Tests

- The following tests, though nonspecific, should be considered in patients suspected of having discitis: CBC with differential, ESR, C-reactive protein (CRP), PPD testing, and blood cultures (especially if the patient is febrile):
- WBC counts are often in the high-normal range.
  - ESR is usually moderately elevated but can be normal; mean 42 mm/hr (range 4–85 mm/hr) (2).
  - CRP is normal in >60% of patients (1).
  - Blood cultures are negative in >80% of patients with isolated discitis (2).

#### Imaging

- Plain radiographs:
  - Disc space narrowing may be seen as early as 1–2 wk after the onset of symptoms.
  - Irregularity of the adjacent vertebral end plates is usually not identified until 3–4 wk after the onset of symptoms (3).
- Technetium 99m bone scintigraphy:
  - High sensitivity but low specificity for detecting discitis (7)
  - Changes may be seen as early as 3–5 days after the onset of symptoms (1,4).
  - Helpful in localizing the affected spinal level(s) when the history or physical exam fails to do so (4)
  - If characteristic findings are present, the addition of plain radiographs is sufficient to make the diagnosis (4).
- MRI with gadolinium enhancement:
  - The gold standard with the ability to differentiate discitis from vertebral osteomyelitis, paraspinal abscess, tumors, or other inflammatory conditions (2,3,9)
  - More sensitive than CT scan, which may only demonstrate erosion of the vertebral end plates due to poor soft tissue enhancement
  - Recommended in children who fail to show improvement after 2–3 days of IV antibiotic therapy
  - Recommended as primary imaging modality if:
    - Thoracic spine is involved due to difficulty interpreting plain radiographs in this region OR
    - In children with >7 days of refusal to walk
  - Recommended in any child with concurrent neurologic deficits or meningeal signs

#### Diagnostic Procedures/Other

The following may be considered as part of the inpatient or outpatient evaluation:

- Biopsies are not recommended in children due to the low yield of positive cultures (35–60%) and high risk of complications (4,5).
- Biopsies should be reserved for patients with known immunodeficiency states or a lack of response to antibiotic therapy (1,4,7).
- If indicated, CT-guided needle biopsy is recommended prior to open surgical biopsy.

**DIFFERENTIAL DIAGNOSIS**

- Vertebral osteomyelitis
- Septic arthritis of the sacroiliac joint
- Paraspinal abscess
- Malignancy: Primary or metastatic
- Tuberculous spondylitis
- Brucellosis
- Spondylolysis/Spondylolisthesis
- Transverse myelitis
- Scheuermann kyphosis

**TREATMENT**

- A delay in antibiotic therapy may lead to a prolonged course, prolonged or recurrent symptoms, and more severe infections (3,4).
- Duration of therapy should be guided by normalization of ESR with serial measurements, unrestricted passive spinal mobility, and resolution of pain.
- Up to 75% of patients may have an associated paravertebral inflammatory mass and may suggest the need for more aggressive or longer duration of antibiotic therapy (1).

**ALERT**

Children with disc protrusion causing nerve root entrapment or the presence of paravertebral abscess require immediate surgical consultation.

**MEDICATION**

- Antistaphylococcal antibiotics:
  - Cefazolin (methicillin sensitive) 25–100 mg/kg/day IV q6h; adult dose 1–2 g
  - Clindamycin (methicillin resistant) 30 mg/kg/day IV q8h, max single dose 900 mg
  - Vancomycin (methicillin resistant) 40 mg/kg/day IV q6h, max single dose 1 g
- If there is a poor response to standard antimicrobial therapy, further treatment should be guided by results of PPD testing and/or biopsy (as indicated):
  - Authors vary on duration of antibiotic therapy.
  - Treatment should begin with IV antibiotics (7–14 days) followed by transition to oral antibiotics (1–6 mo) once the patient shows evidence of clinical and laboratory improvement (4,7,8). Choice of oral antibiotics depends on susceptibilities of the organism.
- Analgesia, rest, and immobilization:
  - Acetaminophen 15 mg/kg/dose PO q4h PRN
  - Ibuprofen 10 mg/kg/dose PO q6h PRN
  - Morphine 0.1 mg/kg IV/IM/SC q2h PRN:
    - Initial morphine dose of 0.1 mg/kg IV/SC may be repeated q15–20min until pain is controlled, then q2h PRN.

**SURGERY/OTHER PROCEDURES**

Surgical debridement is rarely indicated and should only be performed in patients who fail to respond to conventional therapy and demonstrate the presence of an abscess or evolving neurologic deficits (4).

**DISPOSITION****Admission Criteria**

Patients diagnosed with discitis should be managed in an inpatient setting during the early stages to monitor for response to antimicrobial therapy.

**Issues for Referral**

- As inpatient, pediatric orthopedic or neurosurgical consultation is recommended.
- Particular attention should be paid to evolving neurologic deficits and the possible need for surgical consultation.

**Additional Therapies**

Thoracolumbosacral orthosis is recommended if imaging reveals extensive bony destruction, sagittal or coronal deformity, or soft tissue involvement (4).

**FOLLOW-UP****FOLLOW-UP RECOMMENDATIONS**

Follow up with plain x-rays at regular intervals for 12–18 mo to assess return of vertebral height (4).

**PROGNOSIS**

- Several studies have shown the prognosis is good regardless of antimicrobial therapy.
- In children who receive antibiotic therapy, the majority will have resolution of symptoms within 3 wk and fewer long-term complications (3,4).
- Long term, 80% of children in 1 series were asymptomatic with full mobility of the spine (8).
- Partial restoration of disc space height may be seen as early as 2–3 mo following therapy. However, full recovery of disc space height may take 1–3 yr (1).

**COMPLICATIONS**

- Chronic low back pain
- Loss of vertebral height, usually recovered within 1–2 yr
- Spinal fusion if >50% loss in vertebral height (1)
- Limited physical activity

**CODES****ICD9**

- 722.90 Other and unspecified disc disorder of unspecified region
- 722.91 Other and unspecified disc disorder of cervical region
- 722.92 Other and unspecified disc disorder of thoracic region

**PEARLS AND PITFALLS**

- Discitis is a rare cause of back pain in children but often presents with other nonspecific symptoms.
- Rest and analgesia combined with antistaphylococcal antibiotics is the mainstay of therapy.
- Discitis should be considered in any child with refusal to bear weight.
- Any child with neurologic deficits should receive immediate orthopedic or neurosurgical consultation.
- Poor response to antimicrobial therapy should raise the suspicion for less common infectious etiologies, the presence of a paravertebral abscess, or a noninfectious pathology.

# DISLOCATION, KNEE

John Munyak  
Kristopher Hunt

## BASICS

### DESCRIPTION

- Knee dislocation refers to dislocation of the tibiofemoral joint, with a disruption of  $\geq 3$  of the stabilizing ligaments.
- The direction of dislocation is defined by the direction of tibial movement relative to the femur.
- Directions of dislocation include anterior, posterior, or lateral when translational forces are applied; when rotary forces are involved, directions of dislocation include anterior, posterior lateral, medial, or rotary.
- Knee dislocations represent true orthopedic emergencies, and this injury may be limb threatening due to associated neurovascular compromise.

### EPIDEMIOLOGY

The majority of knee dislocations are anterior.

### RISK FACTORS

- As with most dislocations, knee dislocations are more common in males.
- Contact sports

### GENERAL PREVENTION

- Close supervision is an effective means to prevent injury in events such as sporting activities, especially contact sports where large forces are exerted on the lower limbs.
- Appropriate use of padding/equipment in contact sports is necessary to prevent limb injury.
- Safe driving and appropriate use of child restraints are essential in preventing any potential motor vehicle–related injury.

### PATHOPHYSIOLOGY

- Most knee dislocations in any direction involve transmission of large forces to the tibiofemoral joint after blunt-force trauma; low-energy knee dislocations in pediatric populations are uncommon.
- After the force is transmitted, dislocation occurs due to tearing and disruption of the majority of the ligamentous and soft tissue structures supporting the knee. Typically, the anterior cruciate ligament (ACL), posterior cruciate ligament (PCL), and an additional collateral ligament are involved.
- Anterior dislocations usually occur due to a hyperextension mechanism after high-energy trauma is sustained to the joint.

### ETIOLOGY

- 2/3 of knee dislocations are secondary to motor vehicle collisions.
- Other etiologies include falls, sporting injuries, and industrial injuries.

### COMMONLY ASSOCIATED CONDITIONS

- High incidences of popliteal artery, peroneal nerve, and tibial nerve injuries are associated with knee dislocations.
- Most of these associated injuries are due to posterior dislocations; popliteal arterial injury occurs in  $\sim 50\%$  of such dislocations.
- Knee dislocations are frequently associated with proximal tibial fractures.

## DIAGNOSIS

### HISTORY

- Conscious patients may relate a history of a fall, sporting injury, or motor vehicle accident.
- Knee pain with an associated sensation of immobility or dislocation is common.
- In preverbal patients, inability to bear weight on the affected limb and pain may be the only clues.

### PHYSICAL EXAM

- Deformity will be obvious if the joint has not spontaneously reduced.
- If not spontaneously reduced, the affected knee will be grossly deformed, swollen, and immobile.
- In a spontaneously reduced knee dislocation, the examiner will elicit instability in multiple directions.
- If the peroneal nerve is affected, a conscious patient may relate decreased sensation or numbness in the 1st dorsal web space of the foot with or without diminished foot dorsiflexion when compared to the unaffected, contralateral side.
- Vascular assessment may be accomplished with palpation or the use of duplex Doppler US at the dorsalis pedis, posterior tibial, anterior tibial, and popliteal arteries.
- Despite a present distal pulse, the popliteal artery may be injured in  $\sim 10\%$  of cases.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Imaging

Plain films of the knee should be sufficient to confirm the diagnosis of knee dislocation; however, the diagnosis may be made from physical exam alone.

#### Diagnostic Procedures/Other

- In a joint that does not appear grossly deformed but a sufficient mechanism for injury has occurred, a high index of suspicion should remain for a knee dislocation that has spontaneously reduced and an appropriate physical exam and diagnostic testing should ensue.
- Significant controversy exists regarding the use of emergent arteriography in all cases of knee dislocation.
- Patients without a pulse at any time pre- or post reduction require emergent angiography as well as those with other signs of vascular injury including bruit or distal ischemia.
- Some authors advocate for serial vascular examinations on admission for patients with a low-energy mechanism, normal pulses pre- and post reduction, and normal ankle brachial indices.
- If any doubt is present, arteriography should be ordered because intimal tears in the popliteal artery may not be apparent in some cases for several days.

### DIFFERENTIAL DIAGNOSIS

ACL tear, PCL tear, isolated collateral ligament tear, tibia/fibular fracture, knee fracture, femoral fracture, or patellar dislocation

## TREATMENT

### PRE HOSPITAL

Splint the knee in a position of comfort.

### INITIAL STABILIZATION/THERAPY

- If a sufficient trauma mechanism exists, then primary attention should be given to ABCs as well as more severe injuries:
  - Knee dislocations do not directly result in airway, breathing, or circulation compromise aside from vascular compromise to the affected limb.
- The main therapy is reduction of dislocation and analgesia.

### MEDICATION

#### First Line

- Analgesics are indicated.
- Opioids:
  - Morphine 0.1 mg/kg IV/IM/SC q2h PRN:
  - Initial morphine dose of 0.1 mg/kg IV/SC may be repeated q15–20min until pain is controlled, then q2h PRN.
- NSAIDs:
  - Consider NSAID medication in anticipation of prolonged pain and inflammation.
  - Ibuprofen 10 mg/kg/dose PO/IV q6h PRN
  - Ketorolac 0.5 mg/kg IV/IM q6h PRN
  - Naproxen 5 mg/kg PO q8h PRN
- Moderate sedation may be required to aid with the reduction for both anxiolysis and pain reduction.
- See the Procedural Sedation and Analgesia topic for detailed information.

#### Second Line

Pain medications such as anti-inflammatories and narcotic analgesics used post reduction will likely be required due to postreduction pain and inflammatory changes.

### SURGERY/OTHER PROCEDURES

- Early reduction is the hallmark of good therapy.
- Reduction is accomplished with in-line longitudinal traction and manipulation of the joint back into position.
- In the case of an anterior dislocation, for example, an assistant should apply continuous longitudinal traction while the femur is lifted anteriorly, maintaining another hand on the tibia for stability.
- For posterior dislocation, the knee should be promptly immobilized in 15 degrees of flexion so as to avoid any tension on the popliteal artery.
- Arthroscopy may be required if impinging soft tissue between bony structures will not allow for closed reduction.
- In pediatric patients where closed reduction is successful, surgery will likely be required at a later time to repair the involved ligaments.

**DISPOSITION****Admission Criteria**

- All patients with suspected vascular injury, which includes the vast majority of knee dislocations, should be admitted for arteriography and/or serial exams after successful reduction.
- Critical care admission criteria:
  - Many patients will have coexisting injuries due to the blunt force required to create a knee dislocation; the patient with multiple traumatic injuries may require a higher level of care, such as a surgical ICU setting.

**Discharge Criteria**

- Patients with conditions other than knee dislocation may be discharged as appropriate.
- If the patient with knee dislocation has been thoroughly evaluated, deemed to not have vascular compromise, and the orthopedic surgeon recommends discharge, then this is appropriate. However, this is atypical since most patients with knee dislocations have vascular compromise.

**Issues for Referral**

- Emergent orthopedic consultation should be obtained when a knee dislocation is recognized given the emergent potential for operative reduction with failed closed reduction.
- Emergent vascular surgical consultation may be required in cases where arterial damage is apparent with physical exam.

**FOLLOW-UP****FOLLOW-UP RECOMMENDATIONS**

Activity:

- After reduction with or without vascular and ligamentous repair, the affected extremity should be immobilized from the groin to the toes in a fashion allowing for frequent reassessment of the dorsalis pedis pulse.
- The extremity should be immobilized for 8 wk without weight bearing, after which time a long-leg brace may be applied at the discretion of the orthopedist.
- After reduction and weeks of immobilization, intensive quadriceps and hamstring rehabilitation will be required in order to minimize the functional loss of the knee joint.

**PROGNOSIS**

- Inadequate assessment and treatment of vascular injuries within 4 hr can lead to an amputation rate of ~50%; at 8 hr, this rate increases to ~80%.
- After reduction with or without surgical ligamentous repair and arterial repair, the need for a brace for strenuous activities may be permanent.

**COMPLICATIONS**

- Limb loss may result from arterial injury loss of blood flow to the lower leg.
- Other complications include degenerative arthritis, limited range of motion, recurrent dislocation, and associated proximal tibial fracture.

**See Also (Topic, Algorithm, Electronic Media Element)**

- Dislocation, Patella
- Knee, Ligamentous Injury

**CODES**
**ICD9**

- 836.50 Closed dislocation of knee, unspecified part
- 836.51 Anterior dislocation of tibia, proximal end, closed
- 836.52 Posterior dislocation of tibia, proximal end, closed

**PEARLS AND PITFALLS**

- True knee dislocation requires a significant mechanism.
- Knee dislocations are orthopedic emergencies and may be vascular emergencies as well due to associated popliteal injury.
- Palpation and Doppler exam of lower limb arteries are insufficient to rule out arterial injury, and either arteriogram or serial exams must be employed when a knee dislocation has been identified.

## BASICS

### DESCRIPTION

Patellar dislocation occurs when the patella is displaced either medially or laterally from the patellar surface, which is located on the distal femur superior to and between the lateral and medial femoral condyles.

### EPIDEMIOLOGY

#### Incidence

- The majority of injuries sustained to the pediatric patella are dislocations.
- Patellar dislocation is one of the most common causes of hemarthrosis in children.

### RISK FACTORS

Recurrent dislocation is associated with increased quadriceps angle, generalized ligamentous laxity, family history, laxity in the medial patellofemoral ligament, and weakness in the vastus medialis obliquus.

### GENERAL PREVENTION

- Close supervision is an effective means to prevent injury in events such as sporting activities, especially contact sports where large forces are exerted on the lower limbs.
- Appropriate use of padding/equipment in contact sports is necessary to prevent limb injury.
- In cases of chronic dislocation, operative repair may be required to prevent recurrence.

### PATHOPHYSIOLOGY

- The mechanism for a patellar dislocation is commonly a twisting of a planted knee with a lateral force applied.
- The majority of patellar dislocations occur laterally; however, horizontal, superior, and intercondylar dislocations do occur.

### ETIOLOGY

See Pathophysiology.

### COMMONLY ASSOCIATED CONDITIONS

- Fractures in children may result from direct trauma or, more commonly, with a “sleeve” fracture mechanism.
- The patellar “sleeve” fracture takes place when a forceful contraction of the quadriceps tendon occurs against a fixed lower leg, separating the distal patellar “sleeve” from the body of the patella.

## DIAGNOSIS

### HISTORY

- Typically, a history of rotating the knee on a fixed lower leg is related.
- Patients may describe a sensation of the “knee popping out of place.”

### PHYSICAL EXAM

- If dislocated, a lateral mass may be noted that is asymmetric to the contralateral leg, and the knee will commonly be held in flexion.
- Positive Fairbank sign, or apprehension test: When the patella is moved laterally, the patient appears apprehensive though not typically in pain.
- Often the patella will have reduced spontaneously by patient motion en route. If this is the case, a hemarthrosis over the medial patellar retinaculum may be the only clinical finding.
- A large amount of effusion may be noted if a significant amount of time has elapsed prior to reduction.
- If gross instability of the patella exists, it may indicate that the soft tissue disruption to the medial aspect of the knee has become extensive.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Imaging

- Reduction need not be delayed for imaging if the diagnosis is readily apparent from history and physical exam.
- Plain films are sufficient to confirm the diagnosis of patellar dislocation if it is not readily apparent from history and physical exam alone.
- Post reduction plain films should be obtained to document successful reduction and examine the lateral femoral condyle as well as the medial patellar margin, which are the 2 most common sites of associated fracture.

### DIFFERENTIAL DIAGNOSIS

Several bony disruptions may be mistaken for a patellar dislocation, which include but are not limited to distal femoral fracture, quadriceps rupture, patellar tendon rupture, patellar fracture, or frank knee dislocation.

## TREATMENT

### PRE HOSPITAL

Splint the leg in a position of comfort.

### INITIAL STABILIZATION/THERAPY

- If a sufficient trauma mechanism exists, then primary attention should be given to airway, breathing, and circulation and more severe injuries. Patellar dislocations do not directly result in airway, breathing, or circulation compromise.
- The main goal of therapy is reduction of the dislocation.
- Analgesia should be provided if necessary.

### MEDICATION

#### First Line

- See the Procedural Sedation and Analgesia topic for detailed information.
- Opioids:
  - Morphine 0.1 mg/kg IV/IM/SC q2h PRN:
  - Initial morphine dose of 0.1 mg/kg IV/IM may be repeated q15–20min until pain is controlled, then q2h PRN.
- NSAIDs:
  - Consider NSAID medication in anticipation of prolonged pain and inflammation.
  - Ibuprofen 10 mg/kg/dose PO/IV q6h PRN
  - Ketorolac 0.5 mg/kg IV/IM q6h PRN
  - Naproxen 5 mg/kg PO q8h PRN

#### Second Line

Pain medications including NSAIDs and a short course of opiates post reduction should be offered to aid in the rehabilitation process.

### SURGERY/OTHER PROCEDURES

Reduction: Extend knee to 180 degrees, as this will typically force the patella to return to its normal location:

- This may be accompanied by simultaneous pressure against the patella, moving it in a lateral to medial direction.

**DISPOSITION****Admission Criteria**

If a significant trauma mechanism exists, other factors may require admission.

**Discharge Criteria**

Reduction of dislocation and no other injuries or problems that would require admission

**Issues for Referral**

- Consultation with an orthopedist is recommended in cases of associated fracture/dislocation.
- Early consultation is recommended in cases of a "sleeve" fracture, in which case specific therapy is based on the degree of displacement.
- Recurrent episodes require operative repair for effective treatment.

**FOLLOW-UP****PROGNOSIS**

Patients with an isolated, primary patellar dislocation have an excellent prognosis with good functional outcomes.

**COMPLICATIONS**

Complications include but are not limited to degenerative arthritis, patellofemoral syndrome, patellar instability, recurrent dislocations, and fractures.

**See Also (Topic, Algorithm, Electronic Media Element)**

- Dislocation, Knee
- Knee, Ligamentous Injury

**CODES****ICD9**

- 718.36 Recurrent dislocation of lower leg joint
- 836.3 Dislocation of patella, closed

**PEARLS AND PITFALLS**

- Patellar dislocation is typically lateral.
- Reduction can be accomplished simply by extending the leg and manipulating the patella back between the 2 femoral condyles.
- Prereduction films are often unnecessary.

# DISLOCATION, TEMPOROMANDIBULAR JOINT

Mandisa A. McIver  
William I. Krief

## BASICS

### DESCRIPTION

- The temporomandibular joint (TMJ) is comprised of the articular surface lying between the mandibular condyles and the temporal bone.
- Dislocation is defined as displacement of the condyle out of the mandibular fossa.
- TMJ dislocation can result from both traumatic and nontraumatic processes.
- Most dislocations can be managed in the emergency department with outpatient follow-up.
- Anterior dislocation is most common, but posterior, lateral, and superior dislocations can also occur.
- Dislocations are classified as acute, chronic recurrent, and chronic.

### EPIDEMIOLOGY

#### Prevalence

TMJ dislocations represent 3% of all dislocated joints in the body.

### RISK FACTORS

- Shallow mandibular fossa
- Previous TMJ dislocation or trauma
- Dystonic reactions
- Seizures
- Hypermobility syndromes (eg, Marfan, Ehlers-Danlos)
- Prolonged dental procedures
- Psychiatric medications

### GENERAL PREVENTION

Avoid extreme mouth opening.

### PATHOPHYSIOLOGY

- The dislocation is described by the position of the mandibular condyle in relation to the temporal articular groove:
  - Anterior dislocations—most common:
    - Following direct trauma to mandible
    - Resulting from dystonic reaction or seizure
    - Extreme mouth opening (yawning, lengthy dental procedures, general anesthesia, vomiting, seizures, laughing, screaming, singing): The masseter and temporalis muscles elevate the mandible while the lateral pterygoid muscle is still contracting, pulling the mandibular condyle anteriorly out of the temporal fossa.
  - Posterior dislocations can occur after a direct blow to the chin and may cause external auditory canal injury.
  - Lateral dislocations are frequently associated with mandibular fractures.

- Superior dislocations occur after a direct blow to a partially opened mouth:
  - Can result in facial nerve palsy, cerebral contusions, or deafness
- Once dislocated, the condyle stays out of the temporal fossa due to spasms of the lateral pterygoid and temporal muscles.

### ETIOLOGY

- Trauma (40–99% of all TMJ dislocations)
- Extreme mouth opening

### COMMONLY ASSOCIATED CONDITIONS

- Bruxism (abnormal grinding of the teeth)
- Malocclusion/Deep overbite
- Lax ligaments
- Stress
- Rheumatoid arthritis
- Osteoarthritis
- Viral infections (eg, mumps, measles)
- Hypermobility syndromes

## DIAGNOSIS

### HISTORY

- Jaw pain and trismus after extreme mouth opening or after trauma to the jaw
- Difficulty speaking or swallowing
- Malocclusion
- There may be a history of previous dislocations.
- Past medical history may include hypermobility syndromes.

### PHYSICAL EXAM

- Must do a thorough exam of the head, neck, and nervous system.
- Examine the oral cavity for any gingival lacerations or extraoral chin lacerations, which may raise suspicion for an open fracture.
- Unilateral dislocations cause deviation of the jaw away from the affected side.
- Bilateral dislocations cause an underbite or prognathia with pain over both TMJ areas.
- Pay special attention during the neurologic exam to cranial nerves V and VII.
- Assess hearing and inspect the external auditory canal, especially in suspected posterior TMJ dislocations.

## DIAGNOSTIC TESTS & INTERPRETATION

### Imaging

- Mandibular series of radiographs
- Panoramic radiographs
- TMJ radiographs
- CT of mandible

### Diagnostic Procedures/Other

Tongue blade test:

- Patient attempts to grasp and hold a tongue blade between the molars while the examiner twists the tongue blade to the point of breaking
- Mandibular fractures can be ruled out (negative predictive value 96%) if performed successfully (1).
- Both sides should be tested.

### DIFFERENTIAL DIAGNOSIS

- Mandibular fracture
- Maxillary fracture
- Dystonic reaction

## TREATMENT

### INITIAL STABILIZATION/THERAPY

- Assess and stabilize airway, breathing, and circulation.
- Attend to life-threatening conditions 1st:
  - TMJ dislocation is primarily a condition of morbidity.
- Provide adequate analgesia.
- Reduce dislocation as rapidly as feasible.

### MEDICATION

- Analgesia, sedation, and muscle relaxation may be required for successful reduction:
  - Procedural sedation may be necessary if the patient is unable to cooperate.
- Midazolam 0.1 mg/kg IV (max 2 mg) can be used as a muscle relaxant.
- Local injection of lidocaine 2%, 2–5 mL into the TMJ at the site of preauricular depression
- Morphine 0.1 mg/kg IV/IM/SC q2h PRN:
  - Initial morphine dose of 0.1 mg/kg IV/SC may be repeated q15–20min until pain is controlled, then q2h PRN.
- Ketorolac 0.4–1 mg/kg IV/IM:
  - Children > 16 yr of age can be given 30 mg IV as a single dose.

**SURGERY/OTHER PROCEDURES**

- Reduction of anterior TMJ dislocation (following radiologic study):
  - The patient is seated upright facing the physician performing the reduction.
  - Stabilize the head posteriorly with head rest or assistance.
  - Physician should wrap his or her thumbs in gauze for protection.
  - Using the thumbs, apply gentle pressure downward and backward on the occlusal surfaces of the patient's lower molars:
    - The downward pressure moves the dislocated condyles below the articular eminences.
    - The backward pressure shifts the condyles posteriorly into the mandibular fossa.
    - This may require a significant amount of strength. It is common that a senior physician with experience in the procedure may give supervision and instruction to a junior clinician with greater strength, such as a resident or fellow, who actually performs the procedure.
    - The clinician performing the dislocation may stand on a chair, stool, or bed to gain additional force by using body weight in addition to arm strength to lower the jaw.
- Other TMJ dislocations are reduced similarly, with adjustments in direction for the 2nd maneuver.
- TMJ dislocation associated with mandibular fractures often requires open reduction and internal fixation.

**DISPOSITION****Admission Criteria**

- Failed closed reduction
- TMJ dislocation with mandibular fractures requiring open reduction

**Discharge Criteria**

- Stable respiratory condition
- Able to tolerate fluids PO
- Pain well controlled
- Appropriate follow-up arranged

**Issues for Referral**

Follow-up by specialist (oral maxillofacial surgeon, otolaryngologist, or dentist) for evaluation of possible complications and ongoing care

**Additional Therapies**

If recurrent dislocation occurs, a bandage can be placed around the head and chin (Barton bandage) for several days to limit jaw movement.

**FOLLOW-UP****FOLLOW-UP RECOMMENDATIONS**

- Discharge instructions and medications:
  - Avoid extreme mouth opening for at least 6 wk.
  - The patient should hold the chin against his or her chest or hand during yawning to avoid wide mouth opening.
  - Soft diet for 1 wk
  - Warm compresses
  - NSAIDs
  - Muscle relaxants
- Activity:
  - As tolerated

**DIET**

Soft diet for 1 wk

**PROGNOSIS**

- Conservative methods provide temporary alleviation of symptoms with common recurrence.
- Surgical intervention is generally known to be the more effective definitive treatment.
- Pediatric patients with posttraumatic internal derangements of the TMJ are prone to retrognathia and facial asymmetry years later.

**COMPLICATIONS**

- Chronic recurrent dislocations
- Ischemic necrosis of the condylar head
- Traumatic damage to the articular disc
- Mandibular osteomyelitis
- Permanent malocclusion (chronic untreated dislocations)

**REFERENCE**

**ADDITIONAL READING**

- Chaudhry M, Rosh AJ. Dislocation, mandible. *eMedicine.* May 5, 2010. Available at <http://emedicine.medscape.com/article/823775-overview>.
- Pratt A, Loiselle J. Reduction of temporomandibular joint dislocation. In King C, Henretig FM, eds. *Textbook of Pediatric Emergency Procedures.* 2nd ed. Philadelphia, PA: Lippincott Williams & Wilkins; 2008.

**ICD9**  
830.0 Closed dislocation of jaw

**PEARLS AND PITFALLS**

- Prior to attempting reduction of TMJ dislocation, a radiologic study should be performed to exclude any associated fractures.
- Delay in reduction of TMJ dislocations further aggravates muscle spasms and makes reduction more difficult.
- Bilateral dislocations that are associated with severe spasms may require reduction of 1 condyle at a time.

# DISORDERS OF ENERGY METABOLISM (MITOCHONDRIAL DISEASE)

Richard G. Boles  
Solomon Behar  
Derek A. Wong

## BASICS

### DESCRIPTION

- Mitochondrial disease refers to a group of hundreds of different inborn errors of metabolism that result in pathology due to defective energy metabolism.
- Examples of mitochondrial disease include:
  - MELAS (mitochondrial myopathy, encephalopathy, lactic acidosis, stroke)
  - MERRF (myoclonic epilepsy with ragged red fibers)
  - NARP (neuropathy, ataxia, retinitis pigmentosa)
  - Kearns-Sayre syndrome
  - Cytochrome C oxidase deficiency
  - Most patients do not have one of the “named” conditions.

### EPIDEMIOLOGY

#### Prevalence

- Mitochondrial disease as a whole is by far the most common kind of metabolic disorder.
- Common: Some prevalence estimates give a minimal figure as high as 1 in 500.

### GENERAL PREVENTION

Prenatal diagnosis is feasible in a minority of cases.

### PATHOPHYSIOLOGY

- Mitochondrial disease is caused by abnormalities in the ability of cells to make ATP (energy).
- As a consequence, those tissues with the highest energy requirements are affected 1st, especially nerve and muscle tissues:
  - Secondary tissues affected include endocrine glands, liver, kidney, and bone marrow.
- Clinical manifestations are generally intermittent and typically occur at times of high-energy demand, including viral infection, fasting, overexercise, psychological stress, and environmental temperature extremes.

### ETIOLOGY

- Mitochondria have their own DNA (mtDNA) that is maternally inherited from a mother to all of her children, without recombination:
  - Mitochondrial disease can be due to mutations in mtDNA, which are usually maternally inherited.
- Most proteins in the mitochondria are encoded by the chromosomes and imported into mitochondria:
  - Mitochondrial disease can be due to mutations in the nuclear genes encoding those imported proteins; in these cases, inheritance is mendelian (usually autosomal recessive).

## DIAGNOSIS

### HISTORY

- Extremely variable
- Intermittent, protean, and multiple disease manifestations or symptoms are most common.
- Neurologic (including psychiatric) and/or muscular disease
- Multisystem failure associated with an acute stressor, such as a viral illness

- “Functional” disease, such as:
  - Chronic pain syndromes, including migraine
  - GI dysmotility, including irritable bowel or constipation
  - Cyclic vomiting
  - Chronic fatigue/exercise intolerance
- Some common presentations include:
  - Dysautonomia
  - Abnormal movements
  - Cardiomyopathy
  - Renal tubular dysfunction or acidosis
  - Stroke (especially basal ganglial and/or thalamic)
  - Acute loss of milestones
  - Autistic spectrum disorders

### PHYSICAL EXAM

- Often normal
- Myopathy may involve any or all of the following:
  - Skeletal: Hypotonia, decreased bulk, weakness
  - Ocular
  - Cardiac
  - GI
- Encephalopathy (eg, mental retardation)

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

- Often normal (especially in the absence of stressors)
- Urine ketosis
- Anion gap metabolic acidosis during acute illness or deterioration
- Fasting hypoglycemia:
  - Rarely postprandial hypoglycemia
- Increased transaminases (usually mild)
- Renal tubulopathy (especially abnormal urine organic acids when stressed)
- Free carnitine deficiency
- Elevated creatine kinase (CK) when ill
- Elevated lipase while ill
- Neutropenia in some cases
- Lactic acidosis in many cases
- Hyperammonemia (occasional, usually <200 micromolar)

#### Initial Lab Tests

- Chemistry panel, ALT, lipase, CK
  - CBC with differential
  - Urine dipstick
- After initial lab tests above, if mitochondrial disease is suspected, consider:
  - Urine organic acids:
    - Most important test
    - Collect the sample and freeze.
  - Plasma acylcarnitines
  - Plasma carnitines
  - Plasma lactate and pyruvate
  - Blood coenzyme Q10 level
  - Consider mitochondrial DNA screening test.

#### Imaging

- Brain MR or CT if stroke is suspected
  - MR spectroscopy may show an increased lactate peak.
- Upper GI series with small bowel follow-through to rule out malrotation in cases with severe vomiting

### Diagnostic Procedures/Other

Diagnosis may require muscle biopsy and/or sophisticated biochemical and molecular testing performed by an expert geneticist or neurologist.

### DIFFERENTIAL DIAGNOSIS

- Very broad and dependent on clinical presentation
- Consider:
  - Prader-Willi and Angelman syndromes
  - Zellweger syndrome
  - Organic acidemias
  - Congenital defects of glycosylation
  - Disorders of creatine metabolism
  - Chromosomal copy number variants
- Consider a diagnosis of mitochondrial disease when a patient presents with:
  - Idiopathic disease involving at least 2 systems or tissues
  - Idiopathic complex neurologic, neuromuscular, or psychiatric disease
  - Intermittent, transient, “functional,” or dysautonomic disease manifestations
  - Unexplained GI symptoms
  - When there is suspicion of fictitious disorder

## TREATMENT

Avoid fasting by administration of calories, including fruit juices, chocolate milk, etc.

### INITIAL STABILIZATION/THERAPY

- IV fluids with 10% dextrose 0.45% normal saline at a high rate of 1.5–2 times maintenance
- If diagnosed disease:
  - Consult family to avoid fasting in patient:
    - Age <5 mo: Max fast = 4 hr
    - Age 5–11 mo: Max fast = the number of hours equal to the age of the patient in months
    - Age ≥ 1 yr: Max fast = 12 hr
  - Consider a recommendation for the patient to start on coenzyme Q10:
    - 10 mg/kg/day, usually divided b.i.d.
    - 200 mg/day for older children and adults
    - Known side effects are rare and benign.
    - Can be purchased in many drug stores
    - Liquid and gel capsules work best.
  - Avoid systemic steroids and valproic acid.
  - Referral to a tertiary care facility with an expert in mitochondrial disease:
    - Experts may be neurologists, geneticists, or occasionally endocrinologists.

### ALERT

Avoid fasting, especially during illness and prior to medical/surgical procedures.

- D10 0.45% normal saline at 1.5 times maintenance during the perioperative period is generally protective for most procedures.

**MEDICATION**

- Ondansetron for nausea/vomiting at 0.3–0.4 mg/kg/dose (adult dose 12–16 mg) given by standard routes (IV or oral dissolving tablet):
  - Patients with mitochondrial disease do not generally respond to the lower doses but generally respond to higher doses.
- Give L-carnitine by oral or IV route if patient takes this compound:
  - Most patients receive 100 mg/kg/day divided b.i.d. (adult dose 1 g b.i.d.)
- Amitriptyline is frequently used with chronic pain or other functional symptoms:
  - 0.5–1 mg/kg/day qhs
- In critically ill patients, an insulin drip with IV dextrose (generally high concentration of both via central access) can be lifesaving.
- Coenzyme Q10 at 5 mg/kg/dose b.i.d. (adult dose 200 mg b.i.d.)
- Riboflavin 100 mg/day or one B100 tablet/day
- Many patients take other cofactors including vitamin C (250–1,000 mg/day), other antioxidants, and/or creatine (140 mg/kg/day or 5 g/day)

**ALERT**

- Multiple medications frequently provoke adverse reactions in these patients:
  - Systemic corticosteroids (if absolutely needed, watch ketones, can counter effect with IV insulin):
    - Moderate amounts of inhaled steroids are usually tolerated.
  - Oral and injected hormonal contraceptives
  - Valproic acid
- Surgery and anesthesia pose special risks in this population (1):
  - Avoid propofol.
  - Dysautonomia is common, including respiratory arrest with sedative use.
  - Malignant hyperthermia precautions

**DISPOSITION****Admission Criteria**

- Failure to tolerate adequate caloric intake in a patient on fasting avoidance (most are):
  - Less than half of the usual caloric intake often requires admission.
- Serum anion gap  $\geq 20$  mM (sodium minus chloride minus  $\text{HCO}_3^-$ ):
  - Serum anion gap 18–19 is borderline.
- Large urine ketones ( $>40$  mg/dL):
  - Moderate is borderline.
- Loss of abilities, altered mental status (relative to baseline), or new neurologic finding
- Pancreatitis, rhabdomyolysis, apnea, cardiac failure

**Discharge Criteria**

- Ability to tolerate adequate enteral intake
- Negative urine ketones
- Normal serum anion gap ( $<14$  mM)

**FOLLOW-UP****FOLLOW-UP RECOMMENDATIONS**

- Follow the management plan recommended by the specialist, including diet, activity, medications, and cofactors:
  - Adequate hydration and caloric intake are essential.
- Patient/Family should contact the specialist or his or her office the following day.
- Return for:
  - Altered mental status (eg, lethargy, excessive irritability, loss of abilities)
  - Significant vomiting
  - Signs of dehydration
  - Poor enteral intake
  - Increased urine ketones not responding to sugar solutions
  - Difficulty breathing
  - Increased weakness or pain
  - Other worrisome findings

**Patient Monitoring**

- Mental status
- Urine ketones
- Serum anion gap, if very ill

**PROGNOSIS**

- Variable but generally good
- Mitochondrial disease is a chronic illness.

**COMPLICATIONS**

- Stroke
- Seizures (many potential etiologies)
- Liver failure
- Functional bowel disorders
- Chronic pain syndromes
- Rhabdomyolysis
- Pancreatitis
- Renal tubular dysfunction/acidosis:
  - Rarely: Renal failure
- Cardiomyopathy
- Apnea/Hypoventilation (especially drug related)
- Pancytopenia, or any element(s) thereof
- Chronic variable immunodeficiency:
  - Especially: Line infections with sepsis
- Hypoglycemia
- Any endocrinopathy (eg, hypoglycemia, diabetes, hypothyroid, growth hormone deficiency)
- Depression, especially in adolescents
- Malignant hyperthermia
- Any dysautonomia, especially tachycardia
- Multisystem failure
- Sudden death

**REFERENCES**

**ICD9**

277.87 Disorders of mitochondrial metabolism

**PEARLS AND PITFALLS**

- Pearls:
  - Avoid fasting, especially during illness and prior to medical/surgical procedures.
  - Adverse reactions to anesthesia and many drugs are common.
  - GERD is very common in patients with mitochondrial disease. Frequently, GERD is misdiagnosed in these patients as asthma or chronic sinusitis.
  - Urine ketone dipsticks are often effective for evaluation and monitoring.
- Pitfalls:
  - Lactic acid can be fictitiously elevated by use of a tourniquet or improper specimen handling, especially in infants and toddlers.

# DISSEMINATED INTRAVASCULAR COAGULATION

Kristin Welch

Adam M. Silverman

## BASICS

### DESCRIPTION

- Disseminated intravascular coagulation (DIC) is a secondary process caused by systemic activation of coagulation and fibrinolysis by tissue damage from a variety of underlying diseases.
- Characterized by coexistent hemorrhage and microvascular thrombosis
- Acute DIC occurs when clotting factors are consumed more rapidly than they can be replaced:
  - Hemorrhage dominates, overshadowing ongoing thrombosis.
- Chronic DIC is when the body is able to keep up with clotting factor consumption:
  - Thrombosis is predominant clinical feature.

### RISK FACTORS

- Neonates
- Pregnancy
- Malignancy
- Sepsis
- Trauma
- Congenital deficiency of anticoagulants (eg, protein C, antithrombin)

### PATHOPHYSIOLOGY

- Exposure of blood to procoagulants: Endothelial tissue damage from initiating primary disease releases procoagulants into the bloodstream.
- Formation of fibrin in the circulation: Interaction of tissue factor and factor VII leads to thrombin formation, which promotes fibrin formation and deposition as well as platelet aggregation.
- Fibrinolysis: Fibrin formation activates fibrinolysis pathway, producing plasmin that cleaves fibrin and fibrinogen into fibrinogen degradation products (FDPs), which interfere with normal fibrin polymerization and platelet aggregation.
- Depletion of clotting factors and platelets: Ongoing activation of the coagulation system and fibrin deposition consume clotting factors and platelets, leading to bleeding.
- End-organ damage: Clots cause microvascular and macrovascular thrombosis, leading to tissue ischemia and end-organ damage.
- Hemolysis: Intravascular fibrin strands cause mechanical shearing of RBCs, resulting in microangiopathic hemolytic anemia.

### ETIOLOGY

- Precipitated by many disease states
- Neonates:
  - Sepsis
  - Conditions associated with prematurity such as respiratory distress syndrome and necrotizing enterocolitis
  - Perinatal conditions: Fetal anoxia or birth asphyxia
- Sepsis:
  - Variety of gram-negative and gram-positive bacteria
  - Also associated with viral, rickettsial, fungal, and parasitic infections

- Trauma and tissue injury:
  - Crush injury
  - Massive burns
  - Extensive surgery
  - Severe brain injury
  - Severity of coagulopathy is a predictor of adverse outcomes.
- Malignancy:
  - Rare in acute lymphocytic leukemia but reported in patients with uncommon translocation t(17;19)
  - Can present acutely with hemorrhage in patients with acute promyelocytic leukemia due to granules within blast cells that contain procoagulants
  - Chronic disorder of hypercoagulation in patients with solid tumors
- Severe immunologic reactions:
  - Severe anaphylaxis
  - Transplant rejection
  - Acute hemolytic transfusion reactions
- Kasabach-Merritt syndrome:
  - Patients with aggressive giant hemangioma (kaposiform hemangioendothelioma) in which there is prolonged contact of abnormal endothelial surface with blood in areas of vascular stasis
  - Platelets, fibrinogen consumed; fibrinolysis enhanced
  - Usually chronic and compensated but can transform into acute fulminant disease
  - Similar phenomenon occurs in:
    - 50% of patients with hereditary hemorrhagic telangiectasia
    - Some patients with large venous malformations
- Purpura fulminans:
  - Hemorrhagic skin necrosis
  - Associated with homozygous protein C deficiency (neonatal purpura fulminans) or acquired protein C deficiency (eg, meningococcemia)
- Heat stroke
- Obstetric complications:
  - Severe preeclampsia:
    - HELLP syndrome
    - Amniotic fluid embolism from placental abruption, in which there is leakage of thromboplastin-like material into maternal circulation resulting in massive hemorrhage
  - Septic abortion
  - Dead fetus syndrome, in which tissue factor from retained fetus or placenta enters maternal circulation and initiates DIC and fibrinolysis

## DIAGNOSIS

### HISTORY

- Fever
- Trauma
- Malignancy
- Current or recent pregnancy
- Chest pain in the case of pulmonary embolism (PE)
- Leg swelling in the case of deep vein thrombosis (DVT)
- Decreased urine output if renal vein thrombosis
- Spontaneous bleeding
- Recent transfusion

### PHYSICAL EXAM

- Signs of underlying disease (fever, trauma, pregnancy):
  - Excessive bleeding
  - Petechiae
  - Purpura
  - Hemorrhagic bullae
  - Wound, venipuncture site bleeding
  - Epistaxis
  - Hemoptysis
- Excessive thrombosis:
  - Thrombophlebitis
  - Calf swelling in the case of DVT
  - Chest pain, tachycardia, tachypnea, hypoxemia in the case of PE
  - Acral gangrene
  - Thrombotic endocarditis
  - Ischemic infarcts of bowel, CNS, liver, kidneys
- Organ damage or failure:
  - CNS (altered mental status, coma, focal neurologic symptoms)
  - Kidney (edema)
  - Liver (jaundice, contributes to coagulopathy)
  - Lungs (pulmonary hemorrhage/hemoptysis, respiratory distress, respiratory failure)

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

- D-dimer (normal <500 ng/mL):
  - Elevated in 90%
  - Most sensitive lab assay for DIC
- CBC with peripheral smear:
  - Thrombocytopenia (platelets <100,000/mm<sup>3</sup>); due to consumption, platelets often large
  - Platelet count can be normal due to compensation in chronic DIC.
  - Microangiopathic hemolytic anemia; due to mechanical shearing of RBCs by intravascular fibrin strands
- PT (normal 10–12 sec):
  - Prolonged in 50–75%
  - More likely to be normal in chronic DIC
- aPTT (normal 25–38 sec):
  - Prolonged in 50–60%
  - More likely to be normal in chronic DIC
- Fibrinogen level: Low due to consumption in formation of fibrin (normal 180–430 mg/dL)
- FDP (normal 0–10 μg/dL):
  - Present/Elevated in 85–100%
- Electrolytes, BUN, creatinine, glucose:
  - Elevated BUN, creatinine due to renal insufficiency
- Arterial or venous blood gas:
  - Metabolic acidosis
  - Increasing Aa gradient

#### Imaging

- CXR if respiratory distress or if pneumonia is suspected
- Head CT for altered mental status
- Other studies as needed for precipitating condition

#### Pathological Findings

- Microvascular thrombosis
- Fibrin deposition within organs
- Microangiopathic hemolytic anemia

**DIFFERENTIAL DIAGNOSIS**

- Idiopathic thrombocytopenic purpura
- Hemolytic uremic syndrome
- Alloimmune neonatal thrombocytopenia
- Clotting factor deficiencies
- Hepatic failure
- Vitamin K deficiency

**TREATMENT****PRE HOSPITAL**

- Assess and stabilize airway, breathing, and circulation.
- Circulation:
  - Apply pressure to control active bleeding.
  - Establish IV access.
  - IV fluids to support BP.

**INITIAL STABILIZATION/THERAPY**

- Assess and stabilize airway, breathing, and circulation:
  - Control bleeding.
  - Establish IV access.
- Restore and maintain circulating blood volume.
- Treatment of precipitating condition:
  - Antibiotics for sepsis
  - Debridement of devitalized tissue in trauma
  - Evacuation of uterus if retained fetus
  - Chemotherapy in malignancy
  - Cooling for heat stroke

**ALERT**

- TRANSFUSION OF BLOOD PRODUCTS IS CRITICAL.
- Primary treatment of DIC is treatment of the suspected or known underlying derangement (1,2).
- Replace depleted blood components:
  - Indicated in patients with significant bleeding symptoms or those at high risk for bleeding due to impending invasive procedure
- Goal is to reduce or stop significant bleeding, not necessarily to normalize lab values (1,2):
  - Fresh frozen plasma:
    - Provides procoagulant and anticoagulant proteins
    - For prolonged PT and active bleeding
    - 10–15 mL/kg, max 4 units
  - Platelets:
    - If platelets  $<20,000/\text{mm}^3$  or  $<50,000/\text{mm}^3$  with ongoing bleeding
    - 1–2 units/10 kg, max 6 units
  - Cryoprecipitate:
    - For severe hypofibrinogenemia ( $<50$  mg/dL) or fibrinogen  $<100$  mg/dL with active bleeding
    - 10 mL/kg, max 10 units
- Packed RBC transfusions for significant blood loss/anemia

**MEDICATION**

- Medications are secondary to transfusion of blood products in the treatment of DIC (1,2).
- Anticoagulation:
  - Heparin (administration of extrinsic anticoagulants):
    - Not indicated in most cases
    - Use if life threatening or symptomatic thrombi without active bleeding (eg, purpura fulminans, acral gangrene)
    - May be used to interrupt underlying coagulopathy
    - Potential to aggravate bleeding
    - Contraindicated in CNS injury or liver failure
    - Unfractionated heparin 5–10 U/kg/hr IV for chronic DIC
  - Protein C, antithrombin concentrates (restoration of endogenous anticoagulant proteins):
    - Controversial; minimal studies in children
    - Protein C has been effective in children with purpura fulminans due to congenital homozygous protein C deficiency.
    - Mixed results with use of activated protein C in sepsis; some evidence that adults with severe sepsis benefit from administration; study in children showed no benefit (3,4).
- Inhibition of fibrinolysis:
  - $\epsilon$ -aminocaproic acid (EACA)
  - Tranexamic acid
  - Minimal experience in children

**Additional Therapies**

Off-label use of activated factor VII has been used in patients with DIC:

- This therapy is associated with significant morbidity and mortality in other settings.
- Pending evidence of safety and efficacy in treating DIC, use is not recommended.

**DISPOSITION****Admission Criteria**

Critical care admission criteria:

- Severe precipitating illness in combination with DIC requires ICU admission.

**FOLLOW-UP****FOLLOW-UP RECOMMENDATIONS****Patient Monitoring**

Close monitoring of hemodynamic status, mental status, electrolytes, gas exchange, and hematologic and coagulation abnormalities

**PROGNOSIS**

- Depends on underlying condition
- Generally poor, associated with significant morbidity and mortality

**COMPLICATIONS**

- Thrombotic or hemorrhagic stroke
- Digit or limb amputation
- Multiorgan dysfunction
- Death

- Hemophilia
- Hypotension
- Sepsis
- Transfusion Reaction

**CODES****ICD9**

- 286.6 Defibrination syndrome
- 776.2 Disseminated intravascular coagulation in newborn

**PEARLS AND PITFALLS**

- Identification and treatment of the underlying precipitating condition is the most important part of management.
- Use clinical conditions (eg, bleeding) to guide replacement therapy rather than lab values alone.
- The most common cause of DIC is infection and subsequent septic shock. Antibiotics administration is paramount in such a setting.
- In the setting of hemorrhage, if large volumes of RBCs are transfused without concurrent replacement of clotting factors that are not contained with packed RBCs, DIC may develop.

# DIZZINESS/VERTIGO

Steven Krebs

Faye E. Doerhoff

## BASICS

### DESCRIPTION

- Vertigo (also called *true vertigo*) refers to the perception of rotation of either the environment around the patient or the patient within the environment.
- Vertigo is a rare complaint in children:
  - The most common forms are associated with migraine or otitis media (OM)
  - Benign paroxysmal positional vertigo (BPPV) is rare in children and, if present, classified as benign paroxysmal vertigo of childhood (BPVC). No consensus exists as to whether BPPV or BPVC are separate entities or along the spectrum of migraine disorders.
- Dizziness, or pseudovertigo, is a generic term and common complaint in children.
- Dizziness is distinguished from vertigo by the absence of a subjective sensation of rotation.

### EPIDEMIOLOGY

#### Prevalence

Vertigo and dizziness among school-age children has been reported to be 15% (1).

### RISK FACTORS

Recent head injury, recurrent or chronic OM, patient or family history of migraine

### PATHOPHYSIOLOGY

- Vertigo represents a disturbance in either the peripheral or central vestibular system.
- The peripheral vestibular system is comprised of the labyrinth (semicircular canals and the vestibule) and the vestibular nerve, and lie in the petrous portion of the temporal bone:
  - The semicircular canals are stimulated by, and responsible for, detection of rotational movement.
  - The vestibule contains the utricle and saccule, which detect planar motion and orientation.
  - Afferent impulses from the labyrinth travel via the vestibular portion of cranial nerve (CN) VIII to vestibular nuclei in the brainstem and cerebellum.
- The central vestibular system refers to the cortex, brainstem, and cerebellum:
  - Balance and position sensation are supported by cerebellar and vestibulospinal tract efferents going to peripheral muscles.
  - Oculovestibular reflexes are due to vestibular nuclei efferent impulses traveling to CNs III, IV, and VI.
- Lesions in any of these areas or related pathways may affect the vestibular system and result in vertigo, among other symptoms.

### ETIOLOGY

- Vertigo:
  - Peripheral: Labyrinthitis (suppurative or serous), external ear impaction, BPPV or BPVC, intoxication/ingestion, perilymphatic fistula, cholesteatoma, vestibular neuritis, temporal bone fracture, acoustic neuroma, vestibular concussion, Ménière disease, Ramsay Hunt syndrome
  - Central: Migraine, tumor, meningitis, motion sickness, encephalitis, trauma, increased intracranial pressure, seizure, stroke, MS

- Dizziness: Middle ear disease, dehydration, orthostatic hypotension, heat-related illness (heat exhaustion, heat stroke), hypoglycemia, anemia, arrhythmia, anxiety/panic disorder, hyperventilation, depression, presyncope, vasovagal episode, intoxication/ingestion

## DIAGNOSIS

### HISTORY

- The key historical element differentiating vertigo from dizziness is the subjective sense of rotation.
- Nausea and vomiting are commonly associated with vertigo.
- Timing, pattern, and severity of spells:
  - Sudden onset of persistent vertigo suggests trauma, infection, stroke, or ingestion.
  - Peripheral etiologies typically cause more severe vertigo.
  - Central causes are more commonly recurrent, chronic, and/or progressive: Migraine, BPPV or BPVC, seizures, brainstem/cerebellar mass.
  - If recurrent, identify suspected triggers:
    - Provocation by changes in head position, without tinnitus or hearing loss, suggests BPPV or BPVC.
    - Provocation by coughing or sneezing may suggest a perilymphatic fistula (causing increased perilymphatic drainage).
- Details of any headaches or head trauma:
  - Head trauma and headaches are more frequently observed in children with vertigo than healthy controls (2).
  - Prior head injury suggests possible temporal bone fracture or concussion syndrome.
  - Basilar migraine is characterized by throbbing occipital headache associated with vertigo, ataxia, dysarthria, and/or tinnitus: Up to 1 in 5 children with migraine may experience vertigo during their aura.
- Medication/Drug exposure:
  - Any current/recent medications, especially ototoxic drugs (eg, aminoglycosides)
  - Presence of prescription or over-the-counter medications in the home and how they are stored
  - Illicit drug use/ingestion, intentional or accidental
- Details of ear/hearing-related complaints:
  - Recurrent/Chronic ear infections (increased risk of cholesteatoma, perilymphatic fistula)
  - Recent surgical procedures involving ears
  - Presence/Absence of associated hearing loss (central etiologies typically spare hearing)
  - Tinnitus, sensation of ear fullness, and progressive hearing loss are typical for Ménière disease (rare in children).
- History of recurrent or transient altered mental status (basilar migraine, seizures)
- Recent/Current upper respiratory infections or other febrile illness
- Risk factors for dehydration
- Recurrent/Remitting neurologic complaints may suggest MS.

- History of perinatal infections, especially toxoplasmosis, rubella, cytomegalovirus, herpes simplex (TORCH), have been associated with labyrinthitis.
- Family history including migraine, epilepsy, hearing loss
- Thorough review of systems

### PHYSICAL EXAM

- Nystagmus should be found in almost all truly vertiginous patients but may not be present at the time of exam:
  - Check in all gaze and head positions for nystagmus.
  - Fast component of nystagmus is usually in the same direction as perceived rotation.
  - Dix-Hallpike maneuver for BPPV or BPVC:
    - Rapid transition from sitting to supine position with head turned 45 degrees to 1 side and tilted 20 degrees in extension
    - Typical latency is 5–10 sec.
    - Rotary nystagmus indicates a positive test.
    - Fast component of rotary nystagmus is toward affected ear (the one closest to the ground).
- Peripheral vestibular function is evaluated by warm or cold calorimetric response testing:
  - With patient in a 60-degree recumbent position, careful irrigation of cold (10 mL ice water or 100 mL water 7°C below body temperature) or warm (44°C) water
  - Normal response to cold water is slow eye movement toward stimulus and fast movement away.
  - Warm water causes the reverse response.
  - Lack of response indicates peripheral vestibular dysfunction on the affected side.
  - To improve tolerance of the procedure in children, consider use of warm water or warm/cooled air instead of water.
- Cerebellar exam including gait, finger-nose, rapid alternating movements, heel-shin, looking for ataxia, dysmetria:
  - Unsteady gait may result from both cerebellar and vestibular dysfunction.
  - If lesion is unilateral, the patient will fall toward the side of the lesion.
- Thorough CN assessment to identify palsies (may indicate intracranial process)
- Signs of head trauma, especially around the ear/temporal regions, and basilar skull fracture (Battle sign, raccoon eyes)
- Basic assessment of hearing including symmetry (eg, scratch test)
- All aspects of otoscopy are relevant:
  - External auditory canal inspection: Cerumen impaction, foreign body, pus (from tympanic membrane [TM] rupture), herpetic lesions (Ramsay Hunt syndrome), blood and/or clear fluid (traumatic injury)
  - TM for signs of OM, perforation, effusion, mass (suggesting cholesteatoma)
  - Pneumatic otoscopy beneficial for evaluating TM mobility (presence of OM): Hennebert sign—episode of vertigo triggered by change in middle ear pressure (perilymphatic fistula)
- Assess for meningeal irritation (nuchal rigidity, Kernig and Brudzinski signs).
- Visual acuity and field testing

**DIAGNOSTIC TESTS & INTERPRETATION**

Diagnostic testing should be guided by historical and physical findings.

**Lab**

- Other than serum glucose, routine lab testing is not typically necessary.
- Blood glucose
- CBC
- Urine drug screen
- Serum drug levels (EtOH, acetaminophen, salicylates, tricyclics)
- BUN and creatinine to assess renal function
- If meningitis/encephalitis is suspected, lumbar puncture for CSF studies:
  - Culture and Gram stain
  - Cell count, protein, glucose
  - Viral studies as indicated (enterovirus, herpes simplex virus)

**Imaging**

Brain imaging is indicated in posttraumatic, chronic, or recurrent vertigo:

- For posttraumatic vertigo, especially when associated with hearing loss or facial palsy, CT is both fast and reliable for identification of intracranial hemorrhage and should include specific temporal bone imaging.
- MRI is ideal for imaging of the posterior fossa and brainstem.

**Diagnostic Procedures/Other**

- Abnormal orthostatic BP changes (reduction of 20 or 10 mm Hg in systolic BP or diastolic BP, respectively, from supine to standing) may suggest dehydration causing dizziness.
- EEG if associated with altered or loss of consciousness
- ECG to evaluate for arrhythmia

**TREATMENT****PRE HOSPITAL**

In the setting of recent trauma, cervical spine stabilization and evaluation of ABCs

**INITIAL STABILIZATION/THERAPY**

- Assess and stabilize airway, breathing, and circulation.
- Appropriate immobilization in cases of trauma
- Crystalloid 20 mL/kg bolus if dehydrated

**MEDICATION****First Line**

- Dimenhydrinate (Dramamine) 5 mg/kg/day PO divided q6h, max single dose 75 mg/day (2–6 yr) or 150 mg/day (6–12 yr)
- Meclizine (Antivert) 25 mg PO q12h for those  $\geq 12$  yr for vertigo; 25–50 mg prior to travel for motion sickness
- Prochlorperazine PO/PR 2.5 mg per day—b.i.d. (10–14 kg), 2.5 mg b.i.d.-t.i.d. (15–18 kg), 2.5 mg t.i.d. or 5 mg b.i.d. (19–39 kg): IM/IV 0.1–0.15 mg/kg/dose, max 40 mg/day for severe nausea/migraine. Consider coadministration of diphenhydramine 1.25 mg/kg (max single dose 50 mg) to prevent a dystonic reaction.
- Meningitis: See Meningitis topic.

**Second Line**

- Diazepam: Children  $\geq 12$  yr for severe symptoms, PO 2–10 mg/dose t.i.d.–q.i.d., IM/IV 2–10 mg/dose q3–4h PRN
- Steroids (IV or PO) may be of benefit for labyrinthitis, though clear data on this is lacking. Consider in conjunction with neurology or ENT consultation for treatment options.

**DISPOSITION****Admission Criteria**

- Severe cases refractory to medical treatment
- Unable to tolerate PO therapy due to vomiting
- Significant dehydration unable to tolerate PO rehydration
- Critical care admission criteria:
  - Traumatic head injuries with neurologic findings, evidence of intracranial injury, or skull fracture
  - Meningitis/Encephalitis with signs of shock or risk of rapid deterioration

**Discharge Criteria**

- Well-appearing patients with good response to initial therapy
- Patients with symptoms clearly linked to external or middle ear disease that has resolved or is being treated

**Issues for Referral**

- Neurosurgery consultation in the emergency department: Radiologic evidence of intracranial/posterior fossa mass, basilar skull fracture, or intracranial hemorrhage
- Otorhinolaryngology consultation: Evaluation of temporal bone fracture
- Otorhinolaryngology referral: Formal auditory testing in cases with associated hearing loss, evaluation of perilymphatic fistula, cholesteatoma, chronic/complicated OM
- Neurology consultation: Suspected seizure, CNS disease or migraine refractory to outpatient therapy, vertiginous patients with other focal neurologic findings
- Neurology referral: Vertigo not requiring admission for formal vestibular function testing

**Additional Therapies**

- Epley maneuvers may be curative for BPPV in adults, though there is little experience in children.
- Motion sickness may be treated with simple behavioral changes (eg, looking outside vehicle while traveling).

**FOLLOW-UP****FOLLOW-UP RECOMMENDATIONS**

Discharge instructions and medications:

- Follow up with an appropriate specialist as noted.

**PROGNOSIS**

Good prognosis for common causes of vertigo/dizziness in children

**REFERENCES**

1. Russell G, Abu-Arafeh I. Paroxysmal vertigo in children—an epidemiological study. *Int J Pediatr Otorhinolaryngol.* 1999;49(Suppl 1):105–107.

**ADDITIONAL READING**

- Fife TD, Tusa RJ, Furman JM, et al. Assessment: Vestibular testing techniques in adults and children. Report of the Therapeutics and Technology Assessment Subcommittee of the American Academy of Neurology. *Neurology.* 2000;55(10):1431–1441.
- Teach SJ. Dizziness. In Fleisher GR, Ludwig S, eds. *Textbook of Pediatric Emergency Medicine.* 6th ed. Philadelphia, PA: Lippincott Williams & Wilkins; 2010.

**ICD9 CODES**
**ICD9**

- 386.11 Benign paroxysmal positional vertigo
- 780.4 Dizziness and giddiness

**PEARLS AND PITFALLS**

- Vertigo is often accompanied by nystagmus, nausea, and vomiting.
- Vertigo is most commonly associated with migraine or OM.
- Dizziness is most commonly caused by eustachian tube or middle ear disease.
- Complaints of unremitting vertigo or dizziness with neurologic signs may signal a CNS lesion, tumor, or degenerative process.
- Any suspected vestibular or cerebellar findings on neurologic exam should warrant evaluation for a possible posterior fossa mass.

# DROWNING

Donna M. Simmons

## BASICS

### DESCRIPTION

- Drowning is an injury caused by submersion in a liquid and resulting in respiratory insufficiency:
  - Ultimately, this can lead to significant morbidity or death (1).
- Near drowning is survival after a submersion injury.
- Secondary drowning is death due to respiratory failure following a near-drowning event.
- “Wet” drowning is associated with aspiration of fluid into the lungs.
- “Dry” drowning is asphyxia due to laryngospasm that occurs during submersion.
- The difference between wet and dry drowning is not clinically significant. Management is the same, and this terminology is no longer used.

### EPIDEMIOLOGY

#### Incidence

- There were 3,568 unintentional deaths due to drowning in the U.S. in 2006 in persons <85 yr:
  - Of these deaths, 765 (21.4%) were children ≤14 yr.
  - Drowning was the 2nd leading cause of unintentional injury–related death in this age group.
- For children ≤4 yr, drowning was the cause of death in 28.4% of the cases of fatal unintentional injuries.
- The highest incidence occurs among children age ≤4 yr and teens 15–19 yr.
- Males are more likely to die from unintentional drowning (2).
- Children 1–4 yr drown most commonly in pools, and children ≤1 yr are more likely to drown in the bathtub.
- Teen drowning commonly occurs in natural bodies of water with associated alcohol use (3).
- Drowning is most common in blacks (2).

#### Prevalence

The rate of unintentional drowning deaths in 2006 for children ≤14 yr was 1.26 cases per 100,000 population (2).

### RISK FACTORS

- Children who are inadequately supervised
- Lack of barriers around pools
- Overestimating of capability to swim or inability to swim
- Hypothermia:
  - Can cause disorientation, early muscle fatigue, or cardiac arrhythmias
- Hyperventilating prior to a shallow dive lowers PaCO<sub>2</sub>, as swimming uses oxygen and lowers PaO<sub>2</sub>. The slow increase in PaCO<sub>2</sub> delays the stimulus to breathe, resulting in hypoxia, seizure, or loss of consciousness.
- Risk-taking behavior in adolescents
- Impaired judgment due to drugs or alcohol
- Water sports
- Unexpected changes in the currents of the water, such as rip currents in the ocean
- Underlying medical conditions:
  - Cardiac arrhythmias such as congenital long QT or familial polymorphic VT
  - MI, trauma
  - Seizures, syncope
  - Diabetes mellitus and hypoglycemia
  - Depression

### GENERAL PREVENTION

- Supervise children at pools and at beaches.
- Educate parents and children.
- Use secured fencing and gating around pools.
- Use appropriate flotation devices.
- Avoid alcohol and drugs.
- Swim with a partner.

### PATHOPHYSIOLOGY

- Panic leads to a loss of the normal breathing pattern and breath-holding as one struggles to keep above water.
- Gasping with aspiration and laryngospasm:
  - Loss of protective reflexes results in fluid aspiration in 85%, while persistent laryngospasm causes asphyxia without significant aspiration of fluid in 15%.
- Hypoxemia leads to loss of consciousness, multiorgan failure, acidosis, and cardiac arrest.
- When the face is suddenly immersed in cold water, the diving reflex is thought to occur, resulting in inhibition of respiration causing apnea; vasoconstriction of blood vessels to nonessential systems; and shunting of blood to the lungs, heart, and brain:
  - Most pronounced in children relative to adults. Children have greater chance of surviving prolonged submersion in cold water.
  - Resulting risk for dysrhythmia and neurologic injury
- Theoretically, saltwater and freshwater drowning will cause changes in serum electrolytes when a large amount of water is aspirated:
  - During saltwater drowning, hypertonic saltwater draws fluid into the lungs, leading to pulmonary edema, decreased blood volume, hypertonic serum, hypoxemia, and shock.
  - Freshwater drowning causes volume overload as aspirated hypotonic water facilitates the movement of water into the intravascular space.
- Near-drowning victims usually do not aspirate a significant amount of fluid and do not have electrolyte imbalances.
- Loss of surfactant occurs with saltwater (dilutes surfactant) or freshwater (destroys surfactant):
  - The resulting atelectasis and decreased lung compliance leads to V/Q mismatching, intrapulmonary shunting, and hypoxemia.
- Inflammatory mediators are released and may cause pulmonary HTN and edema and result in the development of acute respiratory distress syndrome (ARDS).
- CNS hypoxia and neuronal injury leads to cerebral edema and elevated intracranial pressure (ICP), loss of autoregulation, and seizures.
- Autonomic instability may lead to HTN, tachycardia, diaphoresis, agitation, muscle rigidity, rhabdomyolysis, and myoglobinuria.
- Cardiac dysrhythmia can develop secondary to hypoxia or hypothermia. Acidosis can result in myocardial dysfunction:
  - Tako-tsubo cardiomyopathy has been associated with near drowning (4).
- Acute tubular necrosis from renal hypoxemia and myoglobinuria may lead to renal failure.

## DIAGNOSIS

### HISTORY

- Age and underlying medical problems
- Consider the use of drugs and alcohol.
- Suspect head and spine injuries as possible causes of near drowning.
- Characteristic of the fluid (saltwater, freshwater, sewage) determines risk of infection and aspiration of sediment.
- Duration of submersion and temperature of fluid:
  - Hypothermia is neuroprotective, and complete recovery may occur even with prolonged resuscitation.
- Timing of rescue and resuscitation efforts
- Response to resuscitation
- Associated injuries

### PHYSICAL EXAM

- Perform complete physical exam.
- Assess for hypothermia and hypotension.
- Arrhythmias may occur:
  - Sinus bradycardia and atrial fibrillation are most common.
  - Ventricular fibrillation and asystole may also occur.
- Pulmonary insufficiency or respiratory distress will manifest as shortness of breath or tachypnea, coughing, nasal flaring, grunting, wheezing, stridor, and/or retractions.
- Auscultation may reveal rales and wheezing with bronchospasm.
- Neurologic signs include altered mental status, confusion, lethargy, unconsciousness, and seizures.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

- CBC, electrolytes, glucose, and renal function tests
- Other tests should be performed to assess end-organ injury and metabolic status including liver profile, coagulation studies, and lactate level.
- Blood gas in symptomatic patients

##### Imaging

- CXR for symptomatic patients:
  - May initially be normal or show pulmonary edema or atelectasis
- Consider CT scans for patients with altered mental status or head and neck injuries.

##### Diagnostic Procedures/Other

- Continuous pulse oximetry
- ECG to look for dysrhythmia

### DIFFERENTIAL DIAGNOSIS

Consider other medical conditions, which may be the initial inciting factor:

- CNS injuries, cardiac arrhythmias, MI, complications of diabetes, syncope, closed head injury, spinal cord injury, or seizures

## TREATMENT

### PRE HOSPITAL

- Assess and stabilize airway, breathing, and circulation:
  - Provide supplemental oxygen and support breathing.
  - Provide cervical spine immobilization when cervical spine injury is suspected.
- Assess pulse before beginning CPR, as sinus bradycardia and atrial fibrillation do not require treatment initially in hypothermic patients.
- Prevent cooling:
  - Remove wet clothing and cover with blankets.
  - Minimize movement in patients with severe hypothermia with temperature  $<30^{\circ}\text{C}$  due to risk of development of ventricular fibrillation.
  - Begin rewarming hypothermic patients with temperature  $<33^{\circ}\text{C}$  according to hypothermia protocols.
  - With profound hypothermia, CPR should be performed if ventricular fibrillation develops.

### INITIAL STABILIZATION/THERAPY

- Perform ABCDEs as per Advanced Trauma Life Support (ATLS) and Pediatric Advanced Life Support (PALS) guidelines:
  - Support respirations and intubate if there are signs of respiratory failure ( $\text{PaO}_2 <60$  with high oxygen supplementation) or neurologic deterioration. Use of BiPAP/CPAP may correct hypoxemia in awake patients:
    - Bronchodilators for bronchospasm
    - Avoid excessive hyperventilation, maintain  $\text{PaCO}_2$  at 30–35 mm Hg, and elevate the head to lower ICP.
  - Remove wet clothing and rewarm to  $32^{\circ}\text{C}$  if hypothermic, as continued hypothermia has not been shown to improve outcome.
  - Hypotension is treated with fluid replacement and inotropic support.
- Manage head, spinal, chest, and abdominal injuries appropriately.
- Seizures should be treated to prevent increased metabolic demand.
- Prophylactic antibiotics are not indicated unless there is aspiration of grossly contaminated water.
- Maintain normoglycemia, and correct electrolyte abnormalities.

### DISPOSITION

#### Admission Criteria

- Admit patients with respiratory compromise, abnormal CXR, concerning blood gas, or abnormal vital signs, such as pulse oximetry.
- Admit patients requiring treatment of concomitant injuries, especially those with underlying medical problems that may complicate their course.
- Critical care admission criteria:
  - Patients requiring intubation and those with severe neurologic dysfunction or multiorgan system failure require ICU care.

### Discharge Criteria

- Patients remaining asymptomatic after 8 hr of observation may be discharged.
- Mildly symptomatic patients who have normal pulse oximetry, CXR, and arterial blood gas and who improve after a prolonged observation may be discharged.

### Issues for Referral

#### Rehabilitation

### Additional Therapies

- Extracorporeal membrane oxygenation for persistent respiratory failure despite intubation/ventilation and with rewarming
- Bronchoscopy and bronchoalveolar washings

## FOLLOW-UP

### FOLLOW-UP RECOMMENDATIONS

Return for development of respiratory symptoms, fever, or other signs of ill appearance.

### Patient Monitoring

Follow pulmonary function with blood gas, cardiac monitoring for dysrhythmias and myocardial dysfunction, electrolyte abnormalities, renal function, and neurologic status.

### PROGNOSIS

- Varies with length of submersion, time to resuscitation, and severity of concomitant medical conditions
- Neurologic recovery is possible after prolonged submersion, especially cold water submersion.
- Poor outcomes are associated with:
  - Submersion  $>5$  min (5)
  - Time to resuscitation  $>10$  min (5)
  - Coma on arrival to emergency department (5)
  - Age  $<3$  yr or pH  $<7.1$  (5)
  - Arrest on arrival to emergency department (6)
  - Fixed/Dilated pupils or posturing (6)
  - Warm water submersion (6)

### COMPLICATIONS

- Respiratory failure
- ARDS
- Electrolyte abnormality
- End-organ injury:
  - Permanent neurologic injury
  - Hepatic injury
  - Renal injury
- MI
- Death

## CODES

### ICD9

994.1 Drowning and nonfatal submersion

## PEARLS AND PITFALLS

- Pearls:
  - Survival and neurologic recovery are possible after prolonged submersion in cold water, and exhaustive attempts at resuscitation are warranted in such cases.
  - Manage hypothermia.
- Pitfalls:
  - Need to properly manage hypothermia
  - Not recognizing concomitant injuries head, spinal, chest, and abdomen or treating underlying conditions

# DUCTAL-DEPENDENT CARDIAC EMERGENCIES

Kumarie Etwaru  
Kristy Bunagan  
Robert J. Hoffman

## BASICS

### DESCRIPTION

- The ductus arteriosus is a vascular connection between the main pulmonary artery and aorta.
- It shunts fetal blood away from the lungs and closes within the 1st few days after birth. Infants with ductal-dependent critical congenital heart diseases will present in extremis when the duct begins closing.
- Ductal-dependent lesions are congenital heart diseases that need the ductus arteriosus to remain open after birth in order to supply blood to the lungs and systemic circulation or for mixing of systemic and pulmonary blood.

### EPIDEMIOLOGY

Prevalence per 10,000 births based on the Metropolitan Atlanta Congenital Defect Program:

- Pulmonary atresia 0.8, pulmonary stenosis 6.3, tricuspid atresia 0.5, truncus arteriosus 1.0, Ebstein anomaly 0.6, tetralogy of Fallot (TOF) 6.1, coarctation of the aorta 4.7, aortic stenosis 1.6, hypoplastic left heart 3.3, transposition of great arteries 4.0

### RISK FACTORS

Some factors are associated with an increased incidence of ductal-dependent lesions:

- Genetic or chromosomal abnormalities
- Maternal diabetes or phenylketonuria
- Use of medications such as lithium or phenytoin during pregnancy

### PATHOPHYSIOLOGY

- In the fetus, the right ventricle handles 60% of the total cardiac output.
- The pulmonary circulation has a high vascular resistance while the systemic vascular resistance is low, which facilitates blood flow from the right ventricle to the descending aorta through the ductus arteriosus.
- After birth, with the onset of breathing, the lungs expand and systemic oxygen saturation rises. This causes pulmonary vasodilation and a decrease in pulmonary vascular resistance. Simultaneously, when the placenta is removed, systemic vascular resistance rises, leading to reversal of blood flow in the ductus arteriosus from left to right.
- The ductus arteriosus remains open when there is prostaglandin E2 and low arterial oxygen.
- Any anatomic abnormality in the fetal heart affects normal cardiovascular circulation.
- In lung-dependent coronary heart diseases (CHDs), deoxygenated blood cannot pass through to the lungs to be oxygenated due to lack of opening in the right side of the heart.
- In systemic circulation-dependent CHDs, oxygenated blood cannot reach vital organs due to constriction of the left side of the heart.
- The patent ductus is the only means for oxygenated blood to reach the systemic circulation.

### ETIOLOGY

3 types of ductal-dependent lesions:

- Lung-dependent CHDs are pulmonary atresia, pulmonary stenosis, tricuspid atresia, truncus arteriosus, Ebstein anomaly, and TOF.
- Systemic circulation-dependent CHDs are coarctation of the aorta, severe aortic stenosis, and hypoplastic left heart syndrome.
- Transposition of the great arteries (TGA) depends on the patent duct for mixing of systemic and pulmonary blood flow.

### COMMONLY ASSOCIATED CONDITIONS

- Ebstein anomaly is associated with Wolff-Parkinson-White syndrome.
- Truncus arteriosus and TOF are associated with DiGeorge syndrome (22q11 microdeletion).
- Coarctation of the aorta is associated with Turner syndrome.
- Pulmonary stenosis is associated with Noonan syndrome.

## DIAGNOSIS

### HISTORY

- The presence of other heart defects, the timing of closure of the ductus arteriosus, and the degree of pulmonary vascular resistance determine the onset and severity of symptoms.
- In the 1st days to weeks of life, the presence of critical CHD is herald by increasing cyanosis in a patient who may not be in respiratory distress.
- Depending on the lesion, those affected may develop symptoms of heart failure such as poor feeding, sweating while feeding, and/or tachypnea.
- Other patients may present with acute signs and symptoms of shock with ductal closure.

### PHYSICAL EXAM

- Assess vital signs, with focus on cardiopulmonary and pulse oximetry parameters.
- Severe cyanosis occurs early in infants with TGA, Ebstein anomaly, and pulmonary atresia once the ductus arteriosus closes.
- Aortic coarctation: Arterial HTN in the right arm with lower to normal BP in the lower extremities is the classic finding. If the coarctation is located before the subclavian artery, a pressure difference between the right and left arm exists.
- Auscultatory clues are helpful to early diagnosis:
  - Single S2 for truncus arteriosus, tricuspid atresia, TGA, and hypoplastic left heart
  - Aortic ejection click for truncus arteriosus
  - Single and loud S2 and hyperactive precordium on palpation for critical coarctation of the aorta, severe aortic valve stenosis, and hypoplastic left heart syndrome
  - If ventricular septal defect, a loud holosystolic murmur at the left lower sternal border may be present.
  - Systolic ejection murmurs at the upper sternal border for coarctation of the aorta and aortic stenosis are present.

- Hypercyanotic spells are usually the presenting symptom in an infant with TOF. During a spell, intense cyanosis and hyperpnea present rapidly while the murmur decreases in intensity.
- Signs of heart failure soon develop when the pulmonary vascular resistance begins to fall: Tachypnea, tachycardia, sweating, gallop rhythm, and hepatomegaly.
- With systemic circulation-dependent CHDs, the presentation may be similar to sepsis. These patients experience tachypnea, mottled gray skin, and poor perfusion with decreased peripheral and central pulses.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

- Assess bedside glucose for hypoglycemia.
- Blood gas analysis with lactate measurement to assess oxygenation, ventilation, and perfusion
- CBC with differential count, C-reactive protein:
  - Anemia, heart failure, sepsis, or shock may be clinically similar presentations.
- Comprehensive chemistry (CHEM 20):
  - Various abnormalities may be present.
  - Low bicarbonate, elevation of BUN/creatinine, and elevations of AST/ALT may occur due to hypovolemia or poor perfusion.
- Consider blood culture, urinalysis, urine culture, and CSF analysis/culture if considering sepsis as causal of symptoms.

#### Imaging

- CXR:
  - Radiographic findings include cardiomegaly with increase vascular marking:
    - In a cyanotic neonate, this should prompt consideration of ductal-dependent lesions.
  - Pulmonary atresia: Boot-shaped heart with absent main pulmonary shadow
  - Pulmonary stenosis: Prominent main pulmonary artery
  - TOF: Boot-shaped heart, with right-sided aortic arch in 26–50% of cases
  - Truncus arteriosus: Right-sided aortic arch and prominent vascular markings
  - TGA may demonstrate the “egg on a string” appearance in 1/3 of patients.
- Transthoracic echo with cross-sectional and Doppler flow analysis is the diagnostic modality of choice.

#### Diagnostic Procedures/Other

- ECG:
  - Lung-dependent CHDs have right atrial enlargement or right ventricular hypertrophy (RVH).
  - With coarctation of the aorta and severe aortic stenosis, left ventricular hypertrophy is observed.
  - With TGA, right axis deviation and RVH are also evident plus an upright T wave in V1, which may be the only abnormality present.

- Hyperoxia test:
  - Used to differentiate between cardiac and pulmonary cause of hypoxia/cyanosis
  - A cardiac cause (right to left shunt) is suspected when the PaO<sub>2</sub> is <100 mm Hg after 100% oxygen is administered for 10–15 min.
  - Pulse oximetry reading may be used in lieu of repeated blood gas measurements.

**DIFFERENTIAL DIAGNOSIS**

- Cyanotic heart disease not involving ductal dependence
- CHF
- Pneumonia
- Infections: Sepsis, meningitis
- Persistent pulmonary HTN
- Methemoglobinemia

**TREATMENT**

**PRE HOSPITAL**

Assess and stabilize airway, breathing, and circulation.

**INITIAL STABILIZATION/THERAPY**

- Assess and stabilize airway, breathing, and circulation.
- Administer supplemental oxygen.
- If there is strong suspicion of a ductal-dependent lesion, titrate oxygen to maintain saturation to 85% and start prostaglandin infusion.
- Infants with respiratory failure should be intubated and have an orogastric tube inserted.
- If perfusion is poor and shock is evident, administer 10–20 mL/kg of normal saline IV bolus rapidly.
- Antibiotic prophylaxis should be initiated in patients who presents in shock.
- Cardiology consultation

**MEDICATION**

Prostaglandin E1 infusion (alprostadil):

- Rapid administration is needed to keep the ductus arteriosus open; this is lifesaving.
- Start with 0.05–0.1 µg/kg/min and titrate up as needed (to 0.2 µg/kg/min if needed).
- Continuous vital sign monitoring is needed.
- Side effects include hypotension, apnea, fever and flushing.
- Be prepared to support ventilation, perform endotracheal intubation, and administer fluids and inotropic support:
  - Some prefer to perform endotracheal intubation electively under controlled conditions prior to prostaglandin infusion.

**SURGERY/OTHER PROCEDURES**

- Cardiac catheterization:
  - Routine catheterization is not necessary. 2D-echo can detect anatomic abnormalities and assess blood flow patterns. Catheterization only is essential when discrepancies are seen or is necessary for surgical management.
- Surgical repair procedure depends on the specific heart lesion.
- Atrial septostomy:
  - Sometimes performed urgently or emergently
  - For TGA and tricuspid atresia; creates atrial septal defect to allow blood mixing (oxygenated and deoxygenated) between atria.

- Palliative systemic to pulmonary artery shunts (eg, Blalock-Taussig shunt): For TOF, hypoplastic left heart, tricuspid atresia, pulmonary stenosis:
  - Increases pulmonary blood flow by shunting blood from the systemic circulation
- Fontan procedure: For heart lesions with a single ventricle like tricuspid atresia and hypoplastic left heart:
  - A connection between the superior vena cava with the right pulmonary artery plus a connection between right atria and inferior vena cava to pulmonary arteries are created.
  - Separates the systemic and pulmonary circuits
- Norwood procedure: For hypoplastic left heart syndrome. There are 2 stages:
  - 1st stage creates a connection between main pulmonary artery–aorta, and Blalock-Taussig shunt provides pulmonary blood flow.
  - The 2nd stage is a bidirectional Glenn shunt to decrease blood flow to the right ventricle and a modified Fontan procedure.
- Ross procedure: For aortic or pulmonary stenosis; replacement of the aortic valve with the autologous pulmonary valve or vice versa

**DISPOSITION**

**Admission Criteria**

- Select stable patients may be considered for floor admission.
- Condition requiring surgery within 48 hr
- Critical care admission criteria:
  - Newly diagnosed patients generally should be admitted to an ICU, even if stable, for rapid detection and management of deterioration.
  - Unstable vital signs
  - Prostaglandin needed in the emergency department or required in hospital

**Discharge Criteria**

Unless previously diagnosed and under cardiology care, these patients are not discharged from the emergency department:

- Selective discharge from the emergency department rarely is possible under cardiology recommendations.

**Issues for Referral**

Follow up with cardiology, cardiothoracic surgery, and primary care physicians.

**FOLLOW-UP**

**FOLLOW-UP RECOMMENDATIONS**

Discharge instructions and medications:

- These patients are admitted to the hospital.

**Patient Monitoring**

Caregivers must closely monitor for any deterioration and have ability to immediately return to the emergency department if needed.

**PROGNOSIS**

- Depends on the specific congenital heart lesion and type of intervention
- Morbidity, mortality, and long-term survival have increased, with patients reaching adulthood.

**COMPLICATIONS**

- CHF
- Failure to thrive
- Shock
- Multiorgan system failure
- Death

**CODES**

**ICD9**

- 746.1 Tricuspid atresia and stenosis, congenital
- 746.02 Stenosis of pulmonary valve, congenital
- 747.3 Congenital anomalies of pulmonary artery

**PEARLS AND PITFALLS**

- Mild hypoxia or cyanosis may be the presenting symptom of an infant with serious congenital heart disease.
- Poor feeding or tiring/sweating while feeding may be a symptom of heart failure due to congenital heart disease.
- Prostaglandin E1 infusion is lifesaving for neonates with ductal-dependent lesions.

# DYSRHYTHMIA, ATRIAL

Ameer P. Mody  
Tommy Y. Kim

## BASICS

### DESCRIPTION

- Atrial dysrhythmia is defined as a cardiac rhythm disturbance generated from above the atrioventricular (AV) node.
- Frequently results in tachycardia
- Premature atrial contractions (PACs)/atrial extrasystoles are an early occurrence of P waves followed by a normal or widened QRS.
- Supraventricular tachycardia (SVT), or paroxysmal SVT, is the most common pathologic dysrhythmia in children. Can be atrioventricular reentrant tachycardia (AVRT) (~75%), including Wolff-Parkinson-White (WPW) syndrome, atrioventricular nodal reentrant tachycardia (AVNRT) (~13%), or primary atrial tachycardia (~14%) (1).
- Atrial flutter is a rapid, uniform atrial dysrhythmia with an atrial rate between 240 and 450 bpm.
- Atrial fibrillation is a chaotic, multifocal atrial depolarization with a variable resultant ventricular tachycardia.

### EPIDEMIOLOGY

#### Incidence

- SVT is the most common cardiac dysrhythmia in children (2–4):
  - 89,000 new cases reported per year
  - 2 cases per 1,000 people
- Atrial flutter and fibrillation are uncommon in children without a history of cardiac surgery.
- 5% of patients who have undergone a Fontan operation will have a cardiac dysrhythmia, most commonly atrial flutter.

### RISK FACTORS

- Congenital heart disorders
- Stimulant medications (eg, beta-agonists, caffeine, anticholinergics, cocaine)
- Myocarditis and cardiomyopathies
- Hyperthyroidism
- Pericarditis
- Electrolyte disturbances
- Metabolic acidosis
- Surgically corrected structural heart disease
- Neuromuscular disease

### PATHOPHYSIOLOGY

- The normal electrical impulse of the heart is initiated at the sinoatrial node near the right atrium, to the AV node, to the bundle of His, which divides to the right and left bundle branches to the Purkinje fibers of the ventricular myocardium.
- Atrial dysrhythmias are caused by alternative nodes of conduction in the atria or disordered conduction within the atria.
- AVRT requires an accessory pathway connecting the atrium and ventricle:
  - In orthodromic AVRT, impulses are conducted antegrade down the AV node to the ventricle, then retrograde up the accessory pathway and back down the AV node:
    - This circuit results in a narrow complex tachycardia.
  - In antidromic AVRT, impulses are conducted antegrade down the accessory pathway, then retrograde up the AV node and back down the accessory pathway:
    - This circuit results in a wide complex tachycardia.
  - During sinus rhythm, if the electrical impulse is conducted antegrade down the accessory pathway, then the impulse arrives at the ventricle rapidly, without delay at the AV node, which causes pre-excitation:
    - The finding on ECG during sinus rhythm consists of a short PR interval, a widened QRS with a “delta wave.”
    - This phenomenon is referred to as a WPW pattern.
- AVNRT has 2 conducting pathways within the AV node that are designed fast and slow:
  - These pathways allow for a reentrant loop utilizing the 1st pathway antegrade and 2nd pathway retrograde:
    - This circuit results in a narrow complex tachycardia.

### ETIOLOGY

- Idiopathic
- Accessory pathways
- WPW syndrome
- Myocarditis and cardiomyopathies
- Sick sinus syndrome

## DIAGNOSIS

### HISTORY

- Infants can be asymptomatic or present with irritability and/or poor feeding.
- Older children may present with the sensation of a racing heart, chest pain, palpitations, light-headedness, fatigue, or syncope.
- Inquire about a history of previous episodes, cardiac disease, cardiac surgery, medication use, and family history.

### PHYSICAL EXAM

- The initial goal of examination is to determine the child’s hemodynamic stability:
  - Assess for tachycardia and hypotension.
- Signs consistent with hemodynamic compromise include respiratory distress, pallor, cyanosis, cool extremities, prolonged capillary refill, weakened peripheral pulses, and altered mental status.
- Other findings consistent with cardiac dysfunction include hepatomegaly, edema, and extra heartbeats.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

- Assessment of hemodynamic status takes priority above any diagnostic evaluation.
- Blood gas analysis with electrolyte values (if available) may reveal underlying acidosis or metabolic disturbance.
- Metabolic panel inclusive of calcium and magnesium (as hypocalcemia or hypomagnesemia can be arrhythmogenic)
- Thyroid function tests

### Imaging

- Consider a chest radiograph to evaluate for potential causes or consequences of dysrhythmia.
  - Cardiomegaly: Myocarditis or cardiomyopathy
- Once stable, patients with new-onset atrial dysrhythmia should have an echo to assess cardiac anatomy and function.

### Diagnostic Procedures/Other

ECG characteristics in different forms of atrial tachyarrhythmias will often provide the diagnosis:

- PAC: Isolated early P wave followed by a normal QRS, a block at the AV node, or a block in the bundle branch showing a RSR’ pattern
- SVT (AVNRT): Heart rate > 180 bpm, often > 220 bpm in infants with no beat-to-beat variability, P wave within or after the QRS complex, narrow QRS complex
- SVT (AVRT): Heart rate > 180 bpm, often > 220 bpm in infants with no beat-to-beat variability, no visible P wave:
  - Narrow QRS complex in orthodromic
  - Wide QRS complex in antidromic SVT has an ECG appearance similar to ventricular tachycardia.
- Atrial flutter: Saw-tooth flutter waves that are best viewed in leads II, III, and V1, typical atrial rates of 300 bpm, accompanied typically by AV conduction of 2:1 to 4:1
- Atrial fibrillation: Atrial rates of 300–600 bpm with variable ventricular response to atrial impulses resulting in irregularly irregular heart rates. Irregular P waves are best viewed on lead V1.
- With significant tachycardia, slow down the ECG paper speed to evaluate for the presence of P waves.

### DIFFERENTIAL DIAGNOSIS

- Sinus tachycardia secondary to fever, anemia, sepsis, hypovolemia, thyrotoxicosis, medications, illicit drug use, or shock
- Ventricular tachycardia
- Junctional ectopic tachycardia

## TREATMENT

### PRE HOSPITAL

Assess and stabilize airway, breathing, and circulation.

### INITIAL STABILIZATION/THERAPY

- Cardiac monitoring with rhythm strip analysis should be initiated immediately.
- Most children tolerate atrial dysrhythmias without significant hemodynamic compromise.
- The 1st priority is to differentiate sinus tachycardia from an atrial dysrhythmia.
- Vagal maneuvers may be attempted for awake patients in SVT (2,3,5):
  - Hold a bag of ice water slurry to the face of an infant for 25–30 sec to elicit a diving reflex; successful in 30–60% of cases (6):
    - Immersion of the head in cold water is dangerous and not recommended.
  - Valsalva maneuver for children and adolescents:
    - Bearing down, blowing into a straw
    - Avoid carotid massage and ocular pressure.

- If hemodynamic compromise is present for SVT, atrial flutter, or atrial fibrillation, proceed to synchronized cardioversion (4):
  - Synchronized cardioversion 0.5–1 J/kg
  - 2 J/kg for subsequent attempts
  - Intubation/Airway protection may be required.
  - Sedation/Analgesia should be provided to awake patients:
    - Decision to initiate anticoagulation prior to cardioversion or after cardioversion of atrial fibrillation is best made in conjunction with a pediatric cardiologist.

## MEDICATION

### First Line

For stable SVT, adenosine is preferred (2,4,7,8):

- Adenosine 0.1 mg/kg (up to 6 mg) IV rapid push over 1–2 sec followed by a rapid 5 cc saline flush
- Repeat dose 0.2 mg/kg (up to 12 mg) if no response to the 1st dose after 1–2 min; may repeat a 3rd dose
- Use an antecubital vein or central line.
- Transient asystole may occur.
- Contraindications to adenosine use include a deinnervated heart (eg, heart transplant), 2nd- or 3rd-degree heart block.

### Second Line

- In a hemodynamically stable patient with SVT who is unresponsive to adenosine or where adenosine is contraindicated:
  - Amiodarone 5 mg/kg IV (max 300 mg/dose) over 20–60 min, followed by a continuous infusion of 10 mg/kg/day (3) OR
  - Procainamide 15 mg/kg IV (max 100 mg/dose) over 30–60 min; in children <1 yr of age, 10 mg/kg. Follow with a continuous infusion of 50 µg/kg/min (3).
  - May consider a beta-blocker such as propranolol or esmolol in consultation with a cardiologist
  - Verapamil is contraindicated in infants and children <1 yr of age due to risk of shock and cardiac arrest (9).
- If pharmacologic treatment fails, radiofrequency catheter ablation may be necessary.

## SURGERY/OTHER PROCEDURES

For AVNRT or WPW, the accessory pathway can be ablated by radiofrequency catheter.

## DISPOSITION

### Admission Criteria

Critical care admission criteria:

- Most patients with an atrial dysrhythmia should be admitted to a monitored pediatric unit, preferably a pediatric ICU, for observation and cardiology consultation.

## Discharge Criteria

- Simple, isolated PACs in asymptomatic patients with no risk factors require no additional intervention.
- Patients with a known history of SVT, without hemodynamic compromise, and structurally normal hearts may be discharged home safely after adequate response to medical or vagal cardioversion and a period of observation:
  - Discharge in consultation with a cardiologist.

## FOLLOW-UP

### FOLLOW-UP RECOMMENDATIONS

Follow up with a pediatric cardiologist.

### PROGNOSIS

- 38% of children <4 mo of age and 19% of children >4 mo of age initially present in heart failure (10).
- Sudden death from SVT is uncommon in patients with a normal structural heart.
- Increased risk of sudden death in patients with WPW, 2.3% with a catastrophic event at presentation (11)
- The prognosis of atrial fibrillation and atrial flutter depends on the underlying cardiac defect.

### COMPLICATIONS

- Atrial flutter and fibrillation can lead to atrial thrombus formation and subsequent risk of embolic phenomena.
- Untreated SVT can lead to heart failure.
- Adenosine can rarely precipitate a prolonged asystole, ventricular tachycardia, atrial fibrillation, and/or apnea.

## CODES

### ICD9

- 427.9 Cardiac dysrhythmia, unspecified
- 427.61 Supraventricular premature beats
- 427.89 Other specified cardiac dysrhythmias

## PEARLS AND PITFALLS

- Pediatric patients can tolerate tachycardia for many hours to days but should be treated promptly due to the risk of decompensation.
- A 20 mL/kg bolus of normal saline may help differentiate sinus tachycardia from SVT.
- Preparation for emergent cardioversion should be made prior to administration of adenosine:
  - Use the largest pads or paddles that can fit on the chest wall without the pads touching to minimize transthoracic impedance.
- Adenosine failure may be related to inadequate IV access, insufficient rapidity of administration, or use of caffeine or theophylline.
- Consultation with a pediatric cardiologist is advised for all cases of atrial dysrhythmia.

# DYSRHYTHMIA, VENTRICULAR

Tommy Y. Kim

## BASICS

### DESCRIPTION

Ventricular dysrhythmia is defined as a wide complex (prolonged QRS duration) tachycardia beyond the upper limit of normal for the patient's age.

- Premature ventricular contractions (PVCs) are frequent in children.
- Ventricular tachycardia (VT) consists of  $\geq 3$  consecutive PVCs.
- Ventricular fibrillation (VF) is a form of pulseless arrest. The heart has no organized rhythm, but instead the myocardium quivers and does not pump blood.
- Pulseless VT is treated the same as VF.
- Torsades de pointes is a distinctive form of polymorphic VT, which can be seen in conditions such as long QT syndrome, hypomagnesemia, antiarrhythmic drug toxicity, or other drug toxicities.

### EPIDEMIOLOGY

- VF/VT occurs in up to 19% of out-of-hospital cardiac arrest and up to 27% of in-hospital cardiac arrest (1,2).
- The incidence increases with age, and up to 50% of patients have an underlying cardiac etiology (3–6).

### RISK FACTORS

- Congenital heart disorders
- Myocarditis
- Cardiomyopathies
- Surgically corrected heart disorders
- Long QT syndrome
- Family history of sudden death

### PATHOPHYSIOLOGY

- The normal electrical impulse of the heart is initiated at the sinoatrial node near the right atrium, to the atrioventricular node, to the bundle of His, which divides to the right and left bundle branches to the Purkinje fibers of the ventricular myocardium.
- Ventricular dysrhythmias are caused by disturbances in impulse formation or conduction.

### ETIOLOGY

- Severe electrolyte disturbances (eg, hyperkalemia, hypokalemia, hypocalcemia, hypomagnesemia)
- Metabolic abnormalities (hypoglycemia, metabolic acidosis)
- Congenital heart disorders
- Drug toxicity (eg, tricyclic antidepressants [TCAs], cocaine, antiarrhythmic drugs, macrolide antibiotics, antihistamines)
- Myocarditis and cardiomyopathies
- Cardiac tamponade
- Tension pneumothorax
- Inherited disorders of cardiac conduction (long QT syndrome)
- Electrical burns
- Hypothermia

## DIAGNOSIS

### HISTORY

- Obtain a history for heart disease, metabolic disease, medication use, drug exposure, family history of sudden cardiac death, or electrical burns.
- Most children present with vague, nonspecific symptoms.
- Infants can present with fussiness and difficulty feeding but may not show signs until significantly impaired cardiac output develops.
- Older children can present with chest pain, palpitations, light-headedness, dizziness, fatigue or syncope.

### PHYSICAL EXAM

- The initial goal of the physical exam is to determine the child's hemodynamic stability.
- Signs consistent with hemodynamic compromise include respiratory distress, cool extremities, prolonged capillary refill, weak peripheral pulses, and altered mental status.
- Other findings consistent with cardiac dysfunction include hepatomegaly, peripheral edema, and/or a cardiac gallop.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

- Assessment of hemodynamic status takes priority above any diagnostic evaluation.
- The basic metabolic panel may reveal metabolic causes of dysrhythmia such as hypokalemia or hyperkalemia.
- Calcium and magnesium levels may reveal hypocalcemia or hypomagnesemia, which has been associated with ventricular dysrhythmias.
- Blood gas analysis may reveal potential reversible causes of ventricular dysrhythmias such as severe metabolic acidosis.

#### Imaging

- Obtain a chest radiograph to evaluate for potential causes of dysrhythmias:
  - Cardiomegaly: Myocarditis or cardiomyopathy
  - Free air: Pneumothorax
- Once stable, all patients with significant ventricular dysrhythmias should have an echo to evaluate cardiac anatomy and function. This may be done in the emergency department or during the admission.

#### Diagnostic Procedures/Other

Obtaining an appropriate 12- or 15-lead ECG is critical for diagnosis. The ECG shows a rapid, wide QRS complex:

- QRS complexes are often  $>0.14$  sec.
- QRS complexes can be monomorphic or polymorphic.

### DIFFERENTIAL DIAGNOSIS

Sinus tachycardia, supraventricular tachycardia, junctional ectopic tachycardia, pre-existing bundle branch block, supraventricular tachycardia with aberrancy, antidromic supraventricular tachycardia

## TREATMENT

### ALERT

VF is an unstable rhythm that should be treated immediately with unsynchronized defibrillation. If this rhythm is not converted, progression to asystole and inability to resuscitate is likely.

### PRE HOSPITAL

- Maintain airway, breathing, and circulation.
- CPR for nonperfusing rhythms
- Apply an automated external defibrillator (AED) for children  $>1$  yr, if indicated (7).

### INITIAL STABILIZATION/THERAPY

- The hemodynamic status drives the decision-making process for a child with ventricular dysrhythmias. Children may be hemodynamically stable during the initial assessment, but VT can quickly decompensate to hemodynamic compromise:
  - Stable VT with pulse: Consider antiarrhythmic drugs.
  - Unstable VT with pulse: Requires synchronized cardioversion 0.5–1 J/kg and 2 J/kg for subsequent attempts (8,9)
  - In adolescents and adults, synchronized cardioversion should be performed with 100 J initially and 200 J for subsequent shocks.
- Pulseless VT/VF is a nonperfusing rhythm; CPR should be initiated immediately and followed by defibrillation 2 J/kg and 4 J/kg for subsequent shocks (8,9):
  - In adolescents and adults, defibrillation should be performed with 200 J initially and 360 J for subsequent shocks.
- Numerous toxins, such as beta-blockers, calcium channel blockers, cocaine, digoxin, TCAs, and others, may require treatment by Toxicologic-Oriented Advanced Cardiac Life Support (TOX-ACLS) protocols that differ from standard Pediatric Advanced Life Support (PALS) or ACLS protocols (10).

### MEDICATION

#### First Line

- If defibrillation is unsuccessful, administer epinephrine 0.01 mg/kg, 1:10,000 solution, and continue CPR.
- If stable VT with a pulse, then consider antiarrhythmic drugs:
  - Amiodarone 5 mg/kg IV (max 300 mg/dose) over 20–60 min (8) OR
  - Procainamide 15 mg/kg IV (max 100 mg/dose) over 30–60 min (8)
- If pulseless VT or VF is refractory to defibrillation and epinephrine, then consider antiarrhythmic drugs:
  - Amiodarone 5 mg/kg rapid IV bolus (max 300 mg/dose) (9) OR
  - Procainamide 15 mg/kg rapid IV bolus (max 100 mg/dose, not to exceed 50 mg/min) (9)
  - Because amiodarone and procainamide prolong the QT interval, they should not be given together.

- In the presence of polymorphic VT secondary to prolonged QT syndrome, use of amiodarone is contraindicated, as it may exacerbate the arrhythmia (11).
- Polymorphic VT secondary to long QT syndrome: Administer magnesium sulfate 20–50 mg/kg IV (max 1–2 g/dose), but doses of 2.3–12 mg/kg have been found to be effective (12,13).
- VT secondary to TCA toxicity: Administer sodium bicarbonate 1–2 meq/kg IV bolus (14):
  - Give to max of 50 meq/dose while monitoring for narrowing of QRS complexes, followed by a continuous drip.

### Second Line

Lidocaine 1 mg/kg IV (max 100 mg/dose) if first-line medications are not immediately available or if amiodarone or procainamide are contraindicated

### DISPOSITION

#### Admission Criteria

All patients with a ventricular dysrhythmia should be admitted to a monitored pediatric unit, preferably a pediatric ICU, for observation and cardiology consultation.

#### Discharge Criteria

- In asymptomatic patients who present with isolated PVCs with no risk factors, no treatment is necessary.
- Any symptomatic patient or asymptomatic patients who have couplets, multiform PVCs, or frequent PVCs, consultation with a cardiologist is warranted prior to discharge.

### FOLLOW-UP

#### FOLLOW-UP RECOMMENDATIONS

All patients with a verified ventricular dysrhythmia will need follow-up with a cardiologist.

#### PROGNOSIS

- Better outcome exists with patients who experience VT/VF as the initial rhythm (35% survival) compared to those who develop VT/VF during the course of resuscitation (11%) (5).
- Survival to discharge is better for those with an initial rhythm of VF/VT (20–30%) compared to those with asystole or pulseless electrical activity (5%) (3,5).
- Witnessed arrest has been found to be statistically associated with improved survival in children with VT/VF (3).

#### COMPLICATIONS

Of those who survive cardiac arrest secondary to VT/VF, up to 34% survive with good neurologic outcome (5).

#### ICD9

- 427.1 Paroxysmal ventricular tachycardia
- 427.41 Ventricular fibrillation
- 427.89 Other specified cardiac dysrhythmias

### PEARLS AND PITFALLS

- Children may tolerate rapid ventricular rates for many hours but should be treated promptly due to risk of hypotension and degeneration into VF.
- When preparing for defibrillation, use the largest pads or paddles that can be placed on the child's chest wall without the pads touching to minimize transthoracic impedance.
- Defibrillation success is improved if effective chest compressions are provided.
- Consultation with a cardiologist is advised for all cases of ventricular dysrhythmias.

# DYSTONIA

Katherine Remick  
Patricia Padlipsky

## BASICS

### DESCRIPTION

- Dystonia is involuntary, patterned muscle contractions that result in twisting movements or abnormal postures.
- The onset, duration, severity, and clinical features are highly variable.
- Dystonia is further classified according to age of onset (early or late), anatomic distribution (focal, segmental, or generalized), and/or etiology (primary or secondary).
- Few are true emergencies: Acute laryngeal dystonia, oculogyric crisis, and dystonic storm ("continuous unremitting generalized dystonic spasms" [1]).
- Dystonia can occur in any age group from childhood to adulthood.
- Childhood-onset dystonia is more likely to affect the limbs and become generalized, whereas adult-onset dystonia is more likely to affect the neck or face and remain localized.

### EPIDEMIOLOGY

Studies have demonstrated a wide range in the incidence and prevalence of dystonia depending upon the populations assessed, but in all accounts, dystonia is a rare condition.

#### Incidence

- Focal dystonia is thought to be ~10 times more common than generalized dystonia, with an estimated incidence of 2 vs. 24 cases per million population per year (2).
- Incidence of oculogyric crisis in patients treated with chronic neuroleptics may be as high as 10% (3).
- Acute exposure to haloperidol may lead to development of an oculogyric crisis in as many as 58% (14/24) of children (4).

#### Prevalence

- Best estimates suggest primary, early-onset dystonia to have a prevalence of 2–50 cases per million (5).
- All races and genders can be affected; however, certain populations have a higher frequency of genetic subtypes, which may lead to disease expression (eg, DYT1 mutation is more common in Ashkenazi Jews and leads to a 5-fold increase in disease frequency) (6).

### RISK FACTORS

- Family history
- Underlying medical disorder
- Use of dopamine-receptor blocking drugs
- History of cerebral injury or insult
- Previous dystonic reaction
- Neurosyphilis

### GENERAL PREVENTION

Avoidance of neuroleptics, antiemetics, and other dopamine receptor–blocking medications.

### PATHOPHYSIOLOGY

- Not well understood
- Primarily attributed to basal ganglia corticostriatal-thalamocortical motor circuit dysfunction
- Studies have also shown that cerebellar stimulation can lead to dystonic movements (7).
- In primary dystonia, coexisting subclinical abnormalities in perception and sensory processing may be present (8).

- However, the specific pathophysiology likely varies between the various subtypes of primary dystonia:
  - To date, more than 16 genetic forms have been described (6).
- Dopa-responsive dystonia usually arises from enzymatic defects in dopamine or serotonin synthesis.
- Secondary dystonia develops following any variety of environmental insults (eg, perinatal trauma or CNS infection) and is often associated with other neurologic signs and symptoms.
- Additionally, a number of neurodegenerative diseases (eg, metabolic disorders) can cause secondary dystonia. The dystonic symptoms may vary from a minor complication to one of the primary manifestations of the disease.
- Acute dystonic reactions are usually caused by medications that interfere with central dopamine receptors.

### ETIOLOGY

- Primary dystonia: Any of a variety of genetic mutations or deletions; 16 molecular subtypes described (6)
- Secondary dystonia: Perinatal cerebral injury, infectious or postinfectious encephalopathies, trauma, toxins, medication induced, brain tumors, neurosyphilis, and cerebrovascular disease
- Heredodegenerative dystonia: Homocystinuria, glutaric acidemia, lysosomal storage diseases, ataxia-telangiectasia, Rett syndrome, methylmalonic aciduria, mitochondrial diseases, neurodegeneration with brain iron accumulation, Fahr disease, Hartnup disease, juvenile parkinsonism, Huntington disease, Wilson disease, Pelizaeus-Merzbacher disease
- Acute dystonic reactions including acute laryngeal dystonia and oculogyric crisis: Common offending agents include antiemetics, levodopa, antipsychotics, ergotamines, and anticonvulsants.
- Acute laryngeal dystonia: Phenothiazines
- Dystonic storm: Patients often have an underlying history of dystonia. The storm is often triggered by illness, dehydration, and/or hyperthermia.

### COMMONLY ASSOCIATED CONDITIONS

- Cerebral palsy
- Neurodegenerative disorders
- Psychiatric illness treated with antipsychotics

## DIAGNOSIS

### HISTORY

- History is the most important tool in the diagnosis and evaluation of dystonia.
- Ask about history of involuntary movements: Onset, timing, severity, duration, location, radiation, and frequency.
- In addition, any associated activities, current medications, recent illnesses, drug use or abuse, and additional symptoms should be discussed.
- Past medical history (including birth history, growth and development, and mental health)
- Family history of neurodegenerative diseases and/or movement disorders
- For acute dystonic reactions, ask about possible precipitants such as:
  - Trauma (Any history of trauma should prompt the clinician to consider other causes such as atlantoaxial rotary subluxation.)

- Medication use
- Headaches or signs of increased intracranial pressure
- Exposure to drugs or toxins

### PHYSICAL EXAM

- Involuntary twisting or sustained contraction of muscle groups, may involve laryngeal muscles:
  - Physicians should have a heightened awareness for acute laryngeal dystonia (particularly following use of phenothiazines).
- Opisthotonus
- Complete neurologic exam including motor and sensory evaluation. Evidence of gross sensory loss is uncommon in primary dystonia and should prompt a further workup.
- Mental status exam: Alterations in mental status should lead the clinician to consider alternative etiologies (eg, seizures, toxins, infections).
- Ophthalmologic exam to evaluate for symptoms of increased intracranial pressure or signs of a primary etiology (eg, Wilson disease)

### DIAGNOSTIC TESTS & INTERPRETATION

- Diagnosis of dystonia is based primarily upon physical findings.
- Lab testing is generally not helpful in the diagnosis of primary dystonia.
- The evaluation of a patient with secondary dystonia can be extensive to try and determine the underlying cause.

### Lab

#### Initial Lab Tests

Secondary dystonia:

- The history and physical exam should be used to guide lab testing.
- Initial studies may include CBC, electrolytes, renal and hepatic function, ESR, and serum creatinine kinase (if there is concern for rhabdomyolysis).
- Further tests might include antinuclear antibody, serum ceruloplasmin, copper levels, and rapid plasma reagin.

#### Imaging

Physical findings consistent with focal neurologic deficits or concern for neurodegenerative disease should lead to further evaluation with neuroimaging (head CT or MRI).

#### Diagnostic Procedures/Other

Any patient with an affected relative should be referred to a genetic specialist to undergo further genetic testing.

#### Pathological Findings

No specific neuropathologic findings have been identified. However, in the case of neurodegenerative disease, calcifications or other abnormalities may be seen within the basal ganglia and associated structures.

### DIFFERENTIAL DIAGNOSIS

- Torticollis (infectious or noninfectious)
- Sandifer syndrome
- Musculoskeletal disorder
- Posterior fossa mass
- Soft tissue neck mass
- Tetanus
- Atlantoaxial rotary subluxation
- Psychogenic or pseudodystonia
- Seizure

## TREATMENT

- The primary goals of treatment are aimed at decreasing abnormal postures, decreasing pain, and limiting contracture formation.
- Primary and secondary dystonia may require chronic palliative management.
- In the case of acute dystonic reactions, the risks and benefits of stopping all suspicious medications should be strongly considered.

## MEDICATION

### First Line

- Acute dystonic reactions: Following initial treatment with one of the medications listed below, oral anticholinergic therapy should be continued for 2 wk (especially if long-acting dopamine receptor–blocking agents had been used) (9):
  - Anticholinergic agents: A prompt response to anticholinergic medications helps to confirm the diagnosis:
    - Trihexyphenidyl PO dosing is not well established in pediatrics (antiparkinsonian medication of the antimuscarinic class).
    - Benzotropine 0.02–0.05 mg/kg/dose IV or IM per day b.i.d.
    - Diphenhydramine 1–2 mg/kg IV or IM q6h
  - Benzodiazepines: Diazepam and clonazepam have been used when anticholinergic agents fail to provide an immediate response.
  - Carbidopa/Levodopa: Treatment is initiated at a low-dose, 1/2 tablet (25/100 mg) b.i.d. and gradually titrated to effectiveness.
  - Botulinum neurotoxin injection: Treatment of choice in focal dystonia (7)
  - Baclofen: Intrathecal or intraventricular (10)
- Acute laryngeal dystonia: Immediate treatment with IV diphenhydramine:
  - Botulinum toxin injection of the vocal chords has been used in chronic cases (1).
- Oculogyric dystonia: IM or IV anticholinergics. Oral clonazepam may be effective for chronic oculogyric crises resistant to anticholinergics.
- Dystonic storm: May be resistant to all of the above listed medicines
- Focal or generalized dystonia:
  - Anticholinergics at high doses (trihexyphenidyl) alone or with baclofen
- Trial with L-dopa (up to 10 mg/kg/day for 3 mo) is the 1st choice in all patients with early-onset dystonia:
  - This may also be considered in any patient with focal or generalized dystonia of unknown etiology, to evaluate for dopa-responsive dystonia.
- If a secondary cause of dystonia can be identified, treatment should be directed toward the underlying disease.

### Pregnancy Considerations

It is best to avoid all antihistamines in pregnancy, especially during the 1st trimester.

### Second Line

The combination of benzhexol, tetrabenazine, and pimozide has been proven effective in refractory dystonic storms. In severe cases, patients may require sedation and paralysis (1).

## DISPOSITION

### Admission Criteria

- Patients in dystonic storms should be managed in a pediatric ICU.
- Patients with acute laryngeal dystonia should be admitted for monitoring.

### Issues for Referral

- Any child who presents with primary or secondary dystonia should be referred to a neurologist or movement disorder specialist.
- Secondary causes of dystonia (eg, Wilson disease) may require referral to additional subspecialists depending upon the underlying diagnosis.
- A neurologist should be consulted in the emergency department if the etiology or diagnosis of dystonia remains unclear.

### Additional Therapies

- Deep brain stimulation may be considered in cases of generalized primary dystonia refractory to medical management (11):
  - Approved for use in children  $\geq 7$  yr old
  - A relatively new technology that requires further use to assess target populations
- Physical therapy: To help prevent the development of contractures (12)
- Speech and language therapy
- Occupational therapy
- Transcutaneous electrical nerve stimulation (TENS)
- Sensory and motor training

## FOLLOW-UP

### FOLLOW-UP RECOMMENDATIONS

- Patients who develop acute laryngeal dystonia should be monitored closely for recurrence.
- The family should be educated regarding future avoidance of offending agents if known.
- Movement disorder specialists should be directly involved in the ongoing treatment of any patient with chronic dystonia.

### PROGNOSIS

- The prognosis for patients with acute dystonic reactions is excellent if treated promptly. Immediate use of anticholinergics and/or botulinum toxin injection is lifesaving in acute laryngeal dystonia.
- Patients with dopa-responsive dystonia show marked improvement following treatment with carbidopa/levodopa. Additionally, other primary dystonias may also respond to treatment with levodopa.
- Primary dystonias are highly variable with respect to treatment response and prognosis.
- The prognosis of secondary dystonia varies greatly depending upon the primary disease process.

### COMPLICATIONS

- Rhabdomyolysis
- Compression of the spinal cord, plexus, and peripheral nerves.
- Scoliosis
- Limited physical function
- Medical treatment may lead to sedation, confusion, and decreased memory function.
- Deep brain stimulation with electrode placement can be complicated by hemorrhage, stroke, migration, infection, and electrode malfunctions.

Vidailhet M, Grabli D, Roze E. Pathophysiology of dystonia. *Curr Opin Neurol*. 2009;22:406–413.

### ICD9

- 333.89 Other fragments of torsion dystonia
- 333.90 Unspecified extrapyramidal disease and abnormal movement disorder
- 781.0 Abnormal involuntary movements

## PEARLS AND PITFALLS

- The onset and presentation of dystonia is highly variable.
- The ability to recognize acute laryngeal dystonia can be lifesaving.
- Patients who present in dystonic storms should be managed in an intensive care setting with careful attention to the development of rhabdomyolysis.
- Anticholinergics and benzodiazepines are considered first-line therapy for dystonia.
- Consider the use of botulinum toxin, baclofen, or antiparkinsonian medication early.
- In refractory cases a child may benefit from sedation and paralysis.
- The etiologies of secondary dystonia are diverse, and treatment should be directed at the primary disease.

# EATING DISORDERS

Kalyani Samudra  
Charles W. Pruitt

## BASICS

### DESCRIPTION

- Anorexia nervosa (AN) is an eating disorder characterized by:
  - Weight loss to <85% of expected body weight or failure to make expected weight gains
  - Amenorrhea (absence of  $\geq 3$  consecutive menstrual cycles) if postmenarchal
  - Distorted body image
  - Intense fear of weight gain despite being underweight
  - Restricting subtype: Self-induced starvation is the main method of weight loss.
  - Binge-eating/Purging subtype: Regular bingeing/purging
- Bulimia nervosa (BN) is characterized by:
  - Recurrent binge-eating episodes followed by compensatory behaviors (purging, fasting, excessive exercise) aimed at purging calories and preventing weight gain:
    - Compensatory behaviors occur, on average, twice a week for  $\geq 3$  mo.
  - Purging subtype: Regular self-induced vomiting or laxative, diuretic, ipecac, or enema use
  - Nonpurging type: Compensatory behaviors (fasting, excessive exercise) without purging behavior
- Eating disorder not otherwise specified (EDNOS) is a diagnosis given to patients with disordered eating behaviors that do not meet full criteria for either AN or BN. This category includes patients with:
  - Binge eating disorder: Recurrent bingeing without compensatory behaviors
  - All symptoms of AN but normal weight or normal menses
  - Purging after eating small amounts of food
  - Criteria for BN but less frequent compensatory behaviors
  - A mix of AN and BN symptoms
  - Patients who chew and spit out large amounts of food without swallowing (1)

### EPIDEMIOLOGY

#### Prevalence

- Most common in adolescents/young adults
- Male to female ratio is between 1:6 and 1:10.
- AN: Lifetime prevalence in women ranges from 0.3–3.7% (depending on the definition).
- BN: Lifetime prevalence in women has ranged from 1–4%.
- EDNOS: >50% of patients with eating disorders who present to outpatient settings
- Subsyndromal eating disorder symptoms, which often do not rise to the level of a disorder according to the *Diagnostic and Statistical Manual of Mental Disorders*, 4th ed., are also quite common.
- Eating disorders are more common in Hispanic, Native American, and Caucasian women than in African American and Asian women (2).

### PATHOPHYSIOLOGY

Starvation leads to hypoglycemia, protein and vitamin deficiencies, hypercortisolemia, and endorphin release.

### ETIOLOGY

Multidimensional model:

- A person with risk factors begins dieting, bingeing, or compensatory behaviors.
- Physical changes associated with dieting include increased secretion of corticotropin-releasing hormone, which has anorectic effects.
- Exercising causes norepinephrine and endorphin release, which creates a sense of well-being, which reinforces exercising.
- Psychological reinforcers can include compliments received from others for weight loss or anxiety relief experienced after bingeing/purging.
- Thus, the patient's fasting, bingeing, or purging continues.

### COMMONLY ASSOCIATED CONDITIONS

- Substance abuse disorders are common in patients with BN, binge eating disorder, and in the binge eating/purging type of BN.
- Mood, anxiety, and personality disorders
- AN: Social phobia and obsessive compulsive disorder (OCD)
- BN: Social phobia, OCD, posttraumatic stress disorder, and simple phobia (2)

## DIAGNOSIS

### HISTORY

- Eating disorder patients often deny the seriousness of their condition.
- AN often presents with extreme weight loss, failure to gain weight, food refusal, and dehydration.
- Ask about current dietary practices including fasting; highest and lowest weight; exercise habits; binge eating; self-induced vomiting; and use of diet pills, ipecac, laxatives, and diuretics.
- Ask about use of diet pills, energy pills/drinks, and herbal teas for weight loss (which can contain ephedra or other stimulants).
- Psychiatric history: Depression, anxiety, suicidal/self-injurious thoughts/behaviors; past mental health treatment
- Family history: Obesity, eating disorder, depression, substance abuse
- Menstrual history: Age at menarche, last menstrual period, cycle regularity
- Substance abuse history, sexual history, past physical/sexual abuse
- Review of systems:
  - General: Light-headedness, fatigue, weakness
  - Oropharyngeal: Dental decay, swollen cheeks
  - Pulmonary: Shortness of breath
  - Cardiovascular: Palpitations, chest pain
  - GI: Abdominal pain, heartburn, hematemesis, vomiting, diarrhea, constipation, bloating
  - Reproductive: Regression of secondary sex characteristics; menstrual irregularities
  - Urinary: Decreased urinary volume
  - Metabolic: Weight fluctuations, muscle cramping; cold intolerance
  - Skeletal: Bone pain with exercise
  - Hematologic: Pallor, easy bruising/bleeding (2–4)

### PHYSICAL EXAM

- Look for signs of the eating disorder itself as well as its medical complications.
- The physical exam can be entirely normal, especially early in the course of illness.
- General: Cachexia
- HEENT: Sunken eyes, gingivitis, dental caries, eroded dental enamel, enlarged parotids
- Pulmonary: Wasting of respiratory muscles
- Cardiovascular: Bradycardia, orthostatic hypotension, arrhythmias, acrocyanosis, midsystolic click of mitral valve prolapse; signs of cardiomyopathy from ipecac abuse (Direct cardiotoxicity may cause tachycardia, ECG changes, CHF, hypotension, or shock.)
- GI: Abdominal distention with meals, abnormal bowel sounds, acute gastric distention:
  - Rare: Signs of gastritis, esophagitis, Mallory-Weiss tears, pancreatitis, and colonic dysmotility
- Skeletal: Short stature, arrested skeletal growth (in severe illness)
- Skin: Marks/Scars from self-injury; lanugo, petechiae, conjunctival hemorrhage after vomiting; scars or callouses on the dorsum of dominant hand, poor turgor, pitting edema
- Hematologic: Easy bruising/bleeding
- Endocrine/Metabolic: Hypothermia
- Reproductive: Arrested sexual development
- Psychiatric/Neurologic: Anxiety, depression, irritability, seizures (2–7)

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

- Most test results will be normal.
- Initial labs: Comprehensive chemistry panel, CBC with differential, urinalysis, hCG:
  - Blood chemistries: Hypokalemia (diuretic and laxative use), hyponatremia due to water loading, hypomagnesemia, hypophosphatemia, hypochloremic alkalosis due to purging, increased BUN due to dehydration, hypocalcemia
  - CBC and differential: Anemia, mild leukopenia, thrombocytopenia; increased hemoglobin
  - hCG: Pregnancy is in the differential diagnosis for amenorrhea and vomiting.
  - Thyroid function tests, LFTs
- Urinalysis to screen for renal disease, dehydration, and water loading
- If there is concern for suicidality or ingestion, order urine and/or serum toxicology screens for illicit drugs, acetaminophen, salicylates, or tricyclics.

#### Diagnostic Procedures/Other

ECG for patients who are severely symptomatic, malnourished, have metabolic abnormalities, or have a history of ipecac abuse:

- Bradycardia is the most common abnormality.
- Prolonged QTc is a rare complication.
- ST depression if electrolyte abnormalities
- Dysrhythmias include supraventricular beats and ventricular tachycardia.
- Ischemic changes in ipecac cardiotoxicity (2,6,7)

**DIFFERENTIAL DIAGNOSIS**

- Medical illness can mimic eating disorders:
  - CNS or other malignancy
  - GI: Inflammatory bowel disease, celiac disease, malabsorption syndromes
  - Endocrine disorders: Diabetes mellitus, hyperthyroidism, hypopituitarism, Addison disease
  - Pregnancy
- Psychiatric: Depressive disorders, OCD, schizophrenia

**TREATMENT****PRE HOSPITAL**

Stabilize ABCs per Pediatric Advanced Life Support (PALS) protocol.

**INITIAL STABILIZATION/THERAPY**

- Correct volume depletion and metabolic abnormalities with appropriate IV fluid replacement.
- Diagnose and treat medical complications of eating disorders (see Admission Criteria).
- Multimodal treatment (medications, individual/group/family therapy, nutritional counseling, and frequent medical evaluations)

**MEDICATION**

In general, a psychiatrist should prescribe psychotropic medications if necessary.

**DISPOSITION**

- Once medically stabilized, treatment for eating disorders can take place in a variety of settings, ranging from outpatient programs, partial hospital programs, residential programs, and inpatient programs (either medical or psychiatric).
- Most patients presenting to the emergency department will be appropriate for outpatient care or intermediate levels of care (such as partial hospital).

**Admission Criteria**

- Weight <75% of ideal body weight or acute weight loss with food refusal, intractable vomiting.
  - Consider admission for patients 75–85% of ideal body weight.
- Medical instability:
  - Heart rate <50 bpm or arrhythmia
  - BP <80/50 mm Hg
  - Orthostatic change in pulse or BP
  - Hypokalemia, hypophosphatemia, hypomagnesemia
  - Need for IV fluid/NG tube feeds
  - Temperature <97°F or <36.1°C
- Suicidality or comorbid psychiatric conditions requiring admission
- Consider admission if the patient:
  - Is uncooperative with less intensive treatment
  - Is preoccupied with intrusive thoughts
  - Is very unmotivated or lacks family support
  - Needs supervision during and after all meals
  - Has multiple daily episodes of purging
  - Has failed less intensive treatment programs
- When deciding whether to admit to a psychiatric or general medical unit, consider the patient's medical condition, the skills of the pediatric or psychiatric staff, and whether a specialized program for eating disorders is available (2–5).

**Discharge Criteria**

- Medically stable, not needing NG feeds, IV fluids, or multiple daily lab tests
- Weight must be >85% of ideal body weight, but weight should never be the sole criterion. Consider discharge for patients 75–85% of ideal body weight.
- Consider ability to control restricting/compensatory behaviors, supervision level needed during and after meals, and suicidality (2).

**Issues for Referral**

Consult the psychiatrist in the emergency department for suicidal, psychotic, agitated, or assaultive patients.

**FOLLOW-UP****FOLLOW-UP RECOMMENDATIONS**

- Discharge instructions:
  - Any patient who is discharged will need follow-up within 1 wk.
  - Primary care provider should monitor weight 1–3 times per wk. Also monitor urine specific gravity, orthostatic vital signs, oral temperature, and electrolytes.
  - Primary care provider should establish a target weight and realistic rate of weight gain (usually 0.5–2 pounds per week for outpatients).
  - Dietician can develop meal plan, help patient choose meals, and widen food choices (2).

**PROGNOSIS**

- AN:
  - 50–70% of teens with AN recover.
  - 20% improve but have residual symptoms.
  - 10–20% develop chronic AN.
  - Mortality rates for AN are high.
  - Better prognosis if younger age of onset, shorter illness duration
  - Worse prognosis if lower initial weight, vomiting, binge eating, chronicity of illness, repeated hospitalizations, and obsessive-compulsive personality symptoms
- BN:
  - Prognosis, if untreated, is poor.
  - Long-term outcome is good in ~60%, intermediate in ~30%, and poor in ~10%.
  - Better prognosis if adolescent onset
  - Worse prognosis if comorbid OCD, longer illness duration
  - Comorbid substance abuse increases risk of suicidal behaviors.
- EDNOS: Little is known about prognosis (2,3).

**COMPLICATIONS**

- Severe electrolyte abnormalities
- ECG abnormalities, life-threatening arrhythmias, cardiomyopathy (from ipecac abuse)
- Mallory-Weiss tears, gastric or esophageal rupture, superior mesenteric artery syndrome, pancreatitis
- Renal stones, renal failure
- Aspiration pneumonia
- Dental caries and loss of dental enamel

- Seizures, death
- A potentially life-threatening refeeding syndrome can occur when very low weight patients (<70% of ideal body weight) are fed too rapidly:
  - Consists of fluid retention, hypocalcemia, hypomagnesemia, hypophosphatemia
  - Delirium and cardiac failure can occur.
  - Syndrome is prevented by slow refeeding and phosphorus supplementation (2,4,6).

**ICD-9 CODES**
**ICD9**

- 307.1 Anorexia nervosa
- 307.50 Eating disorder, unspecified
- 307.51 Bulimia nervosa

**PEARLS AND PITFALLS**

- Males with eating disorders are not rare:
  - Higher rates of substance abuse than females
  - Males commonly present with drive to increase upper torso muscle mass rather than fear of becoming obese
- Caffeine, over-the-counter or herbal stimulants (ma huang/ephedra), or thyroid supplements are sometimes abused for weight loss.

# ECTOPIC PREGNANCY

Ilene Claudius

## BASICS

### DESCRIPTION

- Ectopic pregnancy is implantation and maturation of the conceptus outside of the endometrial cavity. 95–97% are found in the fallopian tubes, while the remaining are accounted for by pregnancies in the cornea of the uterus, ovary, cervix, and abdomen (1).
- Rupture of ectopic pregnancy leads to internal bleeding:
  - Current mortality is 0.05%.
  - Remains a leading cause of pregnancy related death in the 1st trimester, accounting for 10% of all pregnancy-related deaths (2)
  - Death rates are highest in girls 15–19 yr old (3).

### EPIDEMIOLOGY

#### Incidence

100,000 cases per year

#### Prevalence

2% of all live pregnancies

### RISK FACTORS

- Previous ectopic pregnancy (number 1 risk factor)
- History of pelvic inflammatory disease
- Tubal ligation or surgery
- Intrauterine device use (at time of conception)
- Congenital abnormalities
- Fallopian tube tumors
- Advanced maternal age
- Smoking
- In utero exposure to diethylstilbestrol
- History of infertility increases ectopic rate

### GENERAL PREVENTION

Education on STI prevention

### PATHOPHYSIOLOGY

Conceptus implants and grows in the fallopian tube, abdomen, ovary, cervix, or abdomen. As it grows, it may present as a nonruptured mass or as a tubal rupture.

### ETIOLOGY

Anything that delays movement of the blastocyst through the fallopian tube, allowing implantation outside of an appropriate location in the uterus; can be due to scarring or anomaly of the fallopian tube

### COMMONLY ASSOCIATED CONDITIONS

1/10,000–1/30,000 heterotopic pregnancies (increases to 1% with fertility drug use)

## DIAGNOSIS

### HISTORY

- Classic triad: Abdominal pain, amenorrhea, and vaginal bleeding
- May or may not be aware of or disclose knowledge of pregnancy
- Typically occurs 5–8 wk after the last menstrual period
- Abdominal/pelvic pain
- 50% have a history of vaginal bleeding

### PHYSICAL EXAM

- Abdominal/pelvic tenderness (80–97% of cases)
- Peritoneal signs if ruptured (tenderness, Cullen sign, etc.)
- Adnexal tenderness (75–98% of cases)
- Abdominal mass (50% of cases)
- Closed cervical os on speculum exam
- Material passing through os, if present, will not contain products of conception.
- May have paradoxical bradycardia/lack of compensatory tachycardia if the ectopic pregnancy ruptures and results in intraperitoneal blood

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

- Urine  $\beta$ -hCG (frequently positive)
- Quantitative serum  $\beta$ -hCG (rises more slowly than intrauterine pregnancy)
- Rh type
- CBC
- Progesterone level alone is not a reliable marker of ectopic pregnancies.
- Type and cross if hemodynamically unstable
- Check CBC, LFTs, and creatinine if methotrexate is planned (4).

### Imaging

- Endovaginal US: Absence of gestational sac with  $\beta$ -hCG > 1,500 mIU/mL (generally 5.5 wk estimated gestational age) indicates probable ectopic pregnancy.
- Other US findings include free fluid (25%), pseudogestational sac (20%), or adnexal mass.

### Diagnostic Procedures/Other

- Laparoscopy
- Negative uterine curettage
- Culdocentesis yielding nonclotting blood is suggestive of a ruptured ectopic pregnancy.

### Pathological Findings

- Products of conception: Extrauterine gestational sac, yolk sac, or fetal parts
- If a dilation and curettage is performed to assist with diagnosis, frozen sections are 93% sensitive for presence of chorionic villi if pregnancy is intrauterine.

### DIFFERENTIAL DIAGNOSIS

- Early normal intrauterine pregnancy
- Miscarriage
- Early abnormal intrauterine pregnancy (eg, blighted ovum)

## TREATMENT

### PRE HOSPITAL

- Address any issues related to ABCs.
- Administer oxygen and IV fluid as needed.

### INITIAL STABILIZATION/THERAPY

- Oxygen
- If hypovolemic due to hemorrhage, support BP with normal saline or blood transfusion if necessary.

### MEDICATION

#### First Line

Analgesics if indicated

#### Second Line

- Methotrexate (50 mg/m<sup>2</sup> IM) can be used after obstetric consultation in select patients for termination (5).
- Rh<sub>0</sub>(D) immune globulin (RhoGAM) in Rh-negative women: If < 12 wk pregnant, 50  $\mu$ g IM; if  $\geq$  13 wk pregnant, 300  $\mu$ g IM. Administer within 72 hr of hemorrhage.

**SURGERY/OTHER PROCEDURES**

Laparoscopy/laparotomy for ruptured ectopic pregnancies or those who are not candidates for methotrexate

**DISPOSITION****Admission Criteria**

- Critical care admission criteria:
  - Hemodynamic instability unresolved with transfusion and/or surgery
- Other indications for floor admission:
  - Need for surgical intervention (severe pain, hemodynamic instability, evidence of rupture, not eligible for medical therapy)
  - Inability to ensure follow-up in candidate otherwise eligible for medical therapy

**Discharge Criteria**

- Follow-up ensured
- Candidate for either medical treatment or needing further workup
- No severe pain or evidence of rupture
- Hemodynamic stability

**Issues for Referral**

- Patients in whom diagnosis is unclear due to a quantitative  $\beta$ -hCG  $<1,000$  mIU/mL and no intrauterine gestational sac should be followed in 2 days for repeat testing by an obstetrician to assess doubling time of  $\beta$ -hCG.
- Patients receiving medical therapy with methotrexate need 2-day follow-up to assess need for subsequent doses.

**FOLLOW-UP****FOLLOW-UP RECOMMENDATIONS**

- Discharge instructions and medications:
  - Follow-up within 2 days for either serial  $\beta$ -hCG testing or assessment of methotrexate effectiveness.
  - Counsel regarding side effects of methotrexate, if used: Nausea, stomatitis, dizziness, alopecia, neutropenia, pneumonitis, vaginal bleeding, increase in abdominal pain.
- Activity:
  - No heavy lifting
  - No sexual intercourse until  $\beta$ -hCG is undetectable
  - No breast-feeding if methotrexate used

**Patient Monitoring**

Return for severe abdominal pain, signs of hemodynamic instability

**DIET**

If medically treated with methotrexate, avoid folic acid-containing foods (eg, folate-fortified foods; green leafy vegetables; many beans, peas, and lentils; beets; fruits such as oranges, bananas, strawberries).

**PROGNOSIS**

- Risk of future ectopic pregnancies is increased by 10–25%.
- Chances of normal pregnancy are dependent on what abnormalities contributed to the ectopic, whether advanced maternal age or fertility issues existed, and the management. 1 large study showed subsequent fertility rates of 83% in a group of women managed expectantly and 64% in those managed surgically (5).

**COMPLICATIONS**

- Rupture leading to hemodynamic instability and/or death
- Failure of medical management with methotrexate (10% risk for single-dose protocol)
- Transient abdominal “separation” pain 3–7 days after methotrexate use, which is thought to be due to an expanding hematoma within the fallopian tube and is self-limited
- Failure of surgical management to remove ectopic pregnancy (5–20% risk with laparoscopic salpingostomy)

**See Also (Topic, Algorithm, Electronic Media Element)**

Vaginal Bleeding During Pregnancy (<20 week gestation)

**ICD9**

- 633.00 Abdominal pregnancy without intrauterine pregnancy
- 633.10 Tubal pregnancy without intrauterine pregnancy
- 633.20 Ovarian pregnancy without intrauterine pregnancy

**PEARLS AND PITFALLS**

- 50% of ectopic pregnancies are missed at initial visit.
- Not all patients with ruptured ectopic pregnancies have tachycardia or peritoneal signs.
- Don't forget to administer RhoGAM if the patient is Rh negative.

# ECZEMA HERPETICUM

Kyle A. Nelson

## BASICS

### DESCRIPTION

- Eczema herpeticum (EH) is an acute skin infection caused by herpes simplex virus (HSV) in patients with atopic dermatitis (AD).
- It has potential to be severe, disseminated, and life threatening (1,2).
- Kaposi varicelliform eruption (KVE) is another term for skin infections by HSV or similar viruses; some use KVE and EH interchangeably.
- EH is more frequently used to specifically describe such an infection with AD (1,2).

### EPIDEMIOLOGY

- Prevalence and incidence are not accurately known but appear to be rising (1).
- It is debated whether rising HSV incidence is resulting in higher EH incidence (1,3,4).
- No gender or racial predilection
- Can affect any age group
- Recent studies report higher incidence in teenagers and young adults (3,4).
- No significant seasonality (4,5).

### RISK FACTORS

- Occurs predominantly in patients with pre-existing skin disorders such as AD (1,2)
- Close contact with persons having “cold sores” (herpes labialis) is common (5).
- Elevated IgE levels may be associated (4,5).
- Reduced cell-mediated and humoral immunity are thought to be risk factors (5):
  - Reduced natural killer cell activity in AD is thought to allow HSV infections that suppress immune function (5).
  - HSV-specific T-cell immunity appears unimpaired in children with EH (5).
- Asthma or hay fever are not risk factors (4).
- Corticosteroids as risk factor is debated (4,5).
- Pimecrolimus, a topical calcineurin inhibitor, has been associated with EH (7).

### GENERAL PREVENTION

- Exposure to persons with active herpes labialis lesions should be avoided.
- Early treatment of EH may limit severity of disease and prevent morbidity/mortality (5).

### PATHOPHYSIOLOGY

- Viral infection from inoculation of skin; either autoinoculation in patients with latent or active infections (eg, herpes labialis) or exposure to an infected individual (1)
- Impaired immunity purported to play role in EH pathophysiology (4); antibodies against HSV appear to limit spread and severity.
- Lesions are pruritic; autoinoculation of eczematous and noneczematous skin may occur (8,9).
- Lesions may coalesce, forming large denuded areas that become superinfected with bacteria (1,5).

### ETIOLOGY

- HSV 1 and HSV 2 can cause EH (1,2,6).
- Other viruses have been associated with KVE, including *Coxsackie*, *Varicella*, and *Vaccinia* (1,2).
- Most children with EH have primary HSV 1 infections; adults may have primary or recurrent infections (4,5).

### COMMONLY ASSOCIATED CONDITIONS

- HSV skin infections have been associated with other skin disorders including irritant contact dermatitis, Darier disease, psoriasis, pemphigus vulgaris, and burn injuries (1,5).
- As immunodeficiency may be associated with EH, consider possible comorbidities.

## DIAGNOSIS

### HISTORY

- Sine quo non skin rash:
  - Typical rash is painful and pruritic.
- Often begins as sudden worsening of AD with crops of typical lesions (5,8)
- Typically begins at sites of pre-existing AD may rapidly disseminate (5,8)
- Patients may report lesions of different stages, similar to varicella (5).
- Skin eruptions may continue for 7–10 days.
- Fever, chills, malaise, and lymphadenopathy are frequent accompanying complaints (1,8).
- Inquire about recurrent herpes labialis and recent exposures (8).

### PHYSICAL EXAM

- Typical EH lesions are umbilicated vesicles or vesicopustules, but papules may occur (1,5).
- Lesions rupture, spontaneously or from excoriation, leaving punched-out lesions that may be hemorrhagic and painful (5).
- Lesions may occur in crops or be widespread (disseminated) and may be at different stages (5).
- Pustules or purulent drainage suggest bacterial superinfection (5).
- Eye involvement is an ophthalmologic emergency (1). Assess visual acuity and corneal staining with fluorescein.
- Viremia may occur and rarely may result in fulminant disease with signs of toxicity and multiple organ system abnormalities (5).

### DIAGNOSTIC TESTS & INTERPRETATION

Diagnosis is usually made clinically, as EH has such characteristic features (1,4).

#### Lab

- Vesicular fluid may be sent for testing:
- Tzanck test, which examines for multinucleated giant cells
  - May be done rapidly but is not sensitive or specific for HSV (1,4)

- Polymerase chain reaction for HSV deoxyribonucleic acid or direct fluorescent antibody tests:
  - More sensitive and specific than Tzanck test but results not readily available (1,4)
- Viral culture:
  - Send in Hanks media.
  - May take >24 hr (1,4)
- Serologic testing is less specific (1).
- HSV IgM may be positive without IgG or initially negative with subsequent seroconversion.
- Consider other lab tests based on clinical scenario:
  - CBC, C-reactive protein, blood culture, wound cultures (4)

### Diagnostic Procedures/Other

Skin biopsy is rarely performed (1).

### Pathological Findings

Microscopy characteristically shows “ground glass” appearance and/or eosinophilic inclusions of nuclei, multinucleated and/or necrotic cells, pallor or ballooning of keratinocytes, acantholytic or necrotic epithelium, and intraepidermal blistering (10).

### DIFFERENTIAL DIAGNOSIS

- Impetigo
- Contact dermatitis
- Shingles (varicella zoster)
- Chickenpox (varicella) if more disseminated

## TREATMENT

### INITIAL STABILIZATION/THERAPY

Depending on disease severity, some patients may show signs of toxicity and should be rapidly stabilized and treated accordingly.

### MEDICATION

#### First Line

- Acyclovir has traditionally been the preferred antiviral therapy (1,4,5):
  - IV route preferred as initial treatment for ill-appearing patients or disseminated EH
    - Typical dose: 15–30 mg/kg/day IV divided into 3 doses × 5–7 days; transition to PO after improvement
  - Oral treatment may be used in well-appearing patients with limited skin involvement.
    - Typical dose: 40–80 mg/kg/day PO divided into 3–5 doses × 7–10 days
  - PO dosing frequently given as adult dosing: 200–400 mg 5 times per day × 10 days
- Valacyclovir:
  - Pharmacologically equivalent to acyclovir
  - Dosing and compliance easier
  - Typical dose: 20 mg/kg PO q8h × 5 days, max 1,000 mg/dose
  - Higher cost
- Famciclovir:
  - While also pharmacologically equivalent to acyclovir, pediatric dosing has not been established.

- Topical acyclovir (Zovirax) may be considered:
  - Apply to affected area 5–6 times per day × 7 days.
- Systemic antibiotics if suspected bacterial cellulitis:
  - *Staphylococcus* species most common
  - *Streptococcus* and *Pseudomonas* species possible (1,5)
  - Consider treatment for MRSA as indicated
  - Cephalexin 25–100 mg/kg/day PO q6–12h
  - Augmentin: <40 kg, 25–45 mg/kg/day PO q12h; >40 kg, 250–500 mg/dose PO q8h
  - Clindamycin: IV, 15–40 mg/kg/day q6–8h; PO, 30–40 mg/kg/day q6–8h
- Antiviral and antibacterial treatment should not be delayed or withheld pending confirmatory lab test results if high clinical suspicion (1).
- For analgesia, consider NSAIDs, acetaminophen, or opioids.
- Pain and inflammation may be prolonged.
- NSAIDs:
  - Ibuprofen 10 mg/kg/dose PO/IV q6h PRN
  - Ketorolac 0.5 mg/kg IV/IM q6h PRN
  - Naproxen 5 mg/kg PO q8h PRN
  - Some clinicians may avoid due to theoretical concern of effect on coagulation and callus formation.
- Acetaminophen 15 mg/kg/dose PO/PR q4h PRN
- Opioids:
  - Morphine 0.1 mg/kg IV/IM/SC q2h PRN:
    - Initial dose of 0.1 mg/kg IV/SC may be repeated q15–20min until pain controlled, then q2h PRN.
  - Fentanyl 1–2 μg/kg IV q2h PRN:
    - Initial dose of 1 μg/kg IV may be repeated q15–20min until pain controlled, then q2h PRN.
  - Codeine or codeine/acetaminophen dosed as 0.5–1 mg/kg of codeine component PO q4h PRN
  - Hydrocodone or hydrocodone/acetaminophen dosed as 0.1 mg/kg of hydrocodone component PO q4–6h PRN
- Antipruritics may prevent autoinoculation and bacterial superinfection.
- 1st-generation antihistamine agents can be sedating; consider for use at night or in regimen with nonsedating antihistamine agents:
  - Diphenhydramine: PO, IM, IV, 5 mg/kg/day divided q6–8h
  - Hydroxyzine: PO, 2–4 mg/kg/day divided q6–8h; IM, 0.5–1 mg/kg/dose q4–6h as needed
- Standard dose of a 2nd- or 3rd-generation H1 antihistamine agent:
  - Less commonly available; more expensive
  - Less sedating than traditional 1st-generation antihistamines; only penetrate blood-brain barrier to slight extent
  - Cetirizine: 5–10 mg/day in adults and children ≥12 yr of age; 2.5 mg (1/2 teaspoon) to 5 mg (1 tsp) once daily in children 2–5 yr; 2.5 mg (1/2 teaspoon) once daily in children 6–23 mo
  - Desloratadine: 5 mg once daily in adults and children ≥12 yr of age; 2.5 mg once daily in children 6–11 yr; 1/2 teaspoon (1.25 mg in 2.5 mL) once daily in children 12 mo to 5 yr; 2 mL (1.0 mg) once daily in children 6–11 mo
- Topical corticosteroids, pimecrolimus, and tacrolimus are often discontinued during active infections due to concern of association with viral infection in patients with AD (1,5).

**Second Line**

- Acyclovir resistance:
  - In cases of acyclovir resistance, valacyclovir, famciclovir, and penciclovir will be ineffective.
  - Administration of foscarnet or vidarabine or cidofovir may be indicated in such circumstances.
  - Dermatology and/or infectious disease consultation should be considered in such cases to assist with management.
- Foscarnet:
  - Typical dose: > 12 yr, 40 mg/kg IV q8–12h for 2–3 wk; dosing < 12 yr not established
- Vidarabine IV dosing for pediatrics is not established.
  - Vidarabine topical for ocular HSV: Apply 0.5-inch ribbon to lower conjunctival sac 3 times per day
- Cidofovir dosing for pediatrics is not established.

**SURGERY/OTHER PROCEDURES**

Wound care for denuded skin (5)

**DISPOSITION**

**Admission Criteria**

Extensive skin involvement, significant bacterial superinfection, signs of dehydration, or signs of sepsis or multiple organ system involvement

**Discharge Criteria**

Well-appearing patients with limited skin involvement, appropriate wound care, and access to follow-up for re-evaluation

**Issues for Referral**

If diagnosis is uncertain, dermatology consultation may be necessary.

**ALERT**

To prevent autoinoculation of eye or other body areas, it is critical to educate patient and control pruritus; in young children, trim fingernails short and consider mitten use.

**FOLLOW-UP**

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**

- Follow-up should occur within a few days to assess clinical status and discern need for additional treatment (eg, antibacterials).
- If good response to medications and no complications, follow-up may be unnecessary.
- Patients should be considered contagious until all lesions have scabbed over.

**PROGNOSIS**

- Most children heal without complications (5).
- Lesions usually heal within 2–6 wk (4).
- Mortality rate is <10% with appropriate treatment and is associated with delayed presentation and treatment (5).
- ~20% of children will have recurrent HSV infections (5).

**COMPLICATIONS**

- Scarring
- Autoinoculation to eyes, mouth, genitals
- Cellulitis
- Sepsis
- Multiorgan failure
- Shock
- Death

ICD9  
054.0 Eczema herpeticum

**PEARLS AND PITFALLS**

- EH treatment should not be delayed to await confirmatory lab test results.
- EH diagnosis should be considered in patients with acutely severe and rapid worsening AD.
- EH around eye and varicella zoster virus infection of the trigeminal nerve may be confused. Varicella zoster virus infections are characterized by periorbital, forehead, and nasal vesicles that do not cross midline.

# EDEMA

David J. Mathison  
Dewesh Agrawal

## BASICS

### DESCRIPTION

Alterations in capillary hemodynamics can lead to increases in interstitial fluid volume, manifesting as tissue swelling, or edema. This can be either localized or generalized (anasarca).

### PATHOPHYSIOLOGY

- 65% of body water is intracellular while 35% of body water is extracellular, divided between the vascular space (1/4) and interstitium (3/4).
- Edema results when fluid shifts from the vascular space to the interstitium. This shift occurs secondary to the following mechanisms:
  - Increased capillary hydrostatic pressure. Hydrostatic pressure is most affected by changes in capillary volumes. In states of generalized fluid overload, increases in venous fluid volume lead to pressure increases in the venules, which are transmitted to the capillary bed. The resultant pressure gradient increases the transcapillary movement of fluid into the interstitial space.
  - Decreased capillary oncotic pressure:
    - Since the concentrations of electrolytes in plasma and the interstitium are relatively equal, osmotic force is governed by charged protein molecules (colloids), predominantly albumin.
    - Hypoalbuminemia results in decreased capillary oncotic pressure, favoring the movement of fluid from the vascular to interstitial compartment to equilibrate the oncotic (or osmotic) pressures.
  - Increased capillary permeability. Cytokine release and inflammatory mediators can influence endothelial leak (eg, permeability), leading to fluid shifts.

### ETIOLOGY

- Generalized increases in hydrostatic pressure occur from increased salt and water retention, such as in CHF, renal insufficiency, and glomerulonephritis.
- Localized increases in hydrostatic pressure occur from venous obstruction. Examples include:
  - Malignancy
  - Deep vein thrombosis (DVT)
  - Vasculitis
  - Venous catheters
  - Portal HTN (eg, hepatic cirrhosis)

- Decreased capillary oncotic pressure generally results in anasarca. Examples include:
  - Decreased protein synthesis:
    - Malnutrition (eg, kwashiorkor)
    - Liver failure
  - Increased protein excretion:
    - Proteinuria (eg, nephrotic syndrome)
    - Protein-losing enteropathy (eg, celiac disease, milk protein enterocolitis, inflammatory bowel disease, right heart dysfunction, post-Fontan cardiac procedure)
  - Increased capillary permeability occurs from:
    - Burns
    - Sepsis/Infection
    - Trauma
    - Anaphylaxis
    - Hereditary angioedema

## DIAGNOSIS

### HISTORY

- Acute or chronic (duration of symptoms)
- Age of onset
- Recent illness:
  - A recent streptococcal infection might be suggestive of an acute postinfectious glomerulonephritis.
- Systemic symptoms: Arthritis, rash, dyspnea, fevers, exercise intolerance, diarrhea, etc.
- Quantify weight gain: This is sometimes qualified by parents using rapid changes in clothing rather than quantified by changes in body mass.
- Quantify urine output and qualify urine consistency and color:
  - Oliguria can be a sign of hypovolemia or renal insufficiency.
  - Frothy urine suggests proteinuria.
  - Hematuria raises concern for acute glomerulonephritis.
- Family history:
  - Nephropathy
  - Hereditary angioedema
- Allergies
- Medical history
- Recent exposures

### PHYSICAL EXAM

- Vital signs:
  - Tachypnea, hypoxemia—pulmonary edema
  - Tachycardia—heart failure
  - HTN—salt retention/volume overload
  - Fever—sepsis, infection

- Growth parameters:
  - When possible, quantify trends in weight vs. trends in height.
  - Growth failure can be seen in chronic liver or kidney diseases.
  - Acute weight gain is characteristic of fluid retention and acute nephropathy.
- Auscultation:
  - S3 gallop—heart failure
  - Crackles/Rales, asymmetry—pulmonary effusion/edema
- Abdominal exam:
  - Hepatomegaly—CHF, intrinsic hepatic disease, portal HTN
  - Isolated ascites is characteristic of portal HTN. Look for fluid wave, shifting dullness, and abdominal distention.
- Evaluate for signs of intravascular volume depletion (eg, tachycardia, pallor, delayed capillary refill).
- Assess for localized vs. generalized edema:
  - Extremity edema can be generalized and positional (eg, after standing).
  - When localized, look for other signs such as pain, erythema, ecchymoses, and blistering to distinguish cellulitis, venous clot, tumor, burn, and trauma.
  - Facial (periorbital) edema is often associated with nephrotic syndrome in children.
- Assess for pitting edema: The tissue swelling from lymphedema classically does not cause pitting.
- Look for scrotal/labial edema.
- Look for dysmorphic features.
- Look for signs of systemic or multisystem illness (eg, clubbing, rash, joint swelling, signs of malnourishment or vitamin deficiency).

## DIAGNOSTIC TESTS & INTERPRETATION

### Lab

#### Initial Lab Tests

Urinalysis with microscopy:

- $\geq 3+$  protein ( $\geq 300$  mg/dL) is suggestive of proteinuria.
- Urinalysis protein may appear falsely elevated with alkaline urine, in concentrated specimens, or with gross hematuria.
- Microscopy evaluates for urine sediment associated with renal disease.

#### Secondary Lab Tests

- Urine protein/creatinine ratio using spot (random) urine protein and urine creatinine levels to quantify the degree of proteinuria:
  - $>0.2$  is abnormal.
  - $>3.5$  is indicative of nephrotic range proteinuria (1); best evaluated by the first morning sample (2).
- Renal function panel (electrolytes, BUN/creatinine, albumin level) to evaluate for renal insufficiency and hypoalbuminemia
- Complement levels (C3, C4, total complement) to evaluate for glomerulonephritis, vasculitis, or acute inflammatory disease:
  - Complement levels are usually normal in nephrotic syndrome.

- C3 is low in cirrhosis, postinfectious glomerulonephritis, and sepsis.
- When C3 and C4 are both low in the presence of kidney disease, it is suggestive of membranoproliferative or lupus nephritis.
- Liver panel (AST, ALT, bilirubin, total protein) to evaluate for hepatic inflammatory disease
- PT to evaluate for signs of liver dysfunction
- Coagulation studies to evaluate for hypercoagulability (see Deep Vein Thrombosis topic)
- Consider the following under the appropriate circumstances:
  - Antinuclear antibody, hepatitis B and C titers, and HIV ELISA to evaluate for potential causes of renal insufficiency and systemic inflammatory disease
  - Consider lipid panel (total cholesterol, triglycerides), which may support a diagnosis of nephrotic syndrome.
  - Consider antistreptococcal titers (antistreptolysin O, anti-DNase-B) to evaluate for antecedent streptococcal infections in the presence of suspected postinfectious glomerulonephritis.
  - Vitamin panel to evaluate for vitamin deficiencies in the presence of malnutrition
  - C1q, C4, C2, and C1 inhibitor to evaluate for inherited or acquired C1 inhibitor deficiency.
  - Stool for alpha-1 antitrypsin to evaluate for protein-losing enteropathy (associated with levels >2.0 mg/g).
  - Stool for leukocytes (and eosinophils) to evaluate for enterocolitis such as from infection, inflammatory disease, or milk protein allergy.
  - Tissue transglutaminase antibody (tTG), endomysial antibody, antigliadin antibody, and serum total IgA level to evaluate for celiac enteropathy (see Celiac Disease topic).

### Imaging

Imaging based on the clinical presentation as indicated:

- Chest radiograph (if patient has respiratory distress) to evaluate for pulmonary edema, effusions, or signs of cardiopulmonary disease
- Renal US to evaluate for acute obstruction (hydronephrosis), intrinsic disease (cysts, kidney size), and congenital anomalies (eg, hypoplasia, horseshoe kidney, etc.)
- Liver US with Doppler to evaluate for parenchymal liver disease and portal obstruction
- Extremity US with Doppler to evaluate for DVT

### Diagnostic Procedures/Other

- Echo to evaluate for left ventricular outflow obstruction, cardiac function, and pericardial effusion if suspected
- Renal biopsy should be considered in steroid-resistant nephrotic syndrome, chronic nephropathies, and acute renal insufficiency.

## TREATMENT

### INITIAL STABILIZATION/THERAPY

- Address any issues related to ABCs.
- Further therapy depends on the etiology.

### MEDICATION

- Generalized edema:
  - Avoid excess sodium:
    - Goal daily sodium intakes = 2–3 mEq/day
    - Avoid saline boluses unless for resuscitation of hypovolemic shock.
  - Fluid restriction
  - Diuretic therapy:
    - Diuretics are effective in conditions of salt/water retention and increased intravascular volumes (eg, heart failure), but use is controversial in conditions of decreased oncotic pressure (eg, nephrotic syndrome) and intravascular volume depletion.
    - Furosemide is first line: Watch for hypokalemia (dosing: 1–2 mg/kg IV/IM, max 40 mg, can repeat every 2 hr if needed).
    - Spironolactone can be an effective alternative to furosemide. Spironolactone can be used in patients with cirrhosis (saves alkalosis) and congenital heart disease (saves hypokalemia and may be cardioprotective by inhibiting fibrosis in the myocardium [3]). Watch for hyperkalemia (dosing: 1–3 mg/kg/day PO divided b.i.d.–q.i.d., max dose 200 mg/day).
    - Bumetanide is a loop diuretic that can be used in recalcitrant edema poorly responding to furosemide (dosing: 0.02–0.1 mg/kg IV, max dose 0.35 mg/kg/day).
    - Excess intravascular volume depletion can lead to shock or acute renal failure.
  - Albumin: Use of albumin is controversial and reserved for severe anasarca with signs of intravascular volume depletion or diuretic-resistant anasarca. Albumin infusions carry a risk for a sudden mobilization of fluid into the intravascular compartment, which can worsen pulmonary edema or CHF. Increasing serum albumin levels to 2.8 g/dL is adequate to restore intravascular oncotic pressures (4). Albumin (0.5–1 g/kg 20 or 25% salt-poor human albumin IV) should be given over 4 hr and immediately followed by furosemide (1–2 mg/kg IV).
  - Corticosteroids: Consider use of IV methylprednisolone or PO prednisone for idiopathic nephrotic syndrome or systemic inflammatory disease. Dosing and use varies and should be made in consultation with a pediatric nephrologist or rheumatologist.
- Localized edema (depends on cause):
  - Anaphylaxis: See Anaphylaxis topic.
  - Burns: Debridement as necessary, topical antibiotics/dressing
  - Thrombosis: See Deep Venous Thrombosis topic for specifics of antithrombotic therapy with unfractionated or low-molecular-weight heparin.

### DISPOSITION

#### Admission Criteria

- Critical care admission criteria:
  - Ventilator support
  - Severely depressed cardiac function
  - Encephalopathy from renal/liver failure
  - Hemodynamic instability
  - Sepsis

- Inpatient admission criteria:
  - Respiratory distress
  - Significant HTN, azotemia, or oliguria
  - Severe infection (eg, peritonitis)
  - Need for further diagnostic or therapeutic procedures
  - Initiation of heparin
  - Significant burn care
  - Postanaphylaxis observation

## FOLLOW-UP

### FOLLOW-UP RECOMMENDATIONS

Consultation with a specialist is essential for underlying disease management.

## ADDITIONAL READING

Hisano S, Hahn S, Kuemmerle NB, et al. Edema in childhood. *Kidney Int Suppl*. 1997;59:S100–S104.

ICD9  
782.3 Edema

## PEARLS AND PITFALLS

- Generalized edema (particularly in the face) without other systemic symptoms is suggestive of the idiopathic nephrotic syndrome of childhood.
- If a patient has anasarca of unknown origin and the urinalysis is negative for protein, send serum tests (including albumin) and consider causes such as liver failure, protein-losing enteropathy, malnutrition, and cardiopulmonary disease.
- Edema of the hands and feet in a newborn girl is suggestive of Turner syndrome.

# ELECTRICAL INJURY

Tzvi Aaron  
Nikhil B. Shah

## BASICS

### DESCRIPTION

Electrical injury is caused by electrical shock from either alternating current (AC) or direct current (DC):

- Commonly occurs from lightning or electrical supply in homes as well as from electricity supplied from batteries, generators, power lines, and other high-voltage supplies
- Wide range of presentation from minimal injury to severe organ involvement and death

### EPIDEMIOLOGY

#### Incidence

- Electrical injuries result in >3,000 admissions annually to specialized burn units.
- Results in ~1,300 deaths per year
- Bimodal pediatric distribution: Toddlers and adolescents:
  - Household appliance–related injury predominates in children <12 yr.
  - High-voltage electrical injury is more common in older children due to risk-taking behavior.
- 2 to 1 male:female overall incidence

### RISK FACTORS

- Exposed electrical outlets, cords, or devices
- Adolescents engaged in risk-taking behavior, such as trespassing in transformer substations or on subways/trains or climbing trees and utility poles

### GENERAL PREVENTION

- Proper adult supervision of children
- Education about childproofing, outlet covers, extension cord and overhead power line dangers, and appliance safety (eg, keeping hair dryers away from bathtubs)
- Avoid areas of destruction after storms such as hurricanes or tornadoes to prevent contact with fallen high-voltage lines
- Targeted education to adolescents and young adults in construction, public utility, and railway transportation trades

### PATHOPHYSIOLOGY

- Electrical current will follow the path of least resistance. If this path is through the body or tissue, significant injury may occur.
- Electrical injuries result from:
  - Direct effects of current:
    - Tissue destruction
    - Muscle contraction and tetany:
      - Supraphysiologic muscle contraction can lead to chest wall paralysis.
    - Cardiac dysrhythmia

- Conversion of electrical energy into thermal energy as current passes through body tissues:
  - Ohm law: Voltage = current x resistance
  - This varies depending on the individual tissue resistance. Generally, the greater the resistance, the more conversion to heat:
    - Blood and nerves are least resistant.
    - Fat and bone are most resistant.
- Secondary effects or injury:
  - From falls or getting thrown

## DIAGNOSIS

### HISTORY

- Mechanism determines severity of injury:
  - Type of current: AC is significantly worse than DC.
  - Type of voltage: High voltage (>1,000 V) is associated with greater morbidity and mortality.
  - Current pathway: Transcranial and transthoracic currents are more commonly fatal.
  - Current intensity: Currents >20–50 mA may cause respiratory and cardiac arrest.
  - Duration of contact
  - Tissue resistance (eg, wet skin worse than dry)
  - Type of contact surface
- Circumstances surrounding the incident
- Secondary injury from trauma

### PHYSICAL EXAM

- Respiratory:
  - Chest wall muscle paralysis from tetanic contraction may lead to respiratory arrest.
- Cardiac: Asystole or dysrhythmia
- Skin:
  - Burns:
    - Superficial injury may appear minor despite significant deep tissue injury.
    - Conversely, the presence of surface burns does not accurately predict the extent of possible internal injuries (1).
    - Type of burn influences severity and extent of tissue damage.
    - “Ferning” is a specific pattern of burn seen after lightning strike with a fernlike pattern seen on skin.
- Oral burns:
  - Children, usually <6 yr, who bite or suck on household electrical cords
  - Cosmetic deformity of the lips may occur.
  - Delayed labial artery bleeding (in 2–3 wk)
- CNS:
  - Transient confusion, amnesia, impaired recall of events, and loss of consciousness (LOC)
  - Seizure
  - Late paralysis (from direct spinal cord injury), transverse myelitis, or transection
  - Cervical spine (C-spine) immobilization is indicated unless patient is completely lucid.

- Musculoskeletal:
  - Palpate the extremities and perform a complete neurovascular exam:
    - Monitor for compartment syndrome.
    - Long bone, scapular, and vertebral compression fractures may result from secondary blunt trauma or intense tetanic contraction.
- Ocular:
  - Delayed cataract formation in 6%
  - Ocular burns, uveitis, and hemorrhage

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

- Urinalysis:
  - Specific gravity, pH, hematuria, and urine myoglobin if urinalysis is positive for hemoglobin
  - Monitor urine output if there are concerns of acute renal failure.
- Other tests:
  - For normal household currents, no other tests are needed.
  - High-voltage injury or symptomatic patients require further evaluation, including:
    - CBC
    - Serum electrolytes and creatinine (Severe rhabdomyolysis may lead to renal failure.)
    - Check serum myoglobin if urine is positive for myoglobin.
    - Creatine kinase (CK) levels in cases with severe rhabdomyolysis from high-voltage injuries may help predict which patients could benefit from early fasciotomy to prevent amputation (2).
    - Cardiac enzymes for patients with chest pain, an abnormal ECG or dysrhythmia, or a high-voltage injury
    - Blood gas analysis for patients needing ventilator support or requiring urinary alkalization for rhabdomyolysis

#### Imaging

- Imaging should be done as clinically indicated for concerns of associated fractures.
- Echo if abnormal ECG

#### Diagnostic Procedures/Other

- Fasciotomy or escharotomy may be required in high-voltage or prolonged low-voltage injuries.
- Obtain early surgical consultation since early fasciotomy may prevent subsequent amputation.

#### Pathological Findings

Histologic exam reveals coagulative necrosis of the epidermis in high-voltage injury.

#### DIFFERENTIAL DIAGNOSIS

Most cases have a known etiology, but other diagnoses to consider include:

- Chemical, ocular, or thermal burns
- Intracranial hemorrhage
- Status epilepticus
- Syncope or arrhythmia
- Toxic ingestion or rhabdomyolysis
- Respiratory arrest

## TREATMENT

### PRE HOSPITAL

- For high-voltage incidents, the source voltage should be turned off before rescue attempt.
- Separate victim from source.
- Rescuers should be aware of scene safety and threat to bystanders or responders.
- Approach victims of electrical injuries as both trauma and cardiac patients:
  - C-spine immobilization prior to movement
  - Cardiopulmonary monitoring
- Assess and stabilize airway, breathing, and circulation.

### INITIAL STABILIZATION/THERAPY

- Assess and stabilize airway, breathing, and circulation.
- Electrical injuries are more similar to a crush injury rather than a thermal injury due to potentially extensive deep tissue damage in the absence of significant cutaneous injury.
- Resuscitation as per Advanced Trauma Life Support (ATLS) and Pediatric Advanced Life Support (PALS) protocols:
  - Cardiopulmonary monitoring:
    - Cardiac medications as needed for arrhythmias
  - IV hydration with normal saline or lactated Ringer:
    - Reduces morbidity in severe burns
    - Prevents renal failure
    - Large volumes may be required due to significant 3rd spacing
    - Sodium bicarbonate 50 mEq/L (1 ampule per liter) to alkalinize the urine (pH 7.5) to increase rate of myoglobin clearance
    - Adequate tissue perfusion, vital signs, and urine output should guide fluid resuscitation.
  - Place Foley catheter and maintain urine output 0.5–2 mL/kg/hr, depending on degree of myoglobinuria.
  - Immobilize fractures and dislocations.
  - Hourly vascular checks for palpable or audible Doppler pulses for extremity burns
- Adequate pain control
- Essential tests:
  - Cardiopulmonary monitoring:
    - Arrhythmia after electrical injury ranges from benign (15%) to fatal.
    - Most common fatal arrhythmia is ventricular fibrillation (from AC); asystole (from high-voltage or DC) may also occur

### MEDICATION

#### First Line

- Morphine 0.1 mg/kg IV/IM/SC q2h PRN:
  - Initial morphine dose of 0.1 mg/kg IV/SC may be repeated q15–20min until pain is controlled, then q2h PRN.
- Fentanyl 1–2 µg/kg IV q2h PRN:
  - Initial dose of 1 µg/kg IV may be repeated q15–20min until pain controlled, then q2h PRN
- Codeine/acetaminophen dosed as 0.5–1 mg/kg of codeine component PO q4h PRN
- Tetanus prophylaxis

#### Second Line

Furosemide (0.5 mg/kg IV) or mannitol (0.25–0.5 mg/kg IV) for myoglobin clearance

### DISPOSITION

#### Admission Criteria

- Inpatient care is required for all patients with anything other than minor low-voltage injuries:
  - LOC or neurologic insult
  - Dysrhythmias or myocardial insult
  - Rhabdomyolysis/myoglobinuria or acidosis
  - Trauma necessitating admission
  - Concerns of deep tissue damage or internal organ injury
  - Major burns
- Early initiation of burn and trauma care, preferably at a specialized center, is recommended.
- Critical care admission criteria:
  - Patients with cardiac or respiratory arrest, LOC, abnormal ECG, hypoxia or respiratory distress, chest pain, myoglobinuria, acidosis, or significant burns or traumatic injuries should be admitted to the ICU.

#### Discharge Criteria

- Healthy children with household current exposures who are asymptomatic can be safely discharged after 4 hr of observation (3).
- Minor burns (including oral burns) or patients with mild symptoms can be observed for several hours and discharged if symptoms resolve and there is no elevation in CK or myoglobinuria.

#### Issues for Referral

- Consider additional consultations with trauma/critical care, orthopedics, plastic surgery, ophthalmology, and general surgery, depending on the type and severity of traumatic injuries.
- Oral or plastic surgeons should evaluate children with oral burns.

### COMPLEMENTARY & ALTERNATIVE THERAPIES

- Burn care should include tetanus immunization as indicated.
- Prophylactic antibiotics are not routinely recommended (4).
- Oral burns can be splinted to prevent microstomia and hold commissure at constant tension.
- Splint injured extremities in functional position as indicated.
- Physical and occupational therapy should be instituted early.

## FOLLOW-UP

### FOLLOW-UP RECOMMENDATIONS

- Discharged patients should follow up with a primary care physician in 24–48 hr.
- Discharge instructions and medications:
  - Continue hydration and monitor urine output.
  - Observe for any new bleeding with oral burns.
  - Analgesics
  - Awareness of possible long-term neurologic or ocular effects. Follow up as indicated.
  - Physical and occupational therapy as needed
  - Appropriate follow-up with specialists

#### Patient Monitoring

Immediate re-evaluation is necessary for:

- Decreased urine output
- Change in mental status
- Chest pain or palpitations
- Bleeding or neurologic deficits
- Respiratory distress

### PROGNOSIS

Patients with exposure to low voltage and without major electrical events, prolonged unconsciousness, or cardiac arrest have excellent outcomes (5).

### COMPLICATIONS

- Delayed labial artery hemorrhage
- Amputation (high-voltage injuries)
- Infection/sepsis in deep tissue injury
- Acute renal failure
- Neurologic sequelae including loss of sensation, myelopathy, paraplegialike syndrome and neurapraxia

### ADDITIONAL READING

Bailey B, Gaudreault P, Thivierge RL. Experience with guidelines for cardiac monitoring after electrical injuries in children. *Am J Emerg Med.* 2000;18:671–675.

### ICD9

- 994.0 Effects of lightning
- 994.8 Electrocutation and nonfatal effects of electric current

### PEARLS AND PITFALLS

- Succinylcholine is contraindicated in electrical injury due to risk of hyperkalemia (6).
- Extensive deep tissue damage may be present despite minimal cutaneous injury.
- Severe morbidity is possible after initial period with minimal or no symptoms.

# EMERGENCY CONTRACEPTION

Janet Semple-Hess

## BASICS

### DESCRIPTION

- Emergency contraception is the use of either combination oral contraceptives (COC), progestin-only pills, or an intrauterine device (copper IUD) postcoitally to prevent pregnancy.
- Although levonorgestrel (Plan B) is the simplest and is well tolerated, 20 other brands of oral contraceptives are approved for use for emergency contraception.
- Use of emergency contraception may reduce the risk of pregnancy by:
  - 75–89% with oral contraceptive pills (OCPs) (1)
  - 99% with a copper IUD (2)
- Background:
  - Median age of first intercourse in the U.S. is 16 yr.
  - 900,000 girls and women ages 12–19 yr will become pregnant each year in the U.S.
  - 90% of adolescent pregnancies are unintended: ~35% end in abortion.

### ALERT

Contraception counseling should include a discussion of safe sex, future contraception, and STI and HIV prevention.

### PATHOPHYSIOLOGY

The exact mechanism of action of the Yuzpe method, first described in 1974 (then with ethinyl estradiol/levonorgestrel) is unknown and may depend upon the stage of the menstrual cycle at the time given:

- May inhibit ovulation, interfere with fertilization, or prevent implantation
- Emergency contraception with OCPs does not terminate an implanted fertilized ovum or fetus.
- Copper IUD interferes with implantation, which occurs between days 6 and 12 after ovulation.

### ETIOLOGY

- Vaginal intercourse without contraception
- Failure of contraception:
  - Condom breakage
  - Displacement of diaphragm, hormone patch, or copper IUD
  - Missed OCP for 3 days
  - Being 2 wk late for Depo-Provera injection

### COMMONLY ASSOCIATED CONDITIONS

Sexually transmitted infections

## DIAGNOSIS

### HISTORY

- Identify time of unprotected coitus.
- Date of last menstrual period
- Confirm consensual nature of coitus or circumstances of sexual assault.
- Inquire about other symptoms.

### PHYSICAL EXAM

- Pelvic exam for STIs or for injuries if sexually assaulted
- Pelvic exam and Pap smear are not required prior to emergency contraception use.
- Pelvic exam is required for copper IUD placement.
- Copper IUD as emergency contraception may be contraindicated if concurrent STI is suspected.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

- Pregnancy testing is typically obtained in all cases. If the patient is pregnant, no emergency contraception is used.
- Pregnancy test is required prior to copper IUD insertion.
- STI screening, HIV testing, and hepatitis B testing, especially if sexual assault has occurred, are preferred but not required to give OCPs as emergency contraception.

## TREATMENT

### PRE HOSPITAL

Stabilization of injuries or bleeding for the sexual assault patient

### INITIAL STABILIZATION/THERAPY

Stabilize injuries/bleeding for sexual assault patient

### MEDICATION

#### First Line

- Levonorgestrel comes in 2 dose regimens:
  - Plan B: 1.5 mg single dose within 3 days of coitus
  - Levonorgestrel (generic): 0.75 mg, 2 pills once only, given within 72 hr of coitus (some authors extend to 120 hr)
  - Antiemetics are generally not needed with levonorgestrel.
  - If patient vomits within 1 hr of dose, this is considered a missed dose. Administer antiemetic and readminister dose.
- Numerous other contraceptive pills may be used. The following is a partial list of medications for this purpose; 2 doses 12 hr apart are necessary:
  - Alesse: 5 pink pills
  - Cryselle: 4 white pills
  - Enpresse: 4 orange pills
  - Jolesa: 4 pink pills
  - Levlén: 4 light orange pills
  - Levora: 4 white pills
  - Lo/Ovral: 4 white pills
  - Low-Ogestrel: 4 white pills
  - Nordette: 4 light orange pills
  - Ogestrel: 2 white pills
  - Ovral: 2 white pills
  - Ovrette: 20 yellow pills
  - Quasense: 4 white pills
  - Seasonique: 4 blue-green pills
  - Tri-Levlen: 4 yellow pills
  - Triphasil: 4 yellow pills

**Second Line**

Antiemetics may be necessary:

- Metoclopramide 10 mg PO/IV/IM:
  - If metoclopramide given IV, administer as piggyback with normal saline over >30 min to prevent akathisia.
- Ondansetron 4–8 mg PO/IV given 30–60 min prior to contraceptive

**SURGERY/OTHER PROCEDURES**

Copper IUD should be placed within 5 days of unprotected coitus. It can be removed with the next menstrual cycle or for left in for up to 10 yr.

**Pregnancy Considerations**

- Emergency contraception (COC or progestin-only) pills are safe to use if pregnant.
- Copper IUD placement should not be used if the patient could be pregnant.

**DISPOSITION****Discharge Criteria**

Patient has tolerated OCP without vomiting

**Issues for Referral**

OB/GYN or primary care provider to discuss long-term contraception

**FOLLOW-UP****FOLLOW-UP RECOMMENDATIONS**

Discharge instructions and medications:

- Consider long-term prescription of OCPs for rest of the cycle.
- Advise the patient that pregnancy may occur with subsequent coitus.
- Consider a 2nd “back-up” prescription in case patient vomits.
- Encourage condom use for STI protection.

- Antiemetics generally are not needed with levonorgestrel but may be prescribed for use in case of vomiting or if other medication is used for postcoital contraception.
- Follow up with a health care provider to discuss long-term contraception within 2 wk.
- Obtain follow-up pregnancy test if next menses is >1 wk late.

**PROGNOSIS**

- Levonorgestrel—if given:
  - Within 1 day of unprotected intercourse: 1/1,000 chance of pregnancy
  - Within 2 days: 1/120
  - Within 3 days: 1/54
- Copper IUD: 1/100 chance of pregnancy

**COMPLICATIONS**

- Nausea/Vomiting (rare with progestin-only pill)
- Pregnancy (no greater risk for ectopic pregnancy)
- Emergency contraception will not disrupt an already implanted pregnancy nor cause birth defects.
- Bleeding, pain, cramping with copper IUD insertion

**REFERENCES**

**CODES****ICD9**

V25.03 Encounter for emergency contraceptive counseling and prescription

**PEARLS AND PITFALLS**

- Pitfalls:
  - Failure to obtain pregnancy test
  - Placing copper IUD in pregnant patient
  - Not ensuring appropriate follow-up
  - Patient fails to tolerate medication due to emesis and does not have timely access to repeat dose
- Pearls:
  - A minor’s right to access contraceptive services without parental consent varies from state to state. Know your state’s law.
  - Currently, only 9 states allow females <17 yr of age to obtain emergency contraception in pharmacies without a prescription.

## BASICS

### DESCRIPTION

- An empyema is a fibrinopurulent entity in the pleural space. This develops from complicated parapneumonic or pleural effusions.
- Direct extension of pneumonia is the most common cause, though extension from retropharyngeal, mediastinal, subdiaphragmatic, or paravertebral infections are possible.
- Empyemas should be considered in the differential diagnosis in a patient with prolonged fever and pneumonialike symptoms and signs.

### EPIDEMIOLOGY

#### Incidence

Current rates range from 1–14 per 100,000 children. The rate of MRSA empyema has been increasing from the turn of the 21st century (1).

### RISK FACTORS

- Pneumonia, particularly with bacteria associated with suppuration
- Anaerobic empyemas are associated with aspiration pneumonias and lung abscesses.
- Empyemas have been associated with lack of antibiotic treatment, age > 2 yr, longer preadmission fever duration, and ibuprofen use (2).

### GENERAL PREVENTION

- Some pneumococcal infections may be prevented by vaccination.
- Hand washing and precautions to limit spread of MRSA and other nosocomial infections can theoretically lower empyema risk.

### PATHOPHYSIOLOGY

- Stage I (exudative) days 1–3:
  - Pneumonia or other thoracic infection leads to local pleural inflammation.
  - A transudative pleural effusion forms.
- Stage II (fibrinopurulent) days 4–14:
  - Infectious pathogens enter pleural space.
  - WBCs enter the pleural space with a large inflammatory response.
  - Fibroblasts follow, creating a fibropurulent pleural mass with beginning loculations.
- Stage III (organizing) ≥ 2 wk:
  - The empyema organizes and forms a cortex or “rind.”
  - Fibrin deposits on both pleural surfaces can restrict lung movement and may lead to restrictive lung disease.

### ETIOLOGY

- Common pathogens:
  - *Staphylococcus aureus*, including MRSA, is most common.
  - *Streptococcus pneumoniae*
  - *Bacterioides* species with aspiration pneumonia

- Rare pathogens:
  - *Streptococcus pyogenes*
  - *Pseudomonas aeruginosa*
  - *Mycobacterium tuberculosis* (especially in developing countries)
  - *Mycoplasma* species
  - *Haemophilus influenzae* type b (post-Hib vaccine)
  - *Actinomyces*
  - Coccidiomycosis, blastomycosis, histoplasmosis

### COMMONLY ASSOCIATED CONDITIONS

- Pneumonia
- Parapneumonic effusion

## DIAGNOSIS

### HISTORY

- Most children have fever for several days.
- Cough, difficulty breathing, respiratory distress, and tachypnea are often present
- Older children may report pleuritic chest pain.

### PHYSICAL EXAM

- Fever, tachycardia, tachypnea
- Respiratory distress, retractions, splinting
- Dullness to percussion on affected hemithorax
- Decreased or absent breath sounds, with egophany
- Concurrent pneumonia can produce crackles or rales.
- A “tension” empyema can deviate the trachea to the opposite hemithorax. These patients pose a significant risk for airway compromise.
- Minimal signs likely indicate a viral or parapneumonic effusion instead of empyema.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

- CBC, C-reactive protein (CRP), and ESR for baseline inflammatory measurement and to track future daily trends
- Blood culture:
  - Up to 25% of children with empyema have positive, concordant blood cultures (3).
- Blood gas if in respiratory distress
- Pleural fluid testing from thoracentesis or chest tube placement:
  - Cell count and differential. Neutrophils almost always predominate.
  - Pleural fluid culture and Gram stain:
    - A positive Gram stain and culture confirms the diagnosis of empyema even with minimal WBCs in the cell count.
  - Acid fast bacilli stain and culture
- PT, INR, PTT prior to fibrinolytic therapy

### Imaging

- CXR: Upright PA and lateral if possible:
  - Compensatory scoliosis can be seen if splinting is present.
- Lateral decubitus x-ray to evaluate layering of the pleural fluid
- US:
  - US may locate the extent of fluid collection or presence of loculations.
  - It is also useful to guide the needle during thoracentesis in a cooperative or sedated patient.
- Chest CT is the imaging modality of choice:
  - Loculations and effusions can be clearly seen.
  - CT is especially useful if the fluid collection is heterogeneous and is often used for preoperative planning.

### Diagnostic Procedures/Other

- Diagnosis of empyema is confirmed if there is:
  - Turbid or purulent pleural fluid
  - A positive Gram stain or pleural culture
  - A relatively high WBC with neutrophil predominance in the pleural fluid
- Because obtaining pleural fluid is invasive, it should not be done without considering other diagnoses, considering antibiotic-only therapy, or considering operative treatment.
- If tuberculous empyema is suspected, an intradermal PPD placement should be done, though a negative PPD does not rule out TB.

### DIFFERENTIAL DIAGNOSIS

Pleural effusions without infection can have the same clinical and CXR findings. The differential therefore includes nonpurulent pleural effusions:

- CHF
- Nephrotic syndrome
- Acute chest syndrome with sickle cell disease
- Serositis from vasculitis (eg, systemic lupus erythematosus or connective tissue disorders)
- Pulmonary extension of ascites
- Intrapleural central line placement
- Sepsis and acute respiratory distress syndrome
- Effusion with WBCs can also be a marker for lymphoma.
- Chylothorax
- Hemothorax from trauma or vascular malformation

## TREATMENT

### PRE HOSPITAL

Assess and stabilize airway, breathing, and circulation.

### INITIAL STABILIZATION/THERAPY

- Assess and stabilize airway, breathing, and circulation.
- Airway: Intubate if the patient has a compromised airway or is in respiratory failure.
- Breathing: Maintain oxygenation and allow the patient to be in a comfortable position, usually sitting upright.
- Circulation: Maintain adequate circulatory volume:
  - Drops in BP may be seen if a large amount of pleural fluid is drained and intrathoracic pressure is thus relieved.

- In patients suspected of having TB empyema, such as recent immigrants or those with recent travel to an endemic area, appropriate airborne precautions should also be taken.

**MEDICATION**

- Parenteral antibiotic therapy should be started as soon as possible, although in stable patients this may be delayed if pleural fluid will be procured. Doing so can increase the yield on pleural cultures.
- S. aureus* and *S. pneumoniae* are the most common pathogens. However, coverage of MRSA and Gram-negative species is recommended:
  - Vancomycin 10–15 mg/kg/dose IV q6h (adult max 1,000 mg/dose) PLUS
  - Ceftriaxone 50 mg/kg/dose IV q8h (adult max 2,000 mg/dose)
- If anaerobes or *P. aeruginosa* are suspected due to lung abscess or aspiration pneumonia:
  - SUBSTITUTE ceftriaxone with piperacillin/tazobactam 100 mg/kg/dose IV q8h (adult max 3,000 mg/dose)
  - Consider an aminoglycoside to broaden coverage for *P. aeruginosa*.
- For penicillin/cephalosporin allergy: Vancomycin plus meropenem 20 mg/kg/dose IV q8h (adult max 1,000 mg/dose)
- If TB is suspected, contact your local infectious disease authority or the Centers for Disease Control and Prevention prior to triple therapy:
  - Isoniazid 10–15 mg/kg/dose PO qd (adult max 300 mg/dose) PLUS
  - Rifampin 10–20 mg/kg/dose PO qd (adult max 600 mg/dose) PLUS
  - Pyrazinamide 20–40 mg/kg/dose PO qd (adult max 2,000 mg/dose)

**SURGERY/OTHER PROCEDURES**

- No one treatment modality is universally superior to any other treatment (4,5).
- Thoracentesis:
  - This procedure can be recommended for patients with stage I parapneumonic effusions for symptomatic relief and diagnosis.
  - Repeated thoracenteses may be required.
- Chest tube thoracotomy:
  - This may be performed in the emergency department to drain a stage I or II empyema.
  - It should be considered for patients with significant respiratory distress or significant amount of effusion on imaging studies.
  - Because the drainage for empyema is likely viscous, empyema chest tube sizes should be of adequate caliber.

Age	Weight	Tube Size (French)
Neonate	<5 kg	8–12
0–1 yr	5–10 kg	10–14
1–2 yr	10–15 kg	14–20
2–5 yr	15–20 kg	20–24
5–10 yr	20–30 kg	20–28
>10 yr	30–50 kg	28–40
Adult	>50 kg	32–40

Adapted from King C, Henretig FM, eds. *Textbook of Pediatric Emergency Procedures*. 2nd ed. Philadelphia, PA: Lippincott Williams & Williams; 2008.

- It is unclear if thoracotomy should be the initial therapy or if surgical treatment should be reserved for children for whom medical management has failed.
- Open thoracotomy: Now relatively rare
- Video-assisted thorascopic surgery (VATS):
  - VATS has better postoperative and cosmetic results than open thoracotomy.
- Intrapleural fibrinolytic therapy:
  - Tissue plasminogen activator, streptokinase, or urokinase may be infused into the chest tube to disrupt the fibrinopurulent mass.
- Fibrinolytics may prevent operative therapy, though operative therapy may still be required after intrapleural fibrinolytics.
- Antibiotic-only therapy

**DISPOSITION**

**Admission Criteria**

- A child in no distress with a small empyema may not need admission if follow-up is assured within 1–2 days. Otherwise, most patients with empyema are admitted.
- The admitting hospital should have a surgery team comfortable with pediatric empyema.
- Critical care admission criteria:
  - Sepsis, unstable vital signs, mechanically ventilated patients, and other severely ill patients should be admitted to an ICU.

**Discharge Criteria**

- Generally, patients with empyema are admitted and not discharged from the emergency department.
- However, a very small empyema may be observed as an outpatient in a select few stable patients.

 **FOLLOW-UP**

**FOLLOW-UP RECOMMENDATIONS**

- Parenteral antibiotics should be continued even with surgical intervention.
- The patient should be followed for any worsening of the empyema.

**Patient Monitoring**

- Fevers >72 hr in duration with appropriate antibiotic treatment warrant surgical drainage.
- Serial CXRs
- Serial CBC, CRP, and ESR

**PROGNOSIS**

Patients who have early recognition and treatment for empyema do well, and the majority will return to normal function.

**COMPLICATIONS**

- Restrictive lung disease
- Airway compromise
- Thoracentesis and chest tube complications include pneumothorax, hemothorax, infection, or damage to mediastinal structures.
- Fibrinolytic complications involve bleeding either locally or elsewhere in the thorax.
- Operative complications can also occur with both VATS and open thoracotomy.

- Wheeler JG, Jacobs RF. Pleural effusions and empyema. In Feigin RD, Cherry JD, Demmler GJ, et al., eds. *Textbook of Pediatric Infectious Diseases*. 5th ed. Philadelphia, PA: Saunders; 2004.

 **CODES**

ICD9  
510.9 Empyema without mention of fistula

**PEARLS AND PITFALLS**

- Consider empyema in a patient with signs and symptoms of pneumonia
- Consider empyema if a large pneumonia
- Consider the airway when sedating a child for empyema drainage
- Large empyema or loculated empyema warrants more aggressive management.

# ENCEPHALITIS

Todd P. Chang

## BASICS

### DESCRIPTION

- Encephalitis is a usually infectious inflammation of brain parenchyma.
- Diagnosis requires 1 of 2 manifestations:
  - Altered mental status
  - Focal neurologic findings
- This is distinct from meningitis, which is meningeal inflammation without parenchymal involvement. However, both may occur concurrently.

### EPIDEMIOLOGY

#### Incidence

- 1,000–2,000 viral encephalitides are reported to the Centers for Disease Control and Prevention annually.
- The most common age for postnatal herpes simplex virus (HSV) encephalitis is between 11 and 17 days of age (1). (See Herpes Simplex Virus topic.)

### RISK FACTORS

- Unimmunized children are at higher risk of encephalitis from measles, mumps, rubella, varicella, polio, or influenza.
- Maternal herpes infection
- Travel to endemic areas for arboviruses

### GENERAL PREVENTION

- Meticulous hand washing
- Droplet precautions for most viral and nonviral causes
- Airborne precautions for TB, measles, or varicella
- Vector avoidance or mosquito repellents in endemic areas
- Vaccination may prevent encephalitis:
  - Varicella
  - Measles
  - Polio
  - Influenza
  - Japanese encephalitis
  - Yellow fever
  - Rabies

### PATHOPHYSIOLOGY

- Infectious encephalitis is spread to the CNS:
  - Via hematogenous routes OR
  - Via neural/axonal spread (HSV, varicella, polio, rabies)
- Cell-to-cell infection occurs rapidly and leads to cellular dysfunction or cell death.

### ETIOLOGY

- Viral causes are most common, though an etiology is not found in most cases.
- Arboviruses and enterovirus are more common during the North American summer months, whereas influenza is a winter pathogen.

- Common viruses:
  - Epstein-Barr virus
  - HSV
  - Varicella zoster virus
  - Cytomegalovirus (CMV)
  - Enterovirus
  - Influenza
  - Adenovirus
  - Arboviruses (eastern equine, western equine, Japanese, St. Louis, California, West Nile)
- Uncommon viruses include HIV, rabies, lymphocytic choriomeningitis virus, measles, mumps, rubella, polio, and human herpesvirus (HHV 6 or HHV 7).
- Nonviral infectious causes include *Mycoplasma pneumoniae*, *Toxoplasma gondii*, *Rickettsia rickettsii*, *Mycobacterium tuberculosis*, *Borrelia burgdorferi*, histoplasmosis, blastomycosis, coccidiomycosis, leptospirosis, neurosyphilis, *Cryptococcus* species, and cerebral malaria (usually *Plasmodium falciparum*).

## DIAGNOSIS

### HISTORY

- Fever or previous flulike symptoms
- Headache, neck pain, altered mental status, irritability, poor feeding, lethargy, hallucinations, seizure, or coma:
  - Headaches may improve when upright.
- Vomiting
- Significant travel to countries with TB, measles, and malaria endemics
- Exposure to mosquitoes or swampy areas
- Exposure to bats in North America increases suspicion of rabies.
- Other medical history or exposure history may explain the altered mental status.

### PHYSICAL EXAM

- A careful neurologic and mental status exam may show focal or general abnormalities:
  - Altered mental status
  - Cranial nerve palsies
  - Motor and sensory abnormalities, tremor
  - Ataxia and gait abnormalities
- Seizures, particularly focal seizures in infants, should prompt testing for HSV.
- Meningismus and signs of meningitis such as photophobia, headache, and neck stiffness may also be present.
- Papilledema may be seen in those with increased intracranial pressure (ICP).
- A skin exam may show rashes or bite marks, suggesting a vectorborne disease.
- Systemic signs, such as effusions in large joints (eg, knees, elbows), hepatosplenomegaly, or cardiopulmonary failure suggest a systemic infection or autoimmune process.

## DIAGNOSTIC TESTS & INTERPRETATION

### Lab

#### Initial Lab Tests

- Lumbar puncture (LP) is the mainstay of diagnosis:
  - CSF WBC  $>8$  cells/mm<sup>3</sup>, especially with monocyte or lymphocyte predominance, is concerning for possible encephalitis, though most are  $<500$ /mm<sup>3</sup>.
  - CSF opening pressure (abnormal if  $>28$  mm Hg)
  - CSF Gram stain and culture
  - HSV polymerase chain reaction (PCR)
  - Enterovirus PCR
  - Consider other assays in consultation with infectious disease specialists.
  - Consultation with public health authorities may be necessary to obtain lab assays for specific viruses.
- Viral samples may be procured from other body fluids, such as blood or nasal secretions.
- CBC as a baseline immunocompetency screen:
  - Neutropenia or lymphopenia may suggest an opportunistic pathogen.
  - Blast cells suggest CNS lymphoma or leukemia.
- Blood culture may yield a bacterial cause, especially if CSF cultures are negative.
- Electrolytes, especially sodium levels:
  - Low serum sodium ( $\text{Na}^+ < 135$ ) may indicate cerebral salt wasting or SIADH
  - High serum sodium ( $\text{Na}^+ > 145$ ) may indicate diabetes insipidus.
- Other tests to discern alternative causes of altered mental status:
  - Serum glucose level: Low or high
  - BUN and creatinine level (uremia): High
  - Ammonia level: High
  - Bilirubin level (kernicterus): High
  - Ethanol level: High
  - Toxicology screen: Positive
  - Serum osmolarity: Higher than calculated osmolarity
  - Consultation with a toxicologist and focused toxicology screening if appropriate

### Imaging

- CT brain without contrast is indicated to evaluate for trauma, cerebral edema, or intracranial hemorrhage:
  - CT brain is also used to rule out evidence of a mass, which may cause increased ICP, which is a relative contraindication to performing an LP.
  - Physical signs suggestive of intracranial lesion or increased ICP include:
    - Significant altered mental status
    - Papilledema
    - Focal neurologic finding
  - Cerebral edema or focal attenuation on CT may be consistent with encephalitis.

- CT brain with contrast is recommended if brain abscesses are suspected, and it has a higher detection rate than without contrast (3).
- MRI is recommended during admission if a causative agent cannot be found. Diffusion-weighted imaging and T2-weighted imaging are more likely to detect early viral encephalitis than other MR studies (4):
  - MRI may show temporal lobe hypodensity in HSV encephalitis.

**DIFFERENTIAL DIAGNOSIS**

- Meningitis
- Postinfectious encephalitis
- Acute demyelinating encephalomyelitis
- Brain abscess
- Neurocysticercosis
- Sepsis/Septic shock
- Seizure disorder and postictal period
- Hemorrhagic or ischemic stroke
- Traumatic brain injury or concussion
- Subarachnoid hemorrhage
- Encephalopathy:
  - Diabetic ketoacidosis
  - Electrolyte abnormalities (Na<sup>+</sup>, Ca<sup>2+</sup>, Mg<sup>2+</sup>)
  - Hyperammonemia from hepatic failure or metabolic disorder (eg, propionic acidemia)
  - Hypoglycemia
  - Uremia
  - Multifocal leukoencephalopathy
- Primary or metastatic neoplasm
- CNS leukemia
- Thyroid storm
- Lupus cerebritis
- Prion disease (eg, Creutzfeldt-Jacob)
- Toxins and drugs

**TREATMENT**

**PRE HOSPITAL**

- Maintain airway control.
- Establish IV access.
- Seizure control (See Medication, Second Line.)

**INITIAL STABILIZATION/THERAPY**

- Airway: Intubate if Glasgow Coma Scale is <8.
- Breathing: For inadequate respiratory effort, consider empiric administration of naloxone.
- Support oxygenation.
- IV access
- Obtain bedside glucose level.
- Minimize cerebral edema:
  - Elevate the head of the bed to 30 degrees.
  - Avoid hypotonic IV solutions.
  - Perform frequent neurologic exams.
- Seizure control (See Medication, Second Line.)
- Isolation precautions for the patient and staff

**MEDICATION**

**First Line**

- Acyclovir for suspected HSV encephalitis:
  - Neonates (<28 days): 20 mg/kg IV q8h (5)
  - Children and adults: 10 mg/kg IV q8h
- Ganciclovir for suspected CMV encephalitis: 5 mg/kg IV q12h

**Second Line**

- Seizure control:
  - If no IV access:
    - Diazepam 0.5 mg/kg (2–5 yr) PR
    - Diazepam 0.3 mg/kg (6–11 yr) PR
    - Diazepam 0.2 mg/kg (≥ 12 yr) PR
    - Midazolam 0.1 mg/kg IM
  - With IV access:
    - Lorazepam 0.1 mg/kg IV, max dose 2 mg; may repeat × 2, q3–5min
    - Phenobarbital 20 mg/kg IV load
    - Fosphenytoin 20 mg/kg IV load
  - If seizures still persist despite these treatments, secure the airway in conjunction with administering more potent anticonvulsants:
    - Pentobarbital coma: 10–15 mg/kg IV over 1 hr, then 1 mg/kg/hr; max 3 mg/kg/hr
    - Propofol 2 mg/kg IV, then 200 μg/kg/hr
- Cerebral edema control:
  - Mannitol 0.25–1 g/kg slow push over 5 min; may repeat q5min; max dose 2 g/kg over 6 hr
  - 3% hypertonic saline 6 mL/kg IV to raise Na<sup>+</sup> by 5 mEq/L, target 150–160 mEq/L
  - Dexamethasone 1–2 mg/kg IV bolus, then 0.25 mg/kg IV q4h (max 16 mg/day) and taper
  - Hyperventilation to reach a pCO<sub>2</sub> of 30–35 mm Hg. This should not be continued for more than a few minutes.
  - Cerebral edema interventions should prompt an immediate CT brain and neurosurgical consult.

**DISPOSITION**

**Admission Criteria**

Critical care admission criteria:

- Sepsis or patients with unstable vital signs despite intervention should be admitted to an ICU.
- All other patients with encephalitis should be admitted to an inpatient floor with neurologic monitoring.

**Discharge Criteria**

Children with encephalitis should not be routinely discharged from the emergency department.

**FOLLOW-UP**

**FOLLOW-UP RECOMMENDATIONS**

- Household contacts with fevers, chills, and flulike symptoms should be monitored closely for signs of encephalitis.
- Reporting is required for certain confirmed cases of epidemic encephalitis, such as West Nile virus.

**PROGNOSIS**

- Prognosis following encephalitis depends on the causative agent, degree of neuroinvasion, timeliness of available treatment, and ICP/cerebral perfusion pressure.
- Despite prompt treatment, HSV encephalitis can cause neurologic sequelae or death, though the risk is significantly lower with antiviral treatment.
- Seizures can occur for months to years following recovery from encephalitis.

**COMPLICATIONS**

- Neurocognitive deficits
- Sensorimotor deficits
- Seizure disorder
- Diabetes insipidus or SIADH

**CODES**

**ICD9**

- 054.3 Herpetic meningoencephalitis
- 072.2 Mumps encephalitis
- 323.9 Unspecified cause of encephalitis, myelitis, and encephalomyelitis

**PEARLS AND PITFALLS**

- Encephalitis usually features altered mental status or focal neurologic signs.
- Other diagnoses with encephalopathy should be ruled out.
- Maintain a high suspicion for HSV encephalitis, and consider empiric treatment.

# ENDOMETRIOSIS

Jeranil Nunez

## BASICS

### DESCRIPTION

- Endometriosis is ectopic, estrogen-dependent endometrial-like tissue located outside of the uterus.
- Most often located in the pelvis, the tissue can also be found nearly anywhere in the body (1):
  - Serosa of the uterus
  - Posterior cul-de-sac
  - Uterosacral ligaments
  - Ovaries
  - Fallopian tubes
  - Abdominal cavity
  - Rarely in the lungs, diaphragm, skin, or CNS
- It is seen almost exclusively in women of reproductive age; rare cases have been described in pre- or postmenarchal women.
- Endometriosis causes cyclic pain that is exacerbated during menstrual periods.
- The most concerning presentation of endometriosis is a ruptured endometrioma, a cystlike implant on ovaries that contains blood, fluid, and menstrual tissue. Patients with a ruptured endometrioma present with acute abdominal pain and a surgical abdomen on exam. Pain control, fluid resuscitation, and expedient surgical consultation are recommended.

### EPIDEMIOLOGY

#### Incidence

- True incidence is unknown
- Increased incidence seen in relatives of affected women

#### Prevalence

- Affects ~5–10% of women of reproductive age in the U.S. (2)
- Present in 12–35% of women of reproductive age and as many as 40% of adolescents undergoing laparoscopy for evaluation of chronic pelvic pain or dysmenorrhea (3)

### RISK FACTORS

- Early menarche
- Nulliparity
- Frequent or prolonged menses

### PATHOPHYSIOLOGY

- Hormonally responsive ectopic endometrial tissue spreads locally and hematogenously.
- Behaves similarly to endometrial tissue with cyclic proliferation and secretory and sloughing phases in response to hormonal fluctuations
  - Induces an inflammatory response with activation of macrophages and increased cytokine production leading to surrounding fibrosis and formation of adhesions

### ETIOLOGY

Theories include altered immune surveillance in the presence of either (4):

- Retrograde menstruation
- Hematogenous dissemination
- Metaplastic differentiation of coelomic epithelium
- Rarely, direct transplantation of endometrial tissue after pelvic or abdominal surgery (eg, C-section)

### COMMONLY ASSOCIATED CONDITIONS

- Infertility
- Endometriosis is found in higher frequency in women with hypothyroidism, fibromyalgia, chronic fatigue syndrome, and certain ovarian malignancies (endometrioid carcinoma, clear cell and mixed subtypes of ovarian cancer).

## DIAGNOSIS

### HISTORY

- Variable presentation often leads to delayed diagnosis. Symptoms do not correlate with severity of disease.
- Chronic pelvic or back pain, often cyclic, increased during menses
- Dysmenorrhea, usually severe
- Deep dyspareunia
- Cyclic bladder or bowel symptoms: Nausea, vomiting, bloating, diarrhea, urinary frequency
- Dyschezia
- Dysuria
- Chronic fatigue
- Infertility

### PHYSICAL EXAM

- Abdomen: Tenderness; peritoneal signs (guarding, rebound tenderness) in the presence of a ruptured endometrioma
- Pelvic: Nonspecific findings related to the site of endometrial implants such as:
  - Pelvic tenderness
  - Adnexal mass/tenderness
  - Uterosacral ligament nodularity or tenderness (diagnosed on rectovaginal exam)
  - Visible cervical or vaginal lesions: Reddish, reddish-blue, blue-black patchy lesions

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

- Pregnancy test to exclude pregnancy
- Serum CA-125 level is elevated in severe disease and is a nonspecific marker. Also elevated in other gynecologic disorders. CA-125 levels >30 IU/mL are suspicious for gynecologic disease (5).

- More recent studies investigating less invasive methods of diagnosing endometriosis include:
  - The presence of serum autoantibodies to Thomsen-Friedenreich antigen (elevated in women with endometriosis) (6)
  - Elevated levels of inflammatory markers in the serum of women with endometriosis such as tumor necrosis factor- $\alpha$ , C-reactive protein, or CCR1 (transmembrane chemokine receptor) mRNA expression on the surface of peripheral blood leukocytes (7)

### Imaging

US (transvaginal), CT, and MRI have limited diagnostic value but can aid in the diagnosis of an ovarian endometrioma and help map the extent of disease in the presence of deeply infiltrating endometriosis involving the bladder or bowel.

### Diagnostic Procedures/Other

Direct visualization of endometrial lesions and biopsy via laparoscopy (preferred), or laparotomy, is the gold standard for the diagnosis of endometriosis:

- Disease is staged according to anatomic location of the lesions and severity of involvement.
- Negative histology does not exclude disease.

### Pathological Findings

- Peritoneal implants have variable appearance:
  - Raised reddish, powder-burn, blue-black, white, or yellowish-brown irregularly shaped patches, with scarred or inflamed peritoneal surface adhesions
- Ovarian endometriosis are superficial implants as described above or cystlike structures (endometriomas) containing blood, fluid, and menstrual tissue “chocolate cysts.”
- Histologically: Similar to endometrial tissue with endometrial-like glands and stroma

### DIFFERENTIAL DIAGNOSIS

- Appendicitis
- Ovarian cysts
- Ovarian torsion
- Ectopic pregnancy
- Pelvic inflammatory disease
- Inflammatory bowel disease
- Irritable bowel syndrome
- Urinary tract infection
- Mittelschmerz
- Gastroenteritis
- Diverticulosis

## TREATMENT

### PRE HOSPITAL

- Pain control as needed
- If a ruptured endometrioma is suspected, IV crystalloid fluid resuscitation should be initiated.

### INITIAL STABILIZATION/THERAPY

- Other life-threatening emergencies should be ruled out first (eg, appendicitis, ectopic pregnancy, ruptured endometrioma, or hemorrhagic ovarian cyst).
- Hydration with IV crystalloid fluids may be necessary if the patient is unable to tolerate oral fluids or medications.
- Adequate analgesia with either PO or IV medications

**MEDICATION**

**First Line**

- Acetaminophen 650–1,000 mg PO q4h PRN
- NSAIDs:
  - Ibuprofen 400–600 mg PO q6h PRN
  - Ketorolac 15–30 mg IV or IM q6h PRN
- Morphine 0.1 mg/kg IV/IM/SC q2h PRN:
  - Initial morphine dose of 0.1 mg/kg IV/SC may be repeated q15–20min until pain is controlled, then q2h PRN.

**Second Line**

A trial of hormonal drug therapy for ~3 mo may be started in consultation with the primary care physician or gynecologist (8):

- Combination oral contraceptives such as:
  - Lo/Ovral: 1 pill PO per day
  - Ortho-Novum: 1 pill PO per day
- Androgens:
  - Danazol 600–800 mg PO per day
- Progestogens:
  - Medroxyprogesterone 10–20 mg PO per day
- Gonadotropin-releasing hormone analogs:
  - Leuprolide 3.5–7.5 mg IM per day

**SURGERY/OTHER PROCEDURES**

- Surgical excision or ablation of ectopic endometrial lesions is curative in some cases of pelvic pain refractory to medical management.
- Lesions can recur.

**DISPOSITION**

**Admission Criteria**

- Critical care admission criteria:
  - Hemodynamic instability unresponsive to fluid administration requiring vasopressor infusions
  - Acute surgical abdomen from ruptured ovarian endometrioma: Critical care or inpatient medical ward admission at the discretion of surgical consult
- Inpatient medical ward admission:
  - Refractory pain
  - Need for further observation or evaluation
  - Exploratory surgery for unclear diagnosis

**Discharge Criteria**

- Pain well controlled
- History and physical exam most consistent with a diagnosis of endometriosis exacerbation
- Gynecologic follow-up ensured

**Issues for Referral**

Referral to an OB/GYN specialist for further evaluation and management is recommended in all cases of endometriosis, especially if the following signs or symptoms are present:

- Chronic pelvic pain
- Infertility
- Suspicion for malignancy

**COMPLEMENTARY & ALTERNATIVE THERAPIES**

Complementary therapies such as herbal treatments, acupuncture, reflexology, and homeopathy have been reported to reduce pain symptoms in some women with endometriosis:

- There are no randomized controlled trials supporting these treatments in endometriosis.

**FOLLOW-UP**

**FOLLOW-UP RECOMMENDATIONS**

Discharge instructions and medications:

- Outpatient pain management regimen
- Trial of hormonal therapy, if necessary, after gynecologic consultation
- Gynecologic referral

**Patient Monitoring**

- Potential side effects of long-term use of analgesics and hormonal therapy
- Careful histories and annual physical exams are recommended.

**PROGNOSIS**

Some patients may exhibit persistent chronic pelvic pain and/or infertility despite maximal medical treatment and surgical excision of lesions.

**COMPLICATIONS**

- Morbidity and mortality is associated with multiple surgical interventions in patients with progressive, refractory symptoms:
  - Scarring
  - Formation or progression of abdominal and/or pelvic adhesions
  - Ureteral or bowel obstruction
  - Bowel perforation
- Chronic pelvic pain
- Ruptured cysts

**CODES**

- ICD9
- 617.0 Endometriosis of uterus
- 617.1 Endometriosis of ovary
- 617.2 Endometriosis of fallopian tube

**PEARLS AND PITFALLS**

- Endometriosis should always be considered in the differential diagnosis of chronic pelvic pain or infertility in girls and women of reproductive age.
- Diagnosis is made with surgical exploration and biopsy.
- Other causes for chronic pelvic pain should be ruled out.
- A significant percentage of women with endometriosis will have symptoms refractory to medical and/or surgical management.
- Certain cancers and other disorders have been seen in women with endometriosis. Annual physical exams are recommended in all women with endometriosis.

# ENVENOMATION, INSECT BITES AND STINGS

Mohan Punja

Robert J. Hoffman

## BASICS

### DESCRIPTION

- Insects are a class of animals within the largest and most diverse phylum—Arthropoda.
- Relevant insects can be divided into the major orders of Hymenoptera (ants, bees, wasps, and hornets), Diptera (mosquitoes, deerflies), Hemiptera (bed bugs), Lepidoptera (caterpillars), Siphonaptera (fleas), and Anoplura (lice).
- Though generally thought of as pests, insects play the vital role in our ecosystem of recycling organic compounds.
- The role of insects in medicine is related to their transmission of pathogens, immune system response to venom, or cutaneous and respiratory system irritation from body parts or secretions.

### EPIDEMIOLOGY

- Hymenoptera stings cause more deaths (40–50) annually than any other envenomation in the U.S.
- There are reported to be between 6 million and 12 million infestations of lice yearly.
- Bed bugs are an increasing problem, especially in urban cities:
  - There are likely millions of unreported insect stings or bites annually.
  - Bed bug infestation is epidemic in the U.S., with particularly heavy infestation in New York City.

### RISK FACTORS

Outdoor activities

### GENERAL PREVENTION

- Protective clothing including long-sleeve shirts and long pants
- Insect repellent
- Many baby soaps and oils contain fragrances that may attract insects.
- Traveling abroad:
  - Appropriate vaccination (eg, Yellow fever) and chemoprophylaxis as per CDC guidelines
- Appropriate mosquito avoidance (mosquito nets, insect repellent, close doors/windows):
  - Insect repellent with <10% DEET is generally considered safe.

### PATHOPHYSIOLOGY

- Hymenoptera: Bees, yellow jackets, wasps, hornets, and ants:
  - Hymenoptera venom contains a mix of peptides including histamine and melittin, which cause cell damage and degranulation of basophils and mast cells.
  - Anaphylaxis usually occurs within 15–30 min and is mediated by IgE; cross-reactivity occurs among vespid venoms.
  - Bees are known to be docile and can only sting once before dying.
  - African honeybees are an aggressive hybrid spreading across the southeastern U.S. and are known for being aggressive and responding to perceived threats in large swarms.
  - Fire ants, especially imported fire ants, infest the southern U.S. and are more aggressive; their unique alkaloid venom tends to cause more pain.
  - Alarm pheromones alert colonies of insects to swarm and attack potential threats, resulting in numerous stings.
  - Systemic toxicity generally occurs with anaphylaxis (not dose dependent) or with large numbers of stings.
- Several varieties of butterflies and moths contain urticating hairs that cause stinging and pruritus from a mechanical irritation; “stinging caterpillars” have spines containing venom typically causing burning pain, edema, and blistering.
- Blister beetles (also known as the Spanish Fly) contain Cantharidin, a vesicant that can cause topical irritation and blistering and if ingested can cause vomiting, GI mucosal sloughing with hematemesis and bloody diarrhea, and hematuria. Touching one’s eye after touching the toxin may cause keratoconjunctivitis or anterior uveitis. Generally, children who eat beetles should be less symptomatic than those ingesting the concentrated preparation.
- Lice include the pubic louse (also known as crabs), head louse, and body louse.
- Bed bugs are difficult to eradicate insects of the *Cimex* genus that infest furniture and bedding, feeding usually at night on human blood via painless bites that cause urticarial eruptions.

### ETIOLOGY

See Pathophysiology.

### COMMONLY ASSOCIATED CONDITIONS

- Viral encephalitides: Eastern equine encephalitis, West Nile virus/western equine encephalitis, Japanese encephalitis
- Papular urticaria is a delayed hypersensitivity reaction to bites/stings manifested by crops of erythematous papules.
- Worldwide, the following conditions cause substantial morbidity and mortality and in North America may be seen in the returning traveler: Malaria, dengue fever, leishmaniasis, lymphatic filariasis, Chagas disease/trypanosomiasis, yellow fever.

## DIAGNOSIS

### HISTORY

- The patient may be able to identify the specific organism after an obvious bite or sting.
- Patients often report immediate local effects such as stinging, paresthesias, and exquisite pain.
- Patients with anaphylaxis may complain of light-headedness or syncope or may arrive in cardiac arrest.

### PHYSICAL EXAM

- Insect bites are usually associated with localized erythema, swelling, and vesicles or pustules.
- Mosquito bites have an appearance of urticaria, characteristically with a central puncture, papule, or vesicle.
- Bed bug bites are dark red on fair-skinned individuals and often appear in linear clusters.
- With stinging caterpillars, the classic “gridlike” pattern may appear 2–3 hr after a sting.
- Stings to the oral mucosa or tongue from swallowed insects may produce edema that compromises the airway.
- Stings to loose skin with great capacity to swell, such as the periorbital area or scrotum, often develop an appearance that is difficult to distinguish from cellulitis.
- Inflammation from a bite or sting and inflammation with cellulitis may both be erythematous, warm, and swollen. Pruritus is suggestive of a bite or sting; pain is suggestive of cellulitis.
- Suspect anaphylaxis in patients appearing pale with wheezing, hoarse voice, or stridor with or without urticaria.
- Consider anaphylactic shock in young patients with sudden cardiovascular collapse or altered mental status.

**DIAGNOSTIC TESTS & INTERPRETATION**

**Lab**

**Initial Lab Tests**

- There are no routinely indicated lab tests.
- Serum tryptase levels may be helpful in follow-up in diagnosing allergic reactions when there is uncertainty.

**DIFFERENTIAL DIAGNOSIS**

- Food/Environmental allergy, food syndrome (eg, scombroid) trauma from sharp objects, and insect or other bite/sting
- Altered mental status: Head trauma, CNS infection, hypoglycemia, metabolic or electrolyte disturbance

**TREATMENT**

**PRE HOSPITAL**

Assess and stabilize airway, breathing, and circulation:

- If anaphylactic reaction, administer epinephrine and/or albuterol as per local protocol.

**INITIAL STABILIZATION/THERAPY**

- Assess and stabilize airway, breathing, and circulation.
- Pain control and local wound care are the mainstays of treatment.
- Retained stingers (eg, honey bees) or embedded hairs should be removed.
- Treatment of anaphylaxis and severe systemic toxicity are similar.

**MEDICATION**

**First Line**

- Itching:
  - Diphenhydramine 1 mg/kg PO/IM/IV q6h PRN
  - Nonsedating antihistamines such as loratadine 5–10 mg per day. These are less sedating but also less effective than diphenhydramine.
  - Topical anesthetic lotions may contain a variety of substances, such as benzocaine, ammonia, baking soda, and essential oils.
- Topical steroids:
  - Hydrocortisone 1–2.5% cream/ointment topical b.i.d.–q.i.d.
  - Triamcinolone 0.1% cream topical b.i.d.
  - Mometasone 0.1% cream/ointment topical per day
- Analgesia:
  - Ibuprofen 10 mg/kg/dose PO/IV q6h PRN
  - Ketorolac 0.5 mg/kg IV/IM q6h PRN
  - Naproxen 5 mg/kg PO q8h PRN

- Acetaminophen 15 mg/kg/dose PO/PR q4h PRN
- 1:1,000 epinephrine for anaphylaxis dosed at 0.01 mg/kg (max 0.3 mg/dose) IM repeated q5min PRN for anaphylaxis
- Prednisone 1–2 mg/kg PO/IM/IV per day
- Dexamethasone 0.15–0.5 mg/kg IV/SC/PO, max single dose 10 mg
- Albuterol 0.1 mg/kg up to 2.5 mg/dose in 3 mL saline by nebulizer q15min

**Second Line**

- For refractory hypotension during anaphylaxis, titrate IV epinephrine 1:10,000 to appropriate BP
- Consider glucagon (20–30 µg/kg bolus, then 5–15 µg/min) for epinephrine-resistant hypotension.

**DISPOSITION**

**Admission Criteria**

- Consider admission for patients with anaphylactic reactions that are severe, even if symptoms are controlled with medications in the emergency department.
- Critical care admission criteria:
  - Persistence of unstable vital signs, anaphylaxis requiring epinephrine infusion, or airway compromise

**Discharge Criteria**

- Most patients may be discharged home.
- Patients with generalized symptoms that resolve should always be observed for 4–6 hr in the emergency department:
  - Patients presenting with respiratory distress or anaphylaxis should be admitted.

**Issues for Referral**

- Allergist: Patients with anaphylaxis or generalized reactions for further testing and immunotherapy
- Ophthalmologist: Patients with eye complaints

**FOLLOW-UP**

**FOLLOW-UP RECOMMENDATIONS**

Discharge instructions and medications:

- Patients with anaphylaxis should be provided with appropriately dosed epinephrine autoinjectors in addition to 3–5 days of oral steroids and antihistamines.

**PROGNOSIS**

Most patients recover without complications within days.

**COMPLICATIONS**

- Cellulitis, impetigo
- Corneal abrasions
- Patients with comorbidities are at risk for uncommon sequelae (ie, patients with coronary artery disease are at increased for MI) such as MI, acute tubular necrosis, or multiorgan failure.
- Anaphylactic reactions may result in shock, multisystem organ failure, or death.

**ADDITIONAL READING**

- Hahn IH, Lewin NA. Arthropods. In Goldfrank LR, Flomenbaum NE, Lewin NA, et al., eds. *Goldfrank's Toxicologic Emergencies*. 8th ed. Stamford, CT: Appleton & Lange; 2006:1629–1642.
- Moffitt JE. Allergic reactions to insect stings and bites. *South Med J*. 2003;96(11):1073.

**See Also (Topic, Algorithm, Electronic Media Element)**

- Anaphylaxis
- Cellulitis
- Rash, Urticaria

**ICD9**  
989.5 Toxic effect of venom

**PEARLS AND PITFALLS**

- Avoid granuloma formation by considering stingers as foreign bodies that must be removed.
- Children will often scratch injuries, which may lead to bacterial infections; consider topical antibiotic prophylaxis with diffuse stings, or at the very least, schedule follow-up with a pediatrician.
- It is a common pitfall to underestimate the severity of an anaphylactic reaction. Carefully assess the airway and cardiovascular status, give IM epinephrine early, and reassess the patient frequently.
- Failure to provide an epi-pen is a frequent source of litigation.

# ENVENOMATION, MARINE

Mohan Punja  
Robert J. Hoffman

## BASICS

### DESCRIPTION

- Marine creatures may cause injury by envenomation, trauma, or ingestion.
- Injury by envenomation is extremely common, especially in coastal areas and specific parts of the world (eg, Australia); organisms found in and around North America are generally less toxic.
- Children may be unable to describe the specific offending organism, increasing the difficulty of directing treatment.
- Dead organisms washed ashore may cause injury to children playing in sand.

### EPIDEMIOLOGY

#### Incidence

Injuries are extremely common, and the incidence varies widely depending on location:

- Cnidarians, which include jellyfish and fire coral, are responsible for most envenomations.
- 2008 poison center data reported 785 jellyfish stings, ~1/2 of which occurred in patients < 19 yr of age. The numbers of unreported envenomations are likely dramatically higher.

### RISK FACTORS

Injuries are concentrated during warm months; occasionally, mass numbers of injuries may occur at a single location.

### GENERAL PREVENTION

- Children should wear protective footwear at the beach and protective clothes/wetsuits.
- Parents should be aware of posted warnings concerning infestations or local wildlife.

### PATHOPHYSIOLOGY

- The mechanism of injury varies widely depending on the organism involved.
- Jellyfish (including the Portuguese Man-of-War):
  - Tentacles of jellyfish have stinging cells that inject venom that may be myotoxic, neurotoxic, or even cardiotoxic. Local adverse reactions are common; anaphylaxis is rare.
- Fish:
  - Stingrays or skates: Tail contains a barb that can cause significant penetrating trauma in addition to significant localized pain and mild systemic toxicity from venom, which is heat labile.
  - These organisms typically must be directly stepped on to cause injury to a human.

- Catfish: Dorsal and pectoral fins contain spines causing self-limited local irritation and pain, typically to patients attempting to handle without gloves.
- Exotic fish:
  - Stone fish: Native Australian fish kept as pets. Highly toxic venom causes smooth and skeletal muscle paralysis. Locate antivenin (1 vial/sting) via a poison control center.
  - Lion fish: An exotic, colorful pet fish commonly causing mild, self-limited but painful envenomation by heat-labile toxin.
- Echinoderms: Sea urchins or starfish have hard, brittle spines filled with venom that may break off and lodge in skin. The animal is not itself venomous, but the spines may be coated with a heat-labile toxin.
- Sponges: Stationary animals attached to the seafloor or coral; they penetrate the skin with tiny spicules to cause a contact dermatitis and a delayed irritant dermatitis.
- Coral, particularly fire coral, may cause a very painful sting. This is distinct from a cut or abrasion, which often will become infected and ulcerate within days of the injury.

### ETIOLOGY

See Pathophysiology.

## DIAGNOSIS

### HISTORY

- The patient may be able to identify the specific organism after an obvious bite or sting.
- Patients may report reaching into an aquarium or attempting to handle pet fish, etc.
- Patients often report immediate local effects such as stinging, itching, paresthesias, and exquisite pain.
- Large numbers of patients from the same location may be due to an infestation of jellyfish.
- Intensely pruritic lesions occurring diffusely under clothing may be “sea bathers eruption,” a hypersensitivity reaction to the larval form of thimble jellyfish.
- Nausea, vomiting, and abdominal pain may be from the systemic effects of venom.
- Stridor, syncope, and difficulty breathing may signal anaphylaxis.

### PHYSICAL EXAM

- Erythema, blistering, vesicles, and urticaria often appear at the site of contact with the offending organism.
- Generalized edema of the affected extremity
- In the case of stingrays, a visible barb may be present in addition to gaping lacerations or only a small puncture wound.

- Tiny spicules may be visible within an abrasion.
- Linear papules or beaded streaks in a “whip mark” pattern may be seen with the Portuguese Man-of-War.
- Pruritic lesions occurring under clothing in the distribution of swimming trunks or clothes are seen with “sea bathers eruption.”

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

- There are no routinely indicated lab tests.
- CBC, basic metabolic panel, LFTs, and coagulation studies in patients who appear systemically ill

#### Imaging

- Plain films are indicated in evaluating for radiopaque retained foreign bodies such as the barb of a stingray.
- Advanced imaging (or surgical exploration) for penetrating trauma

### DIFFERENTIAL DIAGNOSIS

Sunburn, trauma from sharp objects, insect or other bite/sting

## TREATMENT

### PRE HOSPITAL

Decontamination: The patient should be separated from the offending organism, and the area should be irrigated with saline or saltwater:

- Vinegar or 5% acetic acid can be doused on the wound, or compresses soaked in a solution can be applied.
- Hot water is known to deactivate specific venoms (scorpion fish, lionfish, stonefish, sea urchins or sea stars, stingrays and skates). Water must be around 45°C, and the involved area should be immersed for 30–60 min. Take care not to scald patients.
- Urinating on the wound for the purpose of applying warm liquid against the skin is an unproven folk remedy to treat heat-labile toxins:
  - We do not recommend such use, but it may be an option if no medical care or source of hot water is available to irrigate the wound.
- Generally, animals causing puncture wounds are treated with hot water, while those causing urticaria and vesicular eruptions are treated with vinegar.
- Use a flexible straight edge, such as a credit card or driving license, to scrape adherent tentacles from the skin.
- Antibiotics for patients presenting with signs and symptoms of infection from injuries in salt or brackish water should cover gram-negative rods such as *Vibrio vulnificus*.
- Patients with nonhealing lesions or granulomas may need extended therapy for *Mycobacterium marinum* infection.

**INITIAL STABILIZATION/THERAPY**

- Pain control, tetanus prophylaxis, and local wound care are the mainstays of treatment.
- Oral antihistamines, occasionally with topical or oral steroids, are indicated for local urticarial lesions.
- Removal of spines or barbs lodged in skin; for sponges, remove spicules with adhesive tape; for jellyfish or sea urchins, use forceps or gloved hands.
- Antibiotic prophylaxis for open wounds in immunocompromised patients
- Address airway, breathing, and circulation in patients presenting with severe systemic toxicity.

**MEDICATION**

**First Line**

- Consider NSAID medication in anticipation of prolonged pain and inflammation:
  - Ibuprofen 10 mg/kg/dose PO/IV q6h PRN
  - Ketorolac 0.5 mg/kg IV/IM q6h PRN
  - Naproxen 5 mg/kg PO q8h PRN
- Acetaminophen 15 mg/kg/dose PO/PR q4h PRN
- Opioids:
  - Morphine 0.1 mg/kg IV/IM/SC q2h PRN:
    - Initial morphine dose of 0.1 mg/kg IV/SC may be repeated q15–20 min until pain is controlled, then q2h PRN.
  - Hydrocodone or hydrocodone/acetaminophen dosed as 0.1 mg/kg of hydrocodone component PO q4–6h PRN
- 1:1,000 epinephrine for anaphylaxis dosed at 0.01 mg/kg IM to a max of 0.3 mg/dose repeated q5min PRN for anaphylaxis
- Normal saline bolus 20 cc/kg for anaphylaxis
- Diphenhydramine 1 mg/kg up to 50 mg PO/IM/IV q6h PRN
- Prednisone 1–2 mg/kg PO/IM/IV per day

**Second Line**

Hypotension: Vasopressors such as dopamine or norepinephrine:

- Antivenoms generally do not exist for North American envenomations (there is antivenom for Australian wildlife such as stonefish).

**SURGERY/OTHER PROCEDURES**

- Surgical removal of barbs with transfer to trauma center if necessary
- Orthopedic surgery for injuries involving the joint
- Plastic surgery for disfiguring/facial injuries

**DISPOSITION**

**Discharge Criteria**

The vast majority of patients may be discharged home:

- Patients presenting with respiratory distress or anaphylaxis should be admitted.
- Observation in the emergency department is prudent in patients with progressive symptoms or neurologic deficits.

**Issues for Referral**

Contact a local poison control center or medical toxicologist for advice as needed.

**FOLLOW-UP**

**FOLLOW-UP RECOMMENDATIONS**

Discharge instructions and medications:

- Patients with anaphylaxis should be provided with appropriately dosed epinephrine autoinjectors.
- Recommend follow-up in the emergency department or with plastic surgery for open wounds left to close by secondary intention or with a possible retained foreign body.
- Plastic surgery follow-up for disfiguring injuries
- Consider antibiotics for immunocompromised patients or patients with devitalized tissue or puncture wounds.

**PROGNOSIS**

- Most marine envenomations in North America resolve after only minor irritation.
- The need for hospitalization is rare, as is systemic illness.
- In other areas, particularly the West Pacific and Australia, marine envenomations may be lethal.

**COMPLICATIONS**

- Local skin infection may occur; this is particularly common with coral injuries, which may even lead to skin necrosis and ulceration.
- Anaphylaxis may occur to any of these poisons, though it appears most common with jellyfish.
- Spines from sea urchins, as well as barbs from stingrays, may break off in the skin and remain as a foreign body.
- Severe envenomation may rarely result in shock or death in patients who are particularly sensitive to the toxin or in patients with an extremely high dose of venom injected.

- Brush DE. Marine envenomations. In Goldfrank LR, Flomenbaum NE, Lewin NA, et al., eds. *Goldfrank's Toxicologic Emergencies.* 8th ed. Stamford, CT: Appleton & Lange; 2006:1629–1642.
- Currie BJ. Marine antivenoms. *Clin Toxicol.* 2003; 41(3):301–308.
- Kizer KW. Marine envenomations. *Clin Toxicol.* 1983;21:527–555.

ICD9  
989.5 Toxic effect of venom

**PEARLS AND PITFALLS**

- Envenomations and stings in North America generally cause self-limited symptoms such as pain and often do not require emergency care in the emergency department.
- Home aquariums may contain exotic animals with unique toxicities. Consult the regional poison control center for direction or to obtain antivenom.
- Envenomations known to cause significant morbidity or death such as sea snakes, Irukandji syndrome from certain box jellyfish, and stonefish, are extremely uncommon in North America.
- Barbs from stingrays should be treated like penetrating trauma; do not remove a barb that could be lodged in a vital structure. The venom injected can cause pain for up to 48 hr.
- Irrigate and explore wounds to ensure removal of foreign bodies.

# ENVENOMATION, SCORPION

Frank LoVecchio

## BASICS

### DESCRIPTION

- Scorpion venom is neurotoxic.
- Autonomic, somatic, and cranial nerve excitation occurs.
- Symptoms begin within minutes of sting.
- Symptoms persist 1–72 hr.

### EPIDEMIOLOGY

#### Incidence

In 2007, 5,629 scorpion stings in patients <19 yr of age were reported in the U.S.:

- Including 1 fatality in a 2-yr-old child

### PATHOPHYSIOLOGY

- Scorpion venom is neurotoxic.
- Autonomic, somatic, and cranial nerve excitation occurs.
- The mechanism of action is caused by prolonged opening of sodium channels.
- In children, envenomation may result in severe illness, with altered behavior, excitation, and seizures.
- Onset occurs within minutes and progresses to maximum severity in about 1–2 hr but may persist for up to 48–72 hr.

### ETIOLOGY

- *Centruroides sculpturatus*, or bark scorpion:
  - The only toxic scorpion species in the U.S.
  - Found in the southern U.S., Mexico, Central America, and the Caribbean
- Many other species in Asia, Africa, Israel, South America, and the Middle East

## DIAGNOSIS

### HISTORY

- Usually a history of scorpion exposure and sting are readily available.
- Particularly in toddlers or nonverbal children, history of exposure might not be known.
- These cases may be particularly difficult.
- Local effects:
  - Pain
  - Hyperesthesia
- Systemic effects:
  - Coughing or dyspnea
  - Neurologic:
    - Altered mental status
    - Agitation
    - Involuntary muscle contractions
    - Blurred vision
    - Seizure
    - Agitation
    - Hypersalivation

### PHYSICAL EXAM

- Assess vital signs.
- A variety of abnormalities may result:
  - Tachycardia is typical, but bradycardia may occur.
  - HTN initially but hypotension later during severe toxicity
  - Hyperthermia
- Local tissue effects:
  - Lack of erythema
  - Pain
  - Hyperesthesia
- Autonomic effects:
  - Sympathetic symptoms:
    - Pulmonary edema
    - Agitation
    - Perspiration
  - Parasympathetic effects:
    - Hypersalivation

- Somatic effects
  - Involuntary muscle contractions
  - Restlessness
- Cranial nerve effects:
  - Roving eye movements
  - Blurred vision
  - Nystagmus
  - Tongue fasciculations
  - Loss of pharyngeal muscle control
- Grading of envenomation exists:
  - Grade I: Local pain and/or paresthesias at site
  - Grade II: Local pain and pain and/or paresthesias at a remote site
  - Grade III: Either cranial/autonomic or somatic skeletal neuromuscular dysfunction
  - Grade IV: Both cranial/autonomic and somatic skeletal muscle dysfunction

## DIAGNOSTIC TESTS & INTERPRETATION

### Lab

#### Initial Lab Tests

- Grade I and II envenomations:
  - None
- Grade III and IV envenomations:
  - BUN, creatinine
  - Electrolytes
  - Urinalysis
  - CBC
- Severely agitated patients:
  - Creatine kinase
  - Urine myoglobin
- Severe respiratory distress:
  - Blood gas analysis

### Imaging

- Chest radiograph for respiratory symptoms
- ECG for tachycardia

### Diagnostic Procedures/Other

ECG in grade II and greater

## DIFFERENTIAL DIAGNOSIS

- Snake, spider, insect envenomation
- Tetanus
- Diphtheria
- Botulism
- Overdose, dystonic reaction
- Seizures
- Infections

## TREATMENT

### PRE HOSPITAL

- Assess and stabilize airway, breathing, and circulation.
- Obtain vascular access.

### INITIAL STABILIZATION/THERAPY

- Assess and stabilize airway, breathing, and circulation.
- Begin IV fluid administration.
- Supportive care as follows
- Mild envenomations—grades I and II:
  - Oral analgesics
  - Tetanus prophylaxis
- Severe envenomations—grades III and IV:
  - Antivenom (no longer available in the U.S. but is available in Mexico)
  - Fab antivenom is undergoing trials in the U.S. and is available at participating institutions.
  - Tetanus prophylaxis
  - Hypertensive urgencies/emergencies:
    - Standard therapy such as labetalol
  - Hypotension:
    - IV fluid resuscitation and pressor therapy with dopamine
  - Severe agitation:
    - Benzodiazepine
  - Treatment for rhabdomyolysis, if present

### MEDICATION

#### First Line

- NSAIDs:
  - Consider NSAID medication in anticipation of prolonged pain and inflammation:
    - Ibuprofen 10 mg/kg/dose PO/IV q6h PRN
    - Ketorolac 0.5 mg/kg IV/SC q6h PRN
    - Naproxen 5 mg/kg PO q8h PRN
- Acetaminophen 15 mg/kg/dose PO/PR q4h PRN
- Opioids:
  - Morphine 0.1 mg/kg IV/IM/SC q2h PRN:
    - Initial morphine dose of 0.1 mg/kg IV/SC may be repeated q15–20min until pain is controlled, then q2h PRN.
  - Fentanyl 1–2  $\mu$ g/kg IV q2h PRN:
    - Initial dose of 1  $\mu$ g/kg IV may be repeated q15–20min until pain is controlled, then q2h PRN.
  - Codeine or codeine/acetaminophen dosed as 0.5–1 mg/kg of codeine component PO q4h PRN
  - Hydrocodone or hydrocodone/acetaminophen dosed as 0.1 mg/kg of hydrocodone component PO q4–6h PRN

- Local anesthetic:
  - Nerve blockade with long-acting local anesthetic may provide significant analgesia and reduce opioid requirement.
  - Lidocaine, maximum single dose 5 mg/kg
- Sedative/Anticonvulsant:
  - Midazolam: 0.1 mg/kg IV/IM:
    - Very short acting, so redosing may be necessary
  - Lorazepam 0.05 mg/kg IV
- Cardiovascular:
  - Labetalol: 0.3–1 mg/kg/dose IV q10min PRN
  - Dopamine: 2–5  $\mu$ g/kg/min IV; increase 5–10 mcg/kg/min as needed
- Tetanus toxoid: 0.5 mL IM

### Second Line

Antivenom: Current trial for new Fab product

### DISPOSITION

#### Admission Criteria

Critical care admission criteria:

- Grade III and IV envenomations require admission to an ICU.
- If antivenom is given with resolution of symptoms, observe for 1–2 hr if asymptomatic.

#### Discharge Criteria

- Grade I and II envenomations: Discharge after a short observation period (1–2 hr after sting occurred) for progression of symptoms.
- Grade III and IV envenomations given antivenom with resolution of symptoms can be discharged after ~1 hr of observation.

#### Issues for Referral

Consulting a medical toxicologist or local poison control center may be very useful.

## FOLLOW-UP

### FOLLOW-UP RECOMMENDATIONS

Discharge instructions and medications:

- If patient received antivenom, discuss signs and symptoms of delayed serum sickness.
- Discuss possibility of persistence of pain and paresthesias at site.
- Encourage patient to return if there is progression of symptoms.

### PROGNOSIS

- Most cases resolve without sequelae.
- Younger children are more likely to experience severe illness, including airway and respiratory compromise, shock, and death.

### COMPLICATIONS

- Respiratory arrest
- Seizure
- Shock
- Cardiac arrest
- Death

989.5 Toxic effect of venom

### PEARLS AND PITFALLS

- Maintain a high index of suspicion for scorpion stings in endemic areas when patients present with typical symptoms.
- Younger children are more likely to experience severe illness.

# ENVENOMATION, SNAKE

Dean Olsen

## BASICS

### DESCRIPTION

This topic will be a brief review of snakebites resulting from indigenous snakes of the U.S. These include:

- Crotaline subfamily (pit vipers):
  - Rattlesnakes
  - Copperhead
  - Cottonmouth
- Elapid family:
  - Coral snakes

### EPIDEMIOLOGY

Each year, ~3,000 envenomations are reported to poison centers in the U.S. Many are unreported:

- 90–95% are Crotaline
- 1–3% are Elapid
- Remainder are exotic snakes.
- ~20% of reported snakebites are in pediatric patients.

### RISK FACTORS

- Unsupervised outdoor activity where venomous snakes are prevalent
- Playing near woodpiles, heavy brush, or anywhere snakes are known to be present
- Keeping venomous snakes as pets or intentionally handling venomous snakes

### GENERAL PREVENTION

- Avoidance of areas known to contain venomous snakes
- Some studies suggest that wearing pants made of thick material, such as jeans, can decrease the amount of venom delivery if bitten.

### PATHOPHYSIOLOGY

- Snake venom is a complex mixture of proteins, peptides, and enzymes. The exact composition may vary, but there is significant cross reactivity between species.
- Venom is injected from fangs after a strike.
- Based on bite location and depth, it is possible to have a direct intravascular injection of venom. This may result in rapid onset of much more severe toxicity than intramuscular injection.
- Some bites are “dry,” meaning no venom was excreted or injected:
  - Due to coral snake fang location, up to 50% are dry bites.
  - Percentage of crotalid bites that are dry varies with species but ranges from 10–15%.
  - It is impossible to initially know if a bite was with or without venom injection.

- Crotaline snakes:
  - Fangs are located in front of jaw; envenomation from bite is more likely than from elapid snakes.
  - Hemotoxic and myotoxic venom causing coagulopathy and tissue destruction
  - Venom is usually injected subcutaneously, resulting in tissue damage that progresses proximally up the extremity over minutes to hours.
  - Rattlesnake bites may result in severe toxicity or death; copperhead and cottonmouth bites cause mild toxicity with virtually no reported deaths.
- Elapid snakes:
  - Fangs are located in rear of jaw. The only North American elapid, coral snakes strike and chew to advance teeth for fang contact with prey.
  - Much more frequently have a bite with no fang contact and no envenomation
  - Venom is much more potent than that of crotalid.
  - Neurotoxic venom that causes progressive weakness that can progress to respiratory paralysis

### ETIOLOGY

- Crotaline snakes:
  - *Crotalus* species: Eastern and western diamondback, sidewinder, numerous other species across Midwest and Southwest U.S. as well as Mexico
  - *Sistrurus* species: Massasauga and pygmy rattlesnakes
  - *Agkistrodon* species: Cottonmouth and copperhead
- Elapid snakes:
  - *Micrurus* species: Coral snake
  - *Micruroides* species: Western and Sonoran coral snakes
- Exotic snakes are not indigenous to the U.S. but are imported here for use in zoos or illegally to keep as pets.

### COMMONLY ASSOCIATED CONDITIONS

Alcohol intoxication

## DIAGNOSIS

### HISTORY

- History of a bite from a snake with local signs and symptoms of venom effect is strongly suggestive of crotaline snakebite.
- Some patients may not get an accurate identification of the snake.
- Crotaline bites result in pain and swelling that progresses over minutes to hours:
  - Nausea, vomiting, and a metallic taste in the mouth may ensue.
- Elapid snakebites may be asymptomatic initially with rapid onset of symptoms delayed many hours.
- Slurred speech, paresthesias, weakness, cranial nerve palsy, and paralysis may ensue.

### PHYSICAL EXAM

- Crotaline bites result in local, systemic, and lab effects:
  - Vital sign changes include hypotension and tachycardia.
  - Puncture wounds may be visualized. With significant envenomation, swelling with skin discoloration or ecchymosis is apparent.
  - Hemorrhage from the fang wound or elsewhere is possible.
  - Myalgias may result, as can compartment syndrome, with associated pain, paresthesia, and pulselessness. Pallor may or may not be present due to tissue injury and ecchymosis.
  - Obvious necrotic tissue damage at the site of the fang wound or extending proximally is possible, with significant swelling.
- Elapid bites result in neurotoxicity that may be delayed:
  - Slurred speech, paresthesia, fasciculation, weakness, paralysis, ptosis, diplopia, dysphasia, stridor, and respiratory paralysis

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

Crotaline snakebite may cause:

- Elevated PT/INR
- Thrombocytopenia
- Low fibrinogen and increased fibrin split products
- Elevated creatine phosphokinase
- Disseminated intravascular coagulation is rare.

##### Diagnostic Procedures/Other

Obtain ECG in all patients.

##### Imaging

X-rays should be obtained of the bite site to assess for fangs that may be retained in the skin.

### DIFFERENTIAL DIAGNOSIS

Nonvenomous snakebites

## TREATMENT

### PRE HOSPITAL

- Assess and stabilize airway, breathing, and circulation.
- Crotaline snakebites: A lymphatic constriction band may be placed proximal to the bite site to retard venom absorption and distribution to the systemic circulation.
- Coral snakebites: A compression bandage with an ACE wrap may be placed on the affected extremity.
- Transport to a center with antivenom is preferable.

### INITIAL STABILIZATION/THERAPY

- Assess and stabilize airway, breathing, and circulation.
- In crotaline envenomations, treatment is largely based on symptoms.
- Elapid snakebites are treated empirically even if no symptoms are present. Elapid bites are diagnosed with confirmed coral snake exposure and evidence of skin penetration.

**MEDICATION**

**First Line**

- CroFab, crotalin venom antibody, dose 4–6 vials over 1 hr:
  - This is a cleaved antibody; it does not result in serum sickness or severe allergic reactions as previous crotalid/rattlesnake antivenom.
  - Redosing may be necessary:
    - The patient is reassessed after completion of the infusion for evidence of continued swelling or coagulopathy; if present, an additional 4–6 vials in adults or in children are administered.
    - This is repeated until symptoms are controlled. Control is generally considered cessation of progression of swelling and systemic symptoms in addition to trend toward normal coagulation time and correction of thrombocytopenia.
    - Once control is achieved, maintenance doses are given as 2 vials q6h for 3 doses, a total of 6 additional vials.
  - For Crotalinae envenomations, antivenom should be considered as first-line therapy for those patients with moderate to severe envenomations.
  - All bites with progression of symptoms are treated with CroTaline Fab.
  - While each case must be individualized, in the vast majority of patients who have a moderate or severe envenomation, the benefits of antivenom therapy will outweigh the potential risks.
  - Antivenom given in a timely manner can reverse the coagulopathy and thrombocytopenia and halt progression of local swelling.
- Wyeth antivenom:
  - No longer recommended
  - Derived from horse serum, is uncleaved antibody with high incidence of allergic reactions and serum sickness
- Coral snake antivenom:
  - Dose is between 1 and 5 vials in children; 3–5 vials in confirmed bite, even if no symptoms
  - This is derived from horse serum and is not a Fab antivenom. Severe allergic reaction, anaphylaxis, and serum sickness are possible.
  - No longer produced in the U.S., but hospitals continue to stock expired antivenom.
  - The U.S. FDA has approved extension of the expiration date of certain antivenom:
    - It is recommended for hospitals to maintain coral snake antivenom, even if expired.
    - Use of any expired medication is an extraordinary measure taken when no other option is available.
    - Obtain consent from the patient and/or family prior to using expired antivenom.
- Exotic snake antivenom:
  - To treat exotic snakebite, such as cobra, adder, or mamba, a regional zoo or herpetarium is a good resource for antivenom.
  - They often stock antivenom to treat employees in the event one is bitten from their own exotic venomous snakes.

**Second Line**

- Tetanus toxoid is given to all patients with snakebite if tetanus booster is needed.
- Prophylactic antibiotics are usually not necessary.

**SURGERY/OTHER PROCEDURES**

- Fasciotomy may be indicated for confirmed compartment syndrome secondary to a snakebite.
- Most cases of compartment syndrome respond to antivenom.

**DISPOSITION**

**Admission Criteria**

Critical care admission criteria:

- All patients with significant envenomation or receiving antivenom should be admitted to a critical care unit.

**Discharge Criteria**

- Patients may be discharged after antivenom administration and improvement of condition.
- Asymptomatic crotaline snakebites should be observed in a monitored setting for 8 hr:
  - If no venom effect is noted, the patient may be discharged.

**Issues for Referral**

Consider consultation with a poison control center, medical toxicologist, or other clinician with experience managing venomous snakebites.

**FOLLOW-UP**

**FOLLOW-UP RECOMMENDATIONS**

Discharge instructions and medications:

- Follow up with primary care physician in 2 days.

**Patient Monitoring**

The patient should return to the emergency department if symptoms recur.

**PROGNOSIS**

- Most patients do well after treatment with antivenom.
- Crotaline snakebites result in low morbidity and mortality.

**COMPLICATIONS**

- Crotalid (rattlesnake):
  - Coagulopathy
  - Rhabdomyolysis
  - Tissue necrosis
  - Compartment syndrome
  - Dysrhythmia
  - Multisystem organ failure
  - Shock
  - Death
- Elapid (coral snake):
  - Paralysis
  - Respiratory insufficiency
  - Shock
  - Death

**See Also (Topic, Algorithm, Electronic Media Element)**

Call (800) 222-1222 to contact a local poison control center in the U.S.

ICD9  
989.5 Toxic effect of venom

**PEARLS AND PITFALLS**

- Snakebites may be “dry” bites with no venom injected, but it is impossible to differentiate between a dry and venomous bite initially.
- Crotalid bites (rattlesnake, copperhead, cottonmouth) have toxin that is hemotoxic and myotoxic.
- Rattlesnake bites can be deadly, copperhead and cottonmouth bites usually results in milder toxicity without fatality
- Some bites, particularly elapid (coral snake), may result in severe toxicity with no apparent fang puncture marks.
- Coral snake toxicity is delayed after the bite and is severe. If antivenom is available, empiric treatment based solely on the history of the bite is warranted.

# ENVENOMATION, SPIDER

Sophia Sheikh

Brent W. Morgan

## BASICS

### DESCRIPTION

- Spider envenomations discussed here include *Latrodectus mactans* (black widow) species, *Loxosceles reclusa* (brown recluse), and tarantulas.
- Mature female *L. mactans* spiders typically are 1–2 cm in size, shiny black with a red hourglass shape on their ventral abdomen. Immature females are brown, and their hourglass color can vary. The males are also brown but usually much smaller than females.
- *L. reclusa* are usually 1–3 cm, dark brown, and have a characteristic violin (or fiddle) shape. Other species of spiders can have a similar fiddle shape on their cephalothorax. However, none of these other species will have 6 eyes. Thus, spiders with 3 pairs of eyes and a fiddle shape will be brown recluses.
- Tarantulas (family Theraphosidae) range from 2.5–10 cm, usually are reddish brown to black, and are covered in hair.

### EPIDEMIOLOGY

- Spiders are ubiquitous throughout the world. Only a few spider species in the U.S. have fangs that can pierce the human skin and cause significant health effects.
- Brown recluse spiders are native to the central U.S., from the Gulf of Mexico states of Mississippi, Alabama, Louisiana, and Texas east to the Western Georgia region, and north to Kentucky:
  - They are not native to Florida or any state that borders the Atlantic Ocean other than Georgia. They are not native to any area west of Central Texas or north of Nebraska.
  - Generally, this means they are not native to Florida, the Atlantic Coast, the Northeast U.S., and the entire Western U.S., nor Alaska or Hawaii.
  - It is theoretically possible for a brown recluse to be transported to a nonnative state, though reports of this are lacking.
- Black widow spiders are native to nearly the entire continental U.S., with various species sometimes being specific for a geographic region, such as the southern black widow.
  - Black widow spiders are native to all inhabited continents of the world.
- In 2008, according to the American Association of Poison Control Centers (AAPCC), there were a total of 4,191 spider bites and/or envenomations. Of these exposures, 2,524 were from black widow spiders, 1,564 were from brown recluses, and 103 were from tarantulas.

### PATHOPHYSIOLOGY

- All spiders produce some degree of venom to paralyze their prey.
- They release their venom through hollow fangs. Most do not possess fangs long or sturdy enough to pierce human skin. Thus, only a few species are able to poison humans through their bite.
- The venom produced from spiders is more potent than venom from most snakes; however, the amount injected during a bite is much less. It is important to take into account the bite victim's size:
  - *L. mactans* venom contains alpha-latrotoxin, which opens presynaptic cation channels leading to the release of norepinephrine, acetylcholine, dopamine, and GABA. This explains the autonomic and neurologic dysfunction manifested by the bitten patient.
  - *L. reclusa* venom is cytotoxic and composed of hyaluronidase and sphingomyelinase D. They can produce a constellation of symptoms known as loxoscelism, which can either be cutaneous or systemic. Most bites do not produce skin ulceration, and even less will manifest systemic symptoms. Many alleged spider bite–induced skin ulcerations are actually other disease processes including MRSA infections and not spider envenomation.
  - Tarantula venom can paralyze its prey but rarely causes problems in humans. It mainly consists of digestive enzymes. The symptoms associated from a tarantula bite, besides pain, are mostly allergic reactions from urticating hair embedded in the bite wound.

## DIAGNOSIS

### HISTORY

- Bites usually occur when humans invade the spider's habitat (ie, while cleaning out attics or garages, disturbing woodpiles, soil, etc.).
- Often with necrotizing bites, such as that of a brown recluse, there will be no specific history of bite:

### PHYSICAL EXAM

- Bite marks from black widows and brown recluse spiders typically are too small to easily identify. However, those from the tarantula family usually can easily be located.
- *L. mactans* possible symptoms:
  - Local erythema (target lesion with central blanching) and pain that can be delayed
  - Within hours, muscle spasms and fasciculations can develop in the bitten extremity and spread centrally. Spasms can be severe enough to mimic a rigid abdomen or an MI:

- Other symptoms include HTN, CNS effects (seizures, psychosis, hallucinations, etc.), and cholinergic excess (lacrimation, diarrhea, bronchorrhea, increased secretions, mydriasis/miosis, etc.).
- Caution should be taken in the elderly and very young, as respiratory arrest and severe HTN can occur.
- *L. reclusa* possible symptoms:
  - Usually within minutes, pain and burning develops at the bite site.
  - A "bull's-eye" lesion can develop within 12 hr. It is characterized as 1–5 cm in diameter with a central blister encircled by a red erythematous ring that is further enclosed by a white blanched ring.
  - Over the next 1–3 days, the blister can open and become necrotic, spreading to the underlying tissue.
  - Systemic signs occur within 2 days of the bite and include nausea, vomiting, fever, chills, myalgias, and rarely hemolysis.
- Bites from tarantulas do not cause systemic signs but can produce pain and inadvertently lead to intense itching from hair that falls within the bite wound:
  - Tarantula hairs are especially irritating to the respiratory tract, skin, and eyes. This local inflammatory response can produce itching that lasts for weeks.

## DIAGNOSTIC TESTS & INTERPRETATION

### Lab

- *L. mactans*: Electrolytes, creatine phosphokinase, calcium, glucose, and possibly an ECG for those complaining of chest pain
- *L. reclusa*: CBC and chemistry for renal function. If concern for hemolysis, obtain a disseminated intravascular coagulation panel, haptoglobin, and urinalysis looking for hematuria.

### DIFFERENTIAL DIAGNOSIS

- Other spiders and insects can produce similar local symptoms (pain, erythema, swelling, itching, and ulceration) as those seen from the brown recluse and black widows.
- Bacterial infections (such as MRSA) and certain dermatologic or vascular conditions can produce necrotic skin lesions that may wrongly be attributed to brown recluse bites.

**TREATMENT**

**PRE HOSPITAL**

- Clean the wound.
- Cool compresses or intermittent use of ice packs to limit swelling and pain

**INITIAL STABILIZATION/THERAPY**

Assess and stabilize airway, breathing, and circulation.

**MEDICATION**

- Tetanus immunization status should be documented and updated as needed.
- Antibiotics should be given if an infection is suspected (prophylaxis is not recommended).
- Black widow:
  - Benzodiazepines: Act as muscle relaxant:
    - Lorazepam 0.05 mg/kg IV/PO q6h PRN, max single dose 2 mg
    - Most effective when combined with an opioid
  - Opioids: For analgesia and to potentiate benzodiazepine muscle relaxation:
    - Morphine 0.1 mg/kg IV/IM/SC q2h PRN
      - Initial morphine dose of 0.1 mg/kg IV/SC may be repeated q15–20min until pain is controlled, then q2h PRN.
- Brown recluse:
  - First-line therapy includes wound care and pain control.
  - NSAIDs:
    - Consider NSAID medication in anticipation of prolonged pain and inflammation.
    - Ibuprofen 10 mg/kg/dose PO/IV q6h PRN
    - Ketorolac 0.5 mg/kg IV/IM q6h PRN
    - Naproxen 5 mg/kg PO q8h PRN
  - The urticarial response from tarantula hair can be treated using antihistamines and steroids:
    - Diphenhydramine 1.25 mg/kg/dose PO/IV/SC/IM q6h PRN for itching, max dose 50 mg
    - Prednisone 1–2 mg/kg PO divided b.i.d. per day for 2–5 days, max single dose 60 mg/day
    - Dexamethasone 0.2 mg/kg IV/IM/PO per day × 1–2 days, max single dose 10 mg

**Second Line**

Black widow:

- Second-line therapy should be the horse-derived *L. mactans* antivenin:
  - Since it is horse derived, there is a small risk of anaphylaxis.
  - In a review of 163 patients with black widow spider envenomations, there was 1 documented case of anaphylaxis and death after administration of antivenin (1).

- Its indications include failure to control severe pain despite liberal use of first-line therapy; uncontrolled severe HTN; and respiratory distress in the elderly, pediatric, or severely ill.
- The antivenin is administered as 1–2 vials diluted in 50–100 mL of 5% dextrose or 0.9% sodium chloride solution, infused over an hour.
- It should not be given to those who are allergic to horse serum products.
- Skin testing is usually not recommended since it is neither sensitive nor specific in predicting who will have an adverse effect.
- Some authorities recommend pretreatment with antihistamines and having epinephrine infusion readily available.

**COMPLEMENTARY & ALTERNATIVE THERAPIES**

Brown recluse:

- Anecdotal therapies such as dapsone, erythromycin, and hyperbaric oxygen treatment lack scientific evidence to routinely recommend their use.

**SURGERY/OTHER PROCEDURES**

- General wound care practices should be sufficient for most cases of brown recluse bites. Occasionally, large or slow-healing wounds may require surgical wound debridement or skin grafting.
- For tarantula hair embedded in the eye, irrigation and surgical removal by an ophthalmologist may be needed.

**DISPOSITION**

**Admission Criteria**

- Admit patients with systemic signs, renal failure, uncontrolled pain, and those who receive the antivenin.
- For brown recluse bites, monitor for hemolysis.

**Discharge Criteria**

Monitor the patient for 6–8 hr. If no systemic symptoms develop and pain is adequately controlled without the use of antivenin, then the patient can be discharged with appropriate follow-up.

**Issues for Referral**

The ulcer that forms from brown recluse bites typically is limited and heals quickly; rarely it can take several weeks to heal. So it is important that these patients are adequately followed as an outpatient to ensure healing and no further complications arise.

**FOLLOW-UP**

**FOLLOW-UP RECOMMENDATIONS**

- Discharge the patient with prescriptions for adequate analgesia in cases of black widow spider bites:
  - Provide medication for both pain and muscle spasms.
- For brown recluse bites, the patient should be instructed on standard wound care, and follow-up should be ensured prior to discharge.

**PROGNOSIS**

- Fatalities from spider bites in the U.S. are extremely rare. Most patients recover without serious complications.
- Brown recluse bites have a variable prognosis, with some severe envenomations resulting in badly necrotizing lesions.

**COMPLICATIONS**

- Brown recluse bites may result in significant tissue loss and badly ulcerated lesions.
- Infection can develop if wounds are not properly cleaned and managed.
- Black widow bites may rarely result in death.

**REFERENCE**

1. Clark RF, Wethern-Kester S, Vance MV, et al. Clinical presentation and treatment of black widow spider envenomation: A review of 163 cases. *Ann Emerg Med.* 1992;21(7):782–787.

**ADDITIONAL READING**

**CODES**

ICD9  
989.5 Toxic effect of venom

**PEARLS AND PITFALLS**

- Black widow bites can usually be managed with parenteral opioids and benzodiazepines alone. Judicious use of antivenin is recommended.
- Most skin lesions diagnosed as necrotizing spider bite secondary to brown recluse are not the result of a spider bite at all. Overdiagnoses is extremely common, even in areas where brown recluse are not native.

# EPIDIDYMITIS AND ORCHITIS

Kajal Khanna  
Deborah R. Liu

## BASICS

### DESCRIPTION

- Epididymitis is an inflammatory reaction or infection of the epididymis, the tubular structure attached to the upper posterior part of each testicle that collects and stores sperm.
- Orchitis is an inflammation or acute infection of the testicle.
- Epididymo-orchitis involves infection spreading from the epididymis to include the testicle.
- In young adult males, epididymitis accounts for more days lost from service in the military than any other disease.

### EPIDEMIOLOGY

#### Incidence

- 1.2 per 1,000 prepubertal boys yearly
- Peaks for hospital admissions occur in the summer and winter (1).

### RISK FACTORS

- Obstructive anatomic abnormalities
- Genitourinary abnormalities (ureteral or vasal ectopia, bladder exstrophy)
- Anorectal malformations
- Indwelling urethral catheters
- Recent urinary tract instrumentation
- Uncircumcised boys: 3 times more common

### PATHOPHYSIOLOGY

Occurs as an inflammatory and usually postinfectious reaction to a bacterial or viral pathogen or as a complication of an urethral infection caused by the following:

- Sexually transmitted pathogens
- Genitourinary pathogens
- Hematogenous spread to the epididymis from a primary focus of infection (1,2)

### ETIOLOGY

- Neonatal epididymitis:
  - Result of ascending urinary tract bacterial infection (*Escherichia coli*, *Enterococcus faecalis*)
  - Hematogenous spread from primary focus (*Haemophilus influenzae* type b, *Streptococcus pneumoniae*, *Neisseria meningitidis*, *Salmonella* species)
- Prepubescent boys:
  - Typically culture negative, thought to be of postinfectious etiology (elevated titers for enterovirus and adenovirus seen in boys with epididymitis)

- Adolescents:
  - Usually STI (*Chlamydia trachomatis*, *Neisseria gonorrhoeae*, coliform bacteria)
- Various *Brucella* species may cause brucellosis that commonly presents as epididymo-orchitis in any age group:
  - The bacteria are contracted through ingestion of unpasteurized dairy products or other animal products.
- In boys with underlying structural or neurologic abnormalities of the genitourinary tract: *Enterobacteriaceae*, *Pseudomonas aeruginosa*
- Other causes: Trauma, systemic disease such as Henoch-Schönlein purpura
- Bacterial orchitis:
  - Results from extension of infection or inflammation from the epididymis (*E. coli*, *P. aeruginosa*, *Klebsiella* species)
  - From hematogenous seeding from another source)
- Viral orchitis: Mumps, enterovirus, adenovirus, varicella, plus others:
  - Mumps:
    - Orchitis occurs in 30% of patients.
    - Occurs typically 4–6 days after the onset of parotitis
    - Possible increased risk of infertility

## DIAGNOSIS

### HISTORY

- Can be difficult to differentiate between other acute scrotal complaints
- Scrotal pain:
  - Gradual in onset
  - Mild to moderate severity
  - Compared to acute pain of testicular torsion
- Progressive scrotal swelling
- Commonly associated symptoms:
  - Dysuria
  - Urinary frequency
  - Fever
- Rarely associated symptoms:
  - Nausea
  - Vomiting
- Longer duration of symptoms before seeking medical attention in comparison to testicular torsion

### PHYSICAL EXAM

- In differentiating epididymitis from testicular torsion, each of the following have been found to be statistically significant (3):
  - Normal testicular lie
  - Tender epididymis
  - Intact cremasteric reflex
  - Scrotal erythema usually present (though not statistically significant)
- Prehn sign:
  - Alleviation of pain with elevation of scrotum in epididymitis
  - May worsen pain in testicular torsion
  - Not consistent in children
  - Note presence and location of tenderness: Epididymis vs. testicle

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

- Urine testing should be obtained:
  - Urinalysis shows pyuria
  - Bacterial organisms responsible for infectious epididymitis may be isolated from urine or urethral specimens.
  - 40–84% of cultures from boys (typically prepubertal) diagnosed with epididymitis have no identifiable organism (4).
  - Young boys and infants are more likely to have pyuria or bacteruria.
  - Semen sample may be obtained in sexually mature males, though this is not commonly done in the emergency department setting.
- Optional: CBC or C-reactive protein may demonstrate inflammatory changes.

#### Imaging

US should be obtained in cases indeterminate for epididymo-orchitis and is the gold standard imaging test:

- May show enlarged epididymis of mixed echogenicity surrounded by reactive fluid
- Color flow Doppler US usually shows increased testicular or epididymal venous flow.
- 78.6% sensitivity, 96.9% specificity in detecting testicular torsion and decreased blood flow (5)
- Limitations: Blood flow may not be detected in a normal prepubertal testis because of smaller testicular size, typically in patients <8 yr (5).

### DIFFERENTIAL DIAGNOSIS

- Testicular torsion
- Testicular tumor
- Torsion of testicular appendages
- Scrotal hematoma/contusion/trauma
- Inguinal hernia
- Hydrocele

**TREATMENT**

**INITIAL STABILIZATION/THERAPY**

IV access and fluids if systemically ill

**MEDICATION**

- Neonatal epididymitis:
  - Initial antimicrobial therapy directed against uropathogens such as *E. coli*, *E. faecalis*:
    - If Gram stain suggests *E. coli*, consider 3rd-generation cephalosporin such as cefotaxime (50 mg/kg/dose IV q8h)
    - If Gram stain suggests *E. faecalis*, consider ampicillin (50 mg/kg/dose IV q6h) plus aminoglycoside, such as gentamicin (2.5 mg/kg/dose IV q8h)
- Nonbacterial epididymitis in prepubertal boys (culture negative):
  - Consider NSAID medication in anticipation of prolonged pain and inflammation
    - Ibuprofen 10 mg/kg/dose PO/IV q6h PRN
    - Ketorolac 0.5 mg/kg IV/IM q6h PRN
    - Naproxen 5 mg/kg PO q8h PRN
  - Morphine 0.1 mg/kg IV/IM/SC q2h PRN:
    - Initial morphine dose of 0.1 mg/kg IV/SC may be repeated q15–20min until pain is controlled, then q2h PRN.
  - Codeine or codeine/acetaminophen dosed as 0.5–1 mg/kg of codeine component PO q4h PRN
- Epididymitis in prepubertal boys (urinalysis positive):
  - Specific antimicrobial agents are dependent on regional susceptibilities:
    - Cephalexin 25–50 mg/kg/day PO divided q6hours × 10 days
    - Sulfamethoxazole/Trimethoprim (based on 6–12 mg/kg trimethoprim component) divided q12h × 10 days
    - Amoxicillin and clavulanic acid 20–40 mg/kg divided q8h × 10 days
- Epididymitis in adolescents (STI pathogens):
  - Ceftriaxone 250 mg IM × 1 PLUS
  - Doxycycline 100 mg PO b.i.d. × 10 days
- Epididymitis/epididymo-orchitis (due to systemic infection):
  - Antimicrobial therapy, 3rd-generation cephalosporins, directed against the suspected or isolated pathogens (typically *H. influenzae* type b, *Salmonella* species, *S. pneumoniae*, *Mycobacterium tuberculosis*, or *Brucella* species), typically hematogenous spread from primary focus:
    - Ceftriaxone 50 mg/kg/day IV for hematogenous spread
    - Ceftriaxone is not first-line therapy for brucellosis; consider gentamicin 5 mg/kg IV/IM per day × 7 days plus doxycycline as dosing above.
- Orchitis: Management of viral orchitis is supportive.
- Epididymo-orchitis is treated with antimicrobial therapy if the urinalysis is suspicious for a bacterial pathogen. Please refer to the antibiotics discussion above.

**SURGERY/OTHER PROCEDURES**

Surgical indications:

- Scrotal abscess
- Inability to exclude testicular torsion
- Suspected or proven ischemia caused by severe epididymitis

**DISPOSITION**

**Admission Criteria**

- Toxic appearance
- Scrotal abscess
- Infectious epididymo-orchitis that is severe or requires systemic antibiotics, such as brucellosis

**Discharge Criteria**

- Ability to take oral antibiotics
- Well-appearing without scrotal abscess

**FOLLOW-UP**

**FOLLOW-UP RECOMMENDATIONS**

- Bed rest:
  - Scrotal support with elevation
  - Follow up with urology.
- Failure of symptoms to improve within 3 days requires re-evaluation and possible hospitalization.

**Patient Monitoring**

- Follow up with urology for adjunctive imaging: Renal and bladder US and voiding cystourethrogram (VCUG).
- Neonates and infants diagnosed with epididymitis have a higher rate of anatomic abnormalities (6).
- Given the low yield of abnormal findings in older patients with a 1st episode of culture-negative epididymitis, consider selective use of VCUG evaluation after US (7).

**PROGNOSIS**

Complications such as scrotal abscess or orchiectomy are seldom seen with directed therapy and close follow-up of epididymitis.

**COMPLICATIONS**

- Scrotal abscess
- Chronic epididymitis
- Testicular infarction
- Infertility

**See Also (Topic, Algorithm, Electronic Media Element)**

- Scrotal Pain
- Scrotal Swelling
- Testicular Torsion

**CODES**

**ICD9**

- 604.90 Orchitis and epididymitis, unspecified
- 604.91 Orchitis and epididymitis in diseases classified elsewhere
- 604.99 Other orchitis, epididymitis, and epididymo-orchitis, without mention of abscess

**PEARLS AND PITFALLS**

- It may be difficult to differentiate testicular torsion from epididymitis based on history and physical exam.
- Color Doppler US and testicular scintigraphy are both highly specific in detecting testicular torsion but may miss the diagnosis of early or intermittent torsion if blood flow is still present.
- Urology evaluation may be critical.

# EPIDURAL HEMATOMA

Kara E. Hennelly  
Lois K. Lee

## BASICS

### DESCRIPTION

- An epidural hematoma (EDH) is a collection of blood between the skull and the dura mater (outermost layer of the brain).
- Prompt identification of EDHs in patients with head injury is critical, as they are life threatening yet are treatable with surgical intervention.
- EDH should be considered in any patient with head trauma and altered mental status.
- They are typically associated with a blunt impact to the head, although children may have seemingly minor mechanisms. ~50% of children who sustain an EDH fall from a height of  $\leq 5$  feet.
- EDHs are associated with skull fractures in 40–80% of pediatric patients, although less commonly in children  $> 2$  yr of age.

### EPIDEMIOLOGY

#### Incidence

- Epidural hematomas account for 1–3% of closed head injury admissions in pediatrics.
- Male to female predominance of 2–2.5:1
- Mortality rates from EDH range from 0–10%.

### RISK FACTORS

- Significant falls
- Head trauma while not wearing a helmet when biking, snowboarding, playing baseball, etc.
- Being in a motor vehicle accident without using the appropriate car seat/seat belt. Motor vehicle crashes are the most common cause of EDH in adolescents.
- Newborns delivered by vacuum or forceps extraction

### GENERAL PREVENTION

- Appropriate adult supervision to prevent falls in infants and toddlers
- Window guards on windows above the 1st floor
- Age-appropriate motor vehicle restraints
- Wearing helmets when appropriate

### PATHOPHYSIOLOGY

- An EDH occurs when there is:
  - A laceration of the vessels from an underlying fracture OR
  - A shearing force to the epidural arteries or veins
- Younger children typically sustain hemorrhage from dural venous disruption as opposed to vessel laceration.
- Older children and adolescents more commonly have lacerated meningeal arteries as the source of bleeding.
- 18–36% of patients have an arterial source of bleeding identified in the operating room. An additional 10–20% are found to have a venous source (meningeal veins, emissary veins, diploic veins, or dural sinuses). The remaining 30–40% have no source identified and are thought to have oozing from dural venous sites (1).

- Children more commonly sustain EDH in the frontal, parieto-occipital, or posterior fossa regions, in contrast to adults who more typically sustain EDH around the temporal bone with middle meningeal artery shearing.
- Children less commonly sustain EDH in the temporal region because the middle meningeal artery is not yet indented into the temporal bone, as in adult patients.
- As bleeding continues, mass effect takes place and signs of increased intracranial pressure (ICP) occur as the expanding hematoma displaces CSF, intracranial venous blood, and finally brain parenchyma within the fixed cranial space. If untreated, brain herniation may occur and result in death.
- Infants and young toddlers may tolerate elevations in ICP better than adults. This is because their sutures may remain open up to 18 mo of age, and they have larger subarachnoid and extracellular spaces.
- Anemia from hemorrhage may precede signs of increased ICP in these young children.

### ETIOLOGY

EDHs are typically sustained from trauma, including a direct blow to the head, falls, and abusive head trauma.

### COMMONLY ASSOCIATED CONDITIONS

An underlying skull fracture, if present, may be associated with an EDH.

## DIAGNOSIS

### HISTORY

- Concerning mechanisms should prompt an evaluation for EDH:
  - Fall from significant height ( $> 5$  feet)
  - Motor vehicle crash
  - Direct blow to the temporal region
  - Suspicion for abusive head trauma
- The classic history for an EDH is an initial loss of consciousness (LOC) with the impact followed by a lucid interval of minutes to hours where the child is relatively asymptomatic. As the hematoma expands, mass effect causes clinical deterioration, including headache, vomiting, and altered mental status.
  - The classic history is less common in children, occurring in 30–70% of patients (2).
- Pediatric patients more commonly experience headache, vomiting, and lethargy than the classic symptoms of EDH.
- Patients with small EDHs may be asymptomatic.
- Seizures occur in  $< 10\%$  of cases.
- Infants with EDHs may present with lethargy, irritability, repeated vomiting, or “not acting like him- or herself” after a history of head trauma.

### PHYSICAL EXAM

- Assess vital signs, especially noting evidence of the Cushing triad: Bradycardia, HTN, and irregular respirations, which indicate elevated ICP and impending herniation.
- A complete neurologic exam, including Glasgow Coma Scale (GCS) score, thorough motor exam to evaluate for possible hemiparesis or hemiplegia, and cerebellar function, should be performed.
- Pupillary exam noting reactivity to light and extraocular movements. With a dilated pupil, the hematoma is on the same side about 90% of the time (3).
- Palpate the scalp for hematomas and step-offs in the skull.
- Anterior fontanelle should be assessed for fullness or bulging in infants.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

Lab tests are secondary to imaging tests:

- CBC and type and screen may be considered to assess for anemia and as part of the preoperative evaluation.
- Blood glucose may be useful, as hyperglycemia is associated with poor prognosis with severe traumatic brain injury (4).
- PT, PTT, and INR should be sent to assess for coagulopathy and as part of the potential preoperative evaluation.

#### Imaging

- A noncontrast head CT scan should be obtained in patients with suspicion for EDH.
  - The CT appearance of EDH is classically a hyperdense egg-shaped biconvexity that does not cross suture lines.
  - Other important findings include mass effect causing midline shift, ventricular compression, gyral effacement, loss of gray–white matter differentiation (indicative of cerebral edema), and transtentorial herniation.
- Skull films may be helpful in children  $< 2$  yr for identifying a fracture, which would prompt a CT scan to evaluate for possible intracranial hemorrhage. However, absence of a skull fracture does not rule out intracranial hemorrhage.

### DIFFERENTIAL DIAGNOSIS

- Concussion
- Subdural hematoma
- Subarachnoid hemorrhage
- Diffuse axonal injury
- Scalp hematoma (in isolation)
- Skull fracture (in isolation)

## TREATMENT

### PRE HOSPITAL

- Prehospital care includes airway management based upon the skill level of the prehospital care providers.
- Cervical spine immobilization must be maintained if there is suspicion of C-spine injury.
- If the history is concerning by mechanism or symptoms for EDH but the initial neurologic exam is normal, serial neurologic exams must be performed.

### INITIAL STABILIZATION/THERAPY

- The initial management of any patient with closed head injury should include a basic ABCs approach.
- Oxygen should be administered to keep oxygen saturation >95%.
- Endotracheal intubation is required to maximize oxygenation and ventilation and protect against possible aspiration in the following situations:
  - Depressed mental status (GCS <9)
  - Rapidly deteriorating mental status
  - Pupillary abnormalities
  - Respiratory distress
  - Hemodynamic instability
- In patients who are endotracheally intubated, hyperventilation should be avoided unless there are signs of impending herniation. PaCO<sub>2</sub> should be maintained between 35 and 40 mm Hg to prevent cerebral ischemia.
- Patients with hypotension should receive fluid resuscitation (normal saline boluses of 20 mL/kg) to maintain cerebral perfusion pressure (CPP).

### MEDICATION

#### First Line

Mannitol (0.5–1 g/kg over 20 min) should be given for patients with impending herniation.

#### Second Line

Loading with antiepileptic medication (eg, fosphenytoin) is controversial. The rate of early posttraumatic seizures in patients with moderate to severe head injury is low (5–7%), and fosphenytoin minimally affects this rate (5). The risks and benefits of antiepileptic drugs must be carefully considered.

### COMPLEMENTARY & ALTERNATIVE THERAPIES

Elevate the head of the bed 15–30 degrees. This mild elevation may lower ICP without adversely affecting CPP.

### SURGERY/OTHER PROCEDURES

- Surgical craniotomy with hematoma evacuation and vessel repair is the standard treatment.
- Emergent craniotomy is indicated for EDH with:
  - Deterioration of mental status, evidence of elevated ICP, pupillary changes, hemiparesis, other focal neurologic findings, or cerebellar signs
  - Radiologic findings on CT: Temporal location, large size (thickness >10 mm), and midline shift
- Nonoperative management with close observation is an option with neurosurgical agreement in patients with normal neurologic exams and CT findings of small EDH (usually <30 mL and <10 mm thickness).

### DISPOSITION

#### Admission Criteria

- All patients with a diagnosis of EDH should be admitted to the hospital for close observation for at least 24–48 hr, especially postoperatively. Patients with a known epidural hematoma should be admitted to an ICU for close neurologic exam monitoring.

- The admitting hospital should have emergency access to head CT scanning, an appropriate operating room if needed, and experienced personnel who are able to monitor for neurologic changes in pediatric patients.
- Criteria for transfer to a pediatric trauma center after stabilization include:
  - GCS ≤12 in the field
  - Pediatric trauma score ≤8

### Discharge Criteria

- Patients should be observed for at least 24–48 hr after the injury or evacuation of EDH to evaluate for signs of hematoma expansion.
- Repeat CT scan is recommended prior to discharge to evaluate for a potentially expanding hematoma.

### Issues for Referral

If a pediatric neurosurgeon is not available, endotracheal intubation should be performed to secure the airway in any patient with depressed GCS, neurologic abnormality, or concerning radiologic findings (temporal location, >10 mm in size).

## FOLLOW-UP

### FOLLOW-UP RECOMMENDATIONS

- Resuming activity is at the discretion of the neurosurgeon and depends on the age of the child and extent of associated bony injury.
- Pediatric patients with severe traumatic brain injury may require ongoing neurorehabilitation.

### Patient Monitoring

Patients typically are reimaged in 4–6 wk to confirm there is no recurrent hemorrhage.

### PROGNOSIS

- Better neurologic outcomes are obtained in patients who undergo rapid diagnosis by CT scan and surgical intervention, if indicated.
- The most important factor in determining outcome in patients with EDH is their neurologic status prior to surgery.
- Neurologic sequelae such as seizures, hemiplegia, or cranial nerve abnormalities are more likely with acute deterioration, neurologic abnormalities, or altered LOC.
- 85% of patients with EDH have a good neurologic outcome.

### COMPLICATIONS

Delayed diagnosis can result in permanent neurologic sequelae such as seizures, hemiplegia, cranial nerve abnormalities, or death.

## CODES

### ICD9

- 852.40 Extradural hemorrhage following injury, without mention of open intracranial wound, with state of consciousness unspecified
- 852.50 Extradural hemorrhage following injury, with open intracranial wound, with state of consciousness unspecified

## PEARLS AND PITFALLS

- Early consultation with a neurosurgeon is necessary, as patients may rapidly deteriorate as the EDH expands.
- Infants with open sutures may initially have a better tolerance for an expanding EDH. Anemia from blood loss into the EDH may present before signs of increased ICP.
- Children more commonly sustain EDH in the frontal, parieto-occipital, or posterior fossa regions, in contrast to adults who more typically sustain EDH around the temporal bone with middle meningeal artery shearing.
- Posterior fossa EDH occurs after a fall onto the occiput and is usually associated with a skull fracture. Children may present with LOC, headache, and vomiting as well as dizziness, stiff neck, or cerebellar signs. They may have a subacute presentation but can deteriorate quickly due to brainstem compression.

# EPIGLOTTITIS/SUPRAGLOTTITIS

Rachel Gallagher  
Joshua Nagler

## BASICS

### DESCRIPTION

- Epiglottitis is an acute inflammation of the epiglottis that can rapidly progress to severe, life-threatening airway compromise.
- Inflammation may not be limited to the epiglottis but can also include the arytenoid cartilages, aryepiglottic folds, false cords, posterior tongue, and the uvula and therefore is more accurately termed *supraglottitis*.
- The vast majority of cases of supraglottitis are secondary to acute infection.
- Noninfectious etiologies of supraglottitis also exist, including direct trauma and thermal injury.
- Goals of therapy include maintenance of a patent airway, commonly with controlled intubation, and antimicrobial therapy.

### EPIDEMIOLOGY

#### Incidence

- Dramatic decline since widespread *Haemophilus influenzae* type b (Hib) vaccination began in the late 1980s
- The incidence of supraglottitis in children is 0.3–1.8 cases/10,000 admissions (1).
- Peak incidence is 2–5 yrs of age.
- Recent increase in mean age of presentation, with higher incidence in older children and adolescents (2)

### RISK FACTORS

- Unimmunized patients or patients with vaccine failure are at increased risk of supraglottitis caused by Hib. Vaccine failure occurs more commonly in premature children and those with developmental delay, Down syndrome, neutropenia, and immunologic dysfunction (3).
- Immunocompromised patients are at higher risk of less common pathogens including *Candida* and herpes-family viruses.

### GENERAL PREVENTION

Routine vaccination

### PATHOPHYSIOLOGY

- Hib infection most commonly occurs from bacteremic spread and seeding at the epiglottis.
- Most other pathogens cause local infection after penetration of the mucosal surface of supraglottic structures.
- Loosely attached submucosal tissue is easily distensible and allows rapid swelling.
- Inflammation and swelling of the epiglottis and surrounding structures lead to obstruction of the upper airway.
- Early disease may present with partial airway obstruction.
- Progression can lead to complete airway obstruction causing respiratory arrest.

### ETIOLOGY

- In unvaccinated patients or patients with failed Hib vaccination, Hib continues to be the primary cause of supraglottitis. 1/3 of Hib supraglottitis is due to confirmed vaccine failure (4).
- Other bacterial causes include group A beta-hemolytic streptococcus, *Streptococcus pneumoniae*, *Staphylococcus aureus*, *Klebsiella pneumoniae*, *Pseudomonas aeruginosa*, *Haemophilus parainfluenzae*, and nontypeable *H. influenzae*.
- Fungal causes: *Candida* is rare, but infection can occur in immunocompromised hosts.
- Viral: Herpes simplex virus type 1, varicella, and parainfluenza have all been isolated from confirmed cases.
- Trauma: Post-laryngoscopy or secondary to foreign bodies
- Inhalation injury from smoke, steam, or chemical fumes
- Mucosal injury from ingestion of hot foods/liquids or contact with caustic substances

### COMMONLY ASSOCIATED CONDITIONS

- Patients with varicella or other herpesviruses are at increased risk of group A beta-hemolytic streptococcus infection.
- Invasive *H. influenzae* results from hematogenous spread and therefore can be associated with meningitis and pneumonia.

## DIAGNOSIS

### HISTORY

- A typical history includes the acute onset of fever, sore throat, and respiratory distress.
- Symptoms are typically present for <24 hr:
  - ~75% of patients present within 12 hr of onset of symptoms.
- Additional symptoms include:
  - Drooling
  - Difficulty swallowing
  - Difficulty speaking, or “muffled voice”
  - Distress/Anxiety
- Post-vaccination era supraglottitis may present differently:
  - Patients are often adolescents or adults.
  - Predominant symptom is frequently severe pharyngitis rather than respiratory distress.
  - Onset is frequently more insidious.

### PHYSICAL EXAM

- Exam should be limited to avoid agitating a child, which may worsen airway obstruction.
- General appearance:
  - Often toxic appearing, anxious, or irritable
  - Respiratory distress is common
  - Tripod positioning: Sitting upright and leaning forward with the neck extended

- Vital signs:
  - Fever, often reaching 39–40°C (102.2–104°F)
  - Tachypnea and tachycardia are common.
  - Hypoxemia may be present in severe cases.
- Oropharynx:
  - To avoid agitation, defer exam of the mouth and throat in young children.
  - The posterior oropharynx is minimally inflamed despite severe dysphagia.
  - Drooling may be noted.
- Respiratory exam:
  - Distress is common.
  - Stridor increases with progressive disease.
  - Stridor will be absent in complete airway obstruction.
  - Lower lung fields are typically clear.

### DIAGNOSTIC TESTS & INTERPRETATION

- Supraglottitis is diagnosed clinically, often with confirmation of etiology by culture.
- Delay phlebotomy until the airway has been secured or the patient’s respiratory status is stable.

### Lab

- CBC, C-reactive protein (CRP), blood culture, and supraglottic culture for bacterial etiology and sensitivities should be obtained after the airway is secure.
- CBC may have elevated WBCs with left shift, though findings are nonspecific.
- CRP may be elevated, though findings are nonspecific.

### Imaging

- X-rays:
  - Lateral neck radiographs are not routinely used for diagnosis (5). When obtained:
    - Epiglottis appears thick and round, known as “thumb sign.”
    - Aryepiglottic folds are thickened.
    - Vallecular space is obliterated.
  - Chest radiographs should be obtained only to assess for alternative etiologies of symptoms.
- CT scan:
  - Rarely required
  - May identify other airway abnormalities including epiglottic or retropharyngeal abscess or foreign body

### Diagnostic Procedures/Other

- Laryngoscopy:
  - Direct laryngoscopy is the gold standard for evaluation of the supraglottis.
  - Airway evaluation is most safely performed in the operating room, when possible.
- Fiberoptic nasopharyngoscopy is an alternative means for visualization of the supraglottic structures in a stable patient without significant respiratory distress.

### Pathological Findings

Inflamed, erythematous, edematous epiglottis, arytenoids, and aryepiglottic folds with pooled airway secretions on direct laryngoscopy

**DIFFERENTIAL DIAGNOSIS**

- Croup (laryngotracheitis)
- Foreign body aspiration
- Bacterial tracheitis
- Peritonsillar abscess
- Retropharyngeal abscess
- Ludwig angina
- Pertussis
- Pharyngitis
- Anaphylaxis/Angioedema

**TREATMENT****PRE HOSPITAL**

If concern for supraglottitis:

- Minimize evaluation of the airway.
- Communicate with medical control regarding the pending airway emergency and need to mobilize operating room resources.
- Avoid attempts at prehospital intubation if possible.
- Provide nonpharmacologic anxiolysis.

**INITIAL STABILIZATION/THERAPY**

- Initial stabilization focuses on maintaining a patent airway.
- Patients with stridor or progressive respiratory distress are at high risk for complete airway obstruction and require rapid airway management:
  - Endotracheal intubation should be performed in the operating room whenever possible.
  - Inhaled anesthetic induction allows the patient to maintain airway tone and spontaneous respiratory effort until adequately sedated.
  - An endotracheal tube 1 size smaller than indicated by the patient's age/size is recommended.
  - Skilled anesthesiologists and surgical staff should be present.
- Patients with insidious onset of symptoms concerning for supraglottitis and with minimal respiratory distress are at lower risk for complete airway obstruction:
  - If a patient is low risk and cooperative, initiate supplemental oxygen.
  - Obtain portable airway films, or have skilled airway providers accompany the patient to the radiology suite.
  - Consider nasopharyngoscopy.
  - Administer broad-spectrum antibiotics.

**MEDICATION****First Line**

Broad-spectrum antibiotics including:

- Ceftriaxone 50 mg/kg IV q24h OR
- Ampicillin/sulbactam 50 mg/kg IV q6h

**Second Line**

- For possible MRSA: Vancomycin IV 40–60 mg/kg/day divided q6–8h
- For suspected *Candida*: Fluconazole IV 6 mg/kg/day
- Duration of antibiotic therapy is 7–10 days.
- Steroids are not routinely indicated in the management of supraglottitis.

**SURGERY/OTHER PROCEDURES**

- Nasopharyngoscopy is used diagnostically in stable patients at low risk.
- Direct laryngoscopy in a controlled setting is the gold standard for diagnosis and is most commonly followed by endotracheal intubation to maintain the airway.
- Emergent cricothyrotomy or tracheostomy may be required if:
  - A patient cannot be successfully intubated OR
  - A patient presents with complete airway obstruction
- Although rare in children, drainage of epiglottic abscesses may be required.

**DISPOSITION**

Critical care admission criteria:

- All patients should be admitted to the ICU for continued airway management.

**Issues for Referral**

- Ideally, pediatric intensivists, otolaryngologists, and anesthesiologists co-manage patients with supraglottitis.
- Interhospital transfer is best performed by a critical care transport team when available.

**FOLLOW-UP****FOLLOW-UP RECOMMENDATIONS****Patient Monitoring**

Continuous cardiorespiratory monitoring until the patient's status has improved

**DIET**

NPO during acute illness

**PROGNOSIS**

In the absence of hypoxic events or associated illness, patients generally recover completely within 1–2 wks.

**COMPLICATIONS**

- Inability to safely manage the airway can lead to hypoxemia or respiratory arrest and may require emergent cricothyrotomy or tracheostomy.
- Hematogenous spread, particularly with Hib, can result in meningitis or sepsis.
- Postobstructive pulmonary edema occurs in <10% of cases (6).
- Abscess formation on the lingual surface of the epiglottis is a rare complication, seen primarily in older patients.

**See Also (Topic, Algorithm, Electronic Media Element)**

- Croup
- Upper Airway Obstruction

**CODES****ICD9**

- 464.30 Acute epiglottitis without mention of obstruction
- 464.31 Acute epiglottitis with obstruction
- 464.50 Supraglottitis, without mention of obstruction

**PEARLS AND PITFALLS**

- Consider supraglottitis in any child with fever and stridor.
- Avoid any agitation in the patient with possible impending airway obstruction.
- Mobilize resources to expedite controlled intubation in the operating room as early as possible.
- Initiate broad-spectrum antibiotics as soon as access is obtained.
- Older patients tend to have a more insidious presentation and are less likely to require endotracheal intubation.
- Stable patients at low risk for supraglottitis can undergo evaluation with radiography and possibly direct or indirect visualization of glottic structures.
- Patients with high suspicion for disease are best managed with controlled intubation in the operating room.

# EPISTAXIS

Audrey Le  
Sandip Godambe

## BASICS

### DESCRIPTION

Epistaxis is bleeding originating from the naris or both nares.

### EPIDEMIOLOGY

#### Incidence

- In a seminal early study, epistaxis occurred in 30% of children <5 yr of age and 56% of children 6–10 yr of age (1).
- The estimated annual incidence in those <2 yr of age is 19 per 100,000 (2).
- Incidence is higher during winter months secondary to low humidity.

### RISK FACTORS

- Nosebleeds occur in children of all ages, but those between the ages of 2 and 10 yr have more frequent occurrences.
- Concurrent upper respiratory infections predispose to more friable nasal mucosa.
- Allergic rhinitis

### GENERAL PREVENTION

- Limiting local trauma by avoiding nose picking and vigorous nose blowing
- Hydrating the local nasal mucosa can reduce mucosal irritation and prevent nosebleeds:
  - Saline sprays or drops
  - Ointments such as petroleum jelly
  - Augmenting the humidity of the environment with a cool mist vaporizer or humidifier
- Patients who use intranasal medications can be instructed to point the spray laterally.

### PATHOPHYSIOLOGY

- The internal and external carotid arteries supply blood to the nasal cavity and end in multiple anastomoses, the most important of which is the Kiesselbach plexus:
  - The Kiesselbach plexus (Little area) is a venous vascular formation that is firmly adherent to the anterior nasal septal cartilage. The mucosa overlying this plexus is thin, fragile, and prone to injury. Anterior bleeds resulting from insult to this area account for ~90% of epistaxis.
  - The Kiesselbach plexus is supplied by the anastomoses of 4 arteries: Anterior ethmoid artery, great palatine artery, sphenopalatine artery, and superior labial artery.
- Bleeding originating from the posterior aspect of the nasal cavity from insult to the sphenopalatine artery, though less common, tends to bleed more profusely.

### ETIOLOGY

- In children, the most common cause of epistaxis is local trauma from nose picking or local mucosal irritation with upper respiratory tract infections, rhinitis, or sinusitis.
- Direct facial trauma or a foreign body in the naris can also cause bleeding.
- Improper application of intranasal corticosteroids can lead to nosebleeds.
- Sniffing cocaine, heroin, or glue can cause epistaxis.
- Nasal neoplasms are rare but are suggested by recurrent persistent unilateral bleeding and nasal obstruction.

### COMMONLY ASSOCIATED CONDITIONS

- Systemic diseases including liver diseases affecting the synthesis of factors in the coagulation pathway, renal failure, hematologic malignancies, or idiopathic thrombocytopenia can be associated with epistaxis.
- Congenital coagulopathies, such as hemophilia and von Willebrand disease, or acquired coagulopathies from heparin, enoxaprin, or warfarin can increase the risk of nosebleeds.
- Aspirin and NSAIDs alter platelet function.
- Garlic, ginkgo, and ginseng are alternative medications that inhibit platelet function.
- Osler-Weber-Rendu disease, or hereditary hemorrhagic telangiectasia, is characterized by fragile telangiectasias and arteriovenous malformations that can lead to significant bleeding.
- HTN, though not independently associated with nosebleeds, can make them more difficult to control.

## DIAGNOSIS

### HISTORY

- Origin of the nosebleed (bilateral or unilateral)
- Duration and severity of the bleed
- Associated nasal obstruction
- History of nasal or facial trauma
- History of possible foreign body
- Pre-existing medical conditions, medications, or drugs of abuse
- Personal or family history of easy bruising or bleeding may suggest an underlying coagulopathy.

### PHYSICAL EXAM

- The nasal cavity should be viewed using a good light source and a nasal speculum for optimal visualization of any source of bleeding. Clots preventing adequate visualization should be cleared gently.

- Visualization may be enhanced with application of a topical vasoconstrictive medication such as phenylephrine. This may be applied by nasal spray or gauze/cotton soaked in the solution.
- If no anterior source is identified, nasal endoscopy may be necessary to identify the source of active bleeding and will likely require consultation with an otorhinolaryngologist.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

- Lab studies are usually not indicated in easily controlled, simple anterior nosebleeds.
- The history and physical exam may direct the clinician to evaluate hematologic, coagulation, hepatic, or renal function problems:
  - CBC, PT, and PTT should be obtained on patients with significant bleeding.
  - Patients on anticoagulation medications may require a coagulation panel.

#### Imaging

CT scanning may be indicated for patients with significant facial trauma or when there is suspicion of a tumor in those with recurrent or recalcitrant nosebleeds.

#### Diagnostic Procedures/Other

Patients with recurrent nasal bleeding, particularly unilateral, may need to be assessed for an occult nasal foreign body or tumor by nasal endoscopy.

### DIFFERENTIAL DIAGNOSIS

See Etiology and Commonly Associated Conditions sections.

## TREATMENT

### INITIAL STABILIZATION/THERAPY

- Keep the head elevated but not hyperextended, as the latter will cause the flow of blood backward into the pharynx:
  - This may trigger a gag response and vomiting or can result in aspiration of blood.
- Most minor epistaxis will cease with 5–20 min of direct continuous pressure.
- An ice pack placed over the dorsum of the nose can induce vasoconstriction and aid hemostasis.
- A gauze roll placed between upper lip and gums may help compress superior labial artery.

**MEDICATION****First Line**

- Inserting a piece of gauze soaked with a nasal decongestant spray, oxymetazoline, or 1:10,000 epinephrine or phenylephrine into the naris over the anterior nasal septum for 5–10 min can induce local vasoconstriction and stop bleeding (3,4).
- Daily application of antiseptic cream (chlorhexidine/neomycin) to the nostrils can prevent recurrence (5,6).

**Second Line**

- Other medications such as aminocaproic acid, factor supplement, or vitamin K to reverse anticoagulation should be guided by the history. The risks for thrombosis must be weighed against the risk of excessive bleeding:
  - Aminocaproic acid 100–200 mg/kg IV/PO, max 30 g/day
  - Factor VIII: 50 units/kg raises factor to 100%
  - Factor IX: 50 units/kg raises factor to 50%
  - Vitamin K 0.5–5 mg PO/SC/IM
- Empiric antibiotic therapy should be considered when nasal packing is required. If prescribed, antibiotics should be taken until the packing is removed (see below):
  - Cephalexin 25–50 mg/kg/day divided q.i.d.
  - Amoxicillin/Clavulanic acid: 25–45 mg/kg/day divided b.i.d.
  - Clindamycin 10–30 mg/kg/day divided t.i.d.
  - Trimethoprim/Sulfamethoxazole 5–10 mg/kg/day divided b.i.d.

**SURGERY/OTHER PROCEDURES**

- If active anterior bleeding is identified, cautery using silver nitrate sticks or thermal cautery after application of local anesthesia can be effective treatments. This should be limited to 1 side of the nasal septum to avoid perforation.
- Nasal packing with either a commercial product that expands when wet or with petroleum gauze strips may be required in nosebleeds impervious to other treatments (7,8):
  - Packing can be removed after 15–30 min for re-evaluation or left in place to be removed at follow-up visit.
  - Although uncommon, patients with bleeding after packing removal may require specialist consultation for repacking left in place for up to 3 days.
- Prophylactic antibiotics may be considered in children with nasal packing to reduce the risk of toxic shock syndrome and sinusitis (4,9,10). See Medication section.
- In rarer cases when cessation of bleeding is not achieved with cautery or packing, the otorhinolaryngologist may need to surgically ligate the bleeding vessels (11).
- Posterior nosebleeds are more refractory to simple measures and usually require the attention of an otorhinolaryngologist for posterior nasal packing, endoscopic cauterization, or surgical ligation of the vessel.

**DISPOSITION****Admission Criteria**

- Most patients with uncomplicated anterior nosebleeds responsive to simple first-line measures may safely be discharged home.
- Admission is advisable for:
  - Any bleed significant enough to lower the hemoglobin level
  - Any bleed leading to aspiration. This is seen more commonly with posterior nosebleeds.
  - Patients with posterior packing since they can have apnea and hypoxia
- Critical care admission criteria:
  - Any bleed significant enough to cause hemodynamic instability
  - Any bleed leading to airway compromise

**FOLLOW-UP****FOLLOW-UP RECOMMENDATIONS**

- All patients should be given instructions on simple first-line measures for control of nosebleeds as well as general preventative measures:
  - Use a humidifier in the room to increase ambient humidity.
  - Keep the nasal mucosa hydrated with saline washes or gels applied 3 or 4 times daily.
  - If a nosebleed occurs at home, apply continuous pressure by firmly squeezing the soft part of the nose for 10–15 min while leaning forward.
- Patients with nasal packing should follow up within 1–2 days. They may require antibiotics with coverage for staphylococcal and streptococcal organisms while the packing remains in place.
- Based upon the history and severity of the nosebleeds, patients may require follow-up with an otorhinolaryngologist for further evaluation.

**COMPLICATIONS**

- Nasal packing may be complicated by sinusitis, ulcerations, or perforation of the nasal septum.
- Dislodgement of nasal packing into the oropharynx may result in aspiration.
- Infection from nasal packing
- Septal perforation from cauterization

784.7 Epistaxis

**PEARLS AND PITFALLS**

- Pearls:
  - The ABCs remain the 1st priority.
  - Getting a thorough history is essential in identifying any associated or predisposing conditions.
- Pitfalls:
  - Not looking carefully for a potential source of unilateral bleeding may result in failure to diagnose a nasal foreign body or tumor.
  - Failure to hold pressure on anterior nares long enough is a common cause of treatment failure.

# ERYTHEMA INFECTIOSUM

Craig A. McElderry

## BASICS

### DESCRIPTION

- Erythema infectiosum (5th disease) is a common childhood exanthem caused by parvovirus B19.
- Infection with parvovirus is ubiquitous and occurs worldwide.
- Infection appears to occur mostly in late winter or early spring (1).
  - It is relatively common and mildly contagious.
  - It occurs sporadically or in epidemics.

### EPIDEMIOLOGY

#### Incidence

~70% of cases occur in children between 5 and 15 yr of age.

#### Prevalence

Prevalence of immunity to parvovirus rises with age and is more than 60% in adults (1).

### RISK FACTORS

- Exposure to infected individuals
- The transmission rate is ~50% for those living with infected persons and ~20–30% for susceptible teachers and day care workers who are exposed to infected children (2).

### GENERAL PREVENTION

- Good hand washing
- Avoidance of known infected individuals
- A vaccine is in development.

### PATHOPHYSIOLOGY

- Respiratory spread is the most common route of transmission.
- Transplacental, nosocomial, and blood product transmission can also occur.
- The virus selectively infects human erythroid progenitor cells, with the globoside or P blood group antigen as the cellular receptor for the virus.
- The disease is contagious during the week before the rash appears.
- Persons with parvovirus B19 infection are no longer contagious when the rash appears because the viremia has cleared by this point.
- Most symptoms occur secondary to immune complex formation (2).

### ETIOLOGY

- Parvovirus B19 is a nonenveloped, single-stranded DNA virus.
- Parvovirus B19 is the only member of the Parvoviridae family that causes disease in humans.

### COMMONLY ASSOCIATED CONDITIONS

Several other conditions may be caused by parvovirus B19:

- Hydrops fetalis
- Transient aplastic crisis
- Polyarthropathy syndrome
- Chronic red cell aplasia
- Papular, purpuric eruptions on the hand and feet ("gloves and socks" syndrome)

## DIAGNOSIS

### HISTORY

- The prodrome, which occurs after a 3–18-day incubation period, consists of mild symptoms such as fever, malaise, coryza, headache, and nausea.
- The prodrome may be absent.
- Infected persons experience 3 overlapping stages of rash:
  - 1st stage: "Slapped-cheek" facial rash:
    - Occurs 3–7 days after the prodrome
    - Bright erythematous facial exanthem (See Physical Exam.)
    - Exacerbated by sunlight
    - More common in children
    - Fades in 2–4 days
  - 2nd stage: Lacy or reticular body rash:
    - Occurs 1–4 days after the facial exanthem
    - Erythematous rash on the trunk, buttocks, and/or extremities
    - May be the only manifestation of disease
    - Fades in 1–2 wk
  - 3rd stage: Evanescence/recrudescence rash:
    - Lasts 1–3 wk
    - Exanthem fades and reappears in previously affected sites.
    - Varies in relation to factors such as heat, emotional upset, and sunlight exposure
    - Fades without scarring
- Adolescents in particular may develop arthralgia or arthritis
- Patients with sickle cell disease are at risk for aplastic crisis.

### PHYSICAL EXAM

- 1st-stage "slapped-cheek" facial rash:
  - Red papules on cheeks rapidly coalesce in hours to form red, slightly edematous, warm, erysipelaslike plaques symmetrically on both cheeks.
  - Spares perioral areas and nasal bridge
- 2nd-stage rash:
  - Erythematous maculopapular rash on trunk, extending to buttocks and extremities
  - Central clearing of rash results in characteristic reticular pattern
  - Proximal extremity emphasis and dorsal ventral spread
- 3rd-stage rash: Rash is the same as in 2nd stage but comes and goes as described in the History section.

### DIAGNOSTIC TESTS & INTERPRETATION

- Diagnosis of erythema infectiosum is usually made on the basis of the characteristic features.
- The slapped cheek appearance and lacy, reticulate rash are almost pathognomonic for erythema infectiosum.

### Lab

- Usually, no lab tests are necessary.
- CBC if concern for aplastic crisis
- In select cases of aplastic crisis or possible pregnancy exposure, confirmation can be made through various advanced lab methods:
  - Anti-B19 IgM antibody capture radioimmunoassay is considered the best method for confirming parvovirus B19 infection, but it is not readily available.
  - Highly sensitive (up to 97%) ELISA is commercially available, but false positives have been reported due to other viruses or rheumatoid factor.
  - Dot-blot hybridization and polymerase chain reaction testing are also used.

### Pathological Findings

Giant pronormoblasts on a peripheral blood smear or in a bone marrow aspirate are suggestive of parvovirus B19 infection but are not diagnostic.

### DIFFERENTIAL DIAGNOSIS

- Scarlet fever
- Rubella
- Exanthems caused by enteroviruses
- Drug eruptions
- Sunburn
- Collagen vascular diseases
- Allergic reactions
- Consider measles, rubeola, roseola infantum, and erysipelas

### Pregnancy Considerations

- Pregnancy does not alter parvovirus B19 infection in the mother. However:
  - The fetal liver and heart may become infected.
  - Infants may develop anemia from the already shortened RBC life span.
  - Infants may develop myocarditis from direct infection of the heart.
  - Anemia and myocarditis can cause CHF and hydrops fetalis.
- The estimated risk of transplacental infection is 30%.
- Many fetuses are born without symptoms, but there is a 2–6% risk of fetal loss (2).
- 2nd-trimester pregnancies are the most vulnerable because of increased hematopoiesis in the liver.
- Although the placenta has an abundance of P antigen receptors for the virus, 1st-trimester pregnancies have the lowest risk because of the fetal inability to produce IgM and the difficulty of antibody transfer across the placenta.

- If a pregnant woman is exposed to parvovirus B19, acute infection should be confirmed. (See Lab section.)
- If acute infection is confirmed, serial US (weekly or biweekly) should be performed for 10–12 wk after initial infection to prevent hydrops fetalis.
- The risk virtually disappears after 12 wk.
- If hydrops occurs, fetal blood sampling and possible transfusion are necessary.
- Routine testing for parvovirus is not indicated in pregnant women.

## TREATMENT

Generally, erythema infectiosum is benign and self-limited. Treatment is symptomatic. For patients with fever, arthralgias, or pruritis (rare), relief can be obtained using oral antipyretics, analgesics, or antihistamines.

### MEDICATION

- Acetaminophen 10–15 mg/kg/dose PO q4–6h as needed
- Ibuprofen 5–10 mg/kg/dose PO q6–8h as needed
- Diphenhydramine 0.5–1 mg/kg/dose PO q6h
- Treatment with IV immunoglobulin has been used in immunocompromised patients.

### DISPOSITION

#### Admission Criteria

- Aplastic crisis
- Toxic appearance
- Severe arthritis

#### Discharge Criteria

- Nearly all patients with erythema infectiosum can be discharged to home.
- Most health departments do not recommend exclusion from school for children with erythema infectiosum once classic cutaneous features have manifested, because carriers are no longer infectious.

#### Issues for Referral

See Complications.

## FOLLOW-UP

### FOLLOW-UP RECOMMENDATIONS

Discharge instructions and medications:

- As noted above

### COMPLICATIONS

- Hydrops fetalis
- Transient aplastic crisis: More common in patients with a shortened RBC life span, such as patients with the following conditions:
  - Sickle cell anemia
  - Hereditary spherocytosis
  - Thalassemia
  - G6PD deficiency
  - Pyruvate kinase deficiency
  - Autoimmune hemolytic anemia
- Polyarthropathy syndrome
- Chronic red cell aplasia
- Other potential illnesses that occasionally may be linked to or triggered by parvovirus B19 include the following:
  - Viral-associated hemocytopenia
  - Rheumatoid arthritis
  - Systemic sclerosis
  - Systemic lupus erythematosus
  - Autoimmunelike pulmonary disease
  - Idiopathic thrombocytopenic purpura
  - Diamond-Blackfan–like anemia
  - Acute vasculitic syndromes
  - Myocarditis
  - Hepatitis
  - Uveitis
  - Seizures, encephalitis, and other neurologic manifestations
  - Glomerulonephritis/Nephrotic syndrome

## CODES

### ICD9

057.0 Erythema infectiosum (fifth disease)

## PEARLS AND PITFALLS

- Erythema infectiosum is a self-limited childhood exanthem that resolves without complications in the classic cutaneous form.
- Since children with erythema infectiosum are contagious only during the asymptomatic viremic period (occurring ~1 wk before rash appears), restricting them from attending school is not necessary by the time the clinical diagnosis is made.
- Parvovirus B19 infection in a pregnant patient may have devastating effects on the fetus. Recognition of exposure or infection in a pregnant patient or contact is critical.

# ERYTHEMA MULTIFORME

Cynthia Lodding  
Garth Meckler

## BASICS

### DESCRIPTION

- Erythema multiforme (EM) is a rash with abrupt onset thought to result from an immune-mediated hypersensitivity reaction.
- Though once considered on the spectrum of more severe conditions such as Stevens-Johnson syndrome (SJS) and toxic epidermal necrolysis (TEN), it is currently classified as a self-limited non-life-threatening hypersensitivity reaction (1,2).
- EM is characterized by a classic, generalized erythematous maculopapular rash with dusky central clearing called “target” lesions (1) (See Physical Exam below.)
- EM is often divided into minor (EMm) and major (EMM) forms:
  - EMm: Typical lesions distributed acral involving <10% body surface area (BSA), with a predilection for extensor surfaces
  - EMM: Typical cutaneous lesions with involvement of ≥2 mucosal sites (usually oral mucosa, with ocular and genital lesions less common) involving <10% total BSA

### EPIDEMIOLOGY

#### Incidence

- EM occurs at any age but is most frequently seen in young adults, with 20% of cases occurring in children.
- Estimated incidence is 0.01–1% annually.

### RISK FACTORS

- Herpes simplex virus (HSV): HSV-1 and HSV-2 infection are associated with EMm and EMM and may lead to recurrent disease.
- An immunogenetic predisposition has been noted with increased incidence of certain HLA types associated with recurrent EM (HLA-DQ3, B15, B35, A33, DR53, DQB1).
- Male gender
- Previous history of EM

### GENERAL PREVENTION

Since EM is typically associated with infectious causes, prevention is difficult. Suppression of recurrent herpes labialis with antiviral medication may be effective in patients with recurrent disease.

### PATHOPHYSIOLOGY

- The exact pathophysiology of EM is unclear, but it is thought to represent an immune-mediated (lymphocyte) hypersensitivity reaction to an infectious or exogenous antigen.

- EM also has a well-established association with HSV-1. HSV was detected in 2/3 of patients with EM who underwent skin biopsy in 1 study (3). The pathophysiology of HSV-associated EM is thought to be mediated by CD34 cells (Langerhans cell precursors).
- Though less common than infectious causes, reaction to drugs and chemicals can lead to EM through immunologic mechanisms related to CD8+ T cells.

### ETIOLOGY

- HSV types 1 and 2 are the most commonly associated conditions now known to cause EM.
- Other infectious etiologies include:
  - Viral agents (Epstein-Barr, cytomegalovirus, varicella zoster, adenovirus, enterovirus, hepatitis, parvovirus)
  - Bacterial agents (*Mycoplasma pneumoniae*, *Streptococcus pneumoniae*, *Borrelia burgdorferi*, *Salmonella* species, *Yersinia* species, *Mycobacterium tuberculosis*)
  - Fungal agents (*Histoplasma capsulatum*, *Coccidioides immitis*)
  - Parasites (*Trichomonas* species, *Toxoplasma* species)
- Drugs (antibiotics, anticonvulsants, NSAIDs, antifungals)

### COMMONLY ASSOCIATED CONDITIONS

HSV-1 and HSV-2

## DIAGNOSIS

### HISTORY

- Patients typically present with an acute onset of a centripetal rash in an acral distribution with characteristic target lesions described above.
- Rash is asymptomatic but may have associated pain or burning and rarely pruritus.
- 50% of patients experience a nonspecific prodrome of fever, malaise, headache, sore throat, upper respiratory symptoms, chest pain, arthralgias, myalgias, vomiting, or diarrhea.
- 25–50% of children will develop oral lesions concurrently with cutaneous lesions (2).

### PHYSICAL EXAM

Skin:

- Rash usually is symmetric, spreads centripetally, and has a predilection for extensor surfaces. May coalesce and become generalized but involves <10% BSA (1).
- Typical target lesions are <3 cm in diameter, regular, round with well-defined borders, and at least 3 zones: 2 concentric rings (1 with palpable edema), around a central disc (1).
- Atypical targets are round, edematous, palpable lesions with poorly defined borders and only 2 zones.
- Often begins on extremities and may spread to the trunk, face, and neck over 72 hours
- Oral involvement usually limited to lips and anterior mucosa and is rare in EM. Bullous oral lesions often break shortly after formation with resultant swelling and crusting of lips and painful erosions of buccal mucosa and tongue (2).
- Ocular involvement with symmetric purulent conjunctivitis may be seen in EMM.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

- None necessary
- If obtained:
  - CBC may demonstrate leukocytosis with atypical lymphocytosis or eosinophilia.
  - ESR may be elevated but is nonspecific.

##### Diagnostic Procedures/Other

Skin biopsy is indicated only for ambiguous cases:

- Skin biopsy with polymerase chain reaction testing for HSV may reveal an etiology but is not necessary for diagnosis, which is clinical.
- Skin biopsy by a dermatologist may differentiate other conditions such as vasculitis or systemic lupus erythematosus, that mimic the rash characteristic of EM.

##### Pathological Findings

EM is characterized by a T-lymphocytic infiltrate at the dermal–epidermal junction with edema, keratinocyte necrosis, and subepidermal bullae.

**DIFFERENTIAL DIAGNOSIS**

- Steven's-Johnson syndrome (SJS):
  - Systemic symptoms often present
  - Lesions are widely distributed but < 10% BSA, atypical, and flat (rather than typical raised acral targets in EM).
  - Multiple mucous membranes involved: Oral (buccal, palatal, vermillion border, with hemorrhagic erosions, pseudomembranes, ulcers, crusts), ocular, and genital
  - Nikolsky sign positive
- Toxic epidermal necrolysis (TEN):
  - Systemic symptoms usually present
  - Lesions are widespread (> 10% BSA), poorly defined erythematous macules and flat targets.
  - Epidermal detachment in > 10% of BSA
  - Multiple mucous membranes involved: Oral (similar to SJS), ocular, esophageal, genital, rarely colonic
- Urticaria
- Kawasaki disease
- Drug eruptions
- Contact dermatitis
- Behçet disease
- Rocky Mountain spotted fever
- Serum sickness–like reaction
- Herpes gingivostomatitis
- Purpura fulminans

**TREATMENT****INITIAL STABILIZATION/THERAPY**

- EM does not cause severe systemic symptoms. If stabilization is required, this suggests an alternate diagnosis.
- Symptomatic treatment for pain associated with mucosal involvement is detailed below.

**MEDICATION****First Line**

- Oral analgesics as needed:
  - Ibuprofen 10 mg/kg/dose PO/IV q6h PRN
  - Ketorolac 0.5 mg/kg IV/IM q6h PRN
  - Naproxen 5 mg/kg PO q8h PRN
  - Acetaminophen 15 mg/kg/dose PO/PR q4h PRN
  - Codeine or codeine/acetaminophen dosed as 0.5–1 mg/kg of codeine component PO q4h PRN
- Topical analgesics for oral lesions as needed (eg, viscous lidocaine)

**Second Line**

- Recurrent HSV-associated disease may benefit from suppressive therapy:
  - Acyclovir 40–80 mg/kg/day divided t.i.d.; adolescent/adult, 400 mg PO b.i.d. or 200 mg t.i.d.
  - Famciclovir (adolescent/adult) 250 mg PO b.i.d.
  - Valacyclovir (adolescent/adult) 500 mg or 1 g PO daily
- Systemic steroid therapy may be of limited value for symptomatic treatment but does not change morbidity or mortality and is not recommended (4).

**DISPOSITION****Admission Criteria**

- EM is a self-limited disease and should not require hospital admission.
- Rarely, patients with inability to tolerate oral intake despite analgesics may require hospitalization for pain management and IV fluids.

**Discharge Criteria**

- The patient must have reliable caregivers and follow up with a primary care physician.
- The diagnosis of EM should be clear and must be distinguished from life-threatening rashes such as SJS, TEN, and purpura fulminans.

**Issues for Referral**

- Doubt as to the diagnosis should prompt referral to dermatology.
- Ocular involvement should prompt consultation with ophthalmology.

**FOLLOW-UP****FOLLOW-UP RECOMMENDATIONS**

- Discharge instructions and medications:
  - Anticipatory guidance:
    - Rash will typically resolve in 1–3 wk without scarring
    - Temporary hypo- or hyperpigmentation may occur.
    - Recurrence may be seen in up to 1/3 of children with EM.
    - Oral analgesics as needed
- Activity:
  - No restrictions

**PROGNOSIS**

- The expected duration is 1–3 wk, with an average of 7 days. The rash is usually self-limited, and there are no serious or long-term sequelae.
- Recurrences are possible if associated with HSV or with accidental exposure to an offending antigen.
- Reactive hyper- or hypopigmentation may be seen.
- Scarring is unusual in EM.

**COMPLICATIONS**

- Dehydration is a complication of severe oral involvement.
- Recurrence is possible, particularly in HSV-associated disease.

- DermAtlas: <http://dermatlas.med.jhmi.edu/derm/result.cfm?Diagnosis=34>

**CODES****ICD9**

- 695.10 Erythema multiforme, unspecified
- 695.11 Erythema multiforme minor
- 695.12 Erythema multiforme major

**PEARLS AND PITFALLS**

- Consider SJS and TEN, which are life-threatening illnesses with high morbidity and mortality. These typically have more severe clinical features, especially when multiple mucous membranes are involved.
- EM is rare in children under 3 yr of age, and alternate diagnoses should be considered.

# ERYTHEMA NODOSUM

Solomon Behar

## BASICS

### DESCRIPTION

- Erythema nodosum (EN) is characterized by self-limited painful nodules that originate in the hypodermal fat layer below the skin, usually located in the anterior lower extremities.
- Nodules last up to 2 wk, with new lesions developing up to 6 wk after onset.
- EN is a symptom of an underlying condition and not itself a disease.
- Usually affects older children and teenagers

### EPIDEMIOLOGY

#### Prevalence

- 1–5 in 100,000 (among adults)
- In older adolescents/adults, females are affected 3–7 times more frequently than males.

### PATHOPHYSIOLOGY

Delayed type IV hypersensitivity reaction to several antigenic stimuli, generally developing 1–6 wk after the inciting event (eg, infection, medication exposure)

### ETIOLOGY

- Streptococcus and sarcoidosis are the most common identifiable etiologies in adults:
  - Account for 98% of cases with an identifiable etiology from a Scandinavian study of 129 cases of EN (1)
- Variable based on geographic region
- Upward of 50% of EN cases are idiopathic.

- Other causes:
  - Epstein-Barr virus
  - Hodgkin lymphoma
  - Behçet disease: Seen in 50%
  - Systemic mycoses (eg, histoplasmosis, coccidiomycosis)
  - Inflammatory bowel disease
  - TB (BCG vaccine and PPD administration have been linked as well)
  - Pregnancy
  - Medication exposure (sulfonamides, oral contraceptive pills)

## DIAGNOSIS

### HISTORY

- Prodromal illness 1–3 wk before onset:
  - Weight loss, malaise, low-grade fever, cough, and arthralgia with or without arthritis
- This is followed by development of painful subcutaneous nodules on lower extremities.

### PHYSICAL EXAM

- Symmetrical, poorly demarcated, tender nonulcerating nodules usually located on the anterior aspect of the lower extremities:
  - Can also be on the extensor surface of the forearms and thighs
- Genitourinary ulcers occur with Behçet disease.
- Arthritis may occur with sarcoidosis.
- Lymphadenopathy or organomegaly is associated with malignancy.

## DIAGNOSTIC TESTS & INTERPRETATION

Diagnosis is primarily clinical. Testing may be helpful to determine the underlying cause.

### Lab

- CBC: Leukocytosis in infection, sarcoidosis
- ESR: Elevation in rheumatologic disease, infection, sarcoidosis
- Rapid strep test, throat culture, antistreptolysin O (ASO) titers to confirm streptococcal infection

### Imaging

Consider obtaining a chest radiograph:

- If TB risk factors/symptoms are present
- If sarcoidosis: Perihilar lymphadenopathy

### Diagnostic Procedures/Other

- PPD skin test
- Biopsy of the lesion is diagnostic.

### Pathological Findings

Acute septal panniculitis of hypodermal fat lobule without signs of true vasculitis

## DIFFERENTIAL DIAGNOSIS

- Insect bites
- Urticaria
- Folliculitis
- Erysipelas
- Nodular vasculitis
- Thrombophlebitis

## TREATMENT

### INITIAL STABILIZATION/THERAPY

Largely supportive treatment

### MEDICATION

#### First Line

- Treat underlying condition
- Ibuprofen 10 mg/kg/dose PO/IV q6h PRN

#### Second Line

- Prednisone 1 mg/kg/day until lesions resolve:
  - Use if pain and lesions are persistent and debilitating
  - Rule out malignancy and infection before use
- Colchicine if associated with Behçet syndrome (pediatric dosing not established)
- Potassium iodide 150–250 mg PO t.i.d.:
  - Use if NSAIDs have failed

### SURGERY/OTHER PROCEDURES

Consider biopsy if diagnosis is uncertain.

### DISPOSITION

EN is managed as an outpatient with appropriate pain medications.

#### Discharge Criteria

Pain is under control

#### Issues for Referral

Refer to manage primary underlying conditions

## FOLLOW-UP

### FOLLOW-UP RECOMMENDATIONS

- Discharge instructions and medications:
  - Bed rest
  - Ibuprofen (10 mg/kg PO q6h PRN for pain)
- Activity:
  - As tolerated

### PROGNOSIS

Self-resolves in weeks, rarely months

### COMPLICATIONS

None from EN

## CODES

ICD9  
695.2 Erythema nodosum

## PEARLS AND PITFALLS

- Treatment is largely supportive.
- Avoid ibuprofen use in cases of inflammatory bowel disease, as it may cause more GI bleeding.

# ERYTHEMA TOXICUM

Solomon Behar

## BASICS

### DESCRIPTION

- Erythema toxicum is the most common pustular rash of the newborn period, with an unclear etiology and a benign course.
- Also known as erythema toxicum neonatorum
- Erythema toxicum is rare in preterm infants.
- Only 10% of babies with erythema toxicum have it at birth.

### EPIDEMIOLOGY

40–70% of full-term babies

### RISK FACTORS

- Full-term babies
- Vaginal birth
- Primiparous mothers

### PATHOPHYSIOLOGY

Possible mechanism is mast cell degranulation as a reaction to commensal microbes (1,2)

### ETIOLOGY

Unknown

### COMMONLY ASSOCIATED CONDITIONS

Associated with a normal newborn

## DIAGNOSIS

### HISTORY

- Rash appearing on day 2 or 3 of life
- Most common in a full-term baby
- Baby is otherwise afebrile and healthy.
- Lesions typically resolve spontaneously in days to weeks.
- Recurrence of lesions is possible but rare.

### PHYSICAL EXAM

- 2–3-mm macules, papules, and pustules on face, trunk, and extremities, sparing palms and soles
- Classically described as “flea-bitten” appearance
- Absence of signs of systemic illness

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

None needed (peripheral eosinophilia may be noted if a CBC is sent)

##### Diagnostic Procedures/Other

Skin scraping if diagnosis in doubt

##### Pathological Findings

Scraping of pustule reveals eosinophils with Gram, Wright, or Giemsa stain.

### DIFFERENTIAL DIAGNOSIS

- Neonatal herpes simplex infection:
  - Vesicular lesions
  - Infant is ill appearing.
- Miliaria
- Infantile acropustulosis: Pruritic on distal extremities
- Bacterial folliculitis: Tender, red papules/macules
- Transient neonatal pustular melanosis:
  - Usually present at birth
  - More common in African Americans
- Eosinophilic pustular folliculitis: Recurrent lesions tending to be on scalp
- Scabies: Rare

## TREATMENT

Erythema toxicum is a benign neonatal rash that requires no treatment. Once distinguished from other rashes, no further intervention is necessary.

### DISPOSITION

#### **Discharge Criteria**

All newborns with erythema toxicum may be safely discharged home.

## FOLLOW-UP

### FOLLOW-UP RECOMMENDATIONS

- Discharge instructions and medications:
  - Routine care
- Activity:
  - Regular

### DIET

No special diet is necessary. Feeding with powdered formula may be associated with the development of erythema toxicum (3).

### PROGNOSIS

Excellent; typically resolves without sequelae

### COMPLICATIONS

Secondary bacterial infections

## REFERENCES

## ADDITIONAL READING

- Wagner A. Distinguishing vesicular and pustular disorders in the neonate. *Curr Opin Pediatr*. 1997;9:396–405.

### See Also (Topic, Algorithm, Electronic Media Element)

- Herpes Simplex
- Rash, Maculopapular
- Rash, Neonatal

## CODES

### ICD9

778.8 Other specified conditions involving the integument of fetus and newborn

## PEARLS AND PITFALLS

- If lesions are present on the palms and soles, consider a different diagnosis.
- The most dangerous rash in the differential diagnosis is neonatal herpes, which causes lesions that may be initially erythematous macules that progress to vesicular lesions rather than to ulcers. Certainty that neonatal herpes is not causal is critical.

# ESOPHAGEAL VARICES

Emily L. Willner

## BASICS

### DESCRIPTION

- Esophageal varices are distended, tortuous, submucosal veins that are superficial and may bleed spontaneously.
- In patients with portal HTN, which may result from a variety of causes, these veins form due to shunting of blood from the portal to the systemic venous system.
- Hemorrhage from esophageal varices can be massive:
  - This topic will focus on variceal hemorrhage.

### EPIDEMIOLOGY

#### Incidence

- Incidence in children is unknown.
- Esophageal variceal bleeding occurs in up to 10% of children with portal HTN annually.

#### Prevalence

- Variceal bleeding is a common cause of upper GI bleeding in the developing world.
- In developed countries, other causes (ulcers, gastritis) predominate.

### RISK FACTORS

- Identified varices on prior endoscopy
- Portal venous pressure >5 mm Hg or portal vein (PV) to hepatic vein (HV) gradient of >10 mm Hg:
  - PV to HV gradient >12 mm Hg is associated with significantly increased risk of variceal bleeding (1).
- Chronic liver disease of any etiology in order of highest risk (2):
  - Extrahepatic PV obstruction
  - Congenital hepatic fibrosis
  - Cirrhosis

### GENERAL PREVENTION

- Prophylaxis with nonselective beta-blockers may reduce bleeding rates in patients with known varices, though pediatric data is limited.
- Elective banding or injection sclerotherapy of large varices decreases variceal bleeding (3).

### PATHOPHYSIOLOGY

- Increased pressure within the portal venous system leads to shunting of portal venous blood to the lower-pressure systemic venous system.
- This causes dilation of normally very small vessels, forming engorged portosystemic collaterals in the:
  - Distal esophagus
  - Upper stomach
  - Rectum
  - Falciform ligament
  - Skin veins of the abdomen
- Bleeding results when superficial submucosal vessels in the esophagus and stomach become overdistended, fragile, and friable:
  - They may bleed spontaneously or with minor irritation.
  - Bleeding tendency is exacerbated by thrombocytopenia and deficiencies in clotting factors and fibrinogen related to end-stage liver disease.

### ETIOLOGY

- Liver disease due to any cause:
  - Extrahepatic PV obstruction:
    - Perinatal umbilical venous catheter with thrombosis
    - Omphalitis
    - Severe abdominal trauma
  - Intrahepatic PV obstruction:
    - Cirrhosis due to any cause
    - Cystic fibrosis–related liver disease
    - Biliary atresia
    - Congenital hepatic fibrosis
    - Schistosomiasis
  - Posthepatic PV obstruction:
    - Budd-Chiari syndrome
    - Veno-occlusive disease
    - Cardiac disease

## DIAGNOSIS

### HISTORY

- Esophageal varices are normally asymptomatic.
- Esophageal variceal bleeding presents with hematemesis, with or without melena:
  - Obtain best estimate of blood loss.
  - Bleeding is typically painless.
- Significant hemorrhage may lead to light-headedness, syncope or near-syncope, and pallor.
- Patient/caregiver may report a history of liver disease or esophageal varices
- If no history of liver disease, a detailed history of recent symptoms is imperative to detect other causes of upper GI bleeding:
  - Abdominal pain, jaundice, changes in stool, other bleeding or bruising, NSAID use

### PHYSICAL EXAM

- If active variceal hemorrhage:
  - Tachycardia, hypotension, orthostatic vital sign changes
  - Pallor, delayed capillary refill
  - Lethargy or agitation
- Children with PV pressures high enough to cause esophageal varices frequently also have:
  - Dilated periumbilical abdominal wall veins (“caput medusae”)
  - Hemorrhoids
  - Splenomegaly
- Abnormal liver exam:
  - May be firm and small in end-stage cirrhosis or enlarged in other conditions
  - Typically not tender
- Ascites and jaundice are variable, depending on underlying liver disease.
- Abdominal tenderness is variable, though usually not severe:
  - Peritoneal signs suggest alternate diagnosis.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

In order of priority:

- CBC for hemoglobin, platelets
  - Bedside hemoglobin testing if available
- Type and cross-match for blood products
- Coagulation parameters (often abnormal, since clotting factors are produced by the liver)
- Basic metabolic panel (evaluate for electrolyte disturbances, renal impairment)
- Ammonia (increased protein load from blood in GI tract can elevate ammonia)
- Liver enzymes and bilirubin (variable)

#### Imaging

- Useful in acute setting only if the diagnosis is in doubt. Obtain while stabilizing hemodynamics and controlling active bleeding:
  - Upright abdomen x-ray (or cross-table lateral) to check for perforation with free air
  - Hepatic US to check PV pressure if not known hepatic disease or portal HTN
- If hypoxemia or respiratory distress, CXR to check for aspiration of blood

#### Diagnostic Procedures/Other

Upper endoscopy is both diagnostic and therapeutic (3):

- It should be performed in the setting of refractory or massive variceal bleeding OR
- Persistent slow bleeding despite medical management

### DIFFERENTIAL DIAGNOSIS

For hematemesis:

- Gastric or duodenal ulcer
- Gastritis, esophagitis
- Mallory-Weiss tear
- Esophageal foreign body
- Upper GI tract hemangioma/polyp
- Dieulafoy lesion
- Severe coagulopathy or thrombocytopenia
- Swallowed blood from nasopharynx
- Ingested red food, drink, or medication
- In infants: Swallowed maternal blood from birth or breast-feeding

## TREATMENT

### PRE HOSPITAL

Assess and stabilize airway, breathing, and circulation.

### INITIAL STABILIZATION/THERAPY

- Assess and stabilize airway, breathing, and circulation.
- Prevent aspiration of vomited blood:
  - Consider intubation for airway protection if there is obtundation, severe agitation, or respiratory distress.

- Rapid assessment of circulation and perfusion:
  - Obtain vascular access, preferably 2 large-bore peripheral IVs.
  - Begin vascular volume resuscitation with isotonic fluid.
  - In shock, push 20 mL/kg boluses of above fluid over 5–10 min, and repeat as necessary.
  - For massive ongoing bleeding with shock, transfuse unmatched type O, Rh negative blood as soon as available.
- Place NG or orogastric tube and attach to low intermittent suction:
  - Do not use ice water lavage: This is ineffective and can cause hypothermia in children.
- Urgent type and cross-match of blood products in patients with significant blood loss:
  - Transfuse the following as indicated if there is ongoing bleeding:
    - Packed RBCs (10 mL/kg will raise hemoglobin 2.5–3 g/dL) for symptomatic or rapidly worsening anemia
    - Platelets (1 unit per 10 kg body weight) if thrombocytopenia (platelets <50,000/mm<sup>3</sup>)
    - Fresh frozen plasma (10 mL/kg) if coagulopathy (INR >1.5)

**MEDICATION**

**First Line**

Octreotide and vasopressin decrease mesenteric blood flow. Note that vasopressin also causes significant systemic vasoconstriction:

- Octreotide: 1–2 µg/kg IV bolus, followed by 1–2 µg/kg/hr IV infusion (pediatric dosing and safety not formally established) (4)
- Vasopressin: Start at 0.1–0.3 units/min, then titrate dose as needed (0.002–0.008 units/kg/min); max single dose 0.01 units/kg/min

**Second Line**

- IV gastric acid reduction: More beneficial in ulcer bleeding but recommended in significant upper GI bleeding until etiology is certain:
  - Pantoprazole (Protonix) 1 mg/kg IV q12–24h, max single dose 40 mg
- Antibiotics are recommended in adults with variceal hemorrhage and cirrhosis to prevent infectious complications and to decrease rebleeding. Benefit in pediatric patients has not been established:
  - Ceftriaxone 50 mg/kg q24h, max single dose 1 g

**COMPLEMENTARY & ALTERNATIVE THERAPIES**

Esophageal balloon tamponade can be used to temporize refractory hemorrhage while awaiting definitive treatment. However, the procedure is risky and should only be attempted by a specialist with experience with the procedure.

**SURGERY/OTHER PROCEDURES**

- Upper endoscopy with band ligation or injection sclerotherapy of bleeding varices
- Surgical portocaval shunting decreases portal venous pressure and is considered when a combination of medical and endoscopic management fails:
  - Transjugular intrahepatic portosystemic shunt (TIPS): Via venous access, a needle is passed from the hepatic vein, via the liver parenchyma, into the PV.
  - Surgical portocaval shunts are more invasive.
- Liver transplantation in patients with refractory bleeding already on transplant list

**DISPOSITION**

**Admission Criteria**

- Hematemesis complicating varices usually requires admission for observation, monitoring, serial hemoglobin measurements, and consideration of endoscopy.
- Critical care admission criteria:
  - Need for airway stabilization or IV vasoactive infusions, and those with:
    - Significantly altered mental status
    - Shock refractory to volume resuscitation
    - Significant ongoing blood loss
    - Persistent vital sign abnormalities (resting tachycardia, orthostatic changes) or if need for frequent lab monitoring

**Discharge Criteria**

- Discharge is appropriate if it was determined that there was no GI bleeding (eg, negative Gastrocucc testing on red-colored emesis).
- Consider discharge in patients with a minimal amount of blood in an emesis, normal vital signs for age, no ongoing blood loss, stable hemoglobin after several hours of observation, reliable caregivers, and close follow-up.

**Issues for Referral**

- In the emergency department:
  - Consult with a gastroenterologist for patients with known or suspected variceal bleeding.
  - Consult with a surgeon for patients with massive or refractory variceal bleeding.
  - Pediatric patients with refractory variceal bleeding should be transferred to a center with pediatric gastroenterology and surgery.
- Patients with newly diagnosed portal HTN or varices without bleeding should be referred to a pediatric gastroenterologist.

**FOLLOW-UP**

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**

- In patients with variceal bleeding: Continuous cardiovascular, respiratory, and pulse oximetry monitoring and frequent noninvasive BP checks
- Check CBC and coagulation tests every 2–6 hr depending on initial results, ongoing bleeding, and response to treatment.

**DIET**

NPO if upper GI bleeding

**PROGNOSIS**

- Mortality in variceal bleeding in children with cirrhosis correlates with the severity of the underlying liver disease (5).
- Patients with history of variceal bleeding have a high rate of rebleeding.

**COMPLICATIONS**

- Hypovolemia and shock leading to end-organ hypoperfusion and subsequent dysfunction
- Aspiration of vomited blood

**See Also (Topic, Algorithm, Electronic Media Element)**

Gastrointestinal Bleeding, Upper

**ICD9**

- 456.0 Esophageal varices with bleeding
- 456.1 Esophageal varices without mention of bleeding
- 456.20 Esophageal varices in diseases classified elsewhere, with bleeding

**PEARLS AND PITFALLS**

- Early assessment of volume status and resuscitation with fluids and blood are essential.
- Patients taking prophylactic beta-blockers may not be tachycardic despite significant blood loss.
- Consider variceal hemorrhage in children with known liver disease presenting in shock of unknown etiology, even without history of hematemesis or varices.

# ESOPHAGITIS

Michael E. Valente  
Janet Semple-Hess

## BASICS

### DESCRIPTION

- Esophagitis is defined as inflammation of the esophageal mucosa and has numerous etiologies.
- In the pediatric population, common causes of esophagitis are GERD, eosinophilic esophagitis (EE), and caustic ingestions.
- Other etiologies include infection, radiation, and trauma.

### EPIDEMIOLOGY

#### Incidence

>5,000 accidental caustic ingestions occur annually in the U.S., which corresponds to 3–5% of reported accidental ingestions (1,2).

#### Prevalence

The prevalence of esophagitis in the pediatric population is unknown:

- A large cross-sectional survey found prevalence rates of 1.8–8.2% of symptoms associated with GERD (3).

### GENERAL PREVENTION

- Caregivers should be counseled to keep all caustic agents out of child's reach and preferably in locked cabinets.
- Coins and small toys should be kept out of reach of young children and infants.

### PATHOPHYSIOLOGY

- GERD is the most common cause of esophagitis and is due to transient lower esophageal sphincter relaxation and reflux of gastric fluids:
  - GERD esophagitis is characterized by changes in the esophageal mucosa, including basal cell hyperplasia, thickening of the papillae, and infiltration of inflammatory cells.
  - As severity increases, ulceration, scarring, and fibrosis with stenosis can be found.
  - Barrett esophagus with a cellular metaplasia of the columnar epithelium is rare in the pediatric population.
- EE may be based on allergic disorder and abnormal immunologic response or as a result of severe acid reflux disease:
  - In contrast to GERD, EE can involve the mucosa, submucosa, and muscularis.
- Ingestion of caustic agents can cause inflammation and necrosis at various levels of the esophageal mucosa and underlying muscularis:
  - Severity of inflammation depends on type, amount, and concentration of the agent.
  - Full-thickness circumferential injury to the esophagus carries a 20% mortality rate, so early surgical management is vital.
  - Temporal course of caustic esophagitis:
    - Acute phase (1st 24–96 hr) with edema, inflammation, and necrosis
    - Ulceration and granulation phase (3–5 days after injury)
    - Chronic phase of scarring and stricture formation (begins weeks after injury)

### ETIOLOGY

- GERD
- EE
- Caustic ingestions include:
  - Alkalis (lye, potassium hydroxide, and ammonium hydroxide) found in drain cleaners, oven cleaners, and powdered laundry detergents
  - Acids (hydrochloric, sulfuric, oxalic, and nitric acids) found in toilet bowl cleaners, drain cleaners, rust removers, and industrial bleaches
- Infectious esophagitis (rare in children unless immunocompromised):
  - *Candida* and herpes simplex virus (HSV) are the most common pathogens.
  - Bacteria, mycobacteria, fungi, and parasitic organisms such as *Trypanosoma cruzi*, *Cryptosporidium*, and *Pneumocystis* are uncommon causes.
- Traumatic esophagitis may be caused by NG tube placement and foreign bodies (zinc-containing coins, toys, sharp objects, disc batteries).
- Radiation-induced esophagitis may occur in patients after radiation therapy.
- Pill esophagitis results from prolonged contact with some medications (aspirin, potassium, NSAIDs) with the esophageal mucosa.

## DIAGNOSIS

### HISTORY

- In older children, the most common symptoms are dysphagia, odynophagia, and substernal chest pain.
- In older children, symptoms of GERD and its resulting esophagitis often include chest pain after meals and at bedtime.
- In infants and young children, symptoms of GERD are varied:
  - Symptoms of reflux: Frequent spitting up or vomiting
  - Symptoms of esophageal pain: Crying, irritability, back arching (Sandifer syndrome), colic, and refusal to eat
  - Respiratory symptoms (related to reflux and aspiration): Apnea, cyanotic episodes, cough, stridor, and excessive hiccups
- In all children with suspected caustic esophagitis, history is crucial to help predict severity of illness:
  - History of ingestion of alkali, acid, overheated food/liquid, or disc battery
  - Obtain original container or details of exact product ingested, amount ingested, and concentration of ingested agent
  - Timing of ingestion
  - Odynophagia or dysphagia following pill or medication ingestion
  - Early symptoms: Coughing, crying, and vomiting
  - Late symptoms: Mouth or chest pain, drooling, hematemesis, respiratory distress, and stridor
- EE is usually diagnosed in patients with symptoms of relapsing or persistent GERD esophagitis that does not respond to antireflux therapy. One should have a higher index of suspicion in patients with:
  - Allergic conditions in the patient or family
  - Chronic respiratory complaints

- Symptoms of infectious esophagitis include:
  - In older children: Mouth pain, mouth lesions, nausea, dysphagia, odynophagia, and retrosternal chest pain
  - In younger children: Mouth lesions, nonspecific symptoms including fussiness, refusal to drink, and dyspnea
  - In both age groups: Systemic symptoms may be fever, chills, and nausea.
  - History of immunodeficiency can lead to increased incidence and more diverse etiologies of infectious esophagitis.

### PHYSICAL EXAM

- Assess vital signs for tachypnea and tachycardia.
- Assess airway and respiratory system, especially following caustic ingestions.
- Assess circulation and perfusion for signs of shock secondary to esophageal perforation and hemorrhage.
- Evaluate for crepitus as a sign of esophageal perforation and mediastinitis.
- Examine the oropharynx for erythematous plaques, ulcerations, thrush, or dental enamel erosions.
- Evidence of allergic shiners, eczema, and wheezing in patients with suspected EE.
- If GERD is a concern, observe feeding of the infant to assess for symptoms of reflux.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

In the emergency department: If there is a concern for bleeding as a complication of esophagitis:

- Stool occult blood
- Hematocrit

#### Imaging

- In the emergency department: CXR can be used to evaluate for aspiration pneumonia, to evaluate for evidence of perforation following a caustic ingestion, or if foreign body is suspected.
- As an outpatient, barium contrast radiography is useful to evaluate for anatomic abnormalities of the upper GI tract or to identify esophageal strictures (avoid if concern for esophageal perforation).

#### Diagnostic Procedures/Other

In the outpatient/referral setting:

- Esophagogastroduodenoscopy (EGD) for diagnosis and esophageal dilation of fixed esophageal strictures
- Nuclear scintigraphy for pulmonary aspiration in patients with GERD
- Esophageal pH probe studies for evaluating the efficacy of antisecretory therapy

## TREATMENT

### INITIAL STABILIZATION/THERAPY

- Treatment of GERD esophagitis relies on improving esophageal reflux in order to allow time for the esophagus to heal.
- Eosinophilic esophagitis:
  - If known, removal of causative food antigens is crucial.
  - A strict elimination diet with amino acid–based formula is sometimes used in severe cases.
- Caustic esophagitis with alkalis or acids:
  - Evaluate and stabilize cardiorespiratory status (intubation may be required if upper airway edema is present).
  - Flush mouth and surrounding skin with water.
  - Corticosteroid administration is controversial since meta-analysis has failed to demonstrate a benefit. In 2nd- or 3rd-degree injuries and in all cases in which systemic corticosteroids are used, prophylactic systemic antibiotics should be used (2,4).
- For infectious esophagitis, antiviral or antifungal therapy depending on suspected infectious agent, severity of the esophagitis, and host's age and immune status

### MEDICATION

- Treatment for GERD:
  - Histamine H2 antagonists:
    - Ranitidine
    - Famotidine
  - Proton pump inhibitors (PPIs):
    - Omeprazole
    - Lansoprazole
- Eosinophilic esophagitis treatment:
  - Medical treatments investigated include systemic corticosteroids, topical ingested steroids, and leukotriene receptor antagonists.
  - Although PPIs do not treat EE directly, patients with EE often have concurrent GERD that should be treated with PPI therapy.
  - Short courses of oral steroids may have a role in treating emergent EE patients:
    - Fluticasone propionate: Aerosolized fluticasone spray is swallowed instead of being inhaled.
    - Prednisone 1–2 mg/kg/day, max single dose 60 mg/day
  - Leukotriene receptor antagonists: Evidence is limited to adult EE studies.

### SURGERY/OTHER PROCEDURES

- Esophagitis with perforation requires surgical consultation in the emergency department.
- Other surgical procedures may be referred for outpatient follow-up:
  - Surgical correction of gastroesophageal reflux (fundoplication) can be preformed if medical treatment has failed.
  - As EE does not improve with fundoplication, prior to surgery for suspected GERD, EGD with biopsy should be performed to rule out this disorder.

## DISPOSITION

### Admission Criteria

- Patients with caustic esophagitis should be hospitalized in order to:
  - Provide assistance if airway is compromised
  - Provide nutrition to allow esophageal healing:
    - NPO with IV fluids
    - Total parenteral nutrition (TPN) AND/OR
    - Tube feedings
  - Obtain an EGD to evaluate for complications.
- For other types of esophagitis, hospitalization may be required if:
  - Esophagitis is complicated by obstruction or perforation
  - Patient is unable to tolerate PO intake or gain/maintain normal weight for age

### Issues for Referral

- In the emergency department:
  - Notify a poison control center or consult a toxicologist for potentially caustic ingestions.
  - Surgical consult for suspected esophageal perforation
- Outpatient gastroenterologist referral:
  - If endoscopy or biopsy is required for treatment or diagnosis
  - In cases of GERD that are difficult to manage and not responding well to first-line treatment

## FOLLOW-UP

### FOLLOW-UP RECOMMENDATIONS

- Follow-up after caustic ingestion is required to monitor for development of strictures.
- Follow-up for patients with GERD, EE, and infectious esophagitis is required to follow effectiveness of initiated therapy and to monitor for complications.

### COMPLICATIONS

- Severe sequelae of reflux esophagitis include ulceration with chronic blood loss and Barrett esophagus.
- Significant complications of caustic esophagitis include esophageal perforation, mediastinitis, hemorrhage, and death.

### See Also (Topic, Algorithm, Electronic Media Element)

- Gastroesophageal Reflux
- Pain, Chest
- Vomiting

### ICD9

- 530.10 Esophagitis, unspecified
- 530.11 Reflux esophagitis
- 530.12 Acute esophagitis

## PEARLS AND PITFALLS

- All patients with suspected or confirmed esophageal caustic injury should be hospitalized.
- If upper airway edema is present after a caustic ingestion, early intubation to protect the airway is indicated.
- Induction of emesis is contraindicated in all cases of caustic ingestion.
- Treatment of GERD does not immediately resolve symptoms of GERD esophagitis, as time is required for the esophagus to heal.

# ETHANOL POISONING

David J. Story  
Sari Soghoian

## BASICS

### DESCRIPTION

- Ethanol, ethyl alcohol, traditional “alcohol”
- Component of beverages (beer, wine, liquor), mouthwash, cough and cold preparations, colognes, hand sanitizers, and variety of other household items
- CNS depressant causing motor incoordination, slurred speech, ataxia, and decreased level of consciousness
- Ingestion may be intentional, typically among teens, or inadvertent ingestion, common among toddlers

### EPIDEMIOLOGY

#### Incidence

- Unknown in young children
- 80% of high school seniors report having used alcohol.
- 9.5 million youth ages 12–20 yr report having an alcoholic drink in the past month, with 20% of those report being heavy drinkers (5 drinks at least 5 times in the last month).

### RISK FACTORS

- Parents with alcoholism
- Depression
- Binge drinking with peers

### GENERAL PREVENTION

- Limit access to alcohol in the home
- Childproof cabinets/drawers used to store ethanol- and other alcohol-containing household products

### PATHOPHYSIOLOGY

- Ethanol causes dose-dependent CNS depression.
- Enhances GABA binding at the GABA<sub>A</sub> receptor (inhibitory CNS receptor)
- Inhibits NMDA receptor (excitatory CNS receptor)
- 80–90% absorbed from stomach within 60 min
- 90% hepatic elimination by oxidation
- Metabolized by alcohol dehydrogenase to acetaldehyde, then by aldehyde dehydrogenase to acetate

- Small amount metabolized via inducible cytochrome oxidases (MEOS pathway, mostly by CYP 2E1)
- 5–10% renally excreted unchanged
- Metabolism of ethanol interacts with key enzymes in the gluconeogenesis (NADH/NAD<sup>+</sup>) pathway and may cause hypoglycemia and its sequelae (seizures, anoxic brain injury); young children with poor glycogen stores are at greatest risk.
- Ethanol inhibits antidiuretic hormone (ADH) with diuretic effect.
- The average child can metabolize 20 mg/dL/hr of ethanol.

### ETIOLOGY

Oral intake (intentional or unintentional ingestion)

### COMMONLY ASSOCIATED CONDITIONS

- Intentional drug overdose
- Trauma
- Hypoglycemia
- Seizures
- Aspiration
- Trauma
- Depression
- Alcoholism

## DIAGNOSIS

### HISTORY

- Child found near a source of ethanol or had easy access to ethanol
- Inappropriate behavior
- Increased drowsiness or lethargy
- Slurred speech
- Ataxia
- Motor incoordination
- Vomiting

### PHYSICAL EXAM

- Vital signs may demonstrate tachycardia, bradycardia, hypotension, respiratory depression, and hypothermia.
- Neurologic symptoms predominate:
  - Altered mental status: Drowsy to coma
  - Slurred speech
  - Ataxia
  - Nystagmus
  - Dysconjugate gaze
- Flushing and diaphoresis may be present.
- Nausea/vomiting
- Disinhibition may occur with belligerent, loud, boisterous behavior.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

- Capillary blood glucose should be determined immediately.
- Serum ethanol level:
  - Blood alcohol level > 100 mg/dL typically associated with significant sedation;
  - >200 mg/dL, often comatose; >300–500 mg/dL associated with deep coma, respiratory depression, seizures, hypotension
- Chemistry panel to check electrolytes and assess for an anion gap (if concerned for toxic alcohol ingestion)
- Serum osmolality
- Pregnancy test in sexually mature females
- Acetaminophen concentration if any concern for depression, self-harm, or suicidality

**DIFFERENTIAL DIAGNOSIS**

- Carbon monoxide poisoning
- Closed head injury
- Diabetic ketoacidosis
- Ethanol intoxication
- Hypoglycemia
- Sedative/hypnotic ingestion
- Seizures
- Starvation ketoacidosis
- Toxic alcohol ingestion

**TREATMENT****PRE HOSPITAL**

- Assess and stabilize airway, breathing, and circulation.
- Assess for trauma, utilizing cervical collar and/or backboard as needed.

**INITIAL STABILIZATION/THERAPY**

- Assess and stabilize airway, breathing, and circulation.
- Intubation for unprotected airway
- Supportive care
- IV fluids as needed
- Serial monitoring of capillary blood glucose

**MEDICATION**

- Dextrose for hypoglycemia: Feed, if capable, or 1 g/kg IV
- Antiemetics for nausea/vomiting:
  - Metoclopramide 0.1 mg/kg PO/IV q6h
  - Ondansetron 0.1 mg/kg PO/IV q8h
- IV fluids:
  - Normal saline 20 mL/kg IV bolus × 1 for hypotension, repeat up to 2 times

**COMPLEMENTARY & ALTERNATIVE THERAPIES**

Use of caffeine-containing beverages, such as tea or coffee, is commonly attempted by laypersons in an attempt to make patient less sedated.

- This is not demonstrated to be effective or safe and is not recommended for clinical use.

**DISPOSITION****Admission Criteria**

- Loss of airway protective mechanisms
- Profound serum concentration that will take several hours to metabolize
- Concern for patient safety at home
- Labile glucose levels
- Concern for coingestion
- Seizure
- Critical care admission criteria:
  - Unstable vital signs, particularly respiratory depression or hypotension unresponsive to IV fluid therapy
  - Associated trauma requiring intensive care

**Discharge Criteria**

Return to baseline mental status and ability to ambulate

**Issues for Referral**

- Concern for child safety at home should prompt child protective services or social work consultation.
- Intentional use warrants consideration for referral to psychiatrist, psychologist, or substance abuse counselor.

**FOLLOW-UP****FOLLOW-UP RECOMMENDATIONS**

Discharge instructions and medications:

- Refrain from drinking alcohol.

**PROGNOSIS**

- Excellent for rapid, normal recovery for minor ingestions
- Prognosis worsens as blood alcohol level rises. Blood alcohol level > 500 mg/dL may result in severe morbidity and mortality.
- Unrecognized hypoglycemia causing seizure activity places patient at increased risk for aspiration, traumatic bodily injury, and anoxic brain injury.

**COMPLICATIONS**

- Hypoglycemia
- Seizures
- Permanent neurologic or neurocognitive injury

**ADDITIONAL READING**

- American Academy of Pediatrics. Alcohol use and abuse: A pediatric concern. *Pediatrics*. 2001; 108(1):185–189.
- Yip L. Ethanol. In Goldfrank LR, Flomenbaum NE, Lewin NA, et al., eds. *Goldfrank's Toxicologic Emergencies*. 8th ed. Stamford, CT: Appleton & Lange; 2006.

**CODES****ICD9**

980.0 Toxic effect of ethyl alcohol

**PEARLS AND PITFALLS**

- Smaller children lack significant liver mass and have fewer glycogen stores than adults and therefore are at increased risk for hypoglycemia in the setting of ethanol intoxication.
- Children metabolize ethanol more rapidly than adults.
- Always check for ethanol content when assessing a pediatric patient who has ingested household or body care products.
- "Proof" of alcohol is numerically twice the percentage of ethanol present. A 100-proof product contains 50% alcohol.
- Patients who reach emergency medical services in the setting of ethanol or other alcohol intoxication may represent a subset of drinkers at higher risk of trauma, comorbid psychiatric illness, and alcoholism.

# EYE, RED

Eric C. Hoppa

Atima Chumpa Delaney

## BASICS

### DESCRIPTION

- Common causes of red eye(s) include infection, trauma, caustic injury, and allergic or inflammatory conditions.
- Ocular structures can be involved singularly or in combination leading to the red eye.

### PATHOPHYSIOLOGY

- Bacterial or viral infection of the conjunctiva causes inflammation and injection of the conjunctival vessels leading to a red eye.
- Infections in the orbital or preseptal areas can cause conjunctival injection.
- Corneal injury causes conjunctival injection leading to a red eye.
- Blunt trauma may lead to hyphema or traumatic iritis.
- Burns from caustic chemicals cause conjunctival injection and corneal ulceration. Alkali substances cause liquefactive necrosis.
- Mast cell degranulation and histamine release from allergen exposure causes conjunctival vessel congestion and injection.
- Systemic inflammatory conditions can lead to inflammation of the conjunctiva, sclera, or the layers between.
- Disruption of the tear film that lubricates the eye surface can lead to irritation and red eye.

### ETIOLOGY

- Infectious:
  - Conjunctivitis:
    - Bacterial: Often unilateral with purulent drainage. Causes include skin flora, *Pseudomonas aeruginosa*, and *Moraxella catarrhalis*. *Neisseria gonorrhoeae* and *Chlamydia* species may occur in sexually active adolescents.
    - Corneal ulcers: *P. aeruginosa* in contact lens wearers
    - Neonatal: *N. gonorrhoeae*, *Chlamydia trachomatis*
    - Viral: Usually bilateral and associated with upper respiratory infection (URI) symptoms. Causes include adenovirus (20%), herpes simplex virus (HSV), echovirus, and coxsackievirus.
  - Keratoconjunctivitis: HSV or varicella zoster virus (VZV), associated with periocular vesicular lesions.
    - Epidemic keratoconjunctivitis: Adenovirus
  - Orbital cellulitis: Extension of sinusitis caused by mixed flora
  - Preseptal/periocular cellulitis: Extension of skin infection anterior to septal plate, caused by skin or upper respiratory flora

- Traumatic:
  - Penetrating trauma: Ruptured globe
  - Blunt trauma:
    - Corneal/conjunctival abrasion
    - Subconjunctival hemorrhage: Resulting from direct trauma or increased intrathoracic pressure from coughing or vomiting
    - Hyphema
    - Traumatic iritis
    - Acute traumatic glaucoma: Associated with vision loss
- Caustic Injury:
  - Alkaline injury may be more severe than acidic injury.
  - Conjunctivitis from silver nitrate in neonates
- Allergic conjunctivitis: Often associated with chemosis and prominent lymphatic tissue on the palpebral conjunctiva
- Systemic diseases:
  - Kawasaki disease (KD)
  - Stevens-Johnson syndrome (SJS)
  - Iritis/episcleritis: Juvenile idiopathic arthritis (JIA), sarcoidosis, TB, inflammatory bowel disease (IBD), leukemia, collagen vascular diseases
- Disorders of the eyelids or lacrimal ducts:
  - Hordeolum (stye): Obstructed eyelid hair follicles or meibomian glands; often painful with purulent drainage
  - Chalazion: Painless granuloma of the meibomian glands of the inner eyelid
  - Blepharitis: Inflammatory condition with crusting of eyelashes
  - Trichiasis: Eyelashes folded onto the conjunctiva, most often seen in Asian children
  - Congenital nasolacrimal duct obstruction
  - Dry eye

## DIAGNOSIS

### HISTORY

- Onset of symptoms
- Systemic symptoms, such as fever
- In neonates, maternal history of STIs
- History of trauma
- Exposure to alkali or acidic chemicals
- Associated ocular symptoms: Eye pain or drainage, eyelid swelling, visual changes, foreign body sensation, or eye itching
- Associated systemic symptoms:
  - Fever: Infectious or inflammatory etiologies
  - URI symptoms: Viral conjunctivitis
  - Rhinorrhea, sneezing, and itching: Allergic conjunctivitis
  - Rash and joint swelling: Inflammatory conditions
- History of contact lens use
- Associated medical conditions: JIA, IBD, leukemia, immunodeficiency

### PHYSICAL EXAM

- Fever: Infectious or inflammatory etiology
- Ophthalmologic:
  - Visual acuity: Decreased visual acuity in hyphema, iritis, chemical injury, orbital cellulitis, or glaucoma
  - Proptosis may be seen in orbital cellulitis
  - Eyelid edema and/or erythema: Trauma, allergy, or preseptal cellulitis
  - Eyelid: Presence of chalazion or hordeolum
  - Eyelashes: Trichiasis or blepharitis
  - Attempt eversion of eyelids to assess for foreign body.
  - Extraocular movements (EOM): Painful or limited EOM may be seen in orbital cellulitis, ruptured globe, or orbital fracture.
  - Conjunctiva:
    - Diffuse injection: Infectious or allergic conjunctivitis
    - Prominent lymphoid tissue of palpebral conjunctiva: Allergic conjunctivitis
    - Isolated bulbar conjunctival injection: Inflammatory disorders
    - “Ciliary flush”: Bulbar conjunctival injection with limbic sparing can be seen in iritis or KD.
    - Subconjunctival hemorrhage
    - Chemosis: Allergic conjunctivitis
  - Pupillary exam:
    - Irregular shape: Ruptured globe
    - Asymmetry: Iritis on the side with decreased response
  - Cornea/anterior chamber:
    - Hyphema: Blood in anterior chamber seen with tangential lighting either macroscopically or on slit lamp exam
    - Corneal laceration: Iris may protrude through laceration
- Skin:
  - Periorbital vesicles: HSV and VZV
  - Generalized rash: KD, SJS, or JIA
- Lymphadenopathy:
  - Preauricular: Adenoviral conjunctivitis
  - Single large cervical node: KD

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

- Neonates with conjunctivitis: Gram stain, bacterial culture, and Chlamydia DFA and culture
- Neonates with suspected *N. gonorrhoeae* conjunctivitis or conjunctivitis associated with fever should undergo a full sepsis evaluation.
- Older children with conjunctivitis: Gram stain and culture are not usually necessary.
- In suspected orbital cellulitis, consider a blood culture.
- Send HSV culture/direct fluorescent antibody from vesicular lesions if suspecting HSV keratoconjunctivitis.

**Imaging**

- Suspected orbital fracture: CT orbit without contrast
- Ruptured globe: CT orbit to rule out intraocular foreign body; strongly consider CT brain to rule out intracranial injury.
- Suspected orbital cellulitis: CT orbit with IV contrast

**Diagnostic Procedures/Other**

- Fluorescein exam:
  - Instill fluorescein into the eye and illuminate with a cobalt blue light.
  - Uptake of fluorescein by corneal defects appear yellow/green
  - Dendritic staining pattern with HSV infection
- Slit lamp examination:
  - RBCs in anterior chamber: Microhyphema
  - WBCs in anterior chamber: Iritis

**DIFFERENTIAL DIAGNOSIS**

See Etiology section.

**TREATMENT****INITIAL STABILIZATION/THERAPY**

- Place an eye shield over the injured eye with suspected ruptured globe or intraocular foreign body.
- Apply topical anesthetic drops to relieve eye pain prior to detailed exam.
- In chemical injury, perform eye irrigation immediately with normal saline or Ringer lactate solution for 30 min and until ocular pH normalizes to 6.5–7.5.
- Multiple studies show no clinical benefit of patching for corneal abrasions (1).
- Performing hourly saline ocular lavage may prevent corneal damage in *N. gonorrhoeae* conjunctivitis.

**MEDICATION****First Line**

- Anesthetic agents:
  - Proparacaine hydrochloride 0.5%: 1–2 gtt
  - Tetracaine hydrochloride 0.5%: 1–2 gtt
- Conjunctivitis:
  - Erythromycin 0.5% ophthalmic ointment: 0.5-inch ribbon to each eye q.i.d. × 7 days
  - Polymyxin B/trimethoprim sulfate ophthalmic solution: 1–2 drops q4–6h × 5–10 days
  - Moxifloxacin HCl 0.5% ophthalmic solution: 1 drop t.i.d. × 7 days
- Neonatal conjunctivitis:
  - Gonococcal: Ceftriaxone 25–50 mg/kg up to 125 mg IV/IM × 1
  - Chlamydia: Erythromycin 50 mg/kg/day PO divided q6h × 14 days
- Orbital cellulitis: Ampicillin/sulbactam (dosed as ampicillin) 200 mg/kg/day IV divided q6h, max single dose 2 g
- Preseptal cellulitis: Amoxicillin/clavulanic acid (dosed as amoxicillin) 90 mg/kg/day PO divided q8–12h or ampicillin/sulbactam IV (as above)

- HSV keratoconjunctivitis:
  - Acyclovir 30 mg/kg/day IV divided q8h or 80 mg/kg/day PO divided q8h
  - Trifluridine 1% ophthalmic solution to affected eye, 8 times a day
  - In adults, treatment with topical trifluridine and topical or oral acyclovir for HSV keratoconjunctivitis is associated with the best clinical outcomes. The addition of topical interferon and topical steroid may also be of benefit given the extent of the keratitis (2). Treatment with oral acyclovir in children has been shown to be beneficial (3). There are no studies comparing oral and topical antiviral therapies in children.
- Ruptured globe:
  - Antibiotic prophylaxis: Cefazolin 100 mg/kg/day IV divided q8h
  - Antiemetic: Ondansetron 0.15 mg/kg IV/PO q8h
  - Age-appropriate tetanus prophylaxis
- Allergic conjunctivitis: Olopatadine HCl 0.2%: 1 drop to each eye daily (children age >3 yr)

**Second Line**

Cycloplegic agent: Cyclopentolate 0.5%: 1 drop, can repeat in 5 min up to 3 times

**SURGERY/OTHER PROCEDURES**

- Repair of ruptured globe
- Removal of intraocular foreign body
- Drainage of abscess with orbital cellulitis

**DISPOSITION****Admission Criteria**

- Suspected gonococcal conjunctivitis
- Orbital cellulitis
- Preseptal cellulitis with systemic symptoms or failing outpatient therapy
- Ruptured globe
- Intraocular foreign body
- Hyphema

**Discharge Criteria**

Most patients with red eye without systemic diseases can be discharged with proper follow-up unless meeting admission criteria above.

**Issues for Referral**

- Ophthalmologic consultation:
  - Ruptured globe
  - Hyphema
  - Traumatic or inflammatory iritis
  - Suspicion of acute glaucoma
  - Significant chemical injury
  - Neonate with gonococcal conjunctivitis
  - Suspicion of HSV/VZV keratoconjunctivitis
  - Orbital cellulitis
  - Conjunctivitis in contact lens wearers
- Otorhinolaryngology consultation: Orbital cellulitis with sinusitis on CT

**FOLLOW-UP****FOLLOW-UP RECOMMENDATIONS**

- Discharge instructions and medications:
  - Hand hygiene is critical to decrease spread of infectious conjunctivitis to contact lenses.
  - Children with a corneal abrasion should have follow-up for a repeat fluorescein exam within 24 hr.
  - Narcotic pain medications may be necessary for corneal abrasions
  - Do not prescribe topical analgesic drops such as proparacaine or tetracaine, as they interfere with corneal healing.
- Activity:
  - Rest for children with hyphema

**CODES****ICD9**

- 360.00 Purulent endophthalmitis, unspecified
- 379.93 Redness or discharge of eye
- 921.3 Contusion of eyeball

**PEARLS AND PITFALLS**

- Pearls:
  - Anesthetic and cycloplegic agents should only be used for initial evaluation. They should not be given to the patient at discharge.
  - Early ophthalmologic consultation is imperative with red eye and decreased visual acuity
  - Most infectious conjunctivitis is viral, but topical antibiotics are often prescribed to prevent secondary infection.
  - Vertical corneal abrasion(s) may be indicative of a foreign body trapped under the eyelid.
- Pitfalls:
  - Failure to differentiate orbital cellulitis from preseptal cellulitis
  - Inadequate irrigation with chemical injury

# EYE, STRABISMUS

Atima Chumpa Delaney

## BASICS

### DESCRIPTION

- Several terms are used to describe the types of strabismus:
  - Esotropia: Inward turning of the eyes (“crossed eye”)
  - Exotropia: Outward turning
  - Hypertropia: Upward turning
  - Hypotropia: Downward turning
  - Comitant or concomitant strabismus: The degree of misalignment remains nearly constant in all gaze directions. The most common forms of childhood strabismus, including congenital strabismus, fall into this category.
  - Incomitant strabismus: The degree of misalignment changes as the patient looks in different directions. This category includes neurologic palsy, extraocular muscle restriction, CNS gaze disorders, and syndromic strabismus.
- This topic focuses on acute-onset strabismus.
- The major causes of acute strabismus include neurologic palsy and extraocular muscle restriction.

### PATHOPHYSIOLOGY

- The 6 extraocular muscles are innervated by cranial nerves (CNs) III, IV, and VI.
- CN III supplies the medial rectus, superior rectus, inferior rectus, and inferior oblique muscles. The parasympathetic innervation of the pupil and the levator palpebrae muscle are also supplied by CN III.
- A complete CN III palsy results in exotropia, decreased elevation, depression, and adduction as well as ptosis and a dilated pupil. CN III palsy is often incomplete resulting in variations of presentation.
- CN IV supplies the superior oblique muscle. A palsy results in ipsilateral hypertropia.
- CN VI supplies the lateral rectus muscle. A palsy results in ipsilateral esotropia.
- Conditions that restrict the movement of extraocular muscles such as orbital fracture, orbital cellulitis, abscess, and tumors can result in misalignment when trying to look away from the restricting muscle.

### ETIOLOGY

- Neurologic palsies:
  - CN III palsy: Less common:
    - Congenital
    - Head trauma
    - Intracranial tumor
    - Increased intracranial pressure (ICP)
  - CN IV palsy: Most commonly affected CN:
    - Congenital: May worsen acutely following viral illness or head trauma
    - Head trauma
    - Increased ICP
  - CN VI palsy:
    - Head trauma
    - Increased ICP
    - Intracranial tumor
    - Postviral infection
    - Complicated otitis media
    - Abnormality of cavernous sinus
- Traumatic extraocular muscle palsy
- Myasthenia gravis

- Restrictive strabismus:
  - Orbital fracture:
    - Orbital floor fracture may result in an entrapment of the inferior rectus muscle.
    - Medial wall fracture may result in an entrapment of the medial rectus muscle.
  - Orbital hemorrhage, tumor, cellulitis, or abscess
  - Thyroid disease (Graves disease)
- Nonneurogenic nonrestrictive strabismus:
  - Comitant childhood strabismus (benign or essential childhood strabismus)
  - Sensory strabismus
- See respective topics: Traumatic Brain Injury; Neoplasm, Brain; Otitis Media; Myasthenia Gravis; Fracture, Orbital; and Hyperthyroidism.

## DIAGNOSIS

### HISTORY

- Onset of symptoms: Strabismus with acute or subacute onset is less likely to be congenital. Congenital strabismus may also worsen acutely.
- Head trauma
- Orbital trauma
- Double vision (diplopia): Presence of diplopia usually indicates acute or subacute onset of strabismus, whereas nonemergent childhood strabismus is usually not associated with diplopia.
- Fluctuation of symptoms with the time of day and fatigue with activity are suggestive of myasthenia gravis.
- Vomiting, headache, and ataxia may be seen in increased ICP.
- Recent illness: CN VI palsy may occur following a viral illness.
- Underlying medical problems such as thyroid disease or myasthenia gravis

### PHYSICAL EXAM

- General: Abnormal head tilt may compensate for the misalignment of the eyes.
- Ophthalmologic:
  - Decreased visual acuity:
    - Abnormalities along the optical or neurologic pathway can result in decreased visual acuity.
    - Amblyopia, decreased visual acuity without detectable organic cause in one eye, may be seen in patients with long-standing strabismus.
  - Ptosis:
    - CN III palsy
    - Myasthenia gravis
  - Retraction of upper lid:
    - Thyroid disease
    - Orbital hemorrhage
  - Enophthalmos or orbital dystopia (the affected eye is lower than the other) suggests orbital fracture.
  - Periocular ecchymosis and eyelid edema may be present in orbital fracture.
  - Proptosis:
    - Thyroid disease
    - Orbital hemorrhage

- Corneal light reflex:
  - Normal light reflex should be symmetric in both eyes.
  - Temporal to the pupillary center is seen in an esotropic eye.
  - Nasal to the pupillary center is seen in an exotropic eye.
- Pupillary light reflex: CN III palsy may result in dilated pupil.
- Extraocular movements (EOMs):
  - The strabismus is nonemergent if the patient has full and symmetric extraocular eye movements.
  - Pain on attempted eye movement can be seen in orbital fractures.
- Decreased sensation along the cheek and upper lip is suspicious for an orbital floor fracture.
- Palpation of the orbital rims for tenderness, crepitus, and step-off to detect orbital fracture
- Funduscopic exam may reveal papilledema in patients with increased ICP.
- Slit lamp exam can identify associated injuries such as corneal abrasion, hyphema, and microhyphema in patients with trauma.
- Otoscope exam: CN VI palsy may be caused by complicated otitis media.
- Complete neurologic exam: Findings such as focal neurologic deficits, CN palsies, and nystagmus warrant investigation for intracranial mass and elevated ICP.

## DIAGNOSTIC TESTS & INTERPRETATION

### Lab

Routine lab testing is usually unnecessary.

### Imaging

- CT of the orbit when orbital fracture is suspected:
  - “Blowout” fractures refer to fractures involving only the orbital bones.
  - Orbital floor fractures are more common in older children.
  - Orbital roof fractures with concomitant frontal bone fractures are more common in younger children.
- CT of the head should be considered in patients with orbital fracture, especially roof fractures extending from a skull fracture, to rule out associated intracranial injury.
- CT of the orbit may be needed to establish the diagnosis of thyroid eye disease if clinical presentation is atypical. CT shows thickened extraocular muscles without involvement of associated tendons.
- CT or MRI of the brain when a neurologic cause is suspected

**Diagnostic Procedures/Other**

Diagnosis of myasthenia gravis:

- Edrophonium:
  - IM, SC: Weight  $\leq 34$  kg, 2 mg; weight  $> 34$  kg, 5 mg
  - IV: 0.04 mg/kg given over 1 min followed by 0.16 mg/kg given within 45 sec (if no response), max single dose 10 mg
- Neostigmine IM: 0.025–0.04 mg/kg as a single dose. Note: Atropine should be administered either IV (immediately prior) or IM (30 min before neostigmine).

**DIFFERENTIAL DIAGNOSIS**

See Etiology section.

**TREATMENT****INITIAL STABILIZATION/THERAPY**

Eye shield should be applied if a ruptured globe is suspected.

**MEDICATION****First Line**

- Orbital fracture: Prophylactic antibiotic is recommended for orbital fractures involving a sinus. Routine use of prophylactic antibiotic is controversial:
  - Amoxicillin/clavulanate: 20–40 mg/kg/day (amoxicillin component) PO in divided doses q8h or 25–45 mg/kg/day (amoxicillin component) divided q12h for 10–14 days OR
  - Azithromycin:
    - 3-day regimen: 10 mg/kg (max single dose 500 mg/day) PO daily for 3 days
    - 5-day regimen: 10 mg/kg PO on day 1 (max single dose 500 mg) followed by 5 mg/kg (max single dose 250 mg/day) daily on days 2–5
  - Phenylephrine intranasal/spray. Note: Therapy should not exceed 3 continuous days:
    - 2–6 yr: Instill 1 drop q2–4h of 0.125% solution PRN
    - 6–12 yr: Instill 1–2 sprays or instill 1–2 drops q4h of 0.25% solution PRN
    - $> 12$  yr: Instill 1–2 sprays or instill 1–2 drops q4h of 0.25–0.5% solution PRN
- Treatment of myasthenia gravis:
  - Pyridostigmine 7 mg/kg/day PO in 5–6 divided doses

**Second Line**

Some experts recommend oral corticosteroids to reduce the swelling in patients with orbital fractures with limited EOM; consult with otorhinolaryngology at your institution:

- Methylprednisolone: 1–2 mg/kg/day PO in divided doses 1–2 times per day for 3–10 days, max single dose 60 mg/day

**SURGERY/OTHER PROCEDURES**

- May be warranted in patients with intracranial bleeding, brain tumor, and increased ICP
- Orbital fractures with the following conditions generally require surgery:
  - Entrapment of orbital contents resulting in EOM restriction or diplopia
  - Enophthalmos
  - Vertical orbital dystopia

- Timing of surgery to repair orbital fractures is variable, from immediate, early, to delayed repair, depending on the type of fractures and the associated findings. Consult your surgeon for institutional standard of care.

**DISPOSITION****Admission Criteria**

- Increased ICP
- Orbital fractures that require immediate surgery
- Critical care admission criteria:
  - Increased ICP with concerns for cardiorespiratory instability or herniation
  - Myasthenia gravis with concerns for respiratory compromise

**Discharge Criteria**

- Orbital fractures that do not require immediate surgery
- Idiopathic childhood strabismus

**Issues for Referral**

- Consultation in the emergency department:
  - Ophthalmology consultation in patients with strabismus associated with:
    - Diplopia
    - Eye pain
    - CN palsies
    - Visual impairment
    - Hypertropia or hypotropia
    - Orbital fractures
  - Neurosurgery consultation in patients with strabismus associated with:
    - Head trauma
    - Increased ICP
    - Intracranial tumor
  - Otorhinolaryngologist or a plastic surgery consultation in orbital fractures
- Outpatient referral:
  - Most patients with strabismus, who are not seen by ophthalmologist in the emergency department, should follow up with an ophthalmologist.
  - Patients with small orbital fracture without ocular muscle entrapment, enophthalmos, or orbital dystopia may be referred to otorhinolaryngologist or plastic surgeon.
  - All patients with orbital fractures should have follow-up with an ophthalmologist; orbital fractures are frequently associated with ocular injury.

**FOLLOW-UP****FOLLOW-UP RECOMMENDATIONS**

- Discharge instructions and medications:
  - Orbital fractures:
    - Prophylactic antibiotics may be indicated (see Medication section).
    - Nasal decongestant
    - Consider oral corticosteroids in orbital fractures with EOM restriction
- Activity:
  - Orbital fractures:
    - Advise patient not to blow the nose.
    - Sleep with the head of the bed elevated.
    - Apply cold packs to the eye in the 1st 48 hr to reduce swelling.

**CODES****ICD9**

- 378.00 Esotropia, unspecified
- 378.9 Unspecified disorder of eye movements
- 378.10 Exotropia, unspecified

**PEARLS AND PITFALLS**

- Pearls:
  - Determine whether the strabismus is of acute onset.
  - Strabismus with diplopia is usually associated with emergent pathology.
  - Most patients with strabismus need evaluation by an ophthalmologist.
- Pitfall:
  - Failure to refer patients with orbital fracture for a full eye exam by an ophthalmologist to rule out associated ocular injury

# EYE, VISUAL DISTURBANCE

Kristen Breslin

Atima Chumpa Delaney

## BASICS

### DESCRIPTION

- Visual disturbance includes sudden visual loss, change in acuity, diplopia, and abnormal images.
- Diagnoses more likely to present acutely are emphasized here.

### PATHOPHYSIOLOGY

- Periorbital edema or lesions
- Obstruction or distortion of light as it travels through the cornea, anterior chamber, lens, or posterior chamber
- Retinal pathology
- Disorders of the optic nerve or visual cortex
- Lack of coordination of eye movements

### ETIOLOGY

- Trauma
- Infection: Uveitis, keratitis, endophthalmitis
- Autoimmune: Uveitis
- Cardiovascular: Thromboembolic
- Neurologic: Migraine, CNS lesion, increased intracranial pressure (ICP)
- Toxic ingestion

## DIAGNOSIS

### HISTORY

- Eye pain:
  - Pain with eye movement suggests optic neuritis or orbital cellulitis
  - Pain with eye redness can indicate uveitis, keratitis, acute glaucoma, or endophthalmitis.
- Visual loss or change in visual acuity:
  - Sudden, painless vision loss:
    - Central retinal artery occlusion (CRAO) due to emboli, thrombus, hypercoagulable state, autoimmune disease, sickle cell disease (SCD), trauma
    - Central retinal vein occlusion (CRVO) due to HTN, glaucoma, SCD, vasculitis, hypercoagulable state, oral contraceptives, external compression
    - Vitreous hemorrhage
    - Retinal detachment
    - Toxic optic neuropathy: Methanol, ethylene glycol, ethambutol, carbon monoxide, vitamin B deficiencies
    - Optic neuritis: Unilateral or bilateral
    - Cortical blindness: Stroke, hemorrhage
  - Duration and progression of symptoms
  - Constant or intermittent symptoms
  - Trauma or precipitating triggers:
    - Posttraumatic visual loss:
      - Periorbital swelling
      - Corneal irregularity from chemical or thermal burn, corneal abrasion, or foreign body (FB)
      - Hyphema
      - Ruptured globe
      - Intraorbital FB
      - Lens dislocation
      - Commotio retinae (retinal edema)
      - Retinal artery occlusion

- Retinal detachment
- Vitreous hemorrhage
- Traumatic optic neuropathy
- CNS injury (cortical blindness)
- Binocular or monocular:
  - Monocular diplopia: Corneal irregularity, cataract, lens dislocation (ectopia lentis)
  - Binocular diplopia:
    - Cranial nerve (CN) III, IV, or VI palsy
    - Thyroid eye disease
    - Orbital cellulitis, tumor, or fracture
    - CNS lesions: Mass, trauma, ventriculoperitoneal shunt (VPS) malfunction, MS
    - Vertebrobasilar artery insufficiency
    - Basilar or ophthalmic migraine
    - Venous sinus thrombosis
    - Myasthenia gravis
    - Toxin: Alcohol, benzodiazepines, botulism
- Abnormal visual images:
  - Floaters, flashes, or spots: Retinal detachment, vitreous hemorrhage, migraine, occipital CNS lesions, posterior uveitis, chorioretinitis
  - Halos: Cataract, corneal edema, acute glaucoma, vitreous opacities, ingestion (digitalis, chloroquine)
- Contact lens wearers: Increased risk of pseudomonas and acanthamoeba keratitis
- Photophobia: Uveitis, burns, migraines, corneal injury, CNS infection
- Eye redness, watering, or discharge:
  - Purulent discharge increases concern for bacterial infection.
- Fever may be present with infectious causes, including periorbital and orbital cellulitis.
- Vomiting may be present with increased ICP, migraine, acute glaucoma, and vertebrobasilar insufficiency.
- Headache with visual loss can indicate:
  - Migraine
  - Increased ICP including idiopathic intracranial HTN (pseudotumor cerebri)
  - CNS lesion: Mass, hemorrhage, VPS malfunction
  - Venous sinus thrombosis
  - Acute glaucoma
  - Malignant HTN
- Young children may manifest visual changes with abnormal eye contact, squinting, closing one eye, difficulty walking, lack of interest in visual stimuli, and head tilt.
- Past medical history
- Medications or ingestions

### PHYSICAL EXAM

- Observation: Interactions, eye contact, response to visual stimuli
- BP: Malignant HTN
- Ophthalmologic exam:
  - Inspection for periorbital lesions or edema, conjunctival injection, proptosis
  - Visual acuity
  - Visual field exam: Visual field loss can indicate glaucoma, retinal disease or detachment, CNS lesion, increased ICP, or optic neuritis.

- Pupillary exam:
  - Irregular or peaked (tear drop) pupil occurs with ruptured globe
  - Afferent pupil defect (unilateral sluggish direct response to light with normal indirect response): Optic nerve or retinal disease
- Extraocular movements (EOMs): Limited movement due to CN palsies, orbital cellulitis, or ophthalmoplegic migraine
- Funduscopy:
  - Red reflex
  - Leukocoria: Retinoblastoma, cataract, vitreous hemorrhage, retinal detachment, infection
  - Corneal clouding: Acute glaucoma
  - Corneal opacities: Keratitis
  - Papilledema: Increased ICP
  - Retinal pallor: CRAO
  - Retinal hemorrhages, exudates, and dilated retinal veins may be seen in CRVO.
- Hyphema: Usually caused by trauma
- Hypopyon: WBCs in anterior chamber, seen in keratitis, endophthalmitis, iritis
- Neurologic exam:
  - Ataxia can be seen with vertebrobasilar insufficiency or basilar migraine

## DIAGNOSTIC TESTS & INTERPRETATION

### Lab

- Unexplained binocular vision loss: Consider obtaining serum electrolytes, osmolarity, and methanol level for methanol toxicity.
- Hyphema: Sickle cell prep or hemoglobin electrophoresis in patients with unknown SCD status, as sickle cell trait increases the risk of increased intraocular pressure (IOP) (1).
- PT, PTT, platelets in patients with spontaneous bleeding

### Imaging

- Head CT or MRI to evaluate for intracranial lesion in patients with abnormal neurologic findings or papilledema
- CT head and orbits for orbital abscess in patients with proptosis or limitation of EOM
- Orbital CT for orbital fracture or FB:
  - MRI is contraindicated if metal is present.

### Diagnostic Procedures/Other

- Mirror test for conversion disorder: Moving a mirror placed close to the patient's face and observing eye movements
- Fluorescein exam for keratitis, corneal FB, abrasion, or laceration
- Tonometry: Normal IOP = 10–21 mm Hg
- Slit lamp exam of anterior chamber
- Lumbar puncture for opening pressure in idiopathic intracranial HTN

## DIFFERENTIAL DIAGNOSIS

- Conversion disorder (hysterical blindness)
- Malingering
- Hallucinations
- Neck muscle pathology causing head tilt
- Cerebellar disorder causing ataxia

## TREATMENT

### INITIAL STABILIZATION/THERAPY

- Chemical burns, CRAO, and ruptured globe require immediate stabilization and emergent ophthalmologic consultation.
- Remove contact lenses, if present:
  - Discontinue contact lens wear in the setting of trauma, infection, or inflammation.
- Chemical burns:
  - Irrigate immediately with normal saline for 30 min using a Morgan lens or IV tubing, and continue until the ocular surface has a normal pH of 6.5–7.5. (See Burn, Chemical topic.)
  - Use of topical anesthetic facilitates this procedure by making it more comfortable.
- Corneal abrasion:
  - See Corneal Abrasion topic.
- Ruptured globe:
  - Apply eye shield; avoid manipulating the eye or giving topical eye medications.
  - Consider orbital CT to look for intraocular FB
  - Tetanus immunization for penetrating injuries
- Hyphema without a ruptured globe may also be treated with topical steroids and cycloplegic agents in consultation with ophthalmology. (See Hyphema topic.)
- To minimize increased IOP and decrease risk of rebleeding after hyphema, ruptured globe, or vitreous hemorrhage:
  - Antiemetics to prevent vomiting
  - Oral or IV pain control to decrease agitation
  - Bed rest with elevation of the head of bed
- Orbital cellulitis should be treated with broad-spectrum IV antibiotics. (See Orbital Cellulitis topic.)
- Central retinal artery occlusion:
  - Start treatment immediately if the patient presents within 24 hr of vision loss.
  - Immediate digital ocular massage to dislodge emboli: Pressure × 5 sec, release × 5 sec; repeat for up to 15 min
  - IOP reduction with acetazolamide IV/PO and/or topical ocular hypotensive drops such as timolol, a beta-blocker agent, in consultation with ophthalmology
  - Do not use acetazolamide in patients with SCD, as it may cause metabolic acidosis, alter the pH of the aqueous humor, and worsen sickling.
- Optic neuritis may be treated with IV steroids (2) in consultation with neurology.

### MEDICATION

- Consult ophthalmologist for the frequency and duration of treatment with antiviral agents, mydriatic and cycloplegic agents, topical steroids, and hypotensive drops.
- Topical analgesic:
  - Proparacaine: 1–2 gtt once in affected eye
  - Tetracaine: 1–2 gtt once in affected eye
- Topical antibiotics for infection or prophylaxis following corneal injury:
  - Erythromycin eye ointment 0.5% daily to q.i.d.
  - Trimethoprim/polymyxin B/gramicidin 0.025%: 1–2 gtt q.i.d. to q1h
  - Moxifloxacin 0.5%: 1 gtt t.i.d. to q1h
  - Ofloxacin 0.3%: 1–2 gtt t.i.d. to q1h
- Topical antivirals for herpes simplex virus (HSV) keratitis:
  - Trifluridine 1%: 1 gtt daily to 9 times per day
  - Vidarabine 3% ointment daily to 5 times per day

- Topical steroids for hyphema:
  - Prednisolone 1%: 1–2 gtt 4–8 times per day
- Cycloplegic agents to decrease ciliary spasm:
  - Atropine 0.5% (children), 1% (adults): 1 gtt t.i.d.; duration up to 1 wk
  - Cyclopentolate 0.5%: 1 gtt, cycloplegia and mydriasis may last 24 hr
- Hypotensive drops for emergent IOP reduction in consultation with ophthalmology:
  - Timolol 0.5%: 1 gtt q15min × 2

### SURGERY/OTHER PROCEDURES

Surgery may be indicated for ruptured globe, intraorbital FB, retinal detachment, hyphema, chemical burns, traumatic optic neuropathy, full-thickness corneal laceration, lens dislocation, glaucoma, orbital fracture, and some CNS lesions.

### DISPOSITION

#### Admission Criteria

- Ophthalmologic emergencies requiring emergent ophthalmologic evaluation and possible admission:
  - Caustic burns
  - Retinal artery occlusion
  - Ruptured globe
  - IOP >40 mm Hg with eye pain
  - Traumatic vitreous hemorrhage
  - Lens dislocation
  - Retinal detachment
  - Acute vision loss of unknown etiology
- Infectious keratitis, endophthalmitis, and symptomatic retinal detachment require ophthalmologic evaluation within 24 hr and often require admission.
- Admit patients with:
  - Orbital cellulitis
  - Orbital fractures requiring immediate surgery
  - Periocular cellulitis that is severe or unresponsive to oral antibiotics
  - Hyphema if the patient has sickle cell trait, bleeding disorder, large hyphema, or strict bed rest or follow-up cannot be assured
  - Optic neuritis for IV methylprednisolone
  - Idiopathic intracranial HTN with visual changes
  - CNS lesions
  - Venous sinus thrombosis
  - Malignant HTN
  - Significant injuries, CRAO, and acute glaucoma may require admission: Discuss with ophthalmology.

## FOLLOW-UP

### FOLLOW-UP RECOMMENDATIONS

- Ophthalmology follow-up for:
  - Noninfectious uveitis, nontraumatic vitreous hemorrhage, acute maculopathy, CRVO, and optic neuritis within 48 hr
  - Evaluation following uncomplicated corneal FB removal in 24–48 hr
  - Leukocoria within days
- Discharge instructions and medications:
  - Eye patching does not improve healing for corneal abrasions (3).

## ICD-9 CODES

### ICD9

- 368.8 Other specified visual disturbances
- 368.9 Unspecified visual disturbance
- 368.11 Sudden visual loss

## PEARLS AND PITFALLS

- Pearls:
  - Major causes of visual disturbance that require treatment in the emergency department include chemical burns and orbital trauma.
  - Most patients with visual disturbance should be seen by an ophthalmologist for a full eye exam; this may be done in the emergency department or outpatient setting depending on acuity.
- Pitfalls:
  - Do not use an eye patch if infection is suspected.
  - Do not use eye drops with steroids if the patient may have HSV keratitis.
  - Topical anesthetic drops inhibit epithelial healing and should not be prescribed for outpatient use.
  - Do not use cycloplegic agents in acute glaucoma.
  - Do not apply pressure to a ruptured globe or an eye with hyphema.

# FACIAL NERVE PALSY

Genevieve Santillanes  
Marianne Gausche-Hill

## BASICS

### DESCRIPTION

- Facial nerve (cranial nerve VII) palsy may be due to central or peripheral etiologies.
- Central causes are distinguished from peripheral nerve palsy by the presence of forehead sparing.
- In peripheral nerve palsies, the upper and lower face will be affected.
- Differentiation between peripheral and central facial nerve palsy is critical.
- Nerve palsy may be complete, or partial nerve function may be retained.
- No predilection for right or left side of face
- Central neurologic disorders including stroke, MS, and tumors can cause facial nerve palsy.
- This topic will focus on idiopathic peripheral facial nerve palsy (Bell palsy). Other diagnoses will be discussed in the Etiology section.

### EPIDEMIOLOGY

- 30 per 100,000 annual incidence (1).
- 1 in 65 lifetime incidence
- Age: Peak between 10 and 40 yr; unusual before age 10 yr
- Males and females are equally affected.

### PATHOPHYSIOLOGY

- Not definitively known
- Multiple causes of peripheral and central 7th nerve palsy.
- Forehead involvement is spared in central etiologies because nerve fibers to the forehead originate from both cerebral hemispheres (1).
- Bell palsy is idiopathic, but it is widely believed to be secondary to viral infection:
  - Some evidence suggests that it is due to herpes simplex virus (HSV)-1 reactivation (2,3).
  - 1 study showed an increased incidence of HSV-1 DNA in endoneurial fluid of patients with Bell palsy (3).
- Patients with Bell palsy have been noted to have facial nerve swelling during decompression surgery and on MRI:
  - The facial nerve exits the pons at the cerebropontine angle and courses through the internal auditory canal. Swelling of the facial nerve within the narrow canal can cause compression with resultant poor nerve conduction.
  - Symptoms vary depending on the location of nerve damage. Proximal damage may diminish taste, tearing, and salivation. Damage at the stylomastoid foramen results in facial paralysis without associated symptoms.

### ETIOLOGY

- The etiology of facial nerve paralysis in children is diverse and includes (4–7):
  - Bell palsy (66%)
  - Infection (15%)
  - Trauma (13%)
  - Birth trauma (3%)
  - Leukemia (1%)

- Ramsey-Hunt syndrome: Peripheral nerve palsy due to varicella zoster reactivation. Patients usually have an associated vesicular rash of the ear, eardrum, palate, or tongue.
- External compression of facial nerve: Complicated otitis media, cholesteatoma, parotid gland tumor, tumor of the 7th nerve
- Lyme disease may be bilateral. (See Lyme Disease topic.)
- Sarcoidosis
- Basilar or temporal bone fracture
- Brain tumor (gradual onset of symptoms, forehead sparing)
- Stroke (forehead sparing, generally has other neurologic findings)
- MS
- Guillain-Barré syndrome: Facial nerve palsy is bilateral and usually presents with significant weakness of extremities or palsy of other cranial nerves.
- Vaccines: Influenza vaccines not licensed in the U.S. have been associated with Bell palsy.

### COMMONLY ASSOCIATED CONDITIONS

- Antecedent or even concurrent upper respiratory infection may be noted.
- Many viral infections may have associated facial nerve palsy. If these infections are present, then the resulting condition is not idiopathic Bell palsy:
  - Cytomegalovirus
  - Epstein-Barr virus
  - Lyme disease
  - Mumps
  - Rubella
- Diabetes mellitus (adult populations)

## DIAGNOSIS

### HISTORY

- History of tick bites or risk of exposure to ticks in Lyme-endemic areas
- Recent vaccinations
- Rash or arthralgias suggest Lyme disease.
- Pain or vesicular rash suggest Ramsey-Hunt syndrome.
- Acute (<48 hr) or gradual onset. Gradual onset is not typical of Bell palsy.
- Related symptoms:
  - Dry eyes
  - Dribbling or spilling liquid from corner of the mouth
  - Ipsilateral facial paresthesia
- Associated neurologic symptoms. Other etiologies should be investigated if there are any other neurologic symptoms.

### PHYSICAL EXAM

- Characteristic findings of the affected side for a peripheral 7th nerve palsy:
  - Flattening of the nasolabial crease
  - Diminished ability to raise the corner of the mouth to smile
  - Diminished ability to completely close eyelid
  - Inability to wrinkle the forehead: Special attention should be paid to involvement of forehead muscles:
    - Paralysis of forehead muscles indicates a peripheral cause.
    - Forehead sparing raises concern for a central cause.
- To rule out other causes, perform a complete neurologic exam with attention to all cranial nerves, extremity strength, and reflexes.
- Perform a thorough exam of the oropharynx and ears:
  - Vesicles on the face, mouth, or ear are indicative of Ramsey-Hunt syndrome.
  - Otitis media, cholesteatoma, or parotid disease can cause external compression of the facial nerve.

### DIAGNOSTIC TESTS & INTERPRETATION

- Diagnosis is clinical. Testing should be performed only when the diagnosis is uncertain.
- In patients with forehead sparing, consider central causes.

### Lab

- Consider serologic testing for Lyme disease in endemic areas.
- Consider testing for diabetes mellitus:
  - Testing for diabetes in children is not routinely recommended.

### Imaging

- CT/MRI indicated for:
  - Gradual onset of symptoms
  - Sparing of the forehead OR
  - Bilateral or recurrent cases
- CT temporal bone if history of head trauma

### Diagnostic Procedures/Other

Nerve conduction testing may be helpful as an outpatient referral to determine the prognosis for patients with complete paralysis. It is most clinically useful when performed between 3 and 14 days of onset of complete paralysis.

### DIFFERENTIAL DIAGNOSIS

See Etiology section.

**TREATMENT**

**MEDICATION**

Need and utility of pharmacologic treatment is controversial. Spontaneous recovery is typical.

- Artificial tears: 2 gtt to affected eye q2h or PRN to treat dry eye
- Steroids: Not extensively studied in children:
  - Prednisone 1 mg/kg daily for 7 days (various lengths of treatment published in literature)
  - Best result when initiated early in course, especially within 48 hr
  - Less likely to be of benefit when started >7 days after onset
- Antivirals: Contradictory evidence on efficacy of antivirals for treatment of Bell palsy (8,9). Options include:
  - Acyclovir 80 mg/kg/day divided 5 times per day to max 800 mg 5 times daily OR
  - Valacyclovir 20 mg/kg/dose t.i.d. or to a max dose of 1 g b.i.d. for adult dosing

**Pregnancy Considerations**

- Acyclovir and valacyclovir are class B in pregnancy.
- Prednisone is class C in pregnancy.

**COMPLEMENTARY & ALTERNATIVE THERAPIES**

- Patch or taping eye closed, especially at night, is often done to prevent corneal injury.
- Acupuncture has been used alone and in combination with medications for Bell palsy. Available evidence is inadequate to draw conclusions about the efficacy of acupuncture, but there is no evidence of harm (10).
- Physical therapy modalities such as exercise, electrostimulation, biofeedback, massage, and others have been used to treat Bell palsy. Available evidence is inadequate to draw conclusions about the efficacy, but there is no evidence of harm (11).

**SURGERY/OTHER PROCEDURES**

Decompression surgery:

- No conclusive evidence to support surgery (12)
- May be considered in cases of complete paralysis if no improvement after 1 wk
- If surgery is performed, it must occur within 2 wk of onset of complete paralysis.
- Risk of permanent hearing loss after surgery

**DISPOSITION**

**Admission Criteria**

Admission may be warranted for workup if a central cause is suspected.

**Discharge Criteria**

Nearly all patients can be discharged.

**Issues for Referral**

- If bilateral nerve palsy, consider Lyme disease and refer for follow-up with primary care provider or infectious disease specialist.
- Refer recurrent 7th nerve palsy to neurologist or ENT physician for nerve conduction testing.
- Refer to a neurologist if no improvement in 2–3 wk. Consider referral if complete paralysis persists at 1 wk:
  - Consider referral for nerve conduction testing for complete paralysis (on or after 3rd day).

**FOLLOW-UP**

**FOLLOW-UP RECOMMENDATIONS**

- Patients should be followed weekly.
- Discharge instructions and medications:
  - Patients should use artificial tears during the day and eye lubricant at night if the eye cannot be closed completely.
  - Taping the eyelid shut may reduce risk of corneal abrasions and drying of the cornea.

**Patient Monitoring**

- Monitor for improvement on a weekly basis.
- Consider closer monitoring if paralysis is complete.

**PROGNOSIS**

- 90% of children <15 yr of age have a full recovery, often within 3 mo of onset (7).
- Older adolescents have an 84% chance of full recovery.
- Prognosis is best if some recovery occurs during the 1st week:
  - Poor prognosis if no improvement within 3 wk (1)
- Bell palsy complicating pregnancy has a poorer prognosis. 50% have persistent symptoms.
- Persistence of any aspect of symptoms, such as inability to close the mouth, facial paresthesia, pain, or inability to close eye, may result.
- Patients with retroauricular pain, diabetes, complete paralysis, decreased salivary or tear production, or dysgeusia have a worse prognosis.

**COMPLICATIONS**

- Corneal abrasions or ulceration resulting from inadequate tearing or eye closure
- Persistent facial weakness and asymmetry occurs in up to 15% of patients
- 5% have permanent facial paralysis.
- Motor synkinesis: Involuntary muscle movement occurs with a voluntary muscle movement.
- Autonomic synkinesis: Involuntary autonomic response occurs with a voluntary muscle movement (eg, tearing while eating).
- Loss of taste on affected side of tongue
- Rarely, muscle contracture

**See Also (Topic, Algorithm, Electronic Media Element)**

Lyme Disease

**ICD9**

- 351.0 Bell's palsy
- 351.9 Facial nerve disorder, unspecified

**PEARLS AND PITFALLS**

- Bell palsy diagnosis is clinical. If acute-onset unilateral peripheral 7th nerve palsy without other symptoms, no further investigation is needed.
- Consider other causes if symptoms have gradual onset, are bilateral or recurrent, or if other neurologic signs/symptoms are present.
- Ask about risk factors for Lyme disease.
- Certain influenza vaccines not licensed in the U.S. have been associated with facial nerve palsy.

# FAILURE TO THRIVE

Michael E. Valente  
Janet Semple-Hess

## BASICS

### DESCRIPTION

- Failure to thrive (FTT) is a term used to describe inadequate growth in early childhood.
- Most definitions are based on failure to attain growth parameters or growth velocity, with weight being the most commonly used indicator:
  - Weight for age <3rd or 5th percentile
  - Weight as a percentage of median weight for age, <80% or <90%
  - Downward crossing (of weight for age) in  $\geq 2$  major percentile lines on a standard growth chart

### EPIDEMIOLOGY

#### Prevalence

- The prevalence of FTT in the general population is unknown.
- In 2007, the prevalence of underweight children (birth to age 5 yr) participating in U.S. nutrition and public health programs was 4.5% (1).

### RISK FACTORS

The following are associated with FTT:

- Underlying disease (diagnosed or undiagnosed)
- Lower socioeconomic status
- Crowded or unsanitary living environment
- Poor emotional environment
- Prematurity

### PATHOPHYSIOLOGY

Multiple disease (organic causes) and psychosocial factors (inorganic causes) can lead to FTT via:

- Inadequate caloric intake
- Inadequate caloric absorption
- Excessive caloric expenditure

### ETIOLOGY

- Most children with FTT have mixed etiologies. These etiologies can be organized by their pathophysiology:
- Inadequate caloric intake:
  - Incorrect preparation of formula
  - Inappropriate feeding (milk intake, juice intake)
  - Psychosocial factors (behavior problems, poverty, parent–child relationship problems, child abuse/neglect, Munchausen syndrome by proxy)
- Mechanical feeding difficulties (cleft lip/palate, choanal atresia, gastroesophageal reflux, pyloric stenosis)
- Neurologic (cerebral palsy, hypertonia or hypotonia, generalized weakness)
- Anorexia and nausea associated with chronic illness

- Inadequate caloric absorption:
  - Celiac disease
  - Cystic fibrosis
  - Protein-losing enteropathy
  - Food allergy
  - Inflammatory bowel disease
  - Vitamin or mineral deficiencies
  - Hepatobiliary disease
  - Short gut syndrome
  - Parasitism
  - Chronic constipation
  - Hirschsprung disease
  - Malrotation
- Excessive caloric expenditure/Increased metabolism:
  - Endocrine disorders (hyperthyroidism, diabetes mellitus, diabetes insipidus, adrenal or pituitary disease)
  - Malignancy
  - Chronic infection (HIV, immunodeficiency, TB)
  - Renal disease (chronic renal insufficiency, renal tubular acidosis, recurrent urinary tract infections)
  - Hypoxemia (congenital heart defects, chronic lung disease)
- Defective utilization:
  - Inborn errors of metabolism
  - Congenital infections
  - Genetic abnormalities

## DIAGNOSIS

- Plotting growth on standard growth charts is the typical manner of diagnosis.
- The goal of history, physical exam, and diagnostic testing is to:
  - Aid in the determination of the etiology
  - Guide therapy
  - Determine appropriate follow-up

### HISTORY

- Complete dietary history:
  - Amount of food or formula in order to quantify total caloric intake
  - Recall of their last 24-hr intake is useful.
  - How formula is prepared
  - Intake of milk, juice, sodas, sugary drinks, and water
- Feeding history:
  - Feeding routine:
    - When?
    - Where?
    - With/by whom?
  - Food refusals
  - Oversnacking
  - Appropriateness of feeding techniques for developmental age
  - Problems with chewing, swallowing, emesis, or “spit ups”
  - Speed of feedings

- Birth history: To differentiate FTT from small for gestational age
- Chronic medical conditions
- Stool pattern: Frequency and nature (diarrhea and constipation)
- GI symptoms (evidence of milk protein allergy, GI reflux)
- Social history:
  - Changes at home at the time of onset
  - Availability of food
  - Economic hardship
  - Restrictive diet for social or religious reasons
  - Home stressors
  - Homelessness

### PHYSICAL EXAM

- Vital signs
- Plot weight, height/length, and head circumference on standard growth charts
- General assessment, including body fat and muscle mass
- Assessment of respiratory status, including signs of hypoxemia
- Pulmonary exam for evidence of chronic lung disease or infection
- Cardiovascular assessment for congenital heart disease and arrhythmia
- Abdominal exam evaluating for masses, organomegaly, obstruction, constipation, and ascites
- Assessment of hydration and evidence of renal disease
- Neurologic exam including mental status, developmental level, and tone
- Signs of neglect or abuse
- Dysmorphism suggestive of chronic disease or genetic abnormalities
- Skin/mucosal changes
- Observe child/infant while eating/feeding:
  - Caregiver and child interaction while eating
  - Positioning
  - Oral motor difficulties
  - Distractibility
- Quality of caregiver and child interaction

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

- Lab assessment has limited value in determining the etiology of FTT, so diagnostic testing should be individualized based on the clinician’s differential diagnosis after a thorough history and physical.
- Reasonable initial tests to be completed in the emergency department:
  - Glucose
  - CBC with differential
  - Urinalysis
  - Urine culture
  - Electrolytes, including BUN and creatinine
  - LFTs, including total protein and albumin

- Further tests as indicated can be done in the emergency department or an outpatient/inpatient setting depending on the case:
  - Lead level
  - PPD placement
  - HIV testing
  - Sweat tests
  - IgA and antitransglutaminase (to evaluate for celiac disease)
  - Stool microscopy and culture
  - Stool fat
  - Urine organic and serum amino acids
  - ESR
  - Thyroid function tests
  - Iron studies
  - Serum insulinlike growth factor I (IGF-I)
  - Insulinlike growth factor binding protein (IGF-BP3)

### Imaging

- A CXR can be obtained in the emergency department if there is clinical suspicion for TB, pneumonia, or cardiomegaly.
- Bone age, typically performed as an outpatient, may be helpful to distinguish genetic short stature from constitutional delay of growth.

### DIFFERENTIAL DIAGNOSIS

It is important to differentiate FTT from normal variants in growth, including:

- Children who are following appropriate growth curves for:
  - Chromosomal abnormalities: Trisomy 13, 18, and 21, etc. OR
  - Other syndromes affecting growth: Noonan syndrome, Russell-Silver syndrome, fetal alcohol syndrome, and Prader-Willi syndrome, etc.
- Constitutional delay in growth
- Familial short stature
- Premature infants and infants with history of intrauterine growth retardation who have normal growth velocity:
  - When charting growth, corrections for gestational age are necessary until at least 2 yr of age.

### TREATMENT

- In the emergency department:
  - Evaluation and treatment of:
    - Hypoglycemia
    - Electrolyte abnormalities
    - Dehydration
  - Additional emergent treatment is guided by etiology of FTT.
- As an outpatient:
  - High-calorie diet and close follow-up to document catch-up growth.
  - Vitamin and mineral supplementation
  - Additional workup and admission if failure to gain weight in the outpatient setting

### MEDICATION

Medication is dependent on the etiology.

### DISPOSITION

#### Admission Criteria

- Significant FTT, particularly in young infants or patients who lack follow-up to track catch-up growth
- Patient without weight gain after appropriate close outpatient treatment and follow-up
- Negligent or abusive caretakers
- Severe dehydration, malnutrition, or electrolyte abnormality with concern for refeeding syndrome
- Medical causes of FTT identified in the emergency department that require further inpatient workup and/or treatment

#### Issues for Referral

- Social services for patients who have psychosocial factors as a component to their FTT
- Child protective services are required if neglect or abuse is suspected.
- Lactation consultant, nutritionist, and occupational therapist to guide appropriate feeding and maximize caloric intake
- Medical specialist depending on etiology

### FOLLOW-UP

#### FOLLOW-UP RECOMMENDATIONS

- Discharge only those patients in which follow-up is ensured.
- Children with FTT need a high-calorie diet for catch-up growth.
- Diet modification may be needed in certain cases, including high-protein diets and elemental formula in the case of milk protein allergy.

### CODES

#### ICD9

- 779.34 Failure to thrive in newborn
- 783.41 Failure to thrive

### PEARLS AND PITFALLS

- It is important to differentiate FTT from normal variants in growth.
- Most children with FTT have mixed etiologies.
- Admit all patients with FTT who lack follow-up to track catch-up growth.
- Child protective services notification is required if neglect or abuse is suspected.

# FASCIITIS

Emily L. Willner

## BASICS

### DESCRIPTION

- Fasciitis is defined as inflammation of the fascia.
- Multiple etiologies of fasciitis (infectious, traumatic, autoimmune) with varied clinical presentations
- Necrotizing fasciitis (NF) is severe inflammation of the fascia and surrounding subcutaneous tissues due to acute infection by virulent bacteria. It is rapidly progressive, life and limb threatening, and requires rapid diagnosis and treatment.
- Other types of fasciitis include the following:
  - Plantar fasciitis (PF): Overuse or repetitive minor trauma of the foot, leading to inflammation of the plantar aponeurosis. Symptoms include plantar heel pain, especially morning pain and pain after walking or exercising.
  - Nodular fasciitis: Benign growth of reactive fibroblasts in subcutaneous tissues, frequently following minor trauma. It presents as a rapidly growing, firm, and tender nodule. Common locations are the head and neck in infants and the forearms and back in others. It is rare in children.
  - Eosinophilic fasciitis: Autoimmune infiltration of the fascia, especially in the extremities, though sparing the hands and feet. It is associated with peripheral eosinophilia and presents with edema of affected areas, which progresses to indurated, peau d'orange skin. It is very rare in children.
- The focus of this article will be on NF, with some attention to PF.

### EPIDEMIOLOGY

#### Incidence

- NF is rare in children: 0.08–0.3 cases per 100,000 children per year (1):
  - Increased incidence of group A beta-hemolytic streptococcus (GAS)-related NF during the 1990s
  - Estimated to cause 0.018–0.03% of pediatric hospitalizations
- PF is common in older children and teens, especially athletes. It affects ~10% of the general population.

### RISK FACTORS

- NF:
  - Varicella infection, active or recent
  - Immune compromise (congenital or acquired)
  - Recent surgery
  - Skin injury/trauma (may be minor)
  - Chronic medical conditions
  - Diabetes mellitus
  - Malnutrition
  - IV drug abuse
  - In neonates: Omphalitis, circumcision
  - NSAID use is reported as a risk factor in some studies, though not confirmed by others (2).
- PF:
  - Rapid increase in weight-bearing physical activity, especially running
  - Flat or high-arched feet, leg-length discrepancy, tight gastrocnemius or soleus muscles
  - Hard running surfaces, worn shoes

### GENERAL PREVENTION

Varicella vaccination reduces the risk of varicella-related NF.

### PATHOPHYSIOLOGY

- NF affects subcutaneous fat, muscle, and superficial and deep fascia, relatively sparing the skin.
- Infection spreads rapidly along fascial planes, with progression over hours to days.
- Bacterial virulence factors and microvascular occlusion with local ischemia cause necrosis. This damages sensory nerves in affected areas, causing local anesthesia.
- NF may occur in any part of the body, though the trunk is most common in children (3).
- Patients may present with shock, due to streptococcal toxic shock syndrome (STSS) in GAS-related cases.
- GAS M proteins types 1 and 3, exotoxin A, and streptolysin O are virulence factors associated with invasive disease including NF and STSS (4).

### ETIOLOGY

- NF is classified into 2 types, differentiated by microbiologic features:
  - Type I: Polymicrobial infection composed of aerobic and anaerobic bacteria:
    - More common in children <1 yr old, and those with predisposing factors such as immune compromise or diabetes mellitus
    - Common pathogens include *Bacteroides*, *Peptostreptococcus*, *Enterobacter*, *Klebsiella*, and *Proteus* species; *Escherichia coli*, and non-GAS or *Clostridium* species (1).
    - Called “Fournier gangrene” when perineal, and “Ludwig angina” when cervical/intraoral. Ludwig angina causes marked tongue and submandibular swelling and airway compromise; infection can track to the mediastinum.
  - Type II: Single pathogen, usually invasive GAS (*Streptococcus pyogenes*):
    - Colloquially called “flesh-eating bacteria”
    - Associated with varicella infection
    - More frequent than type I NF in healthy children
    - May follow minor skin trauma, surgical procedures, or be without a precipitant
- *Staphylococcus aureus*, including MRSA, is a less common cause of type II NF.
- PF is caused by repetitive microtears of the plantar aponeurosis, causing collagen degeneration in the fascia.

## DIAGNOSIS

### HISTORY

- Diagnosis of NF can be very difficult, as early signs and symptoms are nonspecific.
  - Initial symptoms mimic cellulitis: Fever, local swelling, pain, and erythema.
  - Pain is out of proportion to physical findings.
  - Patients with concomitant STSS may report generalized pain, diffuse rash, malaise, myalgias, or diarrhea.
- PF: Heel pain, classically worst in morning, or at start of physical activity

### PHYSICAL EXAM

- Early physical findings in NF are similar to cellulitis:
  - Fever and tachycardia are common.
  - Skin anesthesia and/or pain out of proportion to exam are helpful if present.
  - Tissue crepitus occurs in a minority of cases (10–37%) but is highly suggestive (4).
  - Later findings are increased swelling, purple/bluish skin discoloration, blisters, and hemorrhagic bullae in the affected area.
  - May present in shock or multisystem organ dysfunction, especially with type II NF.
- PF causes tenderness at the anteromedial calcaneus and along the plantar fascia. Pain may be elicited by passive dorsiflexion of toes.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

##### Initial Lab Tests

- In NF: Blood culture, CBC, electrolyte panel, calcium, BUN, creatinine, glucose, C-reactive protein (CRP):
- The following are also helpful: PT/PTT, AST, ALT, bilirubin, albumin, CPK, and lactate level.
  - Lab findings associated with NF include leukocytosis with left shift; low sodium and calcium; and elevated BUN, creatinine, CPK, CRP, lactate, and glucose. However, these are nonspecific and variable.

#### Imaging

- NF is a clinical diagnosis. The following tests may be helpful if NF is not clear:
  - Gas in soft tissue on x-ray of the affected area is uncommon but pathognomonic.
  - CT and MRI show subcutaneous/fascial inflammation or tissue gas but are more useful in ruling out NF when clinical suspicion is low. If NF is strongly suspected, do not delay surgical exploration.
  - US shows a thickened, distorted fascial layer with associated fluid accumulation. Limited data on bedside US has shown some utility in diagnosis (5).
- PF is a clinical diagnosis. Consider plain radiographs if associated with acute trauma or if diagnosis is in doubt.

#### ALERT

Do not delay surgical exploration for imaging if NF is suspected. An exception is Ludwig angina, which requires CT imaging after airway stabilization and antibiotics to assess for mediastinal extension.

#### Diagnostic Procedures/Other

- Expeditious surgical exploration and complete debridement of necrotic tissue is diagnostic as well as therapeutic.
- Excisional biopsy may demonstrate necrosis or bacteria, but a negative biopsy does not rule out NF where the index of suspicion is high.

#### Pathological Findings

- Necrotic fascia and subcutaneous tissues
- Pathogen(s) frequently isolated from surgical specimen

#### DIFFERENTIAL DIAGNOSIS

- NF: Cellulitis, gas gangrene, myositis, and pyomyositis
- PF: Foot strain, overuse syndrome, stress fracture, bony heel spur

## TREATMENT

### INITIAL STABILIZATION/THERAPY

- Assess and stabilize airway, breathing, and circulation.
- NF:
  - Ensure adequate volume resuscitation, as NF causes capillary leak and results in intravascular volume depletion.
  - Early consultation with a surgeon
- PF: NSAIDs, activity reduction, footwear change, and stretching of the foot/calf

### MEDICATION

#### First Line

- Empiric antibiotics for broad-spectrum coverage of gram-negative anaerobes and streptococci. Consider MRSA coverage (vancomycin or linezolid) until culture result (6):
  - Piperacillin/tazobactam: 240–400 mg piperacillin/kg/day IV divided q6–8h (max 18 g of piperacillin/day) OR
  - Carbapenems such as meropenem (60 mg/kg/day IV divided q8h (max 6 g/day), imipenem or ertapenem, AND
  - Consider vancomycin 40 mg/kg/day IV divided q6h (max 4 g/day)
- When GAS is identified as sole organism:
  - Penicillin G: 100,000–400,000 units/kg/day IV divided q4–6h (max 24 million units/day) AND
  - Clindamycin 25–40 mg/kg/day IV divided q6–8h (max 4.8 g/day)
  - Clindamycin inhibits toxin production. Add when GAS or *Clostridium* is strongly suspected or identified.
- Use analgesics as needed.
- NSAIDs
- Acetaminophen 15 mg/kg/dose PO/PR q4h PRN

#### Second Line

- Alternative regimens in type I NF include:
  - Cefotaxime 50 mg/kg/dose IV q6–8h (max 2 g/dose) OR
  - Ampicillin/sulbactam 100–200 mg ampicillin/kg/day IV divided q6h (max 8 g/day) OR
  - Ciprofloxacin 20–30 mg/kg/day IV divided q12h (max 800 mg/day) AND
  - Clindamycin OR
  - Metronidazole 30 mg/kg/day IV divided q6–8h (max 4 g/day)
- Consider addition of MRSA coverage and an aminoglycoside for extended gram-negative coverage.
- IV immunoglobulin administration in patients with GAS STSS resulted in trends toward improved outcome, but there is insufficient data to conclude benefit in invasive GAS disease (6).

### SURGERY/OTHER PROCEDURES

- Surgery is diagnostic and therapeutic, and surgical re-exploration in 6–48 hr is required. Multiple surgeries are common.
- Adjunctive hyperbaric oxygen therapy in NF is recommended by some experts, though data is conflicting on whether it improves outcome (7).

### DISPOSITION

#### Admission Criteria

- All patients with suspected NF should be admitted.
- Those in whom the diagnosis is in question but not highly likely should be admitted for antibiotics, serial exams, and/or imaging.
- Critical care admission criteria:
  - The majority of patients diagnosed with NF require ICU admission.
  - Any patient with airway compromise, hemodynamic instability, or severe end-organ dysfunction requires ICU care.
  - NF patients frequently develop significant coagulopathy and fluid shifts during surgery, so ICU admission postoperatively is recommended.

#### Discharge Criteria

Patients with PF may be discharged if otherwise stable.

#### Issues for Referral

Patients with NF should be transferred to a hospital with surgery and an ICU.

## FOLLOW-UP

### FOLLOW-UP RECOMMENDATIONS

Patients with PF may follow up with their primary care provider or a sports medicine or orthopedic specialist if conservative treatment fails.

### PROGNOSIS

- Mortality rate in NF is high, ~14–40% of all cases (adult and pediatric) (4):
  - Early surgical intervention improves outcome.
- PF: 80% of cases resolve spontaneously or with conservative treatments within 1 yr.

### COMPLICATIONS

NF: Sepsis, acute respiratory distress syndrome, multisystem organ dysfunction, tissue loss leading to cosmetic or functional difficulties, need for amputation

- Toxic Shock Syndrome

## CODES

### ICD9

- 728.71 Plantar fascial fibromatosis
- 728.86 Necrotizing fasciitis
- 729.4 Fasciitis, unspecified

## PEARLS AND PITFALLS

- Consider NF in patients with apparent cellulitis and unexplained severe pain.
- Patients with suspected NF should be given antibiotics and be transferred to a facility with surgery and critical care support without delay.

# FEBRILE SEIZURE

Jennifer H. Chao

## BASICS

### DESCRIPTION

- Febrile seizures are seizure activity associated with fever and no other identifiable cause (eg, no acute CNS or metabolic abnormalities).
- Febrile seizures can be divided into “typical” or “simple/benign” and “atypical” or “complex.”
- Typical febrile seizures are seen in children between ages 6 mo and 6 yr. They are generalized, occur once in 24 hr, stop spontaneously, and last <15 min.
- Atypical febrile seizures include febrile seizures outside of the usual age range, focal seizures, and prolonged or multiple seizures in 24 hr.

### EPIDEMIOLOGY

- 2–5% of neurologically normal children have febrile seizures.
- 90% occur between 6 mo and 3 yr of age.

### RISK FACTORS

- Male gender
- Multiple febrile episodes
- History of prior febrile seizures
- Family history of febrile seizures
- Precipitous change in temperature is possibly contributory.

### GENERAL PREVENTION

- Despite the common practice of aggressive antipyretic use, such as around-the-clock use of acetaminophen and/or ibuprofen, this has not been demonstrated to prevent febrile seizure:
  - In theory, any measure that prevents infections or fever may reduce the occurrence of febrile seizure.
- Avoid treatment such as cool water bath or alcohol bath during fever, as these may result in very rapid temperature drop.

### PATHOPHYSIOLOGY

See Etiology section.

### ETIOLOGY

- Fever lowers the seizure threshold, resulting in seizure activity.
- Rapid shift in temperature, rise or fall, is believed to be a precipitant.

## COMMONLY ASSOCIATED CONDITIONS

- Fever
- Viral or bacterial illness
- Recent immunizations
- Roseola (human herpesvirus 6)
- Iron-deficiency anemia

## DIAGNOSIS

### HISTORY

- Usually the child presents to the emergency department having already returned to baseline neurologic function after having a generalized seizure while febrile that has self-resolved. These seizures often stop in <5 min and are followed by a brief postictal period.
- There is often no preceding history of illness, and the fever and seizure often are seen to have “come out of nowhere.”

### PHYSICAL EXAM

- Vital sign evaluation including rectal temperature
- A thorough neurologic exam should be conducted:
  - To detect both CNS abnormality
  - To detect other findings of nuchal rigidity, Kernig, or Brudzinski signs
- Physical findings are consistent with illness causing fever

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

- Lab testing should only be utilized as is felt necessary for evaluating the cause of the fever or etiology of seizure if diagnosis is uncertain.
- Assess anticonvulsant levels if patient is undergoing therapy with a medication for which serum concentration assessment is available.
- Consider further workup including lumbar puncture for an infectious etiology of the fever if the child is already on antibiotic therapy or does not return to baseline neurologic function in a timely manner.
- Further lab studies for electrolyte or metabolic abnormalities should be performed if there is suspicion for either based on history or physical.

#### Imaging

None unless intracranial pathology (trauma or mass) is suspected from history or physical. If so, consider cranial CT or MRI.

## Diagnostic Procedures/Other

EEG is indicated if necessary, such as if paralysis to effect endotracheal intubation is performed.

## DIFFERENTIAL DIAGNOSIS

- Febrile delirium
- Shivering
- Breath-holding
- Apparent life-threatening event
- Idiopathic seizure
- Seizure secondary to intracranial pathology (trauma/mass/infection)
- Epilepsy
- Seizure from electrolyte, metabolic, or toxicologic abnormality
- Seizure due to shigella/shiga toxin:
  - Rigors/chills with febrile illness

## TREATMENT

### PRE HOSPITAL

- Address airway, breathing, and respiration issues.
- Cooling measures (undressing/antipyretics)
- If actively seizing, apply oxygen via a nonrebreather mask and consider benzodiazepine therapy.

### INITIAL STABILIZATION/THERAPY

- Oxygen
- Cooling measures (undressing/antipyretics)
- If prolonged (> 10 min), benzodiazepine therapy

### MEDICATION

#### First Line

Antipyretics:

- Acetaminophen 15 mg/kg PO or up to 30 mg/kg PR as initial dose repeated q4h PRN
- Ibuprofen 10 mg/kg PO/IV q6h PRN:
  - IV ibuprofen is newly approved by the FDA.
- IV acetaminophen is expected to receive FDA approval in 2010:
  - As parenteral antipyretics with 100% bioavailability that can be safely and rapidly administered during a seizure, these may play a new role in febrile seizure management.

**Second Line**

- Benzodiazepines:
  - Diazepam: IV (0.1 mg/kg), PR (0.5 mg/kg) max single dose 20 mg
  - Lorazepam: IV (0.05–0.1 mg/kg) max single dose 4 mg
  - Midazolam: IV/IM (0.1 mg/kg), SL/IN (0.2 mg/kg) max single dose 10 mg
- For refractory seizure activity:
  - Phenobarbital 20 mg/kg IV/IM
  - Pentobarbital 5 mg/kg IV
  - Propofol 1 mg/kg IV
    - Use of these medications may result in respiratory depression requiring respiratory support including endotracheal intubation.

**DISPOSITION****Admission Criteria**

- Patients requiring endotracheal intubation, with or without paralysis, and patients requiring prolonged infusion of anticonvulsants to treat status epilepticus should be admitted to a critical care unit.
- Patients who have a febrile seizure in whom there is any concern for other pathology as a cause should be admitted.
- Patients with status epilepticus should generally be admitted.

**Discharge Criteria**

- Return to baseline neurologic function
- If the cause of the fever does not require admission and may be treated as outpatient

**Issues for Referral**

If seizure is atypical—> 15 min, multiple in a 24-hr period or focal, or if the patient is having frequent recurrences of simple febrile seizures—evaluation by neurology should be considered.

**FOLLOW-UP****FOLLOW-UP RECOMMENDATIONS**

Discharge instructions and medications:

- Patients should be discharged with instructions for fever control and any instructions and follow-up pertinent to the illness causing the fever.
- Parents should be advised that if another seizure occurs, they should not put anything in the child's mouth and should lay the child on his or her side in a safe place (to prevent injury). If the seizure lasts > 5 min or there is breathing difficulty, an ambulance should be called. If the seizure self-resolves rapidly, they should contact their doctor or have their child evaluated in the emergency department.

**Patient Monitoring**

- Cardiorespiratory monitor for actively seizing patients
- Vital sign evaluation for postictal patients and patients who have returned to baseline
- Monitor for further seizure activity.

**PROGNOSIS**

Recurrence is more likely if the child is younger at 1st seizure or has a lower temperature on presentation:

- 1/3 of patients will have recurrence.
- Incidence of epilepsy after 1 febrile seizure goes from 1%–2%.
- There are no known long-term neurologic consequences from simple febrile seizures.
- Febrile seizures may be predictive for development of epilepsy but are not considered causal.

**COMPLICATIONS**

If the child presents in status epilepticus, complications are those associated with prolonged seizure activity:

- Injury associated with seizure activity in unsafe surroundings/falls

**ADDITIONAL READING**

**See Also (Topic, Algorithm, Electronic Media Element)**

- Fever in Children Older than 3 Months
- National Institute of Neurological Disorders and Stroke. *Febrile Seizures Fact Sheet*. [http://www.ninds.nih.gov/disorders/febrile\\_seizures/detail\\_febrile\\_seizures.htm](http://www.ninds.nih.gov/disorders/febrile_seizures/detail_febrile_seizures.htm)
- Seizure
- Status Epilepticus

**ICD9**

- 780.31 Febrile convulsions (simple), unspecified
- 780.32 Complex febrile convulsions

**PEARLS AND PITFALLS**

- Pearls:
  - Determination if the child has serious bacterial infection including meningitis is critical.
  - Consider further lab/imaging evaluation with any child who presents with an atypical history or is < 1 yr old.
  - Seizure without focal or other abnormal neurologic findings is not consistent with or suggestive of meningitis.
  - Caregiver education and reassurance is important to ensure proper care of the child and to assuage fears about the repercussions of febrile seizures.
- Pitfalls:
  - Failure to diagnose cause of fever that would warrant intervention, such as urinary tract infection or otitis media
  - Not recognizing febrile status epilepticus and treating for status epilepticus
  - Failure to allow 5–10 min of seizure activity before giving a benzodiazepine:
    - Most febrile seizures cease spontaneously.
    - Benzodiazepines prolong sedation after postictal period, making neurologic evaluation difficult.

# FELON

Yu-Tsun Cheng  
Alan L. Nager

## BASICS

### DESCRIPTION

- A felon is a closed-space infection of the fingertip pulp or phalanx pad.
- One of several types of acute hand infections including paronychia, herpetic whitlow, flexor tenosynovitis, and clenched-fist injuries

### EPIDEMIOLOGY

#### Prevalence

Among hand infections, felons account for ~15%, with the index finger and thumb being the most commonly affected digits.

### RISK FACTORS

- Local trauma including abrasions, cuts, and puncture wounds that may be complicated by the presence of wood splinters or bits of glass.
- Local spread from a paronychia
- Multiple finger-stick blood tests
- Hangnails
- Conditions predisposing to infection:
  - Patients on long-term steroid treatment
  - IV drug abusers
  - Patients with a depressed immune system

### GENERAL PREVENTION

- Avoidance of predisposing factors for paronychia:
  - Nail biting
  - Thumb sucking
  - Excessive dish washing with bare hands
  - Excessive manicuring
- Early recognition and appropriate care of paronychia
- Early recognition and appropriate, sterile care for minor trauma

### PATHOPHYSIOLOGY

- The fingertip pulp is compartmentalized by 15–20 fibrous vertically oriented septa that originate from the underlying periosteum of the distal phalanx and extend to the skin.
- The small compartments contain multiple entities, including sweat glands and fat.
- The skin surface provides a portal of entry for infection within these compartments.
- Routes of bacterial inoculation of the fingertip pulp include local trauma or spread from local infection.
- Infection may begin with cellulitis and then progress to abscess formation within these small, relatively noncompliant compartments, resulting in swelling within a closed space, pain, and ischemia of the affected fingertip.
- Infection at an early stage may resolve spontaneously or with conservative management.

### ETIOLOGY

- *Staphylococcus aureus* is most common.
- Streptococcus organisms
- Growing incidence of MRSA. This may be difficult to determine clinically, but consider risk factors:
  - Prior MRSA infection
  - Prolonged hospital stay
  - Presence of invasive device or feeding tube
  - Recent hospitalization or dialysis
  - Residence in long-term care facility
- Gram-negative organisms:
  - Found in immunosuppressed patients
  - Consider in diabetic patients with frequent finger sticks for serum glucose monitoring
- Anaerobes or oral flora including *Eikenella corrodens* (1–3):
  - Consider in patients with a history of nail biting or thumb sucking

### COMMONLY ASSOCIATED CONDITIONS

- Paronychia
- Immunosuppressed conditions, including diabetes and HIV

## DIAGNOSIS

### HISTORY

- Pertinent history should be obtained, including whether or not there is minor penetrating trauma such as wood splinters, cuts, nail biting, etc.
- Often, there is no history of trauma.
- Presence of paronychia(e)
- Fingertip swelling and/or redness
- Throbbing sensation with tightness and pain, even with mild pressure over the affected fingertip

### PHYSICAL EXAM

- Erythema and swelling of the affected fingertip
- There is often marked tenderness to palpation of the fingertip (pulp):
  - Swelling does not extend proximal to the distal interphalangeal joint of the affected digit.
- Inspection for fluctuance is important in determining the need for drainage.
- At times, the pressure within the swollen fingertip leads to tension and spontaneous drainage via a visible sinus tract.
- Inspect for foreign bodies or associated paronychiae.

### DIAGNOSTIC TESTS & INTERPRETATION

#### Lab

- Not necessary unless there is concern for more serious infections, including septic arthritis
- Consider wound culture if the felon is incised and drained.

#### Imaging

- Consider imaging in chronic or severe cases where there is concern for potential osteomyelitis (including immunocompromised patients).
- Plain film radiographs if there is concern for foreign bodies

#### Diagnostic Procedures/Other

Consider use of US to identify abscess formation.

### DIFFERENTIAL DIAGNOSIS

- Paronychia:
  - Infection of the lateral soft tissue (paronychium) surrounding a fingernail
  - Most common infection of the hand
  - May occur with or without felon
- Herpetic whitlow:
  - Less common viral infection of the hand
  - Resulting from autoinoculation of herpes simplex virus (HSV)-1 or HSV-2 into broken skin
  - Typically presents with prodrome of 1–2 days of burning pain prior to development of skin erythema with characteristic grouped vesicular lesions
  - Unlike felons, pulp space of distal finger is not usually tense and swollen.
  - Drainage is contraindicated, as this may lead to complications including systemic spread.
- Osteomyelitis:
  - Consider in chronic cases of felon
- Flexor tenosynovitis:
  - Consider 4 cardinal signs, as originally described by Kanavel (4):
    - Symmetric swelling of the entire digit
    - Digit semiflexed at rest
    - Severe tenderness over the entire flexor tendon
    - Pain with passive extension of digit
  - Consider STI (disseminated *Neisseria gonorrhoeae* infection), especially if atraumatic (5,6).
  - Requires parenteral antibiotics

## TREATMENT

### INITIAL STABILIZATION/THERAPY

Conservative treatment (without need for incision and drainage) of early felons is appropriate:

- Warm water or saline soaks to promote circulation and facilitate healing
- Elevation to minimize edema and pain
- Oral antibiotics
- Tetanus prophylaxis when indicated
- Identification of foreign bodies
- Identification of abscess formation
- Careful determination for more severe infections (osteomyelitis or flexor tenosynovitis)

### MEDICATION

#### First Line

- A 7–10 day course of oral antibiotics is typically sufficient.
- Empiric antibiotic coverage for *S. aureus* and streptococcal organisms is indicated:
  - 1st-generation cephalosporin (cephalexin):
    - Pediatric: 25–100 mg/kg/day PO divided q6h
    - Adult: 500 mg PO q6h
  - Antistaphylococcal penicillin (dicloxacillin):
    - Pediatric: 25 mg/kg/day PO divided q6h
    - Adult: 500 mg PO q6h
  - Macrolides if penicillin allergic (erythromycin):
    - Pediatric: 30–50 mg/kg/day PO divided q6h
    - Adult: 500 mg PO q6h

#### Second Line

- Consider coverage for MRSA (1,5):
  - Trimethoprim/sulfamethoxazole:
    - Dose based on trimethoprim component
    - Pediatric: 8–10 mg/kg/day PO divided q12h
    - Adult: 160 mg PO q12h
  - Clindamycin:
    - Pediatric: 10–30 mg/kg/day PO divided q6–8h
    - Adult: 300 mg PO q6–8h
- Consider additional coverage for anaerobes and oral flora if there is history of potential exposure:
  - Amoxicillin/clavulanic acid:
    - Dose based on amoxicillin component
    - Pediatric: 25–45 mg/kg/day PO divided q12h
    - Adult: 500 mg PO q8h
  - Clindamycin does offer some anaerobic coverage but does not provide coverage for *E. corrodens*.
- Consider adding gram-negative coverage if the patient is immunosuppressed:
  - If infection appears mild, oral trimethoprim/sulfamethoxazole, amoxicillin/clavulanic acid, or a 3rd-generation cephalosporin (eg, cefdinir) provide moderate gram-negative coverage:
    - Cefdinir: Pediatric, 14 mg/kg/day PO divided q12h; adult, 300 mg PO q12h
  - If concern for more serious infection, consider hospital admission with parenteral beta-lactamase inhibitor:
    - Piperacillin/tazobactam (dose based on piperacillin component): Pediatric (>6 mo), 300–400 mg/kg/day IV divided q6–8h; adult, 3 g IV q6h

### SURGERY/OTHER PROCEDURES

If fluctuance is present on exam, incision and drainage is appropriate. Various methods exist for incision and drainage. Care should be taken to avoid the digital neurovascular structures, flexor tendon sheath, and the nail matrix (see references 7 and 8 for more details):

- The preferred method is a single volar longitudinal incision, which is least likely to injure nearby neurovascular structures.
- An alternative method is the high lateral incision (dorsal midaxial hockey stick incision).
- Perform gentle decompression and irrigation to allow drainage of all septal compartments.
- Following either technique, the wound may be packed with sterile gauze, which should be removed in 1–2 days.
- Allow the wound to close by secondary intention.
- Care should be taken to avoid the flexor tendon sheath, as trauma may lead to iatrogenic flexor tenosynovitis.

### DISPOSITION

#### Admission Criteria

Concern for more serious infection, including flexor tenosynovitis

#### Discharge Criteria

- Adequate drainage achieved if fluctuance is present
- Identification and removal of any foreign bodies
- Adequate follow-up available, particularly if incision and drainage is performed

## FOLLOW-UP

### FOLLOW-UP RECOMMENDATIONS

- Discharge instructions and medications:
  - Elevate and splint affected finger.
  - A 7–10 day course of oral antibiotics is typically sufficient.
  - If incision and drainage is performed, the patient should follow up with the primary care provider in 1–2 days for unpacking of the wound and re-evaluation.
- Activity:
  - Protect the affected finger until the wound heals and pain resolves.

### PROGNOSIS

If treated appropriately and without delay, prognosis is excellent.

### COMPLICATIONS

If left untreated, patients may develop:

- Osteomyelitis of distal phalanx
- Flexor tenosynovitis
- Skin necrosis
- Septic arthritis

## CODES

ICD9  
681.01 Felon

## PEARLS AND PITFALLS

- Expand antibiotic coverage to include oral flora (history of nail biting) and/or MRSA when indicated (see Etiology section).
- Felons may mimic herpetic whitlow, in which case incision and drainage may cause spread to other sites.
- More severe infections (osteomyelitis, flexor tenosynovitis) may be prevented with appropriate and early management.

# FEVER IN CHILDREN OLDER THAN 3 MONTHS

Vincent J. Wang

## BASICS

### DESCRIPTION

- Fever represents one of the most common chief complaints in the emergency department.
- As compared to infants <3 mo old, older infants and children more reliably manifest signs and symptoms specific to the cause of fever:
  - The older the child, the more reliable the physical exam.
  - Infants 3–6 mo of age still demonstrate limited ability to localize infection.
  - Children with developmental delay/mental retardation also exhibit limited ability to localize infection.
- Concern for acute fever without an obvious source depends on the height of fever and the age of the patient:
  - Temperature >38°C or 100.4°F in infants <3 mo of age
  - Temperature >39°C or 102.2°F in infants 3–36 mo of age:
    - Unsuspected (occult) bacteremia has been defined as bacteremia in otherwise well-appearing but febrile infants and toddlers 3–36 mo of age
- In children >36 mo of age, most causes of fever can be identified clinically without the need for extensive evaluation.
- An exhaustive list and description of all causes of fever is beyond the scope of this topic; therefore, an overview will be presented.

### EPIDEMIOLOGY

- Urinary tract infection (UTI)/pyelonephritis occurs in 3–10% of patients with fever (1,2) depending on the age and risk factors. There is increased incidence in:
  - Girls
  - Boys <12 mo
  - Uncircumcised boys <24 mo
  - Children with underlying urologic conditions (eg, spina bifida, posterior urethral valves)
- Bacteremia occurs in <1% (3–5).
- Meningitis occurs in <<1%:
  - Decreased incidence of pneumococcal disease is associated with decreased incidence of meningitis (3).

### RISK FACTORS

- Innate immunologic deficiencies existing from birth that improve over time
- Lack of or incomplete vaccinations
- Day care attendance

### ETIOLOGY

- Most causes of fever are due to viral infections (upper respiratory tract infections, acute gastroenteritis, croup, viral syndromes, etc.).

- Specific bacterial causes include:
  - Otitis media/Sinusitis: Commonly *Streptococcus pneumoniae*, nontypeable *Haemophilus influenzae*, *Moraxella catarrhalis*
  - Pneumonia: *S. pneumoniae*, nontypeable *H. influenzae*, *Staphylococcus aureus*, *Mycoplasma* species, etc.
  - UTI: *Escherichia coli* and other gram-negative organisms
  - Unsuspected bacteremia: *S. pneumoniae*:
    - Routine vaccination with the heptavalent pneumococcal conjugate vaccine has decreased the incidence of pneumococcal disease (3,5).
    - Introduction of a decavalent pneumococcal conjugate vaccine in Europe in 2009 and utilization of newer vaccines in the U.S., such as Prevnar 13, should decrease the incidence further.
    - *Neisseria meningitidis*, *S. aureus*, *Haemophilus* species, *Salmonella* species, and other organisms are less commonly reported.
  - Cellulitis/Abscess:
    - Skin: Group A beta-hemolytic streptococcus (GAS) and *S. aureus* predominate.
    - Dental: Anaerobes such as *Bacteroides*, *Fusobacterium*, and *Peptostreptococcus* species predominate.
  - Osteomyelitis/Septic arthritis: Same as for cellulitis:
    - Consider *Neisseria gonorrhoeae* in adolescents.
  - Bacterial pharyngitis: GAS:
    - More common in school-age children
    - Unlikely <3 yr of age
  - Other causes include but are not limited to other bacterial infections, appendicitis, Kawasaki disease, rheumatologic disease, oncological problems, medication, etc.

## DIAGNOSIS

### HISTORY

- Symptoms of disease may be nonspecific in infants and include history of fever, poor feeding, fussiness, sleepiness, seizure, rash, cough, rhinorrhea, and difficulty breathing.
- In toddlers and older infants:
  - General: Malaise, irritability, decreased oral intake, decreased urine output
  - Pain: Ear, mouth, throat, joint, chest, head, arm/leg, face, abdomen
  - HEENT: Eye redness/discharge, photophobia, facial or periorbital swelling, gum swelling, muffled voice, oral lesions
  - Neck: Neck pain, mass, or swelling
  - Respiratory: Characteristics of cough, rhinorrhea, dyspnea
  - Abdomen: Vomiting, diarrhea, location of pain
  - Genitourinary: Dysuria, discharge, lesions
  - Extremities: Swelling, limp, pain, decreased range of motion
  - Dermatologic: Rash

### PHYSICAL EXAM

- The ability to determine serious bacterial illness (SBI) by physical exam is difficult and unreliable in the younger infant but improves over this age spectrum, especially in patients >6–12 mo of age.
- Specific findings:
  - Head: Localized swelling or tenderness
  - Ear: Red or bulging tympanic membrane, swelling of ear, tenderness of earlobe
  - Face: Swelling/induration, erythema, sinus tenderness
  - Eyes: Conjunctivitis, proptosis
  - Nose: Rhinitis, rhinorrhea
  - Mouth/Pharynx: Lesions, redness, swelling, uvular deviation, trismus, gum swelling associated with dental caries
  - Neck: Swelling, nodes, tenderness, decreased range of motion, meningismus
  - Chest: Rales, wheezing, decreased aeration, egophony, splinting, tachypnea, grunting
  - Abdomen: Location of tenderness, guarding, rebound, referred pain
  - Extremities: Swelling, tenderness, erythema, decreased range of motion, decreased weight bearing
  - Dermatologic: Swelling, induration, fluctuance, erythema

### DIAGNOSTIC TESTS & INTERPRETATION

- Any infant with fever and ill appearance should have a sepsis evaluation performed, empiric antibiotics initiated, and admission ordered for further management.
- Testing for UTI should be based on clinical presentation and risk factors (1).
- Routine testing for bacteremia is not necessary, especially in the well-appearing, fully vaccinated patient >6 mo of age (4,5):
  - Consideration for blood testing for bacteremia can be made in infants 2–6 mo of age but may not be necessary (6).
- Other testing should be based on clinical evaluation.
- Consider any of the following lab tests as indicated.

### Lab

- Urinalysis and urine culture, especially in infants and children with risk factors
- Serum CBC and blood culture
- Serum C-reactive protein and procalcitonin may play a role in the assessment of febrile infants:
  - Their role has not yet been clearly defined.
  - Studies reveal mixed results in this age group.
- CSF: WBC, RBC, glucose, protein, Gram stain, and CSF culture
- Viral testing (for respiratory syncytial virus, influenza, herpes simplex virus [HSV], etc.) based on symptoms, if diagnosis improves management
- Rapid streptococcal antigen testing and throat culture in age appropriate patients (>3 yr of age) based on signs and symptoms

**Imaging**

- Chest radiograph for suspicion of pneumonia:
  - Wheezing and fever in the infant or toddler may be a sign of viral bronchiolitis, for which a chest radiograph is not routinely necessary.
- CT scan or US of the specific site as indicated for suspicion of deep tissue infection, such as abscess, appendicitis, etc.

**Diagnostic Procedures/Other**

- Transurethral catheterization or suprapubic bladder aspiration for urine testing
- Arthrocentesis for septic arthritis
- Suprapubic aspiration and arthrocentesis may be guided by US.

**DIFFERENTIAL DIAGNOSIS**

See Etiology section.

**TREATMENT**

**INITIAL STABILIZATION/THERAPY**

- If ill appearing, address ABCs per Pediatric Advanced Life Support algorithm.
- Treat infection as diagnosed.
- Most causes of fever are viral and require supportive care alone.
- In well-appearing, febrile patients 3–36 mo of age without a focal source, if a CBC is obtained and the WBC > 15,000/mm<sup>3</sup>:
  - Consider treatment for occult bacteremia (7).
  - Treatment may also be limited to higher thresholds of WBC count.

**MEDICATION**

**First Line**

- Acetaminophen or ibuprofen PRN
- The diagnosis guides antibiotic selection.
- UTI:
  - Cefixime 8 mg/kg/day PO daily or divided b.i.d. for 10 days
  - Cephalexin 30–60 mg/kg/day PO divided t.i.d. for 7–10 days
  - Trimethoprim/sulfamethoxazole (dose on trimethoprim component) 6–10 mg/kg/day PO divided b.i.d. for 10 days
- Pneumonia:
  - Amoxicillin (high dose) 80–90 mg/kg/day PO divided b.i.d. or t.i.d. for 10 days
  - Amoxicillin/clavulanic acid (high dose amoxicillin component) 80–90 mg/kg PO divided b.i.d. or t.i.d. for 10 days
  - Azithromycin 10 mg/kg PO daily for 3 days
  - Cefuroxime 20–30 mg/kg/day divided b.i.d. for 10 days
- Cellulitis or abscess:
  - Cephalexin 60–100 mg/kg/day PO divided q.i.d. for 10 days
  - Amoxicillin/clavulanic acid (see above)
- Cellulitis, abscess, MRSA:
  - Clindamycin 30 mg/kg/day PO divided t.i.d. for 10 days
  - Trimethoprim/sulfamethoxazole (see above) and cephalexin (see dose for cellulitis)
- Pharyngitis:
  - Penicillin VK 25–50 mg/kg/day divided t.i.d. to q.i.d. max dose 3 g/day
  - Amoxicillin 40–50 mg/kg/day divided b.i.d. or t.i.d. for 10 days

- Occult bacteremia: Empiric treatment:
  - Ceftriaxone 50 mg/kg IM/IV (single dose)
- Meningitis: 3rd-generation cephalosporin:
  - Ceftriaxone 50–100 mg/kg IV daily
  - Cefotaxime 100–200 mg/kg/day IV divided q6h
- Septic arthritis: IV antibiotics for suspected etiologies and operative intervention (see Arthritis, Septic topic)
- Osteomyelitis: IV antibiotics for suspected etiologies (see Osteomyelitis topic)
- Bacterial gastroenteritis: Routine antibiotic administration is not warranted until the stool culture results are available.

**SURGERY/OTHER PROCEDURES**

- Operative irrigation for septic arthritis
- Incision and drainage for abscesses:
  - Abscess drainage may be guided by US

**DISPOSITION**

**Admission Criteria**

- Ill appearance
- Unreliable follow-up
- Bacterial meningitis, septic arthritis, osteomyelitis, pyelonephritis, rapidly spreading cellulitis
- Pneumonia with hypoxemia or respiratory distress

**Discharge Criteria**

- Well appearing
- Reliable follow-up
- Ability to tolerate PO medications

**FOLLOW-UP**

**FOLLOW-UP RECOMMENDATIONS**

- 24-hr follow-up with the primary care provider (with access to culture results)
- Discharge instructions and medications:
  - Acetaminophen or ibuprofen PRN
  - Return for increased irritability, poor feeding, lethargy, decreased urine output

**PROGNOSIS**

Depends on the results of the evaluation (eg, presence of meningitis, bacteremia, pyelonephritis, etc.)

**COMPLICATIONS**

- Complications depend on the site of infection.
- Death, urosepsis, seizures, hearing loss, developmental delay/mental retardation, abscess, limp, amputation, renal insufficiency/failure

- Urinary Tract Infection

**CODES**

**ICD9**  
780.60 Fever, unspecified

**PEARLS AND PITFALLS**

- Pearls:
  - Recent vaccination improvements have substantially decreased the incidence of SBI in this population. Check the vaccination status.
  - Herd immunity does help, even for the unimmunized.
- Pitfalls:
  - Not recognizing patients at risk for HSV infection
  - Performing an inadequate or incomplete evaluation
  - Not applying vaccination status to your decision-making process

# FEVER IN INFANTS 0–3 MONTHS OF AGE

Vincent J. Wang

## BASICS

### DESCRIPTION

- Fever has traditionally been defined as a temperature of  $>38^{\circ}\text{C}$  or  $100.4^{\circ}\text{F}$  in an infant  $<2\text{--}3$  mo of age.
- Infants in this age group display limited ability to demonstrate signs of infection (1).
- Serious bacterial illness (SBI) is defined as meningitis, sepsis, bacteremia, urinary tract infection (UTI), pyelonephritis, pneumonia, osteomyelitis, acute gastroenteritis, cellulitis, abscess, and septic arthritis.
- This topic focuses on occult fever (without obvious signs of bacterial infection, such as cellulitis, neck abscess, etc).
- Viral infections, such as herpes simplex virus (HSV), respiratory syncytial virus (RSV), or enterovirus, may also cause life-threatening illness.

### EPIDEMIOLOGY

#### Incidence

- UTI/Pyelonephritis occurs in 3–10%.
- Bacteremia occurs in 2–3%.
- Meningitis occurs in ~1%.
- Infants identified as high risk or ill appearing have a 13–21% incidence of SBI.

### RISK FACTORS

- Infants  $<3$  mo have innate immunologic deficiencies that improve over time.
- History of maternal fever during delivery
- History of unexplained jaundice or admission for sepsis

### ETIOLOGY

- Most causes of fever are due to viral infections.
- SBI is most commonly due to *Escherichia coli*, group B streptococcus, and *Listeria monocytogenes*.
- *Neisseria meningitidis*, *Streptococcus pneumoniae*, *Staphylococcus aureus*, *Salmonella* species, and *Haemophilus influenzae* are less commonly reported.

## DIAGNOSIS

### HISTORY

Symptoms of disease may be nonspecific and include:

- History of fever
- Poor feeding
- Vomiting/diarrhea
- Fussiness
- Sleepiness
- Seizure
- Rash
- Cough, rhinorrhea
- Difficulty breathing

### PHYSICAL EXAM

- The ability to determine SBI by physical exam is difficult and unreliable for this age group.
- The physical exam may be normal.
- Signs may be nonspecific and may include:
  - Fever
  - Lethargy
  - Irritability
  - Bulging fontanel
  - Tachypnea, grunting, retractions
  - Joint swelling
  - Abdominal distension
  - Rash
- Rectal temperatures are the gold standard and are strongly recommended over other methods. Axillary and tympanic membrane temperatures are not reliable in this age group.

### DIAGNOSTIC TESTS & INTERPRETATION

- Any infant with fever and ill appearance should have a sepsis evaluation performed, empiric antibiotics initiated, and admission ordered for further management.
- Consider the following lab tests.

#### Lab

- Urinalysis and urine culture
- Serum CBC and blood culture
- CSF WBC, RBC, glucose, protein, Gram stain, and CSF culture
- Serum C-reactive protein (CRP) and procalcitonin may play a role in the assessment of these febrile patients, although their role has not yet been clearly defined:
  - CRP is currently more readily available than procalcitonin, but procalcitonin appears to be more promising (2).
- Consider viral testing (for RSV, influenza, HSV, etc.) based on season and symptoms, especially if a positive test changes patient management or the amount of other testing done.

#### Lab: Established Protocols

- Follow established protocols (if met, may discharge the patient)
- Recommended: Philadelphia protocol (3):
  - Temperature  $\geq 38.2^{\circ}\text{C}$
  - 29–56 days of age
  - WBC  $\leq 15,000/\text{mm}^3$
  - Urinalysis negative
  - CSF WBC  $\leq 8/\text{mm}^3$
  - Serum band to neutrophil ratio  $\leq 0.2$

- Other strategies:
  - Boston criteria (4):
    - Temperature  $\geq 38^{\circ}\text{C}$
    - 28–89 days of age
    - WBC  $\leq 20,000/\text{mm}^3$
    - Urinalysis negative
    - CSF WBC  $\leq 10/\text{mm}^3$
  - Applying Boston criteria to infants 1–2 mo of age
  - Rochester criteria (5):
    - Temperature  $\geq 38^{\circ}\text{C}$
    - $\leq 2$  mo of age
    - No past medical history
    - WBC  $\geq 5,000/\text{mm}^3$  or  $\leq 15,000/\text{mm}^3$
    - Urinalysis negative
    - No CSF testing is included in these criteria.

### Imaging

- Obtain a chest radiograph for findings such as rales, tachypnea, grunting, or wheezing (6).
- Wheezing and fever may be a sign of viral bronchiolitis, for which a chest radiograph may not be necessary.
- CT of the head is not routinely indicated in the evaluation of neonatal meningitis.

### Diagnostic Procedures/Other

- Transurethral catheterization or suprapubic bladder aspiration for urine testing
- Rarely, arthrocentesis for septic arthritis.
- Suprapubic aspiration and arthrocentesis may be guided by US.

### DIFFERENTIAL DIAGNOSIS

- Most causes of fever are due to viral infections, such as RSV, adenovirus, influenza, herpesvirus, coxsackievirus, or enteroviruses.
- Viral testing in combination with utilization of the Boston, Rochester, or Philadelphia criteria may be helpful to distinguish viral infections from bacterial infections (7).

## TREATMENT

### INITIAL STABILIZATION/THERAPY

- If ill appearing, address ABCs per Pediatric Advanced Life Support algorithm.
- If focal infection is identified, treat specifically (eg, meningitis, septic arthritis, UTI). See related topics for these treatments.

### MEDICATION

#### First Line

- Empiric treatment for term infants  $>3$  kg
- Age  $<1$  mo: Combination therapy of:
  - Ampicillin 200–400 mg/kg/day IM/IV divided q4–6h in combination WITH
  - Cefotaxime 50 mg/kg IM/IV q6–8h OR
  - Gentamicin 2.5 mg/kg IV q8h
  - Consider ceftriaxone (50–100 mg/kg IM/IV divided q12–24h) instead of cefotaxime, but AVOID use in infants with:
    - Potential or actual hyperbilirubinemia
    - Liver disease
    - Patients receiving calcium IV

- Age > 1 mo, admitted (failed established protocols): Ceftriaxone or cefotaxime (consider adding ampicillin)
- Age > 1 mo, discharged:
  - No antibiotics (Philadelphia or Rochester criteria)
  - Ceftriaxone for low-risk patients (Boston protocol)

### Second Line

- Vancomycin (10–15 mg/kg IV q6–8h) for suspected *S. aureus* or *S. pneumoniae* meningitis
- Acyclovir (20 mg/kg/day IV q8h) for suspected HSV infection
- Dexamethasone (0.6 mg/kg/day IV divided q6h) for presumed bacterial meningitis for infants > 6 wk old

### DISPOSITION

#### Admission Criteria

- Neonates < 1 mo of age
- Ill appearance
- Unreliable follow-up
- Serum WBC > 15,000/mm<sup>3</sup> in Philadelphia protocol (may follow Rochester or Boston criteria instead) (3–5)
- CSF WBC > 10/mm<sup>3</sup>
- CSF Gram stain showing bacteria
- Evidence of pyelonephritis
- Pneumonia
- Hypoxemia or respiratory distress

#### Discharge Criteria

- Well appearing
- Reliable follow-up
- Serum WBC ≤ 15,000/mm<sup>3</sup> in Philadelphia protocol (may follow Rochester or Boston criteria instead) (3–5)
- Normal CSF indices
- Urinalysis not suggestive of UTI

### FOLLOW-UP

#### FOLLOW-UP RECOMMENDATIONS

- 24-hr follow-up with the primary care provider (with access to culture results)
- If ceftriaxone was given, a repeat dose of ceftriaxone is optional.
- Discharge instructions and medications:
  - Acetaminophen 10–15 mg/kg PO/PR q4–6h
  - Return for increased irritability, poor feeding, lethargy, decreased urine output

### PROGNOSIS

Depends on the results of the evaluation (eg, presence of meningitis, bacteremia, pyelonephritis, etc.)

### COMPLICATIONS

• Complications depend on the site of infection

- Death
- Urosepsis
- Seizures
- Hearing loss
- Developmental delay/mental retardation
- Abscess
- Limp
- Amputation
- Renal insufficiency/failure

### PEARLS AND PITFALLS

- Pearls:
  - Recent vaccination improvements (*H. influenzae* type b and pneumococcal conjugate vaccines) have not substantially decreased the incidence of SBI in this population.
- Pitfalls:
  - Applying the fever criteria incorrectly (Philadelphia, Boston, and Rochester criteria) by selectively using and mixing the criteria
  - Not recognizing patients at risk for HSV infection
  - Performing an inadequate or incomplete evaluation
  - Not applying the birth and postpartum history

# FEVER OF UNKNOWN ORIGIN

Worapant Kriengsoontornkij  
Vincent J. Wang

## BASICS

### DESCRIPTION

- The definition of fever of unknown origin (FUO) in children is commonly defined as:
  - Fever  $\geq 38.3^{\circ}\text{C}$  ( $101^{\circ}\text{F}$ )
  - Fever of at least 8 days in duration
  - No apparent diagnosis after the initial outpatient or hospital evaluation that has included:
    - A thorough history and physical exam AND
    - Initial lab assessment
- FUO is usually an atypical presentation of a common childhood illness.

### EPIDEMIOLOGY

#### Incidence

- FUO accounts 1.5% of pediatric emergency department presentations (1).
- In the general population, prevalence varies by criteria for diagnosis of FUO, institution, and time of studies. The prevalence is around 0.044% if the duration of fever is  $>3$  wk (2).

### RISK FACTORS

- Recent travel
- Immunodeficiency (primary and secondary)
- Parenteral drug abuse
- Immigrant status

### PATHOPHYSIOLOGY

- Resetting of the thermoregulatory center in the hypothalamus by the action of cytokines released in response to bacterial or viral pathogens, circulating immune complexes and pyrogens from tumor cells
- Drug fever: By hypersensitivity reaction
- CNS: Direct damage to thermoregulatory centers (3)

### ETIOLOGY

- The 3 most common etiologic categories of FUO in children are infectious diseases, connective tissue diseases, and neoplasms.
- The most common infections are Epstein-Barr virus (EBV) infection, osteomyelitis, and urinary tract infection (UTI).

## DIAGNOSIS

### HISTORY

- Fever:
  - Intermittent fevers with a high spike and rapid defervescence: Pyogenic infection, TB, lymphoma, and juvenile rheumatoid arthritis (JRA)
  - Remittent fevers with fluctuating peaks and a baseline that does not return to normal: Intermittent fever with antipyretic agent administration, viral infections, infective endocarditis (IE), sarcoidosis, lymphoma, and atrial myxoma
  - Sustained fevers persisting with little or no fluctuation: Typhoid fever, typhus, brucellosis, and many other infections

- Relapsing fevers with periods during which patients are afebrile for  $\geq 1$  day between febrile episodes: Malaria, rat-bite fever, *Borrelia* infection, and lymphoma
- Recurrent episodes of fever over periods of  $>6$  mo duration: Metabolic defects, CNS dysregulation of temperature control, periodic fever syndromes, immunodeficiency
- Temperatures  $\geq 42^{\circ}\text{C}$  ( $107.6^{\circ}\text{F}$ ) are most often noninfectious in origin.
- Exposure to animals including household pets, domestic animals in the community, and wild animals can cause zoonotic infections:
  - Unpasteurized dairy products, contact with animals: Brucellosis
  - Consumption of game meat, raw meat, or raw shellfish: Brucellosis, toxoplasmosis, tularemia, hepatitis
  - Tick bites: Rocky Mountain spotted fever (RMSF), ehrlichiosis, tularemia, tickborne relapsing fever, or Lyme disease. North American mosquitoes and some ticks carry a variety of arboviruses.
  - Tick bite, found in central Texas and eastern Oklahoma, eastward throughout the southeastern U.S., and north along the Atlantic coastal plain into New England. Peak is May–August: Ehrlichiosis.
  - Contact with urine of infected animals (eg, rats) in water or soil: Leptospirosis
  - Cat or dog bite: Pasteurella
  - Contaminated food (undercooked meat, poultry or eggs): Salmonella
  - Skinning, dressing, or eating infected animals (squirrels, rabbits, hares, and muskrats): Tularemia
  - Tick bite (rabbits, deer): Tularemia
- Travelers or immigrants from malaria-endemic areas
- Inhaling aerosolized dust contaminated by parturient cats or by consuming unpasteurized contaminated milk products: Q fever
- Travel to or coming from endemic areas:
  - North Carolina, Tennessee, Missouri, Oklahoma, Arkansas, Virginia, Maryland, South Carolina, and Pennsylvania: RMSF
  - Japan, Southeast Asia, west and southwest Pacific: Scrub typhus
- Pica (ingesting infected cat feces): Toxocara infection, toxoplasmosis
- Medication: Anticholinergic agents, dinitrophenol and uncouplers of oxidative phosphorylation
- Genetic background:
  - Jewish descent: Familial dysautonomia
  - Autosomal recessive transmission pattern in family: Hyperimmunoglobulin D syndrome, familial Mediterranean fever
- Continued, unexplained weight loss, excessive bruising or bleeding, limping: Neoplasm
- Past medical history: Lymphoma, rheumatic fever, HIV infection

### PHYSICAL EXAM

- Absence of sweating in the presence of elevated or changing body temperature:
  - Consider dehydration, anhidrotic ectodermal dysplasia, familial dysautonomia, or exposure to atropine
- Purulent discharge in the nose or posterior pharynx, erythematous and boggy nasal mucosa, tenderness on percussion over sinuses: Sinusitis
- Ear pain, hearing loss, ear discharge, vertigo, bulging and redness of tympanic membrane (TM), air-fluid levels behind the TM: Otitis media (OM)
- A cardiac murmur, often new onset: IE
- Signs of respiratory distress (tachypnea, hypoxemia, retractions, nasal flaring, grunting) are more specific than fever or cough for pneumonia.
- Skin:
  - Petechiae in IE, bacteremia, viral and rickettsial infections
  - Rash begins on the ankles and wrists and spreads to the palms, soles, and centrally: RMSF
  - A primary cutaneous papule or pustule develops approximately 3–10 days after an animal contact at a site of a scratch or bite: Cat scratch disease
  - Eschar: Tularemia, scrub typhus
  - Macular salmon-pink rash: JRA
  - Malar erythema: Systemic lupus erythematosus (SLE)
  - Palpable purpuric lesions: Vasculitis (eg, polyarteritis nodosa)
  - Urticarial and/or seriginous macular rash and band of erythema at the lateral aspects of the hands and feet: Serum sickness
  - Erythema nodosum: Infection, malignancy, JRA, SLE, inflammatory bowel disease (IBD)
  - A seborrheic rash can indicate histiocytosis.
  - Sparse hair, particularly of the eyebrows and eyelashes, and hypohidrosis may suggest anhidrotic ectodermal dysplasia.
- Eyes:
  - Red weeping eyes: Connective tissue disease, especially polyarteritis nodosa
  - Palpebral conjunctivitis: Coxsackievirus, measles, TB, EBV, cat scratch disease, lymphogranuloma venereum
  - Bulbar conjunctivitis: Leptospirosis; if sparing the limbus, Kawasaki disease (KD)
  - Petechial conjunctival hemorrhages: IE
  - Uveitis: Sarcoidosis, JRA, SLE, KD, Behçet disease, vasculitis
  - Chorioretinitis: Cytomegalovirus (CMV), toxoplasmosis, syphilis
  - Proptosis: Orbital tumor, thyrotoxicosis, metastasis (neuroblastoma), orbital infection, Wegener granulomatosis, pseudotumor cerebri
  - Lack of tears and absent corneal reflex: Familial dysautonomia
  - Failure of pupillary constriction due to absence of the sphincter constrictor muscle of the eye: Hypothalamic dysfunction

- Skin and nails:
  - Nail fold capillary abnormalities (dropout of capillary end loops, dilated, tortuous capillaries): Connective tissue diseases such as juvenile dermatomyositis and systemic sclerosis
  - Petechiae, subcutaneous nodules, splinter hemorrhages, clubbing: Vasculitis, IE
- Oral cavity:
  - Recurrent oral candidiasis: Various disorders of immune system
  - Smooth tongue with absence of fungiform papillae: Familial dysautonomia
  - Hyperemia of the pharynx: EBV, CMV, toxoplasmosis, salmonellosis, tularemia, KD, leptospirosis
- Rectal and genitourinary exam:
  - Lymphadenopathy or tenderness can indicate deep pelvic abscess, iliac adenitis, or pelvic osteomyelitis.
- Musculoskeletal:
  - Point tenderness over a bone may suggest osteomyelitis or neoplastic bone disease.
  - Tenderness over the trapezius muscle: Subdiaphragmatic abscess
  - Hyperactive deep tendon reflexes: Thyrotoxicosis

**DIAGNOSTIC TESTS & INTERPRETATION**

**Lab**

**Initial Lab Tests**

- CBC and blood smear (recommended for all children with FUO):
  - Anemia: Malaria, IE, IBD, SLE, TB, leukemia, lymphoma
  - Thrombocytosis: KD
  - Atypical lymphocytes: Viral infection
  - Bizarre or immature forms of lymphocytes: Leukemia
  - Absolute neutrophil count > 10,000/microL or nonsegmented neutrophils > 500/microL suggests a higher likelihood of having a bacterial infection.
- ESR and C-reactive protein (CRP) (recommended for all children with FUO): General indicators of inflammation:
  - An elevated ESR or CRP excludes factitious fever.
  - A normal ESR or CRP: Noninflammatory conditions (eg, dysautonomia, ectodermal dysplasia, thalamic dysfunction, diabetes insipidus, drug fever)
  - The artificially lowered ESR: Consumption of fibrinogen (such as disseminated intravascular coagulopathy)
  - An elevation occurs in noninflammatory disorders: Hypergammaglobulinemia
  - ESR > 30 mm/hr indicates inflammation: Infectious, autoimmune, or malignant diseases
  - ESR > 100 mm/hr suggests TB, KD, malignancy, or autoimmune disease.
- Urinalysis and urine culture to evaluate for UTI (recommended for all children with FUO)
- Blood culture (recommended for all children with FUO): Several sets should be obtained over 24 hr in patients in whom IE, osteomyelitis, or deep-seated abscesses are being considered.

**Secondary Lab Tests**

- BUN, creatinine, and hepatic enzymes are obtained to evaluate renal and/or hepatic involvement: Elevated hepatic enzymes may be a clue to a viral infection without distinctive features (eg, EBV, CMV), or brucellosis.
- Serum electrolytes: Diabetes insipidus
- Lactate dehydrogenase (LDH): Cancer
- HIV antibody
- CSF testing should be performed in children with suspected meningitis.
- Serologic tests may aid in the diagnosis of EBV, CMV, toxoplasmosis, salmonellosis, Lyme disease, tularemia, brucellosis, leptospirosis, cat scratch disease, rickettsial disease, JRA, and SLE.
- Immunoglobulin level: Congenital and acquired immunodeficiency states (eg, HIV, Bruton agammaglobulinemia)

**Imaging**

- CXR (recommended for all with FUO)
- Consider sinus x-rays when upper respiratory infection symptoms are persistent > 10 days, severe, and worsening.
- Consider temporal bone CT scan for suspected mastoiditis. This should be accompanied by an OM.
- Consider the following tests selectively:
  - Echo: IE
  - US: Intra-abdominal abscesses of the liver, subphrenic space, pelvis, or spleen
