- Complete: Full thickness of rectum prolapses through anus (2 layers of rectum with an intervening peritoneal sac, which may contain small bowel).
- Incomplete/Mucosal: Prolapse limited to only 2 layers of mucosa
- Concealed: Internal intussusception of upper rectum into lower, which does not, however, emerge through anus

EPIDEMIOLOGY

- Most cases occur in children <4 years of age around time of toilet training, equal incidence in boys and girls.
- Common in developing countries, perhaps because of poor nutrition and parasitic infection; uncommon in the Western world
- It usually presents between 6 months–3 years of age in patients with cystic fibrosis (CF). Incidence is 20%. Presentation in such children >5 years of age is rare. Highest incidence is in the 1st year of life.
- In older children and adults, strong (6-fold) female predilection

RISK FACTORS

Genetics

No known inheritance pattern aside from the association with CF, which is an autosomally recessive inherited disease

ETIOLOGY

Exact etiology uncertain, but the following are usually related findings and predisposing conditions:

- Excessive straining with bowel movements from constipation and toilet training (hips and knees flexed)
- Diarrhea; may be more of a cause in tropic and subtropical countries
- Malnutrition; can cause loss of the ischioanal fat pad
- Complete prolapse is rarer in children, but when it occurs it may be related to poor fixation of rectum to sacrum and to weak pelvic and anal musculature.
- Complication of past surgery, such as imperforate anus repair
- Infections: Hookworms and other parasitic infections
- CF
- Ulcerative colitis
- Hirschsprung disease
- Ehlers–Danlos syndrome
- Meningomyelocele
- Pertussis
- Rectal polyp
- Pneumonia
- Anorexia
- Rectal neoplasm

DIAGNOSIS

HISTORY

- Usually 1st noted by a parent after child has defecated; may be associated with minimal, painless rectal bleeding
- Often reduces spontaneously; if not, usually easily reduced manually by parent
- Rectal prolapse may cause some discomfort during bowel movements.
- Trauma to the recurrently prolapsed mucosa may lead to ulceration and mucus discharge.
- Ask whether this patient has CF or symptoms of the above conditions.
- Signs and symptoms:
 - Protrusion of rectal layers through anus, usually found during defecation or attempted defecation
 - Although the history of rectal prolapse may be evident, it is often difficult to elicit on examination, and by the time the patient is seen after a prolapse at home, it may already be spontaneously reduced. Thus, the assumption of the diagnosis may have to rest primarily on the parental history.
 - Although usually benign, rectal prolapse is distressing to both the parents and the child.

PHYSICAL EXAM

- Usually, prolapse is not seen on examination while the patient is at rest, unless it is irreducible (dark or bright red mass protruding from child's anus without discomfort).
- May see poor anal tone and/or large anal orifice, especially within hours after the prolapse
- In complete rectal prolapse, concentric mucosal rings can be seen, whereas incomplete (mucosal) prolapse reveals radial folds. If clinician sees >5 cm of rectum emerging, it is most likely a complete prolapse. Asking the patient to strain may allow the mucosa to prolapse. However, this is obviously not helpful in a very young patient.
- A polyp is differentiated in that it is plum-colored and does not involve the entire anal circumference.
- In an intussusception, it is possible to insert the finger around the prolapsing apex of the intussusception, between it and the lining of the anal canal.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Sweat test: All children with rectal prolapse should have a sweat test to rule out CF. This is a simple, noninvasive, inexpensive test with good specificity and sensitivity when performed by an experienced clinician in a qualified facility.
- Stool cultures for bacterial and parasitic infestations, if diarrhea could be causative
- Other tests for the above conditions as clinically indicated

Imaging

Evacuation proctography: A barium enema is given, and movement of barium is observed under fluoroscopy during defecation. This may reveal an internal prolapse not easily recognizable on physical examination. This is not commonly used in children, because full cooperation is essential.

DIFFERENTIAL DIAGNOSIS

- Tumors
- Prolapsing rectal tumor: Very rare
- Trauma
- Sexual abuse (e.g., result of anal penetration)
- Metabolic
- CF: From 10–50% of patients diagnosed with CF >4 years of age have experienced rectal prolapse (either at the time of the diagnosis or as a past event), but few individuals with rectal prolapse have CF.
- Anatomic abnormality (such as absence of Houston valves in infants)
- Solitary rectal ulcer syndrome: An uncommon benign condition usually affecting older children (teenagers). Rectal bleeding on defecation is common. Some studies report an association between this entity and rectal prolapse.
- Prolapsing polyp
- Large hemorrhoids
- Colonic intussusception
- Constipation
- Ehlers–Danlos syndrome
- Hirschsprung disease
- History of imperforate anus
- Pertussis/Pneumonia
- Ulcerative colitis
- History of meningomyelocele

TREATMENT

MEDICATION (DRUGS)

- Stool softeners (i.e., polyethylene glycol) to relieve constipation or medication with the associated condition
- In a patient with CF, addition of pancreatic enzyme supplementation, if not already a part of the regimen, has been shown to improve rectal prolapse dramatically.

ADDITIONAL TREATMENT

General Measures

- Rectal prolapse has a tendency to resolve spontaneously over time (90%; unlikely if 1st episode is in patient >4 years of age)
- Patients who present with a prolapsed rectum should undergo manual reduction in a prone position:
 - Parents should be provided with gloves and lubricant and taught how to reduce the prolapse.
 - The prolapsed bowel may be grasped with lubricated gloved fingers and pushed back in with gentle steady pressure.

- If the bowel has become edematous, firm steady pressure for several minutes may be necessary to reduce the swelling and allow for reduction.
- Digital rectal examination should always follow this procedure to verify complete reduction.
- If the prolapse immediately recurs, it may be reduced again and the buttocks taped together for several hours.
- The prolapse will resolve more successfully and quickly if the patient is treated for constipation:
 - This should include both dietary manipulations (e.g., increased fiber, hydration) and improved defecation methods.
 - It also will usually require the use of supplemental aids such as laxatives (polyethylene glycol).
- A small child should try to defecate with his hips at 90 degrees, his buttocks at toilet seat level, not hunched over, and on an appropriately sized toilet. If a child-sized toilet is unable to accomplish this, then an adult commode can be tried.
- In the rare case of stool infection with diarrhea as the underlying etiology, the appropriate therapy for that infection should be instituted.

SURGERY/OTHER PROCEDURES

- Numerous (> 130) approaches have been attempted and advocated with varying degrees of enthusiasm, suggesting that none is perfect. These include:
- Perianal sutures: Poor results and high complication rate
 - Delorme procedure: Rectal mucosa is excised, and underlying rectal muscle is plicated with sutures.
 - Laparoscopic suture rectopexy: Rectal wall is exposed and then sutured to the fascia of the sacral promontory; 5% full thickness recurrence rate.
 - Abdominal rectopexy: Rectum is mobilized and attached to the sacrum by prosthetic material. Although the procedure provides good results, it has a high complication rate of constipation (> 50%).
 - Anterior resection rectopexy: Resection of the sigmoid loop and upper rectum; good results, but again, high complication rate.
 - Perineal resection: Perineal rectosigmoidectomy with a coloanal anastomosis; good results
 - Circumferential injection procedures (90–100% success rate): Injection of phenol, oil, hypertonic saline, dextrose 50% solution (500 g/L), or ethyl alcohol to promote adhesion and stabilization of the rectum
 - Lockhart–Mummery operation (near 100% success): Mesh pack is placed temporarily in the retrorectal space (8–10 days) to promote adhesions that stabilize rectum.

IN-PATIENT CONSIDERATIONS

Initial Stabilization

Palliative:

- Reassurance of patient and/or family and caregivers
- Although surgery seems to be a quicker and more definite solution, in most cases it is more prudent to allow time and medical management to solve the problem. Surgical procedures are not without risk and may lead to further complications (> 130 procedures exist, more effective in patients < 4 years of age).

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

Ask caregiver to watch whether the child is beginning to strain to defecate.

DIET

- Increase consumption of liquids.
- Add larger amounts of fiber to diet (5 g + age in years)

PROGNOSIS

- With proper medical management, excellent prognosis; surgery is not usually required.
- Treatment of constipation should continue indefinitely, or until the child has demonstrated regular bowel habits on a high-fiber diet on his or her own without evidence of prolapse for at least several months.
- Over a period of months to years on a good dietary and behavioral regimen

COMPLICATIONS

- In some older patients who may also have an overactive external sphincter, the need to generate high rectal pressures to defecate, together with the rectal prolapse, may cause venous congestion; it may lead to the solitary rectal ulcer syndrome.
- Repetitive trauma to mucosa can produce proctitis.
- Surgical complications of repair
- Frequent recurrence

K62.3 Rectal prolapse

FAQ

- Q: What should I do if my child has a rectal prolapse but I cannot reduce it?
- A: You should wrap the prolapse in moist towels and bring your child to the emergency department. Physicians there will try to reduce it. Rarely, if a prolapse is irreducible and left for a period of time, it can cause bowel ischemia and may require surgery.
- Q: My child has rectal prolapse and now he is supposed to have a sweat test to determine whether he has CF. Is this very likely?
- A: No. Although it is important to rule out this disease, most patients with rectal prolapse do not have CF. However, many children with CF suffer from rectal prolapse.
- Q: My child, who has rectal prolapse, is in daycare. How will I know if he is having the prolapse?
- A: You should inform someone in the school (a teacher or guardian) of his condition, and he or she should check the child for prolapse after a bowel movement. Although, if present, it usually resolves spontaneously, the teacher should inform you so you can do a manual reduction, if necessary.

REFRACTIVE ERROR

Monte D. Mills

BASICS

DESCRIPTION

To allow vision, light coming into the eye must focus on the retina. Refractive errors are aberrations in the optic components of the eyes that cause the eye to lose focus. Uncorrected refractive error blurs vision in 1 or both eyes, and may also cause strabismus and amblyopia in children (see “Amblyopia” and “Strabismus”).

GENERAL PREVENTION

- Early detection and correction of refractive errors is important to prevent amblyopia and strabismus. Recognition visual acuity testing using charts should start by age 4 years.
- Children with significant refractive errors are not necessarily symptomatic. All children should be screened for visual acuity in each eye.
- Glasses may not reverse amblyopia, even if the refractive error is appropriately corrected. Patients with suspected amblyopia (i.e., anisometropia, unilateral poor vision, and strabismus) should be rechecked often even if wearing glasses.

EPIDEMIOLOGY

Because of the age-related growth of the optic components of the eye, prevalence of refractive errors varies during childhood. At birth, usual median refractive error is low hyperopia, approximately +2.00 diopters. In adults, the median is emmetropia. The incidence of refractive error requiring correction increases with age.

Prevalence

- In school-aged children in the US, 7–25% have refractive error significant enough to affect visual acuity. ~25% of the adult population of the US have myopia, and ~5% have hyperopia.
- Some ethnic groups have increased prevalence of myopia, including people of Native American, Chinese, and Japanese descent.

RISK FACTORS

Genetics

- Both genetic and environmental factors are important in refractive status. ~60% of myopia can be predicted by parental degree of refraction, although inheritance seems to be polygenic in most cases.
- Some genetic syndromes associated with refractive errors include:
 - Myopia:
 - Stickler syndrome
 - Albinism
 - Marfan syndrome
 - Down syndrome
 - Ehlers–Danlos syndrome
 - Hyperopia:
 - Senior–Loken syndrome
 - WAGR (Wilms tumor, aniridia, genitourinary malformations, and mental retardation) syndrome
 - Astigmatism:
 - Down syndrome
 - Crouzon syndrome
 - Albinism

- Environmental:
 - Environmental factors associated with refractive error in childhood include premature birth, eye surgery, and eye trauma.

PATHOPHYSIOLOGY

- The most important optic components of the eye are the cornea and the lens, which refract light coming into the pupil to focus an image on the retina. The cornea and lens determine the focal length of the eye, which must match the actual eye length (distance from cornea to retina). A sharply focused image on the retina is necessary for recognition of small objects and normal visual acuity; refractive errors cause blurring.
- Refractive errors can be classified in three groups based on the optic effects:
 - Myopia, also called “near-sightedness,” is correctable with concave lenses with negative dioptric power. Myopic eyes may be in focus for closer targets, but blurred for more distant.
 - Hyperopia, correctable with convex lenses with positive dioptric power.
 - Although hyperopia is sometimes called “far-sightedness,” this is a misnomer in children.
 - Small hyperopic refractive errors are easily overcome by focusing the eye, or accommodation, and many hyperopic children have no difficulty seeing near or distant targets.
 - Larger amounts of hyperopia may blur both near and distant targets, or cause eye strain or esotropia because of the focusing effort required for focusing (see “Strabismus”).
 - Astigmatism, correctable with toric lenses, is caused by aspheric aberration. Uncorrected astigmatism creates images that are not focused for near or distant targets.
 - Astigmatism may occur simultaneously with myopia and hyperopia.
- Other terms related to refractive error include:
 - Emmetropia, or neutral refraction (no refractive error)
 - Anisometropia, or unequal refractive error between the 2 eyes
 - Accommodation, the ability to refocus eyes for near targets, and to overcome hyperopia
- In children <8 years of age, because of visual development and plasticity, uncorrected refractive errors may have a significant effect on life-long vision. Amblyopia, which may cause permanent uncorrectable vision loss, and strabismus are among the risks of untreated refractive errors in young children (see “Strabismus” and “Amblyopia”).

PATHOPHYSIOLOGY

- The refractive components of the eye (e.g., cornea, lens, eye length) normally develop simultaneously during early childhood to allow focused images. Factors determining the relative growth and development of these ocular features are not completely understood, and abnormal growth of any component may result in refractive error.
- High myopia (>5 diopters in children) is associated with pathological thinning of the retina and sclera, and is associated with an increased risk of retinal detachment later in life.

COMMONLY ASSOCIATED CONDITIONS

Refractive errors are frequently associated with other ocular conditions. These include:

- Myopia:
 - Childhood glaucoma
 - Retinitis pigmentosa
 - Coloboma
 - Microphthalmia
 - Retinopathy of prematurity
 - Congenital cataract
 - Achromatopsia
 - Retinal detachment
 - Retinal hole
- Hyperopia:
 - Esotropia
 - Leber congenital amaurosis
 - Surgically treated cataracts (aphakia)
- Astigmatism:
 - Congenital ptosis
 - Coloboma
 - Forceps birth injury
 - Glaucoma
 - Retinopathy of prematurity

DIAGNOSIS

SIGNS AND SYMPTOMS

- Loss of vision
- Blurred vision
- Headache
- Squinting

HISTORY

- Age of onset of vision loss
- Associated ocular abnormalities, trauma, injury, or surgery
- History of strabismus, amblyopia
- History of prematurity, genetic disorders, collagen disorders (e.g., Ehlers–Danlos, Marfan syndromes)
- History of headaches, squinting, or subjective vision problems
- Family history of glasses or refractive error, amblyopia, strabismus

PHYSICAL EXAM

- Visual acuity is the most effective diagnostic tool for detecting refractive errors.
- Vision must be tested with each eye separately, using a patch, opaque card, or plastic occluder.
- Testing charts are available with letters as well as pictures and for children who cannot yet read figures (Es). In children who are too young to test with charts, the Bruchner simultaneous red reflex examination can detect high refractive errors and anisometropia, which appear as an asymmetric or distorted red pupillary reflex using the direct ophthalmoscope.
- Strabismus is frequently a secondary sign of refractive error in children and can be detected by cover test, Hirschberg corneal light reflex test, or Bruchner test. Photoscreening, which uses the principle of red reflex testing, is also effective in detecting high or asymmetric refractive errors.

DIFFERENTIAL DIAGNOSIS

- Any cause of monocular or binocular vision loss can simulate refractive error. Because refraction is not easily measured without eye drops and special equipment, possibility of refractive error must be considered in all children with reduced visual acuity and should also be considered in children with strabismus and normal vision. Cycloplegic refraction (measuring refraction after the use of eye drops to relax accommodation), and, in younger children, a trial of correction with glasses, is necessary to eliminate the possibility of residual amblyopia or other cause of poor vision.

**TREATMENT****ADDITIONAL TREATMENT****General Measures**

- Refractive errors are treated by corrective lenses. In young children, this is usually glasses, although contact lenses are frequently used in teenagers.
- Unlike adults, children with neglected refractive error are at great risk for significant long-term complications, including amblyopia and strabismus. Hyperopia and anisometropic hyperopia pose the greatest risk for amblyopia. Therefore, smaller amounts of hyperopia and anisometropia are generally corrected with glasses. Glasses are prescribed to improve vision and treat or prevent amblyopia in children for:
 - Myopia, -3.00 diopters or more in infants and young children, -1.00 diopter or more in school-age children
 - Hyperopia, $+4.00$ diopters or more in infants, $+3.00$ diopters or more in school-age children, or $+1.50$ diopters or more anisometropia (difference between eyes)
 - Any hyperopia in accommodative esotropia. Bifocals may also be prescribed to treat residual esotropia for near targets (high AC/A ratio).
 - Astigmatism of >3.00 diopters in infants and young children, or >1.50 diopters in school-age children
- In general, children accept full correction of all refractive error, although undercorrection of hyperopia by 0.50 – 1.00 diopter may enhance the acceptance of new glasses. Occasionally, if hyperopic correction is not well accepted, a brief period of cycloplegia with topical atropine can reinforce use of the glasses.
- In suspected amblyopia, vision should be retested to measure visual improvement after glasses have been worn for several weeks. Children wearing glasses must be remeasured regularly, usually at least annually, until they have reached visual maturity and the risk of amblyopia has passed (i.e., 8–10 years of age).
- Hyperopic patients may develop accommodative esotropia when their glasses are off, after wearing the glasses for some time. Full correction of hyperopia and continuous correction are key approaches to this unusual complication.

**ONGOING CARE**

Refractive errors change over time due to growth of the eye and its optic components. In general, younger children will need rerefraction and new glasses more frequently. All children wearing glasses should have acuity tested and be rerefacted at least annually.

PROGNOSIS

With treatment, generally glasses in younger children but including contact lenses in older children and teenagers, refractive errors rarely lead to significant functional limitations for daily activities and school. Amblyopia and strabismus must also be treated, if present. Special frames for sports and athletic activities should be considered for children if standard glasses are interfering with those activities.

COMPLICATIONS

In children, the most significant complications of uncorrected refractive errors are strabismus and amblyopia.

- Accommodative esotropia: Uncorrected hyperopia in young children can be overcome by focusing, or accommodation.
 - This involuntary focusing of the eyes is controlled reflexively and integrated with convergence (i.e., crossing the eyes inward).
 - Usually, accommodation is used to focus on near targets, and convergence keeps both eyes pointed at the near target.
 - If excessive hyperopia is present, or an abnormal ratio of accommodative convergence to accommodation exists (AC:A ratio), the eyes may cross with accommodation, producing accommodative esotropia (see "Strabismus").
- Amblyopia: Poor visual development results from a poorly focused image. Anisometropia (unequal refractive error), which blurs vision in 1 eye and is the most frequent cause of unilateral amblyopia, causes ~35% of amblyopia. Less frequently, bilateral high refractive errors may cause bilateral amblyopia (see "Amblyopia").

FAQ

- Q: Will my child always need glasses?
- A: Not necessarily. Many children who wear glasses are able to see well without correction as adults. Contact lenses and refractive surgery are also possible in older children or adults, if correction remains necessary.
- Q: Will wearing glasses weaken my child's eyes?
- A: No, wearing correction for refractive errors will not weaken the eyes or vision, and is important to prevent amblyopia and permanent vision loss. Occasionally, children with hyperopia will develop accommodative esotropia when the glasses are removed, after wearing correction for some time. This is rarely a problem as long as the glasses are worn continuously.
- Q: Is my child too young for glasses?
- A: Glasses can be worn in children as young as a few months old, with appropriate frames. Usually, children get used to glasses quickly and accept correction easily.
- Q: My child can see well, why does he need glasses?
- A: Some children with hyperopia can see charts well, but the accommodation (i.e., focusing) necessary to overcome the refractive error may cause eye strain, fatigue, and esotropia. Others may need glasses for unilateral refractive error and seem to see well with both eyes open. In these children, wearing correction may treat or prevent problems even though they may seem to see well without correction.
- Q: Everyone in my family has needed glasses for myopia in childhood. Is there anything we can do for my child that will prevent the development of myopia?
- A: Unfortunately, few environmental factors have been clearly identified to affect the development of myopia. Reading, particularly at an early age; excessively close visual targets (holding books or toys too close to the face); and light exposure during nighttime have been suggested as factors in myopia development. Avoiding long periods of reading, avoiding intensive near work, using a reasonable reading distance (i.e., 16–18 inches), and avoiding use of night lights may reduce some environmental stimuli.

RENAL ARTERY STENOSIS

Danielle Soranno

Michelle Denburg

Thomas L. Kennedy (5th edition)

BASICS

DESCRIPTION

Narrowing of 1 or both renal arteries and/or their more distal branches, resulting in decreased perfusion, increased renin release, increased vascular resistance, and systemic hypertension

EPIDEMIOLOGY

- Hypertension in infants and young children is often secondary to some identifiable cause. Of those with secondary hypertension, most have intrinsic renal disease (e.g., renal scarring, dysplasia, chronic nephritis).
- Most older children and adolescents with hypertension (i.e., readings consistently exceeding 95th percentile for age and height) have primary or idiopathic hypertension.
- Up to 5% of adults with hypertension have RAS.
- Renal artery stenosis accounts for ~10% of secondary hypertension in children. Its importance clinically is not its frequency, but its potential curability.

RISK FACTORS

Include any condition associated with thromboembolic events (such as a complication of an umbilical artery catheter in newborns), renal trauma including renal artery surgery (e.g., transplantation), or extrinsic compression of the renal artery (e.g., Wilms tumor, neuroblastoma, or pheochromocytoma).

GENERAL PREVENTION

Reduce risk factors, such as thromboembolic events, which can lead to renal artery narrowing.

PATHOPHYSIOLOGY

Arterial narrowing leads to diminished perfusion of the affected kidney, leading to signals in the juxtaglomerular apparatus, which lead to renin release and results in increased vascular resistance and BP.

ETIOLOGY

- Majority are caused by fibromuscular dysplasia. The cause is unknown and is usually an isolated finding.
- Arterial narrowing by atheroma is common in adults, but rare in children.

COMMONLY ASSOCIATED CONDITIONS

- Renal artery stenosis may occur in many other conditions, including congenital anomalies (e.g., renal artery hypoplasia), neurocutaneous disorders (neurofibromatosis [type 1], tuberous sclerosis), vasculitis (Wegener, polyarteritis nodosa, Kawasaki disease, Takayasu arteritis, moyamoya disease), syndromes (Williams, Marfan, Alagille), and infections (e.g., congenital rubella and fungal infection [immunocompromised hosts]).
- The nephrotic syndrome may accompany renal artery stenosis and is probably secondary to it.
- Renal artery stenosis has been associated with multicystic dysplasia in the contralateral kidney.

DIAGNOSIS

Prehospital

Obtain multiple BP readings with an appropriate-size cuff in an upper extremity. Avoid using automated devices (oscillometers). Consider renal artery stenosis in a child with very high BP readings (i.e., at or above the 99th percentile).

HISTORY

- Ask about prior BP determinations, family history of hypertension, previous renal disease, symptoms of hypertension, and preexisting conditions associated with renal artery stenosis.
- Signs and symptoms:
 - Symptoms of hypertension in infants are not specific and include irritability, poor feeding, and vomiting.
 - In children, symptoms include headache, nausea/vomiting, visual disturbance, dizziness, and seizure.
 - Many affected children remain asymptomatic and 1/3 of children with RAS are diagnosed incidentally.

PHYSICAL EXAM

- Obtain multiple accurate BP readings using an appropriate-size cuff in the right upper extremity and compare to the BP nomogram for age, sex, and length/height percentile.
- BP must be repeated until patient is completely relaxed with baseline heart rate.
- Most accurate readings obtained with either a mercury column or an aneroid sphygmomanometer
- The inflatable bladder of the cuff should almost completely encircle the arm.
- Determine the BP in all extremities. A gradient from the upper to lower extremities should prompt evaluation for aortic coarctation or midaortic syndrome.
- Examine the skin for lesions suggestive of vasculitis or neurocutaneous disorder (e.g., café-au-lait macules).
- Assess the child's facies and habitus for features of associated syndromes.
- View the optic fundi for hypertensive vascular changes.
- Auscultate the lower back and abdomen for the presence of a bruit (suggesting turbulent flow).
- In infancy, signs of heart failure may be present.

DIAGNOSTIC TESTS & INTERPRETATION

ECG and echocardiogram to assess for left ventricular hypertrophy and function

Lab

- BUN and creatinine to evaluate for renal insufficiency
- Electrolytes to assess possible hyperaldosteronism with hypokalemia and metabolic alkalosis. Hyponatremia may sometimes occur.
- ESR or CRP to screen for vasculitis

Imaging

- The definitive diagnostic test remains the selective renal arteriogram. If the diagnosis is made, angioplasty may be part of the same procedure. Angiography should not be delayed in any child in whom the diagnosis is strongly suspected.
- Renal ultrasound with Doppler to identify a smaller kidney and/or increased resistance to flow is simple and not invasive, but it is neither sensitive nor specific. Length discrepancy of > 1 cm in children can increase suspicion for RAS.
- Contrast-enhanced CT or MR angiography also is not completely diagnostic and is not therapeutic.
- Nuclear renal scans using DMSA or MAG-3 enhanced with captopril (and more recently angiotensin-receptor blockers) also are not diagnostic for all children.
- Diagnostic accuracy of various imaging studies:

Technique	Sensitivity (%)	Specificity (%)
Ultrasound	73–85	71–92
DMSA with ACE	52–93	63–92
CTA	64–94	62–97
MRA	64–93	72–97

Diagnostic Procedures/Other

- Avoid excessive investigation in children whose BP is minimally or episodically elevated and therefore in whom the diagnosis of renal artery stenosis is less likely.
- Selective renal vein renin determinations suggest unilateral stenosis if the affected side is 1.5 times the contralateral (normal) side. However, the procedure is invasive and requires catheterization of the femoral vein.
- Random renin determinations have little value and may be misleading. If obtained, renin levels should be interpreted in the context of the urine sodium concentration.

Pathological Findings

- Fibromuscular dysplasia is a segmental sclerotic process involving smooth muscle hyperplasia of the media layer of the artery. It is unilateral in 75%.
- Stenosis is usually distal in the renal artery, sometimes involving intrarenal branches.
- The stenotic area(s) of the artery may be associated with distal aneurysms.
- In neurofibromatosis arterial narrowing is at the vessel's ostium and usually involves the intimal layer.

DIFFERENTIAL DIAGNOSIS

- Renal artery stenosis should be suspected and investigated in children with severe, progressive, and/or difficult-to-manage hypertension.
- The differential diagnosis consists of other causes of significant hypertension, including increased intracranial pressure, coarctation of the aorta, midaortic syndrome, rapidly progressive glomerulonephritis, vasculitis, and pheochromocytoma.

TREATMENT

Treat children immediately who are symptomatic (e.g., severe headaches, seizures, blurred vision, facial palsy).

MEDICATION (DRUGS)

- Hypertension accompanying renal artery stenosis is often difficult to control and may worsen over time. Multiple medications given in high doses are common until the diagnosis is made and angioplasty can be done.
- Because renal artery stenosis results in increased renin levels, renin-angiotensin blockade with ACE inhibitor therapy (e.g., enalapril, lisinopril) and/or angiotensin receptor blockers (ARBs, e.g., losartan) is often effective. In children where bilateral renal artery stenosis is known or suspected, ACE inhibitor and ARB therapy must be avoided to prevent acute renal failure. 50% of children will have bilateral disease. Renal function should be checked before and after initiation of ACE inhibition or ARB therapy.
- If BP is easy to control on monotherapy, may consider medical management alone rather than angioplasty
- β -Blockers, calcium channel blockers, diuretics, and direct vasodilators (e.g., minoxidil, hydralazine) are all possibly effective.

ADDITIONAL TREATMENT

General Measures

- If renal artery stenosis is suspected, begin the diagnostic evaluation and pharmacotherapy together.
- If BP is very high, use bed rest until BP is better controlled.

ISSUES FOR REFERRAL

- Nephrology
- Cardiology follow-up for echo changes, if indicated
- Ophthalmologic follow-up for resolution of vascular changes, if indicated

SURGERY/OTHER PROCEDURES

- Actual surgery on the stenotic renal artery has been replaced by angioplasty, which has been successfully carried out in very young infants. Stents are occasionally used.
- Surgery must sometimes be performed, especially in children with neurofibromatosis where the stenosis is frequently at the renal artery's ostium.

IN-PATIENT CONSIDERATIONS

Initial Stabilization

- If symptomatic, use potent, rapidly acting medications such as labetalol or nicardipine.
- Be prepared to have difficulty adequately controlling the BP using a single medication.

Admission Criteria

- Children who present with a BP at or above the 99th percentile
- Children who appear to have symptomatic hypertension
- Children with progressive renal insufficiency

Nursing

- Obtain BP levels frequently and carefully.
- Notify MD if high or low limits exceeded.
- Monitor intake of salt, I&O, and weight.

Discharge Criteria

BP in the 90th–95th percentile

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- The child's BP must be followed closely, both before and after the angioplasty. Response to angioplasty may be immediate, but may require continued antihypertensive therapy at some level for weeks to months.
- Medical therapy should be monitored closely. Until correction, the need for progressively higher doses and/or additional medications is common.
- Disposition:
 - Close follow-up by the primary care provider, mainly for monitoring BP, and a specialist comfortable with the evaluation and treatment of childhood hypertension.
 - Patient and/or family must be familiar with medication, exercise program, and diet.

Patient Monitoring

- Long-term follow-up of the BP is most important. If on no medications, the BP should be checked monthly, preferably somewhere the child is comfortable and the correct cuff is employed. Begin to space visits after 6 months.
- Checking renal growth on serial renal ultrasounds is important (e.g., at 6 months postangioplasty and then yearly). If the child is fully grown, check ultrasound at 6 months.
- Check renal function annually.

DIET

Limit salt intake.

PROGNOSIS

Long-term outcome of percutaneous angioplasty is excellent; most children require no long-term antihypertensive medications.

COMPLICATIONS

- Restenosis of the renal artery, either ipsilateral or contralateral, is uncommon but possible.
- When renal artery stenosis causes severe hypertension, it may cause encephalopathy, severe headache, seizures, or stroke.
- If untreated, chronic hypertension may cause end-organ damage, including heart and kidney.
- Angiography may lead to contrast-induced renal failure. The procedure may also cause injury to the kidney and/or renal artery.
- Rare cases of subarachnoid hemorrhage secondary to coexisting intracranial aneurysm may occur.

RENAL TUBULAR ACIDOSIS

Christopher P. Bonafide

Christopher J. LaRosa

Andres J. Greco (5th edition)

DESCRIPTION

- Renal tubular acidosis (RTA) syndromes are renal transport defects characterized by normal anion gap metabolic acidosis, hyperchloremia, and normal renal function.
- Acidification of the blood occurs when there is an inability to excrete the daily endogenous metabolic acid load (distal RTA), a failure to reabsorb filtered bicarbonate (proximal RTA), or aldosterone deficiency/resistance (hyperkalemic RTA).
- Distal RTA (type I):
 - Caused by impaired acidification of the urine in the distal tubule of the kidney
 - Main defect is either a failure of the apical H^+ -ATP pump, back-leak of secreted hydrogen ions, or insufficient negative charge in the distal tubule.
 - Characterized by an inability to lower urinary pH maximally (<5.5), even in severe systemic acidemia
- Proximal RTA (type II):
 - Caused by impaired bicarbonate reabsorption in the proximal tubule of the kidney
 - Main defect is a more acidic serum threshold for proximal tubular bicarbonate reabsorption (~ 15 mEq/L vs. the normal threshold of ~ 22 mEq/L).
 - Distinguished from distal RTA in that urinary acidification mechanisms are intact in severe systemic acidemia (these patients can decrease urine pH <5.5 , although the setpoint for appropriate acidification is altered).
 - May occur as an isolated defect or as part of the Fanconi syndrome (generalized proximal tubular dysfunction resulting in glycosuria with a normal plasma glucose, phosphaturia, hypophosphatemia, aminoaciduria, and tubular proteinuria)
- Hyperkalemic RTA (type IV):
 - Caused by impaired action of aldosterone on hydrogen and potassium excretion.
 - Main defect is either aldosterone deficiency or resistance, which may occur in the context of renal parenchymal damage.
 - Characterized by hyperkalemia and mild acidosis (serum bicarbonate >17 mEq/L).

EPIDEMIOLOGY

- Primary RTA is very rare.
- The most common forms of RTA in children are proximal and distal.

Genetics

- Distal RTA can be observed sporadically or as an autosomal dominant (chromosome 17q21–22) or recessive transmission with deafness (chromosome 2p13) or without deafness (chromosome 7q33–34). The genes affected encode the chloride-bicarbonate exchanger or the hydrogen-ATPase pump.
- Isolated proximal RTA can occur secondary to mutations in the gene encoding the sodium bicarbonate cotransporter.
- Proximal RTA with Fanconi syndrome occurs in several genetic conditions: cystinosis, Lowe syndrome, Wilson disease, Dent disease, tyrosinemia, hereditary fructose intolerance, galactosemia, and mitochondrial myopathies.
- Hereditary hyperkalemic RTA is most frequently observed in children with congenital adrenal hyperplasia, aldosterone synthase deficiency, and pseudohypoaldosteronism type 1 or type 2 (Gordon syndrome).

COMMONLY ASSOCIATED CONDITIONS

- Distal RTA may also be caused by autoimmune conditions, obstructive uropathy, interstitial renal disease, and medications including lithium, cisplatin, and amphotericin B.
- Osteopenia, rickets, growth failure, nephrocalcinosis, and nephrolithiasis may develop in patients with distal RTA.
- Isolated proximal RTA may also be caused by medications including sulfonamides.
- Proximal RTA with Fanconi syndrome may also be caused by interstitial renal disease, heavy metal exposure, and medications including aminoglycosides, cisplatin, and ifosamide.
- Proximal RTA can occur with vitamin D deficiency and hyperparathyroidism.
- Rickets can occur due to the phosphate wasting in Fanconi syndrome.
- Proximal and distal RTA may occur in the setting of renal transplantation.
- Hyperkalemic RTA may also be caused by HIV infection, obstructive uropathy, interstitial renal disease, diabetes mellitus, and medications including heparin, NSAIDs, ACE inhibitors, calcineurin inhibitors, and sulfonamides.

SIGNS AND SYMPTOMS

- Children with RTA often present with growth failure, polyuria, constipation, and anorexia. Other associated signs and symptoms may include:
 - Dehydration
 - Vomiting
 - Bone pain or deformities
 - Renal colic
 - Severe metabolic acidosis and electrolyte imbalance resulting from mild gastroenteritis
 - Photophobia (in cystinosis)
 - Hypertension (in RTA type IV secondary to renal parenchymal disease or Gordon syndrome)

HISTORY

- Weight loss or poor weight gain
- Urine concentration deficits (polyuria, polydipsia, enuresis)
- Constipation
- Anorexia
- History of hospitalization for dehydration or metabolic acidosis with mild gastroenteritis
- Medications as noted earlier
- Family history of RTA
- Deafness (autosomal recessive distal RTA)
- Developmental delay (autosomal recessive proximal RTA)

PHYSICAL EXAM

- General: Failure to thrive
- Head and neck: Frontal bossing, abnormal eye examination (cystine deposition, glaucoma, cataracts, Kaiser–Fleischer rings)
- Chest: Rachitic rosary (rickets)
- Abdomen: Hepatomegaly, enlarged kidneys
- Extremities: Bowing of legs, widening of epiphysis of wrists

DIAGNOSTIC TESTS & INTERPRETATION

The hallmark of RTA is a hyperchloremic metabolic acidosis with normal anion gap and normal renal function.

Lab

- Serum electrolytes:
 - Helps to identify the presence of metabolic acidosis, hypokalemia, or hyperkalemia.
 - Permits calculation of serum anion gap (SAG).
 - $SAG = Na^+ - [Cl^- + HCO_3^-]$
 - Normal anion gap = 8–16 mEq/L
 - When assessing for RTA, this test should be run STAT to decrease the chance of a falsely low bicarbonate result from cell lysis.
- Serum creatinine: Helps to exclude renal failure.
- Urinalysis: Evaluates for features of Fanconi syndrome (glycosuria) or renal disease (proteinuria).
- Urine electrolytes and pH:
 - If urine pH is <5.5, then type I RTA can be ruled out.
 - Permits calculation of urine anion gap (UAG)
 - $UAG = [urine Na^+] + [urine K^+] - [urine Cl^-]$.
 - Negative urine anion gap is seen in GI losses and proximal RTA.
 - Positive urine anion gap is seen in distal and hyperkalemic RTA.
- Urine spot for calcium/creatinine ratio: Patients with RTA can have hypercalciuria.
- Tubular reabsorption of phosphate (TRP): TRP <60% can be seen in Fanconi syndrome and other causes of proximal RTA.
- 24-hour urine for citrate, calcium, potassium, and oxalate: Hypercalciuria and hypocitraturia are risk factors for nephrocalcinosis and/or nephrolithiasis.

Imaging

- Long bone films/rickets survey: Evaluates for rachitic changes, osteopenia, bone age.
- Renal ultrasound: Evaluates for renal dysplasia, obstructive uropathy, nephrocalcinosis, nephrolithiasis, or hydronephrosis.

DIFFERENTIAL DIAGNOSIS

- GI fluid losses: Diarrhea, ileal conduits, fistulas draining the small bowel, biliary tract, or pancreas
- Use of acetazolamide and other carbonic anhydrase inhibitors
- Parenteral nutrition

**TREATMENT**

- Alkali administration is the primary therapy for children with RTA, with the dose titrated to maintain normal bicarbonate levels.
- Sodium/potassium citrate is preferable for children with distal or proximal RTA, because hypokalemia may also be present.
- Sodium citrate or sodium bicarbonate is used in children with hyperkalemic RTA who require potassium restriction.
- Patients with distal RTA usually require 1–4 mEq/kg alkali therapy per day in 3–4 divided doses.
- Patients with proximal RTA require considerably more alkali therapy (5–20 mEq/kg/d in 4–6 divided doses).
- The dosage of alkali in children with hyperkalemic RTA ranges 1–5 mEq/kg/d, which is usually sufficient to correct the potassium level.
- Sodium polystyrene sulfonate (kayexalate) may be needed for patients with hyperkalemic RTA whose potassium level does not normalize with alkali therapy.
- Mineralocorticoids should be given to treat underlying hypoaldosteronism in hyperkalemic RTA.
- All patients with secondary causes of RTA should be treated for the underlying disease.
- All patients with RTA due to medications should have them withdrawn if the risks of RTA outweigh the benefits of the medication.

**ONGOING CARE**

- Patients with RTA should be closely monitored with frequent potassium and bicarbonate levels until a steady state is reached.
- Normal growth may be attained after the metabolic acidosis is corrected.
- Untreated distal RTA can lead to renal failure by causing progressive nephrocalcinosis. Adequate alkali therapy is usually enough to avoid this complication.
- Patients with hypercalciuria should be monitored with spot urine calcium/creatinine ratio. Alkali therapy should be adjusted to maintain a ratio <0.2 mg/mg.
- Renal ultrasound follow-up is recommended in patients with nephrocalcinosis.

Patient Monitoring

- Avoid hemolyzed specimens that may artificially increase the serum potassium and reduce the plasma bicarbonate levels.
- Administer alkali over several divided doses.
- Closely monitor patients during episodes of gastroenteritis to avoid dehydration and severe metabolic acidosis.

RENAL VENOUS THROMBOSIS

Christine B. Sethna

BASICS

DESCRIPTION

- Renal venous thrombosis is a thrombotic process that begins in the intrarenal venous radicals that usually progresses forward toward the main renal vein and may extend to the inferior vena cava.
- Rarely, the thrombosis may progress in the opposite direction.
- Usually presents clinically as a triad of macroscopic hematuria, palpable abdominal mass and thrombocytopenia in a newborn.

EPIDEMIOLOGY

- Renal venous thrombosis is predominantly a disease of the newborn.
- Slight male predilection
- More frequently unilateral than bilateral
- Left-sided predominance

Incidence

- Poorly defined
- 2.2 per 100,000 live births in a German registry study

Prevalence

Accounts for 20% of neonatal thromboembolism

RISK FACTORS

- Hyperosmolar state after angiocardiography
- Coagulopathy
- Sepsis
- Acute blood loss/shock
- Dehydration/Diarrhea
- Maternal diabetes
- Sickle cell disease
- Maternal lupus anticoagulant
- Central venous lines
- Prematurity
- In utero fetal distress

Genetics

Inherited prothrombotic risk factors are found in 50% of patients with neonatal RVT.

GENERAL PREVENTION

- The infant of a mother with diabetes should be observed for evidence of renal venous thrombosis.
- Patients with nephrotic syndrome are at increased risk of thrombosis in general when treated with diuretics.
- If cyanotic congenital heart disease is present, contrast agents should be used judiciously.
- Parents and caregivers should be educated about the importance of adequate intake and good hydration in the newborn and infant.
- There should be an increased index of suspicion among medical staff when examining an infant with diarrhea or a hyperosmolar state.

PATHOPHYSIOLOGY

- Renal venous thrombosis in newborns and infants is commonly associated with asphyxia, dehydration due to diarrhea, shock, sepsis, hypertonicity, coagulation abnormalities, and hemoconcentration.
- Additional predisposing factors in the newborn include congenital renal anomalies and maternal diabetes.
- In older children, associated with the nephrotic syndrome, cyanotic heart disease, and hyperosmolar states such as with the use of angiographic contrast agents
- In many children, no underlying cause is apparent.
- The slow double circulation of the kidney is especially vulnerable to thrombosis.
- Thrombus formation may be initiated by vascular endothelial cell injury in conjunction with diminished vascular flow.
- Renal venous thrombosis usually starts in the small venous radicals, with progression through the arcuate and interlobular veins toward the main renal vein.
- Renal venous thrombosis causes renal congestion and occasionally infarction.

DIAGNOSIS

HISTORY

- Most patients are newborns.
- Renal venous thrombosis is usually heralded by the sudden onset of hematuria, unilateral or bilateral flank masses, and thrombocytopenia; however, only a fraction will have this “triad” on presentation
- Signs and symptoms:
 - Pallor
 - Tachypnea
 - Abdominal distention
 - Shock
 - Flank pain
 - Fever
 - Oliguria
 - Anuria
 - Hematuria

PHYSICAL EXAM

- 60% of affected patients have a palpably enlarged kidney.
- If lower limbs become edematous, cyanotic, and hypothermic during thrombosis, the inferior vena cava is involved.
- Hypertension at presentation is uncommon/rare, but it may develop later on.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Urine:
 - Proteinuria is common.
 - Most patients have macroscopic hematuria.
- CBC:
 - 90% have progressive thrombocytopenia, and most also have microangiopathic hemolytic anemia.
- Fibrin split products:
 - Fibrin split products may be elevated, with low plasma fibrinogen levels.
- Electrolytes and BUN:
 - Azotemia and other biochemical evidence of acute kidney injury may be present.
 - Variations in plasma electrolytes depend on the presence of diarrhea or renal injury.
- Workup for procoagulable states, such as Factor V Leiden and maternal lupus anticoagulant, should be done.

Imaging

- Ultrasonography: Most useful study; will differentiate renal enlargement and extrarenal masses; will also identify obstruction, cystic changes, and many congenital anomalies; will show renal enlargement, increased echogenicity, calcification and loss of corticomedullary differentiation.
- Doppler ultrasound: Useful to detect resistance of absence of flow in renal veins.
- Radioisotopic reperfusion and excretion studies may also be helpful.

DIFFERENTIAL DIAGNOSIS

- Exclude other causes of renal enlargement (e.g., hydronephrosis, cystic renal disease, renal tumors, abscess, hematoma).
- Hemolytic-uremic syndrome should also be considered because renal venous thrombosis may also result in fragmented erythrocytes and thrombocytopenia.

TREATMENT

MEDICATION (DRUGS)

- Recommendations from the American College of Chest Physicians Evidence-Based Clinical Practice Guidelines (8th edition) for Antithrombotic Therapy in Neonates and Children include:
 - For unilateral renal vein thrombosis in the absence of renal impairment or extension into the IVC, supportive care with monitoring of the RVT for extension or anticoagulation with unfractionated heparin (UFH)/low-molecular-weight heparin (LMWH), or LMWH in therapeutic doses for 3 months is suggested.
 - For unilateral RVT that extends into the IVC, anticoagulation with UFH/LMWH or LMWH for 3 months is suggested.
 - For bilateral RVT, anticoagulation with UFH and initial thrombolytic therapy with tPA, followed by anticoagulation with UFH/LMWH is suggested.

ADDITIONAL TREATMENT**General Measures**

- Correction of underlying pathophysiologic abnormalities should be attempted.
- Management includes supportive therapy, anticoagulant therapy or thrombolysis. Renal outcomes are similar between supportive therapy and anticoagulant therapy.

ISSUES FOR REFERRAL

Patients with renal venous thrombosis should be followed regularly by a nephrologist.

SURGERY/OTHER PROCEDURES

- A surgical approach in the acute phase is rarely indicated. Surgery, complicated by disturbed fluid balance and acid–base status and altered coagulation, is risky.
- Because the thrombosis begins deep within the kidney and spreads to the larger veins, thrombectomy should be considered only in the event of bilateral involvement with involvement of inferior vena cava.
- Ultimately, if the kidney has negligible function and contributes to hypertension or recurrent infections, nephrectomy may be indicated.

IN-PATIENT CONSIDERATIONS**Initial Stabilization**

Treatment is supportive and includes correction of fluid and electrolyte disturbances and treatment of infection.

Admission Criteria

- Neonates with renal venous thrombosis should be admitted to the NICU for close observation and management.
- Fibrinolytic therapy should be initiated in an ICU setting.

Discharge Criteria

Stabilization of renal function and blood pressure

**ONGOING CARE****FOLLOW-UP RECOMMENDATIONS****Patient Monitoring**

- All patients should be observed closely for evidence of hypertension.
- Renal size should be monitored by US.

PROGNOSIS

- Patients must be followed closely for development of hypertension, atrophy, functional loss, and chronic kidney disease.
- Degree of irreversible renal damage depends on the degree of involvement and associated conditions.
- Rare deaths in these patients seem to be unrelated to the renal venous thrombosis and are usually the result of an underlying comorbid condition.
- Recovery of function may occur in affected kidneys. Varying degrees of renal impairment are seen in 30% of patients.
- Hypertension is seen in 20%.
- Most patients have residual renal structural abnormalities (e.g., atrophy, coarse renal scarring).
- Kidney size >6 cm at the time of presentation may correlate negatively with renal outcome.

COMPLICATIONS

- Bilateral renal venous thrombosis may lead to chronic kidney disease.
- Scarring may result in hypertension.

FAQ

- Q: Can renal venous thrombosis occur in the absence of gross hematuria?
- A: Most patients do have hematuria that may be gross. However, hematuria is often microscopic or absent.
- Q: Do patients with renal venous thrombosis usually have hypertension during the acute phase?
- A: Hypertension is uncommon at presentation.

RESPIRATORY SYNCYTIAL VIRUS (RSV)

Kathleen Wholey Zsolway

Alyssa Siegel

BASICS

DESCRIPTION

- A pleomorphic, enveloped RNA virus of the family Paramyxoviridae. There are 2 major groups, A and B, which differ in the largest surface glycoprotein, the G protein. The fusion protein, F protein, is ~95% homologous between the 2 subgroups.
- It is the most common cause of bronchiolitis, a viral lower respiratory tract disease of infants and young children.

EPIDEMIOLOGY

- Incubation period is 2–4 days.
- Virus is detected in secretions 4 days prior to clinical symptoms and 7 days following the resolution of symptoms (viral shedding is demonstrated for as long as 20 days).
- Most effective mode of transmission is via person-to-person spread—by droplet or hand-to-nose contact.
- Nosocomial spread occurs from infected hospital personnel to patients.
- There is a worldwide distribution. Temperate climates experience an annual mid-winter epidemic, whereas epidemics are less predictable in the tropics.
- In the U.S., epidemics may begin in November (or as late as May) and last as long as 12 weeks in urban areas.
- One antigenic strain predominates during any given epidemic.

Incidence

Peak incidence is the 1st 2 years of life.

Prevalence

- 50% of children are infected by their 1st birthday, with a similar attack rate for the uninfected child during the 2nd year of life.
- 40–70% of preschool children and 20% of school-aged children are reinfected with exposure.

RISK FACTORS

Those at greatest risk for severe infection include:

- Children <1 year of age, especially those between the ages of 6 weeks–6 months
- Children with compromised cardiorespiratory status (e.g., bronchopulmonary dysplasia, congenital heart disease)
- Those born prematurely
- Those with immune deficits
- Those with neuromuscular disease
- Those with malignancy

GENERAL PREVENTION

- Nosocomial and household spread can be minimized by strict hand washing and avoidance of contact with infected individuals.
- Routine use of gowns and gloves has been shown to decrease RSV nosocomial spread.
- Patients with RSV infection should be isolated in private or RSV-cohorted rooms.
- Nursing care should be cohorted so that nurses are not caring for both RSV-infected and noninfected patients.
- 2 products are available for the prevention of RSV infection: RSV immune globulin IV (RSV-IGIV), made from RSV antibody-positive donor serum, and palivizumab, a humanized monoclonal antibody produced by recombinant DNA technology:
 - Both products are approved for the prevention of RSV disease in select children <2 years of age with bronchopulmonary dysplasia or with a history of prematurity (birth at <35 weeks' gestation).
 - Specific recommendations are available from the American Academy of Pediatrics (AAP) Committee on Infectious Diseases and Committee on Fetus and Newborn for the use of palivizumab and RSV-IGIV, and these criteria should guide the use of these products.
 - RSV-IGIV is given 1 month prior to and monthly throughout RSV season, whereas palivizumab is given IM monthly throughout RSV season.

PATHOPHYSIOLOGY

- The F protein is responsible for fusing infected cells to adjacent cells, generating a syncytium.
- Infection is initiated in the upper respiratory tract with inoculation of the nose or eyes, and may spread to the lower respiratory tract.
- Obstruction of smaller airways occurs secondary to edema, necrotic tissue, and inflammatory cells.
- Virus-induced epithelial damage may expose certain receptors to environmental irritants. Receptor-irritant complexes may contribute to the signs and symptoms of reactive airway disease.

DIAGNOSIS

HISTORY

- Initial symptoms are nasal discharge, cough, and fever.
- Cough typically progresses over 1–2 days, with tachypnea developing.
- Duration of symptoms will help in the assessment of the typical clinical progression of illness and the anticipated time course for the child.
- Other significant points within the history:
 - Lethargy, apnea, and possible cyanotic episodes
 - Dehydration is secondary to decreased oral intake, as well as to increased insensible losses. Assess oral intake and urine output to rule out dehydration.
 - Increasing respiratory distress
 - Child stopped breathing/had apnea

PHYSICAL EXAM

- Nasal discharge
- Acute otitis media or otitis media with effusion
- Pharyngeal injection
- Conjunctivitis
- Respiratory distress with nasal flaring and retractions, grunting, rales, rhonchi, and expiratory wheezing noted on auscultation
- Risk for hypoxemia increases as the respiratory rate approaches and surpasses 60 breaths per minute.
- Chest may become barrel-shaped as respiratory distress increases.
- Hyperinflation of the lungs will push liver and spleen into palpable positions within the abdomen.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- A definitive diagnosis of RSV can be made by viral isolation, but RSV takes up to 5 days to grow on viral culture medium. Sensitivity may vary among laboratories.
- Rapid diagnostic antigen assays are used for RSV detection, usually with a sensitivity of 80–90%:
 - Immunochromatographic assay
 - Enzyme immunoassay
 - Immunofluorescent assay
- Polymerase chain reaction (PCR) may be superior to rapid antigen testing for low viral loads, but it is not widely available.
- Nasopharyngeal aspirate/washings are specimens of choice for testing.
- Pulse oximetry to rule out hypoxemia

ALERT

- RSV is labile at room temperature. Samples should be placed in viral transport medium at the bedside and transported to the laboratory for immediate inoculation to cell culture.
- Instillation and aspiration of 5 mL of isotonic saline is the preferred method of viral collection, as opposed to nasal swabs.

Imaging

- Chest x-rays are obtained for clinical concerns of pneumonia.
- Significance: Reveals hyperinflation, increased bronchial markings, and areas of atelectasis/infiltrate.
- Note: The pulmonary densities, referred to as “RSV pneumonia,” are frequently areas of atelectasis but may represent bacterial infection, especially in the seriously ill patient.

DIFFERENTIAL DIAGNOSIS

- Infection:
 - Influenza virus
 - Parainfluenza virus type 3
 - Adenovirus
 - Human metapneumovirus
 - Human bocavirus
 - *Chlamydia*
- Environmental: Foreign body in airway
- Tumors: Mass compressing upper airway
- Congenital: Tracheomalacia

**TREATMENT****MEDICATION (DRUGS)**

- Ribavirin: An antiviral agent; has in vitro antiviral activity against RSV, but ribavirin aerosol treatment for RSV infections is controversial. Ribavirin should not be used routinely in the treatment of children with bronchiolitis.
- Corticosteroids have not been proven to be efficacious in bronchiolitis and should not be used routinely.
- β -adrenergic agents: There is some evidence of effectiveness in some patients with RSV bronchiolitis. A trial of a bronchodilator is frequently recommended, but continues to be controversial.
- Mist use is considered controversial because it may irritate the airways.
- Antibiotics are rarely indicated because bacterial disease (lung or blood) is uncommon in hospitalized infants with RSV bronchiolitis.
- Heliox, an inhaled mixture of helium and oxygen, is under investigation for use in cases of severe respiratory distress in the pediatric intensive care unit setting.

ADDITIONAL TREATMENT**General Measures**

- Supportive care: Hydration therapy and supplemental oxygen as needed to maintain oxygen saturation > 94%
- Cardiorespiratory monitoring and pulse oximetry are necessary for infants at risk for apnea and hypoxemia. Duration of hospitalization monitoring depends on the clinical course.
- Mechanical ventilation as clinically indicated

IN-PATIENT CONSIDERATIONS**Initial Stabilization**

Life-threatening apnea may require emergency support with mechanical ventilation.

**ONGOING CARE****FOLLOW-UP RECOMMENDATIONS**

- Bronchiolitis peaks in severity over 48–72 hours; therefore, reassess the patient if seen early in the disease course.
- Symptoms usually last 7 days but may last up to 2–3 weeks, with evidence of reactive airway disease persisting for months to years.
- Periodic breathing may occur 48–72 hours post-extubation, but recurrent apneic episodes are rare, and home monitoring is usually not indicated.

- Fever commonly resolves over 48 hours.
- Respiratory symptoms commonly improve between days 2–5 of illness.
- Evidence of airway hyperactivity may continue for months to years in patients who have had bronchiolitis.

Patient Monitoring

Signs to watch for:

- Increased respiratory rate and increased work of breathing (i.e., use of accessory muscles)
- Lethargy, altered mental status
- Prolonged high fever

PROGNOSIS

- The majority of patients have a mild to moderate disease course with symptomatic support.
- Some infected children proceed to more serious illness, necessitating hospitalization. An average hospital stay for previously healthy children is 5–7 days; full recovery is 2 weeks.
- Infants with underlying cardiac or pulmonary disease are at increased risk for more severe and longer duration of disease; mortality is as high as 30%.
- Reinfections occur throughout life.
- An association between RSV infection and long-term asthma symptoms has been speculated, but remains unclear.

COMPLICATIONS

- Apneic episodes in very young and premature patients
- Pneumonia, rarely bacterial
- Pneumonitis
- Croup
- Respiratory failure
- Hypoxemia
- Hypercarbia
- Asthma
- Acute otitis media
- Dehydration

**CODES****ICD9**

- 079.6 Respiratory syncytial virus (RSV)
- 490 Bronchitis, not specified as acute or chronic

ICD10

- B97.4 Respiratory syncytial virus as the cause of diseases classified elsewhere
- J20.5 Acute bronchitis due to respiratory syncytial virus

FAQ

- Q: How did my child get this illness?
- A: RSV bronchiolitis is caused by respiratory syncytial virus, which is passed from one person to another by contact with nasal secretions and through airborne transmission of droplets.
- Q: For how long is my child contagious?
- A: Viral shedding occurs for 24 hours prior to the onset of clinical symptoms and for up to 21 days from the onset of symptoms.
- Q: Will my child develop asthma because of the wheezing that is occurring now?
- A: Evidence of airway hyperactivity following RSV bronchiolitis may continue for months or even years in some children. It is impossible to predict future episodes of reactive airway disease, but the child should be monitored clinically over time.
- Q: If a patient has severe chronic lung disease with a supplemental oxygen requirement and is <2 years of age at the onset of the RSV season, should RSV-IGIV or palivizumab be recommended for this patient?
- A: The risks and benefits of each therapy must be evaluated on a patient-by-patient basis. RSV-IGIV provides additional protection against other respiratory viral illnesses and may be considered for some selected high-risk infants. However, palivizumab is preferred for most high-risk children secondary to its ease of administration, safety, and effectiveness.

RETINOBLASTOMA

Kelly C. Goldsmith

BASICS

DESCRIPTION

- The most common primary intraocular tumor of childhood
- Malignant tumor of the embryonic neural retina

EPIDEMIOLOGY

- 1:16,000–25,000 live births
- The most common primary intraocular tumor of childhood (ocular leukemia most common overall)
- Represents 3% of all pediatric malignancies
- No sex, race, geographic, or socioeconomic predilection
- 90% diagnosed <4 years of age
- Median age at diagnosis for unilateral disease is 24 months and 12 months for bilateral disease (see “Genetics”)

RISK FACTORS

Genetics

Tumor development depends on loss of function of both copies of the *RB1* gene (located on chromosome 13) in a retinoblast. Hereditary and nonhereditary (sporadic) forms exist.

- Hereditary retinoblastoma (RB):
 - 45% of all RB
 - 1 *RB1* gene is dysfunctional in all cells (germline mutation); mutation in remaining *RB1* gene in any retinal cell will lead to development of a tumor.
 - 90% probability of second mutation occurring in at least 1 (but usually more) retinal cells leading to tumor development (high penetrance)
 - Therefore, multiple tumors are common (Usually bilateral and/or multifocal, but may be unilateral).
 - Mean age at diagnosis: 12 months
 - Only 8% have positive familial history; remainders are new germline mutations.
 - ~40–45% of offspring will develop RB the most common being osteosarcoma (autosomal-dominant transmission, 90% penetrance).
 - *RB1* gene mutation in all cells predisposes to second (non-RB) malignancies as well.
- Nonhereditary RB:
 - 55% of all RB
 - No germline *RB1* mutation; 2 acquired (somatic) *RB1* mutations must occur in a single retinal cell (a rare event).
 - Always unilateral
 - Rarely diagnosed before 6 months (mean, 24 months)
 - No increased risk of RB in offspring
 - No increased risk of second malignancy

PATHOPHYSIOLOGY

- Originates in retinal cell precursor (retinoblast)
- Histology: Small round blue cells with large hyperchromatic nuclei and scant cytoplasm
- Growth of tumor may be endophytic (from inner surface of retina to vitreous) or exophytic (from outer layer of retina into subretinal space); may cause retinal detachment.
- Spread is via optic nerve (common) with potential to invade CNS, direct extension beyond the eye, and lymphatic or hematogenous spread (uncommon).
- Tumor cells may break off from primary mass and grow independently within the eye (called “vitreous seeding”); single tumor with seeding may be confused with multifocal disease.

DIAGNOSIS

HISTORY

- Familial history of RB or any eye tumors: Hereditary RB; siblings may require eye exam
- Leukocoria (white pupil, “cat’s eye reflex”): Often noted in photographs of children with advanced intraocular RB (60%)
- Strabismus, either eso- or exotropic (20%): Esotropia is more common in the general population, so exotropia is more suspicious.
- Eye complaints: RB is rarely painful (unless secondary glaucoma or inflammation is present); vision problems are rare complaints because tumor is usually unilateral.
- Inflammation, heterochromia, and glaucoma: Rare presentations (<10%)
- Neurologic signs, orbital/periorbital masses, bone pain, anorexia, signs of cytopenias: May represent metastatic disease
- Associated conditions: 13q deletion syndrome has RB, dysmorphism, mental retardation, and genitourinary (GU) or other anomalies.

PHYSICAL EXAM

- Only 3% discovered with routine fundoscopic examination.
- Leukocoria or strabismus more common as presenting sign.
- Proptosis and orbital/periorbital masses: Late sequelae of mass effect
- Check for red reflex in darkened room: Screen for RB in office.
- Evaluate for anisocoria.
- Cover test to assess for strabismus (20%)
- Test vision of each eye independently to identify unilateral RB.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Ophthalmologic examination: Confirmation of diagnosis based on ophthalmologic examination by a specialist in pediatric ocular tumors via direct and indirect ophthalmoscopy (and examination under anesthesia [EUA]) and by imaging modalities (MRI or CT). Parents and siblings should also undergo ophthalmologic screening in many cases.
- Biopsy: Biopsy confirmation is rarely necessary (risk for tumor seeding).
- CBC: Assess for bone marrow involvement.
- CSF cytology: Evaluate for leptomeningeal spread (only necessary if tumor has spread beyond the globe).
- Chromosome analysis: Should be performed, but even in hereditary cases, only 5% have mutations detectable by this means.

Imaging

CT or MRI: Evaluate primary tumor (80% have calcification) and optic nerve extension, leptomeningeal spread, pineal blastoma (in 4% of hereditary RB, patients will have bilateral RB and pineal tumor noted on MRI = “trilateral RB”).

Diagnostic Procedures/Surgery

- Biopsy rarely done due to risk for visual damage and spreading tumor cells
- Diagnosis based on dilated ophthalmologic evaluation (often under anesthesia)
- Intraocular and extraocular staging systems exist: The International Classification of Retinoblastoma (ICRB) was introduced in 2003 that more simply stages the extent of disease. Reese–Ellsworth is still in wide use.
- Most RB in the US is intraocular without metastatic disease.
- Patients with tumor extension outside the globe should have a lumbar puncture to assess for tumor cells in CSF and bone marrow evaluation for complete staging.

Pathological Findings

- Biopsy rarely done due to risk of visual damage and spreading of tumor cells

DIFFERENTIAL DIAGNOSIS

- Coats disease: Acquired anomaly, males, retinal telangiectasias
- Persistent hyperplastic primary vitreous (PHPV)
- Inflammatory conditions: Hypopyon, uveitis, iritis, endophthalmitis
- Toxoplasmosis, *Toxocara canis*, other ocular infections
- Retinopathy of prematurity (ROP)

TREATMENT

ADDITIONAL TREATMENT

General Measures

- Primary goals:
 - Eradicate tumor
 - Prevent metastasis
- Secondary goals:
 - Salvage the eye and retain useful vision.
 - Cosmetic considerations
- Treatment must be individualized, depending on bilateral or unilateral disease, potential for salvageable vision, and evidence of local extension or metastatic disease. Referral to a center with oncologic and ophthalmologic specialists is essential.
- Minimal (nonbulky) intraocular disease:
 - Plaque radiotherapy (radioactive seeds sewn to episcleral surface above RB lesion): This provides local radiation to tumor in selected solitary RBs, up to 16 mm in diameter with or without vitreous seeds
 - Photocoagulation (laser directed at tumor blood vessels): For selected small RBs, usually <3 mm
 - Transpupillary thermotherapy (TTT; laser aimed directly at tumor with lower temp vs. photocoagulation): Treatment of peripapillary tumors for which photocoagulation cannot be used
 - Cryotherapy (topical freeze technique): For selected RBs <3–4 mm in diameter without vitreous seeding, which are located anteriorly in the eye
 - Locally delivered chemotherapy: Subtenon/subconjunctival chemotherapy (usually carboplatin) delivered by direct intraocular injection
- Bulky intraocular disease:
 - Current trend is toward eye salvage therapy: Initial systemic chemotherapy for tumor reduction followed by local definitive therapy (as for nonbulky disease)
 - Tumor resection without enucleation is not possible because of risk of tumor spillage; enucleation of involved eye (with long segment of optic nerve removal to ensure tumor-free margins) may be required for large tumors refractory to chemoreduction or when vision is not salvageable.
 - External beam radiation therapy (EBRT): RB is extremely radiosensitive; however, increases risk of second malignancy (especially in hereditary RB). Other effects: Dry eye, cataract, retinopathy, and cosmetic deformity from bone maldevelopment. EBRT is still an important modality but is avoided whenever effective alternative therapies are available.
 - Experimental treatments are available in referral centers
- Metastatic disease:
 - Multiagent chemotherapy with or without autologous bone marrow transplantation; poor results to date
 - Effective treatment requires multidisciplinary collaboration between ophthalmologists, oncologists, and radiation oncologists.

ONGOING CARE

- Frequent ophthalmologic examinations (including EUA) are mandatory to evaluate response to therapy and to screen for disease progression, particularly in hereditary RB.
- Therapy must include genetic counseling regarding the risk of second malignancies (with or without adjuvant XRT), risk to siblings, as well as the risk to future children of affected patients with hereditary RB.
- Primary care physicians must be aware of the risks of second malignancies (see “Prognosis”) and maintain an appropriately high index of suspicion for their development.
- Primary care physicians should be aware of the genetics of RB and screen siblings appropriately.
- Pitfalls:
 - Missed or delayed diagnosis: Ophthalmologic examination by a specialist in pediatric ocular tumors required to establish diagnosis and follow regression or recurrence in treated eyes, follow for development of new tumors in hereditary cases
 - Failure to recognize the possibility that a child with RB has a genetic predisposition, especially in the frequent setting where there is no familial history of RB
 - Failure to refer for appropriate genetic counseling

PROGNOSIS

- Mortality from RB is 3–5% for the US, Japan, and Europe
- Mortality is more concerning for developing countries due to late detection (20–70% in Asia, Africa, and Latin America/Caribbean nations).
- Survival depends on extent (stage) of disease.
- Metastatic disease is uncommon in the US but can occur up to 5 years after diagnosis and has a poor outcome (same for hereditary and nonhereditary).
- Prognosis for vision depends on size and location of tumor(s).
- Second malignancy is most common cause of death in hereditary RB:
 - These include osteosarcoma (most frequent), pineal blastoma, melanoma, fibrosarcoma, and others.
 - Rates of second malignancy in hereditary RB are 10% at 10 years and as high as 40% at 30 years in patients who received EBRT (70% of second tumors occur in the field of radiation, 30% elsewhere).

COMPLICATIONS

- Metastatic spread: Local spread within orbit, through the optic nerve to brain, or to distant sites (uncommon)
- Loss of eye: Surgical enucleation in advanced cases
- Blindness: In advanced, bilateral disease; bilateral enucleation rarely required
- Cosmetic deformity: From enucleation, ocular prosthesis lacks normal eye movements; potential orbital bone hypoplasia secondary to EBRT
- Second malignancy: Patients with hereditary RB have a predisposition to cancer; this risk is greatly increased by exposure to radiotherapy.

CODES

ICD9

190.5 Malignant neoplasm of retina

ICD10

- C69.20 Malignant neoplasm of unspecified retina
- C69.21 Malignant neoplasm of right retina
- C69.22 Malignant neoplasm of left retina

FAQ

- Q: What is the risk that a child with RB will become blind?
- A: Vision is salvageable in 100% of eyes with low-stage involvement, and in 81% overall. In <10% of patients are both eyes affected severely enough to threaten vision (bilateral disease only occurs in hereditary RB).
- Q: What is the chance that a child with RB in 1 eye will get it in the other?
- A: Bilateral disease is seen with hereditary RB. A child with unilateral disease has a 15% chance of having hereditary RB, which would put the contralateral eye at risk; this risk is much higher if the child has multifocal involvement or is <1 year of age.
- Q: What happens to the eye socket after an enucleation?
- A: Prostheses can be made to fit the socket of the enucleated eye to give excellent cosmetic results.
- Q: Is there a test to identify hereditary cases?
- A: Routine chromosome analysis does not reveal a defect related to the RB gene in the majority (95%) of hereditary cases. Specialized molecular tests may be used in research labs, but because there are many possible mutations, this is costly and time-consuming. In general, hereditary cases are determined clinically because of young presentation, family history, and/or bilateral or multifocal unilateral disease.

RETROPHARYNGEAL ABSCESS

Richard M. Rutstein

BASICS

DESCRIPTION

A relatively rare but potentially life-threatening infection occurring in the potential space bounded by the layers of cervical fascia posterior to the esophagus and anterior to the deep cervical fascia.

EPIDEMIOLOGY

Children <6 years of age are most at risk, with 50% of the cases occurring in those <48 months of age.

Incidence

Most large children's hospital centers report 1–5 cases per year.

PATHOPHYSIOLOGY

- Most infections result from pharyngitis or supraglottitis and occur because of suppuration of the retropharyngeal lymph nodes, which lie in 2 paramedial chains and drain various nasopharyngeal structures.
- Other sources of infection in this space include penetrating trauma (e.g., foreign object aspiration, dental procedures, attempts at intubation).
- Extension of infection into this space can arise from vertebral body osteomyelitis or petrositis.

ETIOLOGY

- Infectious: Cultures frequently reveal multiple organisms.
- The predominant organisms isolated include:
 - *Streptococcus* (group A and others)
 - *Staphylococcus aureus*
 - Various anaerobic species (e.g., *Bacteroides*, *Peptostreptococcus*, *Fusobacterium*)
 - One pediatric study cultured *Haemophilus influenzae* type b in 20% of cases; however, the study took place before the routine use of *H. influenzae* type b conjugate vaccines.
- Many of the isolates are β -lactamase producers.

DIAGNOSIS

HISTORY

- Symptoms may be present from hours to days before correct diagnosis. Many patients will have been taking oral antibiotics for presumed pharyngitis/sinusitis.
- Ask about neck trauma, especially penetrating injuries, recent surgery (especially dental), and history consistent with aspiration of a foreign object.
- Physicians must maintain a high index of suspicion. The presentation of a retropharyngeal abscess can be subtle, with the most frequent initial diagnostic impression usually epiglottitis or severe pharyngitis.

Signs and symptoms:

- Most frequent symptoms include sore throat, decreased oral intake, muffled voice, drooling, stiff or painful neck, fever, dysphagia, and stridor.
- Fever
- Stridor (seen in up to 50% of children in 1 study, but only 5% in a more recent series)
- Drooling
- A tender cervical neck region/mass and restricted range of motion
- Classic diagnostic finding of a bulging posterior pharyngeal wall; may be absent or difficult to appreciate in an ill, apprehensive child

PHYSICAL EXAM

- Muffled voice
- Drooling
- Stiff or painful neck
- Fever
- Dysphagia
- Stridor

DIAGNOSTIC TESTS & INTERPRETATION

Lab

CBC may reveal an elevated total leukocyte level, with a significant left shift.

Imaging

- Lateral neck x-ray: Widening of retropharyngeal space and at times an air–fluid level. Negative plain neck film does not rule out retropharyngeal abscess.
- CT scan or MRI of the neck: Most definitive modality; can usually differentiate abscess from local cellulitis/adenitis
- Both plain films and CT scan have false positives and false negatives.

DIFFERENTIAL DIAGNOSIS

- Pharyngitis
- Peritonsillar or lateral wall abscess
- Epiglottitis/Supraglottitis

**TREATMENT****ADDITIONAL TREATMENT****General Measures**

- Start broad-spectrum parental antibiotics, active against *Streptococcus pneumoniae*, *S. aureus*, and oral anaerobic organisms. If patient does not improve, broaden coverage to include drugs active against β -lactamase-producing organisms and anaerobic organisms. Clindamycin or ampicillin–sulbactam are good initial choices.
- Immediate consultation with otolaryngology surgical team:
 - Be prepared to schedule incision/aspiration of abscess for severe cases associated with airway compromise with team experienced in airway management of small children.
 - CT-guided aspiration of the abscess has aided the surgical approach at many sites.
 - Recent data suggest that up to 50% of patients can be successfully managed without surgical intervention.
 - Patients with a well-defined abscess on admission CT are most likely to require surgical intervention.
 - Patients treated with antibiotics alone must be followed closely for signs of worsening clinical status.

ISSUES FOR REFERRAL

After diagnosis is confirmed, urgent consultation with experienced surgical staff is mandatory.

IN-PATIENT CONSIDERATIONS**Initial Stabilization**

Emergency therapy requires maintaining patent airway; be wary of sudden spontaneous drainage of the abscess, with catastrophic aspiration.

**ONGOING CARE****PROGNOSIS**

Excellent with appropriate antibiotics, expectant care, and surgery, if needed, at optimal time.

COMPLICATIONS

- Spontaneous rupture with aspiration of infected material, with subsequent asphyxia or overwhelming pulmonary infection
- Hemorrhage from extension into local arteries, and/or venous thrombosis from involvement of major neck vessels
- Extension of the infection inferiorly can occur, leading to a subdiaphragmatic or psoas abscess.

ICD10

J39.0 Retropharyngeal and parapharyngeal abscess

REYE SYNDROME

Seth L. Ness

Andrew Mulberg (5th edition)

BASICS

DESCRIPTION

- Acute encephalopathy and fatty degeneration of the liver
- The CDC description is of an illness that meets all the following criteria:
 - Acute, noninflammatory encephalopathy that is documented clinically by (a) an alteration in consciousness and, if available, (b) a record of the CSF containing ≤ 8 leukocytes/mm³ or a histologic specimen demonstrating cerebral edema without perivascular or meningeal inflammation
 - Hepatopathy documented by either (a) a liver biopsy or an autopsy considered to be diagnostic of Reye syndrome or (b) a 3-fold or greater increase in the levels of the serum glutamic-oxaloacetic transaminase (SGOT), serum glutamic-pyruvic transaminase (SGPT), or serum ammonia
 - No more reasonable explanation for the cerebral and hepatic abnormalities

EPIDEMIOLOGY

- Peak incidence age 6 years
- Most children range from 4–12 years of age.
- Association with ingestion of aspirin-containing medicines by children with varicella or influenza B
- In 1982, the U.S. Surgeon General issued an advisory on the use of salicylates and Reye syndrome.

Incidence

- Peak incidence of 555 cases in children in the U.S. in 1980
- From 1994–1997, there were no more than 2 cases of Reye syndrome annually.

PATHOPHYSIOLOGY

- Mitochondrial injury of unknown etiology in a viral-infected host results in dysfunction of oxidative phosphorylation and fatty acid oxidation.
- Mitochondrial toxins, usually salicylates, exacerbate the condition when ingested after mitochondrial injury.
- Postmortem:
 - Liver: Grossly yellowish-white, due to increased triglyceride levels; foamy cytoplasm with increased microvesicular fat, decreased glycogen
 - Brain: Marked edema with increased intracellular fluid and loss of neurons
 - Abnormal-looking mitochondria can be detected in many tissues.

DIAGNOSIS

HISTORY

- Prodromal illness: Upper respiratory infection (73%)—influenza B, influenza A, and varicella
- Abrupt-onset vomiting within 47 days of initial illness
- Natural history: Neurologic deterioration in which delirium may progress to seizures, coma, or death

PHYSICAL EXAM

- Slight liver enlargement without jaundice
- Absence of focal neurologic signs
- Neurologic exam varies with stage of disease:
 - Stage 0: Alert, wakeful
 - Stage 1: Difficult to arouse, lethargic, sleepy
 - Stage 2: Delirious, combative, with purposeful or semipurposeful motor responses
 - Stage 3: Unarousable, with predominantly flexor motor responses, decorticate
 - Stage 4: Unarousable, with predominantly extensor motor responses, decerebrate
 - Stage 5: Unarousable, with flaccid paralysis, areflexia, and pupils unresponsive
 - Stage 6: Treated with curare or equivalent drug, and therefore unclassifiable

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Ammonia test: Result may be normal at the onset of vomiting. Serum level >45 g/dL suggests higher mortality.
- CSF: Normal except for elevated intracranial pressure

Imaging

EEG: Characteristic of metabolic encephalopathy with generalized slow-wave abnormalities

Diagnostic Procedures/Other

- Liver and muscle function testing: Elevated levels of transaminases, creatinine kinase, lactate dehydrogenase, and ammonia; increased PT
- Metabolic workup: Abnormalities of organic and amino acids may be present if symptoms are caused by a metabolic disorder.

DIFFERENTIAL DIAGNOSIS

- It is important to distinguish between so-called classic Reye syndrome, associated with aspirin (acetylsalicylic acid) therapy, and Reye-like syndromes, often due to metabolic disorders and other causes, as mentioned subsequently.
- Metabolic diseases: In a report by Hou et al., Reye-like syndrome was secondary to hereditary organic acidemias ($n = 13$), urea cycle defects ($n = 4$), mitochondrial disorders ($n = 3$), fulminant hepatitis ($n = 2$), tyrosinemia ($n = 1$), and valproate-associated hepatotoxicity ($n = 1$). In the U.K., 12% of Reye syndrome cases between 1981–1996 were subsequently reclassified as metabolic disorders.
- CNS infections (e.g., meningitis, encephalitis)
- Toxins
- Drug ingestion (e.g., salicylates, valproate)

ALERT

Failure to recognize early and control or prevent cerebral edema is the immediate cause of death.

TREATMENT

ADDITIONAL TREATMENT

General Measures

Vitamin K, fresh-frozen plasma, and platelets as needed for treatment of secondary coagulopathy

IN-PATIENT CONSIDERATIONS

Initial Stabilization

- Should be tailored based on severity of presentation
- IV glucose to counteract effects of glycogen depletion
- Fluid restriction in patients with cerebral edema (1,500 mL/m²/d), along with mannitol to increase serum osmolality and induce cerebral dehydration

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Cerebral function at presentation is the best predictor of outcome.

PROGNOSIS

- Most patients suffer only mild illness without progression.
- Patients with milder disease (stages 0, 1, 2) tend to recover completely.
- Patients with stage 3 disease are equally likely to recover completely or die.
- Patients with stage 4–5 disease usually do not survive.

COMPLICATIONS

- Elevated intracranial pressure secondary to cerebral edema
- Cardiovascular collapse
- Overall mortality of 31%

CODES

ICD9

331.81 Reye's syndrome

ICD10

G93.7 Reye's syndrome

FAQ

- Q: Is Reye syndrome fatal?
- A: ~30% of children will die, usually due to cerebral edema. Mortality rates are best predicted by neurologic state at the onset of presentation.
- Q: How can the neurologic findings of Reye syndrome be differentiated from those of meningitis?
- A: Aside from elevated intracranial pressure, the lumbar taps of patients with Reye syndrome are at best unremarkable. Elevated leukocyte count is not seen in these cases.

RHABDOMYOLYSIS

Divya Moodalbail

Thomas L. Kennedy (5th edition)

BASICS

DESCRIPTION

Skeletal muscle injury results from trauma, infection, or from inadequate delivery, production, or consumption of energy or oxygen relative to demands. Release of intracellular contents may cause severe electrolyte disturbances including life-threatening hyperkalemia, hyperphosphatemia, and hypocalcemia. The resulting myoglobinuria can cause obstruction of renal tubules and pigment-induced acute renal failure.

EPIDEMIOLOGY

- Rhabdomyolysis is more common in adults, where it is seen most frequently in patients in comas resulting from heroin or cocaine abuse and long periods of remaining motionless.
- Rhabdomyolysis is uncommon in childhood and unusual in the 1st decade.
- It may be seen in heat exhaustion.
- Rhabdomyolysis may be a common clinical problem in a catastrophic disaster (e.g., an earthquake).

RISK FACTORS

Genetics

Many unusual causes of rhabdomyolysis, including muscle enzyme deficiencies, muscular dystrophy, and disorders of mitochondrial metabolism, are heritable disorders.

ETIOLOGY

- The most common causes include physical causes such as muscle trauma from crush or compression injury (crush syndrome), burns, or electric shock. Others include viral illnesses (e.g., influenza, Epstein–Barr virus infection), heat stroke, severe exertion, status epilepticus, and vasculitis with myositis.
- A common cause in adolescents is exercise which is novel, intense, or prolonged, often the result of competition or punitive measures, especially in the presence of extremely hot, humid weather conditions (so-called “March Myoglobinuria”).
- Less common causes in childhood include penetrating trauma (e.g., gun shot); congenital metabolic myopathies; acute dystonic reactions; malignant hyperthermia syndrome; other infections; exposure to some medications, toxins, or illicit drugs; and severe electrolyte disturbances.
- Myopathies involving muscle enzyme or energy substrate deficiencies include carnitine palmitoyltransferase deficiency type II (CPT II deficiency), type V glycogenosis, mitochondrial deficiency disorders, and phosphofructokinase deficiency. Usual triggers for rhabdomyolysis in such conditions are fasting, exertion, or viral illness.

- Rhabdomyolysis is more likely to occur after exertion in association with the dystrophinopathies, which include all forms of muscular dystrophy.
- Infections, in addition to the viral illnesses listed above, include Coxsackievirus, HIV, *Plasmodium*, *Legionella* sp., mycoplasma, SARS, and toxic shock syndrome.
- Causative medications include the lipid-lowering “statin” inhalation anesthetics, propofol, cyclosporine, amphotericin B, itraconazole, and isotretinoin. An overdose of epinephrine and high-dose IV norepinephrine are also on the list.
- Hyperthermia: Malignant hyperthermia, is a rare inherited condition that results in hyperthermia, muscle breakdown, and subsequent rhabdomyolysis, on receiving halogenated hydrocarbon-containing anesthetics or muscle relaxants such as succinylcholine. Neuroleptic malignant syndrome is a rare neurological disorder characterized by hyperthermia, rhabdomyolysis, and autonomic changes in patients receiving neuroleptic or antipsychotic medications
- Toxins and illicit drugs include snake, spider, and vespid venoms, fish toxins, some mushrooms, hydrocarbons, ethanol, methanol, cocaine, heroin, amphetamines, phencyclidine (PCP), and ecstasy. Rhabdomyolysis has also been reported, possibly due to copper toxicity, in Wilson disease.
- Electrolyte disturbances include hypokalemia, severe hypophosphatemia, hypernatremia, hyponatremia, hypocalcemia, and hyperosmolar states such as diabetic ketoacidosis. Hypokalemia can cause rapid muscle ischemia leading to rhabdomyolysis, as potassium is essential for causing vasodilation of the microvasculature supplying the muscles to maintain adequate perfusion.
- It is important to remember that the muscle injury caused by severe hypokalemia (e.g., Bartter syndrome) may rapidly lead to life-threatening hyperkalemia.
- The insult may lead to muscle cell destruction or failure of membrane function with release of intracellular contents including proteins and electrolytes and uptake of large amounts of extracellular water leading to severe hypovolemia and decreased renal perfusion.
- The list of causes here is not exhaustive. Any child with sudden onset of muscle pain, tenderness, or weakness should be suspected of having rhabdomyolysis, and any child with dark urine suspected of myoglobinuria.

COMMONLY ASSOCIATED CONDITIONS

In addition to the previously mentioned causes, rhabdomyolysis has also been reportedly associated with diverse conditions, including asthma, hemolytic-uremic syndrome, and diabetes mellitus. It may also occur in Kawasaki disease and adrenal insufficiency, associations which are rare, but must not be missed.

DIAGNOSIS

- Muscle pain or weakness; rarely focal or diffuse muscle swelling can be seen
- Brownish urine

HISTORY

- Increased exertion, viral illness, muscle injury, and electric shock are conditions associated with muscle breakdown and rhabdomyolysis.
- Rhabdomyolysis is associated with muscular dystrophy and reaction to drugs (e.g., anesthetic agents).
- Any prior history of illness or insult associated with rhabdomyolysis may follow certain illnesses (e.g., influenza) and insults (e.g., crush injury), and thus a history positive for these should be sought.
- Muscle pain or weakness may result from rhabdomyolysis and help suggest diagnosis if present.
- Brownish discoloration of the urine

PHYSICAL EXAM

- Palpate muscle for tenderness and, less commonly, swelling or fullness
- Test for motor strength
- Elicit reflexes to exclude neuropathy
- Examine skin and mucous membranes for signs of vasculitis
- The child with evidence of rhabdomyolysis must be examined looking for signs of child abuse.
- Examine for signs of a concomitant precipitating illness

Lab

- Serum creatine phosphokinase will be elevated to over 100 times normal in rhabdomyolysis.
- CK levels peak within the first 24 hours of insult and trend down over the next few days. If the CK levels continue to rise, it should raise suspicion for ongoing muscle damage or development of compartment syndrome.
- Serum electrolytes, calcium, and phosphorus to reveal hypo/hyperkalemia, hyperphosphatemia, and/or hypocalcemia. There may be metabolic acidosis with a wide anion gap in those conditions associated with lactate production.
- BUN and creatinine: Creatinine level may be elevated out of proportion to that of BUN, secondary to conversion of liberated muscle creatine to creatinine.
- CBC and smear because many of the metabolic disorders causing rhabdomyolysis cause a hemolytic anemia as well.

- Patients with rhabdomyolysis are at increased risk for disseminated intravascular coagulation (DIC) secondary to thromboplastin released from the injured myocytes. It is essential to obtain PT/INR, PTT, platelets, and fibrinogen levels.
- Abnormal plasma acylcarnitine profile and free carnitine level in CPT II deficiency
- Serum uric acid may be elevated secondary to increased purine metabolism.
- LDH, AST, aldolase, and other muscle enzyme levels will be elevated secondary to muscle injury.
- Urinalysis: Urine may appear brown and test positive for blood on dipstick without erythrocytes on microscopy. In this instance the diagnostic possibilities are hemoglobinuria or myoglobinuria. Granular pigmented casts are common.
- Definitive tests for myoglobinuria:
 - Ammonium sulfate solubility testing is a reasonable screening test to help differentiate myoglobin from hemoglobin.
- Other tests:
 - EKG may reveal changes associated with acute hyperkalemia, such as peak T waves, prolongation of PR, absent P wave with prolonged QRS interval or even ventricular tachycardia/fibrillation in severe untreated hyperkalemia

Imaging

Use of radiocontrast in imaging studies as part of diagnostic evaluation can worsen acute renal failure. Use only if absolutely necessary and be certain the child is well hydrated and voiding briskly.

Diagnostic Procedures/Other

Muscle biopsy: Necessary to diagnose metabolic myopathies. A biopsy will demonstrate immunohistochemical features of a myopathy. Immunoblotting is helpful in evaluating the dystrophinopathies.

DIFFERENTIAL DIAGNOSIS

- Any condition associated with muscle pain, tenderness, and/or weakness. Many causes of rhabdomyolysis may be associated with these signs and symptoms but demonstrate no elevation in creatine phosphokinase levels.
- Many viral illnesses
- Lyme disease
- Suppurative myositis
- Guillain-Barré syndrome
- Collagen vascular diseases

TREATMENT

INITIAL STABILIZATION

Treatment is supportive. If an underlying cause is identified, it should be corrected or removed.

General Measures

- Fluid resuscitation is very essential in the management of rhabdomyolysis. Vigorous hydration with crystalloid IV fluids followed by adequate maintenance fluids (e.g., 2–3 times maintenance) should be sufficient to provide brisk urine flow (e.g., >4 mL/kg/h). Myoglobinuric nephrotoxicity is the one of the very few clinical situations in which acute renal failure can be averted by maintaining good urine flow. Alkalinization of the urine is probably beneficial. Furosemide and/or mannitol may be helpful to maintain urine output.

MEDICATION (DRUGS)

- With myoglobinuria, bicarbonate therapy should be given IV to maintain the urine pH > 7.0.
- If urine output declines despite adequate hydration, furosemide (1–4 mg/kg/dose IV) should be given to attempt to prevent oliguric renal failure—furosemide will also maximize potassium elimination by the kidney.
- If severe hyperkalemia occurs, measures should be taken to prevent cardiac dysrhythmias with IV calcium gluconate, sodium bicarbonate, insulin, and glucose. Kayexalate can be given by mouth or per rectum, in order to eliminate potassium through the GI tract.
- With hypocalcemia, give calcium only if symptoms are present.
- Indications for dialysis:
 - Oliguric acute renal failure
 - Severe hyperkalemia refractory to medical management
 - Severe metabolic acidosis
 - Respiratory distress secondary to pulmonary edema

ONGOING CARE

Close monitoring of labs with serial measurements of CK levels, creatinine, and electrolytes is essential. Also the patient should be watched closely for signs of ongoing muscle injury, compartment syndrome, DIC, or oliguria.

PROGNOSIS

- Depends on extent of pre-existing irreversible renal disease, prompt recognition and institution of appropriate therapy, and the diuretic response to fluid replacement. In general, however, outlook for recovery is good.
- Prompt cessation of rhabdomyolysis may be expected when the inciting cause is corrected or resolves.
- Although most children recover promptly, severe muscle injury may cause prolonged muscle weakness and warrant follow-up by physical and occupational therapy.
- With resolution of myoglobinuria, return to normal renal function is the rule.

COMPLICATIONS

- Electrolyte release from muscle can lead to hyperkalemia, hyperphosphatemia, and secondary hypocalcemia.
- Acute renal failure may occur due to myoglobinuria and does in ~20–40% of patients. Dialysis is required in ~50% of those with acute renal failure. Myoglobin may exert direct renal cytotoxicity, tubular obstruction with myoglobin casts, as well as decreased renal blood flow and glomerular filtration rate as a result of hypovolemia.
- Compartment syndrome may result from muscle swelling.
- Furosemide may interfere with alkalinization of the urine.
- Use of bicarbonate may precipitate symptomatic hypocalcemia.
- Calcium therapy for severe hyperkalemia is necessary, but its use with hyperphosphatemia increases risk of vascular calcification.
- Risk factors for acute renal failure include pre-existing renal disease, delay in recognition and treatment, concurrent use of potentially nephrotoxic agents (e.g., NSAIDs), volume depletion, and either hypotension or hypertension.
- Failure to discontinue IV fluids if oligoanuric renal failure develops could produce iatrogenic fluid overload.

ICD10

M62.82 Rhabdomyolysis

RHABDOMYOSARCOMA

Edward F. Attiyeh

BASICS

DESCRIPTION

Malignant tumor of immature mesenchymal cells committed to skeletal muscle lineage

EPIDEMIOLOGY

- 3rd most common extracranial solid tumor of childhood, after neuroblastoma and Wilms tumor
- ~1.2 times more common in boys than girls

Incidence

- ~350 new cases are diagnosed each year in the US.
- Most cases (~60–70%) are diagnosed in children <6 years of age.

RISK FACTORS

Genetics

- Most cases occur sporadically.
- Several predisposing conditions:
 - Li-Fraumeni syndrome:
 - Family cancer syndrome associated with germline mutations of the p53 gene (17p13)
 - The syndrome was 1st described after examining the family records of children with rhabdomyosarcoma.
 - Autosomal dominant inheritance
 - Also predisposes to other soft tissue sarcomas, leukemia, brain tumors, adrenocortical carcinoma, and early-onset breast carcinoma
 - Beckwith-Wiedemann syndrome:
 - Fetal overgrowth syndrome characterized by an abnormality at chromosome 11p15
 - Primarily have an increased incidence of Wilms tumor and hepatoblastoma
 - Neurofibromatosis type I:
 - Autosomal dominant genetic disorder characterized by mutation of the NF1 gene (17q11)
 - Also associated with other soft tissue sarcomas (e.g., malignant nerve sheath tumors, neurofibrosarcomas), leukemia, Wilms tumor, and brain tumors
 - Previous radiation exposure, especially in patients with Li-Fraumeni, neurofibromatosis type I, or hereditary retinoblastoma (RB1 germline mutation)
 - Congenital anomalies of the genitourinary system and CNS are more frequent than expected in children with rhabdomyosarcoma.

PATHOPHYSIOLOGY

- 1 of the “small round blue cell” tumors of childhood
- 2 major subtypes:
 - Embryonal (70% of cases):
 - Spindle-shaped cells, less densely cellular with stroma-rich appearance
 - Associated with a chromosomal abnormality at chromosome band 11p15
 - Alveolar (20% of cases):
 - Small round cells with dense appearance lined up along spaces resembling pulmonary alveoli
 - Associated with translocation between chromosomes 2 and 13 (PAX3-FKHR), or less commonly 1 and 13 (PAX7-FKHR)
- Undifferentiated and pleomorphic types make up the remaining cases.

COMMONLY ASSOCIATED CONDITIONS

- Fetal alcohol syndrome
- CNS and genitourinary anomalies
- Tobacco smoking in fathers
- Marijuana and cocaine use in mothers and fathers in the year before child’s birth

DIAGNOSIS

HISTORY

- A painless firm swelling or mass is the most common presentation.
- Other symptoms depend on site of origin:
 - Head/neck: Nasal congestion or discharge, epistaxis, snoring, sinusitis, dysphagia, otorrhea, chronic otitis media, cranial nerve palsies, proptosis, headache, vomiting, or systemic hypertension (with intracranial growth of tumor)
 - Trunk: Usually few symptoms until tumor widespread
 - Genitourinary/pelvic: Urinary frequency or retention, hematuria, constipation, vaginal discharge or bleeding
 - Extremity: Painful or painless lumps or erythema

PHYSICAL EXAM

- Condition can occur in any location, even in sites in which skeletal muscle is not normally found.
- Distribution of primary tumor sites include:
 - Head and neck (38%): Parameningeal (e.g., middle ear, nasal cavity, paranasal sinuses, nasopharynx, infratemporal fossa, pterygopalatine fossa, parapharyngeal area), orbit (e.g., orbit, eyelid), nonparameningeal (e.g., scalp, parotid, oral cavity, larynx, oropharynx, cheek, hypopharynx, thyroid, parathyroid, neck)
 - Genitourinary tract (21%): Bladder, prostate, uterus, vagina, vulva, and paratesticular region
 - Extremity (18%)
 - Trunk (7%)
 - Retroperitoneum (7%)
- Special attention should be given during physical exam to lymphatic structures and surrounding tissues, because this may identify local invasion and/or lymphatogenous spread.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- CBC
- Electrolytes, liver function tests, and renal function tests in anticipation of starting chemotherapy

Imaging

- To evaluate primary site and confirm diagnosis: CT scan or, preferably, MRI scan
- To evaluate for evidence of distant metastases (present in 20% of patients at diagnosis):
 - Chest radiograph and CT scan
 - ⁹⁹Tc-diphosphonate bone scan
 - PET scan

Diagnostic Procedures/Other

- Biopsy:
 - Should be performed by an experienced surgeon:
 - Avoid contamination of surrounding tissues.
 - Ensure adequate tissue sampling to make the diagnosis.
 - In addition to routine morphologic and immunohistochemical stain assessments, analysis of tumor genetics by traditional cytogenetics, fluorescence in situ hybridization, or reverse transcriptase-polymerase chain reaction (RT-PCR) is helpful in making the diagnosis and may provide information regarding prognosis.
 - Because of the importance of these studies, consultation with a pediatric oncologist before the biopsy is essential.
- Bilateral bone marrow aspirates and biopsies
- Lumbar puncture for cerebrospinal fluid cytology (parameningeal tumors only; to determine whether CNS is involved)

DIFFERENTIAL DIAGNOSIS

- Malignant:
 - Ewing sarcoma
 - Neuroblastoma
 - Non-Hodgkin lymphoma
 - Leukemic chloroma
 - Germ cell tumor
 - Rare soft tissue sarcomas
- Nonmalignant:
 - Trauma
 - Benign tumors: Lipoma, rhabdomyoma, neurofibroma
 - Langerhans cell histiocytosis
 - Abscess

TREATMENT

MEDICATION (DRUGS)

- Chemotherapy: Common pharmacotherapeutic agents used include vincristine, dactinomycin, cyclophosphamide, doxorubicin, etoposide, and ifosfamide. Other agents (e.g., topotecan, irinotecan) are being investigated.
- Most patients require placement of an indwelling central venous catheter for the duration of their therapy.

ADDITIONAL TREATMENT

General Measures

- Therapy is multimodal with chemotherapy, radiation therapy, and surgery. Typically structured as:
 - Neoadjuvant chemotherapy
 - Local control (surgery, radiation therapy)
 - Adjuvant chemotherapy
- Most children are treated at pediatric oncology centers using large cooperative group protocols
- Treatment is characterized by significant side effects, including increased susceptibility to infection, severe mucositis, and poor nutritional status.
- Experimental therapies such as immunotherapy (vaccination with fusion-gene peptide products) are being investigated in clinical trials for patients with high-risk or relapsed disease.

Additional Therapies

Radiotherapy

- Radiation therapy can be used to aid in local control and for control of metastatic disease.

ISSUES FOR REFERRAL

Consultation with a pediatric oncologist is essential before any attempt is made at a diagnostic biopsy.

SURGERY/OTHER PROCEDURES

Trend is toward less radical surgical interventions.

 **ONGOING CARE**

PROGNOSIS

- Overall ~70% of patients can be cured.
- Tumor stage and clinical group are used to predict survival and guide therapy:
 - Staging is based on the anatomic site of the tumor and the extent of spread:
 - Favorable sites include orbit, nonparameningeal head and neck, nonbladder/prostate genitourinary
 - Unfavorable sites include extremities, parameningeal, bladder/prostate
 - Clinical grouping is based on extent of surgical resection. Generally:
 - Stage I: Completely resected
 - Stage II: Gross total resection with microscopic residual disease
 - Stage III: Biopsy only, gross residual disease
 - Stage IV: Distant metastases
- Tumors with alveolar histology (typically extremity lesions) tend to metastasize early.
- The presence of the *PAX3-FKHR* or *PAX7-FKHR* gene rearrangement (seen in tumors with alveolar histology) is an adverse prognostic factor, associated with older patients and more advanced disease stage.
- Recurrence can occur many years after completion of therapy but is rare after 3 years.

COMPLICATIONS

- Rhabdomyosarcoma can compromise the function of surrounding organs.

- Metastatic spread may occur to lymph nodes, lung, bone, bone marrow, liver, or brain.
- Acute effects of therapy:
 - Frequent hospital admissions for chemotherapy or complications of therapy
 - Bone marrow suppression:
 - Transfusions are usually necessary.
 - Neutropenia: Increased risk of bacterial and fungal infections; granulocyte colony-stimulating factor is usually administered daily after chemotherapy to shorten duration of neutropenia.
 - Complications from the GI side effects of chemotherapy or radiotherapy:
 - Nausea and vomiting: Relieved with ondansetron and other antiemetic agents
 - Malnutrition secondary to reduced appetite and mucosal ulcerations
- Late effects of therapy:
 - Cardiomyopathy:
 - Anthracyclines (doxorubicin) weaken cardiac muscle, leading to reduced left ventricular function many years after therapy.
 - ~5% of patients receiving cumulative doses of doxorubicin exceeding 500 mg/m² develop CHF.
 - Radiation to the heart can reduce the cumulative dose threshold to 300 mg/m².
 - Kidney and bladder damage:
 - Urinalysis should be performed to detect hemorrhagic cystitis or tubular damage.
 - BP should be monitored in patients who received irradiation to the kidneys; vascular damage and hypertension may develop many years after therapy.
 - Infertility and delayed puberty:
 - Reduced or absent gonadal function is related to high doses of alkylating agents (e.g., cyclophosphamide, ifosfamide): Boys are at high risk of azoospermia; girls may be fertile but are at risk for premature menopause.
 - Low-dose estrogen therapy with oral contraceptive medications may be necessary for amenorrheic women.
 - 2nd malignant neoplasms:
 - Sarcomas may occur within the radiation field.
 - Myelodysplastic syndromes and acute myeloid leukemia may occur secondary to radiation or chemotherapy.
 - Bowel obstruction and enteritis (abdominopelvic tumors):
 - Adhesions as a consequence of surgery or radiation
 - A history of failure to gain weight or symptoms of malabsorption suggest a need for additional evaluation.
 - Growth abnormalities/functional defects at the primary site:
 - Radiation doses >20 Gy will cause growth retardation in prepubertal children.
 - Scoliosis can occur if the vertebrae are involved in the radiation field.
 - Cataracts can occur after irradiation involving the head.
 - Learning difficulties: Radiotherapy directed to the CNS in children <3 years old with head/neck primary cancers may produce significant cognitive deficits.

 **CODES**

ICD9

- 171.9 Malignant neoplasm of connective and other soft tissue, site unspecified
- 188.9 Malignant neoplasm of bladder, part unspecified

ICD10

- C49.9 Malignant neoplasm of connective and soft tissue, unspecified
- C67.9 Malignant neoplasm of bladder, unspecified

FAQ

- Q: Can a child with rhabdomyosarcoma attend school?
- A: Because chemotherapy for rhabdomyosarcoma is intensive, many children are unable to continue with school during this time but benefit from educational instruction at home.
- Q: Is the treatment associated with infertility?
- A: The present chemotherapy regimens include high cumulative doses of alkylating agents placing boys, in particular, at high risk for infertility. Sperm banking is recommended for adolescent boys before starting chemotherapy.

RHEUMATIC FEVER

David Hehir

BASICS

DESCRIPTION

A postinfectious inflammatory disease caused by rheumatogenic strains of group A β -hemolytic *Streptococcus* (GABHS). Clinically diagnosed using the Jones criteria, acute rheumatic fever (ARF) results in a wide range of disease, from mild joint involvement to chronic carditis. The most significant health care and socioeconomic impact is caused by its most severe form, rheumatic heart disease (RHD).

EPIDEMIOLOGY

- Occurs following pharyngitis with rheumatogenic GABHS strains
- GABHS strains that cause skin infections are classically thought to be associated with glomerulonephritis; however, there is some evidence that ARF can be associated with skin infections in tropical and underdeveloped areas of the world.
- Initial episode seen primarily in patients 5–15 years of age
- No racial or ethnic predilections

Incidence

- Historically, untreated GABHS infection results in ARF in 0.1–0.3% of cases, with attack rates as high as 3% in endemic areas.
- Recent incidence data reveal 0.5/100,000 school-aged children in industrialized countries are affected. Incidence is as high as 500/100,000 in tropical and underdeveloped countries.
- Decrease in incidence due to increased use of antibiotics, improved environmental factors such as overcrowding, and changing virulence patterns of GABHS strains.

Prevalence

12 million people are affected by ARF worldwide, with 400,000 cases of RHD. This accounts for 25–40% of all cardiac disease worldwide.

RISK FACTORS

Genetics

No specific genetic risk factor identified, although numerous studies have demonstrated an association of ARF with specific human leukocyte antigen (HLA) alleles

PATHOPHYSIOLOGY

- GABHS triggers a complex inflammatory host response affecting the heart, joints, brain, blood vessels, and subcutaneous tissue.
- Classic example of molecular mimicry, in which the host produces antibodies to certain GABHS M proteins, which are similar in structure to host proteins such as myosin, resulting in autoimmune tissue damage.
- Aschoff nodules are proliferative lesions noted in the myocardium that may persist for months to years after initiation of disease.

ETIOLOGY

Immune-mediated inflammatory reaction to specific rheumatogenic strains of GABHS.

DIAGNOSIS

HISTORY

- A clinical diagnosis based on the modified Jones criteria (updated 1992): Evidence of recent GABHS infection with the presence of either 2 major or 1 major and 2 minor criteria:
- Major criteria (% affected):
 - Polyarthritis (70%): Migratory arthritis of major joints; more common in adults
 - Carditis (50%): 85% of those with carditis have mitral regurgitation, and 54% have aortic valve involvement. Symptoms range from asymptomatic murmur to fulminant heart failure; carditis is more common and more severe in children
 - Sydenham chorea (15%): Abnormal behavior and/or involuntary, purposeless movements
 - Erythema marginatum (10%): Evanescent, pink rash with serpiginous borders
 - Subcutaneous nodules (2–10%): Painless nodules over extensor surfaces of large joints, the occiput, and/or vertebral processes
- Minor criteria:
 - Fever
 - Arthralgia (mild pain without objective findings): Can only be considered without finding of arthritis
 - Elevated acute-phase reactants: ESR, C-reactive protein
 - Prolongation of the PR interval on electrocardiogram
- Exceptions to the Jones criteria include:
 - Sydenham chorea alone
 - Subclinical carditis (echocardiogram evidence of RHD) in the absence of other criteria should be treated as ARF.
 - Jones criteria cannot be applied to recurrence; World Health Organization (WHO) recommends treating recurrence in a patient with RHD and presence of any major or minor criterion.

PHYSICAL EXAM

- Cardiac:
 - Murmur of valvulitis: Holosystolic mitral regurgitant murmur, Carey-Coombs apical mid-diastolic murmur, or a basal diastolic murmur of aortic insufficiency (major criterion)
 - Pericardial friction rub: Pericardial effusion
- Musculoskeletal:
 - Pain, limited motion, erythema, warmth of 2 or more large joints: Arthritis (major criterion)
- Neurologic: Choreiform movements (must be differentiated from tics, athetosis, and hyperkinesias): Sydenham chorea (major criterion)
- Dermatologic:
 - Evanescent, pink rash with pale centers and serpiginous borders on the trunk and proximal extremities: Erythema marginatum (major criterion)
 - Firm, painless nodules over the extensor surface of large joints, occiput, and/or spinous processes: Subcutaneous nodules (major criterion)

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Specific tests: No specific diagnostic test is available.
- Nonspecific tests:
 - Throat culture: Neither sensitive nor specific. False negative in up to 2/3 of affected patients, or false positive in patients who are colonized
 - Elevated or rising streptococcal antibody titers, antistreptolysin O, anti-DNase B, antihyaluronidase
 - ESR and C-reactive protein elevation

Imaging

- ECG: Prolonged PR interval (minor criterion), junctional rhythm, transient arrhythmias, ST-T wave changes
- Chest radiograph: Cardiomegaly may indicate carditis or pericardial effusion. Pulmonary edema may reflect left heart failure due to valvulitis.
- Echocardiogram: Assess valve involvement, ventricular dilatation, function, and pericardial effusion.

DIFFERENTIAL DIAGNOSIS

- Carditis:
 - Viral
 - Bacterial
 - Rickettsial
 - Parasitic
 - Mycoplasma myocarditis
 - Kawasaki disease
- Arthritis:
 - Poststreptococcal reactive arthritis (PSRA)
 - Serum sickness
 - Septic arthritis (i.e., gonococcal)
 - Lyme disease
- Collagen vascular disease:
 - Juvenile rheumatoid arthritis (small joints, not migratory, and not relieved promptly with aspirin)
 - Systemic lupus erythematosus
 - Bacterial endocarditis
- Chorea:
 - Congenital choreoathetosis
 - Brain tumors
 - Huntington chorea
 - Wilson disease
 - Pediatric autoimmune neuropsychiatric disorders associated with streptococcus (PANDAS)
- Hematologic disorders with joint involvement:
 - Sickle cell anemia
 - Leukemia
- Congenital heart defects: Previously undiagnosed valvular heart disease
- Mitral valve prolapse with regurgitation

TREATMENT

MEDICATION (DRUGS)

First Line

- Anti-inflammatory
 - Aspirin 60–100 mg/kg/d; may be reduced when fever and acute-phase reactants have normalized for 6–8 weeks
- Antibiotics in ARF:
 - Penicillin V potassium (Pen VK):
 - Children: 250 mg 2–3 times/day for 10 days
 - Adolescents, adults: 500 mg 2–3 times/day for 10 days
- Secondary prophylaxis:
 - Benzathine penicillin G IM (600,000 U for weight <27 kg or 1,200,000 U for weight >27 kg) every 3–4 weeks

Second Line

- Anti-inflammatory:
 - Prednisone 2 mg/kg/d for 2 weeks, then taper
- Antibiotics in ARF:
 - Erythromycin, amoxicillin, 1st-generation cephalosporin
- Secondary prophylaxis:
 - Penicillin V 250 mg b.i.d.
 - Erythromycin, sulfadiazine

ADDITIONAL TREATMENT

General Measures

- Primary prevention: Appropriate and early treatment of GABHS pharyngitis
- Interventions to address poverty, crowding, and housing challenges
- Treatment of ARF:
 - Antibiotics: Full course of penicillin or equivalent to eradicate active infection; does not alter course of carditis
 - Anti-inflammatory: High-dose aspirin is standard; steroids may help for severe carditis but remain controversial.
 - Cardiac support: Aggressive support of cardiac function and use of systemic afterload reduction for severe disease
 - Surgical valvuloplasty or valve replacement may be necessary in severe cases.
 - Bed rest: Controversial; still recommended for severe cases
- Secondary prevention:
 - Ideally administered as benzathine penicillin G as a monthly IM injection, but oral daily penicillin or erythromycin is acceptable in areas of low prevalence.
 - Duration based on clinical presentation and degree of cardiac involvement:
 - ARF without cardiac involvement: 5 years or until age 18, whichever is longer
 - ARF with mild or resolved carditis: 10 years or until age 25, whichever is longer
 - ARF with severe carditis or cardiac surgery: Lifelong

- Treatment of chorea:
 - Usually supportive
 - Phenobarbital and haloperidol are most commonly used; chlorpromazine, diazepam, or valproic acid also used

ISSUES FOR REFERRAL

Patients with new murmurs or clinical evidence of heart failure should be referred to a cardiologist.

IN-PATIENT CONSIDERATIONS

Initial Stabilization

Full treatment of streptococcal pharyngitis infection and cardiac support if heart failure present. Treatment phases include primary prevention, management of ARF, and secondary prevention of recurrence.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Patients without carditis:
 - Close follow-up is needed for 2–3 weeks to assess patient's condition for development of acute carditis.
 - Long-term pediatric follow-up is needed to diagnose patients with indolent carditis.
 - Long-term follow-up is needed to evaluate patients who develop chorea.
 - Prophylaxis should be stressed even in patients without carditis.
- Patients with carditis:
 - Cardiology follow-up is needed to assess development or evolution of RHD.
 - Symptoms of worsening heart failure suggest progression of valvular or myocardial disease, recurrent ARF, or endocarditis.
 - Secondary prophylaxis and bacterial endocarditis prophylaxis should be stressed.

PROGNOSIS

- ARF recurrence rate as high as 36% without prophylaxis
- Chorea may last weeks to months and has a similarly high recurrence rate.
- Carditis may resolve spontaneously (70–80%) or progress. Severity of the initial carditis is a major determinant of progression.

COMPLICATIONS

Long-term complications related to evolution of RHD:

- Mitral stenosis
- Mitral regurgitation
- Aortic stenosis
- Aortic regurgitation
- Chronic heart failure

CODES

ICD9

- 390 Rheumatic fever without mention of heart involvement
- 398.90 Rheumatic heart disease, unspecified
- 729.89 Other musculoskeletal symptoms referable to limbs

ICD10

- I00 Rheumatic fever without heart involvement
- I09.9 Rheumatic heart disease, unspecified

FAQ

- Q: Does a negative throat culture rule out ARF?
- A: No. Throat cultures may be negative in 2/3 of patients.
- Q: Is there a vaccine available to prevent ARF?
- A: Not at present. However, research efforts to develop a recombinant multivalent vaccine have been promising. Note that >90 antigenic strains of group A *Streptococcus* have been identified; any vaccines developed ought to focus on those with the greatest virulence.
- Q: What genetic factors predispose to ARF?
- A: Several studies done worldwide have reported a high incidence of certain HLA-DR antigens in patients with rheumatic fever. The specific antigen/allele involved varies with the ethnic group studied.
- Q: Can ECG evidence of carditis alone be used to diagnose rheumatic fever?
- A: This is currently under debate. An ECG finding of carditis without a murmur cannot be used to fulfill the Jones criteria. However, many experts would agree to treat subclinical carditis as ARF, especially in areas of high prevalence.
- Q: Can intravenous γ -globulin be used as a treatment for ARF?
- A: One study revealed that intravenous γ -globulin did not alter the natural history of ARF, with no detectable difference in the cardiac outcome, laboratory findings, or ECG parameters when compared to placebo.

RHINITIS, ALLERGIC

Esther K. Chung
Karen P. Zimmer

BASICS

DESCRIPTION

- Inflammation of the nasal and sinus mucosae, associated with sneezing, swelling, increased mucus production, and nasal obstruction; may be classified as seasonal, perennial, or a combination
- Seasonal: Periodic symptoms, involving the same season for at least 2 consecutive years; most often due to pollens (e.g., trees, grass, weeds) and outdoor spores
- Perennial: Occurring at least 9 months of the year; may be more difficult to detect because of overlap with other infections; may be due to multiple seasonal allergies or continual exposure to allergens (such as dust mites, cockroaches, molds, and animal dander)
- Perennial, with seasonal exacerbations

EPIDEMIOLOGY

Prevalence

Most common allergic disease, affecting ~40 million Americans; affects 40% of children and 15–30% of adolescents

RISK FACTORS

Genetics

- Increased incidence in families with atopic disease
- If 1 parent has allergies, each child has a 30% chance of having an allergy; if both parents have allergies, each child has a 70% chance of having an allergy.

GENERAL PREVENTION

- Minimize exposure to dust mites: Consider removing carpets, upholstered furniture, and curtains; washing bedding in hot water frequently, at least every 1–2 weeks; use pillow and mattress covers.
- Minimize exposure to animal dander:
- Minimize exposure to all animals; consider using solutions containing tannic acid, which will denature animal allergens; shampoo pets frequently if pets cannot be removed from the household; use air-vent filters.
- Minimize exposure to pollens: Keep windows closed, use air conditioning, and avoid leaf raking or lawn mowing.
- Minimize exposure to molds: Keep houseplants out of the bedroom; avoid spending time in the basement, keep humidity at 35–50%.

ETIOLOGY

- Indoor allergens: House dust mite, cockroaches, animal dander, cigarette smoke, hair spray, paint, molds
- Pollens: Tree pollens in early spring, grass in late spring and early summer, ragweed in late summer and autumn
- Multiple environmental factors
- Changes in air temperature

COMMONLY ASSOCIATED CONDITIONS

- Asthma
- Allergic conjunctivitis
- Atopic dermatitis (eczema)
- Urticaria
- Otitis media with effusion
- Sleep, taste, and/or smell disturbance
- Nasal polyps

- Mouth breathing
- Snoring
- Adenoidal hypertrophy and sleep apnea
- Decreased appetite
- Delayed speech

DIAGNOSIS

HISTORY

- Typical symptoms: Patient often reports stuffy nose, sneezing, itching, runny nose, noisy breathing, snoring, cough, halitosis, and repeated throat clearing. Sensation of plugged ears and wheezing may occur.
- Red and itchy eyes
- Symptom occurrence: Seasonal, perennial, or episodic
- Exacerbating factors, including pollen, animals, cigarette smoke, dust, molds
- Family history of atopic disease, such as asthma or atopic dermatitis
- Any related illnesses: Asthma, urticaria, eczema, ear infections, and delayed speech are commonly associated conditions.

PHYSICAL EXAM

- Allergic shiners:
 - Dark discoloration beneath the eyes due to obstruction of lymphatic and venous drainage, chronic nasal obstruction, and suborbital edema
- Dennie–Morgan lines:
 - Creases in the lower eyelid radiating outward from the inner canthus; caused by spasm in the muscles of Müller around the eye due to chronic congestion and stasis of blood
- Allergic salute:
 - A gesture characterized by rubbing the nose with the palm of the hand upward to decrease itching and temporarily open the nasal passages
- Allergic crease:
 - Transverse crease near the tip of the nose, secondary to rubbing
- Nasal mucosa may appear pale and/or edematous; mucoid or watery material may be seen in the nasal cavity; check for nasal polyps, septal deviation.

DIAGNOSTIC TESTS & INTERPRETATION

- Audiometry and tympanometry when indicated
- Sweat test if cystic fibrosis is suspected or if nasal polyps are present
- **Lab**
 - Nasal cytology
 - Specimen of nasal discharge to check for the presence of eosinophils. Have the patient blow his or her nose into a piece of nonporous paper or collect discharge with a cotton swab and transfer the discharge to a glass slide. > 10% eosinophils are considered positive for nasal eosinophilia. Note: Use of intranasal steroids may reduce the number of eosinophils found in nasal discharge.
 - Radioallergen sorbent tests (RAST):
 - In vitro test to measure allergen-specific IgE; expensive; useful in patients who have diffuse atopic dermatitis. The ImmunoCAP system (Pharmacia Diagnostics) is the preferred method for specific IgE testing; uses a single blood sample to identify levels of specific IgE to a number of common respiratory allergens (available as a

profile specific to the region of the country where the patient resides), food antigens (food allergy profile), or both (childhood allergy profile).

- Total IgE: Elevated in allergic rhinitis; not routinely indicated, but may come as part of specific IgE testing; > 100 kU/L is considered elevated.
- CBC: May show eosinophilia; not routinely indicated
- Skin testing:
 - Prick test: Percutaneous, qualitative test in which antigen concentrate is placed on the skin of the volar surface of the arm or upper back, and a needle is inserted; the skin reaction is graded subjectively from 0–4.
 - Intradermal test: Qualitative test in which antigen is introduced intradermally (0.02 mL with a 26–30-gauge needle); more sensitive than the prick test and often used if prick test is negative or equivocal; the degree of swelling and erythema is graded from 0–4.
 - Caution: Skin tests may be difficult to interpret in patients with diffuse eczema and dermatographism.

Diagnostic Procedures/Other

Rhinoscopy to assess the nasal turbinates and to look for nasal polyps

DIFFERENTIAL DIAGNOSIS

- Infection:
 - Viral upper respiratory tract infection
 - Bacterial sinusitis
- Environmental:
 - Foreign body
 - Temperature
 - Odors
- Tumors:
 - Nasal polyps
 - Dermoid cyst
 - Nasal glioma
- Congenital:
 - Cystic fibrosis
 - Choanal atresia
 - Immotile cilia syndrome
 - Septal deviation
 - Primary atrophic rhinitis
- Immunologic:
 - Sarcoidosis
 - Wegener granulomatosis
 - Systemic lupus erythematosus
 - Sjögren syndrome
- Allergic:
 - Nonallergic perennial rhinitis
 - Idiopathic (vasomotor) rhinitis
 - Drug-induced rhinitis
 - Food-induced rhinitis
- Miscellaneous:
 - Rhinitis medicamentosa
 - Rhinitis associated with pregnancy/other hormonal rhinitis
 - Hypothyroidism
 - Idiopathic neonatal rhinitis

TREATMENT

MEDICATION (DRUGS)

- Caution: Cardiac arrhythmias have been seen with patients taking terfenadine and astemizole.
- Improve mucociliary flow:
 - Steam inhalation
 - Normal saline drops
 - Bicarbonate spray
 - N-acetylcysteine (orally or inhaled)
 - Oral guaifenesin
- Antihistamines: Competitively blocking histamine (H₁) receptors; suppress itching, ocular symptoms, sneezing, and rhinorrhea; not very effective against nasal congestion:
- Intranasal 2nd-generation antihistamine:
 - Azelastine: Age ≥ 5 years; 137 mcg; 1 spray per nostril b.i.d. The efficacy of this dose has not yet been established in the pediatric population but rather extrapolated from adult data.
- 2nd-generation antihistamines: Tend not to cross the blood–brain barrier and therefore do not have CNS side effects such as drowsiness
 - Loratadine (Claritin, Schering): FDA-approved for children as young as 2 years. Dose: Ages 2–5 years, 5 mg/d PO; ages 6 years or older, 10 mg/d PO
 - Desloratadine (Clarinex, Schering): FDA-approved for children ≥ 6 months. Dose: 6–12 months, 1 mg/d PO; 12 months–5 years, 1.25 mg/d PO; 6–12 years, 2.5 mg/d PO; > 12 years, 5 mg/d PO.
 - Cetirizine HCl (Zyrtec, Pfizer): FDA-approved for children as young as 6 months of age. Dose: Age 6 months–5 years, 2.5 mg = 1/2 tsp/d (1 mg/mL banana–grape flavored syrup) PO with maximum dose of 5 mg/d (must be divided into 2.5 mg b.i.d. for children < 2 years of age). Age ≥ 6 years, 5–10 mg/d
 - Levocetirizine (Xyal): FDA-approved for children as young as 6 years. Dose: 6–11 years, 2.5 mg/d (half tab) PO; ≥ 12 years, 5 mg/d PO.
 - Fexofenadine (Allegra, Aventis): Age 6–11 years, 30-mg tab b.i.d.; age ≥ 12 years, 60 mg/d b.i.d. or 180 mg/d PO.
- 1st-generation antihistamine side effects include drowsiness, performance impairment, and paradoxical excitement; anticholinergic (e.g., dry mouth, tachycardia, urinary retention, and constipation): Diphenhydramine (Benadryl) 5 mg/kg/d PO divided q.i.d.
- Intranasal steroids: Blunt early-phase reactions and block late-phase reactions; may not be fully effective until several days to 2 weeks after initiation of therapy. Must be used regularly and best when administered lying down with the head back:
 - Beclomethasone (Vancenase, Beconase): For use in children ≥ 6 years of age
 - Flunisolide (Aerobid): For use in children ≥ 6 years of age
 - Fluticasone propionate (Flonase 0.05%): For use in children ≥ 4 years of age
 - Budesonide (Rhinocort): For use in children ≥ 6 years of age
 - Triamcinolone acetonide (Nasacort): For use in children ≥ 6 years of age
 - Mometasone furoate monohydrate (Nasonex): For use in children ≥ 2 years of age
- Intranasal antihistamines: Azelastine hydrochloride (Astellin; approved for children ≥ 5 years; dose: 1–2 sprays per day) or olopatadine (Patanase; approved for children ≥ 6 years; dose: 2 sprays per day) are FDA-approved for use in seasonal allergic rhinitis

- Topical cromolyn (Nasal crom): Mast-cell stabilizer; minimal side effects; does not provide immediate relief (may take 2–4 weeks to see clinical effect): For use in children ≥ 2 years of age
- Oral decongestants: 1- and 2-Adrenergic agonists (i.e., ephedrine, pseudoephedrine, and phenylephrine) act to cause vasoconstriction, decreased blood supply to the nasal mucosa, and decreased mucosal edema. Cardiovascular and CNS side effects include tremors, agitation, hypertension, insomnia, and headaches.
- Topical decongestants: Sympathomimetics such as short-acting phenylephrine (Neo-Synephrine) and long-acting oxymetazoline (Afrin) may be useful for a few days to open nasal passages to allow for delivery of topical steroids; side effects include drying of the mucosa and burning. Use for more than a few (3–5) days may result in rebound vasodilatation and congestion (rhinitis medicamentosa).
- Combined oral decongestants and antihistamines: Numerous preparations on the market
- Leukotriene receptor antagonist (montelukast/Singulair): For use in children ≥ 6 months. Dose for 12 mos to 5 years, 1 granule packet daily; age 2–5 years, 4 mg chewable tab daily; 6–14 years, 5 mg chewable tab daily; age ≥ 15 years, 10 mg chewable tab daily.
- Immunotherapy: Also referred to as hyposensitization or desensitization. Consists of a series of injections with specific allergens, with increasing concentrations of allergens, once or twice weekly. Recommended for patients who have not responded to pharmacologic therapy:
 - Extremely effective and long lasting. After several months to years of treatment, total serum IgE levels decrease, and the intensity of the early-phase response is reduced.
 - Side effects include urticaria, bronchospasm, hypotension, and anaphylaxis.

ADDITIONAL TREATMENT

General Measures

Avoidance therapy: Identify and eliminate known/suspected allergens.

SURGERY/OTHER PROCEDURES

- Removal of allergic polyps
- Inferior turbinate surgery to reduce the size of the turbinate and relieve obstruction
- Endoscopic sinus surgery to relieve obstruction

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

Watch for fever, prolonged or severe headache, dizziness, pain, or purulent discharge; should suggest a diagnosis other than allergic rhinitis alone.

PROGNOSIS

Generally good: Complete recovery occurs in 5–10% of patients.

COMPLICATIONS

- Chronic sinusitis
- Recurrent otitis media
- Hoarseness
- Loss of smell
- Loss of hearing
- High-arched palate and dental malocclusion from chronic mouth breathing

CODES

ICD9

- 477.0 Allergic rhinitis due to pollen
- 477.2 Allergic rhinitis due to animal (cat) (dog) hair and dander
- 477.9 Allergic rhinitis, cause unspecified

ICD10

- J30.1 Allergic rhinitis due to pollen
- J30.2 Other seasonal allergic rhinitis
- J30.9 Allergic rhinitis, unspecified

FAQ

- Q: How does one minimize exposure to dust mites?
- A: Keep household temperature low; maintain humidity at ~40–50%; wash linens weekly at hot temperatures; use a microfilter when vacuuming; place mattress and box spring in tightly woven casing; use air conditioning; use high-efficiency particulate air filter units.
- Q: How often are nasal polyps associated with cystic fibrosis?
- A: In up to 40% of children, nasal polyps are associated with cystic fibrosis. <0.5% of children with asthma and rhinitis have nasal polyps.
- Q: When used on a daily basis, are intranasal steroids safe?
- A: Yes. It is generally accepted that inhaled steroids are safe. Growth suppression has been reported in children using certain intranasal steroids; however, this effect does not appear to be an effect of all intranasal steroids. Importantly, one should use the lowest effective dose of intranasal steroids when treating allergic rhinitis.

RICKETS

Maria Mascarenhas

Sara Karjoo

Alisha J. Rovner (5th edition)

BASICS

DESCRIPTION

- Failure or delay in the mineralization of growing bone and cartilage, caused primarily by a deficiency of vitamin D, calcium, or phosphorus
- See for classification of rickets and vitamin D metabolite levels

EPIDEMIOLOGY

Children at risk for rickets:

- Low-birth-weight and/or premature infants
- Breast-fed infants who do not receive supplemental vitamin D
- Darker skinned infant
- Mother who is deficient in vitamin D during pregnancy
- Higher latitudes, and seasons
- Use of sunscreens and UVR blocking agents
- Chronic renal insufficiency
- Inadequate dietary vitamin D intake (see table)
- Illnesses with malabsorption
 - Cholestatic liver disease
 - Celiac disease
 - Cystic fibrosis

GENERAL PREVENTION

Start vitamin D supplements in breastfed infants, if intake low or patient at risk (see table for at-risk conditions).

PATHOPHYSIOLOGY

Overproduction and deficient calcification of osteoid tissue, with associated osseous deformities; alterations in growth patterns. In addition, there is abnormal organization of cartilaginous growth plates and impairment of cartilage mineralization.

DIAGNOSIS

HISTORY

- Symptoms of hepatic, renal, or GI disease
- Prolonged breastfeeding without vitamin D supplementation:
 - Little or no sunlight exposure (or being covered up when exposed to sunlight)
 - Born to mother who is vitamin D-deficient
- Calcium intake
- Strict vegetarian diet
- Factors influencing calcium absorption:
 - Low vitamin D intake
 - Steatorrhea
 - Antacids
 - Anticonvulsants
- Diet high in foods containing oxalic acid
- Dietary history of Vitamin D–fortified milk in children > 1 year of age
- Amount of exposure to sunlight
- Prolonged use of cholestyramine
- Factors influencing calcium excretion: Diuretics, polyuria, or glycosuria suggests renal tubular dysfunction.
- Bone pain
- Delayed standing or walking
- Anorexia
- Seizures

- Pathologic fractures
- Tetany
- Familial history of rickets
- Signs and symptoms:
 - Anomalies of osteoid tissue
 - Skeletal and dental deformities
 - Growth disturbances and delayed gross motor development
 - Hypocalcemia
 - Tetany
 - Seizures
 - Irritability
 - Listlessness
 - Generalized muscular weakness
 - Bone pain
 - Increased risk of infections

PHYSICAL EXAM

- Failure to thrive
- Long-bone deformities (i.e., varus or valgus deformity)
- Fractures following minimal trauma
- Skull abnormalities (i.e., delay in closure of anterior fontanelle, craniotabes, and frontal bossing)
- Chest deformities (i.e., enlargement of costochondral junctions leading to rachitic rosary)
- Muscular hypotonia
- Waddling gait

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Circulating vitamin D metabolites (25-hydroxyvitamin D, 1,25-dihydroxyvitamin D)
- Circulating levels of parathyroid hormone
- Serum calcium, phosphorous, magnesium, alkaline phosphatase, and total CO₂
- Urinary calcium, phosphorous, magnesium, pH, creatinine, and amino acids, to rule out Fanconi syndrome and proximal renal tubular acidosis

Imaging

- Order 1 view because rickets is symmetrical.
- Knee or wrist films (the earliest sign at the wrist is a loss of clear demarcation between the growth plate and the metaphysis, with loss of the provisional zone of calcification).
- Radiographic findings: Irregular cortices and bony margins, widened metaphyses, widened growth plates, osteopenia

DIFFERENTIAL DIAGNOSIS

- Blount disease
- Fanconi syndrome
- Metastatic bone disease
- Neurofibromatosis type 1
- Proximal renal tubular acidosis

TREATMENT

ADDITIONAL TREATMENT

General Measures

- Studies suggest difference in potency between vitamin D₃ and D₂
- Once intake of vitamin D surpass 4,000 IU/d and 2,000 mg/d calcium, the risk for harm also increases.
- See table "Causes and Management of Rickets."

ISSUES FOR REFERRAL

- To look for other causes of rickets other than low vitamin D intake; these include:
 - No radiographic evidence of healing by 3 months
 - Radiologic evidence of rickets at <6 months of age and between 3–10 years of age
 - Findings of normal alkaline phosphate, 25(OH)-D, very high or low 1,25(OH)-D, high BUN, creatinine.

IN-PATIENT CONSIDERATIONS

Admission Criteria

- Tetany
- Severe hypocalcemia
- Seizures

Discharge Criteria

- Stable laboratory values
- Mental status and neurology exam improvement

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Monitor serum calcium, alkaline phosphatase, and phosphorus levels every 2–4 weeks; reimage bones radiographically monthly until stabilized.
- 1 early radiographic sign of healing is the appearance of the provisional zone of calcification at the boundary between the physis and metaphysis.

PROGNOSIS

- Generally good with vitamin D treatment
- Skeletal changes improve over time with adequate treatment.

COMPLICATIONS

- Fractures
- Seizures
- Failure to thrive, poor motor development
- Frequent infections

Dietary reference intake for calcium and vitamin D

Age	Estimated average requirement (mg/day)	Recommended dietary allowance (mg/day)	Upper level intake (mg/day)	Estimated average requirement (IU/day)	Recommended dietary allowance (IU/day)	Upper level intake (IU/day)
0–6 months	200	200	1,000	400	400	1,000
6–12 months	260	260	1,500	400	400	1,500
1–3 years	500	700	2,500	400	600	2,500
4–8 years	800	1,000	2,500	400	600	3,000
9–13 years	1,100	1,300	3,000	400	600	4,000
14–18 years	1,100	1,300	3,000	400	600	4,000
19–30 years	800	1,000	2,500	400	600	4,000
31–50 years	800	1,000	2,500	400	600	4,000
51–70 years males	800	1,000	2,000	400	600	4,000
51–70 years females	1,000	1,200	2,000	400	600	4,000
> 70 years	1,000	1,200	2,000	400	800	4,000
14–18 pregnant & lactating	1,100	1,300	3,000	400	600	4,000
19–50 pregnant & lactating	800	1,000	2,500	400	600	4,000

*Adapted from the 2010 institute of medicine report brief on dietary reference intakes for calcium and vitamin D

Causes and management of rickets

Causes	Management
Calcium deficiency	–
Low intake	<6 months of age 400 mg/day 6–12 months of age 600 mg/day 1–10 years of age 800 mg/day
Extreme prematurity (birth weight <1,500 g)	Adjust intake to 200 mg/kg/day
Steatorrhea	25-OH-D3 (5–7 mcg/kg/d) if serum levels are low and supplement dietary calcium between 25–100 mg/kg/day
Anticonvulsant (Phenobarbital or phenytoin)	Calcium <6 months of age 400 mg/day 6–12 months of age 600 mg/day 1–10 years of age 800 mg/day vitamin D 200 IU/day of ergocalciferol
Renal tubular acidosis	Base supplement: 3–10 mM/kg/d as NaHCO ₃ or citrate
Vitamin D deficiency	
Insufficient UV light exposure	200 IU/day of vitamin D of ergocalciferol
Breastfed infants who are not supplemented with vitamin D	200 IU/day of vitamin D of ergocalciferol
Liver disease	4,000–8,000 IU/day ergocalciferol
Renal disorders	4,000–40,000 IU/day of Calcitriol
Nutritional rickets and osteomalacia	1,000–5,000 IU/day of ergocalciferol
Vitamin D-dependent rickets	3,000–5,000 IU/day of Calcitriol
Vitamin D-resistant rickets	40,000–80,000 IU/day of ergocalciferol with phosphate supplements, daily dosage is increased at 3–4 month intervals in 10,000–20,000 IU increments
Phosphorus deficiency	
Diet (limited to premature infants)	Adjust formula or parenteral source to give 10 mg/kg/d
Antacid excess	Alternative gastric acid control
Excessive phosphaturia from tubular dysfunction	Supplemental P and calcitriol if low

Classification of rickets and vitamin D metabolite levels

	Calcium	Phosphorus	Alkaline phosphate	25-(OH)-D
Deficient synthesis and supply like:	N or ↓	↓	↑	↓
No sunlight				
Poor diet				
Immaturity				
Malabsorption	N or ↓	↓	↑	↓
Liver disease	N or ↓	↓	↑	↓
Chronic renal failure	N or ↓	↑	↑	N
Vitamin D-dependent rickets (recessively inherited)	↓	↓	↑	N
Vitamin D-resistant rickets (sex-linked dominant)	N	↓	↑	N
Renal tubular disorders (defect of phosphate reabsorption)	N	↓	↑	N

N, normal; ↓, decreased; ↑, increased.

FAQ

- Q: What is the best way to diagnose rickets?
- A: Laboratory investigation and x-rays are the best ways to make the diagnosis. The most common biochemical findings of children with vitamin D-deficient rickets are hypocalcemia, hypophosphatemia, low 25-(OH)-D concentrations, and elevated levels of parathyroid hormone and alkaline phosphatase. The classic radiographic findings occur at the growth plate of long bones and are best seen at the distal end of the radius and ulna

or at the tibia and femoral growth plates around the knee. Widening of the physis, with fraying, cupping, and splaying of the metaphyses and underdevelopment of the epiphysis are common findings.

- Q: What are the recommendations for vitamin D supplementation in infants and children?
- A: To prevent rickets and vitamin D deficiency in healthy infants and children, and acknowledging that adequate sunlight exposure is difficult to determine, the American Academy of Pediatrics recommends a supplement of 200 IU/d for the following:
 - All breastfed infants unless they are weaned to at least 500 mL/d of vitamin D-fortified formula or milk
 - All non-breastfed infants who are ingesting <500 mL/d of vitamin D-fortified formula or milk
 - Vitamin D needs to be started by the 1st 2 months of life because vitamin D stores last 8 weeks post birth.
 - Children and adolescents who do not get regular sunlight exposure, do not consume at least 500 mL/d of vitamin D-fortified milk, or do not take a daily multivitamin supplement containing at least 200 IU of vitamin D
- Q: What are the distinguishing features of vitamin D-deficient and calcium-deficient rickets?
- A: The biochemical features (e.g., hypocalcemia, high alkaline phosphatase, and high parathyroid hormone) and radiographic features (i.e., growth-plate changes) are similar. The distinguishing feature is the difference in vitamin D status. In vitamin D-deficient rickets, 25-(OH)-D levels are low. Typically, in calcium-deficient rickets, 25-(OH)-D levels are normal (> 10 ng/mL) and 1,25-(OH)₂-D levels are high.

RICKETTSIAL DISEASE

Abby M. Green
Suzanne Dawid (5th edition)

BASICS

DESCRIPTION

- Disorders caused by the Rickettsiae family of organisms including those which cause Rocky Mountain spotted fever and other similar tick-borne illnesses, the typhus group, the organism responsible for Q fever, and the organisms that cause ehrlichiosis.
- All organisms are obligate intracellular gram-negative bacteria and therefore are difficult to grow in culture.
- The diseases caused by each group of organisms are similar, encompassing a syndrome including fever, rash, headache, and capillary leak and, with the exception of Q fever, all are transmitted via an insect vector.

GENERAL PREVENTION

- Fleas, ticks, and mites should be controlled in endemic areas with the appropriate insecticides.
- Clothing to cover the entire body should be worn in tick-infested areas. In the case of a recognized bite, ticks should be removed from human skin properly with care not to expel the contents of the tick's stomach into the site of the bite.
- In areas where louse-borne typhus is epidemic, periodic delousing and dusting of insecticide into clothes are recommended.
- Paradoxical effect of rodenticides: Fleas, mites will seek alternate hosts (i.e., humans) when mice or rats are not present. Therefore, rodenticides should not be the only prevention measure taken in endemic areas.
- Except for *Orientia tsutsugamushi* (scrub typhus) and *Ehrlichia*, all rickettsial diseases produce long-term immunity to the etiologic organisms within the same group.

PATHOPHYSIOLOGY

- Spotted fever, typhus, and ehrlichiosis groups cause vasculitis as a result of organisms invading the endothelial cells of small blood vessels or white blood cells. This manifests as rash in cutaneous tissues, and systemic illness due to capillary leak throughout other organs.
- Q fever, caused by *Coxiella burnetii*, causes pneumonitis initially due to proliferation of inhaled organisms in lungs, followed by bloodstream infection and distant organ involvement including hepatitis, endocarditis, and neurologic disease.

ETIOLOGY

- Spotted fever group rickettsia and the agents of ehrlichiosis (*Ehrlichia* and *Anaplasma*) are transmitted to humans by ticks.
- Rickettsialpox and scrub typhus are transmitted by mites associated with mice.
- Epidemic typhus is a louse-borne illness, and endemic typhus, also known as murine typhus, is transmitted by fleas.
- Q fever is acquired via inhalation of the organisms from body fluid or tissue of infected mammals.
- The rickettsial diseases that occur in the U.S. are Rocky Mountain spotted fever, murine typhus, rickettsialpox, epidemic typhus, Q fever, and ehrlichiosis.

DIAGNOSIS

HISTORY

- In general, rickettsial disease should be considered as a diagnosis in a patient with fever, headache, and rash. Progression of rash can be particularly helpful in considering the diagnosis.
- Signs and symptoms:
 - Spotted fever group:
 - Illness often begins with fever, myalgia, and headache
 - Rash occurs 3–5 days following onset of symptoms and is typically described as centripetal, beginning on hands and feet and moving towards the trunk. Rash is variable and may not always follow this pattern.
 - Other symptoms include headache, neurologic changes, hypotension, hyponatremia, and consumptive coagulopathy
 - Fulminant RMSF may cause cardiovascular collapse.
 - Rickettsialpox:
 - Similar to spotted fever group though less severe and with fewer systemic symptoms; rash often includes an inoculation eschar
 - Q fever:
 - Pneumonia is most common; also may cause endocarditis, hepatitis, or osteomyelitis.
 - Rash is not a hallmark of this disease.
 - Also may be a self-limited febrile illness.
 - Typhus group:
 - Epidemic typhus is transmitted by the human body louse and causes fever, headache, and rash that can progress to pulmonary symptoms, neurologic disease, and death.
 - Endemic typhus is transmitted by fleas associated with rodents and causes symptoms similar to epidemic typhus, although with a less prevalent rash.
 - Scrub typhus is also similar but causes marked neurologic symptoms including mental status changes.

– Ehrlichiosis:

- Spectrum of illnesses including human monocytotropic ehrlichiosis and human granulocytotropic anaplasmosis that cause fever, headache, and myalgias similar to the spotted fever group.
- Rash is less common in ehrlichiosis and occurs in <50% of patients. Vasculitis is also not present in ehrlichiosis.

PHYSICAL EXAM

- All rickettsial diseases cause fever and the majority cause rash. Differentiating clinical findings of each group are described subsequently in this section, and the rashes associated with each illness are given in a table in Section VI.
- These 3 findings suggest illness caused by the spotted fever group:
 - Hypotension, cardiovascular instability
 - Hepatosplenomegaly
 - Tache noire (French for black spot): The earliest finding in the spotted fever group, this lesion originates at the site of the infecting bite and may form eschar with regional lymphadenopathy related to the eschar. The lesion is usually found on the head in children and on the legs in adults; present in 30–90% of cases
- These 3 findings suggest illness caused by the typhus group:
 - Impaired level of consciousness
 - Pulmonary and renal involvement
 - Brill-Zinsser disease is actually a recrudescence of a previous infection with epidemic (louse-borne) typhus caused by *R. prowazekii*; can occur years after the initial infection and is usually less severe than the initial episode of louse-borne typhus.
- These 4 findings suggest illness caused by *C. burnetii*, the organism responsible for Q fever:
 - Pulmonary symptoms: Mild pneumonitis/cough; radiographically confirmed pneumonia in moderately ill patients; rapidly progressive pneumonia
 - Endocarditis
 - Hepatitis of varying severity
 - Nervous system findings range from headache to meningitis and encephalitis.
- These 5 findings suggest ehrlichiosis:
 - Acute febrile illness characterized by headache and myalgia
 - Rash in ~50%, spares palms, soles, and face
 - Cytopenia, particularly leukopenia

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Serologic testing is the standard for laboratory diagnosis of rickettsial disease because the organisms are obligate intracellular bacteria and do not grow in culture.
- Serologic tests are available for all rickettsial organisms. There is some cross-reactivity among similar organisms.
- Serologic testing is often negative at the start of illness and requires a convalescent (paired) sample done 2–3 weeks later for comparison. If the convalescent titer is 4-fold or greater than the acute, it is considered positive.
- Polymerase chain reaction (PCR) tests are rarely done in clinical labs and have significant inaccuracy given the similarities in genomes of these organisms.
- The Weil-Felix agglutination test has poor sensitivity and specificity and is not used in the U.S.
- Nonspecific general lab tests may help to make the diagnosis; for example, patients with RMSF often have hyponatremia and thrombocytopenia and may have features of disseminated intravascular coagulation (DIC). Patients with ehrlichiosis often have leukopenia.

DIFFERENTIAL DIAGNOSIS

- Before rash appears, constitutional symptoms associated with the spotted fevers result in a broad differential diagnosis. After rash appears, the diagnoses are more limited.
- Infectious: Measles, meningococemia, secondary syphilis, Coxsackievirus (e.g., hand-foot-and-mouth disease), infectious mononucleosis, enteroviral infection.
- Environmental (poisons): Drug hypersensitivity reaction (i.e., toxicodermatitis)
- Tumors: Leukemia with thrombocytopenia
- Immunologic: Idiopathic thrombocytopenia purpura
- Miscellaneous: Leukocytoclastic angitis, erythema multiforme/Steven-Johnson syndrome

TREATMENT

MEDICATION (DRUGS)

- The 1st-line antibiotic treatment for all rickettsial diseases is doxycycline. Recommended dosage depends on the specific rickettsial infection being treated.
- Therapy is most effective if instituted within the 1st week of illness.
- Antibiotics should be given for 7 days. If the patient is still febrile at that point, antibiotics should be continued until several days after defervescence.

- Studies have shown that there is little risk of tooth staining in children <8 years old who receive <3 courses of doxycycline. In the case of rickettsial disease, the benefit of giving doxycycline far outweighs the risk of side effects.
- Macrolides, trimethoprim–sulfamethoxazole, and the fluoroquinolones have been used with variable success against rickettsial infections but should not be given as 1st-line therapy.

IN-PATIENT CONSIDERATIONS

Initial Stabilization

- Fluid resuscitation, respiratory support as indicated
- Antimicrobial therapy should be instituted as soon as the diagnosis is suspected and should not be delayed while awaiting serologic confirmation.
- Patients may require blood product transfusion in the case of consumptive coagulopathy or severe thrombocytopenia.

ONGOING CARE

PROGNOSIS

Improvement in the patient’s clinical status usually takes place within 1–2 weeks after therapy starts, depending on the severity of illness. This improvement may also be delayed if treatment is begun after the 1st week of illness.

COMPLICATIONS

- Venous thrombosis
- Disseminated intravascular coagulopathy
- Cardiac injury including endocarditis
- Severe disease is more common in patients with G6PD deficiency, cardiac insufficiency, or immunodeficiency.

CODES

ICD9

- 083.0 Q fever
- 083.8 Other specified rickettsioses
- 083.9 Rickettsiosis, unspecified

ICD10

- A77.0 Spotted fever due to *Rickettsia rickettsii*
- A79.89 Other specified rickettsioses
- A79.9 Rickettsiosis, unspecified

FAQ

- Q: Should my child receive antibiotics if he is bitten by a tick in an area endemic to rickettsial disease?
- A: There is no role for prophylaxis against rickettsial diseases for patients who have suffered tick bites.
- Q: Are there differences between typhoid and typhus?
- A: Typhoid, or typhoid fever, is a separate entity from typhus. Typhoid is an enteric infection caused by *Salmonella typhi* and is unrelated to the rickettsial diseases.
- Q: If I contract a rickettsial illness, can I get that illness or a similar illness again?
- A: With the exception of scrub typhus and diseases involving *Ehrlichia*, infection with a rickettsial organism confers immunity to other rickettsia within the same group.

ROCKY MOUNTAIN SPOTTED FEVER

Carolyn A. Paris

Jennifer R. Reid

George A. Woodward

BASICS

DESCRIPTION

- Life-threatening systemic illness (i.e., small vessel vasculitis) caused by infection with *Rickettsia rickettsii*, an obligate intracellular gram-negative bacterium, transmitted by *Ixodidae* tick
- Member of spotted fever subgroup of rickettsial diseases
- Seasonal endemic disease, but may occur in other areas and throughout the year
- Classic symptoms of fever, headache, rash following tick exposure are often not present

EPIDEMIOLOGY

- Most common rickettsial disease in the U.S.
- Seasonal: April–September accounts for 90% of cases
- Geographic:
 - Restricted to countries of western hemisphere
 - Cases reported from all states except Alaska, Hawaii, and Maine; occurs most often in southern Atlantic and south central regions. 1994–2003 >50% of cases in North Carolina, South Carolina, Tennessee, Oklahoma, Arkansas
 - Less often seen in Rocky Mountain states
 - Also occurs in Western Canada, Mexico, Central and South America
- Single isolated cases most common in U.S.; reported in clusters infrequently in U.S. (4.4% familial), more typical in certain endemic areas (e.g., Brazil)
- Up to 2/3 of patients <15 years

Incidence

- Annual incidence: 7 million cases per million people (2002–2007)
- More common and specific pediatric population
- 250–1,200 cases reported per year; likely many unreported cases
- More often reported in American Indians, whites, males and children; incidence highest in 5–9 year olds
- Fatal outcome reported in 20% of untreated, and 5% of treated, cases
- Geographic variations in case fatality occur, likely due to different levels of pathogenicity, host factors and delayed recognition in less endemic regions
- 15% reported deaths in children <10 years

Prevalence

4–22% of children show significant antibody titers in endemic areas, likely representative of subclinical disease

RISK FACTORS

R. rickettsii-infected tick exposure or rural environment or occupation increasing forest exposure in endemic region

GENERAL PREVENTION

- Avoid tick-infested areas; limit skin exposure with long, light-colored clothing, tucked-in socks or boots, inspect frequently
- Use tick repellents or impregnated clothing.
- Remove ticks promptly
 - Do not crush; may increase transmission
 - Avoid direct contact; remove with tweezers or gloved fingers close to skin
 - Apply steady upward traction until tick's grip is released
 - Clean wound
 - Matches, petroleum jelly, nail polish, and rubbing alcohol are not effective for removal
- Vaccine not available in U.S.; may not prevent disease but does prevent deaths

PATHOPHYSIOLOGY

- Transmission usually occurs from tick bite (reservoir):
 - Usually >4 hours of attachment needed to transmit disease (often 24 hours)
 - Can be by transfusion or aerosol route
- Incubation period 2–14 days, average 7 days
- *R. rickettsia* spreads through the lymphatic system, causing a small-vessel vasculitis that affects all organs, especially skin and adrenals. Increased vascular permeability and focal areas of endothelial proliferation cause hyponatremia, hypoalbuminemia, edema, and hypotension
- Immunity is conferred following disease

ETIOLOGY

Wood tick (*Dermacentor andersoni*) in Rocky Mountain states and southwest Canada; dog tick (*Dermacentor variabilis*) in east central region and areas of Pacific coast; Lone Star tick (*Amblyomma americanum*) in Southwest; *Rhipicephalus sanguineus* in Southwest and Mexico; *Amblyomma cajennense* in Central and South America

COMMONLY ASSOCIATED CONDITIONS

- Patients with glucose-6-phosphate dehydrogenase (G6PD) deficiency account for a disproportionate number of deaths
- Serious biological weapon threat due to virulence causing severe disease, difficulty establishing diagnosis, low levels of immunity, agent available in nature, high infectivity, and feasibility of propagation, stabilization, and dispersal; thus development of a cross-protective vaccine against all *Rickettsia* is desirable for biodefense, as well as for travel medicine

DIAGNOSIS

HISTORY

- History: Classic triad of fever, headache, and rash seen in ~50% of cases
- Abdominal pain common mainly in children
- Symptoms usually appear 2–8 days after tick bite
- Gradual fever onset to >40°C (104°F), often unresponsive to antipyretics or antibiotics

- Headache: Intense, retrobulbar or frontal, persistent and difficult to treat; young children may not describe
- Cough, dyspnea
- Nausea, vomiting, abdominal pain, diarrhea
- Tick bite is reported by only 50–60% of cases

PHYSICAL EXAM

- Fever and rash present in 85% of patients
- Skin:
 - Rash: Usually appears by illness day 2–3, may be >6th day; 10–15% never develop rash so absence should not delay therapy
 - Usually small, irregular, erythematous blanching macules, become maculopapular then petechial and confluent hemorrhagic
 - Usually on wrists and ankles first, spreads within hours to trunk, neck, and face; may involve palms, soles, and scrotum:
 - May appear first on trunk or diffusely; can progress to necrosis of ears, nose, scrotum, fingers, or toes
 - Difficult to detect in people with dark skin
- CNS: Meningismus, restlessness, irritability, apprehension, confusion, delirium, lethargy, stupor, coma, ataxia, opisthotonos, aphasia, papilledema, seizures, cortical blindness, central deafness, spastic paralysis, cranial nerve palsy
- Cardiac: CHF, myocarditis, arrhythmias, hypovolemic vascular collapse
- Pulmonary: Pneumonitis, dyspnea, pulmonary edema, hypoxemia, pleural effusions, alveolar infiltrates
- GI: Diarrhea, hepatomegaly, splenomegaly, anorexia, jaundice, mild pancreatitis
- Ocular: Conjunctivitis, venous engorgement, papilledema, cotton wool spots, retinal hemorrhages, retinal artery occlusion, uveitis
- Other: Edema, myalgias (especially calf or thigh), parotitis, orchitis, pharyngitis

DIAGNOSTIC TESTS & INTERPRETATION

Presumptive diagnosis based on signs, symptoms, exposure history, and epidemiologic considerations rather than laboratory aids

Lab

- Nonspecific:
 - CBC: Anemia (30%), thrombocytopenia (from consumptive coagulopathy); normal or low leukocytes days 4–5, subsequent leukocytosis associated with secondary bacterial disease; bandemia common
 - Electrolytes: Hyponatremia
 - Elevated BUN, creatinine, liver function tests, bilirubin, creatine kinase
 - Screen for disseminated intravascular coagulation (DIC), prolonged prothrombin time, decreased fibrinogen (consumption),
 - Arterial blood gases: Acidosis
 - Hypoalbuminemia
 - CSF: Usually clear (leukocyte count <10), may see pleocytosis in 1/3 and increased protein in 1/2 of patients

- Specific serologic tests:
 - Indirect immunofluorescence assay (IFA):
 - Best and most widely available method
 - 2 serum samples obtained weeks apart showing 4-fold increase in IgG and IgM anti-R. rickettsii antibody titers
 - Positive 6–10 days after onset of disease, sensitivity increases to 94% with convalescence serum sample from days 14 to 21 days; specificity 100%
 - PCR, immunohistochemical staining, and culture are best done on biopsy specimen (of rash site or at autopsy) due to low circulating organism levels
 - Routine hospital blood cultures will not detect; available only at specialty labs
 - Weil–Felix test: Oldest specific test, but nonspecific and insensitive so no longer recommended
 - No early specific laboratory tests; serologic data reliable by days 10–12 of illness; negative results do not exclude diagnosis
 - All test results normalize with early intervention

Imaging

Chest radiograph, ECG, and electrocardiogram recommended

DIFFERENTIAL DIAGNOSIS

Measles, meningococcemia, ehrlichiosis, typhoid fever, leptospirosis, rubella, scarlet fever, disseminated gonococcal disease, infectious mononucleosis, secondary syphilis, rheumatic fever, enteroviral infection, immune thrombocytic purpura, thrombotic thrombocytopenic purpura, immune complex vasculitis, drug hypersensitivity reaction, murine typhus, rickettsialpox, and recrudescent typhus

ALERT

Do not exclude diagnosis even if there is no history or evidence of tick bite and/or results of serologic tests are negative.

TREATMENT

MEDICATION (DRUGS)

Treatment should be initiated based on clinical and epidemiological information as laboratory confirmation may not be available during acute illness. All agents are rickettsiostatic (hinder replication), not rickettsicidal, so host can eradicate disease. Treat until there is evidence of clinical improvement and at least 3 days without fever, standard duration is 5–10 days of therapy

First Line

- Doxycycline (usual tetracycline antibiotic):
 - Adults: 100 mg q12h PO/IV
 - Children under 45 kg (100 lbs): 4 mg/kg/d divided b.i.d.
 - Also treats ehrlichiosis (similar presentation)
 - Side effects: Less likely to stain teeth than tetracycline; contraindicated for pregnancy

- Chloramphenicol (advised with pregnancy):
 - Adult: 50–100 mg/kg/d divided q6h (max 4 g/d)
 - Child > 1 month: 50–100 mg/kg/d IV divided q6h
 - Side effects: Peripheral neuropathy, aplastic anemia, “gray baby syndrome” with high dosage, possible association with leukemia, hemolytic anemia with G6PD
 - Not as effective as tetracyclines, or against ehrlichiosis

Second Line

- Quinolones (ciprofloxacin, pefloxacin), macrolide (clarithromycin) with in vitro effect, no clinical evidence of efficacy
- Corticosteroids:
 - May be helpful in severe cases, although no controlled studies published
 - Not advised for mild or moderately ill patients

ADDITIONAL TREATMENT

General Measures

- Treat empirically if clinical suspicion
- Platelets as indicated for thrombocytopenia
- Vitamin K (IM) for prolonged clotting time
- Manage hyponatremia with fluid restriction; avoid sodium supplements
- Albumin if indicated
- Report to state health department

IN-PATIENT CONSIDERATIONS

Initial Stabilization

Volume, electrolyte support as indicated

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Expect improvement in 24–36 hours and defervescence in 2–3 days with treatment, especially if initiated <5 days after onset of symptoms

PROGNOSIS

- Related to early recognition of disease and initiation of appropriate therapy
- Case fatality 2–4% if treated <6 days from onset of symptoms
- Case fatality 15–22.9% if treated >6 days from onset of symptoms:
 - Higher mortality if <4 years, G6PD deficiency, CNS involvement, renal failure, jaundice, cardiovascular collapse, hepatomegaly, thrombocytopenia, DIC, GI symptoms, inappropriate antibiotics, late rash, absence of headache, or male gender
 - Death usually between 8th–15th days (fulminant cases with death in 5–6 days)

COMPLICATIONS

- Uncommon with early appropriate treatment
- Neurologic sequelae:
 - Behavioral disturbances, learning disabilities (more common), emotional lability, hyperactivity, memory loss, seizures
- Dermatologic sequelae:
 - Gangrene of extremities, end organs, skin necrosis
 - Skin rash usually heals without sequelae.
- Hematologic sequelae: DIC

- GI sequelae:
 - Hepatic dysfunction
 - Hypoalbuminemia from hepatic dysfunction, protein loss from damaged vessels
- Cardiac sequelae: Can have persistent cardiac findings, CHF, cardiovascular collapse
- Metabolic sequelae: Hyponatremia from water shift to intracellular spaces, sodium loss in urine
- Renal sequelae: Acute tubular necrosis

CODES

ICD9
082.0 Spotted fevers

ICD10
A77.0 Spotted fever due to Rickettsia rickettsii

FAQ

- Q: In which patients should Rocky Mountain spotted fever be considered in the differential diagnosis?
- A: Anyone with a fever during the spring and summer who has been in an endemic area, regardless of presence of rash or history of tick bite. Nonspecific symptoms (e.g., GI, respiratory, rashes) may lead to misdiagnosis and thus delay therapy.
- Q: Should a child with a tick bite receive antibiotic prophylaxis when a tick is discovered?
- A: There is no evidence that prophylaxis is necessary or efficacious in preventing disease. To contract disease, one must be bitten by a tick that carries the disease (low risk), the tick must transmit the Rickettsia (low risk, usually requires >6 hours of attachment), and the Rickettsia must be pathogenic if inoculated (low risk).

ROSEOLA

Ross Newman
Jason Newland
Louis M. Bell (5th edition)

BASICS

DESCRIPTION

Roseola infantum is a common illness in preschool-aged children characterized by fever lasting 3–7 days followed by rapid defervescence and the appearance of a blanching maculopapular rash (usually on the 4th day of illness) lasting only 1–2 days.

- Incubation period is 5–15 days.
- No gender predilection

EPIDEMIOLOGY

- Roseola affects children from 3 months to 4 years. The peak age is 7–13 months.
- 90% of cases occur in the 1st 2 years of life.
- Roseola can occur throughout the year; outbreaks have occurred in all seasons of the year.

GENERAL PREVENTION

- The virus associated with roseola infantum is usually transmitted via respiratory secretions or the fecal–oral spread.
- Outbreaks in hospitals have been reported, and standard infection control precautions are recommended.

PATHOPHYSIOLOGY

- Unknown
- The typical pattern of rash that appears as the fever disappears may represent virus neutralization in the skin.

ETIOLOGY

- Roseola-like illnesses have been associated with a number of different viruses including enterovirus (coxsackievirus A and B, echoviruses), adenoviruses (types 1, 2, 3), parainfluenza virus, and measles vaccine virus.
- A major cause of roseola is human herpesvirus 6 and 7 (HHV-6 and HHV-7).
- HHV-6 was 1st associated with roseola infantum in 1988.
- HHV-6 and HHV-7 account for 20–40% of unexplained febrile illness in emergency department visits by febrile infants 6 months to 2 years of age.
- Almost all children will acquire a primary infection and be seropositive for HHV6 by the age of 4 years.
- ~30% of children infected with HHV6 will present with the classic manifestations of roseola.

DIAGNOSIS

HISTORY

- Affected children do not look sick.
- Rash
- Fever, typically $>39.5^{\circ}\text{C}$
- Mild cough
- Acute rhinitis
- Lymphadenopathy
- Eyelid edema
- Bulging fontanelle can occur occasionally

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Not helpful in diagnosis. PCR tests are available for detecting HHV-6 and HHV-7.
- CBC: Occasionally, leukopenia with lymphocytosis is noted. Thrombocytopenia is likely secondary to viral bone marrow suppression.

DIFFERENTIAL DIAGNOSIS

- Roseola has a distinctive presentation, but does resemble other viral exanthems.
- Antibiotic-associated rash in a child taking oral antibiotics when rash develops after defervescence
- Rubella and enteroviral infections
- Viral exanthems in preschool-aged children are sometimes called roseola even when fever is concomitant with rash.

ONGOING CARE

PROGNOSIS

Most children with roseola infantum recover without sequelae.

COMPLICATIONS

- Seizures are the most common complication of roseola; between 10–15% of children have a generalized tonic–clonic seizure associated with fever.
- Aseptic meningitis with <200 cells, primarily mononuclear cells, have been reported.
- Encephalitis
- Thrombocytopenic purpura

- B08.21 Exanthema subitum [sixth disease] due to human herpesvirus 6
- B08.22 Exanthema subitum [sixth disease] due to human herpesvirus 7

FAQ

- Q: When can a child with roseola return to daycare?
- A: As soon as fever subsides; there is no infectious risk of spread afterward. The child may return to daycare even with the rash visible.
- Q: Will there be long-term sequelae in the child who has a seizure associated with roseola?
- A: In general, these seizures are typical febrile seizures that hold only a slightly higher risk than the general population for long-term neurologic sequelae (e.g., epilepsy).

ROTAVIRUS

Sheila M. Nolan
Suzanne Dawid (5th edition)

BASICS

DESCRIPTION

Infection with rotavirus causes high fever, profuse nonbloody diarrhea, and vomiting lasting 3–8 days. It is the most common cause of severe gastroenteritis in children in both the developed and developing worlds. All children have serologic evidence of infection by 5 years of age.

EPIDEMIOLOGY

- Rotavirus is the most common cause of severe gastroenteritis throughout the world.
- Rotavirus has a predictable seasonality depending on location:
 - In North America, peaks occur in the early winter in the west, moving northward and eastward.
 - In the northeastern U.S. and Canada, the highest incidence of disease occurs in late winter and early spring.
 - In tropical regions, disease occurs throughout the year.
- Majority of severe disease occurs in children 6–24 months old.
- All children have serologic evidence of disease by the age of 5 years.
- Incubation period is 12 hours to 4 days.
- Exposure to as few as 200 viral particles can result in disease. The virus can persist on surfaces for prolonged periods of time.
- Virus can be shed asymptotically, but shedding may precede disease by 2 days and typically persists for 10 days.

Incidence

- Infection accounts for 20–50% of pediatric hospitalizations for gastroenteritis.
- Causes >500,000 deaths per year in developing countries
- In the U.S., in the pre-vaccine era, rotavirus infection caused at least 50,000 hospitalizations per year and 20–40 deaths per year.

GENERAL PREVENTION

- Reduction of person-to-person transmission by proper hygiene, especially in child care settings.
- 2 vaccines are currently available in the U.S.:
- A live, oral human/bovine reassortant pentavalent vaccine (RotaTeq) was licensed for use in infants in 2006. Vaccination is indicated at 2, 4, and 6 months of age
- A live, attenuated human rotavirus vaccine (Rotarix) was licensed in the U.S. in 2008:
 - Numerous studies have demonstrated significant reductions in rotavirus gastroenteritis (both inpatient and outpatient) in areas where these vaccines have been introduced.
 - A recent study from Mexico demonstrated a 35% reduction in diarrhea-related deaths in children <5 years of age for the 2008 and 2009 rotavirus seasons after the introduction of rotavirus vaccine in 2006.
 - Small studies on hospitalized patients have suggested that the prophylactic use of probiotics may decrease the incidence of nosocomially acquired rotavirus infection.

PATHOPHYSIOLOGY

The cause of diarrhea is unknown but is believed to be a result of multiple disruptions in the normal mechanisms of water reabsorption in the gut:

- Peptides encoded in the viral genome disrupt the transport of glucose and salt, resulting in increased water within the gut.
- Decreased levels of intestinal disaccharidases, including lactase, result in malabsorption of sugars.
- Viral replication within enterocytes results in atrophy and ischemia of small intestinal villi.
- Infection with rotavirus results in activation of the enteric nervous system, resulting in abnormal stimulation of water secretion into the GI tract.

DIAGNOSIS

HISTORY

- Presents with high fever and vomiting, with as many as 20 watery stools a day
- Diarrhea may test heme positive, but is not grossly bloody.
- Up to 10% of children present with vomiting and/or fever without diarrhea.
- 50% of parents of infected infants are also infected; however, only 1/3 of these are symptomatic.

PHYSICAL EXAM

Consistent with dehydration

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Rotavirus ELISA for the presence of viral protein in the stool is highly sensitive and specific.
- PCR is also used in some clinical laboratories.
- Stool tends to be negative for leukocytes; however, this testing is rarely useful.
- Testing for malabsorption via stool assays for reducing substances or by D-xylose absorption assays is often positive.
- 67% of hospitalized children have mild elevations in their transaminases.

DIFFERENTIAL DIAGNOSIS

- Viral infections:
 - Adenovirus
 - Astrovirus
 - Caliciviruses (Norovirus and Sapovirus)
- Bacterial infections:
 - *Salmonella*
 - *Shigella*
 - *Campylobacter*
 - *Escherichia coli*
 - *Yersinia*
 - *Vibrio*
 - *Plesiomonas*
 - *Aeromonas*
 - *Clostridium difficile*
- Parasitic infections:
 - *Giardia*
 - *Cyclospora*
 - *Isospora*
 - *Cryptosporidium*

TREATMENT

IN-PATIENT CONSIDERATIONS

Initial Stabilization

- Supportive care with either oral or IV rehydration, depending on disease severity
- Limited studies have suggested that the addition of lactobacillus early in infection may decrease the duration of symptoms.

ONGOING CARE

COMPLICATIONS

- Disease is typically self-resolving; however, 20% of 1st-time infections are moderate to severe and require medical attention. Severe dehydration may occur, resulting in acidosis and electrolyte disruptions.
- Diarrhea may be more severe and protracted in immunocompromised hosts.

CODES

ICD9

- 008.61 Enteritis due to rotavirus
- 008.69 Enteritis due to other viral enteritis
- 079.0 Adenovirus infection in conditions classified elsewhere and of unspecified site

ICD10

- A08.0 Rotaviral enteritis
- A08.2 Adenoviral enteritis
- A08.32 Astrovirus enteritis

FAQ

- Q: When should children with rotavirus infection resume feeding?
- A: Feeding early in the course of disease promotes intestinal healing and should be instituted within 24 hours of illness. Infants should be given breast milk or diluted or regular-strength formula. Children should be given lactose-free carbohydrate-rich foods. Juices and sodas should be avoided because of their high sugar content.
- Q: Are antiemetics or antidiarrheal agents useful in the treatment of children with rotavirus infection?
- A: No. There have been no studies demonstrating efficacy of these medications in children.
- Q: Is natural infection protective against subsequent infections?
- A: Somewhat. The 1st episode of rotavirus infection tends to be the most severe; however, reinfection may occur, although it is often asymptomatic.

SALICYLATE POISONING (ASPIRIN)

Kevin C. Osterhoudt

BASICS

DESCRIPTION

- May occur with acute or chronic overdosage of:
 - Acetylsalicylic acid (aspirin)
 - Methyl salicylate (oil of wintergreen)
 - Bismuth subsalicylate (Pepto Bismol)
 - Salicylic acid (a keratolytic)
- The potentially toxic acute oral dose of acetylsalicylic acid is > 150 mg/kg.

EPIDEMIOLOGY

- Analgesics are the most common drugs implicated in human exposures reported to US poison control centers.
- Salicylate preparations constitute ~9% of all analgesic poisoning exposures reported to poison control centers.

PATHOPHYSIOLOGY

- Ingested drug is absorbed in stomach and proximal intestine.
- With therapeutic aspirin dosing, serum levels peak in 1–2 hours (standard preparations) or 4–6 hours (enteric coated).
- After oral overdose, absorption may be prolonged and erratic.
- Acetylsalicylate ingestion may produce gastritis and may trigger centrally mediated vomiting.
- After overdose, the elimination half-life of salicylate becomes prolonged.
- As blood pH falls, the proportion of nonionized salicylate rises, and more salicylate shifts into tissues, including brain.
- Toxic salicylate exposures uncouple mitochondrial oxidative phosphorylation and increase oxygen consumption.
- Direct stimulation of the medullary respiratory center leads to hyperventilation and respiratory alkalosis.
- Multiple metabolic derangements produce a wide anion gap metabolic acidosis.
- Dehydration and electrolyte shifts are common.
- Low cerebral glucose concentrations may exist despite normal serum glucose concentrations.
- Pulmonary and/or cerebral edema may occur.

COMMONLY ASSOCIATED CONDITIONS

- Aspirin is often marketed in combination with other pharmaceuticals, which may complicate drug overdose situations.
- Adolescents frequently overdose on more than 1 drug preparation.
- Therapeutic use of acetylsalicylic acid among children with influenza has been associated with the occurrence of Reye syndrome.

DIAGNOSIS

HISTORY

- Aspirin poisoning mimics many illnesses, and chronic overdosage often results in delayed diagnosis.
- Enteric coating may lead to significantly delayed drug absorption.
- Timing of ingestion allows for proper consideration of the risks versus benefits of gastrointestinal decontamination.
- Tinnitus frequently associated with serum salicylate levels > 25 mg/dL

PHYSICAL EXAM

- Hyperpnea indicates primary central hyperventilation and/or compensation for metabolic acidosis.
- Hyperpyrexia: Presence of “fever” may confuse salicylism with infection.
- Hypoxia: Pulmonary edema complicates therapy of aspirin overdose.
- Hypotension indicates severe dehydration, likely complicated by metabolic acidosis and salicylate-mediated myocardial inefficiency.
- Encephalopathy: CNS depression or seizures represent grave toxicity.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Serum electrolytes: A wide anion gap metabolic acidosis is common, and hypoglycemia or hyperglycemia may occur.
- Arterial blood gas: May show mixed respiratory alkalosis/metabolic acidosis
- Salicylate level: Serum salicylate levels > 60–100 mg/dL (acute) or 30–40 mg/dL (chronic) portend serious toxicity.
- Urine pH: Allows monitoring of adequacy of urinary alkalinization
- Acetaminophen level: Acetaminophen may be a coingestant.
- Ferric chloride test: A few drops of 10% ferric chloride will turn brown or purple in 1 mL of urine that contains salicylate.

ALERT

- Respiratory acidosis suggests central nervous system depression and is an ominous sign.
- Salicylate levels after chronic or acute-on-chronic overdose correlate poorly to clinical condition.
- Serial salicylate levels may be necessary to rule out ongoing drug absorption.

DIFFERENTIAL DIAGNOSIS

- Gastroenteritis
- Pneumonia
- Metabolic disease
- Ketoacidosis
- Sepsis
- Meningitis/encephalitis

TREATMENT

ADDITIONAL TREATMENT

General Measures

- Fluids/alkalinization:
 - Intravascular volume should be repleted with intermittent boluses of 10–20 mL/kg of isotonic crystalloid.
 - Altered mentation may imply CNS hypoglycemia and should be treated with dextrose.
 - Acidemia should be treated with sodium bicarbonate to limit salicylate distribution to the brain. Serum pH of 7.5 is reasonable goal.
 - With significant poisoning, an IV infusion of 5% dextrose with 100–150 mEq/L of sodium bicarbonate and 20–40 mEq/L of potassium chloride should be initiated at 1.5–2 times maintenance requirements. Titrate fluid volume to produce urine output of 2–3 mL/kg/h. Titrate alkalinization to produce urine pH between 7.5 and 8, which greatly increases the urinary elimination of salicylate via “ion-trapping” effect.
- Hemodialysis indications:
 - Acute serum salicylate level >100 mg/dL
 - Chronic serum salicylate level >60 mg/dL
 - Severe acidosis or severe electrolyte disturbance
 - Renal failure
 - Persistent neurologic dysfunction
 - Progressive clinical deterioration

ALERT

- Hypokalemia may interfere with the ability to achieve urinary alkalinization.
- Sedating a salicylate-poisoned patient may lead to respiratory depression and clinical deterioration.
- Endotracheal intubation is dangerous and, if performed, must be accompanied by sodium bicarbonate intravenous bolus and hyperventilation to prevent worsening acidemia and salicylate distribution to the brain.
- Hemodialysis equipment must be carefully primed to prevent worsening hypovolemia and cardiovascular collapse.
- If hemodialysis is performed, adjust dialysate to maintain alkalemia.
- Pulmonary edema and/or cerebral edema may complicate fluid management.

IN-PATIENT CONSIDERATIONS

Initial Stabilization

GI decontamination:

- Activated charcoal 1 g/kg (maximum 75 g) may be administered if aspirin is judged to be present in the stomach or proximal intestine.
- Many authorities suggest a 2nd charcoal dose 2–4 hours after the 1st, or if salicylate levels continue to rise.
- Whole-bowel irrigation may reduce drug absorption after large overdoses.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Drug administration education should be offered to victims of chronic overdose.
- Mental health services should be provided to victims of intentional overdose.

PROGNOSIS

- Chronic therapeutic misuse often leads to delayed diagnosis and has the most serious prognosis.
- Single acute ingestion of >300 mg/kg acetylsalicylic acid should be considered life threatening.

COMPLICATIONS

- Nausea and vomiting
- Dehydration
- Metabolic acidosis
- Electrolyte abnormalities
- Disorientation, coma, seizures
- Noncardiogenic pulmonary edema
- Renal failure
- Cerebral edema and death

CODES

ICD9

- 965.1 Poisoning by salicylates

ICD10

- T39.014A Poisoning by aspirin, undetermined, initial encounter
- T39.014D Poisoning by aspirin, undetermined, subsequent encounter
- T39.014S Poisoning by aspirin, undetermined, sequela

FAQ

- Q: What amount of the candy-scented oil of wintergreen is toxic to a toddler?
- A: Oil of wintergreen may contain as much as 98% methyl salicylate. 1 mL of methyl salicylate is the equivalent of 1,400 mg of aspirin. Therefore, 1 teaspoon of oil of wintergreen represents a very serious “aspirin” overdose.
- Q: Is there a prognostic nomogram for aspirin poisoning similar to that used for acetaminophen overdose?
- A: The Done nomogram is applicable only to ingestion of non-enteric-coated aspirin by children with normal mentation and normal blood pH, and the validity of its prognostication is suspect. Its use is not widely recommended.

SALMONELLA INFECTIONS

Edmund A. Milder
Suzanne Dawid (5th edition)

BASICS

DESCRIPTION

Salmonella has a wide range of clinical manifestations from asymptomatic infection to a life-threatening febrile illness.

EPIDEMIOLOGY

- Reservoirs:
 - *Salmonella* species other than *S. typhi*: Animals and animal products (mammals, birds, reptiles, and insects); contaminated food and water; infected humans (fecal shedding may persist for several months)
 - Humans are the only natural reservoir for *S. typhi*: Most commonly transmitted via fecally contaminated food and water; may be transmitted congenitally; chronic carriers may shed *S. typhi* in stool for years.
- Incubation period:
 - *Salmonella* gastroenteritis; symptoms typically begin within 24 hours (12–48 hours).
 - Incubation period of *S. typhi* is 1–3 weeks.
- Age distribution: Children <5 years are most commonly infected with nontyphoidal *Salmonella*; *S. typhi* is most common in 5–25-year-olds.

GENERAL PREVENTION

Personal hygiene (especially hand hygiene) and sanitation measures are the primary means by which to prevent *Salmonella* infections.

- Carriers of *Salmonella* pose a public health risk:
 - Hospitalized patients: Contact precautions for length of illness
 - Outpatients: Should be restricted from preparing food for others, and diapered patients should not attend daycare settings until cleared by public health.
- 3 vaccines against *S. typhi* are licensed for use in persons living in high-risk environments, including those residing with a chronic carrier or living in an endemic area:
 - The Ty21a vaccine is a live attenuated strain that is given orally in 4 doses on alternating days. It is approved only for children >6 years.
 - Typhoid vaccine is a parenteral heat-phenol-inactivated vaccine.
 - The Vi capsular polysaccharide vaccine is a parenteral vaccine that is licensed for children >2 years.
- All vaccines require booster dosing.

ETIOLOGY

3 species are responsible for most human salmonellosis: *S. enteritidis* (>2,000 serotypes exist), *S. choleraesuis*, and *S. typhi*.

COMMONLY ASSOCIATED CONDITIONS

- Acute asymptomatic infection:
 - No clinical signs or symptoms become apparent.
 - Probably most common *Salmonella* syndrome
 - Patients can be identified only by recovery of organisms in stool.

- Acute gastroenteritis:
 - Salmonellosis is the most common type of infectious food poisoning in the US.
 - Symptoms begin 12–48 hours after *Salmonella* ingestion.
 - Predominant manifestations are nausea, vomiting, cramps (often severe), abdominal pain, and diarrhea (rarely, gross blood may be found).
 - Other common features are malaise, myalgia, headache, and fever.
 - Symptoms usually resolve spontaneously in 2–7 days.
- Bacteremia:
 - *Salmonella* organisms may produce acute or intermittent bacteremia.
 - Symptoms: Fever/chills, diaphoresis, myalgia, anorexia
 - Bacteremia may occur before clinical gastroenteritis, and, in infants, may present as a persistent bacteremic state with failure to thrive.
 - Up to 1/20 patients with *Salmonella* gastroenteritis may develop bacteremia (perhaps as high as 1/4 in infants).
 - ~10% of patients with bacteremia will develop focal infections (e.g., osteomyelitis, meningitis).
- Enteric fever (typhoid fever, paratyphoid fever):
 - Caused by *S. typhi* and several other *Salmonella* serotypes
 - Incubation period is 1–3 weeks.
 - Insidious onset of symptoms over 2–7 days: Fever as high as 41°C, malaise, anorexia, abdominal pain, constipation, or diarrhea
 - Additional symptoms and signs: Lethargy, myalgia, headache, cough, rigors, delirium, lymphadenopathy, organomegaly, rose spots
 - Progression of illness: When untreated, illness with high fevers may last weeks; severe morbidity or death may result from especially virulent *Salmonella* strains.
- Asymptomatic chronic carriage: ~1% of patients infected with *Salmonella* gastroenteritis or enteric fever will continue to shed *Salmonella* in the stool for >1 year.

DIAGNOSIS

HISTORY

- Exposure:
 - History of eating raw or undercooked meat or eggs
 - Exposure to pet lizard, turtle, or snake. Less common outbreaks have been tied to exposure to infected pet rodents (hamsters, mice, and rats).
- Common historical features of *Salmonella* gastroenteritis:
 - Nausea and vomiting begin 12–48 hours after ingestion.
 - Diarrhea and abdominal pain with tenesmus follow; pain is typically periumbilical and in the right lower quadrant.
 - Diarrhea lasts 2–7 days.
 - Fever seldom exceeds 39°C; occurs in 50% of affected patients.

- Common historical features of enteric fever:
 - Symptoms begin 3–60 days after exposure.
 - Commonly acquired during foreign travel
 - Diarrhea uncommon early in course
 - Fever ensues, which gradually increases in magnitude.
 - Malaise, anorexia, myalgia, headache, abdominal pain, and vomiting may occur.

PHYSICAL EXAM

- *Salmonella* GI disease may display certain features:
 - Dehydration may be evident.
 - Abdominal pain may closely mimic appendicitis and/or cholecystitis.
 - Stools may be bloody, watery, or contain mucus.
- Important signs of enteric fever:
 - Enlarged liver and spleen
 - Relative bradycardia for height of fever
 - Rose spots: 2–4 mm in diameter; blanching pink papules; most commonly found on anterior thorax; 5–20 are generally apparent at a time; fade 3–4 days after appearance; characteristic of enteric fever, but not specific

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- There are several nonspecific laboratory aids to diagnosis:
 - Stool examination: May have hemocult-positive stools; stool may be positive for fecal leukocytes in enterocolitis.
 - CBC with differential: Normal in simple gastroenteritis; neutropenia, thrombocytopenia, and mild anemia are common in enteric fever.
 - Serum chemistries: Metabolic acidosis and electrolyte abnormalities may occur with severe enteritis; a mild hepatitis is frequently found in enteric fever.
 - Stool and blood culture and identification of *Salmonella* organisms: The gold standard method for laboratory confirmation of infection
 - Bone marrow aspirate culture is positive in ~90% of patients with enteric fever, blood culture in 60%, and stool culture is often negative.
 - Urine culture: May be a source of *Salmonella* organisms in the young or elderly population and in those with enteric fever
 - Biopsy: Needle aspiration of purulent material may yield positive cultures; punch biopsy and culture of rose spots may confirm diagnosis of *S. typhi*.
 - False positives: Leukocytes in the stool are suggestive of colitis, but are more typical of *Campylobacter*, *Shigella*, or milk allergy.
- Pitfall: Enteric fever may precede enteritis symptoms and fecal shedding of bacteria.

DIFFERENTIAL DIAGNOSIS

- The following illnesses may mimic *Salmonella* gastroenteritis and/or enterocolitis:
 - Shigellosis: Severe abdominal pains often are present; associated with high fevers; ulcers of the GI lining are common; stools are often grossly bloody, with sheets of fecal leukocytes.
 - Staphylococcal food poisoning
 - Other bacterial infections of the GI tract

- Viral enteritis: Rotavirus, Norwalk virus, norovirus, and other viruses
- Parasitic infections
- Toxic ingestion
- Noninfectious systemic illnesses marked by inflammatory colitis
- Enteric fever from *Salmonella* infection may be confused with:
 - Other causes of invasive bacterial disease
 - Other causes of fever in a return traveler (e.g., malaria)
 - Other causes of prolonged fever (e.g., viral, *Bartonella*)
 - Spirochetal infection

TREATMENT

MEDICATION (DRUGS)

Various antibiotics may be used to treat *Salmonella* infection:

- *Salmonella* gastroenteritis at high risk of invasive disease: Increasing resistance to amoxicillin, ampicillin, and trimethoprim/sulfamethoxazole; parenteral third-generation cephalosporins or fluoroquinolones are preferred empirically.
- Invasive *Salmonella* disease: IV ampicillin for 2 weeks has been first-line therapy; chloramphenicol, a third-generation cephalosporin, or a quinolone may be used for resistant organisms; cefotaxime for treatment of meningitis; meningitis or osteomyelitis may require 4–6 weeks of parenteral antibiotic therapy.
- Some authorities treat chronic carriers of *S. typhi* who shed for > 1 year with high-dose parenteral ampicillin; high-dose oral amoxicillin (with or without probenecid) or ciprofloxacin; consider cholecystectomy for refractory cases.

IN-PATIENT CONSIDERATIONS

Initial Stabilization

- Acute asymptomatic infection: Should not be treated with antibiotics. Antibiotics do not have an impact on duration of diarrhea and may lengthen duration of carrier state and contagious shedding.
- Acute gastroenteritis (see “FAQ”):
 - Supportive care: Maintain intravascular volume, correct electrolyte abnormalities
 - Do not administer antidiarrheal agents; they prolong GI transit time.
 - Consider antibiotics in individuals at high risk of subsequent systemic invasive illness: Children < 3 months, immunocompromised hosts, patients with hemoglobinopathies or chronic GI tract disease
- Bacteremia, enteric fever, and/or chronic carrier state:
 - Supportive care
 - Antibiotics are indicated; initial therapy usually to be administered intravenously.
 - Surgical drainage of local suppuration is indicated as in most other infections.
 - Corticosteroids (3 mg/kg load, 1 mg/kg q6h) may be beneficial to critically ill patients with enteric fever exhibiting neurologic complications.
 - Antipyretics are controversial in enteric fever syndromes because they may cause precipitous declines in temperature and shock.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Acute GI illness:
 - Symptoms usually resolve spontaneously within 7 days.
 - Supportive care to prevent or treat dehydration may be required.
 - Young children and those with underlying disease processes may be at higher risk of complications.
- Enteric fever:
 - Untreated, this illness will have a prolonged course over weeks.
 - Life-threatening complications are most common during the 2nd or 3rd week of illness, often after a period of apparent clinical improvement.
 - Even with appropriate treatment, up to 20% of patients may suffer relapse which require retreatment with antibiotics.
- Chronic carriage:
 - 1% of patients with *Salmonella* infection will shed bacteria in the stool for > 1 year.
 - Chronic carriers should be identified because they pose a public health risk.

ALERT

- More people with *Salmonella* infestation are asymptomatic than are symptomatic.
- Antibiotic resistance is a growing problem.
- Even with appropriate therapy, patients may shed bacteria on a persistent basis or may suffer relapse.

PROGNOSIS

- Most normal hosts with *Salmonella* gastroenteritis will recover spontaneously.
- Some individuals will develop a chronic carrier state, persistently shedding bacteria in the stool.
- The relapse rate of enteric fever may approach 20% of patients, even when adequately treated.

COMPLICATIONS

- Dehydration and/or electrolyte imbalance is the most common complication arising from acute gastroenteritis.
- Invasive *Salmonella* may lead to complications of bacteremia:
 - Sepsis: Most common in neonates and immunosuppressed individuals
 - Meningitis: Vast majority of cases occur in 1st month of life.
 - Osteomyelitis: Most common in patients with sickle cell anemia
 - Other local infections: Pneumonia, pericarditis
- Complications of enteric fever include intestinal or splenic rupture (at areas of lymphoid hypertrophy), hepatitis, pancreatitis, parotitis, orchitis, arthritis, and myocarditis.
- A postinfectious form of hemolytic uremic syndrome may occur following *Salmonella* infection.

CODES

ICD9

- 003.0 *Salmonella* gastroenteritis
- 003.9 *Salmonella* infection, unspecified
- 558.9 Other and unspecified noninfectious gastroenteritis and colitis

ICD10

- A02.0 *Salmonella* enteritis
- A02.9 *Salmonella* infection, unspecified
- K52.9 Noninfective gastroenteritis and colitis, unspecified

FAQ

- Q: Should all infants with *Salmonella* gastroenteritis be treated with antibiotics?
- A: Clinicians caring for children < 1 year with proven, or suspected, *Salmonella* infection face many treatment dilemmas. Any toxic-appearing infant and any infant with proven *Salmonella* bacteremia should be admitted to the hospital for parenteral antibiotics. High-risk infants (< 3 months of age) with positive stool cultures should be treated with antibiotics after blood cultures are obtained. Well-appearing infants > 3 months of age with *Salmonella* enterocolitis and fever should be observed off antibiotics after surveillance blood cultures are obtained.

SARCOIDOSIS

Peter Weiser

Randy Q. Cron

Frank Pessler (5th edition)

BASICS

DESCRIPTION

A multisystem chronic granulomatous disease that has 2 distinct variations often differentiated by age of onset

EPIDEMIOLOGY

More common in the southeastern part of the US. Disease occurs before age 4 years as arthritis, uveitis, and dermatitis, and in adolescence as Löfgren syndrome with erythema nodosum, polyarthritis, and hilar adenopathy. Adult-type disease with marked pulmonary involvement may also occur in older adolescents. CNS involvement (rare): Seizures, cranial neuropathy, hypothalamic dysfunction.

RISK FACTORS

Genetics

- Blacks are more commonly affected than whites; specific genetic tendencies not identified.
- Early childhood cases of arthritis, uveitis, and dermatitis may result from mutation of the CARD15/NOD2 gene—either spontaneous or hereditary—familial form, the latter also known as Blau syndrome (AD). Some of the mutation-negative patients have systemic/visceral involvement.

PATHOPHYSIOLOGY

T-cell-mediated disease resulting in noncaseating epithelioid giant cell granulomas in affected organs

ETIOLOGY

Unknown (possibly infectious); resembles pulmonary borreliosis; possible association with substantial dust inhalation (e.g., collapse of World Trade Center towers in New York).

DIAGNOSIS

HISTORY

Prolonged malaise, fever, weight loss, rash, painful arthritis, swollen lymph nodes, chronic cough, and hematuria (can be microscopic) may be initial complaints.

PHYSICAL EXAM

- Peripheral lymphadenopathy is most common manifestation.
- Conjunctival injection
- Bilateral parotid gland enlargement and hepatosplenomegaly may be present.
- The arthritis, usually in the ankles, is extremely tender and boggy.
- Rash is diffuse, erythematous, and macular or plaque-like. Can also be erythema nodosum.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- CBC:
 - Mild anemia, leukopenia, lymphopenia
- ESR elevated
- ACE level elevation:
 - Produced in most granulomatous diseases, but is useful in cases in which index of suspicion is high
- Lysozyme level elevation:
 - May be more sensitive than ACE level for detecting sarcoidosis
- Serum calcium and creatinine levels:
 - Important in baseline evaluation
- Urine test for blood:
 - Seen in patients with hypercalciuria
- Synovial effusion are typically mildly inflammatory.
- Biopsy of affected organ, such as peripheral lymph node, parotid gland, skin, conjunctivae, or minor salivary gland or synovium (demonstrating noncaseating granuloma), is helpful.

Imaging

- Chest radiography:
 - May demonstrate hilar adenopathy
- Gallium scan:
 - Demonstrates uptake diffusely in lungs (extremely sensitive test)
- False-positives:
 - ACE level: May be elevated in patients with miliary tuberculosis and biliary cirrhosis. Not a perfect screening test; however, can follow levels in response to treatment.
 - Lysozyme level: Also elevated in lymphoma. May be useful to follow disease activity in proven cases, if ACE levels cannot be used.

ALERT

Uveitis may be occult; ophthalmology evaluation is important.

DIFFERENTIAL DIAGNOSIS

- Infection:
 - Tuberculosis, bacterial sepsis, mumps, HIV, gonorrhea, Lyme disease, pulmonary mycoses
- Tumors:
 - Leukemia, neuroblastoma, lymphoma
- Immunologic: Sjogren disease
 - Oligoarticular juvenile idiopathic arthritis (for early-onset type), systemic juvenile idiopathic arthritis, systemic lupus erythematosus, dermatomyositis, Behçet disease, Crohn disease
 - Immunodeficiency: CVID
- Skin
 - Granuloma annulare; erythema nodosum due to streptococcus/hepatitis B

TREATMENT

Medical therapy during times of disease activity causing clinical symptoms

MEDICATION (DRUGS)

- Corticosteroids may provide rapid improvement; NSAIDs/analgesics have roles.

In cases of chronic disease:

- Immunosuppressive medications such as methotrexate can be used in addition to corticosteroids
- The tumor necrosis factor- α inhibitors, specifically antibodies, infliximab, and adalimumab, show promising preliminary results.
- In cases of hypercalciuria/hypercalcemia, consider hydration and furosemide.
- Cyclophosphamide for neurosarcoid

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Referral to rheumatologist indicated, also regular ophthalmologic assessment:
- Signs to watch for:
 - Climbing creatinine, shortness of breath, or persistent uveal tract inflammation, neurologic deficit
- Pitfalls:
 - Overtreating asymptomatic lymphadenopathy and not detecting hypercalciuria

PROGNOSIS

Variable in early onset. Severe organ involvement, joint and eye damage can occur—needs close follow-up. Löfgren syndrome can resolve after a couple of years. More than 40% of older children with adult-type disease have persistent pulmonary changes, but only a few will have pulmonary symptoms.

COMPLICATIONS

- In children, usually related to uveitis or from hypercalciuria resulting in renal injury. Lung, CNS, and ocular involvement can bring long-term defects.
- In older adolescents, pulmonary problems, such as restrictive lung disease, as well as severe growth delay, may occur.

ADDITIONAL READING

- Baumann RJ, Robertson WC Jr. Neurosarcoid presents differently in children than in adults. *Pediatrics*. 2003;112:e480–e486.

CODES

ICD9

- 135 Sarcoidosis
- 517.8 Lung involvement in other diseases classified elsewhere
- 695.2 Erythema nodosum

ICD10

- D86.0 Sarcoidosis of lung
- D86.9 Sarcoidosis, unspecified
- L52 Erythema nodosum

FAQ

- Q: Why is the outcome better in childhood sarcoid compared with adults with sarcoid?
- A: These may be 2 distinct granulomatous diseases. The 2 have clearly different patterns of organ involvement.

SCABIES

Kathleen Wholey Zsolway

Alyssa Siegel

BASICS

DESCRIPTION

- Results from infestation of stratum corneum by the human mite, *Sarcoptes scabiei* (subspecies *Hominis*, phylum Arthropoda, class Arachnida, and order Acarina)
- Animal scabies, or sarcoptic mange, occurs from contact with an infested canine and produces only a transient rash in humans.
- Crusted scabies, formerly known as Norwegian scabies, is a highly contagious variant of human scabies that occurs in institutional settings, developmentally disabled and immunocompromised patients, including those using long-term topical steroids and with HIV. It requires isolation measures and diligent use of medications for elimination.
- Post-scabetic syndrome consists of persistent pruritus caused by hypersensitivity to mite antigen and may persist for several days after live mite has been eliminated.

EPIDEMIOLOGY

- Affects all age groups, but particularly children
- Epidemics are reported to occur in 15-year cycles.
- Sole reservoir of *S. scabiei* is the human.
- Close, personal contact with an infested human (with or without clinical symptoms) is required for transmission.
- Mites can live isolated from the human body for 2–3 days; extent of fomite transmission is unclear.

Incidence

~300 million cases of scabies in the world annually

GENERAL PREVENTION

- Bedding, clothing, and items of close contact should be washed and dried in hot temperatures at time of treatment.
- All family members and close contacts, symptomatic and asymptomatic, should be treated concurrently to eliminate mite and prevent immediate reinfestation. Contacts may be infested without symptoms.

PATHOPHYSIOLOGY

- Female mite burrows into stratum corneum, rarely penetrating epidermis, for 15–30 days, traveling 2–4 mm/day and laying 1–3 eggs/day.
- Egg laying is completed in 4–5 weeks when female dies within a burrow.
 - Eggs, hatching within a burrow, will undergo several molts and emerge on skin surface as nymphs.
 - After a 2–3-week maturation period, mating will occur; male will die, and gravid female will restart cycle with burrowing.
- Following first exposure, signs and symptoms will develop 10–30 days after scabies infestation; perhaps time lag necessary for body to develop humoral or cellular hypersensitivity to mite and/or its byproducts or time necessary for adequate mass of mites to develop.
- Previously infested patients are immunologically sensitized, leading to development of symptoms 1–4 days after re-exposure.

ETIOLOGY

Etiologic agent is gravid female mite, *S. scabiei*, 0.2–0.4 mm in size.

DIAGNOSIS

HISTORY

- Pruritus: Intensity worse at night when mite activity increases secondary to increase in body temperature
- Evolution of rash:
 - Characteristically changes over time both in appearance and distribution
 - May consist of burrows, papules, and vesicular lesions
 - Recurrent clusters of vesicles and pustules can occur over time.
 - In older children, rash may involve webs of fingers, axillae, arms, wrists, waistline, and genitalia. In young children, may include palms, soles, head, neck, and face.
- Symptoms in other family members or close contacts: Close contact required for transmission

PHYSICAL EXAM

- Distribution of rash usually from neck down in infants; in children, neck and face may also be involved.
- Lesions typically more numerous on hands, especially web spaces, as well as thenar and hypothenar eminences in older children and adults
- Palms, proximal half of foot, and heel are sites of numerous lesions in infants.
- Lesions also seen on wrists, in axillae, around waistline, on gluteal cleft, and surrounding nipples and genitalia
- A burrow, the characteristic lesion of scabies, is present in 90–95% of all symptomatic patients, and forms a “lazy S” shape with a broad base and a punctate brown-black dot at leading edge of mite’s path. If burrows are not easily identified, washable felt-tip marker can be rubbed across web space, and after superficial ink is removed with alcohol or water, ink will have penetrated through stratum corneum outlining burrow.
- Secondary lesions are more numerous and obvious than burrows and may consist of crusted papules, small vesicles, pustules, excoriated broad areas of dermatitis, and areas of secondary infection from impetigo and folliculitis.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Skin scrapings may be obtained to secure definitive diagnosis.
 - The burrows most commonly found on hands and feet should be moistened with alcohol or mineral oil.
 - Scrape a no. 15, round-bellied blade attached to a scalpel handle briskly across burrows
 - Place scraped material on a slide with a drop of potassium hydroxide or mineral oil with a cover slip
 - Under a scanning microscope, presence of gravid female, eggs, larvae, and/or feces is diagnostic.
- New diagnostic methods include detection of *S. scabiei* DNA from cutaneous scales by PCR or ELISA.

DIFFERENTIAL DIAGNOSIS

- Infection:
 - Impetigo
 - Papular viral exanthem
- Environmental: Contact dermatitis
- Immunologic:
 - Atopic dermatitis
 - Papular urticaria
- Miscellaneous:
 - Drug eruption
 - Psoriasis
 - Infantile acropustulosis

**TREATMENT****MEDICATION (DRUGS)**

- 5% permethrin cream (Elimite 5%):
 - Drug of choice due to effectiveness and safety profile
 - Used for infants >2 months and children
 - Apply to entire body surface and leave on for 8–14 hours, then wash off. One application is usually effective, though some recommend a second application 1 week later.
- 1% lindane cream:
 - All members of the affected household should be treated at the same time.
 - Should remain on body for 8–12 hours
 - Effective for older children and nonpregnant women. No longer recommended for use in children due to potential absorption and toxicity.
- 10% crotamiton cream:
 - Not approved for use in children
 - Can be applied for 2 consecutive days followed by cleansing bath 48 hours after last application
 - Treatment failures have been reported.
- 6% sulfur in a petrolatum base:
 - May be used in older children and adults
 - Apply for 3 consecutive days

**ONGOING CARE****FOLLOW-UP RECOMMENDATIONS****Patient Monitoring**

- Pruritus may take up to 4 weeks to resolve after effective treatment. Use of mild-to-moderate topical steroid may improve this symptom.
- Continued appearance of new burrows may indicate ineffective treatment (most commonly misapplication) and warrants repeat evaluation by healthcare professional.

PROGNOSIS

Excellent outcome with topical therapy; resistant cases, necessitating referral to a dermatologist and consideration for oral therapy, have been increasing worldwide.

COMPLICATIONS

- Secondary infections, including impetigo and folliculitis
- Id eruption or auto-sensitization
- Pruritus

FAQ

- Q: How did my child get scabies?
- A: From close contact with an infected person
- Q: How long will my child continue to itch?
- A: Pruritus may continue for weeks; the use of topical hydrocortisone may be helpful.
- Q: Do I need to wash my child's bedding in a special detergent?
- A: Simply wash all bedding in hot, soapy water after your child has been treated.

SCARLET FEVER

Mark L. Bagarazzi

BASICS

DESCRIPTION

- A clinical syndrome consisting of fever, pharyngitis, cervical lymphadenitis, and the characteristic “sandpaper rash,” which results from infection with a strain of *Streptococcus pyogenes* (group A β -hemolytic streptococcus) that elaborates streptococcal pyrogenic toxin
- Toxins include A, B, and C. Toxin A is associated with more virulent disease.
- Similar syndrome may also be seen after infection with certain toxin-producing (enterotoxin G, I) strains of *Staphylococcus aureus*; known as staphylococcal scarlet fever.

GENERAL PREVENTION

- Prompt treatment leads to fewer secondary cases of streptococcal disease.
- Chemoprophylaxis with penicillin is recommended by some experts in children with repeated documented episodes occurring at short intervals.
- Control measures, including hygiene advice and exclusion of pupils for 24 hours while initiating penicillin treatment, were ineffective in a school outbreak.

EPIDEMIOLOGY

- No sex predilection
- Occurs uncommonly before the age of 3 years or after the age of 15 years, possibly related to the requirement for prior sensitization and toxin-specific immunity
- All forms of streptococcal pharyngitis (i.e., with or without pyrogenic toxin) are more common in temperate and cold climates and winter and spring months, with some areas reporting an increased incidence in the fall.
- Incubation period is usually 24–48 hours.

Incidence

Peak incidence during the first few school years

Prevalence

By age 10, 80% of children have developed toxin-specific antibodies.

PATHOPHYSIOLOGY

- Susceptible individuals thought to lack toxin-specific immunity. Supported by results of Dick test, in which a small amount of toxin introduced intradermally produces local erythema in susceptible individuals but no reaction in those with toxin-specific immunity.
- Rash and other toxic manifestations of scarlet fever have been attributed to the development of hypersensitivity to the toxin, which therefore would require prior exposure to the toxin.
- Toxin production depends on lysogeny of the infecting streptococcus by a temperate bacteriophage.

- Pharyngitis is characterized by mucosal erythema and frequently by small crypt abscesses with punctate exudate in enlarged tonsils.
- Edematous papillae protrude from coated mucosa to produce a strawberry tongue.
- Histologic examination of affected skin shows dilated blood and lymphatic vessels and engorged capillaries, most prominently around hair follicles.
- Acute, edematous polymorphonuclear inflammatory reaction is seen microscopically within affected tissues.
- Epidermal inflammatory reaction is usually followed by hyperkeratosis, which accounts for scaling during defervescence.

DIAGNOSIS

HISTORY

- Sudden onset of fever up to 40.5°C, sore throat, headache, nausea, vomiting, and toxicity are classic symptoms for group A streptococcal disease.
- Texture of rash (e.g., feels like sandpaper) is more important than appearance.
- Characteristic rash typically occurs 12–48 hours after onset of fever.
- Patient may complain of abdominal pain or muscle aches before onset of rash, as well as aching in extremities or back.
- There may be close contacts with streptococcal infection.

PHYSICAL EXAM

- Fine maculopapular (sandpaper texture) rash on erythematous background: usually begins on the trunk and spreads to involve almost the entire body within hours to days. Although the rash seen with scarlet fever is generally fine and sandpaperlike, larger papules and petechiae may be seen.
- Deep, red, nonblanching lesions in the antecubital and popliteal areas: “Pastia lines” develop in the skin folds of joints.
- Circumoral pallor: Classic finding
- Rash blanches with pressure and ultimately desquamates: Desquamation occurs within 7–21 days from onset of illness.
- Characteristic toxin-induced scarlet fever exanthem: may rarely be seen without pharyngitis in the setting of pyoderma or an infected wound (known as surgical scarlet fever).
- Systemic toxicity: May indicate incorrect diagnosis
- Dorsum of tongue: Has white coat early in illness with edematous red papillae. White covering desquamates and reveals swollen, red, and mottled strawberry tongue.
- Other findings:
 - Pharynx and tonsils are beefy red and may contain exudate.
 - Hemorrhagic spots on interior pillar of tonsils and soft palate
 - Large, tender anterior cervical nodes

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Rapid streptococcal antigen tests: effective as screening tests; 50–80% sensitivity and >95% specificity. Positive rapid tests do not require culture confirmation.
- Throat culture: The gold standard with best sensitivity (>90%) for group A β -hemolytic streptococci. A culture should be performed when rapid test is negative.
- White blood cell count: usually elevated, although may be elevated in viral pharyngitis as well. Low count would be rare with streptococcal infection.
- Eosinophilia (up to 30%): Common in the recovery phase
- Dick test: of historic interest; no longer used clinically
- Pitfalls:
 - A positive throat culture may be evidence only of carriage in some cases of acute pharyngitis that are actually viral (e.g., Epstein–Barr virus).
 - Milder disease is becoming more common and is easier to miss. Rash may involve only the bridge of the nose, face, shoulders, and upper chest. Circumoral pallor and severe exudative pharyngitis are being seen less frequently.

DIFFERENTIAL DIAGNOSIS

- Nonscarlatinal streptococcal pharyngitis/tonsillitis
- Viral exanthems (measles, rubella, erythema infectiosum)
- Drug eruptions
- Staphylococcal scalded skin syndrome
- Toxic epidermal necrolysis
- Toxic shock syndrome (streptococcal or staphylococcal)
- Kawasaki disease
- Uncommon entities:
 - Infection with *Corynebacterium hemolyticum*
 - Mercury poisoning (acrodyria)
 - Atropine intoxication
 - Boric acid poisoning
 - Rifampin overdose

TREATMENT

ADDITIONAL TREATMENT

Initial Stabilization

- Identical to therapy for streptococcal pharyngitis
- Therapy started as late as 9 days after illness onset should be effective in preventing acute rheumatic fever.
- May withhold treatment until throat culture result is available
- Immediate therapy probably shortens symptomatic period.

MEDICATION (DRUGS)

- Oral penicillin VK:
 - Drug of choice except in penicillin-allergic individuals
 - Resistant strains have not been documented in the US.
 - Dose: 25,000 to 50,000 units/kg (1,600 units = 1 mg) divided into 3–4 doses for 10 days
 - 400,000 units (250 mg) b.i.d. for children <27 kg (or 60 lbs) and 800,000 units (500 mg) twice daily for children ≥27 kg (60 lbs) for 10 days has also been shown to have comparable efficacy and is endorsed by the American Academy of Pediatrics.
- Intramuscular benzathine penicillin G:
 - Equally effective as oral penicillin
 - Dose: 600,000 units for children <27 kg (<60 lbs); 1,200,000 units in larger children and adults
 - Ensures compliance
 - Bringing to room temperature reduces discomfort.
 - Benzathine/procaine penicillin combinations are less painful.
- Clarithromycin and azithromycin have also been shown to eradicate streptococci; however, because of the broad spectra of these antibiotics and the increasing incidence of antibiotic-resistant bacteria, penicillin is still recommended by most experts, except in cases of penicillin hypersensitivity, when patient nonadherence to a 10-day penicillin regimen is suspected, or for patients who fail therapy with a β-lactam:
 - Azithromycin, total dose of 60 mg/kg, given either as 12 mg/kg once daily for 5 days or 20 mg/kg once daily for 3 days
 - Clarithromycin, 15 mg/kg/d, given b.i.d. for 10 days, or 500 mg extended-release tablets given once a day for 5 days (studied in adolescents ≥12 years)
 - There are reports of acute rheumatic fever after the 3-day course of azithromycin.
- Oral erythromycin is indicated in penicillin-allergic individuals. Erythromycin ethyl succinate (40 to 50 mg/kg/d in 2–4 divided doses). Resistance is rare in the US (<5% of isolates).
- Amoxicillin, clindamycin, and first-generation oral cephalosporins (up to 15% of penicillin-allergic persons are also allergic to cephalosporins) are reasonable alternatives to penicillin.
- Recent trials comparing 10-day course of penicillin with shorter duration of therapy with newer oral cephalosporins have shown similar bacteriologic and clinical cure rates, but efficacy in prevention of nonsuppurative sequelae is unknown.
- Cefdinir and cefpodoxime proxetil are approved for use in a more convenient 5-day dosing schedule.
- Tetracyclines and sulfonamides should not be used because of resistance of group A streptococci.
- Positive posttreatment cultures in asymptomatic patients: Retreatment is not recommended.

ONGOING CARE

- Fever and symptoms usually resolve within 24–48 hours of antibiotic treatment.
- Nonsuppurative complications occur after unrecognized disease and when treatment is delayed for >9 days. Acute rheumatic fever occurs an average of 18 days after untreated infection. Acute postinfectious glomerulonephritis occurs an average of 10 days after untreated infection. The risk of glomerulonephritis is not reduced by treatment with antibiotics.

PROGNOSIS

- Overall prognosis is excellent.
- Few patients suffer suppurative complications.
- Risk of developing acute rheumatic fever in untreated streptococcal infections is about 3% under epidemic conditions (0.3% in endemic situations).
- Risk of developing acute postinfectious glomerulonephritis depends on nephritogenicity of infecting strain. Attack rate is 10–15% with nephritogenic strains.

COMPLICATIONS

- Acute otitis media
- Sinusitis
- Suppurative cervical lymphadenitis
- Pneumonia with or without effusion/empyema
- Peritonsillar cellulitis/abscess
- Retropharyngeal abscess
- Meningitis
- Brain abscess
- Thrombosis of intracranial venous sinuses
- Osteomyelitis
- Hepatitis
- Arthritis
- Acute rheumatic fever
- Acute postinfectious glomerulonephritis
- Erythema nodosum, possibly

- 034.1 Scarlet fever

ICD10

- A38.9 Scarlet fever, uncomplicated
- J02.0 Streptococcal pharyngitis

FAQ

- Q: Should household contacts have throat cultures performed?
- A: Obtain cultures only from symptomatic household contacts. Cultures should not routinely be obtained in asymptomatic contacts.
- Q: Should posttreatment throat cultures be performed?
- A: Only in symptomatic individuals and patients at risk for acute rheumatic fever and acute postinfectious glomerulonephritis
- Q: Can scarlet fever recur?
- A: Yes, there have been documented reports of recurrent scarlet fever.
- Q: Have there been documented child care outbreaks of scarlet fever?
- A: Yes, outbreaks have been traced back to a single strain.
- Q: How soon can children return to school or child care?
- A: When they are afebrile, and after at least 24 hours of antibiotic therapy.
- Q: Is there any known association between scarlet fever or other group A streptococcal infections and neuropsychiatric disorders?
- A: Retrospective epidemiologic studies have shown that subjects with newly diagnosed obsessive compulsive disorder, attention deficit hyperactivity disorder, major depressive disorder, Tourette syndrome and other tic disorders were more likely to have had a diagnosis of streptococcal infection in the previous year.

SCLERODERMA

Peter Weiser
Randy Q. Cron

BASICS

DESCRIPTION

Scleroderma means “hard skin.” It can be systemic or localized.

- Systemic sclerosis (SSc) or progressive systemic sclerosis (PSS):
 - CREST: A variant form of systemic sclerosis, almost nonexistent in children
- Localized:
 - Morphea
 - Linear
 - En Coup de Sabre
 - Parry-Romberg syndrome

EPIDEMIOLOGY

- Systemic:
 - Age of onset: 30–50 years; very rare in children
 - Sex ratio: <7 years, Male = Female; >7 years, Female > Male (3:1); 15–44 years, Female > Male (15:1)
- CREST:
 - Earlier age of onset than systemic sclerosis
 - Female > Male

Incidence

- Systemic: 0.27 per million annually
- CREST: Affects ~1/2 of patients with systemic disease
- Localized: Approximately 10× more common than systemic sclerosis

PATHOPHYSIOLOGY

- Systemic involvement:
 - Vasculopathy: Based on high association with Raynaud phenomenon; vascular injury leading to fibrotic changes as a part of overcorrection
 - Serum factors: Endothelin
 - Immune dysfunction: Autoimmunity directed against connective-tissue antigen such as laminin or type IV collagen, PDGF receptor stimulating fibrosis
- Localized form:
 - Alteration of normal glycosylation and hydroxylation of collagen
 - May represent distinct early and late processes:
 - Early: Increased hydrophilic glycosaminoglycan; increased T cells, macrophages, and plasma cells; mast-cell hyperplasia
 - Late: Increased collagen content; collagen is embryonic with narrow fibrils and immature cross-banding; atrophy of rete pegs

DIAGNOSIS

HISTORY

- Thickening of skin
- Tightness of joints
- Discoloration of skin
- Often insidious onset
- Morning stiffness
- Heartburn, dysphagia, reflux, cough with swallowing

Signs and symptoms:

- Systemic sclerosis:
 - Diagnostic criteria (1 major criterion or 2 minor criteria required)
 - Major: Sclerodermatous changes (tightness, thickening, induration) proximal to metacarpophalangeal or metatarsophalangeal joints
 - Minor: Sclerodactyly-sclerodermatous changes limited to digits (unable to pinch skin over the digit), digital pitting, bibasilar pulmonary fibrosis not due to primary lung disease
 - CREST:
 - Calcinosis
 - Raynaud phenomenon
 - Esophageal dysmotility
 - Sclerodactyly
 - Telangiectases
 - Same characteristics as systemic sclerosis, but calcinosis is more severe
 - Distal symptoms are more severe.
 - Associated with anti-centromere antibody
- Localized:
 - Fibrosis limited to skin, SC tissue, and muscle; comes with loss of subcutaneous tissue pulp of the fingers
 - Systemic features:
 - Rare: Visceral involvement later in disease
 - Occasional: Evolution into another connective tissue disease such as mixed connective tissue disease or systemic lupus erythematosus (SLE)
 - Very rare: Raynaud phenomenon
 - Forms:
 - Morphea: ≥ 1 oval or round indurations that become hard and whitish early on, have active inflammatory border with violaceous color. Forms: Plaque or guttate; limited number of lesions; generalized: extensive; nodular: SC
 - Linear: ≥ 1 linear areas affecting subcutaneous tissue, muscle, and bone; can cross joint lines
 - En Coup de Sabre: Involves face or scalp; may be associated with seizures
 - Parry-Romberg syndrome: Form of linear scleroderma; congenital dysplasia of subcutaneous tissue; neurologic changes such as TIAs in the corresponding brain matter under the lesion without its direct extension into the skull

PHYSICAL EXAM

- Findings:
 - Skin:
 - Stage 1: Edema. Tense, non-pitting, perhaps warm or tender, but often asymptomatic
 - Stage 2: Sclerosis. Waxy, hard texture; bound to SC structures, back of digits, face (loss of forehead wrinkles, reduced mouth orifice)
 - Stage 3: Atrophy. Shiny appearance, hypopigmented or hyperpigmented, calcium deposits in SC tissue. Telangiectases: Macular dilatations that fill slowly, unlike spider telangiectasias
 - Ulcerations on finger tips with prolonged healing

- Pitfalls:
 - Failure to appreciate limited mouth opening
 - 2 conditions:
 - Primary phenomenon or Raynaud disease
 - Secondary Raynaud phenomenon
 - Primary Raynaud phenomenon is not associated with underlying disease:
 - Milder form
 - 75% are women.
 - Secondary Raynaud phenomenon is associated with underlying disease such as lupus, Sjögren syndrome, mixed connective tissue disease, dermatomyositis, and polymyositis; more serious:
 - Triple phase: Blanching of digits with sharp border to normal colored skin, cyanosis erythema, tingling/numb sensation of the digits
 - Present in ~90% of patients with systemic sclerosis
 - Usually fingers; also toes, nose, ears, and tongue; often spares thumb
 - Pathophysiology: Arterial vasoconstriction, venous stasis to cyanosis, reflex vasodilatation to erythema
 - Calcinosis, especially over extensor joint surfaces in systemic form only
 - Musculoskeletal:
 - “Creaking” of thickened tendons
 - Contractures, especially proximal interphalangeal joints and elbows
 - No intra-articular inflammation
 - Muscle inflammation in ~30% of cases
 - GI:
 - Mucosal telangiectasias of mouth
 - Decreased incisor distance/mouth opening secondary to skin tightness of the lips
 - Sicca syndrome with parotitis
 - Loosening of teeth secondary to periodontal membrane disease
 - Esophageal disease: Esophagitis, occasional ulceration or stricture
 - Large-bowel disease less common
 - Cardiac:
 - Primary cause of morbidity
 - Possibly due to Raynaud phenomenon of coronary arteries and pulmonary artery hypertension
 - Pulmonary:
 - Interstitial fibrosis with gradual obliteration of vascular bed and resulting cor pulmonale
 - Parenchymal disease is almost universal; frequently asymmetric; may have hacking cough, dyspnea on exertion, pleural rub
 - Combined pulmonary vascular and pulmonary parenchymal disease
 - Primary pulmonary vascular disease with right ventricular failure
 - Renal: Due to decreased renal plasma flow, proteinuria, hypertension
 - CNS: Cranial nerve involvement, especially sensory branch of trigeminal nerve
 - Sicca syndrome:
 - Xerostomia (dry mouth)
 - Keratoconjunctivitis sicca (dry eyes)

DIAGNOSTIC TESTS & INTERPRETATION

Lab

There are no specific diagnostic tests.

- Nonspecific tests:
 - Systemic form:
 - ANA: Often positive
 - Hemoglobin: 25% have anemia due to chronic disease or vitamin B12 and folate deficiencies resulting from chronic malabsorption in sclerodermatous gut.
 - Eosinophilia: Present in 50%
 - Sclero-70 (Scl-70 or topoisomerase 1) antibodies: Present in 26% of adults; more common with diffuse disease than with peripheral vascular disease
 - Anti-centromere antibody: Present in 22%, almost exclusively with CREST
 - Muscle biopsy
 - Localized forms:
 - Eosinophilia: Present in 25–50% during active disease
 - ANA: Positive in 37–67%

Imaging

- Chest radiograph:
 - Bibasilar pulmonary fibrosis
 - Rib notching
 - Calcifications (in CREST)
- High-resolution chest CT:
 - Ground-glass attenuation
 - Honeycombing
- Bone radiograph:
 - Acro-osteolysis: Resorption of tufts of distal phalanges, especially with severe Raynaud phenomenon
 - Periarticular or subcutaneous calcification (15–25% patients)
 - Bony erosions

Diagnostic Procedures/Other

- For sicca syndrome:
 - Schirmer test for dry eyes
 - Lip biopsy
 - Rose bengal staining of cornea
- ECG:
 - First-degree block
 - Right and left bundle-branch block
 - Premature atrial contractions (PACs) and premature ventricular contractions (PVCs): Nonspecific T-wave changes, ventricular hypertrophy
- Pulmonary function tests:
 - Restrictive lung disease: Present in 34% of patients with systemic sclerosis
 - Earliest changes are decreased FVC and small airway disease.
 - Decreased diffusing capacity of the lung for carbon monoxide (DLCO): Present in 18% of patients with systemic sclerosis at the time of diagnosis

Pathological Findings

- Periungual nailfold changes: Capillary dropout and dilated loops; occasional redundant cuticular growth and digital pitting
- Histologic:
 - Skin: Loss of subcutaneous fat, increased amount of fibroblasts
 - Muscle: Increased collagen and fat; negative immunofluorescence
 - Esophagus: Atrophic muscle replaced by fibrous tissue more commonly affects smooth muscle of lower 2/3 of esophagus.

- Esophageal manometry and pH probe: Decreased or absent peristalsis of distal esophagus—distal dilatation, hiatus hernia, stricture
- Dilatation of second and third part of duodenum and proximal jejunum

DIFFERENTIAL DIAGNOSIS

- Graft vs. host disease
- Phenylketonuria
- Borrelia infection: Acrodermatitis chronica atrophicans
- Porphyria cutanea tarda
- Scleredema
- Stiff skin syndrome (mucin deposition in the dermis, hardening of the subcutaneous tissue with normal looking epidermis)
- Eosinophilic fasciitis

TREATMENT

MEDICATION (DRUGS)

Disease modification: Many agents have been tried; however, there are few controlled trials and no proven treatment exists. Medications include:

- Localized:
 - Imiquimod, calcitriol ointment, PUVA therapy; methotrexate
- Systemic:
 - Colchicine: Inhibits fibroproliferative process
 - Immunosuppressives:
 - Steroids, chlorambucil, methotrexate, cyclosporine, cyclophosphamide, rituximab
- Pitfall: Avoid excessive use of immunosuppressive therapy late in disease when inflammatory component has resolved.

ADDITIONAL TREATMENT

General Measures

- Supportive care: Avoid trauma and excessive cold—keep extremities warm AND dry
- Management of Raynaud phenomenon:
 - Avoid beta-blockers, caffeine, and stimulating ADHD medications

Additional Therapies

- Physical therapy
 - Helps retard development of contractures and muscle atrophy
 - Pitfall:
 - Insufficient physical therapy resulting in permanent joint contractures

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Localized forms:
 - Physical exam for joint mobility, muscle bulk, and growth
 - Difficult to follow slow disease progression, thus photography of lesions every 3–6 months is recommended
- Systemic forms:
 - Physical exam for digital ulcerations, joint mobility, muscle bulk, and growth
 - Yearly pulmonary function tests
 - Yearly barium swallow
 - ECHO

PROGNOSIS

- Natural course includes several phases:
 - Initial: Inflammation
 - Late: Sclerosis
 - Occasional regression over 3–5 years
- Ultimate prognosis depends on severity of skin tightness, joint contracture, and visceral involvement.
- Mortality:
 - Males > Females
 - Nonwhites > Whites
- Most common cause of death in pediatric patients is secondary to cardiac, renal, and pulmonary complications.

COMPLICATIONS

- Localized:
 - Skin thickening
 - Joint contractures
 - Leg length discrepancies
 - CNS bleed in Parry-Romberg

- M34.9 Systemic sclerosis, unspecified
- L94.0 Localized scleroderma [morphea]

FAQ

- Q: Is a biopsy necessary?
- A: Biopsy is often useful to confirm diagnosis and assess degree of inflammation.
- Q: Is the sclero-70 antibody useful?
- A: Not for diagnosis; it is positive only in a subset of individuals with the systemic form and, therefore, useful for predicting more severe disease.

SCOLIOSIS (IDIOPATHIC)

Ali Al-omari

John P. Dormans

BASICS

DESCRIPTION

- Scoliosis: Lateral curvature of spine exceeding 10 degrees (with rotation of spine); curves <10 are termed spinal asymmetry; considered idiopathic only after other causes have been excluded
- Kyphosis: Anteriorly concave curvature of vertebral column

EPIDEMIOLOGY

- Female-to-male ratios:
 - 1.4:1 for curves 11–20 degrees
 - 5.4:1 for curves >20 degrees

Prevalence

- Generally considered 1.5–3% for curves ≥10 degrees
- 0.3–0.5% for curves >20 degrees

RISK FACTORS

Genetics

Positive familial history for idiopathic scoliosis in 30% (not predictive of severity)

ETIOLOGY

By definition, unknown; listed are some theories, none proven in isolation:

- Genetic:
 - Positive familial history for scoliosis in 30% (not predictive of severity)
- Connective tissue disorder:
 - Associated with several connective tissue disorders
 - Alterations in connective tissue of the spine, paraspinous muscles, and platelets
 - May be related to osteopenia (decreased mineral bone density) of vertebral bodies
- Neurologic (equilibrium system):
 - Abnormalities noted in vestibular, ocular, proprioceptive, and vibratory functions
- Hormonal:
 - Lower levels of melatonin secreted from pineal body in those with adolescent idiopathic scoliosis
 - Growth-stimulating hormone: More of an influential factor than etiologic factor studies
 - Vertebral growth abnormalities
 - Asymmetric growth rates between the right and left sides of the spine

COMMONLY ASSOCIATED CONDITIONS

Connective tissue disorders

DIAGNOSIS

HISTORY

- Onset: Consider when first noted, by whom, rate of worsening, previous treatment, patient recent growth, the physical change of puberty, associated signs or symptoms, familial history, etc.
- Patients with idiopathic scoliosis usually should not have pain, although they might have a discomfort or mild pain.
- Back pain in scoliotic patients must be investigated thoroughly and taken seriously.
- If night pain, consider tumor such as osteoid osteoma.
- Other signs or symptoms: Review of systems (especially neurologic)

PHYSICAL EXAM

- General inspection to look for skin changes such as café au lait spots, pigmentation, or other signs of neurofibromatosis; also dysraphic signs (e.g., hairy patches, midline hemangioma, skin dimpling)
- Assess for skeletal maturity, hyperelasticity, contracture, congenital anomalies
- Assess for deformity; asymmetry of spine, shoulders, and trunk, including decompensation; abnormalities of thoracic kyphosis or cervical or lumbar lordosis
- Adam forward-bending test used to look for rib or paraspinous elevations
- Assess for leg length discrepancy, congenital anomalies, and neurologic abnormalities (including abnormal abdominal reflex)
- Special finding:
 - Crankshaft phenomenon:
 - Progression of curve size and rotation following posterior spinal fusion in a young child, result of continued anterior spinal growth
 - Patient is Risser 0, open triradiate cartilages, <10 years old, and prior to occurrence of peak height velocity (time of maximum spinal growth)
 - Consider anterior fusion in addition to posterior fusion
- Physical exam tricks:
 - Measure rib rotation with scoliometer test
 - Abnormal abdominal reflex may suggest intraspinal pathology, including syrinx
- Perform Adams forward test after the pelvis is leveled by inserting appropriately sized block underneath the short leg in patients with scoliosis and leg length discrepancy

DIAGNOSTIC TESTS & INTERPRETATION

Pulmonary function testing is useful preoperatively for more severe curves

Lab

Usually not helpful unless to rule out associated metabolic conditions

Imaging

- Plain standing posterior–anterior and lateral scoliosis films on long 3-foot radiograph cassette
- One must look for soft tissue and congenital bony abnormalities (Wedge vertebrae, bars, hemivertebrae)
- Curve is measured using Cobb method.
- The status of the triradiate cartilage and Risser classification of iliac apophysis ossification are indicators of maturity.
- The triradiate cartilage usually closes before the iliac apophysis appears (Risser 0).
- Risser sign is defined by the amount of calcification present in the iliac apophysis and measures the progressive ossification from anterolaterally to posteromedially.
 - A Risser grade of 1 signifies up to 25% ossification of the iliac apophysis, proceeding to grade 4, which signifies 100% ossification.
 - A Risser grade of 5 means the iliac apophysis has fused to the iliac crest after 100% ossification.
- MRI not routinely necessary for adult idiopathic scoliosis without back pain
- 7% prevalence of intraspinal abnormalities found in left thoracic curves, so MRI maybe indicated
- Curve patterns classified according to King or Lenke classifications
- Renal ultrasound or IVP used for evaluation of patient with congenital scoliosis (look for associated renal abnormalities)

DIFFERENTIAL DIAGNOSIS

- Adolescent idiopathic scoliosis (11–17 years)
- Juvenile idiopathic scoliosis (4–10 years)
- Infantile idiopathic scoliosis (0–3 years)
- Congenital scoliosis—due to bony abnormalities of the spine that are present at birth (failure of formation or segmentations of vertebrae)
- Scoliosis associated with neurofibromatosis

- Scoliosis associated with tumors (e.g., osteoid osteoma)
- Neuromuscular scoliosis (e.g., cerebral palsy, spina bifida, muscle disorders)
- Postural scoliosis (e.g., from leg length discrepancy):
 - No rib hump or rotation
 - Does not have fixed deformities
 - Disappears with forward bending
 - Long curve
 - No progression

TREATMENT

ADDITIONAL TREATMENT

General Measures

- Treatment:
 - Concepts for treatment are based on severity of deformity and on likelihood of progression.
- Observation:
 - Curves <25 degrees:
 - Immature patients (Risser 0, 1, 2) should be re-evaluated in 4–6 months.
 - Skeletally mature patients (Risser 4 or 5) usually do not require ongoing follow-up unless special circumstances exist.
 - Curves 25–45 degrees in skeletally mature patients:
 - Risser 4 or 5 patients usually re-evaluated in 6 months to 1 year
 - Mature patients usually re-evaluated yearly

Additional Therapies

- Brace treatment:
 - Curves 25–45 degrees (Risser 0, 1) and 30–45 degrees (Risser 2 or 3):
 - Brace on initial evaluation
 - Curves ≥25 degrees (in Risser 0–3 patient) that have demonstrated >10 degrees progression during period of observation
 - Continue brace treatment until maturity (2 years postmenarchal and Risser 4 in females, Risser 5 in males)
- Brace types:
 - Thoracolumbosacral orthosis: Success reported when used >16–18 hours daily; significantly improved outcome when compared with natural history
 - Milwaukee: Seldom needed except for higher thoracic or cervical curves
 - Nighttime bending brace

SURGERY/OTHER PROCEDURES

- Recommended when curves exceed 45–50 degrees:
 - Exception: Balanced thoracic and lumbar curves <55 degrees may be observed for progression.
- Thoracic curves and double major curves:
 - Posterior segmental fixation instrumentation remains current state of the art.
 - Anterior spinal instrumentation for selected curves
 - The role of thoracoscopic technique being defined
- Isolated thoracolumbar and lumbar curves:
 - Anterior spinal fusion using solid rod segmental constructs

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Watch for back pain associated with idiopathic scoliosis (may indicate other diagnosis):
 - Present in 23% at time of initial evaluation (additional 9% during follow-up)
 - Of those with back pain, only 9% found to have identifiable cause such as spondylolysis, Scheuermann, syrinx, disc herniation, tumor, tether cord

PROGNOSIS

- Overall, good for most patients
- Risk of curve progression related to patient's maturity (Risser sign, menarcheal status) and to size of curve
- Curves <20–25 degrees have low risk of progression, even if patient is immature.
- Curves 25–45 degrees have higher risk of progression, particularly in the immature patients.
- Curves >45–50 degrees have much higher risk of progression, regardless of maturity.

COMPLICATIONS

Natural history:

- Reduced pulmonary function for patients with thoracic curves >60 degrees
- Progression of lumbar curves >50 degrees in adult life with degenerative disc disease and pain in some
- Cosmetic and emotional issues

- M41.119 Juvenile idiopathic scoliosis, site unspecified
- M41.129 Adolescent idiopathic scoliosis, site unspecified

FAQ

- Q: How long do you observe a patient with spinal asymmetry before ordering a radiograph?
- A: It depends on the presence or absence of abnormalities on the physical exam. If any of the signs mentioned here are seen or significant back pain is present, a radiograph or referral is indicated. The scoliometer is also a useful tool in screening patients.
- Q: If a child presents with scoliosis and back pain that occurs especially at night and is relieved with aspirin, what diagnosis is suggested?
- A: Scoliosis is associated with osteoid osteoma.

SEBORRHEIC DERMATITIS

Kara N. Shah

BASICS

DESCRIPTION

- An erythematous, scaly, greasy dermatitis that favors the sebaceous areas of the body, including the scalp, face, postauricular, central chest, and intertriginous areas
- The distribution pattern and clinical course varies with age. Infants commonly manifest predominantly self-limiting scalp involvement (“cradle cap”), while adults and adolescents more commonly demonstrate chronic involvement of the face, ears, and scalp.

GENERAL PREVENTION

Frequent washing with a medicated shampoo containing sulfur, selenium sulfide, salicylic acid, tar, corticosteroid, an antifungal agent, or zinc pyrithione or application of a medicated lotion, foam, gel or cream containing either one of the aforementioned compounds can reduce disease flares. There are no other preventive measures and modulation of dietary intake is of no benefit.

EPIDEMIOLOGY

- There are 2 populations in whom seborrheic dermatitis develops: Infants, in which seborrheic dermatitis usually develops after the first 3–4 weeks of life, peaks at age 3 months, and usually resolves by 1 year of age; and adolescents and adults, in whom it usually persists, although the disease may be seen in children of all ages.
- In adults, seborrheic dermatitis is more common in males.
- The development of seborrheic dermatitis during infancy does not predict the development of adolescent and/or adult disease.

Incidence

Although it is one of the more common skin diseases seen in infants as well as in adolescents and adults, the incidence of seborrheic dermatitis is unknown.

Prevalence

- Affects 2–5% of the adult population.
- Affects ~6% of children 2 to 10 years of age.
- Affects ~ 18% of infants <2 years of age.

RISK FACTORS

Genetics

Controversy exists as to whether there is a genetic predisposition. There is evidence that it is more common in families, but not spouses, of affected patients.

PATHOPHYSIOLOGY

- Although not an infection per se, there is increasing acceptance that the lipophilic yeast *Malassezia*, a commensal skin organism, is a contributing factor. Increased sebaceous gland activity likely favors the growth of *Malassezia*. The use of topical antifungal agents such as ketoconazole significantly decreases the number of *Malassezia* yeast in seborrheic dermatitis patients with subsequent clinical improvement.

- The local host immune response to *Malassezia* toxins or enzymes also plays a probable role in the development of seborrheic dermatitis. Seborrheic dermatitis is one of the most common cutaneous manifestations of AIDS in adults, where it can be particularly severe and recalcitrant to standard therapy.
- Androgen-mediated stimulation of sebaceous gland activity is likely important, given that seborrheic dermatitis presents in infancy and puberty.
- The histopathologic findings are nonspecific and include parakeratosis, acanthosis, spongiosis, elongation of the rete ridges, and a mild lymphocytic dermal inflammatory infiltrate.

ETIOLOGY

- A multifactorial disease influenced by both genetic and environmental factors
- It is not clear whether the infantile and adolescent/adult forms share a common etiology or whether they are distinct disorders.

DIAGNOSIS

HISTORY

- Infants usually present after 3–4 weeks of life, with a peak prevalence at age 3 months and resolution usually by 1 year of age. It is generally asymptomatic. There may be a coexistent atopic dermatitis.
- Adolescents and adults usually present with a chronic, recurrent, often pruritic rash that begins sometime after puberty. Many patients have tried multiple treatments, including shampoos and medicated creams and/or lotions, with initial improvement but prompt recurrence after discontinuation.

PHYSICAL EXAM

- The characteristic lesions are erythematous scaling patches often with an orange/yellow hue and greasy in appearance. In persons with darker skin complexion, affected areas may appear as hypopigmented, scaling patches resembling tinea versicolor.
- In infants, seborrheic dermatitis most commonly involves the scalp (“cradle cap”) but can also involve the face, neck, umbilicus, diaper area, and intertriginous areas. Cradle cap may appear as thick, greasy adherent scaling of the scalp. Rarely, infants may present with diffuse involvement of the head, neck, body and extremities.
- Adolescents and adults may present with a pruritic, scaling scalp dermatitis or with involvement of the face (favoring the perinasal areas, beard area, and eyebrows), postauricular area and external ear canals, and presternal area. Blepharitis with erythema and scaling of the eyelid margins may also occur.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- There are no specific tests for seborrhea.
- Microscopic examination with a potassium hydroxide wet mount preparation or a fungal culture of skin scrapings will differentiate seborrheic dermatitis from a dermatophyte infection.

Diagnostic Procedures/Surgery

Skin biopsy may be helpful if the presentation is unusual or in cases not responding to conventional therapy; however, findings are not necessarily diagnostic for seborrheic dermatitis.

DIFFERENTIAL DIAGNOSIS

- Infection:
 - Fungal infections with dermatophytes are commonly confused with seborrheic dermatitis. Tinea faciei, tinea corporis, and tinea barbae usually cause localized scaly circinate inflammatory patches, although infection of hair follicles can result from misdiagnosis and treatment with topical steroids and often presents as an inflammatory plaque.
 - Tinea capitis presents most commonly with diffuse or patchy fine white adherent scaling on the scalp with broken hairs and/or patchy or diffuse hair loss. Cervical adenopathy is often present. Tinea capitis is primarily a disease of infants and prepubertal children.
 - Tinea versicolor presents with multiple small round to oval hypopigmented or hyperpigmented macules favoring the upper chest and back and typically sparing the face. Tinea versicolor is generally seen in adolescents and adults.
 - Dermatophyte infections can be differentiated by microscopic examination of hairs or skin scrapings using a potassium hydroxide wet mount preparation and by fungal culture.
- Malignancy:
 - Langerhans cell histiocytosis is an uncommon infiltrative disorder of monocytes, macrophages, and dendritic cells that may present with a scaly erythematous eruption on the scalp, behind the ears, or in the intertriginous regions. It is differentiated from seborrheic dermatitis by the presence of small reddish-brown crusted papules or vesicles, purpuric lesions, hepatosplenomegaly, and adenopathy. It is currently not clear whether Langerhans cell histiocytosis is a reactive or a neoplastic disease.

- Immunologic:
 - Atopic dermatitis usually begins in infancy and is characterized by a chronic, recurrent pruritic dermatitis that is usually seen in the context of a personal or family history of atopy.
 - Atopic dermatitis in infants favors the face (but typically spares the perinasal and periocular areas) and extensor aspects of the extremities and spares the diaper area.
 - In children and adults, atopic dermatitis favors the flexural aspects of the extremities but may also involve the face, scalp, and trunk.
 - Some infants and adolescents manifest features of both atopic dermatitis and seborrheic dermatitis.
 - Psoriasis vulgaris in children and adults is characterized by symmetric, well-demarcated erythematous plaques with a thick white micaceous scale
 - Lesions favor the extensor aspects of the extremities.
 - Scalp involvement is common and present with erythematous scaly plaques in the scalp.
 - Other features of psoriasis include characteristic nail changes such as nail pitting and onycholysis.
 - In infants, psoriasis may involve the diaper area and other intertriginous areas or may present with diffuse involvement of the trunk, face, and extremities.
 - It is generally accepted that there is often an overlap in the clinical manifestations of psoriasis and seborrheic dermatitis, which is often referred to as “sebopsoriasis.”
 - Leiner disease results in a severe generalized erythematous, exfoliative dermatitis accompanied by severe diarrhea, recurrent infections, and failure to thrive. It may result from a number of nutritional and immunologic disorders, such as acrodermatitis enteropathica, severe combined immunodeficiency syndrome, and complement deficiencies.

TREATMENT

ADDITIONAL TREATMENT

General Measures

- In infants, mild scalp seborrhea can be treated with intermittent use of a mild shampoo.
 - A sulfur or salicylic acid shampoo (i.e., Sebulex) may be used for several days as needed.
 - Scales can be loosened with application of mineral oil or baby oil followed by gentle brushing or combing of the scalp to loosen scales.
- Persistent scalp seborrhea and seborrheic dermatitis involving the face, diaper area, and body will usually respond to treatment with a short course of a low-potency topical corticosteroid lotion or cream or to a topical antifungal such as ketoconazole cream.
- Adolescents with mild scalp seborrhea often respond to intermittent use of a shampoo with zinc pyrithione (e.g., Head & Shoulders), selenium sulfide (e.g., Selsun), a topical corticosteroid (e.g. Capex) or tar (e.g., Neutrogena T-Gel).
 - Those with more erythema, scaling, and/or and severe pruritus may consider treatment with a medium-potency topical corticosteroid solution or foam.

- Dense, diffuse scalp involvement may be treated overnight for several days as needed with a topical corticosteroid such as Derma-Smoothe/FS lotion, Luxiq foam or fluocinonide 0.05% solution.
- Ketoconazole or clobetasol shampoo is an alternative therapy.
- Seborrheic dermatitis of the face and body may be treated with a low-potency topical corticosteroid lotion, foam, gel or cream, a topical antifungal cream such as ketoconazole; with a topical sulfur/sulfacetamide wash, lotion, or cream (e.g. Clenia); or with one of the topical calcineurin inhibitors, tacrolimus ointment and pimecrolimus cream, which have anti-inflammatory properties and have also been shown to have potent antifungal activity against *Malassezia in vitro*.
- If the seborrheic dermatitis is particularly widespread, severe, or is refractory to topical treatment, oral ketoconazole has been shown to be effective.
- Blepharitis should be treated with warm water compresses, cleansing with a gentle shampoo, and if necessary, application of sodium sulfacetamide ophthalmic ointment or cautious application of a topical calcineurin inhibitor such as Elidel 1% cream or Protopic 0.1% ointment to the eyelid margins.
 - Topical steroids may be effective, but the side effects of its use around the eye (such as glaucoma) make this a poor choice for chronic therapy.

ONGOING CARE

- In infants, seborrheic dermatitis self-resolves by the age of 1 year, but often requires intermittent therapy until resolution occurs.
- Although some improvement should be seen with treatment by 10–14 days, long-term intermittent therapy may be required, especially in adolescents in whom seborrheic dermatitis is often chronic.
- Seborrhea may rarely be complicated by secondary bacterial or candidal infections, which present with erythema, tenderness, and ulceration.
- Patients who are intermittently using topical corticosteroids should be monitored for the development of adverse effects, including local cutaneous atrophy, dyspigmentation, and striae.
- Seborrhea may be caused or complicated by associated underlying disorders, including immunodeficiency diseases such as AIDS, which should be considered in cases that are resistant to treatment.

PROGNOSIS

- The infantile form will self-resolve by the end of the first year of life.
- The adolescent form may persist into adulthood.

ADDITIONAL READING

ICD10

- L21.0 Seborrhea capitis
- L21.1 Seborrheic infantile dermatitis
- L21.9 Seborrheic dermatitis, unspecified

FAQ

- Q: Does therapy speed resolution of the disorder?
- A: Treatment does not appear to influence the underlying cause of this disorder, which appears to be caused by hormonally-mediated sebaceous gland activity, skin colonization with the lipophilic yeast *Malassezia* and the resultant local inflammatory response.
- Q: Shouldn't the use of topical corticosteroids worsen the dermatitis if it is caused by a fungal infection?
- A: Topical corticosteroids are commonly used to treat seborrheic dermatitis. These agents seem to work because of their anti-inflammatory effect. Although in the past high-potency steroids were used for this indication, adverse effects are associated with their prolonged use. Currently, low-potency corticosteroids or non-steroidal therapies are preferred.
- Q: Does seborrheic dermatitis cause permanent hair loss?
- A: Patients can be reassured that it does not cause permanent hair loss.

SEIZURES-FEBRILE

Juliann Paolicchi

Eric Masch (5th edition)

Amy R. Brooks-Kayal (5th edition)

BASICS

DESCRIPTION

- Simple febrile seizures (FS): Single, brief (< 15 minutes), generalized seizures during fever (rise or fall) in developmentally and neurologically normal children usually between 6 months and 5 years of age without intracranial infection
- Complex febrile seizures: Febrile seizures that either last > 15 minutes, have focal features or postictal focal weakness, or recur within 24 hours
- Febrile status epilepticus: continuous or intermittent seizures without neurologic recovery for a period of 30 minutes or longer. (See status epilepticus.)
- Febrile seizure syndrome: Generalized epilepsy with febrile seizures plus (GEFS+): Febrile seizures with generalized tonic-clonic seizures, complex partial seizures, and absence seizures. Strong family history of similar seizures.

EPIDEMIOLOGY

Strongly age dependent: 90% between 6 months and 3 years with the peak period between 12 and 18 months. 4% occur before 6 months, and 6% after age 3.

Incidence

Typically, 2–4% of children <5 years of age; however, in certain populations, the incidence can be as high as 15%.

Genetics

- Inheritance: Multifactorial in most cases. To date, at least 5 different genetic loci have been identified.
- Febrile seizure syndrome: Multiple genes identified including *SCN1A*, *SCN2A*, *SCN1B*, and GABA(A) gamma 2 subunit genes

DIAGNOSIS

HISTORY

- Previous history of FS, afebrile seizures, neurologic or developmental abnormality
- Presence of neurologic and developmental abnormality increases risk of subsequent epilepsy. Occurrence of previous afebrile seizures suggests a seizure precipitated by fever, as opposed to febrile seizure.

- Diagnosis of FS after age 6 years is unusual.
- Precipitating factors: Degree and duration of fever; symptoms and duration of intercurrent illness, recent history of head trauma, possibility of ingestion of toxic substance
 - Degree of fever is variable, and 25% of FS occurs between 38 and 39C.
 - FS is most common at the onset of fever and may be the first sign of illness.
 - Low fever, ingestion, head trauma, or prolonged illness before seizure suggest cause other than fever alone.
- Past medical history: Gestation, birth, general health, growth and development, and current medications.
- Family history: Both febrile and afebrile seizures can be hereditary. A family history of febrile seizures is typically present.
- Neurologic findings: Recent onset of headaches, vomiting not in the setting of GI illness, lethargy, weakness, sensory deficits, or changes in vision, behavior, balance, or gait suggests underlying brain pathology or infection and the need for neuroimaging and/or lumbar puncture.

PHYSICAL EXAM

- Vital signs:
 - Degree of fever
 - Tachycardia or hypotension (suggests sepsis)
 - Tachypnea (suggests respiratory infection)
 - Head circumference
- Signs of head trauma or possible abuse: Retinal hemorrhages and evidence of intracranial hypertension such as bulging fontanelle should be noted on head, eyes, ears, nose, and throat (HEENT) exam
- Possible meningitis: Kernig and Brudzinski signs, nuchal rigidity,
 - NOTE: These signs are less reliable in children <12 months of age, especially if <6 months of age.
- Careful neurologic examination: Specific attention should be directed to mental status and any focal abnormalities of motor strength, tone, sensation, or gait if relevant.

DIAGNOSTIC TESTS & INTERPRETATION

- EEG:
- Not indicated after simple febrile seizure, and not indicated acutely
 - Should be considered in children who are neurologically abnormal, experience recurrent complex febrile seizures or in whom the history suggests a cause other than fever alone.
 - EEG abnormalities have not been shown to have a correlation with either recurrence of FS or the development of epilepsy.

Lab

- Routine testing:
 - Not indicated for simple FS
 - May be indicated for the cause of the fever: i.e., tox screen if ingestion identified in history, electrolytes and glucose in the setting of fever, vomiting, and diarrhea.
- Lumbar puncture: Should be performed in any child in whom CNS infection is suspected, especially children <12 months of age because clinical signs of meningitis are less reliable. Any older child who appears toxic and has meningeal or other clinical signs suggesting CNS infection should undergo a lumbar puncture.
- AAP recommendations for LP in FS include:
 - Meningeal signs
 - Infants 6–12 months in whom the immunization status for *Haemophilus influenzae* type B or *Streptococcus pneumoniae* is deficient or unknown
 - Children on antibiotic therapy

ALERT

- Infants presenting with FS may have serious bacterial infections (bacteremia, meningitis, or sepsis) underlying fever without meningeal signs.
- Prolonged FS with focal features can be associated with HSV encephalitis. Both conditions are indications for lumbar puncture.

Imaging

Acute imaging (CT or MRI) recommended in children with febrile status epilepticus, have a large head circumference, or a persistent neurologic deficit including unresponsiveness, focal features on neurologic examination, and signs of increased intracranial pressure.

Non-emergent head MRI:

- Reserved for children with:
 - Complex (focal or prolonged) febrile seizures
 - Focal neurologic deficits, even transitory, after seizure
 - Focal abnormality on EEG other than postictal slowing.

DIFFERENTIAL DIAGNOSIS

- History, physical exam, and as indicated earlier, lumbar puncture and acute neuroimaging are usually sufficient to exclude non-epileptic causes of seizures:
 - Chills due to fever in an ill child
 - CNS infection
 - Anoxia/stroke/hemorrhage
 - Trauma
 - Intoxication
 - Metabolic encephalopathy
 - Neurodegenerative disorder
 - Brain lesion or tumor
 - Epileptic conditions
 - Previous history of afebrile seizures
 - Certain neurogenetic conditions present with seizures in the setting of high fevers, i.e., Angelman and Dravet syndrome
 - Neurocutaneous syndromes (tuberous sclerosis, Sturge–Weber, neurofibromatosis)
 - Previous brain injury (history of stroke, CNS infection, hemorrhage, birth asphyxia, cerebral palsy)

**TREATMENT****ADDITIONAL TREATMENT****General Measures**

- Treatment of single FS not indicated
- Antiepileptic medication is typically reserved for children in whom diagnosis of epilepsy is established with neurologic evaluation.
 - Anti-epileptic medication does not prevent the subsequent development of epilepsy.
- Abortive therapy is recommended in children with complex FS, and recurrent simple FS.
- Treatment with antipyretics does not significantly affect the recurrence rate of FS.
- The AAP does not recommend continuous or intercurrent treatment with anti-epileptic medication for recurrent simple FS, but does recognize that recurrence “can increase anxiety in some parents and their children and as such appropriate educational and emotional support should be provided.”

MEDICATION (DRUGS)

- Primary therapy is abortive. Rectal diazepam, 0.3–0.5 mg/kg, can be administered at time of febrile seizure if it persists for >5 minutes.
 - Focality and a prolonged FS, > 10 minutes; more likely to have recurrence; Therapy with abortive medication should be considered with the first incidence of FS.

- Oral administration of diazepam, 0.3 mg/kg q8h, during febrile illnesses reduces risk of recurrent febrile seizures; however, causes sedation, and is typically useful only for children with a history of recurrent FS within an illness.
- Antiepileptic medications that have been studied to be effective in recurrent FS include phenobarbital, valproate, and primidone but had limiting side effects in 40% of patients in a recent analysis.
- Phenytoin and carbamazepine are ineffective as prophylaxis.
- There is limited data to support the use of levetiracetam for FS.

**ONGOING CARE****PROGNOSIS**

- Recurrent FS occur in 30% of children with FS, and 50% of children with recurrence have a third FS.
- The four predictors of occurrence are age at onset, FS in a first degree relative, low precipitating fever, and short duration between fever onset and seizure. The risk factors are cumulative: 70% with 4 factors, 20% with none.
- Age of presentation is the strongest predictor of recurrence: 50–60% of infants <12 months have recurrence.
- 90% of recurrences occur within 2 years, 75% within 1 year, and 50% within 6 months
- Overall, the risk of children with FS developing epilepsy is 2%, compared with 1% in the general population.
- Risk factors for the development of epilepsy include: focal, prolonged, and recurrent seizures. The risk factors were cumulative: 25% higher in children with 3 factors compared with none.
- No evidence that occasional febrile seizures or even febrile status epilepticus causes subsequent neurologic or cognitive deficits.

**CODES****ICD9**

- 780.31 Febrile convulsions (simple), unspecified
- 780.32 Complex febrile convulsions

ICD10

- R56.00 Simple febrile convulsions
- R56.01 Complex febrile convulsions

FAQ

- Q: What should be done if the child has another febrile seizure?
- A: Emergency measures include placement of the child recumbent or supine with head turned to avoid aspiration. Place nothing in the mouth. Abortive therapy should be initiated at 5 minutes of seizure activity. If not available, EMT services should be activated. For children who have had prolonged or recurrent series of seizures, instructions to administer rectal diazepam are recommended.
- Q: What restrictions should be placed on general activity of a child with recurrent febrile seizures?
- A: No specific activity restrictions are recommended. Children at risk for recurrent seizures are recommended not to swim or bathe unattended, sleep in a top bunk bed, climb to high places, and wear a helmet when biking or using any wheeled toy.

SEIZURES, PARTIAL AND GENERALIZED

Juliann M. Paolicchi

Eric Masch (5th edition)

Amy R. Brooks-Kayal (5th edition)

BASICS

DESCRIPTION

Seizures arise from abnormal, excessive, electrical neuronal discharges in the cerebral cortex that lead to alterations of consciousness, behavior, motor activity, sensation, or autonomic function. Epilepsy is defined as 2 or more seizures without acute provocation.

Seizures are classified as partial (begin in local area of cerebral cortex) and primary generalized (begin simultaneously in both hemispheres).

- Partial seizures types:
 - Simple partial (consciousness not impaired)
 - Complex partial (consciousness impaired)
 - Partial seizures evolving to generalized tonic-clonic convulsions
- Primary generalized seizure types:
 - Absence, atypical absence, myoclonic, tonic, atonic, tonic-clonic

EPIDEMIOLOGY

Incidence

1% of children will have 1 seizure by age 14 years. The highest incidence is in infancy. In childhood, 30% of 1st seizures occur before age 4 years and nearly 80% occur before age 20 years.

Prevalence

4–9 per 1,000 children in developed countries have epilepsy.

RISK FACTORS

- Developmental disability present in 35% of children who develop epilepsy
- Active neurologic disease/illness (CNS infection, trauma, hemorrhage/stroke)
- History of previous seizure
- Recent withdrawal of anticonvulsant medication
- History of remote neurologic insult (stroke, intracranial hemorrhage, cerebral palsy, head trauma, meningitis)
- Family history of seizures
- Brain tumor
- Neurodegenerative disorder

Genetics

- Idiopathic seizures: A multifactorial pattern
- Epilepsy syndromes with defined genetic loci: Generalized epilepsy with febrile seizures, autosomal dominant nocturnal frontal lobe epilepsy, benign familial neonatal convulsions, severe myoclonic epilepsy of infancy
- Other epilepsy syndromes (benign rolandic, childhood, juvenile absence, juvenile myoclonic epilepsy) are heterogeneous or show autosomal dominant pattern with variable penetrance.

DIAGNOSIS

HISTORY

- Age, family history of seizures/epilepsy, developmental status
- Health at seizure onset: Febrile, ill, exposed to illness, complaints of not feeling well, sleep deprived.
- Precipitating events other than illness: Trauma, toxins, ingestion, previous head injury

- Current medications and change in antiepileptic medication
- Other neurologic signs: Confusion, encephalopathy, weakness, sensory deficits, and change in vision, behavior, balance, or gait
- Detailed history of symptoms during seizure
 - Aura: Subjective sensations
 - Behavior: Preceding and during seizure
 - Loss of consciousness
 - Vocal: Cry, gasp, speech
 - Motor: Head or eye turning or deviation; jerking, posturing, stiffening, automatisms. Important to determine if generalized or focal
 - Respiration: Cyanosis, change in breathing pattern
 - Autonomic: Pupillary dilatation, drooling, incontinence, pallor, vomiting
- Symptoms after seizure: Amnesia, confusion, sleepiness, lethargy, transient focal weakness (Todd's paresis)

PHYSICAL EXAM

- Vital signs: ABCs need to be checked immediately, and recurrently, if child continues to seize or be unresponsive.
- Fever, tachycardia/bradycardia, or hypertension
- Signs of head trauma and child abuse: Retinal hemorrhages, evidence of intracranial hypertension, presence of fractures, bruising
- Head circumference/abnormal head growth: Microcephaly
- Signs of systemic infection: Meningismus (CNS infection), unresponsiveness
- Skin examination: Café au lait or ash leaf spots; facial hemangioma, suggesting neurocutaneous disorders
- Neurologic examination: Pupillary asymmetries, altered mental status, fixed eye deviations, and focal motor weakness (Todd's paralysis) suggest focal onset of seizures and possible underlying structural lesion.
- Seizures: If there is a question of continuing seizures, proceed with recommendations for "Status Epilepticus."

ALERT

- Attention to adequate airway and breathing and need for oxygenation or ventilatory support is the primary focus at presentation. A serum glucose level should be assessed as soon as possible.
- If the child continues to seize or has recurrent seizures, administration of an abortive benzodiazepine should be administered either rectally or IV.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Glucose
- Oximetry or arterial blood gas indicated if child is actively seizing
- The standard laboratory evaluation of electrolytes, blood urea nitrogen, CBC, liver enzymes, calcium, and magnesium did not show unsuspected abnormalities or contribute to the diagnosis or management in 2 Class 1, and 2 Class 2 studies.
- Antiepileptic drug (AED) levels if indicated. Few of the newer AEDs have relevant serum levels.

- Testing should be based on clinical history (i.e., vomiting, diarrhea, dehydration, or continued unresponsiveness) and toxicology screening in any child in whom there is a question of drug exposure from substance abuse.

Imaging

- Neuroimaging: Based on evidence-based reviews that showed low yields of emergent CT or MRI in children presenting with seizures without focal signs or deficits, current recommendations are:
 - MRI is the preferred modality overall.
 - Emergent neuroimaging, either CT or MRI, should be performed in any child with a postictal focal deficit (Todd's paresis) or who remains unresponsive postictally.
 - Nonurgent MRI recommended for children with: cognitive or motor impairment of unknown etiology, abnormalities on neurologic examination, focal seizures, children <1 year of age, or abnormal EEG findings other than benign partial epilepsy or a primary generalized epilepsy.

Diagnostic Procedures/Other

- EEG:
 - Indicated urgently if the patient fails to awaken within hours after convulsions cease (children with neurologic deficits may have longer recovery), or if there is concern that child may be continuing to seize.
 - Nonurgent EEGs indicated for 1st afebrile seizure or complicated febrile seizure.
- Lumbar puncture: Meningeal signs, infants <6 months of age, or alteration of consciousness; if intracranial hypertension, mass lesion, or hydrocephalus suspected, defer lumbar puncture until after neuroimaging.

DIFFERENTIAL DIAGNOSIS

- Nonepileptic events:
 - Syncope
 - Breath-holding spells
 - Hyperventilation
 - Psychogenic seizures
 - Movements related to gastroesophageal reflux (Sandifer syndrome)
 - Sleep disorders: Benign sleep myoclonus, night terrors, somnambulism, narcolepsy-cataplexy
 - Migraine/headache syndromes, especially complicated migraine
 - Nonepileptic movements: Startle disease, shuddering spells, paroxysmal dyskinesias, tics, drug-induced dystonia
 - Behavioral: Stereotypies, self-stimulatory behaviors, inattention/ADHD
- Definite seizure or epilepsy (e.g., generalized tonic-clonic, complex partial, absence, myoclonic, tonic, atonic):
 - Idiopathic (presumed genetic)
 - Remote symptomatic (previous history of stroke, intracranial hemorrhage, birth asphyxia, head trauma, meningitis)
 - Acute symptomatic: CNS infection, anoxia, trauma, stroke/hemorrhage, intoxication, metabolic encephalopathy, anticonvulsant withdrawal
 - Neurodegenerative disorder
 - Brain tumor
 - Malformations of cortical development (lissencephaly, agenesis of corpus callosum, holoprosencephaly)

- Neurocutaneous syndromes (tuberous sclerosis, Sturge-Weber syndrome, neurofibromatosis)
- Febrile seizure: Seizure associated with fever in children <6 years of age with no history of afebrile seizures. Children younger than 6 months should undergo lumbar puncture (see “Seizures, Febrile” chapter).

TREATMENT

MEDICATION (DRUGS)

- The choice of AED for long-term management of epilepsy depends on the specific seizure type. Monotherapy always preferred
- Many formulations, such as liquid, sprinkle capsules, and extended-release forms are available, and should be individualized to the patient. For teenagers, extended-release forms are recommended for compliance.
- Partial-onset seizures (with or without secondary generalization):
 - Oxcarbazepine: 20–40 mg/kg/d
 - Levetiracetam: Initial dosing of 10–20 mg/kg/d and increase to 60 mg/kg/d
 - Additional options:
 - Lamotrigine: 5–15 mg/kg/d in patients not taking valproate, 1–5 mg/kg/d in patients on valproate
 - Topiramate: 4–10 mg/kg/d; build up dose slowly to minimize cognitive side effects.
 - Valproate: 10–15 mg/kg/d, increased to 20–60 mg/kg/d for blood levels of 50–100 mg/d
 - Zonisamide: Initial dosing 1–2 mg/kg/d and increase to maximum dose of 10 mg/kg/d in nightly or b.i.d. dosing
- Acute treatment of seizures:
 - Fosphenytoin: 20 mEq of phenytoin per kg IM/IV and phenobarbital 10–20 mg/kg IV used less for chronic maintenance therapy (cognitive, behavioral, cosmetic effects)
- Primary generalized epilepsies (including absence, myoclonic, tonic, or clonic seizures): Ethosuximide, 15–40 mg/kg/d in 2 divided doses = initial AED for absence seizures. Titration is based on efficacy (seizure freedom) and EEG normalization.
- Alternatives for generalized seizures: Valproate, lamotrigine, topiramate, levetiracetam, rufinamide, and zonisamide. Adverse effects of valproate include thrombocytopenia, pancreatitis, hyperammonemia, and fatal hepatotoxicity. CBC and liver function tests should be routinely monitored. Children <5 years and on polytherapy (more than 1 AED) have an increased risk of hepatotoxicity from valproate, and children <10 years have an increased risk of serious rash from lamotrigine.
- Prolonged seizures (>5 minutes) or acute repetitive seizures: Rectal diazepam (0.3–0.5 mg/kg per dose) can be administered by parents/caregivers. Effective at stopping the seizure with minimal risk of respiratory depression.
- Patients refractive to AED treatment: Other options—ketogenic diet, vagus nerve stimulator, surgical resection

ALERT

- Hyponatremic seizures: Serum sodium <120 mEq/dL in infants with gastroenteritis. Slow sodium correction indicated
- Apnea and hypoventilation from excessive administration of benzodiazepines, phenobarbital for seizures. Monitor ventilation and oxygenation; avoid large doses.

ADDITIONAL TREATMENT

General Measures

- Chronic AED therapy is not indicated after acute symptomatic seizures (transient metabolic disturbances [e.g., hyponatremia, intoxication]) or after a single unprovoked seizure in a child with normal neurologic examination and EEG.
- Chronic AED therapy may be considered after 1st seizure symptomatic of an acute, structural brain lesion (i.e., brain tumor).

ALERT

A 2-fold risk of increased suicidality has been associated with AED use, with an FDA black box warning on product labeling. Monitoring for suicidal ideation and mood changes is warranted in all patients taking AEDs.

ONGOING CARE

PROGNOSIS

- In a child who is neurologically normal with an unprovoked seizure, the risk of recurrence is 24% in 1 year and 45% in 14 years.
- If there is evidence of prior neurologic insult, the risk of recurrence is 37% in 1 year.
- If the patient has 2 seizures separated by >24 hours, risk is 70% in 1 year.
- The EEG is the most significant predictor of recurrence: 15% risk in 1 year in a child with a normal EEG and 41% with an abnormal EEG.
- The risk is increased (up to 80%) in children with abnormal examinations, focally abnormal EEGs, onset of seizure in sleep, positive familial history of seizures, partial seizures, or postictal (Todd's) paralysis.

COMPLICATIONS

- Brain damage:
 - From brief seizures: No convincing evidence
 - From prolonged seizures (>30 minutes): Brain injury may occur secondary to hypoxia (respiratory compromise).
 - Untreated or poorly controlled epilepsy: Increased risk of intractable epilepsy syndromes, sudden unexplained death (SUDEP)
- Injuries: Rarely, serious injury occurs with brief seizures from loss of consciousness and resultant falls (see “Safety” below).
- Daily precautions: Few restrictions are needed with the exceptions of driving (see state laws), operating heavy machinery, or dangerous sports, such as scuba diving, parachuting, or rock climbing.
- Supervised bathing and swimming, showering safer than bathing, helmets with all wheeled toys (bikes, scooters, skateboards); avoid top bunk beds or locked bedrooms, and heights.
- Chronic epilepsy is associated with inattention, depression, and deficits in memory and academic performance.
- Patient monitoring: Dependent on treatment and as mentioned above

CODES

ICD9

- 345.90 Epilepsy, unspecified, without mention of intractable epilepsy
- 780.39 Other convulsions

ICD10

- G40.101 Localization-related (focal) (partial) symptomatic epilepsy and epileptic syndromes with simple partial seizures, not intractable, with status epilepticus
- G40.109 Localization-related (focal) (partial) symptomatic epilepsy and epileptic syndromes with simple partial seizures, not intractable, without status epilepticus
- G40.901 Epilepsy, unspecified, not intractable, with status epilepticus

FAQ

- Q: How do I know my child has epilepsy?
- A: The term “epilepsy” is applied to children with 2 or more seizures without an acute cause.
- Q: Will my child always have epilepsy?
- A: The likelihood of outgrowing epilepsy depends on the syndrome. In many cases, anticonvulsants can be discontinued if the child has been seizure free for 2 years.
- Q: Why take an antiepileptic medication?
- A: The purpose of antiepileptic medication is to decrease further seizures. They do not, however, affect the long-term course of epilepsy.
- Q: Why did my child's seizures change?
- A: Generalized tonic-clonic seizures may arise in childhood absence epilepsy; children may develop different epilepsy syndromes. Medications may cause seizures milder, or can become less effective.

SEPARATION ANXIETY DISORDER

Ushama Patel

BASICS

DESCRIPTION

- Separation anxiety is characterized by developmentally inappropriate and excessive anxiety about being apart from the individuals to whom a child is most attached.
- Frequently, the individual worries excessively that harm may come either to a parent or an attachment figure or himself or herself, which would result in their separation.

EPIDEMIOLOGY

The prevalence is 3.5%. It is slightly higher in females than males.

ETIOLOGY

- Temperament is that of behavioral inhibition which is a child's tendency to approach unfamiliar situations with distress, restraint, and avoidance
- Insecure attachment between mother and child
- Increased parental anxiety
- Parenting style of being excessively controlling and overprotective
- Exposure to negative life events

COMMONLY ASSOCIATED CONDITIONS

- Depression (62%)
- Simple phobia (46%)
- Social phobia (34%)
- Generalized anxiety disorder (29%)
- Obsessive compulsive disorder (10%)
- Alcohol abuse in adolescence

DIAGNOSIS

- Separation anxiety is a normative part of development, typically beginning around 6 or 7 months of age, peaking around 18 months and decreasing after 30 months.
- DSM IV criteria are:
 - Developmentally inappropriate and excessive anxiety concerning separation from home or from those to whom the individual is attached, as evidenced by 3 (or more) of the following:
 - Recurrent excessive distress when separation from home or major attachment figures occurs or is anticipated
 - Persistent and excessive worry about losing, or about possible harm befalling, major attachment figures
 - Persistent and excessive worry that an untoward event will lead to separation from a major attachment figure (e.g., getting lost or being kidnapped)
 - Persistent reluctance or refusal to go to school or elsewhere because of fear of separation
 - Persistently and excessively fearful or reluctant to be alone or without major attachment figures at home or without significant adults in other settings
 - Persistent reluctance or refusal to go to sleep without being near a major attachment figure or to sleep away from home
 - Repeated nightmares involving the theme of separation
 - Repeated complaints of physical symptoms (such as headaches, stomachaches, nausea, or vomiting) when separation from major attachment figures occurs or is anticipated
 - Duration of disturbance is at least 4 weeks.
 - Onset is before age 18 years.
 - Disturbance causes clinically significant distress or impairment in social, academic, or other important areas (occupational).

HISTORY

- Overwhelming fear of losing or becoming separated from a parent
- Child fears that separation could be due to death, kidnapping, or serious accident.
- Nightmares about separation
- Avoidance behaviors such as procrastination during the morning routine before school or refusing to leave the side of a parent
- Somatic complaints such as stomachaches and headaches
- Interferes with normative development in a number of ways such as difficulty attending school, participating in extracurricular activities, and attending sleepovers

PHYSICAL EXAM

There are no pertinent findings on physical exam.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- There are no pertinent findings on lab work.
- Scales:
 - CGI (Clinical Global Impressions) improvement scale
 - Pediatric anxiety scale

DIFFERENTIAL DIAGNOSIS

- Generalized anxiety disorder where anxiety is generalized
- Social anxiety where anxiety is during social situations
- Specific phobia where anxiety is due to a specific object
- Panic disorder where anxiety is focused on the fear of having a panic attack

TREATMENT

MEDICATION (DRUGS)

- Selective serotonin reuptake inhibitors (SSRIs; first-line): Initiate half the starting dose for children with anxiety disorders
- Side effects include GI upset, headaches, dizziness, and agitation.
- There is a black-box warning by the FDA indicating that all antidepressants may increase suicidal thinking and behavior in children and adolescents.
- Fluoxetine (Prozac) (10–60 mg)
- Sertraline (Zoloft) (25–200 mg)
- Paroxetine (Paxil) (10–40 mg)
- Benzodiazepines—side effects include sedation, dizziness, and weakness.
- Lorazepam
- Clonazepam
- Alprazolam

ADDITIONAL TREATMENT

General Measures

- Psychosocial
 - Psychosocial treatment of choice is cognitive behavioral therapy.
- Pharmacological
 - First-line choice of pharmacological treatment is SSRI.
 - Second line of choice is a tricyclic antidepressant (trials show less compliance due to side effects).
 - Benzodiazepines can be considered on a short-term basis alone or in combination with SSRI or TCA while waiting for SSRI or TCA to reach a therapeutic level.

Additional Therapies

- Psychosocial treatment:
 - Cognitive behavioral therapy
 - Individual psychotherapy
 - Group therapy
 - Behavior modification
 - Psychoeducation
 - Family therapy

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Monitoring of response to psychosocial treatment should be performed routinely every 2–3 months.
- If medication is initiated, close monitoring on a weekly basis is recommended for the first 4 weeks followed by monthly monitoring.
- Cognitive behavioral therapy is performed on a weekly or twice weekly regimen.
- Monitoring of any emerging comorbidities is suggested.

PROGNOSIS

- Generally favorable course and outcome
- Separation anxiety disorder may be a precursor to panic disorder in adulthood.

SEPSIS

Virginia M. Pierce

Christine S. Cho (5th edition)

BASICS

DESCRIPTION

The terms SIRS (systemic inflammatory response syndrome), infection, sepsis, severe sepsis, and septic shock are defined as:

- SIRS: nonspecific inflammatory response to bodily injury, defined as at least 2 of the following 4 criteria (one of which must be abnormal temperature or leukocyte count):
 - Temperature >38.5 or $<36^{\circ}\text{C}$
 - Tachycardia (mean HR >2 SDs above normal)
 - Tachypnea (mean RR >2 SDs above normal)
 - Leukocytosis, leukopenia, or $>10\%$ bands
- Infection: suspected or proven infection or clinical syndrome associated with high probability of infection
- Sepsis: SIRS in the presence of infection
- Severe sepsis: sepsis accompanied by evidence of altered end-organ perfusion (cardiovascular dysfunction OR acute respiratory distress syndrome [ARDS] OR 2 or more other organ dysfunctions)
- Septic shock: sepsis with cardiovascular dysfunction (hypotension, need for vasoactive drug to maintain normal BP, or any combination of unexplained metabolic acidosis, increased arterial lactate, oliguria, prolonged capillary refill, and core-to-peripheral temperature gap)

EPIDEMIOLOGY

Incidence

The incidence of severe sepsis varies with age, with significantly higher rates in infants (5.2 per 1,000 infants <1 year of age) than in older children (0.5 per 1,000 children age 1–4 years, about 0.2 per 1,000 children age 5–14 years, and 0.4 per 1,000 age 15–19 years).

Prevalence

Sepsis is among the most common (10–25%) medical diagnoses on admission to PICUs.

RISK FACTORS

- Although sepsis may occur in previously healthy children, it is a particular concern for children with chronic underlying conditions that render them immunosuppressed or vulnerable to invasive infections.
- Hyposplenism, either surgical or functional (e.g., sickle cell anemia)
- Neutropenia ($<1,000$ neutrophils/ mm^3 of blood, and especially $<500/\text{mm}^3$)
- Primary or acquired syndromes of immunodeficiency (e.g., AIDS, severe combined immunodeficiency)
- Malignancy
- Organ transplant recipients
- Chronic use of high doses of steroids
- Indwelling central venous catheters
- Extensive burns
- Multiple trauma injuries
- Prematurity
- Unimmunized children

GENERAL PREVENTION

- Routine vaccination for *Haemophilus influenzae* type b (Hib), *Streptococcus pneumoniae*, and *Neisseria meningitidis*, particularly in high-risk patients (e.g., asplenia)
- Antibiotic prophylaxis for household or daycare exposure to Hib or *N. meningitidis*
- Prompt evaluation for fever in immunosuppressed patients
- Aseptic technique for insertion and care of vascular catheters, minimizing duration of use

ETIOLOGY

- Sepsis is caused by microbial invasion of the bloodstream or by the release of microbial products/toxins into the bloodstream. The responsible pathogens vary with age, host immune status, and location of the child (community or hospital setting).
- The most common causes in the first 4 weeks of life are group B streptococcus and Gram-negative enterics (e.g., *Escherichia coli*). Other important pathogens include *Listeria monocytogenes*, *Enterococcus* spp., herpes simplex virus, and enterovirus.
- In neonates with a history of hospitalization, instrumentation, or mechanical ventilation, consider *Staphylococcus aureus*, coagulase-negative staphylococci, Gram-negative bacilli, and *Candida* spp.
- In otherwise healthy older infants and children, leading sepsis pathogens include *S. pneumoniae*, *N. meningitidis*, and *S. aureus*. Group A streptococci, *Salmonella* spp., and rickettsiae are other causes.
- Patients with underlying immune defects are also susceptible to a broad range of additional organisms.

DIAGNOSIS

Have a high suspicion for sepsis; presenting signs of fever and tachycardia are nonspecific. Hypotension is not a sensitive sign of septic shock.

HISTORY

- Identify children with “Risk Factors”
- Duration of illness before presentation:
 - Abrupt onset of symptoms more typical of invasive bacterial infection
- Change in behavior may be initial sign of systemic infection

PHYSICAL EXAM

All patients with suspected sepsis should have a full set of vital signs (e.g., temperature, pulse, respiratory rate, BP, pulse oximetry).

- Temperature:
 - Fever is the hallmark of an infection; infants may demonstrate hypothermia.
- Stertor, stridor:
 - Assess for signs of airway obstruction

- Auscultation of the chest:
 - Assess adequacy of breathing (tachypnea, rales)
- Tachycardia, hypotension, poor skin perfusion, delayed capillary refill, presence of mottling, weak or bounding peripheral pulses:
 - Evidence of inadequate circulatory function
- Altered mental status (somnolence, confusion, disorientation, agitation, irritability):
 - Evidence of severe systemic disease, possible poor cerebral perfusion
- Presence of petechiae and purpura:
 - May be associated with meningococemia or disseminated intravascular coagulation (DIC)
- Thorough physical exam:
 - Look for focus of infection

DIAGNOSTIC TESTS & INTERPRETATION

Lab

Patients with suspected sepsis should have:

- Blood culture:
 - Prior to starting antibiotics when possible
 - Culture yield is related to sample volume.
- CBC with differential:
 - Elevated WBC count with increased band count suggestive of invasive infection
 - Depressed WBC count may also be seen.
- Electrolytes, glucose, ionized calcium:
 - Metabolic acidosis, hypoglycemia, hypocalcemia
- BUN, creatinine, liver function tests:
 - Evaluate for end-organ injury
- Arterial blood gas (ABG) and lactate:
 - Monitor acid–base status
- PT, PTT, fibrinogen, fibrin degradation products, platelets, peripheral smear:
 - Screen for DIC
- Urinalysis and urine culture:
 - Potential source of infection
- Lumbar puncture (when hemodynamically stable):
 - Required for diagnosis of meningitis
- Gram stain and culture of petechiae, abscess contents, purulent wound drainage, indwelling devices, sputum, tracheal aspirate (especially within a few hours after intubation), other body fluids suspected to be infected:
 - May yield causative organism

DIFFERENTIAL DIAGNOSIS

- Congenital heart disease (e.g., ductal-dependent disease, or defects resulting in congestive heart failure)
- Myocarditis, pericarditis, cardiomyopathy
- Cardiac dysrhythmia
- Myocardial infarction
- Pulmonary embolus
- Congenital adrenal hyperplasia
- Thyrotoxicosis, hypothyroidism
- Inborn error of metabolism
- Hypoglycemia
- Diabetic ketoacidosis

- Severe anemia
- Methemoglobinemia
- Neoplasm
- Hemophagocytic lymphohistiocytosis
- Macrophage activation syndrome
- Dehydration
- Pyloric stenosis
- Necrotizing enterocolitis
- Volvulus
- Intussusception
- Pancreatitis
- Infant botulism
- Toxic ingestion/poisoning
- Trauma (accidental or nonaccidental)

TREATMENT

Rapid recognition of sepsis is critical. Early reversal of shock is associated with reduced mortality.

ADDITIONAL TREATMENT

General Measures

- Ensure a patent airway (consider endotracheal intubation)
- Provide supplemental oxygen
- Assist ventilation (e.g., bag-valve-mask device) as needed
- Obtain large-bore peripheral intravenous access (consider central venous line or intraosseous line)
- Volume resuscitation: Bolus 20 mL/kg of normal saline, repeat as needed; consider blood after initial 60–80 mL/kg of crystalloid
 - Early, aggressive fluid resuscitation is imperative. Inadequate early fluid resuscitation is associated with increased mortality.
- Inotropic agents: If hemodynamic instability persists despite fluid resuscitation, start dopamine (begin at 5 μ g/kg/min, titrate up to 20 μ g/kg/min as needed). If the child has fluid refractory/dopamine-resistant shock, then start epinephrine (0.05–0.3 μ g/kg/min) for cold shock or norepinephrine for warm shock to restore normal BP and perfusion.
- Consider stress-dose hydrocortisone for catecholamine-resistant hypotension and in patients at risk for adrenal insufficiency.
- Correct hypoglycemia (0.5–1 g/kg of dextrose) and hypocalcemia.
- Broad-spectrum intravenous antibiotics that cover the likely causative pathogens should be initiated promptly. Once the causative pathogen is identified, antibiotic therapy can be targeted appropriately. Empiric choice should include consideration of patient age, immune status, need for penetration into certain tissues (e.g., CNS), and whether the infection was community- or nosocomially-acquired.
 - Neonates ≤ 4 weeks: ampicillin and gentamicin (no meningitis); ampicillin and cefotaxime (with meningitis). Add acyclovir to either regimen if herpes simplex virus infection suspected. Switch ampicillin to vancomycin if CSF Gram stain or culture reveals Gram-positive cocci.
 - Infants and children ≥ 4 weeks: cefotaxime or ceftriaxone (no meningitis); vancomycin and cefotaxime or ceftriaxone (with meningitis)

- Patients with immunosuppression and/or central venous catheters: vancomycin plus aminoglycoside plus advanced generation cephalosporin (e.g., cefepime)
- Patients with an intra-abdominal focus of infection: carbapenem; ticarcillin-clavulanate or piperacillin-tazobactam; ceftriaxone, cefotaxime, or cefepime plus metronidazole; ampicillin plus gentamicin plus metronidazole or clindamycin
- Drainage or eradication of focus of infection
- Pitfalls:
 - Recognize the patient with “Risk Factors”
 - Initial priorities in management are ensuring adequate airway, breathing, and circulation.
 - Provide adequate initial volume resuscitation; early reversal of shock is associated with improved outcome.
 - Evaluate for a focus of infection amenable to source control and eradicate it if is possible (e.g., drainage of infected fluid collection, debridement of infected tissue, removal of implanted devices/foreign bodies).
 - Consider meningitis when appropriate.
 - Continuous monitoring and reassessment of the patient are essential.

IN-PATIENT CONSIDERATIONS

Admission Criteria

- Patients with sepsis should be admitted for close monitoring.
- Patients with severe sepsis or septic shock should be admitted to an ICU.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Admit all patients with suspected sepsis to the hospital; consider ICU admission.
- Continuous BP monitoring for the development of refractory shock
- Serial vital signs and physical exams to monitor response to therapy
- Monitoring for complications of sepsis and the development of multiple organ dysfunction syndrome (MODS):
 - Chest radiograph and serial ABGs for evidence of acute lung injury/ARDS
 - Urine output, BUN, creatinine for acute renal failure
 - Serial coagulation studies (PT/PTT) and platelets for development of DIC
 - Serial blood glucose levels for hypo- or hyperglycemia
 - Serial liver function tests for evidence of hepatic dysfunction
 - Serial neurologic examinations for evidence of CNS dysfunction

PROGNOSIS

- Case fatality rates have improved from nearly 50% to $\sim 10\%$. With implementation of clinical practice guidelines focused on early reversal of shock, several recent studies have demonstrated reduction of in-hospital mortality rates to $\sim 4\text{--}8\%$ for patients with severe sepsis.
- Mortality is higher in children with chronic illnesses than in previously healthy children.
- Development of ARDS or MODS is associated with increased mortality.

COMPLICATIONS

- Sepsis is one of the leading causes of pediatric mortality, accounting for 7% of deaths in children.
- The most common complications are those resulting primarily from either acute hypoperfusion of vital organs or from organ injury incurred by the uncontrolled systemic inflammatory response:
 - Acute lung injury
 - Acute renal failure
 - DIC
 - Hypoglycemia
 - ARDS
 - Refractory shock
 - MODS

SEPTIC ARTHRITIS

Sujit S. Iyer

Rakesh D. Mistry

BASICS

DESCRIPTION

Microbiologic infection and inflammation of the usually sterile joint space

EPIDEMIOLOGY

- Toddler and school age (2–6 years) most commonly affected
- Predominant sex: Male > Female, 2:1
- Lower extremities (knee and ankle) and large joints (shoulder, hip, elbow) commonly affected

PATHOPHYSIOLOGY

- Entry of bacteria into joint space:
 - Hematogenous spread
 - Direct inoculation (penetrating trauma)
 - Extension from bone infection (mainly in children < 1 year old when vessels cross from metaphysis to epiphysis)
- Influx of inflammatory cells within the joint capsule
- Rapid destruction of cartilaginous structures within the joint by bacterial and lysosomal enzymes:
 - If untreated, may progress to necrosis of the intra-articular epiphysis

ETIOLOGY

- Bacteria:
 - *Staphylococcus aureus* most common etiology outside of perinatal period (methicillin-sensitive and methicillin-resistant)
 - Streptococci
 - *Kingella kingae*
 - *Haemophilus influenzae*
 - *Salmonella*
 - *N. gonorrhoeae*
 - *Neisseria meningitidis*
 - *Borrelia burgdorferi* (Lyme)
- Aseptic arthritis:
 - Rubella
 - Parvovirus
 - Hepatitis B or C
 - Mumps
 - Herpesviruses (Epstein–Barr virus, cytomegalovirus, herpes simplex virus, varicella zoster virus)
 - Epstein–Barr virus
 - Varicella
 - *Candida albicans* (neonatal)

COMMONLY ASSOCIATED CONDITIONS

- Neonatal septic arthritis may be associated with *S. aureus*, group B streptococcus, *Escherichia coli*, and *Candida*.
- Sickle cell disease is associated with *Salmonella* infection, although *S. aureus* is still the most common.
- Immunocompromised patients: *Mycoplasma*, *Ureaplasma*, *Klebsiella*, or *Aspergillus* infection

DIAGNOSIS

HISTORY

- Fever, rigors
- Affected joint pain, or refusal to walk or move joint in preverbal children
- History of recent trauma does not rule out septic arthritis.
- Pain of bacterial arthritis worsens over 1–3 days and does not wax and wane.
- Septic arthritis is rarely polyarticular.
- Lyme arthritis is typically more subacute, without constitutional symptoms.

PHYSICAL EXAM

- Fever occurs within the first few days of illness in 75% of patients but less commonly in infants. Only 50% of children with gonococcal arthritis have fever.
- Children with septic arthritis usually appear ill.
- The joint appears warm and swollen.
- Infants may demonstrate “pseudoparalysis.”
- Hip involvement causes the leg to be held flexed, abducted, and externally rotated.
- The child with septic arthritis usually has pain through any range of motion. In contrast, most traumatic injuries allow some painless range of motion of that joint.
- Lyme infection is characterized by a painless joint that is warm, swollen, and tender.
- There is usually a more delayed presentation with minimal external findings when the hip or shoulder joints are infected.
- Consider hip involvement when the patient complains of knee or thigh pain.
- In the frightened or uncooperative child, it is possible to have the parent perform an examination for tenderness and range of motion while the physician observes from a distance.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Synovial fluid analysis in septic arthritis:
 - The WBC count is often $> 100,000/\text{mm}^3$, but may be as low as $50,000/\text{mm}^3$ in early infections.
 - The glucose level in the synovial fluid is $< 50\%$ that of the serum.
 - Culture of the joint reveals an organism in 70–80% of cases (except for gonorrhea).
 - Inoculation of joint fluid into blood culture bottle facilitates recovery of *K. kingae*.
 - Emerging technology of real-time PCR for *K. kingae* toxin from joint fluid may show higher yield of identification than routine Gram stain or culture alone.
 - A Gram stain of synovial fluid reveals pathogens in 50% of cases.

- Other supportive tests:
 - ESR is elevated (> 30 mm/h) in 95% of cases. Retain suspicion if > 20 mm/h.
 - The C-reactive protein (CRP) is increased. In one study, a CRP < 1.0 mg/dL had a negative predictive value of 87% in a population in which the prevalence of septic arthritis in tested patients was 29%.
 - Blood cultures are positive in 30–40% of cases.
 - A high peripheral WBC count is neither sensitive nor specific for septic arthritis.
- An immunofluorescent antibody assay for *B. burgdorferi*, when available, may be helpful in the rapid differentiation between bacterial arthritis and Lyme disease. Modest inflammation (25–50,000 WBC) is usually evident in the synovial fluid.

Imaging

- Radiography is rarely helpful in diagnosis; may show widening of joint space and/or displacement of the normal fat pads in the knee or elbow; and is less often positive in the shoulder or hip.
- Ultrasound of the affected joint usually delineates the amount of fluid within the joint capsule. Increased blood flow on color Doppler may suggest infection. However, this test cannot differentiate between an infectious and a purely inflammatory disease.
- A technetium-99 bone scan reveals increased uptake in the perimeter of the joint during the “blood pool” phase of the study.
- False-positives:
 - Bone scan cannot easily differentiate septic arthritis from epiphyseal osteomyelitis.
 - Evaluation of synovial fluid from patients with rheumatologic disease may mimic that of infectious arthritis; however, the clinical picture should allow differentiation of these entities.

DIFFERENTIAL DIAGNOSIS

- Osteomyelitis with contiguous spread
- Cellulitis causing decreased range of motion of joint secondary to inflammation
- Tuberculous arthritis
- Psoas abscess or retroperitoneal abscess with associated hip pain
- Prepatellar bursitis (knee)
- Tumors:
 - Osteogenic sarcoma (long-bone pain spreading to joint space)
 - Leukemia/lymphoma
- Trauma:
 - Occult fracture in proximity to growth plate
 - Ligamentous injury (sprain)
 - Foreign-body synovitis
 - Traumatic knee effusion/hemarthrosis
- Immunologic:
 - Toxic synovitis
 - Postinfectious
 - Acute rheumatic fever
 - Reactive arthritis
 - *Campylobacter*, *Shigella*, *Yersinia*, *Chlamydia* infection
 - Reiter syndrome (after GI or chlamydial infection), arthritis, uveitis, urethritis
 - Collagen vascular
 - Systemic lupus erythematosus
 - Juvenile rheumatoid arthritis

- Henoch–Schönlein purpura
- Behçet syndrome (iritidocyclitis, genital and oral ulcerations)
- Inflammatory bowel disease (Crohn disease, ulcerative colitis)
- Serum sickness
- Erythema multiforme/Stevens–Johnson syndrome
- Miscellaneous:
 - Knee
 - Apophysitis (e.g., Osgood–Schlatter disease)
 - Patellofemoral pain syndrome (chondromalacia patella)
 - Osteochondritis dissecans
 - Hip
 - Slipped capital femoral epiphysis
- An algorithm using 4 or more of the following factors has been used to successfully differentiate septic arthritis and transient synovitis of the hip:
 - Fever
 - ESR > 20 mm/h
 - CRP > 1.0 mg/dL
 - WBC > 11,000 cells/mL
 - Joint space fluid apparent on plain radiograph
 - The absence of all of these parameters is strongly associated with the absence of septic arthritis.
- Pitfalls:
 - Clinical examination in conjunction with the history of acute onset should raise the suspicion of septic arthritis, even in the face of “negative” laboratory screening tests. The most accurate determinations can be inferred from analysis of the synovial fluid.
 - Realize that some children, especially neonates and young infants, will not manifest signs of systemic disease early in the course of the illness.
 - Observe failure or success of therapy, especially when the extremity is immobilized.

TREATMENT

MEDICATION (DRUGS)

- Choice of antibiotics depends on age of child as outlined.
- Antistaphylococcal penicillin and first-generation cephalosporins are usual first-line antibiotics.
- The incidence of methicillin-resistant *S. aureus* (MRSA) septic arthritis is increasing in many communities. Therefore, in areas where prevalence of MRSA is high (> 15%), vancomycin or clindamycin should be considered as first-line treatment until susceptibilities are identified. Addition of ceftriaxone in sickle cell patients. Duration of therapy (intravenous and by mouth) for various organisms:
 - Treat for at least 2 weeks after resolution of fever and joint effusion
 - At least ≥ 28 days: *S. aureus*, Gram-negative organisms, group B streptococcus, and for infections of the shoulder and hip
 - At least ≥ 4 days: *H. influenzae*, *N. meningitidis*, streptococci
 - At least ≥ 7 days: *N. gonorrhoeae*
- Intra-articular injection of antibiotics is not recommended.
- Unproven therapies:
 - Steroid therapy in the first 4 days has been shown in small studies to reduce residual dysfunction; however, this has yet to be proven effective in larger studies.

IN-PATIENT CONSIDERATIONS

Initial Stabilization

- Drainage of infection: Should occur as soon as possible if bacterial cause is suspected
- Indications for open surgical drainage/irrigation:
 - Hip involvement
 - Shoulder involvement (controversial)
 - Thick, purulent, or fibrinous exudate unable to pass through 18-gauge needle
 - All other joints not undergoing open drainage should undergo needle aspiration.
- Antibiotic administration immediately after joint aspiration is performed.
- Immobilization of extremity
- Pain management

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Involve orthopedic surgery and physical therapy services in follow-up
- Once the patient is receiving oral therapy, serum bactericidal titers (SBTs) must be monitored on a weekly basis if possible. Oral antibiotic titers should be kept at 8 times the SBT.
- When to expect improvement: With appropriate antibacterial therapy, one should see improvement of symptoms with 2 days of initial administration.
- Signs to watch for:
 - Continued pain, fever, or lack of improvement of range of motion after 3–4 days of appropriate antibiotic treatment
 - Rising ESR or CRP in the face of antibiotic treatment
 - Severe cases of septic arthritis may require serial drainage and debridement.

PROGNOSIS

- Depends on duration of illness prior to institution of appropriate therapy
- Incidence of residual joint dysfunction increased if antibiotic therapy not instituted within first 4 days of illness

COMPLICATIONS

- Permanent limitation of range of motion due to tissue destruction and scarring
- Growth disturbance if the epiphysis is involved

CODES

ICD9

- 711.00 Pyogenic arthritis, site unspecified
- 711.05 Pyogenic arthritis, pelvic region and thigh
- 711.06 Pyogenic arthritis, lower leg

ICD10

- M00.861 Arthritis due to other bacteria, right knee
- M00.869 Arthritis due to other bacteria, unspecified knee
- M00.9 Pyogenic arthritis, unspecified

FAQ

- Q: How can one differentiate toxic synovitis from septic arthritis on the initial visit?
- A: Although this is sometimes a difficult diagnosis to make with certainty, patients with toxic synovitis usually exhibit certain characteristics that patients with septic arthritis do not:
 - Almost always involves the hip joint
 - History of previous viral infection
 - Some painless range of motion of the involved joint is possible.
 - The ESR is < 20 mm/h.
 - Fever is low grade.

SERUM SICKNESS

Denise A. Salerno

BASICS

DESCRIPTION

- Serum sickness:
 - Type III hypersensitivity reaction that occurs 7–21 days after injection of foreign protein or serum (usually in the form of antiserum)
 - Immune complexes deposit in the skin, joints, and other organs.
 - Clinical syndrome consists of skin rash, itching, fever, malaise, proteinuria, vasculitis, and joint pain.
- Serum sickness-like reactions:
 - Characterized by fever, rash, lymphadenopathy, and arthralgia
 - Occur 1–3 weeks after drug exposure
 - Immune complexes, vasculitis, and hypocomplementemia are absent.
 - This type of reaction, most commonly associated with medications, is commonly referred to as serum sickness also.
 - More common than true serum sickness because equine serum antitoxins have been replaced with human antitoxin sera
- Clinically, these entities present and are treated the same.

EPIDEMIOLOGY

- Limited information is available regarding the incidence of adverse drug reactions in children; generally believed to occur less frequently in children than in adults.
- >90% of serum sickness cases are drug-induced.
- <5% of serum sickness cases are fatal.

RISK FACTORS

Genetics

People with a genetic predisposition to produce IgE are more susceptible.

GENERAL PREVENTION

- No known way to prevent first occurrence
- Take careful history of previous allergic reactions
- Skin testing prior to antiserum administration will prevent anaphylaxis but not serum sickness.
- When the need for antiserum arises, consider prophylactic antihistamines.

PATHOPHYSIOLOGY

- Serum sickness—type III immune complex, antigen–antibody complement reaction:
 - Antibodies form 6–10 days after the introduction of foreign material.
 - Antibodies interact with antigens, forming immune complexes that diffuse across the vascular walls.
 - They become fixated in tissue and activate the complement cascade.
 - C3a and C5a are produced, resulting in increased vascular permeability and activated inflammatory cells.
 - Polymorphonuclear cells and monocytes cause diffuse vasculitis.
- Serum sickness-like reaction
 - Abnormal inflammatory reaction in response to defective metabolism of drug byproducts

ETIOLOGY

- Common causative agents:
 - Horse antithymocyte globulins
 - Human diploid-cell rabies vaccine
 - Streptokinase
 - Hymenoptera venom
 - Penicillins
 - Cephalosporins (especially cefaclor)
 - Sulfonamides
 - Hydralazine
 - Thiouracils
 - Metronidazole
 - Naproxen
 - Dextrans
- Case-reported agents:
 - Minocycline
 - Amoxicillin
 - Infliximab
 - Bupropion

DIAGNOSIS

HISTORY

- Suspect in any patient who has been taking any new drug during the past 2 months, and who has an unexplained vasculitic rash.
- Presentation and evolution of rash: Typically, the rash first appears on the sides of the fingers, hands, and feet before becoming widespread.
- Associated pruritus is often present.
- Fever is present in 10–20% of cases, and is usually mild.
- Arthritis or arthralgia is present >50% of the time; usually involves the metacarpophalangeal and knee joints.
- Associated abdominal pain: Some cases may have visceral involvement.
- History of hematuria: There can be modest renal involvement, usually presenting as proteinuria and microscopic hematuria.
- Patient reports any neurologic symptoms: Peripheral neuropathy, brachial plexus involvement, and Guillain-Barré syndrome have been reported associations.
- Previous history of a similar rash: Was it associated with any medications in the past? The rash and symptoms of serum sickness will occur sooner on repeat exposure. Try to differentiate from simple drug rash; timing of rash after exposure is important in differentiating the two.
- Has patient had any drug or antitoxin exposure in the past month, especially to penicillins, cephalosporins, sulfonamides, hydralazine, thiouracils, streptokinase, metronidazole, naproxen, or dextrans?

PHYSICAL EXAM

- Erythematous purpuric rash starts at the sides of the feet, toes, hands, and fingers and then becomes more widespread.
- Erythema multiforme, maculopapular, purpuric, or urticarial type rash
- Mild-to-severe fever
- Generalized lymphadenopathy; may be localized to lymph nodes that drain the injection site
- Splenomegaly, occasionally
- Edema of the face and neck
- Joint pain

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Not extremely helpful in establishing diagnosis because no abnormality is universally present. Diagnosis usually apparent by classic findings and history of foreign protein or drug exposure:
 - Urinalysis: May show proteinuria and/or hematuria
 - Complement levels variably reduced before returning to normal
 - Leukocytosis or leukopenia with or without eosinophilia
 - Erythrocyte sedimentation rate may be slightly elevated.
 - Direct immunofluorescent staining of rash biopsy (not routinely recommended as part of workup) shows deposits of IgM and C3 complement in capillary walls.

DIFFERENTIAL DIAGNOSIS

- Erythema multiforme
- Mononucleosis
- Systemic lupus erythematosus
- Rocky Mountain spotted fever
- Henoch-Schönlein purpura
- Hypersensitivity syndrome reaction
- Drug-induced pseudoporphyria
- Acute generalized exanthematous pustulosis
- Wegener granulomatosis
- Pitfalls:
 - A history of fever, rash, and arthralgias is commonly seen with many childhood illnesses. One must always consider differential diagnoses.
 - Symptoms may be so minimal that patient does not seek medical attention.
 - Often misdiagnosed as simple drug allergy

TREATMENT

ADDITIONAL TREATMENT

General Measures

- Stop suspected medication/antigen immediately and avoid its future use
- Topical steroids to relieve itching
- Antihistamines to inhibit the action of vasoactive mediators
- Antipyretics for fever
- NSAIDs to relieve joint pain
- Oral corticosteroids for severe cases:
 - Recommended to administer and taper over 10–14-day period
 - Shorter course may result in relapse, and recurrent symptoms are more difficult to alleviate.
- Admit if symptoms are severe or diagnosis is unclear
- Future avoidance of triggering agent if identified

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

When to expect improvement:

- Usually self-limited illness that resolves in a few days to weeks
- If symptoms persist for >1 month, reconsider the diagnosis.

PATIENT EDUCATION

- An initial episode of serum sickness cannot be prevented. Future episodes can be prevented by avoiding the causative medication (and class of medications) if it has been identified.

PROGNOSIS

Excellent. Most cases are mild and transient with no long-term sequelae.

COMPLICATIONS

- Shock
- Digital necrosis
- Guillain-Barré syndrome (rare)
- Generalized vasculitis (rare)
- Peripheral neuropathy (rare)
- Glomerulonephritis (rare)
- Acute flaccid paralysis (case report)
- Increased risk of anaphylaxis with repeat exposure to precipitating substance
- Fatality (rare, usually due to continued administration of antigen)

- T80.62XA Other serum reaction due to vaccination, initial encounter

FAQ

- Q: My child broke out all over her body with an itchy rash and hives a few days after taking cefaclor, was this serum sickness?
- A: It is more likely that she is allergic to cefaclor. The difference is that drug allergies are type I IgE-mediated hypersensitivity reactions that occur very soon after drug exposure in a previously sensitized individual. Serum sickness is a type III antibody-antigen immune complex and complement amplified hypersensitivity reaction that occurs 1–3 weeks after an initial exposure.
- Q: If my child has had serum sickness, is she at risk for getting it again?
- A: Yes, if she receives the same medication or related medications again. The symptoms will occur more quickly, usually in 2–4 days, and may be more severe.

- Q: Can the vaccines that my doctor recommends for my child give my child serum sickness?
- A: It is possible but pretty rare. There have been a few reports of serum sickness-like reactions occurring after receiving vaccines submitted to the Vaccine Adverse Event Reporting System (VAERS).
- Q: Is there any way to prevent my child from getting serum sickness?
- A: Unfortunately, there is no way to predict if your child will have a serum sickness-like reaction to a particular medication. It is extremely important to be aware of your child's exact allergies to medications and to inform all healthcare providers caring for your child.
- Q: My oldest child had serum sickness after taking cefaclor. Is it true that all my children should now avoid taking cefaclor?
- A: No, there is no known genetic predisposition to serum sickness. Your other children do not need to avoid the medication that caused serum sickness.
- Q: How is the Arthus reaction different from serum sickness?
- A: The Arthus reaction is also a type III hypersensitivity reaction but causes only a local reaction. It is a local vasculitis caused by formation of antigen-antibody complexes in local vessel walls, which then activate the inflammation process. The reaction occurs within hours after an individual is injected intradermally with an antigen against which he or she has been actively immunized.
- Q: My child was diagnosed with serum sickness 1 year ago. He still gets episodes of rash, fever, and joint pain every now and then. How can this be cured?
- A: Serum sickness is a self-limited disease, and as long as the offending agent is stopped your child will completely recover. If there are continuing symptoms and your child is no longer taking the offending agent, then other causes for these symptoms need to be considered.

SEVERE ACUTE RESPIRATORY SYNDROME (SARS)

Nicholas Tsarouhas

BASICS

DESCRIPTION

Clinical criteria for severe acute respiratory syndrome (SARS) must be interpreted in the context of the prevailing epidemiologic laboratory criteria as published by the World Health Organization (WHO) and the Centers for Disease Control and Prevention (CDC).

- WHO clinical criteria (5/01/03):
 - Suspect SARS case:
 - A person presenting after November 1, 2002, with high fever ($>38^{\circ}\text{C}$), and
 - Cough or difficulty breathing, and
 - Close contact with SARS patient or travel criteria to SARS area (see “History”)
 - Probable SARS case:
 - A suspect case with radiographic pneumonia or respiratory distress syndrome, or
 - A suspect case with confirmatory laboratory studies (see “Lab”), or
 - A suspect case with autopsy findings
- CDC clinical criteria (12/12/03):
 - Early illness:
 - 2 or more constitutional symptoms—fever, chills, rigors, myalgia, headache, diarrhea, sore throat, or rhinorrhea
 - Mild-to-moderate illness:
 - Temperature $>100.4^{\circ}\text{F}$ ($>38^{\circ}\text{C}$)
 - 1 or more lower respiratory findings—cough, shortness of breath, or difficulty breathing
 - Severe illness:
 - Clinical criteria of mild-to-moderate illness, and
 - 1 or more of the following—radiographic evidence, acute respiratory distress syndrome, or autopsy findings
- SARS time line:
 - November 2002: A series of severe idiopathic respiratory illnesses begin occurring in Southeast Asian countries (China, Hong Kong, Vietnam, and Singapore).
 - February 11, 2003: The Chinese Ministry of Health notifies the WHO that 305 cases of acute respiratory syndrome of unknown etiology have occurred in Guangdong province in southern China from November 16, 2002 to February 9, 2003.
 - Late February: SARS outbreak in Toronto
 - March 12: WHO issues global SARS alert as number of reported cases steadily increases.
 - March 14: CDC activates emergency operations center with first confirmed death of SARS patient.
 - March 15: WHO issues travel advisories and warnings.
 - March 17: 167 cases and 4 deaths reported in 7 countries
 - March 24: CDC implicates a coronavirus as the causative SARS agent.
 - April 10: The New England Journal of Medicine e-publishes “A Novel Coronavirus Associated with SARS.”
 - April 13: Vancouver team sequences the coronavirus.

- April 16: WHO confirms coronavirus as the cause of SARS as a Netherlands team infects monkeys with the virus. The monkeys go on to develop SARS, and then have the coronavirus recovered from them.
- April 18: Worldwide cases rapidly multiplying—3,461 cases, 170 deaths, 27 countries
- May 17: Deaths dramatically rise—7,761 cases, 623 deaths, 31 countries
- June 9: Reported cases slow—8,421 cases, 784 deaths, 32 countries
- July 5: WHO declares the SARS epidemic over.
- Since July 2003: <12 confirmed new cases, including a “second SARS mini-outbreak” in March 2004, started by a young postgraduate student who was working at an institute of virology in Beijing.
- Overall statistics to date:
 - Worldwide: $>9,000$ cases, nearly 1,000 deaths, 29 countries affected
 - US: 134 suspected cases, 19 probable cases, 8 confirmed cases, no deaths, 17 states
- Transmission:
 - Direct or indirect contact of mucous membranes with infectious respiratory droplets or fomites
 - Period of infectivity: Most likely during period with active symptoms (fever, cough)
 - Incubation period: 2–10 days; mean 6 days
 - All cases can be traced to contact with individuals from Asian countries or community, spread from an individual whose illness could be traced to Asia.
 - There have been no suspected SARS cases among casual contacts of the US cases.
 - Many healthcare workers were infected after providing care to SARS patients.
 - No evidence that SARS is transmitted from asymptomatic individuals
 - However, healthcare workers who developed SARS may have been a source of transmission within healthcare facilities during early phases of illness, when symptoms were mild and not recognized as SARS.
 - There is no evidence that SARS can be spread after recovery from the disease.
- Pediatric population:
 - Children pose a lower risk of transmission than do adults; only 1 reported case of transmission of SARS from pediatric patient.
 - Vertical transmission of SARS-CoV from infected mothers to their newborns has not been observed.
 - None of the newborns had clinical, laboratory, or radiological evidence suggestive of SARS-CoV infection.

GENERAL PREVENTION

- Vaccine:
 - Human clinical trials in China continue to show promise for vaccine development.
 - Safety concerns exist, however, for vaccine production workers.
- Hospital infection control precautions:
 - Hospitalized patients meeting SARS case definition should be placed in a negative-pressure, single examination room.
 - Protective equipment appropriate for standard, contact, and airborne precautions (e.g., hand hygiene, gown, gloves, and N95 respirator) in addition to eye protection are recommended for healthcare workers to prevent transmission of SARS in healthcare settings.
- Pediatric patients with potential SARS exposure:
 - Children who have been exposed to an ill individual who is suspected of having SARS, or children who have traveled to an area where SARS is occurring, should be evaluated based on the following:
 - If well, parents should self-monitor the child’s condition for fever or respiratory tract illness. Attendance at child care or school is not restricted.
 - If the child is not well, parents should contact their physician and the child should be isolated at home.
 - If the child is not well and is experiencing breathing difficulty, he or she should be hospitalized. Healthcare workers should be informed before the admission, so SARS precautions can be initiated.
 - Children who have been exposed to individuals who are not ill but have traveled to areas where SARS is occurring do not require isolation.

PATHOPHYSIOLOGY

The virus attaches itself to human receptor cells and initiates a nonspecific acute lung injury response leading to diffuse, severe alveolar damage.

ETIOLOGY

- A previously unrecognized coronavirus (a single-strand RNA virus)
- Coronaviruses are a common cause of mild-to-moderate upper respiratory infections in humans and have occasionally been linked to pneumonia.
- Many believe that the virus originated in an animal species in China, then mutated in such a way that it was able to attach itself to human receptor cells.

DIAGNOSIS

HISTORY

- Recent travel:
 - Travel (including transit in an airport) within 10 days of onset of symptoms to an area with recently documented or suspected transmission of SARS is an important epidemiologic criterion for the diagnosis of a SARS case.
 - At the height of the SARS epidemic, these areas included China, Hong Kong, Singapore, Taiwan, Toronto, and Hanoi.
- Recent contact with a SARS patient:
 - Close contact within 10 days of onset of symptoms with a person known or suspected to have SARS infection is another important epidemiologic criterion.
- The clinical presentation of SARS in children > 12 years of age is similar to that of adults.
- Constitutional symptoms, such as fever, chills, rigors, headache, malaise, myalgias, and diarrhea, are common in older patients.
- One meta-analysis (Stockman et al.) of 6 pediatric case series of 135 SARS cases noted the following symptom prevalence: Fever (98%), cough (60%), and nausea or vomiting (41%).
- Respiratory symptoms:
 - At the onset of illness, most cases have mild respiratory symptoms.
 - After 3–7 days, the onset of a dry, nonproductive cough begins, often with dyspnea that may be accompanied by, or progress to, hypoxemia.

PHYSICAL EXAM

- Fever: The illness generally begins with fever.
- Tachypnea, increased work of breathing, or rales
- Adult patients generally present with evidence of respiratory distress.
- Importantly, however, although some children present with cough or difficulty breathing, many have remarkably normal examinations. Thus, the case definitions above may not be sufficiently sensitive for young children.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Detection of SARS coronavirus: Confirmatory laboratory criteria for the diagnosis of SARS:
 - Antibody by ELISA or indirect fluorescent-antibody assay (IFA)
 - RNA by reverse transcriptase polymerase chain reaction (RT-PCR) assays
 - Viral culture
- SARS virus may be detected in blood, nasopharyngeal aspirates, throat, and stool samples.
- CBC: Hematologic abnormalities are common in children with SARS.
 - Leukopenia (lymphopenia or neutropenia)
 - Thrombocytopenia
- Liver enzymes: Some patients have elevated transaminases.
- Raised serum lactate dehydrogenase is also commonly seen.

Imaging

- The characteristic feature of pulmonary SARS-CoV infection is patchy airspace consolidation predominantly located at the periphery of the lungs and in the lower lobes.
- Many patients, however, have normal chest radiographs.
- Pitfalls: Not searching for alternative diagnoses, even during an epidemic of SARS; other microbiologic studies should still be performed to confirm or rule out other infectious diseases.
 - Not performing convalescent antibody testing in equivocal cases; undetectable antibody > 28 days after onset of illness excludes the diagnosis.

DIFFERENTIAL DIAGNOSIS

- Bacterial infections:
 - Pneumococcus*
 - Staphylococcus*
 - Legionella*
 - Mycoplasma*
 - Chlamydomphila pneumoniae*
- Viral infections:
 - Respiratory syncytial virus
 - Influenza A and B

TREATMENT

IN-PATIENT CONSIDERATIONS

Initial Stabilization

- There is no proven effective treatment.
- CDC currently recommends that patients with SARS receive the same treatment and supportive care that would be used for any patient with serious community-acquired atypical pneumonia of unknown cause.
- Steroids, interferon, ribavirin, oseltamivir, and other antivirals have been used without consistent success.

ONGOING CARE

PROGNOSIS

- Patients 12 years of age and younger:
 - Milder disease
 - Fewer ICU admits
 - Decreased need for supplemental oxygen
 - Less likely to receive methylprednisolone
- No pediatric deaths were reported.
- Overall fatality rate: 11%
 - Highest: 27% (Taiwan)
 - Lowest: 0 (US)

COMPLICATIONS

- Overall, in 10–20% of cases, the respiratory illness was severe enough to require mechanical ventilation.
- In children, only 5% required admission to an ICU, and < 1% required mechanical ventilation.

CODES

ICD9

- 079.82 SARS-associated coronavirus
- 480.3 Pneumonia due to SARS-associated coronavirus

ICD10

- B97.21 SARS-associated coronavirus causing diseases classd elswhr
- J12.81 Pneumonia due to SARS-associated coronavirus

FAQ

- Q: Is the clinical presentation and course different in children?
- A: Fortunately, younger children tend to have a shorter and milder course, consisting mainly of low-grade fever, cough, and rhinorrhea. Adolescents, conversely, follow a more severe course, similar to that of adults.
- Q: What constitutes close contact with a SARS patient?
- A: Close contact includes having cared for or lived with a person known to have SARS, or having a high likelihood of direct contact with respiratory secretions and/or body fluids of a patient known to have SARS.

SEVERE COMBINED IMMUNODEFICIENCY

Michael Keller

Timothy Andrews (5th edition)

BASICS

DESCRIPTION

Severe combined immunodeficiency (SCID) is characterized by onset of severe, life-threatening infections in infancy owing to defects in development or survival of T lymphocytes. It is the most profound form of primary immunodeficiency, and the diagnosis is a medical emergency.

EPIDEMIOLOGY

- Most patients present within the first year of life.
- The most common four molecular defects are:
 - X-linked SCID (IL2-R α): 45% of cases.
 - Adenosine deaminase (ADA) deficiency: roughly 16% of cases
 - Interleukin-7 receptor deficiency: 10%.
 - Janus-associated kinase 3 (JAK3): 7%.

Incidence

- Estimated at: 1 in 50,000–100,000 live births (though may be underestimated due to associated early mortality).
- SCID due to Artemis defects (Anthabascan SCID) occurs in 1 in 2,500 live births in the Navajo population due to a founder mutation.

Genetics

- X-linked and autosomal recessive inheritance
- Digeorge syndrome is autosomal dominant, but only a very rare subset of these patients has complete athymia and SCID.
- See table in Section VI

ETIOLOGY

- Results from defects in signaling pathways required for development or survival of T lymphocytes. These include:
 - DNA repair mutations preventing VDJ recombination (RAG1/2, Lig4, Artemis)
 - Defects in IL2/7 signaling pathway (X-linked SCID, IL-7Ra, JAK3)
 - Athymia (Digeorge syndrome)
 - Accumulation of metabolites toxic to lymphocytes (ADA, PNP deficiency)

DIAGNOSIS

HISTORY

- Patients present with both severe illnesses due to common infections (chronic rotavirus, adenovirus, influenza, oral candidiasis), and opportunistic infections (pneumocystis, CMV).
- Chronic diarrhea and failure to thrive are common.
- There may be a family history of early, unexplained deaths, or consanguinity.

PHYSICAL EXAM

- Evaluation should focus on the presence of infection.
- Often an emaciated-appearing infant
- Absent or hypoplastic lymphoid tissue (lack of thymic shadow on CXR, lack of tonsils or lymph nodes).
- Dermatologic evaluation may reveal atypical rashes (morbilliform or eczema-like).

DIAGNOSTIC TESTS & INTERPRETATION

- CBC with differential to assess for degree of lymphopenia; the lower limit normal absolute lymphocyte count in the neonatal period is $>2,800/\text{mm}^3$. Of note, many infants with SCID will still have a normal ALC.
- Lymphocyte enumeration:
 - T lymphocytes (CD3+) are markedly decreased or absent.
 - B lymphocytes (CD20+) and NK cells (natural killer, CD16/56+) vary on the basis of the type of SCID (see table in section VI).
- Mitogen and antigen stimulation tests (T/B-cell functional assays) are markedly decreased or absent.
- Immunoglobulin levels are usually low or absent, although patients can have normal IgG levels in the first few months of life owing to transplacentally derived maternal IgG.

- TRECs: T-cell recombination excision circles are a reflector of lymphocyte recombination and thymic output. They are used in prenatal screening (presently in WI, MA, and NY), and are uniformly absent in SCID. They are run off of a standard Guthrie blood spot card. Of note, they are known to be decreased in premature infants, but not to the degree seen in SCID (<30 copies/reaction).
- Appropriate cultures to identify pathogens

DIFFERENTIAL DIAGNOSIS

- Reticular dysgenesis
- Bone marrow or thymic infiltrative processes (hematologic or other malignancies).
- HIV infection
- Iatrogenic immunodeficiency

TREATMENT

ADDITIONAL TREATMENT

General Measures

- Bone marrow transplant is the definitive treatment in most cases. Because of the underlying lack of T-cell function, preconditioning (chemotherapy) is not strictly required, though reduced-intensity conditioning is often given to attempt to ensure complete engraftment.
- Aggressive and early specific antibiotic/antifungal/antiviral therapy for infections
- *Pneumocystis carinii* prophylaxis
- If required, patients should receive only irradiated, leukocyte reduced blood products. There is a risk of graft versus host disease owing to viable donor leukocytes that may survive in nonirradiated products.
- IV immunoglobulin replacement: This may be required even after bone marrow transplant because of variable B-lymphocyte reconstitution.
- Enzyme replacement therapy has been used in adenosine deaminase-deficient patients.
- Gene therapy has been successful in clinical trials for X-linked and ADA forms, though development of vector-associated leukemia remains a major concern.

ONGOING CARE

- Close monitoring of clinical status should be done before bone marrow transplant. This may be every 2–4 weeks, depending on the patient's status.
- The posttransplant course is variable:
 - Overall success rate for matched bone marrow transplant in severe combined immunodeficiency is > 70%, and is highly dependent on the age and health of the patient at transplantation, and the type and degree of matching of the graft. Success in early transplants (<2 months old) has been reported to be as high as 95%.
 - Patients should still be followed closely for signs of infection, graft failure, and graft versus host disease.

COMPLICATIONS

- Untreated, nearly all patients will succumb to infection prior to 2 years of age.
- Graft versus host disease may result from maternal T cells that cross into fetal circulation or from transfusion of nonirradiated blood products.
- Omenn syndrome is an autoimmune phenomenon caused by clonal, autoreactive T-cells, and resembles graft-versus-host disease. It occurs most commonly in patients with RAG1/2 mutations.
- Clinical disease can be caused by live vaccines in previous undiagnosed severe combined immunodeficiency patients (including BCG or rotavirus).
- Increased risk of hematologic malignancy (30×)
- Radiation sensitivity is present in forms of SCID caused by DNA repair defects (Artemis, Ligase-4, DNA-PKcs, Cernunnos).

ICD-9 CODES

ICD9

279.2 Combined immunity deficiency

ICD10

- D81.0 Severe combined immunodeficiency with reticular dysgenesis
- D81.1 Severe combined immunodeficiency w low T- and B-cell numbers
- D81.9 Combined immunodeficiency, unspecified

FAQ

- Q: How should children with severe combined immunodeficiency be managed before bone marrow transplant?
- A: Children suspected to have severe combined immunodeficiency should be isolated from potential sources of infection. They should not attend public places, and should be kept away from any relatives who are ill. Prophylactic antibiotics to prevent opportunistic infections such as *pneumocystis* are usually given, and replacement of immunoglobulin is also commonly provided prior to transplant.

- Q: Should patients with severe combined immunodeficiency receive live viral vaccines?
- A: Live viral vaccines are contraindicated in severe combined immunodeficiency. Patients suspected of severe immunodeficiency should not receive live viral vaccines until their immunodeficiency is defined. If the patient is receiving IV immunoglobulin therapy, vaccinations are not required. In addition, siblings of patients with severe combined immunodeficiency who live in the same household should generally not receive live viral vaccines because of the risk of viral shedding in the siblings.
- Q: What is the chance of another child being affected with severe combined immunodeficiency?
- A: The risk of another child being born with severe combined immunodeficiency in a family with a previously affected child will depend on the type of SCID, and would depend on whether a mutation is de novo or transmitted. A mother who carried the gene for X-linked SCID would have a 50% chance of an affected male or carrier female; autosomal recessive causes would carry a 25% chance of an affected child. Genetic counseling should be offered to female carriers of X-linked severe combined immunodeficiency.
- Q: Can SCID be diagnosed prenatally?
- A: Prenatal testing is available. Amniocentesis can be performed, and fetal cells can be tested for known genetic cause of severe combined immunodeficiency.
- Q: Can SCID be screened for via newborn testing?
- A: Newborn testing is done in several states (WI, NY, MA) via analysis of TRECs from Guthrie blood spot cards (see Tests above). TRECs can also be sent electively in other states.

SEXUAL ABUSE

Sarah M. Frioux

Cindy W. Christian

BASICS

DESCRIPTION

Sexual abuse is the involvement of children in sexual activities that they cannot understand, for which they are not developmentally prepared, to which they cannot give informed consent, and/or that violate societal norms.

- Associated problems:
 - Physical abuse
 - Domestic violence
 - Neglect
 - Emotional abuse
- Pitfalls:
 - Failing to consider sexual abuse in the differential diagnosis of nonspecific behavioral and physical complaints

EPIDEMIOLOGY

- Children of all ages may be victimized, with a peak age of vulnerability between 7 and 13 years.
- Girls are victimized more than boys, although abuse of boys is thought to be underreported. Boys represent ~20% of cases reported to child protection agencies.
- Race and socioeconomic status are not believed to play a role in the epidemiology of sexual abuse.

Incidence

~150,000 substantiated cases are identified each year in the US. This is likely to be a significant underestimation of the actual numbers.

DIAGNOSIS

HISTORY

- The physician interview should be detailed enough to know whether a report to child protection or law enforcement is needed, especially if it is the first professional interview of the child:
 - Prior to the examination, however, the child may have been interviewed by the police, social service workers, or a forensic interviewer.
- The interview should be conducted with the child separate from family members; diagnosis often depends on the history obtained from the child.
- Ask open-ended, nonleading questions.
- Use developmentally appropriate language.
- Special questions:
 - Identity of alleged perpetrator/relationship to child
 - Time of last possible contact
 - Method of disclosure
 - Specific types of sexual contact included in the abuse
 - Previous official reports of the abuse
 - Review of systems including genital pain, bleeding, dysuria, constipation, painful bowel movements, and behavioral changes

PHYSICAL EXAM

- Most sexually abused children have normal genital examinations:
 - The abuse may not have caused injury to tissues.
 - Mucosal injuries heal quickly and may be resolved by the time the child is examined.
- Prepubertal children require detailed external genital inspection only:
 - Genital examination can be done with child in supine frog-leg position.
 - Use of the techniques of labial separation and labial traction will allow complete examination of the vulvar structures.
- Adolescent girls usually do not require a full pelvic examination:
 - Prepubertal girls should not have speculum examination unless anesthesia is used.
- Few physical findings are diagnostic of abuse:
 - These include the presence of semen or sperm, acute genital/anal injuries without an adequate accidental explanation, syphilis, and *Neisseria gonorrhoeae* (excluding perinatal infection).
 - Look for acute genital injuries and marked disruptions in hymenal tissue.
- Many genital findings are unlikely to be related to abuse. These include small labial adhesions, *Candida albicans* dermatitis, erythema of the vestibule, and small mounds or projections on an otherwise normal hymen.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Universal STI screening is not necessary:
 - If child has disclosed high-risk contact or child/parent desires, consider testing for *N. gonorrhoeae*, *Chlamydia trachomatis*, *Trichomonas vaginalis*, syphilis, hepatitis B virus infection, and HIV.
- Testing for *N. gonorrhoeae* and *C. trachomatis* may be performed with vaginal/urethral culture or nucleic acid amplification techniques (NAATs):
 - Cultures have historically been the gold standard method for diagnosing STIs in prepubertal children. Recently, NAAT has proven to be sensitive and specific for *N. gonorrhoeae* and *C. trachomatis* infection in this age group.
 - Be familiar with your laboratory's methods of identification and confirmation. Some labs no longer process cultures for these pathogens.
- The unestrogenized hymen is very sensitive; therefore, great care should be taken when inserting a swab through the hymenal opening. Allow 10–15 seconds for swabs to absorb secretions:
 - Cultures for *N. gonorrhoeae* from rectum, vagina (prepubertal), cervix (adolescent), penile urethra, and/or throat; misidentification of *N. gonorrhoeae* can be a problem if confirmatory tests (e.g., sugar fermentation, latex agglutination) are not properly done.

- Chlamydia cultures from rectum, vagina (prepubertal), cervix (adolescent), and/or penile urethra; obtain cells for chlamydia culture by gently scraping the vaginal wall with a swab (in young children).
- NAAT has higher sensitivity than culture. Repeat NAAT should be performed prior to treatment to confirm infection in young children.
- Rapid plasma reagin (RPR), hepatitis B serology, HIV, if indicated
- Forensic evidence collection (for an acute assault)

Diagnostic Procedures/Other

- The labial traction technique (gently grasping the posterior portion of the labia majora and pulling laterally, down, and toward the examiner) allows for the best visualization of the hymenal edges.
- When available, the use of colposcopy is generally recommended for purposes of magnification and photodocumentation of the examination.

DIFFERENTIAL DIAGNOSIS

- Infection with genital discharge:
 - *N. gonorrhoeae*
 - *C. trachomatis*
 - *T. vaginalis*
 - Group A streptococcus
 - *Haemophilus influenzae*
 - *Staphylococcus aureus*
 - *Corynebacterium diphtheriae*
 - *Mycoplasma hominis*
 - *Gardnerella vaginalis*
 - *Shigella flexneri* (discharge may be bloody)
- Infection with genital bleeding:
 - UTI
 - Vulvovaginitis
- Infection with genital inflammation/pruritus:
 - STIs
 - Pinworms
 - Scabies
 - *C. albicans* (in pubertal girls)
 - Group A streptococcal vulvovaginitis or perianal cellulitis
- Trauma:
 - Accidental trauma, including straddle and impaling injuries
 - Mechanical friction from tight clothing or obesity
 - Accidental tourniquet of genitals by hair
- Congenital:
 - Variations in hymenal configuration (septated, cribriform, microperforate, imperforate hymens)
 - Urethral caruncles; vestibular bands
 - Ectopic ureterocele; hemangiomas
 - Syndromes associated with anogenital anomalies
- Psychosocial:
 - Normal behaviors (masturbation, playing doctor)
 - Exposure to sexual activity (e.g., in which the child witnesses sexual acts)
 - False allegations of sexual abuse

- Dermatologic:
 - Contact dermatitis
 - Seborrhea
 - Diaper dermatitis
 - Lichen sclerosis et atrophica
 - Balanitis xerotica
 - Nevi
- Miscellaneous:
 - Nonspecific vulvovaginitis
 - Rectovaginal fistula
 - Labial adhesion (agglutination)
 - Urethral prolapse
 - Phimosis, paraphimosis
 - Foreign body

TREATMENT

MEDICATION (DRUGS)

- Prophylactic antibiotics are effective against common STIs, such as gonorrhea, chlamydia, and trichomonas:
 - Generally not used for prepubertal children, because these infections are uncommon and rarely result in more serious outcomes like pelvic inflammatory disease
 - Prophylaxis against STIs may be considered for acute sexual assaults, stranger assaults, or children with severe genital injuries.
- Identified STIs should be treated with the appropriate regimen according to published guidelines from the Centers for Disease Control and Prevention (CDC).
- Consider pregnancy prevention (e.g., emergency hormonal contraceptive) for adolescents, after ensuring the patient is not pregnant
- Tetanus booster for patients with acute, serious genital or other injuries
- Hepatitis B vaccination for unimmunized patients
- Hepatitis B immune globulin for patients with recent sexual contact with known positive perpetrator
- Sitz baths for comfort

ADDITIONAL TREATMENT

General Measures

- Report suspected abuse to the local child welfare agency.
- Report suspected sexual abuse to law enforcement.
- Consult a social worker.
- Inform the parents of the report.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Cases will be investigated by child welfare and/or the police.
- Need for foster care placement and/or ongoing supervision is decided by child welfare investigators.
- Most children are referred for short- or long-term counseling.
- Persistent physical/genital complaints may indicate ongoing abuse, an STI, or psychological problems.
- Patient victimizing younger child: Young perpetrators are often victims of previous abuse.

PROGNOSIS

- Varies greatly depending on specifics of abuse sustained, available support systems
- More extensive injuries (e.g., deep lacerations, tears) may take weeks to months to heal.
- The emotional impact of sexual abuse may take years to resolve.

COMPLICATIONS

- STIs, such as gonorrhea, genital warts, *C. trachomatis*, syphilis, HIV, and herpes simplex virus, are identified in only a small percentage of sexually abused children.
- Emotional problems such as posttraumatic stress disorder (PTSD), feelings of helplessness, impaired trust, low self-esteem, depression, adolescent substance abuse, and suicide attempts are seen in some victims of sexual abuse.
- Aggressive, hypersexual, withdrawn behavioral problems may be consequences of having been abused.

FAQ

- Q: What does “intact hymen” mean?
- A: “Intact hymen” is not a medical term and should be avoided in describing the medical examination of the genitals. The hymen should be inspected for signs of trauma. There is a wide variation of normal hymenal appearances, and caution should be used in interpreting findings.
- Q: Can there be penetration without physical findings?
- A: Yes. Although full penetration of an erect penis into the prepubertal vaginal canal (through the hymen) will likely leave injury, the healing properties of the vulvar tissues are great, so that past injuries are sometimes difficult or impossible to identify. Furthermore, penetration may be partial (as in vulvar coitus) and may not leave any injuries to the tissue. Physical injuries may not be identified despite a history of penetration.
- Q: Are STIs always transmitted sexually?
- A: No. All STIs may be transmitted vertically (from mother to infant). The incubation periods of different infections vary, so they are expressed at different ages accordingly. Casual transmission of STIs is postulated for some organisms, but not for others. Gonorrhea and syphilis are considered diagnostic of sexual abuse outside of congenital infection. Chlamydia, herpes simplex virus 2, and trichomonas are probably due to sexual abuse and should be reported for evaluation. Condyloma acuminata is probably related to sexual abuse in school-aged and older children but may be transmitted to younger children innocently during toileting or diaper changes. Nevertheless, children presenting with condyloma should be referred for evaluation. Herpes simplex virus type 1 and bacterial vaginosis are nonspecific infections that are not usually related to sexual abuse. Candida is unlikely to be related to sexual abuse.
- Q: How often do sexually abused children have physical evidence of the abuse?
- A: In most cases, there are no specific physical indicators of abuse.

SEXUAL AMBIGUITY

J. Nina Ham

Lorraine E. Levitt Katz

BASICS

DESCRIPTION

Genitalia can be defined as ambiguous when it is not possible to categorize the gender of the child based on outward appearances.

- “Disorders of sexual development” (DSD) is the preferred terminology to replace terms such as “intersex,” “hermaphroditism,” or “pseudohermaphroditism,” which are perceived as pejorative by patients:
 - Preferred terms include 46XX DSD; 46XY DSD; ovotesticular DSD; 46XX testicular DSD; and 46XY complete gonadal dysgenesis.
 - These represent general categorizations, however, and when available, specific diagnoses are preferable.
- Pitfalls: Girls with congenital adrenal hyperplasia (CAH) may appear quite virilized at birth and be mistaken for boys. Nevertheless, they have good female reproductive potential with adequate control of their disease and should be assigned a female sex.

EPIDEMIOLOGY

- CAH is the most common cause of sexual ambiguity, with a worldwide incidence of 1/10,000–20,000.
- Disorders causing sexual ambiguity occur congenitally, and the time of presentation is the newborn period. Children with 5 α -reductase deficiency demonstrate virilization with puberty.

RISK FACTORS

Genetics

- CAH is caused by defects in the genes encoding adrenal steroidogenic enzymes. It follows an autosomal recessive inheritance pattern:
 - The most common form is 21-hydroxylase deficiency (due to mutations in the gene CYP21A).
 - Sexual ambiguity can also be seen in defects in 17-hydroxylase (CYP17), 3 β -hydroxysteroid dehydrogenase (HSD3B2), 17-ketosteroid reductase (HSD17B3), and 11 β -hydroxylase (CYP11B1).
 - Congenital lipoid adrenal hyperplasia has been associated with defects in steroidogenic acute regulatory protein (StAR) and, less commonly, cholesterol desmolase.
- Gonadal dysgenesis is associated with chromosomal aberrations.
- Syndromes of gonadal dysgenesis can also arise from mutations in the Wilms tumor suppressor gene (WT-1), steroidogenic factor 1 (SF-1), sex-determining region Y (SRY), and the SRY homeobox gene SOX9.
- 5 α -Reductase deficiency is an autosomal recessive disorder that manifests only in genetic males.
- Androgen resistance syndromes are due to defects in the androgen receptor gene, located on the X chromosome. Thus, inheritance follows an X-linked recessive pattern.

GENERAL PREVENTION

- Avoid the use of androgenic steroids during pregnancy.
- Prenatal diagnosis of CAH and maternal steroid treatment to prevent virilization of female fetuses is possible, but is still best considered on a research basis.

PATHOPHYSIOLOGY

- 46XX DSD:
 - Masculinization of the female fetus is usually caused by androgens produced by the fetus or transferred across the placenta from the mother. The most common cause is CAH in which the fetal adrenal glands overproduce androgens in an attempt to correct cortisol deficiency.
- 46XY DSD:
 - Incomplete masculinization of the male fetus can be caused by enzyme disorders of testosterone synthesis (e.g., CAH and 5 α -reductase deficiency), unresponsiveness to testosterone action (androgen insensitivity syndromes), or defects in testicular development (complete or partial gonadal dysgenesis).
- Ovotesticular DSD:
 - Includes patients with both ovarian and testicular elements. These patients can be 46XX/46XY (chimeric) or 45X/46XY (mixed gonadal dysgenesis).
 - Phenotypically, individuals may exhibit a range from female external genitalia to ambiguous to normal male.
- Gonadal dysgenesis:
 - Partial dysgenesis of the gonads following differentiation into testes will result in a spectrum of abnormalities ranging from phenotypically female external genitalia with the absence of müllerian structures to micropenis or cryptorchidism.
 - Mixed gonadal dysgenesis: Individuals with the mosaic genotypes XO/XY and XX/XY have gonads containing both ovarian and testicular elements and external genitalia ranging from normal female to ambiguous to normal male.

DIAGNOSIS

Ambiguous genitalia in the neonate should be treated as an emergency, and the diagnostic evaluation undertaken as soon as possible.

HISTORY

Obtain a careful pregnancy and family history addressing:

- Drug ingestion
- Exposure to teratogens
- Infections during the pregnancy
- Androgenic changes in the mother
- Family history suggestive of CAH

PHYSICAL EXAM

Notable features:

- Palpable gonads: Imply the presence of Y-chromosome material
- Fusion of the labia
- Existence of a vagina
- Position of the urethra
- Length and diameter of the penis or clitoris
- Development of the scrotum
- Other dysmorphic features
- Hypertension is seen with 17 α -hydroxylase and 11-hydroxylase deficiencies.
- Features of the classic disorders of adrenal steroidogenesis

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Specific tests:
 - Karyotype
 - Steroid levels: 17-hydroxyprogesterone, 17-hydroxypregnenolone, dehydroepiandrosterone (DHEA), testosterone, dihydrotestosterone (DHT), 11-deoxycortisol, androstenedione
 - In the case of suspected CAH, ACTH-stimulated values may aid in diagnosis.
- Nonspecific tests: Electrolytes: Hyponatremia, hyperkalemia, and metabolic acidosis are associated with several adrenal enzyme deficiencies.

Imaging

- Pelvic ultrasound
- Urethrogram

DIFFERENTIAL DIAGNOSIS

- Gonadal dysgenesis:
 - Partial dysgenesis of the gonads
 - Mixed gonadal dysgenesis
 - Ovotesticular DSD
- 46XX DSD:
 - CAH: Inherited adrenal enzymatic defects, including 21-hydroxylase, 11-hydroxylase, and HSD3B2 deficiencies can cause virilization of females.
 - Maternal androgen exposure
 - Exogenous androgens or endogenous production (e.g., maternal virilizing tumor)
 - Multiple congenital anomalies
 - Ambiguous genitalia can be a part of a spectrum of congenital anomalies, especially those of the urologic system and rectum.
 - Idiopathic
- 46XY DSD:
 - CAH: Deficiencies in HSD3B2, 17 α -hydroxylase, StAR protein, and cholesterol desmolase result in insufficient androgen synthesis potentially causing undervirilization of boys:
 - 5 α -Reductase deficiency prevents the conversion of testosterone to DHT, which is necessary for the development of the male external genitalia.
 - Syndromes of androgen resistance are due to abnormalities in androgen receptor or postreceptor defects. Patients with incomplete forms of androgen resistance may present with sexual ambiguity.
- Multiple congenital anomalies
- Idiopathic

TREATMENT

ADDITIONAL TREATMENT

General Measures

- Treatment of CAH:
 - Acute salt-wasting adrenal crisis
 - Volume resuscitation with 5% dextrose in normal saline (D5NS)
 - Chronic management of CAH consists of cortisol replacement 12–25 mg/m² per 24 hours divided as q8h and fludrocortisone 0.05–0.3 mg/d.
- Counseling of families

SURGERY/OTHER PROCEDURES

Surgery may be necessary so that the sexual phenotype and gonads are consistent with the gender assignment. Dysgenetic testes and ovaries should be removed.

IN-PATIENT CONSIDERATIONS

Initial Stabilization

- Gender assignment: The results of the diagnostic evaluation should be available within 48–72 hours. Parents should be counseled that the diagnostic information as well as surgical factors, prediction of hormone function, and potential for fertility will be taken together as a whole. Gender assignment should be made through a multidisciplinary team approach with consultations from endocrinology, urology, genetics, psychiatry/psychology, and social work.
- Treatment of CAH:
 - Acute salt-wasting adrenal crisis
 - Volume resuscitation with D5NS
 - Stress hydrocortisone 25–50 mg IV immediately after the serum studies are drawn. This should be followed by 100 mg/m² per 24 hours of hydrocortisone intravenous divided q4h.
 - Hydrocortisone is gradually tapered over the next few days.
 - Fludrocortisone 0.05–0.3 mg/d when able to take PO

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Hormone replacement therapy at puberty may be necessary.
- Long-term follow-up may involve monitoring hormone levels, linear growth, and sexual development.

PROGNOSIS

The cosmetic outcome from surgery is usually good. The potential for gender-appropriate sexual function is usually good with therapy. The potential for reproductive function depends on the diagnosis. Long-term studies of psychological adjustment are under way.

COMPLICATIONS

- 21-Hydroxylase-, HSD3B2-, and StAR protein-deficient forms of CAH are associated with mineralocorticoid deficiency and consequent life-threatening salt-losing adrenal crises presenting in the 1st 2 weeks of life.
- CAH is also associated with cortisol deficiency, requiring emergent and chronic cortisol replacement.
- Dysgenetic testes and ovaries have an increased risk of malignant degeneration and should be removed.
- An incorrect or hastily made sexual assignment can cause family members additional emotional stress.

CODES

ICD9

- 255.2 Adrenogenital disorders
- 259.8 Other specified endocrine disorders
- 752.7 Indeterminate sex and pseudohermaphroditism

ICD10

- E25.0 Congenital adrenogenital disorders associated with enzyme deficiency
- Q56.0 Hermaphroditism, not elsewhere classified
- Q56.4 Indeterminate sex, unspecified

FAQ

- Q: Should a child's sex assignment be consistent with the karyotype?
- A: In the past, surgery was performed when the team decision focused on sexual function potential. Recently, there is a trend to raise the child consistent with the karyotype. This is a major decision that should involve the family and the treatment team.
- Q: What clues can the physical exam give to the timing of in utero events causing sexual ambiguity?
- A: In the virilized female, labioscrotal fusion results from androgen exposure prior to 12 weeks' gestation. Thereafter, androgen exposure can cause only clitoromegaly.

SEXUAL PRECOCITY

Andrew C. Calabria

Andrea Kelly

Rachana Shah (5th edition)

BASICS

DESCRIPTION

- Sexual precocity has traditionally been defined as physical signs of sexual development before age 8 years in girls and age 9 in boys.
- Recently, new guidelines were proposed for lowering the age considered to be normal for sexual development in girls:
 - Signs of puberty as young as age 7 in white girls and age 6 in black girls may be normal.
 - These new guidelines have not been universally adopted.
- The entire clinical picture, including rate of progression and the presence of neurologic symptoms, must be taken into account.

EPIDEMIOLOGY

- Precocious puberty is 5–6 times more common in girls.
- 80–90% of affected girls have idiopathic central precocious puberty.
- Precocious puberty in boys is more likely to be associated with underlying pathology.
- ~50% of affected boys have idiopathic central precocious puberty.
- Increased incidence seen in internationally adopted children and in children born premature or small for gestational age

Incidence

Precocious puberty occurs in 1 in 5,000 children

Genetics

- Familial male precocious puberty (testotoxicosis): Sex-limited, autosomal dominant inheritance of activating mutation in the luteinizing hormone (LH) receptor
- McCune–Albright syndrome: Sporadic, postzygotic, somatic mutation in the stimulatory subunit of G-protein receptor; precocious puberty more common in girls

PATHOPHYSIOLOGY

- Central precocious puberty can be associated with CNS disorders
- Peripheral precocious puberty arises from peripheral sex hormone sources, including gonadal and adrenal disorders, abdominal or pelvic tumors, or exogenous sex steroids.
- Peripheral precocious puberty can progress to central precocious puberty due to maturation of the hypothalamic–pituitary axis by sex steroids.

ETIOLOGY

Central precocious puberty (gonadotropin-releasing hormone [GnRH]–dependent):

- Associated with gonadotropin (LH and/or follicle-stimulating hormone [FSH]) levels that are elevated beyond the normal prepubertal range. Results from activation of hypothalamic–pituitary–gonadal axis.
- Peripheral precocious puberty (GnRH-independent): Gonadotropin-independent elevation of sex steroids arising (i) directly from gonads and/or adrenals, (ii) through stimulation of gonads by GnRH-independent mechanism, or (iii) from an exogenous source

DIAGNOSIS

SIGNS AND SYMPTOMS

- Careful chronology of physical changes, growth spurt, onset of menses
- Presence of neurologic, visual, or behavioral changes to suggest a CNS lesion

HISTORY

Family history of early puberty or hyperandrogenic disorders (e.g., congenital adrenal hyperplasia)

- Presence of exogenous sex steroids in the home

PHYSICAL EXAM

- Plot accurate height (using wall-mounted stadiometer), weight, and growth velocity. Growth acceleration within the past year may be strong evidence for puberty.
- Carefully stage breasts, color of vaginal mucosa, and pubic hair in girls.
- Carefully stage testicular volume (with Prader gonadometer), penile size, and pubic hair in boys.
- Carefully evaluate for abdominal masses.
- Examine skin for acne and café au lait spots.
- Perform comprehensive neurologic evaluation to assess for possible CNS pathology.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Sex steroids: Estradiol, total testosterone
- Adrenal steroids: 17-OH progesterone, dehydroepiandrosterone sulfate (DHEA-S), androstenedione
- Gonadotropins: FSH, LH (ultrasensitive or immunochemiluminometric [ICMA]-LH most accurate; also listed as “pediatric”)

- Prolactin: May be elevated with CNS tumors
- Thyroid-stimulating hormone (TSH) and free thyroxine (T₄)
- Human chorionic gonadotropin (hCG) levels
- Provocative tests should be done when the aforementioned tests are abnormal or equivocal:
 - GnRH test for central precocious puberty; prepubertal GnRH response is predominantly FSH, whereas pubertal response is predominantly LH
 - Adrenocorticotropic hormone (ACTH) stimulation test for adrenal abnormalities. Exogenous corticosteroid therapy will interfere with ACTH test, but does not interfere with GnRH test of pituitary–gonadal axis.

Imaging

- Bone age: If advanced, further studies are warranted, guided by history and physical examination. If not advanced, or if the patient has only mild breast or pubic hair development (but not both), premature thelarche or premature adrenarche, respectively, is the most likely diagnosis.
- MRI of head: As indicated by history, physical examination, and laboratory tests; almost always done in boys because they are much less likely than are girls to have idiopathic sexual precocity
- Ultrasound of gonads/adrenals: As indicated by examination and studies. Look for tumors in both sexes; in girls, ultrasound can also evaluate development of ovaries and uterus.

ALERT

- Obese children often have advanced bone age.
- Palpation of breast tissue (buds) can be difficult due to adiposity.

DIFFERENTIAL DIAGNOSIS

- Causes of central precocious puberty:
 - Often idiopathic (girls more often than boys)
 - Any cause of peripheral precocious puberty
 - Tumors:
 - CNS tumors
 - Hypothalamic hamartoma: Most common CNS mass to cause precocious puberty; benign (nonprogressive), congenital malformation of neurons that secrete GnRH
 - Hypothalamic–chiasmatic glioma: Often associated with neurofibromatosis
 - Astrocytoma
 - Ependymoma

- Post-CNS trauma or damage:
 - Surgery
 - Radiation: May occur after 18-Gy exposure
 - Hydrocephalus and other CNS malformations
 - Infection: Brain abscess, meningitis, encephalitis, granuloma. Lesions may result in stimulation or lack of inhibition of the GnRH-secreting area of the hypothalamus, resulting in early activation of the pituitary
- Mimickers of central precocious puberty:
 - Human chorionic gonadotropin-secreting tumors (pineal gland or liver): Ectopic hCG activates LH receptors in testes
 - Severe acquired hypothyroidism: High levels of TSH may cross-stimulate gonadal FSH and/or LH receptors
- Causes of peripheral precocious puberty:
 - Tumors:
 - Gonadal tumors
 - Adrenal tumors
 - Environmental: Exogenous estrogens (creams and oral forms) and/or exogenous androgens (anabolic steroids or testosterone formulations)
 - Congenital adrenal hyperplasia: Poorly controlled CAH can activate the hypothalamic–pituitary–gonadal axis in either gender
 - Severe acquired hypothyroidism: High levels of TSH may cross-stimulate gonadal FSH and/or LH receptors.
 - McCune–Albright syndrome: Triad of precocious puberty, café au lait spots, and polyostotic fibrous dysplasia
 - Familial male precocious puberty (familial testotoxicosis)
 - Refeeding after severe malnutrition during early development (such as adopted children who had kwashiorkor)
- Incomplete pubertal development:
 - Premature thelarche
 - Premature adrenarche

TREATMENT

MEDICATION (DRUGS)

- Central precocious puberty: GnRH agonists are the treatment of choice. Adjunctive therapy with growth hormone may improve final adult height.
- Calcium supplementation may preserve bone mass accretion during GnRH agonist therapy.
- Peripheral precocious puberty: Aromatase inhibitors and antiandrogens (spironolactone or ketoconazole). Glucocorticoids for congenital adrenal hyperplasia

ONGOING CARE

- When to expect improvement:
 - Depends on cause. For example, sexual changes of McCune–Albright syndrome are due to autonomously functioning ovarian cysts, which regress variably over time.
 - Treatment of central precocious puberty with a GnRH agonist usually results in cessation of menses within 2 months, slowing or nonprogression of pubertal changes over 4–6 months, and decreased acceleration of bone age within 12 months.
- Typically, GnRH agonists such as leuprolide (Lupron) are administered in a depot form every 28 days. Some children require shortening of the interval, often prompted by reports of moodiness, development of acne, or breakthrough menses. A new longer-acting formulation of leuprolide is now available for every 3 month injection. An 12-month duration implantable formulation (histrelin) is also available.
- The length of treatment is highly individualized but typically continues until the age of normal pubertal onset.

PROGNOSIS

- With treatment, improvement in predicted height may be achieved, but most children do not reach target height predicted by midparental height measurements.
- Earlier treatment results in improved final height.
- Treatment may decrease psychosocial distress.
- Effect of GnRH agonists on fertility has not been fully elucidated.

COMPLICATIONS

- Short stature
- Psychosocial stresses of early puberty

ICD10

E30.1 Precocious puberty

FAQ

- Q: If my child is treated with GnRH agonists, will he/she go through puberty when we stop the medication?
- A: Yes, children on GnRH agonist treatment do proceed through normal puberty when the medication is stopped. Effects on fertility have not been fully studied long-term.
- Q: If my child already has some pubertal changes, can they be reversed?
- A: If GnRH agonists are used, menses will cease, and breast tissue and pubic hair will often regress.

SHORT-BOWEL SYNDROME

Maria R. Mascarenhas

Judith Kelsen

BASICS

DESCRIPTION

Malnutrition, malabsorption, and/or fluid and electrolyte loss after extensive small-bowel resection

PATHOPHYSIOLOGY

- Markedly decreased mucosal surface area due to resection
- Loss of trophic hormones
- Loss of peptide hormones that regulate motility
- Abnormal transit
- Malabsorption of protein, fat, carbohydrate, vitamins, electrolytes, and trace elements, depending on site of resected intestine (see “Follow-Up”). The patient can lose as much as half of the intestine if the duodenum, distal ileum, and ileocecal valve (ICV) are present. If the ICV is gone, patients may not be able to tolerate even a 25% loss of intestine without the help of total parenteral nutrition (TPN).
- Normal bowel length: 150–200 cm (26 weeks gestation); 200–300 cm (at birth in full-term infant); 600–800 cm (adult)
- Infants have no intestinal reserve and do not tolerate small-bowel resection as well as do adults. However, long-term prognosis may be better because of hypertrophy and hyperplasia of the intestine.
- Gastric acid hypersecretion occurs soon after intestinal resection, but is transient.
- Bowel adaptation can occur over time. Increased surface area due to bowel dilatation, villus hypertrophy, and bowel lengthening can occur. Stimulation of luminal contents is needed for bowel growth and factors such as glutamine, short-chain fatty acids, tropic hormones, and growth factors may be important for bowel growth.

ETIOLOGY

- Infants: Intestinal resection for necrotizing enterocolitis
- Congenital anomalies include intestinal atresias, gastroschisis, omphalocele, apple peel syndrome, and meconium ileus.
- Malrotation may result in volvulus with bowel resection secondary to ischemic injury.
- Older children: Neoplasms and radiation enteritis
- Intestinal resection secondary to Crohn disease, trauma, pseudo-obstruction syndrome

DIAGNOSIS

HISTORY

- Stooling pattern: Number, size, nature (watery, bulky, foul smelling), presence of blood and mucus
- Weight loss or gain: Gaining length/height
- Abdominal distention and flatulence
- Intense perianal rashes related to stool acidity and malabsorption of carbohydrates
- Abdominal pain and characteristics
- Vomiting and characteristics
- Diet history: Appetite, oral intake, tube feeds, parenteral nutrition (PN)
- Medication history
- Surgical history

PHYSICAL EXAM

- Weight, length, and head circumference measurements (if applicable); try to get previous growth chart if available
- Look for signs of vitamin deficiencies in examination of mouth, lips, skin, hair loss, and healing difficulties
- Abdominal examination: Surgical scars, ostomies, distention, hepatosplenomegaly, bowel sounds
- Rectal examination: Consistency of stool, heme positivity, perianal rash

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Stool tests:
 - CBC: Check for anemia and mean corpuscular volume
 - Electrolytes: Check for losses and adequacy of replacement
 - Minerals: Calcium, phosphorus, magnesium, iron; check for losses and adequacy of replacement therapy
 - Albumin and prealbumin: Check for protein stores and nutritional status
 - Prothrombin time/partial thromboplastin time and protein induced by vitamin K absence (PIVKA): Assess vitamin K status
 - A new test known as the PIVKA-II assay is a more sensitive measure of vitamin K status; however, it is more useful in adolescents.
 - Liver function tests: Alanine transaminase (ALT), γ -glutamyl transpeptidase (GGT), bilirubin if on PN to check for TPN-associated liver disease
 - Vitamin levels: Vitamin A, 25-hydroxy vitamin D, vitamin E, folic acid, B12; check for adequacy
 - Zinc level: Check status and adequacy of supplementation
 - Carnitine: Check status if on long-term PN and presence of liver disease
 - Breath tests: Lactose and lactulose breath test to check for lactase deficiency and bacterial overgrowth, respectively

- Stool tests:
 - Stool for pH and reducing substances: Check for carbohydrate malabsorption
 - Stool smear for fat (Sudan stain—qualitative): Check for excessive fat loss
 - Stool for blood: Check for mucosal damage
 - Stool elastase: Measure of pancreatic insufficiency
- Tests of absorption:
 - Xylose absorption test and lactose breath test to check for carbohydrate malabsorption
 - 72-hour quantitative fecal fat collection along with concomitant diet record
 - Carotene levels to check for fat absorption
 - 24-hour stool collection for α -1-antitrypsin clearance to check for protein absorption

Imaging

Upper GI series with small-bowel follow-through and barium enema to evaluate length, caliber, and location of remaining bowel

Diagnostic Procedures/Other

Endoscopy:

- Upper endoscopy: Look for presence of inflammation that may be contributing to malabsorption; get cultures for bacterial overgrowth
- Lower endoscopy: Look for presence of colitis, especially eosinophilic colitis, as well as caliber of anastomotic site if in colon

DIFFERENTIAL DIAGNOSIS

- Infants: Necrotizing enterocolitis, volvulus, atresia (jejunal and ileal), gastroschisis, meconium peritonitis, congenital short-bowel syndrome
- Older children: Mid-gut volvulus (due to malrotation), Crohn disease, adhesions causing intestinal obstruction, strictures, trauma, aganglionosis of the intestine

TREATMENT

MEDICATION (DRUGS)

- Supplementation of vitamin (E, D, K, B12, folic acid) deficiency, calcium, magnesium, iron, and zinc
- H₂-receptor antagonists and proton pump inhibitors decrease gastric acid hypersecretion and reduce gastric secretory volume.
- Antidiarrheal drugs: Codeine, diphenoxylate, and anticholinergic drugs (e.g., loperamide) to decrease motility (caution in patients with slow transit or bacterial overgrowth)
- Ion-exchange resins: Cholestyramine binds intraluminal dihydroxy bile acids to prevent bile acid-induced diarrhea.
- Octreotide/somatostatin: Decreases gastric, pancreatic, and intestinal secretions; slows GI motility and splanchnic blood flow
- Bacterial overgrowth: Commonly used oral antibiotics are metronidazole, trimethoprim-sulfamethoxazole, vancomycin, and gentamicin.

- Prokinetic agents: Reglan to treat delayed gastric emptying
- Miscellaneous: Sucralfate to treat bile reflux, probiotics to treat bacterial overgrowth, ursodiol for cholestasis, Polycitra for electrolyte losses, dietary fiber to enhance absorption-caution in infancy
- Duration of treatment: Depends on amount and site of bowel resected and degree of intestinal adaptation that occurs. The more the resection, the longer is the therapy. Successful enteral feeds decrease the duration of PN. Macronutrient losses decrease with intestinal adaptation. Micronutrient supplementation may be lifelong (e.g., vitamin B12).

SURGERY/OTHER PROCEDURES

- Surgery is useful in patients who develop strictures and partial obstruction or in those who have very short intestine length.
- Intestinal interpositions (isoperistaltic or antiperistaltic) can be used to delay gastric emptying, slow intestinal transit, and increase absorption, intestinal valves, and reversed intestinal segments.
- Intestinal lengthening and tapering procedures, including the Bianchi and step enteroplasty procedures, increase absorptive surface area.
- In patients with extremely short intestines and PN dependency, small-bowel transplantation or small-bowel/liver transplantation is considered.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- When to expect improvement: Depends on site and extent of bowel resection
- Signs to watch for:
 - Vomiting, diarrhea, weight loss, severe fluid and electrolyte abnormalities, sepsis, bowel dilatation, intestinal obstruction
- Major cause of death: Sepsis and cholestatic liver disease

DIET

- Fluid and electrolyte therapy: Extremely important in the acute phase immediately after bowel resection. In the chronic phase, it is important to keep up with ongoing losses, especially when enteral feeds are started.
- Oral diet: In those patients who are able to avoid PN or tube feeds, a low-lactose diet may be well tolerated. Low-oxalate diets are helpful in preventing oxalate stones. In general, a high-calorie diet regardless of carbohydrate and fat composition should be the mainstay of treatment.
- Enteral feeds: More successful in the patient with less extensive resection, intact ICV, and colon in continuity. In extensive loss, feeds initiated after electrolytes are stabilized.
 - Feeds started very slowly, often started with elemental diet to facilitate absorption, and for concern for allergic injury.
 - Enteral feeds stimulate intestinal adaptation. Before 1 year of age formula should have low osmolality: Higher fat content than carbohydrate.
 - After > 1 year of age there is no advantage of elemental formulas over intact formulas with respect to tolerance, unless small-bowel damage is present.

- Enteral feeds are important for development of developmental milestones, with suck and swallow.
- PN: Important in the acute phase postoperatively, when nutrition must be maintained in the face of paralytic ileus; indispensable in the chronic phase when full enteral feeds cannot be instituted and nutrition needs to be maintained.
 - Balanced solutions of protein, glucose, and fat should be administered.
 - Prophylactic measures to prevent PN-induced liver damage should be instituted (e.g., prevention of overfeeding, early introduction of enteral feeds, cycling of PN when patient is stable). If cholestasis is present, it is necessary to modify amount of trace elements in PN.
 - Need permanent central access to deliver concentrated PN solutions
- Intravenous fish-based oil emulsion (composed of omega-3 polyunsaturated fatty acids) has been studied as a preventive measure against PN-associated liver disease with promising results.

PROGNOSIS

- Depends on site and amount of bowel resected
- The greater the amount of bowel resected, the worse is the prognosis.
- Loss of ICV portends a worse prognosis.
- Loss of jejunum and ileum creates a poorer clinical condition than loss of colon.
- The longer it takes to tolerate full enteral feeds in a patient, the worse is the prognosis. Most progress is made in the 1st year after bowel resection.
- Development of severe TPN liver disease: Poor prognosis

COMPLICATIONS

- Fluid and electrolyte loss, resulting in diarrhea, dehydration, and metabolic acidosis
- Calcium and magnesium deficiency, resulting in bone disease and osteoporosis
- Carbohydrate malabsorption
- Fat malabsorption
- Vitamin A deficiency: Increased susceptibility to infections
- Vitamin D deficiency: Bone disease (e.g., rickets)
- Vitamin E deficiency: Peripheral neuropathy, hemolysis
- Vitamin K deficiency: Prolonged clotting time, bruising
- Vitamin B12: Macrocytic anemia and thrombosis
- Folic acid: Macrocytic anemia
- Gallstones: Due to disturbed enterohepatic circulation of bile salts and lithogenic bile formation
- Renal stones: Due to fat malabsorption and increased oxalate absorption
- Failure to thrive
- TPN-dependent liver disease: Cholestasis, end-stage cirrhosis and portal hypertension
- Zinc deficiency: Poor growth, infections
- Carnitine deficiency: Contributes to development of steatosis
- Sepsis
- Small-bowel bacterial overgrowth and D-lactic acidosis due to stasis, causing encephalopathy, ataxia, and other neurologic symptoms

ICD10

K91.2 Postsurgical malabsorption, not elsewhere classified

FAQ

- Q: What are the favorable prognostic factors in short-bowel syndrome?
- A: Poor prognosis is related to the greater length of the bowel resected, loss of the ICV, loss of jejunum and ileum, longer time to tolerate full enteral feeds, and development of severe TPN–liver disease. Neonates have greater chances of bowel adaptation than do adults.
- Q: Are elemental formulas better than intact formulas in the management of patients with short-bowel syndrome in patients > 1 year of age?
- A: Recent studies have shown similar rates of absorption, stomal output, and electrolyte losses between elemental and intact formulas. The disadvantages of elemental formulas include high osmolality and cost.

SHORT STATURE

Jeffrey D. Roizen

Vaneeta Bamba

Mitchell Schwartz (5th edition)

BASICS

DEFINITION

- Growth failure, which ultimately leads to short stature, occurs when height crosses percentiles downwards over the normal growth curves. Evidence of growth failure necessitates diagnostic evaluation even if short stature is not yet present.
- Failure to thrive refers to infants and children who fail to gain weight along their growth percentile curves. They may or may not be short and are underweight for height.
- Idiopathic short stature is defined as height below the 3rd percentile.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Extremes of normal growth:

- **Familial short stature**
 - Normal exam, no systemic illness
 - Short parent(s)
 - Normal height velocity (HV)
 - Normal age of onset of puberty
 - Normal bone age
 - Short stature throughout childhood
 - Final adult height close to the midparental height and around the 3rd or 5th percentile
- **Constitutional short stature/delay of growth**
 - Normal exam, no systemic illness
 - Height percentile below the target range defined by parental heights
 - Delayed bone age
 - Reduced HV (especially in late childhood—below 25th percentile)
 - Associated with delay of puberty, positive family history, usually boys
 - Final adult height in the normal range and commensurate with target height
- **Idiopathic short stature**
 - Categorizes otherwise normal patients who cannot be diagnosed with a variant of normal growth or any of the causes of short stature. May not always turn out to be a true normal variant.
 - This is a diagnosis of exclusion and groups patients whose calculated predicted height is >2 standard deviations (SD) below the midparental height, whose height is below the 3rd percentile, with or without delay of skeletal maturation, and without identifiable diagnosis after appropriate evaluation.

Primary short stature: Usually the consequence of an abnormality of the skeletal system. Bone age often not delayed or only delayed mildly.

- **Skeletal defect:** Can be primary or secondary to a metabolic abnormality. This may lead to disproportionate short stature and/or significant dysmorphism. Occasionally, the skeletal abnormalities are subtle and do not lead to disproportionate short stature.

- **Skeletal dysplasia**
 - Achondroplasia, hypochondroplasia
 - Osteochondrodysplasia
 - Genetic transmission (may be new mutation)
 - Defects in growth of tubular bones and/or axial skeleton
 - Typical radiologic findings on skeletal survey radiograph
- **Short stature due to congenital error of metabolism**
 - Diffuse skeletal involvement
 - Mostly autosomal-recessive inheritance
 - Dysmorphic features
 - Typical biochemical abnormalities
 - More common type (mucopolysaccharidosis)
- **Chromosomal abnormalities**
 - Autosomes or sex chromosomes
 - Usually associated with other somatic abnormalities or mental retardation
 - Clinical findings may be subtle (mosaicism).
 - More common forms: Trisomy 21, trisomy 18, trisomy 13, Turner syndrome
- **Intrauterine growth restriction (IUGR) and small for gestational age (SGA)**
 - Often with poor postnatal growth
 - Etiology may be due to maternal, fetal, or placental problems.
 - IUGR is seen in congenital infection, fetal exposure to toxin, placental abnormalities, maternal disease, Russell–Silver syndrome, and other congenital anomalies.
 - Risk for SGA is increased with maternal cigarette smoking and cocaine use, maternal medical history of chronic hypertension, renal disease, antiphospholipid syndrome, and malaria
 - Patients with SGA have lab values consistent with mild growth hormone (GH) resistance (elevated GH concentrations but low IGF and IGFBP3 concentrations) in the neonatal period.
- **Primordial dwarfism:** Due to intrinsic fetal defect leading to both prenatal and postnatal growth failure (may be associated with specific genetic anomaly)

Secondary short stature:

- **Malnutrition**
 - Especially <2 years of age (most common in first 6 months of life)
 - Caloric (malnutrition and/or protein) malnutrition
 - Vitamin and mineral deficiencies (vitamin D, iron, zinc deficiency)
- **Chronic illness**
 - Many chronic diseases initially present with poor growth.
 - Cardiovascular: Ventricular septal defect, patent ductus arteriosus, tetralogy of Fallot, transposition of the great vessels, aortic stenosis, pulmonic stenosis, aortic coarctation, atrioventricular (AV) canal
 - Pulmonary: Asthma, cystic fibrosis, bronchopulmonary dysplasia
 - GI/liver: Inflammatory bowel disease, celiac disease, malabsorption, short-bowel syndrome, chronic gastroenteritis, cystic fibrosis
 - Renal: Nephrotic syndrome, chronic glomerulonephritis, renal tubular acidosis, chronic renal failure, nephrogenic diabetes insipidus, uropathy, congenital anomalies

- Metabolic: Poorly controlled diabetes mellitus, storage disorders, chronic infections (HIV), and immune deficiencies
- Hematopoietic: Anemia, leukemia, sickle cell disease

Medications

- Corticosteroids
- Sex steroids
- Methylphenidate, dextroamphetamine
- Psychosocial growth retardation
- GH deficiency or resistance, hypothyroidism, Cushing syndrome, adrenal disorder, rickets
- Among secondary short stature, endocrine causes are least frequent.

HISTORY

- **Question:** Child short for their midparental height?
- **Significance:** Gender-adjusted midparental height is calculated to estimate the target height.
 - Calculate mean parental height (MPH)
 - For boys, add 6.5 cm (2.5 inches) to MPH
 - For girls, subtract 6.5 cm (2.5 inches) from the MPH. The 2 SD range for this calculation is 10 cm.
 - If the child's height percentile is dramatically decreased relative to this range, an evaluation may be warranted.
- **Question:** Height velocity?
- **Significance:** HV for an interval of at least 6 months should be annualized and plotted on a HV curve. This is an important measure of a patient's growth and is separate from height at any point in time, which may only reflect prior events. Normal HV is at least 4 cm/year from age 4 to puberty.
- **Question:** Weight-to-height ratio?
- **Significance:**
 - Increased in hypothyroidism, Cushing syndrome, pseudohypoparathyroidism, and GH deficiency
 - Normal or decreased in emotional deprivation, anorexia, and chronic diseases such as chronic renal failure, renal tubular acidosis, inflammatory bowel disease, malabsorption, malnutrition, lung and heart disease
- **Question:** Complications during pregnancy, labor, and delivery?
- **Significance:** Clues from the pregnancy may provide information about possible maternal disorders, intrauterine drug exposure, or placental abnormalities that lead to IUGR and/or SGA. Birth trauma can be associated with hypopituitarism.
- **Question:** Family history?
- **Significance:**
 - Heights of grandparents, siblings, and other relatives?
 - Any family members with short stature? What was the timing of puberty in parents and siblings? Any history of endocrine disorders or chronic illnesses affecting a major organ system?
 - If short stature runs in the family, this may lend evidence to familial or genetic short stature, isolated GH deficiency, or skeletal dysplasia.
 - Delayed pubertal maturation in parents may lend support to a diagnosis of constitutional growth delay.
 - Disorders such as diabetes mellitus, diabetes insipidus, thyroiditis, hypophosphatemic rickets, arthritis, and inflammatory bowel disease can lead to short stature

- **Question:** Social situation?
- **Significance:** Emotional stressors affect growth and development, either directly (abnormal GH production) or indirectly (inadequate nutrition).
- **Question:** Current and past dietary history (evidence of underuse of calories ingested)?
- **Significance:** Estimate approximate total daily caloric intake. Low caloric intake or inefficient use of calories may point to nutritional disorders such as malabsorption, rickets, anorexia, or other calorie restriction.
- **Question:** Chronic illness or any hospitalization, surgery, or head trauma?
- **Significance:** Growth failure may be the only sign of a chronic disorder such as rheumatoid arthritis, celiac disease, and inflammatory bowel disease. Previous hospitalizations or surgery may be a sign of underlying pathology. Chronic inflammation or treatment with exogenous steroids can also lead to growth failure, as in asthma. Head trauma may be cause for pituitary insufficiency.
- The history should be completed by obtaining a detailed review of systems, specifically inquiring about the occurrence of headache, vomiting, visual disturbance, anorexia, diarrhea or constipation, polyuria and polydipsia, medications, activity pattern, sleep hygiene, and general development.
- While boys are more frequently referred for short stature, girls may be more likely to have a pathologic reason for short stature.

PHYSICAL EXAM

- **Finding:** Abnormal upper to lower segment ratio?
- **Significance:** Primary short stature (short stature due to an intrinsic defect in the skeletal system)
- **Finding:** Low weight to height ratio?
- **Significance:** Points toward malnutrition
- **Finding:** Edema?
- **Significance:** Chronic renal failure, malnutrition
- **Finding:** Frontal bossing, flat nasal bridge, and truncal fat deposition?
- **Significance:** GH deficiency
- **Finding:** General dysmorphism?
- **Significance:** Underlying genetic disorder such as Russell–Silver syndrome or 22q11 deletion syndrome
- **Finding:** Abdominal distention and gluteal wasting?
- **Significance:** Malabsorption and celiac disease
- **Finding:** Webbed neck, increased carrying angle, shield chest?
- **Significance:** Turner syndrome
- **Finding:** Abnormal trunk-to-limb ratio?
- **Significance:** Achondroplasia or a mutation in the SHOX gene
- **Finding:** Smooth tongue?
- **Significance:** Iron deficiency
- **Finding:** Round face, ear lobe abnormality, and mental retardation?
- **Significance:** Pseudohypoparathyroidism
- **Finding:** Temporal thinning of the hair, sparse hair, dry hair?
- **Significance:** Hypothyroidism, GH deficiency, hypopituitarism

- **Finding:** Midline abnormalities?
- **Significance:** Hypopituitarism
- **Finding:** Delayed pubertal maturation?
- **Significance:** Turner syndrome, constitutional delay, hypopituitarism, hypothyroidism, inflammatory bowel disease, chronic renal disease
- **Finding:** Leg bowing, rachitic rosary, widening of wrists?
- **Significance:** Rickets, malabsorption

DIAGNOSTIC TESTS & INTERPRETATION

- **Test:** Celiac panel
- **Significance:** May reveal asymptomatic celiac disease
- **Test:** CBC with differential
- **Significance:** Anemia, infection, lymphoma, or leukemia
- **Test:** C-reactive protein and erythrocyte sedimentation rate
- **Significance:** Infection, inflammation
- **Test:** Electrolyte panel, glucose
- **Significance:** Renal disorders, diabetes mellitus, and diabetes insipidus
- **Test:** Metabolic panel
- **Significance:** Malnutrition, liver disease, bone disorder, pseudohypoparathyroidism
- **Test:** Urinalysis
- **Significance:** Urinary tract infection, diabetes, renal disorder, metabolic problem
- **Test:** Thyroxine and thyroid-stimulating hormone
- **Significance:** Hypothyroidism, hypopituitarism
- **Test:** X-ray study of the left hand and wrist
- **Significance:** Bone age determination
- **Test:** Karyotype or genome wide array
- **Significance:** Turner syndrome in short girls, SHOX deletion, other chromosomal disorders
- **Test:** IGF-1 and IGFBP-3 concentrations
- **Significance:** These are a proxy for GH secretion. Unlike GH secretion which is pulsatile and diurnal, IGF-1 and IGFBP3 show little fluctuation, although they vary with age and Tanner stage. While classically IGF-1 and IGFBP-3 are low in GH deficiency, they can also be low in hypothyroidism, chronic illness, or states of poor nutrition. Normal IGF-1 and IGFBP-3 concentrations make GH deficiency less likely.

TREATMENT

ADDITIONAL TREATMENT

General Measures

- Overall goal: Determine if the patient has short stature and/or growth failure. Identify significant changes in weight and head circumference.
- Determine if patient's profile fits normal variant of growth or if profile fits with pathologic short stature.
 - Screening evaluation, referral to pediatric endocrinologist, or observation
 - For endocrine disease, replacement of the absent hormone (thyroid hormone for hypothyroidism, rhGH for GH deficiency, hydrocortisone for adrenal insufficiency) or removal of the excess hormone (removal of the ACTH-secreting or glucocorticoid-secreting tumor or gradual decrease in exposure to glucocorticoid therapy) will enable normalization of growth rate.

ISSUES FOR REFERRAL

- It is critical to obtain accurate measurements of height, weight, and head circumference to adequately evaluate the abnormally growing child.
- Slow growth velocity, plateau in growth, delayed bone age, abnormal thyroid tests, poorly controlled diabetes, physical findings consistent with GH deficiency, hypothyroidism, or rickets
- Protein-losing enteropathy, malabsorption, hepatic disorder
- Chronic lung disease, abnormal sweat chloride test
- Congenital heart disease, occult cardiac disease
- Elevated creatinine, low serum bicarbonate, abnormal urinalysis
- Growth failure is usually a relatively slow or subacute process and therefore does not require emergency workup.

ICD10

- E34.3 Short stature due to endocrine disorder
- R62.52 Short stature (child)

SICKLE CELL DISEASE

Kim Smith-Whitley

BASICS

DESCRIPTION

Sickle cell disease (SCD), a group of inherited hemoglobin disorders in which sickle hemoglobin (HbS) predominates, is characterized by hemolysis, vascular occlusion, and an increased risk of bacterial infection with encapsulated organisms.

EPIDEMIOLOGY

- The frequencies of SCD genotypes from highest to lowest are SCD-SS (60%), SCD-SC (25–30%), SCD-Sβ⁺ thalassemia, SCD-Sβ⁰ thalassemia, and other relatively infrequent variants.
- Although population data indicate that patients with SCD-SS and SCD-Sβ⁰ thalassemia experience more complications than patients with other variants, disease severity varies widely among all individuals with SCD regardless of disease genotypes.

Prevalence

- 1 in 375 African American newborns has SCD.
- 1 in 12 African Americans has sickle cell trait.

RISK FACTORS

Genetics

- SCD has an autosomal recessive inheritance.
- Common genotypes include SCD-SS, SCD-SC, SCD-Sβ⁺ thalassemia, and SCD-Sβ⁰ thalassemia.

DIAGNOSIS

HISTORY

- SCD genotype
- Baseline hemoglobin and reticulocyte count
- Baseline pulse oximetry values (SpO₂)
- Interval history of SCD complications
- Onset of pain, location of pain
- Prior blood transfusions and complications
- Current medications, including analgesics and hydroxyurea

PHYSICAL EXAM

- Fever
- Pallor (may be accentuated at time of splenic sequestration or transient aplastic episode)
- Scleral icterus
- Signs of respiratory distress (due to acute chest syndrome)
- Flow murmur may be present.
- Splenomegaly
- Warmth, tenderness, decreased range of motion at site of pain
- Abnormal neurologic findings suggestive of CNS infarction or hemorrhage

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Diagnostic:
 - Hemoglobin electrophoresis: Definitive test along with DNA analysis
 - Screening test: “Sickledex” or “shake” tests are not recommended to establish a diagnosis or carrier status; do not use for screening in children <12 months of age or those who have been transfused recently, because of false-negative results.
- Monitoring:
 - CBC: Hemoglobin values vary depending on age and SCD genotype; peripheral blood smear—sickled forms, targets, nucleated RBCs, and increased polychromasia are common (sickle forms may be absent in transfused patients, patients with high hemoglobin F levels, or patients with phenotypes other than SCD-SS).
 - Reticulocyte count: Increased
 - Quantitative hemoglobin electrophoresis
 - Chemistry panel: Elevated lactate dehydrogenase (LDH), unconjugated bilirubin, aspartate aminotransferase (AST) (evidence of hemolysis)
 - Transcranial Doppler (TCD) ultrasonography annually to determine stroke risk in children with SCD-SS or Sβ⁰ thalassemia aged 2–16 years
 - Ophthalmologic examinations to screen for retinopathy
 - Neurocognitive testing to detect neurocognitive deficits should be considered.

TREATMENT

General Measures

- Infection prophylaxis with penicillin starting by 2 months of age
- Pneumococcal vaccines (13-valent as per American Academy of Pediatrics [AAP] recommendations and 23-valent at 2 and 5 years of age)
- Meningococcal vaccines (MedImmune and Menactra) as per AAP recommendations
- Routine immunizations, including hepatitis B series and yearly influenza vaccine.
- Consider folic acid supplementation.
- Teach parents to monitor for fever, splenomegaly, pain (including dactylitis), and increased pallor.
- Encourage good oral hydration and supply family with medications to treat uncomplicated painful episodes at home.

COMPLEMENTARY & ALTERNATIVE THERAPIES

- Transfusion therapy can prevent the development of SCD complications and decrease associated morbidity or recurrence of complications when used appropriately:
 - When children with SCD-SS receive erythrocyte transfusions, avoid posttransfusion hemoglobin levels >12 g/dL.
 - Erythrocyte antigen matching for ABO as well as C, D, E, and Kell is recommended.
 - Monitor children carefully for erythrocyte antibodies and/or delayed transfusion reactions.

Measures for Specific Complications

- Fever (rule out sepsis):
 - History, physical exam, CBC, reticulocyte count, blood culture (urine culture, CSF culture, throat culture as indicated by exam)
 - Parenteral antibiotics to provide 24–48-hour coverage until blood cultures are negative
 - Close monitoring for other SCD complications
- Pain (vaso-occlusive episode):
 - Hydration: Avoid excessive hydration and encourage incentive spirometer use for acute chest syndrome prevention.
 - Analgesics:
 - Patients and their families can often tell physicians what therapies have been helpful in the past.
 - In general, for mild pain, start with mild nonnarcotic medications (acetaminophen, ibuprofen) and mild oral opioids (codeine, oxycodone).
 - Consider stronger agents such as oral ketorolac, hydromorphone, and morphine for initial management of moderate pain.
 - For severe pain, use parenteral medications such as morphine, hydromorphone, and ketorolac.
 - Comfort measures (massage, heating pad, warm soaks)
 - Frequent reassessment for pain control and side effects of medications is mandatory.
- Acute chest syndrome:
 - Initial findings: Chest tenderness, cough, hypoxia, fever, infiltrate on chest radiography, leukocytosis, exacerbation of anemia
 - Parenteral antibiotics
 - Pain management
 - Supplemental oxygen for hypoxia
 - Incentive spirometry or chest physiotherapy
 - RBC cell transfusion for moderate to severe illness

- Splenic sequestration:
 - History, physical examination, CBC, reticulocyte count, blood culture as indicated, type, and screen
 - Initial findings: Increased spleen size, acute pallor, shock (if episode severe), anemia, thrombocytopenia, elevated reticulocyte count
 - Sequestration episode may have a more insidious onset or be chronic in nature.
 - Fever management (if indicated)
 - Close, frequent observation of hemoglobin level, reticulocyte count, spleen size, and cardiovascular status
 - Fluid bolus and maintenance hydration
 - RBC transfusion: Avoid transfusing to hemoglobin values > 10 g/dL, as hemoglobin may increase as the episode resolves and RBCs are released from the spleen.
 - Repeated sequestration episodes may be an indication for splenectomy.
- Transient aplastic episode:
 - History, physical exam, CBC, reticulocyte count (blood culture as indicated), type and screen, human parvovirus B19 serology
 - Initial findings: Pallor, tachycardia, absent or low reticulocytes unless recovery phase
 - Fever management (if indicated)
 - Close observation of hemoglobin level, reticulocyte count, and cardiovascular status
 - Respiratory isolation (95% of cases are due to infection with human parvovirus B19)
 - RBC transfusion for evidence of cardiovascular compromise
- Stroke (acute care):
 - History, physical exam, CBC, reticulocyte count, blood culture as indicated, type, and screen
 - Initial findings: Syncope, weakness, numbness, limpness, hemiparesis, seizure, headache, slurred speech, aphasia, somnolence, coma
 - Imaging: Head CT, brain MRI and MRA; consider arteriogram if aneurysm suspected
 - IV fluid bolus and maintenance hydration
 - Supplemental oxygen
 - RBC transfusion (given as simple or exchange transfusion)
 - Supportive (e.g., anticonvulsives)
- Stroke (primary and secondary stroke prevention), chronic care: Monthly RBC transfusions to keep HbS level <30%

ONGOING CARE

PROGNOSIS

Population estimates of life expectancy from 1978–1988 data range from 42–48 years for SCD-SS and from 60–68 years for SCD-SC. However, many believe that early SCD diagnosis (newborn screening), penicillin prophylaxis, comprehensive medical care, hydroxyurea therapy, and broader indications for chronic RBC transfusions (using chelation therapy or RBC exchange to treat transfusional iron overload) may increase life expectancy.

COMPLICATIONS

- Acute:
 - Painful episodes
 - Dactylitis: Painful swelling of hands and feet
 - Bacterial infection:
 - *Streptococcus pneumoniae* in young patients
 - Gram-negative organisms in older children and adults
 - *Salmonella* infections are problematic for patients of all ages.
 - Acute chest syndrome: A pneumonia-like illness defined as a new infiltrate on chest radiography
 - Neurologic: Including stroke (infarctive and hemorrhagic) and transient ischemic attack
 - Acute splenic sequestration: Acute enlargement of the spleen, with a decreased hemoglobin and increased reticulocyte count
 - Aplastic episode: Transient decrease in RBC production characterized by a decrease in hemoglobin and reticulocyte count; human parvovirus B19 is most common cause.
 - Cholecystitis: Risk is greatest after age 10 years.
 - Priapism: A prolonged penile erection, which can be seen in males of all ages
 - Hematuria
- Chronic:
 - Delayed linear growth and puberty
 - Cholelithiasis
 - Retinopathy: Particularly in children with SCD-SC
 - Neurologic: Sequelae of stroke, “silent” cerebral infarction, cerebral vasculopathy, and/or abnormal cerebral blood flow velocity
 - Hypersplenism: Particularly in young children or patients with SCD-SC or SCD-Sβ⁰⁺ thalassemia
 - Avascular necrosis: Particularly of the hips
 - Pulmonary hypertension
 - Renal: Proteinuria, microalbuminuria, nephrotic syndrome, acute glomerulonephritis
 - Pulmonary function abnormalities
 - Primary nocturnal enuresis
 - Leg ulcers

- 282.60 Sickle-cell disease, unspecified

ICD10

- D57.1 Sickle-cell disease without crisis

FAQ

- Q: How long will my baby with SCD live?
- A: No one can predict how long a child with SCD will live. When studies were done on a large number of individuals with SCD almost 2 decades ago, these individuals were living, on average, into their 40s if they had the SS type of SCD and into their 60s if they had the SC type of SCD.
- Q: Is there any “cure” for SCD?
- A: Bone marrow transplantation (BMT) is the only known cure for SCD in children.
- Q: What is hydroxyurea therapy?
- A: Hydroxyurea is a medication that has been shown to reduce the number of painful episodes and acute chest syndrome events in adults with SCD. Hydroxyurea therapy in children > 5 years of age has a similar safety profile to that of adults.

SINUSITIS

Esther K. Chung
Karen P. Zimmer

BASICS

DESCRIPTION

- Sinusitis is inflammation of the mucous membranes lining the paranasal sinuses, but most commonly is used to describe bacterial rhinosinusitis, which is a clinical diagnosis made by the presence of upper respiratory tract symptoms that have not improved in 10 days or have worsened after 5–7 days. Diagnosis of sinusitis should be considered based on persistence and/or severity of symptoms.
- Classification based on duration of symptoms:
 - Acute: Persistent nasal and sinus symptoms for 10–30 days
 - Subacute: Clinical symptoms for 4–12 weeks
 - Chronic: Symptoms lasting at least 12 weeks
 - Recurrent: Acute sinusitis with complete resolution of 10 days between episodes; 3 episodes in 6 months or 4 episodes in 1 year
- Classification by severity of illness:
 - Persistent symptoms: With > 10–14 days but < 30 days; nasal discharge and/or daytime cough
 - Severe: Temperature of > 39°C (102.2°F) with concurrent purulent nasal discharge for 3 days and/or, facial pain, headache, and/or periorbital edema

GENERAL PREVENTION

- Avoid allergen exposure and treat allergies if present.
- Practice daily nasal hygiene through the use of normal saline drops/spray.
- Improve mucociliary clearance by increasing ambient humidity with a humidifier.

PATHOPHYSIOLOGY

- Normal sinus function depends on patency of paranasal sinus ostia, function of the ciliary apparatus, and secretion quality.
- A buildup of secretions is due to ostial obstruction, reduction in ciliary function, and overproduction of secretions.

ETIOLOGY

- Viral pathogens (e.g., rhinovirus, parainfluenza virus) have been recovered in respiratory isolates, but their significance is unknown.
- Most illnesses of short duration (< 7 days) are thought to be from viral infections and should not be treated with antibiotics.
- Bacterial pathogens: Increasing prevalence of penicillin resistance:
 - *Streptococcus pneumoniae* (30–40%)
 - *Haemophilus influenzae*, nontypable (~20–28%)
 - *Moraxella catarrhalis* (~20–28% in children)
 - Group A Streptococci
 - Group C Streptococci
 - Peptostreptococci
 - Other *Moraxella* species
 - *Streptococcus viridans*
 - *Eikenella corrodens*
 - *Staphylococcus aureus*
 - *Pseudomonas aeruginosa* (in patients with cystic fibrosis)
 - Anaerobic organisms
 - Fungal pathogen: *Aspergillus*

DIAGNOSIS

HISTORY

- Some or all of the following may be present:
 - Nasal discharge: consistency, color. In older patients, nasal discharge may not be the primary complaint, but concurrent rhinitis is a common feature.
 - Postnasal drainage, nasal congestion
 - Fever
 - Recent history of an upper respiratory tract infection (URI)
 - Sore throat from mouth breathing due to nasal obstruction
 - Cough present during the day; may be worse at night
 - Malodorous breath
 - Hyposmia/anosmia
 - Maxillary dental pain
 - Ear pressure or fullness
 - Headache and facial pain are uncommon in young children with sinusitis, but may be seen in older children and adolescents
 - Fatigue
 - Irritability
 - Snoring
 - Hyponasal speech

PHYSICAL EXAM

- Fever may be present.
- Nasal-sounding voice may be present.
- Malodorous breath may be noted.
- Purulent drainage in the nose and/or oropharynx may be appreciated.
- Nasal mucosa may be erythematous, pale, and/or boggy.
- Frontal, maxillary, and ethmoid areas may be tender to palpation/percussion.
- Headache and/or facial pain may change with position, increasing in intensity as the patient leans forward.
- Transillumination is not a reliable aid in diagnosis.
- Proptosis, eye swelling, and impaired extraocular movements suggest orbital infection.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- For chronic or recurrent sinusitis, consider:
 - Sweat chloride test to rule out cystic fibrosis
 - Immunoglobulin levels, IgG subclass levels, complement levels, and testing for HIV
 - Mucosal biopsy to assess ciliary function

Imaging

- Imaging is not recommended in uncomplicated cases of sinusitis in children ≤ 6 years of age; and it is controversial in children > 6 years of age.
- Sinus radiographs:
 - Caldwell view (anteroposterior) for identifying frontal sinusitis
 - Waters view (occipitomental) for identifying maxillary sinusitis
 - Plain radiographs do not adequately identify ethmoid sinusitis.
 - Findings suggestive of sinusitis include complete sinus opacification, mucosal thickening ≥ 4 mm, and air–fluid levels.

- CT scans of the paranasal sinuses: Useful in complicated, recurrent and chronic sinusitis; poor response to medical therapy; and/or history of polyposis
- CT scan of the head with contrast: Indicated when sinusitis is accompanied by signs of increased intracranial pressure, meningeal irritation, proptosis, toxic appearance, limited extraocular movements, or focal neurologic deficits, or in patients being considered for sinus-related surgery
- MRI of the sinuses: Reserve for complicated cases; will show mucosal thickening and fluid; imaging modality of choice for fungal sinusitis
- Pitfalls:
 - Sinus radiographs may be abnormal in asymptomatic children or those with mild URIs
 - Studies have shown a relatively high incidence of sinus abnormalities on CT scan in asymptomatic children, especially in infants < 12 months of age. The significance of opacified sinuses in asymptomatic children is not well understood.
 - Up to 1/3 of patients with symptoms of chronic sinusitis may have normal CT scans.

DIFFERENTIAL DIAGNOSIS

- Infection: Viral URI with or without mucopurulent rhinitis
- Environmental: Allergic rhinitis
- Drug-induced: Rhinitis medicamentosa
- Tumors:
 - Nasal polyps
 - Hypertrophied adenoids
 - Neoplasms
- Trauma: Foreign body (e.g., bead, cotton, tissue)
- Congenital:
 - Septal deviation
 - Unilateral choanal atresia
 - Immotile cilia
- Other: Vasomotor rhinitis

TREATMENT

ADDITIONAL TREATMENT

General Measures

- If orbital or CNS infection is suspected by history and examination, antibiotics should be started immediately, and emergency CT studies should be performed.
- Pitfalls:
 - Diagnosis of sinusitis is being made with increasing frequency and may result in overtreatment, given that up to 45% will have spontaneous resolution.
 - With widespread antibiotic use, there are increasing numbers of resistant organisms.

MEDICATION (DRUGS)

- Antibiotics:
 - Appropriate drug choice is dependent on local resistance patterns.
 - High-risk children include: Age < 2 years, antibiotic use within 3 months, and child care attendance

- First-line treatment (no major risk factors): Amoxicillin 45–90 mg/kg/d divided b.i.d. 10–21 days or 7 days symptom-free
- First-line treatment (high-risk children): Amoxicillin/clavulanic acid (80–90 mg/kg/d of amoxicillin component with 6.4 mg/kg/d of clavulanate divided b.i.d. × 10–21 days or 7 days symptom-free
- Second-line treatment: Second-generation or higher cephalosporins (i.e., cefuroxime axetil 30 mg/kg/d divided b.i.d.), macrolides (i.e., clarithromycin 15 mg/kg/d divided b.i.d., azithromycin 10 mg/kg/d on day 1 then 5 mg/kg/d for 4 days)
- Course of therapy is controversial, but treatment to 7 days beyond symptom resolution is generally accepted.
- Complicated sinusitis (CNS or orbital involvement): IV antibiotics and hospitalization; ceftriaxone (100 mg/kg/d divided b.i.d.) or ampicillin-sulbactam (200 mg/kg/d divided q.i.d.); vancomycin (60 mg/kg/d divided q.i.d.) is added to cefotaxime if source of infection is known or highly likely to be caused by penicillin-resistant *Streptococcus pneumoniae*
- Chronic sinusitis: Use a broad-spectrum antibiotic for 4 weeks; amoxicillin/clavulanate (80–90 mg/kg/d of amoxicillin component with 6.4 mg/kg/d of clavulanate divided b.i.d.); macrolides (clarithromycin, azithromycin); or cefuroxime axetil (250–500 mg divided b.i.d.)
- Other pharmaceuticals:
 - Decongestants: These decrease nasal airway resistance and increase ostia patency in some studies, but the overall effect on acute sinusitis is unknown.
 - Topical decongestants should be used only for short-term therapy (5–7 days), because rebound mucosal congestion may occur.
 - Systemic decongestants (e.g., pseudoephedrine) have side effects that include tachycardia, hypertension, jitteriness, and insomnia.
 - Mucolytics, such as guaifenesin, may improve mucous clearance.
 - Topical nasal steroids: May reduce and prevent mucosal swelling, that can lead to ostial occlusion; particularly useful for patients with allergic rhinitis.
- Other:
 - Humidifier: Improves mucociliary clearance
 - Normal saline: Squirt into each nostril daily or b.i.d.; removes sensitizing agents, increases humidity, and enhances mucociliary transport; vasoconstricts, and improves drainage and ventilation.

SURGERY/OTHER PROCEDURES

- Maxillary sinus aspiration: If unresponsive to multiple antibiotics, severe facial pain, and orbital or intracranial complications; should be performed by a trained ear, nose, and throat (ENT) specialist.
- Surgery: Performed as a last resort after medical therapy attempted and in patients with orbital or CNS complications

ONGOING CARE

PROGNOSIS

- Spontaneous resolution in up to 50% of patients
- Usually improves within 72 hours of initiation of antibiotics
- Excellent for those who are otherwise healthy

COMPLICATIONS

- Periorbital cellulitis
- Orbital cellulitis
- Orbital abscess
- Meningitis
- Intracranial abscess
- Optic neuritis
- Cavernous or sagittal sinus thrombosis
- Epidural, subdural, and brain abscesses
- Osteomyelitis of the maxilla
- Osteomyelitis of the frontal bone (Pott puffy tumor)

PATIENT MONITORING

- Immediate referral is indicated if there are CNS symptoms, periorbital edema, visual changes, facial swelling, extraocular muscle involvement, or proptosis
- Radiographic soft tissue changes may last for up to 8 weeks; therefore, reimaging is of limited value.
- Referral to an otolaryngologist when the sinusitis is chronic and not responsive to medical therapy; recurrent; complicated; or when there is polyposis

CODES

ICD9

- 461.9 Acute sinusitis, unspecified
- 473.9 Unspecified sinusitis (chronic)

ICD10

- J01.90 Acute sinusitis, unspecified
- J01.91 Acute recurrent sinusitis, unspecified
- J32.9 Chronic sinusitis, unspecified

FAQ

- Q: Are all of the sinuses present at birth?
- A: No, the maxillary and ethmoid sinuses form during the third and fourth gestational month, and are present at birth. They continue to enlarge until the preteen years. The sphenoid sinuses are pneumatized by 5 years; isolated sphenoid sinusitis is rare. The frontal sinuses are present at age 7–8 years and are not completely developed until late adolescence.
- Q: Does the nasal discharge seen with sinusitis have to be purulent and thick?
- A: No. Although the nasal discharge is often described as purulent and thick, it may also be clear or mucoid, or thick or thin. Multiple studies have shown that a change in color or consistency is not a specific sign of a bacterial infection.
- Q: Are radiographic studies useful in the diagnosis of sinusitis?
- A: There is evidence to suggest that plain radiographs (x-rays) have limited value in the diagnosis of sinusitis, and are not recommended in cases of uncomplicated sinusitis. Mucosal thickening may be seen with viral upper respiratory tract infections and allergic rhinitis. Studies have shown that x-rays do not correlate well with CT scans in the diagnosis of chronic sinusitis.
- Q: Can one make the diagnosis of sinusitis based on CT scan results alone?
- A: No. Up to 50% of patients who had CT scans performed for other reasons had soft tissue changes in their sinuses. Mucosal thickening and opacification on CT imaging have been seen in large numbers of asymptomatic patients. These findings seem to occur more frequently in infants <12 months of age. Given the poor specificity of CT imaging of the paranasal sinuses, results must be used in the context of the patient’s clinical presentation.

SLEEP APNEA—OBSTRUCTIVE SLEEP APNEA SYNDROME

Akinyemi O. Ajayi

BASICS

DESCRIPTION

- Sleep-disordered breathing encompasses a range of breathing disorders occurring during sleep. These conditions include primary snoring (PS), respiratory events related to arousals (RERA), and obstructive sleep apnea syndrome (OSAS).
- Obstructive apnea is defined as the cessation of air flow at the nose and mouth despite respiratory effort, associated with some gas-exchange abnormality and/or loss of regular sleep patterns.
- Distinct from central apnea (cessation of air flow that is not accompanied by respiratory effort), which indicates brain immaturity or dysfunction
- Many children with OSAS exhibit partial airway obstruction. This is known as obstructive hypoventilation or hypopnea and is more commonly seen in children than is complete obstruction.
- OSAS may be subdivided into mild, moderate, and severe forms according to degree of severity.
- Upper airway resistance syndrome is a respiratory disorder characterized by partial airway obstruction and arousals leading to sleep fragmentation, and is not associated with gas-exchange abnormalities.
- In infants, OSAS is uncommon; however, it may exist with craniofacial anomalies, neurologic disorders associated with low muscle tone, laryngomalacia or tracheomalacia, and gastroesophageal reflux.
- Impaired arousal mechanisms also contribute to abnormalities seen in OSAS.
- In older children, OSAS may be associated with obesity. This form may resemble the adult type of OSAS.
- PS or habitual snoring implies snoring that does not lead to abnormalities in gas exchange or sleep fragmentation.
- Central apnea up to 20 seconds may be a normal finding in premature or newborn infants during the first months of life.
- Periodic breathing: 3 or more episodes of central apnea lasting at least 3 seconds each, separated by <20 seconds. Periodic breathing may be found in the newborn; however, it should not exceed >4% of sleep time (from a sleep study) and is not associated with bradycardia or hypoxemia.

ALERT

- Normal-size tonsils do not exclude OSAS.
- Tonsillar size does not predict the presence of OSAS.
- Treatment of gastroesophageal reflux in infants with obstructive apnea may be helpful even in the absence of obvious symptoms of reflux.

Genetics

- Several genetic disorders with associated craniofacial anomalies, hypotonia, and obesity may lead to OSAS. These include:
 - Pierre Robin syndrome
 - Treacher Collins syndrome
 - Down syndrome
 - Mucopolysaccharide disorders
 - Arnold–Chiari malformations
 - Prader–Willi syndrome
 - Hereditary neuromuscular disorders

COMMONLY ASSOCIATED CONDITIONS

- Adenotonsillar hypertrophy
- Craniofacial anomalies including midfacial hypoplasia and mandibular hypoplasia.
- Laryngomalacia
- Neurologic and neuromuscular disorders that cause hypotonia may underlie poor ventilation during sleep.
- Gastroesophageal reflux
- Obesity
- Metabolic disorders
- Allergic rhinitis, nasal septum deviation, nasal polyps
- Sedatives, seizure medications, and anesthesia

DIAGNOSIS

HISTORY

- Nocturnal symptoms include difficulty breathing when asleep, snoring, apnea, and restless sleep with frequent arousals.
- Daytime symptoms: Excessive sleepiness, frequent upper respiratory/ear infections, conductive hearing loss, mouth breathing, poor appetite, and a hyponasal voice
- Other concerns: ADHD, gastroesophageal reflux, poor school performance, and headaches (especially in the morning and upon awakening)
 - OSAS rarely produces these symptoms acutely, but tends to occur over weeks to months.
 - Parents may notice that symptoms worsen with upper respiratory infections.
- The possibility of sleep-disordered breathing or a primary sleep disorder should be considered in children evaluated for attention deficit hyperactivity disorder.

PHYSICAL EXAM

- Assessment of the child's growth. In severe cases of OSAS, failure to thrive has been reported.
- Obesity remains a risk factor, especially in older children.
- Assessment of tonsillar size
- Presence of mouth breathing, hyponasal speech, adenoidal facies, midfacial hypoplasia, retrognathia, micrognathia, or other craniofacial anomalies may be present at times and may suggest the diagnosis.
- Nasal obstruction due to polyps, nasal septum deviation, turbinate hypertrophy, or congestion

- Tongue size
- Mobility and elevation of the soft palate; hard palate integrity
- In extreme cases, cardiac involvement may lead to cor pulmonale and heart failure. Examination may suggest signs of pulmonary hypertension or congestive heart failure, such as an increased second heart sound.
- A neurologic examination to evaluate general muscle strength, tone, and developmental status, especially in infants and children who do not improve after adenotonsillectomy

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Polysomnography:
 - The gold standard for the diagnosis of OSAS is nocturnal polysomnography, to differentiate the type of sleep apnea and to assess severity.
 - Polysomnography is an 8–10-hour-long multichannel study performed in a controlled setting that can assess respiratory and/or sleep abnormalities.
 - Indices such as oxygenation, ventilation, apnea index (AI), apnea hypopnea index (AHI), arousal index, arousal awakening index, and periodic limb movements index are determined along with sleep parameters such as sleep efficiency and sleep stages.
 - Monitoring includes EEG, electro-oculogram, electromyogram, arterial oxygen saturation, end tidal CO₂ tension, air flow, respiratory effort, and EKG.
 - Normative respiratory and sleep variables for children have recently been published and include an apnea-hypopnea index of <1 being normal.
 - Scoring for pediatric polysomnography differs from that of adults. This includes using 2 respiratory cycles to define both obstructive apnea and central apnea or 2 respiratory cycles associated with a 30% decline in airflow and a >4% decline in oxygen level to define hypopnea. Lower AHI values are considered significant in children, compared with adults.
- Other studies:
 - Validated questionnaires are helpful to screen for OSAS in the office.
 - Routine blood work is generally noncontributory; in severe forms, polycythemia, hypercarbia, and elevated bicarbonate may be noted.
 - Evaluation for gastroesophageal reflux may include pH monitoring during sleep, barium swallow, or radionuclide studies (milk scan).
 - Home testing is not approved for use in children with suspected obstructive sleep apnea syndrome

Imaging

- Lateral neck x-ray is easy to perform to assess adenoid and tonsillar size, as well as patency of the nasopharyngeal airway.
- Nocturnal audio- and videotaping, as well as abbreviated nap polysomnography, are useful studies if the results are positive, but generally have a poor negative predictive value.
- Upper airway endoscopy as well as bronchoscopy may be performed to evaluate anatomic or dynamic causes for airway obstruction (pharyngeal hypotonia, pharyngeal stenosis, laryngotracheomalacia, vocal cord polyps, papilloma).

- Head or neck CT or MRI should be considered for complex craniofacial anomalies. If central apnea is noted, then MRI studies should also evaluate the brain stem to evaluate for an Arnold–Chiari malformation.
- In severe cases of OSAS, a cardiac evaluation, including ECG, chest x-ray, and Doppler ECG, may be indicated.

DIFFERENTIAL DIAGNOSIS

- PS or habitual snoring: By definition is not associated with sleep-disordered breathing, but may progress to OSAS. Between 20% and 50% of children with habitual snoring may have OSAS.
- Upper airway resistance syndrome: This condition is associated with sleep fragmentation and daytime sleepiness.
- Obesity–hypoventilation syndrome: A variant of OSAS
- Central apnea and periodic breathing
- Congenital central hypoventilation syndrome
- Other causes of excessive daytime sleepiness include:
 - Disorganized home environment, emotional stress
 - Substance abuse/drug intoxication: Psychotropic medications, antihistamines, anticonvulsants, narcotics
 - Narcolepsy: Onset typically around adolescence, but cataplexy may occur later and delay the diagnosis.
 - Classic tetrad of symptoms of narcolepsy includes excessive daytime somnolence, cataplexy, hypnagogic hallucinations, and sleep paralysis.
 - In addition, fragmented night time sleep may be seen.
 - Epilepsy: Absence spells of unresponsiveness, electroencephalogram changes
- Causes of obstructive apnea include any cause of lymphoid hypertrophy in the upper airway (allergies viral/bacterial tonsillitis, neoplasm, epiglottitis, retropharyngeal abscess); chronic phenytoin exposure; and excessive storage material in upper airway submucosa.
- Causes of abnormal laxity of upper airway soft tissues: Down syndrome, acute polyneuropathy (Guillain–Barré syndrome), chronic neuromuscular disease, Prader–Willi syndrome, myasthenia gravis
- Causes of abnormal control/coordination of upper airway musculature: Almost any cause of diffuse CNS dysfunction, including cerebral palsy, and acquired lesions of the CNS such as stroke and head trauma
- Causes of central apnea: Beyond infancy, most commonly due to drugs that suppress ventilatory drive; in premature infants may be due to nonspecific immaturity of neural ventilatory control mechanism, sepsis, and, rarely, seizures, brainstem compression, brain tumors, Arnold–Chiari type 2 (although increasingly seen with type 1)
- Reflux may potentiate central apnea and should be investigated (see “Gastroesophageal Reflux” topic).
- Androgen steroids may cause central apnea in adults.

TREATMENT

INITIAL STABILIZATION

- Severe cases may require urgent intervention.
- Severe cases of upper airway obstruction are usually diagnosed during polysomnography or during procedures involving sedation or anesthesia.
 - Ensure adequate ventilation and oxygenation, with quick assessment of the cause.
 - Temporary relief of the obstruction should be undertaken by an experienced team.
 - Transfer to an intensive care unit where the airway can be monitored carefully.
 - Following relief of airway obstruction, pulmonary and airway edema, as well as copious secretion production, may develop.
 - Modalities of care should include placement of a nasopharyngeal airway, noninvasive ventilation with continuous positive airway pressure/bilevel positive airway pressure (CPAP/BiPAP), or placement of an endotracheal tube for mechanical ventilation.
- Risk factors for postoperative complications in children with OSAS include age <3 years, severe OSAS, pulmonary hypertension, obesity, prematurity, failure to thrive, craniofacial or neuromuscular disorders, and/or upper respiratory tract infection.

General Measures

- In most cases, adenotonsillectomy is first-line therapy. However, some patients continue to have significant postoperative OSAS that requires further evaluation.
- Noninvasive ventilatory support with CPAP or BiPAP may be helpful.
- In complicated cases, when craniofacial malformations are involved, surgical procedures such as tongue reduction, uvulopalatopharyngoplasty, or mandibular or maxillary advancement may be indicated.
- When there is evidence of gastroesophageal reflux, treatment with acid-suppression agents and chalasias precautions are indicated.
- Weight loss may be useful in obese children.
- Laser surgery and dental appliances may be useful in adults with mild OSAS, but there is no experience with these approaches in children.
- In extreme cases, a tracheostomy may be indicated, especially when significant craniofacial abnormalities exist.

ONGOING CARE

COMPLICATIONS

- Complications are due to chronic hypoxemia, hypercarbia, acidosis, as well as impaired sleep and include:
- Pulmonary hypertension, later cor pulmonale (rare)
 - Systemic hypertension has been reported in adults and a few pediatric cases.
 - Congestive heart failure; arrhythmias are common in adults with underlying coronary artery disease.
 - Neurodevelopmental complications: Daytime somnolence, poor school performance, hyperactivity, and social withdrawal
 - Poor growth and failure to thrive
 - Postanesthesia respiratory failure and death have been reported in children with OSAS.

PATIENT MONITORING

- Clinical improvement is expected soon after adenotonsillectomy. In children <1 year of age with severe forms of OSAS, underlying craniofacial anomalies, or neurologic disorders, repeat overnight polysomnography is indicated 6–8 weeks after surgery.
- Regrowth of adenoid tissue may occur months to years after adenoidectomy. Therefore, if clinical symptoms, such as snoring, difficulty breathing while asleep, or a decline in school performance recur, a re-evaluation is indicated.

FAQ

- Q: Can my child still have OSAS after adenotonsillectomy?
- A: Yes, at times the adenoid tissue can grow back again. In addition, some cases of OSAS are related to a small upper airway that is restricted by anatomic or neurologic conditions. In these cases, adenotonsillectomy will not always resolve OSAS.
- Q: Does OSAS cause neurologic problems?
- A: Several studies suggest neurocognitive deficits in children with OSAS. The most common findings include reduced school performance and ADHD.

SLIPPED CAPITAL FEMORAL EPIPHYSIS

David D. Sherry

BASICS

DESCRIPTION

- Slipped capital femoral epiphysis (SCFE) is displacement of the epiphysis of the head of the femur.
- Pitfall: Hip pain may be absent; there may be no pain, or only thigh or knee pain due to referred pain

EPIDEMIOLOGY

- Males > Females (3:2)
- Left hip twice as often as right, 25% bilateral
- Associated with obesity, increased height, genital underdevelopment, pituitary tumors, growth hormone therapy

Incidence

- 1–5 per 100,000
- Age of onset: Boys, 14–16 years; girls, 11–13 years (essentially, premenarche)

RISK FACTORS

Genetics

5% of children affected have a parent with SCFE

PATHOPHYSIOLOGY

- Unclear: Abnormal stress on normal physeal plate vs. a process that weakens the plate
- The femoral head slips posteriorly and inferiorly, exposing the anterior and superior aspects of the metaphysis of the femoral neck.
- Associations: Obesity, endocrine dysfunction, primary hypothyroidism, pituitary dysfunction, hypogonadism, cryptorchidism, chemotherapy, pelvic radiotherapy, renal rickets

DIAGNOSIS

HISTORY

- Pain in hip or knee
- Occasional history of trauma; however, usually not sufficient to explain the findings
- 3 patterns
 - Chronic: Most common, onset of symptoms > 3 weeks, lack of full internal rotation of hip
 - Acute: Sudden onset with inability to walk or severe pain and difficulty walking
 - Acute-on-chronic: Sudden exacerbation of symptoms that have been present for a while

PHYSICAL EXAM

- Limp if unilateral, or waddling gait if bilateral
- Tenderness and occasional palpable thickening over hip
- Thigh atrophy
- Lack of full internal rotation of hip and decreased motion in all planes secondary to mechanical limitation due to the slip
- Procedure: When the hip is flexed, the thigh is forced into external rotation.

DIAGNOSTIC TESTS & INTERPRETATION

Imaging

- Anteroposterior and lateral view (frog leg or Lowenstein)
- Measure degree of displacement
 - Minimal: Alteration in plane of epiphysis relative to femoral neck; significant if angle < 82 degrees
 - Mild: Displacement < 1 cm
 - Moderate: Displacement > 1 cm, < 2/3 diameter of femoral neck

- Epiphyseal plate widened and irregular
- Decreased height of physis
- “Blanch sign”: Dense area in femoral neck
- A “Klein line” drawn along the superior femoral neck on the anteroposterior view should transect the epiphysis but not on the slipped side.
- Hormonal evaluation if suspected

Pathological Findings

Histologic findings include widening of the epiphyseal plate, large clefts, and necrotic debris in the cartilage and synovitis

DIFFERENTIAL DIAGNOSIS

- Septic arthritis of the hip
- Ischemic necrosis
- Tuberculosis of the hip; however, pain is associated with movement in all directions, and there should be other evidence of disease.
- Renal rickets
- Achondroplasia
- Shwachman syndrome: Metaphyseal chondrodysplasia with pancreatic insufficiency

TREATMENT

ADDITIONAL TREATMENT

General Measures

- Designed to prevent complications and further slipping; urgent orthopedic consultation mandatory
- Conservative: Bed rest with traction; probably does not reduce slipping; temporizing until surgery can be scheduled
- Manipulative reduction: Risk of damage to epiphyseal vessels or breakdown of callus; probably only to be considered if within 24 hours of acute slip
- Epiphyseal fixation: Risk of damage to articular surface or growth plate
- Intertrochanteric osteotomy
- Salvage: Hip fusion

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

Chondrolysis and avascular necrosis are uncommon side effects of slipped capital femoral epiphysis.

COMPLICATIONS

- Ischemic necrosis of epiphysis: Usually due to manipulative reduction of the slippage; more common in males; x-rays reveal increased density, irregularity, and ultimately collapse of epiphysis.
- Chondrolysis (acute cartilage necrosis): 1–40%, more common in females and blacks; etiology unclear; x-rays reveal narrowed joint space, sclerosis of acetabular rim, and osteoporosis of femoral head.

SMALLPOX (VARIOLA VIRUS)

Hamid Bassiri

Joanne N. Wood (5th edition)

BASICS

DESCRIPTION

- Smallpox is a life-threatening, acute eruptive, contagious disease caused by the variola virus.
- The disease is characterized by a febrile prodrome followed by the development of a rash.
- Rash evolves in a characteristic fashion: macules → papules → vesicles → pustules. Scabs form and fall off leaving scars called pockmarks.
- There are 2 clinical forms of smallpox:
 - Smallpox minor is a less common and less severe form of the disease.
 - There are 5 types of smallpox major, the more common and serious form of the disease.
 - Ordinary smallpox
 - Modified smallpox
 - Flat smallpox
 - Hemorrhagic smallpox
 - Variola sine eruptione

EPIDEMIOLOGY

- The last documented case of endemic smallpox was in Somalia in 1977. The last case in the US was in the late 1940s.
- Smallpox was declared eradicated by the World Health Organization in 1979.
- Historically in unvaccinated individuals ordinary smallpox accounted for 90% of cases and hemorrhagic accounted for 7% of cases. Flat and modified smallpox accounted for the remainder of cases.
- Modified smallpox was rare in unvaccinated individuals but accounted for 25% of cases of disease in vaccinated individuals.

GENERAL PREVENTION

- Prior to 1972, all children in the US were vaccinated.
- Vaccines were produced from the vaccinia virus, an orthopoxvirus that is closely related to the variola virus.
- Historically, the vaccine was prepared from virus grown on the skin of animals and in some cases the vaccine was contaminated with animal proteins, bacteria, and adventitious viruses.
- Newer smallpox vaccines are developed from vaccinia clones grown in tissue culture and therefore are free of contamination from bacteria and other viruses.
- Laboratories in the US and Russia have stockpiles of smallpox virus. There is concern that scientists in the Soviet Union may have illegally transported samples of this virus to other nations.
- Due to concern regarding the possible use of smallpox as a bioterrorism weapon, the US has increased the production of smallpox vaccine.
- The only currently FDA-licensed smallpox vaccine, ACAM2000, is used for active immunization of persons determined to be at highest risk for infection. ACAM2000, which replaced Dryvax in the US, is currently provided for Strategic National Stockpile use.
- The Advisory Committee on Immunization Practices recommends smallpox vaccination for:
 - Public-health response teams responsible for investigating suspected smallpox cases
 - Hospital-based healthcare teams responsible for assessing and caring for suspected smallpox cases

- Vaccine efficacy:
 - 95% efficacious in preventing disease if given prior to exposure
 - May prevent smallpox or decrease severity if given 1–3 days after exposure
 - May decrease severity of disease if given 4–7 days after exposure
- Length of immunity after vaccination is estimated to be 3–10 years. Vaccine may decrease the severity of disease for 10–20 years.
- Vaccine administration:
 - A skin abrasion is created using a bifurcated needle dipped in the vaccine.
 - The vaccine site should be loosely covered to prevent the spread of virus to others.
 - After 3–4 days a red pruritic papule appears at the vaccination site. A vesicle and then a pustule forms. After a few weeks a scab forms that falls off leaving a scar.
- Contraindications to vaccine:
 - Atopic dermatitis or exfoliative skin disorder
 - Immunosuppression
 - Pregnancy or breastfeeding
 - Close contact of someone who is pregnant, immunosuppressed, or has skin disease
 - Allergy to vaccine component
 - Moderate or severe acute illness
 - Inflammatory eye disease
 - Heart disease (myocardial infarction, stroke, cardiomyopathy, heart failure, or angina)
 - 3 or more risk factors for heart disease
 - Age < 1 year
 - These contraindications may be re-evaluated if smallpox is reintroduced into the population.
- Common adverse reactions to vaccination:
 - Fever, swelling, lymphadenitis, and headache are seen in 2–16% of adults receiving the vaccine for the first time.
 - A mild rash occurs in ~8% of cases.
- Less common vaccine reactions:
 - Vaccinia keratitis and vision loss
 - Accidental inoculation with blister formation
 - Moderate-to-severe generalized rash
 - Eczema vaccinatum
 - Encephalitis
 - Congenital vaccinia and generalized vaccinia
 - Myopericarditis
 - Progressive vaccinia/vaccinia gangrenosum
 - Bacterial superinfection

PATHOPHYSIOLOGY

- The virus infects the upper respiratory tract and replicates. Rarely, primary infections via skin, conjunctiva, or placenta can occur.
- The virus then enters the bloodstream causing primary viremia and is taken up by macrophages.
 - Patient is asymptomatic during this time.
- Next the virus enters the reticuloendothelial system where it continues to replicate.
- Secondary viremia occurs as the virus enters the bloodstream and the organs.
 - Virus enters the epidermis causing necrosis and swelling.
 - Virus infects the bone marrow, kidneys, liver, lymph nodes, spleen, and other organs.
 - The virus causes coagulopathy and multiorgan system failure.

- Exact mechanisms of viral toxicity are not understood but may involve both direct viral cytopathic effects and inflammatory mediators.

ETIOLOGY

- The variola virus, a member of the poxvirus family and the orthopox genus, causes smallpox.
- Variola is a double-stranded DNA virus. It is usually transmitted during face-to-face contact via respiratory aerosol or direct contact with the virus via skin lesions.
- Transmission of the virus via air in enclosed settings or via infected fomites is uncommon.
- Humans are the only vectors.

DIAGNOSIS

- Ordinary smallpox:
 - Incubation period of 7–17 days, followed by febrile prodrome lasting 1–4 days.
 - The prodrome is characterized by high fever, headache, back pain, chills, abdominal pain, and emesis.
 - Eruptive phase begins with lesions of the mouth, tongue, and oropharynx.
 - Then the rash develops:
 - Often starts on face and spreads to rest of body within 24–48 hours.
 - On day 1 the rash is macular.
 - On day 2 the rash becomes papular.
 - On days 4–5 the rash is vesicular.
 - By day 7 the rash has become pustular.
 - By 2–3 weeks the scabs have formed.
 - Scabs fall off and leave scars.
- Modified smallpox:
 - Milder than ordinary smallpox
 - Accelerated course
 - Lesions are not as deep.
- Flat smallpox:
 - Characterized by a soft, flat, semiconfluent or confluent rash that does not progress to pustules
 - Can result in significant skin loss
- Hemorrhagic smallpox:
 - Shorter incubation time
 - Skin becomes dusky.
 - Bleeding occurs in the skin and mucous membranes.
 - Can be difficult to diagnose unless exposure to variola virus is known
- Variola sine eruptione:
 - May be asymptomatic or cause a febrile influenza-like illness
 - Noncontagious
 - Seen in infants with protective maternal antibodies and in vaccinated individuals
- If there has not been a release or circulation of smallpox, the CDC Protocol for evaluating patients for smallpox can be used to guide the assessment of a suspicious rash illness.
- CDC protocol for evaluating patients for smallpox:
 - If a patient has an acute, generalized rash on the body, with vesicles or pustules:
 - Use the major and minor criteria to assess the likelihood of smallpox

- Major criteria:
 - Febrile prodrome: 1–4 days prior to rash onset including a temperature $\geq 101^{\circ}\text{F}$ and 1 or more of the following: prostration, headache, backache, chills, vomiting, or severe abdominal pain
 - Classic smallpox lesions are deep-seated, firm/hard, round, well-circumscribed vesicles or pustules that can become umbilicated or confluent as they evolve on any one part of the body (e.g., the face or arm); all the lesions are in the same stage of development
- Minor criteria:
 - Centrifugal distribution: greatest concentration of lesions on face and extremities
 - First lesions appear on the oral mucosa, palate, face, or forearms.
 - Patient appears toxic or moribund.
 - Slow evolution: lesions evolve from macules to papules to pustules over days (each stage lasts 1–2 days).
 - Lesions on the palms and soles
- High risk of smallpox:
 - Febrile prodrome and classic smallpox lesions in same stage of development
- Moderate risk of smallpox:
 - Febrile prodrome and 1 other major smallpox criterion, or
 - Febrile prodrome and ≥ 4 minor smallpox criteria
- Low risk of smallpox:
 - No febrile prodrome, or
 - Febrile prodrome and < 4 minor smallpox criteria

• Online tool for evaluation risk of smallpox is available at: <http://www.bt.cdc.gov/agent/smallpox/diagnosis/riskalgorithm/>

DIAGNOSTIC TESTS & INTERPRETATION
Diagnostic Procedures/Other

- Use the CDC smallpox evaluation protocol to guide testing
 - If high risk of smallpox:
 - Consult infectious disease and/or dermatology
 - Public-health agency will advise on management and collection of samples.
 - Variola testing will be performed at an approved laboratory prior to other testing.
 - If moderate risk of smallpox:
 - Consult infectious disease and/or dermatology
 - Perform testing for varicella and other disorders including herpes simplex virus as indicated
 - If no diagnosis made after testing and consultation ensure adequacy of specimen and have consultants re-evaluate
 - If still cannot rule out smallpox, then classify case as high-risk case
 - If low risk of smallpox, and history and physical exam are highly suggestive of varicella then varicella testing is optional.
 - If low risk of smallpox and diagnosis is uncertain then testing should be done for varicella and other disorders as indicated.
- Variola testing:
 - Should not be performed in low- and moderate-risk cases because of risk of false positives
 - Should only be performed in high containment facilities designated by national authorities
 - Lesion specimens (fluid, cells, and scabs) are preferred for testing but blood, tonsillar swabs, and biopsy specimens may be used.
 - Serologic studies and electron microscopy cannot distinguish between the variola virus and other orthopoxviruses.

- PCR assays can distinguish variola virus from other orthopoxviruses.
- Variola virus can be cultured.
- Historically variola was identified by the characteristic pocks it produced when grown on chorioallantoic membranes of chick embryos.

DIFFERENTIAL DIAGNOSIS

- Multiple rash illnesses, including the following, can be confused with smallpox:
 - Varicella and Herpes zoster
 - Herpes simplex virus
 - Measles
 - Rubella
 - Monkeypox and Tanapox
 - Viral exanthema including Enterovirus
 - Disseminated Molluscum contagiosum
 - Impetigo, insect bites, or scabies
 - Post-smallpox vaccine rash (Vaccinia)
 - Secondary syphilis
 - Acne and contact dermatitis
 - Drug reactions including erythema multiforme
 - Meningococemia can be confused with the hemorrhagic form of smallpox.

ALERT

- Varicella can be confused with smallpox.
- Lesions in varicella are in different stages, superficial, concentrated on the trunk and face, and often spare palms and soles.
- Lesions of smallpox are all at the same stage, deep, concentrated on face and limbs, and often involve palms and soles.

TREATMENT

MEDICATION (DRUGS)

- Patients suspected of having smallpox should be vaccinated against smallpox, especially if they are in the early stages of the disease.
- No treatment has been proven to be effective.
- The efficacy of antivirals developed since the eradication of smallpox is unknown. Although cidofovir has been suggested for therapy of smallpox infections, there is currently not enough data to support its use.
- Several new medications are under investigation (e.g., ST-246, CI-1033) for therapy, but have not yet been approved for use.
- The use of vaccinia immune globulin (VIG) can be considered for complications from vaccinia immunization but not for therapy of smallpox infection.

ADDITIONAL TREATMENT

General Measures

- Suspected cases of smallpox require notification of state and local authorities, who should then notify the CDC.
- Use CDC smallpox evaluation protocol to guide reporting and infection control measures.
 - For all patients with acute, generalized vesicular or pustular rash:
 - Institute airborne and contact precautions
 - Alert infection control at time of admission
 - If high risk: Report to state and local public-health agency immediately

- Individuals recently exposed (within 3–4 days) to someone with contagious smallpox (e.g., someone with oral or skin lesions) should receive postexposure vaccination, as this offers the potential to limit disease but also provides significant protection from death.
- Individuals with smallpox may be contagious during the febrile prodrome and are most contagious during the early rash phase. They remain contagious until all the scabs have fallen off.

ONGOING CARE

PROGNOSIS

- The mortality rate for variola minor was $< 1\%$.
- Historically the overall mortality rate for variola major was 30% but was close to 100% for the flat and hemorrhagic forms of the disease.
- The highest mortality rates occurred among young children, pregnant women, elderly individuals, and those with immunodeficiencies.
- Long-term sequelae include pockmarks, vision loss, and limb deformities.

COMPLICATIONS

- Secondary bacterial infections: Skin, lung, joint, bone, sepsis, etc.
- Corneal ulcers and keratitis
- Arthritis
- Encephalitis

B03 Smallpox

SNAKE AND INSECT BITES

Payal S. Kadia

Jill C. Posner

BASICS

DESCRIPTION

- Injury to the human skin and/or subcutaneous tissues caused by bite, envenomation, or sting, causing usually local, but in some cases systemic, effects
- Snake bites:
 - Crotalinae (pit vipers: Cotton mouths, copperheads, and rattlesnakes)
 - Elapidae (coral snakes)
- Spider bites:
 - Black widow (*Latrodectus mactans*)
 - Brown recluse (*Loxosceles reclusa*)
- Insect stings: Hymenoptera: Fire ants (*Solenopsis*), yellow jackets, wasps, bees

EPIDEMIOLOGY

- Only 15% of all snake bites are from poisonous snakes, and only ~2/3 of those involve true envenomation. Crotaline snakes are the most common cause of venomous snake bites in the US. Coral snake bites constitute <1% of all snake bites.
- The black widow spider is found in most areas of North America but especially in southern New England. The brown recluse spider is found mainly in southern and midwestern states.
- 1–4% of the US population is at risk for anaphylaxis from Hymenoptera stings.

Incidence

- Annually, ~8,000 people sustain a poisonous snake bite in the US, 99% of which are from crotaline snakes, and 12–15 fatalities occur.
- The incidences of black widow and brown recluse spider bites are unknown.
- 50–150 people die each year from sting anaphylaxis.

PATHOPHYSIOLOGY

- Snake bites:
 - Although there are ~120 snake species in the US, only 15% envenomate substances are capable of causing fatal reactions.
 - Snake venom consists of numerous enzymes and polypeptides that are neurotoxic, cytotoxic, and hemotoxic.
 - Pit viper venom produces significant local inflammation and injury to the vascular endothelium, and may lead to coagulopathy, thrombocytopenia, and shock.
 - The venom of the coral snake is primarily neurotoxic and may produce neuromuscular paralysis and respiratory depression.
- Spider bites:
 - Most of the 20,000 species of predominantly venomous spiders in the US lack fangs capable of penetrating human skin or toxin strong enough to produce more than a mild reaction. However, the black widow and brown recluse spiders can cause significant harm.
 - The black widow venom, α -latrotoxin, is a neurotoxin that stimulates myoneural junctions and nerve terminals by increasing synaptic release of acetylcholine and by initiating a massive influx of calcium, causing severe skeletal muscle pain and cramping and autonomic disturbances such as hypertension and sweating. Pediatric patients are more severely inflicted given the ratio of mg of venom to kg of body weight.

- The brown recluse venom, mainly sphingomyelinase D, acts on RBC membranes, platelets, endothelial cells, and other cells, resulting in tissue infarction and necrosis. Systemic symptoms are more likely to occur in children, presumably because of a smaller ratio of body weight to venom volume. Hemolysis, hemoglobinuria, disseminated intravascular coagulation, shock, seizures, and death rarely may occur.
- Insect stings:
 - The fire ant bites with its jaws and then swings its head around to inflict multiple stings. The venom has a direct toxic effect on mast cell membranes, causing an immediate wheal-and-flare reaction at the bite site.
 - The venoms of the bee, hornet, yellow jacket, and wasp contain antigens that trigger an IgE antibody response, resulting in allergic reactions that vary in severity from mild local effects to profound anaphylactic reactions.

DIAGNOSIS

HISTORY

ALERT

- If the snake is brought in for identification, use caution! The head of a dead snake can deliver a venomous bite for up to 1 hour after death/decapitation.
- Snake bites:
 - Poisonous snakes have triangular-shaped heads, a pit (heat sensor in front of each eye), fangs, slitlike pupils, and a single row of subcaudal plates, and may have a rattle:
 - The corals have oval heads, yet are still poisonous.
 - Nonpoisonous snakes have oval heads, no pits, rows of small teeth, round pupils, a double row of subcaudal plates, and no rattles.
 - In the Elapidae family, the coral snake can be differentiated from the benign king snake by the pattern of the colored bands: “Red on yellow, kill a fellow; red on black, venom lack.”
- Spider bites: Identification of spider (rare): The black widow is about the size of a quarter, glossy black, gray, or brown, with a red, orange, or yellow hourglass-shaped marking on the ventral surface. A single bite can deliver a lethal dose of venom. The brown recluse is small (1–1.5 cm), gray or reddish/brown, with a brown violin-shaped mark on the dorsum of the cephalothorax.
- Insect bites:
 - Type of insect
 - Previous history of insect bite allergy

PHYSICAL EXAM

- Crotalinae (pit viper) bites:
 - Intense local pain and burning occur in the 1st few minutes, followed by edema and perioral numbness that may extend to the scalp and periphery. Paresthesias may be accompanied by a metallic taste in the mouth.
 - Local ecchymosis and vesicles appear within the 1st few hours, and by 24 hours hemorrhagic blebs are present. Lymphadenitis may result.
 - Without treatment, necrosis extending throughout the bitten extremity generally ensues. Compartment syndrome is uncommon.
 - Nausea, vomiting, weakness, chills, and sweating can also occur with systemic absorption of venom.
 - Neuromuscular involvement (e.g., diplopia, dysphagia, lethargy) can develop within several hours.
 - Signs of hypovolemic shock, hemorrhagic diathesis, and neuromuscular dysfunction may occur in life-threatening envenomations.
- Elapidae (coral snake) bites:
 - Mild, often unimpressive local signs and symptoms (pain, swelling), but significant neurologic effects that include extremity paresthesias, weakness, fasciculations, and bulbar dysfunction that can progress to flaccid paralysis and respiratory failure.
 - Inspect bite wound for fang punctures.
 - Carefully assess neurovascular integrity, and consider compartment pressures if severe edema.
- Black widow spider bites:
 - No local symptoms associated with bite
 - Within 8 hours after bite, regional or generalized pain and muscle cramping, fasciculations; abdominal rigidity without tenderness is a hallmark sign.
 - Children often have nausea and vomiting.
 - Respiratory difficulty may occur.
 - Hypertension, tachycardia, and cholinergic effects (diaphoresis, salivation, lacrimation, and bronchorrhea)
 - Death may occur from respiratory or cardiovascular collapse.
 - Syndrome can last 3–6 days.
- Brown recluse spider bites:
 - Spectrum from minor local reaction to severe necrosis
 - Local reaction: Pain, erythema, swelling, and pruritus, classic “bull’s eye” lesion
 - Ischemia and skin necrosis: A bright red papule appears within a few hours of the bite and can evolve within 48–72 hours into a hemorrhagic vesicle surrounded by purple discoloration (necrosis) or blanching (vasospasm), “the bull’s eye.” Shortly after, a firm, purple necrotic lesion appears, and within 7–14 days black eschar is visible. Ulcer healing can take weeks to months, leaving a deep scar.
- Insect bites:
 - Small local reactions: Painful, pruritic, urticarial lesion at the sting site
 - Large local reaction: Swelling and erythema, may become several centimeters in diameter
 - Anaphylaxis is rare with fire ants but occurs more frequently with bee stings.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Snake bites: CBC, platelet count, PT/PTT, fibrinogen, fibrin split products, serum electrolytes, creatine kinase, creatinine, urinalysis
- Spider bites: CBC, PT/PTT, fibrinogen, serum electrolytes, creatinine, creatine kinase, urinalysis
- Insect bites: No tests done routinely

DIFFERENTIAL DIAGNOSIS

- Black widow spider bites: Acute abdomen, renal colic, opioid withdrawal, tetanus
- Poisonous snake bites: Nonpoisonous snake bite (leaves scratches, not punctures), rodent bites, thorn wounds
- Brown recluse spider bite: Other spider bites, insect bites and stings (including Lyme), cellulitis, poison ivy/oak, Stevens-Johnson syndrome, toxic epidermal necrolysis, erythema nodosum, chronic herpes simplex, purpura fulminans, diabetic ulcer, gonococcal hemorrhagic lesion, pyoderma.

TREATMENT

- Crotalinae (pit vipers) bites:
 - Remove constrictive items (jewelry or clothing) and immobilize extremity at or below level of heart. Cryotherapy, arterial tourniquets, excision, and incision are not recommended. Oral suctioning is never recommended!
 - Rapid transport to medical facility
 - Address airway, breathing, and circulation.
 - The use of a constrictive band is controversial. Main indication is for cases of prolonged transport time to a medical facility or rapid progression of systemic symptoms. A flat band is placed 5–10 cm proximal to the bite, with enough pressure to impede lymphatic and superficial venous flow but not arterial flow. 1–2 fingers should fit easily between the band and the patient’s extremity.
- Elapidae (coral snakes): Constriction bands, suction, and drainage do not prevent coral snake venom absorption.

ADDITIONAL TREATMENT

General Measures

- Crotalinae (pit vipers) bites:
 - Wound care: Irrigation and dressing
 - Determine if envenomation has occurred via serial examinations (q30min) and laboratory studies (q4h).
 - Antivenom: Administration of antivenom should be made in consultation with a toxicologist and/or herpetologist. General indications include progressive local swelling, pain or ecchymosis, and any systemic signs or symptoms.
 - 2 Crotalinae antivenom products used to be available: Antivenin (Crotalidae) Polyvalent (ACP) (Wyeth Laboratories) and Crotalidae Polyvalent Immune Fab (Ovine) (Altana, Inc.), approved by the FDA in October 2000. However, administration of ACP antivenom was commonly associated with serum sickness and anaphylaxis and it is now no longer manufactured.

- Some hospitals (in endemic areas) and many zoos stock antivenoms. In addition, the regional poison control center may have access to the Antivenom Index and will be able to help locate the nearest supply.
- Data suggest that the use of Fab preparations is safe and effective and is associated with fewer immediate and delayed hypersensitivity reactions than ACP, though they do occur and must be monitored.
- Early administration of Fab within 6 hours is advised. Initial dose is 4–6 vials of Fab diluted in 250 mL normal saline infused over 1 hour.
- Supportive care: Volume replacement, packed red blood cells, platelets, fresh-frozen plasma, cryoprecipitate as indicated for hypovolemia and bleeding diathesis. Observe closely for respiratory and renal failure.
- Frequent assessment of tissue perfusion; fasciotomy only for elevated compartment pressures
- Empiric antibiotics are controversial but may be indicated in cases of extensive tissue involvement
- Analgesia and tetanus prophylaxis
- Elapidae (coral snakes):
 - Crotalinae antivenom is ineffective in treating Elapidae envenomation. Antivenom that was formerly manufactured by Wyeth Laboratories is no longer in production, but an alternative formulation from Mexico (Coralmyl) is being tested.
 - Any degree of flaccid paralysis is an indication for antivenom therapy.
 - Local wound care, supportive care, analgesia, and tetanus vaccination as above
- Black widow spider bites:
 - To alleviate muscle pain and cramping, parenteral opioids and benzodiazepines can be administered.
 - 10% calcium gluconate had been used anecdotally, but is no longer recommended.
 - Latrodectus-specific antivenom is available for more severe envenomations given via IV infusion. Specific indications include young age, pregnancy, life-threatening hypertension and tachycardia, or severe symptoms refractory to other treatment measures. Administration of an equine serum preparation has been associated with hypersensitivity reactions and occasionally death. 1 vial is generally all that is needed.
- Brown recluse spider bites:
 - Most bites can be treated on an outpatient basis with local wound care with Burrow solution or hydrogen peroxide and symptomatic treatment for pain and pruritus.
 - No specific antivenom is available in the US.
 - Patients with systemic symptoms, serious infection, or extensive necrosis warrant hospitalization, IV fluids, and aggressive supportive care.
 - Surgical excision advocated in the past, but is no longer indicated
 - Neither dapsone nor hyperbaric oxygen therapy has proved to be effective; dapsone in children is associated with methemoglobinemia.

- Insect bites or stings:
 - Rarely require more than ice, and antihistamine for pruritus
 - If stinger remains in skin, remove by pinching with forceps or scraping. Emphasis should be on quick removal to decrease exposure to venom. Do not squeeze venom gland.
 - Life-threatening anaphylaxis should be treated with subcutaneous epinephrine (0.01 mL/kg 1:1,000, max 0.3 mL), methylprednisolone (2 mg/kg), and/or diphenhydramine (1.25 mg/kg).
- Bacterial superinfection is rare, but if present can usually be treated with oral and/or topical antibiotics.

ONGOING CARE

PROGNOSIS

- Snake bites: Because the majority of snake bites are from nonvenomous snakes, and ~1/3 of bites from venomous snakes do not involve envenomation, the majority of bites cause only local injury. However, once serious injury is established, prognosis becomes unclear.
- Spider bites: Children have severe reactions and rare fatalities.
- Insect bites: Most bites and stings cause minimal local effects, although some cause serious systemic reactions and, rarely, death.

SOCIAL ANXIETY DISORDER

C. Pace Duckett

BASICS

DESCRIPTION

- Social anxiety disorder, also known as social phobia, is a psychiatric condition with developmental underpinnings. The disorder is characterized by marked and persistent fear of social situations in which the person is exposed to unfamiliar people or possible scrutiny by others.
- Diagnostic types:
 - Generalized: Individuals experience anxiety and fear across most social situations.
 - Non-generalized: Individuals experience anxiety and fear towards specific situations (such as public speaking).
- DSM-IV criteria:
 - A marked and persistent fear of one or more social or performance situations in which the person is exposed to unfamiliar people or to possible scrutiny by others.
 - The feared situation provokes anxiety and may precipitate a panic attack.
 - The feared social situation or performance is avoided.
 - Symptoms have persisted for >6 months.
 - The anxiety, avoidance, or distress leads to significant impairment in social or academic functioning.
 - There must be evidence of the capacity for age-appropriate social relationships with familiar people and the anxiety must occur in peer situations, not just in interactions with adults.

EPIDEMIOLOGY

Incidence

Approximately 5% of youths suffer from social anxiety disorder. The prevalence is somewhat higher in girls than in boys. It is the third most common psychiatric disorder in the US.

RISK FACTORS

- Shyness
- Avoidant temperament
- Behavioral inhibition
- Familial heritability pattern
- Moderate genetic component based on twin studies

COMMONLY ASSOCIATED CONDITIONS

- Anxiety disorders (36%)
 - Generalized anxiety disorder (10%)
 - Specific phobia (10%)
 - Selective mutism (8%)
 - Obsessive compulsive disorder (6%)
 - Panic disorder (2%)
- ADHD (10%)
- Depression (2%)

DIAGNOSIS

HISTORY

- The diagnostic evaluation should entail gathering of data through separate interviews with the child/adolescent and the parents.
- Current symptoms should be elicited with attention to severity, duration, and level of functional impairment.
- Core symptoms of marked anxiety in social situations, fear of negative scrutiny by others, and avoidance of these situations should be present.
- Distress can be manifested by physical symptoms such as blushing, palpitations, trembling, or GI upset.
- Younger children may exhibit periods of selective mutism in social situations, while having the ability to talk freely while at home.
- Older children may appear oppositional and exhibit school refusal.
- Symptoms may be exacerbated by environmental transitions such as a new school or the family moving.

PHYSICAL EXAM

There are no pertinent findings on physical exam.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

There are no pertinent findings on physical exam.

Diagnostic Procedures/Other

- Diagnostic scales:
 - Social Anxiety Scale for Adolescent (SAS-A)—self-administered for adolescents aged 13–17
 - Multi-Dimensional Anxiety Scale for Children (MASC)—broad anxiety scale self-administered for ages 8–19
 - Liebowitz Social Anxiety Scale for Adolescents (LSAS-A)—clinician-administered scale for ages 13–17

DIFFERENTIAL DIAGNOSIS

- Anxiety disorders
- Depression
- Autistic spectrum disorders

TREATMENT

MEDICATION (DRUGS)

- SSRIs (first-line): Initiate half the starting dose for children with anxiety disorders
 - Side effects include GI upset, headaches, dizziness, and agitation.
 - There is a black-box warning by the FDA indicating that all antidepressants may increase suicidal thinking and behavior in children and adolescents.
 - Close monitoring is recommended following initiation.
 - Fluoxetine (Prozac) (10–60 mg)
 - Sertraline (Zoloft) (25–200 mg)
 - Paroxetine (Paxil) (10–40 mg)
 - Citalopram (Celexa) (10–60 mg)
 - Escitalopram (Lexapro) (10–20 mg)
 - Fluvoxamine (Luvox) (25–200 mg)

- SNRIs (second-line):
 - Side effects include somnolence, insomnia, dizziness, anxiety, headache, sweating, and tremor.
 - There is a black-box warning by the FDA indicating that all antidepressants may increase suicidal thinking and behavior in children and adolescents.
 - Venlafaxine extended release (Effexor XR) (25–225 mg)
- Benzodiazepines (second-line):
 - Side effects include sedation, dizziness, and weakness.
 - Lorazepam (Ativan)
 - Clonazepam (Klonopin)
 - Alprazolam (Xanax)
 - Alprazolam XR (Xanax XR)

ADDITIONAL TREATMENT

General Measures

- There are 2 types of treatment for social anxiety disorder—psychosocial treatment and pharmacotherapy.
 - The psychosocial treatment with the strongest evidence is cognitive behavioral therapy (CBT).
 - The SSRIs are the first-line agents for medication management.
 - Combination treatment with SSRIs and CBT is superior to either treatment alone.
- Psychosocial treatments: There is an emphasis on relaxation techniques such as breathing exercises and progressive muscle relaxation.
 - Exposure to a hierarchy of avoided situations with concomitant cognitive reframing is core to CBT.
 - Psychoeducation with the family is imperative for decreasing parental accommodation of avoidant patterns.

Additional Therapies

- CBT
- Individual psychotherapy
- Group therapy
- Psychoeducation

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Monitoring of response to psychosocial treatment should be performed routinely every 2–3 months.
- If medication is initiated, close monitoring on a weekly basis is recommended for the first 4 weeks followed by monthly monitoring.
- CBT is performed on a weekly or twice weekly regimen.
- Monitoring of any emerging comorbidities is suggested.

PROGNOSIS

- Social anxiety disorder is generally considered a chronic condition that does not remit without intervention.
- Serious comorbidities may develop in adulthood, such as depression and alcohol dependence.

CLINICAL PEARLS

- Pitfalls:
 - Incomplete assessment of the comorbid psychiatric illnesses
 - Parental accommodation of the child’s avoidant patterns

SORE THROAT

Cynthia R. Jacobstein

BASICS

DEFINITION

Sore throat or pain with swallowing is a common presenting complaint in the pediatric population. The majority of cases have an infectious etiology, with viral causes being the most common.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

• Infectious

- Pharyngitis/tonsillitis
- Viral: Adenovirus/influenza/parainfluenza, Epstein–Barr virus (EBV), cytomegalovirus (CMV), human immunodeficiency virus
- Bacterial: Group A β -hemolytic Streptococcus (*Streptococcus pyogenes*), groups C and G Streptococci, diphtheria, *Neisseria gonorrhoeae*, anaerobic bacteria, tularemia, *Arcanobacterium haemolyticum*
- Stomatitis: Herpes simplex virus, coxsackievirus
- Other infectious etiologies include peritonsillar cellulitis/abscess, retropharyngeal abscess, epiglottitis/supraglottitis, Lemierre syndrome

• Environmental

- Irritative pharyngitis: Exposure to smoke or dry air

• Trauma

- Foreign body: Either retained or causing laceration to posterior pharynx
- Burns: Hot liquids/foods
- Voice overuse

• Tumor

- Rare in pediatric population

• Allergic/inflammatory

- Allergens causing chronic postnasal drip that leads to irritant pharyngitis

• Miscellaneous

- Kawasaki disease
- PFAPA: Periodic fever, aphthous stomatitis, pharyngitis, adenitis
- Psychogenic pain
- Referred pain

APPROACH TO THE PATIENT

The majority of cases of sore throat have an infectious cause, with most (~70–80%) of these having a viral etiology. Once the life-threatening and/or noninfectious causes have been excluded, the goal is to determine if the pharyngitis is caused by group A β -hemolytic Streptococci (GABS), which should be treated with antibiotics, or one of the many other infectious etiologies.

- **Phase 1:** Use history and physical exam to separate infectious from noninfectious causes. If etiology seems infectious, consider testing for group A Streptococcal infection.
 - The clinical appearance of GABS pharyngitis may be indistinguishable from pharyngitis of viral etiologies. The therapy for these illnesses is different:
 - Antibiotics for group A Streptococcus vs. symptomatic care for viral pharyngitis. The practitioner should perform diagnostic testing (i.e., rapid Strep antigen and/or culture) when GABS pharyngitis is considered.
 - In general, it is not recommended to treat pending the culture results; rather, wait until the GABS pharyngitis is confirmed with a positive antigen or culture before starting antibiotics.

HISTORY

- **Question:** Sore throat in association with fever, headache, and/or abdominal pain?
- **Significance:** Common association of symptoms present in group A Streptococcal pharyngitis
- **Question:** Sore throat in association with fever, upper respiratory infection symptoms (cough, rhinorrhea, conjunctivitis)?
- **Significance:** More suggestive of viral pharyngitis
- **Question:** Presence of drooling, voice changes?
- **Significance:** Possibility of more severe infectious etiology, including retropharyngeal or peritonsillar abscess, epiglottitis
- **Question:** Foreign body exposure?
- **Significance:** Retained foreign body (e.g., fishbone) or laceration/irritation from foreign body
- **Question:** Irritant exposure (e.g., dry air from heating or cooling system)?
- **Significance:** Pharyngeal mucosal drying
- **Question:** Immunization status and travel history?
- **Significance:** Possibility of diphtheria in the non- or incompletely immunized patient, especially if recent travel to countries of the former Soviet Union
- **Question:** Sexual activity (including oral sex and possibility of abuse)?
- **Significance:** Gonococcal pharyngitis

PHYSICAL EXAM

- **Finding:** Pharyngeal erythema with or without exudate?
- **Significance:** Suggestive of infectious etiology, though does not reliably differentiate viral from bacterial causes
- **Finding:** Tender cervical adenopathy?
- **Significance:** Suggestive of infectious etiology; anterior cervical nodes described in classic GABS infection; posterior cervical nodes +/- hepatosplenomegaly suggest possibility of EBV.
- **Finding:** Concomitant pharyngitis and conjunctivitis?
- **Significance:** Suggestive of adenovirus infection
- **Finding:** Stridor/drooling?
- **Significance:** Raises concern for etiologies that may cause airway obstruction
- **Finding:** Asymmetric enlargement of tonsillar pillar with deviation of uvula away from enlarged side +/- trismus?
- **Significance:** Peritonsillar abscess
- **Finding:** Mild erythema with cobblestoning of posterior pharyngeal mucosa?
- **Significance:** Suggests allergic or irritant etiology
- **Finding:** Vesicular or ulcerative lesions in oropharynx?
- **Significance:** Suggestive of viral etiologies including herpes simplex (lesions commonly in anterior oropharynx) or coxsackievirus (lesions commonly in posterior oropharynx).
- **Finding:** Diffuse fine blanching erythematous papular rash?
- **Significance:** Suggestive of scarlet fever, which is caused by GABS

DIAGNOSTIC TESTS & INTERPRETATION

- **Test:** Throat swab for Strep antigen test with subsequent culture if antigen test is negative
- **Significance:** Useful for definitive diagnosis of group A Streptococcal infection. A negative antigen test should be followed by throat culture to improve sensitivity. The sensitivity of current rapid antigen tests ranges from 80% to 90%. The sensitivity of a correctly obtained throat culture swab ranges from 90% to 95%.

- **Test:** CBC and Mono spot if indicated
- **Significance:** Atypical lymphocytosis/presence of heterophil antibodies suggestive of EBV infection. EBV titers (if indicated) should be sent in those <4 years of age because of low sensitivity (~50%) of Mono spot in this age group.

Imaging

- Lateral neck x-ray:
 - Enlarged epiglottis suggests epiglottitis; widened prevertebral soft-tissue space suggestive of retropharyngeal abscess
- CT scan of neck:
 - For diagnosis of retropharyngeal abscess in setting of suggestive lateral neck x-ray

TREATMENT

ADDITIONAL TREATMENT

General Measures

- The treatment of viral pharyngitis is largely supportive care, including fluids and pain control.
- Penicillin is the drug of choice for treatment of GABS pharyngitis. PO and IM regimens are available. A once-daily amoxicillin regimen has been endorsed as an alternative treatment option. Macrolide antibiotics (e.g., azithromycin), clindamycin, or some first-generation cephalosporins (provided no allergy in the form of immediate-type hypersensitivity to β -lactam antibiotics) may be used for those with penicillin allergy.

ISSUES FOR REFERRAL

- Fluctuant peritonsillar abscess: Drainage may be done by otolaryngologist
- Presence of foreign body: May need removal by otolaryngologist, or x-ray to look for air in retropharyngeal soft tissue

IN-PATIENT CONSIDERATIONS

Initial Stabilization

- Factors that make sore throat an emergency include:
 - Airway compromise: Epiglottitis, retropharyngeal abscess, peritonsillar abscess, significant tonsillar hypertrophy, diphtheria
- The patient may present with toxic appearance, fever, drooling, voice change, and sitting in the sniffing position (to optimize airway). Make NPO, supplemental oxygen; consider airway adjuncts (e.g., nasal pharyngeal airway), IV access to facilitate airway management (if patient able to tolerate). Consider anesthesia consult for endotracheal intubation in most controlled setting.

Admission Criteria

- Signs/symptoms of airway compromise: General toxicity, stridor, drooling. Patient may need emergency airway protection/stabilization
- Significant dehydration secondary to poor oral intake

- R07.0 Pain in throat

FAQ

- Q: What is the incidence of group A Streptococcal disease as the cause of pharyngitis?
- A: Group A Streptococcus is the most common bacterial etiology of infectious pharyngitis. The incidence of this disease is ~15–30% of all cases of infectious pharyngitis.
- Q: When must antibiotic therapy begin in group A Streptococcal pharyngitis in order to prevent rheumatic fever?
- A: Antibiotics should be started within 9 days from the onset of symptoms in order to prevent this nonsuppurative complication of group A Streptococcal pharyngitis.

SPEECH DELAY

Maureen McMahon

BASICS

DEFINITION

- Speech delay is delay in the acquisition of spoken language.
- Language is a system of symbols through which humans communicate thoughts, feelings, and ideas. It has 3 components—receptive, expressive, and visual language.
 - Receptive language is the ability to process and understand language.
 - Expressive language is the ability to communicate through speech, written, or formal sign language.
- Speech delay can be primary, as in specific language impairment (SLI) or developmental language disorder (DLD); or secondary to another condition, such as a syndrome or neurologic disorder. SLI is impaired speech/language in an otherwise normally developing child who lacks signs or stigmata of other conditions.
- Constitutional language delay, a retrospective diagnosis, is language delay associated with eventual achievement of normal speech and language milestones by school age. There are no subsequent difficulties with learning to read or write.
- Expressive language disorders include the following:
 - Verbal dyspraxia: Little speech produced with great effort, very dysfluent, single words most commonly
 - Speech programming deficit disorder: Poorly organized difficult-to-understand speech
- Mixed receptive and expressive disorders:
 - Verbal auditory agnosia: Impaired ability to decode speech, resulting in a severe expressive impairment. Can often learn language visually.
 - Phonologic/syntactic deficit disorder: Most common type of DLD. Comprehension exceeds spoken ability. Speech is dysfluent, grammatically incorrect with short utterances.
 - Most frequent causes of speech delay:
 - Hearing loss
 - Specific language impairment
 - Autism spectrum disorder
 - Intellectual disability (formerly mental retardation)

EPIDEMIOLOGY

- Up to 15% of 2-year olds have speech and language delays.
- 5% of school-aged children have speech and language delays.
- 3:1 male-to-female ratio in DLD

RISK FACTORS

- Family history of speech/language delay or disorder
- Male gender
- Low maternal education
- Maternal depression
- Prematurity
- Birth weight < 1,000 g

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- **Hearing loss**
 - Isolated genetic hearing loss
 - Hearing loss secondary to in utero CMV infection: Full syndrome at birth or asymptomatic infection with delayed onset of progressive hearing loss
 - Acquired hearing loss: Following head trauma, tumor-associated, following bacterial meningitis, as the result of frequent acute otitis media or chronic otitis media with effusion
- **Intellectual disability**
- **Autism spectrum disorder**
- **Specific language impairment**
- **Constitutional language delay**
- **Environmental**
 - Lack of stimulation and/or poor linguistic environment
 - Child abuse or neglect
 - Lead poisoning
- **Congenital**
 - Cerebral palsy
 - Hydrocephalus
 - Down syndrome
 - Fragile X syndrome
 - 22q11 Microdeletion syndrome
 - Fetal alcohol syndrome
 - Turner syndrome
 - Klinefelter syndrome
 - Prader–Willi syndrome
 - Angelman syndrome
 - Muscular dystrophy
 - Tuberous sclerosis
 - Neurofibromatosis
 - Williams syndrome
 - Branchio-oto-renal (BOR) syndrome
 - Craniofacial anomalies such as Treacher Collins, Goldenhar syndromes
- **Nutritional**
 - Malnutrition
 - Iron deficiency
- **Infectious**
 - HIV encephalopathy
 - Other in utero viral infection
 - Congenital toxoplasmosis
 - Congenital syphilis

ALERT

- Avoid late referral of congenital hearing loss: Amplification and therapy by 6 months of age can result in near normal rate of speech/language acquisition.
- Constitutional language delay is a retrospective diagnosis. Do not assume that a delayed toddler is a “late bloomer” and avoid missing a language disorder.
- Avoid overlooking fine or gross motor delays.
- Avoid missing a genetic or neurologic diagnosis.

HISTORY

Does the family note a concern about speech delay or hearing impairment?

- **Question:** Perinatal history?
- **Significance:** Prenatal care, maternal illness, NICU admission, hyperbilirubinemia requiring exchange transfusion, treatment with ototoxic drugs such as gentamicin, newborn hearing screen results
- **Question:** Full developmental history?
- **Significance:** To determine if global delay or isolated speech and language delay
- **Question:** Parental concern about delayed expressive language?
- **Significance:** Often the presentation of autism
- **Question:** History of feeding, swallowing difficulties, or poor acceptance of textured foods?
- **Significance:** Signs of oromotor dysfunction and may indicate a neurologic problem
- **Question:** Family history of speech delay, hearing loss, neurologic disorder, or syndrome?
- **Significance:** May direct further evaluation
- **Question:** Any regression or loss of language milestones?
- **Significance:** Should prompt a neurologic and metabolic workup
- **Question:** What is the social interaction of the child?
- **Significance:** Lack of interest in playing is a red flag for autism.
- **Question:** Any concern regarding child abuse or neglect, or psychosocial deprivation?
- **Significance:** May have occurred as the result of a parental, genetic, or developmental disorder, drug or alcohol abuse, poverty, child malnutrition, or environmental toxins like lead
- **Question:** History of frequent acute otitis media or otitis media with effusion and conductive hearing loss?
- **Significance:** May precede speech delay
- **Question:** Visual impairments?
- **Significance:** May impact speech development since interpretation of facial expressions and gestures is a component of infant receptive language development
- **Question:** History of traumatic brain injury?
- **Significance:** Speech delay may occur with a seizure disorder.

PHYSICAL EXAM

Complete examination looking for signs that may be associated with speech delay.

- **Finding:** Microcephaly?
- **Significance:** Associated with intellectual disability, in utero CMV infection, or dysmorphic features
- **Finding:** Macrocephaly?
- **Significance:** Associated with hydrocephalus, various syndromes
- **Finding:** Dysmorphic features?
- **Significance:** Suggestive of a syndrome
- **Finding:** Excess drooling and open-mouth posture?
- **Significance:** Signs of poor oral motor control of muscles used for speech production

- **Finding:** Craniofacial abnormalities?
- **Significance:** Articulation difficulty may be due to velopalatal insufficiency (VPI) seen with unrepaired cleft lip or palate.
- **Finding:** Scarred tympanic membranes or middle ear fluid?
- **Significance:** May be clue to acquired intermittent or chronic conductive hearing loss
- **Finding:** Macroorchidism?
- **Significance:** Fragile X syndrome
- **Finding:** Neurologic exam—hypertonia or hypotonia, abnormal reflexes, other focal findings?
- **Significance:** Suggestive of neurologic impairment
- **Finding:** Café-au-lait spots, hypopigmented macules, Shagreen patch, axillary or inguinal freckling?
- **Significance:** Skin findings suggestive of a neurocutaneous syndrome

DIAGNOSTIC TESTS & INTERPRETATION

- The American Academy of Pediatrics recommends a specific development screening tool be administered at the 9, 18, and 24 or 30-month well-child care visits, and an autism-specific tool be administered at the 18 and 24-month visits.
- Office development screening tools:
 - Denver Developmental Assessment II
- Early Language Milestone Scale (ELMS)
- Clinical Linguistic and Auditory Milestone Scale (CLAMS)
- Hearing evaluation:
 - 41 states have mandated Universal Newborn Hearing Screening Programs.
 - Automated Auditory Brainstem Response (AABR) and Transient Evoked Otoacoustic Emissions (OAEs) are the methods used for screening hearing.
 - Hearing should be tested in all speech-delayed children, even if the newborn hearing screen was normal.
 - <6 months of age: The definitive test is Brainstem Auditory Evoked Response (BAER).
 - >6 months of age in a neurologically normal child: The definitive test is behavioral audiometry, such as visual reinforcement audiometry (VRA), performed by a trained audiologist.
- Selected speech/language milestones:
 - 2 months: Cooing, response to voice
 - 6 months: Babbling
 - 4–9 months: Turns to sound, responds to name
 - 9 months: Dada/mama nonspecific, begins to understand “no”
 - 9–12 months: Jargon
 - 12 months: Dada, mama specific, 1 additional word, jargon is complex, points to gesture, follows 1-step command
 - 18 months: 10 words, knows body parts
 - 2 years: 50 words, 2-word phrases, 50% intelligible by strangers, pronouns, can point to specific objects in a picture, may know 1 color, follows 2-step commands
 - 3 years: 300–500 words, tells stories, 75% intelligible by strangers
 - 4 years: Grammatically correct sentences, 100% intelligible by strangers
- Routine cranial imaging or screening tests for metabolic diseases are not recommended.
- **Test:** Full speech and language evaluation
- **Significance:** To delineate the disorder and determine therapy

- **Test:** Individuals with Disabilities Education Act (IDEA) mandates Early Intervention services from birth to 3 years.
- **Significance:** Children can get a full developmental evaluation and appropriate therapy if sufficient delays are demonstrated.
- **Test:** EEG
- **Significance:** Indicated if there is concern for seizures
- **Test:** Genetics evaluation
- **Significance:** Should be obtained for congenital hearing loss or if there is concern for a syndrome or genetic diagnosis
- **Test:** Prolonged sleep EEG
- **Significance:** Indicated with loss of language milestones (consider the diagnosis of Landau–Kleffner syndrome)

TREATMENT

ADDITIONAL TREATMENT

General Measures

- Congenital hearing loss is managed by a team consisting of an otolaryngologist, audiologist, and speech/language therapist who individualize management. Options are amplification, cochlear implant for the severely impaired, or use of sign language.
- Speech and language therapy can be provided through physician referral or parent-generated referral to early intervention programs.
- Sign language can be used as a bridge to promote communication while the child learns verbal skills. It will not preclude or delay the development of speech.
- Augmentative communication devices such as picture boards or programmed computers with voice synthesizers can be used by children with physical impairments such as cerebral palsy.

ONGOING CARE

- Children with DLD usually speak adequately by school age. Some percentage will go on to have difficulty reading and writing
- Children with constitutional language delay will achieve normal milestones by the time they start school.

CODES

ICD9

- 315.34 Speech and language developmental delay due to hearing loss
- 315.39 Other developmental speech or language disorder

ICD10

- F80.4 Speech and language development delay due to hearing loss
- F80.9 Developmental disorder of speech and language, unspecified

FAQ

- Q: Do second- and third-born children speak later than first-born children?
- A: No, the norms for expected speech/language development are the same regardless of birth order. Second- and third-born children should have the same degree of motivation to speak as their first-born sibling.
- Q: When should I refer a child for speech/language evaluation?
- A: If the parents or physician have any concern for speech delay, then referral for evaluation is wise. Some speech-delayed children will eventually normalize and meet all milestones. It is difficult to distinguish who is constitutionally delayed from those who have another disorder. There are several indications for a prompt referral. No pointing or babbling by 1 year, no single words by 16 months, no 2-word spontaneous phrases by 2 years, no sentences by 3 years, poor intelligibility for age, or any regression in language skills.
- Q: Do children raised in bilingual households have expressive language delay?
- A: No, living in a bilingual household is not a cause of expressive language delay. However, toddlers who are learning 2 languages may interchange words in both languages. Total vocabulary and phrase length are typically normal in these children by 2–3 years of age.

SPEECH PROBLEMS

Judith A. Turow

BASICS

DEFINITION

- Language: A system of symbols with a systematic relationship that is used to communicate new ideas
- Speech: The expression of language in a verbal fashion
- Phonemes are the units of sound in speech.
- Phonology is the order in which speech sounds form words.
- Articulation: The process by which words are expressed through muscular movements controlled by complex neuromuscular changes with the production of vocal and articulate sounds
- Children can have central, structural, or functional reasons for speech disorders. The most common speech problems include:
 - Disorders of articulation: Articulation disorders can be organic or functional and occur when children misarticulate words by:
 - Using substitutions of 1 sound for another, commonly “W” for “R”
 - Omitting sounds commonly at the beginning of a word “kip” for “skip”
 - Distorting or adding sounds as “puhlay” for “play”
 - Apraxia is a motor disorder of speech involving central programming for the production of phonemes and the sequencing of voluntary muscle movements for the production of words. Also called “apraxic dysarthria”
 - Dysarthria is a disorder of speech sound production with demonstrable dysfunction or structural abnormality of the tongue, lips, teeth, or palate.
 - Phonologic disorders are functional problems with multiple phoneme errors.
 - Disorders of voice are noted to be disorders of pitch, loudness, quality, and resonance.
 - Dysphonia: A disorder of the voice
 - Rhinolalia: Altered speech due to some abnormality of nasal structures
 - Hoarseness is the most common problem, and results from problems with the vocal folds or their nerve supply. The most common condition in childhood is vocal nodules, which can be removed, but need to be followed by a period of voice rest.
 - Hypernasal speech is the result of a short, cleft or paralyzed palate as a result of an incompetent palatopharyngeal sphincter. It may also occur with a profoundly deaf child because nasal sounds provide the maximal feedback.
 - Hyponasal speech is often acutely due to nasal congestion as seen with viral upper respiratory tract infections or in association with adenoidal hypertrophy when chronic.

- Disorders of fluency include pauses, hesitations, repetitions, interjections, or prolongations.
 - Aphasia is a loss or impairment of ability to produce and/or comprehend language owing to brain damage. It is usually due to damage of the language centers of the brain (Broca aphasia is due to damage in the frontal lobe, and Wernicke aphasia is due to damage of the temporal lobe).
 - Dysrhythmia: A disorder of coordination between respiration and articulatory function (see “Stuttering” chapter)
- Secondary speech disorders are speech disorders not associated with dysfunction or structure but due to other diseases or adverse environmental factors, including mental retardation, hearing defects, psychiatric disorders, and extreme social deprivation, isolation, or institutionalization.
- Mixed speech disorder: A mixture of 2 or more of the categories above (e.g., a cleft lip with abnormal hearing and mental retardation)
- Developmental language impairment and specific language impairment (see “Speech Delay” chapter)

EPIDEMIOLOGY

Communication disorders are the most common developmental problems in preschool-aged children:

- Nearly 20% of 2-year-olds are thought to have delayed onset of speech.
- By age 5, 19% of children are considered to have speech and language disorders—6.4% from speech impairment, 4.6% from speech and language impairment, and 8% from language impairment.
- 50% of mentally retarded children fail to acquire any symbolic communication skills.
- The majority of language disorders, up to 85%, are seen in boys.

DIAGNOSIS

HISTORY

- Is there a history of prolonged feeding time, tongue thrusts, choking on foods, and/or nasal reflux during feeding? Dysarthria is often preceded by dysphasia.
- Persistent nasal reflux during feeding is always a pathologic sign and may be indicative of velopharyngeal insufficiency due to an anatomic or neurologic abnormality.
- Frequent pneumonia, recurrent upper respiratory tract infections, or nasal congestion? Is there evidence for palatal insufficiency?
- Recurrent ear infections, or recent infections implying chronic or acute middle ear fluid?
- Any disorders of the mouth, palate, or tongue? Is there a structural reason for dysarthria?
- Prematurity, intrauterine growth retardation, or meningitis? Are there factors that predispose the child to deafness or mental retardation?
- Family history of speech problems?
- Family history of deafness?
- History of lower motor neuron damage or trauma to the pharynx?

- History of hearing loss?
- Voice overuse?
- Odd/stereotypic behavior, unusual social interactions, or limited play skills? Is there evidence for autism spectrum disorder, pervasive developmental disorder?
- Discrepancy among the areas of skill sets, or regression of skills? Is there any evidence of autistic regression or Landau-Kleffner syndrome (epileptic aphasia)?

PHYSICAL EXAM

Finding:

- Iris heterotropia, white forelock (piebaldism), or dystopia canthorum: Seen in Waardenburg syndrome and with associated deafness
- Microcephaly: May be associated with brain damage from underlying in utero infection, toxin exposure, or genetic disorder
- Enlarged tonsils: Potential reason for abnormal resonance, such as hyponasal speech
- Any impaired sucking or swallowing, bifid or notched uvula, drooling, abnormal gag reflex, tongue thrusts, evidence of tracheotomy scar, potential reason for functional or structural dysarthria, potential reason for damage to vocal cords?
- Upper motor neuron signs, such as involuntary grimacing, drooling, abnormalities of the gag reflex, impairment of sucking and swallowing: May be seen with cerebral palsy, Möbius syndrome

DIAGNOSTIC TESTS & INTERPRETATION

Diagnostic Procedures/Other

- Formal testing to examine overall cognitive level, language related to the cognitive level, and other atypical features (including stereotypies, poor socialization skills, sensory aversions)
- Speech and language pathologist
- Psychoeducational testing
- Hearing evaluations
- Screening audiometry: High false-negative rate and inappropriate for the younger child
- Formal audiologic testing including tympanometry and audiometry and possible brainstem evoked response testing for hearing loss
- Speech evaluation
- Videofluoroscopic speech study
- Nasometer: Microchip-based instrument to measure sound coming from the oral and nasal cavities; test to aid in the evaluation of resonance
- Language evaluation:
 - The Early Language Milestone (ELM) Scale (revised ELM 2 now available): Covers language development from birth through age 36 months and intelligibility of speech from ages 24–48 months
 - The Clinical Linguistic and Auditory Milestone Scale (CLAMS): Tests language development from birth through 36 months, confirming normal language in the 14–36-month age range, although less useful for confirming receptive language delay in 14–36-month-old children, or expressive language delay in children <25 months
- Metabolic and cytogenetic testing for disorders including Fragile X syndrome

- Apex SNHL (sensorineural hearing loss) microarray for molecular diagnosis of genetic deletions in nonsyndromic SNHL
- Central nervous system (CNS) imaging is rarely helpful, except with autistic regression or Landau-Kleffner syndrome (epileptic aphasia)

DIFFERENTIAL DIAGNOSIS

- Infectious:
 - Prenatal: Toxoplasmosis, rubella, cytomegalovirus, or herpes virus (TORCH) infections
 - Postnatal infections, particularly bacterial meningitis caused by:
 - *Neisseria meningitidis*
 - *Haemophilus influenzae*
 - *Streptococcus pneumoniae*
 - Recurrent throat infections
 - Recurrent ear infections
- Environmental: Isolation and/or social deprivation
- Structural:
 - Cleft lip or palate
 - Notched uvula
- Genetic:
 - Waardenburg, branchio-oto-renal, or Stickler syndromes; neurofibromatosis type 2
 - Autosomal recessive (AR) inheritance
 - Refsum disease, Usher syndrome, Pendred syndrome, Biotinidase deficiency
 - X-linked recessive
 - Alport syndrome
 - Mohr-Tranebjaerg syndrome
- Developmental:
 - Mental retardation
 - Autism spectrum disorder
 - Apraxia
- Neuromuscular:
 - Cerebral palsy
 - Broca or Wernicke aphasia
 - Möbius syndrome
 - Landau-Kleffner syndrome
- Nutritional: Malnutrition
- Acquired hearing loss
 - Noise exposure
 - Aminoglycoside-acquired hearing loss
 - Hyperbilirubinemia, severe
 - Trauma to the head and neck
 - Cholesteatoma
- Acquired voice loss/dysfunction:
 - Trauma to the head and neck
 - Tracheotomy
 - Adenoid enlargement
 - Chronic/recurrent nose and/or throat infections
 - Nasal allergies
 - Voice abuse

 **TREATMENT**

ADDITIONAL TREATMENT

General Measures

- Home-based programs through early intervention for preschool children up to age 5.
- Special education enrollment for school-aged children
- Audiologic assessment for all children with speech disorders is a must and should include hearing testing. Referral to an otolaryngologist to evaluate the function and structure of anomalies of the head and neck
- Referral to a speech therapist: Children who have oral-motor deficits (especially speech apraxia) and require intensive speech and language therapy

- Signing and/or picture card system may be helpful with severe speech and language problems to teach child how to communicate:
 - Use of signing by nonverbal children has been shown to be an effective bridge to spoken language. Picture exchange is another method of communicating.
- Referral to psychologist/child developmentalist
- Referral to an occupational therapist trained in sensory integration techniques: Can assist in management of children who show aversive behaviors
- American Sign Language teacher

 **ONGOING CARE**

FOLLOW-UP RECOMMENDATIONS

- The prognosis for most children with expressive language problems is excellent. Most will have normal language skills by the time they enter primary school.
- However, if there are persistent speech and/or language problems by 5 years of age, there is a 70–80% chance of continued communication difficulty and reading disorders.
- Pearls:
 - “Rule of 4s”: Divide the child’s age in years by 4; the quotient is approximately equal to the percentage of the child’s speech that should be intelligible to strangers:
 - A 1-year-old should be intelligible to strangers 1/4 of the time
 - A 2-year-old, 1/2 of the time
 - A 3-year-old, 3/4 of the time
 - A 4-year-old, essentially 100% of the time
 - The average 1-year-old should be speaking at least 1 word (other than mama, dada, or family names), following at least a 1-step command not accompanied by physical gestures, and pointing with 1 finger to desired objects.
 - A 2-year-old will be speaking 2-word phrases and following 2-step commands.
 - Between ages 2 and 3, the average child uses “telegraphic speech” (e.g., “go home now”).
 - The average 3-year-old should be fluent in the present tense and have a speaking vocabulary of 500–1,000 words.
 - The average 5-year-old follows 3-step commands, names 5 colors, has a vocabulary of >2,000 words, and makes up rhymes.

 - R47.9 Unspecified speech disturbances

FAQ

- Q: Does ankyloglossia make a difference in the emergence of language?
- A: The tongue has to move freely for speech with such sounds as /t/, /d/, /n/, and /l/, but misarticulation caused by ankyloglossia is quite rare.
- Q: Does “signing” delay speech?
- A: In fact, signing may promote speech development and progression owing to the increased ability of the child to communicate.
- Q: Is gender or birth order a risk factor for delayed speech?
- A: Studies show male children lag 1–2 months behind in vocabulary and grammar when compared to females. Studies on birth order are inconclusive.
- Q: Does bilingualism make a difference in speech progression?
- A: Toddlers from bilingual homes may show some delays early on. Speech progression is enhanced if the two languages are spoken in separate contexts (e.g., the 1st language is spoken at home all the time and the 2nd language is spoken out of home all the time, rather than a mixture of both languages in the same environment), but this is not always practical for families.

SPINAL MUSCULAR ATROPHY

Jennifer A. Markowitz
Peter B. Kang (5th edition)

BASICS

DESCRIPTION

- Spinal muscular atrophy (SMA) is a progressive disorder of motor neurons in the spinal cord and brainstem.
- Major symptom is proximal weakness.
- 3 forms are described based on clinical features:
 - Type I, also known as Werdnig-Hoffman disease, typically presents by 6 months; these children never sit.
 - Type II typically presents between 6 and 18 months; these children sit independently but never walk.
 - Type III, also known as Kugelberg-Welander disease, may be diagnosed later; these children stand and walk at some point.
- There appears to be a spectrum of severity within and between each type.

EPIDEMIOLOGY

The most common genetic cause of infant mortality

Incidence

Incidence estimated at 1 in 6,000–10,000 live births; carrier frequency 1 in 40–50, though some variation between populations seems to exist

RISK FACTORS

Genetics

- Genetic testing is recommended in all cases, even when the diagnosis appears clear.
- Genetic counseling is critical for all families with children affected by SMA, as the chance of recurrence is 25%.
- SMN2 copy number varies among the general population and is loosely correlated with SMA type (type I likely to have fewer copies); however, all copies of SMN2 are not equal (some make more SMN protein than others) and an individual patient's SMN2 copy number should not be used for prognostic purposes.
- Universal newborn screening is strongly recommended by some but is not yet in place.

ETIOLOGY

- All 3 types of proximal SMA follow an autosomal recessive inheritance and are caused by mutations in the survival motor neuron (SMN) gene on 5q11.2 to 13.3.
- 2 copies of SMN on each chromosome. SMN1 (SMNt), the telomeric copy, produces stable SMN protein. SMN2 (SMNc), the centromeric copy, is an inverted duplication of SMN1 with a single nucleotide change in an exonic splice enhancer, which produces mostly an unstable, truncated protein product and a smaller percentage of stable, full-length SMN protein. Individuals with SMA harbor homozygous deletions of exon 7 in the SMN1 gene, which renders it nonfunctional. The presence of SMN2 essentially “rescues” individuals with SMN1 deletions, since complete absence of SMN protein appears to be embryonically lethal. The level of SMN protein roughly correlates with the severity of disease.

- The SMN protein plays a role in RNA processing; it is unclear why motor neurons (anterior horn cells) are selectively vulnerable to this defect, although a role in axonal mRNA trafficking and splicing is being explored.

COMMONLY ASSOCIATED CONDITIONS

Other anterior horn cell diseases:

- SMARD (SMA with respiratory distress) or diaphragmatic SMA, due to mutations in the IGHMBP2 gene on chromosome 11q
- Distal SMAs, a group of disorders with distal weakness, genetically heterogeneous
- Other variants are associated with arthrogryposis, pontocerebellar hypoplasia, congenital fractures, and congenital heart disease. Few such cases have been shown to have SMN mutations.
- Fazio-Londe disease: Rare degeneration of anterior horn cells in the brainstem, childhood onset
- Kennedy disease, or X-linked spinal and bulbar muscular atrophy: Anterior horn cell disease with adult onset; affected men have gynecomastia, bulbar weakness, and reduced fertility.

DIAGNOSIS

HISTORY

- Hypotonia and weakness are the primary features. Infants with SMA I will be floppy and less active and have delayed motor milestones, with preserved language/social interaction (a bright, alert demeanor is often remarked upon).
- Some babies with type I present with feeding problems and failure to thrive.
- History of reduced vigor of prenatal movements

PHYSICAL EXAM

- Weakness and absent or reduced reflexes suggest a neuromuscular rather than central etiology for hypotonia. A proximal pattern of weakness is consistent with SMA, myopathies, and muscular dystrophies; a distal pattern usually suggests polyneuropathies.
- Weakness is almost universally symmetric, but occasional cases of asymmetric weakness have been reported in SMA III.
- Extraocular movements remain intact in SMA.
- Facial strength diminishes in children with type I over time, and jaw contractures may be present in type II.
- Dysmorphic features, or involvement of other organs, may point to alternative diagnoses. Occasionally, SMA presents with contractures (spectrum of arthrogryposis multiplex congenita).
- Tongue fasciculations strongly suggest SMA, but their absence does not exclude the diagnosis.
- Tremor of a specific type, polyminimyoclonus, is often present in type II.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Initial screening tests: Serum creatinine kinase may be mildly elevated.
- Genetic testing:
 - Genetic testing of DNA extracted from blood (SMN deletions): Now the gold standard in diagnosis, may be done prenatally, >95% sensitive
 - Genetic testing for Prader-Willi syndrome (fluorescence in situ hybridization and methylation) may be indicated if there is no SMN gene deletion and electromyography (EMG) is normal in an infant who appears to have SMA.
- Other testing:
 - EMG may be helpful if the clinical presentation is atypical for SMA or if genetic testing is negative. EMG shows high-amplitude, long-duration motor units with a reduced recruitment pattern.
 - With the advent of molecular testing, muscle biopsy is rarely performed. Use when genetic testing is unrevealing. The characteristic findings are fiber-type grouping with generalized atrophy of muscle fibers.
 - If the entire evaluation is negative, MRI of the spine may be indicated to evaluate for an anomaly or mass lesion.

DIFFERENTIAL DIAGNOSIS

- Other genetic neuromuscular disorders include congenital muscular dystrophy, congenital myopathy, glycogen storage disorders (Pompe disease), myotonic dystrophy, mitochondrial disease, congenital myasthenia gravis, and Prader-Willi syndrome.
- More acute course may suggest infant botulism or Guillain-Barré syndrome, although the latter is rare in this age group.
- Systemic disorders: Sepsis, meningitis, acute bowel syndromes
- SMA II differential: Congenital muscular dystrophy, congenital myopathy, and congenital myasthenia gravis
- SMA III differential includes Duchenne, Becker, and the limb girdle muscular dystrophies.
- Spinal cord mass lesions may rarely resemble SMA.

TREATMENT

ALERT

An apparently minor respiratory infection may carry a higher risk of respiratory failure in SMA I and later stages of SMA II and III. Depending on family/patient wishes regarding respiratory support, consider admitting such a patient to the hospital for observation. Infants with SMA may be exquisitely sensitive to postural shifts—watch for hypoventilation, for example, with forward truncal flexion associated with some seating arrangements.

ADDITIONAL TREATMENT

General Measures

- A multidisciplinary approach to care is recommended, with early and proactive involvement of orthopedics, nutrition, pulmonary, and physical and occupational therapy, as well as social work and psychological support for families and patients.
- Physical therapy is appropriate for all 3 types; though it may not affect the course in SMA I, it can lessen discomfort and make care easier by improving range of motion and preventing contractures
- A wheelchair provides mobility in SMA II. Children as young as age 2 may be considered for a motorized wheelchair, depending on developmental level. Adults with SMA III may require the use of a wheelchair later in their course.
- Bracing of ankles, wrists, and back can help reduce contractures and slow progression of scoliosis.
- Spinal fusion surgery may preserve respiratory function.
- Low threshold for empiric antibiotics for respiratory infection is appropriate.
- Chest physiotherapy and early implementation of cough assist device can help prevent pneumonia and atelectasis.
- Be wary of symptoms of hypoventilation (disturbed sleep, daytime fatigue, moodiness, morning headaches), which may occur prior to other symptoms of respiratory insufficiency.
- Low threshold to order a sleep study if hypoventilation is suspected
- In acute respiratory illness, supplemental oxygen is appropriate, as long as the patient is also evaluated and treated for hypercarbia.
- Noninvasive positive-pressure ventilation (BiPAP and other regimens) may improve quality of life and life expectancy in patients with decreased respiratory function. More aggressive respiratory management is becoming more common and accepted among families and physicians, but the extent of interventions varies widely. Start discussions about family/patient preferences early, as respiratory decompensation can occur very quickly.
- Avoid catabolic state with proactive nutritional support, including tube feeding.
- However, note that type II patients may have increased adiposity, and overweight is also a risk.
- Monitor for osteopenia, which is almost universal in types I and II, and ensure adequate calcium and vitamin D intake.
- Social and psychological support for caregivers and patients

ONGOING CARE

PATIENT EDUCATION

- Families of SMA: <http://www.fsma.org>
- Fight SMA: <http://www.fightsma.org>
- Muscular Dystrophy Association: <http://www.mdasa.org>
- Spinal Muscular Atrophy Foundation: <http://www.smafoundation.org>

PROGNOSIS

- Survival in all 3 forms has been increasing with improved supportive care and, in type I, ventilatory support.
- Most children with SMA type I die by 2 years without major pulmonary interventions. With ventilatory support, patients may survive several years longer; survival as long as 2 decades has been observed with tracheostomy and full mechanical ventilation.
- Children with SMA type II typically survive into late adolescence or early adulthood; this life expectancy is increasing with more aggressive pulmonary management.
- Individuals with SMA type III survive well into adulthood, and often have a normal life expectancy. In 1 study of patients with SMA type III with onset <3 years, 50% could not walk 20 years later; for those with onset >3 years, 30% could not walk 20 years later.
- Intelligence is generally preserved.
- Death typically ensues from respiratory complications. Discuss the level of respiratory interventions, including resuscitation, early in SMA I and in the advanced stages of SMA II and III.

COMPLICATIONS

- Recurrent pneumonias, hypoventilation
- Swallowing difficulties may require tube feeding.
- Scoliosis may require surgery.

CODES

ICD9

- 335.0 Werdnig-Hoffmann disease
- 335.10 Spinal muscular atrophy, unspecified
- 335.19 Other spinal muscular atrophy

ICD10

- G12.0 Infantile spinal muscular atrophy, type I [Werdnig-Hoffman]
- G12.1 Other inherited spinal muscular atrophy
- G12.9 Spinal muscular atrophy, unspecified

FAQ

- Q: Can routine vaccinations be given to children with SMA?
- A: Yes. In addition to routine vaccinations, yearly influenza and RSV vaccinations are recommended.
- Q: How much respiratory support should a child with SMA receive?
- A: Standards of care are evolving rapidly, and a consensus remains elusive. However, noninvasive respiratory interventions are becoming more widely accepted. Noninvasive respiratory options should be offered to all patients with SMA I and those in the later stages of SMA II. Tracheostomy is more controversial.
- Q: Are more effective therapies for SMA being developed?
- A: There are ongoing studies in animal models and on humans, involving both pharmacologic and gene-based therapies. Families of SMA, the Muscular Dystrophy Association, and other groups are sources of information on such research.

SPLENOMEGALY

Matthew J. Ryan

BASICS

DEFINITION

- A palpable spleen is found in most premature infants and in 30% of term infants. A spleen tip is still palpable in 10% of infants at 1 year of age and in 1% of children at 10 years of age.
- Normal spleens are not greater than 6 cm at 3 months, 7 cm at 12 months, 9.5 cm at 6 years, 11.5 cm at 12 years, and not greater than 13 cm for adolescents.
- The clinical significance of splenomegaly found on radiologic study, but not palpable on physical exam, is unclear in the absence of other laboratory or clinical data.
- Normal spleens are soft at the midclavicular line, nontender, and often palpable only on deep inspiration.
- Dullness on percussion beyond the 11th intercostal space suggests splenomegaly.
- A spleen edge palpated >2 cm below the costal margin is always an abnormal finding.
- Splenic tenderness is abnormal.

PATHOPHYSIOLOGY

- The spleen is a hematopoietic organ with 2 main parts:
 - White pulp is the lymphoid tissue.
 - Red pulp is the red cell mass.
- Splenic sinusoids are lined with macrophages that destroy abnormal red cells.
- The spleen also serves as a reservoir for platelets. A normal-sized spleen can hold 1/3 of the circulating platelets; an enlarged spleen can hold up to 90% of the circulating platelet mass.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

• Infectious

- Bacterial:
 - Bacteremia
 - Pneumonia
 - Sepsis
 - Subacute bacterial endocarditis
 - Salmonellosis
 - Tuberculosis
 - Brucellosis
 - Staphylococcal shunt infections
 - Tularemia
 - Syphilis
 - Leptospirosis

- Viral:
 - Epstein–Barr virus (mononucleosis)
 - Cytomegalovirus
 - HIV
 - Rubella
 - Herpes
 - Hepatitis A, B, C
- Rickettsial/protozoan:
 - Rocky Mountain spotted fever
 - Malaria
 - Toxoplasmosis
 - Trypanosomiasis
 - Babesiosis
 - Schistosomiasis
 - Visceral larval migrans
 - Kala azar
- Fungal:
 - Histoplasmosis
 - Coccidioidomycosis
- **Hematologic disorders**
 - Hereditary spherocytosis
 - Sickle cell disease in early childhood or during splenic sequestration crisis
 - Hemoglobin C disease
 - Thalassemia major
 - Autoimmune hemolytic anemia
 - Glucose-6-phosphate dehydrogenase deficiency
 - Isoimmunization disorders
 - Infantile pyknocytosis
 - Iron-deficiency anemia (rare)
 - Thrombocytopenic purpura
- **Vascular disorders**
 - Cavernous transformation of the portal vein
 - Budd–Chiari syndrome
 - Splenic vein thrombosis
 - Congenital portal vein stenosis or atresia
 - Splenic hematoma
 - Splenic hemangioma
- **Liver disease/cirrhosis** (examples include, but are not limited to)
 - Biliary atresia
 - Wilson disease
 - Cystic fibrosis
 - α -1-Antitrypsin deficiency
 - Hereditary hemochromatosis
 - Congenital hepatic fibrosis
 - Autoimmune hepatitis
 - Primary sclerosing cholangitis

• Metabolic diseases (storage)

- Gangliosidosis
- Mucopolysaccharidoses
- Metachromatic leukodystrophy
- Wolman disease
- Gaucher disease
- Niemann–Pick disease
- Amyloidosis

• Neoplastic diseases

- Leukemia
- Lymphoma
- Lymphosarcoma
- Neuroblastoma
- Histiocytosis X
- Familial hemophagocytic lymphohistiocytosis

• Miscellaneous

- Serum sickness
- Connective-tissue disorders
- Juvenile rheumatoid arthritis
- Systemic lupus erythematosus
- Sarcoidosis
- Splenic hamartoma
- Splenic cysts: Congenital and post-traumatic
- Trauma: Subcapsular hematoma

• Nonsplenic upper left quadrant abdominal masses

- Large kidney
- Retroperitoneal tumor
- Adrenal neoplasm
- Ovarian cyst
- Pancreatic cyst
- Mesenteric cyst
- Rib anomaly

ALERT

- Life-threatening causes: Sepsis, severe hemolytic anemia, trauma, splenic sequestration
- A large-bore IV access route should be rapidly placed when a life-threatening cause is suspected.

APPROACH TO THE PATIENT

General goal is to determine the etiology of the large spleen.

- **Phase 1:** Establish the presence of enlarged spleen, not a palpable spleen that is pushed down by inflated lungs
- **Phase 2:** Rule out common causes such as a viral infection, bacterial infection, or anemia
- **Phase 3:** Rule out malignancy or storage disease or other rare causes of large spleen

HISTORY

- **Question:** History of acute illness?
- **Significance:** Suggests infection
- **Question:** History of GI bleeding with splenomegaly?
- **Significance:** Suggests portal hypertension
- **Question:** Familial history of hematologic or immune disease?
- **Significance:** Suggests genetic etiology
- **Question:** An enlarged liver, developmental delay, or neurologic findings?
- **Significance:** May suggest a storage disease or metabolic disorder

PHYSICAL EXAM

Begin the abdominal examination in the lower left quadrant, because an enlarged spleen may be missed in the upper quadrant exam. Stand to the right of the patient; use the right hand to palpate and the left hand to support the patient's left lower rib cage. Flexing the legs at the knees may help to relax the abdominal musculature.

- **Finding:** Auscultate?
- **Significance:** For rub or bruit
- **Finding:** Look for signs of storage disease?
- **Significance:** Retinal exam, coarse facies
- **Finding:** Complete evaluation of lymph nodes?
- **Significance:** Enlargement suggests infection or neoplasia.
- **Finding:** Palpate for ascites or hepatomegaly?
- **Significance:** Suggests underlying hepatic disease
- **Finding:** Prominent abdominal veins or hemorrhoids?
- **Significance:** Suggest increased portal venous pressure
- **Finding:** Pain/tenderness?
- **Significance:** Suggests capsular distention secondary to perisplenitis or trauma; also raises the question of splenic infarct.
- **Finding:** Asthmatic patients may have palpable spleen?
- **Significance:** Secondary to overinflation of lungs and depressed diaphragm

DIAGNOSTIC TESTS & INTERPRETATION

Discriminating laboratory tests: If no hemolytic disease, with signs of infection

- Blood culture
- Thick smear of blood for malaria
- Viral testing
- **Test:** CBC with manual differential and smear
- **Significance:** For sickle cell disease, hemolytic anemia, leukemia
- **Test:** Decreased WBC count and platelets
- **Significance:** Often seen with splenic sequestration or portal hypertension
- **Test:** Reticulocyte count
- **Significance:** For hemolytic anemia
- **Test:** Hepatic function panel (liver enzymes, albumin, bilirubin) and PT/INR, PTT
- **Significance:** For cirrhosis, hepatic obstruction
- **Test:** Serum LDH
- **Significance:** For hemolysis or tumor screen

Imaging

- If no hemolytic disease, no sign of infection, no sign of congestion:
 - Ultrasound with Doppler
 - Liver spleen scan
 - Biopsy of lymph node, liver, or other tissue, depending on findings
- If no hemolytic disease, no sign of infection, but signs of congestion:
 - Ultrasound with Doppler
 - MRI; consider MRA/MRV
 - CT scan

TREATMENT

ADDITIONAL TREATMENT

General Measures

Depends on underlying etiology

ISSUES FOR REFERRAL

- Disproportionate size of spleen
- Increasing size over serial examinations
- Unexplained lymphadenopathy
- Liver dysfunction
- Ascites
- Signs of storage or metabolic disease
- Howell–Jolly bodies on peripheral smear, suggesting splenic dysfunction

CODES

ICD9

- 289.51 Chronic congestive splenomegaly
- 789.2 Splenomegaly

ICD10

- R16.1 Splenomegaly, not elsewhere classified
- D73.2 Chronic congestive splenomegaly

FAQ

- Q: How long will the enlarged spleen secondary to a viral infection be present?
- A: The enlarged spleen may persist for several months.
- Q: Should a child with an enlarged spleen refrain from sports?
- A: Contact sports should be avoided for a child with an enlarged spleen. An enlarged spleen is engorged with blood, and a splenic rupture would be a catastrophic event. Children with persistent splenomegaly should be considered for a spleen guard.

STAPHYLOCOCCAL SCALDED SKIN SYNDROME (SSSS)

Mark L. Bagarazzi

BASICS

DESCRIPTION

- A spectrum of generalized exfoliative skin eruptions, that resemble scalding injuries but are caused by an epidermolytic toxin produced by certain strains of *Staphylococcus aureus*
- Known as Ritter disease or pemphigus neonatorum in neonates
- Spectrum of disease includes:
 - Bullous impetigo: Characterized by discrete, flaccid bullae containing clear or cloudy yellow fluid localized to the site of staphylococcal infection
 - Staphylococcal scarlet fever: A mild generalized scarlatiniform eruption with exfoliation, but without the strawberry tongue and palatal enanthem of streptococcal scarlet fever. Evidence based on toxin production now suggests that staphylococcal scarlet fever often represents an abortive form of toxic shock syndrome.
 - Classic staphylococcal scalded skin syndrome (SSSS): Characterized by abrupt onset of fever, irritability, and diffuse, blanchable erythema in association with marked skin tenderness in which toxin circulates throughout the body, causing blisters at and distant to the site of infection
- Pitfalls
 - Differentiation from streptococcal disease with need for penicillinase-resistant antibiotic therapy (e.g., nafcillin)
 - A methicillin-resistant strain of *S. aureus* has been reported to cause SSSS.
 - Adhesive occlusive dressings used to apply topical local anesthetic prior to venipuncture have been shown to cause injury and discomfort in areas previously free of blistering in patients with SSSS.
 - Diagnosis should be made clinically and should not be delayed several days while waiting for the results of cultures or other diagnostic tests, that are largely confirmatory.

GENERAL PREVENTION

- Eradication of staphylococci to prevent recurrences after first attack
- Preventing skin from becoming overly moist or macerated
- Scrupulous care in performance of even minimally invasive health promotion measures such as vitamin K prophylaxis and metabolic screening can reduce neonatal cases.
- Isolation of hospitalized patient
 - Suspected or documented cases should be placed in contact isolation.

EPIDEMIOLOGY

- The vast majority of cases occur in neonates or even in the intrauterine environment (as in Ritter disease) and children <5 years of age.
- Antibodies to exfoliative (epidermolytic) toxin A (ETA) (see below) have been found in 88% of cord blood samples and are absent in acute sera of patients with SSSS.
- Most cases are caused by type 71 (75% of cases) or type 70, with occasional cases due to types 3A, 3B, 3C, and 55.
- Large screening experiments reveal toxin-producing strains in 5–6% of individuals.
- Occurs rarely in adults, due to increased circulating antibodies and adult kidney excretion of the toxin
- Occurs most frequently in adults in association with immunosuppression or renal impairment

Incidence

No differences in incidence based on gender or socioeconomic status

PATHOPHYSIOLOGY

- The soluble exotoxins referred to as exfoliative (epidermolytic) toxin A or B (ETA or ETB), produced by certain strains of *S. aureus* and usually belonging to phage group II in the United States, are responsible for SSSS.
 - The exotoxins are glutamate-specific trypsin-like serine proteases. The active site of the exfoliative toxins appears to be conformationally blocked in its native state. The target for the toxins has been identified as desmoglein-1, a desmosomal glycoprotein that plays an important role in maintaining cell-to-cell adhesion in the superficial epidermis. It is speculated that binding of the exfoliative toxin's active site to desmoglein-1 results in a conformational change that opens the active site of the toxin to cleave the extracellular domain of desmoglein-1, resulting in disruption of intercellular adhesion and formation of superficial blisters.
- Generalized desquamation with early intra-epidermal bullae demonstrating a cleavage plane just beneath the granular cell layer
- Nikolsky sign develops within 12 hours to 3 days, accompanied by flaccid thin-walled bullae. Bullae rupture spontaneously within hours, separating the superficial epidermis into large sheets revealing moist red surfaces resembling burns. 1–3 days later, the denuded areas dry and the entire body surface undergoes a secondary flaky desquamation. The entire skin heals within 10–14 days.

DIAGNOSIS

- Pitfall: Confusion with toxic epidermal necrolysis (TEN) may lead to possible use of corticosteroids or simple discontinuation of antibiotics, resulting in enhanced infection from prolonged toxin production.

HISTORY

- Nonspecific virus-like prodrome with irritability is the typical presentation of SSSS.
- Rash typically begins periorally, then extends to the trunk and extremities and finally desquamates.
- Recent, seemingly trivial, localized extracutaneous infection
 - Infections involving the nasopharynx, middle ear, conjunctivae, pharynx, tonsils, umbilicus, or urinary tract are frequently recalled.
- Recent medication use: A history of recent drug use suggests TEN.

PHYSICAL EXAM

- Erythroderma: Usually extremely painful
- Fever: Usually abrupt onset after prodrome
- Large flaccid bullae that leave behind denuded skin resembling a burn after rupturing; bullae often appear in areas of trauma, or in areas that are rubbed or touched, including intertriginous zones.
- Distribution of lesions: Usually involve perineal, periumbilical, and intertriginous areas of the neonate; in older children, the extremities are usually involved.
- Crusting seen in a radial pattern (sunburst) around the mouth, nose, and eyes; occurs without mucous membrane involvement
- Sandpaper texture of rash and increased erythema or petechiae in skin creases; Pastia lines are seen in the scarlatiniform variant.
- Nikolsky sign: Gentle friction applied obliquely to apparently healthy skin will cause wrinkling, then sloughing.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Skin biopsy: Used to differentiate SSSS from TEN; the cornified skin layer is recovered in SSSS, whereas the entire necrotic epidermis should be recognized in TEN.
- Excision of some exfoliated skin for frozen or permanent histologic section; easier to obtain than a biopsy; often useful in arriving at the diagnosis

DIFFERENTIAL DIAGNOSIS

- Toxic epidermal necrolysis (TEN)
- Kawasaki disease
- Erythema multiforme bullosum
- Erythema multiforme major (Stevens-Johnson syndrome)
- Streptococcal or staphylococcal toxic shock syndrome (TSS)
- Bullous varicella
- Burns, including inflicted burns in suspected child abuse
- Primary bullous disorders (e.g., bullous mastocytosis)
- Chronic bullous disease of childhood
- Pemphigus vulgaris or foliaceus
- Epidermolysis bullosa

TREATMENT

General Measures

- Apply principles of good burn care in severe cases, including:
 - Cases affecting large areas of skin should be managed in a critical care setting.
 - Fluid and electrolyte management should include daily maintenance requirements as well as replacement of “third-space” fluid loss based on the percentage of affected body surface area (BSA). Fluid should be replaced as an isotonic solution calculated at 3 mL/kg of affected BSA. Most experts recommend replacement of one half of losses over the first 8 hours and the other half over the next 16 hours.
 - Children should be allowed to rest unclothed on sterilized linens, and handling of the child should be kept to a minimum. Wound care should focus on maintenance of developing eschars. This is usually followed by débridement, and affected areas are eventually dressed with silver sulfadiazine or a similar agent.
 - FDA-approved absorbable, synthetic wound dressing with properties of natural epithelium appear to reduce pain, accelerate epithelialization and reduce nursing time in SSSS.

MEDICATION (DRUGS)

- Antistaphylococcal agents: Parenteral antibiotic therapy (e.g., nafcillin, oxacillin, cephalosporins, clindamycin) should be used for extensive skin involvement or serious systemic disease. Oral therapy (e.g., dicloxacillin, cloxacillin, amoxicillin/clavulanate, cephalexin, clindamycin) is generally sufficient for bullous impetigo. Duration of therapy is typically 7–10 days. Topical preparations are of no benefit.
- Corticosteroids have been shown to be detrimental both in experimental animal models as well as clinical trials.

ONGOING CARE

PROGNOSIS

- Exfoliated areas eventually dry with a flaky desquamation within 3–5 days of initiating appropriate antibiotic therapy.
- Usually, complete recovery within 10–14 days without scarring
- Prognosis is more guarded in infants and those with underlying illness.
- Mortality reported as 1–10% in neonates and 3% in children but as high as 60% in adults with underlying disease

COMPLICATIONS

- Occasional shedding of hair and nails
- Fungal or bacterial superinfection following desquamation
- Serious fluid and electrolyte disturbances in cases involving large surface areas, which may lead to poor temperature control, hypovolemia, sepsis syndrome, and death. Neonates are particularly susceptible.

PATIENT MONITORING

Patients may be followed via telephone as long as lesions are healing well and parents do not report significant complications.

ICD10

- L00 Staphylococcal scalded skin syndrome

FAQ

- Q: Can SSSS recur?
- A: Yes
- Q: Is SSSS contagious?
- A: Yes, the staphylococci are spread primarily from person to person (familial clusters have been reported), even from mother to fetus, most efficiently by someone with lesions, but asymptomatic carriers may also spread infection. Spread of organisms does not necessarily lead to signs of toxin production in those acquiring infection.
- Q: How can one distinguish TEN from SSSS?
- A: TEN is frequently confused with SSSS and may be differentiated by skin biopsy showing cleavage plane at the dermal–epidermal junction. TEN or Lyell disease is more common in adults and is usually secondary to drug hypersensitivity (e.g., sulfonamides, barbiturates, pyrazolone derivatives).
- Q: Can staphylococcus be isolated from the bullae?
- A: SSSS bullae are sterile, although organisms may be found in a distant focus, such as the nares or conjunctivae. In bullous impetigo, however, staphylococci may be isolated from the bullae.

STATUS EPILEPTICUS

Juliann Paolicchi

Eric Marsh (5th edition)

Amy R. Brooks-Kayal (5th edition)

Keith Nagle (5th edition)

BASICS

DESCRIPTION

- Status epilepticus (SE) is defined as >30 minutes of continuous seizure activity or sequential seizures in 30 minutes without full recovery of consciousness. In practice, convulsive seizures >5 minutes in duration are treated as presumptive SE, since it is uncommon for convulsive seizures to continue >5 minutes and more likely to continue into SE.
- SE presents in several forms:
 - Generalized SE: Continuous or repeated generalized convulsion(s) with persistent loss of consciousness and neurologic function
 - Nonconvulsive SE or absence SE: Persistent encephalopathy, often with variable subtle motor signs such as myoclonus or nystagmus
 - Repeated partial seizures with an alteration of consciousness (focal status epilepticus) or preserved consciousness (epilepsia partialis continua)
 - SE is also classified by etiology:
 - Acute symptomatic (26%)
 - Remote symptomatic (33%) prior history of CNS disease
 - Progressive encephalopathy (underlying, progressive CNS disorder)
 - Febrile (22%)
 - Cryptogenic (15%)

ALERT

- The most common etiology for SE in children with epilepsy is low antiepileptic medication (AED) levels. Check levels on any patient on AED treatment.
- Neuromuscular blockers used in intubation may obscure ongoing seizures. EEG monitoring is mandatory for all patients who have had pharmacologic paralysis for airway control during SE.
- Continued encephalopathy after convulsions have ended may indicate continued electrographic seizures (non-convulsive SE)
- Nonepileptic SE (psychogenic) is often mistaken for SE. EEG establishes the diagnosis.
- Rhabdomyolysis may complicate SE. Hydration should be maintained, and creatine kinase levels can be followed.

GENERAL PREVENTION

- Need for long-term antiepileptic drug (AED) therapy after SE depends on the etiology, patient's age, and circumstances in which SE occurred.
 - Chronic AED therapy is indicated when SE is caused by structural brain lesions or in patients with known epilepsy.
 - Chronic AED therapy is generally not needed in children who have SE from transient metabolic disturbances (e.g., hyponatremia, intoxication, fever), or in idiopathic SE as a first seizure.

- Educate family members regarding first aid for seizures. Discuss potential risks of seizure recurrence even if the child is taking an AED. Review risks of climbing, swimming, bathing, and not having head protection for wheeled toys (bikes, skateboards, scooters).
- Provide caregivers with rectal diazepam with instructions for its use for seizure >5 minutes in duration.
- Neurology consultation is recommended.

EPIDEMIOLOGY

Incidence

- Incidence in the pediatric population is 17–23/100,000. In children <1 year old, incidence is 135–156/100,000.

RISK FACTORS

- History of epilepsy most common (10–20% of children with epilepsy have had SE) with AED withdrawal the most common cause
- Other: Brain tumor, neurodegenerative disorder, history of remote neurologic insult (stroke, intracranial hemorrhage, birth asphyxia, head trauma, meningitis) or condition (cerebral palsy)

Genetics

Some inherited conditions increase risk of SE, including neurocutaneous syndromes (tuberous sclerosis, Sturge–Weber) and familial epilepsy syndromes, especially GEFS+. There is evidence for a genetic predisposition to SE.

PATHOPHYSIOLOGY

SE can be due to acute and chronic factors.

- Most common inciting acute factors are fever, metabolic derangements (e.g., electrolyte imbalances, renal failure), intoxications, trauma, neoplasm, anoxia and stroke/hemorrhage, discontinuation of seizure medications.
- Chronic causes include pre-existing epilepsy, neurodegenerative disorders, brain tumors, and neurocutaneous syndromes (tuberous sclerosis, Sturge–Weber), familial epilepsy syndromes (GEFS+).

DIAGNOSIS

HISTORY

- Ask about prior seizures, treatment with AEDs, and other neurological abnormality.
- Ask specifically about precipitating factors: Fever, preceding illness, head trauma, change in antiepileptic medication, and family history of seizures.

PHYSICAL EXAM

- Vital signs: Fever, respiratory rate/O₂ sats (adequacy of air exchange and abnormal breathing patterns), heart rate, BP (hypertension suggests intracranial hypertension)
- Signs of head trauma: Retinal hemorrhages, excess bruising, bone fractures, evidence of intracranial hypertension such as bulging fontanelle

- Meningismus signals CNS infection, intracranial hemorrhage or spine trauma. May be absent in young infants with meningitis
- Signs of systemic infection: Fever (also potentiates seizure activity), petechiae, mucosal lesions, lymphadenopathy
- Skin examination: Check for neurocutaneous disorders.
- During convulsions: Observe for focal features or asymmetry.
- Postictal exam: Transient neurologic abnormalities (e.g., pupillary asymmetries, eye deviation, and focal motor weakness [Todd paresis]) may not correlate with the underlying structural lesion. After seizure has stopped, a neurological examination should be performed, with attention to mental status, focal weakness, tone, or sensation.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Initial:
 - STAT glucose, electrolytes, calcium, magnesium, and arterial blood gas
 - AED levels if indicated
 - CBC, liver function tests
 - Toxicology screen, urinalysis
 - TESTS:
 - LP: Indicated to evaluate CNS infection. Contraindications include intracranial hypertension known or suspected from exam or CT scan; cerebral mass lesion; obstructive hydrocephalus. Lumbar puncture may be deferred if suspicion of CNS infection is low, i.e., patient is afebrile, and an alternate etiology is present.
 - Neuroimaging, CT or MRI: Indicated for SE, especially with partial-onset seizures (including aura), focally abnormal EEG, focal neurological signs, or history of head trauma. MRI is the preferred neuroimaging test, but CT may be more appropriate for urgent imaging or if the patient is medically unstable.
 - EEG: Recommended to determine focal versus generalized abnormalities and continued electrographic seizures. Urgent EEG recommended in patients with persistent SE or encephalopathy, and in those with concern for nonconvulsive SE and nonepileptic SE.

DIFFERENTIAL DIAGNOSIS

- Nonepileptic SE (psychogenic or pseudo SE). Clinically suspected with eye closure; asynchronous, thrashing limb movements; purposeful resistance to passive movement; and normal concurrent EEG. Induction of a seizure by suggestion further supports this diagnosis.
- Movement disorders (including dystonia, chorea, and very frequent tics) can be mistaken for persistent seizure activity.
- Postanoxic myoclonus: Status after prolonged cardiopulmonary arrest. These movements are usually nonrhythmic and segmental but can appear rhythmic at times. EEG is recommended for diagnosis.

TREATMENT

INITIAL STABILIZATION

- ABCs (stabilization of airway, supporting respiration, maintaining BP, and gaining intravascular access)
- BP, EKG, and respiratory function should be monitored.
- Airway control may be maintained by head positioning, and oral airway placement and oxygen supplementation provided via nasal cannula, mask, or bag–valve–mask ventilation. If the need for respiratory assistance persists, endotracheal intubation may be required.
- For hypoglycemia: 2–4 mL/kg of D25 (25% dextrose)
- Rectal acetaminophen and a cooling blanket for fever

General Measures

- AED administration should be initiated whenever seizure activity persists for >5 minutes
- Benzodiazepines are initial management of patients with active convulsions.

Lorazepam IV (0.05–0.1 mg/kg/dose at 2 mg/min maximum, up to a total dose of 0.3–0.5 mg/kg) more effective and with less respiratory depression than diazepam (0.1–0.2 mg/kg/dose at 5 mg/min, up to a total dose of 1.0 mg/kg, not to exceed a total dose of 10 mg).

Midazolam (0.1–0.3 mg/kg IV followed by infusion if needed of 1 mcg/kg/min)

Respiratory depression and hypotension are common side effects of benzodiazepine administration.

- SE persists: Administer an IV loading dose fosphenytoin (20 mg/kg “phenytoin equivalents” at a rate of 3 mg/kg/min, max rate 150 mg/min, max daily dose, 1500 mgPE). Additional 5-mg/kg doses may be given if needed to stop convulsions (to maximum total dose of 30 mgPE/kg)
- Alternative treatment choices:
 - IV phenobarbital at a loading dose of 20 mg/kg (maximum rate, 50 mg/min). Additional 5–10-mg/kg increments (to total maximum dose of 30–40 mg/kg) may be given as necessary to stop convulsions. Respiratory depression and hypotension are potential serious side effects.
 - IV valproate at a loading dose of 20–40 mg/kg (over 5–10 minutes) May be followed by infusion if needed of 5 mg/kg/hr or repeated doses up to 60 mg/kg/day divided 2–4 times a day. Monitoring to keep total valproate levels between 50 and 100 mg/L is recommended. Thrombocytopenia, pancreatitis, hepatitis, and skin rashes are potential side effects. IV valproate should be changed to a PO formulation before 14 days.

- If IV access is difficult to obtain, diazepam (0.5 mg/kg to a maximum of 20 mg), IM fosphenytoin, or buccal midazolam can be administered.
- Refractory SE exists if the above medications fail and the patient continues to have convulsions or is in nonconvulsive SE.
- Alternative agents for this situation include the use of IV AEDs, i.e., valproate, levetiracetam, and/or the induction of pharmacologic coma with midazolam, pentobarbital, phenobarbital, or propofol or inhalational anesthetics (isoflurane) administered in an intensive care unit with neurologic consultation. EEG monitoring is required, with the goal of inducing a suppression-burst pattern for the first 24 hours.

ONGOING CARE

PROGNOSIS

The morbidity and mortality of SE reflect etiology and are lower in children than in adults. Recent mortality estimates in children range from 2–5% with risk of new neurological sequelae estimated at 15%, and subsequent epilepsy at 30%. Refractory status epilepticus, however, has a morbidity estimated at 32%, and a mortality of 17%.

CODES

ICD9

345.3 Grand mal status

ICD10

G40.901 Epilepsy, unsp, not intractable, with status epilepticus

FAQ

- Q: Does SE cause brain injury?
- A: Research suggests that neuronal loss may occur at 30 minutes of SE. This illness represents a neurologic emergency. Other determinants of outcome are hypoxic brain injury due to hypoventilation during a seizure and brain injury because of an identifiable underlying cause of SE, such as encephalitis. Outcome in children with idiopathic SE without hypoxia is usually very good. Outcome of SE due to other brain injury (e.g., hypoxia, encephalitis, trauma) depends on the severity of the inciting process.
- Q: How safe is administration of rectal diazepam for children with cluster seizures?
- A: Studies suggest that when dosing guidelines are followed, this agent is safe and effective in terminating clusters of seizures, obviating a trip to the emergency room.
- Q: How likely is SE likely to recur?
- A: It is estimated at 17% in the first year, and predominantly in children with other neurologic conditions.

STEVENS-JOHNSON SYNDROME AND TOXIC EPIDERMAL NECROLYSIS

Alexis Weymann

James R. Treat

Paul S. Matz (5th edition)

BASICS

DESCRIPTION

Stevens–Johnson syndrome (SJS) and toxic epidermal necrolysis (TEN) are severe, potentially fatal mucocutaneous drug reactions, characterized by epidermal necrosis involving skin and at least 2 mucous membranes. The cutaneous necrosis leads to widespread epidermal detachment and loss of skin barrier function. Given the potential risk for infection and fluid and electrolyte imbalances with widespread denudation, SJS and TEN are considered medical emergencies.

EPIDEMIOLOGY

Incidence

- Overall annual risk of 0.5–1.9 per million in the general population
- The precise incidence in children is unknown.
- Patients with HIV have a 1,000-fold increased risk.

RISK FACTORS

- Exposure to inciting medications
- Infection with *Mycoplasma pneumoniae*, HIV
- Genetic background
- Coexistence of cancer
- Concomitant radiotherapy

Genetics

- Recently, strong associations have been made between HLA alleles and SJS/TEN.
- HLA-B*1502 (most commonly found in Han Chinese and Thai populations) has been linked to significantly increased risk of carbamazepine- and phenytoin-related SJS/TEN.
- HLA-B*5801 has been associated with allopurinol-related SJS/TEN in Han, Thai, and Japanese populations.

GENERAL PREVENTION

- The FDA recommends checking for HLA-B*1502 in Asian populations where this HLA subtype is highly prevalent before prescribing carbamazepine.
- Once SJS/TEN has occurred, the inciting medication and any cross-reacting medications should be avoided.

PATHOPHYSIOLOGY

- Widespread keratinocyte and mucosal cell death occurs secondary to CD8+ T-cell mediated apoptosis via Fas and Fas Ligand pathways and/or direct granulysin secretion. Fas receptors are located on keratinocytes and when activated with Fas Ligand, induce apoptosis and therefore necrosis of epidermal cells. Granulysin is released from cytotoxic T cells and induces apoptosis by creating holes in target cell membranes.
- The exact mechanism by which the implicated drug or infection triggers activation of cytotoxic T cells and the upregulation of the Fas/FasL pathway is unknown.
- Soluble Fas Ligand is increased in patients with SJS/TEN.

- IVIG theoretically acts to block the Fas–FasL ligand connection, thereby interrupting keratinocyte death and epidermal necrosis. Trials that show a benefit of IVIG use, demonstrate improvement of disease severity but not complete abolition of symptoms; this may be due to IVIG being started too late in the disease progression or because there may be an alternative pathway to keratinocyte destruction as well.

ETIOLOGY

- Over 100 medications have been implicated in causing SJS/TEN. High-risk drugs include: Aromatic amine anticonvulsants such as carbamazepine, phenobarbital and phenytoin, lamotrigine, beta-lactam antibiotics, sulfa medications (including trimethoprim-sulfamethoxazole and sulfasalazine), minocycline, cephalosporins, quinolones, NSAIDs in the oxicam class, allopurinol, and nevirapine.
- A greater risk of developing SJS/TEN is seen in the first 8 weeks of treatment with these medications with the highest risk being 1–3 weeks after exposure.
- *M. pneumoniae* is a well-established non-drug cause of SJS/TEN and is more commonly implicated in children and adolescents.
- There is scant evidence that vaccines, neoplastic syndromes, and autoimmune disease such as systemic lupus erythematosus (SLE) may play a role in etiology.
- <5% of cases have no known cause.
- Herpes simplex virus-associated erythema multiforme (EM) was historically categorized on the spectrum with SJS and TEN, but new classification schemes place EM as a separate entity.

DIAGNOSIS

HISTORY

- Prodromal period of 1–7 days of low-grade fever, sore throat or upper respiratory infection or dysphagia, and general malaise; patient may also complain of pain or stinging in the eyes.
- Subsequent development of targetoid red papules and plaques with dusky, blistered or eroded center as well as mucosal (lip, intraoral, conjunctival, urethral, anal) pain with blistering and erosions
- Recent initiation of high-risk agent (see above list) or upper respiratory symptoms such as chronic cough indicative of mycoplasma infection

PHYSICAL EXAM

- Acute phase: Early skin lesions are flat, erythematous targetoid lesions with a dusky center that usually start on the face, pre-sternal area of chest, and palms and soles. >90% of patients also have ocular and/or genital mucosa involvement consisting of erythema and erosions as well as hemorrhaging, crusting, and blisters. The skin and mucosal lesions are very tender. Intraoral lesions may precede the cutaneous rash.

- Ocular involvement at the onset of disease is common. Early ocular disease ranges from acute conjunctivitis, eyelid edema, and ocular discharge to pseudomembrane formation and corneal erosion.
- Secondary phase: As the lesions progress over hours to days, they necrose, blister, and slough off, causing large areas of epidermal detachment. Lesions are characterized by a positive Nikolsky sign (epidermal detachment upon mechanical stress).
- Extensive mucosal involvement may also include the esophagus, distal regions of the GI tract, and the respiratory epithelium.
- Occasionally mycoplasma-induced SJS can only involve the mucosal surfaces with little or no cutaneous involvement.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

Initial lab tests

- CBC with differential, metabolic panel, hepatic function test, coagulation studies, urinalysis, mycoplasma serology or PCR if indicated
- Anemia and lymphocytopenia are common and indicate a poor prognosis.

Imaging

- Chest x-ray and abdominal x-ray may be indicated depending on the extent of mucosal and systemic involvement.

Clinical Diagnosis

- The diagnosis of SJS and TEN is largely clinical, based on history and physical exam.
- By definition, <10% affected body surface area (BSA) is SJS; 10–30% affected BSA is SJS/TEN overlap; >30% affected BSA is TEN.

Diagnostic Procedures

- Skin biopsy with cryosection should be performed to confirm the clinical diagnosis if in doubt.
- Histological examination with direct immunofluorescence (DIF) should be performed to rule out other autoimmune blistering diseases such as paraneoplastic pemphigus if in doubt.

Pathological and Diagnostic Findings

- Skin biopsy shows full-thickness epidermal necrosis and few inflammatory cells; the skin biopsy in TEN may additionally show skin lysis at the subepidermal level.
- DIF shows no immunoglobulin or complement deposition in the epidermis or in the epidermal-dermal zone.

DIFFERENTIAL DIAGNOSIS

- Staphylococcal-scalded skin syndrome (SSSS)
- Linear IgA dermatosis
- Pemphigus—paraneoplastic pemphigus, pemphigus vulgaris, and bullous pemphigus
- Acute generalized exanthematous pustulosis
- Disseminated fixed bullous drug eruption
- Drug-induced hypersensitivity syndrome
- Drug reaction with eosinophilia and systemic symptoms (DRESS)

TREATMENT

MEDICATION (DRUGS)

First Line

- Stop all potentially offending medications.
- Early admission to burns unit or pediatric intensive care unit (PICU) for initial stabilization and management of fluid, electrolytes, and nutritional requirements, airway stability, and eye care
- Early ophthalmology and dermatology consultations
- Meticulous wound care with bland emollients; avoid silver sulfadiazine as it may cause SJS due to its sulfa moiety. Topical antibiotics should be used in areas of superinfection. The prophylactic use of topical antibiotics is somewhat controversial. Most agree that they should be applied to areas with a higher risk of superinfection, such as the perioral, periocular, and intertriginous areas.

Medications/Therapeutics

- 0.5–1 gram/kg per dose given for 2–4 days for total of 2–3 grams/kg total
- There have been variable results from a limited number of quality studies looking at the effects of IVIG. Most studies, however, have demonstrated a beneficial effect especially if started early in the course, and so early administration of high-dose IVIG is recommended.
- Adverse effects of IVIG include acute renal failure, DIC, osmotic nephrosis, anaphylaxis, serum sickness, aseptic meningitis, PE, and DVT, among others.
- Steroids (prednisolone, dexamethasone, methylprednisolone) were the mainstay of therapy in the 1990s but now are less commonly used because of the increased risk of sepsis, infection, and other complications when used especially in TEN when there is widespread epidermal loss. Pulse steroid use is being investigated.
- Thalidomide, cyclosporine, TNF antagonists, plasmapheresis, and cyclophosphamide are other therapeutics that have been studied in the treatment of SJS/TEN but none have sufficient amounts of reliable data to support their use.
- Prophylactic systemic antibiotics are not recommended, as they place the patient at an increased risk of candidemia and resistant infections.

ADDITIONAL TREATMENT

- Pain control is key to patient comfort.
- Good oral care using agents such as “magic mouthwash” helps debride dead skin and provide oral anesthesia.

SURGERY/OTHER PROCEDURES

- +/- Surgical debridement: Studies have shown surgical debridement of wounds prior to wound care yielded no additional benefit.
- +/- Synechial and vaginal adhesion breakup

Discharge Criteria

- When afebrile, the loss of skin is clearly done and re-epithelialization has occurred; cleavage of synechiae in the eyes is no longer needed and the patient can eat and drink appropriately.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Follow up with a dermatologist and/or wound care specialist. Re-epithelialization often starts within days and may take up to 3 weeks to be completed.

Patient Monitoring

- SCORTEN is a well-validated, widely used scoring system in adults used for its predictive value, which is best at day 3. Variables include age, percentage BSA affected, BUN, serum glucose, HR, serum bicarbonate, associated malignancy.
- Monitor for skin, urinary tract, and pulmonary infections, synechiae in the eyes as well as vaginal and urethral adhesions.

PROGNOSIS

- Mortality is 1–5% in SJS; 25–35% in TEN.
- Largely depends on amount of BSA affected, time to cessation of offending medication, and time to initiation of supportive care
- More severe disease often seen in elderly patients
- Children have lower mortality and faster re-epithelialization.

COMPLICATIONS

- Mucosal complications occur in > 70% of patients with acute phase mucosal involvement. Ocular complications occur in 50% of patients with TEN.
- Systemic—sepsis, multiorgan failure, major metabolic dysregulation
- Mucosal—respiratory failure, pneumonia, pulmonary embolus, UTI, GI hemorrhage, obstruction, and perforation
- Cutaneous—skin infections, scarring, hypo-/hyperpigmentation, nail dystrophies
- Ocular—synechiae, dry eyes, bacterial conjunctivitis, suppurative keratitis, endophthalmitis, impaired tear ducts, corneal ulcers, vision loss

CODES

ICD9

- 695.13 Stevens-Johnson syndrome
- 695.15 Toxic epidermal necrolysis

ICD10

- L51.1 Stevens-Johnson syndrome
- L51.2 Toxic epidermal necrolysis [Lyell]

CLINICAL PEARLS

- The progression of disease from flat, targetoid lesions to sheets of widespread epidermal necrosis and sloughing may be hours. As such, SJS and TEN are true medical emergencies.
- The systemic severity of SJS and TEN is often underestimated based on the severity of skin disease.
- Ocular involvement is often early and severe.
- The key to therapy is cessation of the offending medication and supportive care, and in many areas IVIG has become first line therapy.

STOMATITIS

Lee R. Atkinson-McEvoy

BASICS

DESCRIPTION

- Inflammation of the mucous membranes of the mouth
- Gingivostomatitis is when stomatitis is accompanied by inflammation of the gingiva.
- Recurrent aphthous stomatitis, known more commonly as canker sores, does not have an identified infectious agent.
- Herpangina is a disease caused by coxsackievirus group A and marked by stomatitis consisting of 1–2 mm oral vesicles and ulcers, and systemic symptoms, most notably fever.

EPIDEMIOLOGY

- Enteroviral infections occur commonly in summer and fall months.
- Recurrent aphthous stomatitis has a prevalence of 20–37% in children.
- Herpes simplex virus (HSV) type 1:
 - Up to 90% of the adult population has serologic evidence of previous infection.
- Age of child:
 - Herpangina and herpetic gingivostomatitis occur in infants, toddlers, and preschool-aged children.
 - Coxsackievirus (hand-foot-and-mouth disease) occurs most frequently in toddlers and young school-aged children.
 - Aphthous stomatitis occurs in older children and adults.

GENERAL PREVENTION

- Hand washing can prevent spread of viral infections.
- Due to the long life of enterovirus on surfaces, toys and other objects used by affected children should be sterilized before being used by other children.
- Contact isolation should be observed for children with viral stomatitis in the hospital setting.

PATHOPHYSIOLOGY

- Infection, inflammation, or trauma leads to interruption of the integrity of the mucosal epithelium.
- Ongoing inflammation leads to further denudation of the epithelium.
- Inflammatory cells and mediators can produce exudates and erythema of the ulceration.

ETIOLOGY

- Multiple etiologies, with viral infections (e.g., HSV type 1), and recurrent aphthous stomatitis being the most common in children
- Recurrent aphthous stomatitis is believed to be mediated by antibody-dependent cell-mediated cytotoxicity due to multifactorial insults, including trauma, stress, hormonal fluctuations, infections, vitamin or nutritional deficiencies, and allergens. There is also a familial tendency in 40% of cases.
- Herpangina is caused by coxsackievirus group A.
- Stomatitis:
 - Enterovirus, including coxsackievirus
 - HSV, particularly type 1

DIAGNOSIS

HISTORY

- Ask about associated symptoms:
 - Fever, malaise, diarrhea, and other constitutional symptoms occur with coxsackievirus infection, herpangina, and primary herpetic gingivostomatitis.
- Ask about chronic medical problems:
 - Immunodeficiency states (e.g., HIV and neutropenia), poor nutritional status, and inflammatory bowel disease are associated with development of mucosal ulceration.
- Ask about medications and possible exposures to medications:
 - Medications, particularly penicillins, sulfa-containing drugs, and antiepileptics, have been associated with Stevens–Johnson syndrome, which has oral mucositis as part of its constellation of symptoms.
- Signs and symptoms:
 - Inflammation
 - Pain in the mouth
 - Decreased intake
 - Drooling
 - Fever
 - Malaise
 - Diarrhea
 - Constitutional symptoms

PHYSICAL EXAM

- Recurrent aphthous stomatitis lesions are usually well demarcated, round to oval, and have a white-yellow fibrinous pseudomembranous cap with surrounding erythema.
- Enteroviral infections are associated with small shallow ulcerations with smooth borders on the posterior oral cavity structures such as the tonsils, soft palate, and pharynx. In addition, vesicular lesions may be present on the palms and soles.
- Hand-foot-and-mouth disease, due to coxsackievirus (a type of enterovirus), consists of lesions in the mouth as well as the palms and soles.
- Herpangina consists of oral vesicles and ulcers, typically around the fauces, near the tonsillar pillars.
- HSV infections cause shallow ulcers with irregular, erythematous borders that coalesce; these lesions are found on the lips, tongue, and gingiva.
- Gingivitis in association with stomatitis is usually present in drug-induced causes of stomatitis, as well as with HSV.
- Herpetic whitlow is the transmission of HSV with development of lesions on the extremities, notably the fingers, due to direct contact with lesions in the mouth.
- Varicella presents with grouped vesicles or erosions on the tongue, gingival and buccal mucosae, and the lips. The lesions are shallow ulcers with erythematous borders that usually do not coalesce. In addition, diffuse vesicles in varying stages of healing can be found on the skin, particularly the trunk and extremities. In severe cases, there may be lesions in the oral cavity, particularly on the soft palate.

- Smallpox may also present with small red spots on the tongue and in the oral mucosa following a prodromal period with fever. These spots then can become ulcerated. This is followed by the development of a diffuse erythematous rash that becomes papular over the entire body, including the palms and soles. The rash becomes pustular, then crusted.
- Stevens–Johnson syndrome presents with large irregular ulcers, which may occasionally be deep. There is occasionally a hemorrhagic component to these ulcers. Ulcers are also sometimes present on other mucosal surfaces. Target lesions, bullae, and urticarial lesions may also be present.
- Behçet syndrome and Reiter syndrome may have painless ulceration of the oral mucous membranes. Generally these oral lesions are accompanied by skin lesions and diffuse systemic symptoms.
- Oral lichen planus is a chronic inflammatory disease usually seen in adults, but can occur in children. It causes bilateral white striations, papules, or plaques on the buccal mucosae, tongue, and gingivae. Erythema, erosions, and blisters may or may not be present.
- Familial Mediterranean fever syndrome is an autosomal recessive disease that presents with painful febrile episodes. Associated with these episodes are recurrent oral aphthae.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- HSV can be diagnosed with direct fluorescent antibody staining, rapid enzyme immunoassay, or viral culture of the lesion.
- Enterovirus can be cultured from stool, nasopharyngeal, throat, CSF, and blood specimens.
- Polymerase chain reaction testing of CSF fluid can also diagnose an enteroviral infection.

Diagnostic Procedures/Other

Usually there is no need for laboratory testing for simple stomatitis. If there are other systemic signs of illness (e.g., diarrhea or arthritis), a more thorough workup for more severe illnesses such as Crohn disease, Reiter syndrome, or cyclic neutropenia should be done.

DIFFERENTIAL DIAGNOSIS

- Infection:
 - Enterovirus, including coxsackievirus
 - HSV
 - Varicella
 - Smallpox (variola)
 - Candidal infection
 - HIV-associated aphthous ulcers
- Hematologic:
 - Cyclic neutropenia
- Trauma
- Medications (e.g., chemotherapeutic agents)
- Miscellaneous:
 - Stevens–Johnson syndrome
 - Oral lichen planus
 - Reiter syndrome or disease (reactive arthritis, rash, conjunctivitis, urethritis, diarrhea, and stomatitis with painless erosive ulcers)
 - Behçet syndrome (associated with ulcerations of the oral and genital mucous membranes)
 - Crohn disease
 - PFAPA syndrome: Periodic fever, aphthous stomatitis, pharyngitis, and adenitis

TREATMENT

MEDICATION (DRUGS)

- Analgesics:
 - Acetaminophen or ibuprofen
 - Acetaminophen with codeine may be used in severe cases, when intake of fluids is greatly affected by pain. Codeine should be used cautiously, as it may cause constipation and CNS depression.
 - Viscous lidocaine 2% (but see “General Measures”)
 - Silver nitrate in a single application for recurrent aphthous stomatitis has been shown to reduce the severity of pain without altering healing time.
 - Topical nonsteroidal anti-inflammatory agents or corticosteroids may be required for severe recurrent aphthous ulcers.
- Acyclovir may be given orally for HSV infections to decrease the length of infection, but in order to be effective it needs to be given within the first 48 hours of development of oral lesions. Acyclovir is usually more beneficial when used for household contacts who begin to exhibit symptoms, and when treatment can be initiated early. Topical acyclovir has not been shown to be effective.

ADDITIONAL TREATMENT

General Measures

Rinses:

- Salt-water rinses (normal saline or 1 tsp of table salt mixed with 16 oz of tepid water or 1 tsp of baking soda with 32 oz of water) q1–2h while ulcers are present may aid in reducing pain and shortening the duration of the ulceration.
- Magic mouthwash: Equal parts of diphenhydramine and Maalox™ or Kaopectate™. In severe cases, 2% viscous lidocaine can be added in an equal amount, but care must be taken to limit the application of lidocaine on ulcerated mucosa, as it may be absorbed and possibly result in arrhythmias. In addition, when applied to the posterior pharynx, lidocaine can decrease the gag reflex, increasing the risk of aspiration.
- Avoid certain foods that can trigger eruption of new lesions or prolong the course of the existing lesions. Acidic, hard, salty, or spicy foods should be avoided. In addition nuts, chocolate, citrus fruits, and carbonated beverages can worsen outbreaks.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

Young children should be followed closely. If dehydration occurs due to poor oral intake, IV rehydration should be considered.

PROGNOSIS

- Most cases of stomatitis are mild and resolve within 1–2 weeks.
- HSV stomatitis is most severe during the initial infection; however, it tends to recur in response to stress or trauma, as the virus has a long latent period within the nerves of the face, particularly the trigeminal nerve.
- Recurrent aphthous stomatitis also recurs in response to stress or trauma.

COMPLICATIONS

- Infectious:
 - Cellulitis
 - Lymphadenitis
- Miscellaneous:
 - Dehydration, particularly in young children
 - Pain

ICD-9 CODES

ICD9

- 523.10 Chronic gingivitis, plaque induced
- 528.00 Stomatitis and mucositis, unspecified
- 528.2 Oral aphthae

ICD10

- B00.2 Herpesviral gingivostomatitis and pharyngotonsillitis
- K12.1 Other forms of stomatitis

FAQ

- Q: Is stomatitis contagious?
- A: Yes, this is a contagious infection. To avoid spreading the illness, careful hand washing should be done. In cases of suspected enteroviral infections, careful sterilization of toys and surfaces with which the affected child has contact should be done before use by unaffected children.
- Q: How can I get my child to take food and liquids if stomatitis is painful?
- A: The inability to stay hydrated is one of the complications of stomatitis. Children will not have their regular intake of solids due to mechanical effects of these on painful ulcers. Using regular analgesics, such as acetaminophen or ibuprofen, can help decrease pain. Topical administration of magic mouthwash (see “General Measures”) before offering fluids may be helpful. Small amounts of nonacidic, cool liquids (and popsicles) frequently may be better tolerated than large amounts given all at once. If your child has decreased urine output or altered mental status, seek medical attention.
- Q: When should I take my child to seek medical care?
- A: Children with stomatitis are at high risk for dehydration if they have many lesions. If your child won't take even sips of liquids, has marked decreased urine output, or is lethargic and difficult to arouse, bring him in to be evaluated. If the lesions do not heal in 7–10 days, bring your child in to be evaluated.
- Q: When can my child return to school/day care?
- A: Young children with herpes or enteroviral stomatitis can infect others via oral secretions. In cases of young children who drool frequently or place toys in their mouths, there is a high risk for transmitting the illness. Children become less contagious when the lesions heal. In the case of varicella, children are contagious until all vesicles are crusted over.

STRABISMUS

Monte D. Mills

BASICS

DESCRIPTION

- From the Greek *strabismos* (to squint), strabismus is abnormal misalignment of the eyes. The misalignment can be constant or intermittent, and the eyes can be misaligned in any direction.
- When the deviation between the eyes is constant in all gaze positions, the deviation is comitant.
 - Most childhood strabismus is comitant.
- Incomitant strabismus, with a variable angle depending on the direction of gaze, is seen with palsy of cranial nerve III, IV, or VI, and in some strabismus syndromes such as Duane and Brown syndromes and Graves ophthalmopathy.
- Patients with intermittent strabismus may benefit from treatment, even if the deviation is not present constantly.

EPIDEMIOLOGY

Most patients with idiopathic comitant strabismus are otherwise developmentally and neurologically normal.

Prevalence

Strabismus of all types has an overall prevalence of 4–5%.

RISK FACTORS

- Premature birth
- Cerebral palsy
- Seizure disorders
- Developmental delays
- Congenital or acquired loss of vision
- Other ocular abnormalities

Genetics

- ~30% of strabismus patients have affected family members.
- Inheritance appears to be multigenic.
- No specific genes have been associated with idiopathic childhood strabismus syndromes.
- Genetic causes have been identified for some rarer strabismus syndromes, including congenital fibrosis syndromes (chromosome 12p) and Kearn Sayer syndrome (mitochondrial deletion).

PATHOPHYSIOLOGY

- No specific pathologic abnormality of the motor nerves, extraocular muscles, or orbits is seen in most patients with idiopathic, comitant strabismus.
- Patients with parietic strabismus demonstrate atrophy of cranial nerves and extraocular muscles.
- Graves disease, myasthenia, and other neuromotor diseases that cause strabismus have specific pathologic features in the extraocular muscles.
- The pathophysiology of the most common forms of childhood strabismus is poorly understood. Infants with strabismus demonstrate subtle abnormalities in both motor function (asymmetric smooth pursuit movements) and binocular sensory function (suppression, anomalous retinal correspondence). No neuroanatomic abnormalities have been consistently demonstrated in infants with idiopathic strabismus.

- Accommodative esotropia, a common strabismus syndrome, is caused by abnormalities in the reflexive convergence that is necessary for looking at near objects.
 - If the ratio of accommodation (focusing for near) to convergence (rotating eyes inward to keep each eye on the target) is abnormally high, focusing on near targets leads to excessive convergence and esotropia.
- Less often, strabismus syndromes are caused by anatomic restriction to extraocular rotation (Graves disease, Brown syndrome), congenital or acquired paresis, or palsy of extraocular muscles (III, IV, or VI palsy, Duane syndrome, Moebius syndrome) or abnormalities of vision (sensory strabismus).

COMMONLY ASSOCIATED CONDITIONS

- Strabismus can be a sign of more significant ocular or neurologic abnormality. Retinoblastoma, retinal detachment, brain tumor, and other treatable conditions may initially present with ocular misalignment.
- Frequent coincident ophthalmic diagnoses are amblyopia (30–60%), nystagmus (8–10%), and refractive error (30–50%).

DIAGNOSIS

- Patients rarely “grow out of” strabismus.
- Infants as young as 3 months of age can have careful examinations of eye movement and alignment.
- Delayed diagnosis may worsen prognosis.

SIGNS AND SYMPTOMS

- The strabismus is identified by the relative direction of the eyes. Esotropia is an inward deviation or crossing; exotropia is an outward deviation; hypertropia and hypotropia are deviations up and down.
- Strabismus is frequently recognized by parents and primary care practitioners, but amblyopia may be asymptomatic.

HISTORY

- Age of onset of deviation
- Frequency, duration, and direction of deviation
- Subjective vision problems or complaints
- History of eye or head trauma, premature birth, seizure disorder, neurologic abnormality, or other motor problems
- Previous use of glasses, patching, or other therapy
- Family history of strabismus, amblyopia, refractive error, or childhood vision problems

PHYSICAL EXAM

- Patients capable of recognition are tested with charts (letters, pictures, Es), younger patients are tested by the ability to fixate and hold visual fixation on targets (toys, lights) in each eye. It is very important to test each eye separately, in order to detect possible amblyopia and other causes of monocular vision loss (see Amblyopia). Patients capable of reading charts should have complete ophthalmic examination if they cannot recognize at least the 20/40-size target with each eye, or if there is a difference of > 1 chart line between eyes.

Ocular alignment:

- Hirschberg test: With patient looking at a flashlight, observe the location of the reflection of the light on the corneal surface. Normally, the reflection should be centered in the pupil and symmetric. In strabismus, the reflection will be displaced laterally (esotropia) or medially (exotropia) in 1 eye.
- Bruchner test: With a direct ophthalmoscope using the largest light, and the patient looking directly at the light, the light is shone into the patient’s eyes. Normally, the pupils should be orange or red and the pupils should symmetrically fill with light. Asymmetric brightness or color between the 2 eyes or shadows in the pupil of either eye is abnormal and may indicate strabismus or other eye problems.
- Cover test (alternate cover test): With the patient holding his or her visual attention on a single target, the eyes are alternately occluded to force the patient to switch fixation between eyes. Normally, switching fixation should not cause the eyes to move. Movement of the eyes with alternate occlusion signifies strabismus and merits complete evaluation.
- Ocular rotations:
 - Comitant strabismus will demonstrate a consistent angle of deviation in all gaze directions. Incomitant strabismus, including cranial nerve palsies, thyroid ophthalmopathy, and Duane and Brown syndromes, will be greater in one direction and smaller or absent in others. Ductions (movements of each eye) may be restricted in certain directions with incomitant strabismus.
- Complete ophthalmic examination, including evaluation of vision, alignment, ocular anatomy, and cycloplegic refraction, is indicated whenever there is suggestion or suspicion of strabismus or abnormal vision based on history, screening tests, or examination.

DIAGNOSTIC TESTS & INTERPRETATION

The diagnosis of strabismus is based on clinical examination, and no laboratory or radiologic tests are routinely necessary.

Lab

Serologic testing for antiacetylcholine receptor antibodies is a specific test for myasthenia gravis, a very rare cause of strabismus.

Imaging

Depending on the clinical situation, imaging studies of the orbits and brain may be helpful in evaluating cranial nerve palsies, suspected traumatic strabismus, and strabismus associated with neurologic disease.

DIFFERENTIAL DIAGNOSIS

- The differential diagnosis of abnormal eye movement in childhood includes palsy of cranial nerve III, IV, or VI, orbital fracture or craniofacial anomaly, systemic or localized motor abnormalities such as myasthenia gravis, orbital fibrosis syndrome, infantile botulism, and idiopathic orbital pseudotumor.
- The most common reason for mistaken referral of infants for esotropia is “pseudoesotropia,” caused by wide epicanthal folds giving the false appearance of esotropia.
 - This can be easily recognized by the normal corneal light reflex (Hirschberg test) and normal cover test.
- Sensory strabismus, due to reduced vision in 1 or both eyes, can be comitant or incomitant and can be caused by any ocular, optic nerve, or central cause of vision loss.
 - Sensory deviations are most frequently exotropic, but may be in any direction.
- Special strabismus syndromes include Duane syndrome (congenital aberrant innervation of cranial nerve III), Moebius syndrome (congenital absence of cranial nerve VI and VII), Brown syndrome (congenital or acquired monocular elevation defect due to abnormality of the trochlea-superior oblique tendon complex), myasthenia gravis, and thyroid ophthalmopathy (Graves disease).

TREATMENT

ADDITIONAL TREATMENT

General Measures

- Prompt diagnosis and treatment are important for successful outcome from childhood strabismus.
- Depending on the diagnosis, treatment may include glasses, patching, orthoptic exercises, surgery, or a combination of these therapies.
- Glasses are useful, and may be curative, in certain forms of strabismus, especially accommodative esotropia.
 - With accommodative esotropia, glasses reduce or eliminate esotropia by reducing the need to focus the eyes to overcome hyperopia.
- Occlusive therapeutic patching is used to treat amblyopia.
 - In addition to the improved prognosis for long-term stability of surgical correction after amblyopia is treated, patching may sometimes improve alignment even without surgery. However, patching and other amblyopia treatments are usually only an adjunct to strabismus treatment.

- Eye exercises (orthoptic exercises) are useful in certain patients with convergence insufficiency, but are generally not effective in the common forms of childhood esotropia and exotropia.
 - Vision therapy (aside from orthoptic exercises noted earlier) is not effective for strabismus.

SURGERY/OTHER PROCEDURES

- Surgery is frequently necessary to realign the eyes to treat strabismus.
 - The ocular insertions of the extraocular muscles are shifted, either weakening or strengthening the muscle's effectiveness relative to the other muscles.
- In most patients, strabismus surgery can be performed in an ambulatory setting with minimal operative risk and postoperative morbidity.
- In large case series, ~20% of patients require >1 surgery for satisfactory alignment.

ONGOING CARE

Visual acuity testing with each eye separately, and long-term follow-up until patients reach the age of visual maturity (~10 years) is important even after successful surgical correction.

ICD CODES

ICD9

- 378.00 Esotropia, unspecified
- 378.9 Unspecified disorder of eye movements
- 378.10 Exotropia, unspecified

ICD10

- H50.00 Unspecified esotropia
- H50.9 Unspecified strabismus
- H50.10 Unspecified exotropia

FAQ

- Q: Does strabismus interfere with learning?
- A: No. Patients with normal vision and childhood strabismus should not necessarily have difficulty learning. Learning problems should not be blamed solely on strabismus.
- Q: Is “vision training therapy” an effective treatment for strabismus?
- A: Eye exercises are sometimes helpful in treating a limited number of patients with childhood strabismus. Orthoptic exercises have been effective in only certain specific conditions including convergence insufficiency, and are not effective in the majority of patients with more common types of esotropia and exotropia. There is very little practical or scientific evidence that vision training therapy as commonly practiced has value in patients with comitant childhood strabismus, except for treatment of amblyopia with patching or penalization (see “Amblyopia”).
- Q: Does early surgical correction of strabismus improve the long-term outcome?
- A: Correction of esotropia prior to 2 years of age has been demonstrated to improve the chance of developing normal binocularity. However, not all patients develop binocularity even after early treatment. Many other factors influence the visual outcome in strabismus patients.
- Q: Is correction of strabismus in older children and adults just cosmetic?
- A: No. Older children and adults may have measurable visual improvement after treatment of strabismus, including expansion of visual fields and restoration of binocularity. In addition, the psychologic and social effects of disfiguring strabismus may justify corrective surgery even if no visual improvement is expected.
- Q: In patients with accommodative esotropia treated with glasses, will the glasses be necessary for the rest of the patient's life?
- A: Many patients wearing glasses for accommodative esotropia are able to stop wearing glasses later in childhood (age 12–14 years) without recurrence of esotropia.

STREP INFECTION: INVASIVE GROUP A β -HEMOLYTIC STREPTOCOCCUS

Avani Shah Mehta

Jill C. Posner

BASICS

DESCRIPTION

- Infection associated with isolation of group A β -hemolytic Streptococci (GABHS) from a normally sterile body site or from wound specimen in patient with necrotizing fasciitis (NF) or streptococcal toxic shock syndrome (STSS)
- Infection can result in a number of syndromes: Deep and systemic infections (e.g., bacteremia, endocarditis, meningitis, pneumonia, osteomyelitis, septic arthritis, surgical wound infection), NF, and STSS. Case definition for STSS includes the following:
 - (I) Isolation of GABHS:
 - (A) From a normally sterile site (e.g., blood, CSF, tissue, peritoneal fluid)
 - (B) From a nonsterile site (e.g., throat, vagina, sputum)
 - (II) Clinical signs of severity:
 - (A) Hypotension
 - (B) 2 or more of the following signs:
 - Renal impairment
 - Coagulopathy
 - Hepatic involvement
 - Adult respiratory distress syndrome
 - A generalized erythematous macular rash that may desquamate
 - Soft-tissue necrosis, including NF or myositis, or gangrene
- A definite case is an illness fulfilling criteria IA and II (A and B).
- A probable case is an illness fulfilling criteria IB and II (A and B) and no other identifiable cause.

EPIDEMIOLOGY

The rate of STSS and fatal cases of invasive GABHS appear to be lower in children as compared with adults.

Incidence

- During the mid-1980s and early 1990s, there was a notable increase in the incidence, morbidity, and mortality. However, these statistics have been stable since 1996.
- It is estimated that the annual incidence in the US is 3.5 cases per 100,000 persons, ~8,950–11,500 cases per year.
- In infants <1 year old, incidence is 5.3 cases per 100,000 persons.
- Increased incidence in winter/early spring

RISK FACTORS

- Prior to varicella vaccine, the most common antecedent in children was varicella.
- Several reports have suggested an association between the use of NSAIDs and invasive GABHS infection. There are no data to support a causal link.
- A recent case series (Jean 2010) reported an increased morbidity and mortality with coinfection of invasive GABHS and H1N1 influenza, even in previously healthy patients.
- Other high-risk groups include patients with diabetes mellitus, chronic cardiac or pulmonary disease, HIV infection or AIDS, and those with a history of IV drug use.

GENERAL PREVENTION

- Routine immunization against varicella
- Isolation of hospitalized patients: In addition to standard precautions, droplet precautions are recommended for children with pneumonia, and contact precautions should be used for children with extensive or draining cutaneous infections for at least 24 hours after the start of antimicrobial therapy.
- Multivalent GABHS vaccine (covering 26 serotypes) currently in phase 2 trial

PATHOPHYSIOLOGY

- The pathogenic mechanism has not been fully elucidated; however, an association with streptococcal pyrogenic exotoxin (SPE) has been suggested. These toxins, especially SPE A, B, and C, as well as mitogens and superantigens, stimulate large numbers of T cells to release a variety of cytokines, leading to capillary leak, hypotension, and organ damage.
- Portal of entry may be inapparent or unimpressive.
- Shock and multiorgan system failure may ensue.
- In NF, an area of cellulitis develops initially, followed by bullous skin changes and rapid progression of subcutaneous tissue necrosis involving fat and fascia. Skeletal muscle is rarely involved.

ETIOLOGY

Streptococcus pyogenes is the only species within this group of β -hemolytic Streptococci.

DIAGNOSIS

HISTORY

- Historic features vary depending on the GABHS syndrome.
- Consider GABHS infection in any child with varicella who has any of the following:
 - Return of fever after defervescence
 - A temperature of $\geq 39^{\circ}\text{C}$ (102.7°F) beyond the 3rd day of illness
 - A fever persisting beyond the 4th day of illness
- In children without varicella, presentation can be nonspecific with fever, chills, myalgias, malaise, pain, and/or macular erythematous rash.
- Severe pain and hyperesthesia out of proportion to the clinical findings
- Portal of entry is unknown in 25–50% of cases.
- A preceding clinical pharyngitis is not common.
- Children <10 years old are less likely to present with cutaneous/soft-tissue infection, and are more likely to present with abscesses, osteomyelitis, epiglottitis, otitis media, meningitis, or primary bacteremia.
- Incubation period for STSS is unknown.

PHYSICAL EXAM

- Vital signs:
 - Elevated temperature
 - Tachycardia
 - Hypotension is a later sign.
- Toxic appearance is common but not the rule, especially early in the disease course.
- Skin exam varies:
 - In many instances, there are no cutaneous findings or, in cases of varicella, the lesions may not appear superinfected.
 - Alternatively, there may be an initial erythematous cellulitic area that rapidly progresses to a violaceous color with bullous formation.
 - A generalized macular erythematous rash is sometimes observed with STSS.
- Deep infections will have physical exam findings consistent with the specific focus (e.g., joint pain and limitation of mobility in septic arthritis, respiratory symptoms in GABHS pneumonia).

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- CBC
- Electrolytes, BUN, creatinine (Cr), and glucose levels
- Liver function tests
- Screen for disseminated intravascular coagulation (DIC)
- Creatine kinase level: May be helpful in differentiating NF from cellulitis
- WBC count: Not elevated in all pediatric case series
- Blood culture: Positive for *S. pyogenes* in >50% of cases
- Culture of wound and tissue aspirates
- Throat culture: Positive in 50% of cases:
 - A rise in antibody titers to streptolysin O, deoxyribonuclease B, or other streptococcal extracellular products 4–6 weeks after infection may help confirm the diagnosis if culture results are negative. These antibodies may remain elevated for several months and indicate an infection in the recent past (not current).

Imaging

MRI: Defines the extent of involvement in NF

DIFFERENTIAL DIAGNOSIS

- Bacterial sepsis
- STSS
- Other soft-tissue infections:
 - Cellulitis
 - Erysipelas
 - Clostridial or mixed anaerobic and aerobic fasciitis/gangrene
- Diagnostic pitfalls include the following:
 - Not considering the diagnosis until hemodynamic instability is apparent
 - Do not exclude diagnosis even in the absence of rash, cellulitis, or superinfected varicella lesions. Rash is only 1 of 6 clinical signs of severity in the criteria for STSS.
 - Recognize that the involvement of subcutaneous structures in NF may be much more extensive than what might be suggested on physical exam.
 - Failing to search for a localized infection as a source of toxin in STSS

TREATMENT

MEDICATION (DRUGS)

- IV antibiotic therapy for both GABHS and *Staphylococcus aureus* should be instituted promptly.
- Oxacillin (150 mg/kg/d divided q6h) or nafcillin (200 mg/kg/d divided q4–6h; maximum, 12 g/d) plus clindamycin (25–40 mg/kg/d divided q6h or q8h). In penicillin-allergic patients, consider vancomycin (40 mg/kg/d divided q6h) plus clindamycin. Vancomycin should be used in place of β -lactamase-resistant penicillins in areas with high prevalence of community-acquired methicillin-resistant *S. aureus*.
- Following the identification of GABHS from blood, body fluid, or tissue specimens, the drugs of choice are high-dose penicillin G (200,000–400,000 U/kg/d in 4–6 divided doses) plus clindamycin (helps stop toxin production via protein synthesis inhibition).
- No penicillin G-resistant isolates of GABHS have been reported. There are strains resistant to clindamycin, so this drug should not be used alone until it is shown to be sensitive.
- Large numbers of GABHS organisms can overcome the efficacy of penicillin: The synergistic use of clindamycin should be considered in cases of NF and STSS.
- Inotropes should be administered as indicated.
- The use of IV immunoglobulin may be considered in patients with STSS who remain unresponsive to other treatment modalities and for patients with infection in an area that precludes drainage. Various regimens have been used: 150–400 mg/kg/d for 5 days; 1–2 g/kg as single dose.
- However, a recent multicenter, retrospective cohort study (Shah 2009) suggested that the use of IVIG for STSS was associated with higher costs but no improved outcomes in children.
- At this time, the optimal regimen is unknown.

ADDITIONAL TREATMENT

General Measures

- Volume resuscitation
- Replete electrolytes as indicated
- Blood products as indicated for anemia or thrombocytopenia
- Airway support for severe depression of level of consciousness or respiratory insufficiency

SURGERY/OTHER PROCEDURES

- Consider surgical consult early in management of NF.
- Fasciotomy to relieve compartment syndrome.
- Extensive debridement of necrotic tissue is often indicated.

ONGOING CARE

PROGNOSIS

- Fulminant course with rapid deterioration is characteristic of invasive GABHS infections.
- Improved prognosis with early recognition and aggressive management
- Case fatality rate in pediatric series is 13.7% (36.7% for STSS and 24% for NF)
- Emm/M strain types 1, 3, 12 have worse prognosis.
- Increasing age, occurrence in winter/early spring, or development of GI symptoms have worse prognosis.

COMPLICATIONS

- From deep and systemic infections:
 - Sepsis syndrome
 - Hematologic seeding and development of focal infection
 - Complications associated with specific site of involvement (e.g., meningitis—neurologic impairment; septic arthritis—joint destruction)
- From NF:
 - Severe tissue necrosis usually requires extensive surgical debridement and often results in amputation of involved extremities.
 - Compartment syndrome
 - Functional disabilities
 - Cosmetic sequelae
- From STSS:
 - Multiorgan system failure from systemic hypotension and direct effects of inflammatory mediators
 - Adult respiratory distress syndrome
 - DIC
 - Acute tubular necrosis resulting in renal failure
 - Hepatic failure
 - Cardiac insufficiency
 - Cerebral ischemia and edema
 - Metabolic derangements

- B95.0 Streptococcus, group A, causing diseases classd elswhr

FAQ

- Q: For whom should the diagnosis of invasive GABHS be entertained?
- A: Consider GABHS in any child with varicella who experiences recrudescence of fever, fever $\geq 39^\circ\text{C}$ (102.2°F) beyond the 3rd day of illness, or any fever beyond the 4th day of illness. A high index of suspicion should be maintained in patients with septicemia, and in febrile patients with pain and hyperesthesia out of proportion to the clinical findings.
- Q: Should the use of NSAIDs be restricted in patients with varicella?
- A: There are several reports suggesting an association between the use of NSAIDs and the development of invasive group A streptococcal diseases, but there has been no study to establish a causal relationship. It has been demonstrated that NSAIDs inhibit immune-mediated defense mechanisms, enhance the production of cytokines, and suppress the pain and fever that might encourage a patient with invasive GABHS infection to seek medical attention sooner. No formal recommendations for restricting the use of NSAIDs are being made at this time.
- Q: Should close contacts of patients with invasive GABHS infections receive chemoprophylaxis?
- A: Chemoprophylaxis of household contacts of people with invasive GABHS remains controversial. Although the risk of developing disease for household contacts is elevated in comparison to the risk of sporadic disease development, the overall frequency of invasive GABHS disease remains small. Testing for GABHS colonization and chemoprophylaxis of household contacts of people with invasive GABHS is not routinely recommended. However, in high-risk populations (people > 65 years or those suffering from HIV infection, chickenpox, or diabetes mellitus), targeted chemoprophylaxis may be considered. Chemoprophylaxis is not recommended in schools or child care facilities.

STROKE

Irfan Jaffree

Peter M. Bingham (5th edition)

BASICS

DESCRIPTION

A neurologic deficit progressing over minutes to hours, due to insufficient perfusion of the brain or spinal cord. Also, otherwise “asymptomatic,” remote strokes may present as epilepsy.

EPIDEMIOLOGY

Incidence

- Overall incidence is ~2.5 per 100,000, but certain groups are at higher risk (those with heart disease, sickle cell disease, hereditary thrombophilias).
- Neonatal stroke incidence 1 in 4,000 live births.

RISK FACTORS

Genetics

Various hereditary and metabolic disorders: Neurocutaneous diseases, Down syndrome, collagen disorders, congenital heart disease syndromes, coagulation disorders, hereditary cavernoma or telangiectasia, hyperhomocysteinemia, mitochondrial diseases (MELAS), and others

ETIOLOGY

- Underlying causes of stroke include hematologic, circulatory, and cardiac disorders.
- Hematologic:
 - Factor V mutation
 - Prothrombin gene mutation
 - Anticardiolipin/antiphospholipid syndrome
 - Sickle cell
 - Hemolytic uremic syndrome
 - Hyperhomocysteinemia
 - Dyslipidemia
 - Protein S or C
 - Antithrombin III deficiency
 - Asparaginase treatment
 - Hyperviscosity syndromes (including leukemia)
 - Thrombocytopenia ± iron deficiency
 - Extreme dehydration
 - Mixed connective tissue disease
 - Systemic lupus erythematosus
 - Methyl-tetrahydrofolate reductase (MTHFR) mutation
- Vascular:
 - Carotid or vertebral dissection (MTHFR associated with vertebral dissections in children)
 - Arteriovenous malformation (AVM)
 - Carotid trauma
 - Moyamoya
 - Cavernous angioma (“occult cerebrovascular malformations”)
 - Vasculitis (especially due to bacterial meningitis)
 - Brain tumor surgery
 - Rarely, aneurysm, Takayasu arteritis, chronic meningitides (tuberculosis, Lyme disease, lupus, or sarcoidosis)
 - Infective endocarditis
- Cardiac:
 - Rheumatic heart disease, cyanotic congenital heart disease, heart failure, cardiomyopathy
 - Possible association with mitral prolapse, atrial septal defects
 - Atrial myxoma, aortic dilatation (Marfan syndrome), pulmonary AVM
 - Single ventricle

DIAGNOSIS

HISTORY

- Inquire about substance use, prior trauma (including head, neck, seat belt injury for dissection and cardiac contusion), infection, excessive bleeding or spontaneous clotting, or history of heart disease.
- Prior surgical history of ASD or VSD repair, PFO closure, cardiac catheterization, or prosthetic heart valves
- Family history of premature thrombosis, hemoglobinopathy, or vascular malformations (e.g., cavernous hemangioma or hereditary hemorrhagic telangiectasia)
- Perinatal stroke frequently presents with neonatal seizures: May be associated with multiple gestation
- Complications of labor or fetal exposure to vasoactive compounds may be associated.
- Recent travel to/from areas of endemic infections.

PHYSICAL EXAM

- Note level of alertness and capacity for sustained attention; fluency, appropriateness, and construction of speech; comprehension; emotional state; and subjective or objective pain.
- Vital signs, color, and respiratory pattern may disclose existing or impending respiratory failure due to loss of protective airway reflexes.
- General examination should include peripheral pulses and perfusion; palpation and auscultation of the precordium and cervical area may reveal evidence of dysrhythmia or anatomic lesions.
- Note confrontation visual fields, funduscopy (especially for papilledema, retinal hemorrhage for shaken baby), eye movements, facial symmetry, pattern of movement of affected limbs, and extensor response of great toe to plantar stimulation (Babinski sign).
- In the absence of sensory complaints, detailed sensory exam is often fruitless. Conversely, isolated sensory complaints are rarely an indication of stroke.
- Examine for signs of neurocutaneous syndromes (neurofibroma, shagreen patch, ash lesions, axillary freckling, telangiectasia, nevi, facial angiomas).

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Blood chemistry, particularly glucose; mild hyperglycemia may reflect stress response.
- Toxin screen
- Carbon monoxide poisoning in winter months.
- CBC, PT, and PTT may prompt important therapeutic decisions.
- Consider lumbar puncture (if neuroradiologic findings show no risk of incipient herniation) to look for evidence of inflammatory/infectious basis (vasculitis, though CSF occasionally normal).

- ESR, CRP for endocarditis
- TSH and free T₄ (atrial fibrillation)
- More extensive testing in undiagnosed cases may include the following:
 - Tests for specific coagulopathies (see “Etiology and Differential Diagnosis”)
 - Varicella serology (may be a common cause of stroke in children, postvaricella angiopathy)
 - Toxin screen (association with cocaine, amphetamines, OCP)
 - Amino acid screening (for homocysteine)
 - Hemoglobin electrophoresis (sickle hemoglobin)
 - Lipid profile (hypercholesterolemia)
 - RPR

Imaging

- Individuals with stable vital signs and suspected stroke should undergo a brain imaging study promptly:
 - Non-contrast-enhanced images to look for possible hemorrhage, may be followed by contrast-enhanced images to evaluate for possible focal encephalitis or underlying vascular lesions (MR/conventional angiography)
 - Many diagnostic questions can be resolved equally well by CT or MRI, although CT may be preferable in suspected subarachnoid hemorrhage; MRI—especially diffusion-weighted MRI—is much more sensitive in the 1st 24 hours after symptom onset and may identify venous or sinus thrombosis or smaller bilateral lesions pointing to systemic embolization.
 - Cervical spine imaging may help in posterior circulation infarcts to look for vertebral abnormalities.
- More extensive testing in undiagnosed cases may include the following:
 - ECG to assess for rhythm dysfunction
 - Echocardiography (atrial-septal defect, luminal lesion transthoracic/transesophageal)
 - Carotid Doppler (stenosis/dissection)
 - Specialized vascular neuroradiologic studies (MRA, CTA, conventional angiography)

ALERT

- AVMs may not be seen on angiography immediately after a primary intracerebral hemorrhage. Consider repeat angiography weeks or months later.
- CT scan may be normal in the 1st 24 hours after nonhemorrhagic stroke. A follow-up study may be necessary.
- Suspected transient ischemic attack (TIA) should prompt a vigorous diagnostic evaluation.

DIFFERENTIAL DIAGNOSIS

Several disorders may mimic the presentation of stroke:

- Migraine
- Demyelinating disease
- Focal encephalitis
- Postepileptic paralysis (Todd paresis)
- Conversion disorder
- Brachial plexus palsy, spinal cord lesion, intracranial neoplasm, abscess, subdural empyema, or mitochondrial disease may present as stroke.

**TREATMENT****MEDICATION (DRUGS)**

- Investigational therapies include hypervolemic hemodilution, thrombolytic agents, calcium channel antagonists, and neuroprotective agents such as glutamate receptor antagonists.
- In most cases, there is no contraindication to pharmacotherapy appropriate to any identified underlying condition; the decision to use antiplatelet or thrombolytic therapy or anticoagulation is complex and depends on risk of hemorrhage, experience of the clinician, and potential side effects.

ADDITIONAL TREATMENT**General Measures**

- Patients with radiologically documented or clinically suspected stroke who have stable airway, breathing, and circulation are most often hospitalized for observation and supportive therapy:
 - Those with a diminished or fluctuating level of alertness or with radiographically extensive area(s) of infarction are often monitored in an intensive care unit for changes in respiratory status or signs of increased intracranial pressure.
- Strokes involving the posterior fossa or cerebellum, or affecting a large area of the cerebrum, are of particular concern because of the risk of tentorial or subfalcine herniation: A neurosurgical consult should be obtained for these cases and for those with intracranial hemorrhage above or below the tentorium.
- Consultation with neurology, cardiology, hematology, other pediatric subspecialists

Additional Therapies

Rehabilitation and physical therapy may improve outcome: Institute as soon as the patient's condition permits.

IN-PATIENT CONSIDERATIONS**Initial Stabilization**

- Stroke may present as new-onset seizures: Follow protocol for emergency treatment of seizures.
- Urgent neurosurgical evaluation indicated in cases of large cerebral hemispheric stroke, intracranial hemorrhage, or posterior fossa ischemic stroke
- Empiric antibiotics indicated in the setting of stroke and fever (abscess, septic emboli, empyema)

**ONGOING CARE****FOLLOW-UP RECOMMENDATIONS**

The usual course in stroke of any cause is for gradual improvement after the acute onset of symptoms: Significant recovery of neurologic function may continue for months after the ictus, especially in infants and toddlers.

PATIENT EDUCATION

- Internet information for families: National Stroke Association: www.stroke.org
- Children's Hemiplegia and Stroke Association: www.chasa.org
- Pediatric Stroke Network: www.pediatricstrokenetwork.com

COMPLICATIONS

- Remote sequelae that may not be evident for months or years after stroke include epilepsy, hydrocephalus, learning difficulties, depression, short attention span, posture disturbances (especially cerebral palsy), sphincter disturbances, pressure sores, and susceptibility to infection if airway protective reflexes are impaired.
- Other complications include the following:
 - Seizures
 - Respiratory insufficiency
 - Intracranial hypertension
 - Motor, visual, cognitive deficits and neglect syndromes
 - Autonomic disturbances
 - Infection susceptibility

**CODES****ICD9**

- 436 Acute, but ill-defined, cerebrovascular disease
- 779.89 Other specified conditions originating in the perinatal period

ICD10

- I67.8 Other specified cerebrovascular diseases
- P96.89 Other specified conditions originating in the perinatal period

FAQ

- Q: Will my child have another stroke?
- A: The chance of recurrence depends on remediation of the underlying cause. Available evidence suggests that children with no identifiable underlying basis for stroke have a very low recurrence risk.
- Q: Are there any medications for acute stroke?
- A: Tissue plasminogen activator (TPA) appears to be useful in some cases of adult nonhemorrhagic stroke, but its usefulness in childhood stroke has not been studied. Depending on the presence or degree of secondary cerebral hemorrhage, many specialists favor the use of heparin or low-molecular-weight heparin in the setting of stroke due to venous sinus thrombosis.
- Q: What can be done to reduce the risk of future strokes?
- A: Risk factor modification like diet, exercise, BP control, and treating underlying cause of stroke if identified. Medication compliance.

STUTTERING

Gary A. Emmett

BASICS

DESCRIPTION

Stuttering is an involuntary disturbance in the normal fluency and timing of speech which is not appropriate for the age of the speaker. Various patterns are seen:

- Prolongation of sounds or syllables
- Repetition of sounds or syllables or even whole words
- Pauses in the middle of words
- Blocking—either silence or pauses filled with nonsense sounds in the middle of words, as if considering what to say next
- Avoidance—word substitutions that are used to skip known problem words; also called circumlocution
- Overemphasis of some syllables or words; also called tension
- Stuttering is significant when it interferes with the patient's life in academic, occupational, or social arenas. Many children with developmental delays have disfluencies of speech, but it is not considered stuttering unless the disfluencies are present more frequently than expected for the level of disability.

EPIDEMIOLOGY

- At least 1% of all studied populations affected
- Males stutter 3 times more often as females.
- Stuttering is found in every culture and language. The language spoken in the home does not increase or decrease the amount of stuttering.
- Stuttering begins between 2 and 7 years of age with 98% of cases presenting by age 10.
- Girls start stuttering several months earlier on average than boys; but they also speak, in general, earlier than boys do.

RISK FACTORS

Genetics

Stuttering does cluster in families:

- Monozygotic twins have a higher concordance for stuttering than dizygotic twins.
- The more closely related one is to a stutterer, the more likely one is to stutter.
- Identical twins have a concordance for stuttering of $\geq 30\%$.
- In specific families with a high propensity for stuttering, Kang et al. (and others) have shown single gene defects that correlate highly with dysfluency.

GENERAL PREVENTION

There is no known prevention strategy for stuttering.

PATHOPHYSIOLOGY

Stuttering appears to be associated with an excessive amount of dopamine, or closely related vasoactive compounds, in the brain:

- Patients with Parkinson disease often develop adult-onset stuttering.
- PET scans show increased vasoactive substances in the brains of those who stutter.
- Medications that increase brain dopamine (antidepressants) or are dopaminergic (major tranquilizers) can induce stuttering in non-stutterers; medications that lower dopamine (e.g., clomipramine) may stop stuttering.
- Many differences exist between the brains of stutterers and non-stutterers in glucose uptake, dopamine release, and metabolic activity of the basal ganglia, but no single physiologic process has been well defined as the cause of stuttering.

ETIOLOGY

- Specific etiology is not known, but many factors contribute. Stuttering may be more pronounced when a child is fatigued, excited, upset, rushed, or exposed to some other stressor.
- Environmental factors are thought to have a role. Children adopted by a parent who stutters are more likely to stutter than children adopted by a parent who does not stutter.

COMMONLY ASSOCIATED CONDITIONS

- Other language problems: Articulation disorders, phonologic disorders, learning disabilities, dyslexia, ADHD
- Students with developmental delay or intellectual impairment are found to stutter up to 25% of the time.

DIAGNOSIS

HISTORY

- Stuttering runs in families by both nature and nurture.
- Age of onset and length of persistence:
 - Onset is insidious, with the child often unaware of the problem.
 - If stuttering starts after the 10th birthday, suspect an intracranial mass or brain ischemia.
- Physiologic stuttering is rarely present during oral reading, singing, acting, and reciting in rhythm, or while talking to pets or inanimate objects.
- Medications, especially those that increase dopamine, may activate stuttering.
- Increased intracranial pressure from disease or trauma may lead to stuttering.

PHYSICAL EXAM

- There are no specific physical exam findings of stuttering. Observations of children improve the ability to make this diagnosis. Stuttering is 2 or more repetitions of a speech unit.
- Stutterers often improve in one-to-one situations with familiar people, so ask the parents to bring in a video recording of the child in a variety of situations: when talking in public, singing, and talking to a pet or infant.
- Observations that may be made in the office and correlate strongly with the diagnosis of stuttering include:
 - Multiple repetitions and/or prolongations
 - Rising pitch with difficult words
 - Grimacing or other physical tension, such as taking deep breaths or jerking the head back when speaking
 - Inappropriate emphasis of words not normally emphasized, extremely slow speech, or speech without intonation
- Although unwillingness to speak to the examiner is normal, unwillingness to speak to the parent is not.

DIAGNOSTIC TESTS & INTERPRETATION

Diagnostic Procedures/Other

- None currently available, but PET scan may be a useful modality in the future
- If stuttering begins after the age of 10, or if the patient has additional neurologic or developmental problems, a workup for brain abnormalities should be considered.

DIFFERENTIAL DIAGNOSIS

- Developmental:
 - Normal development: Disfluencies associated with rapid onset of full speech capabilities that will usually resolve very quickly
 - Transitory dysfluency is an ill-defined term but generally means stuttering in preschool-aged children that lasts < 1 year.
 - Cluttering: Patients with extremely rapid speech will have disfluencies that resolve with slowing down of speech.
 - Pervasive developmental disorder (autism spectrum disorder): May also have echolalia, tonelessness, and poor eye contact
- Neurologic:
 - Tics/Tourette syndrome: Similar time of onset, initially somewhat similar symptoms. Stuttering is usually not associated with simultaneous physical movement.
 - Trauma, tumor, or major CNS disease, such as Parkinson disease, may cause late-onset stuttering.
- Medications:
 - Any medication that increases the presence of dopamine may worsen (or cause) stuttering. Examples are SSRI-type antidepressants or major tranquilizers.

TREATMENT

ADDITIONAL TREATMENT

General Measures

- Therapy must work on improving the child's fluency and increasing acceptance and tolerance of this problem by the patient and his or her family.
- In a multicultural learning atmosphere, sensitivity to the learning styles of each social group is paramount in achieving successful results.

Additional Therapies

- Speech therapy:
 - Stuttering in young children can be resolved with very short courses of therapy, often ≤ 3 months. Stuttering remains resolved in $\geq 95\%$ of these early treatment cases. The younger the patient is at the time of referral to speech therapy, the shorter the course of therapy needed, and the more likely that the therapy will be successful.
 - Many experts in dysfluency believe that early intervention is more likely to be successful than waiting to start therapy if the stuttering has not spontaneously resolved by the 7th birthday.
 - Among the more successful new programs for young children who stutter is the Lidcombe Program of Early Stuttering Intervention, an intense behavioral therapy program in which the belief is that stuttering is physical in nature. The program teaches parents and caregivers how to praise the child for speaking fluently and how to correct them occasionally when they stutter. Parents are supported throughout the process by the clinician. The therapy ultimately enables the child to speak fluently and to monitor his or her own speech.
- Other therapies:
 - A successful new therapy for adolescents and adults is a hearing-aid type device (SpeechEasy, www.speecheasy.com) that feeds the individual's speech directly back into an earpiece.
 - Devices that make hearing monaural or provide a white noise background in the ear also improve stuttering.
 - Information for families is available through organizations such as The Stuttering Foundation, a nonprofit organization (www.stutteringhelp.org).

ALERT

- Because stuttering waxes and wanes with time, temporary improvement does not equal cure.
- Any behavioral therapy must be done under the guidance of a well-trained professional because inappropriate criticism may worsen stuttering.
- Waiting to see if stuttering goes away by age 7 is not the best strategy for young children, as was often taught in the past.
- The literature does not give a clear time frame for how long stuttering in preschool children should last before requiring evaluation and treatment, but a significant stutter that lasts for > 1 year should be referred to a speech therapist.
- No medications are known to reduce stuttering safely. Acupuncture, hypnosis, and yoga have been used with some success, but not in controlled studies.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

If stuttering is reported by the parents in a preschool-aged child, follow up in 1–2 months to see if it was only a transitory dysfluency that has resolved. If not, obtain a speech therapy consult for evaluation.

Patient Monitoring

- Periodic follow-up to ensure that speech therapy is in place and that progress is being made
- Reassessment to ensure that child is adapting to social situations and interacting with others

PATIENT EDUCATION

The following suggestions, though helpful to parents, should be recommended in conjunction with, but not in place of, speech therapy. Parents may be too critical of their own children.

- Take time out of each day to speak with the child one-on-one.
- Model slow speech
- Wait for the child to speak. Take turns speaking.
- Allow for transition time between activities and tasks.
- Keep a notebook of things that help make speech better and things that elicit stuttering.

PROGNOSIS

- Up to 80% of stuttering cases spontaneously regress by age 16.
- Severity of stuttering does not relate to persistence of stuttering.
- The longer stuttering exists, the more likely it will persist.

COMPLICATIONS

- Anxiety and depression, often far out of proportion to the degree of dysfluency
- Blocking and hesitation, giving an impression of delayed intellectual development
- Voluntary withdrawal from social interaction to avoid embarrassment

ICD9

315.35 Childhood onset fluency disorder

ICD10

F80.81 Childhood onset fluency disorder

FAQ

- Q: Are some children more prone to stuttering?
- A: Yes, "sensitive" children (many different definitions in many different studies) are more likely to stutter, as are the children of highly critical parents.
- Q: Should family and friends complete the sentences of children who stutter?
- A: No, children who cannot complete a thought should be gently asked to slow down and try again with no time limit set; or, others should simply wait until the child has completed his or her sentence. Children with a stuttering problem should also be praised when they do not stutter.

SUBDURAL HEMATOMA

Dennis J. Dlugos
Sabrina E. Smith

BASICS

DESCRIPTION

A subdural hematoma (SDH) is a collection of blood between the outer pial and inner dural meningeal layers. The bleeding is usually venous in origin, although either cortical arteries or bridging veins may be torn.

EPIDEMIOLOGY

- Heterogeneous causes; occur in all age groups
- Incidence in infants <1 year old estimated at 20–25/100,000

RISK FACTORS

- In infants and young children, SDHs are frequently the result of abusive head trauma.
- In older children, SDHs are often the result of motor vehicle collisions.
- Neonatal SDHs occur with spontaneous deliveries, but may be more frequent following deliveries with forceps or vacuum extraction. SDHs related to birth usually resolve.
- Risk factors for abusive head trauma include disability or prematurity of the child, unstable family situations, parents of young age, and low socioeconomic status.
- 1 study found that fathers were the most frequent perpetrators, followed by boyfriends, female babysitters, and mothers, in descending order of frequency.
- Accidental trauma

Genetics

There is no clear genetic predisposition, except when hereditary coagulopathy or metabolic disease is implicated.

GENERAL PREVENTION

- Parents should be counseled about appropriate methods to channel frustration and anger toward infants and children. Shaking an infant when the parent is angry is never appropriate.
- Bicycle helmets, car seats, and seat belts are all valuable in preventing head injuries in children.

PATHOPHYSIOLOGY

- SDHs may be acute or chronic:
 - Arterial SDHs grow quickly, whereas venous SDHs may accumulate slowly, remaining undetected for weeks or months.
 - Acute SDHs contain blood, whereas chronic SDHs contain proteinaceous exudate and blood-breakdown products.
 - Rebleeding may be the underlying cause of many chronic SDHs.
- Significant force is usually required for SDH unless there are predisposing circumstances; SDH is only rarely due to trivial or minor trauma. However, SDH can occur with relatively minor trauma in individuals with bleeding disorders, children on chronic dialysis, and those with enlarged extracerebral spaces or cortical atrophy.

- SDHs in abusive head trauma may be due to the striking of the infant's head against a surface (such as a mattress):
 - The sudden deceleration associated with the impact may tear bridging veins traveling in the subdural space.
- The term shaking-impact syndrome may be more accurate than shaken-baby syndrome.

ETIOLOGY

- See "Risk Factors."
- SDHs can also occur after ventricular shunting and extracorporeal membrane oxygenation (ECMO).

COMMONLY ASSOCIATED CONDITIONS

- Some metabolic disorders, such as glutaric aciduria type I and Menkes disease, can be associated with both acute and chronic SDHs.
- Victims of motor vehicle collisions with SDH may have other intracranial injuries, such as diffuse axonal injury.
- Traumatic SDHs are often associated with cerebral contusions. Other associated injuries include skull fractures, diffuse axonal injury, and penetrating injuries.
- Sequelae: Epilepsy, developmental delay, cerebral palsy

DIAGNOSIS

A careful history and detailed physical exam are essential to explore possible causes of the SDH, assess the child's neurologic status, and look for evidence of other injuries. Prompt neuroimaging is critical.

HISTORY

- Newborns: SDHs due to birth trauma may present with lethargy, pallor, poor feeding, apnea, and seizures. However, many term newborns with small SDHs are asymptomatic.
- Infants and young children: SDHs may also present with a nonspecific history of lethargy, irritability, vomiting, poor feeding, apnea, and seizures.
- Older children: Present with a history of trauma and alteration of consciousness
- Caution:
 - Be suspicious if the stated history does not fit with the pattern or severity of the injury.
 - Physicians and other health care professionals with experience in child abuse should be consulted early if abuse is suspected.

PHYSICAL EXAM

- Newborns may present with decreased responsiveness, a bulging fontanelle, hypotonia, or hypertonia. Retinal hemorrhages are not specific at this age, because they are seen in up to 40% of newborns following a vaginal delivery.
- Infants and young children may also present with nonspecific physical signs, but focal neurologic signs may be present. Retinal hemorrhages are most often associated with abusive head trauma, but they have been reported after accidental trauma leading to SDH. Bilateral retinal hemorrhages with retinal folds or detachments are particularly associated with abusive head trauma.

- Other signs of child abuse include burns, lacerations, and bruises in various stages of healing, and belt marks, choke marks, and multiple fractures of different ages.
- Older children present with signs of external head trauma, decreased responsiveness, and focal neurologic signs.
- SDHs present with nonspecific signs, such as vomiting, irritability, lethargy, failure to thrive, anemia, and seizures.

DIAGNOSTIC TESTS & INTERPRETATION

Imaging

- CT scan is the imaging study of choice in acute head trauma with neurologic signs:
 - SDH appears as an extra-axial area of increased density, crescentic in shape, and often associated with cerebral contusion or mass effect.
 - CT also may show evidence of cerebral edema, with loss of gray matter/white matter differentiation and small ventricles.
 - Subacute SDHs may be difficult to distinguish from adjacent gray matter on CT scan.
 - Loss of gray/white matter differentiation may occur.
 - Chronic SDHs appear as areas of low density on CT scan, often bilateral.
- MRI is helpful to clarify subacute and chronic SDHs and to identify small SDHs missed by CT.
- Ultrasound is less helpful, because it may be difficult to distinguish the subdural space from the subarachnoid space.
- If child abuse is suspected, a skeletal survey or bone scan is useful to look for fractures of different ages.
- Incidental SDH may be found on neuroimaging studies in newborns; frequently no intervention is required other than close follow-up.

DIFFERENTIAL DIAGNOSIS

- SDHs are usually traumatic, but separating accidental from nonaccidental trauma may be difficult: Falls in infants may cause linear skull fractures, rarely SDHs. On noncontrast head CT, homogeneous hyperdense subdural hematoma is more common following accidental trauma, while mixed-density subdural hematoma is more common following nonaccidental trauma.
- Macrocephaly or other signs/symptoms since birth may help to date the origin of the SDH to the perinatal or neonatal period.
- Epidural hematomas, subarachnoid hemorrhages, and acute SDHs cannot be distinguished clinically:
 - The lucid interval sometimes seen with epidural hematomas in adults is not a reliable sign.
 - A head CT should differentiate.
- Chronic SDHs must be differentiated from benign enlargement of the subarachnoid spaces, a self-limited condition characterized by progressive macrocrania and extra-axial fluid collections with the density of spinal fluid:
 - MRI can differentiate benign enlargement of the subarachnoid spaces from SDH.
 - Rarely SDH can also occur in children with benign enlargement of the subarachnoid spaces.

TREATMENT

MEDICATION (DRUGS)

Seizures:

- Phenytoin and levetiracetam are good choices if IV medication is needed, with phenobarbital as a reasonable alternative, especially in neonates.
- Prophylactic anticonvulsants given for a few weeks are effective in reducing early posttraumatic seizures but may not affect long-term risk of epilepsy.

ADDITIONAL TREATMENT

General Measures

- The treatment of choice for large, acute SDHs is surgical evacuation. Smaller SDHs may be managed conservatively, with careful monitoring for signs of neurologic deterioration.
- While awaiting surgery, attention to airway, breathing, and circulation (ABCs) is critical. Tracheal intubation should be performed if the child's Glasgow Coma Scale score is <8 or if airway protective reflexes are impaired.
- Measures to control intracranial pressure (ICP) include elevating the head of the bed 30° to promote venous drainage and osmotic therapy with mannitol:
 - ICP monitoring should be considered.
 - Mild hyperventilation (PcO₂ 30–35 mm Hg) may be helpful but should not be instituted prophylactically.
 - The efficacy of these measures in improving long-term outcome following large SDHs has not been established. Mild hypothermia and hypertonic saline have been used in some cases of traumatic brain injury in adults, but these are not proven therapies in children.
- Seizures should be treated promptly.
- Treatment of chronic SDHs is more controversial:
 - If there are no signs of elevated ICP, conservative treatment is reasonable, and most collections will resolve.
 - Subdural taps are indicated if ICP rises.
 - If taps are not successful, a subdural peritoneal shunt may be placed.
- Treatment of SDHs that develop after ventricular shunting is particularly challenging.

ISSUES FOR REFERRAL

Social work services should be consulted in cases of known or suspected child abuse.

SURGERY/OTHER PROCEDURES

The treatment of choice for large, acute SDHs is surgical evacuation.

IN-PATIENT CONSIDERATIONS

Initial Stabilization

- Children with SDHs may be critically ill on presentation.
- The aggressiveness of acute therapy depends on the child's clinical condition.
- Neuroimaging studies and, if necessary, prompt neurosurgical consultation should be performed.

IV Fluids

Isotonic fluids should be given, because hypotonic fluids may worsen cerebral edema.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Children with neurologic sequelae from head injury may benefit from admission to a rehabilitation hospital.

PROGNOSIS

- In general, long-term outcome is related to the condition of the child at time of presentation. Prolonged elevation of ICP, concomitant ischemic brain injury, or significant cerebral edema before treatment is worrisome and indicates a poor prognosis.
- Children typically have a better outcome from head injury than do adults, but children <7 years of age often do worse than older children, especially if the SDH is the result of abusive head trauma.

COMPLICATIONS

- SDHs may result in mass effect, focal neurologic signs, and coma.
- Increased ICP and seizures are other serious complications.
- Neurologic sequelae of SDHs are more severe than epidural hematomas because of associated cerebral contusions.
- Long-term problems include headache, seizures, hydrocephalus, cerebral palsy, difficulty concentrating, poor school performance, fixed neurologic deficits, and neurobehavioral problems.
- Epilepsy eventually develops in ~10–15% of patients after severe head injury: This risk generally does not warrant the use of prophylactic anticonvulsants.

CODES

ICD9

- 432.1 Subdural hemorrhage
- 852.20 Subdural hemorrhage following injury without mention of open intracranial wound, unspecified state of consciousness

ICD10

- S06.5X0A Traumatic subdural hemorrhage without loss of consciousness, initial encounter
- S06.5X0D Traumatic subdural hemorrhage without loss of consciousness, subsequent encounter
- S06.5X0S Traumatic subdural hemorrhage without loss of consciousness, sequela

FAQ

- Q: When did the bleed occur?
- A: With chronic SDHs, the time and type of injury may be difficult to establish, because no trauma may be reported and the trauma may have occurred weeks or months before. Neuroimaging can give some indication of the injury's timing.
- Q: What limitations should be imposed after an acute SDH?
- A: Because SDH may recur with minor trauma, it is prudent to avoid any activities that have significant risk of fall or a blow to the head for weeks to months or until neuroimaging resolution of the hematoma.
- Q: Why are anticonvulsants not used to prevent seizures following SDHs?
- A: Seizure medications may be given for a few weeks to prevent early seizures following an SDH. After a few weeks, the risks and side effects of the medications outweigh the risk of developing seizures. If seizures begin at a time remote to the injury, then seizure medications can be restarted.
- Q: My baby twisted out of my arms, fell head-first onto a tile floor, and suffered a head injury. Will I be reported for child abuse?
- A: Not if the injuries fit with the stated history. In this case, the most likely injury would be a linear skull fracture. If more serious intracranial injuries occur, they will probably not be associated with retinal hemorrhages or other injuries, such as older fractures in multiple stages of healing.

SUBSTANCE USE DISORDERS

Matthew L. Prowler

BASICS

DESCRIPTION

DSM-IV-TR criteria:

- Substance abuse—a maladaptive pattern of substance use leading to significant impairment or distress: Failure to fulfill role obligations at home and school (absences, suspensions, expulsions); physically hazardous situations (in car with driver impaired by substance use); legal/criminal problems; continued use despite social or interpersonal problems
- Substance dependence—differentiated from abuse by the presence of:
 - Tolerance—a need for markedly increased amounts of substance to achieve intoxication; diminished effect with continued use of same amount
 - Withdrawal symptoms develop, and use of same (or similar) substance is necessary to avoid withdrawal.
 - Efforts to cut back are unsuccessful; substance taken in larger amounts than intended; a great deal of time is spent in activities necessary to obtain substance; important social/recreational activities are given up or reduced.

EPIDEMIOLOGY

- Estimated rates for substance use vary by substance. Most recent epidemiologic data from the annual survey, “Monitoring the Future,” a long-term study sponsored by the National Institute on Drug Abuse (NIDA):
 - Cigarettes: Approximately 40% of American youth have tried cigarettes by 12th grade, and about 1 in 5 those reporting lifetime prevalence >20% of 12th graders is a current smoker.
 - Alcohol: More than 20% of 12th graders surveyed admitted to having ≥ 5 drinks in a row on at least one occasion in the 2 weeks prior to the survey (considered “binge drinking”).
 - Marijuana: More than 5% of 12 graders reported daily use of marijuana and more than 1/3 have used in the last 12 months.
 - Prescription drugs: The adolescent misuse of addictive prescription drugs has become a growing problem in the US in recent years. The proportion of 12th graders in 2010 who reported use of these prescription drugs (amphetamines, sedatives, tranquilizers, and narcotics other than heroin) without medical supervision in the prior year was 15%, those reporting lifetime prevalence >20%.

RISK FACTORS

- Social and familial environmental factors: Lack of parental supervision or discipline, minimal peer affiliation, lack of engagement in structured activities, low socioeconomic status
- Familial heritability pattern: Genetic heritability as high as 0.8 in twin studies

COMMONLY ASSOCIATED CONDITIONS

- ADHD
- Conduct disorder
- Mood disorders
- Post-trauma states

DIAGNOSIS

PHYSICAL EXAM

- Fatigue/malaise: Cannabis, sedative-hypnotic, opiate intoxication, stimulant withdrawal
- Increased heart/respiratory rate: Stimulants, cannabis
- Increased blood pressure: Stimulants, cannabis, PCP
- Decreased blood pressure/respiratory rate: Opiates
- Injected conjunctiva: Cannabis
- Nystagmus: PCP
- Pupillary constriction: Opiates
- Pupillary dilatation: Opiate withdrawal, cocaine, PCP

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Drug screens are available for urine and blood samples. Urine drug screens (UDS) are the most commonly used.
 - When administered, care should be given to individual drug half-lives, as a negative screen may not indicate that a patient is not using drugs.
 - Pay attention to lab cutoff concentrations for sensitivity of positive findings. For instance, some labs use 50 ng/mL and 500 ng/mL for cannabis and amphetamine, respectively, while other labs use 100 ng/mL and 1,000 ng/mL.
- For alcohol intoxication:
 - Blood levels >100 mg/dL: Impaired balance and drowsiness
 - >200 mg/dL: Marked muscular incoordination, vomiting, stupor
 - >300 mg/dL: Loss of consciousness, incontinence
 - >400 mg/dL: Can be fatal

Diagnostic Procedures/Other

- Screening tools: CRAFFT substance abuse screening test—a brief, validated tool (6 items) designed for screening in pediatric primary care settings. Multiple longer screening instruments exist for use in subspecialty offices (e.g., POSIT, PESQ, AADIS).
- Interview:
 - A thorough substance use history includes: Age of onset, duration, frequency, and route of ingestion for each drug used. It may be helpful to outline a brief timeline or drug chart.
 - Note if there are any temporally related events in patient’s life that correspond to increased use.
 - Other questions that help ascertain severity: Ask about context of use; does the patient use alone or with peers; have there been negative consequences of use or clear functional impairment.
 - Explore the motivation to quit or change behavior.
 - Explore adolescent’s attitudes and beliefs regarding substance use and perceived risks or benefits of continued use.

TREATMENT

ADDITIONAL TREATMENT

General Measures

- Inpatient rehabilitation: Acute stabilization in cases of substance abuse severely affecting functioning; high-risk behavior or severely symptomatic comorbid states are demonstrated.
- Partial hospitalization: Child remains in the home, but attends daily therapeutic program.
- After-school intensive outpatient programs: Usually 2–3 times/week, group therapy based.
- Outpatient therapy: Less acute, but may be intensive with several visits a week, consisting of psychotherapy and/or psychopharmacology.

Additional Therapies

- Psychotherapeutic treatments: The most efficacy has been shown for the following therapeutic approaches:
 - Cognitive behavioral therapy (CBT)
 - Family therapy
 - Motivational interviewing/enhancement
- Pharmacologic treatments:
 - Limited research has focused on medication management of substance use disorders in adolescents.
 - While off-label, there have been positive findings for nicotine replacement therapy (NRT) and bupropion for smoking cessation in adolescents.
 - There is early evidence that buprenorphine is a safe and effective treatment for opiate-dependent adolescents and young adults.
 - Treating comorbid conditions: There is evidence that treatment of comorbid ADHD and Bipolar Disorder leads to better outcomes of substance use.
- Support groups:
 - 12-Step model: Multi-step approach to recovery, group-support, utilizes higher power concept; usually adverse to psychopharmacologic treatments
 - Alcoholics Anonymous (AA)/Narcotics Anonymous (NA): Adult groups, but some fellowships may welcome younger members.
 - Teen Anon/Family Teens Support Group: Designed specifically for teens and families of teens with substance use disorders
 - Local community/Religious support group
 - There is evidence of higher rates of abstinence in adolescents engaged in support groups compared to those not participating in such groups.

ONGOING CARE

Patient Monitoring/Prognosis

- Substance use disorders may be chronic conditions, and relapse is common.
- Long-term monitoring, including regular follow-up visits to assess for relapse and/or signs of continued substance use into adulthood.
- Engagement in treatment is a good prognostic factor.

CODES

ICD9

- 292.0 Drug withdrawal
- 304.90 Unspecified drug dependence, unspecified
- 305.90 Other, mixed, or unspecified drug abuse, unspecified

ICD10

- F19.10 Other psychoactive substance abuse, uncomplicated
- F19.20 Other psychoactive substance dependence, uncomplicated
- F19.230 Other psychoactive substance dependence withdrawal, uncomplicated

CLINICAL PEARLS

- As compared to adult users, adolescents may experiment with many drugs, rather than identify a single drug of choice.
- As opposed to regular daily use, adolescents may demonstrate great variability in the use of drugs—periods of abstinence, interrupted by rapid transitions to binge-like consumption.

SUDDEN INFANT DEATH SYNDROME (SIDS)

Norman Lewak

BASICS

DESCRIPTION

- Sudden infant death syndrome (SIDS) is the sudden death of an infant <1 year of age, which remains unexplained after a thorough case investigation, including performance of a complete autopsy, examination of the death scene, and review of the clinical history.
- SIDS always occurs during a sleep period.

EPIDEMIOLOGY

- Most common cause of death in postneonatal infancy
- Peak age of incidence: 2–4 months; uncommon after 6 months; rare before 2 weeks
- Incidence has been decreasing over the years:
 - 1970s: ~2.5 SIDS deaths per 1,000 live births
 - 1980s: ~1.4 per 1,000—reduced both by improved perinatal care and by identifying diseases that had appeared to be SIDS but were not (e.g., infant botulism)
 - 1992: “Back to Sleep” campaign started in the US with a subsequent reduction in the 1990s from 1.13 cases per 1,000 births in 1992 to 0.62 per 1,000 in 1999.
 - 2000s: Leveled off at 0.51 SIDS deaths per 1,000 live births
- Recurrence in families is rarely seen: There is no evidence for a genetic factor.

RISK FACTORS

Etiology unknown by definition; risk factors include:

- Male sex
- Poverty
- Poor prenatal care
- Low birth weight
- Prematurity
- Maternal smoking
- Maternal drug abuse
- Prone sleep position
- Exposure of infant to 2nd-hand smoke
- Exposure of infant to increased warmth
- Bed sharing with parent
- Soft bedding
- Nonuse of pacifier
- Although African American infants are at higher risk for SIDS, this is not thought to be related to genetic factors.

Genetics

- Genetic studies have been inconclusive in SIDS. However, most seem to agree that there are data to support a slight increased risk for SIDS siblings. The best explanation for this is that the populations studied, although all with a diagnosis of SIDS, were probably made up of varying subpopulations. It is likely that there is a large group of classic SIDS that is not genetic as well as much smaller populations made up of other entities.

- 2 of the previous subgroups already considered new diseases are medium-chain acylcoenzyme A dehydrogenase (MCAD) deficiency, a metabolic genetic entity, and infant botulism, a nongenetic environmental entity. There are probably other subgroups that will prove to have familial abnormalities, perhaps related to serotonin metabolism or the depth of sleep. There are probably also other environmental factors aside from the ones already noted as risk factors: Smoking, drugs, poverty, and prematurity. Whether new findings establish a new disease or simply establish the boundaries of a distinct subgroup will be argued, but if such divisions do arise, genetic counseling for the parents will be more accurate.

GENERAL PREVENTION

- Avoid maternal tobacco use and drug abuse during pregnancy.
- Avoid 2nd-hand smoke exposure to infant.
- Use supine (back) sleep position on a firm surface.
- Avoid overheating infant from excess room temperature, clothing, and/or bedding.
- Offer a pacifier to infant during sleep times. For those infants that are breastfeeding, introduce a pacifier after breastfeeding is well established.
- Encourage breastfeeding among expectant women and new mothers as it is associated with a reduced risk of SIDS.
- Apnea monitors or intercoms are not recommended for routine use, but may be indicated on a case-by-case basis for infants with a history of apnea or chronic disease associated with apnea. Apnea monitors have not been shown to be associated with a reduced risk of SIDS.

PATHOPHYSIOLOGY

- As a syndrome defined by only a limited number of similar epidemiologic and pathologic findings, it is not surprising that a number of recently described entities have been separated from the SIDS umbrella. These include infant botulism, MCAD deficiency, and long QT syndrome. Current thought supports a “triple risk model” of SIDS. This model envisions that SIDS occurs when a vulnerable infant during a vulnerable developmental period is stressed by an environmental challenge.
- Findings consistent with **biologic vulnerability** have been seen in SIDS. Tissue changes have been found in (research) postmortem exams of SIDS infants. Recently these changes have been related to a decrease of serotonin. Some investigators have postulated that these changes may be genetic; others point to the evidence that tobacco exposure to the fetus has been implicated in the brainstem changes. Also, many investigators have pointed out that prematurity, poverty, and poor nutrition during pregnancy, along with drug abuse, could probably join tobacco use in pregnancy as precursors of the brainstem pathology in the fetus.
- There is a **developmental vulnerable period** of brainstem control of respiration, which peaks at 2–4 months. During this transition period when control of respiration changes from an infantile to an adult pattern, it is postulated that a vulnerable infant is less likely to resume breathing during the usual apneas of infantile sleep—resulting in fatal obstructive apnea.

- Any theory on the pathophysiologic mechanism of the **environmental challenge** must explain how that theory relates to known risk factors. There are currently 2 major theories: Failure of arousal and carbon dioxide rebreathing:
 - Failure of arousal of a sleeping infant: It is postulated that deep sleep is the trigger for failure of the respiratory center during the vulnerable period. Even mildly increased warmth during sleep deepens the sleep; prone sleeping babies are warmer than supine ones; and soft bedding and/or sleeping in the parental bed increases the warmth. Also, not using a pacifier may cause deeper sleep.
 - Carbon dioxide rebreathing caused by prone sleeping in a soft bed or bed sharing could also affect the respiratory center
- Another commonality in SIDS is that there is obstructive apnea, long described as the “final common pathway” in all infants who carry the SIDS label:
 - Obstructive apnea is consistent with the intrathoracic petechiae found in SIDS infants.
 - This obstructive apnea can be related to an anomalous “dive reflex,” postulated by some investigators to be the final event in SIDS. The “dive reflex” is seen in certain birds and amphibians as a protective mechanism when the animal dives into the water. Water in the airway causes laryngeal spasm (closure) to protect the lungs from the immersion. It is thought that infants are born with this residual phylogenetic tendency, which may be stimulated under certain conditions by saliva.

DIAGNOSIS

ALERT

- Being misled by the current concerns about missing child abuse. Physicians should be aware that in the infant whose death appears to be typical SIDS, the final diagnosis will be SIDS in ~80% of cases and only 3–6% will be attributable to child abuse.
- The physician should state clearly to the family that this death appears to be SIDS and give no suggestion that abuse is a consideration. In the families whose babies die of SIDS, even a hint of such suspicion can be devastating. If abuse is found later, nothing has been lost by initially treating that family as if their baby died of SIDS. This is also true in the ~15% in which another medical condition will be the final diagnosis.
- The Consumer Product Safety Commission, a federal agency, has added crib safety to its area of interest. They have joined with the American Academy of Pediatrics and Keeping Babies Safe to publicize a “Safe Sleep Initiative.” Although their focus is generally on accidental morbidity and mortality from cribs (thus adding a new meaning to “crib death”), they have included supine (back) sleeping in their list of safe sleeping actions. Thus, preventing SIDS has been rightfully included in their initiative. However, this confluence of entities (which also includes “suffocation”) adds unnecessary guilt to SIDS parents. Thus, once again physicians must be aware of the information that is disseminated to families in our society.

HISTORY

Previously healthy infant found dead during a time of sleep:

- Typical case: Between 1 and 6 months of age; no family history; no history of an apparent life-threatening event (ALTE); no history suggestive of child abuse; may have had an antecedent mild upper respiratory tract infection
- Atypical case (but still probably SIDS): Outside the typical age range; a family history of a sibling with SIDS; history of an ALTE; had a severe preexisting medical problem, but one that usually does not cause death

PHYSICAL EXAM

Normal-appearing infant without obvious reason for death:

- May have postmortem lividity and/or a pink, frothy discharge from the mouth or nose
- May have bruising from resuscitation attempts

DIAGNOSTIC TESTS & INTERPRETATION
Lab

These may be done as indicated:

- Toxicology screen
- Individual testing, such as test for infant botulism
- Skeletal survey: May reveal fresh rib fractures consistent with resuscitation attempts

Pathological Findings

A death scene review, review of the history, and a complete autopsy must be performed in all SIDS cases:

- External exam: Many have a pink, frothy discharge from the nose and mouth. May have bruising and/or fractured ribs from resuscitation attempts.
- Internal exam: Most have intrathoracic petechiae and some have mild pulmonary inflammatory changes (that are insufficient and not the cause of death)

DIFFERENTIAL DIAGNOSIS

Many proposed etiologies for “crib death” over the centuries have been proposed for sociopolitical purposes (i.e., society has difficulty accepting that healthy babies die for “no reason”):

- Various terms for proposed causes that are “mother blaming”: overlying, suffocation, infanticide, and child abuse
- Proposed causes advanced to “absolve” the mother: Sepsis, pneumonia, heart disease, metabolic disease, an enlarged thymus (status thymolympathicus)
- Of all unexpected infant deaths that appear clinically to be SIDS, ~15% will be caused by another medical condition:
 - Infections: Infant botulism, sepsis, myocarditis, overwhelming pneumonia
 - Metabolic disease: MCAD deficiency (a familial condition)
 - Cardiac arrhythmia: Long QT syndrome (a familial condition)

TREATMENT

ADDITIONAL TREATMENT

General Measures

- Resuscitation attempts by the 1st responders have proved to be futile by definition.
- Immediate physician management and follow-up
- Suggestions for a community SIDS plan (public health department; may be mandated by state law):
 - Autopsy in all infants who die suddenly and unexpectedly
 - Immediate results of initial autopsy findings given to family
 - Use of the term SIDS by coroner rather than the proxy terms of “undetermined,” “unknown,” or “sudden unexpected infant death” (SUID)
 - Continuing public health contact for the family
- Immediate physician management:
 - After taking the history and evaluating the physical findings, if it appears to be SIDS, the family should be told that “it looks like SIDS.”
 - Explain to the family what happens in that community following such a death.
 - Provide immediate emotional support to the involved family members and others, including child care provider.
 - Ensure that the family has resources available during the immediate grief period.
 - Arrange physician follow-up within 2–3 days to discuss the initial autopsy results and the emotional status of the family.
- Ongoing management, follow family closely:
 - Inform family of the initial autopsy findings.
 - Inform family of the final autopsy report.
 - If the coroner uses a proxy term for SIDS, tell the family that some coroners are avoiding the term SIDS but that current pediatric practice warrants the SIDS terminology.
 - Refer family to a SIDS support group.
 - Continue contact with the family.
 - Refer family for emotional counseling as needed.
- Siblings (or any children who are close to the family) should not be forgotten. They should participate in all events around the death. They should be assured that this only happens to infants and that they (the sibling or other child) are in no way responsible. Be aware that siblings often get upset with this new infant who is “taking their place” and at such times “wish that the new infant would ‘go away.’”

ICD10

R99 III-defined and unknown cause of mortality

FAQ

- Q: How does one tell the difference between SIDS and intentional suffocation?
- A: Victims of child abuse are usually identified by history or signs of previous abuse, such as old healed rib fractures on radiography, or signs of current abuse, such as bruises other than those related to resuscitation attempts. Although it is possible to suffocate an infant without leaving marks or other evidence, such an act would have to be premeditated. Because abusive parents act impulsively in fits of rage, this would not be consistent with a premeditated act of infanticide.
- Q: Does a 2nd SIDS death in a family indicate abuse?
- A: No. According to an American Academy of Pediatrics (AAP) report, 2nd SIDS deaths in a single family are SIDS in 87% of cases.
- Q: Do all families who experience a SIDS death require counseling?
- A: What they need above all else is an accurate diagnosis and explanation that their child’s SIDS death was neither predictable nor preventable. All families also require support from other family members and friends. Being there to facilitate the (probably gradual) return of the normal activities of daily living is what others can do for them. This is the role for the SIDS support groups—not as counselors but as new friends who can understand what needs to be done. The SIDS support groups can be found through the state or local health department.
- Q: Is the flattened head from putting infants in a “back to sleep” position a reason for concern?
- A: The skull shape in almost all babies with a flattened occiput, positional plagiocephaly, almost always returns to a normal configuration by 1–2 years of age. Cosmetic surgery is possible but it is unclear if it is ever needed.

SUICIDE

Leonard J. Levine
Jonathan R. Pletcher

BASICS

DESCRIPTION

- Suicidal behavior is a voluntary self-harming act with the goal of ending one's own life.
- Attempted suicide occurs when the act does not succeed in its goal (also, failed or near-suicide).
- Suicidal ideation is any thought, with or without a specific plan, to end one's life.
- Suicidality can include suicidal ideation, preparatory acts, and/or attempts.

EPIDEMIOLOGY

- Suicide is the third leading cause of death for the 10–14, 15–20, and 20–24-year-old age groups.
- Adolescent mortality from suicide tripled between the 1950s and the 1990s.
- Females attempt suicide at a rate 2–4 times that of males. Females are most likely to attempt suicide through ingestion.
- Males 15–24 are 5 times as likely to die by suicide as females.
- Males are most likely to use more lethal methods, such as firearms and hanging, when attempting suicide.
- Completed suicide rates are highest in non-Hispanic white (13.5/100,000) and Native American (14.3/100,000) adolescents. Suicide rates for black males 10–19 years old doubled between the years 1980 and 1995.
- Gay, lesbian, bisexual, and questioning youth report higher rates of suicide thoughts and attempts than their heterosexual peers.

Incidence

- Annually in the US ~2,000 adolescents die from suicide and over a million suicide attempts come to medical attention; there as many as 11 times the number of attempts as completed suicides.
- Overall, suicide accounted for 6.9 deaths per 100,000 persons aged 15–19 years in 2007.
- In 2007, suicide accounted for 0.9 deaths per 100,000 persons aged 10–14 years, and 12.7 deaths per 100,000 persons aged 20–24 years.
- In 2009, 14% of youth surveyed in grades 9–12 reported seriously considering suicide at some point in the preceding year: >6% reported attempting suicide in the previous year.

RISK FACTORS

- Previous suicide attempt(s)
- Mood disorders
- Disruptive behavior
- Substance/alcohol abuse
- Family history of suicide
- Family history of mental illness or substance abuse
- History of sexual or physical abuse
- Family conflict or disruption
- Presence of firearms in the home

GENERAL PREVENTION

- Universal screening of all adolescents for suicidality and its primary root cause of depression should occur in primary and acute care settings. As many as 4 out of 5 adolescent suicide attempters were not identified by healthcare providers in the months leading up to the attempt.
- Brief, validated screening tools are available for medical settings.
- Warning signs, aside from obvious emotional distress, can include:
 - Chronic physical symptoms, with or without discrete physiologic etiology (e.g., chronic headache, abdominal pain)
 - Change in level of functioning in school, work, or home
 - Changes in mood or affect
 - Direct inquiry about suicidal ideation and plans
- If suicidal ideation is reported, components of risk assessment include the following:
 - Frequency and timing of suicidal thoughts
 - Active planning
 - Access to lethal means such as firearms
 - History of past suicide attempt(s)
 - History of mental health problems, including substance abuse, and treatment
 - Acute or anticipated psychosocial stressor
 - Family history of suicide
 - Family violence
 - Exploration of coping strategies and social support
- Referral or consultation with a psychiatrist or mental health professional is indicated with any question or risk for suicide attempt

PATHOPHYSIOLOGY

- Decreased central serotonergic activity may result in aggressive or impulsive behaviors, which may be aimed at oneself.
- An underlying psychiatric or personality disorder acutely worsened by a stressful life event may trigger a suicidal act.
- Feelings of isolation and lack of external support (particularly from caregivers) may result in hopelessness and despair.
- Suicide may be an impulsive act designed to punish loved ones or express frustration or rage. All suicidal behaviors must be carefully evaluated and taken seriously.

ETIOLOGY

Suicidal behavior in adolescents results from the interaction of longstanding individual and family conditions, social environment, and acute stressors:

- Psychiatric disorders:
 - Suicidal behavior is included in the diagnostic criteria for major depressive episode and borderline personality disorder (DSM-IVTR).
 - Additionally, psychotic disorders, conduct disturbance, adjustment disorder, and panic disorders have all been found to be associated with suicidal behavior.
- Intense emotional state, in particular shame or humiliation, can be “trigger events” for a suicidal act.
- Personality and social factors, such as antisocial behavior, aggressive or impulsive proclivities, and social isolation, can also contribute.

DIAGNOSIS

HISTORY

- The provider should sensitively ascertain if the patient has a weapon or access to lethal method of self-harm.
- A comprehensive history should always be obtained or reviewed by a trained mental health worker. Components of a comprehensive history include:
 - Method and timing (particularly if method is ingestion)
 - Lethality of attempt (e.g., number of pills, seriousness of physical injury)
 - Circumstances of attempt (e.g., remote site, public display)
 - History of prior attempts
 - Level of planning of attempt
 - Current affect and psychological status (e.g., feelings and/or level of depression, hopelessness, impulsivity, self-esteem)
 - Family consistency and dynamics
 - Pharmaceuticals available at home; what is missing
 - History of interpersonal conflict or personal loss
 - Family history of suicide
 - History of substance use
 - History of psychological disorder or disease state
 - History of abuse, neglect, or incest
 - Social supports and coping strategies
 - Feelings of regret or continued desire for self-harm
- The following historical information increases the risk for a future, potentially lethal suicide attempt:
 - History of potentially lethal attempt
 - Family history of suicide or attempted suicide
 - Unstable family structure
 - Poor social support system, lack of feeling connected

PHYSICAL EXAM

- Even without a history of ingestion, closely observe vital signs, skin, mucous membranes, and pupils for evidence of toxidrome.
- Examine the skin for signs of physical abuse or self-mutilation
- A complete neurologic examination is essential for the evaluation of intracranial processes, acute mental status changes, and ingestions.

DIAGNOSTIC TESTS & INTERPRETATION

Different laboratories offer different spectra and sensitivities in their toxicology screens.

Lab

- Serum and urine toxicology screens
- Urine pregnancy test to assess pregnancy as a potential precipitating factor and to recognize potential danger to the fetus
- Acetaminophen level, as it is highly hepatotoxic and is used frequently by teenagers
- EKG is indicated for many pharmacologic ingestions, including antidepressants and benzodiazepines.

Imaging

Abdominal plain film: If history of iron or vitamin ingestion, or severe trauma

DIFFERENTIAL DIAGNOSIS

- CNS trauma: Any insult to the cerebral cortex can result in disinhibitory behaviors.
- Psychiatric disorders, with particular attention to depression, personality disorder, and substance abuse
- Psychosocial trauma or maladjustment:
 - Emotional or physical abuse, with the suicide attempt being a way to gain attention, obtain help, or to serve as a means of escape
 - Feelings of isolation or abandonment, such as following the revelation of pregnancy or homosexuality

**TREATMENT****MEDICATION (DRUGS)**

- For recent ingestions, GI decontamination with activated charcoal may be appropriate, as is the administration of pertinent antidotes (e.g., naloxone for opioids, N-acetylcysteine for acetaminophen).
- Although psychotherapy is an essential component to the care of the suicidal adolescent, pharmacotherapy with antidepressants can also play a role, especially given the high association with comorbid mood disorders.
 - Keep in mind when prescribing tricyclic antidepressants (TCAs) their high lethality potential. TCAs are typically not indicated in treating depression in children and adolescents.
 - Several SSRIs (fluoxetine, sertraline, and citalopram) have been shown to be effective in treating depressive disorders in adolescents. Use of SSRIs in patients with the potential for suicidal behavior requires close monitoring. In general, SSRIs may cause an increase from 1% to 2% in the risk of suicidality in depressed teens.

ADDITIONAL TREATMENT**General Measures**

- Parents and professionals should avoid minimizing attempts as “not serious” or as “just seeking attention.”
- Psychiatric disposition should be determined by, or in conjunction with, a mental health professional. Considerations for admission include the following:
 - Historical factors indicating high risk for repeated attempt
 - Ongoing suicidal ideation and/or planning
 - Family instability and lack of support
 - Altered mental status
 - Lack of alternative interventions (e.g., intensive psychiatric follow-up, day treatment program)
 - Medication initiation that has risk for increasing suicidal thoughts, e.g., SSRIs
- When discharge to a caregiver is being considered, the following minimal criteria should be in place at the time of discharge:
 - The patient reliably expresses regret and denies ongoing suicidal thoughts.
 - The patient is medically stable.
 - The patient’s family is involved and reports understanding of the seriousness of the attempt.
 - The patient and parents agree to contact a health professional or go to the emergency department if suicidal intent recurs. The patient and family must have 24-hour access to mental health or physical health professionals.

- The patient must not have impaired mental status (e.g., severely depressed, psychoses, delirium, intoxication).
- Lethal methods of self-harm are not immediately available to the patient.
- Follow-up and treatment of underlying mental health disorders have been arranged. This ideally involves much more than providing a phone number to psychiatric services or asking the family to contact their insurer.
- Acute precipitants and crises have been addressed.
- Caregivers and patients are in agreement with the discharge plan.
- Barriers to obtaining follow-up treatment, in particular insurance and fear of stigma, have been addressed and will not preclude the next step toward ongoing treatment.

Additional Therapies

In addition to medication, important psychiatric interventions include acute, short-term, inpatient psychiatric hospitalization, partial hospitalization (with intensive treatment and support), and outpatient therapy.

IN-PATIENT CONSIDERATIONS**Initial Stabilization**

- Circulation, airway, breathing (CABs)
- Monitoring of behavior and vital signs if history of ingestion. One-to-one monitoring is typically indicated until formal mental health evaluation is obtained.
- Decontamination of GI tract and circulation as indicated
- When available, a Poison Control Center may be helpful with evaluation and treatment of most drug ingestions.
- Ongoing safety is of primary concern: Provide immediate physical protection (remove all weapons) and enforce around-the-clock observation.

**ONGOING CARE****FOLLOW-UP RECOMMENDATIONS**

Long-term psychotherapy (individual and family therapy) is often needed for adolescents who attempt suicide. Improvement may be slow and punctuated by frequent setbacks.

PROGNOSIS

- 20–50% of those attempting suicide will try again.
- Psychiatric hospitalization has not been shown to decrease risk of attempted suicide in patients with a history of mood disorder or substance abuse.
- Multiple reports show that a majority of adolescents who attempt suicide disengage with treatment after a few visits.

COMPLICATIONS

- Long-term organ damage or physical disability, depending on the method used
- Long-lasting emotional scars in families of victims, resulting from frustration, anger, and guilt
- Repeat suicide attempt or completion

**CODES****ICD9**

- 300.9 Unspecified nonpsychotic mental disorder
- V62.84 Suicidal ideation

ICD10

- R45.851 Suicidal ideations
- T14.91 Suicide attempt
- Z91.5 Personal history of self-harm

FAQ

- Q: Should I ever keep suicide attempts or plans confidential?
- A: No. The limits of confidentiality should be clearly outlined to patients and families at the first visit or early in the patient’s adolescence. These limits include anything that will directly place the patient’s life in danger, such as suicidal intent, ongoing or recent abuse, or homicidal intentions.
- Q: If I directly question my patients about suicide, won’t that put the idea in their head?
- A: No. In the majority of cases, patients will be relieved by having a professional who wants to talk about suicide. There is only risk in asking if nothing is done with the answer. Appropriate referral to mental health services or counseling will save patients’ lives.
- Q: Is a patient who is engaging in self-injurious behavior but denies suicidal ideation actually suicidal?
- A: Certainly any adolescent who is practicing self-mutilation to cope with emotional distress is at risk of developing additional unhealthy coping behaviors. Furthermore, they are likely suffering from a mood disorder that places them at risk for developing suicidality. There is no evidence to support management of self-injurious behavior as if the patient has a secret agenda.

SUPERIOR MESENTERIC ARTERY SYNDROME

Henry Lin

Tracie Wong

Vera de Matos (5th edition)

BASICS

DESCRIPTION

Superior mesenteric artery (SMA) syndrome is extrinsic obstruction of the distal duodenum by the superior mesenteric artery or its branches; it is also called Wilkie syndrome, cast syndrome, or aortomesenteric duodenal compression syndrome.

EPIDEMIOLOGY

Incidence

- Rare, incidence in general population between 0.013% and 0.3% (based on GI barium series)
- More common in adolescents and following corrective scoliosis surgery
 - Increased incidence rate following scoliosis surgery of 0.5–2.4%

ETIOLOGY

- The superior mesenteric artery arises from the aorta at the L1 vertebral body level and forms an acute downward aortomesenteric angle that is normally between 25–60°.
- The third portion of the duodenum lies within the aortomesenteric angle and narrowing of the angle (6–25°) can lead to duodenal compression by the SMA anteriorly and the vertebra posteriorly.
- Any factor that narrows the aortomesenteric angle can cause duodenal compression. Common conditions that predispose to narrowing of this angle are:
 - Illnesses associated with significant weight loss leading to loss of the mesenteric fat pad
 - Anorexia nervosa, malignancy, spinal cord injury, trauma or burns
 - Rapid linear growth in children
 - Increase in lordosis of the back, such as from immobilization by body cast, scoliosis surgery, or prolonged bed rest in a supine position
 - Weight percentile for height of <5% is a risk factor for development of SMA syndrome following scoliosis surgery.
 - Variations of the ligament of Treitz: A short ligament lifts the third or fourth part of the duodenum into the narrower segment in the aortomesenteric angle.

DIAGNOSIS

HISTORY

- Clinical presentation can be acute or chronic with gradual, progressive symptoms.
- Symptoms are generally consistent with proximal small bowel obstruction, including the following:
 - Nausea, vomiting (bilious and nonbilious), postprandial nausea and vomiting, epigastric abdominal pain, eructation, weight loss, early satiety, dehydration, bloating, failure to thrive

PHYSICAL EXAM

- Nonspecific findings of small bowel obstruction include the following:
 - Abdominal distension
 - Succussion splash
 - High-pitched bowel sounds
- No pathognomonic signs or symptoms, but a history of weight loss, immobilization, or back surgery followed by symptoms of early satiety, bloating, and vomiting after meals would suggest the diagnosis.

Imaging

- Imaging should show duodenal obstruction with dilated stomach and proximal duodenum, active peristalsis, and a narrow angle between the aorta and the SMA.
- Abdominal radiograph is usually the initial diagnostic imaging test.
 - Findings can be nonspecific, but may also reveal suggestive findings of obstruction including a distended stomach or a dilated proximal duodenum with a sharp cutoff of the third portion of the duodenum where the SMA crosses the duodenum
- Additional evaluation with upper gastrointestinal series.
 - Passage of contrast is typically delayed and often stops at the third portion of the duodenum. Contrast passes when the patient is moved to a prone position, where gravity will increase the aortomesenteric angle
 - Similar findings can be seen with CT

- Additional imaging may be required if the diagnosis remains unclear.
 - Superior mesenteric arteriography with simultaneous barium contrast radiography to show SMA superimposed on duodenum.
 - CT and MR angiography have now replaced superior mesenteric arteriography.
- Determination of the aortomesenteric angle in severe cases may help with decision for surgery.

DIFFERENTIAL DIAGNOSIS

- Causes of small bowel obstruction
 - Luminal obstruction: Foreign body
 - Intramural obstruction: Duplication cyst, web, tumor, bezoar, stricture
 - Extramural obstruction: Tumor, annular pancreas, bands, adhesions, volvulus, intussusception
- Duodenal dysmotility
 - Intrinsic neuronal disorder, muscular weakness (holovisceral myopathy, diabetes), fibrosis (scleroderma, lupus retroperitoneal fibrosis), collagen vascular diseases, chronic idiopathic intestinal pseudo-obstruction
- Anorexia nervosa/bulimia

TREATMENT

General Measures

- Correct fluid and electrolyte imbalances
- Decompress obstruction
 - Insert nasogastric tube to decompress stomach and proximal duodenum
- Feed to improve nutrition and weight gain
 - Feeding in a prone position may help, but may require a jejunal tube to bypass the obstruction
 - Decreasing viscosity of feedings has a theoretical advantage

- If a patient had recent spinal surgery:
 - Frequent repositioning of patients in body casts
 - Reversal of back surgery may be necessary in some patients
- Surgery is typically unnecessary and only indicated if supportive care is ineffective. Usually performed in patients with a prolonged history of weight loss or pronounced duodenal dilation
 - Surgery options include duodenojejunostomy, Roux-en-Y duodenojejunostomy, gastrojejunostomy, and anterior transposition of the third part of the duodenum.
- Definitive treatment is aimed at correcting the precipitating factor.

 **ONGOING CARE**
PROGNOSIS

- Delay in diagnosis of SMA syndrome can result in electrolyte disturbances, dehydration and malnutrition, and in severe cases, possible intestinal perforation or death.
- Most patients do not require surgery and improve with supportive care alone.

ICD10
K55.1 Chronic vascular disorders of intestine

FAQ

- Q: When the diagnosis of superior mesenteric artery syndrome is suspected, what are the next steps in management?
- A: The logical sequence is to confirm the diagnosis with an imaging study such as an upper GI contrast study and also to initiate supportive care of refeeding and mobilization.
- Q: The following treatment modalities are known to be useful in treatment of superior mesenteric artery syndrome: Do nothing, or feed with a jejunal tube, a liquid diet, prone feeding, or total parenteral nutrition. Which program works?
- A: All of the above have been used in superior mesenteric artery syndrome. Weight gain has also been accomplished with total parenteral nutrition.
- Q: Does radiographic testing or a feeding clinical trial help in confirming the diagnosis?
- A: Yes, it may be helpful to confirm the diagnosis and look at the aortomesenteric angle with a CT or MR angiography. In addition, a clinical trial of feeding and weight gain often becomes the criterion for confirmation of the diagnosis.

SUPRAVENTRICULAR TACHYCARDIA

Francesca Byrne

Jonathan R. Kaltman (5th edition)

BASICS

DESCRIPTION

- Supraventricular tachycardia (SVT) is a tachycardia originating at or above the atrioventricular (AV) node. The heart rate in infants generally ranges from 220–320 beats per minute (bpm) and in older children from 150–250 bpm.
- Most infants and children with SVT have structurally normal hearts.
- Of patients who present in infancy, 40–70% will be asymptomatic by 1 year of age. However, ~1/3 of these patients may experience a reappearance of their tachycardia at an average age of 8 years. Most older children who present with SVT will have persistent recurrence of their tachycardia.

EPIDEMIOLOGY

- SVT is the most common arrhythmia in childhood.
- 50–60% of pediatric patients present in the 1st year of life.

RISK FACTORS

Genetics

- Wolff-Parkinson-White (WPW) syndrome has been noted in several families, and an autosomal dominant mode of inheritance has been demonstrated:
 - ~20% of cases of WPW have associated congenital heart disease, with Ebstein anomaly, L-looped transposition of the great arteries, and hypertrophic cardiomyopathy being the most common.
- ~50% of the cases of junctional ectopic tachycardia occur in a familial setting with an autosomal dominant mode of inheritance.

PATHOPHYSIOLOGY

There are 2 major mechanisms for SVT:

- Re-entry tachycardia: This is the most common mechanism for SVT. It involves a circuit rhythm within the atria (atrial flutter), within the AV node (AV nodal re-entry tachycardia), or using an accessory pathway (AV re-entrant tachycardia). Re-entrant tachycardias are characterized by sudden onset and termination, regular rate, and responsiveness to pacing maneuvers and direct current cardioversion.
- Automatic tachycardia: Automaticity refers to a cell's or group of cell's enhanced ability to spontaneously depolarize, which can override suppress the sinus node. Examples are ectopic atrial tachycardia, multifocal atrial tachycardia, and junctional ectopic tachycardia. Automatic tachycardias are characterized by warm-up and cool-down phases, an irregular rate that is sensitive to the body's catecholamine state, and lack of responsiveness to pacing and cardioversion.

ETIOLOGY

SVT can frequently be precipitated by exercise, infection, fever, or drug exposure (e.g., cold medications).

COMMONLY ASSOCIATED CONDITIONS

- SVT is commonly observed in patients who have undergone surgery for congenital heart disease.
- SVT is frequently observed after the Mustard/Senning procedure, the Fontan operation, and repair of an atrial septal defect.

DIAGNOSIS

HISTORY

- Infants will manifest signs and symptoms of low cardiac output if the tachycardia has gone unnoticed for a prolonged period: Findings may include tachypnea, retractions, irritability, decreased feeding, excessive sweating, hypotension, poor perfusion, and decreased urine output. Most infants with tachycardia for >48 hours present with evidence of congestive heart failure.
- The toddler and older child may experience palpitations, shortness of breath, chest pain, and dizziness or syncope:
 - It is important to know what the child was doing at the time the arrhythmia started and whether the rhythm had an abrupt onset and termination.
 - Older children often report being able to terminate episodes of tachycardia by performing a vagal maneuver (e.g., Valsalva, gagging, or standing on their head).

PHYSICAL EXAM

The following need to be assessed in all patients presenting with SVT:

- Heart rate
- Respiratory rate
- BP
- Hydration status
- Peripheral perfusion
- Liver size
- Mental status
- Presence of gallop rhythm on auscultation

DIAGNOSTIC TESTS & INTERPRETATION

Imaging

A chest radiograph may reveal cardiomegaly if there is CHF or underlying structural heart disease.

Diagnostic Procedures/Other

- Diagnosis is made by recording an electrocardiogram during the arrhythmia. This can be accomplished with a 12-lead electrocardiogram, 24-hour Holter recording, or transtelephonic event monitor.
- Patients with WPW syndrome have diagnostic ventricular pre-excitation (short PR interval and a delta wave) on the surface electrocardiogram during sinus rhythm.
- An exercise stress test and/or electrophysiologic testing may be indicated in older patients with WPW syndrome to help determine the risk of rapid conduction through the accessory pathway.
- Nonpharmacologic maneuvers (ice, vagal) and pharmacologic maneuvers (e.g., IV adenosine, 50–300 mcg/kg/dose) may distinguish tachycardias that involve the AV node from other types of SVT.

DIFFERENTIAL DIAGNOSIS

- Narrow-complex SVT needs to be distinguished from sinus or junctional tachycardia and sick-sinus syndrome with tachyarrhythmia.
- Structural heart disease should be excluded in all cases of newly diagnosed SVT.
- Wide-complex tachycardia from either aberrantly conducted SVT or SVT with antegrade conduction down an accessory pathway can be seen in a small percentage of patients and may be difficult to distinguish from ventricular tachycardia. Generally, unless there are preexisting data that the patient has SVT, wide-complex tachycardia should always be interpreted as ventricular tachycardia until proven otherwise.
- Differentiating between types of SVT (re-entrant vs. automatic) can be accomplished by evaluating the regularity of the rate, modes of onset and termination, and the tachycardia's responsiveness to pacing and cardioversion.

TREATMENT

ADDITIONAL TREATMENT

General Measures

- Re-entrant SVT:
 - In a stable child, adenosine (IV rapid bolus, 0.1 mg/kg and may increase by 0.1 mg/kg to a maximum of 0.3 mg/kg) 50–300 mcg/kg) may be used to block the AV node and achieve pharmacologic cardioversion for re-entrant SVT that requires the AV node as part of the circuit. The half-life of the drug is < 10 seconds. Because of the risk of atrial fibrillation, DC cardioversion should be available for back-up. Use adenosine with caution in patients with asthma as it can cause acute bronchospasm.

- Verapamil should be avoided for acute treatment of SVT in children <12 months of age because of its vasodilating and negative inotropic effect.
- Nonpharmacologic vagal maneuvers, including ice to the face without obstructing respiration, Valsalva, gag, and headstand, may be helpful. In younger children, Valsalva can be achieved by having the child blow into an obstructed straw or thumb. Pacing maneuvers via an esophageal catheter may also be used.
- Oral digoxin is an option in patients with hemodynamically stable SVT needing chronic therapy. Digoxin, however, is contraindicated in patients with WPW because it may potentiate faster conduction down the accessory pathway, making ventricular fibrillation more likely in some patients.
- β -Blockers (propranolol or nadolol) are the treatment of choice in individuals with WPW. Procainamide and amiodarone may be used in cases that are more resistant. β -Blockers are usually given to patients with exercise-induced SVT.
- Atrial flutter may be treated with digoxin, procainamide, sotalol, or amiodarone as a single agent or in combination.
- Catheter ablation using radiofrequency energy or cryoenergy is an alternative to long-term drug therapy and may be used for the following reasons:
 - SVT refractory to medical therapy
 - Side effects from the medical regimen
 - Patient choice
 - Life-threatening arrhythmias
 - Rapid conduction properties of an accessory pathway (e.g., WPW)
 - Concomitant congenital or acquired heart disease
- Automatic SVT: Automatic tachycardias may be responsive to antiarrhythmics such as procainamide, flecainide (should generally be avoided if the patient has structural heart disease), amiodarone, or β -blockers either alone or in different combinations. Ectopic atrial tachycardia and junctional ectopic tachycardia are also amenable to catheter ablation.

IN-PATIENT CONSIDERATIONS

Initial Stabilization

- Always assess the child’s ABCs (airway, breathing, and circulation).
- Initial management of SVT depends on the child’s hemodynamic condition.
- Presentation with cardiovascular collapse warrants treatment with synchronized DC cardioversion (0.5–2.0 J/kg).

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- As SVT may recur, neonates and infants generally should receive maintenance therapy for the 1st year of life and then be observed off medications if they are not having breakthrough episodes of SVT.
- Patients with recurrences in the 1st year of life or those requiring multiple medications may ultimately have their medications discontinued if they have a prolonged period of time without episodes.
- In children who present beyond infancy, spontaneous resolution of the tachycardia substrate is less likely, and treatment may need to be continued into adulthood. These patients may be considered for catheter ablation therapy.
- Over-the-counter sympathomimetic cold medications and caffeine should be avoided, as they may increase the likelihood of SVT

COMPLICATIONS

Complications from SVT can arise from 1 of 3 causes:

- Persistent tachycardia can lead to CHF and cardiovascular collapse. This is especially true of the infant whose symptoms go unrecognized for 24–48 hours.
- Some patients with WPW syndrome (<5%) can have rapid conduction through the accessory pathway. A rapid ventricular response to atrial flutter/fibrillation can potentially cause ventricular fibrillation and sudden death. Patients with WPW syndrome who receive digoxin and/or verapamil are at increased risk.
- Side effects of pharmacologic agents used to treat SVT include bradycardia, other arrhythmias due to proarrhythmic effects (digoxin, procainamide, amiodarone, flecainide), and noncardiac side effects (GI, liver, pulmonary, and thyroid dysfunction).

- I47.1 Supraventricular tachycardia

FAQ

- Q: How should infants on chronic therapy be monitored?
- A: Parents with infants on chronic therapy for SVT should be educated about counting the heart rate by palpation or auscultation at least 1 or 2 times daily. This method of surveillance is just as effective as apnea/bradycardia monitors. Because alarm monitors can increase parental anxiety with frequent false alarms, they are generally not recommended.
- Q: What is the concern with verapamil?
- A: Verapamil is an L-type calcium channel blocker that blocks conduction in the AV node and is very effective in treating SVT in adults. Because myocardial contractility in infants depends mostly on the trans-sarcolemmal L-type calcium channels, hypotension and cardiovascular collapse have been reported in children <1 year of age.
- Q: What are the indications, success rates, and risks of catheter ablation?
- A: Refractory arrhythmias, the need for multiple medications, undesirable side effects from the medications, life-threatening events (syncope, cardiac arrest), wide-complex tachycardia (cannot differentiate SVT from VT), and elective ablation are some of the indications. The success rate of radiofrequency catheter ablation varies from 80–97%, depending on the location of the bypass tract or ectopic focus. The incidence of major complications is <2%, with the most common being heart block requiring a pacemaker, cardiac perforation, brachial plexus injury, and embolization. The risk of complete heart block is greater in patients whose accessory pathway is located close to the AV node. In such patients, cryoablation is a safer ablation technique because of its potentially reversible electrical and thermal effects.

SYMPATHOMIMETIC POISONING

Robert J. Hoffman

Doug Finefrock

Yuki Yasaka (5th edition)

BASICS

DESCRIPTION

- Excess autonomic stimulation by adrenergic agents produces the clinical syndrome typically described as “sympathomimetic.”
- Overdose from sympathomimetic agents occurs secondary to the use of prescription drugs, nonprescription drugs such as OTC cold medicine (e.g., pseudoephedrine), dietary supplements (e.g., ephedra, synephrine) and illicit drugs such as cocaine, amphetamine, and methamphetamine.
- The sequelae of sympathomimetic overdose are generally related to the neurological and cardiovascular systems.
- Severe problems may include agitation-induced hyperthermia, cardiac dysrhythmia, hypertension, myocardial ischemia and infarction; CVA; seizure; and cardiovascular collapse.

EPIDEMIOLOGY

- Cocaine, methamphetamine, and MDMA (ecstasy) are the 3 most common illicit stimulant drugs causing emergency visits in the US.
- Prescription stimulants such as methylphenidate and albuterol are often are frequent causes of intentional as well as unintentional poisoning.

RISK FACTORS

- Prescription sympathomimetics, such as methylphenidate, pose some risk factor for both the recipient of the prescription as well as siblings.
- Adolescents are at increased risk for using drugs of abuse.

PATHOPHYSIOLOGY

- Relevant pathophysiology is based on the adrenergic receptor type stimulated by the drug in question. The adrenergic receptors of relevance include $\alpha 1$, $\beta 1$, and $\beta 2$ receptors.
- Ephedrine and pseudoephedrine stimulate both α and β receptors:
 - Excessive cardiovascular stimulation results in symptoms qualitatively similar to those that occur with catecholamines.
 - Ephedrine and pseudoephedrine have weaker penetration of the CNS relative to drugs of abuse.
 - As a result, users may suffer from systemic complications of the relatively larger doses necessary to achieve the CNS “high” of other stimulants.
- Nonelective β -adrenergic agonists
- Isoproterenol, rarely used, is the prototypical nonselective β -agonist causing the following:
 - Tachycardia, hypotension, tachydysrhythmia, myocardial ischemia and flushing due to its cardiostimulatory and vasodilatory properties
 - Commonly CNS effects of anxiety, fear, and headache occur.

- Selective $\beta 2$ adrenergic agonists are commonly used, and these include albuterol, levalbuterol, salmeterol, terbutaline, and others.
- Common adverse effects include the following:
 - Tachycardia, palpitations, and tremor
 - Hypotension, often with widened pulse pressure
 - Nausea, vomiting, and sometimes diarrhea
 - Hyperglycemia and hypokalemia
 - Elevation of CPK as well as troponin, though myocardial infarction is never expected to occur in otherwise healthy children with selective $\beta 2$ agonist exposure.
 - Anxiety, fear, and headache also may occur.
- $\alpha 1$ selective agonists include phenylephrine and phenylpropranolamine, though the latter is no longer commercially produced in any meaningful quantity in the US.
 - Hypertension due to direct vasoconstrictive effects is the most common effect.
 - Reflex bradycardia may occur, particularly with phenylpropranolamine.
 - Headache due to elevated BP and even CVA may occur.

ETIOLOGY

Causative agents:

- Agents with combined α - and β -adrenergic activity: Epinephrine, norepinephrine, dopamine, ephedrine, and pseudoephedrine
- $\alpha 1$ adrenergic agonists: Phenylephrine, phenylpropranolamine
- β -adrenergic agonists: Nonselective β -agonist isoproterenol
- Selective $\beta 1$ agonists: Dobutamine
- Selective $\beta 2$ agonists: Albuterol, salmeterol, terbutaline, ritodrine
- OTC agents: Ephedrine-containing cold medicine, ephedra, Ma Huang
- Illicit drugs: Cocaine, amphetamine, methamphetamine, MDMA (ecstasy)
- Theophylline and caffeine may cause a clinical syndrome of sympathomimetic poisoning.

COMMONLY ASSOCIATED CONDITIONS

- Many sympathomimetic agents are capable of producing psychiatric symptoms, particularly psychosis.
- This psychosis is similar to or indistinguishable from schizophrenia.
- 2 rare results of MDMA use include serotonin syndrome and SIADH with symptomatic hyponatremia.

DIAGNOSIS

SIGNS AND SYMPTOMS

- The clinical effects of these agents' overdose vary based on their receptor selectivity.
- Most agents have some degree of combined α - and β -adrenergic activity (ephedrine, pseudoephedrine).
 - Hypertension, tachycardia, dysrhythmia, acute coronary syndromes, pulmonary edema and cerebrovascular injury, anxiety, a sense of impending doom, apprehension, fear, and headache may occur.
 - At very high doses, agents cross the blood-brain barrier, which results in central nervous system symptoms, such as headache, seizures, and intracranial hemorrhage.

HISTORY

- History of exposure may be helpful, but is often unavailable or deliberately concealed, particularly use of illicit drugs such as cocaine, methamphetamine, and ecstasy.
- The use of OTC medicines, such as multisymptom cold preparations or dietary supplements may be obtained.
- High suspicion of sympathomimetic overdose especially in patients with the sympathomimetic toxidrome.
- The onset of symptoms usually occurs within 1 hour.
 - Typically, prescription and OTC sympathomimetic agents are inhaled or orally administered.
 - Inhalation or injection results in immediate symptoms.
 - Cocaine, amphetamine, and methamphetamine or the sympathomimetics most commonly used in this manner.
 - Sympathomimetic toxicity following ingestion typically peaks 1–4 hours and last 4–8 hours, but sustained-release preparations may alter this time course.

PHYSICAL EXAM

Sympathomimetic toxicity is a clinical diagnosis.

- Vital sign derangement is the most common and most reliable indicator of toxicity.
- Mental status changes are also common though less reliable as they do not occur with the same regularity and may be the result of toxicologic or psychiatric phenomenon.
- The patient's general appearance (e.g., agitation, diaphoretic, delirium, psychotic) is often suggestive of toxicity.
- HEENT: Headache, mydriasis, visual changes, epistaxis

- Chest: Chest pain due to dysrhythmia, myocardial ischemia, myocardial infarction, etc. may be a complaint.
- Tachycardia and hypertension are the most common vital sign abnormalities.
- Skin: Diaphoresis, flushing, the track marks associated with IV drug use.
- CNS: Focal neurologic findings may occur. Focal cranial nerve abnormalities are particularly concerning for the possibility of cerebrovascular accident. CNS stimulation or agitation is very common.

DIAGNOSTIC TESTS & INTERPRETATION

- Sympathomimetic overdose is a clinical diagnosis and assays are only adjunctive.
- Unless there are specific forensic indications, such as malicious poisoning or child abuse, drug of abuse screening is not recommended and is not useful.
- Serum acetaminophen level should be considered in patients with ingestion with intent of self harm.
- The measurement of electrolytes, BUN, creatinine, and blood sugar may be useful.
- Cardiac markers (e.g., CPK-MB, troponin) are appropriate to screen for cardiac injury.
- An EKG should be obtained to assess for ischemia as well as dysrhythmias

Imaging

A noncontrast head CT should be obtained in unresponsive patients or those with focal neurologic deficits.

DIFFERENTIAL DIAGNOSIS

- Hyperthyroidism/Thyroid storm
- Anticholinergic syndrome
- Pheochromocytoma
- Withdrawal syndromes
- Mania
- Subarachnoid hemorrhage
- Serotonin syndrome
- Neuroleptic malignant syndrome
- Other situations of increased endogenous catecholamine release

TREATMENT

INITIAL STABILIZATION

Managing ABCs should be addressed first, but sympathomimetic toxicity usually does not result in illness requiring any specific airway, breathing, or circulation issues.

General Measures

Maintaining vital signs within acceptable limits and controlling patient agitation are commonly required.

- Managing ABCs is paramount.
- If protocol permits, sedation of agitated patients with a benzodiazepine may be appropriate.
- Use of benzodiazepines is helpful to address both cardiovascular stimulation as well as psychomotor agitation.
- Use of specific cardiovascular medications may be needed.
- Use of antipsychotics, such as haloperidol or droperidol, is relatively contraindicated both because these medications may lower seizure threshold, impair heat dissipation, and increase risk of cardiac dysrhythmia.

SPECIAL THERAPY

- Severe hyperthermia should be treated with active cooling.

- Patients with core temperature of $\geq 107^\circ\text{F}$ should be placed in an ice bath and have core temperature monitored.

IV Fluids

- Unless there is a contraindication, at least maintenance IV fluid should be administered.
- This may serve to protect against rhabdomyolysis as well as potential dehydration that may occur with stimulant exposure.

MEDICATION (DRUGS)

Agitation, vasoconstrictive effects, chronotropic and inotropic effects, and psychomotor agitation are the most common issues requiring medication therapy for sympathomimetic toxicity.

First Line

- Psychomotor agitation may be managed with benzodiazepines.
- The quantity of benzodiazepine required will directly depend on degree of adrenergic stimulation.
- In some cases, large doses may be required for sedation.
 - Lorazepam in doses of 0.1 mg/kg IV q15min titrated to effect is preferred due to predictable duration of action.
 - Diazepam 0.1 mg/kg IV q15min titrated to effect may also be used.
- Vasoconstrictive effects may be managed with a variety of medications.
 - Phentolamine 0.1 mg/kg/dose (up to 5 mg/dose) IV repeated q10min PRN
 - A dihydropyridine calcium channel blocker, such as nifedipine or amlodipine, may be used.
 - Sodium nitroprusside 0.3–10 mcg/kg/min IV, titrated to effect
- Chronotropic and inotropic effects may be managed with conduction-modulating calcium channel blockers such as diltiazem or verapamil.

Second Line

- A β -blocker may be used only if an α -adrenergic antagonist is concomitantly administered.
- Use of a β -blocker without α -adrenergic blockade may result in paradoxical increase in BP and death.
 - Labetalol has some α -adrenergic blockade and may be used alone as a second-line agent: 0.2–0.5 mg/kg/dose IV, maximal dose 20 mg, followed by infusion of 0.25–1 mg/kg/h
 - Esmolol: 500 mcg/kg/min IV bolus followed by infusion 50 mcg/kg/min titrated to effect up to 500 mcg/kg/min
- Severe cardiovascular symptoms resulting from β -agonists or methylxanthines such as theophylline or caffeine may be treated with a β -blocker.
 - This treatment may seem counter-intuitive in the management of hypotension.
 - Severe β_2 agonist effects resulting in hypotension may be counteracted by using a β -blocker.
 - Such therapy should only be undertaken under the direction of a medical toxicologist, intensivist, or other clinician familiar with and experienced with use of such cardiovascular medications.

ONGOING CARE

DISPOSITION

Admission Criteria

Any patient with severely deranged vital signs, end-organ manifestations such as chest pain, severe headache, focal neurologic deficit, or agitation should be admitted.

Discharge Criteria

Any patient with vital signs within safe limits, normal mental status, and no evidence of end-organ damage or manifestations may be discharged from the emergency department or inpatient unit.

PROGNOSIS

If end-organ damage such as myocardial infarction or CVA are prevented, prognosis for full recovery to pre-morbid status is excellent.

COMPLICATIONS

The most common catastrophic complications are cardiovascular, including dysrhythmia, myocardial infarction, and CVA.

SYNCOPE

Nancy Drucker

BASICS

DEFINITION

Loss of consciousness, typically lasting no longer than 1–2 minutes, due to a transient drop in cerebral perfusion pressure

GENERAL PREVENTION

- Avoiding circumstances predisposing to the most common form of syncope (vasovagal)
- Sitting or lying down when warning signs occur
- Maintaining adequate hydration, especially during illness/exertion

PATHOPHYSIOLOGY

Most common mechanism is vasovagal or neurocardiogenic, in which a variety of stimuli and conditions—pain, dehydrated state, emotional upset, carotid pressure—trigger increased vagal tone, leading to slowed heart rate and peripheral vasodilatation and decreased cerebral perfusion.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- **Cardiac**
 - Congenital heart defect, myocarditis, cardiomyopathy, coronary artery anomaly, heart block (congenital or acquired complete heart block, status post cardiac surgery), arrhythmia secondary to Long QT syndrome, Brugada syndrome, arrhythmogenic right ventricular dysplasia, catecholaminergic polymorphic ventricular tachycardia, Wolff–Parkinson–White. Syncope due to an arrhythmia may be familial, may occur as unprovoked syncope, or as exercise-induced syncope that may resemble an epileptic convulsion.
- **Neurologic**
 - Migraines (predisposed to orthostatic intolerance), arteriovenous malformation; pulmonary hypertension; intracranial hypertension due to hydrocephalus, mass, pseudotumor

- **Pulmonary**
 - Pulmonary hypertension
- **Other**
 - Medications/toxins
- Other causes of syncope by age group include the following:
 - Toddlers:
 - Pallid or cyanotic breath-holding spells; these occur in response to pain, fear, excitement, or frustration, begin with a deep inspiration or exhalation, although the precipitating “gasp” may not be apparent (anemia may be associated).
 - Older children:
 - Adrenal insufficiency
 - Dysautonomia, orthostatic hypotension
 - Dehydration
- Syncopal spells in children may be accompanied by a convulsion (nonepileptic) that usually lasts < 1 minute (EEG shows normal findings).
- Alternative causes of loss of consciousness not due to syncope include:
 - Head trauma
 - Epilepsy (“temporal lobe syncope”)
 - Psychogenic
 - Stroke
 - Hypoglycemia (rare except in certain metabolic disorders)

HISTORY

- **Question:** Detailed history of the spell (focus on signs/symptoms prior to the event)?
- **Significance:** Most important information used to distinguish syncope from seizure or head trauma
- **Question:** The child or observers may recall “presyncopal” signs?
- **Significance:** Often present in patients with benign syncope—such as warmth, diaphoresis, light-headedness, nausea, palpitations, auditory or visual changes—all lasting only a few seconds before loss of consciousness

- **Question:** Family history?
- **Significance:** Obtaining a careful history is essential. Family history of sudden unexpected death, seizures, syncope, cardiomyopathy, or arrhythmias especially at younger ages or requiring pacemaker/implantable defibrillator should trigger further testing and investigation.
- **Question:** Syncope during exercise or without warning?
- **Significance:** May indicate an underlying arrhythmia
- **Question:** Generalized tonic–clonic movements?
- **Significance:** May occur with syncope—presyncopal signs point to the nonepileptic nature of the event
- **Question:** Increasing duration of unconsciousness?
- **Significance:** Suggests increasing probability that the event is epileptic, rather than syncope
 - Caution: Syncope may be associated with a convulsion in an epileptic patient.
 - Epilepsy may rarely mimic a syncopal episode or recurrent presyncopal symptoms; “temporal lobe syncope” seems to occur principally in adults or adolescents.
- **Question:** Details of body position, eye movements, and respiratory pattern?
- **Significance:** May help determine etiology
- **Question:** Carbon monoxide poisoning?
- **Significance:** May cause syncope-like spells; ask about potential exposure

PHYSICAL EXAM

Key findings to document include the following:

- Vital signs with orthostatic pulse and BP changes
- Right and left arm BPs
- Funduscopy: Possible papilledema
- Cranial bruits
- Precordial thrill
- Heart sounds (gallop, click, rub, significant murmur)

DIAGNOSTIC TESTS & INTERPRETATION

Often only a thorough physical exam, detailed history, and family history are needed if findings are consistent with vasovagal syncope.

- **Test:** EKG* and cardiac consultation
- **Significance:** If the event is suspected to be symptomatic of a heart condition or there is a concerning history/family history, an EKG* and cardiac consultation may be indicated.
- **Test:** Treadmill electrocardiogram, Holter monitoring, echocardiogram, EEG, MRI (Chiari malformation)
- **Significance:** Children with unexplained syncope may undergo more extensive testing.
- **Test:** Glucose, CBC, blood gases, spinal tap
- **Significance:** Laboratory testing may be appropriate based on clinical suspicion of underlying causes.

ALERT

Pitfall: Recurrent syncope due to prolonged QT interval may be missed on routine EKG; prolongation of QT interval may only be noted on treadmill testing or cardiac monitoring.

TREATMENT

ADDITIONAL TREATMENT

General Measures

- Clinical intervention is aimed primarily at training the patient in prevention/anticipation:
 - Avoiding circumstances predisposing to the most common form of syncope (vasovagal)
 - Sitting or lying down when warning signs occur
 - Maintaining adequate hydration, especially during illness/exertion
- Therapy is otherwise addressed to underlying causes, in the unusual circumstance that one is found.
- Syncope during exercise always warrants a cardiovascular evaluation, with EKG as initial step.

ONGOING CARE

- Many children experience a developmental stage in which for unknown reasons they have frequent vasovagal episodes; they may retain a tendency to syncopal spells through adulthood.
- Persistent and frequent spells may prompt more extensive laboratory testing, as described above.

FAQ

- Q: Do breath-holding spells cause brain damage?
- A: Pallid breath-holding spells appear to be uniformly benign; in rare cases, older children with cyanotic breath-holding spells have had neurologic sequelae of recurrent hypoxemia.
- Q: What limitations in activity are appropriate for children with recurrent syncope who have normal heart structure and function?
- A: Precautions should be taken similar to those for children of similar age who have epilepsy—closely monitored water recreation and restrictions on climbing; however, most children with recurrent syncope do not experience spells in the midst of vigorous activity.

SYNOVITIS—TRANSIENT

David D. Sherry

BASICS

DESCRIPTION

Transient inflammatory process resulting in arthralgia and arthritis (especially affecting the hip) and occasionally rash precipitated by an exposure to an infectious agent

EPIDEMIOLOGY

Any age at risk, common in ages 3–10 years, with males affected 1.5 times more commonly

RISK FACTORS

Genetics

No specific associations

PATHOPHYSIOLOGY

A type III hypersensitivity reaction mediated by immune complex deposition within the skin and joint spaces

ETIOLOGY

Usually viral (especially upper respiratory, but also enterovirus)

DIAGNOSIS

HISTORY

- Preceding viral syndromes
- Day care
- Relatively rapid onset of symptoms, with refusal to bear weight, in a nontoxic-appearing child
- Recent nonspecific upper respiratory or GI infection

PHYSICAL EXAM

- General examination usually benign, with occasional low-grade fever
- Child refuses to bear weight but may tolerate limited ranging of joint.
- Effusions in peripheral joints are rare and usually small and evanescent.
- Pitfalls:
 - Distinctions between transient synovitis and a septic joint may be impossible.
 - Extreme pain and guarding on passive ranging raises suspicion for septic joint.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- CBC:
 - Usually mild leukocytosis
- ESR:
 - Usually midrange elevation (35–50 mm/h)

Imaging

- Radiography:
 - Usually normal findings or demonstrates small effusion; no evidence of periosteal changes
- Ultrasound:
 - Affected hip joints may have demonstrable effusions.
- MRI:
 - Normal signal intensity may help differentiate transient synovitis from septic hip.

Diagnostic Procedures/Other

- Joint aspirate culture is usually not needed.
- Be wary of contaminated joint aspiration cultures
- Up to 50% of infected joints are negative on culture.

DIFFERENTIAL DIAGNOSIS

- Infection:
 - Lyme disease
 - Septic
 - Tuberculosis
 - Gonorrhea
- Environment
- Trauma (fracture or soft-tissue injury):
 - Slipped capital femoral epiphysis
 - Avascular necrosis
- Tumors:
 - Osteoid osteoma
- Immunologic:
 - Juvenile rheumatoid arthritis
 - Spondyloarthropathy
- Psychological:
 - Psychogenic limp
 - Imitative limp
- Miscellaneous:
 - Hypothyroidism

TREATMENT

MEDICATION (DRUGS)

- Usually responsive to NSAIDs such as ibuprofen (up to 10 mg/kg/dose q.i.d.)
- Very rarely, a short course of oral steroids is necessary.
 - Usually 1–3 weeks of a tapering course of NSAIDs are effective.

ADDITIONAL TREATMENT

General Measures

Pitfalls:

- Missing a septic hip or, alternatively, overinvestigating transient synovitis with invasive procedures
- Avoid initiation of therapy until septic joint is not in the differential.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Usually significant improvement in 24–48 hours

Patient Monitoring

Ongoing synovitis despite therapeutic levels of NSAIDs or any bony changes indicates need to change diagnosis.

PROGNOSIS

Excellent, although on occasion patients will experience recurrence of symptoms with subsequent viral syndromes or if there is an underlying spondyloarthropathy.

COMPLICATIONS

Questionably associated with subsequent avascular necrosis of femoral head and coxa magna

- M67.30 Transient synovitis, unspecified site
- M67.351 Transient synovitis, right hip
- M67.359 Transient synovitis, unspecified hip

FAQ

- Q: Are there any chronic sequelae from transient synovitis?
- A: Not usually. This is generally a benign disease, but there is a questionable association with avascular necrosis of the femoral head.
- Q: Is there an association with chronic arthritis?
- A: No, there is no known increased risk for chronic arthritis in affected children unless this is the first manifestation of a spondyloarthropathy.

SYPHILIS

Esther K. Chung

BASICS

DESCRIPTION

- Systemic infection caused by the spirochete, *Treponema pallidum*
- Can be congenital or acquired
- Consider sexual abuse when syphilis is diagnosed in young children.

EPIDEMIOLOGY

- Congenital syphilis is transmitted from an infected mother to her unborn or newborn baby.
- Acquired syphilis is sexually transmitted from an infected to an uninfected individual.
- Infection transmitted to the fetus at any stage of disease; during primary and secondary syphilis, rate of transmission is 60–100%.
- Nasal secretions are highly infectious in congenital syphilis, and open, moist skin lesions are infectious in congenital and acquired syphilis.

RISK FACTORS

- Lack of prenatal care
- Maternal use of illicit drugs
- Sexual abuse
- Infection with HIV

DIAGNOSIS

SIGNS AND SYMPTOMS

- Congenital syphilis:
 - Clinical manifestations range from asymptomatic to death or stillbirth.
 - Clinical signs include periostitis, osteochondritis, persistent rhinorrhea, or maculopapular rash.
- Acquired syphilis:
 - Primary stage: Painless, indurated ulcers (chancres), single or multiple, at the site of inoculation ~3 weeks after exposure (range 10–90 days); lesions usually resolve without treatment in 3–6 weeks.
 - Secondary stage: Generalized rash, which is often maculopapular and involves the palms and soles; condyloma lata, hypertrophic papular lesions; fever, malaise, lymphadenopathy; signs appear 3–6 weeks after initial chancre and may last 2–10 weeks
 - Relapse: Symptoms of secondary syphilis may recur 1 or more times before the latent period.
 - Latent period: Untreated, illness may enter a latent stage; patients are asymptomatic, not contagious; lasts 1–40 years or more; patients seroreactive but without other evidence of disease.
 - Early latent period: first 4 years of latent period
 - Late latent period: Subsequent years
 - Tertiary stage: Up to 1/3 of untreated secondary syphilis cases progress to tertiary or late disease; can occur many years after the primary infection; may see gummatous changes of the skin, bone, and/or viscera, or cardiovascular syphilis
 - Neurosyphilis: CNS involvement in 3–7% of untreated cases; can develop at any stage of disease; signs include changes in mood/behavior, hyperactive reflexes, impaired memory and/or judgment, and Argyll–Robertson pupils

HISTORY

- Newborn/infants:
 - Obtain a detailed prenatal history; inquire about all syphilis testing done on the mother; if mother has a history of syphilis, ensure documented treatment. The local department of health should have detailed records that include titers and treatment on all cases of syphilis.
 - Newborns should be evaluated for congenital syphilis if the mother is not adequately treated for syphilis—mother treated with nonpenicillin regimen, such as erythromycin; mother treated adequately but without a 4-fold decrease in antibody titers in early or high-titer syphilis; maternal syphilis treated <1 month (30 days) before delivery; maternal syphilis treated prior to pregnancy with insufficient follow-up to assess serologic response to treatment; maternal titer has increased 4-fold, if the infant's titer is 4-fold greater than the mother's titer, or if the infant is symptomatic.
- Older children/adolescents:
 - Ask about possible sexual abuse in children.
 - Ask about sexual activity in adolescents, including experience, number of lifetime partners, ages of partners, history of other STDs.
 - Ask about other risk behaviors.
 - Ask about risk factors for HIV exposure.

PHYSICAL EXAM

- Early congenital syphilis:
 - Low birth weight; irritability, bulging fontanel, if neurosyphilis is present
 - Alopecia (scalp and eyebrows)
 - Fissures in the lips, nares, anus; mucocutaneous lesions
 - Rhinitis (“snuffles”) may occur at one to several weeks of age and may be blood-tinged and purulent
 - Lymphadenopathy
 - Pneumonia: Check for tachypnea and/or respiratory distress.
 - Myocarditis
 - Hepatosplenomegaly with or without jaundice
 - Pseudoparalysis of an extremity
 - Rash: bullous (“syphilitic pemphigus”) and/or maculopapular (“blueberry muffin”) lesions symmetrically distributed on palms, soles, and other parts of the body
 - Condyloma lata: Flat, wartlike, moist lesions around the anus/vagina, chancres
- Late congenital syphilis:
 - Bony deformities, such as short maxilla, high-arched palate, saddle nose, mulberry molars, Higoumenaki sign (enlargement of the sternoclavicular portion of the clavicle), protuberance of the mandible, saber shins, scaphoid scapulae
 - Rhagades, neurologic involvement

- Acquired syphilis:
 - Primary syphilis:
 - Chancre (painless ulcer), single, most commonly located on the genitalia, and/or
 - Painless inguinal adenopathy
 - Secondary syphilis: Flulike illness with fever, headache, sore throat, nasal discharge, generalized arthralgias and myalgias, malaise, generalized painless and mobile lymphadenopathy; hepatosplenomegaly; maculopapular rash involving the palms and soles that may involve mucous membranes; condyloma lata (moist, papular lesions); alopecia; signs of meningitis, hepatitis, nephropathy, ocular involvement

DIAGNOSTIC TESTS & INTERPRETATION

- Pitfalls:
 - Mothers of infants with congenital syphilis should also be tested for gonorrhea, chlamydia, HIV, and hepatitis B virus infection.
 - In newborns, cord blood testing may result in false-positive and false-negative results; therefore, serum from the infant is the preferred source of testing.
 - False-positive nontreponemal test (e.g., rapid plasma reagin [RPR]) results may be seen with lab error, autoimmune disease, tuberculosis, lymphoma, viral infections (including Epstein–Barr, hepatitis, varicella, HIV, and measles viruses), endocarditis, malaria, and IV drug abuse.
 - False-positive treponemal tests may be seen in other spirochetal diseases (i.e., Lyme disease, leptospirosis), and rarely in autoimmune disease (i.e., systemic lupus erythematosus) and viral infections.

Lab

- Nontreponemal tests:
 - VDRL (Venereal Disease Research Laboratory) or RPR test to measure nonspecific antibodies
 - Used for routine screening; quantitative serum titers generally correlate with disease activity; need to confirm positive results with a treponemal antibody test. 4-fold titer change (e.g., from 1:8–1:32) necessary to document clinically significant change. Titers for different nontreponemal tests are not equivalent; therefore, use same test (and preferably same lab) when following serial titers.
 - VDRL (not RPR) used on CSF to rule out neurosyphilis.
- Treponemal antibody tests:
 - FTA-ABS (fluorescent treponemal antibody-absorption), TPHA (*T. pallidum* hemagglutination), MHA-TP (microhemagglutination assay for *T. pallidum* antibodies), or EIA (enzyme immunoassay for antitreponemal IgG)
 - Treponemal tests remain positive for life once infected; not useful for measuring treatment effectiveness
- Dark-field microscopy

- CSF analysis:
 - Findings include mononuclear pleocytosis, moderately elevated protein, normal glucose
 - Should be performed in all patients with acquired syphilis of > 1 year's duration.
 - Perform on infants when congenital syphilis suspected, if the physical examination is consistent with syphilis, if infant's titer is 4-fold greater than that of mother, if dark-field or fluorescent antibody test positive on body fluids, and on all children being treated with antibiotics for syphilis.
 - Remember that CSF protein levels in normal newborns are higher than in older children; some are as high as 150–200 mg/dL.

Imaging

Long-bone plain films: Rule out metaphyseal osteochondritis and/or diaphyseal periostitis.

DIFFERENTIAL DIAGNOSIS

- Congenital syphilis:
 - Herpes simplex virus (HSV)
 - Toxoplasmosis
 - Cytomegalovirus
 - Rubella
 - Neonatal hepatitis
 - Osteomyelitis
- Acquired syphilis:
 - Chancroid (*Haemophilus ducreyi*)
 - Granuloma inguinale
 - Calymmatobacterium granulomatis
 - Lymphogranuloma venereum (*Chlamydia trachomatis*)
 - Scabies
 - Mycotic infections
 - Genital herpes (HSV)
 - Venereal warts (human papillomavirus, HPV)
 - Viral exanthem (e.g., enteroviruses may cause a maculopapular rash involving the palms and soles)

TREATMENT

MEDICATION (DRUGS)

- Infants <28 days of age:
 - Aqueous crystalline penicillin G (50,000 U/kg/dose) IV q12h for first 7 days of life, then q8h for a total of 10 days or procaine penicillin G (50,000 U/kg/dose) IM daily for 10 days
 - If > 1 day of treatment is missed, restart 10-day course.
- Infants >28 days of age:
 - Aqueous crystalline penicillin G (50,000 U/kg/dose) IV q4–6h for 10 days
- Primary and secondary syphilis:
 - Benzathine penicillin G 50,000 U/kg IM (maximum, 2.4 million units), single dose
 - Doxycycline 100 mg PO b.i.d. or tetracycline 500 mg PO q.i.d. for 14 days for nonpregnant, penicillin-allergic patients
- Early latent syphilis (< 1 year's duration):
 - Benzathine penicillin G 50,000 U/kg IM (maximum, 2.4 million units), single dose
 - Doxycycline 100 mg PO b.i.d. or tetracycline 500 mg PO q.i.d. for 14 days for nonpregnant, penicillin-allergic patients
- Late latent syphilis or disease of unknown duration:
 - Benzathine penicillin G 50,000 U/kg IM (maximum 2.4 million U) weekly for 3 consecutive weeks
 - Doxycycline 100 mg PO b.i.d. or tetracycline 500 mg PO q.i.d. for 4 weeks for nonpregnant, penicillin-allergic patients
- Alternative therapy can be found at www.cdc.gov/nchstp/dstd/penicillinG.htm.

ONGOING CARE

DISPOSITION

Issues for Referral

All cases should be reported to the local department of (public) health.

PROGNOSIS

- The prognosis is better the earlier syphilis is detected and treated.
- Following appropriate therapy, the disease is usually totally arrested.
- With late findings of syphilis involving the nervous and/or cardiovascular systems, there may not be clinical improvement.
- Untreated infection in the neonate progresses to neurosyphilis within 1 year.
- Osteochondritis and periostitis in the newborn are usually self-limited and heal in the first 6 months of life.
- Hemolytic anemia seen in congenital syphilis may persist for weeks.

COMPLICATIONS

- Stillbirth or spontaneous abortion
- Perinatal death in 40% of pregnancies in mothers with untreated early syphilis
- Hydrops fetalis
- Prematurity
- Nephrosis
- Failure to thrive
- Disseminated intravascular coagulation
- Pseudoparalysis of Parrot: Paralysis of one of the limbs of an infant affected by congenital syphilis; usually unilateral
- Acute syphilitic leptomeningitis
- Cranial nerve palsies
- Interstitial keratitis—5–20 years after birth
- Cerebral infarction
- Seizure disorder, mental retardation
- Rhagades: Cluster of scars radiating around the mouth
- Mulberry molars: Maldevelopment of the cusps in the first molars
- Clutton joints: Painless arthritis of the knees and, rarely, other joints
- Hutchinsonian triad: Hutchinson teeth (notched upper central incisors), interstitial keratitis, eighth-nerve deafness
- Saber shins: Anterior bowing of the midportion of the tibia

PATIENT MONITORING

- Congenital syphilis:
 - Clinical follow-up and serial nontreponemal serologic testing every 2–3 months until titer decreases 4-fold or test is nonreactive
 - After adequate treatment, nontreponemal tests should be nonreactive after 6 months; infants with a history of abnormal CSF findings need serial CSF analyses every 6 months until CSF is normal.
 - Treated infants, follow-up at 1, 2, 4, 6, and 12 months of age; serologic tests should be performed 2, 4, 6, and 12 months after therapy until they become nonreactive or the titer has decreased 4-fold.
 - If titers have not shown a decline by 6–12 months, require reevaluation and treatment.

- Primary and secondary syphilis:
 - Clinical follow-up and serial nontreponemal titers at 6 and 12 months after treatment (more often, if at high risk for reinfection or treatment failure): Nontreponemal titers should drop 4-fold within 6 months of treatment of primary or secondary syphilis, and within 12–24 months after treatment of latent or tertiary syphilis.

CODES

ICD9

- 090.9 Congenital syphilis, unspecified
- 091.2 Other primary syphilis
- 097.9 Syphilis, unspecified

ICD10

- A50.9 Congenital syphilis, unspecified
- A51.2 Primary syphilis of other sites
- A53.9 Syphilis, unspecified

FAQ

- Q: Can an infant have congenital syphilis if the mother had a negative RPR during pregnancy?
- A: A mother with a negative RPR during pregnancy may have acquired syphilis late in pregnancy and transmitted it to her fetus. If the mother was not tested at delivery, then the diagnosis may have been missed.
- Q: What is the prozone phenomenon?
- A: When a nontreponemal test is falsely negative due to high concentrations of antibody to *T. pallidum*; diluting the serum will result in positive test results.

TAPEWORM

Jessica K. Hart
Samir S. Shah

BASICS

DESCRIPTION

- Tapeworms cause 2 major types of zoonotic disease syndromes, depending on whether humans are the definitive or intermediate host. When humans serve as definitive hosts, adult tapeworms infect the GI tract and interfere with nutrition. These infections are often asymptomatic. When humans serve as intermediate hosts for the larval cestode, serious pathology results.
- Causative organisms include:
 - *Taenia saginata* (beef tapeworm)
 - *Taenia solium* (pork tapeworm)
 - *Diphyllobothrium latum* (fish tapeworm)
 - *Dipylidium caninum* (dog tapeworm)
 - *Echinococcus granulosus*

EPIDEMIOLOGY

- Beef tapeworm:
 - Widespread in cattle-breeding areas of the world, with a prevalence of > 10% in areas of Africa, such as Ethiopia and Kenya, and the former Soviet Union.
- Pork tapeworm:
 - Cysticercosis has a high prevalence in developing areas of Central and South America.
 - In the US, immigrants account for >90% of cases.
- Fish tapeworm:
 - Infection is most prevalent in temperate climates of Europe, North America, and Asia. Persons who prepare raw fish are most at risk.
 - In the US, infected salmon have been implicated in most cases.
- Dog tapeworm:
 - Found in dogs and cats worldwide
- Echinococcosis:
 - Associated with the practice of feeding sheep viscera to dogs.
 - It is hyperendemic in sheep-raising areas of South America, Australia, areas of Africa, China, central Asia, and the western US.

GENERAL PREVENTION

- Adult tapeworms:
 - Proper cooking of meat and fish prevents transmission of beef, pork, and fish tapeworms.
- Pork tapeworm:
 - The refrigeration of pork infested with cysticerci at temperatures >0°C (32°F) does not affect parasite survival. However, storage of pork for 4 days at –5°C (21.2°F) or 1 day at –24°C (–11.2°F) kills most cysticerci.
- Fish tapeworm:
 - Brief cooking (at 56°C [132.8°F] or higher for 5 minutes) or freezing (–18°C [–0.4°F] for 24 hours) renders the fish safe for consumption.
- Dog tapeworm:
 - Periodic deworming of pets prevents infections.
- Echinococcosis:
 - Careful disposal of sheep viscera and mass chemotherapy of dogs can interrupt the life cycle of *E. granulosus* as the cestode moves between sheep and carnivore hosts.

PATHOPHYSIOLOGY

- Beef tapeworm:
 - Cattle (intermediate host) ingest the eggs of *T. saginata* in contaminated feeds. The eggs hatch, releasing embryos. The embryos penetrate intestinal mucosa, enter the bloodstream, and settle in various tissues, where they develop into larvae. Larvae in undercooked meat are consumed by humans and mature into adult tapeworms within the human (definitive host) GI tract. They grow up to 25 m long.
- Pork tapeworm: Humans are the only definitive host for the adult pork tapeworm, whereas both humans and pigs are intermediate hosts for its embryonic form, cysticercus.
 - Pigs (intermediate host) ingest *T. solium* eggs. In the intestine, the eggs release embryos that penetrate the mucosa, enter the bloodstream, and settle in various tissues to differentiate into cysticerci (infective larvae). Cysticerci are ingested by humans (definitive host) who consume undercooked pork.
 - Humans (intermediate host) ingest food contaminated with human feces containing *T. solium* eggs. The eggs hatch, liberating embryos (oncospheres). Penetration through the intestinal mucosa leads to blood-borne distribution to the brain, subcutaneous tissues, muscle, and eye, where they develop into cysticerci.
- Fish tapeworm:
 - When sewage containing *D. latum* eggs contaminates freshwater lakes and streams, larvae hatch into the water. These larvae are eaten by crustaceans and fish. Humans are infected when they consume these undercooked fish. The larvae mature into adult tapeworms in the intestines of humans.
- Dog tapeworm:
 - Larvae develop in fleas (intermediate host) after ingestion of the eggs; humans are infected through accidental ingestion of infected fleas.
- Echinococcosis (hydatid disease):
 - Humans ingest eggs of *E. granulosus* through contaminated dog feces. After ingestion, the eggs hatch and release embryos (oncospheres) in the small intestine. Penetration through the mucosa leads to blood-borne distribution to the liver, lungs, and other sites, where development of cysts begins. Within the cysts, new larvae (scolices) develop, accumulate fluid, and encroach on surrounding structures.

DIAGNOSIS

HISTORY

- Recent travel or immigration:
 - Tapeworm infections are more prevalent in other countries.
- GI tract:
 - Nausea, weight loss, diarrhea, abdominal tenderness or distention.
 - Fish and, rarely, dog tapeworm infections can be complicated by intestinal obstruction.
 - May observe proglottids that resemble rice or seeds in stool from dog tapeworm infections.

- Jaundice:
 - Hepatic cysts from echinococcosis may be palpable in the right upper quadrant.
 - Biliary tree extension can lead to obstructive jaundice and cholangitis.
- Respiratory tract:
 - Pulmonary hydatid cyst due to *E. granulosus* causes cough, dyspnea, and hemoptysis; rupture of a cyst can cause anaphylaxis.
- Hematologic:
 - Anemia from vitamin B12 deficiency occurs in 2% of fish tapeworm infections. Other signs of pernicious anemia include glossitis, peripheral neuropathy, decreased vibration sense, and ataxia.
- CNS:
 - New-onset seizures (partial or generalized) occur with neurocysticercosis and some species of *Echinococcus*.
 - Neurocysticercosis may present with alteration in mental status, signs of elevated intracranial pressure (headache, vomiting, visual changes), or meningitis
 - Neurocysticercosis and vitamin B12 deficiency due to fish tapeworm can mimic psychotic illness with delirium or hallucinations.
 - CNS symptoms in neurocysticercosis typically appear 5–7 years after initial infection (range: 6 months to 30 years).
- Note: For echinococcosis, a presymptomatic stage may last for years before the enlarging cysts cause symptoms. The variability of signs and symptoms depends on the target organ.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Beef tapeworm:
 - Identification of scolex in stool.
 - Ziehl–Neelsen stain of stool or perianal adhesive tape preparations identifies eggs.
 - Collection of proglottids in saline with microscopic examination.
 - ELISA test detects *Taenia* antigens in stool.
- Pork tapeworm:
 - Enzyme immunoassay blot (most sensitive) and serologic assays.
 - Stool samples for intestinal worms as for beef tapeworm.
- Fish tapeworm:
 - Stool samples for eggs and proglottids are diagnostic.
 - Mild eosinophilia (5–15%).
 - Low vitamin B12 levels (50%).
 - Megaloblastic anemia 2%.
- Dog tapeworm
 - Characteristic egg packets (loose membrane containing up to 20 eggs) may be identified in stool or perianal adhesive tape preparations.

- Echinococcosis:
 - IgE levels are elevated. Eosinophilia is present in <25% of infected persons.
 - Polymerase chain reaction (PCR) of stool
 - Mild elevation of hepatic enzymes may be present with hepatic hydatid cysts.
 - The Casoni skin test (injection of hydatid fluid into the dermis) yields an erythematous papule in <60 minutes in 50–80% of infected patients. There is a false-positive result in 30% of uninfected patients.
- Serologic testing is falsely negative in 10–50% of cases. False-negative results are more likely in patients with pulmonary hydatid cysts and in children. No serologic test excludes the diagnosis of hydatid cysts.

Imaging

- Pork tapeworm:
 - Contrast-enhanced CT or MRI of the brain may reveal cysticerci; ring-enhancing lesions with surrounding edema represent a dying parasite; calcification represents a resolved infection.
 - Imaging is usually diagnostic.
- Echinococcosis:
 - On x-ray, pulmonary cysts demonstrate a sharply demarcated, smooth-bordered cyst; there is a crescent-shaped air level after cyst rupture. Liver and spleen lesions may calcify over time.
 - Hydatid cysts: Internal septa or daughter cysts after cyst rupture are detected by CT, MRI, or ultrasound; present in ~50% of patients with unilocular liver cysts.

Diagnostic Procedures/Other

Echinococcosis: In seronegative persons, a presumptive diagnosis can be confirmed by demonstrating protoscolices or hydatid membranes in liquid obtained by ultrasound-guided percutaneous cyst aspiration. This procedure is controversial because anaphylaxis may occur with cyst rupture.

DIFFERENTIAL DIAGNOSIS

- Non-tapeworm gastroenteritis.
- Inflammatory bowel disease.
- Cholecystitis or biliary obstruction (i.e., gallstones, neoplasms, or liver disease).
- B12 deficiency from dietary deficiency, decreased ileal absorption, pancreatic insufficiency
- Idiopathic epilepsy.
- Echinococcal cysts must be differentiated from benign cysts, cavitary tuberculosis, abscesses, and neoplasms.

TREATMENT

MEDICATION (DRUGS)

- Beef tapeworm, pork tapeworm, fish tapeworm, dog tapeworm, and most other intestinal cestodes:
 - Praziquantel: 5–10 mg/kg as a single dose; no safety profile exists for children <4 years of age.
 - Niclosamide (second line for beef tapeworm): Children 11–34 kg, 1 g as a single dose; children >34 kg, 1.5 g as a single dose (not available in the US).
 - Supplement with vitamin B12 for fish tapeworm.

- Neurocysticercosis:
 - Treatment should be individualized based on number, location, and viability of cysticerci on MRI or CT scan. Although antiparasitic drugs are cysticercidal and hasten radiologic resolution, most symptoms result from the host inflammatory response and may be exacerbated by treatment.
 - Treatment may not be indicated for single degenerating cysts, calcifications, or encephalitis. Most experts recommend therapy for patients with nonenhancing or multiple cysticerci.
 - Albendazole: 15 mg/kg/d (maximum, 800 mg/d) in 2 divided doses for 8–30 days or praziquantel 50–100 mg/kg/d in 3 divided doses for 30 days.
 - Symptomatic therapy includes anticonvulsants for seizures and shunt placement for hydrocephalus.
 - Corticosteroids control host inflammation in the first 2–3 days of therapy for certain forms of neurocysticercosis. Data on optimal dose or duration are lacking but 1 mg/kg/day of prednisone or 0.5 mg/kg/day of dexamethasone is often used.
 - Antiparasitic therapy is contraindicated in patients with diffuse cerebral edema (“cysticercal encephalitis”) because the inflammatory response that follows treatment may worsen cerebral edema. These patients should be treated with high-dose corticosteroids.
 - No definite recommendations exist regarding the use of corticosteroids alone.
- Echinococcosis:
 - Albendazole 15 mg/kg for 1–6 months.
 - May require 3 courses of therapy with drug-free intervals of 14 days between courses.
- Note: The benzimidazoles, including albendazole, are contraindicated in patients with blood dyscrasia, leukopenia, and liver disease. Prolonged courses require monitoring of liver function and hematopoiesis.

SURGERY/OTHER PROCEDURES

Echinococcosis: Surgical resection of intact hydatid cysts, especially if >10 cm or secondarily infected

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Beef tapeworm:
 - Stool should be checked for eggs and proglottids 1 month after therapy.
- Pork tapeworm:
 - Repeat CNS imaging studies at 2-month intervals (with continued therapy) until successful elimination of parenchymal brain cysticerci.
- Fish tapeworm:
 - Perform stool examination 6 weeks after therapy to test for cure.
- Dog tapeworm:
 - No follow-up stool examination required, but the appearance of proglottids >1 week after therapy indicates treatment failure.
- Echinococcosis:
 - Requires prolonged follow-up with ultrasound or other imaging procedures.

COMPLICATIONS

- Cysticercosis:
 - Cysticerci develop in the brain, muscle, eye, or other organs.
- Echinococcosis:
 - Cysts grow slowly, causing symptoms only when relatively large.
 - They frequently develop in the liver (50–70%) and lung (20–30%); 5–10% of cysts involve other organs, including the eye, brain, spleen, heart, bone, and kidneys.
 - Spontaneous rupture of cysts can cause anaphylaxis.
 - Bone involvement can cause pathologic fractures.
 - Renal involvement causes pain or hematuria.

CODES

ICD9

- 123.0 *Taenia solium* infection, intestinal form
- 123.2 *Taenia saginata* infection
- 123.9 Cestode infection, unspecified

ICD10

- B68.0 *Taenia solium* taeniasis
- B68.1 *Taenia saginata* taeniasis
- B71.9 Cestode infection, unspecified

FAQ

- Q: Can vegetarians develop neurocysticercosis?
- A: Yes, because neurocysticercosis results from ingestion of *T. solium* eggs in products contaminated with infected fecal matter. GI symptoms result from infected pork consumption.
- Q: Is treatment for neurocysticercosis always indicated?
- A: The findings are controversial. In many children, the lesion disappears spontaneously within 2–3 months. Guidelines for treatment depend on the number and location of lesions, as well as the viability of the parasites within the nervous system. A growing parasite deserves active management, either with antiparasitic drugs or surgical excision.

TEETHING

Julie A. Boom

BASICS

DEFINITION

Teething is the normal developmental process of primary tooth eruption, often characterized by parental reports of fever, fussiness, increased drooling, increased finger sucking, alterations in bowel pattern, and/or decreased appetite.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- **Congenital/anatomic**
 - Natal teeth, neonatal teeth
 - Gastroesophageal reflux resulting in esophagitis with decreased appetite
- **Infectious**
 - Primary herpes gingivostomatitis causing pain or drooling
 - Human herpesvirus 6 causing fever
 - Coxsackievirus oral infection causing fever or drooling
 - Epiglottitis causing severe drooling with fever
 - Viral illness causing fever $>38.3^{\circ}\text{C}$ (101°F), diarrhea, or upper respiratory symptoms
- **Toxic ingestion causing drooling**
- **Trauma**
 - “Lancing” of gums (i.e., incising the gum to expose the erupting tooth) causing pain
 - Hair tourniquet syndrome causing pain and irritability
 - Corneal abrasion causing pain
- **Miscellaneous:** Drooling, gum rubbing, and finger sucking may be normal developmental behaviors.

APPROACH TO THE PATIENT

The overall goal is to determine if the infant has any other signs or symptoms of another illness that would require additional investigation (e.g., fever 38.8°C [102°F], diarrhea, or irritability); avoid overdiagnosing teething, which might delay diagnosis of a more serious illness.

- **Phase 1:** Careful history and physical exam
- **Phase 2:** Workup of specific signs or symptoms that are not consistent with teething
- **Phase 3:** Provide relief of discomfort for the child who is teething

ALERT

Of note, fever $>38.8^{\circ}\text{C}$ (102°F), irritability, or diarrhea should not be attributed to teething, and other etiologies should be considered, such as acute otitis media, urinary tract infection (UTI), septicemia, meningitis, septic arthritis, or viral infection.

HISTORY

- **Question:** Age?
- **Significance:** The average age for the eruption of the first tooth is ~ 6 months.
 - 1% of infants acquire the first tooth before 4 months of age, and 1% after 12 months of age.
 - Rule of thumb: Age (months) $- 6 =$ average number of teeth (up to 2 years of age)
 - Eruption usually begins with the lower central incisors.
- **Question:** Swelling or bluish discoloration of the gums?
- **Significance:**
 - Primary tooth eruption is frequently associated with swelling of the gums.
 - A bluish area of gum swelling may represent an eruption cyst secondary to a hematoma. This condition requires parental reassurance only.
- **Question:** Consolability?
- **Significance:**
 - Infants who are teething may be fussy but should be consolable.
 - An infant who is irritable and not consolable should be evaluated for serious systemic illness such as septicemia, meningitis, septic arthritis, or UTI.
- **Question:** Fever?
- **Significance:** Several studies suggest that mild temperature elevation may occur 1–3 days before tooth eruption.
- **Question:** Other symptoms?
- **Significance:**
 - One recent study found that the following symptoms may be seen 4 days before and 3 days after tooth eruption: Increased biting, drooling, gum rubbing, sucking, irritability, wakefulness, ear-rubbing, facial rash, decreased appetite for solid foods, and mild temperature elevation.
 - In this study, congestion, sleep disturbance, stool looseness, increased stool number, decreased interest in drinking, cough, nonfacial rashes, vomiting, and fever $>38.8^{\circ}\text{C}$ (102°F) were not associated with the teething period. Another recent study did not validate these findings.

- **Question:** Sleeping habits?
- **Significance:**
 - A teething child should be able to sleep with minimal disturbance.
 - Changes in sleeping habits, such as frequent nighttime awakening, should suggest common problems with sleep associations often seen in young children 6–12 months old.
- **Question:** Illness in the home?
- **Significance:** An acute illness should be investigated as the cause of the child’s symptoms.

PHYSICAL EXAM

- **Finding:** Swelling with slight pallor over the gum where the tooth will erupt?
- **Significance:** Normal finding
- **Finding:** Bluish discoloration overlying the gum where a tooth is expected?
- **Significance:** This represents a hematoma, known as an “eruption cyst,” which is a normal finding.
- **Finding:** Irritability?
- **Significance:** Irritability on physical exam suggests a more serious illness than teething. In addition to the infectious etiologies noted, the child should be evaluated for hair tourniquet syndrome and/or corneal abrasion.
- **Finding:** Oral ulcers?
- **Significance:** Viral enanths, such as those seen with herpes simplex virus or coxsackievirus, should be considered.
- **Finding:** Presence of cervical lymphadenopathy?
- **Significance:** Oral, dental, or pharyngeal infections should be considered.
- **Finding:** Signs of dehydration, such as dry mucous membranes, absent tears, sunken fontanel, or tenting of the skin?
- **Significance:** Infectious etiologies that result in poor oral intake or diarrhea should be considered.
- **Finding:** Oral erythema and abrasions with excessive drooling?
- **Significance:** The possibility of caustic ingestion should be explored.

DIAGNOSTIC TESTS & INTERPRETATION

No laboratory tests are indicated in the otherwise healthy child with teething.

TREATMENT

ADDITIONAL TREATMENT

General Measures

- Application of cold/frozen objects locally onto the gums: Many find that cold objects work well, but care must be taken because direct contact with a frozen object may result in local irritation.
 - Liquid-filled teething rings should be chilled but not frozen. Extreme temperatures may alter the integrity of the plastic cover and result in bacterial contamination with organisms such as *Pseudomonas*.
- Objects for chewing: Choking hazards, such as raw carrots, must be avoided.
- Teething rings should not be attached to a tether around the child's neck, as they represent a strangulation hazard. Teething rings made prior to 1998 should be discarded as they might contain diisononyl phthalate, a softening agent now thought to be toxic.
- Acetaminophen (15 mg/kg PO q4h) or ibuprofen (10 mg/kg PO q6h) may be used for pain relief as needed, but should not be given around-the-clock so as not to mask fever.
- Home remedies or treatments given by parents:
 - Most over-the-counter preparations marketed for the relief of teething symptoms contain 7.5–10% benzocaine as the active ingredient. Excessive use of benzocaine preparations has been associated with methemoglobinemia.
 - Homeopathic remedies may contain a variety of ingredients including belladonna alkaloids, chamomile, and ground coffee. Depending on the size of the child and the amount of medication or herb ingested, toxicity is possible.
- Remedies that have been used in the past and are no longer recommended include: Alcoholic liquors, paregoric, 2% lidocaine solution (excess may result in seizures), honey, emetics, purgatives, lancing the gums, and rubbing the gums with a thimble until the tooth breaks through the gum.

ISSUES FOR REFERRAL

- Children who have delayed eruption of their first primary tooth beyond 12 months require additional investigation for the following: Anodontia, hypothyroidism, hypopituitarism, rickets, Gaucher disease, and multiple syndromes such as osteodystrophies, Apert syndrome, and Down syndrome. Most of these conditions require referral to a specialist for management.
- Children with premature eruption may have a familial cause; however, referral for evaluation of hyperpituitarism should be considered.
- Referral to a dentist should be considered for children with significant variation in eruption caused by dental infections, additional teeth in the path of eruption, insufficient space in the dental arch, and/or ectopic placement of teeth.
- Natal teeth that are stable and do not interfere with breastfeeding may remain. Loose natal teeth may need to be removed to prevent choking and aspiration. Natal teeth can interfere with breastfeeding and cause ulceration, which is another indication for removal.

FAQ

- Q: What is the difference between natal teeth and neonatal teeth?
- A: Natal teeth are present at birth, whereas neonatal teeth erupt during the 1st month of life. The incidence of natal teeth is 1:2,000–6,000 live births and usually involves the lower central incisor. Natal teeth can be associated with various conditions including Pierre Robin sequence, cleft lip and/or palate, chondroectodermal dysplasia, and Hallermann–Streff, Ellis–van Creveld, and Sotos syndrome. There is often a familial history of natal or neonatal teeth. 95% of natal teeth are normal primary incisors that may have formed superficially and erupted early. Only 5% of natal teeth are supernumerary (extra) teeth. Therefore, if a natal tooth is removed, a primary tooth will not erupt in its place in most cases. Because primary teeth act as space holders for the secondary teeth, early loss of a primary tooth may result in significant crowding of the secondary teeth.
- Q: Does primary tooth eruption in preterm infants occur at the same time as in full-term infants?
- A: In healthy preterm infants who had relatively uneventful neonatal courses, the first primary tooth erupts at the usual chronological age. Premature infants requiring prolonged oral intubation and/or who experience inadequate nutrition due to the severity of neonatal disease may have delays in tooth eruption. The initial eruption sequence remains the same (lower central incisors first).
- Q: Does obesity affect dental development?
- A: Obese children, ages 8–15, have been shown to have advanced dental development compared to their nonobese peers. This can have important implications for planning the timing of orthodontic treatment.

TENDONITIS

David D. Sherry

BASICS

DESCRIPTION

Inflammation of a tendon or along the tendon sheath

EPIDEMIOLOGY

- Increases with age and at time of puberty
- May be slightly more common in girls

RISK FACTORS

Genetics

Hypermobility individuals may be prone to tendonitis.

PATHOPHYSIOLOGY

Inflammation and microtearing may be present.

ETIOLOGY

Frequently associated with repetitive motion/overuse activities

DIAGNOSIS

HISTORY

- Trauma or overuse:
 - Verify acute nature of injury
- Signs and symptoms:
 - Pain
 - Tenderness

PHYSICAL EXAM

- Evidence of hematoma:
 - Palpate around and about affected areas, detecting point tenderness especially at tendon insertions as well as over bony prominences
- Evidence of bursitis or arthritis:
 - Systemic conditions, such as spondyloarthropathy, can lead to inflammation of tendons, bursa, and joints, and bursitis can mimic the pain of tendonitis.
- Pop or snap felt at the time of the event:
 - Sometimes this is felt when tendons and ligaments are torn or avulsed.

- Caution: False-positives:
 - Patients may have torn ligaments, fractures, or arthritis, not just tendonitis on examination.
- Pitfalls:
 - Overdiagnosis in young children, in whom overuse is rare and other diagnoses should be considered
- Underdiagnosis in older children in whom repetitive activities are likely to occur

DIAGNOSTIC TESTS & INTERPRETATION

Lab

ESR: Occasionally helpful to rule out inflammatory conditions if history and/or physical exam are suggestive

Imaging

Plain radiograph: Affected area may be indicated to rule out a fracture, avulsion, or identify a bone spur.

DIFFERENTIAL DIAGNOSIS

- Infection:
 - Especially gonococcal disease, septic arthritis, or osteomyelitis
- Environmental:
 - Fracture
- Metabolic:
 - Homocystinuria

- Congenital:
 - Generalized hypermobility
 - Marfan syndrome
 - Ehlers–Danlos
- Immunologic:
 - Ankylosing spondylitis and the reactive spondyloarthropathies (inflammatory bowel disease, reactive arthritis)
 - Inflammatory arthritides
- Psychological:
 - Amplified musculoskeletal pain

TREATMENT

MEDICATION (DRUGS)

- NSAIDs
- Rarely do soft-tissue steroid injections have a role in children

ADDITIONAL TREATMENT

General Measures

- Rest/reduced use of the affected tendon/muscle group is essential, occasionally requiring splinting.
- Duration of therapy:
 - 1–4 weeks

Additional Therapies

- Physical or occupational therapy
- Either self-directed or formal help with resumption of desired activity, through gentle range of motion exercises against low resistance and advanced as tolerated

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Improvement often takes 2–6 weeks.

Patient Monitoring

If the provocative activity is resumed too soon, the irritation will recur.

PROGNOSIS

Usually good for children; however, many will suffer recurrences if proper exercises before desired activity are not continued.

COMPLICATIONS

Ongoing pain and predisposition for recurrence

CODES

ICD9

726.90 Tendonitis

ICD10

M77.9 Enthesopathy, unspecified

FAQ

- Q: Which activities can result in overuse syndromes and tendonitis?
- A: Virtually any repetitive activity in which children engage can cause tendonitis. For example, pain in the tendons of the thumb has occurred in children overusing video games.

TERATOMA

Jane E. Minturn

BASICS

DESCRIPTION

Embryonal neoplasm composed of tissue derived from all 3 germ layers (endoderm, mesoderm, and ectoderm):

- Gonadal or extragonadal location
- Mature or immature and may occur with or without associated malignant elements
- A subset of the broader class of germ cell tumors

GENERAL PREVENTION

There is no known prevention for the development of teratomas and other germ cell tumors.

EPIDEMIOLOGY

- Gonadal and extragonadal germ cell tumors account for ~3% of childhood malignancies (<15 years) and 15% of malignancies of ages 15–19 years.
- Incidence of germ cell tumors as a whole is ~2.5 cases per million in white children and 3 cases per million in black children <15 years of age.
- One suggestive epidemiologic association is with high maternal hormone levels during pregnancy.
- More controversial associations include younger gestational age; viral infections including herpes simplex virus, varicella-zoster virus, cytomegalovirus, mumps; other congenital anomalies; maternal urinary tract infection or tuberculosis; and paternal occupation in chemical industries.
- Sacrococcygeal teratoma: Accounts for 50% of all childhood teratomas and up to 78% of extragonadal germ cell tumors. Most prevalent in infants (1:40,000 live births); girls more frequently affected (4:1 female to male)
- Testicular and ovarian teratomas account for 5% and 25% of childhood teratomas, respectively.
- Vaginal tumors: Most prevalent in girls <3 years old
- Mediastinal tumors: Arise in anterior mediastinum, rarely heart or pericardium. Average age of the pediatric patient is 3 years, but also found in adolescents; most common extragonadal germ cell tumor in adults
- Intracranial teratoma: Midline, primarily pineal or suprasellar. Comprise 50% of congenital brain tumors (≤60 days of life)

Genetics

- Isochromosome 12p [i(12p)] is characteristic in adult mixed germ cell tumors. Pediatric tumors show no clear pattern of genetic aberration.
- No pattern of inheritance is known.

PATHOPHYSIOLOGY

- Absence of normal mitotic/meiotic arrest of primordial germ cells in gonads leading to gonadal tumor formation. Aberrant migration of primordial germ cells during embryonal development, causing germ cells to come to rest outside the gonads leading to extragonadal tumors.
- Mature teratoma: Contains well-differentiated, nonmitotic tissues from all 3 germ layers, such as squamous epithelium, neuronal tissue, muscle, teeth, cartilage, bone, GI, and respiratory epithelium.
- Immature teratoma: Contains various embryonic elements representative of all 3 germ layers, such as neuroepithelial tissues; divided histologically into 4 grades, 0–3, dependent on degree of immaturity and mitotic activity.
- Teratoma with malignant germ cell elements: Foci of malignant tissue that resemble other germ cell tumors such as embryonal carcinoma, yolk sac tumor (endodermal sinus tumor), and choriocarcinoma, in addition to mature or immature tissues. Prone to local recurrence and metastasis.

DIAGNOSIS

HISTORY

- External mass, constipation, urinary abnormalities, lower extremity weakness:
 - Sacrococcygeal mass may impinge on nerve structures.
 - Anterior sacrococcygeal mass may have no external component.
 - Fetal sacrococcygeal teratoma often initially picked up on prenatal ultrasonography.
- Cough, wheeze, dyspnea, superior vena cava syndrome suggest anterior mediastinal mass.

- Blood-tinged vaginal discharge: Vaginal teratoma
- Abdominal pain, nausea, vomiting, constipation, urinary tract symptoms: Ovarian tumors present late with a large mass. Symptoms mimicking acute abdomen may indicate ovarian torsion.
- Painless scrotal swelling or painful testicular torsion: Testicular mass may be teratoma.
- Cryptorchidism: Associated with germ cell tumors in boys

PHYSICAL EXAM

- Palpable mass either externally or internally, signs of spinal cord compression: Sacrococcygeal tumor
- Vaginoscopy reveals a polyploid lesion arising from the vaginal wall: Examination under anesthesia is usually necessary.
- Palpable abdominal mass, peritoneal symptoms: Ovarian mass may be large.
- Palpable mass in scrotum: Testicular origin
- Decreased breath sounds, consolidation, wheezing, superior vena cava syndrome: Mediastinal mass may be an emergency.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Serum α -fetoprotein (AFP) and β -human chorionic gonadotropin (β -HCG): Pure teratomas are not associated with elevated tumor markers. Elevation of either of these markers indicates the presence of more malignant germ cell elements and requires review of the histologic material.
- CBC and chemistry profile, with electrolytes, BUN, creatinine, liver function tests, uric acid, and lactate dehydrogenase: Workup to rule out other malignancies or associated organ dysfunction

Imaging

- Plain radiograph: May reveal mature calcified tissues, such as bone or teeth, within tumor
- Chest radiograph: Shows mediastinal mass
- CT scan: Necessary to evaluate the primary site and regional disease
- Transscrotal ultrasound as initial imaging for testicular mass shows heterogeneous mass with calcifications

- Prenatal MRI for fetal sacrococcygeal teratoma diagnosed by ultrasound: Allows more accurate prenatal counseling and improved preoperative planning
- Chest CT and bone scan: If malignancy is suspected or proven, these are indicated for evaluation of metastasis.
- Ultrasound, if CT is not readily available:
 - May be helpful, but will rarely suffice as the sole imaging study of the primary site
 - May be first evidence of anterior sacrococcygeal mass or to differentiate testicular mass from hydrocele

DIFFERENTIAL DIAGNOSIS

- Sacrococcygeal: Pilonidal cyst, meningocele, lipomeningocele, hemangioma, abscess, bone tumor, epidermal cyst, chondroma, lymphoma, ependymoma, neuroblastoma, glioma
- Abdominal: Wilms tumor, neuroblastoma, lymphoma, rhabdomyosarcoma, hepatoblastoma, retained twin fetus
- Vaginal: Rhabdomyosarcoma (sarcoma botryoides), clear cell carcinoma
- Ovarian: Cyst, appendicitis, pregnancy, pelvic infection, hematoocolpos, sarcoma, lymphoma, other ovarian tumors
- Testicular: Epididymitis, testicular torsion, infarct, orchitis, hernia, hydrocele, hematocele, rhabdomyosarcoma, lymphoma, leukemia, other testicular tumors
- Mediastinal: Hodgkin and non-Hodgkin lymphoma, leukemia, thymoma

TREATMENT

SURGERY/OTHER PROCEDURES

- Every effort should be made to preserve fertility in gonadal teratomas. An experienced pediatric–gynecology oncologic surgeon is critical.
- Sacrococcygeal teratomas should undergo complete resection to include the coccyx for definitive therapy and patients followed closely postoperatively with tumor markers. Fetal surgery indicated when early signs of hydrops develops
- Mature teratoma: Full surgical excision, irrespective of site, is curative in prepubescent patients. One exception is in postpubescent testicular germ cell tumor (with high-risk of mature teratoma relapse in lymph nodes), where orchidectomy, post-adjuvant chemotherapy and +/- post-chemotherapy lymph node dissection are recommended.
- Immature teratoma:
 - Complete surgical resection is therapy of choice. Close observation and tumor marker evaluation for normalization
 - In cases of elevated AFP and incomplete surgical resection; chemotherapy should be offered given risk of microscopic foci of endodermal sinus tumor.
- Teratoma with malignant components:
 - Surgery plus chemotherapy with etoposide, cisplatin or carboplatin, and bleomycin
 - Patients with residual disease should have additional surgery and additional chemotherapy if total resection is not possible.
 - High-dose chemotherapy with autologous stem cell support and radiation are reserved for salvage therapy in recurrent disease.

ONGOING CARE

- Serial physical exams and imaging studies of primary site
- Tumor markers (AFP or β -HCG) if elevated at diagnosis
- If chemotherapy or radiation therapy used, need to monitor for secondary malignancies, long term. Short term, need to monitor blood counts, chemistries, renal function, and audiology

CODES

ICD9

- 183.0 Malignant neoplasm of ovary
- 220 Benign neoplasm of ovary
- 222.0 Benign neoplasm of testis

ICD10

- D27.9 Benign neoplasm of unspecified ovary
- D29.22 Benign neoplasm of left testis
- C56.9 Malignant neoplasm of unspecified ovary

FAQ

- Q: What is the chance of cure for immature/malignant teratomas?
- A: With current chemotherapy as outlined above, overall survival is 85–97% (dependent on disease stage).
- Q: Can a benign tumor recur? If so, can it then be malignant?
- A: Yes. If there is residual tissue left behind, the tumor can recur. If there were unrecognized areas of malignancy, the recurrence can be a malignant teratoma. The greatest risk for the latter is with the immature teratomas.

TETANUS

Hamid Bassiri

Joanne N. Wood (5th edition)

BASICS

DESCRIPTION

- Tetanus is a disease characterized by muscle rigidity and spasms due to a neurotoxin produced by *Clostridium tetani* in infected wounds.
- There are 4 clinical forms of tetanus: Generalized, localized, cephalic, and neonatal.

EPIDEMIOLOGY

- Tetanus remains a major problem in developing countries but is rare in the developed world because of widespread immunization.
- Rare cases have been reported in patients with protective levels of anti-tetanus antibodies.
- In the US 40 or fewer cases of tetanus are reported per year.
- Generalized tetanus is the most common form of disease. Neonatal tetanus is rare in the US but common in countries in which women are not immunized and nonsterile care of the umbilical cord is practiced.

RISK FACTORS

- Inadequate immunization
- Neonate born to unimmunized mother
- Elderly with declining immune status
- Injection drug use
- Chronic wounds
- Acute traumatic injury
- Nonsterile delivery conditions and practice of applying mud or feces to umbilical cord

GENERAL PREVENTION

- All wounds should be cleaned with soap and water and foreign bodies should be removed.
- Universal immunization with tetanus toxoid is vital.
 - Primary series: DTaP given at 2, 4, 6, 15–18 months and 4–6 years
 - Booster dose: Tdap at 11–12 years
 - Unimmunized pregnant women should complete primary series prior to delivery if possible or at least receive 2 doses of Td 4 weeks apart.
- Tetanus prophylaxis should be initiated at the time of injury, depending on the nature of the wound. For clean, minor wounds:
 - If the patient has had ≥ 3 prior doses of tetanus toxoid and it has been < 10 years since the last dose, no tetanus prophylaxis is indicated. If it has been ≥ 10 years since the last dose, tetanus toxoid is indicated.
 - If the patient has had < 3 prior doses of tetanus toxoids, tetanus toxoid is indicated.
- For all other wounds:
 - If the patient has had ≥ 3 prior doses of tetanus toxoid and it has been < 5 years since the last dose, no tetanus prophylaxis is indicated. If it has been ≥ 5 years since the last dose, tetanus toxoid is indicated.
 - If the patient has had < 3 doses of tetanus toxoid, tetanus toxoid and tetanus immune globulin (TIG) should be given at separate sites.

- Type and dose of IM tetanus toxoid for wound prophylaxis:
 - For a child < 7 years old use DTaP. If pertussis vaccine is contraindicated use DT.
 - For a child 7–10 years old use Td.
 - For an adolescent 11–18 years old who has not received Tdap, give Tdap. For those who have received Tdap or for whom pertussis is contraindicated, administer Td.
- TIG dose is 250 U IM (regardless of age or weight).
- If TIG is unavailable, IV immunoglobulin (IVIG) or equine tetanus antitoxin (after testing for sensitivity) can be used.

PATHOPHYSIOLOGY

- *C. tetani* produces tetanospasmin, a powerful metalloprotease neurotoxin.
- Tetanospasmin can be absorbed directly into skeletal muscles adjacent to the injury.
- Tetanospasmin can travel to the CNS, via retrograde axonal transport through peripheral nerves, or via lymphocytes.
- Tetanospasmin affects the CNS, and the peripheral and autonomic nervous systems:
 - In the CNS, tetanospasmin prevents the release of gamma-aminobutyric acid (GABA) into the post-synaptic cleft, thereby removing the inhibitory control of alpha motor neurons, resulting in sustained excitatory discharges (motor spasms).
 - In the peripheral nervous system, tetanospasmin binds to gangliosides and blocks inhibitory impulses to motor neurons.
 - The mechanism by which tetanospasmin causes autonomic instability (cardiac arrhythmias, blood pressure lability, and respiratory failure) is not as well understood.
- Tetanospasmin does not directly affect cognitive processes.
- Infection with tetanus does not confer immunity, and thus all patients with tetanus need to be immunized with 3 doses of tetanus toxoid starting at diagnosis.

ETIOLOGY

- Tetanus is caused by *C. tetani*, a spore-forming, anaerobic, Gram-positive bacillus.
- *C. tetani* is found in soil, animal and human feces, house dust, salt and fresh water.
- Under anaerobic conditions inoculated spores become vegetative and produce tetanospasmin.
- Anaerobic conditions in wounds are promoted by large amounts of necrosis, foreign bodies, and other ongoing infections with suppuration.

DIAGNOSIS

HISTORY

- Incubation period is usually 3–21 days but can vary.
 - Sites of inoculation farther from the CNS are associated with longer incubation periods.
- Generalized tetanus:
 - “Lockjaw” or trismus is initial symptom in 50–75% of cases.
 - Other early complaints include dysphagia, neck pain and stiffness, stiffness and pain in other muscle groups, urinary retention, restlessness, irritability, and headache.
 - More muscles groups involved as disease progresses.
 - Noise, light, touch, and other stimuli can trigger painful spasms.
- Local tetanus:
 - Painful muscle contractions and stiffness limited to the area near the wound.
 - Can persist for several weeks.
 - Can progress to generalized tetanus.
- Cephalic tetanus:
 - Caused by *C. tetani* infections of head and neck wounds.
 - May complicate chronic infections of the head and neck including chronic otitis media.
 - Affects cranial nerves, especially cranial nerve VII.
 - Can progress to generalized tetanus.
- Neonatal tetanus:
 - Occurs following vaginal delivery to unimmunized mothers.
 - Presents at around 1 week of life with irritability and poor feeding.
 - Rapidly progresses to generalized tetanic spasms.

PHYSICAL EXAM

- Vital sign abnormalities:
 - Severe and labile episodes of hypertension and tachycardia.
 - Hypotension may be a late feature.
 - Initially, patients are afebrile.
 - Fever may develop with sustained contractions or from superinfections.
- Trismus is often initial presenting sign.
- Persistent trismus causes *risus sardonius*, wrinkling of the forehead and distortion of the eyebrows and the corners of the mouth
- As the disease progresses, other muscle groups develop tetanic contractions and spasms:
 - Can lead to a severe opisthotonic posture.
 - Can mimic seizures.
 - Can be extremely painful.
 - Can be associated with potentially fatal laryngospasm and tetany of the respiratory musculature.
 - The anxiety and pain associated with these spasms may precipitate additional spasms.
- Sweating can occur from autonomic instability.
- Normal mental status usually seen.
- Cephalic tetanus:
 - Cranial nerve palsies and muscle spasms including trismus can be seen.
 - Look for underlying wound or chronic infection of the face, scalp, neck, or ear.

DIAGNOSTIC TESTS & INTERPRETATION**Diagnostic Procedures/Other**

- Laboratory tests often yield little information.
- Gram stain and anaerobic wound cultures yield *C. tetani* in <1/3 of cases.
- The WBC count is usually normal or mildly elevated.
- Presence of protective tetanus antibody titer does not exclude possibility of disease.
- CSF studies are unremarkable.
- EEG and electromyogram findings are nonspecific.

DIFFERENTIAL DIAGNOSIS

- Infections:
 - Dental infections, retropharyngeal and peritonsillar abscesses, poliomyelitis, viral encephalitis, and meningoenephalitis may present with trismus and/or cranial nerve findings.
- Toxins and medications:
 - Dystonic reactions to phenothiazine medications may resemble tetanus. Diphenhydramine will effectively treat these reactions.
 - Strychnine poisoning may mimic generalized tetanus.
 - Malignant neuroleptic syndrome can cause increased muscular rigidity resembling titanic spasms.
- Metabolic:
 - Hypocalcemic tetany is usually not as severe as the contractions seen with tetanus.
- Stiff-man syndrome can result in fluctuating tonic muscle contractions resembling titanic spasms.
- Bell's palsy may resemble cephalic tetanus.

**TREATMENT****MEDICATION (DRUGS)****First Line**

- Neutralization of unbound neurotoxin:
 - Human TIG 3,000–6,000 U IM as a single dose. Part of the dose may be infiltrated around the wound.
 - Administer prior to antibiotics and wound manipulation.
- Tetanus toxoid should be administered IM at a site contralateral to where TIG is given.
- Antibiotics—used to decrease the number of vegetative *C. tetani* that produce tetanospasmin:
 - First line: Metronidazole 30 mg/kg/d PO or IV in 4–6 divided doses. Maximum 4 g/d.
 - Alternative: Penicillin G 100,000–200,000 U/kg/d IV in 4–6 divided doses.
 - Treat for 10–14 days.
 - Do not use cephalosporins as they are not effective.
- Sedation and muscle relaxation:
 - Diazepam 0.1–0.2 mg/kg IV q4–6h.
 - Phenothiazines, especially chlorpromazine, may be helpful.
 - Carefully titrate sedation to desired effect and monitor for respiratory depression.
- Nondepolarizing neuromuscular blockade and mechanical ventilation—use if spasms cannot be adequately controlled or if spasm of airway and respiratory musculature compromises ventilation:
 - Vecuronium 0.08–0.1 mg/kg IV followed by a continuous infusion or hourly dosing intervals.
 - Pancuronium or doxacurium can be used.
 - Avoid use of succinylcholine because of increased risk of hyperkalemia and arrhythmia.

- Management of autonomic dysfunction:
 - Beta-blockers (such as labetalol 0.4–1.0 mg/kg/hr) may be needed to control hypertension and arrhythmias.
 - Magnesium sulfate has been shown to significantly reduce cardiovascular instability and act as an adjunctive agent to control muscle spasms.

Second Line

If TIG is not available:

- IVIG 200–400 mg/kg may be used but is not FDA approved for this use.
- Equine tetanus antitoxin (TAT) can be given in doses of 1,500–3,000 U IM or IV (to achieve a serum concentration of 0.1 IU/mL), but only after a skin test for sensitization is negative or desensitization has been performed:
 - TAT is not available in the US.
 - Anaphylactic reactions can occur with varying severity in up to 20% of patients.

ADDITIONAL TREATMENT**General Measures**

- Keep patient in a quiet, darkened room with minimum stimulus.
- Monitor cardiac and respiratory status closely.
- Be prepared to perform a tracheotomy to prevent fatal laryngospasm.
- Monitor for and treat urinary retention and constipation.
- Parenteral nutrition is usually required to maintain adequate nutrition and hydration.
- Monitor for and correct electrolyte abnormalities, especially hyperkalemia.

SURGERY/OTHER PROCEDURES

Aggressive surgical debridement and removal of foreign bodies from the infected wound is crucial.

IN-PATIENT CONSIDERATIONS**Initial Stabilization**

- Prompt recognition of clinical signs of tetanus and initiation of emergency care are critical.
- All suspected cases of tetanus should be rapidly transferred to a tertiary care center capable of providing sophisticated ventilatory and cardiovascular support in an intensive care setting.
- In the emergency department, treatment with TIG should be initiated to neutralize unbound neurotoxin. However, supportive care including aggressive airway management, ventilatory support, and pharmacologic interventions (sedation, muscle relaxation) are also critical to ameliorate the effects of bound neurotoxin.

**ONGOING CARE****PROGNOSIS**

- Signs and symptoms usually progress for ~1 week. The patient's condition plateaus for ~1 week and then gradually improves over the next 2–6 weeks.
- Overall mortality rates have decreased with advances in the ability to provide respiratory support in an intensive care setting.
- Mortality rates vary from 1–18% for localized tetanus, 15–30% for cephalic tetanus, 45–55% for generalized tetanus to 50–100% for neonatal tetanus.

- Children and young adults have a better prognosis than older individuals.
- A more rapid onset and progression of disease from trismus to generalized spasms is associated with a more severe course.
- In the absence of complications, survivors usually recover fully without long-term sequelae.

COMPLICATIONS

- Most complications are related to the severe tetanic muscle contractions:
 - Rhabdomyolysis and hyperkalemia
 - Vertebral body and other fractures
 - Muscle hemorrhages
- Respiratory failure from spasms of the upper airway or diaphragm is the most common cause of death in acute phase.
- Arrhythmias and myocardial infarctions are most common cause of death later in disease.
- Cerebrovascular hemorrhages may be seen in rare cases, especially in neonatal tetanus.
- Pneumonia, including aspiration, can occur.

FAQ

- Q: What are characteristics of a tetanus-prone wound?
- A: Punctures and avulsion wounds; crush injuries and burns; wounds from frostbite or missiles; wounds contaminated with saliva, soil, or feces; all wounds—even minor ones—may be inoculated with spores and lead to the development of tetanus.

TETRALOGY OF FALLOT

Christopher J. Petit

BASICS

HISTORY

Described by Fallot of Marseilles in 1888, and classified by Mavde Abbott in 1936. Tetralogy of Fallot is the most common form of cyanotic congenital heart disease. It was first successfully palliated in 1944. Now, infants with tetralogy of Fallot commonly undergo complete repair.

DESCRIPTION

Anatomic hallmark is anterior malalignment of infundibular septum:

- A large and unrestrictive ventricular septal defect (VSD)
- Various degrees of right ventricular outflow tract obstruction (RVOTO)
- Overriding aorta
- Right ventricular hypertrophy (RVH): secondary to unrestrictive VSD

Prevalence

3.5–8% of all congenital heart disease

Genetics

- Tetralogy of Fallot (TOF) is associated with a chromosome 22q11 microdeletion in 5–16% of cases
- May be associated with other syndromes including Trisomy 21, Alagille syndrome, CHARGE syndrome, VACTERL syndrome, fetal alcohol syndrome, and those syndromes involving a variety of limb abnormalities. May also affect infants of diabetic mothers. TOF may also be associated with midline abdominal defects (e.g., omphalocele) as in the pentalogy of Cantrell.

PATHOPHYSIOLOGY

Severity of clinical signs and symptoms depends on the degree of RVOTO and resulting cyanosis due to right-to-left shunting. Most infants present with cyanosis due to right → left shunting, while rarely patients can present with overcirculation.

DIAGNOSIS

SIGNS AND SYMPTOMS

Heart murmur in the newborn period:

- Various degrees of progressive cyanosis reflect severity of RVOT obstruction
- History of paroxysmal cyanosis, especially when crying or during and after physical exercise
- Rarely, a history of tachypnea and feeding intolerance (in “Pink Tetralogy”) reflecting overcirculation

PHYSICAL EXAM

Various degrees of cyanosis may be present at birth or may appear later during infancy or childhood as a result of progression of the RVOT/pulmonary stenosis.

- Normal S1 and single loud S2 secondary to a more anteriorly located aorta
- Systolic ejection murmur at left upper sternal border secondary to RVOTO

DIAGNOSTIC TESTS & INTERPRETATION

Imaging

- Electrocardiography: Right axis deviation (+90–180°), RVH
- Chest radiograph: Right aortic arch (30%), decreased pulmonary vascular markings, boot-shaped heart (coeur en sabot) with concave main pulmonary artery (PA) segment
- Echocardiography: Anterior malalignment VSD, infundibular stenosis, overriding aorta, RVH. May also see: Other (muscular) VSDs, valvular pulmonary stenosis and/or branch PA stenosis, abnormal (right-sided) aortic arch anatomy, coronary artery anomalies, ASD.
- Cardiac catheterization: Generally not indicated unless concern is present regarding branch PA anatomy, coronary anatomy, or multiple additional VSDs that need to be defined before surgery
- MRI: Magnetic resonance imaging is commonly performed in older children/adults with repaired TOF to evaluate RV size and function and to determine severity of pulmonary valve leakage.

DIFFERENTIAL DIAGNOSIS

- TOF should be considered in all cyanotic infants with a heart murmur, or in children with a history of hypercyanotic spells.
- Important subtypes of TOF include:
 - TOF with pulmonary atresia: Pulmonary blood flow arises from the ductus arteriosus. These infants are prostaglandin-dependent and always require neonatal intervention.
 - TOF with absent pulmonary valve. These patients are often acyanotic, but may have significant airway complications due to bronchial compression/hypoplasia due to enlarged main and branch pulmonary arteries.
- Differential diagnosis if cyanotic: Transposition of the great arteries (TGA), tricuspid atresia (TA), total anomalous pulmonary venous return (TAPVR), truncus arteriosus, double-outlet right ventricle (DORV)
- Differential diagnosis if not cyanotic: VSD, DORV, peripheral pulmonic stenosis (PPS), valvular pulmonic stenosis (PS)

TREATMENT

MEDICATION (DRUGS)

Hypercyanotic spells (aka “tet spells”): Profound cyanosis due to infundibular spasm and decreased pulmonary blood flow.

- Knee–chest position:
- Oxygen
- Morphine sulfate (0.1 mg/kg IV or IM)
- IV fluid bolus and/or NaHCO₃
- Elevate the systemic blood pressure (fluids pressors, etc.)

- β -blocker (esmolol infusion for immediate therapy, propranolol for long-term prophylaxis)
- Phenylephrine (0.02 mg/kg IV)
- Presurgical management:
 - Polycythemia: Oral iron supplement for iron deficiency to avoid microcytosis
 - β -blocker for “tet spell” prophylaxis
 - Subacute bacterial endocarditis (SBE) prophylaxis

SURGERY/OTHER PROCEDURES

- Palliative surgery: Systemic-pulmonary shunt
- Corrective surgery: VSD patch closure and right ventricular outflow tract reconstruction (either an RV-to-PA conduit or a patched reconstruction of the MPA segment)

ONGOING CARE

PROGNOSIS

Generally good if condition treated surgically in a timely manner:

- >90% of children with TOF are expected to survive to adulthood.
- Surgical mortality is low in most centers: 5-year survival >95%, 20-year survival ~94%
- Long-term quality of life in adulthood is comparable with that of the general population.
- Young patients with TOF have a greater risk of requiring additional help in school.
- Residual hemodynamic abnormalities are quite common
- Pulmonary insufficiency (PI) is common with transannular patch repair:
- Residual RVOTO may occur.
- Right ventricular dysfunction +/- ventricular arrhythmias in adulthood from right ventricular volume overload secondary to PI

- In the setting of severe RV dysfunction and dilatation due to severe PI, some patients require surgical revision of the right ventricular outflow tract in adolescence or adulthood
- Left PA stenosis
- Residual VSD occurs rarely
- Conduction abnormalities (e.g., complete heart block, right bundle branch block [RBBB])
- Supraventricular and ventricular arrhythmias

COMPLICATIONS

Preoperatively:

- Paroxysmal hypoxic spells (i.e., hypercyanotic spells, “tet spell”)
- Bacterial endocarditis
- Cerebrovascular accident (CVA) secondary to cyanosis, polycythemia, and microcytic anemia
- Postoperatively: Right ventricular dysfunction and ventricular arrhythmia. Postoperative sudden death (ventricular arrhythmias and/or complete heart block). Exercise intolerance and dyspnea due to severe RV dilatation/dysfunction in the setting of PI

CODES

ICD9

745.2 Tetralogy of fallot

ICD10

Q21.3 Tetralogy of Fallot

FAQ

- Q: What is the etiology of the “tet spell”?
- A: There is an increased impedance to flow through the RVOT and/or pulmonary vascular bed that leads to a dramatic decrease in pulmonary blood flow and an increased right→left shunt at the level of the VSD. Therefore, treatment should be aimed at increasing pulmonary blood flow either by decreasing pulmonary vascular resistance (e.g., O₂, morphine) or increasing systemic vascular resistance (e.g., knee–chest position, phenylephrine) or decreasing dynamic obstruction by decreasing heart rate and thus increasing RV preload (e.g., β -blockers).
- Q: When is an optimal time for surgical repair of TOF?
- A: At The Children’s Hospital of Philadelphia, elective repair of “typical” TOF is performed in early infancy (3–6 months). Progressive hypoxemia or recurrent “tet spell” indicates a need for earlier surgical intervention. Patients with TOF with pulmonary atresia are treated in the newborn period or infancy, and patients with TOF with absent pulmonary valve are treated on a patient-by-patient basis dictated by the degree of airway disease.

THALASSEMIA

Peter de Blank
Janet Kwiatkowski (5th edition)

BASICS

DESCRIPTION

Thalassemia syndromes are hereditary microcytic anemias that result from mutations that quantitatively reduce globin synthesis.

- Normal hemoglobin is a tetramer of 2 α and 2 β chains:
 - α -Thalassemia: Reduced or absent α -globin production
 - β -Thalassemia: Reduced or absent β -globin production

GENERAL PREVENTION

Thalassemia can be prevented by identifying and counseling potential parents who can have children with thalassemia. Diagnosis can be made in early pregnancy by chorionic villus sampling.

EPIDEMIOLOGY

- α -Thalassemia: Predominantly in Chinese subcontinent, Malaysia, Indochina, and Africa, and in African Americans
- β -Thalassemia: Mediterranean countries, Africa, India, Pakistan, Middle East, and China

Genetics

- α -Thalassemia:
 - Normally, there are 4 α -globin genes, 2 on each chromosome 16.
 - Most mutations in α -thalassemia are large deletions.
 - Deletions may be in *trans* conformation (1 deletion on each chromosome, common in African Americans) or *cis* conformation (2 genes deleted on same chromosome, common in Asians).
 - Hemoglobin Constant Spring is an α -globin gene mutation caused by a point mutation that reduces or eliminates production of α -globin, leading to a more severe phenotype.
 - The 4 α -thalassemia syndromes reflect the inheritance of molecular defects affecting the output of 1, 2, 3, or 4 α genes.
- β -Thalassemia:
 - Normally, there are 2 β -globin genes, 1 on each chromosome 11.
 - Most mutations in β -thalassemia are point mutations.
 - Many mutations abolish the expression completely (β^0), whereas others variably decrease quantitative expression ($\beta+$).
 - Heterozygous state for β -globin mutation produces β -thalassemia trait.
 - Homozygous state produces β -thalassemia major or β -thalassemia intermedia.
 - NOTE: Rare dominant β -thalassemia mutations exist, causing ineffective erythropoiesis with a single mutation (due to creation of unstable β -globin variants)

Genotype	Name	Degree of anemia
α thalassemia		
$\alpha\alpha/\alpha-$	Silent carrier	Asymptomatic
$\alpha-\alpha-$ or $\alpha\alpha/--$	α -thalassemia trait	Asymptomatic
$\alpha-/-$	α -thalassemia intermedia, HbH disease	Moderate to severe
$--/--$	α -thalassemia major	Hydrops fetalis
β -thalassemia		
$\beta\beta/+$ or β/β^0	β thalassemia trait	Asymptomatic
β/β^0 or $\beta+/+$	β thalassemia intermedia	Variable, intermittent or chronic transfusions
$\beta^0/\beta+$ or β^0/β^0	β thalassemia major	Severe, chronic transfusions

PATHOPHYSIOLOGY

- Decrease in either α - or β -globin synthesis leads to fewer completed $\alpha_2\beta_2$ tetramers produced per RBC, which results in a decrease in intracellular hemoglobin and microcytosis.
- Unpaired globin chains precipitate resulting in apoptosis of red cell precursors (ineffective erythropoiesis) and damage to the RBC membrane leading to hemolysis.
- Ineffective erythropoiesis causes hepatosplenomegaly and osseous changes.
- The erythrocyte's life span is shortened by hemolysis and splenic trapping.
- Degree of anemia varies depending on the specific gene defect.
- Chronic transfusion therapy, and to a lesser degree, increased absorption of dietary iron in thalassemia major lead to iron accumulation.
- Increased absorption of dietary iron and intermittent transfusions in thalassemia intermedia lead to iron accumulation.
- Iron overload leads to cardiac arrhythmias and congestive heart failure (CHF) that can be fatal, liver inflammation and fibrosis, and endocrinopathies (e.g., diabetes mellitus, hypothyroidism, gonadal failure), osteoporosis.

DIAGNOSIS

HISTORY

- Severe α -thalassemia (4 gene deletion) presents prenatally by ultrasound or at birth with hydrops fetalis and severe anemia.
- Severe β -thalassemia usually presents between 3 and 12 months old, as the production of the normal fetal hemoglobin decreases.
- α -Thalassemia syndromes will present with microcytosis in infancy. Hemoglobin H disease may present later, with mild to moderate anemia on screening or after worsening hemolysis related to intercurrent infection.
- Mediterranean, African, or Asian are common ethnic backgrounds in patients with thalassemia.
- Familial history of anemia, long-term transfusions, recurrent iron therapy for presumed iron-deficiency anemia, or splenectomy. Siblings and/or parents may be affected.

PHYSICAL EXAM

- Pallor indicates anemia.
- Heart murmur: Flow murmurs are often heard in significant anemia. Patients with severe anemia may present with CHF.
- Variable degrees of icterus: Hemolysis leads to increased bilirubin production.
- Abnormal facies (frontal bossing and maxillary hyperplasia): Facial bone expansion by hypertrophic marrow in poorly transfused patients with β -thalassemia
- Failure to thrive: Related to anemia and energy expended in ineffective erythropoiesis
- Variable degrees of hepatosplenomegaly (or CHF) due to extramedullary hematopoiesis

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- CBC with RBC indices:
 - Mean cell volume, mean cell hemoglobin, and mean cell hemoglobin concentration are all decreased in both α - and β -thalassemia.
 - RBC volume distribution width is usually normal.
 - Mentzer index [MCV/(RBC count)] can distinguish thalassemia trait from iron-deficiency anemia:
 - <13 suggests thalassemia
 - >13 suggests iron deficiency anemia
 - Peripheral smear may reveal microcytosis, hypochromia, anisocytosis, poikilocytosis, target cells, nucleated RBCs, and/or polychromasia.
 - Hemoglobin 9–12 g/dL in α - or β -thalassemia trait
 - Hemoglobin usually 7–10 g/dL in HbH disease
 - Hemoglobin usually 7–10 g/dL in β -thalassemia intermedia
 - Hemoglobin <7 g/dL in thalassemia major (without transfusions)
- Reticulocyte count: Usually mildly elevated in HbH and β -thalassemia intermedia and major
- Indirect bilirubin: May be elevated in severe thalassemia where there is significant red cell destruction

- Hemoglobin electrophoresis:
 - α -Thalassemia trait (2 defective genes) will have 5–10% Hb Barts (a tetramer of 4 γ chains) at birth, which should be detected on the newborn's screen. This disappears in 1–2 months, after which time the electrophoresis will be normal in α -thalassemia trait.
 - β -Thalassemia trait: HbF 1–5%, HbA2 3.5–8%, remainder HbA. The elevated HbA2 will distinguish α - from β -thalassemia trait.
 - HbH disease (3 defective α genes): 5–30% HbH (β_4), remainder HbA
 - Hydrops fetalis (4 defective α genes): Mainly Hb Barts(γ_4)
 - β -Thalassemia major (2 defective β genes): HbF 20–100%, HbA2 2–7%. In most cases, little or no HbA is detected, unless recently transfused.
- Iron studies, serum ferritin: Useful to help distinguish thalassemia from iron deficiency

DIFFERENTIAL DIAGNOSIS

- Iron deficiency anemia can be distinguished with iron studies.
- Anemia of chronic inflammation (can be distinguished with soluble transferrin receptor assay)
- Lead poisoning

TREATMENT

- Silent carriers (single α gene deletion) and α -and β -thalassemia trait:
 - Genetic counseling only
 - Distinguish from iron deficiency microcytosis to avoid excess iron supplementation.
- For HbH disease:
 - Folic acid daily
 - Transfusions whenever necessary (aplastic episode, infection)
 - Splenectomy if evidence of hypersplenism
 - Cholecystectomy if necessary
- For β -thalassemia intermedia:
 - Folic acid daily
 - No iron supplements
 - Transfusions whenever necessary (aplastic episode, infection, acute complication)
 - Splenectomy less commonly performed due to increased risk of thrombosis and pulmonary hypertension.
 - Cholecystectomy if necessary
 - HbF-inducing agents such as hydroxyurea may be beneficial.
 - Monitoring and treatment of iron overload
- β -Thalassemia major:
 - Stem cell transplantation (umbilical cord blood or bone marrow) using histocompatible sibling donor can cure the disease and is being used more frequently.
 - Regular transfusions of RBCs every 3–4 weeks to maintain Hb at 9–10 g/dL
 - Chelation therapy: It is important to balance the treatment of iron overload with the dangers of overchelation (toxicity to ears, eyes, bone).

- Chelation options include:
 - Deferoxamine (SC or IV infusion over 8–24 hours)
 - Deferasirox (once daily PO chelator). Side effect include GI discomfort, rash, renal failure +/- proteinuria, hepatic failure
 - Deferiprone (currently available in the US only through compassionate use protocol). Especially good for cardiac iron removal. Side effects include arthropathy, GI upset, agranulocytosis.
- Folic acid daily
- Penicillin prophylaxis (125–250 mg b.i.d.) for splenectomized patients
- *Pneumococcus*, *Meningococcus*, and *Haemophilus influenzae* vaccines before splenectomy and annual influenza A vaccination
- Cholecystectomy if indicated
- No iron supplements
- Genetic counseling for those with any thalassemia syndrome

ALERT

Thalassemia trait is often treated incorrectly as presumptive iron-deficiency anemia. Iron studies should be performed to confirm the diagnosis if there is no improvement in Hb level after a few weeks of iron therapy.

ONGOING CARE

For patients with thalassemia major and intermedia:

- Serum ferritin, blood chemistries, and liver function tests should be monitored.
- Annual monitoring for cardiac complications (echocardiogram, EKG) and endocrine function is recommended.
- Liver iron quantitation by biopsy, MRI, or other techniques are necessary intermittently to quantitate the status of iron overload accurately.
- Newer cardiac T₂* MRI techniques to assess the degree of cardiac iron loading, which correlates with risk of cardiac complications.
- Annual audiologic and ophthalmologic screening is recommended for persons receiving chelation therapy (to monitor for chelator toxicity).
- DXA scan or bone peripheral quantitative computed tomography (PQCT) annually

PROGNOSIS

- Life expectancy for patients with β -thalassemia major has improved over the years because of regular transfusions and chelation therapy.
- Bone marrow transplant from a histocompatible sibling donor may be curative.

COMPLICATIONS

Most complications occur in patients with β -thalassemia intermedia or major and can be divided into 2 categories

- Complications related to anemia/ineffective erythropoiesis and hemolysis (seen mostly in thalassemia intermedia):
 - Skeletal abnormalities secondary to hyperplastic marrow
 - Osteopenia, osteoporosis, and fractures
 - Growth retardation

- Extramedullary hematopoiesis
- Leg ulcers
- CHF owing to severe anemia
- Thrombophilia, particularly in thalassemia intermedia after splenectomy
- Hypercoagulability: DVT, PE
- Gallstones from hemolysis
- Pulmonary hypertension
- Allo- or auto-immunization with RBC antibodies
- Complications of iron overload:
 - Cardiac abnormalities: Pericarditis, arrhythmias, CHF
 - Hepatic abnormalities: Cirrhosis and liver failure (onset usually after second decade)
 - Endocrine disturbances: Delayed puberty, growth retardation, diabetes mellitus, hypothyroidism, hypoparathyroidism
 - Infection: Particularly *Yersinia* species

- D56.9 Thalassemia, unspecified

FAQ

- Q: Is prenatal testing available?
- A: Yes.
- Q: In a transfused patient, when does iron overload become a problem and when is chelation started?
- A: Usually after the age of 3–4 years.
- Q: At what age should monitoring for cardiac iron overload begin in β -thalassemia major?
- A: 6–10 years of age.

THORACIC INSUFFICIENCY SYNDROME

Fiona M. Healy

Robert M. Campbell, Jr.

Oscar H. Mayer

BASICS

DESCRIPTION

- Thoracic insufficiency syndrome (TIS) is the inability of the thorax to support normal respiration or lung growth.
- Patients are skeletally immature with varied anatomic deformities that often include:
 - Flail chest syndrome: Rib absence due to a congenital malformation or chest wall tumor resection, rib instability in cerebrocostomandibular syndrome, and others
 - Constrictive chest wall syndrome, including rib fusion and scoliosis: VACTERL association, chest wall scarring from radiation treatment, windswept deformity of the chest from progressive scoliosis, and others
 - Hypoplastic thorax syndrome including Jeune syndrome, Jarcho-Levin syndrome, Ellis-van Creveld syndrome, spondylothoracic dysplasia (STD), and others
 - Progressive congenital scoliosis (without rib anomaly) or neuromuscular scoliosis
- The recognizable anatomic abnormalities often occur before respiratory insufficiency, with patients compensating for low lung volumes and poor respiratory mechanics with an increased respiratory rate.
- Subsequently decreased activity and chronic respiratory insufficiency

PATHOPHYSIOLOGY

- The thorax is the respiratory pump, requiring an adequate diaphragm (abdominal) and chest wall movement. Limitation in resting volume (functional residual capacity [FRC] and/or the ability of the rib cage to expand during respiration can significantly alter respiratory function and cause TIS.
- The window of rapid lung growth and alveolar development is during the first 3 years of life, although alveolar development is felt to continue through 5 or 8 years of age, if not longer. Without concurrent thoracic growth, however, the lung cannot grow normally.
- Growth of the thoracic pump is also necessary so that the respiratory system can continue to meet a patient's metabolic demands. Thoracic spinal height (TSH) directly contributes to thoracic volume and lung volume. At birth, the TSH is 13 cm normally, then during the first 5 years of life, thoracic spinal growth is 1.4 cm/year, 0.6 cm/year from 5–10 years, and 1.2 cm/year from 10–18 years of age. A thoracic length of 22 cm at skeletal maturity, the normal TSH of a 10 year old, appears to be the minimum height necessary for normal respiration.

- Complex scoliosis spinal rotation with spinal lordosis into the convex hemithorax, the “windswept” deformity of the thorax, can further diminish transverse volume available for lung growth.
- Unilateral caudal rotation of the ribs in neuromuscular disease, the “collapsing parasol deformity,” typically occurs on the convex side of the scoliosis and may also severely narrow the thorax, worsen thoracic mechanics, and further increase work of breathing.

ETIOLOGY

- The etiologies of TIS can be grouped into unilateral or bilateral volume depletion deformities (VDDs) of the thorax that reduce the volume available for the lungs in certain subsets of patients with rare syndromes. This causes primary TIS, or deformity of the chest from scoliosis.
- In addition, progressive congenital scoliosis without rib anomalies can result in TIS from a variant of type II VDD of the thorax.
- Type IIIB VDD of the thorax can also develop in neurogenic scoliosis, as in spinal muscular atrophy with marked intercostal muscle weakness.
- Spinal deformity, such as lumbar kyphosis in spina bifida, collapses the torso into the pelvis, raising abdominal pressure that blocks diaphragm excursion, causing secondary TIS.

COMMONLY ASSOCIATED CONDITIONS

- Congenital renal abnormalities can occur in 33% of congenital scoliosis.
- Cervical spine abnormalities, causing stenosis and proximal instability
- Spinal cord abnormalities, including spinal cord syrinx and tethered cord, which are especially prevalent in meningomyelocele
- Jeune syndrome:
 - Congenital renal abnormalities
 - Hepatic fibrosis
 - Cervical spinal stenosis in 60% of cases
- Ellis-van Creveld syndrome
- STD:33% have congenital diaphragmatic hernia
- Cerebrocostomandibular syndrome, Pierre Robin syndrome: Mmicrognathia
- Severe tracheal compression and severe narrowing can occur in advanced scoliosis or severe anteroposterior narrowing.

DIAGNOSIS

HISTORY

- Onset of clinical scoliosis
- Onset of respiratory symptoms:
 - Relative exertional intolerance
 - Ineffective cough
 - Pneumonia
 - Hospitalizations for respiratory symptoms
 - Need for supplemental oxygen or ventilator support (BiPAP or CPAP)
- Progression of the spinal or chest wall deformity
- Current symptoms:
 - Chronic respiratory insufficiency
 - Exertional limitation relative to age and gross motor capability
 - Recurrent respiratory illnesses
 - Balance problems
 - Back pain

PHYSICAL EXAM

- Comprehensive respiratory examination:
 - Assessment of work of breathing including accessory muscle use and thoracoabdominal asynchrony
 - Qualitative assessment of chest wall compliance and motion
- Visual assessment
- Thumb excursion test: The palms of each hand are loosely positioned posteriorly over each side of the chest with the thumbs aligned on either side of the spinal column, and relative excursion is assessed by the amount of lateral thumb movement.
- Assessment for rib hump by having the patient bend forward while standing upright
- Measure of liver size to evaluate for hepatomegaly and possible cor pulmonale

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Serum bicarbonate as an indirect assessment for chronic hypoventilation
- Arterial blood gas if there is a concern for acute respiratory failure
- Liver function testing to assess for coincident liver failure
- Brain-type natriuretic peptide to help assess for progressive heart strain or failure
- Genetic testing as indicated based on suspected underlying condition

Imaging

- Standing anteroposterior and lateral radiographs to establish severity of scoliosis in the sagittal and coronal planes; bending films to establish the flexibility of the curve
- Chest CT scan with 5-mm cuts noncontrast with optimal pediatric settings to minimize radiation, with spinal and chest wall reconstruction to assess in 3-dimensional orientation
- MRI of spine and spinal cord to look for spinal cord abnormality
- Additional radiologic testing may be employed in certain cases (e.g., ventilation-perfusion scan of the lungs to quantify right vs. left functional perfusion asymmetry)
- Echocardiogram to evaluate for cor pulmonale and pulmonary hypertension

Diagnostic Procedures/Other

- Pulmonary assessment:
 - Pulmonary function testing
 - Dynamic lung volumes and flows:
 - Forced vital capacity (FVC)
 - Timed expiratory volume (forced expiratory volume in 0.5 or 1 second) and the ratio to FVC
 - Forced expiratory flow between 25% and 75% of vital capacity (FEF 25–75%)
 - Static lung volume measurements:
 - Total lung capacity (TLC), FRC, residual volume (RV), and RV/TLC
 - Specialized measurements of respiratory system compliance (stiffness) and partitioned measurements of chest wall and lung compliance
 - Pulse oximetry and end-tidal carbon dioxide measurement
 - Overnight polysomnography to assess the degree of underlying respiratory insufficiency and need for supplemental oxygen or noninvasive ventilation
 - Exercise testing adapted for the capabilities of the patient (6-minute walk test) can be used to assess for exertional limitation.
- Genetic assessment:
 - If there is significant thoracospinal abnormality and certainly if there is other dysmorphology, a genetics assessment is very helpful to comprehensively assess for an underlying disorder.

TREATMENT

ADDITIONAL TREATMENT

General Measures

- Bracing and halo-gravity traction can be used as a temporizing procedure and at best has been shown to control some forms of scoliosis or partially improve, but not correct, scoliosis.
- Physical and occupational therapy

SURGERY/OTHER PROCEDURES

- The goal of surgical treatment of TIS is to gain the biggest, most symmetrical, and most functional thorax by skeletal maturity through repeated expansions of the chest wall along with spinal growth and correction of spinal deformity without the growth inhibition effects of spinal fusion.
- Vertical expandable prosthetic titanium rib (VEPTR) expansion thoracoplasty techniques enable five types of acute thoracic reconstructions to handle each of the subtypes of TIS. The procedure can be performed as early as 6 months of age to exploit the growth potential of the developing lungs and provide additional thoracic volume and compensatory lung growth. After implantation to stabilize the initial thoracospinal reconstruction, it can then be expanded about every 6 months commensurate with patient growth until skeletal maturity.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- After TIS surgery, patients are followed with radiographs at regular intervals.
- Pulmonary follow-up should include careful assessment for respiratory insufficiency.
- Longitudinal measure of lung function and growth to demonstrate an improvement in respiratory status or lung function, or at the very least a decrease in the rate of decline, in the most severely affected patients

PROGNOSIS

- Prognosis will vary depending on the underlying cause of TIS, severity of respiratory insufficiency, and the age of the patient at surgery.
- For older patients near skeletal maturity, the focus is chest wall reconstruction and spinal stabilization, hopefully with stabilization in pulmonary function. Significant improvement in vital capacity is doubtful because of late onset in treatment.
- The expectation in infancy would be for growth preservation and an increase in lung volume above the preoperative value as a percent of predicted. There does appear to be an inverse relationship between the age of the patient at the time of surgery and the level of positive impact of VEPTR insertion on lung function.

- Jeune syndrome is one of the more severe forms of TIS with 60–70% mortality in early infancy from respiratory failure. However, after VEPTR insertion, the outcomes are more favorable.
- Of those patients with TIS due to an STD, 47% die in infancy from respiratory complications and pulmonary hypertension. VEPTR treatment of STD is controversial.

COMPLICATIONS

- In the immediate postoperative period—wound infection, skin slough, and bleeding
- Migration of fixation over 3–5 years
- Device breakage is very uncommon.
- Neurologic complications are rare.

- 518.82 Other pulmonary insufficiency, not elsewhere classified
- 786.09 Other respiratory abnormalities

ICD10

- R06.89 Other abnormalities of breathing

THROMBOSIS

Char Witmer

BASICS

DEFINITION

Pathologic arterial or venous intravascular occlusion secondary to abnormal thrombus formation.

The following are common thrombotic events:

- Deep venous thrombosis (DVT): Involves large systemic veins outside CNS
- Cerebral sinovenous thrombosis: Involves intracranial venous sinuses
- Ischemic stroke: CNS arterial occlusion with infarction of brain tissue
- Intracardiac thrombosis: Mural, valvular, or foreign body associated
- Femoral artery thrombosis: Can be associated with vessel catheterization
- Renal vein thrombosis: Commonly in the neonatal period; may be unilateral or bilateral
- Myocardial infarction: Kawasaki disease, antiphospholipid antibody syndrome or with severe familial hypercholesterolemia
- Budd–Chiari syndrome: Thrombosis of the hepatic vein
- Portal vein thrombosis

EPIDEMIOLOGY

- Incidence of venous thrombosis in children is estimated at 0.7 per 100,000 per year. It is likely that the actual incidence is higher.
- Age distribution is bimodal, peak rates in the neonatal and adolescent age groups
- Idiopathic thrombosis is rare in children.
- >90% of pediatric venous thrombosis is associated with additional risk factors.
- Central venous lines are the most common risk factor for venous thrombosis in children.

RISK FACTORS

- **Neonatal**
 - Prematurity
 - Maternal diabetes
 - Umbilical catheters or other central lines
 - Sepsis
 - Polycythemia
 - Perinatal asphyxia
- **Malignancy/bone marrow disorders**
 - Leukemia (hyperleukocytosis, acute promyelocytic leukemia)
 - Myeloproliferative disorders
 - Paroxysmal nocturnal hemoglobinuria
- **Medications**
 - L-Asparaginase
 - Oral contraceptives
 - Heparin-induced thrombocytopenia
 - Steroids
- **Anatomic**
 - Indwelling catheters
 - Congenital heart disease
 - Prosthetic heart valves
 - Intracardiac baffles
 - Tumor compression
 - Atresia of the inferior vena cava
 - Thoracic outlet obstruction (Paget–Schroetter syndrome)
 - May–Thurner syndrome (compression of the left iliac vein by the artery crossing over it)

Miscellaneous

- Infection
- Trauma
- Surgery
- Obesity
- Prolonged immobilization or paralysis
- Dehydration
- Antiphospholipid syndrome

Risk factors/conditions specific for arterial disease

- Kawasaki disease
- Takayasu arteritis
- Hyperlipidemia
- Antiphospholipid syndrome

COMMONLY ASSOCIATED CONDITIONS

- Nephrotic syndrome
- Inflammatory disorders
- Liver disease
- Sickle cell disease
- Diabetes mellitus

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Primary prothrombotic states:

- **Inherited**
 - Factor V Leiden gene mutation
 - Prothrombin 20210A gene mutation
 - Protein C deficiency
 - Protein S deficiency
 - Antithrombin deficiency
 - Homocystinemia (mild to moderate) from minor defects in enzymes such as methylenetetrahydrofolate reductase or severe in homocystinuria
 - Elevated lipoprotein(a)
 - Plasminogen deficiency
 - Dysfibrinogenemia
 - Heparin cofactor II deficiency
- **Acquired:** Antiphospholipid antibody syndrome

ALERT

- Normal ranges for coagulation tests are age dependent: Diagnosing an inherited deficiency in any of the anticoagulant proteins can be difficult in the neonatal period. Repeat testing at 6–12 months of age is necessary.
- Consumption can occur during acute thrombosis; therefore, low levels of the anticoagulant proteins must be repeated.
- Warfarin will decrease the levels of protein C, protein S, and clotting factors II, VII, IX, and X.

APPROACH TO THE PATIENT

- **Phase 1:** Perform complete history and physical exam; establish diagnosis using the appropriate radiographic study
- **Phase 2:** Send initial laboratory studies (CBC, PT/aPTT, D-dimer, β -hCG testing in postmenarchal females and antithrombin) and begin anticoagulation therapy with unfractionated heparin or low-molecular-weight heparin. Patients with life- or limb-threatening thrombosis may require thrombolysis.
- **Phase 3:** Complete lab workup for hypercoagulable state; outpatient anticoagulation; follow thrombosis radiologically

HISTORY

Presence of risk factors previously listed

- **Question:** Current (or recent) central venous or arterial catheter?
- **Significance:** Most significant risk factor for thrombosis
- **Question:** Family history of thrombosis?
- **Significance:** May be an inherited thrombophilia
- **Question:** Personal history of thrombosis?
- **Significance:** Patients with history of thrombosis are at increased risk of recurrence.
- **Question:** Neonatal seizure?
- **Significance:** Common and often the only presenting sign for cerebral sinovenous thrombosis or arterial ischemic stroke
- **Question:** Chest pain or shortness of breath?
- **Significance:** Suggestive of pulmonary embolism

PHYSICAL EXAM

- **Finding:** Unilateral swelling/edema of a limb?
- **Significance:** Extremity DVT
- **Finding:** Bilateral lower extremity edema of a limb?
- **Significance:** Thrombosis of the inferior vena cava
- **Finding:** Plethoric, swollen head and neck?
- **Significance:** Superior vena cava syndrome
- **Finding:** Pale extremity with decreased perfusion/pulses?
- **Significance:** Arterial thrombosis
- **Finding:** Abdominal mass in neonate with hematuria?
- **Significance:** Renal vein thrombosis
- **Finding:** Tachypnea, shallow respirations?
- **Significance:** Pulmonary embolism
- **Finding:** Unexplained hepatosplenomegaly?
- **Significance:** Hepatic or portal vein thrombosis
- **Finding:** Superficial dilated cutaneous veins distal to the site of venous occlusion?
- **Significance:** Post-thrombotic syndrome
- **Finding:** Chronic discoloration (darkening) of the skin, ulcerations, pain, intermittent swelling?
- **Significance:** Post-thrombotic syndrome

DIAGNOSTIC TESTS & INTERPRETATION

- General evaluation of the hemostatic system:
 - PT, aPTT, fibrinogen
 - CBC with platelet count
 - D-dimer
 - β -hCG in postmenarchal female
- The following tests are used to investigate for a prothrombotic state:
 - Phase 1:
 - Factor V Leiden mutation analysis
 - Prothrombin 20210A mutation analysis
 - Lupus anticoagulant screen (dilute Russell viper venom time, aPTT)
 - Anticardiolipin antibodies (IgG, IgM)
 - Anti- β 2-glycoprotein antibodies (IgG, IgM)
 - Protein C activity
 - Protein S activity
 - Antithrombin activity
 - Fasting homocysteine
 - Fasting lipoprotein(a)
 - Factor VIII activity

- Phase 2: For patients whose phase 1 studies are normal, but there is a strong family history of thrombosis:
 - Plasminogen
 - Thrombin time or dysfibrinogenemia screen
 - Activated protein C resistance clotting assay
 - Heparin cofactor II
 - Plasminogen activator inhibitor type 1
 - Factor IX and XI activity

Imaging

Radiologists should be consulted for choosing the best imaging study for diagnosis and follow-up.

- Contrast angiography: Gold standard, but invasive and sometimes technically difficult to perform in small children
- Ultrasound: Most commonly used imaging study because of noninvasiveness, absence of radiation, and ability to be performed at the bedside
- In the diagnosis of upper extremity-related DVT, often a combination of ultrasound and venography is necessary:
 - Compression ultrasound of the upper central veins may be impeded by the distal end of the clavicle.
 - Venography has poor sensitivity for diagnosing thrombosis of the internal jugular veins.
 - Recommended approach for diagnosis of an upper extremity thrombosis is to start with ultrasound and proceed to venography if the ultrasound is normal and there is a high clinical suspicion for thrombosis.
- Echocardiogram may be useful in evaluating atrial thrombi, which may result from central venous catheters.
- Pulmonary angiography, ventilation–perfusion scans, and spiral CT scans are the imaging studies used for the diagnosis of pulmonary embolism, although none of these have been studied in children.
- In patients with a pulmonary embolism, it is important to look for a source of thrombosis in the upper and lower extremities.
- Other diagnostic imaging options include CT or MRV:
 - Noninvasive
 - Sensitivity and specificity not known
 - May be helpful in evaluating proximal thrombosis
- For diagnosis of cerebral sinovenous thrombosis, the most sensitive imaging study is a brain MRI with venography.

TREATMENT

- Unfractionated heparin:
 - Given as a bolus followed by an infusion, adjusted to maintain the aPTT at 1.5–2.5 times baseline
 - Younger children require higher doses of heparin to achieve a therapeutic level secondary to physiologically decreased antithrombin levels.
- Low-molecular-weight heparin:
 - More predictable dose response
 - Given subcutaneously twice a day
 - Equivalent in efficacy to unfractionated heparin in the acute management of uncomplicated DVT
 - Renal clearance
- Thrombolytic therapy:
 - Recombinant tissue plasminogen activator
 - May be given systemically or locally
 - High risk of bleeding

- Warfarin:
 - Oral anticoagulant
 - Initially started when a patient is already receiving a form of heparin. The heparin is discontinued when the warfarin is in the therapeutic range.
 - Warfarin is adjusted to maintain an international normalized ratio (INR) of 2.0–3.0 for treatment of DVT
 - Used for outpatient management
- Aspirin:
 - Beneficial in stroke and other arterial events
 - Irreversibly inhibits platelet function

General Measures

- Therapy for acute thrombosis and long-term management is individualized.
- Consult a pediatric hematologist or someone with expertise in pediatric anticoagulant therapy.

ONGOING CARE

COMPLICATIONS

- Inferior vena cava filters are used to prevent pulmonary embolism. There are limited pediatric studies. They should only be considered in the setting of a lower extremity DVT with a contraindication to anticoagulation (i.e., recent extensive surgery or active bleeding) or if a patient experiences a pulmonary embolism while on therapeutic anticoagulation. Temporary filters should be placed and removed as soon as possible as they are a nidus for further thrombosis formation. The risk/benefit ratio needs to be considered individually.
- Vary depending on the location and severity of the thrombosis
- In DVT, pulmonary embolism is the most significant acute complication. Recurrent thrombosis and post-thrombotic syndrome are common chronic complications.
- In arterial thromboembolic disease, the ischemic injury to the involved organ determines the acute and long-term complications.

ALERT

- Central venous catheter-related thrombosis may be subtle despite extensive damage to the venous system. Recurrent line infection, line occlusion, and prominent venous collaterals on the chest suggest upper extremity DVT. The long-term consequences of this are not known.
- Warfarin can cause purpura fulminans if started in a non-heparinized patient.

FAQ

- Q: If an inherited prothrombotic condition is identified, should family members be tested?
- A: Yes, if they have other risk factors for thrombosis such as malignancy, major surgery, oral contraceptives, or obesity.
- Q: When is it appropriate to use low-molecular-weight heparin rather than unfractionated heparin?
- A: There are several potential advantages to low-molecular-weight heparin. The pharmacokinetics is much more predictable, and frequent monitoring is not necessary. It is administered subcutaneously, not intravenously. The risk of bleeding may be slightly lower. Low-molecular-weight heparin cannot be completely reversed with protamine and it is renally cleared.
- Q: When is it appropriate to use thrombolytic therapy?
- A: Studies do not clearly demonstrate a role for thrombolytic therapy in deep venous thrombosis. However, if a thrombus is high risk (i.e., limb-threatening), thrombolytic therapy can be used. Intracranial bleeding, other active bleeding and surgery within 7 days are contraindications to thrombolytic therapy. For arterial thrombotic events, thrombolytic therapy is often the treatment of choice because of the rapid resolution of the clot and restoration of blood flow.
- Q: What precautions should be taken for invasive procedures and for athletics when a patient is on anticoagulant therapy?
- A: Lumbar punctures, arterial punctures, and surgical procedures should be avoided. If they are necessary, then the child should have the anticoagulant reversed or held before the procedure. The child should not participate in contact sports such as football, karate, and boxing.

TICK FEVER

Brian T. Fisher

BASICS

DESCRIPTION

- Both endemic relapsing fever and Colorado tick fever (CTF) will be discussed in this chapter.
- Relapsing fever in its endemic form is a vector-borne infection with characteristic recurrent fevers caused by several species of spirochetes of the genus *Borrelia*. In the US, the vector for endemic relapsing fever is ticks of the genus *Ornithodoros*. Epidemic relapsing fever is transmitted by the body louse and is no longer found in the US.
- CTF is a febrile, usually benign, systemic illness caused by a double-stranded RNA coltivirus in the family Reoviridae and transmitted by a tick bite. Although the primary reservoir for infection is the *Dermacentor andersoni* tick, the causative organism has been isolated from many other ticks. The virus is referred to as Colorado tick fever virus.

EPIDEMIOLOGY

- Endemic relapsing fever:
 - Reported in almost all western states up to and including Texas.
 - Sites of high exposure include limestone caves and forested areas.
 - Most cases present during June through September; ~450 cases were reported in the US between 1977 and 2000.
 - Infection in the United States most commonly occurs after exposure to *Ornithodoros hermsi* and *Ornithodoros turicata*. The former feeds on rodents in forests at elevations of 1,500–8,000 feet, while the latter prefer drier locations at lower elevations.
- CTF:
 - Human infections typically occur in areas where *D. andersoni* is found: Western US and southwestern Canada at elevations of 4,000–10,000 feet
 - Cases usually occur between April and July when adult ticks are most active. There are 200–400 reported cases in the US annually, but this may be an underestimation.
 - Infection is more common in males and the median age of those infected is 43 years but 25% of cases occur in those younger than 20 years.
- Transfusion-related and laboratory-associated infection are rare but have been reported.

GENERAL PREVENTION

- Both of these infections can be prevented by avoidance or protection from the tick vector.
- Light-colored, long-sleeved shirts and pants should be worn when tick-infested areas cannot be avoided.
- Permethrin should be applied to clothing and diethyltoluamide (DEET) applied to exposed skin to help repel ticks.
- Persons who enter endemic areas should inspect themselves and each other frequently for adherent ticks.

- Avoid rodent-infested homes in endemic areas. If necessary, rodent-nesting materials should be removed with protective gloves.
- Confirmed cases should be reported to health authorities so that control measures can be instituted.

PATHOPHYSIOLOGY

- Endemic relapsing fever:
 - When an *Ornithodoros* tick feeds on a natural host (e.g., squirrels, chipmunks, and rodents), *Borrelia* subsequently invade all tissues of the tick including the salivary glands. Once infected, ticks remain capable of transmitting disease for many years. Transovarial infection of tick offspring is possible but is thought to be rare.
 - Ticks in the larval stage are unlikely to be infectious.
 - *Borrelia* is transmitted to humans when the tick takes a blood meal and then detaches itself. Transmission is possible after only 30 seconds of feeding.
 - *Ornithodoros* ticks typically feed at night and for short periods. The exposed person is often unaware of the tick bite.
 - After transmission, spirochetemia develops resulting in systemic symptoms. Antibody production ultimately leads to agglutination and phagocytosis of the spirochetes with symptom resolution.
 - The spirochete is capable of various strategies (e.g., spontaneous antigenic variation and sequestration in certain organs) to evade the immune system. This results in recurrent spirochetemia with associated febrile episodes. Tick-borne disease may relapse 10–15 times before final resolution.
 - Between episodes of spirochetemia, organisms likely persist in the CNS, bone marrow, liver, and spleen.
 - Pathologic findings in humans include petechial hemorrhages on visceral surfaces, hepatosplenomegaly, and a histiocytic myocarditis.
- CTF:
 - Ticks are infected during their larval stage when they feed on viremic, intermediate hosts such as chipmunks, ground squirrels, and porcupines.
 - Once infected, ticks remain infected for life (as long as 3 years)
 - Human infection typically takes place when the adult *D. andersoni* wood tick attaches and ingests a blood meal from an incidental human host.
 - CTF virus is thought to infect hematopoietic cells, causing leukopenia and prolonged viremia for up to 3–4 months.

ETIOLOGY

- Endemic relapsing fever is caused by several species of spirochetes in the genus *Borrelia*. *B. hermsii* and *B. turicatae* are the 2 most common species found in the US. Epidemic relapsing fever is caused by *B. recurrentis*, which is transmitted by *Pediculus humanus* (human body louse).
- CTF is caused by CTF virus, a double-stranded RNA coltivirus in the family Reoviridae.

DIAGNOSIS

HISTORY

- Both endemic relapsing fever and CTF most commonly present with symptoms including high fever, headache, myalgias, and chills. A thorough history documenting recent travel and a description of the fever curve are necessary to help direct the clinician to either diagnosis.
- Endemic relapsing fever:
 - Fevers present after a mean incubation period of 5–7 days (range 4–> 18 days). Symptoms resolve after 3–6 days but then recur within 7 days. Relapses may be less severe than the initial episode with prolonged asymptomatic intervals.
 - Patients commonly complain of headache, myalgia, nausea, vomiting, arthralgias, and abdominal pain. Less commonly, patients are symptomatic with confusion, dry cough, diarrhea, photophobia, rash, dysuria, or hepatosplenomegaly.
 - Patients rarely are aware of a recent tick bite.
- CTF:
 - CTF has a usual incubation period of 3–5 days (range 1–14 days):
 - In ~50% of patients, fever will present in a “saddleback” pattern. The fever persists for 2–3 days with resolution for 2–3 days. Fever then recurs and lasts for another 2–3 days. Some patients will have a 3rd febrile period.
 - Patients may complain of lethargy, photophobia, retro-orbital pain, and conjunctival injection.
 - Less commonly, patients will have gastrointestinal symptoms, pharyngitis, nuchal rigidity, and a rash.
 - Unlike endemic relapsing fever, 90% of patients presenting with CTF will have a previous history of tick exposure.

PHYSICAL EXAM

High fevers (39–41°C) are common to both endemic relapsing fever and CTF:

- Endemic relapsing fever:
 - In addition to the typical fever curve and symptoms described above, the clinical presentation is varied and the physician's exam should evaluate for, but not be limited to, the following:
 - Elevated pulse and BP are common.
 - Tender hepatosplenomegaly with jaundice
 - Nuchal rigidity suggesting meningitis
 - Gallop on cardiac auscultation suggesting underlying myocarditis
 - A macular rash starting on the trunk that becomes generalized and or petechial in nature
 - Neurologic deficits are less common but can include delirium, cranial nerve deficits (7th or 8th nerve palsy), and visual impairment from iridocyclitis.
- CTF:
 - Similar to that of endemic relapsing fever, the clinical presentation for CTF is varied but may include the following:
 - A small, red painless papule may be seen.
 - A maculopapular rash with petechial lesions has been reported in ~10% of cases.
 - Pharyngitis is reported in 20% of cases.
 - Hepatosplenomegaly has been found in some patients.
 - Nuchal rigidity and delirium are rare but, if present, suggest meningitis or encephalitis.

DIAGNOSTIC TESTS & INTERPRETATION

- Endemic relapsing fever:
 - The diagnosis can be readily made by identification of loosely coiled spirochetes on thin and thick smears of the peripheral blood. Blood samples taken at the time of fever have the highest yield.
 - Increased sensitivity can be obtained by examining Acridine orange–stained preparations of dehemoglobinized thick smears or buffy coat preparations.
 - The organism can only be cultured on special culture medium. Intraperitoneal inoculation of mice with the patient's blood can lead to spirochetemia in the mice.
 - Multiple serologic antibody studies exist, including direct and indirect immunofluorescence, ELISA, and immunoblot analysis:
 - A 4-fold rise in titers between acute and convalescent studies is considered confirmatory.
 - These studies may have false-positive reactions in patients with prior spirochete infections such as Lyme disease.
 - Polymerase chain reaction (PCR) analysis can be useful in identifying the causative organism but is not readily available.
 - Other nonspecific laboratory findings may include leukocytosis, anemia, thrombocytopenia, unconjugated hyperbilirubinemia, elevated hepatic transaminases, and proteinuria.
 - If myocarditis is present, an electrocardiogram can reveal abnormalities such as a prolonged corrected Q-T interval.
 - In cases complicated by meningitis, the CSF will typically have moderately elevated protein and a mononuclear pleocytosis.
- CTF:
 - PCR testing and viral cultures are available in certain laboratories. PCR testing is the most sensitive and timely approach for diagnosing acute infection.

- Various techniques (e.g., complement fixation, indirect immunofluorescence, EIA and Western blot) have been used to establish a serologic diagnosis:
 - Serologic testing for antibody presence is not diagnostic in the acute phase because antibodies are slow to rise. Presence of a 4-fold rise in neutralizing antibody titers at >2 weeks after onset can be confirmatory.
 - Associated laboratory findings include leukopenia and thrombocytopenia.
- In patients with meningitis or encephalitis, CSF studies may also reveal elevated protein and a lymphocytic pleocytosis.

DIFFERENTIAL DIAGNOSIS

- Endemic relapsing fever and CTF resemble each other clinically. Presence of biphasic or relapsing fever along with a history of travel to an area where appropriate vectors are found are helpful clues in diagnosing either disease. Leukopenia and a history of a tick bite may differentiate CTF from endemic relapsing fever.
- Relapsing fever and CTF may be misdiagnosed as influenza or enteroviral infections, especially with the 1st febrile episode.
- Other infectious illnesses that may present with recurrent fevers include but are not limited to yellow fever, dengue fever, lymphocytic choriomeningitis, brucellosis, malaria, leptospirosis, rat bite fever, and chronic meningococemia. The patient travel history and animal exposure should help differentiate among some of these diagnoses.

**TREATMENT****MEDICATION (DRUGS)**

- Endemic relapsing fever:
 - The treatment of choice is oral tetracycline/doxycycline for 7–10 days. Children <8 years of age and pregnant women should receive erythromycin or penicillin.
 - Newer macrolides may be effective but are not routinely recommended.
 - In > 50% of cases, treatment results in a Jarisch-Herxheimer reaction (severe fevers, rigors, diaphoresis, and hypotension) related to rapid clearing of the spirochetemia. Close observation, IV fluids, and good supportive care are important in treating possible reactions.
 - Some experts support the use of an initial single dose of oral penicillin (7.5 mg/kg) or IV penicillin G (10,000 U/kg given over 30 minutes) in patients presenting with systemic symptoms. It is thought that this initial dose of penicillin leads to gradual clearance of spirochetes decreasing the risk of the Jarisch-Herxheimer reaction. These patients should then receive a 10-day course of tetracycline or erythromycin because penicillin has been associated with an increased rate of relapse.
 - Single-dose tetracycline or erythromycin has been successful for the treatment of louse-borne epidemic relapsing fever in Ethiopia.
- CTF:
 - There is no specific therapy for patients with CTF. Treatment is primarily supportive.
 - Thrombocytopenia should be monitored closely because generalized bleeding rarely results in death of children.
- Ribavirin has been shown in animal studies to be helpful and thus could be considered in certain severe situations.

**ONGOING CARE****PROGNOSIS**

- Endemic relapsing fever:
 - Generally responds rapidly to appropriate antibiotic therapy.
 - Mortality in patients treated appropriately is thought to be <1%.
 - Untreated louse-borne relapsing fever is associated with a much higher rate of fatality.
- CTF:
 - Usually a self-limiting illness without sequelae
 - Death is rare but has been reported in children with generalized bleeding likely secondary to thrombocytopenia.
 - Prolonged weakness may persist for ≥3 weeks and is more likely in those patients >30 years old.

COMPLICATIONS

- Endemic relapsing fever:
 - May be associated with splenic rupture, diffuse histiocytic interstitial myocarditis, hepatitis, pneumonia, ARDS, and iridocyclitis
 - CNS complications include meningitis, meningoencephalitis, and focal deficits such as cranial nerve palsy.
 - In utero infection may result in fetal loss or severe neonatal infection.
- CTF:
 - Complications are rare but most commonly occur in children.
 - May lead to aseptic meningitis, encephalitis, myocarditis, pneumonitis, hepatitis, hemorrhage, and epididymo-orchitis

TICS

Rebecca K. Lehman

Mohammad M. Qasaymeh (5th edition)

Jonathan W. Mink (5th edition)

BASICS

DESCRIPTION

- A tic is a sudden, repetitive, stereotyped, involuntary movement (e.g., blinking, grimacing) or vocalization (e.g., throat clearing, grunting, barking). Tics can be further classified as simple (e.g., nose twitching, grunting) or complex (e.g., head shaking, trunk flexion, echolalia, neologism). Tics characteristically change in anatomic location, frequency, type, complexity, and severity over time, although each tic has a stable appearance from one occurrence to the next. Most individuals are able to suppress their tics for brief periods of time, and some endorse having premonitory sensory urges preceding tics. Tics typically abate during sleep but can persist in some cases.
- *DSM-IV-TR* classification of tic disorders:
 - Tourette syndrome (TS): Onset before age 18 years and at least 2 motor tics and 1 vocal tic present in some combination over the course of ≥ 1 year
 - Chronic motor or vocal tic disorder: Onset before 18 years and single or multiple motor or vocal tics, but not both, for ≥ 1 year
 - Transient tic disorder: Onset before 18 years and motor and/or vocal tics that have been present ≥ 4 weeks but ≤ 1 year
 - Tic disorder not otherwise specified (NOS): Motor and/or vocal tics that do not fit a specific tic disorder (e.g., lasting <4 weeks, onset > 18 years)
- Pediatric autoimmune neuropsychiatric disorder associated with streptococcus (PANDAS):
 - A controversial entity first described in 1998. In theory, group A β -hemolytic streptococcal (GABHS) infection triggers antibodies that cross-react with the basal ganglia and cause obsessive-compulsive disorder (OCD) symptoms and/or tics in some individuals.
 - The National Institute of Mental Health (NIMH) defines PANDAS as follows:
 - Presence of OCD and/or a tic disorder
 - Prepubertal onset
 - Sudden, explosive onset of symptoms and a course of dramatic exacerbations and remissions
 - Temporal relationship between symptom onset and exacerbations and GABHS infections
 - Presence of neurologic abnormalities (hyperactivity, choreiform movements, tics) during exacerbations
 - These diagnostic criteria do not always prove helpful in distinguishing PANDAS from other “standard” tic disorders. The high incidence of GABHS infections and high prevalence of asymptomatic carriers make it difficult to prove a link between GABHS infection and tics.

EPIDEMIOLOGY

- Described in almost all ethnic groups
- Affects males $>$ females
- Typical onset is between ages 5 and 7 years.

Prevalence

- The prevalence of chronic tics and TS in school-age children is 3–6% and 0.1–1%, respectively.
- Transient tics occur in 20–25% of children.

RISK FACTORS

Genetics

No single gene has been associated with tics or TS; however, the family history is often positive for tics. The prevalence of TS in 1st-degree relatives is 10 times that in the general population.

GENERAL PREVENTION

Tics cannot be prevented, but educating patients, families, and school personnel about tics can help to minimize their impact. Identification and aggressive management of comorbid conditions strongly influences patient outcomes.

PATHOPHYSIOLOGY

The pathophysiology of underlying tics and TS is not completely understood but is thought to involve abnormal dopamine neurotransmission within the basal ganglia. Evidence also implicates problems with serotonin, norepinephrine, and acetylcholine.

ETIOLOGY

Theory: Environmental or hormonal perturbations trigger tics in genetically susceptible individuals.

COMMONLY ASSOCIATED CONDITIONS

- ~50% of children with chronic motor tics or TS meet diagnostic criteria for attention deficit hyperactivity disorder (ADHD), and ~50% have OCD or obsessive-compulsive traits.
- Anxiety, learning disabilities (LD), oppositional defiant disorder, conduct disorder, and rage episodes are also associated with TS.

DIAGNOSIS

The diagnosis of tics is clinical. Physical examination, laboratory tests, and imaging studies typically are normal.

HISTORY

- Document a description of the patient’s past and current tics, including age of onset, type, anatomic location(s), duration, number, frequency, complexity, severity, and exacerbating (stress/anxiety) or alleviating factor(s).
- Determine the degree to which the tics are causing interference and/or impairment.
- Assess for comorbid conditions, including ADHD, anxiety disorders (including OCD), LD, and disruptive behaviors.
- In prepubertal patients with severe, sudden-onset OCD symptoms and/or tics, inquire about recent GABHS infections.

PHYSICAL EXAM

Physical examination is usually normal. Tics may not be seen; thus, it may be necessary to depend on history. Having the child intentionally reproduce the sound(s) and/or movement(s) of concern and/or having the parents provide video can aid in differentiating tics from other movement disorders.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

There is little evidence to support routine testing for GABHS in children suspected of having PANDAS. Throat cultures should be obtained in children with symptoms of pharyngitis.

Diagnostic Procedures/Other

Diagnosis depends largely on history. Diagnostic tests are unnecessary. Psychological testing may elucidate comorbid conditions (ADHD, OCD, LD).

DIFFERENTIAL DIAGNOSIS

- Usually, diagnosis is straightforward. Complex or dystonic tics can be more difficult to diagnose because they can resemble purposeful, normal movements or other abnormal movements. In general, tics can be distinguished from other movement disorders based on their stereotyped appearance, waxing and waning course, associated premonitory urges, and ability to be suppressed for brief periods of time.
- Hemifacial spasm (HFS) is a rare condition that results in frequent, involuntary muscle contractions involving one side of the face. Initially, the spasms are intermittent and are restricted to a few muscles; over time, they become continuous and spread to involve the entire hemiface. Early cases of HFS may be difficult to distinguish from motor tics. However, HFS is limited to one side of the face, and the spasms last longer than tics.
- Chorea is characterized by rapid, random, purposeless movements that often have a “dance-like” quality. Unlike tics, chorea is not stereotyped.
- Myoclonus is a sudden, brief, shock-like movement. “Sleep starts” that often occur in normal individuals as they drift off to sleep are a typical example. Myoclonus is not suppressible and is not associated with a premonitory sensation.
- Stereotypies are patterned, episodic, repetitive, purposeless, rhythmic movements. The movements are constant in pattern and location, without variation over time.
- Fasciculations are fine, random, spontaneous worm-like or twitching movements that occur in the setting of chronic denervation. They reflect spontaneous firing of single motor units and are easily distinguished from tics based on their clinical appearance and electrophysiologic signature.
- Myokymia refers to involuntary, spontaneous, localized twitching of a few muscle bundles. It results from hyperexcitability of peripheral nerve motor axons and is readily distinguished by its clinical and electrophysiologic appearance.

- Tremor is a regular oscillatory movement around a central point or plane, whereas tics are repetitive but irregular and nonoscillatory.
- Dystonia is characterized by repetitive, sustained muscle contractions that cause abnormal postures and movements, often with a twisting quality. A dystonic tic (i.e., tic that results in a sustained posture) can be difficult to distinguish from dystonia; however, the presence of a premonitory urge would suggest the former diagnosis.
- Periodic limb movement disorder (PLMD) is associated with repetitive, often stereotyped limb movements during non-rapid eye movement (non-REM) sleep. Since the movements only occur during sleep and are generally restricted to the lower limbs, they are easily distinguished from tics. PLMD can be associated with restless leg syndrome; however, the diagnosis is made by polysomnography.
- Partial seizures may be confused with tics. The automatisms accompanying partial seizures may look like tics, but they are not associated with premonitory sensations, nor are they under partial voluntary control. EEG is normal in children with tics but may be abnormal in those with seizures.

TREATMENT

Many tics do not interfere with children's lives and therefore do not require specific treatment. Educating the child and family about tics is often sufficient. Clinical decisions must take comorbid symptoms into account, and treatments must target the most impairing symptoms first. The waxing and waning nature of tics confounds treatment; it may take weeks to identify whether an intervention is helping.

MEDICATION (DRUGS)

- Mild/Occasional tics: Medication not needed
- Moderate or severe: α -2 agonist or dopamine antagonist may reduce severity/frequency.
- With OCD: Selective serotonin reuptake inhibitors can be helpful. Fluoxetine, fluvoxamine, and sertraline appear to be equally effective.
- With ADHD: Guanfacine (or clonidine) may help hyperactivity/impulsivity. Consider addition of a stimulant if symptoms are refractory or if inattention is the primary complaint.
- PANDAS: As above. There is insufficient evidence to support the use of long-term antibiotics and/or immunomodulation.

First Line

- Clonidine and guanfacine are considered 1st-line (off-label) medications. Avoid abrupt discontinuation, which can cause rebound hypertension.
- Clonidine: Start 0.05 mg at bedtime. Increase by 0.05 mg every week as needed and as tolerated to a maximum of 0.3–0.4 mg/day, divided 3 or 4 times/day. Sedation and orthostatic hypotension are common initial adverse effects. A transdermal clonidine patch is an alternative to oral preparations.
- Guanfacine: Start 0.5 mg at bedtime. Increase by 0.5 mg every week as needed and as tolerated to a maximum of 3–4 mg/day, divided twice a day. Guanfacine is less likely than clonidine to cause sedation and hypotension.

Second Line

- Atypical and typical antipsychotic medications are considered 2nd-line medications. Weight gain is common with all antipsychotic medications, but the atypical agents are generally preferred because they are better tolerated overall and are less likely to cause extrapyramidal side effects.
- Commonly used atypical agents include:
 - Risperidone: Start 0.01 mg/kg daily. Increase by 0.02 mg/kg/day every week as needed and as tolerated to a maximum of 0.06 mg/kg/day.
 - Ziprasidone or olanzapine: Reasonable alternatives
- Typical antipsychotics (haloperidol, pimozide) are potent medications for tics but are associated with troublesome side effects, such as sedation, weight gain, metabolic syndrome, and galactorrhea. More serious side effects include extrapyramidal reactions, neuroleptic malignant syndrome, and tardive dyskinesia. Pimozide is associated with QT prolongation, which can lead to ventricular arrhythmias. The use of typical antipsychotic should be limited to refractory and disabling tics.

ADDITIONAL TREATMENT

General Measures

There is no evidence that lifestyle changes or restriction of activities modify the course of tic disorders.

Additional Therapies

- A recent randomized controlled trial of children and adolescents with TS and chronic tic disorder demonstrated that a comprehensive behavioral intervention—consisting of awareness training, competing response training, relaxation training, and social support—resulted in greater improvement in tic severity than supportive therapy and education alone. The effect size of the intervention was on par with that of medication.
- Focal motor (or vocal) tics may be treated with injections of botulinum toxin into the affected muscles (especially useful for focal dystonic tics).

SURGERY/OTHER PROCEDURES

Recent experimental data have shown deep brain stimulation (DBS) as a potential treatment for adults with severe and refractory tics.

ONGOING CARE

DIET

There is no evidence that dietary modifications alter the course of tic disorders.

PATIENT EDUCATION

The Tourette Syndrome Association (www.tsa-usa.org) is a valuable resource for information. There are many local chapters.

PROGNOSIS

Although common, tics cause impairment in a minority of children. Peak severity occurs in preadolescence. Most patients have partial or complete resolution of tics as adults. Long-term outcome depends on associated comorbidities.

COMPLICATIONS

Tics can be emotionally distressing and can result in social disability. Injuries—due to complex tics, compulsions, impulsivity, inattention, and other factors—may be more common in patients with TS than in the general population. Chronic repetitive, and forceful tics can cause musculoskeletal problems (e.g., cervical spine arthritis, disc herniation) or other neurologic problems (e.g., cervical myelopathy, stroke secondary to vertebral artery dissection).

CODES

ICD9

- 307.20 Tic disorder, unspecified
- 307.21 Transient tic disorder
- 307.22 Chronic motor or vocal tic disorder

ICD10

- F95.2 Tourette's disorder
- F95.9 Tic disorder, unspecified
- G25.69 Other tics of organic origin

FAQ

- Q: Can a child with tics and ADHD be treated with stimulant medication?
- A: Although there have been concerns of stimulants making tics worse, there is no evidence that stimulants cause chronic tics. Furthermore, several recent studies have shown that treatment of ADHD with stimulants does not worsen tics and may lead to improvement.
- Q: Should mild tics be treated if they lead to teasing?
- A: The best approach is to educate the child, parents, and teacher about tics. The child can be armed with a response to questions, such as "Those are tics. They are just something I do, and I can't help it."

TOXIC ALCOHOLS

Thomas Nguyen
Robert J. Hoffman
Khalid Alansari (5th edition)

BASICS

DESCRIPTION

- Toxic alcohols discussed here include ethylene glycol, isopropyl alcohol, and methanol.
- Ethylene glycol is a sweet, odorless, colorless liquid commonly used as automobile antifreeze solution as well as for other uses.
- Isopropyl alcohol is used as rubbing alcohol as well as in liquid soaps, hand sanitizers, and for other uses.
- Methanol is used in windshield wiper fluid, Sterno, paint removers, and other products.

EPIDEMIOLOGY

- Exposure to toxic alcohols is common; mild morbidity occurs regularly.
- Severe morbidity or death occurs without treatment but is uncommon in treated patients.

RISK FACTORS

Toxicity via dermal absorption rarely occurs in infants or young children with permeable skin.

GENERAL PREVENTION

Poison proofing homes and giving parents poison prevention advice is the most effective way to prevent toxic alcohol exposures in children.

PATHOPHYSIOLOGY

All toxic alcohols have direct effects as intoxicants. More importantly, ethylene glycol and methanol are metabolized to toxic by-products that result in severe morbidity or mortality:

- Ethylene glycol is metabolized to oxalic acid and glycolic acid, ultimately forming calcium oxalate crystals, which may precipitate in the renal tubules and cause renal failure.
- Methanol is metabolized to formaldehyde and then formic acid, which may damage the retina and cause visual impairment or blindness.
- The metabolism of ethylene glycol and methanol to their toxic metabolites may be prevented by competitively inhibiting alcohol dehydrogenase with either fomepizole or ethanol.
- Therapy to inhibit alcohol dehydrogenase is used for ethylene glycol and methanol exposure.
- Isopropyl alcohol is metabolized to acetone and causes ketosis without acidosis.
- Inhalational absorption of isopropyl alcohol may rarely occur.

DIAGNOSIS

HISTORY

- Typically, a history of exposure is available.
- In absence of this history, an osmolar gap or anion gap with metabolic acidemia is suggestive of toxic alcohol exposure.
- Signs and symptoms:
 - Inebriation may occur after exposure.
 - Isopropyl alcohol may cause severe gastrointestinal irritation or hemorrhage.

PHYSICAL EXAM

- Tachycardia and hypotension are the most frequent vital sign abnormalities that occur.
- Hyperpnea or tachypnea often accompanies metabolic acidemia.
- Cardiovascular effects may include hypocalcemic QT prolongation and myocarditis.
- Neurologic abnormalities may include ataxia, CNS depression, coma, dysarthria, focal neurologic changes, hyporeflexia, hypotonia, nystagmus, or seizure.
- Gastrointestinal effects may include gastritis, emesis, hematemesis, pain, or pancreatitis.
- Ophthalmologic findings may include blurred vision, diplopia, hazy vision, or nystagmus.
- Constricted visual fields, hyperemic optic disc with retinal edema, and transient or permanent blindness may result from methanol exposure.
- Hematuria, renal insufficiency, or renal failure may occur, particularly from ethylene glycol.
- Fluid and electrolyte abnormalities from ethylene glycol or methanol may include hypokalemia, hypocalcemia, hypomagnesemia, and elevated anion gap metabolic acidosis.
- Acetonemia and ketonemia may result from isopropyl alcohol ingestion.
- Hypoglycemia may be associated with toxic alcohol exposure as well as with ethanol therapy.
- Respiratory irritation from isopropyl alcohol inhalation or respiratory depression from any toxic alcohol ingestion may occur.

DIAGNOSTIC TESTS & INTERPRETATION Diagnostic Procedures/Other

- Check serum electrolytes, BUN, creatinine, and glucose:
 - As metabolism occurs, an increased anion gap metabolic acidemia results with ethylene glycol or methanol toxicity.
 - Absence of this gap early after ingestion is expected and does not rule out ingestion.
 - Elevated anion gap metabolic acidemia supports the diagnosis of ethylene glycol or methanol exposure.
 - Acidemia is an indication for use of fomepizole or ethanol as well as potential indication for hemodialysis.
 - Fomepizole treatment should not be delayed waiting to determine if acidemia will develop.
 - Anion gap metabolic acidemia does not result from isopropyl alcohol poisoning.
- Blood gas analysis should be performed to assess for degree of metabolic acidemia in any patient with low serum bicarbonate:
 - Initial use of venous blood gas to screen for abnormality is acceptable.
 - Repeated blood gas analysis should occur every 1–2 hours if acidemia results.
- Serum level of ethylene glycol, isopropyl alcohol, or methanol should be obtained:
 - An ethylene glycol or methanol level > 20 mg/dL is an indication for fomepizole or ethanol infusion.
 - An ethylene glycol or methanol level > 50 mg/dL is an indication for hemodialysis.

- Serum ionized calcium is useful in managing ethylene glycol toxicity.
- Urinalysis with microscopic examination is recommended with ethylene glycol exposure:
 - Presence of oxalate crystals corroborates poisoning.
 - Absence of crystals does not exclude the possibility of ethylene glycol toxicity.
 - Fluorescence of urine is unreliable and is neither sensitive nor specific for exposure.
- Proteinuria and hematuria may be present with ethylene glycol or isopropyl alcohol exposure.
- Serum osmolality or osmolarity may be useful in predicting the level of ethylene glycol, isopropyl alcohol, or methanol if rapid laboratory quantification cannot be performed.
- Serum ethanol level should simultaneously be performed to determine quantity of ethanol contribution to osmolar gap.
- An elevated osmolar gap can be used to rule in, but not exclude, toxic alcohol exposure.
- An elevated osmolar gap indicates the presence of unmeasured solute such as ethanol, ethylene glycol, isopropyl alcohol, or methanol.
- Absence of an osmolar gap does not exclude the possibility of toxic alcohol exposure.
- Osmolar gap is calculated as follows:
Osmolar gap = Measured serum osmolality – Calculated osmolality.
- The measured osmolality is determined by the laboratory.
- The calculated osmolality is determined as follows:
 $2 \times [\text{Na} (\text{mEq/L})] + [\text{BUN} (\text{mg/dL})/2.8] + [\text{glucose} (\text{mg/dL})/18]$.
- Normal osmolar gap is < 15 mEq/L.
- Any patient with increased osmolar gap should be presumed to have toxic alcohol exposure.
- Additional tests may include ECG to detect cardiac conduction disturbance (prolonged QTc) or serum acetaminophen and salicylate levels in patients with intentional ingestion or with presumed intent of self-harm.
- Tests necessary to rule out differential diagnoses should be obtained when appropriate.

DIFFERENTIAL DIAGNOSIS

Drugs and disorders that may alter laboratory values include acetone, diethylene glycol, ethanol, iron, isoniazid, lactic acidemia, mannitol, methanol, propylene glycol, renal failure, salicylates, toluene, and various forms of ketoacidosis.

TREATMENT

MEDICATION (DRUGS)

- For ethylene glycol or methanol poisoning, either fomepizole or ethanol is used to competitively inhibit alcohol dehydrogenase, thus preventing the formation of toxic metabolites.
- Fomepizole is highly preferable to ethanol in children, as ethanol has many severe adverse side effects such as hypoglycemia, CNS depression, and hypothermia.

- Indications for fomepizole or ethanol include:
 - Serum level of ethylene glycol or methanol > 20 mg/dL
 - Metabolic acidemia, urine oxalate crystals, pH < 7.3 with any quantity of detectable ethylene glycol or methanol
- Use of fomepizole or ethanol will prolong the half-life of ethylene glycol and methanol:
 - Without therapy, the ethylene glycol half-life is 3–4 hours, while methanol is 14–20 hours.
 - With fomepizole or ethanol, the ethylene glycol half-life is 12 hours, while methanol is 30–50 hours.
- Some clinicians consider a necessary duration of therapy longer than several days to be an indication for hemodialysis. Successful use of prolonged therapy with fomepizole to avoid hemodialysis has been reported.
- Fomepizole is contraindicated in patients with documented allergic reaction to the drug.
- Ethanol should be used with extreme caution in Asians because aldehyde dehydrogenase deficiency may result in flushing, severe illness, and hypotension.
- The loading dose of fomepizole is 15 mg/kg IV.
- Maintenance dosing is 10 mg/kg q12h for 4 doses.
- Fomepizole induces its own metabolism, and after 4 maintenance doses the maintenance dose is increased to 15 mg/kg q12h thereafter.
- Each dose is diluted into 100 mL of normal saline or D5W and infused over 30 minutes to prevent burning at the infusion site.
- Each time after hemodialysis is performed, a loading dose must be readministered.
- Ethanol is administered as a 10% solution in D5W. This dilution requirement often results in a very large quantity of free water administration.
- The ethanol loading dose is 10 mL/kg of a 10% solution infused IV over 1 hour.
- A maintenance dose of 1.0–2.0 mL/kg of 10% ethanol is then given IV.
- Target blood ethanol level is 100–125 mg/dL.
- Patients receiving ethanol should have the ethanol level and serum glucose checked hourly.
- Oral ethanol may be used when IV is not available or if the patient is willing and capable of drinking. This is possibly feasible in adolescents.
- Adjunctive treatment with folate or Leucovorin for methanol, and thiamine and pyridoxine for ethylene glycol, may be given IV q6h:
 - This continues until methanol or ethylene glycol levels are undetectable.
 - Folate or tetrahydrofolate (Leucovorin) may hasten the elimination of formic acid resulting from methanol exposure.
 - Leucovorin 1–2 mg/kg may be administered IV q6h.
 - Pyridoxine and thiamine hasten elimination of ethylene glycol metabolites.
 - Pyridoxine may be given as 1–2 mg/kg up to 100 mg maximum IV q6h.
 - Thiamine may be given as 50 mg to children < 20 kg or 100 mg to children > 20 kg, administered IV over at least 5 minutes and repeated q6h.

ADDITIONAL TREATMENT

General Measures

Supportive care is the most important general principle. The illness is managed with intent of close monitoring and addressing issues as they arise:

- For ingestion < 1 hour previously, an attempt to aspirate gastric contents with a nasogastric tube is reasonable.
- Treatment for ethylene glycol or methanol exposure should focus on acid-base correction and preventing organ damage.
- Hemodialysis should be considered for the following:
 - Any patient with severe metabolic acidemia from ethylene glycol or methanol
 - Any patient with evidence of end-organ damage, particularly if metabolic acidemia is present
 - Any patient with profound hypotension or life-threatening symptoms resulting from isopropyl alcohol toxicity

IN-PATIENT CONSIDERATIONS

Initial Stabilization

- Prompt evaluation of airway, breathing, circulation, serum glucose, and ECG (A,B,C,D,E) is critical.
- Consultation with a medical toxicologist or poison center is recommended.

Admission Criteria

- Any patient requiring therapy with fomepizole, ethanol, or hemodialysis
- Any patient with renal impairment, visual impairment, or other organ effect
- Any patient for whom consequential ingestion is suspected and ethylene glycol or methanol levels are unavailable

IV Fluids

- IV fluid to maintain adequate blood pressure may be necessary.
- Maintenance IV fluid may be required in patients who are unable to take PO.
- IV fluid may be necessary to aid in prevention of calcium oxalate crystals in the urine.
- IV fluid may be helpful to prevent renal injury if rhabdomyolysis occurs.

Nursing

- Protect inebriated patients from falls.
- For the duration of inebriation or therapy with ethanol, vigilance for detection of hypoglycemia should be maintained.

Discharge Criteria

- Inpatients who have received therapy with fomepizole, ethanol, or hemodialysis must be medically and metabolically stable for at least 12–24 hours prior to discharge.
- Patients with ethylene glycol or methanol exposure who have not developed symptoms or metabolic derangement may be discharged within 24 hours.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Asymptomatic patients with undetectable ethylene glycol or methanol levels and no metabolic acidemia may be safely discharged.
- Most exposures for which ethylene glycol or methanol levels cannot be obtained should be followed for 12–24 hours to detect development of metabolic acidemia or other symptoms.

- From the hospital, patients with ethylene glycol or methanol level < 20 mg/dL, no anion gap, no metabolic acidemia, and stable renal function and vision may be discharged.
- Patients with isopropyl alcohol exposure who develop no symptoms or have only mild symptoms may be discharged within 4–6 hours.

Patient Monitoring

Symptomatic exposure to ethylene glycol or methanol may warrant intensive care monitoring.

PROGNOSIS

- For ethylene glycol and methanol exposure, prognosis depends upon the degree of toxin metabolism as well as adequacy of care.
- Speed and adequacy of therapy with fomepizole or ethanol, as well as prompt hemodialysis when indicated, is critical.
- For isopropyl alcohol, prognosis depends upon severity of intoxication and adequacy of supportive care.

COMPLICATIONS

Blindness, coma, hepatic injury, hypertension or hypotension, myocarditis, temporary or permanent neurologic injury, pancreatitis, renal failure, respiratory depression, rhabdomyolysis, or seizure may occur as a result of toxic alcohol exposure.

TOXIC SHOCK SYNDROME

Mark L. Bagarazzi

BASICS

DESCRIPTION

- Toxic shock syndrome (TSS) is an acute febrile illness characterized by myalgia, vomiting, diarrhea, pharyngitis, diffuse desquamating macular erythroderma, erythema of mucous membrane and conjunctiva, multiorgan system involvement by direct inflammatory damage or ischemia, disseminated intravascular coagulopathy (DIC), and hypotension.
- TSS is most commonly caused by group A β -hemolytic streptococci (GABS or *Streptococcus pyogenes*) or TSS toxin-1 (TSST-1)—producing strains of *Staphylococcus aureus* (including methicillin-resistant isolates). Cases have also been reported in association with group B, C, and G1 streptococci and *Streptococcus mitis*.

GENERAL PREVENTION

- Avoidance of tampon use after first episode of TSS
- Scrupulous wound care
- Limitation of intravaginal foreign body use (e.g., tampon, sponge) and strict adherence to manufacturer's directions

EPIDEMIOLOGY

- Early 1980s: >90% of cases (almost exclusively owing to *S. aureus*) occurred in menstruating women; associated with superabsorbent tampon use. The frequency of cases occurring in menstruating women dropped in the mid-1980s because of changes to less absorbent or tampons of different composition. In 1996, <50% of cases were associated with menstruation.
- Mean age: 22 years
- Incubation period for postoperative *S. aureus*-mediated TSS can be <12 hours.
- Preceding varicella infection dramatically increases the risk for acquiring invasive disease owing to group A β -hemolytic streptococci including TSS.
- Currently, about 60% of cases occur in girls and women.

Incidence

- Current incidence of menses-related disease: 1–5/100,000 women of menstrual age per year
- In US from 2000–2004, case-fatality rate in patients aged <10 years with streptococcal TSS was 7.7%. Streptococcal TSS incidence is highest among young children.

RISK FACTORS

- Use of superabsorbent tampon, diaphragm, or contraceptive sponge; local or invasive staphylococcal or streptococcal infection
 - Including but not limited to bacteremia, endocarditis, pyogenic arthritis, sinusitis, osteomyelitis, pneumonia, pharyngitis, pancreatitis, cholecystitis, abscess, cervical adenitis
- Superficial and surgical wounds; childbirth; abortion, varicella infections; immunosuppressive (including corticosteroids and nonsteroidal anti-inflammatory drugs) or immunomodulatory therapy.

DIAGNOSIS

SIGNS AND SYMPTOMS

- U.S. Centers for Disease Control and Prevention (CDC) criteria for diagnosis of staphylococcal TSS:
 - Fever 38.9°C (102.0°F) or higher
 - Diffuse macular erythroderma
 - Desquamation 1–2 weeks after onset, particularly affecting palms and soles
 - Hypotension below fifth percentile for children, orthostatic changes >15 mm Hg or orthostatic syncope, or dizziness
 - Involvement of three or more organ systems: gastrointestinal, muscular, mucous membrane, renal, hepatic, hematologic, or neurologic.

All 5 of the aforementioned criteria with blood culture(s) positive for *S. aureus* only and negative serology for Rocky Mountain spotted fever (RMSF), leptospirosis, and measles. 4 of 5 criteria termed probable. 4 criteria plus death before desquamation yields complete syndrome.

- U.S. Centers for Disease Control and Prevention criteria for diagnosis of streptococcal TSS:
 - Hypotension or shock
 - Any 2 of the following: Renal impairment, DIC, thrombocytopenia, hepatic impairment, adult respiratory distress syndrome, erythematous macular rash that may desquamate, or soft-tissue necrosis
 - Isolation of group A β -hemolytic streptococci from a normally sterile site constitutes a definite case. Isolation of group A β -hemolytic streptococci from a nonsterile site constitutes a probable case.
- Pitfalls:
 - Production of TSST-1 by isolate is only presumptive evidence unless case meets diagnostic criteria.
 - Failure to meet US Centers for Disease Control and Prevention's diagnostic criteria
 - Failure to identify soft-tissue or muscular site of local infection
 - Failure to identify or remove foreign body
 - Erythroderma may not be appreciated if patient is already hypotensive.
 - Diagnosis still must be considered in the absence of an identifiable focus.

HISTORY

- Recent use of tampons, contraceptive sponge, or diaphragm are all known risk factors.
 - May occur at any time during menses
- Any surgical procedures including catheters (e.g., intravenous, peritoneal dialysis)
 - Incubation period for postoperative TSS may be as short as 12 hours
- Nonsurgical wounds, burns, childbirth, abortion, or puerperal infections.
- Other active streptococcal or staphylococcal infections:
 - History frequently elicits probable recent infections.

- Abrupt onset of high fever, rapid-onset hypotension, rapidly accelerated renal failure, and multisystem organ failure are all historical findings associated with either staphylococcal or streptococcal TSS. Chills, malaise, headache, pharyngitis, fatigue, and dizziness or syncope are also seen frequently.
- Profuse watery diarrhea (often with fecal incontinence), vomiting, abdominal pain, generalized erythroderma, conjunctival injection, and severe myalgias are all historical findings seen commonly in staphylococcal TSS but less frequently in streptococcal TSS. The presence of a foreign body is also more common with staphylococcal TSS than with streptococcal TSS.
- Evidence of increasingly painful local soft tissue infection (e.g., abscess, cellulitis, myositis, or necrotizing fasciitis) are all historical findings seen commonly in streptococcal TSS but less frequently in staphylococcal TSS.
- Tampons with ingredients such as polyacrylate, polyester foam, cross-linked carboxymethylcellulose; or claims of superabsorbency are associated with TSS.

PHYSICAL EXAM

- Any sign of soft-tissue infection (e.g., cellulitis, necrotizing fasciitis, myositis, soft-tissue abscesses, sinusitis):
 - Often seen before onset of TSS
- Overall appearance:
 - Patients with TSS are always moderately to severely ill.
- Altered vital signs:
 - Fever, tachycardia, tachypnea, orthostasis, or frank hypotension. Tachycardia is the prelude to hypotension.
- Abnormal skin, mucous membranes, and soft tissues:
 - Erythroderma, peripheral cyanosis and edema, bulbar conjunctival hyperemia, subconjunctival hemorrhages, beefy red mucous membranes, and muscle tenderness are seen with TSS.
- Mental status changes:
 - Altered mental status, including somnolence, agitation, disorientation, and obtundation within 24–72 hours are seen with TSS.
- Intensity of erythroderma:
 - May be most intense surrounding the infected focus (e.g., perineum)
- Desquamation:
 - Begins on trunk and extremities 5–7 days after symptom onset. Full thickness desquamation of fingers, toes, palms, and soles begins 10–12 days after onset.
- Vesicle or bullae formation, or presence of violaceous hue:
 - Ominous findings associated with increased fluid loss and potentially hypotensive shock

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Antibodies to TSST-1 (available for informational purposes/research only from Toxin Technology, Inc., www.toxintechnology.com):
 - Test result will be positive several weeks after acute presentation.
- Antibodies to antistreptolysin O (ASO), antideoxyribonuclease B, or other streptococcal extracellular products:
 - May increase 4–6 weeks after infection in streptococcal-mediated disease
- Complete blood count:
 - Usually reveals thrombocytopenia early in the course of disease, thrombocytosis during the recovery phase, anemia early in disease, normal or slightly elevated leukocyte count with left shift, and absolute lymphopenia. Neutropenia is more ominous than lymphopenia.
- Blood cultures:
 - Positive in 60% of streptococcal TSS, rarely (<5%) positive in staphylococcal TSS
- Local cultures:
 - *S. aureus* may be isolated from vagina or cervix in menstrual TSS, or from other infectious focus in nonmenstrual cases. Isolation of group A streptococci from a sterile site is a definite case, whereas isolation from a nonsterile site constitutes a probable case.
- Pitfall:
 - *S. aureus* isolated from nares or vagina may represent a false-positive finding because 10–30% of those affected are healthy carriers.
- Coagulation studies:
 - May reveal prolonged prothrombin and partial thromboplastin times (PT/PTT) with or without evidence of DIC; low fibrinogen, elevated fibrin degradation products.
- Urinalysis:
 - May reveal sterile pyuria
- Lumbar puncture:
 - May reveal cerebrospinal fluid pleocytosis
- Creatine phosphokinase (CPK):
 - May be elevated, reflecting skeletal muscle involvement

DIFFERENTIAL DIAGNOSIS

- Septic shock owing to *Neisseria meningitidis*
- Streptococcal and staphylococcal scarlatiniform eruptions
- Leptospirosis
- RMSF without characteristic rash
- Fulminant viral infection (e.g., adenovirus)
- Kawasaki disease, although TSS may present simultaneously with Kawasaki disease. Coronary artery dilatation has been reported in cases presenting as TSS.
- Toxic epidermal necrolysis (TEN)
- Drug-induced hypersensitivity (e.g., vancomycin)

TREATMENT

SPECIAL THERAPY

- Remove all foreign bodies.
- Surgical débridement with myositis and necrotizing fasciitis; abscess drainage
- Antibiotics: Parenteral administration with antistreptococcal and staphylococcal therapy eradicates source of the toxin, but does not affect the course of the acute illness.

MEDICATION (DRUGS)

- Use both a bacterial cell wall inhibitor, such as semisynthetic antistaphylococcal penicillins (i.e., nafcillin, oxacillin, dicloxacillin, and cefuroxime or ampicillin/sulbactam) as well as a protein synthesis inhibitor (e.g., clindamycin, linezolid) to end production of toxins, enzymes, and cytokines.
- Continue therapy for 10–15 days or until causative bacteria is eradicated on follow-up cultures.
- Clindamycin or erythromycin if patient is allergic to penicillin
- Intravenous immunoglobulin (IVIG) remains controversial with no adequately powered prospective studies:
 - Placebo-controlled multicenter study did not show a significant benefit in 28-day survival in patients with definite streptococcal TSS.
 - Anecdotal reports of efficacy for streptococcal TSS
 - May be considered for infections refractory to aggressive therapy or in patients with infection in an area that cannot be drained.
 - Optimal regimen is not known, although single doses of 1–2 g/kg, as well as several days of 150–450 mg/kg/d have been studied.
- Corticosteroids: Have not been systematically studied

ONGOING CARE

- Poor prognosis is often heralded by development of pulmonary edema, falling cardiac index, and rising pulmonary capillary wedge pressure.
- Temperature usually returns to normal within 2 days.
- Toxin-mediated cardiomyopathy should resolve if fatal arrhythmia does not occur during decompensated stage.
- Gastrointestinal, hepatic, and musculoskeletal changes resolve rapidly with rare permanent sequelae except for muscle weakness.
- Hair and nail loss may occur 4–16 weeks after illness onset; should resolve within 5–6 months.
- Encephalopathy is common, rarely causes seizures; both usually resolve within 4–5 days.

PROGNOSIS

- Recurrences are associated with inadequate treatment.
- Mortality 5–7% for staphylococcal disease. Myocardial and pulmonary failure are the most common causes of death.
- Mortality is higher in nonmenstrual TSS (men and women >45 years of age) owing to delayed recognition.
- Death usually occurs within the first few days; may occur as late as 2 weeks following onset.
- Permanent renal damage is extremely rare.

COMPLICATIONS

Multisystem organ failure secondary to distributive shock/hypotension including:

- Pulmonary edema
- DIC
- Acute renal failure (oliguric and nonoliguric)
- Hepatic failure
- Myocardial edema and decreased contractility with or without arrhythmias
- “Stunned” myocardium demonstrating severe ventricular contractile dysfunction
- Cerebral edema with toxic or ischemic encephalopathy
- Metabolic disturbances
- Telogen effluvium; temporary hair and nail loss
- Neuropsychologic disturbances including memory loss; abnormal electroencephalogram (EEG) rare

A48.3 Toxic shock syndrome

FAQ

- Q: Can toxic shock syndrome recur?
- A: Yes. Inadequate eradication of the nidus of infection, as in continuing sinusitis or a case that involves a foreign body, can lead to recurrent staphylococcal toxic shock syndrome. Moreover, some people with some immune system defects may develop recurrent toxic shock syndrome.
- Q: Can toxic shock syndrome be diagnosed in patients who have no risk factors?
- A: Yes, there have been reports meeting the case definition where none of the known associated factors was present.

TOXOPLASMOSIS

Richard M. Rutstein

BASICS

DESCRIPTION

Toxoplasma gondii is an intracellular protozoan parasite with a complex life cycle; its definitive host is the cat. In addition to causing asymptomatic infection and clinical disease in humans, the organism is capable of causing asymptomatic and symptomatic infections in a wide range of other mammals and birds:

- Pitfalls:
 - Failure to consider diagnosis in an at-risk or symptomatic infant
 - Failure to consider the significant risk of late sequelae in an asymptomatic exposed/infected neonate and therefore failure to offer therapy to the asymptomatic infected neonate

EPIDEMIOLOGY

- The rate of acquired infection, usually asymptomatic, varies widely through the world and increases with age.
- At birth, 70–90% of children with congenital toxoplasmosis are asymptomatic. Late sequelae (e.g., chorioretinitis, mental retardation, seizures, sensorineural hearing loss) occur in 25–50% of untreated infants considered asymptomatic at birth.

Incidence

Worldwide, the incidence of congenital infection ranges from 1–7/1,000 live births; in the US, incidence is estimated at 0.1–1/1,000 live births. It is believed that 400–4,000 infants are born annually in the US with congenital toxoplasmosis.

Prevalence

Seroprevalence rates among pregnant women vary from 4–80% worldwide; in the US, a serologic survey found that 15% of women of child-bearing age were seropositive.

GENERAL PREVENTION

- Avoidance of undercooked meats
- Seronegative women need to exercise caution in caring for cats as well as eating undercooked meat.
- Maternal/Neonatal antibody screening is important in areas with a significant incidence of toxoplasmosis.

- Treatment of pregnant women with documented seroconversion to prevent congenital infection is generally offered, although its efficacy is not proven. If fetal infection is established, aggressive treatment during pregnancy with spiramycin, pyrimethamine, and sulfonamide may palliate the severity of the disease in the infant; however, recent evidence has not shown a protective effect of prenatal treatment against the development of neurologic or ocular sequelae.

PATHOPHYSIOLOGY

- Toxoplasmosis is acquired by the ingestion of oocysts or intact viable tissue cysts in inadequately cooked meat.
- After ingestion, the oocysts and cysts are disrupted by the digestive process, and viable infective organisms cross the GI lining. Hematologic spread leads to infection of multiple organs, most notably the heart, skeletal muscle, and the brain. There, slowly growing or dormant cysts remain for the patient's lifetime.
- Congenital toxoplasmosis generally occurs during a primary maternal infection. An exception may be when the pregnant woman is severely immunocompromised; congenital infection has occurred in children of HIV-infected women with latent toxoplasmosis infection.
- Primary infection in the 1st trimester is associated with a higher incidence of symptomatic congenital disease, although most congenital infections occur late in pregnancy and affected neonates have subclinical infection at birth. Overall, 30–40% of infants born to mothers with primary infection during pregnancy will be congenitally infected; 25% of those will have ocular or intracranial disease noted in infancy.

DIAGNOSIS

HISTORY

- For acquired infection: History of contact with cats; eating raw or undercooked meat (especially pork)
- For congenital infection: History of maternal exposure or positive titers (IgG and/or IgM)

PHYSICAL EXAM

- Acquired infection: Adenopathy, rash, fever, malaise, hepatosplenomegaly
- Congenital infection: Microcephaly or macrocephaly, hydrocephalus, chorioretinitis, hepatosplenomegaly, petechiae, sensorineural hearing loss, intracerebral calcifications

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Screen all pregnant women or their infants in high-incidence areas by use of toxoplasmosis-specific IgM or rise in IgG titer over time.
- PCR analysis of amniotic fluid may assist in diagnosis; in 1 study, the specificity and positive predictive values were 100% and sensitivity was 92%.
- Several states now mandate neonatal screening; filter paper test for IgM detects 75% of cases, many asymptomatic.
- For the at-risk neonate, diagnosis is made by demonstration of specific IgM, IgA, or IgE titers, or rise in IgG titers, and/or clinical symptoms in the infant of a mother with recent primary infection.
- Thrombocytopenia
- Elevated result on liver function tests

Imaging

Head CT or MRI demonstrating calcifications

Diagnostic Procedures/Other

Early and frequent audiologic and ophthalmic evaluations are a necessity. Many affected infants will have normal results of neonatal examinations.

DIFFERENTIAL DIAGNOSIS

- Primary infection: Acute disease symptoms of adenopathy, fever, rash: Primary Epstein-Barr virus, cytomegalovirus, HIV infection
- For the newborn with micro/macrocephaly, hepatosplenomegaly, eye disease; other congenital infections: Cytomegalovirus, syphilis, rubella

**TREATMENT****MEDICATION (DRUGS)**

Pyrimethamine and sulfadiazine for the 1st year of life for all congenitally infected infants whether symptomatic or not, although the efficacy of treatment, for preventing or limiting sequelae, is controversial:

- Folic acid is given during the course of therapy to minimize hematologic side effects.

**ONGOING CARE****FOLLOW-UP RECOMMENDATIONS**

- Continued attention to neurologic development and frequent audiologic and ophthalmic evaluations throughout the 1st few years of life
- For children with early symptomatic disease, careful attention to neurologic condition and early intervention services to optimize outcome

PROGNOSIS

- Most acquired infections are asymptomatic or associated with mild short-lived symptoms.
- Most congenital infections are asymptomatic, although late sequelae occur in >50% of untreated infants.
- Symptomatic newborns are at significant risk for sequelae, most frequently neurologic (e.g., hydrocephalus, retardation) or ophthalmologic (e.g., retinitis, blindness).
- Prenatal treatment appears to decrease risk to newborn; therapy of all infected infants, symptomatic or not, for 1 year, improves outcome.

COMPLICATIONS

- Congenital infection: Retardation, retinitis, hydrocephalus, seizures, microcephaly, sensorineural hearing loss
- Acquired infection (all rare): Adenopathy, mononucleosis-like syndrome, myocarditis, pneumonia, meningitis/encephalitis

FAQ

- Q: What is the risk of congenital infection in a mother with stable toxoplasmosis?
- A: The risk of congenital infection in the child of a mother with long-standing toxoplasmosis infection is considered low; the exception is for mothers with a significant degree of immunosuppression or deficiency.
- Q: What is the risk of congenital infection in children of a mother with documented primary infection during pregnancy?
- A: ~30–40% of infants born to mothers with primary infection during pregnancy will be infected themselves. This rate may be lower if the mother receives therapy (spiramycin or pyrimethamine/sulfadiazine) prenatally. Of the infected infants, most (70–90%) are normal at birth; with treatment for 12 months, it appears most will have a favorable outcome.

TRACHEITIS

Charles A. Pohl

BASICS

DESCRIPTION

Infection of the trachea associated with airway inflammation and obstruction:

- Acute tracheitis: Sudden onset; higher morbidity and mortality
- Subacute tracheitis: Indolent presentation and course; more common among children with prolonged intubation, tracheostomy, and/or underlying respiratory or neurologic conditions

EPIDEMIOLOGY

- Viral prodrome common
- Increased incidence during viral respiratory season (fall and winter): Up to 75% coinfecting with influenza A
- Gender predisposition unclear (2:1 male-to-female ratio has been reported)
- 3% mortality rate

GENERAL PREVENTION

- Routine childhood immunization with *Haemophilus influenzae* type B, influenza, and pneumococcal vaccines
- Avoid overaggressive suctioning of children with artificial airways.

PATHOPHYSIOLOGY

- Epithelial damage from a viral infection or mechanical trauma (e.g., endotracheal intubation, surgical procedure) occurs in the trachea at the level of the cricoid cartilage. As a result, the damaged tissue is more susceptible to bacterial superinfection.
- Mucosal damage characterized by marked subglottic edema, copious purulent secretions, and a pseudomembrane (mucosal lining, inflammatory products, and bacteria). These changes lead to marked airway obstruction.
- Toxic shock syndrome may be a consequence if the infection is associated with toxin-producing strains of *Staphylococcus aureus* or *Streptococcus pyogenes*.

ETIOLOGY

- Bacteria:
 - *S. aureus* (most common), group A β -hemolytic streptococcus, *Moraxella catarrhalis*, nontypeable *H. influenzae*, *Streptococcus pneumoniae*
 - *Pseudomonas aeruginosa* and other gram-negative enteric bacteria have been associated with nosocomial infections.
 - *Mycobacterium tuberculosis*, *Mycoplasma pneumoniae*, *Corynebacterium diphtheria*, *H. influenzae* type B, and respiratory anaerobic bacteria are uncommon pathogens.
- Viruses: Influenza, parainfluenza, respiratory syncytial, herpes simplex, and measles viruses have been found with bacterial pathogen(s).
- Fungi: Seen with underlying immunodeficiency disorders or chronic steroid use

DIAGNOSIS

HISTORY

- Hyperpyrexia; nonpainful, brassy cough; noisy respirations; lethargy; dyspnea; rapid progression of airway occlusion (hours to a few days)
- Hoarseness, dysphagia, neck pain, drooling, and croupy cough are less common.
- Presence of upper airway infection
- Lack of clinical improvement with racemic epinephrine should raise the suspicion for tracheitis.
- An indolent progression of symptoms, including increase of supplemental oxygen requirement and tracheal secretions (thicker and color changes), may be seen in subacute tracheitis.
- Affects any age (peak age 2–6 years)

PHYSICAL EXAM

- Toxic appearance; anxious, agitated, or lethargic; labored breathing with signs of severe respiratory distress (e.g., air hunger posture, retractions); pallor or cyanosis; severe stridor; concomitant signs of pneumonia
- Deviated uvula suggests a peritonsillar abscess.
- Asymmetric lung sounds are often found in patients with foreign bodies in the airway.
- Generalized lymphadenopathy and splenomegaly are clues for infectious mononucleosis.

DIAGNOSTIC TESTS & INTERPRETATION

Imaging

- Radiographs must be completed in controlled settings by personnel who are trained in airway management.
- Lateral and anteroposterior neck films: Findings include distention of the hypopharynx, subglottic narrowing, and irregularity of the tracheal wall owing to mucosal sloughing or the presence of a pseudomembrane.
- Chest radiograph: Obtain if pneumonia, which may be concurrent, is suspected.

Diagnostic Procedures/Other

- Laryngoscopy or bronchoscopy:
 - Direct visualization and suctioning of obstructed airway is both diagnostic and therapeutic.
 - Findings include a red, edematous, and/or eroded trachea and bronchi with purulent secretions and pseudomembrane.
 - Consider in an ill-appearing child with an unclear diagnosis or when the child's condition does not respond to current management.
- Tracheal bacterial culture (for aerobic and anaerobic bacteria): The gold standard for diagnosis
- Tracheal gram stain for pathogens and white blood cells (especially polymorphonuclear leukocytes): Helps differentiate bacterial infection from colonization

- Blood culture: Occasionally may be helpful in diagnosis (<50% positive)
- CBC: Little diagnostic value but may show leukocytosis with a left shift
- ESR and/or C-reactive protein: May be elevated

DIFFERENTIAL DIAGNOSIS

- Infectious:
 - Epiglottitis/Supraglottitis (presence of supraglottic inflammation)
 - Peritonsillar and parapharyngeal abscesses
 - Retropharyngeal abscess
 - Infectious mononucleosis (Epstein-Barr virus)
 - Diphtheria (rare)
- Environmental:
 - Aspiration or inhalation of a caustic substance, including alkali products (e.g., oven cleaner) or smoke
 - Foreign body aspiration
 - Generalized allergic reaction or anaphylaxis leading to angioedema
- Tumors (rare):
 - Papillomas secondary to human papillomavirus
 - Hamartoma and inflammatory pseudotumor
 - Laryngeal tumors
- Trauma:
 - Posttraumatic tracheal stenosis
 - Blunt trauma to neck
- Congenital:
 - Tracheal stenosis
 - Vascular ring and slings
 - Laryngotracheal web and clefts
 - Laryngotracheomalacia
 - Vocal cord paralysis
 - Arnold-Chiari malformation

ALERT

- Watch for sudden deterioration from tracheal inflammation and secretions. Continuous monitoring is necessary.
- Bacterial tracheitis must be considered in all children with sudden upper respiratory distress and hyperpyrexia.

TREATMENT

MEDICATION (DRUGS)

Select antibiotic therapy based on gram stain and culture results of tracheal secretions. Also consider known prior colonization and institutional pathogens in children with pre-existing artificial airway and hospital-acquired infections:

- Mild illness:
 - Empiric therapy with amoxicillin–clavulanic acid or a 2nd-generation cephalosporin for 10–14 days (50 mg/kg/24 hours depending on the antibiotic used)
 - Consider a semisynthetic penicillin such as dicloxacillin (40 mg/kg/24 hours) if *H. influenzae* type B vaccine completed and clindamycin (10–30 mg/kg/24 hours) if presence of a penicillin allergy
- Moderate to severe illness:
 - Empiric therapy with a 2nd- or 3rd-generation cephalosporin or with ampicillin-sulbactam
 - Consider vancomycin (40 mg/kg/24 hours) if a hospital-acquired infection is present or if pneumococcal resistance is suspected.
- Anaerobic, pseudomonas, and other gram-negative coverage should be considered in children not responding to initial therapy or having pre-existing artificial airways.
- In contrast to croup, nebulized racemic epinephrine and steroids do not provide significant relief.
- Duration: Based on clinical response; usually 10–14 days

ADDITIONAL TREATMENT

General Measures

- Support by stabilizing circulation, airway, breathing (CABs).
- Maintain airway.
- Initiate IV, O₂, and monitor.
- Rapid assessment of CABs is essential with emphasis on airway control.
- Supplemental oxygen is usually needed.
- Anticipate and prepare for emergent endotracheal intubation and tracheostomy.
- Endoscopy with suctioning and debridement is often necessary for diagnosis and therapy.
- Subsequent airway suctioning and monitoring prevents adverse outcomes.
- Increased ventilatory support is often required for children with pre-existing artificial airways.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Routine surveillance cultures in children with artificial airways are not recommended. They usually represent colonization in an asymptomatic patient.
- Signs to watch for:
 - Toxic appearance, excessive secretions, persistent fever, or worsening respiratory distress after introducing antibiotics suggest a resistant organism, an unusual pathogen, or a different diagnosis.
 - Recurrent respiratory distress, especially stridor, with subsequent respiratory tract infections suggests underlying tracheal stenosis.
 - Sudden deterioration on a ventilator may indicate endotracheal tube obstruction, pneumothorax, or mechanical problems.

DIET

NPO until the airway is stabilized and the patient is able to tolerate oral foods

PROGNOSIS

- Most children recover without any sequelae.
- Younger patients are more likely to require intubations and longer hospital stays.
- Children at risk for subacute tracheitis are more likely to have recurrent episodes.

COMPLICATIONS

- Atelectasis
- Pulmonary edema and pneumonia
- Septicemia
- Staphylococcal toxin syndromes (e.g., toxic shock syndrome)
- Prolonged mechanical ventilation with associated complications (including air leak, infection, pneumothorax, and tracheal stenosis)
- Subglottic stenosis
- Respiratory failure and arrest
- Death (<3.7%)

CODES

ICD9

464.10 Acute tracheitis without mention of obstruction

ICD10

- J04.10 Acute tracheitis without obstruction
- J04.11 Acute tracheitis with obstruction

FAQ

- Q: How can you differentiate a child with severe croup from one with tracheitis?
- A: Infectious croup and tracheitis can present with similar features of fever, toxic appearance, respiratory distress, and stridor. Direct endoscopic visualization and culture of the upper airway is the test of choice to distinguish these medical conditions. Croup is commonly associated with parainfluenza virus and a “steep sign” of the upper trachea on an anteroposterior neck radiograph.
- Q: Is influenza A virus a common pathogen of tracheitis?
- A: This subject is controversial. Influenza A virus is frequently recovered from tracheal cultures in children who present with tracheitis. It remains unclear, though, whether this virus is a pathogen or predisposing factor in tracheitis.
- Q: Is the supraglottic area usually involved in tracheitis?
- A: No. Unlike with epiglottitis, the supraglottic region is usually spared in tracheitis. Lack of supraglottic involvement suggests bacterial tracheitis rather than epiglottitis.

TRACHEOESOPHAGEAL FISTULA AND ESOPHAGEAL ATRESIA

Wendy J. Kowalski

BASICS

DESCRIPTION

- Esophageal Atresia (EA) is a congenital malformation of the esophagus where the esophagus ends in a blind pouch. There is a complete disconnection between the proximal pouch and the distal esophagus.
- Tracheoesophageal fistula (TEF) is a congenital malformation in which there is an abnormal connection between the esophagus and the trachea.
- There are 5 basic types of TEFs with varying incidences:
 - Proximal esophageal atresia with a fistula between the distal esophagus and the trachea (86%).
 - Esophageal atresia without a fistula (7%). There is typically a long gap between the 2 esophageal ends.
 - H-type fistula: TEF between the esophagus and cervical trachea without any atresia (4%).
 - Esophageal atresia with a proximal TEF (2%).
 - Esophageal atresia with both a proximal and a distal fistula (<1%).

EPIDEMIOLOGY

- Incidence 1/3000 to 1/4500 live births with slight male predominance
- 30–40% are born prematurely due to the polyhydramnios
- Increased incidence among twins

RISK FACTORS

- TEF generally accepted to be a multifactorial disorder. No specific environmental factor has been identified.
- Environmental: Prenatal methimazole, exogenous sex hormones, diethylstilbestrol, maternal alcohol and smoking, working in horticulture, insulin-dependent diabetes mellitus in the first trimester, anthracycline, and vitamin A deficiency.
- Intrauterine anoxia or vascular compromise of the tracheobronchial tree.
- A baby who has other anomalies or gastrointestinal atresias should be evaluated closely for TEF or EA.
- 50–75% of patients with TEF have other associated anomalies (cardiac, genitourinary, musculoskeletal, and CNS). Of these with associated anomalies, 15–25% of these will be a part of the VATER, VACTERL, or CHARGE association).
 - **VACTERL:** Vertebral defects, **A**nal atresia, **C**ardiac defects, **T**EF, **R**adial or **R**enal anomalies, and **L**imb anomalies
 - **CHARGE:** **C**oloboma, **H**ear disease, **C**hoanal Atresia, **R**etarded growth, **G**enital hypoplasia, and **E**ar anomalies with deafness

Genetics

- The role of genetics is unclear especially when assessing the incidence in identical twins. Usually only 1 twin is affected.
- Recent isolation and identification of new genetic mutations that cause syndromic forms of inherited TEF include the following: SOX2, FOX, NMYC, FANCA, FANCB, and CHD7.
- Occurs as part of a known genetic syndrome in 6–10% of patients, including full trisomies, Opitz syndrome, Feingold syndrome, Fanconi anemia, and Pallister–Hall syndrome.

PATHOPHYSIOLOGY

The trachea and the esophagus develop from a common foregut during the 3rd and 4th weeks of embryogenesis. The foregut divides into a ventral and a dorsal tube. The underlying mechanism of separation is unknown. When this process of division is abnormal due to genetic factors, as part of a syndrome or because of compression by extrinsic structures, EA and/or TEF may result.

ETIOLOGY

There is no consensus on the exact etiology or underlying mechanism.

DIAGNOSIS

HISTORY

- Prenatal:
 - History of polyhydramnios
 - Absent stomach bubble or a proximal esophageal pouch may be seen on prenatal ultrasound though usually the anatomy looks normal. Absent stomach bubble has a 56% positive predictive value for EA.
- Postnatal:
 - Respiratory symptoms at or shortly after birth due to aspiration of gastric contents which can cause a pneumonitis or compression of trachea/lungs by dilated or air-filled distended pouch or fistula
- Excessive salivation that requires frequent suctioning
 - Choking, coughing, or emesis during feedings
 - Inability to pass a catheter through the esophagus and into the stomach

PHYSICAL EXAM

- Vital signs: Tachypnea, hypoxia, or fever may indicate aspiration.
- Head: Abnormal ocular findings (coloboma) or ear anomalies may suggest associated syndrome
- Lungs: Persistent cough; recurrent cough with feeds; retractions, crackles, and/or wheezes with pneumonitis or pneumonia
- Cardiac: Thorough exam for a murmur that may suggest associated cardiac disease
- Abdominal: Flat or scaphoid abdomen if there is no fistula to the stomach or abdominal distension if there is a fistula between the trachea and the distal esophagus and the baby has been crying or received positive pressure ventilation

- Genitourinary: Assess for associated anomalies of the genitalia or palpable, large kidneys.
- Perianal: Document patent anus.
- Musculoskeletal: Inspection of spine, palpation of radial bone, and thumb to rule-out their absence.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Electrolytes/BUN/Creatinine: If poor feeding, on intravenous fluids, as part of a preoperative evaluation or if there is excess loss of fluid through oral secretions
- CBC with differential: If concern for aspiration or other infection or for preoperative evaluation
- Blood type and screen: For preoperative evaluation

Imaging

- Prenatal ultrasound: Findings that suggest EA or TEF are only present 40% of the time.
- Anteroposterior/lateral chest radiograph: First line to make the diagnosis after a nasogastric or orogastric feeding tube is passed.
 - Feeding tube curled up in esophageal pouch and absence of GI gas are highly suggestive of EA;
 - Feeding tube curled up in esophageal pouch with presence of GI gas suggests TEF;
 - Right upper lobe pneumonia or pneumonitis may also be seen due to aspiration of gastric contents
- Abdominal radiograph: Absence of air in the stomach and lower GI tract suggests EA without fistula
- Upper GI with contrast is contraindicated because of the risk of aspiration; however, it is useful for the diagnosis of H-type fistulas
- Bronchoscopy and/or endoscopy: Useful for suspected H-type fistulas
- Echocardiogram and Renal Ultrasound to evaluate for any associated anomalies and to determine the side of the aortic arch before surgery
- Radiographs of limbs if any abnormalities are noted on exam and of the vertebrae to look for any defects

DIFFERENTIAL DIAGNOSIS

- Gastroesophageal reflux
- Esophageal duplication
- Esophageal web/stricture
- Trauma to proximal esophagus
- Vascular ring/sling
- Pulmonary hypoplasia
- Tracheomalacia
- Central or neurologic cause of the feeding disorder and drooling

TREATMENT

ADDITIONAL TREATMENT

General Measures

Preoperative Management:

- Make the patient NPO and administer intravenous fluids
- Place a Replogle suction catheter into the upper esophageal pouch and elevate the head of the bed 30 degrees to minimize the secretions and risk for aspiration of gastric contents.
- Administer broad spectrum antibiotics.
- Avoid positive pressure ventilation if possible.
- Monitor closely for abdominal distention especially if there is a known distal TEF. The baby may need an emergent, venting gastrostomy to prevent gastric perforation, respiratory failure and death.
- Use comfort measures to reduce crying and subsequent gastric distention.
- Assess for associated anomalies as noted in the physical exam and imaging sections.

SURGERY/OTHER PROCEDURES

- Definitive treatment is surgical correction.
- The surgical options depend on the medical condition of the baby, the type of defect, and the distance between the esophageal segments.
- Primary end-to-end anastomosis and fistula ligation via thoracotomy is the desired method of correction; may not be feasible in long-gap atresias, in patients who are severely ill from associated problems, such as cardiac disease or in premature infants.
- If the distance between the 2 esophageal segments is too long, the stretching to make them meet will cause excessive tension on the anastomosis and is a risk for anastomotic leak or esophageal stricture.
- Delicate closure of the TEF is needed to prevent tracheal stenosis.
- An intra-operative chest tube is often placed to drain any potential leaks from the esophageal anastomosis.
- An intra-operative oral-gastric tube is often passed through the anastomosis and firmly secured to the baby's face.
- Gastrostomy is recommended when primary anastomosis is not immediately feasible and a gastrostomy tube is necessary for feeding or it may be placed emergently if there is a concern for gastric distention and perforation.
- Closure, even in severe cases, can occur within 8–12 weeks of life with esophageal elongation procedures as well as natural lengthening of esophagus as infant grows.
- If primary end-to-end anastomosis is not achievable, other suboptimal surgical options exist (e.g., gastric pull-up, creation of neoesophagus with colonic tissue, extrathoracic elongation), all of which are associated with a higher complication rate.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Immediate (postoperative):
 - Aggressive pulmonary treatment to minimize risk of respiratory infection.
 - Low pressure ventilation and respiratory support.
 - Empiric postoperative antibiotics to reduce infection risk especially if a chest tube is in place.
 - Frequent oral suctioning.
 - Low intermittent suction on orogastric tube that was passed intraoperatively
 - Total parenteral nutrition
 - Perform a dye study about 7 days post-op to look for any anastomotic leaks that would drain into the chest tube or oral-gastric tube
 - If no anastomotic leaks are present, the chest tube can be removed and the infant can be fed either orally or through the orogastric tube
 - Feedings can be advanced rather quickly once the anastomoses are proven intact and patent
- Long term:
 - Management of nonsurgical and surgical complications—airway issues like tracheomalacia, wheezing, or stridor; feeding issues like reflux and esophageal dysmotility; weight gain; infections
 - Coordination of care if associated with other congenital anomalies
 - Genetic evaluation and counseling

PROGNOSIS

- Several prognostic classifications have been developed which take into account birth weight, and the presence of associated anomalies.
- Survival is nearly 100% for infants with birth weight > 1500 g, no major cardiac disease, no other congenital anomalies and no respiratory complications who have EA with a distal TEF.
- In premature infants with associated anomalies, only a 50% survival is reported.
- In infants with severe associated anomalies, especially cardiac, survival has been reported at 30–50%.

COMPLICATIONS

- The course of a premature baby is typically more complicated and has the potential for more adverse outcomes.
 - Anastomotic leak: Early complication following surgical repair, in up to 15%; most resolve spontaneously but half of the cases will end up developing an esophageal stricture. Worst case scenario is mediastinal sepsis with the need for re-exploration and possible esophageal ligation.
 - Esophageal stricture: Seen in 5–40% of cases about 2–3 weeks post-op, especially after repair of long-gap atresias as tension on anastomosis increases stricture risk or after an anastomotic leak; often requires dilatation.
 - Esophageal dysmotility/dysphagia: Seen in >75% of patients (100% of those requiring colonic interposition).
 - Gastroesophageal reflux: Seen in 40–60% of patients with TEF and persists into adulthood; may contribute to strictures, poor growth, aspiration, and development of lung disease; treated with aggressive medical management.
 - Recurrent TEF: Uncommon complication following initial repair; increased risk following anastomotic leak; should be suspected when choking, coughing, and wheezing recur.

- Tracheomalacia: Reported in up to 75% of patients, but only 10–20% manifest clinical symptoms (i.e., barking cough, stridor, difficulty breathing with feeds); usually improves as the tracheal rings harden
- Injured recurrent laryngeal nerve: Especially with H-type fistula repair; presents with hoarse cry and recurrent aspiration
- Long term: Poor growth, chronic respiratory infections, wheezing, chest wall deformities and scoliosis

ALERT

- Meticulous postoperative care is essential for successful recovery after tracheoesophageal reconstruction. The fresh suture lines need to be protected so that they can heal properly.
- Mechanical ventilation with low pressures.
- Extubation only when the likelihood of requiring re-intubation is low.
- Careful manipulation of the head and the neck. Avoid hyperextension and forceful turning of the head.
- Careful oral suctioning—do not go too deep into the esophagus or the trachea so as to avoid injury to the surgical sites.
- Pay close attention to the depth of insertion of the oral-gastric tube and be sure it is secure since it is usually ends right at or passes through the anastomosis site.

TRACHEOMALACIA/LARYNGOMALACIA

Marleine Ishak
Sumit Bhargava
Ronn E. Tanel (5th edition)

BASICS

DESCRIPTION

- Laryngomalacia:
 - Narrowing and collapse of the supraglottic structures of the larynx
 - Most common congenital anomaly of the larynx
 - Most common noninfectious cause of stridor in children
- Tracheomalacia:
 - Narrowing and collapse of the extrathoracic or intrathoracic trachea
 - Common cause of chronic wheezing in infants and children
 - Classified as primary or secondary:
 - Primary: Congenital; results from immature development of the tracheal structures; may occur with other congenital anomalies such as tracheoesophageal fistula, laryngomalacia, and facial anomalies
 - Secondary: Acquired in a normally developed trachea after some insult such as prolonged positive pressure ventilation, recurrent infection or aspiration, or external compression

ETIOLOGY

- Laryngomalacia:
 - Multiple factors likely involved
 - Inward collapse of aryepiglottic folds (cuneiform cartilages) during inspiration
 - Elongated, flaccid, omega-shaped epiglottis prolapses posteriorly into the pharynx during inspiration.
 - Immaturity of the laryngeal cartilage results in weakness and collapse during inspiration.
 - Immaturity of neuromuscular control results in hypotonia of pharyngeal muscles.
- Tracheomalacia:
 - Weakness of the tracheal wall secondary to softening of the anterior cartilaginous rings and to decreased tone of the posterior membranous wall
 - During exhalation, increased collapsing pressure across a compliant airway wall causes invagination of the posterior membrane.
 - With increasing age, the length, area, thickness, and amount of cartilage increases in the anterior rings as well as the size and contractility of the membranous wall.

DIAGNOSIS

HISTORY

- Laryngomalacia:
 - Symptoms may be present at birth or delayed until 1–2 months of age.
 - Inspiratory stridor
 - May be asymptomatic during sleep or quiet breathing
 - Worsens with crying, agitation, feeding, upper respiratory infections, supine positioning
- Tracheomalacia:
 - Primary: Symptoms may be delayed until 2–3 months of age.
 - Secondary: Symptoms delayed until after causative insult occurs
 - Expiratory wheeze (or inspiratory stridor if extrathoracic trachea involved)
 - Harsh barking cough
 - May be asymptomatic during sleep or quiet breathing
 - Worsens with crying, agitation, feeding, and upper respiratory infections

PHYSICAL EXAM

- Laryngomalacia:
 - High-pitched or vibratory, low-pitched inspiratory stridor
 - Suprasternal retractions
 - Positional changes noted: Usually worsens with flexion of neck, supine position
 - Stridor transmitted throughout the chest on auscultation
- Tracheomalacia:
 - Homophonous expiratory wheeze (intrathoracic)
 - High-pitched inspiratory stridor (extrathoracic)
 - Intercoastal retractions, worse during acute respiratory infections

DIAGNOSTIC TESTS & INTERPRETATION

Diagnostic Procedures/Other

- Flexible fiberoptic laryngo/bronchoscopy:
 - Performed during spontaneous breathing
 - Most efficient method to evaluate stridor or chronic wheezing
 - Visualize the degree and extent of laryngomalacia and/or tracheomalacia.
 - Evaluate for other airway lesions in the differential diagnosis.

- Barium swallow:
 - Best noninvasive test to evaluate stridor or chronic wheeze
 - Especially of value in evaluation of patients with concomitant swallowing abnormalities
 - May see external compression of esophagus from vascular malformation
- Chest radiograph:
 - Usually normal in both laryngomalacia and tracheomalacia
 - Important to rule out other causes of chronic cough or abnormalities that may cause external airway compression
- Airway fluoroscopy:
 - Lateral views are the most useful to visualize the defect.
 - May be normal; does not rule out diagnosis
 - Inspiratory collapsing larynx may be seen in laryngomalacia.
 - Expiratory narrowing or collapse of the trachea may be seen in tracheomalacia.
- MRI:
 - Evaluates for thoracic/vascular anomalies that may cause external compression of the airway
 - May provide more precise measurements of airway size
 - May be performed dynamically to show changes in airway caliber during respiratory cycle
- Pulmonary function tests:
 - Might show diminished expiratory flow, typical notching on the flow volume loop, a biphasic flow volume loop, or flow oscillations.

DIFFERENTIAL DIAGNOSIS

- Laryngomalacia: Differential diagnosis of chronic stridor:
 - Abnormalities of the vocal cords: Vocal cord paralysis
 - Laryngeal abnormalities: Laryngeal cleft, laryngeal web, subglottic hemangioma, papilloma
 - Subglottic stenosis (biphasic stridor)

- Tracheomalacia: Differential diagnosis of chronic homophonous wheeze:
 - Structural abnormalities: Vascular compression/ring, tracheal stenosis/web, cystic lesion, mass/tumor
 - External compression from mediastinal mass, vascular ring
 - Nonstructural abnormalities: Gastroesophageal reflux disease, retained foreign body, chronic bacterial bronchitis

ALERT

- Do not miss other causes for presenting symptoms (see Differential Diagnosis above).
- Investigate lower airway in more severe cases of laryngomalacia for other airway anomalies.
- Treat diseases that may exacerbate symptoms and delay spontaneous resolution.
- The use of bronchodilators may increase the tracheal wall collapsibility by decreasing muscular tone, thereby making the symptoms worse.
- Bronchoscopy should ideally be done under conscious sedation during spontaneous breathing to avoid altering vocal cord movement and airway dynamics.
- The use of rigid bronchoscopy may stent open the trachea, making tracheomalacia more difficult to identify.

TREATMENT

ADDITIONAL TREATMENT

General Measures

- Laryngomalacia:
 - Usually resolves spontaneously by 15–18 months of age
 - Observation and reassurance
 - Treatment of exacerbating factors, such as upper respiratory infections, asthma, or gastroesophageal reflux disease
 - Tracheostomy may be needed in severe cases to bypass airway obstruction.
 - In rare situations, laryngeal surgery is necessary: Epiglottoplasty, resection of arytenoids
- Tracheomalacia:
 - Usually resolves spontaneously by 18–24 months of age
 - Observation and reassurance
 - Treatment of exacerbating factors, such as upper respiratory infections, asthma, or gastroesophageal reflux disease
 - Bronchoconstrictor therapy to increase tone of airway wall: Bethanechol chloride, ipratropium bromide
 - Continuous positive airway pressure may be needed in more severe cases.

- Tracheostomy may be needed in severe cases to bypass lesion or to provide continuous positive airway pressure.
- Humidification of secretions may help some patients, especially during respiratory infections.
- Aortopexy may be needed in severe cases to suspend the anterior trachea and widen the airway.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Monitor for recurrent respiratory symptoms, poor growth, and other exacerbating conditions (asthma, gastroesophageal reflux disease).

PROGNOSIS

- In cases of isolated laryngomalacia and/or tracheomalacia, prognosis is usually excellent.
- In patients with history of tracheoesophageal fistula, vascular ring, or other airway anomalies, tracheal dysfunction may persist after corrective surgery.

CODES

ICD9

- 519.19 Other diseases of trachea and bronchus
- 748.3 Other anomalies of larynx, trachea, and bronchus
- 748.3 Other anomalies of larynx, trachea, and bronchus

ICD10

- J38.7 Other diseases of larynx
- Q32.0 Congenital tracheomalacia
- Q31.8 Other congenital malformations of larynx

FAQ

- Q: When will the symptoms improve?
- A: As anatomic structures mature with age, laryngomalacia symptoms may improve by 6 months of age with usual resolution by 18 months of age. Tracheomalacia may last longer, but in both entities symptoms usually resolve completely by age 2 years.
- Q: Should all patients have an endoscopic evaluation?
- A: No. Diagnosis is usually made based on the appropriate history and physical examination. Infants with mild to moderate typical presentation need only careful monitoring for recurrence or worsening of symptoms and for poor growth. However, airway evaluation should be performed in all cases where a different pathology is considered or when symptoms worsen or persist past the expected age of resolution.
- Q: What should I do when symptoms worsen?
- A: Calm the patient; provide humidification of secretions and treatment of intercurrent infection. In cases where associated bronchospasm is suspected, a trial of steroids or bronchodilators may be considered.

TRANSFUSION REACTION

Cynthia F. Norris

BASICS

DESCRIPTION

Any acute or subacute adverse reaction that develops as a consequence of the administration of blood components:

- Types include:
 - Acute reactions: Hemolytic, febrile, allergic, anaphylactic, hypervolemia, bacterial sepsis, transfusion-related acute lung injury (TRALI)
 - Delayed reactions: Delayed hemolytic, transfusion-associated graft-versus-host disease (TA-GVHD)
 - Late complications of transfusion: Infection, alloimmunization, iron overload

EPIDEMIOLOGY

Incidence

10% of blood product recipients develop some type of transfusion reaction.

GENERAL PREVENTION

- Acute hemolytic: Proper labeling of blood specimens and products and adherence to procedures for correct identification of product and recipient will eliminate most acute hemolytic transfusion reactions.
- Febrile: Pretransfusion antipyretic or administration of leukodepleted products; the latter is recommended for long-term transfused patients who have a high incidence of febrile transfusion reactions.
- Allergic: Pretransfusion antihistamine or administration of washed erythrocyte products (in patients with repeated or severe allergic reactions)
- Hypervolemia: Administer appropriate volumes (typically 10–15 mL/kg) at appropriate rate, usually over 3–4 hours unless hypovolemic or actively bleeding; patients with chronic anemia are euvolemic and should be transfused with smaller volumes over longer time periods.
- Bacterial sepsis: Sterile technique in blood collection, storage, and administration; inspection of product before transfusion; bacterial screening of platelet products before they are transfused
- Delayed hemolytic: Appropriately performed antibody screen and cross-match as pretransfusion testing; check blood bank records for previous antibodies
- Anaphylactic: If due to anti-IgA in an IgA-deficient recipient, provision of IgA deficient products may be possible.
- TRALI: Deferral of donors is implicated in proven TRALI cases.
- GVHD: Patients at risk must receive irradiated blood products.

PATHOPHYSIOLOGY

- Acute hemolytic:
 - Antigen–antibody interaction leads to complement activation on the surface of the transfused RBCs, resulting in acute intravascular hemolysis and vasomotor instability.
 - Usually, ABO blood group incompatibility
 - Most commonly due to medical error
- Febrile:
 - Prior exposure to blood products may result in the formation of antibodies to leukocytes or plasma protein antigens; on re-exposure, the antigen–antibody interaction releases pyrogens; cytokines released into the product can also cause fever in the recipient.
 - More frequent in patients with past transfusions or pregnancy
- Allergic:
 - Recipient allergic response to donor plasma proteins or other constituents of plasma
 - Sporadic and donor dependent
- Hypervolemia: Also called TACO (transfusion-associated circulatory overload)
 - Circulatory overload leading to heart failure
 - Administration of an excessive volume of a blood product or infusion at an excessive rate
- Bacterial sepsis:
 - Intravascular infusion of viable bacteria and endotoxins leads to fever, chills, and/or acute septic shock.
 - Contaminated blood product; most commonly a platelet product near the end of shelf life
- Delayed hemolytic:
 - Previously transfused patients who are sensitized to a minor blood group antigen develop an anamnestic response on re-exposure. Antibody is below detectable levels in antibody screen and cross-match; after transfusion, titers rise (usually within 3–10 days) and extravascular hemolysis occurs.
- Anaphylactic:
 - Overwhelming acute allergic reaction. Can be mediated by anti-IgA formed by a recipient who is IgA deficient and receives blood products containing IgA.

- TRALI:
 - Antibodies to white cell antigens in the donor or recipient cause leukocyte aggregates that deposit in the lung.
 - Multiparous female donors with HLA sensitization often are implicated.
- GVHD:
 - Patients with inherited or acquired T-cell immunodeficiency can develop TA-GVHD from transfused immunocompetent T cells; can also occur if the donor and recipient are related and share HLA types.

DIAGNOSIS

HISTORY

- Acute hemolytic: Fever, chills, abdominal or flank pain, pink or tea-colored urine, tachycardia, hypotension, oliguria
- Febrile: Fever, chills
- Allergic: Urticaria; sometimes bronchospasm; rarely anaphylaxis
- Hypervolemia: Hypertension, dyspnea, rales, cardiac arrhythmia
- Bacterial sepsis: Fever, chills, hypotension
- Delayed hemolytic: Fever, malaise, dark urine, jaundice; rarely shock, renal failure
- TRALI: Acute dyspnea, tachypnea, rales, decreased oxygenation

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Acute hemolytic:
 - Direct Coombs test: Positive
 - CBC: Anemia
 - Urinalysis: Hemoglobinuria
 - PT, PTT, fibrinogen, fibrin split products: Disseminated intravascular coagulation (DIC)
- Febrile:
 - Direct Coombs test: Negative or no change from pretransfusion
 - Immediate Gram stain of the product
 - Blood culture of the patient and product
 - All results should be negative; a diagnosis of exclusion.
- Allergic:
 - No specific testing
- Bacterial sepsis:
 - Immediate Gram stain and blood culture of the transfused product: Result positive for bacteria

- Delayed hemolytic:
 - CBC: Anemia
 - Bilirubin: Elevated
 - Indirect Coombs test (antibody screen): Positive
 - Direct Coombs test: Positive (mixed field) if done early
- TRALI:
 - Leukocyte antibody testing in the implicated donor(s)
- Anaphylaxis:
 - IgA level in recipient. If undetectable, test for anti-IgA antibody (of the IgE class).

Imaging

Hypervolemia (TACO) and TRALI:

- Chest radiograph: Increased pulmonary vascular markings or infiltrates

TREATMENT

ADDITIONAL TREATMENT

General Measures

- Acute hemolytic:
 - Stop transfusion immediately.
 - Hydration, pressors, and diuretics to maintain circulation and urine output
 - Treat disseminated coagulation with plasma.
- Febrile:
 - Stop transfusion.
 - Antipyretics (acetaminophen)
 - May resume transfusion if patient is stable and acute hemolytic transfusion reaction and bacterial sepsis are ruled out
- Allergic:
 - Stop transfusion.
 - Antihistamine (diphenhydramine)
 - Steroids or epinephrine in severe reactions
- Hypervolemia: Diuretics (furosemide)
- Bacterial sepsis:
 - Stop transfusion.
 - Fluids if hypotensive
 - Antibiotics to eradicate *Staphylococcus* and Gram negatives including *Yersinia* species
- Delayed hemolytic: Depends on degree of hemolysis; if profound, management as acute hemolytic reaction. If mild, no therapy may be needed.
- TRALI: Supportive care, usually resolves in 12–24 hours
- Anaphylaxis: Epinephrine STAT, IV fluids, pressors, respiratory support

ONGOING CARE

COMPLICATIONS

- Posttransfusion hepatitis: Caused by hepatitis B or C viruses, others
- AIDS: Caused by HIV
- Cytomegalovirus (CMV):
 - Symptomatic infection in patients with inherited or acquired immunodeficiency states, premature neonates
 - These individuals should receive CMV-safe products.
- Other transfusion transmissible infections: Epstein-Barr virus, syphilis, malaria, toxoplasmosis, human T-lymphotropic virus I (HTLV-I), Chagas disease, babesiosis, filariasis, West Nile virus, parvovirus B19
- Alloimmunization:
 - Formation of antibodies to erythrocyte, platelet, and HLA antigens can develop in some multiply transfused patients; may cause delays in pretransfusion testing, febrile transfusion reactions, delayed hemolytic transfusion reactions, and platelet transfusion refractoriness.
 - HLA alloimmunization may also affect eligibility and organ procurement for solid organ transplantation.
- Iron overload: Long-term transfusion recipients will accumulate iron as a by-product of erythrocyte breakdown; an iron-chelating drug (deferoxamine or deferasirox) will enhance its excretion.

CODES

ICD9

- 999.80 Transfusion reaction, unspecified
- 999.83 Hemolytic transfusion reaction, incompatibility unspecified
- 999.89 Other transfusion reaction

ICD10

- T80.89XA Other complications following infusion, transfusion and therapeutic injection, initial encounter
- T80.92XA Unspecified transfusion reaction, initial encounter
- T80.919A Hemolytic transfusion reaction, unspecified incompatibility, unspecified as acute or delayed, initial encounter

FAQ

- Q: What is the risk of acquiring certain viral infections?
- A: Hepatitis B: 1:350,000 transfused units; hepatitis C: 1:1,935,000 transfused units; HIV: 1:2,135,000 transfused units
- Q: What is the risk of developing bacterial sepsis?
- A: 1:50,000 red cell units; 1:5,000–10,000 platelet units
- Q: Is directed donor blood safer?
- A: No, there is no evidence that the infection risk is lower, and some studies suggest that the infection risk may be higher.
- Q: Is it safe to give a transfusion to a patient with fever?
- A: Yes. However, if the temperature rises during the transfusion or if symptoms such as chills or hypotension develop, the transfusion should be stopped and the patient evaluated for a transfusion reaction.

TRANSIENT ERYTHROBLASTOPENIA OF CHILDHOOD

Julie W. Stern

BASICS

DESCRIPTION

An acquired, self-limited suppression of red cell production in an otherwise healthy child

EPIDEMIOLOGY

- Mean age at diagnosis is 26 months; <10% are >3 years of age at diagnosis.
- Slight male predominance (male/female 5.1:3.1)
- No seasonal predominance

RISK FACTORS

Genetics

There is no simple genetic pattern; familial transient erythroblastopenia of childhood has been reported (rarely), suggesting a combination of environmental factors and genetic propensity.

GENERAL PREVENTION

There is no known way to prevent transient erythroblastopenia of childhood.

ETIOLOGY

- Unknown
- Possible viral causes include parvovirus B19 and human herpesvirus 6 (HHV-6), but this remains hypothetical.
- A serum inhibitor, such as an IgG directed at the committed erythroid stem cell progenitor, has also been proposed but not yet proven.

DIAGNOSIS

HISTORY

- Pallor: Typically slow in onset and therefore often missed by parents; often noted by an adult who sees the child less frequently
- Activity level:
 - Often preserved because of slow onset of anemia
 - An extremely anemic child may be irritable, sleepy, and/or lethargic.
- History of fever, easy bruisability, or frequent/severe infections (especially bacterial): Should alert the clinician to consider other diagnoses such as leukemia and bone marrow failure syndromes

PHYSICAL EXAM

- Child is generally well appearing and not chronically ill.
- Pallor
- Tachycardia secondary to anemia
- Usually no organomegaly, ecchymosis, petechiae, or jaundice

DIAGNOSTIC TESTS & INTERPRETATION

Diagnostic Procedures/Other

- CBC:
 - Low hemoglobin, normal mean corpuscular volume, normal RBC morphology
 - Total WBC count/morphology and platelet count should be normal; if not, consider leukemias.
 - Absolute neutrophil count may be decreased (rarely <500/ μ L), but morphology must be normal.
 - Red cell distribution width may be elevated during recovery.
- Reticulocyte count: Low to zero during anemic phase; should be high during recovery
- Chemistry/Blood bank: Bilirubin, lactate dehydrogenase, ferritin, iron levels, and direct and indirect Coombs testing should be normal to rule out iron-deficiency anemia and immune hemolysis.
- Parvovirus titers, parvovirus PCR testing
- Immunoglobulin (Ig) levels in some cases
- Hemoglobin electrophoresis with quantitative fetal hemoglobin: Should be normal in transient erythroblastopenia of childhood, fetal Hgb elevated in Diamond-Blackfan anemia
- Chest radiograph: To determine degree of cardiomegaly

- Bone marrow aspiration:
 - Not mandatory to make diagnosis
 - May be necessary to rule in transient erythroblastopenia of childhood and rule out other diagnoses such as Diamond-Blackfan and the leukemias
 - Presence or absence of early RBC precursors may help predict time to recovery.
 - Maturation of megakaryocytes and the myeloid cell line must be normal, especially if neutropenia is present.

DIFFERENTIAL DIAGNOSIS

- Environmental: Iron-deficiency anemia
- Metabolic: Hypothyroidism
- Congenital: Diamond-Blackfan anemia (this diagnosis usually made within 1st year of life)
- Neoplasm: Leukemia, myelodysplastic syndromes
- Miscellaneous: Renal disease, anemia of chronic disease, blood loss (usually GI)

TREATMENT

MEDICATION (DRUGS)

- No role for prednisone, iron supplements, anabolic steroids, or other immunosuppressive agents
- Short-term folic acid may be indicated during reticulocytosis.

ADDITIONAL TREATMENT

General Measures

- Initial inpatient observation for complications of severe anemia; daily CBC at least initially to gauge rate of fall of hemoglobin/rise of reticulocyte count and to estimate time to recovery

- Packed RBC transfusion:
 - Only if there is evidence of cardiovascular compromise
 - If a transfusion is needed, transfuse slowly to prevent fluid overload. A good rule of thumb is to transfuse the same number of mL/kg as the patient's hemoglobin over 3–4 hours. Should a 2nd transfusion be needed, attempt to use a 2nd aliquot of the same unit to decrease donor exposure.
- Normal activity and diet for age, as tolerated
- Instruct family on signs and symptoms of severe anemia.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Clinic visits weekly to monitor hemoglobin and reticulocytes. These visits may need to be more frequent in the beginning of the illness and less frequent as recovery becomes evident.
- Elevation of reticulocyte count is the 1st sign of recovery.

PROGNOSIS

- All children recover usually within 1–2 months from diagnosis (up to 8 months to recovery).
- Prognosis is excellent.
- Recurrence is rare.

COMPLICATIONS

- Cardiovascular compromise secondary to severe anemia is often less than expected given the level of anemia. High-output CHF is unusual.
- Neurologic symptoms including confusion and transient hemiparesis have been reported but are rare.

- A significant number of patients also have neutropenia (absolute neutrophil count $\leq 1,500/\mu\text{L}$) during either the acute or recovery phase of the illness.

ALERT

- Isolation is necessary because of possible teratogenicity of parvovirus 19 and contagion within the hospital.
- Transient erythroblastopenia of childhood must be an isolated normocytic, normochromic anemia. If the other cell lines are affected (except for mild neutropenia) or if the anemia is macrocytic, consider bone marrow failure syndromes.
- Iron therapy has no place in the treatment of transient erythroblastopenia of childhood. Be sure to check RBC indices and reticulocyte count prior to instituting iron therapy for anemia.

CODES

ICD9

284.81 Red cell aplasia (acquired)(adult)(with thymoma)

ICD10

D60.1 Transient acquired pure red cell aplasia

FAQ

- Q: Can other children in a family get this illness?
- A: The cause(s) of this illness in otherwise normal children is unknown. It is very rare for other family members to be affected. It is appropriate to reassure parents with regard to this issue.
- Q: Are transfusions always necessary?
- A: No. Only in cases of heart failure is a transfusion necessary. Most often, children can be managed with watchful waiting.
- Q: How can transient erythroblastopenia of childhood be distinguished from Diamond-Blackfan syndrome?
- A: Children with Diamond-Blackfan syndrome are usually < 1 year old and can have elevated hemoglobin F levels. If a bone marrow aspirate is obtained during the recovery phase of transient erythroblastopenia of childhood, the diagnosis will be clear. Often, however, only time will tell. Children with transient erythroblastopenia of childhood always recover; those with Diamond-Blackfan syndrome do not.
- Q: Is transient erythroblastopenia of childhood a precursor to leukemia?
- A: No. However, if recovery does not occur in a timely manner, or if neutropenia worsens, a bone marrow aspirate may be indicated if not previously completed.

TRANSIENT TACHYPNEA OF THE NEWBORN (TTN)

John I. Takayama

BASICS

DESCRIPTION

Early onset of tachypnea (respiratory rate >60 breaths/minute) in the newborn following uneventful, normal preterm or term, vaginal, or cesarean delivery; sometimes with retractions, expiratory grunting, or nasal flaring; rarely with cyanosis; relieved by minimal oxygen (FIO₂ <40%)

EPIDEMIOLOGY

Incidence

- 4–6 per 1,000 live births (common)
- Incidence is higher in males than females.

RISK FACTORS

Early gestational age and cesarean section delivery have been identified as major risk factors. Other factors include maternal diabetes, macrosomia, and parental history of asthma.

GENERAL PREVENTION

- When possible, infants should be delivered by vaginal birth because TTN is seen more in infants born by cesarean section.
- Elective cesarean section should be postponed until 39 weeks' gestation or later.

ETIOLOGY

- Slow or decreased absorption of fetal lung fluid, including fluid accumulation in the interstitial space, resulting in decreased pulmonary compliance, decreased tidal volume, and increased dead space. Disruption of sodium transport by lung epithelia has been postulated recently as reason for ineffective transepithelial alveolar fluid movement.
- Mild immaturity of the surfactant system may contribute to decreased pulmonary compliance and result in increased respiratory rate. In some infants with TTN, a decreased amount of phosphatidylglycerol has been found in their amniotic fluid.

DIAGNOSIS

HISTORY

- Usually presents as early onset of tachypnea (within 1st few hours of life)
- Maternal risk factors: TTN is twice as likely for infants of mothers with asthma compared with infants of mothers without asthma.
- Birth-related risk factors (mechanisms unknown):
 - Maternal sedation
 - Maternal fluid administration
 - Maternal exposure to sympathomimetics
 - Prolonged labor
 - Cesarean section
 - Preterm birth
 - Fetal asphyxia
- Presence of risk factors for other conditions (e.g., maternal fever) may make the diagnosis of TTN less likely and other diagnoses more likely (e.g., pneumonia or sepsis).

PHYSICAL EXAM

- Respiratory rate >60/minute
- Grunting, nasal flaring, intercostal retractions; at times, cyanosis
- Barrel-chest appearance
- Lungs clear on auscultation; sometimes rales or crackles but not rhonchi
- Absence of signs and symptoms more specific for infection and neurologic as well as cardiac conditions (e.g., fever, cyanosis without respiratory distress)

DIAGNOSTIC TESTS & INTERPRETATION

- Pulse oximetry: Oxygen saturation should be maintained at >96%.
- Arterial blood gas: Metabolic acidosis with base deficit suggests asphyxia; not usually ordered.
- CBC: Decreased or increased WBC count and increased immature forms (e.g., bands) suggest infection; not usually ordered.
- If febrile, blood culture: Positive results indicate infection.

Imaging

Chest radiograph: TTN is indicated by prominent central pulmonary vascular markings (central perihilar streaking), fluid lines in the interlobar fissures, hyperaeration, flat diaphragms, and, occasionally, pleural fluid.

DIFFERENTIAL DIAGNOSIS

- Respiratory:
 - Meconium aspiration
 - Respiratory distress syndrome
 - Pneumothorax
 - Pneumomediastinum
- Infection:
 - Pneumonia
 - Sepsis
- Neurologic:
 - Cerebral hypoventilation
 - Birth asphyxia
- Cardiac:
 - Congenital cyanotic heart disease
- Metabolic:
 - Conditions manifesting as metabolic acidosis
- Miscellaneous:
 - Congenital cystic adenomatoid malformation (CCAM)
 - Congenital diaphragmatic hernia

ALERT

Because TTN is a diagnosis of exclusion, it is important to consider and exclude other diagnoses by carefully relying on history, examination, and appropriate laboratory aids.

TREATMENT

ADDITIONAL TREATMENT

General Measures

- Emergency care: Usually not required
 - Initially, nothing by mouth until respiratory status is stabilized and diagnosis is clarified.
 - Oxygen: May help reduce respiratory distress if the patient is hypoxic
 - Antibiotics if pneumonia or sepsis suspected
 - Neither furosemide (diuretic) nor racemic epinephrine has been shown to improve TTN.
- Supportive care:
 - IV fluids if NPO
 - Monitoring of respiratory status using continuous pulse oximetry and respiratory and heart rate surveillance
- Duration of therapy:
 - Typically 2–5 days

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- When to expect improvement:
 - Rapid respirations slow gradually.
 - 12–72 hours
- Signs to watch for:
 - Fever, lethargy, poor feeding, early jaundice
 - Persistent or increased need for oxygen

PATIENT EDUCATION

Infant can go home when the breathing rate is low enough so that he or she feeds well and when oxygen is no longer required.

PROGNOSIS

- Generally considered a self-limited condition with no recurrence and no residual pulmonary dysfunction. Some studies, however, have demonstrated associations with persistent pulmonary hypertension of the newborn.
- Infant may be at risk for breathing problems such as asthma. Recent evidence indicates a higher incidence of wheezing and asthma in children with TTN diagnosis.

COMPLICATIONS

- Hypoxia
- Rarely, respiratory failure requiring continuous positive airway pressure or mechanical ventilation

CODES

ICD9

770.6 Transitory tachypnea of newborn

ICD10

P22.1 Transient tachypnea of newborn

FAQ

- Q: How long does the rapid breathing last?
- A: Most babies are better in 1 day, but TTN may persist for 2–3 days.
- Q: Are chest x-rays required?
- A: No. If the baby is eating well and having no other medical issues, observation is sufficient.

TRANSPOSITION OF THE GREAT ARTERIES

Bradley S. Marino

BASICS

DESCRIPTION

Abnormal anatomic relationship between the great arteries and the ventricles in which the aorta arises from the anatomic right ventricle and the pulmonary artery arises from the anatomic left ventricle

Incidence

Incidence is 20–30 per 100,000 live births, with a 60–70% male predilection.

Prevalence

Transposition of the great arteries represents up to 7% of all cases of congenital heart disease.

PATHOPHYSIOLOGY

- Systemic and pulmonary circulations are separated and function in parallel.
- Desaturated systemic venous blood is ejected from the right heart to the aorta, whereas the oxygenated pulmonary venous blood is ejected from the left ventricle into the lungs.
- Survival depends on defects that permit mixing between the two circulations (patent ductus arteriosus [PDA], patent foramen ovale [PFO], ventricular septal defect [VSD]).

DIAGNOSIS

HISTORY

- Infants are of normal birth weight, or sometimes large for gestational age.
- Cyanosis
- Tachypnea often without retractions
- Poor feeding

PHYSICAL EXAM

- General:
 - Moderate to severe cyanosis
- Cardiovascular:
 - Heart sounds: Single loud S₂, but no heart murmur is heard in infants with intact ventricular septum; soft systolic murmur in those infants with a VSD, and a systolic ejection murmur of valvar or subvalvar aortic or pulmonic stenosis may be heard.
- Respiratory:
 - Generally dyspnea and tachypnea present without retractions in a neonate without a VSD; with a large VSD and congestive heart failure (CHF), retractions may be present.
- Abdomen:
 - Hepatomegaly may occur with a large VSD and CHF.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

Arterial blood gas:

- Hypoxemia (pO₂ often in low 30s) unchanged in 100% FIO₂. Infants with inadequate mixing have pO₂ <25 torr with metabolic acidosis.

Imaging

- Chest radiograph:
 - Mild cardiomegaly with an egg-shaped heart with narrow superior mediastinum (so-called egg on a string) and increased pulmonary vascular markings.
- EKG:
 - Initially normal, progressing to right ventricular hypertrophy and right axis deviation
- Echocardiogram:
 - 2D ECHO and color-flow Doppler studies usually provide all anatomic and functional information required for management of infants with D-transposition of the great arteries (D-TGA). The study should focus on the alignment of the great arteries and other associated anomalies, specifically defects that promote intercirculatory mixing, the presence of left or right ventricular outflow tract obstruction, and the coronary anatomy.

Pathological Findings

- In D-TGA, the aorta originates anteriorly from the right ventricle and carries desaturated blood to the body, and the pulmonary artery originates posteriorly from the left ventricle and carries oxygenated blood to the lungs. There is fibrous continuity between the pulmonary and mitral valves; subaortic conus (infundibulum) is present. In the normal heart, the aorta arises posteriorly from the left ventricle, there is fibrous continuity between the aortic and mitral valves, and subpulmonary conus is present.
- TGA types:
 - The most common type of TGA, known as D-TGA has transposed great arteries with cardiac segments (S,D,D): Situs solitus of the atria and viscera (S), dextroventricular segment situs (D), aortic valve annulus to the right of the pulmonary artery (D).
 - L-TGA or “corrected transposition,” has transposed great arteries with cardiac segments (S,L,L): Situs solitus of the atria and viscera (S), levoventricular segment situs (L), and the aortic valve annulus is to the left of the pulmonary artery (L).

- Associated abnormalities include: PDA and PFO with intact ventricular septum (50%); VSD (40%), posterior malalignment VSD with left ventricular outflow tract obstruction (e.g., subpulmonic stenosis, pulmonary stenosis, pulmonary atresia; 10%), anterior malalignment VSD with right ventricular outflow tract obstruction (e.g., subaortic stenosis, aortic stenosis, coarctation of the aorta or interruption of the aortic arch; 10%); coronary branching abnormalities (33%); leftward juxtaposition of the atrial appendages (5%); and straddling of the atrioventricular valve,

DIFFERENTIAL DIAGNOSIS

The differential diagnosis for the neonate with TGA is that for the cyanotic neonate.

- Cardiac:
 - Lesions with ductal-dependent pulmonary blood flow:
 - Tricuspid atresia with normally related great arteries
 - Tetralogy of Fallot
 - Tetralogy of Fallot with pulmonic atresia
 - Critical pulmonic stenosis
 - Pulmonary atresia with intact ventricular septum
 - Ebstein anomaly
 - Heterotaxy (most forms)
 - Ductal-independent mixing lesions:
 - Total anomalous pulmonary venous connection without obstruction
 - Truncus arteriosus
 - Lesions with ductal-dependent systemic blood flow:
 - Hypoplastic left heart syndrome
 - Interrupted aortic arch
 - Critical coarctation of the aorta
 - Critical aortic stenosis
- Pulmonary:
 - Primary lung disease
 - Airway obstruction
 - Extrinsic compression of the lungs
- Neurologic:
 - CNS dysfunction
 - Respiratory neuromuscular dysfunction
- Hematologic:
 - Methemoglobinemia
 - Polycythemia

TREATMENT

MEDICATION (DRUGS)

- Correction of metabolic acidosis, hypoglycemia, and hypocalcemia improves myocardial function.
- Prostaglandin E1 (PGE1) is used for severe cyanosis to promote left (aorta) to right (pulmonary artery) shunting at the ductus arteriosus, thereby increasing pulmonary blood flow, distention of the left atrium and improved mixing at the atrial level. Side effects of PGE1 include apnea, fever, and hypotension.

SURGERY/OTHER PROCEDURES

- Interventional catheterization:
 - Balloon atrial septostomy (Rashkind procedure) is used in the severely hypoxemic infant with an intact or restrictive atrial septum to promote intercirculatory mixing at the atrial level and stabilize the neonate before definitive or palliative surgery.
- Definitive surgery for D-TGA includes procedures that redirect the pulmonary and systemic venous return at the atrial, ventricular, and great artery levels.
 - Atrial inversion: Atrial inversion procedures involve baffling the pulmonary venous blood flow to the tricuspid valve (systemic circulation), and the systemic venous blood flow to the mitral valve (pulmonary circulation). The 2 atrial inversion operations include the Mustard procedure, in which prosthetic or pericardial baffles are used to redirect the blood, and the Senning procedure, in which the baffles are composed of an atrial septal flap and the right atrial free wall. The Senning or Mustard procedures may be used in the following infants:
 - Infants with D-TGA with intact ventricular septum who have not had surgical repair within the first month of life.
 - Neonates with D-TGA with intact ventricular septum and severe pulmonic stenosis. Most centers would perform a Rastelli procedure for this anatomic variant (see subsequent list items).
 - Neonates with D-TGA with “unswitchable coronaries” (<1% of cases).
 - Ventricular inversion:
 - D-TGA with a VSD and severe pulmonic stenosis: The Rastelli operation may be used to redirect blood flow at the ventricular level. In this operation, the proximal main pulmonary artery is divided and oversewn, and the left ventricular blood flow is baffled to the aorta by creating an intraventricular tunnel between the VSD and the aortic valve. A conduit is placed from the right ventricle to the pulmonary artery to redirect the right ventricular blood flow.

- Arterial switch:
 - D-TGA with intact ventricular septum and “switchable” coronaries: The arterial switch operation (ASO) is performed in which the great arteries are transected above their respective semilunar valves and switched with reimplantation of the coronary arteries into the neo-aortic root (native pulmonary valve root).
 - D-TGA with anterior malalignment VSD with severe aortic stenosis: ASO with VSD patch closure and transannular patch of the right ventricular outflow tract.

ONGOING CARE

PROGNOSIS

- Without treatment, mortality is 30% within the first week of life, 50% within the first month, 70% within the first 6 months, and 90% within the first year.
- In most centers, the mortality rate after ASO for D-TGA with intact ventricular septum or D-TGA with a VSD is <3%. Factors that have been shown to increase the mortality risk include an intramural course of the left coronary artery, retropulmonary course of the left coronary artery, complex arch abnormalities, right ventricular hypoplasia, multiple VSDs, and straddling atrioventricular valves.

COMPLICATIONS

- Complications of intra-atrial surgeries include obstruction of pulmonary venous return (<2% of cases), obstruction of systemic venous return (5% of cases), residual intra-atrial baffle shunt (20% of cases), tricuspid regurgitation (5–10%), absence of sinus rhythm (>50% of cases), supraventricular arrhythmias (50%), and moderately to severely depressed right ventricular function (20%). Follow-up observation is recommended every 12 months to detect arrhythmias, tricuspid regurgitation, or depressed right ventricular function that generally occur years after surgery. Arrhythmias include sinus node dysfunction (e.g., marked sinus bradycardia, ectopic atrial rhythm, junctional rhythm, or junctional bradycardia) and supraventricular tachycardia, especially atrial flutter.
- Complications after the Rastelli operation include left ventricular outflow tract obstruction, conduit obstruction, and complete heart block. Follow-up observation is recommended every 12 months to monitor for conduit obstruction, left ventricular outflow tract obstruction, and heart block.
- The most common complication after the ASO is neo-aortic root dilation with or without neo-aortic insufficiency. Other rarer complications include supralvalvar pulmonary stenosis at the anastomotic site (5% of cases), supralvalvar aortic stenosis at the anastomotic site (5% of cases), and coronary artery obstruction, that may lead to ischemia and infarction. These complications are uncommon and usually hemodynamically insignificant. Mortality varies depending on the period of time being assessed:
 - Early mortality is usually related to kinking or obstruction of the coronary arteries during transfer to the neo-aorta, an “unprepared” left ventricle, or hemorrhage from the multiple suture lines.
 - Late mortality (i.e., 1–2%) usually results from myocardial ischemia, pulmonary vascular obstructive disease, or during reoperation for supralvalvar stenosis.

- Follow-up observation is recommended every 12 months to monitor for neo-aortic root dilation, neo-aortic valve insufficiency, supralvalvar aortic or pulmonic stenosis, and coronary artery ischemia.

TRANSVERSE MYELITIS

Yang Mao-Draayer

BASICS

DESCRIPTION

Inflammation in the spinal cord causing acute or subacute loss of motor, sensory, and autonomic function, often preceded by mid-back pain; may be postinfectious, postvaccination, or associated with multiple sclerosis (MS). While acute transverse myelitis (ATM) implies an inflammatory disease of the spinal cord, acute transverse myelopathy is a broader term that refers to any process that acutely impairs spinal cord function. Presumed pathophysiology of ATM is autoimmune-mediated inflammation and demyelination of the spinal cord. Postinfectious etiology largely predominates in children.

EPIDEMIOLOGY

Incidence

1–4/million per year, affecting all ages, with bimodal peaks between the ages of 10 and 19 years and between 30 and 39 years. Boys and girls are affected equally.

COMMONLY ASSOCIATED CONDITIONS

- ATM is most commonly associated with infection.
- It may be part of demyelinating disorders: May either occur as 1st episode of MS or in that disease setting; may also occur with demyelination of optic nerves (i.e., optic neuritis), also called Devic disease or neuromyelitis optica (NMO); may occur in monophasic demyelinating disease—acute disseminated encephalomyelitis (ADEM)—multiple demyelinating lesions in the brain as well as in the spinal cord.
- ATM may be associated with systemic inflammatory diseases (e.g., systemic lupus erythematosus, primary antiphospholipid syndrome, juvenile rheumatoid arthritis, sarcoidosis, connective tissue disease, vasculitis); may present with acute or recurrent transverse myelitis.
- ATM is rarely seen in association with metabolic causes of myelopathy (e.g., vitamin B₁₂ deficiency).
- ATM does not usually occur in association with inherited demyelinating diseases (e.g., adrenomyeloneuropathy/leukodystrophy, Pelizaeus-Merzbacher, globoid cell leukodystrophy, and metachromatic leukodystrophy); these usually present with chronic myelopathy.

DIAGNOSIS

HISTORY

- Most prominent is neurologic dysfunction consistent with a spinal cord dysfunction at a specific level. Bilateral, but not necessarily symmetric, symptoms are usually present.
- ATM may be suggested by history of back pain, sensory level, and urinary/fecal incontinence or retention. The patient often has lower extremity weakness or inability to bear weight, possibly with decreased spontaneous use of hands.
- Details of the temporal course of the symptoms are important, because sudden onset of weakness raises the possibility of acute structural or vascular causes of myelopathy. In ATM, onset of spinal cord dysfunction usually progress in 4 hours to 21 days; the patient's signs usually plateau and evolve toward spasticity/hyperreflexia.
- ATM is often preceded by respiratory illness, vaccination, or systemic illness. One should determine if there is a prior history of infection or systemic inflammatory disease.
- Other important findings in history include vascular/ischemia, neoplasia, MS, radiation exposure, trauma, or immunodeficiency to rule out other causes of acute myelopathy.

PHYSICAL EXAM

- Extreme irritability: Extent of weakness may be assessed by spontaneous activity and how vigorously the child resists examination.
- Fever, hypertension, tachycardia, meningeal signs may be present; in such cases, CNS infection needs to be ruled out; point tenderness over the spine may suggest trauma or infection.
- Neurologic: Check visual acuity and color vision; funduscopic examination for optic nerve head pallor (optic neuritis).
- Increased tone: Spastic weakness is usually symmetric, legs more than arms.
- Reflexes are usually brisk, with positive Babinski sign.
- Sensory ataxia, a sensory level (a partial level is commonly seen) that may spare joint position, and vibration may be present.
- Urgent complication: Sphincter dysfunction, urinary retention or incontinence; check for loss of anal wink, bladder dilatation, and large post-void residual urine (> 100 mL).

DIAGNOSTIC TESTS & INTERPRETATION

Diagnostic Procedures/Other

- A diagnosis of ATM requires evidence of inflammation of the spinal cord. MRI and CSF analysis are the 2 most important tests and are mandatory in suspected ATM. Enhancing spinal cord lesion or pleocytosis or increased IgG index is required for the diagnosis. If both tests are negative, repeat tests in 2–7 days is recommended.

- The 1st priority in acute myelopathy is to rule out structural causes—compressive myelopathy. Gadolinium-enhanced MRI of spine (above the level that could explain weakness or sensory deficit) excludes structural causes of myelopathy and can indicate transverse myelitis.
- The 2nd priority is to define the presence/absence of spinal cord inflammation and to rule out other CNS infections. Lumbar puncture is usually done after imaging, often showing normal or slightly increased protein levels and mild pleocytosis with lymphocyte predominance. Elevation of IgG index and presence of oligoclonal bands are indicative of ATM, MS, or other systemic inflammatory disease. CSF Gram stain; bacterial, viral, and fungal culture; VDRL, Lyme antibodies; and PCR of specific viruses should all be negative in ATM.
- The 3rd priority is to determine the extent of demyelination. Gadolinium-enhanced MRI of the brain and the orbit and evoked potential studies (e.g., visual evoked potential, somatosensory evoked potential) may identify other sites.
- Investigation for underlying systemic inflammatory/metabolic disorder includes ESR and ANA; for granulomatous disease or infection, includes PPD/anergy panel, serum angiotensin-converting enzyme (ACE; elevated in sarcoidosis), RPR, Lyme titer; B₁₂ and very-long-chain fatty acid (VLCFA).
- Viruses associated with ATM include the herpes viruses (EBV, VZV, HSV); CMV; mumps; rubella; influenza; hepatitis A, B, and C; and HIV. Positive IgM or >4-fold increase in IgG levels on 2 successive tests to a specific infectious agent suggests diagnosis of parainfectious ATM.

DIFFERENTIAL DIAGNOSIS

- Presentation of ATM in toddlers may resemble osteomyelitis, arthritis, toxic synovitis, or even a sudden abdominal problem: Extreme irritability, unwillingness to bear weight.
- Extremity weakness seen in ATM may resemble an acute neuromuscular disorder (e.g., Guillain-Barré syndrome or polymyositis), in which case the definitive myelopathic signs (e.g., spastic tone, hyperreflexia, upturned toes, sensory level) are not present. Guillain-Barré syndrome is frequently confused with ATM, particularly when the latter does not show typical upper motor neuron findings; normal MRI (except possible nerve root enhancement in GBS) and the albuminocytologic dissociation (high-protein, low cell count) in CSF from patients with Guillain-Barré syndrome help distinguish the 2 conditions.

- Other causes of myelopathy that require different treatment must be excluded—for example, urgent, surgically remediable cause of myelopathy (e.g., epidural abscess, tumor, arteriovenous malformation); emergency basis radiation, and/or high-dose IV corticosteroid therapy for neoplastic cord compression.
- ATM may be the presenting feature of MS, especially in patients with partial ATM and abnormal initial brain MRI; in such cases, MS treatments and follow-up MRIs should be considered.
- NMO (or Devic disease) is a rare (even rarer in children than adults) and aggressive demyelinating disease. When children present with recurrent transverse myelitis with an elongated (>3 vertebral segments) intramedullary spinal cord lesion, serum NMO antibody testing should be obtained to facilitate the diagnosis and treatment.
- Compressive myelopathies: Vertebral osteomyelitis/discitis; intrinsic or extrinsic tumor; spine trauma; epidural abscess
- Infectious causes of myelopathy:
 - Poliomyelitis: Concern about underlying immunodeficiency
 - Lyme disease: In children with possible exposure, serology is nonspecific but sensitive unless antibiotics are given early in the course, which ablates immune response
 - Syphilis: Usually chronic, tertiary form (tabes dorsalis), although meningovascular myelitis may cause acute myelopathy.
- Vascular causes: Cord ischemia (postcardiac surgery), cord arteriovenous malformation

 **TREATMENT**

ADDITIONAL TREATMENT

General Measures

- IV methylprednisolone may be useful in ATM or other acute demyelinating diseases based on observational studies. IV immunoglobulin or plasmapheresis may be a safe and effective therapeutic alternative in patients who do not respond to or are intolerant of IV methylprednisolone.
- Cyclophosphamide has been reported to be useful in myelitis associated with systemic inflammatory diseases.
- Symptomatic management: Anticipate urinary retention to prevent perforated bladder. Bowel/bladder regimen, catheterization, prophylactic antibiotics, and stool softeners are often used.

- Unlike acute polyneuropathy (i.e., Guillain-Barré syndrome), ATM rarely causes respiratory insufficiency unless patients have cervical lesions. In such cases, an intensive care setting to anticipate respiratory failure or autonomic instability, mechanical ventilation, and cautious use of antihypertensive agents may be necessary.
- Physical and occupational therapy (PT/OT) may help promote functional recovery and prevent contractures.

 **ONGOING CARE**

PROGNOSIS

- 1/3 of individuals with ATM recover completely, with the symptoms mostly resolved (gradually) in 3–6 months; 1/3 are left with moderate disability, and 1/3 have severe disability. Residual neurologic deficits include fixed weakness and sensory or autonomic deficits. Sphincter dysfunction improves more slowly than do other deficits. Treatment is largely symptomatic, and long-term PT/OT may be beneficial.
- Prognostic factors: Older age, increased deep tendon reflexes, and presence of the Babinski sign may indicate a better course. Rapid progression, back pain, and spinal shock predict poor recovery.
- ATM may be the presenting feature of MS, especially in patients with partial ATM and abnormal initial brain MRI; in such cases, follow-up MRIs and MS therapy should be considered.

FAQ

- Q: What is the usual clinical course of ATM?
- A: The course of ATM in children proceeds through 3 stages: (a) Initial motor loss precedes sphincter dysfunction in most patients; there is often a sensory loss below certain levels, usually over 2–3 days; (b) plateau phase, where the mean duration of plateau is 1 week; and (c) recovery phase.
- Q: What causes the pain and irritability commonly seen in children with ATM?
- A: Pain in ATM may be as a result of (a) neuropathic pain from nerve root inflammation, (b) nociceptive pain from dural inflammation, (c) muscle spasm from motor dyscontrol, (d) bladder distention from dysautonomia, (e) psychological distress from loss of motor control, or (f) dysesthesia from demyelination of spinothalamic tract.
- Q: When should MS be considered?
- A: MS should be considered when the history indicates other neurologic symptoms, such as internuclear ophthalmoplegia, optic neuritis, focal weakness, and numbness that lasts at least 24 hours to days that have now resolved completely, other lesions on brain/spine MRI at the time of presentation, or subsequent new MRI lesions.

TRICHINOSIS

Carolyn A. Paris
Jennifer R. Reid
George Anthony Woodward

BASICS

DESCRIPTION

- Infection caused by ingestion of undercooked meat containing nematode (roundworm) larval cysts of the *Trichinella* genus
- Most common cause of infection worldwide

EPIDEMIOLOGY

- Worldwide distribution with an estimated 10,000 cases per year, and mortality rate of 0.2%, in main 55 countries reporting
- Historically, most US infections are due to *Trichinella spiralis* in commercial pork.
- Currently, more US infections are associated with wild game meat (especially bear) or through spillover to domestic animals.
- Occasional grouped outbreaks (e.g., families and communities with common exposure)
- Consider in patients with a history of travel, consumed foreign meat or wild game (e.g., bear, cougar, hyena, lion, panther, fox), horse, dog (China), seal, or walrus meat.
- Carried by rodents, domesticated animals (e.g., dogs, cats), raccoons, opossums, skunks
- Disease not transmissible person to person

Incidence

Between 2002–2007 in the United States, average of 11 cases annually:

- Decreasing number of cases are attributed to decline in prevalence of *Trichinella* in commercial swine (1.41% in 1900, 0.125% in 1966, and 0.013% in 1995), federal regulation preventing uncooked meat consumption by commercial swine, and increased public awareness regarding properly frozen and cooked meat.

Prevalence

~4% of cadavers in 1970 study with evidence of previous infection (additional estimates range from 10–20% prevalence)

RISK FACTORS

- Consumption of inadequately cooked meat, even in small quantities
- *Trichinella* species consumed
- Compromised immune status of host

GENERAL PREVENTION

- Consume only fully cooked meat, especially pork and wild game; meat should reach > 160°F internally, no pink
 - Freezing kills *T. spiralis* in pork (<6 in. thick) at –20°F for 6 days, –10°F for 10 days, and –5°F for 20 days.
 - Freezing may not kill other *Trichinella* species, particularly in wild game.
- Freezing, curing, smoking, salting, and drying meat (including jerky) are not reliable sterilization methods.
- Routinely clean meat processing equipment.
- Irradiation may not kill *Trichinella* but should prevent ability to replicate.

- Avoid feeding swine uncooked meat scraps.
- Actively control rodents.
- Thoroughly cook all meat; internal temperature should reach > 160°F.

PATHOPHYSIOLOGY

- *Trichinella* are obligate intracellular parasites capable of infecting only warm-blooded animals.
- At least 8 *Trichinella* species identified: *T. spiralis*, *T. britovi*, *T. pseudospiralis*, *T. papuae*, *T. nativa*, *T. nelsoni*, *T. murrelli*, and *T. zimbawensis*; *T. spiralis* most common worldwide.
- Life cycle of all species comprises 2 generations in the same host (broad range species—mammal, birds and reptiles), but only humans become clinically affected.
- Larvae in undercooked meat eaten by the patient are released after cyst wall digestion by gastric enzymes, pass to the small intestine, invade mucosa, then develop into adult worms.
- Incubation period 1–2 weeks
- Fertilized females release larvae (~500) over 2–3 weeks. Adult worms are expelled in feces; they do not multiply in a human host.
- Newborn larvae travel the bloodstream to seed skeletal muscles. There they grow 10-fold, coil, and encyst. Muscle fibers enlarge and become edematous; may have granulomatous reactions in nonskeletal muscle, but larvae are found only in skeletal muscle.
- Cysts (hyaline capsules) may calcify over several months to years.

ETIOLOGY

Consumption of undercooked infected meat; see Description

COMMONLY ASSOCIATED CONDITIONS

- Rheumatic syndromes: Polyarteritis nodosa–like systemic necrotizing vasculitis, symmetrical polyarteritis, glomerulonephritis.
- Immunocompromised hosts are at risk for more serious or prolonged infection

DIAGNOSIS

Requires combination of epidemiologic, clinical, and laboratory findings

HISTORY

- Ingestion of inadequately cooked meat (commercial pork, noncommercial pork, game animals, foreign meat)
- Others with similar symptoms and same dietary exposure

- Signs and symptoms:

- Clinical severity varies, asymptomatic (subclinical) most common, fulminant to fatal rare; depends on *Trichinella* species and inoculum size
- Children often have fewer and milder symptoms than adults.
- Death can occur due to myocarditis, encephalitis, or pneumonia.
- Many signs and symptoms (i.e., periorbital edema, muscle edema, eosinophilia due to allergic reaction to parasite antigens)
- Nonspecific signs and symptoms may mimic other illnesses.
- Enteral phase (24 hours to 7 days after infection): Symptoms due to intestinal ulceration from mucosal invasion by adult worms
 - Diarrhea, abdominal pain, nausea, vomiting, anorexia
 - May persist for weeks
- Parenteral phase (1–8 weeks after infection): Symptoms due to systemic invasion:
 - General: Fever (begins at 2 weeks, peaks after 4 weeks, night spikes to 40–41°C), weakness, malaise, myalgias
 - Ocular: Periorbital edema, subconjunctival hemorrhage, conjunctivitis, disturbed vision, ocular pain, chemosis
 - Muscular: Myalgias, myositis (usually in extraocular muscles, then masseters, tongue, neck, limb flexors, lumbar muscles, intercostals, and diaphragm) with dyspnea, cough, hoarseness
 - Neurologic: Headache, focal paralysis, delirium, psychosis
 - Skin: Urticarial rash, subungual hemorrhages
 - Parenteral phase symptoms typically peak 2–3 weeks after infection.
 - Malaise and weakness may persist for weeks.
 - Cardiac: Myocarditis, arrhythmias secondary to myocarditis
- Convalescent phase (begins 2nd month, may last months to years): Myalgias, weakness

PHYSICAL EXAM

Fever, periorbital edema, muscular tenderness, generalized edema, urticaria: See “Signs and symptoms” in the History section.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Complete blood chemistry and differential: Eosinophilia (up to 70%, peaks 10–21 days post inoculation but prior to clinical symptoms), leukocytosis (moderate)
- Elevation of muscle enzymes (LDH, CPK, aldolase)
- Specific anti-*Trichinella* antibody detection
- Serologic tests are available through the US Centers for Disease Control and Prevention or state and some private and state labs.
- Detection of *Trichinella*-specific DNA by polymerase chain reaction (availability limited)

- *Trichinella* serology:
 - 2 tests required to ensure accurate diagnosis: 1st to detect antigen (ELISA) and the 2nd to detect antibodies to parasite surface antigens (FA)
 - Bentonite flocculation (1:5 or 4-fold increase), latex flocculation test, enzyme-linked immunosorbent assay, or immunofluorescence

Imaging

- X-ray: May show enlarged heart or calcified cysts in muscle (6–24 months post infection)
- Cardiac: Myocarditis may show ECG changes (premature contractions, prolonged PR interval, small QRS with intraventricular block, and flattening or inversion of T waves).
- Neurologic: Small CNS lesions, ring calcifications; IV enhancement on CT scan
- Electromyography: Results resemble those of polymyositis and inflammatory myopathies.

Diagnostic Procedures/Other

- Skeletal muscle biopsy (especially deltoid or gastrocnemius muscle from the patient at least 17 days after infection):
 - Inflammatory cells surround encysted larvae in necrotic muscle fibers.
 - Granulomatous reaction present in nonskeletal muscle but not encysted larvae.
 - Usually unnecessary, negative result possible in infected patient due to sampling error
- Can test suspected meat if available

DIFFERENTIAL DIAGNOSIS

- Infection: Viral syndromes, parasitic, spirochete, gastroenteritis, influenza, sinusitis, typhoid fever, measles, scarlet fever, meningitis, rheumatic fever, encephalitis, encephalomyelitis, poliomyelitis, tetanus, schistosomiasis, hookworm, Strongyloides, or helminthic infection
- Miscellaneous: Fever of unknown origin, dermatomyositis, myocarditis, inflammatory bowel disease, angioneurotic edema, rheumatoid arthritis, glomerulonephritis, polyneuritis, eosinophilic leukemia, polyarteritis nodosa, nonabsorption syndromes

TREATMENT

MEDICATION (DRUGS)

First Line

- Systemic corticosteroids for severe symptoms (not recommended as monotherapy, may prolong adult worm survival in intestines) *plus*
- Albendazole (Albenza)
 - 15 mg/kg/day divided b.i.d for 15 days
 - Max dose 800 mg/day
 - Teratogenic/embryotoxic in rats
 - Approved <2 years
- Mebendazole and albendazole are most efficacious during the enteral phase (active against intestinal worms, little effect on muscle-embedded larvae).

Second Line

Pyrantel pamoate (Antiminth):

- Used during pregnancy; not approved <2 years
- Effective only against adult worms, not encysted larvae

ADDITIONAL TREATMENT

General Measures

- Most patients recover without specific therapy.
- Symptomatic treatment: Acetaminophen or NSAIDs, bed rest

ISSUES FOR REFERRAL

Cardiac, neurologic, pulmonary complications

IN-PATIENT CONSIDERATIONS

Admission Criteria

Cardiac, neurologic, or pulmonary complications indicate more severe disease.

Discharge Criteria

Resolution of cardiac symptoms

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Expect improvement over several weeks.
- At 3–4 weeks, retreatment may be indicated if symptoms persist or there are ova in the feces.

Patient Monitoring

Cardiopulmonary monitoring

DIET

- Avoid further exposures.
- Breast-feeding may continue; the single case report of cessation of milk production was associated with parenteral mebendazole.

PATIENT EDUCATION

If concern for trichinosis exposure or symptoms, seek medical care early. Treatment is most efficacious the 1st week after exposure.

PROGNOSIS

- Mild to moderate illness usually resolves spontaneously with minimal sequelae. Muscle swelling and weakness may persist.
- Poorer prognosis (can be fulminant and fatal) with cardiac, CNS, or pulmonary involvement.
- Children usually are less symptomatic, have fewer complications, and recover more quickly.

COMPLICATIONS

- Cardiac: Myocarditis (may result in death 4–8 weeks after infection), secondary arrhythmias, hypotension, pericardial effusion
- Neurologic: Meningoencephalitis, CNS granulomas, headaches
- Pulmonary: Pneumonia, pneumonitis, pleural effusion, pulmonary embolism or infarct
- Renal: Glomerulonephritis
- Hepatic: Fatty change
- Muscular: Prolonged myalgias
- Ocular: Retinal hemorrhages
- Complications rarely are permanent.

FAQ

- Q: How can I prevent infection?
- A: Be sure meat is fully cooked (internal temperature $\geq 160^{\circ}\text{F}$ [71°C], not pink) or frozen (-20°F for 6 days, -10°F for 10 days, or -5°F for 20 days). *Trichinella* larvae in game may be relatively resistant to freezing. Frozen bear meat has yielded infective larvae after >2 years of freezing.
- Q: Is trichinosis contagious from person to person?
- A: No, except through infected breast milk.
- Q: Do special precautions need to be taken when treating a patient with presumed trichinosis?
- A: Only thorough hand washing. No isolation required.
- Q: What should we recommend for a patient who has eaten contaminated meat?
- A: Treatment with mebendazole or thiabendazole should be considered.
- Q: What are the classic hallmarks of trichinosis?
- A: Diarrhea, abdominal pain, periorbital edema, myositis, fever, and eosinophilia, especially when combined with history of ingestion of potentially poorly cooked meat.

TUBERCULOSIS

Andrew P. Steenhoff

Barbara M. Watson (5th edition)

BASICS

DESCRIPTION

- Pediatric tuberculosis (TB) is the disease state caused by *Mycobacterium tuberculosis*, an acid-fast bacillus (AFB). Pediatric TB should be regarded as a spectrum of exposure through infection to disease because progression from an infected person (exposure) to infection and subsequently disease can occur much faster (within 3–6 months) in children <2 years of age (occurring within the incubation of the disease stated below).
- Progression through this spectrum depends on age; such disease progression being 40–50% for children up to 2 years old, ~20% for 2–4 year olds, and 10–15% for those ≥5 years old, the 5–10-year-old children being the most protected age group. Adolescence is another vulnerable age group.

EPIDEMIOLOGY

- The most common route of infection is via the respiratory tract. TB is spread from a person with disease by droplet nuclei that are inhaled by other people. A child becomes infected with TB after close and prolonged contact with an adult or adolescent who has active untreated infectious disease, usually pulmonary TB, in a poorly ventilated space. However, there are people who develop TB without knowledge of an infectious contact.
- Congenital infection occurs, although rarely, in the setting of an untreated mother in the last trimester of pregnancy.
- Infection with the tubercle bacillus needs to be differentiated from disease (i.e., TB).
- The interval between onset of infection and disease is 10–12 weeks.
- The greatest chance of disease occurring (i.e., of developing a positive result in tests using purified protein derivative [PPD], now renamed tuberculin skin test [TST]) is within the 1st 2 years after infection. However, for infants and children <5 years, progression through the spectrum of pediatric TB (exposure–infection–disease) is age dependent (see Description).
- Postpubertal adolescents and immunosuppressed people, including people with diabetes, with chronic renal failure, the malnourished, and those taking steroids for any reason have higher risks for progression of infection to disease.

GENERAL PREVENTION

- Prevention of disease by using isoniazid (isonicotinic acid hydrazide-INH), 10 mg/kg/day PO for 9 months, or if compliance is not anticipated, 2 times a week as direct observed therapy at 20 mg/kg, with a maximum dose of 900 mg usually administered by a school nurse, child care worker, or the local TB control program, ideally without breaks in treatment, although the patient has 12 months to complete the course. If a break occurs near the end of treatment, it need not be restarted, because such treatment is ~90% effective against development of active TB for 20 years in nonimmunosuppressed children. This recommendation prevents disease in the treated patient and, as a public health measure, interrupts transmission to contacts of that infected person with 90% efficacy.

- Other drugs for latent TB include 4 months of rifampicin if a child cannot tolerate INH, 4 months of INH and rifampin in case of granulomas or fibrosis consistent with latent tuberculosis infection (LTBI), and finally 6 months of INH by direct observed therapy is the last resort (for a total of 72 doses).
- Bacille Calmette-Guérin (BCG) vaccine is recommended only for infants and children who test negative to PPD and who are continually exposed to contagious adults or to adults with TB that is resistant to both INH and rifampin, and who cannot be kept away from the contagious adult.

COMMONLY ASSOCIATED CONDITIONS

- HIV infection: Factor in the increase in TB, because 1 in 240 US residents is infected with HIV, and the bacillus grows stronger and evades detection (chest radiographs may appear normal).
- Lymphoma
- Diabetes
- Chronic renal failure
- Malnutrition
- Immunosuppression, including chronic daily steroid use, high-dose steroid use or tumor necrosis factor- α (TNF- α) agonists, cancer chemotherapy
- Social issues: Incarcerated adolescents, infants and children in homeless shelters

DIAGNOSIS

HISTORY

- Exposure: Family member with TB or positive skin test
- Migrant farm workers
- Immigration from a TB-endemic geographic area (e.g., Haiti, Southeast Asia, Africa, South and Central America, Russia, and elsewhere in Eastern Europe, where greater concern about drug-resistant strains ought to be exercised); visit by individuals from those countries; or visited the above countries
- Higher incidence in Native Americans
- Contact with adults who have active TB
- HIV-positive people
- Immunosuppressed state
- Incarcerated adolescents and their relatives who visit
- Homeless people
- Poor people in urban areas
- Exposure to milk from untested herds
- Malnutrition
- Long-term steroid usage

PHYSICAL EXAM

- Cervical and/or axillary adenopathy
- May reflect underlying disease or state (e.g., HIV, malnutrition, long-term steroid use)
- Pulmonary rales or clear chest
- Enlarged liver or spleen
- Site specific findings (e.g., gibbus [vertebral TB]) or focal neurologic signs (TB meningitis)

- Signs and symptoms:
 - Failure to thrive
 - Cervical or axillary lymphadenopathy without any other cause or that is prolonged
 - Cough >2 weeks
 - Weight loss
 - Change in sensorium
 - Fever in infants and adolescents, rarely in children 5–10 years of age
 - Decreased energy levels/playfulness >2 weeks

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Culture sputum, 3 gastric washings (early morning) performed with tube down over night, pleural fluid, CSF, urine
- Culture may take 2–3 weeks by the radiometric method.
- Positive culture results are found in <50% of children.

Imaging

Chest radiographs may show hilar adenopathy with or without atelectasis. However, any infiltrate, pleural effusion in a child with a positive TST result, and a risk factor for TB should be considered a TB suspect until proven otherwise. Infiltrates from bacterial or viral pathogens generally clear within 6–8 weeks; TB infiltrates tend not to clear so rapidly.

Diagnostic Procedures/Other

- Skin testing: TST
 - The Mantoux test comprises 5 tuberculin units with PPD administered intradermally. Details may be found at <http://www.cdc.gov/tb>.
 - The US Centers for Disease Control and Prevention does not recommend routine skin testing in low-risk groups in communities with low prevalence of TB.
 - Children at high risk should be tested annually:
 - Those in contact with adults from regions of the world with high TB prevalence
 - Children who spend time in homeless shelters
 - Those in contact with adults with TB, HIV, and other disease-producing immunosuppressed states: A skin test result may become positive 3–6 weeks after exposure; however, most commonly, it does not turn positive for 3 months—hence the rationale for treating an exposed child with INH and retesting with a PPD in 3 months.
 - A positive TST is a SENTINEL public health event indicating TB transmission in a community even if all other tests and examinations are negative.
 - A promising new molecular diagnostic test, Xpert MTB/RIF, is both simple and accurate. FDA approval is awaited.

DIFFERENTIAL DIAGNOSIS

- Malignancy
- Cervical or axillary adenopathy
- Pulmonary infiltrate: Other chronic organisms, disorders, and conditions (e.g., *Nocardia*, histoplasmosis). Infiltrates owing to bacterial or viral pathogens resolve faster than TB; thus, re-evaluation of a suspect in 8–12 weeks clarifies this differential.
- Hilar adenopathy: In TB it is usually unilateral, but Epstein-Barr virus, adenovirus, pertussis, and malignancy may possibly mimic symptoms.
- Miliary disease: Pulmonary effects, hepatosplenomegaly with or without CNS involvement
- GI disease: Most common differential diagnosis is Crohn disease.
- Meningitis: Fungal meningitis, partially treated bacterial meningitis (rarely)

**TREATMENT****MEDICATION (DRUGS)**

- Initial treatment in areas with multidrug-resistant TB >4%: Until sensitivities are known, a 4-drug regimen should be started: INH, 10–15 mg/kg/day; rifampin, 10–20 mg/kg/day; pyrazinamide (PZA), 15–30 mg/kg/day; and either ethambutol, 15–20 mg/kg/day, or streptomycin, 20 mg/kg/day (depending on whether diagnosis is meningitis or miliary TB, for which a bactericide is desired); however, many cases in children of foreign-born parents are increasingly streptomycin resistant, making ethambutol a better choice.
- If the organism is sensitive to therapy, treatment with the initial 4 primary drugs should continue for the 1st 2 months; by then, all sputum specimens should have a negative result on culture, followed by 4 months of INH and rifampin. When this regimen is adhered to, prognosis and a complete cure are achieved in 97–98% of patients.
- If a cavity is seen in chest radiograph or sputum specimens continue to test positive, or the TB is miliary, disseminated, or meningeal, the duration of treatment needs to be longer (9–12 months).

ADDITIONAL TREATMENT**General Measures**

- Hospitalization (if the patient has disease):
 - In cases of extensive disease (e.g., miliary TB or meningitis), and when an adult source case is not known, aggressive attempts should be made to obtain an organism from gastric aspirates, sputum induction, bronchoalveolar lavage, CSF, pleural or joint aspirate, bone aspirate, liver or tissue biopsy, and, in some cases, blood cultures.
- Isolation policies:
 - Unless the clinician can verify that the parent or any adult visitors are not themselves contagious, many infection control units require isolation of the child because the family members' state of contagion remains unknown at admission.
 - Nonpulmonary TB (e.g., GI TB, meningitis, bone TB, and TB with joint involvement) also does not require isolation.
 - Children >8 years of age and adolescents should be isolated until they have completed 10 days of therapy. Occasionally, immunocompromised children <8 years old also have cavitary disease and hence they too should be isolated.

**ONGOING CARE****FOLLOW-UP RECOMMENDATIONS****Patient Monitoring**

Follow-up and contact tracing are key to making TB preventable.

PROGNOSIS

- Mortality for untreated TB is 40% over 4 years.
- For miliary TB and meningeal TB, prognosis depends on the stage of presentation as already discussed.
- For outbreaks of multidrug-resistant TB, death rates range from 70–90% within 4 months of diagnosis.

COMPLICATIONS

- Missed diagnosis: Failure to consider TB in a child who is failing to thrive and whose TST is negative
- TB meningitis: Outcome depends on the stage at which anti-TB medication starts:
 - If pharmacotherapy is started at stage I, complete recovery occurs in 94%, with neurologic sequelae in 6%.
 - If delayed until stage II, complete recovery occurs in 51%, with neurologic sequelae in 40% and death in 7%.
 - If delayed until stage III, complete recovery occurs in 18%, with neurologic sequelae in 61% and death in 20%.
- Miliary TB
- Bone TB: Most commonly spinal manifestation
- Renal TB: Presents as a fever of undetermined origin (FUO), with or without urinary symptoms
- Congenital TB manifests with hepatosplenomegaly; may have CSF abnormalities and abnormalities on CSF testing and chest radiograph: Patients too young for TST to be useful
- Drug toxicity: Pediatric patients are much more tolerant of anti-TB medications than adults; thus, regular monitoring of liver function test results is not routinely required, although clinical monitoring for symptoms such as abdominal pain and loss of appetite on a monthly basis remains the cornerstone for identifying any toxicity.
- Hepatitis with INH, rifampin, and PZA; neurologic and hematologic complications with INH; skin rashes predominantly with rifampin and INH, but reports have occurred with all anti-TB medications; ototoxicity with streptomycin; but ocular toxicity with ethambutol in the pediatric age group has not been documented, and therefore it is a safe drug to use. Management of common side effects and drug interactions may be found in the 2006 American Thoracic Society/US Centers for Disease Control and Prevention/Infectious Disease Society of America (see Additional Reading).

ICD10

- A15.9 Respiratory tuberculosis unspecified
- P37.0 Congenital tuberculosis

FAQ

- Q: Should all children in close proximity to inner-city areas with a prevalence of TB be screened annually with PPD?
- A: The AAP and CDC encourage targeted screening based on risk factors indicated above. The targeted screening questionnaire should be administered at every visit until age 2 years, then annually thereafter. See tools at <http://www.cdc.gov/tb>.
- Q: Can we use the whole blood assay “QuantiFERON-TB Gold” to differentiate children who were born in other countries and had BCG instead of the TST (parents are requesting the test)?
- A: The test is not licensed for pediatric use and hence cannot be interpreted. A large study in navy recruits in 2006 demonstrated in foreign-born individuals with a TST >20 that the QuantiFERON-TB Gold Test was equivalent.

TUBEROUS SCLEROSIS COMPLEX

Garrick A. Applebee

BASICS

DESCRIPTION

- Tuberos sclerosis complex (TSC) is a neurocutaneous syndrome characterized by a spectrum of signs and symptoms that present over a patient's lifetime, including neurologic disorders, multisystem tumor growth, and dermatologic manifestations.
- First described by Bourneville in 1880, the classic diagnostic triad of adenoma sebaceum, mental retardation, and seizures has been revised to include other manifestations because many patients with tuberous sclerosis do not exhibit this triad.

EPIDEMIOLOGY

Incidence

Current estimates suggest an incidence of 1 in 5,000 to 1 in 15,000 births. ~60–70% of cases reflect sporadic mutation; 30–40% of cases are familial.

RISK FACTORS

Genetics

- 2 clearly identified loci for familial and sporadic cases based on linkage analyses are 9q34 and 16p13, corresponding to TSC1 and TSC2 genes, respectively. TSC1 encodes the protein hamartin and TSC2 encodes the protein tuberin. Together, hamartin and tuberin join to form a regulatory complex of mTOR (the serine kinase mammalian target of rapamycin). Permanent activation of mTOR through mutations in the genes coding for these proteins causes dysregulation of cellular growth, differentiation, and migration, leading to the clinical symptoms and multisystem cellular overgrowth seen in TSC.
- > 1,000 mutations in these genes are known to exist, leading to highly variable phenotypes in this disorder.
- TSC2 mutations: More common in sporadic cases, associated with more severe phenotypes
- 15–20% of cases meeting clinical criteria have no identifiable gene mutations.

ETIOLOGY

Tuberous sclerosis either is inherited in an autosomal-dominant pattern or results from a spontaneous/sporadic mutation.

DIAGNOSIS

HISTORY

- Primary symptoms include seizures, mental defects, and skin lesions.
- All types of seizures are seen in TSC. Seizures may begin at any time and are present in 70–80% of patients. In infancy, infantile spasms are a common presenting seizure; 1/3 of patients develop infantile spasms.
- Mental retardation and neurobehavioral abnormalities (e.g., autism spectrum disorders, present in 25% of patients) may manifest as developmental delay, but some patients are without cognitive defect.
- Skin lesions may appear in infancy or during early childhood.
- It is important to take a full family history, reviewing involved systems.
- Inquire about history of seizures, mental retardation, skin lesions, and cardiac or renal disease/cancers.
- Screening for symptoms of hydrocephalus (headache, vomiting) is important: 10% of patients develop CSF obstruction from subependymal giant cell tumors.
- Women are primarily affected by pulmonary lymphangiomyomatosis, which may manifest as dyspnea or pneumothorax in early adulthood.

PHYSICAL EXAM

- Maintain a high level of suspicion for tuberous sclerosis in any patient presenting with:
 - Infantile spasms or childhood seizures
 - Autism
 - Intellectual impairment/developmental delay
 - Peculiar skin lesions
 - Ash leaf and café au lait spots are small (often <5 mm) but may be found anywhere on skin and are often present at birth. Examination with a Wood's lamp may help to identify hypopigmented lesions (e.g., ash leaf spots).
- Facial angiofibromas are typically found around the nose and cheeks and look like acne; they develop in later childhood to adolescence. They neither itch nor suppurate.
- Ungual fibromas appear around the nail bed.
- Shagreen patches are brownish leathery skin patches near the sacrum.

- Fundoscopic examination may reveal whitish-yellow areas in epipapillary and peripapillary regions around the optic nerve head. They rarely impair vision. Papilledema may be seen with hydrocephalus.
- Signs of heart failure or tachyarrhythmia may be seen in infants with cardiac tumors.
- Flank pain, nausea, vomiting, and hematuria may suggest renal involvement.
- Procedures: Dilated fundoscopic examination may also aid in full visualization of the optic nerve head.
- Definite diagnosis requires 2 major or 1 major plus 2 minor features:
 - Major criteria: Facial angiofibroma, unguinal fibroma, shagreen patch, hypomelanotic papule (ash leaf spot), cortical tuber, subependymal giant cell tumor, retinal hamartoma, cardiac rhabdomyoma, renal angiomyolipoma, lymphangiomyomatosis
 - Minor criteria: Pitting in tooth enamel, hamartomatous rectal polyps, bone cysts, cerebral white matter radial migration lines, gingival fibromas, retinal achromic patch, "confetti" skin lesions (grouped lightly pigmented spots), multiple renal cysts
- As with other dominant, multisystem conditions, the findings in TSC have variable penetrance, and clinical manifestations may appear at different developmental points.
- Although seizures and mental retardation are common in TSC, they vary, are nonspecific, and so are not considered in the diagnostic criteria.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Blood and CSF lab test results are typically normal unless renal function is significantly compromised by renal cysts or renal angiomyolipomas.
- ECG may reveal cardiac dysrhythmias, present in 47% of persons with cardiac rhabdomyomas.
- In patients with mental retardation or seizures, EEG helps to evaluate cerebral activity.
- In infants with suggestive history, an EEG may help diagnose infantile spasms, which are associated electrographically with a highly disorganized pattern of large-amplitude, asynchronous, sharp waves termed *hypsarrhythmia*.

- Later in childhood, patients with tuberous sclerosis may develop Lennox-Gastaut syndrome, which consists of mental retardation, seizures, and a characteristic EEG pattern of slow (i.e., 2.5 Hz) spike-wave complexes.

Imaging

- Subependymal or other cerebral calcifications on CT, often found in the course of emergent evaluation of new seizures, suggest TSC—consider MRI.
- Guidelines suggest MRI of the brain with gadolinium administration yearly or in alternate years until age 21 years and every 2–3 years thereafter. Imaging will identify tubers, subependymal nodules, hydrocephalus, and giant cell tumors. These appear hyperintense on T-weighted images and may enhance with gadolinium.
- Echocardiogram can detect cardiac rhabdomyomas in infants with tuberous sclerosis; prenatal ultrasound commonly identifies these tumors.
- CT of the lungs is indicated in women with TSC to screen for lymphangiomyomatosis.
- Renal ultrasound (every 1–2 years) or CT will demonstrate renal lesions.

Pathological Findings

Findings reflect the primary tissue in which lesions are identified:

- Brain:
 - 3 characteristic lesions are cortical tubers, subependymal nodules, and subependymal giant cell tumors.
 - In tubers, the cerebral cortical architecture is disrupted, and these regions may undergo calcification, which can be visible on skull radiographs or brain CT.
 - Subependymal nodules consist of large abnormal astrocytes emanating from the lateral ventricular surface.
 - Subependymal giant cell tumors are low-grade benign astrocytic neoplasms.
- Skin:
 - Facial angiofibromas may be mistaken for acne and are highly suggestive of tuberous sclerosis; they appear as pinkish-yellow plaques on the malar regions and nasolabial folds.
 - Ash leaf spots are hypopigmented hypomelanotic macules occurring anywhere on the body.

- Ungual fibromas are fleshy growths along the lateral borders of the nail bed.
- Shagreen patches are areas of shaggy leathery skin typically in the lumbosacral area.

- Retina:
 - Whitish-yellow angiomyolipomas or hamartomas occur near the optic nerve head or the retinal periphery and may calcify.
- Heart:
 - Rhabdomyomas in the ventricular wall occur in infancy and contain abundant nodules of large eosinophilic cells; this is the most common type of cardiac tumor of infancy and early childhood and may also occur in the absence of TSC.
- Kidney:
 - Renal cysts, polycystic kidneys, angiomyolipomas, and, more rarely, renal carcinomas
- Other organ systems:
 - Less commonly affected are the lungs, GI tract, spleen, vascular bed, and lymphatic system.

DIFFERENTIAL DIAGNOSIS

Neurocutaneous syndromes in which skin lesions, mental retardation, and seizures are characteristic features should be considered:

- Neurofibromatosis
- Sturge-Weber syndrome
- von Hippel–Lindau disease
- Neurocutaneous melanosis
- Albright syndrome
- Incontinentia pigmenti
- Linear sebaceous nevus

TREATMENT

MEDICATION (DRUGS)

- Rapamycin is an immunosuppressant agent that inhibits mTOR, thereby inhibiting the cellular proliferation seen in tuberous sclerosis patients. Its use in targeting a number of tuberous sclerosis complications is in development.
- Anticonvulsant therapy as needed. Infantile spasms may be treated with adrenocorticotropic hormone or vigabatrin (not available in the US)
- Medical management of heart failure or cardiac dysrhythmias is indicated in tuberous sclerosis patients with cardiac rhabdomyomas.

ONGOING CARE

PROGNOSIS

Cognitive disability unfortunately will not improve unless the cognitive impairment results from uncontrolled seizures. Seizure control is medically refractory in up to 40% of cases, and some children require epilepsy surgery to remove cortical tubers or subependymal nodules. Cardiac tumors may also require surgical intervention. Renal angiomyolipomas can be embolized angiographically or surgically corrected. Subependymal giant cell astrocytomas that cause hydrocephalus may require resection.

Q85.1 Tuberous sclerosis

FAQ

- Q: Can tuberous sclerosis be transmitted in subsequent pregnancies?
- A: An affected patient with the tuberous sclerosis gene mutation has a 50% chance of transmitting the mutation to his or her children.
- Q: Is genetic testing available?
- A: Molecular genetic testing for mutations at the TSC1 and TSC2 loci are available but are not required for diagnosis because not all clinical cases of TSC have identifiable mutations.
- Q: Will my child need brain surgery?
- A: In the event of refractory seizures, removal of cortical tubers may help seizure control. Surgery may also be indicated in cases of obstructive hydrocephalus. If a brain tumor is detected by MRI, neurosurgical evaluation is indicated.

TULAREMIA

Brian T. Fisher

Louis M. Bell Jr. (5th edition)

BASICS

DESCRIPTION

Tularemia is an infection caused by *Francisella tularensis*, a small, fastidious, nonmotile, gram-negative coccobacillus that requires cysteine-enriched agar for growth; 4 subspecies have been described:

- *Tularensis* (type A): Found primarily in North America; causes the most severe cases of tularemia in humans
- *Holarctica* (type B): Most widespread subspecies found in North America, Europe, and Asia; less virulent than *tularensis*
- *Novicida*: Found primarily in North America, but recent case report from Australia; does not require cysteine for growth; low virulence with occasional human infection
- *Mediasiatica*: Recovered from ticks and animals in Central Asia; not associated with disease in immunocompetent humans
- An additional species, *Francisella philomiragia*, has also been reported. This is a rare cause of human disease and is possibly associated with salt water exposure.
- Tularemia typically presents with fever, myalgias, and headache 3–6 days after initial exposure. The extent of the illness depends on infecting dose, subspecies, and route of entry.
- 4 clinical forms are typically described:
 - Ulceroglandular tularemia constitutes 75% of all cases. A papule, which ruptures and ulcerates, occurs at the site of entry. Regional lymphadenopathy and sometimes pharyngitis accompanies systemic symptoms of fever, myalgias, and headache. Bacteria may disseminate to end organ sites such as the spleen, liver, lungs, kidneys, and intestines:
 - Glandular tularemia is identical to the ulceroglandular form but without an identified primary skin lesion.
 - Oculoglandular tularemia occurs when the organism gains access via the conjunctival sac, usually from the patient rubbing the eyes with contaminated fingers. Yellow nodules and ulcers may appear on the palpebral conjunctiva associated with enlarged preauricular nodes.
 - Typhoidal tularemia presents with fever of unknown origin, without localizing lymphadenopathy or skin findings. Shock, pleuropulmonary findings, odynophagia, diarrhea, and bowel necrosis are often associated.

- Oropharyngeal tularemia occurs after the ingestion of contaminated food or water. An ulcerative or membranous tonsillitis accompanies a painful sore throat. Lower GI tract involvement with vomiting, diarrhea, and abdominal pain may be associated.
- Pneumonic tularemia occurs after inhalation of the organism. It can also be present in association with ulceroglandular and typhoidal tularemia. Pulmonary tularemia is the most fulminant and lethal form. Symptoms include fever, dry cough, and pleuritic chest pain. Tularemia in this form is a feared potential biological weapon because an exposure to only 1–10 colony-forming units can result in infection.

ALERT

- *F. tularensis* is currently listed as a class A bioterrorism agent because of its potential ease for dissemination and infection as well as potential for high case fatality rates.
- In the past, resistant forms of *F. tularensis* have been engineered, but the actual use of this organism as a bioterrorism agent has not been documented.
- The diagnosis of inhalation tularemia should raise the suspicion of bioterrorism.

EPIDEMIOLOGY

- *F. tularensis* is found primarily in the northern hemisphere from the 30–70° latitudes. A case of tularemia caused by subspecies *novicida* has been reported from Australia.
- Wild mammals (e.g., rabbits, hares, squirrels, beavers, deer, and rodents) may be infected, as well as invertebrates (e.g., ticks, deerflies, horseflies, and mosquitoes).
- Humans acquire tularemia after a bite by an infected arthropod or through contact with tissues or body fluids of an infected animal. The subspecies *holarctica* has been shown to persist in various water sources, and water-borne transmission to humans has been reported.
- Inhalational exposure can happen in the laboratory setting or after the organism is aerosolized during meat preparation.
- Most commonly reported during the summer months in children between 5 and 9 years of age and those >75 years old

RISK FACTORS

- Most frequently infected groups include hunters, trappers, farmers, and veterinarians.
- Activities involving wild animals or exposure to various arthropod vectors.
- Infection has been linked to landscapers using lawn mowers and brush cutters.
- Laboratory personnel working with samples known to be or potentially infected with *Francisella*.

GENERAL PREVENTION

- Isolation of the hospitalized patient:
 - Standard precautions are recommended for protection against secretions. Human-to-human transmission has not been reported.
- Control measures:
 - Protective clothing and insect repellent should be used to minimize insect bites.
 - Inspection for ticks and their immediate removal should be routine after outdoor activity in endemic areas.
 - Rubber gloves should be worn while handling or cooking wild animals (e.g., rabbits, lemmings) possibly contaminated with *Francisella*.
 - Laboratory workers should wear rubber gloves and masks in a biosafety level 3 environment when working with specimens potentially containing *Francisella*.

PATHOPHYSIOLOGY

- Entry into the human is via skin, mucous membranes, or inhalational.
- A primary lesion develops at the site of exposure.
- Local tender lymph node swelling ensues.
- After skin inoculation or inhalation, the organism can spread via the bloodstream to various organs.

ETIOLOGY

Human infection can result from various modes of entry:

- Skin contact with infected animals
- Vector-borne infection described after the bite of a tick, mosquito, horsefly, or deerfly
- Inhalation of aerosolized organism seen in laboratory workers, crop harvesting, disturbance of contaminated hay, and grass cutting.
- Ingestion of contaminated food products or water

DIAGNOSIS

HISTORY

- In the right clinical setting, a history that elicits any occupational exposure or recreational activity previously noted as risk factors should raise suspicion for tularemia.
- History of a recent tick, mosquito, or fly bite may be recalled among affected patients.
- A history of a papule that became ulcerated is classic for the ulceroglandular form.
- Fever > 101°F for 2–3 weeks is common, with associated weight loss.

PHYSICAL EXAM

- A papule or ulcer may be seen at the inoculation site.
- Skin lesions should be sought, especially when lymphadenopathy is present.
- Lymph node swelling is typically tender with overlying erythema.
- After a 3–6-day incubation period, symptoms may include fever, myalgias, and headache.
- Hepatosplenomegaly, purulent conjunctivitis, adenopathy, an ulcerative skin lesion, and tonsillitis are other localized findings.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Serum tube agglutination titers of 1:160 or greater are generally considered positive.
- A 4-fold rise in titers over a 2-week period is necessary to define a current infection.
- Cultures of blood, skin, ulcers, lymph nodes, gastric washings, and respiratory secretions require special media containing cysteine.
- Laboratory personnel should be made aware of the infection risk from specimens. Growth of the organism requires a biosafety level 3 laboratory.
- Polymerase chain reaction (PCR) tests are available in some laboratories. They are more sensitive than culture and can be performed on tissue samples. Current PCR techniques do not differentiate subspecies, but such techniques are under development.
- Fluorescent in situ hybridization techniques have been utilized in the research setting to differentiate subspecies and may be clinically useful in the future.

DIFFERENTIAL DIAGNOSIS

Depending on the form of tularemia, the infection can mimic other illnesses such as streptococcal or staphylococcal infection, mononucleosis, cutaneous anthrax, pasteurellosis, Q fever, legionellosis, typhoid fever, or mycobacterial disease. In general, tularemia should be considered in the following differential diagnoses:

- Fever of unknown origin
- Fever with purulent conjunctivitis
- Fever with hepatosplenomegaly
- Fever with skin ulcer

TREATMENT

MEDICATION (DRUGS)

- IV antibiotic therapy with streptomycin or gentamicin is considered 1st-line therapy.
- 2nd-line therapeutic options include ciprofloxacin, doxycycline, or chloramphenicol. Relapses have been associated with the latter two.
- Duration of treatment is typically 7–10 days. In severe disease, some experts recommend gentamicin in combination with ciprofloxacin.
- Vaccine:
 - A live attenuated vaccine has been in existence since the 1940s.
 - It is moderately effective against severe forms of tularemia.
 - Currently in the US, the vaccine is reserved for at-risk personnel.
 - Significant research into various vaccine techniques continues to evolve given concerns of *F. tularemia* as an agent of bioterrorism.

IN-PATIENT CONSIDERATIONS

Initial Stabilization

- If respiratory compromise is present, oxygen supplementation and/or assisted ventilation must be rapidly addressed.
- Recognition and prompt aggressive treatment of shock should be a major priority.

ONGOING CARE

PROGNOSIS

When recognized and treated with appropriate antibiotics, the course is generally < 1 month. Mortality is low, except in cases of fulminant disease or are otherwise immunocompromised. The subspecies *tularensis* is thought to be more virulent than the others. Both typhoidal and pneumonic tularemia are associated with the highest risk for mortality.

COMPLICATIONS

- Lymph node suppuration, meningitis, endocarditis, hepatitis, and renal failure have all been associated with tularemia.
- Infection with *F. tularensis* may be complicated by necrotic and granulomatous lesions in the liver and spleen as well as parenchymal degeneration.
- A sepsis syndrome with shock, fever, myalgias, and severe headache can be seen. Recognition and prompt aggressive treatment of shock should be a major priority.
- Skin manifestations, including vesiculopapular rash, erythema nodosum, and erythema multiforme have been associated with tularemia.

ULCERATIVE COLITIS

Judith Kelsen

Jonathan Markowitz

BASICS

DESCRIPTION

Ulcerative colitis (UC) is a disease characterized by remitting and relapsing inflammation of the large intestine. UC and Crohn disease (CD) are the disorders that represent the idiopathic inflammatory bowel diseases (IBDs). The hallmark symptoms of UC are abdominal cramping, diarrhea, and bloody stools. There are multiple patterns of presentation in children. UC routinely affects the rectum, with contiguous involvement extending proximally that can include the entire large intestine.

EPIDEMIOLOGY

- Yearly incidence is 2/100,000 in 10–19-year-olds
- 20–30% of patients with UC present before the age of 20 years.
- Incidence peaks between 15 and 30 years of age.
- Total prevalence is 50–75 per 100,000.

RISK FACTORS

Genetics

- HLA association: Bw52, DR2 (Japan); A2, Bw35, Bw40 (Ashkenazi Jews); A7, A11 (the Netherlands)
- Genome-wide association studies (GWAS) utilizing high-density SNP array technology has identified multiple loci associated with CD and UC.
- Recent study identified 5 new IBD susceptibility loci that are associated with early-onset disease.
- Higher concordance in monozygotic than in dizygotic twins
- Family history in ~15–20% of patients
- There is an increased incidence of family history in patients diagnosed prior to 20 years of age.

DIAGNOSIS

Patients with UC typically present with chronic symptoms of rectal bleeding, diarrhea, and abdominal pain that often occurs at the time of defecation. Rectal bleeding occurs in ~83–95% of patients with UC. Colonoscopy with histology is a gold standard in diagnosis of UC.

HISTORY

A detailed history is important in making the diagnosis:

- Rectal bleeding (90%)
- Abdominal pain (90%)
- Diarrhea (50%)
- Weight loss (10%)
- Growth failure
- Recent travel (enteric infections)
- Antibiotic use (*Clostridium difficile*)
- Family history of IBD
- Appendectomy is protective against developing UC.

PHYSICAL EXAM

- Fever
- Evidence of weight loss or poor growth
- Signs of anemia
- Uveitis
- Mouth sores
- Arthritis
- Abdominal tenderness or distention
- Perianal/Rectal examination (UC should not be associated with perianal disease.)

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- CBC; anemia, iron deficiency
- Iron studies (iron deficiency)
- ESR, CRP; disease activity
- Electrolytes (hydration), CMP. Serum albumin may be low, hypoalbuminemia may be present in fulminant colitis.
- Hepatic function panel (hepatobiliary disease)
- Perinuclear antineutrophil cytoplasmic antibody (pANCA; positive in 80% of UC patients, 20% of CD patients)
- Stool for blood, white cells (colitis)
- Fecal calprotectin and fecal lactoferrin (FL): may be elevated during times of active inflammation.
- Stool cultures, *C. difficile* toxin A and B (infection)

Imaging

- Plain abdominal radiograph: This is important in diagnosing perforation, ileus, obstruction, and toxic megacolon. In toxic megacolon, the colon is dilated, and there are multiple air–fluid levels indicative of ileus. Serial x-rays are mandatory.
- Barium enema can demonstrate strictures and mucosal disease.
- An upper GI with small bowel follow-through (UGI/SBFT) can demonstrate the entire small bowel to exclude small intestinal disease indicative of CD.
- New imaging modalities, such as MR enterography, CT enterography, and ultrasound are currently being performed in place of UGI. MRI and US have the advantage of avoiding radiation exposure.
- MRI may have a role in differentiating transmural and mucosal inflammation and is also useful for demonstrating perianal fistulas that would indicate CD rather than UC.
- Ultrasound may be useful for evaluating associated hepatobiliary disease.
- Radionuclide imaging can differentiate between CD (small and large bowel involvement) and UC (only large bowel involvement).

Diagnostic Procedures/Other

- Colonoscopy (with biopsies) is a gold standard and is necessary to confirm the diagnosis of UC. It is critical to visualize the entire colon, including terminal ileum, to differentiate CD from UC.
- Upper endoscopy may increase chances of detecting CD.
- Endoscopic retrograde cholangiopancreatography (ERCP) is useful in diagnosing primary sclerosing cholangitis (3% of UC patients).

- Video capsule endoscopy (VCE) is more sensitive than UGI/SBFT for diagnosing small bowel disease indicative of CD rather than UC.
- Pitfalls:
 - The combination of positive pANCA and negative anti-*Saccharomyces cerevisiae* antibody (ASCA) has a reported sensitivity of 60–70% and a specificity of 95–97% for UC in adults. The sensitivity and specificity are poorer in pediatric patients.
 - Inflammation of the small intestine demonstrated by colonoscopy, VCE, UGI/SBFT, or radionuclide imaging is suggestive of CD, not UC.
 - Perianal disease (perianal skin tags, perianal fistulas, perianal abscess) is indicative of CD, not UC.
 - Infectious colitis (especially *C. difficile*) can mimic the findings of UC. *C. difficile* infection must be evaluated with assays for both toxin A and toxin B, or up to 40% of infections can be missed.
 - Toxic megacolon is a surgical emergency. The patient has a dilated colon with breakdown of its barrier to toxins entering the systemic circulation. Signs and symptoms include peritonitis, mental status changes, and fluid and electrolyte imbalance. Plain abdominal radiograph shows a segment or total colonic dilatation. Risk factors include 1st attack, pancolitis, concurrent use of opiates or anticholinergics, and recent barium enema or colonoscopy.

Pathological Findings

- Chronic or chronic active colitis, with inflammation limited to the mucosa
- Colitis: Crypt architectural distortion, cryptitis (aggregation of inflammatory cells in the crypt epithelium), crypt abscess
- Site of colon affected:
 - Rectum (virtually 100%)
 - Left side (50–60%)
 - Pancolitis (10%)
- Small intestine should not be involved, but occasionally the terminal ileum can show some inflammation on radiologic or histologic examination. This is thought to be from refluxed colonic contents (backwash ileitis).
- Skip lesions are not seen in UC.
- Chronic gastritis may be present in patients with UC.

DIFFERENTIAL DIAGNOSIS

- CD
- Infectious colitis: *Salmonella*, *Shigella*, *Campylobacter*, *Yersinia*, *Escherichia coli* (enterohemorrhagic), *Aeromonas*, amebiasis, *C. difficile*, cytomegalovirus
- STDs (herpes simplex, lymphogranuloma inguinale, chlamydia)
- Trauma due to anal sex or sexual abuse
- Congenital Hirschsprung enterocolitis
- Bleeding juvenile polyps
- Milk protein allergy
- Eosinophilic colitis
- Autoimmune enteropathy
- Irritable bowel syndrome (IBS)
- Appendicitis
- Hemolytic-uremic syndrome
- Henoch-Schönlein purpura

TREATMENT

MEDICATION (DRUGS)

- Mild disease can be treated with oral mesalamine, topical corticosteroid enema or foam, or mesalamine enema/suppositories.
- Moderate disease: Mesalamine, a short course of oral corticosteroid, low-residue diet
- Probiotics; may have important role in pouchitis
- Immunomodulators such as azathioprine and 6-mercaptopurine may help to maintain disease remission and minimize the need for recurrent courses of steroid. Methotrexate has fewer published data in UC but also may have efficacy.
- Infliximab: Monoclonal antibody against tumor necrosis factor (TNF)- α . It has become clinically important in the treatment of moderate to severe UC or steroid-resistant UC.
- Fulminant disease: Hospitalization, if concern for toxic megacolon—complete bowel rest with total parenteral nutrition, broad-spectrum antibiotics (IV ampicillin, gentamicin, and metronidazole), IV corticosteroids, serial abdominal radiographs, frequent examinations, stool chart (frequency, amount of blood, and volume of stool output); early surgical consult
- If treatment of acute symptoms with IV steroids fails (after 3–5 days), therapy with infliximab (usually given as a 5-mg/kg infusion) can be started. A 2nd dose is usually given ~2 weeks after the initial infusion.
- Pediatric Ulcerative Colitis Activity Index (PUCAI): Obtained on day 3–5; may identify patients with severe UC who will require escalation of therapy with infliximab or cyclosporine. Prevents unnecessary prolonged exposure to corticosteroids.
- IV cyclosporine infusion is an alternative to infliximab for treating fulminant colitis. Must be used with an immunomodulator and is nephrotoxic. Should be used by experienced clinicians. It is no longer 1st-line therapy due to adverse effects.
- Patients with fulminant disease who fail therapy with infliximab or cyclosporine should be referred for colectomy. Those with chronically active disease unresponsive to medication should also consider colectomy.
- Therapy of toxic megacolon is aimed at preventing perforation with decompression of the bowel. Management includes complete bowel rest, discontinuation of anticholinergics and narcotics, avoidance of endoscopy or barium enema, and broad-spectrum antibiotics; frequent examinations are required. Close communication with surgical colleagues is crucial.
- Methylprednisolone (IV): 1–2 mg/kg/day (equivalent to prednisone 60 mg maximum)
- Prednisone (PO): 1–2 mg/kg/day oral (up to maximum 60 mg/day)
- Mesalamine (PO): 40–60 mg/kg/day (maximum 4.8 g/day)
- Mesalamine (enema): 4 g at bedtime
- Mesalamine (suppository): 500 mg b.i.d.

- Hydrocortisone enema: 100 mg once a day to b.i.d.
- Hydrocortisone foam: 80 mg once a day to b.i.d.
- 6-mercaptopurine (6-MP) (PO): 1.0–1.5 mg/kg to start (keep absolute neutrophil count [ANC] > 500)
- Azathioprine (PO): 2.0 mg/kg (keep ANC > 500)
- Infliximab (IV): 2–3 mg/kg weeks 0, 2, 6, then every 8 weeks
- Cyclosporine (IV): 4 mg/kg/day for 2 weeks (therapeutic levels vary depending on the technique used in the laboratory)
- Cyclosporine (PO): 6–8 mg/kg/day for 6–8 months

SURGERY/OTHER PROCEDURES

- Urgently required for perforation, significant and persistent bleeding, toxic megacolon, and failure of medical treatment for fulminant colitis
- Can be electively performed for chronic incapacitating disease, growth failure, dysplastic changes in the colon, or long-standing disease (usually after 10 years)
- Because UC is limited to the colon, colectomy is considered a curative procedure.
- Ileoanal anastomosis and pouch construction is surgery of choice for most pediatric patients and usually is performed in 3 stages.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Outpatient follow-up with a pediatric gastroenterologist should be arranged. Important parameters to follow as an outpatient include abdominal symptoms, stool frequency/consistency, height/weight, hemoglobin, WBC count (for patients on immunosuppressives), ESR, albumin, bilirubin and liver enzymes, fecal occult blood testing, and colonoscopic cancer screening (patients with long-standing disease). The PUCAI, a validated index for monitoring severe disease in pediatric patients.

COMPLICATIONS

- Bleeding
- Anemia
- Toxic megacolon
- Extraintestinal manifestations include hepatobiliary disease (3–5%), uveitis (up to 4%), arthritis affecting large joints (10%), spondylitis (6%), erythema nodosum (> 5%), pyoderma gangrenosum (> 1%), renal calculi (5%)
- Malignancy risk is 8% 10–25 years after colitis is diagnosed and it increases ~10% for every subsequent decade.
- Colonic stricture

- K51.911 Ulcerative colitis, unspecified with rectal bleeding
- K51.912 Ulcerative colitis, unspecified with intestinal obstruction

FAQ

- Q: Will my child have this disease forever?
- A: Some people will have only the initial attack and then be symptom free, but usually an individual will have episodes of recurrences and remissions. Surgical removal of the colon represents a curative procedure, although some patients may develop inflammation in the pouch created out of the remaining bowel (pouchitis).
- Q: What is the cause of UC?
- A: Both genetic and environmental factors are important in the development of UC.
- Q: Where can I learn more about UC?
- A: The North American Society for Pediatric Gastroenterology, Hepatology and Nutrition provides a Web site for children with IBD and their families (www.gastrokids.org). The Crohn's and Colitis Foundation of America (www.CCFA.org) is a nonprofit organization dedicated to the care and education of people with CD and UC.
- Q: What new therapies will be used in the near future?
- A: Biologic agents, a broad category of therapies that uses our recently improved knowledge of the immune system, represent a new way of treating IBD, with several new treatments likely to be released within the next few years.

UPPER GASTROINTESTINAL BLEEDING

Maria R. Mascarenhas

Judith Kelsen

BASICS

DEFINITION

Vomiting of blood, whether bright red or dark, constitutes upper GI bleeding or hematemesis. This usually indicates bleeding from the GI tract proximal to the ligament of Treitz. The clinician must differentiate upper GI bleeding from hemoptysis (coughing up blood), nose bleeds, and bleeding from the mouth and pharynx. Sometimes, upper GI bleeding can present with melena or the passage of tarry stools.

GENERAL PREVENTION

- Avoid drugs that are likely to cause bleeding or gastritis, especially in a susceptible patient.
- In patients with chronic GI conditions, optimize therapy and monitoring.
- Correct coagulopathy
- Prophylactic sclerotherapy or banding is helpful for patients with known variceal bleeding.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- 95% of the causes of upper GI bleeding are due to mucosal abnormalities or esophageal varices.
- Mucosal lesions are more likely to be associated with antecedent occult bleeding.
- In ~80–95% of patients, bleeding stops spontaneously.
- **Neonatal period**
 - Swallowed maternal blood
 - Necrotizing enterocolitis
 - Duodenal web, antral web
 - Hemorrhagic disease of the newborn
 - Esophagitis
 - Gastritis
 - Stress ulcer
 - Foreign body irritation
 - Vascular malformation
 - GI malformation
- **Infancy**
 - Esophagitis/gastritis
 - Stress ulcer
 - Mallory–Weiss tear
 - Pyloric stenosis
 - Vascular malformation
 - Duplication cysts
 - Metabolic disease
- **Preschool age**
 - Esophageal varices
 - Esophagitis/gastritis/ulcer
 - Foreign body/bezoar
 - Mallory–Weiss tear
 - Vascular malformation
 - Meckel diverticulum
- **School age**
 - Esophageal varices
 - Infection
 - Esophagitis/gastritis/ulcer
 - Mallory–Weiss tear
 - Inflammatory bowel disease
 - Drugs: NSAIDs, alpha-adrenergic antagonists
 - *Helicobacter pylori*
- All ages: Liver failure—coagulopathy, HSP

APPROACH TO THE PATIENT

Determine the cause of the bleeding and begin treatment. Place nasogastric (NG) tube and lavage contents of stomach to determine if bleeding is active and extent of bleeding.

- **Phase 1:** Determine whether the emesis contains blood; red food coloring, fruit-flavored drinks and juices, vegetables, and some medicines may resemble blood. A pH-buffered Gastrocult test identifies blood in the vomitus or gastric aspirate.
- **Phase 2:** Assess severity of bleeding. Is there a change in vital signs, hematocrit, BP, capillary filling, pulse?
- **Phase 3:** Determine the site of bleeding and begin treatment. Examine airway for bleeding: Epistaxis may contaminate emesis to make it resemble upper GI bleeding. Usually diagnosis requires imaging or endoscopy.

Hints for Screening Problems

- Bright red blood signifies active bleeding.
- Darker blood or coffee grounds blood usually means that the blood has had some time to become denatured by gastric acid.
- The rate of bleeding determines the clinical presentation. The more rapid the rate, the larger the volume of bleeding, leading to a greater drop in hemoglobin and change in pulse and BP. Slower bleeding usually presents with anemia and heme-positive stools.
- Any significant blood loss will lead to pallor, tachycardia, orthostasis, poor capillary refill, CNS changes (e.g., restlessness, confusion), and hypotension.
 - Hypotension is a late sign and may not be present even with significant blood loss because vasoconstriction maintains BP until decompensation occurs.
- Initial hemoglobin values may be unreliable because a delay in hemodilution may falsely produce near normal values.
- Absence of blood in the emesis or in NG lavage fluid does not rule out the upper GI tract as the site of bleeding, because a competent pylorus may mask bleeding from a duodenal site.
 - In some cases of massive upper GI bleeding, the patient may not vomit blood but may pass large, black, tarry, or sticky stools (e.g., melena).

HISTORY

- **Question:** Amount of blood (i.e., drops vs. 1 teaspoon vs. 1 tablespoon)?
- **Significance:** Indicates severity of bleeding
- **Question:** Presence of blood in emesis?
- **Significance:** Indicates bleeding from upper GI tract or swallowed blood. Vomitus may not have blood at all, but patient may have recently ingested foods that might resemble.
- **Question:** Source of bleeding?
- **Significance:** Hematemesis from the esophagus, stomach, or duodenum vs. hemoptysis vs. swallowed blood from the nose, mouth, or pharynx

- **Question:** Blood coughed?
- **Significance:** Indicative of hemoptysis
- **Question:** Bleeding from the nose?
- **Significance:** Swallowed and then vomited—did not originate in the upper GI tract
- **Question:** Prolonged retching before hematemesis?
- **Significance:** Suggests a Mallory–Weiss tear
- **Question:** Recent stress (e.g., burns, head trauma, surgery)?
- **Significance:** Suggests an ulcer or gastritis
- **Question:** Toxic ingestion?
- **Significance:** May result in an ulcerated esophagus, which can bleed. Ingestion of certain medications such as aspirin (as well as other anti-inflammatory drugs) and steroid therapy can lead to gastritis and ulcers. Ingestion of such drugs in combination with ethanol can lead to gastritis.
- **Question:** Abdominal pain and vomiting blood?
- **Significance:** Suggests esophagitis, gastritis, and peptic ulcers
- **Question:** Cracked nipples in a breastfeeding mother?
- **Significance:** May lead to the infant swallowing maternal blood and subsequent hematemesis
- **Question:** Gastroesophageal reflux?
- **Significance:** Suggests esophagitis
- **Question:** Past history of GI disease?
- **Significance:** Gastroesophageal reflux, peptic ulcer disease, or previous GI surgery may suggest symptoms are due to recurrence of disease.
- **Question:** Jaundice, hepatitis, or liver disease?
- **Significance:** Suggests portal hypertension and variceal bleeding
- **Question:** Neonatal history of umbilical vein catheterization or infection?
- **Significance:** Portal vein thrombosis (e.g., sepsis, shock, exchange transfusion, omphalitis, IV catheters) suggests portal hypertension and bleeding varices due to cavernous transformation of the portal vein.
- **Question:** Familial history of bleeding diathesis?
- **Significance:** Von Willebrand disease, hemophilia

PHYSICAL EXAM

- **Finding:** Any skin petechiae, ecchymosis, or hemangiomas?
- **Significance:** Evidence of chronic liver disease (e.g., spider angioma, palmar erythema, jaundice)
- **Finding:** Head, ears, eyes, nose, and throat—nasopharyngeal source of bleeding?
- **Significance:** Swallowed blood
- **Finding:** Freckles on buccal mucosa?
- **Significance:** Osler–Weber–Rendu syndrome, Peutz–Jeghers syndrome
- **Finding:** Oral thrush?
- **Significance:** Candidal esophagitis

- **Finding:** Oral mucosal lesions?
- **Significance:** Corrosive ingestions
- **Finding:** Abdomen?
- **Significance:**
 - Hepatosplenomegaly
 - Ascites
 - Portal hypertension
- **Finding:** Isolated splenomegaly?
- **Significance:** Cavernous transformation of the portal vein; portal hypertension
- **Finding:** Rectal examination—heme-positive stool may or may not be present?
- **Significance:** If positive, confirms the presence of upper GI bleeding.

DIAGNOSTIC TESTS & INTERPRETATION

Initial hemoglobin may not be accurate, and hemoglobin should be measured serially.

- **Test:** Gastrocult
- **Significance:** If possible, check the red substance for blood. In neonates, may need to check for fetal hemoglobin with the Apt test—a test to identify fetal hemoglobin.
- **Test:** CBC
- **Significance:** If leukopenia, anemia, or thrombocytopenia is present, consider chronic liver disease and portal hypertension. If anemia is present with normal erythrocyte indices, there is truly an acute cause for bleeding. If erythrocyte indices indicate iron-deficiency anemia, consider varices or a mucosal lesion (i.e., chronic blood loss).
- **Test:** Coagulation profile
- **Significance:** If PT or PTT is abnormal, consider liver disease or disseminated intravascular coagulation (DIC) with sepsis. If DIC screen is negative, consider liver disease. Make sure, however, that blood sample was not contaminated with heparin.
- **Test:** Bleeding time
- **Significance:** Abnormal in patients with previous history (or family history) of bleeding disorders
- **Test:** Liver function test results
- **Significance:** Abnormal in chronic liver disease
- **Test:** Upper endoscopy
- **Significance:** Diagnosis can be made in 75–90% of patients.
- **Test:** Capsule endoscopy
- **Significance:** May play a role in locating small bowel lesions
 - Sclerotherapy/banding, injection of ulcers, heated probes
 - Thermo-regulation, argon plasma coagulation

Imaging

- Barium tests:
 - Not as useful as esophagogastroduodenoscopy (EGD), but can identify a large ulcer. Air-contrast upper GI series is better than regular upper GI test.
- Bleeding scan:
 - Useful in the patient with significant bleeding in whom endoscopy undiagnostic. There are 2 types of scans: Technetium sulfur colloid and tagged erythrocyte. The former detects rapid bleeding, but can miss small bleeds, especially if patient is not bleeding during the scan. The latter can detect small bleeds, especially if intermittent.
 - Meckel scan: Can detect Meckel diverticulum as source of bleed
- Angiography:
 - Useful in detecting vascular causes of upper GI bleeding; can also be therapeutic (i.e., injection of coils into a vascular malformation may occlude it). Invasiveness and need for specialized training of clinicians are limitations.

TREATMENT

ADDITIONAL TREATMENT

General Measures

Disease-specific therapy:

- Peptic ulcer disease:
 - Proton pump inhibitors
 - H2 blockers
 - Sucralfate
 - Prokinetic agents
 - *H. pylori* eradication
- Esophageal varices:
 - Vasopressin or somatostatin infusion
 - Sclerotherapy or banding
 - Sengstaken-Blakemore tube
 - Portosystemic shunts

Initial management of the emergency depends on diagnosis and clinical condition of the patient:

- Stabilize the patient with IV fluids and blood products if necessary
- Order laboratory tests: Complete blood chemistry, PT or PTT, EGD screen, liver function tests, blood type, and cross-match
- Insert an NG tube and lavage with saline to determine site as well as rate of ongoing bleeding. No need for cold saline.
- Monitor patient's vital signs and hemoglobin as necessary
- Make appropriate diagnosis and institute appropriate therapy (i.e., EGD, bleeding scans)

ISSUES FOR REFERRAL

Immediate referral if bleeding is profuse, if patient is hemodynamically unstable, or if bleeding will not stop. Refer any patient with evidence of chronic iron-deficiency anemia and heme-positive stools.

SURGERY/OTHER PROCEDURES

- Esophageal varices:
 - Sclerotherapy or banding
 - Sengstaken-Blakemore tube
 - Portosystemic shunts
- If bleeding stops quickly, workup is less emergent.

ONGOING CARE

- Monitor hemoglobin in the hospital until patient's condition is stable.
- Once patient is discharged, monitor patient's hemoglobin weekly as well as Hemoccult cards until stable.
- More specific follow-up depends on the underlying condition.

ICD10

K92.2 Gastrointestinal hemorrhage, unspecified

FAQ

- Q: When do you refer a patient?
- A: Any bleeding—immediate referral if bleed is large, the patient is hemodynamically unstable, and bleeding will not stop. Patients with evidence of chronic iron-deficiency anemia and heme-positive stools.
- Q: What makes upper GI bleeding an emergency?
- A: Any persistent bleed with change in vital signs; significant drop in hemoglobin

URETEROPELVIC JUNCTION OBSTRUCTION

J. Christopher Austin

Michael C. Carr

BASICS

DESCRIPTION

Ureteropelvic junction (UPJ) obstruction is a partial blockage of the kidney at the point where the renal pelvis transitions into the proximal ureter.

EPIDEMIOLOGY

- 45% of all cases of significant prenatal hydronephrosis are due to UPJ obstruction.
- Occurs more commonly in males (M/F 2:1)
- Left-sided lesion more common (66%)
- Bilateral in 10–40%
- 50% of patients have an additional genitourinary malformation (most common are vesicoureteral reflux, contralateral UPJ obstruction, multicystic dysplastic kidney, and renal agenesis).
- Of patients with VATER association, 21% have UPJ obstruction and thus should be screened with renal ultrasound. (VATER stands for vertebral defects, anal atresia, tracheoesophageal fistula with esophageal atresia, and radial and renal anomalies.)

PATHOPHYSIOLOGY

- The obstruction can cause varying degrees of hydronephrosis.
- Mild forms of UPJ obstruction result in dilation of the renal pelvis without loss of function.
- More severe forms result in dilation of the renal pelvis and calyces with loss of renal parenchyma and decreased function.
- In the most severe cases, the kidney may have cystic dysplasia and very poor function. Congenital hydronephrosis owing to an intrinsic narrowing is nearly always asymptomatic.
- When the obstruction is intermittent owing to a crossing vessel, the renal pelvis becomes distended (most commonly owing to the transient increase in urine output), which drapes it over the vessel and kinks the ureter, resulting in an acute obstruction. The acute distention of the renal pelvis results in pain (renal colic).

ETIOLOGY

- Intrinsic: A congenital narrowing of the UPJ, which is most commonly owing to abnormal musculature and fibrosis of this area, resulting in an adynamic segment
- Extrinsic: Kinking at the UPJ, which is most commonly owing to the renal pelvis draping over a lower pole crossing vessel. This type of obstruction can be intermittent.

DIAGNOSIS

HISTORY

- Antenatal:
 - If unilateral, timing and severity of hydronephrosis and status of the contralateral kidney are factors.
 - When bilateral or affecting a solitary kidney, renal insufficiency is a concern.
 - The presence of oligohydramnios, increased renal echogenicity, and cystic changes are indicators of poor renal function and dysplasia.
- Postnatal:
 - Feeding intolerance/respiratory distress (very rarely caused by UPJ obstruction)
- Older children:
 - History of episodic abdominal (may not lateralize well), flank, or back pain
 - Length of episodes (usually 30 minutes to several hours); associated nausea and vomiting
 - Relation of episodes to fluid intake; history of urinary tract infections or gross hematuria

PHYSICAL EXAM

- Newborn: Palpate kidneys. Affected kidney may feel enlarged but should not be tense. A tense mass can indicate a severe obstruction and should be imaged promptly.
- Older child: Careful abdominal exam for enlarged kidney and tenderness; costovertebral angle tenderness

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Newborn: If bilateral or a solitary kidney, serial assessments of renal function are necessary (serum electrolytes and creatinine) starting at 24–48 hours of age. With a normal contralateral kidney, no immediate laboratory testing is necessary.
- Older children: Urinalysis to detect hematuria or pyuria. Culture if infection suspected.

Imaging

Antenatally detected hydronephrosis: Infants with antenatally detected hydronephrosis typically are evaluated with 3 imaging studies—renal/bladder ultrasound, voiding cystourethrogram (VCUG), and renal scan:

- Renal/Bladder ultrasound: In most cases, immediate imaging is not necessary. Because of a period of relative oliguria of a newborn in the 1st 24–48 hours of life, an ultrasound may underestimate the degree of hydronephrosis. This should not preclude evaluating an infant during this time as long as any normal study is followed up with a repeat study in 4–6 weeks. Evaluation should reveal the severity of dilation of the renal pelvis and calyces, changes in the amount and echogenicity of the parenchyma, and the presence of cortical cysts:
 - The evaluation of the full bladder is important for excluding dilated distal ureters, thickening of the bladder wall owing to outlet obstruction, and ureteroceles.
 - In cases of bilateral hydronephrosis, a solitary hydronephrotic kidney, or a tense kidney on physical examination, imaging should be promptly performed.
- VCUG: This study will detect the presence of vesicoureteral reflux as well as exclude the presence of posterior urethral valves and other abnormalities of the bladder:
 - The test can be delayed until after discharge from the nursery unless there is concern about posterior urethral valves, in which case it should be performed early.
- Renal scan: This study can quantify the differential renal function or the amount each kidney contributes to overall renal function (the normal differential is 50% ± 5% for each kidney):
 - The 2 most commonly used radionuclides are mercaptoacetyltriglycine (MAG-3) and diethylenetriamine penta-acetic acid (DTPA). In addition to the ability to detect diminished function, if there is poor drainage of the affected kidney, furosemide is given to wash out the radiotracer.
 - The time for washing out half of the accumulated radiotracer (T1/2) is often given in the report.
 - A prompt T1/2 (<10 minutes) is indicative of a nonobstructed kidney.
 - A slower T1/2 may be indicative of obstruction when it is >20 minutes. An intermediate T1/2 (10–20 minutes) is indeterminate for obstruction. Owing to effects of hydration, the amount of hydronephrosis, and variables in the timing of the diuretic administration, the T1/2 may be unreliable.

- Intravenous pyelogram (IVP): This study is most useful for evaluating the anatomy of the kidney and the ureters:
 - It can also be used for evaluating an older child with intermittent symptoms if it can be done during a symptomatic episode.
 - A normal study during a symptomatic episode of abdominal or flank pain excludes an intermittent UPJ obstruction as the cause of the child's pain.
 - If a normal study is obtained while the child is asymptomatic, an intermittent UPJ obstruction remains a possible cause.
- MRI: A new technique being studied that provides both anatomic and functional detail. Dynamic contrast-enhanced MRI requires sedation and placement of a bladder catheter. The images are obtained following infusion of gadolinium-DTPA. Lasix is given 15 minutes before the start of the study. This technique is being studied for use instead of ultrasound and renal scans in the hope that it will be a more precise tool in deciding whether or not the child requires surgical repair. The studies are currently preliminary, but this may be an important technique in the future.

DIFFERENTIAL DIAGNOSIS

- Vesicoureteral reflux: Higher grades of reflux will result in the dilation of the upper urinary tract.
- Distal ureteral obstruction: Obstruction at the level of the bladder owing to ureterovesical junction obstruction, ureterocele, or an ectopic ureter
- Bladder outlet obstruction: Dilation of the upper urinary tract secondary to obstruction of the lower urinary tract owing to posterior urethral valves, urethral atresia, or stricture
- Megacalycoses: Congenital dilation and increased numbers of calyces without significant renal pelvis dilation or obstruction
- Multicystic-dysplastic kidney: Can be difficult to differentiate severe hydronephrosis from cysts by ultrasound. Renal scan will demonstrate no function in multicystic-dysplastic kidneys.
- Triad syndrome: A triad of hypoplastic abdominal wall musculature, bilateral undescended testes, and dilation of the urinary tract (also known as "prune belly" syndrome or Eagle-Barrett syndrome)

TREATMENT

ADDITIONAL TREATMENT

General Measures

- The decision to observe or surgically correct a UPJ obstruction depends on several factors. One must consider the age and overall health of the neonate, the amount of functional impairment of the kidney, whether it is a unilateral or bilateral process, the drainage pattern on renal scan, and whether or not it is symptomatic. There is no strict rule for who should be observed and who should undergo surgery. This decision should be made on an individual basis.

- Antibiotic prophylaxis: Newborns should be started on a once-a-day daily dose of amoxicillin or cephalixinat at 1/4 to 1/2 the normal therapeutic dose. The antibiotic can be switched to trimethoprim, trimethoprim/sulfamethoxazole, or nitrofurantoin at 2 months of age. The duration that infants should be left on antibiotics is controversial among practicing pediatric urologists. Almost all agree that infants should be started on prophylactic antibiotics at birth. They should be continued at least until the infant undergoes a VCUG to exclude reflux. Several factors including age, sex, and degree of hydronephrosis are taken into account when deciding whether or not to stop the prophylaxis.
- Observation: Infants with the hydronephrosis thought to be owing to a narrowing at the UPJ are typically observed when there is preserved function (>40%) in the affected kidney and the contralateral kidney is normal. The pattern of drainage is taken into account, and if there is prompt drainage and normal differential function (50% ± 5%), these patients are followed with less frequent follow-up studies than those with less function or poor drainage. Most patients have follow-up imaging studies done at 3–6 month intervals during their 1st year of life, and they are gradually spaced out as time goes by if the hydronephrosis remains stable or improves.
- Older children with hydronephrosis owing to a UPJ obstruction are often detected during a symptomatic episode. If the UPJ obstruction is asymptomatic and the function of the kidney is preserved, the child may be observed as well.

SURGERY/OTHER PROCEDURES

- The gold standard for the repair of the UPJ obstruction has been a pyeloplasty:
 - During the procedure, the narrowed UPJ is most commonly excised and the ureter is reanastomosed to the renal pelvis.
 - This procedure is successful 95% of the time.
- Less invasive approaches include endoscopically incising the narrowing (endopyelotomy) or balloon dilation:
 - These approaches have been used in adults with rates of success in the 50–70% range but are considerably less invasive.
 - Endoscopic procedures have not been routinely offered as a 1st-line therapy for the treatment of UPJ obstructions because of their limited experience in children and the lower rates of success.

- Laparoscopic pyeloplasty is being performed in older children and adolescents and will likely be more common in the next several years. Robotically assisted procedures are now being done, further enhancing the minimally invasive approach. Both offer a similar rate of success to a traditional pyeloplasty with decreased perioperative morbidity because of the small incisions for the laparoscopic instruments.

CODES

- ICD9
 - 593.4 Other ureteric obstruction
 - 753.21 Congenital obstruction of ureteropelvic junction
- ICD10
 - N13.8 Other obstructive and reflux uropathy
 - Q62.11 Congenital occlusion of ureteropelvic junction

FAQ

- Q: My unborn baby has hydronephrosis. My obstetrician told me that it is most likely a UPJ obstruction. Is my baby going to need surgery to correct this?
 - A: Not necessarily; only ~1/3 of babies with significant hydronephrosis ultimately require surgical correction.
- Q: Will my child's kidney look normal after the surgery to fix it?
 - A: Often the kidney has less dilation and an improved appearance, but not completely normal. Of greater importance is that there is no longer obstruction and the function is preserved or improved.

URETHRAL PROLAPSE

Stephen A. Zderic

BASICS

DESCRIPTION

- Circular eversion of the distal urethral mucosa through the external urethral meatus
- Classification of urethral prolapse:
 - I: Minimal segmental inflammation
 - II: Circumferential prolapse with edema
 - III: Edematous mass protruding beyond the labia minora
 - IV: Severe hemorrhagic inflammation or necrosis and ulceration of the prolapse

EPIDEMIOLOGY

- Prepubertal girls <10 years of age
- Preponderance among African American females (90–100% of patients in reported series)
- Patients above average for height and weight

RISK FACTORS

Genetics

Predominance in African American females.

ETIOLOGY

Etiology unclear; proposed theories include:

- Poor adherence between smooth muscle layers of the urethra
- Estrogen deficiency
- Female circumcision

DIAGNOSIS

HISTORY

- 95% present with bleeding/bloody spotting on underwear.
- 21% have dysuria, frequency.
- Occasionally, a patient presents with urinary retention.
- Some are asymptomatic and detected only incidentally.

PHYSICAL EXAM

- Circular (doughnut-shaped) protrusion of urethral meatus with a reddish-purple mass surrounding the urethral meatus that is at the center
- Tissue appears inflamed and friable.
- To help distinguish between a urethral and vaginal mass, the vulva can be retracted downward and laterally.

DIAGNOSTIC TESTS & INTERPRETATION

Imaging

- If the appearance is atypical for urethral prolapse, ultrasound may be used to rule out bladder tumor (sarcoma botryoides) or prolapsed ureterocele.
- Urethral prolapse with typical presentation requires no imaging.

DIFFERENTIAL DIAGNOSIS

- Prolapsing ureterocele (or ectopic ureter, urethral polyp, bladder)
- Sarcoma botryoides
- Condyloma
- Hydrometrocolpos
- Periurethral abscess
- Trauma

TREATMENT

ADDITIONAL TREATMENT

General Measures

- Do not try to manually reduce the prolapsed tissue.
- Conservative: Sitz baths followed by topical estrogen cream b.i.d.:
 - Some suggest topical antibiotics.
- Surgical: Most typical surgical approach is excision of prolapsed segment over a urethral Foley catheter, suturing the proximal urethral margin to the adjacent vestibule.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Outpatient visit to assess success of estrogen cream or surgical repair

ADDITIONAL READING

CODES

ICD9

- 599.5 Prolapsed urethral mucosa
- 753.8 Other specified anomalies of bladder and urethra

ICD10

- N36.8 Other specified disorders of urethra
- Q64.71 Congenital prolapse of urethra

FAQ

- Q: What is the most common presenting complaint?
- A: Bleeding
- Q: What is the “first aid” for this problem?
- A: Avoid infection. You may use antibiotic cream. Keep tissue moist. Do not push the tissue back into the urethra.

URINARY TRACT INFECTION

Mercedes M. Blackstone

BASICS

DESCRIPTION

- Urinary tract infection (UTI) is significant growth of bacterial urinary tract pathogen(s):
 - For suprapubic aspirate, any growth is significant.
 - For urine obtained by catheterization, $\geq 50,000$ CFU/mL, suspect if $\geq 10,000$ CFU/mL.
 - For urine obtained by clean-catch technique, $\geq 100,000$ CFU/mL
- Upper tract infection or pyelonephritis: Infection of the renal parenchyma; most febrile babies with a positive culture have upper tract infection.
- Lower tract infection or cystitis: Infection limited to the bladder, not involving the kidneys; occurs more in older children and adolescents; usually no fever

EPIDEMIOLOGY

Incidence

- Bimodal age distribution with peak incidence in infants <1 year (40 per 1,000)
- 2nd peak in adolescent females

Prevalence

- Overall prevalence of about 7% in febrile infants and young children; varies according to risk factors below
- Higher prevalence in white girls

RISK FACTORS

- Sex/Age: Boys are most at risk for UTI during 1st year of life; girls until school age and again in adolescence.
- Circumcision status: Uncircumcised males <1 year have 10 times the incidence of UTI compared with circumcised males.
- Race/Ethnicity: White children are 2–4 times more likely than blacks to have UTI:
 - May be due in part to differences in blood group antigens on the surfaces of uroepithelial cells, which affect bacterial adherence
- Abnormal urinary tract: Children with vesicoureteral reflux (VUR) and obstruction are at higher risk for UTI.
- Voiding dysfunction
 - Requiring frequent catheterization
 - Sexual activity
 - Clinical decision rule in febrile girls 2–24 months. Consider testing if ≥ 2 of following are present:
 - Temperature $\geq 39^\circ\text{C}$, fever for ≥ 2 days, white race, age <1 year, absence of another potential source of fever

GENERAL PREVENTION

- Teach correct wiping—front to back—to young children.
- Consider prophylactic antibiotics for select children with recurrent infection, VUR, urologic anomalies:
 - Existing evidence with 1-year follow-up does not support antibiotic prophylaxis for all patients with VUR.
- Attention to good voiding and stooling habits; treat constipation
- Consider single-dose postcoital antibiotics for adolescents with recurrent UTI.

PATHOPHYSIOLOGY

- Bacterial invasion of the urinary tract from ascending skin or gut flora
- Shorter urethra in females puts them at increased risk.
- Poor bladder emptying (neurogenic bladder, obstructive uropathies) facilitates movement of pathogens into the upper tract.
- In young infants, can be from hematogenous spread

ETIOLOGY

Urinary tract pathogens:

- *Escherichia coli* is responsible for about 80% of UTIs in children.
- Other fairly common microbes include *Klebsiella* species, *Enterococcus*, *Proteus mirabilis*.
- Less common: *Enterobacter cloacae*, group B hemolytic streptococci, *Citrobacter*, *Pseudomonas* species, *Staphylococcus aureus*, *Serratia* species, and *Staphylococcus saprophyticus* (teenage girls)

COMMONLY ASSOCIATED CONDITIONS

- ~5–10% of babies with febrile UTIs (pyelonephritis) are bacteremic, but the clinical course is likely unchanged.
- VUR or urinary anomalies

DIAGNOSIS

HISTORY

- Babies:
 - Symptoms are nonspecific, most often have fever alone
 - Can have vomiting, irritability, poor feeding, and lethargy
 - Rarely, failure to thrive or jaundice
- Older children:
 - Classic symptoms of the lower tract include urgency, frequency, dysuria, hesitancy, suprapubic discomfort, hematuria, and malodorous urine. Classic symptoms of the upper tract include chills, nausea, flank pain, and fever.
 - May have history of constipation
 - Can also present with secondary enuresis
- Special question:
 - Has the young child had a history of UTI, unexplained fevers, or urinary tract anomaly?

PHYSICAL EXAM

- Temperature and blood pressure should be documented
- Babies and toddlers: Often no physical findings or fever alone
 - Less common: Abdominal pain or distention, poor growth or weight gain, malodorous urine
 - Associated findings: May see evidence of foreign body, phimosis, labial adhesions, or midline abnormality of the lower back, which could indicate a neurogenic bladder
- Older children:
 - Lower tract: Suprapubic tenderness; may see evidence of constipation
 - Upper tract: Fever; costovertebral angle tenderness to percussion

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Urine culture collected sterilely is the gold standard for diagnosis:
 - Bladder catheterization in young children (or less commonly, suprapubic aspirate)
 - Midstream clean catch method for older cooperative children
 - A specimen should not be obtained by applying a bag to the perineum; contamination rates are too high.
- False positives:
 - Contaminated urine by perineum or stool organisms
- Cultures take 24–48 hours, so several rapid screening tests are available:
 - Conventional urinalysis: ≥ 5 WBC/HPF (uses centrifuged urine)
 - Enhanced urinalysis (combines microscopy on uncentrifuged urine with Gram stain): ≥ 10 WBC/mm³ or positive Gram stain
 - High sensitivity and specificity; helpful in neonates
 - Urine dipstick alone equivalent to conventional microscopy:
 - Leukocyte esterase (LE) indicates presence of urinary leukocytes.
 - Nitrites are formed by nitrate-splitting bacteria (high rate of false negatives because urine has to sit in the bladder for ≥ 4 hours for nitrites to be detected).
 - Both suggest possible UTI; together they are highly specific.
- Serum testing is not routinely indicated in the patient with suspected UTI.
 - Blood culture: Not indicated in the well-appearing patient ≥ 2 months since bacteremia does not alter management
 - Inflammatory markers: White blood cell (WBC) count, C-reactive protein (CRP), erythrocyte sedimentation rate (ESR), and procalcitonin (PCT) may all be elevated in UTIs but are not particularly helpful in predicting diagnosis or distinguishing between upper and lower tract disease.
 - Serum creatinine: Not necessary for routine UTI but should be obtained in patients with recurrent disease or renal anomalies.

ALERT

Pitfalls:

- 10–25% of babies will have a negative urinalysis despite culture- or nuclear scan–documented UTI, so a culture should always be obtained in this population.
- Conversely, there are very high rates of asymptomatic bacteriuria in the pediatric population, so a mildly positive urinalysis should be weighed in the context of the pretest probability for UTI.
- Failure to culture by sterile means: Leads to a contaminated culture that is difficult to interpret
- Failure to screen a young child with another possible source of fever; children with otitis media, upper respiratory infections, and gastroenteritis can have a concurrent UTI.

Imaging

- There is controversy surrounding indications for imaging in routine UTIs.
- Ultrasound: Identifies hydronephrosis, congenital anomalies, and abscesses. Not good at detecting scars or VUR:
 - Recommended by AAP practice parameter for febrile children 2–24 months with UTI
 - If prenatal ultrasound beyond 32 weeks gestation was normal, may not be necessary.
- Voiding cystourethrogram (VCUG): Test of choice to detect and characterize VUR:
 - No longer routinely recommended by the AAP after first febrile UTI
 - Indicated for young children with recurrent febrile UTIs or an abnormal renal ultrasound
- In addition to the children covered by the AAP parameter, consider imaging for UTIs in all boys, children with recurrent infections, and children with voiding dysfunction or urinary abnormalities.
- Renal cortical scan: Detects acute pyelonephritis and renal scarring. Unclear utility in clinical setting; consider in febrile children if diagnosis is unclear.

DIFFERENTIAL DIAGNOSIS

- The differential diagnosis of isolated or prolonged fever is very broad.
- Infants: Gastroenteritis, occult bacteremia, occult pneumonia, meningitis, viral syndrome
- Older children and adolescents:
 - Common: Vaginal foreign body, vulvovaginitis/urethritis, epididymitis, gastroenteritis, sexually transmitted infection, pelvic inflammatory disease
 - Less common: Excessive drinking, urinary calculi, diabetes mellitus or insipidus, appendicitis, Kawasaki disease, tubo-ovarian abscess, ovarian torsion, group A streptococcal infection
 - Rare: Mass adjacent to bladder, spinal cord process (tumor, abscess), hypercalcemia

**TREATMENT****MEDICATION (DRUGS)****First Line**

- Empiric antibiotic therapy should be initiated in febrile children with suspected UTI in order to prevent scarring.
- *E. coli* is the most common pathogen associated with 1st UTI; it is typically sensitive to multiple antimicrobials.
- Gram staining, when available, can help guide empiric therapy.
- Empiric inpatient therapy: IV therapy with a 3rd-generation cephalosporin such as cefotaxime (120 mg/kg/day divided t.i.d.) or ceftriaxone (75 mg/kg/day) or the combination of ampicillin (100 mg/kg/day divided q.i.d.) and gentamicin (7.5 mg/kg/day divided t.i.d.):
 - High-risk patients who are immunocompromised, have indwelling catheters, or have recurrent UTIs should initially receive broad-spectrum antibiotics that cover the organisms involved in prior infections.

- Empiric outpatient therapy: Options include cefixime (8 mg/kg/day divided b.i.d.), cefdinir (14 mg/kg once daily), amoxicillin-clavulanate (45 mg/kg of amoxicillin component per day divided b.i.d.), amoxicillin (20–40 mg/kg/day divided b.i.d.), co-trimoxazole (6–12 mg TMP/kg/day divided b.i.d.), or cephalexin (50–100 mg/kg/day divided q.i.d.):
 - High rates of resistance to amoxicillin and co-trimoxazole in many communities make them poor initial choices in most cases.
- Antibiotic duration (IV/oral):
 - Children ≤ 2 years of age with a febrile UTI, recurrent UTI, or urinary tract abnormalities should receive a total of 7–14 days of antibiotic therapy.
 - Older children without fever or significant history who likely have an uncomplicated cystitis are eligible for a short course of antibiotics (5–7 days).
- Antibiotic prophylaxis after UTI:
 - Benefit somewhat unclear
 - AAP recommends the use of prophylactic antibiotics (co-trimoxazole 2 mg TMP/kg once daily or nitrofurantoin 1–2 mg/kg/day in 1–2 divided doses; maximum dose 100 mg/day) until imaging is completed.
 - Continued prophylaxis may be warranted for some patients with VUR; the duration is often determined in consultation with a urologist.

**ONGOING CARE****FOLLOW-UP RECOMMENDATIONS****Patient Monitoring**

- Consider a repeat urine culture after 2 days of therapy if the patient is not improving on an appropriate antibiotic regimen.
- Such patients should also receive imaging with ultrasound and consideration of VCUG or renal scan.
- Urinalysis and urine culture for subsequent febrile illnesses

PROGNOSIS

Prompt treatment of febrile UTIs reduces the risk for scarring and its sequelae. These children generally have a very good prognosis.

COMPLICATIONS

- Repeated febrile UTIs in young children may lead to renal scarring.
- Renal scarring in childhood carries a risk of hypertension, pre-eclampsia, and end-stage renal disease as an adult.

**CODES****ICD9**

- 590.80 Pyelonephritis, unspecified
- 595.9 Cystitis, unspecified
- 599.0 Urinary tract infection, site not specified

ICD10

- N11.9 Chronic tubulo-interstitial nephritis, unspecified
- N30.90 Cystitis, unspecified without hematuria
- N39.0 Urinary tract infection, site not specified

FAQ

- Q: Which children should have a radiologic evaluation after their 1st UTI?
- A: All boys, girls < 3 years of age, and anyone with urologic abnormalities or recurrent UTIs. Imaging should be considered for febrile UTIs at any age.
- Q: Does a urine culture need to be done if the catheterized dipstick or urinalysis is negative?
- A: $> 10\%$ of febrile infants with pyelonephritis will have a false-negative screening test (dipstick, urinalysis). A sterile urine culture should be done.

URTICARIA

Christopher P. Raab

BASICS

DESCRIPTION

- Urticarial lesions are best described as raised, pruritic circumscribed erythematous papules.
- Single lesions may coalesce as they enlarge, forming generalized, raised, erythematous areas.
- They are transient, typically lasting several hours.
- Also known as “hives” or “nettle rash”
- Acute: <6 weeks duration
- Chronic: >6 weeks duration
- Other similar but nonurticarial entities:
 - Angioedema: Urticarial-like lesions that form in the deep dermal, subcutaneous, and submucosal layers
 - Anaphylaxis: Hypersensitivity reaction after exposure to an antigen, producing weakness, respiratory compromise secondary to airway edema, urticarial rash, pruritus, and hypotension; can lead to shock

EPIDEMIOLOGY

- Female:male ratio of 3:2
- No variation in race

Incidence

Lifetime incidence of 15–25%

GENERAL PREVENTION

When a trigger is identified, avoidance is the main preventive measure.

PATHOPHYSIOLOGY

- Immune mediated:
 - Antigen is cross-linked to IgE on a mast cell.
 - This causes mast cell activation leading to the release of vasoactive mediators, such as histamine, leukotrienes, prostaglandin D₂, platelet-activating factor, and other vasoactive mediators.
 - These vasoactive mediators cause pruritus, vasodilatation, and capillary leak, which lead to the characteristic findings.
 - Common triggers include some medications such as penicillins, foods such as milk or eggs, and envenomations.
- Non-immune mediated:
 - Degranulation of mast cells secondary to other non-IgE reactions such as physical changes, chemicals, some medications such as beta-lactams and sulfa-containing drugs, and some foods
- Autoimmune mediated:
 - Degranulation of mast cells caused by cross-linking of IgE by IgG, or IgG binding to the high-affinity IgE (FcεRI) receptor on mast cells

ETIOLOGY

Acute Urticaria

- Viral infections are thought to make up ~80% of all cases of acute urticaria in children. Most commonly isolated causes include the following viruses:
 - Epstein-Barr
 - Coxsackie A and B
 - Hepatitis A, B, and C
- Parasitic infections
- Bacterial infections (especially group A strep)
- Medications: Most frequently reported include the following:
 - NSAIDs
 - Opiates
 - Vancomycin
- Radiocontrast
- Foods
- Transfusion of blood products
- Food additives and dyes
- Natural remedies including cranberry, feverfew, glucosamine, and ginger
- Insect venom including bees, wasps, hornets

Chronic Urticaria

- Idiopathic: Most have an unknown cause, but many feel that an association with an autoimmune mechanism is likely.
- Physical (~20–30%):
 - Dermatographism (9%): Stroking of skin causes linear urticaria at site of contact.
 - Cholinergic (5%): Diffuse erythema and elevated but pale urticarial lesions; intense pruritus. Associated with sweating reflex, so often associated with overheating or exertion. May be worsened in combination with other triggers in specific combinations.
 - Cold (3%): Urticarial lesions present at areas of skin exposed to low temperatures; has a familial and nonhereditary form.
 - Aquagenic: Urticarial lesions arise when the patient is exposed to water (e.g., bathtub, swimming pool).
 - Delayed pressure/vibratory: Deep or prolonged pressure on skin produces significant urticaria and often angioedema. Vibratory urticaria is a form of delayed pressure urticaria caused by repetitive vibration (e.g., use of a jackhammer).
- Mast cell disease:
 - Urticaria pigmentosa: Excessive number of mast cells in skin, bone marrow, lymph nodes, and other tissues. Flares are characterized by pruritus, flushing, tachycardia, nausea, and vomiting.
 - Systemic mastocytosis

- Systemic disease:
 - Rheumatologic:
 - Urticarial vasculitis: Erythematous wheals that resemble urticaria but histologically appear as leukocytoclastic vasculitis; often presents with systemic symptoms and lasts >24 hours
 - Muckle-Wells syndrome: Chronic recurrent urticaria, deafness, amyloidosis, and arthritis
 - Neoplasms
 - Infections: Parasites especially noted to cause chronic urticaria
 - Autoimmune: Antibodies to IgE or IgE receptor (FcεRI)

DIAGNOSIS

HISTORY

- Description of rash: Lesions may not be present at time of exam due to transient nature. Digital photos are often useful.
- Duration of symptoms, acute versus chronic:
 - If acute (<6 weeks), ask about:
 - Viral symptoms including rhinorrhea, cough, fever, congestion, malaise
 - Any medications (prescription or over the counter) or any herbal remedies
 - Any new foods or beverages
 - Any new exposures to perfumes, chemicals, or other skin products
 - If chronic (>6 weeks):
 - History of previous episodes including timing, exposures, any past history of urticaria or angioedema
 - Other symptoms or variations in presentation
 - Symptoms of systemic diseases, such as hyperthyroidism, systemic lupus erythematosus (SLE), rheumatoid arthritis, polymyositis, amyloidosis, infections, and lymphoma
 - Duration of lesions

PHYSICAL EXAM

- Appearance of rash: Has classic wheal and flare appearance
- Respiratory: Look for evidence of stridor, wheezing, or dyspnea. If present, be concerned for airway compromise or lower airway edema from an anaphylactic reaction.
- Facial or neck swelling: A concern for possible airway compromise
- A full physical exam should be performed to look for signs of systemic disease or malignancy, such as:
 - Upper respiratory tract infections
 - Thyromegaly
 - Lymphadenopathy or splenomegaly that suggests lymphoma
 - Joint examination for any evidence of connective tissue disease, rheumatoid arthritis, or SLE

DIAGNOSTIC TESTS & INTERPRETATION**Lab**

- Testing is often fruitless unless indicated by history and physical examination.
- Skin testing may be performed if the causative agent is thought to be 1 of several food items.
- If symptoms are difficult to handle or persist > 3 months, consider:
 - CBC with differential
 - ESR
 - Thyroid studies (thyroid-stimulating hormone [TSH], free T4, antithyroglobulin, and antiperioxosomal antibody)
- If symptoms are atypical, last > 1 year, or are suggestive of urticarial vasculitis:
 - Complement studies
 - ANA titer
 - Liver function tests
 - Skin punch biopsy

DIFFERENTIAL DIAGNOSIS

- Viral exanthema
- Atopic dermatitis
- Contact dermatitis
- Insect bites
- Maculopapular drug rash
- Erythema multiforme
- Plant-induced eruptions
- Henoch-Schönlein purpura
- SLE

**TREATMENT**

Emergent treatment: If any difficulty breathing, stridor or wheezing, or other signs of anaphylaxis, give epinephrine 0.01 mL/kg of the 1:1,000 solution SC/IM.

MEDICATION (DRUGS)

- Acute urticaria:
 - Usually self-resolving but can treat with 2nd-generation nonsedating antihistamines
 - 1st-generation antihistamines: Diphenhydramine 1 mg/kg/dose or total 5 mg/kg/d divided PO q6h or hydroxyzine 2 mg/kg/day PO divided q6h for pruritus
- Chronic urticaria: See below.

First Line

Antihistamines/H1 antagonists:

- Less sedating, longer acting, and should be mainstay of therapy:
 - Cetirizine (Zyrtec): Dosing varies by age from 2.5–10 mg daily
 - Loratadine (Claritin): 5 mg daily
 - Fexofenadine (Allegra): Not indicated for those <6 years of age; >6 years of age can use 30 mg twice daily.
- 1st-generation antihistamines are effective but more sedating:
 - Diphenhydramine (Benadryl): 5 mg/kg/day divided q6h
 - Hydroxyzine (Atarax): 0.6 mg/kg/dose q6h
 - Cyproheptadine (Periactin): 2 mg up to 3 times a day: Primary treatment for cold urticaria

Second Line

Increase 2nd-generation H1 antagonist dose to maximum for age. In adult guidelines, increasing the dose up to 4-fold is more effective.

Third Line

- Addition of a second nonsedating 2nd-generation H1 antihistamine
- Leukotriene inhibitors: Minimal additive response noted in clinical studies
- Montelukast (Singulair): 5 mg daily
- Other:
 - Combined H1 and H2 antagonist
 - H2 antagonists: Added as 2nd agent because skin cells have both H1 and H2 receptors and a synergistic effect can be achieved by addition of an H2 blocker
 - Ranitidine (Zantac): 2–4 mg/kg/day divided twice daily; doxepin (Sinequan): A tricyclic antidepressant. > 12 years of age 10–50 mg/day and can slowly titer up to 100 mg/day. Potent antihistamine but poorly tolerated due to sedation, hypotension, anticholinergic side effects, and massive weight gain
- Other immune-modifying agents used in chronic urticaria:
 - Other nonstandard therapies have been tried in small case studies: Cyclosporine, colchicine, dapson, IV immunoglobulin (IVIG), plasmapheresis, methotrexate, cyclophosphamide, calcium channel blockers, ephedrine
 - Corticosteroids: Titer to lowest effective dose. Start with standard dose of 0.5–1 mg/kg/day of prednisone; often poorly tolerated secondary to substantial side effects including hypertension, immunosuppression, hyperglycemia, physical changes

**ONGOING CARE****FOLLOW-UP RECOMMENDATIONS****Patient Monitoring**

- Watch for signs and symptoms of anaphylaxis; this is the major complication.
- Patients with chronic urticaria should follow up with their physician on a regular basis to monitor symptoms and response to therapies.

PROGNOSIS

Chronic urticaria:

- Resolution in 50% by 12 months
- Another 20% resolve by 5 years.
- 10–20% >20 years; many of those who continue to have symptoms are felt to have an autoimmune etiology.
- May have recurrences; physical urticaria subtypes are more likely to recur.

COMPLICATIONS

Anaphylaxis with resulting edema of the upper airway is the major life-threatening complication. The patient should seek immediate medical attention.

**CODES****ICD9**

- 708.0 Allergic urticaria
- 708.8 Other specified urticaria
- 708.9 Urticaria, unspecified

ICD10

- L50.0 Allergic urticaria
- L50.8 Other urticaria
- L50.9 Urticaria, unspecified

FAQ

- Q: When should I refer patients to a specialist, and to what specialty should I send them?
- A: Often, referral is made when a trigger cannot be identified, if it is felt to be a food or medication trigger, and/or the symptoms persist for >6 weeks. Refer to a dermatologist or allergist-immunologist experienced in the evaluation and workup of urticaria.
- Q: When should treatment with corticosteroids or other nonstandard therapies be used to treat chronic urticaria?
- A: Typically, these medications carry significant side effects and should be reserved for those patients in whom the urticaria is causing significant alterations in activities of daily living.
- Q: When does a patient need to be hospitalized or observed during an episode of urticaria?
- A: Concerning signs include extensive angioedema, respiratory symptoms such as stridor or wheezing, or nausea/vomiting. Symptoms of anaphylaxis should be treated with epinephrine and the patient observed for several hours to ensure that symptoms do not recur.

VACCINE ADVERSE EVENTS

Kristen Feemster

BASICS

ALERT

Adverse events after immunization may be a true vaccine-associated event or may be a coincidental event that would happen without immunization. Epidemiologic studies are important to establish causation.

DESCRIPTION

- A clinically significant event that occurs after administration of a vaccine and has been causally related to the vaccine
- All suspected adverse events should be reported; however, reporting does not imply causation.
- Contraindication to immunization = condition that increases risk of a serious adverse reaction
- Precaution for immunization = condition that might increase risk of an adverse event or may decrease effectiveness of vaccine to mount an immune response
 - Usually a temporary condition
 - Immunization indicated with a precaution if benefits outweigh risk

EPIDEMIOLOGY

- Adverse events monitored prelicensure to establish safety and postlicensure to identify rare adverse events that would not be detected in prelicensure studies. Reporting is guided by:
 - National Childhood Vaccine Injury Compensation Program:
 - Established by National Childhood Vaccine Injury Act of 1986 to establish a no-fault mechanism to manage claims of vaccine injury outside of the civil law system and provide compensation
 - Petitioners can file claims based on the Vaccine Injury Table (see “Patient Education”) created by the program or can attempt to prove causation for an injury that is not listed.
 - Covers vaccines recommended for routine administration to children
 - Program also mandates reporting of adverse events by health care professionals and creation of vaccine information materials.
 - Vaccine Adverse Event Reporting System (VAERS)
 - Passive surveillance system to monitor all vaccines licensed in the US
 - All reports reviewed by FDA medical officers
 - Can detect possible unrecognized adverse events but limited ability to determine true causal relationships
 - Reporting to VAERS mandated by the National Childhood Vaccine Injury Compensation Program
 - Vaccine Safety Datalink
 - Active surveillance system formed by CDC in partnership with managed care organizations covering 9 million people
 - Can perform better observational studies to help determine causation

- Clinical Immunization Safety Assessment Network (CISA)
 - Network of 6 academic centers established by CDC in 2001 to develop research protocols to diagnose, evaluate, and manage adverse events
 - Develops evidence-based guidelines for immunizing people at risk for serious adverse events after vaccination

Incidence

- Difficult to measure incidence owing to current reporting systems for adverse events
- There are ~30,000 reports each year to VAERS.
 - 13% are considered serious adverse events.
- As of April 2011, there were almost 14,000 claims filed under the National Childhood Vaccine Injury Compensation Act since 1988 and about 2,500 families were compensated.

DIAGNOSIS

- Common mild adverse events after vaccination include:
 - Fever
 - Local erythema, swelling, and/or tenderness
 - Sleepiness and decreased appetite
 - Increased fussiness
 - Mild rash: Occurs in 1 of 25 people up to 1 month after varicella vaccination
- Moderate to serious adverse events to currently recommended vaccines are rare but include:
 - Syncope, particularly among adolescents
 - Febrile seizures (MMR, varicella, and DTaP vaccines)
 - Temporary joint pain or stiffness (MMR)
 - Temporary thrombocytopenia (MMR)
 - High fever
- To minimize the possibility of vaccine adverse events and to maximize the effectiveness of vaccination, the following contraindications and precautions should be followed.

Contraindications

General contraindications for vaccination include:

- History of an **anaphylactic** reaction to a vaccine component:
 - History of egg allergy no longer contraindication to influenza vaccination unless documented history of anaphylactic reaction
- Pregnancy for **live-virus vaccines** unless mother is at high risk for the vaccine-preventable condition
- Primary T-cell immunodeficiencies (i.e., severe combined immunodeficiency):
 - No live vaccines
 - Inactivated vaccines can be safely administered but may not generate an adequate immune response
- Primary B-cell immunodeficiencies:
 - If severe (i.e., X-linked agammaglobulinemia), no live bacterial vaccines, live-attenuated influenza vaccine (LAIV), or yellow fever vaccine
 - Less severe antibody deficiencies can receive live vaccines except for OPV.

- Phagocyte dysfunction:
 - No live bacterial vaccines
 - All live-virus and inactivated vaccines probably safe and effective
- Secondary immunosuppression (transplant, malignancy, autoimmune disease):
 - No live vaccines depending on degree of immunosuppression
 - Can achieve adequate response to vaccination within 3 months to 1 year after stopping immunosuppressive therapy
- HIV/AIDS:
 - Can give MMR and varicella vaccine unless severely immunocompromised
 - No OPV or LAIV
- High-dose corticosteroids > 14 days:
 - No live virus vaccines until therapy discontinued for at least 1 month
- History of Guillain-Barré syndrome:
 - Contraindication for LAIV only
 - A precaution for receipt of MCV4 (conjugate meningococcal vaccine) ONLY if not at high risk for meningococcal disease
- Progressive neurologic disorder (infantile spasms, poorly controlled epilepsy):
 - Contraindication for **DTaP** only
 - Children with stable neurologic conditions can be vaccinated.
- Encephalopathy within 7 days of previous DTP, DTaP, or Tdap dose that is not attributable to another cause
- Hib conjugate vaccine should not be given to infants <6 weeks of age

Precautions

General **precautions** for receiving a vaccine include moderate to severe acute illness with or without fever. Vaccine-specific **precautions** include:

DTaP/DTP

- Fever $\geq 104^{\circ}\text{F}$ or shocklike state within 48 hours of previous DTaP/DTP dose
- Persistent, inconsolable crying >3 hours within 48 hours of previous DTaP/DTP dose
- Seizure within 3 days of previous DTaP/DTP dose
- **Tdap:**
 - Progressive or unstable neurologic disorder
 - History of Arthus hypersensitivity reaction after previous tetanus toxoid-containing dose
 - Wait 10 years between doses of tetanus toxoid-containing vaccines.
- Any **tetanus toxoid-containing vaccine:**
 - Guillain-Barré within 6 weeks of a previous tetanus toxoid-containing vaccine dose
- **Hepatitis B:**
 - Infants $<2,000$ g in weight
- **Hepatitis A, IPV, and HPV vaccines:**
 - Pregnancy
- **Varicella:**
 - Receipt of antibody-containing blood product within past 11 months
 - Immunocompromised household contacts are not a contraindication or precaution but if rash develops 7–25 days after vaccination, should avoid direct contact with immunocompromised individual

- **MMR:**
 - Receipt of antibody-containing blood product within past 11 months
 - History of thrombocytopenic purpura
- **Rotavirus:**
 - Immunosuppression
 - Receipt of antibody-containing blood product within 6 weeks
 - Moderate to severe gastroenteritis
 - Previous history intussusceptions
- The following are NOT precautions or contraindications to the receipt of any vaccine:
 - Mild or recent illness
 - History of a mild to moderate local reaction to vaccine in the past
 - Concurrent antimicrobial therapy
 - Breastfeeding
 - History of other nonvaccine allergies
 - Stable neurologic conditions (e.g., cerebral palsy, developmental delay)

DIFFERENTIAL DIAGNOSIS

- Allergic reaction to an unrelated exposure
- Intercurrent illness

 **ONGOING CARE**

Approach to the Patient

- Before vaccination:
 - Discuss benefits and review potential adverse events so that families know what to expect.
 - Actively review Vaccine Information Sheets.
 - Solicit concerns so that they can be addressed.
- If a patient presents with a potential adverse event:
 - Take thorough history and perform exam to characterize symptoms and determine timing of symptom onset.
 - Evaluate for other potential causes of symptoms.
 - Determine likelihood of causality.
 - Report all adverse events to VAERS.
 - If the family would like to file a claim, refer to National Childhood Vaccine Injury Compensation Program.

MANAGEMENT

- **Addressing safety concerns:**
 - Despite increasing vaccine safety concerns, health care professionals are one of the most trusted sources of information regarding vaccines.
 - Actively review the required Vaccine Information Sheets with parents.
 - Emphasize benefits of vaccination and review potential consequences of not accepting vaccination.
 - Actively solicit concerns before vaccination.
 - If parents have specific concerns, refer to additional information sources such as the Vaccine Education Center at the Children’s Hospital of Philadelphia or the “Parents Guide to Immunization” from the Centers for Disease Control and Prevention (see additional references in the “Patient Education” section)
 - Document vaccine discussions.

• **Reporting adverse events:**

- VAERS is the primary reporting site for suspected adverse events. Health care providers, vaccine recipients, or parents of vaccine recipients and vaccine manufacturers can all report. However, health care providers are required to report:
 - Any adverse event listed by vaccine manufacturer as a contraindication for the receipt of additional doses of the vaccine
 - Any adverse event included on the VAERS table of reportable events that occurred within the specified time period
- Health care providers, parents, and/or individuals who suspect a vaccine-related adverse event can report to VAERS.
- **Vaccine Injury Compensation Program:**
 - Covers all vaccines recommended for routine administration by the Advisory Commission of Immunization Practices
 - To qualify for compensation, must prove there was an injury listed in the Vaccine Injury Table that occurred within prescribed time period, prove that a vaccine caused an injury not listed on the table, or prove that a vaccine aggravated a preexisting condition
 - Effects of injury must last >6 months after vaccination and have resulted in hospitalization, surgery, or death.

- T88.8XXA Other specified complications of surgical and medical care, not elsewhere classified, initial encounter

FAQ

- Q: Many parents request spacing vaccines. Is there evidence that giving multiple vaccines at a time is too much for a child’s immune system?
- A: Recommended vaccines have a very small amount of antigen compared to natural infection and they activate a small proportion of immune system memory. Additionally, all vaccines given together have been tested when given at the same time to make sure they remain safe and effective.
- Q: What is the bottom line regarding autism and vaccines?
- A: Multiple studies including a recent Institute of Medicine report have not shown any causal relationship between thimerosal-containing vaccines and autism or MMR and autism. Additionally, the US court system through the Omnibus Autism Proceedings has recently ruled that there is insufficient evidence to show any causal relationship between thimerosal-containing vaccines or MMR and autism.

VAGINITIS

Marianne Ruby
Gary A. Emmett

BASICS

DESCRIPTION

- Vaginitis is an inflammatory process of the vagina often caused by infection, but also caused by foreign bodies and other irritants.
- Vulvovaginitis is inflammation of the vulva and vagina; it is more common in prepubertal girls.
- Bacterial vaginosis is an overgrowth of vaginal flora, primarily anaerobic, associated with an elevation in vaginal pH, a malodorous discharge, and often a sensation of burning. This condition has been referred to as gardnerella, haemophilus, and nonspecific vaginitis.
- Vaginal discharge is a vaginal secretion that may or may not be associated with inflammation or infection.

ALERT

Any infection that raises suspicion of sexual abuse must be reported to the local authorities immediately.

EPIDEMIOLOGY

- Candidiasis may present cyclically with menses, possibly owing to changing estrogen levels.
- Gonorrhea is more likely to be symptomatic at the time of menses owing to easier access to the upper reproductive tract.
- Body mass index (BMI) at the extremes is associated with increased risk of vulvovaginitis.
- The epidemiology of bacterial vaginosis is not well known because it is not a reportable disease, and 50% of cases may be asymptomatic.

PATHOPHYSIOLOGY

- Physiologic leukorrhea is a normally occurring vaginal discharge that is clear or white, nonpruritic, nonirritating, and rarely malodorous:
 - The amount of discharge markedly varies from individual to individual and may be profuse.
 - In menstruating girls, as a result of varying estrogen levels, the volume of discharge varies with the menstrual cycle and is especially heavy at the time of ovulation.
- Candidiasis occurs more commonly when the glycogen level in the vaginal mucosa is increased, as in pregnancy and diabetes:
 - Use of antibiotics also increases the occurrence of candidiasis by eliminating competitive organisms.
- For bacterial vaginosis, the inciting cause is not known, but the etiologic cascade involves a decline in levels of lactobacillus, leading to an increased pH and increased overgrowth of normal bacterial flora. The change in the vaginal environment decreases the normal defenses against pathogens.
- The normal trauma of sexual intercourse may increase the likelihood of vaginitis by causing microscopic breakdown of the mucosal surface.
- During toileting, wiping from the anus toward the vagina may introduce bacteria not normal to the vagina and induce a vaginitis.

ETIOLOGY

- All ages:
 - Chemical irritants such as soaps, bubble baths, detergents, and fabric softeners
 - Allergic reactions
 - Foreign material, such as paper products, sand, soil, and small objects
 - *Candida albicans*, especially if exposed to antibiotics
 - Trauma from repeated rubbing, such as with masturbation
 - Sexual abuse
- Prepubertal females:
 - Diapers and nonbreathable clothing
 - Coliform bacteria from the child's toileting practices
 - β -Hemolytic group A streptococcus
 - Infestations, including pinworms and scabies
- Postpubertal females:
 - Noninflammatory, physiologic leukorrhea
 - Bacterial vaginosis
 - Trichomonas
 - *Chlamydia trachomatis*
 - Gonorrhea
 - Herpes simplex virus, types I and II
 - Human papilloma virus (HPV)
 - Chancroid
 - Lymphogranuloma venereum (LGV)
 - Behçet disease
 - Epstein-Barr virus

DIAGNOSIS

HISTORY

- Presence, color, odor, and duration of discharge
- Child is itchy or having a burning sensation or dysuria:
 - Itching and burning may be signs of vaginal inflammation.
 - Dysuria raises the suspicion for a urinary tract infection, but burning at the start of micturition (urination) may be seen with vulvovaginal inflammation.
- Conditions that make symptoms better or worse: Inflammation may be related to specific clothing, especially tight pants. Nighttime itching/discomfort may signal pinworm infestation.
- Treatment that has worked in the past may work again:
 - The success or failure of over-the-counter products may affect the treatment choices.
 - Over-the-counter treatment may affect culture results for candida.
- Any other recent health problems: Recent respiratory or gastrointestinal distress increases the risk for group A streptococcal infection.
- Any new medication, especially an antibiotic, introduced around the time of symptom onset:
 - Antibiotics increase the risk for candidal vaginitis.

- STIs should be considered if there is known sexual activity and should be considered even when sexual activity is denied.
- If appropriate, character and timing of the last menses: Gonorrhea is associated with increased symptoms at the time of menses. Some girls may have cyclic yeast infections associated with menses.
- Any new chemical exposures such as soaps, spermicides, or feminine hygiene products: Vaginitis often follows vaginal exposure to cleaning and other chemical agents.
- Any chronic illnesses such as diabetes, inflammatory bowel disease, or immunocompromised conditions: Vaginitis is much more common in these situations.
- Previously similar symptoms: Some people have a tendency toward repeated vaginal inflammation, especially candidiasis.

PHYSICAL EXAM

- Vital signs including height, weight, and temperature
- Calculate the BMI.
- Tanner pubertal development scores
- Examine the entire skin for other lesions or dermatoses.
- Abdominal examination to assess for abdominal pain and masses
- Evaluate external genitalia for tenderness, erythema, discharge, ulceration, edema, excoriation, traumatic injuries, warts (HPV), lymphadenopathy, and pigmentary changes.
- Evaluate vagina for findings above, if possible.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

The following common gynecologic tests may help with differentiating normal physiologic leukorrhea from 3 common etiologies:

- Odor/"whiff" or "amine" test: Prepared with 10% KOH
- Wet mount of the vaginal discharge is mixed with saline for microscopic evaluation (see "Physical Exam").
- Nitrazine paper measures pH with lateral vaginal wall specimen.
- Chlamydial polymerase chain reaction (PCR) assay should be performed on all sexually active patients.
- Gonorrhea PCR or culture from cervical specimen
- Culture for fungi (yeast)
- Pap test starting at age 18 years with history of sexual activity

DIFFERENTIAL DIAGNOSIS

- Bacterial vaginosis
- Chlamydia
- Gonorrhea
- Trichomonas

- Candidiasis
- Herpes simplex virus infection
- HPV
- Physiologic leukorrhea
- Psoriasis
- Lichen sclerosus (hypotrophic dystrophy of the vulva)
- Congenital abnormalities, such as ectopic ureter
- Sexual abuse

TREATMENT

MEDICATION (DRUGS)

- Topical steroids:
 - Lichen sclerosus requires very-high-potency topical steroids for amelioration. Apply to vulva twice daily for 2–4 weeks. Overuse may lead to thinning of the skin. Steroids can also promote the growth of yeast.
 - In moderate inflammation of the vulva caused by irritants, apply low-potency steroids lightly to vulva twice daily for 5–14 days, until symptoms have subsided for 2 days. Extreme overuse may also lead to skin thinning.
- Antifungal agents—including topical butoconazole, miconazole, and terconazole—applied as directed will relieve vaginal candidiasis; as an alternative, oral fluconazole 6 mg/kg in 1 dose to maximum dose of 150 mg may be effective.
- Antibiotics are used in many causes of vaginal infection:
 - Bacterial vaginosis is treated in older children with metronidazole 500 mg PO twice daily for 7 days or topically with metronidazole gel or clindamycin cream or suppository.
 - In infections with coliform bacteria, treat with amoxicillin at 40 mg/kg/d to maximum of 500 mg twice daily; β -hemolytic group A streptococcus will usually respond to the same dosage of amoxicillin.
 - In patients with penicillin allergy, trimethoprim/sulfa, azithromycin, or ciprofloxacin (in older children) is appropriate in either type of bacterial infection.
 - Chlamydia is treated with either azithromycin 1,000 mg PO in a single dose or doxycycline 100 mg PO twice daily for 7 days.
 - Uncomplicated gonorrhea is treated with ceftriaxone 250 mg IM once or azithromycin 1,000 mg PO or cefixime 400 mg PO once. Treat for chlamydia simultaneously unless the child is known not to have chlamydia.
 - Trichomonas responds to metronidazole 2 g in a single dose.
- Other anti-infective agents used in vaginitis include the following:
 - Herpes simplex virus is treated with famciclovir 250 mg 3 times daily for 7–10 days, with valacyclovir 1 g PO twice daily for 7–10 days, or with acyclovir 400 mg 3 times daily for 7–10 days. In recurring herpes simplex virus, prolonged use of these agents may be useful.
- In pinworms, mebendazole 100 mg is taken once by mouth. May be recommended for entire family, but is not used in pregnancy

ADDITIONAL TREATMENT

General Measures

- Removal of irritant/foreign body: In vaginitis caused by chemical irritants or foreign materials, the practitioner should attempt to identify and remove the cause. On occasion, especially in younger children, intravaginal foreign bodies may have to be removed under anesthesia.
- Promoting good hygiene: Girls should be educated in good toilet hygiene and proper front-to-back wiping.
- Sitz baths: Local treatment should include sitz baths (sitting in plain warm water) followed by air drying of the vulvar area, use of topical emollients (Vaseline or Aquaphor), and topical low-potency steroids (short course) to control inflammation and/or itching.
- Trauma from repeated rubbing or other causes is treated in the same manner.
- Congenital abnormalities, such as ectopic ureter, will respond to the above regimen but will eventually need definitive surgical treatment.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Follow-up appointment or phone call should be arranged 1 week following the initial diagnosis.
- To prevent recurrence in younger children, avoid irritants such as bubble bath, encourage proper wiping technique, and avoid unnecessary antibiotics.
- In sexually active adolescents, consistent use of condoms should be stressed to prevent the spread of STIs.

ALERT

- Antibiotic use may result in the development of candidiasis.
- Caution with over-the-telephone therapy of vaginal pruritus as candidiasis may be incorrect. If a patient using an antifungal is not better in 5 days, she must see the practitioner.

PROGNOSIS

When treated, patients with vaginitis, vulvovaginitis, and bacterial vaginosis generally do well.

COMPLICATIONS

- Pelvic inflammatory disease (PID)
- Scarring in the female reproductive tract
- Pelvic pain syndrome and infertility
- Untreated bacterial vaginosis has been associated with premature labor, premature rupture of membranes, and increased risk of acquiring STIs.

CODES

ICD9

- 041.9 Bacterial infection, unspecified, in conditions classified elsewhere and of unspecified site
- 616.10 Vaginitis and vulvovaginitis, unspecified

ICD10

- N76.0 Acute vaginitis
- N76.1 Subacute and chronic vaginitis

FAQ

- Q: Is the presence of gardnerella on vaginal culture sufficient to diagnose bacterial vaginosis?
- A: No. The diagnosis of bacterial vaginosis requires 3 of the following criteria: Elevated pH, fishy odor, clue cells on a wet mount, vaginal discharge, and/or a positive Gram stain.
- Q: Can vaginitis be confused with a urinary tract infection?
- A: Yes. Prominent vulvar and vestibular inflammation would strongly suggest a vulvovaginal source.
- Q: Can girls be asymptomatic for herpes simplex virus and HPV infections?
- A: Yes. Sexually active girls may carry these diseases without symptoms.

VASCULAR BRAIN LESIONS (CONGENITAL)

Sabrina E. Smith

Dennis J. Dlugos

BASICS

DESCRIPTION

- Developmental venous anomalies (DVAs) are the most common vascular malformation of the brain, representing 60% of all central nervous system vascular malformations. Also known as venous angiomas, DVAs are made up of a cluster of venous radicles that drain into a collecting vein. They occur in 2.5–3% of the general population.
- DVAs are associated with cavernous malformations (see below) in 8–40% of cases, and 20% of patients with mucocutaneous venous malformations of the head and neck have DVAs. They are also associated with sinus pericranii, a communication between intracranial and extracranial venous drainage pathways in which blood may circulate bidirectionally.
- Cavernous malformations (CMs), also known as cavernous hemangiomas or cavernomas, are multilobulated, low-pressure and slow-flow vascular structures filled with blood, thrombus, or both. They do not contain elastin or smooth muscle. There is no intervening brain tissue except at the periphery of the lesion.
- Arteriovenous malformations (AVMs) are abnormal clusters of vessels that connect arteries and veins without a true capillary bed and have intervening gliotic brain tissue.
- Vein of Galen malformations (VOGMs) are a specific type of congenital arteriovenous malformation that involve the vein of Galen, which flows into the straight sinus after draining the internal cerebral veins and basal veins.
- Sturge–Weber syndrome (SWS), also known as encephalotrigeminal angiomatosis, is characterized by leptomeningeal angiomas, facial port wine stain (capillary malformation), and glaucoma. Some patients have all 3 findings, though others have just 1 or 2 features.

PATHOPHYSIOLOGY

- DVAs are an extreme variation of normal venous development. Typically, venous drainage in the brain occurs through a superficial system and a deep system. DVAs result when a deep venous territory drains toward the surface, or when a superficial territory drains to the deep venous system instead of draining in the expected direction. Intervening brain tissue is normal. The mechanism responsible for DVA formation is unknown.
- The pathogenesis of CMs is unknown, though the report of cases of new cavernoma development adjacent to a DVA suggests that DVAs may lead to CM formation. Most CMs occur sporadically, though familial syndromes exist. Several genes have been associated with familial CMs.

- The cause of AVM formation is unknown. A failure of normal capillary development with dysplastic vessels forming between primordial arteriovenous connections has been suggested.
- VOGMs are embryonic arteriovenous malformations consisting of choroidal arteries draining into the precursor of the vein of Galen. They develop between weeks 6 and 11 of fetal life.
- SWS occurs sporadically in 1/40,000–50,000 births, and no gene defect had been identified. The pathophysiology is thought to be venous dysplasia, in which the primordial venous plexus that is normally present at 5–8 weeks of gestation fails to regress. The location of this plexus around the cephalic end of the neural tube and under the ectoderm destined to form the facial skin accounts for the clinical features. Venous stasis occurs due to the absence of normal cortical venous structures, and hypoperfusion of brain tissue occurs. These findings are unilateral in the majority but can be bilateral in up to 20% of cases.

DIAGNOSIS

HISTORY

- DVAs are usually benign and asymptomatic, coming to clinical attention as an incidental finding on a neuroimaging study.
- Headache, seizure, and intracerebral hemorrhage are common in patients with CMs and AVMs. Focal neurologic deficits may result from intracerebral hemorrhage or compression of underlying brain structures by the vascular malformation.
- 95% of newborns with VOGMs present in CHF. Others present with hydrocephalus, subarachnoid hemorrhage, intraventricular hemorrhage, or failure to thrive.
- Infants and older children usually present with hydrocephalus, headache, seizures, exercise-induced syncope, or subarachnoid hemorrhage.
- Facial port wine stain, seizures and glaucoma are common in SWS. Other neurologic symptoms include hemiparesis, developmental delay, mental retardation, and stroke-like episodes presenting with hemiparesis and visual field defects.

PHYSICAL EXAM

- Physical exam is normal in children with DVAs and children with CMs or AVMs that have not ruptured. Focal neurologic deficits may persist following intracerebral hemorrhage associated with CMs or AVMs.

- In newborns with VOGMs, signs of congestive heart failure such as tachycardia, respiratory distress and hepatomegaly may occur. A continuous cranial bruit heard may be heard over the posterior skull, and bounding carotid pulses and peripheral pulses may be present. Scalp veins may be dilated.
- Older infants and children with VOGMs also may present with CHF, but more often demonstrate increased head circumference, focal neurologic signs, and failure to thrive. Proptosis may be noted.
- Children with SWS often have a facial port wine stain, most often in the V1 distribution. Glaucoma is also common. Hemiparesis or seizures may develop.

DIAGNOSTIC TESTS & INTERPRETATION

Routine blood studies are usually normal. Chest x-ray studies and electrocardiogram may reveal typical changes of high-output CHF in patients with VOGMs.

Imaging

- Neuroimaging studies are required for definitive diagnosis.
- DVAs can be visualized on contrast-enhanced CT or MRI. Diagnosis is made by visualization of the typical “caput medusa” appearance of the radially arranged veins draining into a collecting vein, seen as a linear or curvilinear focus of enhancement. They can also be visualized with conventional angiography, though this is not required unless a patient presents with an acute hemorrhage.
- MRI is better than CT at demonstrating CMs, which have a mulberry appearance. On MRI they are well-circumscribed lesions of mixed signal intensity on T1 and T2-weighted sequences. Contrast enhancement is variable. They are best seen on gradient-echo-T2-weighted images or susceptibility-weighted images, which are sensitive to hemosiderin or deoxyhemoglobin.
- AVMs can be seen with CT/CTA, MR/MRA and conventional angiography. Dynamic sequences are required to characterize the anatomy of feeding and draining vessels. Conventional angiography is the gold standard.
- VOGMs can be diagnosed on fetal ultrasound or MRI. In newborns cranial ultrasound shows a large, hypoechoic structure in the region of the vein of Galen. CT shows a high-density mass that enhances with contrast. MRI shows an area of decreased signal intensity or signal void because of high flow within the malformation. CT and MRI also show areas of cerebral ischemia or hemorrhage. Conventional angiography is required before intervention.
- In SWS, CT may show calcifications or atrophy. Gadolinium-enhanced MRI is the most sensitive study, showing leptomeningeal enhancement due to pial angiomas. Initial CT and MRI are often normal in the newborn period, so follow-up imaging is required.

DIFFERENTIAL DIAGNOSIS

- The differential diagnosis for headaches and seizures, common presenting symptoms of brain vascular malformations, is broad. CNS infection, vascular malformation, hydrocephalus and mass lesion can result in both. Other causes of seizure include dysplasia, remote brain injury, genetic and idiopathic. Other causes of headache include benign conditions such as migraine and tension headaches and structural abnormalities such as Chiari I malformations.
- VOGMs must be considered in any newborn with unexplained CHF (especially high-output failure), hydrocephalus, or intracranial hemorrhage. Other causes of high-output CHF in the newborn include anemia, hyperthyroidism, and other arteriovenous malformations.
- Intracranial hemorrhage may result from AVMs, CMs, aneurysms, bleeding diatheses, hypertension, or trauma in neonates and children. In older children, sickle cell disease, vasculopathies including moyamoya syndrome, and vasculitis can also lead to hemorrhage.

TREATMENT

ADDITIONAL TREATMENT

General Measures

- DVAs do not typically require treatment.
- Anticonvulsants should be used to treat seizures.
- Surgical resection is the only treatment option for CMs, though conservative management may be indicated if the risk of surgery outweighs the potential benefit.
- Treatment options for AVMs include resection via microsurgery, embolization, stereotactic radiosurgery and conservative management. Risk of hemorrhage ranges 0.9–34% per year, so decisions about treatment should be guided by symptoms at presentation and structural features of the AVM.
- Treatment of choice for VOGMs in all ages is endovascular embolization. Direct surgical intervention has unacceptable risks and is no longer recommended. Radiosurgery has been used in a small number of clinically stable older patients. Refractory CHF prompts intervention in neonates. Treatment in older infants and children is indicated to prevent cerebral ischemia (from arterial steal or from venous infarction) and to prevent hydrocephalus. Embolization can be completed in stages over a few months after CHF is controlled.
- Ventriculoperitoneal shunts may be required in patients who develop hydrocephalus following intracerebral hemorrhage related to CM or AVM, or in patients with VOGMs.

- Treatment in SWS is targeted to symptoms, using anticonvulsants for seizures and eye drops or ocular shunts for glaucoma. Low-dose aspirin is recommended at the time of diagnosis to prevent further brain injury due to impaired cerebral blood flow. Seizures can lead to ongoing brain injury by increasing metabolic demand in brain tissue that has abnormal perfusion at baseline, so aggressive seizure management is recommended. Some children with intractable epilepsy may be good candidates for epilepsy surgery.

ONGOING CARE

- Generally, no specific follow-up is required for patients with DVAs.
- Follow-up with a neurologist is indicated for patients with CMs, AVMs, VOGMs, and SWS.
- Neurosurgical consultation is indicated for patients with CMs, AVMs, VOGMs.
- A follow-up CT or MRI is indicated to evaluate patients with new neurologic signs or symptoms.
- Ophthalmologic follow-up is indicated for patients with SWS and most patients with VOGMs, especially prior to treatment when hydrocephalus may develop.

PROGNOSIS

- Prognosis is excellent for patients with isolated DVAs.
- Prognosis for patients with CMs and AVMs depends on the size, location, presenting symptoms, and specific characteristics of the lesion. Patients who have experienced an intracerebral hemorrhage have worse prognosis than those who have not.
- For patients with VOGMs, earlier age of symptoms is associated with worse prognosis. Mortality in neonates with symptomatic lesions is 36%. In a recent meta-analysis of 337 patients treated with endovascular embolization between 2001 and 2010, 84% had a good or fair clinical outcome, and mortality was 16%.
- Prognosis in patients with SWS depends on the extent and location of involvement. Seizures occur in the majority (~85%) with low-normal intelligence or mental retardation in ~35%.

COMPLICATIONS

- Death can occur in patients with intracerebral hemorrhage due to CMs or AVMs.
- Mortality approaches 100% in untreated patients with VOGMs.
- In severe case of VOGMs, 80% of cardiac output may be delivered to the head because of the low vascular resistance within the malformation. Cardiac ischemia may occur because of decreased coronary artery blood flow.
- Intracerebral hemorrhage may occur as a result of CMs, AVMs, and VOGMs or as a complication of treatment.

- Longer-term complications from CMs, AVMs, and VOGMs include mental retardation, seizures, hydrocephalus, and chronic motor impairment.
- In patients with SWS, visual impairment can result if glaucoma is difficult to control. Persistent hemiparesis can develop.

PATIENT MONITORING

- Serial neuroimaging should be performed in patients with CMs, AVMs, and VOGMs to guide the timing of treatment and to assess for recurrence.
- Head circumference should be monitored in patients with VOGMs as a marker of hydrocephalus.

CODES

ICD9

- 747.81 Anomalies of cerebrovascular system
- 759.6 Other hamartoses, not elsewhere classified

ICD10

- Q28.3 Other malformations of cerebral vessels
- Q85.8 Other phakomatoses, not elsewhere classified

FAQ

- Q: Can the AVM recur after treatment?
- A: Arteriovenous malformations have a propensity to recur. Imaging studies give a good indication of the likelihood of recurrence.
- Q: How does a vascular malformation cause seizures?
- A: Seizures can result from ischemia, hemorrhage, or acute hydrocephalus associated with the malformation.

VENTRICULAR SEPTAL DEFECT

Ronn E. Tanel

Stanford Ewing (5th edition)

BASICS

DESCRIPTION

- A ventricular septal defect (VSD) is an opening in the ventricular septum, resulting in a communication between the left ventricle (LV) and the right ventricle (RV). The ventricular septum can be divided into 4 major areas:
 - Inlet/canal septum
 - Membranous/conoventricular septum
 - Muscular septum (largest)
 - Conal/infundibular/outlet septum (includes conal septal hypoplasia and malalignment types)
- There are several corresponding types of VSDs that have different natural histories and associated problems:
 - Inlet VSDs: Usually part of an atrioventricular (AV) canal defect, 5–7% of all VSDs
 - Membranous/conoventricular VSDs: 80% of all VSDs by classic teaching; fewer than muscular VSDs by echo data
 - Muscular VSDs: Usually single and small but can be multiple and of variable size; 5–20% of all VSDs by classic teaching, but 90% are inaudible
 - Conal septal hypoplasia VSDs: Usually large and unrestrictive; associated with aortic valve (AoV) cusp prolapse and aortic insufficiency
 - Anterior malalignment VSDs: Usually associated with RV outflow tract obstruction. Paradigms: Tetralogy of Fallot, double outlet RV
 - Posterior malalignment VSDs: Usually associated with LV outflow tract obstruction. Paradigms: Subaortic stenosis with coarctation or interrupted aortic arch
- There may also be multiple VSDs of different types in a single patient. Many complex forms of congenital heart disease include a VSD.

EPIDEMIOLOGY

Incidence

VSDs are the most common form of congenital heart disease, occurring in ~1.5–5.7 per 1,000 term births and ~4.5–7.0 per 1,000 preterm births, by classic teaching. Echo data show a high incidence of asymptomatic muscular VSDs, occurring in ~53 per 1,000 live births.

RISK FACTORS

Genetics

3% of children with VSDs have a parent with a VSD. VSD is the most common lesion in trisomies 21, 13, and 18, but >95% of children with VSDs have normal chromosomes. Congenital heart disease that includes a conal septal malalignment VSD (e.g., tetralogy of Fallot) or VSD with a conal truncal malformation (e.g., truncus arteriosus or interrupted aortic arch type B) have an 8–50% incidence of microdeletion of chromosome 22.

PATHOPHYSIOLOGY

- Both the size of the VSD and the ratio of pulmonary (PVR) to systemic vascular resistance (SVR) determine the direction and amount of shunting.
 - Small VSD: The VSD imposes high resistance to flow with a large LV-to-RV pressure gradient, usually resulting in normal RV pressures. The restrictive size results in a small left-to-right shunt. The VSD size is usually $\leq 1/4$ the size of the AoV annulus. The workload of the ventricles is normal.
 - Moderate VSD: The VSD imposes modest resistance to flow, usually resulting in mildly elevated RV pressures. The amount of shunting can still be large and is determined by the PVR/SVR ratio. The VSD size is usually $1/3$ – $2/3$ the size of the AoV annulus. The workload of the ventricles is increased.
 - Large VSD: The VSD imposes no resistance to flow and is unrestrictive, resulting in systemic RV pressures and RV hypertension. The workload of the ventricles is markedly increased.
- The lower the PVR/SVR ratio, the greater the degree of left-to-right shunting. A large left-to-right shunt leads to pulmonary vascular congestion, tachypnea, tachycardia, and hepatomegaly, all signs of congestive heart failure (CHF). The amount of CHF correlates directly with shunt size, and usually peaks at 6–8 weeks of age, timed with the nadir of physiologic anemia. Lack of significant CHF in patients with a large VSD signifies elevated PVR and requires careful evaluation. Cardiac catheterization may be required in these patients to provide additional data.
- If a large VSD is left untreated, pulmonary vascular obstructive disease will eventually develop, leading to reversal of the shunt, cyanosis, and RV failure (Eisenmenger syndrome).

DIAGNOSIS

HISTORY

- Small VSD: The child is usually asymptomatic, with normal growth and development. Most commonly, a murmur is detected at 1–6 weeks of age.
- Moderate VSD: The child is usually symptomatic with slow weight gain and sparing of longitudinal growth. There is often an increased incidence of respiratory infections. Sweating and fatigue with feeding may be present.
- Large VSD: The child is usually quite symptomatic, especially with a larger shunt, showing signs of CHF and marked failure to thrive.
- Children with Eisenmenger syndrome have cyanosis, fatigue, and symptoms of right heart failure.

PHYSICAL EXAM

- Small VSD:
 - The child usually appears healthy with normal growth.
 - The heart action is quiet but there is often an associated systolic thrill along the left sternal border with a membranous VSD, in contrast to a small muscular VSD.
 - Heart sounds are normal. A high-frequency, pansystolic murmur is present in membranous VSDs, whereas in muscular VSDs the murmur is not pansystolic.
 - The murmur is loudest over the region of the VSD.
- Moderate VSD:
 - The child usually appears in mild distress with tachycardia and tachypnea.
 - The heart action is increased and there is often still an associated thrill.
 - The P2 component of S2 may be normal or accentuated.
 - A medium frequency, pansystolic murmur is present over the location of the VSD.
 - A mid-diastolic rumble is present over the mitral listening area (apex), as a result of a significant shunt and indicates $\geq 2:1$ pulmonary to systemic flow ratio. Hepatomegaly may be present.
- Large VSD:
 - The child usually appears ill with marked distress and marked tachycardia and tachypnea, proportional to the size of the left-to-right shunt.
 - The heart action is markedly increased without a thrill. The P2 component of S2 is loud and narrowly split as a result of pulmonary hypertension.
 - A soft, low-frequency pansystolic murmur is present over the VSD.
 - The loudness of the mid-diastolic rumble is proportional to the size of the left-to-right shunt.
 - CHF physical exam signs are proportional to the size of the left-to-right shunt, but are usually present to a significant degree.
- If significant aortic insufficiency develops, a high-frequency, early diastolic murmur is heard along the left sternal border.
- In newborns whose PVR has not yet fallen, the increased heart action remains the key to diagnosis as auscultation may be unimpressive.
- Likewise, in children with elevated PVR, the increased heart action remains the key to diagnosis. Auscultation shows a narrowly split S2 with a loud P2. The murmur loudness is dependent on VSD size and shunt, but often is soft or absent and unimpressive.

- Once Eisenmenger syndrome develops (secondary to pulmonary vascular obstructive changes), patients manifest cyanosis, clubbing, an increased RV impulse, a narrowly split S2 with a loud P2 component and a soft or absent VSD murmur. There may be a systolic murmur of tricuspid insufficiency at the left lower sternal border (LLSB), a high-frequency early diastolic murmur of pulmonary insufficiency, or an S3 at the LLSB. There is usually associated jugular venous distention and hepatomegaly, indicating high right-sided filling pressures.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- ECG:
 - Small VSD: Normal
 - Moderate VSD: Left ventricular hypertrophy (LVH)
 - Large VSD: Biventricular hypertrophy (BVH) and left atrial enlargement (LAE)
 - Eisenmenger syndrome: Right ventricular hypertrophy (RVH) and right atrial enlargement (RAE)
- Cardiac catheterization:
 - Generally reserved for patients with difficult VSD anatomy, associated lesions, or for the assessment of pulmonary vascular reactivity

Imaging

- Chest radiograph:
 - Small VSD: Normal
 - Moderate VSD: Hyperinflation, cardiomegaly, increased pulmonary vascular markings
 - Large VSD: Cardiomegaly, markedly increased pulmonary vascular markings, Kerley B lines
 - Eisenmenger syndrome: Normal heart size, prominent central pulmonary arteries, and decreased peripheral vascular markings
- Echocardiogram:
 - All children with a murmur consistent with a VSD should undergo echocardiogram to define the location, size, and number of VSDs and any associated defects. Color/spectral Doppler allows visualization of the shunt direction and the amount of restriction to the VSD, if any.

TREATMENT

ADDITIONAL TREATMENT

General Measures

- Small VSD: No intervention; observation and subacute bacterial endocarditis (SBE) prophylaxis for indicated procedures
- Moderate VSD: If signs of CHF develop, digoxin, diuretics, afterload reduction, and increased caloric intake are indicated.
- Large VSD: CHF often develops and requires aggressive therapy as noted above.
- Membranous and muscular VSDs often become smaller or close spontaneously. Generally, observation and/or medical therapy is indicated for a few months.

- Conoseptal hypoplasia and malalignment VSDs do not close spontaneously and therefore require surgical closure, often in infancy.
- After 1 year of life, a significant left-to-right shunt (Qp:Qs \geq 2:1) or elevated pulmonary artery pressures are an indication for surgery.
- Children with elevated pulmonary artery pressures (\geq 1/2 systemic) should undergo repair before 2 years of age, even if CHF symptoms are controlled.
- Development of complications, including aortic insufficiency, subaortic membrane, and double-chamber RV, is usually an indication for surgical repair.
- Surgical correction may be contraindicated if the PVR is $>$ 8 Wood units/m².
- Recent series of surgical VSD closure report a mortality of 0.6–2.3%.
- Complete heart block occurs in $<$ 2% of patients postoperatively, but requires pacemaker therapy when it occurs.

ONGOING CARE

PROGNOSIS

- Spontaneous closure: Usually by age 2 years; 90% of small muscular VSDs and 8–35% of small conoventricular VSDs
- Prognosis with surgical closure is excellent.
- The risk of Eisenmenger syndrome is considered minimal if large VSDs are surgically closed by 2 years of age.
- Caveat: Despite timely VSD surgical closure, a tiny percentage of patients still go on to develop Eisenmenger syndrome.

COMPLICATIONS

- All VSDs: Endocarditis—overall rate of 15 cases per 10,000 person-years of follow-up
- Moderate-to-large VSDs: LV volume overload, left atrial hypertension, CHF, poor growth, Eisenmenger syndrome
- Specific types:
 - Inlet VSDs: Often associated with cleft mitral valve with significant AV valve insufficiency
 - Membranous/conoventricular VSDs: Risk for development of aortic insufficiency, subaortic membrane, or double-chamber RV
 - Muscular VSDs: Isolated—near-zero risk for the development of subsequent lesions
 - Conal septal hypoplasia VSDs: Risk for development of aortic insufficiency
 - Malalignment VSDs: Usually associated with outflow tract obstruction and distal great artery hypoplasia/obstruction

PATIENT MONITORING

SBE prophylaxis is recommended for 6 months after complete closure (spontaneous or surgical) of a VSD.

Q21.0 Ventricular septal defect

FAQ

- Q: Should children with a murmur consistent with a VSD undergo echocardiogram?
- A: Yes, to define the location, size, and number of VSDs, and any associated lesions.
- Q: Should children with VSD have SBE prophylaxis?
- A: Based on the revised 2007 American Heart Association Guidelines, isolated VSD does not warrant SBE prophylaxis. However, SBE prophylaxis is recommended for 6 months following complete surgical or interventional catheterization closure (no residual defect) of a VSD.
- Q: Should asymptomatic children with a small VSD have activity restrictions?
- A: No, if there are no other problems

VENTRICULAR TACHYCARDIA

Arvind Hoskoppal

Jonathan R. Kaltman (5th edition)

BASICS

DESCRIPTION

- Ventricular tachycardia (VT) is a series of 3 or more repetitive beats originating from the ventricle at a rate faster than the upper limit of normal for age. It usually is a wide complex rhythm, but can appear narrow in infants. VT may, but not always, have atrioventricular (AV) dissociation.
- Sustained ventricular tachycardia: Lasts >30 seconds
- Nonsustained ventricular tachycardia: Lasts from 3 beats–30 seconds
- May be monomorphic or polymorphic
- Torsades de pointes: Associated with congenital long QT syndrome, acquired long QT, and Brugada syndrome; the QRS complexes gradually change shape and axis throughout the tachycardia. VT may present at any age.
- Premature ventricular contractions (PVCs) have been reported in 0.8–2.2% of otherwise healthy children.

Genetics

- Long QT syndrome may be inherited in an autosomal-recessive or -dominant pattern. It is related to a variety of cardiac ion channel defects, and may be associated with hearing loss and/or a family history of sudden death.
- Brugada syndrome is related to a defect in the cardiac sodium channel (SCN 5A) and appears to be inherited in an autosomal-dominant pattern.

PATHOPHYSIOLOGY

VT may result from a reentrant mechanism, triggered mechanism, or abnormal automaticity.

ETIOLOGY

- Diverse and often overlapping
- Idiopathic
- Myocarditis or dilated cardiomyopathy
- Long QT syndrome (LQTS)
- RV dysplasia
- Brugada syndrome

- Congenital heart disease (e.g., tetralogy of Fallot, transposition of the great arteries, aortic stenosis, hypertrophic cardiomyopathy, myocardial tumors, Ebstein anomaly, and pulmonary vascular occlusive disease)
- Metabolic disturbances (hypoxia, acidosis, hypo/hyperkalemia, hypomagnesemia, hypothermia)
- Drug toxicity (e.g., digitalis toxicity, antiarrhythmic agents)
- Substance abuse (cocaine, methamphetamine)
- Myocardial ischemia (e.g., Kawasaki disease, congenital coronary anomalies)
- Trauma

DIAGNOSIS

Based on electrocardiogram (ECG) or rhythm strip

HISTORY

- Varies widely, ranging from asymptomatic to sudden cardiac death
- Other symptoms include palpitations, presyncope or syncope, exercise intolerance, and dizziness.

PHYSICAL EXAM

- Can be normal; occasional heart rhythm irregularity secondary to frequent PVCs
- Acute, sustained VT may have signs of hemodynamic compromise, including lack of pulse
- Signs of underlying heart disease, if any are present

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Serum electrolytes, including magnesium and potassium levels, blood gas, and serum drug levels as appropriate
- Urine toxicology screen

- ECG:
 - ≥ 3 consecutive ventricular complexes faster than the upper limit of normal for age.
 - Bundle branch morphology (right or left) may indicate the site of origin of the VT. May have AV dissociation.
 - Typically, repolarization (T-wave) abnormalities are present.
 - The QTc interval should be measured in lead II during sinus rhythm.
 - Evaluate for Brugada syndrome in leads V1 and V2 (right bundle branch block, coved-type ST elevation, and T-wave inversion in the right precordial leads).
- Echocardiogram: Rule out congenital heart disease (CHD), pericardial and pleural effusions, tumors, and assess ventricular function.
- Ambulatory Holter monitor: Quantitative assessment of ventricular ectopy, and frequency of VT.
- Exercise stress test (>5 years old):
 - Benign PVCs are characteristically suppressed with exercise and return in the immediate recovery period.
 - Exacerbation or worsening of ventricular arrhythmias is concerning.
- Cardiac catheterization: Assessment of hemodynamics and possible coronary artery imaging
- Electrophysiologic study indications:
 - Confirm diagnosis and mechanism of a wide complex rhythm.
 - Evaluate suspected VT in the setting of structural or functional heart disease, syncope, or cardiac arrest.
 - Evaluate nonsustained VT in patients with CHD.
 - Determine appropriate medical therapy in a patient with inducible VT.
 - Evaluate syncope in the setting of palpitations (SVT versus VT).
 - Characterize VT with consideration for catheter ablation.
 - *Note:* Electrophysiologic studies are generally not helpful in individuals with LQTS.

DIFFERENTIAL DIAGNOSIS

Wide complex tachyarrhythmia:

- Should always suspect ventricular tachycardia until proven otherwise
- Supraventricular tachycardia (SVT) with aberrancy
- Antidromic tachycardia (antegrade conduction down an accessory pathway during an AV reciprocating tachycardia, e.g., Wolff–Parkinson–White syndrome)
- Atrial flutter or fibrillation with rapid antegrade conduction over an accessory pathway

TREATMENT

- **Acute:**
 - If the patient is hemodynamically compromised, prompt synchronized direct-current (1–2 joules/kg; adult, 100–400 joules) cardioversion is indicated.
 - Asynchronous cardioversion for ventricular fibrillation or pulseless ventricular tachycardia
 - Cardiopulmonary resuscitation as necessary
 - Lidocaine (1 mg/kg bolus over 1 minute, followed by an infusion at 20–50 mcg/kg/min, assuming normal liver and kidney function)
 - If torsades de pointes, MgSO₄ may be given.
 - Overdrive ventricular pacing may terminate the tachycardia; however, pacing may accelerate the VT or induce ventricular fibrillation.
 - IV amiodarone (side effect: hypotension, responds to volume)
- **Chronic:**
 - Medications:
 - Class IB (mexiletine and phenytoin). β -blockers (propranolol, atenolol, nadolol) are used in LQTS and may be effective in exercise-induced VT and postoperative CHD.
 - Class III agents (amiodarone and sotalol) should be avoided in patients with LQTS.
 - Class IC agents (flecainide) may be proarrhythmic and sudden death has been reported in patients with structural heart disease who were taking class IC agents.
 - Atrial pacing at rates slightly faster than VT rates may suppress tachycardia.
 - Catheter ablation using radiofrequency energy or cryoenergy
 - Automatic implantable cardioverter defibrillators

ONGOING CARE

PROGNOSIS

- Generally very good in patients with idiopathic VT and a structurally normal heart
- Suppression of ventricular ectopy with exercise has a favorable prognosis.
- In patients with heart disease (congenital or acquired) or LQTS, VT may increase the risk of presyncope, syncope, and possibly sudden death.

COMPLICATIONS

- Cardiovascular compromise (sudden death)
- Acquired cardiomyopathy (from long-standing VT and a lack of AV synchrony)

PATIENT MONITORING

- Depends on the underlying cause
- ECG, Holter monitor, and exercise stress test

CODES

ICD9

- 426.82 Long QT syndrome
- 427.1 Paroxysmal ventricular tachycardia
- 746.89 Other specified congenital anomalies of heart

ICD10

- I45.81 Long QT syndrome
- I47.2 Ventricular tachycardia
- I49.8 Other specified cardiac arrhythmias

FAQ

- Q: Do frequent single PVCs require treatment?
- A: In an otherwise healthy child with a structurally normal heart, normal QT interval, and PVCs that suppress with exercise, no treatment is indicated.
- Q: Should siblings of patients with LQTS be evaluated?
- A: Yes, siblings and parents (even if asymptomatic) should have an ECG, Holter monitor, and exercise stress test for definitive evaluation of the QT interval. Commercial genetic testing is currently available to detect mutations in some of the most common genes that cause the Long QT syndrome. The test will positively identify ~75% of patients with the LQTS. Genetic testing may be considered in patients in whom there is a high suspicion of the LQTS.

VESICoureTERAL REFLUX

Hsi-Yang Wu

Howard M. Snyder

BASICS

DESCRIPTION

Vesicoureteral reflux (VUR) occurs when urine passes backward from the bladder to the ureters or kidneys.

EPIDEMIOLOGY

Prevalence

VUR occurs in ~1% of children. There are now clearly 2 different groups of patients:

- Those who were detected prenatally without any history of UTI:
 - ~20–30% of patients with prenatal hydronephrosis have VUR.
 - The ratio of males to females in this group is 3:1. This is believed to be caused by a period of high-pressure voiding in boys, which resolves by 18 months.
- Those who were detected after an acute UTI:
 - ~30–50% of children with UTI will have reflux, and they tend to be 2–3-year-old girls.
 - Since most children achieve urinary continence by this time, the cause of the UTI tends to be voiding immaturity and increased intravesical pressure.

RISK FACTORS

Genetics

- 30% of siblings will have low-grade reflux, but the great majority will have been asymptomatic, and renal scarring is rare.
- Parents with VUR have a 60% chance of having children with reflux:
 - Whether or not to screen siblings is controversial.
 - We elect to screen siblings with a history of recurrent febrile illnesses and girls who have not yet toilet trained.

PATHOPHYSIOLOGY

- VUR in combination with urinary tract infection can lead to pyelonephritis, renal scarring, and possibly end-stage renal disease. Primary VUR is classified into 5 grades by the International Reflux Study based on the voiding cystourethrogram (VCUG):
 - Grade I: Reflux into ureter
 - Grade II: Reflux into renal pelvis without dilation of calyces
 - Grade III: Blunting of calyces, mild dilation of ureter
 - Grade IV: Grossly dilated ureter, moderate calyceal dilation with maintained papillary impressions
 - Grade V: Grossly dilated ureter with loss of papillary impressions
- The grading scale is important because spontaneous resolution rates are significantly different between grades I–III and grades IV–V.

ETIOLOGY

- A combination of abnormal anatomy and abnormal voiding pressure:
 - Primary VUR results from either a short ureteral tunnel through the bladder wall or transient high-pressure voiding, which occurs normally in the 1st 18 months of life.
 - Patients with primary low-grade VUR can expect improvement and even resolution of the VUR with time as the ureteral tunnel grows or when bladder pressures decrease.
- Secondary VUR occurs when there is an associated lesion responsible for the abnormal anatomy or increased intravesical (bladder) pressure:
 - Patients with secondary reflux require treatment of their primary problem, and still may require surgery to treat their secondary reflux. Secondary reflux may occur in neurologically normal patients with dysfunctional voiding, ureteroceles, posterior ureteral valves, and prune belly syndrome, or in neurologically abnormal patients with spina bifida.
 - Although it may seem arbitrary, the distinction between primary and secondary reflux is important because the large prospective trials have been conducted on patients with primary reflux, and it is not appropriate to extend those findings to patients with secondary reflux.
 - Another important distinction is whether the diagnosis of VUR was made as a result of a prenatal diagnosis of hydronephrosis or whether the child presented with urinary tract infection.

DIAGNOSIS

HISTORY

- Prenatal dilation of the urinary tract or UTI as presentation
- Family or sibling history of VUR
- Family history of UTI, suggestive of adherent uroepithelium
- Family history of renal failure
- Voiding history: Age at potty training
- Daytime or nighttime incontinence
- Frequency of urination
- Sensation of emptying the bladder completely
- Signs of dysfunctional voiding:
 - Urgency
 - Frequency
 - Damp underwear
 - Associated constipation: Frequency of bowel movements, suggestive of pelvic floor immaturity
- Evidence of holding urine during a bladder contraction:
 - Squatting, crossing legs
 - Compressing urethra with heel (Vincent's curtsy)

PHYSICAL EXAM

- Abdominal palpation (mainly to check for hard stool)
- Check for labial adhesions in girls
- Phimosi s in boys
- Inspection and palpation of spine (possible neurogenic bladder)
- BP

DIAGNOSTIC TESTS & INTERPRETATION

Lab

A serum creatinine and urinalysis for proteinuria may be obtained if the renal ultrasound suggests significant renal scarring.

Imaging

- Renal/bladder ultrasound: This is usually obtained at the time of UTI, or if the patient had a prenatal diagnosis of hydronephrosis, at 1 week of life. The ultrasound is not as sensitive as dimercaptosuccinic acid (DMSA) scan for renal scarring. The lack of hydronephrosis does not mean that the patient does not have VUR. However, renal bladder ultrasound is a useful tool for following renal growth.
- VCUG: A contrast study is necessary for the 1st VCUG, to delineate the urethral anatomy in boys, and to accurately grade the reflux in both sexes:
 - An age-appropriate volume should be instilled in the bladder. The voiding portion of the study is important, since approximately 20% of VUR can be missed if voiding is not observed.
 - Follow-up VCUGs can be performed using radionuclide to decrease the radiation dose to the child.
- DMSA renal scan: The most accurate way to diagnose pyelonephritis and renal scarring:
 - Unfortunately, it is not possible to predict which patients will develop scarring after an acute episode.
 - If the diagnosis of upper tract infection versus cystitis is important, then the DMSA scan during an acute episode is useful.
 - The DMSA is not usually helpful with nonfebrile UTI in patients >6 months of age, since cystitis is rarely associated with high fevers.
 - Some advocate using DMSA to determine which patients require VCUG. This may allow for better segregation of high-risk patients.

DIFFERENTIAL DIAGNOSIS

In the prenatally detected group, hydronephrosis can also be due to ureteropelvic or ureterovesical junction obstruction. The important task is to differentiate primary from secondary VUR so that the parents can be appropriately counseled.

TREATMENT

ADDITIONAL TREATMENT

General Measures

- 4 prospective randomized controlled trials have concluded that medical management (prophylactic antibiotics) and surgery have essentially equal outcomes in regard to hypertension, growth, and renal scarring. Surgery was more effective at preventing pyelonephritis.
- The rate of renal scarring was equal in the medical and surgical arms of the International Reflux Study. However, the timing of renal scarring was different: In the medically treated arm, new renal scars continued to form during 5 years of follow-up, whereas in the surgical arm, the renal scars stopped within 10 months of surgery. Surgery was 95% successful in correcting reflux with a 4% complication rate. Surgery involves creation of a longer muscular backing for the ureter to create a flap-valve mechanism.
- Patients with low-grade reflux should be maintained on prophylactic antibiotics, since grades I to III have a significant rate of spontaneous resolution. Patients with high-grade reflux should be initially maintained on prophylactic antibiotics, but earlier consideration for surgical correction should be given owing to the lower rate of spontaneous resolution. Likewise, patients with reflux and renal scarring should be considered for earlier surgery since they have already shown a propensity toward UTI and renal damage.
- Antibiotic prophylaxis does not mean treatment-dose antibiotics. The antibiotics chosen are highly concentrated in the urine, and the use of high doses only selects out resistant organisms and leads to complications such as yeast infections. Amoxicillin at 10–15 mg/kg/d is used for the 1st 2 months of life, then trimethoprim/sulfamethoxazole (40 mg/200 mg/5 mL) at 0.25 mL/kg/d (equivalent to 2–3 mg/kg daily of trimethoprim) or nitrofurantoin at 1–2 mg/kg/d.
- Patients who are detected with VUR in infancy should probably have a contrast VCUG at 18 months to 2 years to determine the grade of reflux, since this can improve as voiding pressures normalize.
- In toilet-trained children, maintenance of a regular voiding pattern and regular bowel movements decreases the risk of febrile UTI and increases the chance of VUR resolution.
- Patients being managed on antibiotic prophylaxis undergo annual follow-up nuclear VCUG to document improvement or resolution of VUR. Grading is less precise with nuclear VCUG, but the radiation dose is lower. A renal ultrasound is also obtained to follow renal growth and check for gross renal scars.
- Indications for crossing over to surgery are:
 - Patient or parent wishes
 - Noncompliance with medical therapy
 - Breakthrough infections while on medical therapy (This is a relative indication. A careful review of voiding habits should be carried out to ensure that dysfunctional voiding is not responsible for the UTI. Lack of new renal scarring may suggest that continued medical management is appropriate.)
 - New renal scarring
 - Persistence of reflux after an appropriate period of antibiotic prophylaxis

- The use of injectable bulking agents has at best 80% success 1 year after 1 treatment, progressively decreasing as the grade of VUR increases. As additional experience is gained with injection therapy, success rates tend to increase. The minimally invasive nature of these treatments is balanced with a lower success rate. Deflux (dextranomer/hyaluronic acid) is the most commonly used injectable in the US and is widely used in treating grade I–III VUR. Deflux treatment in higher grades of VUR and the use of laparoscopic ureteral reimplantation are currently being explored in select patients.
- The use of continuous antibiotic prophylaxis has been questioned because while it decreases the risk of UTI, it has not been shown to decrease renal scarring compared to placebo. The NIH is currently sponsoring a multi-institutional trial to determine the benefits of continuous prophylaxis versus placebo treatment. The Swedish Reflux Trial showed a decreased rate of febrile UTI in girls with grades III–IV VUR who underwent injection therapy or prophylaxis, compared to those on surveillance. New renal scarring was less frequent in girls on prophylaxis compared to those on surveillance.
- The management of patients who continue to have VUR after several years of prophylactic antibiotics is controversial. Although most feel comfortable taking boys with VUR off antibiotics after age 6 because the risk of renal scarring is decreased and boys are at low risk for UTI, the adolescent girl is at increased risk for complications during pregnancy if she has a past history of UTI. The few studies on this subject seem to indicate that the patients with VUR and recurrent UTI are at risk for pregnancy-related complications whether or not the VUR has been surgically corrected, suggesting that the propensity toward UTI plays a more important factor.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

Patients with renal scarring should have annual BP checks and urinalysis for proteinuria.

PROGNOSIS

- In primary VUR, 80–90% of grades I and II reflux, 70% of grade III, 40% of grade IV, and 25% of grade V resolve over a 5-year period.
- The annual rate of spontaneous resolution is between 15% and 20% for grades I–III.
- Bilateral reflux is less likely to resolve than unilateral reflux.
- Patients age 5 years or older at presentation are less likely to resolve than those who present at <5 years of age.
- Ultimately the goal is prevention of renal scarring rather than resolution of the reflux, since low-pressure sterile reflux does not lead to renal scarring.
- The patient's propensity toward UTI must be considered as well as whether the reflux is resolving.

CODES

ICD9

- 593.70 Vesicoureteral reflux unspecified or without reflux nephropathy
- 753.8 Other specified anomalies of bladder and urethra

ICD10

- N13.70 Vesicoureteral-reflux, unspecified
- Q62.7 Congenital vesico-uretero-renal reflux

FAQ

- Q: How soon after a UTI should the VCUG be performed?
- A: Once the patient is clinically stable and afebrile and sterile urine has been documented, the VCUG can be performed.
- Q: Why not operate immediately to repair the reflux when it is diagnosed?
- A: Depending on the grade of reflux, many cases will resolve in time (see “Treatment”).

VIRAL HEPATITIS

Jeremy King

Vani V. Gopalareddy

BASICS

DESCRIPTION

Viral hepatitis is defined as a systemic viral infection, in which the predominant manifestation is that of hepatic injury and dysfunction. It is primarily caused by hepatotropic viruses, which include hepatitis A to E; however, 10% of cases are caused by other viruses, such as Epstein-Barr virus (EBV), cytomegalovirus (CMV), herpes simplex virus (HSV), varicella-zoster virus (VZV), rubella, parvovirus, adenovirus, enteroviruses such as coxsackie B, and others. In the US, hepatitis B accounts for 40% of acute viral hepatitis cases, whereas hepatitis A and C account for 30% and 20%, respectively.

EPIDEMIOLOGY

Incidence

- Hepatitis A: 125,000–200,000 infections per year worldwide. ~22,000 US cases per year. 10% occur in daycare centers that care for children who are not toilet trained.
- Hepatitis B: 140,000–320,000 infections per year worldwide. ~40,000 US cases per year. Since the 1991 implementation of universal vaccination of infants, the incidence of acute hepatitis B virus (HBV) cases in US children has declined from 3.03 per 100,000 in 1990 to 0.34 in 2002.
- Hepatitis C: 20,000 infections per year in the US
- Hepatitis E: Common in poorly developed countries but rare in the US. Can cause chronic hepatitis in liver transplant patients

Prevalence

- Hepatitis B: US has a low prevalence with <1% of the population infected. Higher rates in certain subgroups such as immigrants from endemic areas, homosexuals, and parenteral drug users
- Hepatitis C: US has prevalence of 1.8%, representing ~3.9 million people (85% chronically infected)

RISK FACTORS

- Hepatitis A (transmission: Fecal–oral):
 - Daycare attendance, household exposure, travel to endemic areas
 - Maximum infectivity 2 weeks before jaundice
- Hepatitis B and C (transmission: Blood, body fluids, and sexual contact):
 - Recipients of blood or blood products
 - IV drug users
 - Multiple sexual partners
 - Homosexual males
 - Body piercing and tattoos
 - HIV-positive status
 - Infants born to a mother with hepatitis B or C
 - Household contacts with hepatitis B or C

GENERAL PREVENTION

- Good sanitation, hygiene, screening blood products, condom use, safe disposal of needles
- Hepatitis A:
 - Vaccine (Havrix, Vaqta): 0.5-mL dose IM and 2nd dose 6–12 months later
 - Current guidelines recommend that all children between the ages of 1 and 18 years should be vaccinated.

- Use for travelers to endemic regions, daycare workers, and children with other liver diseases, and during outbreaks.
- Avoid return to daycare center for 2 weeks after illness subsides.
- Hepatitis A immunoglobulin for close contacts of infected individuals.

- Hepatitis B:
 - Screen all pregnant women.
 - Hepatitis B vaccine to all infants at birth; complete 3 vaccine series 0.5-mL dose IM during infancy
 - Vaccine and hepatitis B immunoglobulin to high-risk infants

PATHOPHYSIOLOGY

- Acute viral hepatitis tends to affect the liver parenchyma, whereas chronic viral hepatitis affects portal and periportal areas.
- In acute hepatitis, there is spotty necrosis, panlobular disarray, increased cellularity, pleomorphism of hepatocytes, and focal parenchymal necrosis.
- Chronic viral hepatitis is defined by continuing viral replication and inflammation of the liver for >6 months and affects the portal tracts predominantly but also extends into the parenchyma (interface hepatitis).
- Worsening injury leads to extensive fibrosis that occurs between portal tracts (portal bridging), nodular changes, and, finally, cirrhosis.

DIAGNOSIS

HISTORY

History should focus on risk factors for viral exposure, sick contacts, travel history, and high-risk behaviors. Family history of liver or autoimmune disease, medications, or drug and alcohol use should also be explored.

PHYSICAL EXAM

- Jaundice, hepatomegaly, or tenderness over the liver may or may not be present.
- Signs and symptoms:
 - Fever
 - Malaise and fatigue
 - Nausea and vomiting, anorexia
 - Jaundice: In hepatitis A, seen in 88% of adults but only 65% of children
 - Hepatomegaly
 - Right upper quadrant (RUQ) abdominal pain
 - Dark urine and pale stools
 - Arthralgias/arthritis
 - The vast majority of affected patients are minimally symptomatic or asymptomatic, especially with chronic infection.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Liver function tests:
 - Marked elevation of aspartate aminotransferase/alanine aminotransferase (AST/ALT) during acute infection. May be normal to mildly elevated in chronically infected individuals
 - Bilirubin from mild to marked elevation

- In severe hepatitis, monitor PT/PTT, albumin, electrolytes, glucose, and CBC.
- Biochemical markers for each virus for diagnosis, management, and monitoring:
 - Antihepatitis A virus (HAV) IgM: Recent infection
 - Anti-HAV IgG: Past exposure or immunization acquired
 - Hepatitis B surface antigen (HBsAg): Current infection, acute or chronic
 - Hepatitis B surface antibody (HBsAb): Immunized or resolved infection
 - Hepatitis B “e” antigen (HBeAg): Significant infectivity, viral replication
 - Hepatitis B “e” antibody (HBeAb): End of severe infectivity (except in precore mutants). Endpoint for hepatitis B therapy
 - Hepatitis B virus core antigen (HBcore) IgM: Early phase of acute infection, not present in chronic HBV
 - HBcore total Ab: Exposed to HBV
 - HBV DNA: Quantification useful to assess viral load
 - HBV mutations: Useful to assess resistance to treatment with lamivudine
 - HDV Ab: Exposure to hepatitis D
 - HCV Ab: Exposure to HCV
 - HCV RNA: Quantitative, assess viral load; qualitative, assess presence/absence of virus
 - HCV genotype: Useful to determine duration of treatment and likelihood of response
 - HBV genotyping not clearly established to guide therapy or determine prognosis

Diagnostic Procedures/Other

Liver biopsy is often needed to determine type and extent of liver damage. It is usually indicated prior to initiation of antiviral therapy in children because risk of treatment may sometimes outweigh the benefit.

Pathological Findings

A wide array of histologic features is possible on liver biopsy, including inflammation, necrosis, and fibrosis, based on the severity and chronicity of disease.

DIFFERENTIAL DIAGNOSIS

- Many disorders give rise to elevated transaminases, and clues to a viral origin are based on the history, serology, and histologic findings.
- One often invokes the diagnosis of non-A, non-B, non-C hepatitis when the cause is almost certainly viral but no virus is isolated.
- Other possibilities include drug-induced, ischemic, alcoholic, or autoimmune hepatitis, as well as Wilson disease or α_1 -antitrypsin deficiency.

TREATMENT

MEDICATION (DRUGS)

- Hepatitis A:
 - No specific therapy is available.
 - Postexposure prophylaxis with pooled human serum globulin at dose of 0.02 mL/kg for household contacts, intimate exposure contacts, and children and staff in nursery or daycare centers with outbreaks

- Hepatitis B:
 - Postexposure prophylaxis with hepatitis B vaccine and hepatitis B immunoglobulin (HBIG) is indicated for neonates born to mothers who are hepatitis B carriers, after sexual contact with carriers, and after accidental exposure to infected blood products.
 - There is no treatment for acute hepatitis B, though lamivudine is reported to be effective in fulminant hepatitis due to HBV.
 - Chronic hepatitis B is treated with the antiviral agents interferon, adefovir, tenofovir, or entecavir when ALT is elevated.
 - The most successful treatment is still interferon with 33% success rate in meta-analysis of adult studies. Interferon- α : 10 MU/m² given 3 times a week for 6 months (not recommended for use in infants and very young children <2 years).
 - Response rates may be slightly lower for nucleoside analog reverse transcriptase inhibitors (nRTIs) like lamivudine, adefovir, and entecavir, although they have fewer side effects. Endpoint to stop treatment is not clear.
 - Lamivudine is no longer used owing to a high rate of resistance with prolonged treatment.
 - Adefovir dipivoxil (Hepsera) is approved for children >12 years at the dose of 10 mg/d and entecavir (Baraclude) for children >16 years at a dose of 0.5–1 mg daily.
 - Adefovir often works well in patients with lamivudine-resistant disease.
 - Tenofovir appears to have more potent antiviral activity than other nRTIs and rare resistance. It is not yet approved in children but trials in adolescents are under way.
 - The factor most predictive of treatment response in children with chronic hepatitis B is an elevated pretreatment ALT. Low viral DNA, young age, and female sex imply favorable response.
 - Each year, 5–10% of children spontaneously clear hepatitis Be antigen (HBeAg), at which point the disease usually becomes inactive, although a few will later reactivate.
 - Some pediatric studies suggest that antiviral therapy hastens but does not increase the rate of HBeAg seroconversion.
- Hepatitis C:
 - Antiviral therapy is indicated for children with progressive disease or advanced histologic features.
 - Pegylated interferon and ribavirin is the treatment of choice for chronic hepatitis C and was approved for children >3 years of age in 2008.
 - The combination dose is PEG-IFN (60 mcg/m² once weekly) + ribavirin (15 mg/d in 2 divided doses).
 - Treatment duration depends on genotype:
 - Genotypes 1 and 4: 1 year (type 1 most common in US)
 - Genotypes 2 and 3: 6–12 months (types more likely to respond to therapy)
 - Maintaining higher doses is possible by balancing side effects with erythropoietin and granulocyte-macrophage-colony-stimulating factor (GM-CSF) to counter hemolytic complications and leukopenia.
 - Several protease inhibitors have recently been approved for treatment of chronic HCV in adults in combination with PEG-IFN and ribavirin. Initial results are excellent, but these drugs are not yet approved for use in children.

ADDITIONAL TREATMENT

General Measures

- Severe cases need inpatient care; acute liver failure requires intensive care at a liver transplant center.
- Monitor and correct coagulation defects and fluid, electrolyte, and acid–base imbalances.
- Report acute cases to public health department.
- Patients with acute liver failure should be transferred to a pediatric transplant center.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Serial measurement of serum AST/ALT, viral markers, α -fetoprotein, and ultrasound of the liver
- Liver biopsy pretreatment and for evaluation of disease progression

PROGNOSIS

- Hepatitis A:
 - Mild disease usual
 - Rarely results in relapsing, fulminant, or cholestatic disease
 - No chronic liver disease
 - Mortality <1%
 - Protective antibodies develop in response to infection and persist for life.
- Hepatitis B:
 - Fulminant hepatitis 1–2%
 - Mortality 0.5–2%
 - Chronic sequelae: Carrier state 10–95%, chronic hepatitis 5–10% (but 90% if vertically acquired), cirrhosis <5%, hepatocellular carcinoma (more common in HBV to viral integration into the genome)
- Hepatitis C:
 - Fulminant hepatitis 1%
 - Chronic sequelae: Carrier state 10–20%, chronic hepatitis 10–50%, cirrhosis 10–20%, hepatocellular carcinoma 5–10%
 - HCV is the most common indication for liver transplantation in adults.
 - In adult studies, sustained virologic response to therapy may decrease HCV-related hepatocellular carcinoma.

COMPLICATIONS

- Patients with advanced liver disease due to chronic hepatitis B or C are at risk of complications associated with cirrhosis and portal hypertension.
- Patients with chronic hepatitis B or with cirrhosis due to hepatitis C are at increased risk of hepatocellular carcinoma.
- Hepatitis B
 - Hepatitis D coinfection: Acute hepatitis B and D virus infection occur simultaneously:
 - Mortality rate of 1–10%
 - Hepatitis D superinfection: Acute hepatitis D occurs in a chronic carrier of hepatitis B:
 - Mortality rate of 5–20%
 - Acute liver failure occurs more frequently, chronic hepatitis 75%
 - Chronic HDV causes cirrhosis in 70–80% of patients and is a rapidly progressive disease compared with chronic hepatitis B alone. Cirrhosis has been noted to occur in as little as 2–10 years.

Pregnancy Considerations

Hepatitis E: Mortality of 20% caused by acute liver failure in pregnant women

CODES

ICD9

- 070.1 Viral hepatitis A without mention of hepatic coma
- 070.30 Viral hepatitis B without mention of hepatic coma, acute or unspecified, without mention of hepatitis delta
- 070.9 Unspecified viral hepatitis without mention of hepatic coma

ICD10

- B17.10 Acute hepatitis C without hepatic coma
- B19.9 Unspecified viral hepatitis without hepatic coma
- B19.10 Unspecified viral hepatitis B without hepatic coma

FAQ

- Q: Why do infants who acquire HBV at birth have a higher incidence of chronicity?
- A: The immaturity of the neonatal immune system contributes to the higher incidence of chronicity in this population. Furthermore, prenatal exposure to HBeAg may result in immune tolerance to the virus.
- Q: Should a mother with HCV positivity breastfeed?
- A: Transmission of HCV via breast milk is unlikely.

VOLVULUS

Joy L. Collins

BASICS

DESCRIPTION

Volvulus is torsion of the gut upon itself or upon a narrow mesenteric pedicle. It may be acute and complete or chronic and intermittent. Segmental volvulus may occur in the small intestine or colon, but in children midgut volvulus is the most common form.

- Of patients with abnormal rotation, 50–80% will be symptomatic in infancy. Most patients will present by age 1 year with symptoms of acute bowel obstruction.
- Patients with a rotational anomaly may present with midgut volvulus without any preexisting symptoms.
- Malrotation with midgut volvulus is most common in neonates.

COMMONLY ASSOCIATED CONDITIONS

- Incomplete rotation of the intestine during fetal development is the most common form of malrotation.
- Incomplete malrotation results in a narrow mesenteric stalk for the midgut loop centered on the superior mesenteric artery and vein, and obstructing bands (Ladd bands) across the duodenum, predisposing to midgut volvulus.

DIAGNOSIS

HISTORY

- Symptoms of acute or recurrent obstruction at birth or in the 1st year of life
- Recurrent bilious emesis (most important symptom) with or without acute abdomen
- ALERT: Some patients with midgut volvulus present with NONBILIOUS emesis.
- Feeding intolerance

- Chylous ascites and/or protein-losing enteropathy due to lymphatic congestion and bacterial overgrowth. These may present as history of abdominal distension, diarrhea, edema, or generalized/localized extremity swelling.
- In older children, recurrent abdominal pain and emesis. Older infants may have symptoms that mimic colic.
- Bloody stools or blood-tinged mucus per rectum

PHYSICAL EXAM

- Abdominal tenderness or fullness with or without distention
- Irritability, lethargy
- Brawny edema of abdominal wall
- Drawing up of legs
- Tachypnea and tachycardia

DIAGNOSTIC TESTS & INTERPRETATION

Lab

May see metabolic acidosis, thrombocytopenia

Imaging

- Abdominal radiograph may show dilated stomach and duodenum or may be normal.
- Abdominal ultrasound may show inversion of normal position of superior mesenteric artery (SMA) and vein (SMV; if SMV is located to left of SMA, suggestive of malrotation).
- Upper GI tract radiography may show abnormal position of the ligament of Treitz and, if volvulus is present, a corkscrew appearance of the midgut.
- The radiographic appearance, though, may be confusing because there are many patterns of duodenal malrotation reported. Abdominal radiograph may show double bubble sign of duodenal obstruction.

- In the absence of a corkscrew or Z-shaped duodenum, patterns that usually indicate volvulus or obstructing Ladd bands, colon position has greater prognostic implication, especially when the cecum is positioned in the right upper quadrant (RUQ) or left upper quadrant (LUQ).
- Barium enema shows an abnormal position of the cecum (but 10% of patients will have normal position of the cecum).
- In cases of colonic volvulus, contrast enema shows beak deformity at site of volvulus.

DIFFERENTIAL DIAGNOSIS

- Duodenal atresia
- Perforated viscus
- Necrotizing enterocolitis
- Meconium ileus or meconium plug syndrome
- Ileal atresia
- Hirschsprung enterocolitis
- Appendicitis
- Intussusception
- Pyelonephritis

TREATMENT

ADDITIONAL TREATMENT

General Measures

- Emergent surgical exploration is indicated for volvulus
- Close monitoring of fluids and electrolytes to prevent shock, gastric suction, and intravenous antibiotics (as bowel resection may be required)
- Laparotomy with intestinal detorsion and resection of ischemic portions of the intestine

- Ladd procedure: Volvulus is untwisted in a counterclockwise direction, transduodenal bands are divided, mesenteric base is broadened, intestine is arranged in a position of nonrotation, and appendix is removed.
- If the entire midgut is ischemic, the volvulus may be untwisted, with re-exploration in 12–24 hours.
- Some surgeons feel that there is a role for laparoscopic approach to Ladd procedure in the stable patient.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Prognosis depends on extent of involvement and degree of ischemia.
- Monitor closely for feeding intolerance postoperatively.
- Persistent symptoms after surgical repair suggest pseudo-obstructive motility disorder.
- Although rare, patients may have recurrent volvulus after a Ladd procedure.
- Pitfalls:
 - May take hours to days to become symptomatic
 - Symptoms may be mistaken for colic in infants or cyclic emesis in older children.
 - Delayed diagnosis may result in strangulation and infarction, leading to short gut syndrome.

COMPLICATIONS

- Intermittent or acute obstruction
- Strangulation resulting in ischemia and loss of midgut
- Protein-losing enteropathy can also result from strangulation.
- Short gut syndrome if significant length of intestine is lost or is poorly functional postoperatively

CODES

ICD9

- 537.89 Other specified disorders of stomach and duodenum
- 560.2 Volvulus
- 751.4 Anomalies of intestinal fixation

ICD10

- K31.819 Angiodysplasia of stomach and duodenum without bleeding
- K56.2 Volvulus
- Q43.3 Congenital malformations of intestinal fixation

FAQ

- Q: In what age group is volvulus most common?
- A: Midgut volvulus is most common in the neonatal period.
- Q: How can the signs and symptoms of volvulus be distinguished from gastroesophageal reflux?
- A: Although both intermittent volvulus and gastroesophageal reflux (GER) may present with vomiting, the emesis in GER is not bilious. Bilious emesis, abdominal pain, and lethargy are signs of an abdominal obstruction, requiring further examination.
- Q: Should one think of intermittent volvulus in the differential diagnosis of children with presentation of protein-losing enteropathy?
- A: In children with unusual presentations of protein-losing enteropathy, especially with emesis as a contributing feature, exclude intermittent volvulus.
- Q: Have cases of gastric, small bowel, and colonic volvulus been reported?
- A: Yes, but rarely. Gastric volvulus patients do not manifest the full spectrum of signs and symptoms such as abdominal distension, vomiting, and abdominal pain. There are 2 main types of gastric volvulus: Organoaxial (longitudinal axis of rotation) and mesentericoaxial (transverse axis of rotation through greater and lesser stomach curves). In 2/3 of cases, there is an associated abnormality where the stomach is affixed to the esophagus.

Small bowel volvulus has been reported in association with ascariasis.

Colonic volvulus (usually sigmoid or cecum) is quite rare in children, and has been associated with Hirschsprung disease. Colonic volvulus also has been seen in mentally handicapped children, many times in association with aerophagia and chronic constipation. Colonic volvulus is a significant cause of death in the mentally handicapped population.

VOMITING

Matthew J. Ryan

BASICS

DEFINITION

- Vomiting is the forceful expulsion of gastric contents through the mouth.
- Regurgitation is defined as small, effortless mouthfuls of food or stomach contents.
- Retching is contraction of the abdominal musculature against a closed glottis therefore there is no expulsion of stomach contents. This is also referred to as “dry heaves.”

DIAGNOSIS

- Vomiting is a prominent feature of many disorders of infancy and childhood and is often the only presenting symptom of many diseases.
- Vomiting can be:
 - A defense mechanism to expel ingested toxins
 - An abnormality of or damage to the area postrema (a.k.a. the chemoreceptor trigger zone or vomiting center) located at the base of the fourth ventricle in the brain.
 - A result of intestinal obstruction or anatomic/mucosal abnormalities
 - The result of a generalized metabolic disease
- A full history should include medication and drug use, trauma, family history of migraines and, in adolescents, questions regarding feeding disorders (bulimia) and intercourse (pregnancy). Special attention should be directed to the timing of the emesis related to meals, position and time of day.

HISTORY

- Fever: Infectious causes of vomiting are common.
- Abdominal pain and frequent, forceful, or bilious emesis: Often associated with anatomic or obstructive intestinal disorder. Very commonly obstruction of a lumen (i.e., common bile duct stone or ureteropelvic junction (UPJ) obstruction) can present as vomiting.
- Age of patient: Pyloric stenosis and inborn errors of metabolism almost always present in infancy with vomiting, dehydration, and biochemical abnormalities.
- Mental retardation, pica, and patchy baldness: Indicate foreign body or hair ingestion and the development of a gastric bezoar.
- Nausea and epigastric pain related to meals: Often indicate gastritis, gastric emptying delay, or gallbladder disease

- Alleviated by meals: May signify gastroesophageal reflux or gastric ulcer
- Alternating vomiting and lethargy: May indicate intussusception
- Chronic headaches, fatigue, weakness, weight loss, and early morning vomiting: Neurologic causes of vomiting secondary to increased intracranial pressure
- Right- or left-sided abdominal pain: May indicate renal disease, inflammatory bowel disease
- Periodic chronic vomiting on a monthly basis may suggest a cyclic vomiting syndrome (CVS).

PHYSICAL EXAM

A careful and complete physical examination can often provide excellent clues as to the cause of vomiting in children:

- Visible bowel loops: Obstruction
- Palpation for bowel loops and tenderness, and auscultation for evidence of absent bowel sounds or borborygmi (rumbling bowel sounds): Intestinal obstruction
- Rectal examination: Testing the stool for occult blood
- Discoloration of skin and sclera: Jaundice (liver/gallbladder or metabolic disease)
- Orange tint of sclera or skin: Hypervitaminosis A
- Unusual odor: Metabolic disease
- Chronic vomiting: Evidence of neurologic dysfunction, including nystagmus, head tilt, papilledema, abnormal reflexes, and weakness
- Tense anterior fontanelle: May indicate meningitis, hydrocephalus, or vitamin A toxicity
- Enlarged parotid glands and hypersalivation: Bulimia and other feeding disorders
- Pelvic examination: Pregnancy, pelvic inflammatory disease, or ovarian disease

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- CBC: Anemia and iron deficiency can occur with intestinal duplication and obstruction, gastritis/esophagitis, inflammatory bowel disease (IBD) and ulcer disease.
- Blood chemistry:
 - Electrolyte abnormalities are found in pyloric stenosis and metabolic abnormalities.
 - An elevated alanine aminotransferase, conjugated bilirubin, and gamma-glutamyl transferase (GGT) can indicate liver, gallbladder, or metabolic disease.
- Urinalysis: Pyelonephritis, nephrolithiasis
- Amylase/lipase: Pancreatitis
- BUN/creatinine: If elevated, renal disease
- Urine culture: UTI
- Stool studies: occult blood, infection

Imaging

- Plain abdominal radiographic study: Obstruction
- Abdominal ultrasound:
 - Liver, gallbladder, renal, pancreatic, ovarian, or uterine disease
 - In infants, abdominal ultrasound is the test of choice for pyloric stenosis.
 - Useful when considering abdominal abscess and appendicitis
- Contrast radiography: Intestinal anatomic abnormalities (malrotation, intussusception, volvulus)
- Gastroesophageal scintigraphy (gastric emptying study): Evaluate rate of gastric emptying
- Abdominal CT: Not generally indicated for evaluation of vomiting, although it is an effective tool when more anatomic abdominal detail is required (abscess, tumor). Also, a head CT is helpful in evaluation of neurologic causes of vomiting although brain MRI provides better imaging of the brain stem where the vomiting center is located.

Diagnostic Procedures/Surgery

- Endoscopy: Esophageal, gastric, and duodenal inflammation (esophagitis, gastritis, ulcer disease, celiac disease, eosinophilic enteritis) as well as for obtaining cultures for unusual infections (duodenal *Giardia*, *Helicobacter pylori*/cytomegalovirus gastritis)
- Gastroesophageal manometry to evaluate for primary or secondary motility disorders

DIFFERENTIAL DIAGNOSIS

- Disorders of GI tract:
 - Anatomic:
 - Esophageal: Stricture, web, ring, atresia
 - Stomach: Pyloric stenosis, web, duplication
 - Intestine: Duodenal atresia, malrotation, duplication
 - Colon: Hirschsprung disease, imperforate anus
 - Motility:
 - Achalasia
 - Gastroesophageal reflux
 - Intestinal pseudo-obstruction
 - Obstruction:
 - Foreign body/bezoar
 - Intussusception
 - Stricture Crohn disease
 - Volvulus
 - Incarcerated hernia
 - Hepatobiliary disease
 - Eosinophilic enteritis
 - Appendicitis
 - Necrotizing enterocolitis
 - Peritonitis
 - Celiac disease
 - Peptic ulcer
 - Trauma:
 - Duodenal hematoma
 - Pancreatitis (pseudocyst)

- Neurologic:
 - Intracranial mass lesions:
 - Tumor
 - Cyst
 - Subdural hematoma
 - Cerebral edema
 - Hydrocephalus
 - Pseudotumor cerebri
 - Migraine (head, abdominal)
 - Seizures
 - Post concussion syndrome
- Renal:
 - Obstructive uropathy:
 - Ureteropelvic junction obstruction
 - Hydronephrosis
 - Nephrolithiasis
 - Renal insufficiency
 - Glomerulonephritis
 - Renal tubular acidosis
- Metabolic:
 - Inborn errors of metabolism:
 - Galactosemia
 - Fructose intolerance
 - Hereditary fructose intolerance
 - Amino acid or organic acid metabolism
 - Urea cycle defects
 - Fatty acid oxidation disorders
 - Lactic acidosis
- Infection:
 - Sepsis
 - Meningitis
 - UTI
 - Parasites
 - *Giardia*
 - *Ascaris*
 - *H. pylori*
 - Otitis media

 - Gastroenteritis
 - Viral hepatitis (A, B, C)
 - Pneumonia
 - *Bordetella pertussis*
- Endocrine:
 - Diabetes:
 - Diabetic ketoacidosis
 - Gastroparesis
 - Adrenal insufficiency
- Respiratory:
 - Sinusitis
 - Laryngitis
- Immunologic:
 - Food allergy
 - Anaphylaxis
 - Graft-versus-host disease
 - Chronic granulomatous disease

- Other:
 - Pregnancy
 - Rumination
 - Bulimia
 - Psychogenic
 - Motion sickness
 - Cyclic vomiting syndrome
 - Overfeeding
 - Pain
 - Medications:
 - Drugs (chemotherapy)
 - Vitamin toxicity
 - Vascular (superior mesenteric artery syndrome)
 - Porphyria
 - Familial dysautonomia

ALERT

Evidence of hematemesis, intestinal obstruction (bilious vomiting), dehydration, neurologic dysfunction, or an acute abdomen should be treated as a medical emergency, and hospitalization should be considered.

TREATMENT

- Therapy should be directed toward the underlying etiology. Historically, antiemetic medications are contraindicated in cases of acute vomiting although some studies now suggest ondansetron may reduce frequency of admission.
- Oral rehydration therapy is typically the first line of treatment. IV fluids are appropriate if oral rehydration therapy fails or is contraindicated.
- Neurotransmitters involved in vomiting include dopamine, acetylcholine, histamine, endorphins, serotonin, and neurokinin. The mechanism of many antiemetic medications is blockade of these neurotransmitters.

ISSUES FOR REFERRAL

- Chronic vomiting (2–3 weeks)
- Weight loss
- Severe abdominal pain or irritability
- GI bleeding
- Evidence of intestinal obstruction
- Serum electrolyte abnormalities
- Abnormal neurologic examination
- Dehydration
- Signs of an acute abdomen
- Lethargy

CODES

ICD9

- 536.2 Persistent vomiting
- 787.01 Nausea with vomiting
- 787.03 Vomiting alone

ICD10

- R11.10 Vomiting, unspecified
- R11.11 Vomiting without nausea
- R11.2 Nausea with vomiting, unspecified

FAQ

- Q: What are the most common causes of vomiting in an infant?
- A: Gastroesophageal Reflux and milk protein allergy although congenital pyloric stenosis, sepsis and malrotation must be ruled out.
- Q: What is the appropriate ER management for a patient presenting with hematemesis?
- A: Insertion of 2 large IVs with IV fluid rehydration are the initial steps to stabilize the patient. Oftentimes, NG lavage is both therapeutic and diagnostic to help determine the amount and briskness of the GI bleed.
- Q: Is bilious emesis always associated with small bowel obstruction?
- A: Repeated episodes of vomiting can cause duodenal contents to reflux into the stomach resulting in bile stained emesis without small bowel obstruction. Nevertheless, evaluation should include an abdominal film looking for air-fluid levels and bowel loop distension.

VON WILLEBRAND DISEASE

Char Witmer

BASICS

DESCRIPTION

- An inherited bleeding disorder caused by either a quantitative deficiency or qualitative defect of the von Willebrand protein
- Characterized by mucocutaneous bleeding or bleeding after surgical procedures

EPIDEMIOLOGY

Prevalence

- The prevalence of von Willebrand disease in the general pediatric population is estimated to be ~1%.

RISK FACTORS

Genetics

- The gene for von Willebrand factor is found on chromosome 12.
- Type 1 (see "Pathophysiology") follows an autosomal dominant inheritance pattern with variable penetrance.
- Type 2 varies; it can be autosomal dominant or recessive.
- Type 3 follows an autosomal recessive inheritance pattern.

GENERAL PREVENTION

- Avoid contact sports.
- For patients with recurrent epistaxis, measures should be taken to avoid drying of the mucosa by applying petroleum jelly, humidifying the air, and reducing trauma to the nasal mucosa by keeping the fingernails short and discouraging nose picking.
- It may be advisable for patients to wear an emergency ID bracelet indicating that they have von Willebrand disease in the event they are involved in an accident that renders them unconscious.
- Avoid medications that negatively affect platelet function (i.e., ibuprofen, aspirin).
- Combination oral contraceptive pills are very effective for some patients with menorrhagia.
- Appropriate hemostatic therapy prior to dental extractions or surgical procedures to prevent bleeding

PATHOPHYSIOLOGY

- Von Willebrand factor is a large multimeric protein that allows platelets to adhere to sites of endothelial injury, initiating the primary step in hemostasis—formation of the platelet plug.
- Von Willebrand factor also serves as a carrier for factor VIII in the peripheral circulation, protecting it from degradation. Deficiency of von Willebrand factor results in a shorter factor VIII half-life, causing a lower level of circulating factor VIII.

- When the von Willebrand factor is either deficient or defective, primary hemostasis is compromised, resulting in a bleeding diathesis characterized by easy bruising, frequent epistaxis, menorrhagia, and prolonged bleeding following surgical or dental procedures.
- Von Willebrand disease is an inherited bleeding disorder; however, acquired forms of von Willebrand disease have been described in association with hypothyroidism, Wilms tumor, other neoplasms, cardiovascular disorders with increased shear stress, myeloproliferative disorders, uremia, and medications including ciprofloxacin, griseofulvin, and valproate therapy.
- Classification: There are three major categories of von Willebrand disease:
 - Type 1:
 - Mild to moderate quantitative deficiency of von Willebrand factor
 - The most common type, accounting for 70–80% of patients
 - Generally a mild bleeding disorder
 - Type 2:
 - Qualitative deficiency of von Willebrand factor
 - Diagnosed in 15–20% of patients
 - Tend to be more significant bleeding symptoms than in type 1
 - Type 2 von Willebrand disease is further classified into four subtypes.
 - Type 2A: Loss of the intermediate- and high-molecular-weight multimers. The loss is secondary to either abnormal assembly or secretion of multimers or increased proteolytic degradation. The multimer deficiency results in decreased platelet binding.
 - Type 2B: An abnormal von Willebrand factor that spontaneously binds to normal platelets, resulting in accelerated clearance of these platelets and loss of high-molecular-weight multimers. This can result in mild thrombocytopenia.
 - Type 2N: The abnormal von Willebrand factor does not bind factor VIII optimally. This decrease in binding results in a shorter plasma half-life of factor VIII, resulting in reduced plasma factor VIII levels. Type 2N can be confused with mild hemophilia.
 - Type 2M: The abnormal von Willebrand factor fails to bind normally to platelets. Normal multimers
 - Type 3:
 - Near-complete quantitative deficiency of von Willebrand factor, which also results in a secondary deficiency of factor VIII
 - Accounts for <5% of patients and results in a severe bleeding disorder

DIAGNOSIS

HISTORY

- A family history of von Willebrand disease or bleeding tendency is an important question in the evaluation for von Willebrand disease. However, be aware that variation in frequency and severity of bleeding symptoms can occur from person to person, even within an affected family.
- Mucosal bleeding is especially common in von Willebrand disease.
- Bruising is common, with increased quantity, increased size (> 5 cm), and often in unusual locations with minimal trauma.
- Recurrent and/or prolonged epistaxis
- Menorrhagia occurs in 50–75% of women with von Willebrand disease.
- Excessive posttraumatic or postsurgical bleeding

PHYSICAL EXAM

- Bruises: Increased number, size, and/or unusual location
- May be entirely normal

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Screening tests for a bleeding disorder:
 - PT is normal in von Willebrand disease.
 - Activated partial thromboplastin time (aPTT) may be prolonged if there is a decrease in factor VIII levels but can be normal.
 - Platelet count is normal except in type 2B patients, who may have mild thrombocytopenia.
 - Bleeding time is usually prolonged, but may be normal in patients with mild type 1 von Willebrand disease (not recommended as a screening test).
 - Platelet function assay (PFA)-100 is usually prolonged, but may be normal in mild type 1 von Willebrand disease (not recommended as a screening test).
- Specific tests for von Willebrand disease include:
 - Von Willebrand factor antigen: Quantitation of von Willebrand factor by immunoassay
 - Von Willebrand factor activity (ristocetin cofactor): Assesses the function of von Willebrand factor using the antibiotic ristocetin, which induces platelet aggregation in the presence of von Willebrand factor
 - Factor VIII: Factor VIII clotting activity
 - Von Willebrand factor multimers: Multiple molecular forms of von Willebrand factor evaluated on agarose gel
 - Multimer analysis is important in delineating the type of von Willebrand disease. Do not send as part of the initial screening for von Willebrand disease.

DIFFERENTIAL DIAGNOSIS

- Primary hemostatic disorders:
 - Platelet function abnormalities, congenital thrombocytopenia
 - Mild inherited coagulation factor deficiencies
 - Hemophilia A (type 3 von Willebrand disease and type 2N are similar to mild and moderate factor VIII deficiency)
- Acquired and secondary hemostatic disorders:
 - Liver disease
 - Uremia
 - Acquired thrombocytopenia
 - Drugs that affect platelet function
 - Acquired factor inhibitors (extremely rare in children)
- Connective tissue disorders:
 - Ehlers-Danlos syndrome
 - Osteogenesis imperfecta
 - Scurvy
- Prolonged aPTT but no bleeding symptoms:
 - Inhibitor
 - Factor XII deficiency

ALERT

- The diagnosis of von Willebrand disease is not always straightforward:
- Because of normal physiologic variation in plasma levels of von Willebrand factor, repeated measurements over time may be necessary to establish the diagnosis.
- Conditions that may increase von Willebrand factor levels:
 - The newborn period
 - Surgery
 - Liver disease
 - Hyperthyroidism
 - High-stress states
 - Pregnancy
 - Inflammatory or infectious disease
 - Steroids
 - Oral contraceptives
 - Other estrogens

TREATMENT

General Measures

- There are several options for the management of bleeding in patients with von Willebrand disease. Superficial bleeding can usually be stopped by applying local pressure, ice, or topical thrombin, particularly in type 1.
- There are two main approaches to systemic therapy in von Willebrand disease: Increasing the release of endogenous von Willebrand factor or exogenous replacement of von Willebrand factor. The appropriate therapy depends on the type of von Willebrand disease and the clinical scenario.

MEDICATION (DRUGS)

- Desmopressin (DDAVP) is a synthetic analog of vasopressin that stimulates endothelial cell release of von Willebrand factor. It is effective in patients who have a functional von Willebrand factor, as in type 1 von Willebrand disease. It may be used for some patients with type 2 von Willebrand disease, but is ineffective in type 3:
 - Available in intravenous and intranasal formulations

- An infusion of 0.3 mcg/kg results in a 3–5-fold increase in von Willebrand factor and factor VIII; nasal administration is slightly less effective.
- Side effects include facial flushing, light-headedness, or nausea.
- Prior to use in a surgical setting, patients should have a trial to demonstrate an appropriate response (10% of patients do not respond).
- May worsen thrombocytopenia in type 2B, not recommended
- DDAVP may not be useful when prolonged hemostasis is required. After 24–48 hours, there is depletion of stored von Willebrand factor, causing it to be ineffective (tachyphylaxis).
- It is important to remember that DDAVP will also cause fluid retention and, in some cases, hyponatremia. This can be avoided with fluid restriction following treatment.
- Humate-P or Alphanate:
 - Plasma-derived, intermediate-purity factor VIII concentrate products with adequate levels (especially large multimers) of von Willebrand factor
 - Therapy of choice for some patients with type 2 von Willebrand disease and all patients with type 3 von Willebrand disease
 - Useful in type 1 von Willebrand disease when prolonged hemostasis is necessary
- Aminocaproic acid or tranexamic acid:
 - Antifibrinolytics
 - Stabilize the fibrin clot by inhibiting the physiologic process of clot lysis
 - Best for oral mucosal bleeding
- Dose is 100 mg/kg given PO q6h

ONGOING CARE

PROGNOSIS

- Von Willebrand disease type 1 is often a very mild bleeding disorder and may go undetected.
- Most patients with von Willebrand disease have a normal life expectancy and, with proper education and treatment, minimal risk for permanent disability.
- Type 3 von Willebrand disease is a severe bleeding disorder, and life-threatening hemorrhage can occur.

COMPLICATIONS

- Significant perioperative bleeding can occur, especially with tonsillectomy, but the most common complications are recurrent epistaxis, prolonged bleeding with cuts and abrasions, and menorrhagia.
- Patients with type 3 von Willebrand disease have a more severe bleeding disorder and can have bleeding complications similar to those seen in hemophilia such as hemarthroses and intracranial hemorrhage.

FAQ

- Q: What sports activities can a person with von Willebrand disease participate in safely?
- A: People with type 1 von Willebrand disease can participate in most activities, although it is usually advised to avoid situations in which significant trauma takes place, like contact sports such as football or boxing. Patients with type 3 should avoid activities with moderate trauma. For type 2 patients, the risk of bleeding varies.
- Q: Is life expectancy lower in people with von Willebrand disease?
- A: For most patients with von Willebrand disease, their life expectancy and quality of life will be normal.
- Q: Are there any medications contraindicated in a patient with von Willebrand disease?
- A: Aspirin should not be given, as it interferes with platelet function. Nonsteroidal anti-inflammatory agents cause a milder effect on platelets and should also be avoided when possible. Patients should use acetaminophen for fever or pain.

WARTS

Julia Belkowitz
Marney Gundlach (5th edition)

BASICS

DESCRIPTION

- Warts (verrucae) are benign epithelial tumors that can occur on any epithelial surface of the body and produce characteristic lesions at various anatomic sites.
- Types of warts:
 - Common warts (verruca vulgaris): Rough, minimally scaly papules and nodules on the fingers, hands, face, arms, and legs
 - Flat warts (verruca plana): Rough, flat-topped, minimally scaly papules on face, legs, and arms
 - Plantar warts (weight-bearing warts): Painful inward-growing papules and plaques on the bottom of the feet
 - Anogenital warts (condyloma acuminata): Skin-colored flat warts or moist, pink to brown, cauliflower-like lesions around the vagina and anal openings
 - Laryngeal warts (laryngeal papillomatosis): Transmitted vertically at delivery and present with stridor and progressive airway obstruction in children
- Transmission:
 - Humans are the only reservoir for human papillomavirus (HPV).
 - HPV can be transmitted by direct skin-to-skin or mucous membrane contact and by fomites.
 - Autoinoculation from common warts at another site should be considered as a possible mode of spread.
 - Clinical signs develop 1 month or more after inoculation.

EPIDEMIOLOGY

Prevalence

Affects 5–10% of children

GENERAL PREVENTION

- During contact sports, all lesions should be completely covered prior to participation. If the lesions are too extensive to completely cover, the athlete should not be allowed to participate.
- Quadrivalent HPV vaccination (protection against serotypes 6, 11, 16, 18) is recommended for girls ages 9–26 years for prevention of cervical cancer and genital warts and for boys 9–26 years to reduce likelihood of genital warts. Bivalent vaccine (protection against serotypes 16 and 18) is also available. Vaccinations are given in a 3-dose series.

PATHOPHYSIOLOGY

- The viruses have specific affinity for epidermal cells and cannot replicate in dermal connective tissue cells or other types of nonepithelial tissues.
- After implantation in the epidermis, the viruses enter the nuclei of lower and midepidermal cells. The viruses then take over the machinery of cell production. While replicating themselves, they induce a rapid proliferation of epithelial cells.
- The quantity of the virus, location of the warts, preexisting skin injury, and cell-mediated immunity all play a role in the transmission of the virus.

ETIOLOGY

- Warts are caused by HPV, which is a subgroup of papovaviruses, small double-stranded DNA viruses.
- There are > 100 types of HPV:
 - Anogenital warts are often caused by types 6, 11 (most common), 16 and 18, and 31 and 45 (high risk).
 - Laryngeal papillomatosis is associated with types 6 and 11.

DIAGNOSIS

HISTORY

- Obtain wart exposure history from family members and caretakers.
- Determine the duration of the warts.
- Elicit any history of immunodeficiency.

PHYSICAL EXAM

- Common warts:
 - May be solitary or multiple and range in size from millimeters to centimeters
 - Linear patterns may be seen from autoinoculation.
 - Filiform or threadlike warts may be seen in the skin creases and on mucous membranes.
- Flat warts:
 - Small, rough, flat-topped, and minimally keratotic papules
 - Size ranges from 1–3 mm
- Plantar warts:
 - Painful, inward-growing, hyperkeratotic papules and plaques on the plantar surface of the feet
 - As a result of trauma from weight bearing, the surface of these lesions may have small black dots from thrombosed blood vessels.
- Anogenital warts:
 - May be skin-colored, flat warts or moist, pink to brown, cauliflower-like lesions in the skin creases, vulva, and scrotum, and in and around the vaginal and anal openings
 - In adolescent and adult males, the warts are localized to the penis (penile lesions are rarely seen in younger boys). The lesions are brown to slate-blue, pigmented macules and papules.
- Laryngeal warts:
 - Present with stridor and progressive airway obstruction in children

DIAGNOSTIC TESTS & INTERPRETATION

Tests are rarely needed.

Lab

Pap smears will show the presence of koilocytic cells in adolescent females with vulvar condyloma. HPV DNA testing is also available.

Diagnostic Procedures/Other

- Biopsy of flat warts shows koilocytic cells with an eccentric, shrunken nucleus surrounded by a perinuclear halo.
- Electron microscopy will show the distinctive viral particles.
- Antigen detection and molecular hybridization techniques have been used in adults to detect HPV in scrapings and biopsies of lesions.

DIFFERENTIAL DIAGNOSIS

- Common warts:
 - Molluscum contagiosum
 - Callus
- Flat warts:
 - Moles
 - Epidermal nevi
 - Tinea versicolor
 - Milia
 - Molluscum contagiosum
 - Granuloma annulare
 - Folliculitis
 - Lichen nitidus
 - Lichen planus
- Plantar warts:
 - Corns
 - Calluses
 - Foreign bodies
- Anogenital warts:
 - Irritant contact dermatitis
 - Molluscum contagiosum
 - Skin tags
 - Hemorrhoids
 - Condyloma lata of syphilis

ALERT

- Underlying immunodeficiency should be considered in any otherwise healthy child with extensive HPV infection. Hereditary severe combined immunodeficiency, acquired immunodeficiency syndrome, and selective T-cell immune defects should be considered.
- Treatment of genital warts in children and in those with immunodeficiency should be carried out in consultation with a dermatologist.
- Laryngeal papillomatosis should be treated by an otolaryngologist.

TREATMENT

When to expect improvement:

- Spontaneous resolution has been observed in common, flat, genital, and plantar warts. In healthy individuals, 75% of warts regress without treatment within 3 years without scarring.
- Any therapy and its side effects must be measured against the high rate of resolution without intervention.
- With the various treatment modalities, a response is generally seen within weeks to several months.
- Combination therapy is often required.

ADDITIONAL TREATMENT

General Measures

- Communication with families about expectations prior to therapy is important.
- Pain management using icepacks, EMLA, or other agents must be considered.
- For hyperkeratotic lesions, treatment response may be improved for many modalities if the lesion is first pared down with a scalpel or debrided with pumice or an emery board.

Additional Therapies

- Destructive techniques:
 - Salicylic acid:
 - Evidence for effectiveness of treatment
 - Can cause scarring
 - Should be considered 1st-line treatment, except in facial warts
 - Duct tape
 - Occlusion with duct tape for 6 days followed by debrided, and repeat treatment until resolution; inexpensive and associated with little discomfort
 - Causes local irritation and stimulates an immune response
 - Though early data seemed promising, more recent studies show no benefit over placebo.
 - Cryotherapy:
 - Involves using liquid nitrogen and deep-freezing the warts
 - Causes necrosis and blister formation
 - Is inexpensive, produces a rapid response, and does not require anesthesia; however, the treatment is painful and may lead to infection, scarring, and damage of normal skin
 - Cantharidin:
 - A topical applicant that triggers painless intraepidermal blisters
 - Should only be applied in the office setting
 - There is a high incidence of wart recurrence and postinflammatory pigment changes.
- Electrocautery and CO₂ laser ablation:
 - Require local or general anesthesia
 - Can leave scars, and healing of the open wounds may take several months.
- Phototherapies:
 - Yellow, pulsed, dye laser
 - Generates 585-nm light, which is absorbed by oxyhemoglobin in the skin and converted to heat energy
 - Pretreatment with salicylic acid may reduce the number of treatments required.
 - There is a small chance of scarring.
 - Treatment may be painful for young children.

- Photodynamic therapy:
 - Photosensitizing agent applied to wart; causes damage to cells
 - Benefits in recalcitrant warts demonstrated
- Immunotherapies
 - Cimetidine:
 - An H₂-blocker that causes nonspecific stimulation of T lymphocytes
 - This therapy has not been proven to be effective.
 - Intralesional therapies:
 - Direct injection of immune-stimulating antigen (e.g., *Candida* or mumps, etc.) treats both primary site and distant lesions.
 - Requires multiple treatments; needles can be painful and/or frightening to children.
 - Side effects include pruritus at site, fever, and myalgia.
 - Imiquimod:
 - The 1st member of a class of immune response modifiers
 - A 5% cream is applied to the warts and results in an increase in the production of cytokines, especially interferon- α .
 - The cream is approved for home treatment of adults with external anogenital warts.
 - Data have supported efficacy in children with warts.
 - Zinc
 - New use as immune modulator in warts
 - Oral administration in zinc-deficient patients shows resolution of lesions.
 - Inexpensive and painless, not yet well studied
- Antimitotic therapies:
 - Podophyllotoxin:
 - Applied to pared-down warts
 - Treatment takes several weeks to months.
 - May be painful and produce scarring
 - Especially useful in genital warts
 - Podophyllin resin not recommended owing to potential neurotoxicity
 - Retinoids
 - Topical home application of 0.05% tretinoin cream
 - Option for facial flat warts
 - Oral retinoids are not recommended.
- Chemotherapeutic agents such as 5-FU and bleomycin have been studied, but concerns about safety caution use.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

Patients receiving treatment should be followed up at 3–4-week intervals to check the results and assess for any side effects.

PROGNOSIS

In healthy individuals, 75% of warts will spontaneously resolve without treatment within 3 years.

COMPLICATIONS

- Irritation and secondary infection of common warts may result in itching and pain.
- HPVs have also been associated with melanoma, keratoacanthoma, squamous cell carcinoma, leukoplakia, and oral carcinoma.
- Laryngeal warts can cause stridor and airway obstruction.

CODES

ICD9

- 078.10 Viral warts, unspecified
- 078.11 Condyloma acuminatum
- 078.19 Other specified viral warts

ICD10

- B07.0 Plantar wart
- B07.8 Other viral warts
- B07.9 Viral wart, unspecified

FAQ

- Q: How can one differentiate corns and/or calluses from warts?
- A: Using a no. 15 blade, pare down the surface of the wart. If the surface is smooth with normal markings without small black dots (thrombosed blood vessels) at the base, then they are not warts.
- Q: I am not sure if the lesions are warts. What else can I do in the office to confirm the diagnosis?
- A: Apply 3–5% acetic acid solution, and the lesions will turn white if they are warts. This, however, is not a specific test.
- Q: A child is seen for anogenital warts. What is the role of the physician?
- A: The child needs a complete medical examination. The anogenital area should be examined for any signs of sexual abuse. All skin lesions should be documented and possibly photographed. Serologic studies for syphilis and cultures for gonorrhea should be considered. Family members and caretakers should be asked about anogenital and common warts. Parents should be informed that anogenital warts could be caused by sexual abuse, particularly in children >3 years of age. Consultation with a child abuse expert should be considered.

WEIGHT LOSS

Mark F. Ditmar

BASICS

DEFINITION

A documented decrease in weight from a previous measurement. Outside of the newborn period (weight loss in the first 2 weeks is common), acute illnesses resulting in fluid loss, and obese adolescents voluntarily on a designed weight reduction program, weight loss is an unusual and worrisome symptom, regardless of the percentage decline.

DIAGNOSIS

- Determine the acuity or chronicity and severity of weight loss, and the need for hospitalization
- Attempt to narrow the diagnostic possibilities by history and physical exam, particularly by assessing if the loss might be attributable to diminished intake, diminished absorption, or increased requirements.

DIFFERENTIAL DIAGNOSIS

- **Congenital/anatomic**
 - Congenital heart disease
 - Pyloric stenosis
 - GI malformation (duodenal atresia, annular pancreas, volvulus)
 - Short bowel syndrome
 - Lymphangiectasia
 - Superior mesenteric artery syndrome
 - Gastroesophageal reflux
 - Immunodeficiency disorders
 - Hirschsprung disease
- **Infectious**
 - Urinary tract infection (UTI)
 - Tuberculosis
 - Stomatitis
 - Osteomyelitis
 - HIV
 - Hepatitis
 - Parasitic disease
 - Abscess, intra-abdominal
 - Gastroenteritis
 - Pericarditis
 - Histoplasmosis
 - Acute severe febrile illness (pyelonephritis, pneumonia, septic arthritis)
- **Toxic, environmental, drugs**
 - Lead poisoning
 - Mercury poisoning
 - Vitamin A poisoning
 - Chronic methylphenidate, dextroamphetamine, or valproic acid use
 - Substance abuse, especially amphetamines and crack cocaine
- **Trauma**
 - Chronic subdural hematomas
- **Tumor**
 - Diencephalic syndrome
 - Leukemia
 - Lymphoma
 - Pheochromocytoma
 - Other neoplasms

- **Genetic/metabolic**
 - Diabetes mellitus
 - Diabetes insipidus
 - Hyperthyroidism
 - Cystic fibrosis
 - Shwachman syndrome
 - Addison disease
 - Hypercalcemia
 - Congenital adrenal hyperplasia
 - Lactose intolerance
 - Renal tubular acidosis
 - Chronic renal failure
 - Hypopituitarism
 - Inborn errors of metabolism
 - Storage diseases
 - Muscular dystrophy
 - Lipodystrophy
- **Allergic/inflammatory**
 - Inflammatory bowel disease
 - Juvenile idiopathic arthritis
 - Systemic lupus erythematosus
 - Sarcoidosis
 - Pancreatitis
 - Hepatitis
 - Celiac disease (gluten enteropathy)
- **Functional/miscellaneous**
 - Malnutrition
 - Child abuse
 - Postoperative
 - Dieting
 - Rumination syndrome
 - Depression/affective disorders
 - Anorexia nervosa
 - Inability to eat (new orthodontic appliances, loss of teeth, chronic mouth ulcerations)
 - Chronic congestive heart failure
 - Chronic pulmonary disease
 - Chronic renal disease
 - Iron deficiency
 - Zinc deficiency
 - Cerebral palsy
 - Postinfectious malabsorption
 - Factitious (e.g., scale error)

ALERT

Emergency care:

- Significant dehydration:
 - Abnormal vital signs with orthostasis, decreased urine output, decreased skin turgor, delayed capillary refill (>3 seconds)
 - Mandates cardiovascular support (IV hydration) and a more urgent diagnosis (e.g., inborn error of metabolism, obstructive GI disease, congenital adrenal hyperplasia, diabetic ketoacidosis)
- Abnormal mental status, significant lethargy may be seen in:
 - Severe dehydration
 - Hypoadrenalism
 - Hypoxic states
 - Toxic ingestions
 - Renal or respiratory failure
 - Increased intracranial pressure
 - Severe electrolyte abnormalities
- Increasing vomiting in the setting of known weight loss in infants:
 - High risk for dehydration, hypoglycemia, and electrolyte abnormalities

- Need to evaluate for treatable conditions (e.g., obstructive GI disease, inborn errors of metabolism, congenital adrenal hyperplasia, congenital heart disease) in which a delay is life-threatening
- Severe malnutrition (weight loss >20% of ideal body weight):
 - High risk for metabolic derangements, including dysrhythmias secondary to electrolyte abnormalities
- Aggressive evaluation is warranted.

HISTORY

Determine that weight loss is real and not due to scale error, different scales, different technique (e.g., clothed vs. unclothed).

- **Question:** Child's diet?
- **Significance:** A prospective 3-day dietary record can be useful for demonstrating insufficient caloric intake.
- **Question:** Age?
- **Significance:** The patient's age can very much indicate the most likely causes of weight loss to which questions about the history can be directed.
 - Patient <2 weeks old: Physiologic weight loss, underfeeding, inappropriate feeding, inborn errors of metabolism, congenital heart disease, gastroesophageal reflux
 - Patient <4 months old: Malnutrition, improper formula preparation, cystic fibrosis, gastroesophageal reflux, pyloric stenosis, congenital heart disease, congenital adrenal hyperplasia, inborn errors of metabolism
 - Patient 4 months to 8 years old: Chronic infection, cystic fibrosis, malabsorption, neglect/abuse, renal disease, liver disease, diabetes mellitus
 - Patient >8 years old: Eating disorder, chronic infection, neoplasm, renal disease, liver disease, substance abuse, diabetes mellitus, inflammatory bowel disease, collagen vascular disease
- **Question:** Cramping, bloating, or abnormally greasy, voluminous stools?
- **Significance:** Possible malabsorption
- **Question:** Vomiting, especially projectile?
- **Significance:** Suggestive of intestinal obstruction, gastroesophageal reflux, inborn errors of metabolism
- **Question:** Polyuria, polydipsia, and polyphagia?
- **Significance:** Possible diabetes mellitus
- **Question:** Headaches, especially early morning?
- **Significance:** Possible increased intracranial pressure, CNS malignancy
- **Question:** Maternal history of multiple miscarriages, neonatal deaths, or consanguinity?
- **Significance:** Possible inborn error of metabolism
- **Question:** History of severe infections, persistent candidal infections?

- **Significance:** Immunodeficiency, congenital or acquired
- **Question:** Fear of fatness, preoccupation with food, distorted body image, and/or amenorrhea?
- **Significance:** Possible eating disorder
- **Question:** Delayed puberty?
- **Significance:** Suggests chronic severe weight loss, pituitary abnormalities, anorexia nervosa
- **Question:** Foreign travel?
- **Significance:** Possible chronic infection (e.g., tuberculosis, parasitic disease)
- **Question:** Tiring during feeding or difficulty feeding due to cough and dyspnea?
- **Significance:** Suggests congestive heart failure in newborn/infant, hypothyroidism
- **Question:** Increased appetite with weight loss?
- **Significance:** Suggests hyperthyroidism, cystic fibrosis, pheochromocytoma
- **Question:** Altered mental status, seizures, unusual body/fluid odors?
- **Significance:** Inborn error of metabolism
- **Question:** Chronic sadness or irritability, insomnia or hypersomnia?
- **Significance:** Depression/affective disorder

PHYSICAL EXAM

- **Finding:** Clubbing?
- **Significance:** Suggests chronic cardiac, pulmonary, or intestinal disease
- **Finding:** Significant abdominal distension?
- **Significance:** Suggests celiac disease
- **Finding:** Hypothermia, bradycardia?
- **Significance:** Suggests anorexia nervosa, hypothyroidism
- **Finding:** Tachycardia, resting?
- **Significance:** Hyperthyroidism, pheochromocytoma, anemia, acute weight loss
- **Finding:** Orthostatic changes?
- **Significance:** Significant weight loss, possibly acute
- **Finding:** Hypotension, resting?
- **Significance:** Addison disease, anorexia nervosa, significant acute dehydration
- **Finding:** Visual field abnormalities?
- **Significance:** Suggests possible CNS malignancy
- **Finding:** Swollen joint?
- **Significance:** Juvenile idiopathic arthritis inflammatory bowel disease
- **Finding:** Muscle weakness?
- **Significance:** Connective tissue disorder, electrolyte abnormality, muscular dystrophy
- **Finding:** Enlarged liver and/or spleen?
- **Significance:** Suggests malignancy, chronic infection, storage disease, inborn error of metabolism

ALERT

- Be certain that the weight loss is real. In some studies, up to 25% of weight loss is an artifact as a result of measurement errors (e.g., excessive movement of scale, dressed vs. undressed patient).
- Newborns with weight loss, especially at the 2-week visit, may manifest passivity and paradoxical lack of interest in breastfeeding, although the reason for their problem is malnourishment due to inadequate intake (often from improper positioning or too infrequent feedings). They may not act "hungry." Observation of the feeding technique (by a practitioner with expertise or a lactation consultant) is vital.

DIAGNOSTIC TESTS & INTERPRETATION

- **Test:** CBC for evidence of:
 - **Significance:**
 - Anemia—macrocytic associated with folate/B12 deficiency, microcytic with iron deficiency or chronic infection
 - Polycythemia—suggestive of chronic pulmonary or cardiac disease
 - Neutropenia—suggestive of hematologic malignancy, Shwachman syndrome, immunodeficiency
 - Lymphopenia—suggestive of immunodeficiency
 - Eosinophilia—suggestive of parasitic disease
 - Leukocytosis—suggestive of infection
 - Thrombocytosis—suggestive of chronic infection, malignancy
 - Lymphoblasts—suggestive of leukemia
- **Test:** Erythrocyte sedimentation rate
- **Significance:** May be elevated in inflammatory bowel disease, chronic infections, rheumatoid diseases
- **Test:** Serum electrolytes
- **Significance:** Abnormalities in dehydration, adrenal insufficiency (low sodium, high potassium), renal disease, anorexia nervosa
- **Test:** BUN, creatinine
- **Significance:** Abnormal in renal disease, dehydration
- **Test:** Stool for occult blood and pH, reducing substances (Clinitest)
- **Significance:**
 - Occult blood suggests inflammatory bowel disease.
 - Low pH and positive reducing substances suggest malabsorption.
- **Test:** Urinalysis
- **Significance:**
 - Hematuria and/or proteinuria suggest renal disease.
 - Glycosuria suggests diabetes mellitus.
 - Very low specific gravity suggests diabetes insipidus, chronic renal failure, and hypercalcemia.
 - Pyuria suggests UTI.
 - pH >6 suggests renal tubular acidosis (type I).
- **Test:** Urine culture
- **Significance:** Evaluation for UTI

- **Test:** Serum protein levels
- **Significance:** Very low levels imply impaired liver function, severe chronic weight loss, or protein malabsorption.
- **Test:** Tuberculosis skin test
- **Significance:** Possible chronic infection
- **Test:** Liver function tests
- **Significance:** Evaluation for hepatitis, chronic liver disease.

Depending on age and clinical findings, other tests to consider include: Thyroid function tests, sweat test, tests for malabsorption (e.g., lactose breath test, stool fat, stool for trypsin), tests for metabolic disease (e.g., plasma ammonia, lactate, serum/urine amino acids, urine organic acids), imaging studies (e.g., CT, MRI, bone scan), immunologic studies.

TREATMENT

ADDITIONAL TREATMENT

General Measures

Treatment is dependent on the etiology of the weight loss.

ISSUES FOR REFERRAL

Weight loss is a diagnostic exigency—a cause must be found or the loss self-resolved. If a diagnosis is not uncovered in the setting of continued weight loss, referral to a pediatric diagnostic center is indicated.

CODES

ICD9

783.21 Loss of weight

ICD10

R63.4 Abnormal weight loss

FAQ

- Q: How common is weight loss in the first 2 weeks of life?
- A: Formula-fed babies may lose up to 7% of birth weight and breastfed newborns up to 10% before regaining their birth weight by 2 weeks of age. An infant who has not regained his or her birth weight by 2 weeks requires evaluation and intervention.

WEST NILE VIRUS (AND OTHER ARBOVIRUS ENCEPHALITIS)

Jessica Newman

Jason Newland

BASICS

DESCRIPTION

- Viruses transmitted by an arthropod vector that can cause CNS infections, undifferentiated febrile illness, acute polyarthropathy, and hemorrhagic fevers
- Most arboviral infections are asymptomatic.
- West Nile virus (WNV) is an arbovirus in the flavivirus family.
- WNV was 1st recognized in the US in 1999 during an outbreak of encephalitis in New York City.
- More than 150 arboviruses are known to cause human disease.
- Other arboviruses can produce similar syndromes or acute hemorrhagic fevers.

EPIDEMIOLOGY

- Arboviruses are spread by mosquitoes, ticks, and sand flies. The major vector for WNV in the US is the Culex mosquito. WNV has been spread through blood transfusions, transplanted organs, and rarely intrauterine.
- Arboviruses are maintained in nature through cycles of transmission among birds, horses, and small animals. Humans and domestic animals are infected incidentally as “dead-end” hosts.
- Disease among birds has been a hallmark of WNV in the US and has served as a sensitive surveillance indicator of WNV activity.
- Each North American arbovirus has specific geographic distributions and is associated with a different ratio of asymptomatic to clinical infections. These agents cause disease of variable severity and have distinct age-dependent effects. WNV has now been identified throughout the US and is also found in Europe, Africa, and Asia.

Incidence

- The peak incidence of arboviral encephalitis occurs during the late summer and early fall. Seasonality depends on the breeding and feeding seasons of the arthropod host.
- WNV is the leading cause of arboviral CNS disease. Encephalitis is most commonly seen in older adults, generally aged >60 years. Cases of WNV in children are unusual.
- Fewer than 10 and 20 cases, respectively, of Eastern equine encephalitis and Western equine encephalitis are reported nationally each year. Eastern equine encephalitis tends to produce a more fulminant illness than LaCrosse or Western equine encephalitis.

GENERAL PREVENTION

- Public health department efforts focus on surveillance of viral activity to predict and prevent outbreaks:
 - Active bird surveillance to detect the presence of WNV activity
 - Active mosquito surveillance to detect viral activity in mosquito populations
 - Passive surveillance by veterinarians and human health care professionals to detect neurologic illnesses consistent with encephalitis
 - Screening of blood and organ donors

- Personal precautions to avoid mosquito bites including use of repellents, protective clothing, and screens; avoiding peak feeding times (dawn and dusk); and installation of air conditioners
- Coordination of mosquito control programs in endemic infection areas
- Vaccines for prevention of most arbovirus infections are not available. A vaccine is available for Japanese encephalitis and yellow fever (YF) for travelers to endemic areas who are planning prolonged stays.
- Infection control measures:
 - Standard precautions are recommended for the hospitalized patient.
 - Respiratory precautions are recommended when vector mosquitoes are present.
 - Patients with dengue and YF can be viremic and should be protected against vector mosquitoes to avoid potential transmission

PATHOPHYSIOLOGY

- The incubation period for WNV and other arboviral encephalitis agents is 2–14 days (up to 21 days in immunocompromised hosts).
- The incubation period reflects the time necessary for viral replication, viremia, and subsequent invasion of the CNS.
- Virus replication begins locally at the site of the insect bite; transient viremia leads to spread of virus to liver, spleen, and lymph nodes. With continued viral replication and viremia, seeding of other organs including the CNS occurs.
- Virus can rarely be recovered from blood within the 1st week of onset of illness but not after neurologic symptoms have developed.

ETIOLOGY

- Arboviruses can be divided into 2 groups based on the predominant clinical syndrome.
- In the US, 7 arboviruses are important causes of encephalitis: WNV, California encephalitis virus (LaCrosse strain), Eastern equine encephalitis, Western equine encephalitis, St. Louis encephalitis, Powassan encephalitis virus, and Venezuelan equine encephalitis virus.
- Arboviruses such as yellow fever, dengue fever, and Colorado tick fever typically cause acute febrile diseases and hemorrhagic fevers and are not characterized by encephalitis.
- Clinical manifestations of WNV:
 - Asymptomatic: Most common
 - Self-limited febrile illness: 67% of symptomatic cases
 - Neuroinvasive disease: Aseptic meningitis, encephalitis, or flaccid paralysis—<1% cases

DIAGNOSIS

HISTORY

- The diagnosis of arboviral infections of the CNS is difficult.
- Characteristic epidemiology that suggests a specific etiology is an important part of the history.
- The season of disease, prevalent diseases within the community, and animal exposures may provide clues to the diagnosis:
 - Enteroviral infections are seen in the warmer months (summer and early fall) in temperate climates.
 - Mosquito propagation in damp climates or standing water during the summer months may increase the likelihood of arthropod-borne viruses.
 - History of an animal bite or bat exposure may suggest the possibility of rabies.
- WNV (symptomatic infection) is characterized by sudden onset of fever, headache, myalgias, muscle weakness, and GI symptoms (nausea, vomiting, or diarrhea).
- Neuroinvasive WNV can be characterized by neck stiffness and headache, mental status changes, movement disorders, or flaccid paralysis.

PHYSICAL EXAM

- Encephalitis caused by arboviruses is characterized by acute onset of fever and headache in almost all patients. Associated symptoms may include seizures, altered consciousness, disorientation, and behavioral disturbances. Neurologic signs are more commonly diffuse, but may be focal. These clinical findings can help to distinguish patients with meningitis, which is characterized by nuchal rigidity and fever usually without an altered sensorium.
- Other signs possibly observed in WNV infection:
 - A rash is seen in ~50% of patients and is described as nonpruritic, roseolar, or maculopapular on the chest, back, and arms, which lasts 1 week.
 - Diffuse lymphadenopathy is also common.
- Neurologic examination in WNV infection may reveal motor weakness or flaccid paralysis, increased deep tendon reflexes and extensor plantar responses, and tremor or abnormal movement of extremities

DIAGNOSTIC TESTS & INTERPRETATION

The diagnosis of arboviral encephalitis depends on the recognition of epidemiologic risk factors and typical signs and symptoms with the aid of laboratory and radiographic studies.

Lab

- Routine laboratory tests:
 - CBC typically reveals a mild leukocytosis.
 - Mild increase in ESR rate
 - Mild to moderate CSF pleocytosis, predominately mononuclear cells
 - Elevated CSF protein
 - Normal CSF glucose

- Serology:
 - IgM and IgG ELISA or IFA for WNV and other arboviruses are performed at state public health laboratories and the CDC.
 - The diagnosis of arbovirus encephalitis is made by 1 of the following:
 - Detection of virus-specific IgM antibodies in the CSF is confirmatory.
 - A 4-fold rise in serum antibody titers is confirmatory. Acute-phase titers should be collected 0–8 days after onset of symptoms. Convalescent phase titers should be collected 14–21 days after acute specimen. A single negative acute-phase specimen is inadequate for diagnosis, but a positive test can provide evidence of recent infection.
 - Isolation of the virus from tissue, blood, or CSF
 - Polymerase chain reaction (PCR) to detect viral RNA

Imaging

- Imaging studies such as MRI or CT can assist in ruling out other potential causes of encephalopathy or encephalitis.
- MRI has proved useful in differentiating postinfectious encephalomyelitis from acute viral encephalitis. The former is characterized by enhancement of multifocal white matter lesions.

Diagnostic Procedures/Other

EEG:

- Diffuse generalized slowing of brain waves
- Periodic high-voltage spike waves originating in the temporal lobe region and slow-wave complexes at 2–3-second intervals are suggestive of herpes simplex virus infection.

DIFFERENTIAL DIAGNOSIS

Infectious:

- Viral:
 - Herpes simplex virus
 - Enterovirus
 - HIV
 - HHV-6
 - Epstein-Barr virus
 - Cytomegalovirus
 - Lymphocytic choriomeningitis virus
 - Rabies
 - Mumps
 - Influenza
 - Adenovirus
- Nonviral:
 - Cat-scratch disease (*Bartonella henselae*)
 - *Mycoplasma pneumoniae*
 - Postinfectious encephalomyelitis: Generally follows a vague viral syndrome, usually upper respiratory tract, by days to weeks
 - Abscess/subdural empyema

- Meningitis:
 - Tuberculous
 - Cryptococcal or other fungal (histoplasmosis, coccidioidomycoses, blastomycoses)
 - Bacterial
 - Listeria
 - Toxoplasmosis
 - *Plasmodium falciparum* infection (malaria)
 - Parasites (cysticercosis, echinococcus, amebiasis, trypanosomiasis)
- Noninfectious: Tumor, carcinomatous meningitis, systemic lupus erythematosus, sarcoidosis, vasculitis, hemorrhage, toxic encephalopathy, metabolic disorders

TREATMENT

ADDITIONAL TREATMENT

General Measures

- No specific antiviral therapy is available.
- Supportive therapy including cardiorespiratory function, fluid and electrolyte balance, seizure control, and reduction of intracranial pressure is important.
- Consider IVIG and plasmapheresis for associated GBS.
- Recovery can be seen after prolonged periods of coma.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Neurobehavioral follow-up should be considered in children with severe or complicated disease.
- If WNV is diagnosed during pregnancy detailed fetal US should be considered 2–4 weeks after illness onset with evaluation for congenital anomalies and neurologic deficits.
- Infant serum should be tested for WNV IgM at birth and 6 months with IgG at 6 months.

PROGNOSIS

- Prognosis for recovery depends on the specific infecting agent and host factors such as age and underlying illness.
- Eastern equine and Japanese encephalitis have the worst prognoses, with mortality occurring in 30% of cases.

COMPLICATIONS

- Optic neuritis
- Seizures
- Coma
- Death
- Guillain-Barré syndrome
- Severe neurologic sequelae
- Myocarditis
- Pancreatitis
- Hepatitis

CODES

ICD9

- 062.2 Eastern equine encephalitis
- 064 Viral encephalitis transmitted by other and unspecified arthropods
- 066.40 West Nile Fever, unspecified

ICD10

- A83.2 Eastern equine encephalitis
- A85.2 Arthropod-borne viral encephalitis, unspecified
- A93.8 Other specified arthropod-borne viral fevers

FAQ

- Q: Should testing for arboviruses, including WNV, be performed on all patients with encephalitis?
- A: Diagnostic testing for arboviruses is not recommended for all patients with encephalitis. The prevalence of these diseases is low, and the diagnosis of more common causes of childhood encephalitis (e.g., herpes simplex virus) should be pursued initially. Patients with no other identifiable cause of encephalitis who have epidemiologic risk factors such as geographic location, season, and exposure history suggestive of arbovirus encephalitis should be evaluated. Testing of patients with aseptic meningitis or Guillain-Barré syndrome is low yield.

WHEEZING

Samuel Goldfarb

Lee Brooks

BASICS

DEFINITION

Wheezing is a continuous sound that is caused by turbulent airflow through an obstructed airway.

- Often described as musical in nature and with a variable pitch
- Wheezing is an expiratory sound; stridor is an inspiratory sound.
- Wheezing occurs from obstruction in the intrathoracic airway, whereas stridor is caused by an obstruction in the extrathoracic airway.
- If heard in both inspiration and expiration, there is a fixed obstruction or separate lesions in both the intrathoracic and extrathoracic airways.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Extrathoracic (usually results in stridor rather than wheezing):

- **Nasal/nasopharynx**
 - Acute: Nasal turbinate edema or secretions, foreign body
 - Chronic: Adenoidal enlargement, nasal polyps, choanal stenosis, midface hypoplasia
- **Oropharynx**
 - Acute: Peritonsillar abscess, retropharyngeal abscess, palatine tonsillitis
 - Chronic: Adenotonsillar hypertrophy, macroglossia, micrognathia
- **Hypopharynx**
 - Acute: Acute nasal, nasopharyngeal, or oropharyngeal obstruction
 - Chronic: Hypopharyngeal hypotonia, glossoptosis, obesity, neoplasia
- **Larynx**
 - Acute: Laryngospasm, laryngotracheobronchitis (croup), epiglottitis, foreign body (large and irregular)
 - Chronic: Laryngomalacia, papillomatosis, hemangioma, granuloma, congenital cyst or web, laryngocele
- **Glottis**
 - Acute: Vocal cord paralysis or paresis, vocal cord inflammation or polyp, psychogenic wheezing
 - Chronic: Paradoxical vocal cord motion (vocal cord dysfunction), psychogenic wheezing, brainstem compression, injury to the vagus, glossopharyngeal or recurrent laryngeal nerves, papillomatosis
- **Subglottis/extrathoracic trachea**
 - Acute: Laryngotracheobronchitis (croup), bacterial, rachitic, recent endotracheal extubation
 - Chronic: Subglottic stenosis (congenital or after prolonged intubation), papillomatosis

Intrathoracic:

- **Trachea (extrinsic compression)**
 - Acute: Uncommon
 - Chronic:
 - Vascular: Vascular ring/sling, compression by an aberrant pulmonary artery
 - Cardiac: Left main bronchus compression, recurrent laryngeal nerve compression “cardiovascular syndrome”
 - Anterior mediastinum
 - Lymphoma, thymoma, teratoma
 - Middle mediastinum: Lymphoma, lymphadenopathy (tuberculosis, mycotic infection, sarcoidosis)
 - Posterior mediastinum: Neurogenic tumors, esophageal duplication or cyst, bronchogenic cyst
 - **Trachea (intramural lesions)**
 - Acute: Uncommon
 - Chronic: Tracheomalacia
 - Congenital: Cartilaginous defect (Campbell–Williams syndrome), muscular defect (Mounier–Kuhn syndrome), s/p tracheoesophageal fistula repair, external compression/distortion, complete tracheal rings
 - Acquired: Chronic inflammation (recurrent infection, gastroesophageal reflux, recurrent aspiration), prolonged positive pressure ventilation, external compression
 - **Trachea (intraluminal lesions)**
 - Acute: Foreign body (irregularly shaped and elongated), bacterial tracheitis (with chronic tracheostomy tube usage)
 - Chronic: Tracheal granulomas, hemangioma, papillomatosis, tracheal web
 - **Bronchi/bronchioles**
 - Acute: Viral bronchiolitis, bronchopneumonia, foreign body (small, smooth shape), granuloma, neoplasia
 - Chronic: Asthma, bronchopulmonary dysplasia, bronchomalacia, carcinoid, adenoma
- ### APPROACH TO THE PATIENT
- **Phase 1:** Determine the severity of the patient’s general status and degree of respiratory distress and triage accordingly
 - **Phase 2:** Construct a differential diagnosis
 - **Phase 3:** Initiate appropriate therapies
- ### HISTORY
- **Question:** Pattern of the wheezing?
 - **Significance:**
 - A rapid onset suggests a foreign body or a postexposure exacerbation of asthma.
 - A slow onset suggests an infection.
 - Periods of recurrent wheezing suggest asthma.
 - Nocturnal and early morning wheezing or coughing are consistent with gastroesophageal reflux, sinusitis, and/or sensitivity to common bedroom allergens.
 - Wheezing in association with or soon after a meal can be seen in swallowing dysfunction, gastroesophageal reflux, or, less commonly, tracheoesophageal fistula.
 - Wheezing that worsens with crying is suggestive of tracheomalacia and/or bronchomalacia or a fixed intraluminal or extraluminal obstruction.

- **Question:** Wheezing correlated with exertion?
- **Significance:** Suggests asthma triggered by exercise
- **Question:** Multiple exacerbations with recurrent or chronic symptoms?
- **Significance:**
 - Recurrent cycles of exacerbations, with clearing in between, suggest a process such as asthma, cystic fibrosis, ciliary dyskinesia, and bronchopulmonary dysplasia.
 - Chronic or persistent wheezing is more common with fixed anatomic abnormalities.
- **Question:** Common triggers?
- **Significance:** Could be:
 - Smoke
 - Dust
 - Animal dander
 - Change in humidity or temperature
 - Change in seasons (pollens, grasses, molds)
 - Exercise
 - Infections (usually viral)
 - Inflammation of any sort
 - meals (aspiration, GERD, TEF)
- **Question:** Family history?
- **Significance:** A family history of wheezing, asthma, allergic rhinitis, or atopy suggests a diagnosis of asthma.
- **Question:** An episode of choking preceding the first onset of wheezing?
- **Significance:** Suggests foreign body aspiration

PHYSICAL EXAM

- **Finding:** Patient’s degree of respiratory difficulty?
- **Significance:**
 - Tachypnea
 - Accessory muscle usage—use of intercostal and sternocleidomastoid muscles and abdominal musculature indicates increased expiratory effort to overcome airway obstruction.
 - Nasal flaring—with increasing respiratory difficulty, the nares will be dilated to decrease the resistance to air flow.
- **Finding:** Auscultate—assess airflow, adventitious sounds, and the inspiratory-to-expiratory ratio
- **Significance:**
 - Aeration: Decreased aeration is much worse prognostically than wheezing since it is directly related to the amount of aeration and ventilation. With decreased aeration, wheezing may not be audible.
 - Ratio of inspiration to exhalation: With increased intrathoracic airway obstruction, the time needed to exhale will become greater because of a greater decrease in airway caliber during exhalation. Normal ratio is 1:3.
- **Finding:** Presence of nasal crease, the “allergic salute” (i.e., rubbing the nose with the palm of the hand), atopic dermatitis, boggy nasal turbinates, clear postnasal drainage, allergic shiners, or Dennie lines?
- **Significance:** Suggestive of allergic rhinitis or atopic disease including asthma

- **Finding:** Patients with first-time, persistent, or atypical episodes of wheezing?
- **Significance:** “All that wheezes is not asthma”: Although most episodes of wheezing will represent viral infections or asthma, clinicians need to be mindful of alternative diagnoses.
- **Finding:** The 3 R’s of asthma?
- **Significance:**
 - Recurrence: Symptoms that recur multiple times with full resolution in between episodes
 - Reactivity: Symptoms that can be triggered during exposures (temperature extremes, smoke, dust, humid or dry air, aromas, etc.)
 - Reversibility: Symptoms that resolve with bronchodilator therapy

DIAGNOSTIC TESTS & INTERPRETATION

- **Test:** Bronchodilator responsiveness
- **Significance:**
 - A postbronchodilator improvement in wheezing indicates a reversible process such as asthma.
 - A bronchodilator may worsen wheezing in disorders of airway wall rigidity such as bronchomalacia or tracheomalacia.
 - There may be no change following a bronchodilator in situations with foreign bodies, fixed airway obstruction due to significant inflammation (i.e., status asthmaticus) or airway remodeling.
- **Test:** Pulmonary function testing (spirometry)
- **Significance:**
 - Spirometry remains the standard and most helpful measure of pulmonary function.
 - Normative data have been described in children > 6 years of age.
 - Methacholine challenge test is a provocative test to evaluate for asthma.
 - Exercise test with spirometry to evaluate for exercise-induced asthma
- **Test:** Pulse oximetry measurement of oxygen saturation (SpO₂)
- **Significance:** Pulse oximetry is an insensitive measure of mild-to-moderate respiratory difficulty during wheezing, but oxyhemoglobin saturation < 92% may be seen in severe compromise.
- **Test:** Arterial blood gas
- **Significance:**
 - Arterial blood gases provide a direct measure of oxygenation (PaO₂) and ventilation (PaCO₂) and can also help to determine severity.
 - A normal or high normal PaCO₂ in a tachypneic patient (when it should be low) may be a sign of impending respiratory failure.

Lab

- **Test:** Microbiologic studies
- **Significance:**
 - Positive bacterial culture of sputum is helpful in directing or focusing antibiotic therapy. A Gram stain showing sheets of polymorphonuclear leukocytes and predominant organism is helpful to differentiate a potentially causative organism from the multitude of normal flora.
 - Positive respiratory virus screen or culture (often within 12 hours) can prevent needless antibiotic therapy and may be helpful in predicting future disease.

- **Test:** Tuberculosis skin test
- **Significance:** Mantoux purified protein derivative—tuberculosis
- **Test:** CBC including eosinophil count, quantitative immunoglobulins, IgE, complement, HIV testing, allergy skin testing

Imaging

Chest radiography (posteroanterior and lateral views): Should be strongly considered in all patients with new-onset wheezing or an asymmetric lung exam. Can show findings suggestive of airway obstruction (hyperinflation, hyperlucency, flattening of the diaphragms). Asymmetry in aeration on right and left lateral decubitus films suggests foreign body or other obstructing lesions on the side having the greatest air trapping.

TREATMENT

ADDITIONAL TREATMENT

General Measures

- A trial of bronchodilator therapy (e.g., albuterol) may be both therapeutic and diagnostic of the reversible airway obstruction characteristic of asthma.
- For acute asthma exacerbation—corticosteroids PO or IV
- Ipratropium bromide may be helpful in reducing airway secretions and reducing airway obstruction, but it is not FDA approved for treatment of asthma.
- Inhaled corticosteroids, antileukotriene agents, and less frequently methylxanthines (aminophylline and theophylline) are used as maintenance medications.
- Antibiotics should be used in patients with suspected pneumonia.
- In emergency setting epinephrine, terbutaline, and magnesium sulfate can be used along with supportive care such as supplemental oxygen.

ALERT

Factors that may indicate a respiratory emergency:

- Signs of mild-to-moderate respiratory difficulty: Tachypnea, intercostal and suprasternal retractions, nasal flaring, head bobbing and exaggerated shoulder movement during breathing, abdominal breathing and subcostal retractions, relative difficulty speaking in complete sentences, significant wheezing, prolonged exhalation, and low PaCO₂ in the face of tachypnea
- Signs of impending respiratory failure: Cyanosis, fatigue, inability to speak in > 1- or 2-word phrases, altered mental status (e.g., confusion, agitation), decreased respiratory drive, inadequate ventilation (poor air flow), no audible wheezing, high normal or rising PaCO₂ in the face of tachypnea or respiratory distress
- Determine which patients require assisted ventilation (e.g., bag-mask ventilation, noninvasive [nasal] ventilation, or endotracheal intubation)
- Lack of response to aggressive bronchodilator therapy, without a history of asthma or recurrent wheeze, or biphasic adventitious sounds should immediately raise the suspicion of a fixed lesion.

CODES

ICD9

786.07 Wheezing

ICD10

R06.2 Wheezing

FAQ

- Q: What percent of recurrent wheezing resolves by school age?
- A: Roughly 40% of children with ≥ 1 episodes of wheezing before 3 years clear by 6 years of age.
- Q: Should chest radiographs be routinely obtained in children experiencing their first episodes of wheezing?
- A: For a child with new-onset asymmetric wheezing, a chest radiograph should be obtained. For a child with symmetric wheezing, chest radiography may not be helpful and should be ordered judiciously.

WILMS TUMOR

David T. Teachey

BASICS

DESCRIPTION

Wilms tumor is a malignant tumor of the kidney occurring in the pediatric age group. It is also called nephroblastoma.

EPIDEMIOLOGY

More common in girls than boys

Incidence

- 1 in 10,000 live births
- Increased incidence in children with neurofibromatosis

Prevalence

- Most common primary malignant renal tumor of childhood
- 5–6% of all childhood cancer

RISK FACTORS

Genetics

- 15–20% are presumed hereditary
- Familial cases are more often bilateral and occur at an earlier age.
- Associated with WAGR syndrome, Beckwith–Wiedemann syndrome, and Denys–Drash syndrome
- A tumor-suppressor gene related to Wilms tumor (*WT1*) has been localized to chromosome 11p13. Mutations in this gene occur in ~20% of Wilms tumors.
- Another tumor suppressor gene *WT2* (IGF2, H19, p57) has been localized on 11p15.

ETIOLOGY

- 20% of Wilms tumors have a mutation in the *WT1* tumor suppressor gene.
- Causes in the remaining 80% of patients are unknown.

COMMONLY ASSOCIATED CONDITIONS

- 12–15% of patients have other congenital anomalies
- May be associated with aniridia, hemihypertrophy, and cryptorchidism
- Associated syndromes: WAGR (Wilms tumor, aniridia, genitourinary [GU] abnormalities, mental retardation), Beckwith–Wiedemann syndrome (macroglossia, omphalocele, visceromegaly, hemihypertrophy), and Denys–Drash syndrome (ambiguous genitalia, progressive renal failure, and increased risk of Wilms tumor)

DIAGNOSIS

HISTORY

- Abdominal distention
- Abdominal pain (20–30% of cases)
- Hematuria (20–30% of cases)
- Fever, anorexia, vomiting
- Family history of Wilms tumor
- Rapid increase in abdominal size (suggestive of hemorrhage in the tumor)

PHYSICAL EXAM

- Asymptomatic abdominal mass extending from flank toward midline (most common presentation)
- Anemia (secondary to hemorrhage in the tumor)
- Fever
- Hypertension (owing to increased renin production in 25% of cases)
- Varicocele (indicates obstruction to spermatic vein owing to tumor thrombus in renal vein or inferior vena cava)
- Aniridia, hemihypertrophy, cryptorchidism, hypospadias
- Signs of Beckwith–Wiedemann and neurofibromatosis

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- CBC
- Electrolytes
- Urine analysis: For microscopic hematuria
- Liver and kidney function tests
- Coagulation factors

Imaging

- Ultrasound of abdomen:
 - Diagnostic of mass of renal origin
 - Evaluate for extension of tumor into inferior vena cava.
- CT scan of abdomen, chest radiograph, and chest CT: To evaluate for metastatic disease
- Bone scan: Only if clear cell sarcoma, renal cell carcinoma, or rhabdoid tumor on pathology
- MRI of head: Only for clear cell sarcoma and rhabdoid tumors
- EKG and echocardiogram in patients that will receive anthracycline chemotherapy

Pathological Findings

- Gross pathology:
 - Often cystic with hemorrhages and necrosis
 - Usually no calcification (useful in differentiating from neuroblastoma, which is calcified on plain radiograph)
 - May extend into the inferior vena cava
- Histology:
 - Triphasic pattern blastemal, epithelial, and stromal cell
 - Blastemal cells aggregate into nodules like primitive glomeruli; the presence of diffuse anaplasia indicates a poor prognosis.
- Clinicopathologic staging:
 - Stage I: Tumor is restricted to one kidney and completely resected. The renal capsule is intact.
 - Stage II: Tumor extends beyond the kidney, but is completely excised.
 - Stage III: Residual nonhematogenous tumor is confined to the abdomen.
 - Stage IV: There is hematogenous spread to lungs, liver, bone, or brain.
 - Stage V: Bilateral disease

DIFFERENTIAL DIAGNOSIS

- Polycystic kidney
- Renal hematoma
- Renal abscess
- Neuroblastoma
- Other neoplasms of kidney: Clear-cell carcinoma, rhabdoid tumor

ALERT

Rarely, Wilms tumor may present with polycythemia. It can present as fever of unknown origin without any other signs or symptoms.

TREATMENT

SPECIAL THERAPY

Radiotherapy

- Not required for stage I and II patients unless anaplastic, clear cell, or rhabdoid
- Radiotherapy to tumor bed with 1,080 cGy for stages III and IV. If gross tumor spillage or peritoneal seeding, treat whole abdomen
- Whole-lung radiation (1,200 cGy) for pulmonary metastasis

MEDICATION (DRUGS)

- Chemotherapy:
 - For stages I and II favorable histology: Vincristine and actinomycin D every 3 weeks for 6 months
 - For stages III and IV favorable histology, stage I–III focal anaplasia, and stage I diffuse anaplasia: Vincristine, actinomycin D, and doxorubicin for 6–15 months
 - Add cyclophosphamide and/or etoposide for higher-stage anaplastic tumors (stage IV focal or II–IV diffuse).
- Side effects of therapy:
 - Temporary loss of hair
 - Peripheral neuropathy
 - Impaired function of the remaining kidney over years following radiation
 - Cardiac toxicity with doxorubicin
 - Second malignant neoplasms in few cases

SURGERY/OTHER PROCEDURES

- Nephrectomy:
 - Preoperative chemotherapy in case of very large tumors with inferior vena cava extension
 - For bilateral disease, nephrectomy of more affected side and partial nephrectomy of the other side, followed by chemotherapy and radiation

ONGOING CARE

PROGNOSIS

- Stages I and II: >90% cured
- Stage III: 85% cured
- Stage IV: 70% cured
- Favorable prognostic factors:
 - Tumor weight <250 g
 - Age at presentation <24 months
 - Stage I disease
 - Favorable histology
- Poor prognostic factors:
 - Diffuse anaplastic pathology
 - Clear cell sarcoma variant
 - Rhabdoid tumor variant
 - Lymph node involvement
 - Distant metastasis
 - Tumors with loss of heterozygosity (LOH) of chromosomes 1p and/or 16q

COMPLICATIONS

- Extension into inferior vena cava
- Metastasis to lungs and liver
- Cardiac toxicity secondary to doxorubicin
- Liver dysfunction secondary to actinomycin D and radiation therapy

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Every 3 months for 18 months, every 6 months for 1 year, and then yearly
- Chest radiograph, urinalysis, and abdominal ultrasound at regular intervals

CODES

ICD9

189.0 Malignant neoplasm of kidney, except pelvis

ICD10

- C64.1 Malignant neoplasm of right kidney, except renal pelvis
- C64.2 Malignant neoplasm of left kidney, except renal pelvis
- C64.9 Malignant neoplasm of unsp kidney, except renal pelvis

FAQ

- Q: What should be done to protect the remaining kidney during sports?
- A: Children should wear a kidney guard to protect the unaffected kidney during contact sports.
- Q: Can a child grow and live normally with 1 kidney?
- A: Yes.

WILSON DISEASE

Waqar Waheed

Molly E. Rideout (5th edition)

BASICS

DESCRIPTION

Wilson disease (WD), also known as hepatolenticular degeneration, is an autosomal recessive disorder of copper metabolism affecting the liver and brain.

EPIDEMIOLOGY

Children usually present with hepatic manifestations; adolescents and young adults may present with neurologic symptoms.

Incidence

- Incidence is 15–25 per million.
- Worldwide carrier rate is 1:100.

Prevalence

- Prevalence is 1:30,000.
- Most cases present between ages 5 and 35.
- Worldwide distribution

RISK FACTORS

Genetics

- Autosomal recessive inheritance with 1 of >200 known defects of the WD gene (ATP7B) on chromosome 13q14.3 membrane (ATPase)
- The affected protein facilitates biliary excretion of excess copper; incorporates copper into apo-ceruloplasmin for transport
- Heterozygotes are generally asymptomatic.
- Future siblings have 25% risk of disease.
- Direct mutational analysis is limited owing to the high number of mutations, except in isolated populations.

PATHOPHYSIOLOGY

- Loss of ATP7b function causes impaired biliary copper excretion (the only route for elimination of copper) and ceruloplasmin biosynthesis.
- Copper accumulates 1st in the liver, leading to cirrhosis.
- After liver is saturated, copper overflows and settles in the brain and other tissues.
- In the brain, copper collects primarily in the basal ganglia, leading to impaired motor control.
- Other tissues affected by copper accumulation are kidneys, heart, blood, and cornea.
- Failure to incorporate copper during ceruloplasmin biosynthesis produces an apoprotein that is rapidly degraded.

COMMONLY ASSOCIATED CONDITIONS

- Renal: Copper accumulation leads to Fanconi syndrome with tubular dysfunction, causing glycosuria, hypophosphatemia, and low uric acid.
- Hematologic: Hemolytic anemia, coagulopathy from liver failure
- Cardiac: Cardiomyopathy/dysrhythmias develop from copper deposits.

DIAGNOSIS

HISTORY

- Hepatic:
 - In children, symptoms of hepatic disease predominate, ranging in severity from asymptomatic hepatomegaly or elevated transaminases to chronic hepatitis to fulminant hepatic failure.
 - Average age for onset of hepatic symptoms ~10 years
 - Fulminant liver failure is associated with hemolysis and coagulopathy unresponsive to vitamin K
- Neurologic:
 - Neurologic symptoms are rare before age 10 years.
 - Neurologic signs in children: Behavior change, decline in school performance, poor hand–eye coordination, motor abnormalities—dystonia, tremors, dysphagia, dysarthria
- Psychiatric: Develop depression, anxiety, psychosis, and/or obsessive–compulsive disorder.
- Other: Nonspecific complaints are common—abdominal pain, nausea, anorexia, and fatigue.
- Signs and symptoms:
 - 45% of all patients present with liver disease, 35% with neurologic symptoms, 10% psychiatric
 - Remaining 10%: Hemolytic anemia, jaundice, cardiomyopathy, other
 - Consider WD in all cases of liver abnormality in which viral and autoimmune causes have been excluded.
 - WD accounts for 8–10% of all chronic active hepatitis in children.
 - Also consider WD in patients with unexplained neuropsychiatric symptoms.

PHYSICAL EXAM

- Ophthalmologic:
 - Kayser-Fleischer (KF) rings: Copper deposits on Descemet membrane of cornea (at limbus)
 - May require slit-lamp examination to see
 - 95% with neurologic signs have KF rings
 - 50–65% with hepatic presentation have KF rings
 - KF rings not pathognomonic for WD; may be seen in cholestatic liver disease
- Cardiovascular: Signs of cardiomyopathy, dysrhythmia, congestive heart failure
- Abdominal:
 - Hepatomegaly, ascites
 - Splenomegaly from portal hypertension
- Skin:
 - Jaundice due to hemolysis
 - Bleeding diathesis from liver disease
 - Edema
- Neurologic:
 - Movement disorders
 - Neurologic deficits

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Serum ceruloplasmin:
 - Low sensitivity and specificity
 - Level is usually low; however, up to 1/3 of patients have normal values.
 - An acute-phase reactant; during inflammation, infection, or trauma, level may increase to reference range.
 - Made mostly in the liver, it is the major carrier of copper in blood.
 - Very low (<50 mg/L): Strong evidence for WD
 - Low (<200 mg/L) plus symptoms and KF rings: Diagnostic of WD
 - Ceruloplasmin levels also low in renal or GI protein loss, Menkes disease, and end-stage liver disease
- Serum copper:
 - Low total serum copper (<80 mcg/dL) in WD
 - Level is decreased in proportion to decreased ceruloplasmin in circulation.
 - In acute fulminant liver failure, serum copper is increased owing to sudden release of stores (most is not bound to ceruloplasmin).
- Urinary copper excretion:
 - Reflects unbound copper in blood
 - Level is high in WD: >100 mcg/24 hours in symptomatic patient is diagnostic.
 - In equivocal cases, marked increase in urinary copper output after initiation of chelation therapy may help in diagnosis.
- Other:
 - Mild to moderate elevations of serum aminotransferase levels
 - Mutational analysis: useful for screening, if familial mutation is known

Imaging

- Abdominal ultrasound for liver size and pathology
- MRI of the brain with focus on basal ganglia should be obtained prior to initiation of therapy.
- “Face of the giant panda” sign that is characteristic of Wilson disease (red nuclei, substantia nigra, tegmentum)

Diagnostic Procedures/Other

- Liver biopsy is the definitive procedure for tissue diagnosis and hepatic disease staging.
- Biopsy should be obtained when diagnosis is not straightforward and in younger patients.
- Hepatic parenchymal copper concentration >250 mcg/g dry weight
- Hepatic copper level <50 mcg/g dry weight excludes WD.

DIFFERENTIAL DIAGNOSIS

- Liver disease:
 - Viral hepatitis
 - Autoimmune hepatitis/primary biliary cirrhosis
 - Menkes disease
 - Cholestatic disease from parenteral nutrition

- Neurologic disease:
 - Essential tremor
 - Sydenham or Huntington chorea
 - Hereditary dystonia
 - Other neurodegenerative diseases
- Psychiatric disease: Depression, psychoses
- KF rings: Seen in other causes cholestatic liver disease
- Low ceruloplasmin:
 - End-stage liver disease
 - Menkes disease
- Protein loss from GI or renal abnormalities

TREATMENT

Early diagnosis is essential to limiting morbidity and mortality.

MEDICATION (DRUGS)

- **Penicillamine**
 - Mode of action (MOA):
 - Chelates copper and promotes renal excretion
 - Also induces metallothionein, interferes with collagen cross-linking, immunosuppressant
 - Improvement takes up to a year.
 - Dosages:
 - Initial dose: 1–1.5 g/d, b.i.d. or q.i.d., 1 or 2 hours after food
 - May start at a lower dose (250–500 mg/d) with gradual escalation over a few weeks.
 - Maintenance dose: 0.5–1 g/d
 - Fulminant liver failure if discontinued abruptly
 - Acute neurologic deterioration after initiation of therapy in up to 20%: Reduce dose to 250 mg/d
 - Side effects in 20–30%:
 - Pyridoxine deficiency, manifested by intercurrent infection or a growth spurt. B₆ supplementation 50 mg/wk
 - Skin complications due to interference with collagen and elastin formation
 - Hypersensitivity reactions (rash, fever, lymphadenopathy), bone marrow suppression, myasthenia gravis, optic neuritis, nephritis, lupuslike syndrome
 - Monitoring: CBC, liver function tests (LFTs), urinalysis, urine copper
- **Trientine**
 - Has become initial drug of choice
 - Used in combination with zinc
 - Chelates copper/promotes renal excretion
 - Dosages: Pediatric dose 20 mg/kg/d divided b.i.d.–t.i.d. to maximum of 750–1,000 mg/d
 - Maintenance therapy: 900–1,200 mg/d b.i.d. or t.i.d., empty stomach
 - Fewer side effects than penicillamine
 - Most improve with continued treatment.
 - Risk of sideroblastic anemia, hemorrhagic gastritis, nephritis, arthritis, worsened neurologic signs
 - Serum copper increases during treatment.
 - Also chelates iron, creating toxic complex; do not give supplemental Fe.
- **Zinc**
 - Routinely combined with trientine
 - Also used alone as maintenance therapy
 - Used successfully in asymptomatic or presymptomatic affected family members of individuals with Wilson disease

- MOA:
 - Interferes with absorption from GI tract by inducing metallothionein in enterocytes, which chelates metals. The copper is bound within the enterocyte and not absorbed into the portal circulation. It is shed in stool as enterocytes are normally shed.
 - Also induces copper binding metallothionein in the liver, thereby reducing the damaging effects of free copper
- Dosage: 50 mg t.i.d., empty stomach
- Side effects:
 - Few side effects: Gastric irritation, nausea (ameliorated by taking with meat [but no carbohydrates] or change the formulation to acetate, sulphate, or gluconate)
 - Take without food, except as above
 - After chelation for 4–6 months, with normal labs, usually OK to change to zinc for maintenance
 - May create a negative copper balance, removing all extra copper stores, resulting in improvement of hepatic and brain function, and loss of KF rings
 - Overtreatment may result in anemia or decreased wound healing from copper deficiency
 - No altered dose needed for surgery
 - Compliance with overall therapy monitored by urine zinc levels
- **Ammonium tetra-tiomolibdate**
 - Not FDA approved, limited data
 - Complex with copper in the intestinal tract, preventing absorption
 - Absorbed drugs form a complex with copper and albumin in blood. This complex is metabolized by liver and excreted in bile.
 - Particularly suited for treatment of neurologic manifestation in Wilson disease, as it is not associated with exacerbation on initiation of treatment.
 - S/E: Bone marrow suppression, ↑ aminotransferases
- **Antioxidants and experimental therapies**
 - Antioxidants (vitamin E/N-acetylcysteine) may protect against oxidative damage.

ADDITIONAL TREATMENT

General Measures

- Immunize for hepatitis A, B.
- Avoid excess alcohol.
- Well water or water via copper pipes needs to be tested: If >0.1 ppm Cu, find alternative source.

Additional Therapies

Patients with fulminant liver failure require liver transplant to survive.

SURGERY/OTHER PROCEDURES

- Orthotopic liver transplant required for fulminant liver failure or end-stage liver cirrhosis, which is resistant to chelation therapy.
- Uncertain indication for therapy-resistant neurologic symptoms. Several case reports suggest improved neurologic symptoms after transplantation.
- 5% with WD need liver transplants.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Patients require lifelong dietary copper restriction and chelation therapy.
- Continual monitoring for compliance and side effects of medications is crucial.
- Sudden discontinuation of therapy may precipitate fulminant hepatic failure.
- 1st-degree relatives >age 3 years should be screened with history, physical exam, LFTs, CBC, serum ceruloplasmin, 24-hour urine copper, and ophthalmologic examination for KF rings.
- Reproductive and genetic counseling for carriers should be offered. Prenatal testing

DIET

Low-copper diet for life: Avoid liver and other organ meats, shellfish, nuts, mushrooms, and chocolate.

PROGNOSIS

- If WD is recognized early and treated, most patients experience complete recovery.
- Progression to hepatocellular carcinoma is rare, unlike hemochromatosis.

FAQ

- Q: Are medications for WD safe during pregnancy?
- A: Women of reproductive age who are treated can have normal pregnancies. Doses of both trientine and penicillamine should be reduced during pregnancy, especially in the 3rd trimester, to promote wound healing in the case of a surgical delivery. Zinc doses can remain unchanged. Interruption of therapy is not recommended during pregnancy.

WISKOTT-ALDRICH SYNDROME

Elena Elizabeth Perez

BASICS

DESCRIPTION

- An X-linked primary immunodeficiency caused by a mutation in the WAS gene, and originally described as clinical triad of thrombocytopenia with small platelets, eczema, and recurrent infections with opportunistic and pyogenic organisms
- Also associated with IgA nephropathy, autoimmune disorders, and an increased incidence of B-cell lymphomas. Increased bleeding tendency secondary to thrombocytopenia likely results from impaired platelet production, increased turnover, and defective function.
- Disease variants also resulting from WAS gene mutations include X-linked thrombocytopenia (XLT) and X-linked neutropenia (XLN). Classic WAS is characterized by broad immunodeficiency, decreased number and function of T cells, disturbed marginal B-cell homeostasis, and skewed immunoglobulin isotypes, with defective antibody responses to vaccinations, impaired NK-cell cytotoxicity, and abnormal regulatory T-cell function as well as reduced phagocyte chemotaxis.

EPIDEMIOLOGY

- Presents in infancy with serious bleeding episodes secondary to thrombocytopenia (such as circumcision with increased bleeding, bloody diarrhea, ecchymoses)
- Recurrent infections usually start after 6 months of age:
 - Bacterial: Otitis media, sinusitis, meningitis, sepsis, and pneumonia
 - Viral infections: Herpes simplex virus, varicella with systemic complications
- Milder phenotypes may lack history of recurrent infections.
- Decline in T- and B-cell numbers with time
- Eczema is usually present by 1 year of age (may be resistant to therapy, sometimes requiring systemic antibiotics).

Incidence

- For WAS/XLT estimate is 10 in 1 million live births.
- Prevalence of XLT equal to WAS

RISK FACTORS

Genetics

- X-linked recessive disease
- Defective Wiskott-Aldrich syndrome protein gene located on X p11.22p–11.23
- ~60% of cases will have a positive family history for Wiskott-Aldrich syndrome.
- X-linked thrombocytopenia without the other findings is caused by mutations of the same gene.
- Genotype/phenotype correlation:
 - Lack of WASP expression: Increased infections, severe eczema, intestinal hemorrhage, death from intracranial bleeding, and malignancies
 - Survival rate significantly lower in WASP-negative patients

ETIOLOGY

- Mutations in the gene for the Wiskott-Aldrich syndrome protein (WAS)
- WAS protein (WASP) is involved in the reorganization of the actin cytoskeleton in hematopoietic cells:
 - Following activation of WASP, reorganization of actin cytoskeleton results in polarization of cells (e.g., polarized actin mesh in platelets for clotting and in macrophages for phagocytosis, and polarization of T or B cells to form immunologic synapses).
- WAS protein (WASP) is a cytoplasmic protein involved in cell mobility, immune regulation, cell signaling, cell-to-cell interactions, signaling, and cytotoxicity.
- Defects in WASP can lead to dysfunction in adaptive and innate immunity, immune surveillance, and platelet homeostasis and function as well as neutropenia.
- “Classic” WAS and XLT result from loss-of-function mutations.
- XLT can be misdiagnosed as idiopathic thrombocytopenic purpura (ITP) that does not carry increased risk of malignancy, so testing for WASP expression and WAS gene mutation is important in any male with thrombocytopenia and small platelets.
- XLN results from “activating” mutations in WAS that lead to increased actin polymerization; profound neutropenia, with or without associated lymphopenia; decreased T-cell proliferation in vitro; and increased risk of myelodysplastic changes in bone marrow.
- WASP is also important for regulatory T-cell function.

DIAGNOSIS

HISTORY

- Persistent or severe bleeding in infancy due to thrombocytopenia
- Recurrent infections, especially by bacteria with capsular polysaccharides (e.g., *Pneumococcus*)
- Eczema can be of variable severity:
 - “Acute on chronic”
 - 80% of cases associated with eczema
 - May result from imbalance of cytokines skewed toward Th2
- Older patients may report recurrent viral infections.
- Most common autoimmune features include autoimmune hemolytic anemia, cutaneous vasculitis, arthritis, and nephropathy.
- Less common autoimmune features include inflammatory bowel disease, idiopathic thrombocytopenic purpura, and neutropenia.
- Autoimmune features are poor prognostic indicators and can occur simultaneously.
- Maternal family history of Wiskott-Aldrich syndrome or X-linked thrombocytopenia

PHYSICAL EXAM

- Evaluation should focus on presence of infection.
- Dermatologic examination is significant for the extent of eczema and the presence of petechiae or ecchymoses.
- Splenomegaly

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- CBC with differential
- Small platelets, decreased mean platelet volume, decreased platelet count
- Normal IgG, decreased IgM, increased IgA and IgE (reflecting immune dysregulation)
- Reduced or absent responses to polysaccharide antigens and isohemagglutinins to ABO antigens
- T- and B-lymphocyte enumeration and mitogen stimulation studies may progressively deteriorate with increasing age.

Diagnostic Procedures/Other

- WAS disease scoring system useful for defining clinical phenotypes associated with WAS mutations (XLN, XLT, vs. classic WAS)
- Sequencing of WAS gene
- Lymph node biopsy in suspected malignancy
- Bone marrow aspirate to evaluate thrombocytopenia

DIFFERENTIAL DIAGNOSIS

- Other causes of thrombocytopenia such as idiopathic thrombocytopenic purpura
- In 1 cohort, approximately 7% of patients diagnosed as having ITP actually had WAS as an underlying cause of thrombocytopenia.
- Severe atopic disease with dermatitis and secondary skin infections
- HIV infection
- Hyper-IgE syndrome
- Diagnosis should be considered in any boy who has congenital or early-onset thrombocytopenia with small platelets.
- Definitive diagnosis:
 - Male patient
 - Congenital thrombocytopenia ($<70,000/\text{mm}^3$)
 - Small platelets (mean platelet volume <0.5 fL)
 - Mutation in the Wiskott-Aldrich syndrome protein gene or absent Wiskott-Aldrich syndrome protein mRNA

TREATMENT

ADDITIONAL TREATMENT

General Measures

- Antibiotics for acute infections and prophylactically in postsplenectomy patients
- Splenectomy may be helpful for persistent severe thrombocytopenia in select patients. However, this may greatly increase the risk of overwhelming infections with encapsulated organisms.
- Splenectomy should be reserved for emergencies in classic WAS patients who are candidates for HCT, since it is a risk factor for death. Splenectomy in XLT with severe bleeding may increase platelet counts, but risk of severe infection requires lifelong antibiotic prophylaxis

- Thrombocytopenia precautions: No aspirin and avoidance of situations in which trauma (especially head trauma) is likely to occur, such as contact sports
- Platelet transfusions may be necessary for severe bleeding. Use irradiated blood products to avoid graft versus host disease, and cytomegalovirus-negative products in case of bone marrow transplantation.
- IV immunoglobulin replacement therapy is helpful in managing recurrent infections in some patients:
 - Hematopoietic stem cell transplantation is the treatment of choice for the classic WAS phenotype.
 - Allogeneic stem cell transplant from HLA genotypically identical sibling or 9/10 or 10/10 allele matched unrelated donor for any WAS patient with disease score 3–5 (see references) or with absent WASp expression
 - Outcomes are improving with 5-year survival rates >80% for matched sibling donors and similar for matched unrelated donor grafts <5 years of age. Transplant outcomes for patients >5 years of age with matched sibling or matched unrelated are also improving over time.
- Consider food allergy as exacerbating factor for eczema.
- First retroviral-based gene therapy trial in WAS recently completed in Germany with good immune reconstitution and increase in platelet counts in 9/10 patients. Lentiviral-based gene therapy trials are starting in the near future
- XLT patients have excellent long-term survival with supportive treatment, but HLA-matched sibling transplant can be considered owing to morbidity.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Signs and symptoms of malignancy should be evaluated expeditiously.
- As patients age, a progressive increase in infectious and autoimmune complications may occur.

COMPLICATIONS

- Progressive decline in immunologic function with an increase in infections. Humoral and cellular immune systems are affected.
- Increased frequency of autoimmune phenomena such as arthritis and vasculitis. The most common is hemolytic anemia. Vasculitis, Henoch-Schönlein purpura, inflammatory polyarthritis, and inflammatory bowel disease are also observed.
- ~100-fold increased risk of malignancy compared with the general pediatric population. Malignancy is more common in adolescents. Associated with Epstein-Barr virus
- Bleeding episodes can be life threatening.

- Immune reconstitution via stem cell transplant or gene therapy needed to prevent autoimmune disorders, lymphoma, and other malignancy
- Success of bone marrow transplant in last 10 years significantly improved.
- Splenectomy not recommended for classic WAS but may have role in XLT

FAQ

- Q: What is the life expectancy for patients with Wiskott-Aldrich syndrome?
- A: Before currently available therapies, most affected patients died in childhood. Currently, many patients live into their 3rd and 4th decades, even without bone marrow transplantation. Major causes of mortality are infections (44%), bleeding (23%), and malignancies (26%). Incidence of malignancy increases in 3rd decade of life. Successfully transplanted patients have a prolonged life expectancy. Patients with no gene expression have a poorer outcome.
- Q: Should patients with Wiskott-Aldrich syndrome receive live viral vaccines?
- A: These vaccines should be avoided because of the variable cellular immune defects associated with Wiskott-Aldrich syndrome. In general, patients receiving IV immunoglobulin do not require vaccinations.
- Q: What is the chance of a sibling having Wiskott-Aldrich syndrome?
- A: As with any X-linked disease, there is a 50% chance of another affected male child or asymptomatic carrier female. Genetic counseling should be offered to carrier females.
- Q: Can Wiskott-Aldrich syndrome be diagnosed prenatally?
- A: In families with affected males, fetal blood sampling can be performed in male fetuses to assess the size of the platelets. Small platelet size and family history of Wiskott-Aldrich syndrome suggest an affected infant.

YERSINIA ENTEROCOLITICA

Julia F. Shaklee

Louis M. Bell, Jr. (5th edition)

Eric J. Haas (5th edition)

BASICS

DESCRIPTION

Yersinia enterocolitica is a gram-negative bacillus that produces an enteric infection characterized by fever, diarrhea, and abdominal pain that may mimic acute appendicitis.

EPIDEMIOLOGY

- *Y. enterocolitica* is an uncommon cause of infection in the US but affects infants and young children most frequently.
- Incidence is estimated at 9.4 per 100,000 for infants, 1.4 per 100,000 for young children, and 0.2 per 100,000 for other age groups.
- Transmission of *Y. enterocolitica* occurs through ingestion of contaminated food or water (particularly raw or undercooked pork or unpasteurized milk products) or contact with infected animals (swine are the principal reservoir). Fecal–oral and person-to-person transmission are also possible.
- Epidemics related to the improper handling of raw pork intestine (chitterlings) have been reported in the US, particularly during holiday festivities.
- Transmission through transfusion of contaminated blood products is also possible. In fact, the FDA has reported that contamination of the US blood supply by bacteria, although rare, is most frequently due to *Y. enterocolitica*.
- The incubation period is ~1–14 days (average 4–6). The average duration of organism excretion is ~2–3 weeks following diagnosis; however, asymptomatic carriage can persist even longer.
- Systemic disease or bacteremia occurs more commonly in young infants or those with predisposing conditions, including a clinical state of iron overload or deferoxamine therapy, immunosuppression, diabetes mellitus, malnutrition, and cirrhosis or other liver diseases.

GENERAL PREVENTION

- Infection control:
 - Enteric precautions are indicated for patients with enterocolitis until symptoms resolve.
- General measures:
 - Attempts to eliminate reservoirs and reduce frequency of ingesting contaminated foods and beverages are necessary.
 - Avoidance of undercooked meats, especially pork and unpasteurized milk, as well as preparation of meats near or during preparation of infant bottles for feeding is essential.

PATHOPHYSIOLOGY

- The portal of entry for *Y. enterocolitica* is the gastrointestinal tract.
- *Y. enterocolitica* adheres to epithelial cells and mucus, producing heat-stable enterotoxins, which play a role in the development of watery diarrhea.
- Another cytotoxin then directly injures the distal small and large bowel, producing stools characterized by blood and mucus.
- Release of these toxins leads to the development of an enterocolitis, most commonly in younger age groups.
- Mesenteric adenitis and/or terminal ileitis may lead to a pseudoappendicular syndrome, typically in the older child or young adult.
- Septicemia may lead to focal abscesses in a variety of organs, including the lung, liver, spleen, and kidney.

ETIOLOGY

- The genus *Yersinia* consists of 11 species, of which *Y. enterocolitica*, *Y. pseudotuberculosis*, and *Y. pestis* are the 3 most commonly encountered pathogens.
- *Y. enterocolitica* is a facultative, non–lactose-fermenting, urease-positive, gram-negative bacillus.
- Over 60 serotypes and 6 biotypes of *Y. enterocolitica* have been identified. Serotypes O:3, O:5.27, O:8, and O:9 and biotypes 2, 3, and 4 are most commonly isolated from patients. Serotype O:3 is the most common type in the US.

DIAGNOSIS

Y. enterocolitica infection is uncommon in the US. Diagnosis is dependent upon elucidation of the pertinent exposure history as well as recognition of typical symptoms and laboratory testing.

HISTORY

- Enterocolitis is the most common manifestation of *Y. enterocolitica* infection in young children and is characterized by fever, abdominal pain, and diarrhea with blood or mucus.
 - 25% of patients have hematochezia.
 - Typical duration of illness is 1–3 weeks, but may be longer (up to several months).
 - The history taking should include exposure to unpasteurized milk products and raw pork or poultry, especially the preparation of pork chitterlings.

- A pseudoappendicitis syndrome due to mesenteric adenitis and/or terminal ileitis predominates in older children and adults and is associated with fever, right lower quadrant abdominal pain, and leukocytosis.
- *Yersinia* bacteremia is found most commonly in infants <1 year of age or those with predisposing conditions, particularly states of iron overload (e.g. sickle cell disease, thalassemia).
- Extraintestinal manifestations of *Y. enterocolitica* infection are uncommon and include pharyngitis, suppurative lymphadenitis, pyomyositis, osteomyelitis, abscess, UTI, pneumonia, endocarditis, meningitis, peritonitis, panophthalmitis, conjunctivitis, and septic arthritis.

PHYSICAL EXAM

Because of the wide range of clinical symptoms, including extraintestinal manifestations, the physical exam is nonspecific for this infection.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- *Y. enterocolitica* can be isolated from blood, sputum, CSF, urine, and bile; these specimens do not require selective culture media techniques. Stool samples should be plated on selective media such as cefsulodin-triclosan-novobiocin agar. If routine enteric media (MacConkey) are used, a cold enrichment technique will increase recovery of the organism. The laboratory should be notified that *Yersinia* is suspected if not routinely sought.
- Serologic methods (tube agglutination assay, ELISA) are available with a rise in titers noted 1 week after onset of symptoms and peak titers observed by the 2nd week of illness. These tests identify IgM, IgG, and IgA antibodies against *Y. enterocolitica*.
- Cross-reactivity between *Y. enterocolitica* and *Brucella abortus*, *Rickettsia* species, *Moraxella morganii*, *Salmonella* species, and thyroid tissue antigen make serodiagnosis of limited usefulness.

Imaging

Abdominal ultrasound can be used to distinguish pseudoappendicitis from acute appendicitis through demonstration of bowel wall edema in the terminal ileum and cecum.

DIFFERENTIAL DIAGNOSIS

- *Y. enterocolitica* should be considered in all patients with fever, abdominal pain, and stools with blood or mucus, as well as in patients with the extraintestinal manifestations described above.

- Pitfalls:
 - Not all bacterial colitis presents with bloody or mucus-appearing diarrhea. Therefore, suspicion should exist if the diarrhea is prolonged or environmental exposures pose a risk for developing infection.
 - The possibility of *Y. enterocolitica* bacteremia should be considered in blood transfusion–related illnesses, thalassemia, or prior history of liver disease.

TREATMENT

ADDITIONAL TREATMENT

General Measures

- The benefit of treatment of uncomplicated enterocolitis, mesenteric adenitis, or pseudoappendicitis has not been established in immunocompetent hosts.
- Antimicrobial therapy has been shown to benefit patients with systemic infections, focal extraintestinal infections, and enterocolitis in an immunocompromised host.
- For most isolates, trimethoprim/sulfamethoxazole, chloramphenicol, aminoglycosides, tetracycline or doxycycline, fluoroquinolones, and 3rd-generation cephalosporins are effective treatment options.
- *Y. enterocolitica* is usually resistant to most penicillins and 1st-generation cephalosporins.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Symptoms of enterocolitis usually abate within 2 weeks of the onset of illness.
- Shedding of the organism in stool can last more than 6 weeks after diagnosis.
- For extraintestinal manifestations, the expected course is dependent upon the specific organ system involved.

PROGNOSIS

- The prognosis is usually quite good, as most infections are gastrointestinal.
- Systemic disease (i.e., septicemia with subsequent secondary spread) has higher morbidity and mortality. Mortality related to septicemia can be as high as 50%.

COMPLICATIONS

- Postinfectious sequelae may occur 1–2 weeks after gastrointestinal symptoms and include erythema nodosum as well as reactive arthritis involving weight-bearing joints. These complications are seen most often in adults, particularly those with HLA-B27 antigen.
- Reiter syndrome, myocarditis, glomerulonephritis, erysipelas, chronic diarrhea persisting for months, and hemolytic anemia have also been reported.
- Intestinal perforation and ileocolic intussusception are possible.

FAQ

- Q: How long is a child considered infectious with *Y. enterocolitica*?
- A: Although the typical course of enterocolitis is ~14 days, shedding of the organism in the stool can last 6 weeks or longer. Enteric precautions should be discussed with the child's parent or caregiver to ensure infection control.
- Q: If there is no history of stools with blood or mucus, can you exclude *Y. enterocolitica* as the likely infectious agent in a child with diarrhea?
- A: No. In fact, early in the course of illness, the diarrhea is more likely to be watery owing to the enterotoxins produced (see "Pathophysiology").
- Q: How is the diagnosis of *Y. enterocolitica* determined if you are unable to isolate the organism from a clinical specimen?
- A: When a diagnosis cannot be made during acute infection or in the clinical setting of postinfectious complications, a serologic titer of >1:128 is suggestive of previous infection of *Y. enterocolitica*. Keep in mind the possibility of cross-reactivity with *Brucella*, *Rickettsia*, *Morganella*, and *Salmonella* species as well as thyroid antigens.

Appendix I

Syndromes Glossary

Megan Aylor, MD and Evan Fieldston, MD

4P SYNDROME

4p syndrome (deletion 4p syndrome)—characterized by ocular hypertelorism, broad or beaked nose; microcephaly, low-set ears, pre-auricular dimples; hypotonia, severe mental deficiency, seizures; scoliosis.

5p syndrome—see “cri du chat syndrome.”

13q syndrome (deletion 13q syndrome)—characterized by microcephaly, high nasal bridge, eye defect, thumb hypoplasia; typically involves malformations of the brain, heart, kidneys, and digits; usually lethal.

Agenaes syndrome—autosomal-recessive; characterized by recurrent intrahepatic cholestasis, with lymphedema.

Aarskog syndrome—X-linked recessive; characterized by short stature, mild-to-moderate mental deficiency, musculoskeletal and genital anomalies; hypertelorism, small nose with anteverted nares, broad philtrum and nasal bridge, abnormal auricles and widow’s peak, brachyclinodactyly, broad thumbs, broad feet with bulbous toes, simian crease, ptosis, syndactyly, “shawl” scrotum, cryptorchidism, inguinal hernia, hyperopic astigmatism, large corneas, ophthalmoplegia, strabismus, delayed puberty, mild pectus excavatum, prominent umbilicus; delayed bone age.

a beta lipoproteinemia—autosomal-recessive transmission of mutation in MTP gene; characterized by inability to make beta-lipoproteins (i.e. LDL, VLDL, chylomicrons), preventing absorption of dietary fats and fat-soluble vitamins; early signs include failure to thrive, diarrhea, and acanthocytosis (star-shaped RBCs); childhood features include poor muscle control, ataxia, progressive pigmentary degeneration of the retina; by adulthood, there is significant cerebellar ataxia; absent or reduced lipoproteins and low carotene, vitamin A, and cholesterol levels.

acanthosis nigricans—skin disorder characterized by dark, thick, velvety skin in body folds and creases; can occur in healthy people or associated with medical problems, including obesity, glucose-resistance, diabetes, lymphoma, cancers of the GI or GU tracts, or those on hormones (i.e., growth hormone or oral contraceptives).

achondroplasia—autosomal-dominant, often new mutation; characterized by short limbs, short stature, megaloccephaly, small foramen magnum (low risk of cord compression), caudal narrowing of spinal canal, low nasal bridge, prominent forehead, mild hypotonia, normal intelligence, relative glucose intolerance.

acrodermatitis enteropathica—autosomal-recessive; characterized by zinc deficiency due to abnormal absorption of zinc, manifest with vesicobullous and eczematous skin lesions in the perioral and perineal areas, cheeks, knees, and elbows; photophobia, conjunctivitis, and corneal dystrophy; chronic diarrhea; glossitis; nail dystrophy; growth retardation; superinfections and candidal infections; treatment requires lifelong zinc supplementation.

Adie syndrome—tonic pupil, usually characterized by mydriasis (dilated pupil) with little or no reaction to light, but may manifest as miotic, poorly reactive pupils; pupil may react to accommodation; associated with hyporeflexia.

960

agenesis of corpus callosum—cause unknown (suspected chromosomal, genetic, toxic, infectious, and mechanical etiologies depending on associated findings); complete or partial absence of the major tracts connecting the right and left hemispheres, usually associated with hydrocephalus, seizures, developmental delay, spasticity, and hypertelorism; can be isolated or found with Arnold-Chiari malformation, Dandy-Walker syndrome, Andermann syndrome, schizencephaly, holoprosencephaly, Aicardi syndrome, and midline facial defects; may also be seen in a variety of other syndromes, including Crouzon syndrome, fetal alcohol syndrome, Opitz syndrome, and Turner syndrome.

Aicardi syndrome—X-linked dominant, lethal in homozygous males; characterized by microcephaly, agenesis of corpus callosum, infantile spasms, chorioretinal lacunae, and costovertebral skeletal abnormalities.

Alagille syndrome (arteriohepatic dysplasia)—autosomal-dominant; characterized by paucity or absence of intrahepatic bile ducts with progressive destruction of bile ducts, cholestasis, peripheral pulmonary stenosis, peculiar facies (broad forehead, deep-set eyes that are widely spaced and underdeveloped, a small, pointed mandible), cardiac lesions, vertebral arch defects, and changes in the renal tubules and interstitium.

Albers-Schonberg disease (marble bone disease)—mostly autosomal-dominant, rarely autosomal-recessive; patients are prone to fractures and have mild anemia and craniofacial disproportion; radiologic changes include increased cortical bone density, longitudinal and transverse dense striations at the ends of the long bones, lucent and dense bands in the vertebrae, and thickening at the base of the skull.

Albright syndrome—see “McCune-Albright syndrome.”

Alexander disease—caused by mutation in gene for glial fibrillary acidic protein (GFAP); 3 subtypes: Infantile, juvenile, adult; characterized by megaloccephaly in infants, dementia, spasticity and ataxia; may cause seizures in younger children; patients become mute, immobile, and dependent; hyaline eosinophilic inclusions occur in the footplates of astrocytes in subpial and subependymal regions; progressive disease with death with most patients dying within 10 years of onset; features similar to Canavan syndrome.

Alport syndrome—defective type IV collagen, most often X-linked, but with autosomal-dominant and -recessive forms; characterized by progressive nephritis to renal failure and neurosensory deafness; usually presents in infancy with hematuria, with proteinuria and hearing loss being later findings.

Andermann syndrome (Charlevoix disease)—autosomal-recessive; characterized by agenesis of the corpus callosum, mental deficiency, progressive neuropathy, and characteristic facies.

Andersen disease (glycogen storage disease, type IV)—caused by a defect of amylo(1,4 to 1,6) transglucosidase (brancher enzyme); characterized by hepatomegaly and failure to thrive in the 1st few months of life, progressing to liver cirrhosis and splenomegaly.

Angelman syndrome—maternal chromosome 15 interstitial deletion (genomic imprinting); “puppetlike” gait (ataxia and jerky arm movements), seizures, paroxysmal laughter, mental deficiency, absent or severely reduced speech, microcephaly; often blonde hair and blue eyes, characteristic facies with maxillary hypoplasia, large mouth, tongue protrusion and prognathia.

Apert syndrome (acrocephalosyndactyly)—autosomal-dominant; characterized by craniosynostosis, high and flat frontal bones, underdevelopment of the middle 3rd of the face, hypertelorism and proptosis; a narrow, high, arched palate; a short, beaked nose; syndactyly of the toes and digits; mental deficiency is common.

arthrogryposis multiplex congenita—congenital, usually nonhereditary fixed contracture of many if not all major joints; of heterogeneous cause, including neurologic, muscular, joint and tissue, and fetal crowding or in utero constraint on fetal movement.

Asperger syndrome—developmental disorder on the higher-functioning end of the autism spectrum; patients are often viewed as brilliant, eccentric, and physically awkward, fail to develop relationships with peers, have repetitive and stereotyped behaviors, usually with hand movements.

Ataxia-telangiectasia syndrome (Louis-Bar syndrome)—autosomal-recessive; characterized by progressive ataxia, degenerative central nervous system function, telangiectasia, lymphopenia, immune deficit (low to absent IgA and IgE), growth deficiency, and mental deficits.

Bart syndrome—autosomal-dominant dermolytic variant of epidermolysis bullosa; congenital aplasia of the skin; characterized by nail defects and recurrent blistering of the skin and mucous membranes.

Bartter syndrome—hypertrophy of the juxtaglomerular apparatus; characterized by hypokalemic alkalosis, hypochloremia, and hyperaldosteronism; patients have normal blood pressure but the renin level is elevated; may lead to mental retardation and small stature.

Beckwith-Wiedemann syndrome (exomphalos-macroglossia-gigantism syndrome)—usually sporadic; characterized by hypoglycemia, macrosomia, macroglossia, omphalocele, and visceromegaly; patients have unusual linear fissures in lobule of external ear, umbilical anomalies, and renal medullary dysplasia.

Behçet syndrome—unknown cause; vasculitis of large and small vessels; involves relapsing iridocyclitis and recurrent oral and genital ulcerations, white matter changes, aseptic meningitis, pulmonary aneurysm, arthritis, and arthralgias.

blind loop syndrome—stasis of small intestine, usually secondary to incomplete bowel obstruction or a problem of intestinal motility; can occur following GI surgery or from inflammatory bowel disease or scleroderma.

Bloch-Sulzberger syndrome (incontinentia pigmenti)—X-linked dominant; characterized by skin pigmentation disorder with

malformation of eyes, teeth, bones, hair, nails, heart, and CNS; usually associated with mental deficiency and commonly with seizures.

Bloom syndrome—autosomal-recessive, more common in Ashkenazi Jews; chromosome instability leading to impaired growth, long, narrow face, pigmentation changes, dilated blood vessels in the skin, photosensitivity, and butterfly distribution of erythema and telangiectasia, mental deficiency, chronic lung problems, diabetes, male infertility, early menopause, and early development of cancer.

Blount disease (tibia vara)—unknown cause, possibly from effects of weight on growth plates; medial portion of tibia fails to develop normally causing angulation and irregularity of the medial aspect of the tibial metaphysis adjacent to the epiphysis; lower leg resembles bowleg, but is progressive and worsens over time; can involve one or both legs; more common in African American children, associated with obesity and early walking.

blue diaper syndrome—rare X-linked or autosomal-recessive disorder of defective tryptophan absorption; characterized by bluish stains on the diapers, digestive disturbances, irritability, fever, and visual difficulties.

Brill disease (Brill-Zinsser disease)—reactivation of dormant typhus, caused by epidemic form, *Rickettsia prowazekii*.

bronchiolitis obliterans—characterized by obstruction of bronchioles by granulation tissue; begins with necrotizing pneumonia secondary to viral infection (e.g., adenovirus, influenza, measles), tuberculosis (TB), or inhalation of fumes, talcum powder, or zinc.

Byler disease (Progressive Familial Intrahepatic Cholestasis)—autosomal-recessive; characterized by cholestasis, hepatomegaly, pruritus, splenomegaly, elevated bile acids, and gallstones.

Canavan syndrome—autosomal-recessive leukodystrophy; characterized by progressive neurological deficits, usually beginning in infancy, with macrocephaly, hypotonia, loss of milestones, seizures, swallowing difficulties, and sleep disturbance.

Caroli disease—autosomal-dominant; characterized by cystic dilatation of the intrahepatic bile ducts; characterized by recurrent bouts of cholangitis and biliary abscesses secondary to bile stasis and gallstones.

Caroli syndrome—autosomal-recessive; characterized by cystic dilatation of the intrahepatic bile ducts; more complex form of Caroli disease, leading to hepatic fibrosis; can be associated with polycystic kidney disease.

Cat-eye syndrome—duplication of segment of chromosome 22; characterized by coloboma of iris, down-slanting palpebral fissures, anal atresia, cardiac defects, renal agenesis; mild mental deficiency.

Charcot-Marie-Tooth disease (hereditary motor and sensory neuropathy (HMSN) or peroneal muscular atrophy)—various inheritance patterns; most common cause of chronic

peripheral neuropathy; characterized by foot drop, high-arch foot; patients may have stocking-glove sensory loss.

CHARGE association—unknown etiology, likely insult in second month of gestation; characterized by coloboma, heart disease, choanal atresia, retarded growth and development and/or CNS anomalies, genital anomalies and/or hypogonadism, and ear anomalies and/or deafness.

Chédiak-Higashi syndrome—autosomal-recessive; characterized by partial oculocutaneous albinism, increased susceptibility to infection, lack of natural killer cells, and large, lysosomelike granules in many tissues; patients have splenomegaly, hypersplenism, hepatomegaly, lymphadenopathy, nystagmus, photophobia, and peripheral neuropathy.

Coats' disease (retinal telangiectasis)—telangiectasia of retinal vessels, with subretinal exudates; usually unilateral, but can be bilateral.

Cobb syndrome—noninherited very rare association of spinal angiomas or AVMs with congenital, cutaneous vascular malformations, such as port-wine stains or angiomas.

Cockayne syndrome—autosomal-recessive; characterized by dwarfism, microcephaly, mental retardation, birdlike facies, premature senility, and photosensitivity.

Congenital rubella syndrome—see “fetal rubella syndrome.”

Cornelia de Lange syndrome (Brachmann-De Lange syndrome, de Lange syndrome)—unknown cause, most cases sporadic; characterized by prenatal growth retardation, microcephaly, hirsutism, synophris, anteverted nares, down-turned mouth, mental retardation, and congenital heart defects.

cri du chat syndrome (5p deletion syndrome)—usually sporadic; characterized by catlike cry in infancy, microcephaly, downward palpebral fissures, low birth weight, growth retardation, mental deficiency, hypotonia, round face, hypertelorism, epicanthal folds, and simian crease.

Crigler-Najjar syndrome, Type I (glucuronyl transferase deficiency)—autosomal-recessive; absence of hepatic uridine 5'-diphospho-glucuronosyltransferase activity leading to unconjugated hyperbilirubinemia on 1st day of life without evidence of hemolysis; requires phototherapy to prevent kernicterus.

Crigler-Najjar syndrome, Type II—autosomal-recessive; less severe unconjugated hyperbilirubinemia due to partial activity of uridine 5'-diphospho-glucuronosyltransferase; kernicterus is less common than in Type I.

Crouzon syndrome (craniofacial dysostosis)—autosomal-dominant with variable expression; characterized by exophthalmos due to shallow orbits, hypertelorism, craniosynostosis, and hypoplasia of maxilla; patients have oral cavity anomalies and premature closure of the external auditory meatus.

cyclic neutropenia—most often autosomal-dominant; lack of granulocyte macrophage colony-stimulating factor (GM-CSF); characterized by fever, mouth lesions, cervical adenitis, and gastroenteritis occurring every 3–6 weeks; neutrophil count may be zero.

De Sanctis-Cacchione syndrome—autosomal-recessive; characterized by xeroderma pigmentosum with mental retardation, dwarfism, and hypogonadism; skin is unable to repair itself after exposure to ultraviolet light; patients may have erythema, scaling bullae, crusting telangiectasia, keratoses, photophobia, corneal opacities, and tumors of the eyelids.

Diamond-Blackfan syndrome (congenital pure red cell aplasia)—failure of erythropoiesis; characterized by macrocytic anemia, pallor, weakness, elevated fetal hemoglobin, without hepatomegaly.

DiGeorge syndrome—microdeletion of 22q11.2 most often; characterized by thymic hypoplasia or aplasia with hypocalcemia; patients have tetany, seizures, abnormal facies, congenital heart disease, and increased incidence of infection.

Down syndrome—see “trisomy 21.”

Dubin-Johnson syndrome—autosomal-recessive; characterized by elevated conjugated bilirubin, large amounts of coproporphyrin I in urine, and deposits of melaninlike pigment in hepatocellular lysosomes.

Dubowitz syndrome—autosomal-recessive; characterized by prenatal and postnatal growth retardation, mental retardation, hyperactivity, stubbornness and shyness, hypotonia, microcephaly, facial features that can resemble fetal alcohol syndrome, eczematike skin disorder, and ocular abnormalities.

Eagle-Barrett syndrome (prune-belly syndrome)—characterized by deficiency of the abdominal musculature, dilatation and dysplasia of the urinary tract, cryptorchidism, dilatation of the posterior urethra, and a hypoplastic or absent prostate; associated with Trisomy 21, Trisomy 18, Tetralogy of Fallot, and ventricular septal defects.

ectodermal dysplasia—variable inheritance; characterized by poor development, or absence, of teeth, nails, hair, and sweat glands; hyperextensible skin, hypermobile joints, and easy bruisability.

Ehlers-Danlos syndrome—autosomal-dominant, variable expression (Type I); characterized by abnormal collagen leading to hyperextensible joints and skin, poor wound healing with parchment-thin scars, narrow maxilla, mitral valve prolapse, and aortic root dilatation. Types II-X have different modes of inheritance, severity of disease, and related findings.

Eisenmenger syndrome—combination of pulmonary hypertension and right-to-left cardiac shunting within the heart that is the progressive result of a structural heart defect that allows for left-to-right shunting and increased pulmonary blood flow; over time, pulmonary hypertension develops with reversal of the shunt direction; ventricular septal defects are the most common cause.

FABRY DISEASE

Fabry disease—X-linked deficiency of ceramide trihexosidase (alpha-galactosidase-A) leading to lipid storage disease; characterized by tingling and burning in the hands and feet; small, red maculopapular lesions on the buttocks, inguinal area, fingernails, and lips; and an inability to perspire; proteinuria, progressing to renal failure; increased risk of cardiovascular disease.

Farber syndrome—autosomal-recessive deficiency of acid ceramidase; characterized by subcutaneous nodules, arthritis, and laryngeal involvement with hoarseness.

fetal alcohol syndrome—characterized by prenatal and postnatal growth deficiency, microcephaly, hypoplastic maxillary bone; abnormal palpebral fissures; smooth philtrum with thin, smooth upper lip; epicanthal folds; cardiac septal defect; delayed development; and mental deficiency.

fetal hydantoin syndrome—characterized by prenatal and postnatal growth deficiency, wide anterior fontanel, midface hypoplasia, low nasal bridge, ocular hypertelorism, cupid bow upper lip, cleft lip and palate, mental deficiency, and cardiac defects.

fetal rubella syndrome—in utero rubella exposure (especially in the 1st trimester); characterized by mental deficiency, microcephaly, deafness, cataract, glaucoma, patent ductus arteriosus, cardiac septal defects, hepatosplenomegaly, anemia, and thrombocytopenia.

fetal valproate syndrome—midface hypoplasia, long philtrum, thin vermilion border, small mouth; aortic and ventricular abnormalities; long, thin fingers and toes; meningomyelocele.

fetal warfarin syndrome—Coumadin exposure, mostly in the 1st trimester, leading to nasal hypoplasia, mental deficiency, low birth weight, mild hypoplasia of nails and fingers, and stippled epiphyses on radiographs.

fibrodysplasia ossificans progressiva (FOP)—autosomal-dominant, single nucleotide defect, mostly fresh mutations; characterized by short hallux, ossification of muscles and subcutaneous tissues, and hearing loss; any trauma (e.g., surgery, biopsy, IM injections) can cause ectopic ossification.

Fragile X syndrome—X-linked in males and females, more easily recognized phenotype in males; characterized by mental deficiency, autism or autisticlike behaviors, macrocephaly, prognathism, dental crowding, large ears, blue eyes, mild connective tissue dysplasia, and macro-orchidism.

Friedreich ataxia—autosomal-recessive; progressive loss of large myelinated axons in peripheral nerves, with symptoms usually appearing in late childhood or adolescence; characterized by progressive cerebellar and spinal cord dysfunction; patients have high-arched foot, hammer toes, and cardiac failure.

fructose intolerance, hereditary—autosomal-recessive; involves deficiency of fructose-1-phosphate aldolase or fructose 1,6-diphosphatase; characterized by vomiting, diarrhea, hypoglycemic seizures, and jaundice.

962

Gardner syndrome—autosomal-dominant; variant of familial adenomatous polyposis; characterized by multiple GI polyps with malignant transformation, skin cysts, supernumerary teeth, and multiple osteoma.

Gaucher disease—autosomal-recessive deficiency of glucocerebrosidase, leading to accumulation and storage of glucocerebroside in the reticuloendothelial system; 3 types: (a) adult, or chronic, (b) acute neuropathic, or infantile, (c) subacute neuropathic, or juvenile; characterized by splenomegaly, hepatomegaly, delayed development, strabismus, swallowing difficulties, laryngeal spasm, opisthotonos, and bone pain.

Gianotti-Crosti syndrome (papular acrodermatitis of childhood)—infectious exanthem associated with nonicteric hepatitis; caused by a variety of viruses, often Hepatitis B and EBV; most common in children aged 3 months to 15 years, with 90% of cases in children 4 years and younger.

Gilbert syndrome—generally autosomal-recessive; reduced activity of glucuronyltransferase activity leading to mild unconjugated hyperbilirubinemia that worsens with stresses on the body, such as fasting.

Gilles de la Tourette syndrome—dominant trait with partial penetrance; characterized by multiple motor and vocal tics that begin before the age of 18; high rate of associated neurobehavioral difficulties, including obsessive-compulsive disorder, ADHD, anger control problems, and poor social skills.

Glanzmann thrombasthenia—autosomal-recessive; involves defective primary platelet aggregation (size and survival of platelets is normal).

Goldenhar syndrome—usually sporadic; characterized by oculo-auriculo-vertebral dysplasia and mandibular hypoplasia; patients have a hypoplastic zygomatic arch; malformed, displaced pinnae, and hearing loss.

Goltz syndrome—mostly sporadic and female, thought to be X-linked dominant; poikiloderma with focal dermal hypoplasia, syndactyly, polydactyly, spinal defects, colobomas, strabismus, nystagmus, and dental anomalies.

Gorlin syndrome—autosomal-dominant; characterized by basal cell carcinomas, macrocephaly, broad facies, and rib anomalies.

Gradenigo syndrome—complication of otitis media or mastoiditis; acquired palsy of the abducens nerve (CN VI) and pain in the trigeminal nerve distribution, with diplopia, ocular and facial pain, photophobia, and lacrimation.

Hand-Schuller-Christian disease—see "histiocytosis X."

Hartnup disease—autosomal-recessive defect in transport of monoamine monocarboxylic amino acids by intestinal mucosa and renal tubules; characterized by photosensitivity and a pellagralike skin rash; patients may have cerebellar ataxia.

histiocytosis X—formerly called eosinophilic granuloma, Langerhans cell histiocytosis,

Hand-Schuller-Christian disease, or Letterer-Siwe disease; abnormal increase in macrophages, monocytes, and dendritic cells; patients may have a few solitary bone lesions or seborrheic dermatitis of scalp, lymphadenopathy, hepatosplenomegaly, tooth loss, exophthalmos, or pulmonary infiltrates; skull x-rays notable for "punched out" lesions.

Holt-Oram syndrome—autosomal-dominant with variable expression; characterized by upper limb defects (including syndactyly, absent thumb, phocomelia), cardiac anomalies (including ostium secundum atrial septal defect, ventricular septal defect), and narrow shoulders.

homocystinuria syndrome—autosomal-recessive; deficient cystathionine synthetase activity leading to mental deficiency, seizures, myopia, lens subluxation, malar flush, sparse fine hair, slim skeletal build, osteoporosis, vascular abnormalities, and thromboses.

Hunter syndrome (mucopolysaccharidosis II)—X-linked recessive; involves an accumulation of heparan sulfate and dermatan sulfate and enzyme deficiency of l-iduronate sulfatase; characterized by macrocephaly, coarse facial features, hypertrophy of internal organs, and mental deficiency.

Hurler syndrome (mucopolysaccharidosis IH)—autosomal-recessive; involves an accumulation of heparan sulfate and dermatan sulfate, and enzyme deficiency of α -l-iduronidase; characterized by coarse facial features, growth arrest, progressive mental deficiency, glaucoma, arthritis, and cardiac valvular disease.

Hutchinson-Gilford syndrome (progeria syndrome)—mostly sporadic; characterized by premature aging, severe growth failure, atherosclerosis, alopecia, and dystrophic nails.

Hyper-IgE (Job syndrome)—characterized by recurrent deep tissue and skin staphylococcal infections; patients have eosinophilia and IgE levels that are 10 times greater than normal.

incontinentia pigmenti—see "Bloch-Sulzberger syndrome."

Jeune thoracic dystrophy (asphyxiating thoracic dystrophy)—autosomal-recessive congenital dwarfism; characterized by small thorax, lung hypoplasia, respiratory distress, short limbs, and polydactyly; kidney lesions may progress to renal insufficiency or failure.

Job syndrome—see "Hyper-IgE."

Kabuki syndrome—sporadic; characterized by growth deficiency, mental deficiency, hypotonia, long palpebral fissures with eversion over the lateral portion of lower eyelid, ptosis, arching eyebrows, large protuberant ears, open mouth, cleft palate, extremity and rib deformities, joint hyperextensibility; cardiac anomalies.

Kallmann syndrome—genetic hypogonadism; characterized by isolated gonadotropin deficiency and anosmia.

Kartagener syndrome—autosomal-recessive; characterized by sinusitis, bronchiectasis, situs inversus, infertility and immotile cilia.

Kasabach-Merritt syndrome—characterized by giant hemangioma causing a consumptive coagulopathy, thrombocytopenia, and microangiopathic hemolytic anemia.

Kleine-Levin syndrome—characterized by unusual hunger, somnolence, and abnormal behavior.

Klinefelter syndrome—47 XXY karyotype; characterized by seminiferous tubule dysgenesis, testicular atrophy, eunuchoid habitus, gynecomastia, and behavior disorders.

Klippel-Feil syndrome—due to a defect in cervical spine development; characterized by a short neck, limited neck motion, and low occipital hairline. May also have associated genitourinary tract abnormalities.

Krabbe leukodystrophy—autosomal-recessive neurodegenerative disorder; characterized by lysosomal enzyme deficiency, leading to loss of myelin in white matter; patients develop hyperreflexia, rigidity, swallowing difficulties, seizures, and blindness; usually presents by age 6 months, and most patients die by 2 years of age.

Larsen syndrome—usually autosomal-recessive; characterized by hyperlaxity, multiple congenital dislocations, and characteristic facies.

Laurence-Moon-Biedl syndrome—characterized by mental retardation, retinitis pigmentosa, hypogonadism, and spastic paraplegia.

Lawrence-Seip syndrome—association of acanthosis nigricans, generalized complete absence of subcutaneous fat, muscle hypertrophy, hyperlipemia, diabetes mellitus, and hepatosplenomegaly with cirrhosis.

Lennox-Gastaut syndrome (childhood epileptic encephalopathy)—characterized by intractable seizures of various types, mental retardation, and characteristic slow spike wave EEG pattern.

LEOPARD syndrome—autosomal-dominant with variable expression; characterized by lentigenes, EKG abnormalities, ocular hypertelorism, pulmonic stenosis, abnormalities of genitalia, retardation of growth, and deafness.

Lesch-Nyhan syndrome—X-linked disorder of purine metabolism; characterized by hyperuricemia as a result of diminished or absent hypoxanthine guanine phosphoribosyl transferase (HPRT) activity, choreoathetosis, compulsive self-mutilation, mental retardation, spastic cerebral palsy, and growth failure.

Letterer-Siwe disease—see “histiocytosis X.”

Lowe syndrome (oculocerebrorenal syndrome)—X-linked disorder; characterized by congenital cataracts, hypotonia, mental retardation, rickets, and Fanconi syndrome.

Maffucci syndrome—characterized by multiple enchondroma of the bone and soft tissue

hemangiomas; patients have short stature, skeletal deformities, scoliosis, and high risk of malignant transformation.

Marfan syndrome—mutation of fibrillin gene on chromosome 15; connective tissue disorder characterized by ectopia lentis, dilatation of the aorta, scoliosis, pneumothorax, pectus excavatum or carinatum, and long, thin extremities.

McCune-Albright syndrome—characterized by polyostotic fibrous dysplasia; multiple large café-au-lait macules with irregular edges, and endocrinopathies such as precocious puberty, hyperthyroidism, gigantism and Cushing syndrome; more commonly in girls.

MELAS syndrome—(Mitochondrial myopathy, Encephalopathy, Lactic Acidosis, and Strokelike episodes); causes seizures, hemiparesis, hemianopsia, or cortical blindness, sensorineural hearing loss, and short stature.

Menkes disease (kinky hair disease)—X-linked recessive progressive neurodegenerative disorder; characterized by short, friable, colorless scalp hair, failure to thrive, mental retardation, optic atrophy, hypopigmentation, hypothermia, growth failure, seizures, and progressive CNS failure.

Möbius syndrome—characterized by cranial nerve dysfunction causing bilateral facial weakness, feeding difficulties, and impairment of ocular abduction.

Morquio syndrome (mucopolysaccharidosis type IV)—characterized by skeletal dysplasia, short-trunk dwarfism, kyphoscoliosis, short neck, hypoplasia and corneal clouding and cardiac valve disease; patients have laxity of the odontoid processes, and are at risk for life-threatening atlantoaxial subluxation.

multiple hereditary exostosis—autosomal-dominant disorder characterized by presence of multiple osteochondromas (exostosis) occurring most commonly on the metaphysis of long bones, but may also occur on the ribs, scapula, vertebral bodies, and iliac crest; exostoses become calcified and cause skeletal deformities such as short stature, limb length discrepancy or deformity of the extremities.

nail-patella syndrome—autosomal-dominant; characterized by dystrophic and hypoplastic nails, hypoplastic patellae and iliac horns, and malformed radial heads; may lead to nephrotic syndrome and renal failure.

Niemann-Pick disease—autosomal-recessive disorder of lipid metabolism with 4 subtypes; characterized by failure to thrive, hepatomegaly, and rapidly progressive neurodegeneration; in its most severe form patients are normal at birth but by 6 months experience delayed development and loss of developmental milestones; 50% have a macular cherry red spot.

Noonan syndrome—autosomal-dominant; clinical features similar to Turner syndrome; characterized by cardiac disease (most commonly or pulmonary valve stenosis), hypertelorism, downward palpebral slant, epicanthal folds, webbed neck; short stature, and low set, posteriorly rotated ears; patients may also have cryptorchidism, and a bleeding diathesis.

Osler-Weber-Rendu syndrome (hereditary hemorrhagic telangiectasia)—autosomal-dominant vascular dysplasia; characterized by telangiectases of the skin, respiratory tract mucosa, lips, nails, and conjunctiva as well as arteriovenous malformations of the lung, liver, and brain.

Osteogenesis imperfecta, Type I—autosomal-dominant with variable expression; characterized by postnatal growth deficiency, fragile bone with frequent fractures, hyperextensibility, blue sclerae, yellowish or bluish gray teeth, and presenile deafness.

Osteogenesis imperfecta congenital (Type II)—mostly autosomal-dominant, but autosomal-recessive subtypes; characterized by short limbs, short broad bones, and defective ossification, deep blue sclerae; usually stillborn or die in infancy of respiratory failure.

Osteogenesis imperfecta, Type III—autosomal-dominant; more severe than Type I, with prenatal growth deficiency, multiple fractures present at birth, bluish sclera in infancy (normal in adulthood).

Osteogenesis imperfecta, Type IV—autosomal-dominant; normal or moderate short stature, significant bone deformities, normal sclera, femoral bowing in neonatal period that straightens with time.

Parinaud syndrome—characterized by weakness of upward gaze, nystagmus to convergence and accommodation, pupillary changes, and eyelid retraction; classically seen with pineal tumors.

Patau syndrome—see “trisomy 13.”

Pelizaeus-Merzbacher disease—X-linked-recessive; characterized by abnormal myelin in the CNS, nystagmus, developmental delay, spasticity, and ataxia; patients may also have optic atrophy and seizures.

Peutz-Jeghers syndrome—autosomal-dominant; characterized by melanotic macules on the lips and mucous membranes, intestinal polyposis, and increased risk of malignancy.

Pickwickian syndrome—characterized by obesity and hypoventilation; patients may have sleep apnea, daytime somnolence and cyanosis.

Pierre Robin syndrome—characterized by severe micrognathia, glossoptosis, and cleft palate.

Poland syndrome—characterized by a unilateral absence or hypoplasia of the pectoralis muscle with ipsilateral breast hypoplasia and upper limb abnormalities.

Prader-Willi syndrome—autosomal-dominant disorder of chromosome 15 imprinting; characterized by hypotonia and initial failure to thrive, followed by marked obesity due to an insatiable appetite; other features include mental retardation, hypogonadism, small hands and feet, and short stature.

Progeria syndrome—see “Hutchinson-Gilford syndrome.”

Prune-belly syndrome—see “Eagle-Barrett syndrome.”

RIEGER SYNDROME

Rieger syndrome—sporadic autosomal-dominant; characterized by ocular abnormalities, hypodontia, and maxillary hypoplasia; less common features include renal, cardiac, neurologic, and umbilical abnormalities.

Riley-Day syndrome—autosomal-recessive familial dysautonomia occurring almost exclusively in persons of Ashkenazi Jewish descent; affects sensory and autonomic functions; characterized by poor feeding, aspiration, alacrima, excessive sweating with skin flushing, high threshold to pain, markedly decreased reflexes, smooth tongue and impaired taste, and erratic BP and temperature.

Rotor syndrome—autosomal-recessive; characterized by mild conjugated bilirubinemia and jaundice that may be exacerbated by infection, surgery, pregnancy, or drugs; usually asymptomatic with normal life expectancy; clinically, similar to Dubin-Johnson; however, patients with Rotor have normal appearing hepatocytes.

Rubinstein-Taybi syndrome—characterized by broad thumbs and toes, short stature, mental retardation, beaked nose, and congenital heart defects.

Russell-Silver syndrome—characterized by intrauterine growth retardation (IUGR), small triangular facies, 5th finger clinodactyly, hemihypertrophy, genitourinary malformations, and short stature.

Sandhoff disease (GM2-gangliosidosis type II)—autosomal-recessive progressive neurodegenerative disorder; characterized by deficient hexosaminidase activity leading to clinical manifestations nearly identical to Tay-Sachs disease, with macular cherry red spot, blindness, progressive loss of developmental milestones, and seizures, as well as hepatosplenomegaly, cardiac involvement, and mild skeletal abnormalities.

Sanfilippo syndrome, types A, B, C, and D (mucopolysaccharidosis types IIIA, B, C, and D)—autosomal recessive group of disorders caused by a deficiency in 1 of 4 distinct enzymes with clinically similar manifestations; characterized by accumulation of heparan sulfate, which leads to hyperactivity and destructive behavior and progresses to neurologic deterioration.

Scheie syndrome (mucopolysaccharidosis type IS)—autosomal recessive disease caused by an enzyme defect affecting α -L-iduronidase which leads to accumulation of heparan sulfate and dermatan sulfate; characterized by stiff joints, corneal clouding, aortic valve disease, and normal intellect.

scimitar syndrome—characterized by dextrocardia, hypoplasia of the right lung with systemic arterial supply, and anomalous right pulmonary vein draining in to the inferior vena cava, giving characteristic scimitar (curved swordlike) shape on chest radiograph.

Seckel syndrome—rare autosomal-recessive disorder; characterized by dwarfism, microcephaly, sharp facial features with underdeveloped chin, and mental retardation.

Shwachman-Diamond syndrome—autosomal-recessive; characterized by exocrine pancreatic dysfunction, bone marrow dysfunction with risk of malignant transformation, and skeletal abnormalities with moderate dwarfism.

Smith-Lemli-Opitz syndrome—autosomal-recessive disorder of cholesterol synthesis resulting in multiple malformations; characterized by growth retardation, microcephaly, ptosis, anteverted nares, micrognathia, syndactyly, hypospadias with cryptorchidism, and mental retardation.

Sotos syndrome (cerebral gigantism)—characterized by macrocephaly, large hands and feet, prominent mandible, rapid growth, mental retardation, and poor coordination.

Stickler syndrome—autosomal-dominant; characterized by progressive myopia, leading to retinal detachment and blindness; patients may also have Pierre Robin anomaly at birth and may develop sensorineural hearing loss and osteoarthritis during adolescence.

Sturge-Weber syndrome—characterized by a port-wine stain on the face at the 1st branch of the trigeminal nerve; patients have ipsilateral leptomeningeal angiomas with intracranial calcifications leading to seizures and mental retardation and may also have ocular complications, such as glaucoma.

Swyer-James syndrome—characterized by unilateral hyperlucent lung following bronchiolitis obliterans.

Tay-Sachs disease (GM2-gangliosidosis type I)—autosomal-recessive, most common among Ashkenazi Jews (carrier state 1 in 25); characterized by deficient hexosaminidase activity which leads to accumulation of GM2 gangliosides in the CNS; patients have loss of motor milestones, seizures, macular cherry-red spot, and progressive neurodegeneration leading to blindness, paralysis, and death within the 2nd or 3rd year of life.

Tourette syndrome—see “Gilles de la Tourette syndrome.”

Treacher Collins syndrome—autosomal dominant with variable expression; characterized by mandibulofacial dysostosis; patients have hypoplastic zygomatic arches and mandibles, micrognathia, downward slanting palpebral fissures, coloboma of the lid, deformities of the external ear with associated conductive hearing deficits, and a cleft palate with or without cleft lip.

trisomy 13 (Patau syndrome)—characterized by midline defects including holoprosencephaly, aplasia cutis congenita, cleft lip, microphthalmia, postaxial polydactyly, clenched hands with overlapping fingers, and cardiovascular anomalies; majority abort spontaneously and most live born infants die within the 1st year of life.

trisomy 18 (Edwards syndrome)—characterized by a small face, prominent occiput, micrognathia, low-set ears, clenched hands with overriding fingers, a short sternum, and rocker bottom feet; patients are small for gestational age and have severe mental retardation,

cardiac and renal anomalies, and usually do not survive past the 1st year of life.

trisomy 21 (Down syndrome)—characterized by mental retardation and characteristic facies as well as congenital heart disease (particularly atrioventricular canal defects), GI disorders (Hirschprung disease, duodenal atresia), leukemia, hearing loss, and thyroid disease. One of the most common chromosomal abnormalities in liveborn children.

tuberous sclerosis—autosomal-dominant with highly variable expression; characterized by seizures, mental retardation, intracranial tubers and subependymal calcification, retinal hamartomas, cardiac rhabdomyomas, and renal hamartomas; pathognomonic skin lesions include hypopigmented macules (ash leaf spots), connective tissue nevi (shagreen patch), adenoma sebaceum, and subungual or periungual fibromas.

Turcot syndrome—characterized by adenomatous colonic polyposis associated with malignant brain tumors, especially medulloblastoma and glioblastoma.

Turner syndrome—classically, 45 XO karyotype, another 15% are mosaic and may have less marked features; characterized by gonadal dysplasia with sterility and primary amenorrhea, short stature, sparse pubic and axillary hair and underdeveloped breasts with wide spaced nipples; also low hairline, webbed neck, shield chest, congenital lymphedema of the extremities, cardiac disease (coarctation of the aorta), and increased carrying angle.

Usher syndrome—autosomal recessive; characterized by early retinitis pigmentosa, vestibular dysfunction, and sensorineural deafness.

vanishing testes syndrome—characterized by bilateral gonadal failure with normal external male genitalia, 46 XY karyotype, absent testes, and no male puberty.

VATER association—characterized by Vertebral defects, Anal atresia, Tracheoesophageal fistula with Esophageal atresia, and Radial and/or renal anomalies; may be expanded to VACTERL to include Congenital heart defects or other Limb defects.

Vogt-Koyanagi-Harada syndrome—disorder of melanocyte containing organs characterized by vitiligo, uveitis, dysacusis or tinnitus, aseptic meningitis, and premature graying of hair.

von Gierke disease (Glycogen Storage Disease Type I)—autosomal-recessive inherited defect in glucose-6-phosphatase; characterized by fasting hypoglycemia, growth retardation, hepatomegaly, lactic acidosis, hyperlipidemia, and hyperuricemia.

von Hippel-Landau disease—autosomal dominant with variable penetrance (chromosome 3); neurocutaneous syndrome predisposing to benign and malignant neoplasms, most commonly cerebellar, retinal or spinal hemangioblastoma; associated with pheochromocytoma, renal cell carcinoma, pancreatic tumors and cystic lesions of the kidneys, pancreas, liver, and epididymis.

Waardenburg syndrome—autosomal dominant; characterized by white forelock, heterochromic irides, lateral displacement of the inner canthi, broad nasal bridge, and sensorineural deafness.

Wegener granulomatosis—necrotizing granulomatous vasculitis involving (a) the airways, leading to rhinorrhea, chronic sinusitis, nasal ulceration; (b) the lungs, causing hemoptysis, dyspnea and cough; (c) the kidneys, manifested as hematuria and/or proteinuria due to glomerulonephritis; other symptoms include fever, malaise, weight loss, myalgias, arthralgias, ophthalmic involvement, neuropathies, and cutaneous nodules or ulcers.

Werner syndrome—autosomal recessive; characterized by short stature, gonadal atrophy, sclerodermalike skin changes, cataracts, subcutaneous calcification, premature arteriosclerosis, diabetes mellitus, and a wizened and prematurely aged facies.

Williams syndrome—deletion in subunit 7q11.23 (elastin allele); characterized by hypercalcemia in infants, supraaortic stenosis, peripheral pulmonary artery stenosis, characteristic facies, mental retardation, growth delay, and stellate iris; affected children are often very talkative and musically inclined.

Wiskott-Aldrich syndrome—X-linked recessive; characterized by thrombocytopenia, severe eczema, and recurrent infections.

Wolff-Parkinson-White syndrome—accessory conduction pathway found in 25% of patients with supraventricular tachycardia; typical electrocardiographic findings include a short PR interval and slow upstroke of the QRS (delta wave); usually occurs in patients with a normal heart but also may occur in patients with Ebstein anomaly and cardiomyopathy; slightly increased risk for sudden death due to cardiac arrhythmia.

Wolman disease—autosomal-recessive lysosomal storage disease leading to fat deposition in visceral organs; fatal in infancy, this condition is characterized by intractable vomiting, failure to thrive, abdominal distention, steatorrhea, hepatosplenomegaly, and adrenal calcification.

Zellweger syndrome (cerebrohepato renal syndrome)—autosomal-recessive disorder of peroxisome import characterized by hepatic cirrhosis, renal cysts, dysmorphic facies, seizures, mental retardation, hypotonia, glaucoma, and congenital stippled epiphyses.

Zollinger-Ellison syndrome—characterized by gastrin secreting islet cell tumors leading to gastric acid hypersecretion and production of duodenal and jejunal ulcers.

Appendix II

Cardiology Laboratory

Ilana Zeltser

BLOOD PRESSURE MEASUREMENT

Between 1% and 3% of the pediatric population has hypertension. Most cases of hypertension are early manifestations of essential hypertension. Approximately 10% of children have secondary hypertension, and 80% of these patients have underlying renal parenchymal or renal vascular disease. After renal disease, coarctation or hypoplasia of the aorta is the second most common cause of secondary hypertension.

Accurate determination of the blood pressure is an integral part of the physical examination. The blood pressure cuff must be the correct size; a small cuff will

falsely overestimate the blood pressure. The blood pressure cuff should be 50% of the circumference and 2/3 the length of the extremity. Second, the patient should be sitting and calm. Finally, once the cuff is sufficiently inflated, the cuff should then be released slowly at a rate of 3 to 4 mmHg/sec. The 1st Korotkoff sound corresponds to the systolic pressure, although the 5th Korotkoff sound, the disappearance of sound, represents the diastolic pressure.

The report from the Second Task Force on Blood Pressure Control in Children published standard blood pressure measurements for children from birth to 18 years of age (Figure 1). These reference standards do not distinguish between racial or ethnic groups. In

general, blood pressure increases with height, weight, age, and sexual maturation. Blood pressure is higher in males than in females during the 1st decade of life and tends to widen around the onset of puberty. Blood pressure follows a circadian rhythm, being highest late in the day and lowest at night while sleeping.

When cardiac disease is suspected, blood pressure measurements should be obtained in all 4 extremities. A difference of greater than 10 mmHg between upper and lower extremity blood pressures is pathologic and suggests the presence of aortic coarctation, aortic arch hypoplasia or interrupted aortic arch.

B. Boys

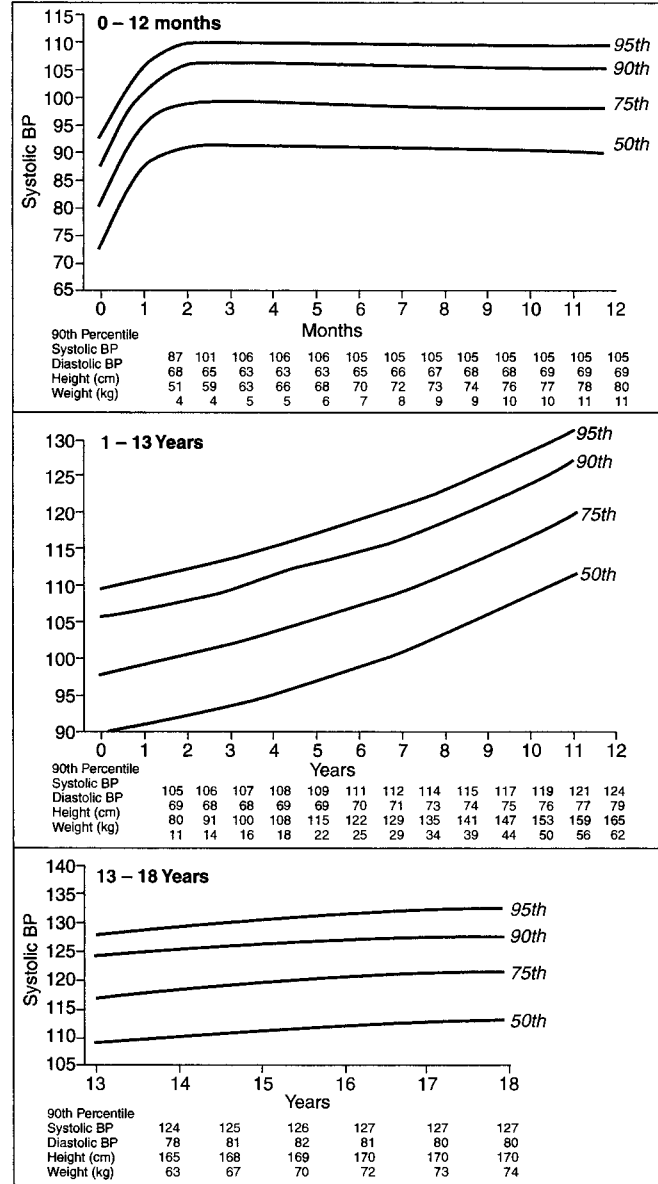

FIGURE 1. Standard blood pressure measurements in accordance with age and gender. A: Girls. B: Boys. BP, blood pressure. (From Horan MJ. Report of the Second Task Force on Blood Pressure Control in Children—1987. Pediatrics 1987;79:1-25, with permission).

FIGURE 2. Pulsus paradoxus. EXP, expiration; INSP, inspiration. (Modified from Park MK. Pediatric cardiology for practitioners, 3rd ed. St. Louis: Mosby-Year Book 1996:15, with permission).

Pulse Pressure

The pulse pressure is the calculated difference between the systolic and diastolic pressures. A widened pulse pressure is present in: (a) high cardiac output states (anemia, fever, exercise, thyrotoxicosis), (b) diastolic run-off lesions (patent ductus arteriosus, aortic insufficiency, arteriovenous malformations), or (c) complete heart block. Narrow pulse pressure states may reflect: (a) low cardiac output states, (b) mitral or aortic valve stenosis, or (c) pericardial tamponade or constrictive pericarditis.

Hint: Normally, with inspiration, there is a small diminution of the systolic blood pressure compared to the diastolic pressure, resulting in a slight narrowing of the pulse pressure. Pulsus paradoxus exists when this response is exaggerated, and there is a greater than 10 mmHg drop in the systolic blood pressure

with inspiration, resulting in narrowing of the pulse pressure. Pulsus paradoxus indicates underlying cardiopulmonary disease and may be associated with cardiac tamponade, constrictive pericarditis, or severe respiratory compromise (e.g., status asthmaticus). See Figure 2 for a schematic illustration of pulsus paradoxus.

CYANOSIS

Central cyanosis can be detected when the absolute concentration of deoxygenated hemoglobin is at least 3 gm/dL in a child with a normal hemoglobin. The best indicator of cyanosis is the tongue, which is free of pigmentation and has a rich vascular supply. Whether or not cyanosis is manifest depends on (a) the hemoglobin and (b) factors that alter the affinity of

hemoglobin (temperature, serum pH, level of 2,3-diphosphoglycerate and the percentage of fetal versus adult hemoglobin). For example, a newborn with polycythemia (hemoglobin of 20 g/dL) and an arterial saturation of 80% will have 4 g/dL of deoxygenated hemoglobin and will appear cyanotic. In contrast, an anemic newborn (hemoglobin of 10 g/dL) with an arterial saturation of 80% will have only 2 g/dL of deoxygenated hemoglobin and will not appear cyanotic.

Hint: Central cyanosis should not be confused with acrocyanosis, a common physical finding in newborns as a result of peripheral vasoconstriction.

Hyperoxia Test

In infants with cyanosis and hypoxia, the differential diagnosis includes abnormalities of the cardiovascular, pulmonary, neurologic, and hematologic systems. In all neonates with hypoxemia, the hyperoxia test is a useful diagnostic tool to identify those neonates with a cardiovascular etiology. If a right radial arterial PaO₂ on 100% FiO₂ is less than 150 mmHg, severe congenital heart disease is likely. The infant is presumed to have ductal dependent congenital heart disease and the low PaO₂ is attributed to the obligatory mixing of oxygenated with deoxygenated blood within the circulatory system.

ELECTROCARDIOGRAPHY

The surface electrocardiogram (ECG) reflects the electrical activity in the heart and can provide information regarding the depolarization and repolarization of the heart muscle. The electrical signal represents the propagation of a wavefront through a cardiac chamber. Movement toward a recording electrode results in an upward deflection on the ECG, although movement away produces a negative deflection.

Correct ECG lead placement is of paramount importance in its accurate interpretation. The limb leads create a 360° frontal plane, although the precordial leads view the electrical activity in a horizontal plane (Figure 3). The standard ECG paper speed is 25 mm/sec with an amplitude of 1 mV/mm (Figure 4).

One should establish a systematic approach when interpreting ECGs. After noting the paper speed, standardization, and the patient's age, the signals can be analyzed. One should comment on the following: (a) rhythm, (b) rate, (c) axes of P, QRS, and T waves, (d) PR, QRS, and QT intervals, (e) waveform voltage, and (f) P, QRS, and T wave morphology (see Figure 4).

Rhythm

Sinus rhythm occurs when there is a P-wave prior to every QRS complex, and the axis of the P-wave is positive in leads I, II, and aVF.

Rate

Heart rate norms depend on the patient's age. In general, the heart decreases with increasing age (Table 1). When the ECG is at standard paper speed, 1 mm (1 small box) is equal to 0.04 seconds, and 5 mm (1 large box) is 0.2 seconds. Thus if there is one QRS complex every 0.2 seconds, then the heart rate is 300 beats/min. If the heart rate is inappropriately fast, then the rhythm may be sinus

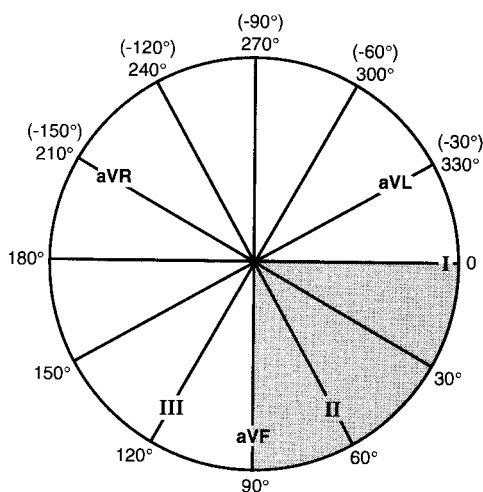

FIGURE 3. Hexaxial reference system (frontal axis). The shaded area represents the normal axis.

FIGURE 4. A normal electrocardiogram showing waveforms and intervals. The standard paper speed is 25 mm per second; therefore, a single 1-mm box equals 0.04 second, and a large (5-mm) box equals 0.20 second.

tachycardia or an arrhythmia. If sinus tachycardia is suspected, an underlying systemic process is usually responsible for stimulating the sinus node. Fever, anxiety, thyrotoxicosis, anemia and myocardial disease are among the more common causes of sinus tachycardia. Alternatively, if the heart rate is inappropriately slow, then the rhythm must be

differentiated between sinus bradycardia and an arrhythmia. Sinus bradycardia is common in trained athletes. Other etiologies of sinus bradycardia include increased intracranial pressure, hypothyroidism, malnutrition, anorexia, hypoxia, sinus node dysfunction, electrolyte abnormalities, and pharmaceuticals.

Axes

The limb leads are oriented in a hexaxial reference plane so that the angle between any two leads is 30°. With respect to the P-wave axis, the rhythm should be noted to be originating from the sinus node or an alternative pacemaker. The normal QRS axis changes with age. In the newborn period, the mean vector of depolarization is rightward, reflecting the dominance of the right ventricle in early infancy. As the left ventricular mass increases relative to the right side, the QRS axis shifts more leftward. Table 1 demonstrates expected ranges for the QRS axis with respect to age. When left axis deviation is present, there is frequently left ventricular hypertrophy or a left bundle branch block. Conversely, when right axis deviation is present, there is often right ventricular hypertrophy or a right bundle branch block. When the QRS axis is superior (northwest axis), an endocardial cushion defect or tricuspid atresia are possible.

The T-wave represents ventricular repolarization. Within the first 72 hours of life, the T-wave should invert in lead V1. As the left ventricle becomes progressively more dominant, the T-wave axis parallels the QRS axis. Thus, during adolescence, the T-wave becomes upright in lead V1 and the T wave axis becomes leftward. Finally, the QRS-T angle should be ≤90°. When there is an abnormally wide angle, the following are possible: (a) right or left ventricular hypertrophy associated with a strain pattern, (b) a ventricular conduction disturbance, or (c) myocardial dysfunction (see Figure 3).

Intervals

Measuring the intervals between deflections on the ECG evaluates the properties of the electrical conduction system. Refer to Table 1 for normal age-corrected values of intervals. The PR interval is measured from the onset of the P-wave to the beginning of the QRS complex and reflects the time for atrial depolarization and delay through the AV node. In general, with age, the heart rate is slower and the PR interval is longer. Abnormal prolongation of the PR interval, or 1st degree AV block, usually represents a delay in AV node conduction. This delay can be as a result of myocarditis, congenital heart disease, electrolyte abnormalities (hyperkalemia), hypoxia, ischemia, medications, or toxins (e.g., digitalis, quinidine). A short PR interval is present when there is either (a) an abnormal electrical connection between the atrium and ventricle, as seen in Wolff-Parkinson-White syndrome, Lown-Ganong-Levine syndrome, glycogen storage disease, or hypertrophic cardiomyopathy. Finally, a variable PR interval suggests either (a) a wandering atrial pacemaker or (b) Wenckebach phenomenon.

The QRS interval is measured from the onset of the Q-wave to the completion of the S-wave and represents ventricular depolarization. The QRS duration represents the intraventricular conduction time and is normally less than 0.09 seconds in children younger than 4 years and less than 0.1 seconds in children older than 4 years. When the QRS complex is wide, there is a delay or abnormal propagation of the electrical impulse through the ventricular myocardium. QRS widening is seen with a bundle branch block, preexcitation (e.g., Wolff-Parkinson-White syndrome), intraventricular block, ventricular arrhythmias and ventricular paced rhythms.

Table 1. Heart Rate, PR Interval, and QRS Duration

Age	Heart Rate (Beats/min)		PR Interval in Lead II (Seconds)		QRS Duration (Seconds)	
	Mean	Range	Mean	Range	Mean	Range
<1 day	126	95–155	0.106	0.082–0.138	0.05	0.025–0.069
1–7 days	135	100–180	0.107	0.079–0.130	0.05	0.025–0.068
8–30 days	160	120–190	0.100	0.075–0.128	0.053	0.026–0.075
1–3 months	147	95–200	0.098	0.075–0.126	0.052	0.027–0.069
3–6 months	139	114–170	0.105	0.078–0.137	0.053	0.028–0.075
6–12 months	130	95–170	0.105	0.077–0.138	0.055	0.03–0.070
1–3 years	121	95–150	0.113	0.090–0.140	0.056	0.032–0.070
3–5 years	98	70–130	0.119	0.092–0.150	0.058	0.03–0.069
5–8 years	86	65–120	0.124	0.094–0.155	0.059	0.035–0.075
8–12 years	86	65–120	0.129	0.093–0.165	0.062	0.038–0.079
12–16 years	86	65–120	0.135	0.098–0.169	0.065	0.040–0.081

Adapted with permission from Liebman J, Plonsey R, Gillette PC: *Pediatric Electrocardiography*. Baltimore, Williams & Wilkins, 1982, pp 96–97 and Cassels DE, Ziegler RF: *Electrocardiography in Infants and Children*, Philadelphia, WB Saunders, 1966, p 100.

Hint: Left bundle branch block is diagnosed when there is a monophasic R wave in lead I and no Q wave in lead V6. Right bundle branch block is diagnosed when there is a wide S wave in leads I and V6, right axis deviation, and an M-shaped (RSR' pattern) QRS complex in lead V1. Left anterior hemiblock can be diagnosed in the setting of left axis deviation associated with right bundle branch block.

Finally, the QT interval represents the time it takes for ventricular depolarization and repolarization. The QT interval is measured from the onset of the Q-wave to the termination of the T-wave. Given that the QT interval should shorten with increasing heart rates, the QT measurement should be adjusted for heart rate using the following formula: $QTc = QT \text{ measured} / \sqrt{\text{square root of the R-R interval}}$. The QTc interval is generally less than 0.45 seconds for infants younger than 6 months, and less than 0.44 seconds for children. The QTc is prolonged in Long QT syndrome wherein there are multiple genetic abnormalities of either the cardiac potassium or sodium channels. Other conditions that prolong the QTc interval include head injury, myocarditis, medications (such as, procainamide, amiodarone, quinidine) and electrolyte abnormalities (e.g., hypocalcemia, hypomagnesemia, hypokalemia).

Waveforms

Abnormal morphologic characteristics of the waveforms often indicate underlying pathology. When the P-wave amplitude is greater than 3 mm in lead II or lead V1, right atrial enlargement is present. If the P-wave has a duration greater than 0.1 seconds in lead II or is biphasic with a prominent negative component in lead V1, left atrial enlargement is present.

The amplitude of the QRS complex is evaluated in the precordial leads and depends on the child's age. The normal Q-wave represents septal depolarization and is seen in the inferolateral leads. The absence of Q-waves in leads V5 and V6, coupled with the presence of Q-waves in lead V1, is consistent with congenitally corrected transposition of the great arteries (L-TGA). Abnormally tall R-waves in lead V1 or deep S-waves in V5 and V6 represent right ventricular hypertrophy. Similarly, tall R-waves in leads V5 and V6 or deep S-waves in lead V1 represent left ventricular hypertrophy. Conversely, low-voltage QRS complexes suggest myocarditis, pericarditis, pericardial effusion, or hypothyroidism.

Finally, abnormalities of T-wave morphology can also suggest pathology. For example, tall, peaked T-waves can be seen with ventricular hypertrophy associated with strain, myocardial infarction, or hyperkalemia. Conversely, low-voltage, flat T-waves are associated with electrolyte abnormalities (hypokalemia, hypoglycemia), hypothyroidism, myocarditis, pericarditis, ischemia or medications (i.e., digitalis).

CHEST ROENTGENOGRAM

Despite the increasing use of alternative methods of noninvasive imaging, the plain chest roentgenogram continues to provide important information to the clinician when cardiac disease is suspected. The study is inexpensive, expedient, readily available, and minimally harmful, and therefore serves as a convenient tool in assessing patients. It can provide important information regarding cardiac size, pulmonary vascularity, and specific cardiac abnormalities. The normal cardiac silhouette in the anterior-posterior and lateral views is shown in Figure 5.

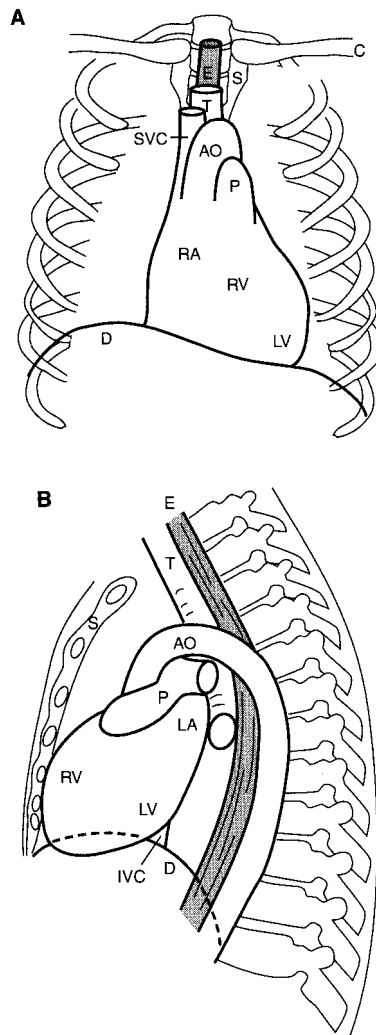

FIGURE 5. Normal cardiac silhouette. A: Anterior-posterior view. B: Lateral view. AO, aorta; C, clavicle; D, diaphragm; E, esophagus; IVC, inferior vena cava; LA, left atrium; LV, left ventricle; P, pulmonary outflow tract; RA, right atrium, RV, right ventricle; S, sternum; T, trachea; SVC, superior vena cava. (Modified from Sapire DW. Understanding and diagnosing pediatric heart disease. East Norwalk, CT: Appleton & Lange, 1991:64, with permission).

Heart Size

Cardiomegaly, or an enlarged heart, is associated with both congenital and acquired heart disease. Several factors influence the interpretation of cardiac size on a chest radiograph. First, given that the pericardium rests on the diaphragm, the apparent size of the heart will vary with the respiratory cycle and posture. For example, during exhalation or when a patient is in the supine position, the cardiac silhouette is horizontally stretched, and may appear larger. Conversely, during inspiration or in the standing position, the heart is most vertical and appears smaller. Second, the thymic shadow often blends with the cardiac silhouette making an accurate determination of heart size difficult.

A quantitative assessment of cardiac size should be made on the inspiratory film, when 9 to 10 ribs are visualized above the level of the diaphragm. The cardiothoracic ratio is then determined by comparing the transverse dimension of the heart relative to the

width of the thoracic cavity. The heart is considered enlarged if the cardiothoracic ratio exceeds 0.6 in the anterior-posterior dimension.

Individual cardiac chamber sizes can also be assessed on the standard plain film. For example, a large bulge appreciated to the right of the sternum suggests right atrial enlargement. Right ventricular hypertrophy is often demonstrated by an "up-tilting" of the apex of the heart from the diaphragm and an obliteration of the retrosternal space on the lateral projection. Left atrial enlargement is best seen in the lateral view as it displaces or compresses the esophagus. Left ventricular enlargement is best visualized in the anterior-posterior projection and appears as although the apex of the heart is "sagging."

Pulmonary Vascularity

When there is a suspicion of congenital heart disease, the appearance of the pulmonary vascular markings plays an important role in understanding the pathophysiology. In general, when a large left-to-right shunt is present (as in atrial septal defect, ventricular septal defect, patent ductus arteriosus) pulmonary arterial flow is increased and the vessels appear sharp and prominent. In the cyanotic neonate, when there is a paucity of pulmonary vascular markings, one must be suspicious of a right-sided obstructive lesion with a right-to-left shunt. In the case of pulmonary venous congestion, bronchial cuffing, and Kerley B lines, one must suspect pulmonary venous obstructive disease or congestive heart failure.

Specific Cardiac Lesions

Distinctive radiographic configurations have been associated with specific cardiac lesions. The "boot-shaped" heart seen in patients with tetralogy of Fallot reflects right ventricular hypertrophy and hypoplasia of the main pulmonary artery segment, causing a concavity of the upper left heart border. In patients with total anomalous pulmonary venous return without obstruction, a "snowman" or "figure-eight" pattern has been described. This radiographic finding represents right atrial and right ventricular enlargement secondary to the large left-to-right shunt and the presence of a large left-sided vertical vein. The chest roentgenogram of a patient with discrete aortic coarctation often shows a prominent indentation of the aorta resembling a "figure 3." The description of "an egg on a string" is used for the chest x-ray findings in patients with transposition of the great arteries, reflecting the narrowed mediastinum and right heart enlargement.

ECHOCARDIOGRAPHY

In pediatric patients, echocardiography is performed in a systematic manner and obtains subcostal, apical, parasternal, and suprasternal views (Figure 6).

M-Mode Echocardiography

A parasternal short-axis view using M-mode echocardiography reveals a cross section of the left ventricle and can be used to measure dimensions at different points in the cardiac cycle. Most commonly, it is used to obtain a shortening fraction (SF), calculated in the following manner:

$$SF = 100 \times [(LV \text{ end-diastolic dimension} - LV \text{ end-systolic dimension}) / LV \text{ end-diastolic dimension}]$$

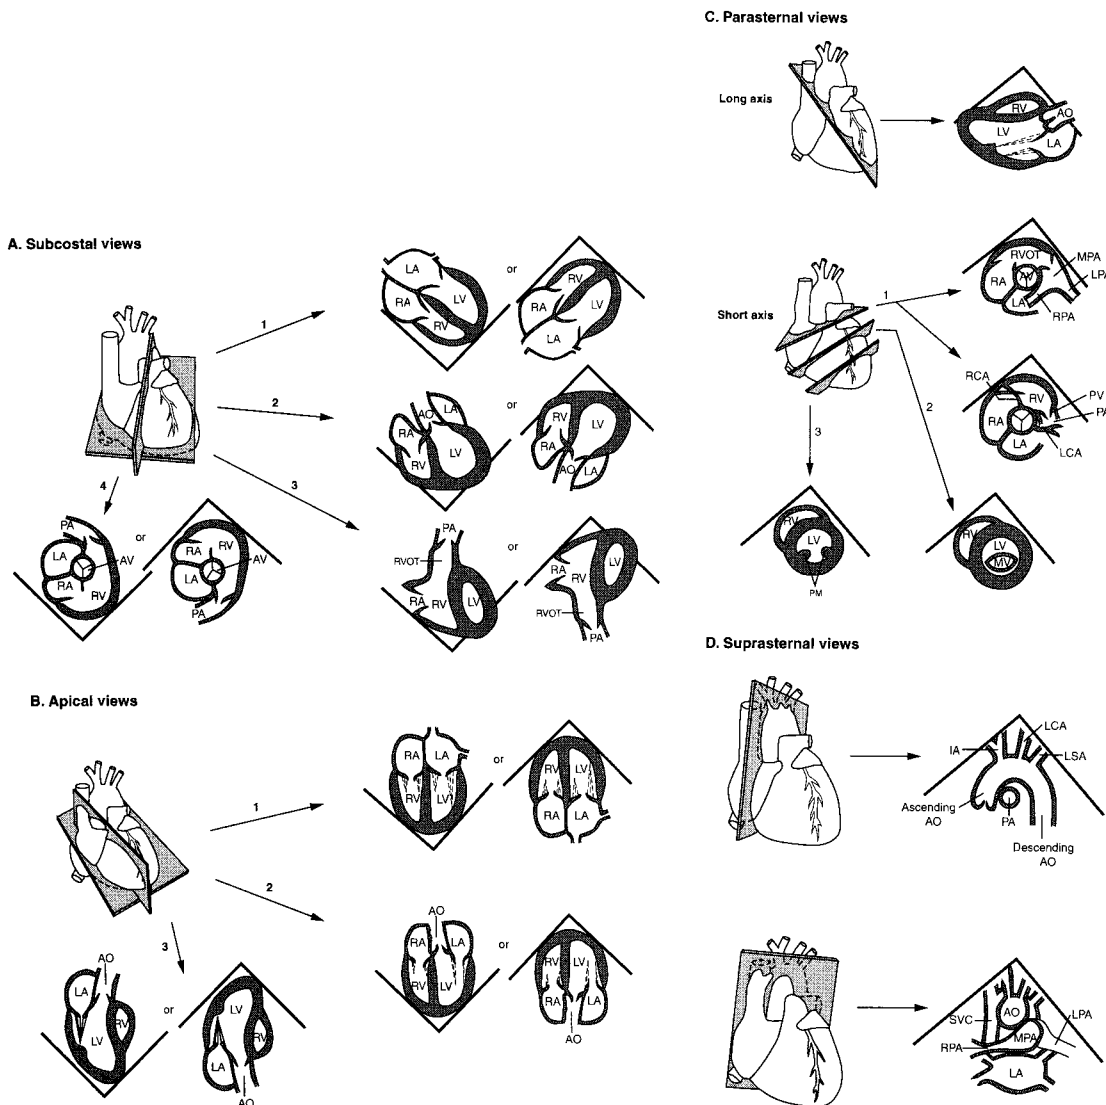

FIGURE 6. Echocardiographic series. The numbers represent different planes along a sweep of the echocardiographic beam. A: Subcostal views. B: Apical views. C: Parasternal views. D: Suprasternal views. AO, aorta; AV, aortic valve; IA, innominate artery; LA, left atrium; LCA, left coronary artery; LPA, left pulmonary artery; LSA, left subclavian artery; MPA, main pulmonary artery; MV, mitral valve; PA, pulmonary artery; PM, papillary muscle; PV, pulmonary valve; RA, right atrium; RCA, right coronary artery; RPA, right pulmonary artery; RV, right ventricle; RVOT, right ventricular outflow tract; SVC, superior vena cava. (Modified from Park MK. Pediatric cardiology for practitioners, 3rd ed. St. Louis: Mosby-Year Book, 1996:70–73, with permission).

The normal value for the SF is 28% to 38%, independent of age.

Doppler Echocardiography

Doppler echocardiography detects a frequency shift that reflects the direction and velocity of blood flow. Doppler echocardiography is used to detect valvular insufficiency or stenosis and abnormal flow patterns.

CARDIAC CATHETERIZATION

Cardiac catheterization allows sampling of oximetric and hemodynamic data. The normal pressures and oxygen saturations for children are shown in Figure 7. Cardiac catheterization, an invasive procedure, is often used in conjunction with angiography to confirm the

diagnosis and physiology of acquired or congenital heart disease. The technique also has therapeutic applications, such as coil embolization of a patent ductus arteriosus, coil embolization of aortopulmonary collaterals, pulmonary artery angioplasty and stent placement, balloon valvuloplasty of semilunar valvular stenosis, and device closure of atrial and some ventricular septal defects.

Shunts

Data obtained from cardiac catheterization can be used to calculate the degree and direction of an intracardiac or extracardiac shunt. The calculation is based on the Fick principle, using oxygen as the indicator. The oxygen content equals the dissolved oxygen (which is usually negligible) plus the oxygen capacity [hemoglobin (g/dL) × 1.36 mL O₂/dL × 10] multiplied by the oxygen saturation (as a percentage).

Flow (Q) is equal to the oxygen consumption divided by the arteriovenous oxygen content difference:

$$Q_p = VO_2 / PV - PA$$

$$Q_s = VO_2 / AO - MV$$

in which

Q_p = pulmonary flow

Q_s = systemic flow

VO₂ = oxygen consumption per unit time

PV = pulmonary venous oxygen content

PA = pulmonary arterial oxygen content

MV = mixed venous oxygen content

AO = systemic arterial (aorta) oxygen content

A shunt is calculated with the effective pulmonary blood flow (Q_{p eff}):

$$Q_{p \text{ eff}} = VO_2 / PV - MV$$

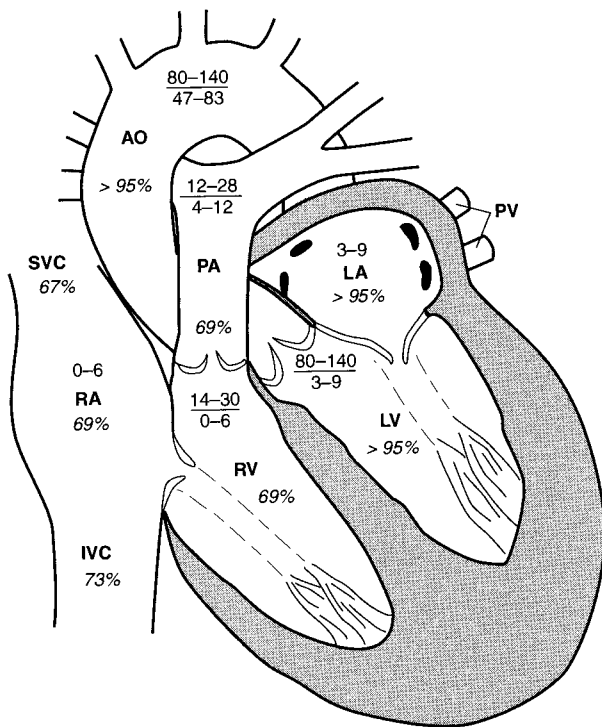

FIGURE 7. Normal pressures (systolic over diastolic, in mmHg), mean pressures, and oxygen saturations for children during cardiac catheterization. The data are based on information compiled from healthy patients between the ages of 2 months and 20 years. AO, aorta; IVC, inferior vena cava; LA, left atrium; LV, left ventricle; PA, pulmonary artery; PV, pulmonary vein; RA, right atrium; RV, right ventricle; SVC, superior vena cava.

A left-to-right shunt is the pulmonary flow less the effective pulmonary flow ($Q_p - Q_{p\text{ eff}}$), and a right-to-left shunt is the systemic flow less the effective pulmonary flow ($Q_s - Q_{p\text{ eff}}$).

Resistance

Systemic and pulmonary vascular resistance can also be calculated using the catheterization data. This calculation is based on Ohm's law (resistance equals the pressure change across the vascular bed divided by flow):

$$R_s = AO - RA/Q_s$$

$$R_p = PA - LA/Q_p$$

in which

R_s = systemic resistance

R_p = pulmonary resistance

AO = mean systemic (aorta) pressure

RA = mean right atrial pressure

PA = mean pulmonary artery pressure

LA = mean left atrial pressure

A pulmonary resistance (R_p) of 2.5 Wood units or less is considered within the normal range; however, no vascular bed is static and variations in flow can affect the result obtained.

Appendix III

Surgical Glossary

Sanjeev K. Swami, MD

AORTOPEXY

aortopexy—a procedure in which the aorta is approximated to the anterior thoracic wall; for the treatment of tracheomalacia.

Battle's sign—bruising over the mastoid process; seen in patients with a basilar skull fracture.

Bishop-Koop procedure—resection of a dilated loop of bowel proximal to meconium obstruction, with end-to-side anastomosis between the proximal bowel and obstructed loop, combined with end ileostomy; for the treatment of meconium ileus.

bladder augmentation—a procedure in which a portion of the intra-abdominal GI tract is used to increase the volume of the bladder.

Blalock-Taussig shunt—a procedure in which the subclavian artery is anastomosed to the pulmonary artery; provides pulmonary blood flow, for the temporary treatment of tetralogy of Fallot.

Boix-Ochoa procedure—restoration of the intra-abdominal esophageal length, repair of the esophageal hiatus, fixation of the esophagus to the hiatus, and restoration of the angle of His; for the treatment of incompetent lower esophageal sphincter.

Charcot triad—fever, jaundice, right upper quadrant pain; seen in patients with cholangitis.

Chordee correction—a procedure in which the corpus spongiosum is moved ventrally and the corpus cavernosa are approximated dorsally; for the treatment of chordee (abnormal penile curvature which can be associated with epispadias or hypospadias).

Clatworthy mesocaval shunt—division of the common iliac veins and side-to-end anastomosis of the inferior mesenteric vein to the left renal vein; for the treatment of portal hypertension.

Cohen procedure—trigonal reimplantation of the ureter; for the treatment of vesicoureteral reflux.

colonic conduit diversion—a procedure involving 2 stages: (1) a loop diversion using a colonic segment, and (2) an end-to-side anastomosis of the colonic segment to the GI tract.

colonic interposition—replacement of the esophagus with a colonic segment; for treatment of esophageal atresia or stricture when gastric mobilization is not feasible.

Dance sign—empty right lower quadrant, seen in patients with ileocecal intussusception.

diaphragmatic placation—surgical shortening of the diaphragm (abdominal, transthoracic, or bilateral); for the treatment of diaphragmatic eventration.

distal splenorenal shunt—see “Warren shunt.”

Drapanas mesocaval shunt—prosthetic graft implantation from the inferior mesenteric vein to the inferior vena cava; for the treatment of portal hypertension.

Duckett transverse preputial island flap—technique in which a flap of foreskin is used to

elongate the urethra; for the treatment of hypospadias.

Duhamel procedure—resection of the aganglionic colon above the dentate line with stable anastomosis to the rectal stump, normally performed in children 6–12 months of age; for the treatment of Hirschsprung disease (see “Martin modification”).

end-to-side portocaval shunt—procedure in which the portal vein is divided and anastomosed to the inferior vena cava; for the treatment of portal hypertension.

esophagectomy—resection of the esophagus, with gastric pull-up and anastomosis with the cervical esophagus; for the treatment of esophageal atresia or stricture.

Fontan procedure—a procedure in which a graft is created to connect the pulmonary artery to the right atrium bypassing the right ventricle; for the treatment of hypoplastic left heart syndrome or other congenital heart diseases with single ventricle physiology.

Fredet-Ramstedt surgery—relaxation of the pyloric sphincter; for the treatment of pyloric stenosis.

gastroschisis—defect of the anterior abdominal wall lateral to the umbilicus (usually on the right), the viscera are not covered by a sac.

Glenn shunt—a shunt from the superior vena cava to the pulmonary artery, bypassing the right atrium and right ventricle; for the treatment of tricuspid atresia or stenosis.

Gridiron incision—see “McBurney incision.”

Hegman procedure—surgical release of the tarsal, metatarsal, and intertarsal ligaments; for the treatment of metatarsus adductus.

Heller myotomy—myotomy of the anterior lower esophagus (always accompanied by a Thal fundoplication); for the treatment of achalasia.

ileal loop diversion—resection and implantation of ureters into an isolated ileal segment, with an ileal stoma and primary anastomosis of ileum to cecum.

ileal ureter—ileal interposition between the renal pelvis and bladder when the ureteral length is insufficient for anastomosis; for the treatment of urinary obstruction.

ileocecal conduit diversion—bilateral ureteral diversion and anastomosis to an isolated ileocecal segment and cecostomy with primary anastomosis of ileum to the right colon.

J-pouch—creation of an ileal reservoir in the distal ileum using a J-shaped anastomosis; used following colectomy.

Jateene procedure—arterial retransposition; for the treatment of transposition of the great vessels.

Kasai procedure—resection of atretic extrahepatic bile ducts and gallbladder with Roux-en-Y anastomosis of the jejunum to the remaining common hepatic duct; for the treatment of biliary atresia or other extrahepatic obstruction.

Kimura procedure (parasitized cecal patch)—a multistep operation in which (1) a side-to-side anastomosis is made with a portion of the distal ileum and the right colon, and (2) an ileoanal pull-through is performed; for the treatment of Hirschsprung disease.

King operation—resection of the knee with placement of a Kuntscher rod to the femur to the tibia, followed by a Syme amputation for the treatment of proximal focal femoral deficiency (PFFD).

Koch pouch diversion—a procedure involving bilateral ureteral diversion with anastomosis to a neobladder formed from an isolated ileal segment, combined with an ileal stoma and primary anastomosis of ileum to ileum.

Ladd's bands—fibrous bands found in the abdomen in patients with malrotation, often cause obstruction; resected during Ladd's procedure.

Ladd's procedure—restoration of intestinal anatomy from a malrotated state involving: counterclockwise reduction of midgut volvulus, splitting of Ladd's bands, division of peritoneal attachments to the cecum and ascending colon, and appendectomy; for the treatment of intestinal malrotation.

Lanz incision—an abdominal incision made in the left iliac fossa; for colostomy formation.

Left hepatectomy—resection of the left hepatic lobe (medial and lateral segments).

MAGPI procedure—distal advancement of the urethral meatus and granuloplasty; for the treatment of hypospadias.

Mainz pouch diversion—a procedure involving bilateral ureteral division with anastomosis to a neobladder formed from isolated cecum and terminal ileum; combined with an ileal stoma and primary anastomosis of the ileum to the right colon.

Martin modification (of Duhamel procedure)—right and transverse colectomy with ileoanal pull-through and side-to-side anastomosis of the remaining left colon to the ileum; procedure preserves some absorptive capacity of the large bowel; for the treatment of total colonic Hirschsprung disease.

McBurney (gridiron) incision—abdominal incision from the anterior superior iliac spine to the umbilicus; used for appendectomy.

Mikulicz procedure—a diverting enterostomy performed proximal to the meconium obstruction without resection; for the treatment of meconium ileus.

Mini-Pena procedure—anterior sagittal anorectoplasty; for the treatment of anterior rectoperianal tula (boys) or rectal-fourchette tula (girls).

Mitrofanoff technique—a modification of neobladder diversion procedures, in which vascularized appendix is used to create the stoma.

mustard technique—redirection of blood through an atrial septal defect (ASD) using a

pericardial “baffle”; for the treatment of transposition of the great vessels; because of associated increased turbulence, this technique is not widely used today.

Mustardé procedure—correction, using simple mattress sutures, of a prominent ear with normal or absent antihelical folds.

Nissen fundoplication—a technique involving a 360° wrap of the gastric fundus around the gastroesophageal junction; for the treatment of incompetent lower esophageal sphincter; patient is rendered unable to vomit or belch.

Norwood procedure—a 3-stage palliative procedure including (1) atrial septectomy, transection, and ligation of the pulmonary artery, “neo-aorta” formation using the proximal pulmonary artery, and creation of a synthetic aortopulmonary shunt (Blalock-Taussing shunt) or with a Sano Modification; (2) creation of a Glenn shunt; and (3) performance of a modified Fontan procedure; for the treatment of hypoplastic left heart syndrome.

onlay island flap—a technique in which a flap of foreskin is used to elongate the urethra; for the treatment of hypospadias.

omphalocele—defect of the anterior abdominal wall at the umbilicus, viscera covered by a sac.

orchiopexy—testicular pull-down and attachment; for the treatment of undescended testis. Also called “orchidopexy.”

orthoplasty—surgical correction of excessive penile curvature.

parasitized cecal patch—see “Kimura procedure.”

Pena procedure—posterior sagittal anorectoplasty performed in children 1–6 months of age; for the treatment of imperforate anus.

Pentalogy of Cantrell—diaphragmatic hernia, cardiac abnormalities, omphalocele, absence or malformation of the pericardium, and stern cleft.

Pfannenstiel incision—an abdominal incision used to gain access to the lower abdomen and bring pelvic organs within reach without dividing muscular tissue.

pharyngoplasty—elevation of the posterior pharyngeal wall following a primary cleft palate repair (to narrow the pharyngeal space); for the treatment of velopharyngeal incompetence.

Potts shunt—anastomosis of the descending aorta to the pulmonary artery for the permanent treatment of tetralogy of Fallot.

proximal splenorenal shunt—end-to-side anastomosis of the splenic vein to the left renal vein with splenectomy; for the treatment of portal hypertension.

pyeloplasty—resection of an atretic ureter with primary anastomosis to the renal pelvis; for the treatment of ureteropelvic junction obstruction.

pyloromyotomy—relaxation of the pyloric sphincter; for the treatment of pyloric stenosis.

Ramstedt operation—relaxation of the pyloric sphincter; for the treatment of pyloric stenosis.

Rashkind procedure—balloon atrial septostomy; for the treatment of transposition of the great vessels.

Rastelli repair—a technique involving the closure of a ventricular septal defect (VSD) with a patch and the creation of a conduit from the distal pulmonary artery to the right ventricle; for the treatment of transposition of the great vessels.

Ravitch procedure—a procedure involving (1) creation of osteotomies between the manubrium and costal cartilages, (2) a greenstick fracture of the manubrium, and (3) the temporary insertion (for 6 to 12 months) of a stabilizing bar; for the treatment of pectus excavatum or pectus carinatum.

right colon pouch—a procedure involving bilateral ureteral division with anastomosis to a neobladder (formed from an isolated segment of the right colon), combined with an ileal stoma and primary anastomosis of the ileum to the transverse colon.

right hepatectomy—resection of the right hepatic lobes (anterior and posterior segments).

rooftop (bilateral subcostal) incision—an abdominal incision used to access the liver and portal structures.

Roux-en-Y anastomosis—division of the jejunum distal to the ligament of Treitz with end-to-side anastomosis of the duodenum to the distal jejunum and anastomosis of the proximal jejunum (typically) to the bile duct.

Rovsing's sign—right lower quadrant pain with palpation of the left lower quadrant; seen in patients with appendicitis.

S-pouch—the creation of an ileal reservoir in the distal ileum using an S-shaped conuration following colectomy.

Sano modification—synthetic shunt connecting the right ventricle to the pulmonary arteries as part of a stage 1 Norwood procedure; provides pulmonary blood flow after ligation of proximal pulmonary arteries; for the treatment of hypoplastic left heart syndrome.

Santulli-Blanc enterostomy—a modification of the Bishop-Koop procedure that involves the resection of a distal dilated bowel segment with side-to-end anastomosis to the proximal enterostomy; for the treatment of meconium ileus.

Senning procedure (venous switch)—technique involving intraatrial redirection of venous return so that systemic caval return is shunted through the mitral valve to the left ventricle, and pulmonary return is brought through the tricuspid valve to the right ventricle; for the treatment of transposition of the great vessels.

side-to-side portocaval shunt—a procedure in which the portal vein is anastomosed to the inferior vena cava; for the treatment of portal hypertension.

side-to-side splenorenal shunt—side-to-side anastomosis of the splenic vein to the left renal vein; for the treatment of portal hypertension.

Sistrunk operation—complete excision of a thyroglossal duct cyst.

Soave procedure—a technique involving endorectal pull-through; for the correction of Hirschsprung disease.

Stamm gastrostomy—placement of an open gastrostomy tube; the opening is designed to close spontaneously on removal of the tube.

Sting procedure—subureteric Teflon injection; for the endoscopic correction of vesicoureteral reflux.

Sugiura procedure—a technique that involves lower esophageal transection and primary anastomosis, devascularization of the lower esophagus and stomach, and splenectomy; for the treatment of esophageal varices.

Swenson procedure—resection of the posterior rectal wall to the dentate line (aganglionic region); for the treatment of Hirschsprung disease; technically difficult and rarely performed.

Syme amputation—amputation of the foot, calculated to bring the end of the stump above the opposite knee at maturity; for the treatment of proximal focal femoral deficiency (PFFD).

Thal procedure—a procedure involving a 180° anterior wrap of the gastric fundus around the gastroesophageal junction, preserving the patient's ability to vomit and belch; for the treatment of incompetent lower esophageal sphincter.

Thiersch operation—a procedure in which a distal rectal segment that has prolapsed is approximated to the external sphincter muscle; for the treatment of rectal prolapse.

trisegmentectomy—resection of the right hepatic lobe and the quadrate lobe of the liver (right posterior segment, right anterior segment, and medial segment).

ureteropyelostomy—partial resection and side-to-side anastomosis of a partially duplicated ureter.

uretocalycostomy—a technique for the treatment of urinary obstruction involving division of the ureter (distal to the obstruction) and intrarenal anastomosis to the most dependent renal calyx; when the renal pelvis is insufficient for anastomosis, the lower pole of the kidney is resected.

vaginal switch operation—a procedure in which the vagina is separated from the urinary tract; for treatment of duplicated vagina.

Van Ness procedure—rotational 180° osteotomy of the femur in which the foot and ankle are brought to the level of the opposite knee; for prosthetic attachment for the treatment of femoral deficiency.

venous switch—see “Senning procedure.”

VENTRICULAR-PERITONEAL SHUNT PROCEDURE

ventricular-peritoneal shunt

procedure—a procedure in which a Silastic catheter is positioned in a lateral ventricle and tunneled subcutaneously to drain into the peritoneal cavity; for the treatment of hydrocephalus. The shunt is occasionally positioned to drain into the central venous system, the pleura, or the right atrium.

Warren (distal splenorenal) shunt

—a procedure in which the splenic vein is anastomosed to the left renal vein; for the treatment of portal hypertension.

Waterston aortopulmonary

anastomosis—a procedure involving anastomosis

of the ascending aorta and the right pulmonary artery; for the temporary treatment of tetralogy of Fallot.

Whipple procedure—resection of the pancreatic head, duodenum, and gallbladder with gastrojejunostomy, hepatojejunostomy, and pancreaticojejunostomy.

Appendix IV

Medications

Monica Darby, Shannon Manzi, and Susan McKamy

MEDICATIONS

Table 1. Medications

	Dosages	Dosage Forms
Acetaminophen (Feverall, Tylenol, Ofirmev)	<p>IV, PO or rectally: Premature infants, age <3 months: 10–12 mg/kg q8–12h. Infants, age <3 months: 10–15 mg/kg repeated q8h. Children: 10–15 mg/kg repeated q4–6h, up to 5 doses daily. (Do NOT exceed 75 mg/kg/day or 4 g/day). Adults: 325–650 mg q4–6h. Do not exceed 3 g/day.</p>	<p>Injection: 10 mg/mL Suspension: 160 mg/5 mL Suppositories: 120 mg, 325 mg, 650 mg Tablets: 160 mg, 325 mg, 500 mg Tablets, chewable: 80 mg Also available in combination with codeine; see codeine monograph.</p>
Acetazolamide (Diamox)	<p>PO or IV: Children and adults: 8–30 mg/kg/day in 4 divided doses. Do not exceed 1 g/day. Lower doses are used for diuresis or correction of metabolic acidosis. The higher doses are used for the treatment of hydrocephalus or seizures. <i>Altitude sickness (adults):</i> 250 mg q8–12h beginning 24–48 hours before ascent and continuing for at least 48 hours after arrival.</p>	<p>Injection: 500 mg Tablets: 125, 250 mg Capsule, sustained release: 500 mg</p>
Acetylcysteine (Mucomyst, Mucosil, Acetadote)	<p>Acetaminophen poisoning: IV: 150 mg/kg as an initial infusion over 1 hour followed by a second infusion of 50 mg/kg over 4 hours, followed by a third infusion of 100 mg/kg over 16 hours. Therapy may continue at a rate of 6.25 mg/kg/hr until acetaminophen level reaches 0 and AST/ALT levels decrease. PO: 140 mg/kg PO followed by 70 mg/kg for 17 doses administered q4h until acetaminophen levels are nontoxic. Usually administered as a 5% solution diluted in juice or soda. <i>Inhalation (administer 10% solution undiluted):</i> Infants: 2–4 mL of 10% soln repeated t.i.d. or q.i.d. Children and adolescents: 6–10 mL of 10% soln repeated t.i.d. or q.i.d.</p>	<p>Injection: 200 mg/mL in 30 mL vials Solution for inhalation: 10% or 20% in 10-mL and 30-mL vials</p>
Acyclovir (Zovirax)	<p>PO: <i>Varicella zoster (chickenpox):</i> 80 mg/kg/day in 4 divided doses for 5 days. Do not exceed 800 mg/dose (3,200 mg/day). <i>Herpes simplex virus:</i> Children: 40–80 mg/kg/day in 3–4 divided doses. Adults: 200 mg q4h while awake (5 doses daily). Chronic suppressive therapy at a dose of 400 mg b.i.d. may be used for up to 1 year or longer. IV: <i>Neonatal HSV encephalitis:</i> Full term infants: 60 mg/kg/day in 3 divided doses for 10–14 days. <i>HSV encephalitis:</i> 1,500 mg/m²/day in 3 divided doses for at least 10 days and up to 21 days. <i>Other HSV infections:</i> 750 mg/m²/day in 3 divided doses for 7 days. <i>Varicella zoster infections:</i> 1,500 mg/m²/day in 3 divided doses for 7 days. <i>Topically:</i> Apply ointment q3h up to 6 times daily for 7 days. Use a disposable finger cot or glove when applying the ointment to avoid transmission of the virus. Dosage may need to be adjusted in patients with renal dysfunction. Ensure adequate hydration.</p>	<p>Capsules: 200 mg Injection: 500-mg, 1-g vials Ointment: 5%, 15 g Suspension: 200 mg/5 mL</p>
Adenosine (Adenocard)	<p>IV (given via rapid push followed by a saline flush): Neonates: 0.05 mg/kg initially followed by doses increasing in 0.05 mg/kg increments q2min to a maximum dose of 0.25 mg/kg. Children: 0.1 mg/kg initially, followed by increased doses (double dose to 0.2 mg/kg OR increase by 0.05 mg/kg increments) q2min to a maximum dose of 0.35 mg/kg or 12 mg/dose. Adults: 6 mg followed by 12 mg with a repeat dose of 12 mg, if needed.</p>	<p>Injection: 3 mg/mL (2-mL vial)</p>

Table 1. Medications (continued)

	Dosages	Dosage Forms
Albumin, human (Albuminar, Albutein, Plasbumin)	<p>IV (as a 5% solution for hypovolemic patients or 25% for fluid- or sodium-restricted patients): Children: 0.5–1 g/kg infused over 2–4 hours. May repeat to a maximum of 6 g/kg/day. Adults: 25 g infused over 2–4 hours. Usually not to exceed 125 g/day.</p>	<p>Injection: 5% (50 mL, 250 mL, 500 mL); 25% (20 mL, 50 mL, 100 mL)</p>
Albuterol (Proventil HFA, Ventolin HFA, Proair HFA)	<p>PO: Age 2–<6 years: 0.3–0.6 mg/kg/day in 3 divided doses to a maximum of 12 mg/day. Age ≥6–<12 years: 6–8 mg/day in 3–4 divided doses to a maximum of 24 mg/day. Age > 12 years: 6–16 mg/day in 3–4 divided doses to a maximum of 32 mg/day.</p> <p>Inhalation: <i>Metered-dose inhaler:</i> Age < 12 years: 1–2 inhalations q.i.d. Age > 12 years: 1–2 inhalations up to 6 times a day. Exacerbation: < 10 kg: 2–4 puffs; 10–30 kg: 4–6 puffs; > 30 kg: 6–8 puffs <i>Nebulization of 0.5% solution:</i> < 10 kg = 0.25 mL, 10–30 kg: 0.5 mL; > 30 kg: 1 mL usually repeated q4–6h, but may be administered more frequently (including continuously) in severely ill patients under controlled conditions.</p>	<p>Aerosol HFA: 90 mcg/actuation Solution for inhalation: 0.5%, 0.083% Syrup: 10 mg/5 mL Tablets: 2 mg, 4 mg Tablets, extended release: 4 mg, 8 mg</p>
Allopurinol (Zyloprim)	<p>PO: <i>Neoplastic diseases:</i> Age < 10 years: 10 mg/kg/day in 3 divided doses to a maximum of 300 mg/day. Age > 10 years: 600–800 mg/day in 2 or 3 divided doses.</p> <p>IV: <i>Neoplastic diseases:</i> Age < 10 years: 100 mg/m²/dose q8h, max 600 mg/day Age > 10 years: 200–400 mg/m²/day divided in 1–3 doses, max 600 mg/day. Note: The metabolism of mercaptopurine and azathioprine is decreased by allopurinol. Decrease dose of mercaptopurine or azathioprine by 75%.</p>	<p>Tablets: 100 mg, 300 mg Injection: 3 mg/mL</p>
Alprostadil (Prostin VR Pediatric)	<p>IV: A continuous infusion beginning at a dose of 0.05–0.1 mcg/kg/min. Dosage may be adjusted downward or gradually upward based on the patient’s response. Usual dosage range is 0.01–0.4 mcg/kg/min.</p>	<p>Injection: 500 mcg/mL (1-mL vial)</p>
Aluminum and magnesium hydroxides (Maalox, Mylanta)	<p>PO: Children: 5–15 mL 4–6 times daily or more frequently. Adults: 15–45 mL 4–6 times daily or more frequently.</p>	<p>Suspension: Aluminum hydroxide 200 mg, magnesium hydroxide 200 mg/5 mL with simethicone 20 mg/5 mL</p>
Amikacin (Amikin)	<p>IV (dose should be based on ideal body weight): Neonates: Age 0–4 weeks, < 1,200 g: 7.5 mg/kg/dose q18–24h. Age ≤ 7 days: 1,200–2,000 g: 7.5 mg/kg/dose q12–18h. > 2,000 g: 10 mg/kg/dose q12h. Age > 7 days: 1,200–2,000 g: 7.5 mg/kg/dose q8–12h. > 2,000 g: 10 mg/kg/dose q8h or 30 mg/kg/dose q24h. Infants and children: 15–22.5 mg/kg/day in 3 divided doses daily. The dose for the treatment of nontuberculous mycobacterial infections is 15–30 mg/kg/day in 2 divided doses, to a maximum of 1.5 g/day as part of a multiple-drug regimen. Increase to 30 mg/kg/day for patients with cystic fibrosis. Adults: 15 mg/kg/day in 2–3 divided doses. Dosage adjustment is required in patients with renal dysfunction.</p>	<p>Injection: 50 mg/mL, 250 mg/mL</p>

(continued)

Table 1. Medications (continued)

	Dosages	Dosage Forms
Aminocaproic acid (Amicar)	<p>IV: Children: 100 mg/kg over the first hour followed by an infusion of 33.3 mg/kg/hr or 100 mg/kg q6h. Maximum daily dose is 30 g. Older children and adults: 4–5 g over the first hour followed by an infusion of 1 g/hr for 8 hours or until control is achieved.</p> <p>PO: Doses are the same or alternatively, 100 mg/kg may be administered q4–6h to a maximum of 5 g/dose.</p>	<p>Injection: 250 mg/mL (20-mL vial) Solution: 1.25 g/5 mL (16-oz bottle) Tablet: 500 mg</p>
Amiodarone (Cordarone)	<p>PO: Children (use BSA for children ≤ 1 year): Loading dose of 10–15 mg/kg/day or 600–800 mg/1.73 m²/day in 1–2 divided doses for 4–14 days or until adequate control of arrhythmia is achieved or prominent adverse effects occur. Then reduce dosage to 5 mg/kg/day or 200–400 mg/1.73 m²/day as a single dose for several weeks. A further dose reduction to 2.5 mg/kg/day should be attempted if the arrhythmia does not recur. Adults: Loading dose of 800–1,600 mg/day in 1–2 divided doses for 1–3 weeks, followed by dose of 600–800 mg/day in 1–2 divided doses for 1 month. Maintenance dose usually 400 mg/day, but may be lower for supraventricular arrhythmias.</p> <p>IV: Children (only limited information is available): Initial loading dose of 5 mg/kg over 1 hour followed by a continuous infusion of 5 mcg/kg/min has been used. The continuous infusion dosage may be increased to 10 mcg/kg/min and then to 15 mcg/kg/min until the desired effect is achieved. Due to the leaching of DEHP from IV administration sets, especially at the slow rates usually used in infants, bolus dosing q6h should be considered if IV therapy is expected to be long term. Adults: Loading dose of 150 mg administered over 10 minutes (15 mg/min) followed by 360 mg over 6 hours at a rate of 1 mg/min, followed by the maintenance dose of 540 mg over 18 hours at a rate of 0.5 mg/min. If necessary, maintenance infusion of 0.5 mg/min may be continued past the initial 24 hours. Additional bolus doses of 150 mg may be administered over 10 minutes for breakthrough arrhythmias.</p> <p>VT/VF dosing: Child: 5 mg/kg IV push Adult: 300 mg IV push</p>	<p>Injection: 50 mg/mL Tablets: 200 mg</p>
Amitriptyline (Elavil, Endep)	<p>PO: <i>Chronic pain:</i> 0.1 mg/kg/day at bedtime initially, advancing to 0.5–2 mg/kg/day over a 2–3 week period. <i>Depression:</i> 1 mg/kg/day to start, advancing to a maximum of 5 mg/kg or 100 mg, whichever is less. Adolescents and adults: 25–50 mg at bedtime or in divided doses, increasing daily doses by 25 mg to a maximum of 100 mg/day for adolescents and 300 mg for adults. Dosage should be decreased to the lowest effective dose after symptom control has been reached.</p>	<p>Tablets: 10 mg, 25 mg, 50 mg, 75 mg, 100 mg, 150 mg</p>
Amlodipine (Norvasc)	<p>PO: <i>Hypertension:</i> Children: 0.1 mg/kg/dose (max 10 mg) given once daily. Adults: 2.5–5 mg initial, max 10 mg/day. Doses may be titrated upward at 5–7 day.</p>	<p>Tablets: 2.5 mg, 5 mg, 10 mg</p>
Amoxicillin (Amoxil, Trimox)	<p>PO: Children ≤ 20 kg: 20 mg/kg/day in 2 or 3 divided doses for UTIs. 40 mg/kg/day in 2 or 3 divided doses for otitis media, upper respiratory infection, or skin infections. Acute otitis media due to highly resistant strains of <i>S. pneumoniae</i> may require doses of 80–90 mg/kg/day in 2 or 3 divided doses. Children > 20 kg and adults: 250–500 mg/dose t.i.d. or 500–875 mg b.i.d. Maximum daily dose is 3 g. <i>Endocarditis prophylaxis:</i> 50 mg/kg (up to 2 g) 1 hour before procedure. Dosage must be adjusted in patients with renal dysfunction.</p>	<p>Capsules: 250 mg, 500 mg Drops: 50 mg/mL Suspension: 125 mg/5 mL, 200 mg/5 mL, 250 mg/5 mL, 400 mg/5 mL Tablets, chewable: 125 mg, 200 mg, 250 mg, 400 mg Tablets: 500 mg, 875 mg</p>

Table 1. Medications (continued)

Medication	Dosages	Dosage Forms
Amoxicillin and clavulanic acid (Augmentin, Augmentin ES-600)	<p>PO (based on the amoxicillin component): 20–40 mg/kg/day in 3 divided doses to a maximum of 1.5 g/day, or 25–45 mg/kg/day in 2 divided doses to a maximum of 1.75 g/day using the b.i.d. formulation of the drug. Use the higher doses for respiratory tract infections and otitis media. Otitis media infections caused by multidrug-resistant <i>pneumococcus</i>: 80–90 mg/kg/day in 2 divided doses using the ES-600 suspension to avoid higher than recommended doses of clavulanic acid. Dosage must be adjusted in patients with renal dysfunction.</p>	<p>Suspension: Amoxicillin 125 mg and clavulanic acid 31.25 mg/5 mL; b.i.d. formulation—amoxicillin 200 mg and clavulanic acid 28.5 mg/5 mL; amoxicillin 250 mg and clavulanic acid 62.5 mg/5 mL; b.i.d. formulation—amoxicillin 400 mg and clavulanic acid 57 mg/5 mL; b.i.d. formulation—amoxicillin 600 mg and clavulanic acid 42.9 mg/5 mL Tablets: Amoxicillin 250 mg and clavulanic acid 125 mg; amoxicillin 500 mg and clavulanic acid 125 mg; b.i.d. formulation—amoxicillin 875 mg and clavulanic acid 125 mg Tablets, chewable: Amoxicillin 125 mg and clavulanic acid 31.25 mg; b.i.d. formulation—amoxicillin 200 mg and clavulanic acid 28.5 mg; amoxicillin 250 mg and clavulanic acid 62.5 mg; b.i.d. formulation—amoxicillin 400 mg and clavulanic acid 57 mg</p>
Amphotericin B (Fungizone)	<p>IV (infusion over 2–8 hours): Begin with 0.25–0.5 mg/kg. Doses may be doubled on each subsequent day to a maximum of 1 mg/kg as the patient tolerates. Once therapy is established, alternate day doses at a maximum of 1.5 mg/kg/day may be used. Bladder irrigations of 50 mg daily in 1 L of sterile water instilled over 24 hours have been used to treat bladder infections. Do NOT confuse with liposomal amphotericin dosing.</p>	Injection: 50-mg vial
Amphotericin B, cholesteryl (Amphotec)	<p>IV: Children and adults: 3–4 mg/kg/day as a single infusion. Doses of 6 mg/kg/day have been used to treat invasive <i>Candida</i> or <i>Cryptococcus</i> infections. Admix with 5% dextrose injection to a final concentration of ~0.6 mg/mL for administration over 3–4 hours. In patients who tolerate the longer infusion time well, the time can be shortened to 2 hours.</p>	Injection: 50-mg vial, 100-mg vial
Amphotericin B, lipid complex (Abelcet)	<p>IV (infuse over 2 hours): Children and adults: 2.5–5 mg/kg/day in a single infusion. Admix with 5% dextrose to a final concentration of 1 mg/mL. A final concentration of 2 mg/mL may be used for pediatric patients or patients requiring fluid restriction.</p>	Suspension for injection: 5 mg/mL
Amphotericin B Liposomal (AmBisome)	<p>IV (infuse over 2 hours): Children: 3–5 mg/kg/day Adults: 2–6 mg/kg/day Administer as an infusion at a concentration of 132 mg/mL over 2 hours. The infusion time may be decreased to 1 hour in patients who tolerate the 2 hr infusion.</p>	Injection: 50-mg vial
Ampicillin (Principen)	<p>IV: <i>Meningitis:</i> Neonates, age <7 days: <2,000 g: 100 mg/kg/day in 2 divided doses. ≥2,000 g: 150 mg/kg/day in 3 divided doses. Neonates, age >7 days: <1,200 g: 100 mg/kg/day in 2 divided doses. 1,200–2,000 g: 150 mg/kg/day in 3 divided doses. >2,000 g: 200 mg/kg/day in 4 divided doses. Infants and children: 150–300 mg/kg/day in 4–6 divided doses to a maximum of 12 g/day. Adults: 150–200 mg/kg/day in 6–8 divided doses to a maximum total daily dose of 14 g. <i>Moderate infections:</i> Neonates, age <7 days: <2,000 g: 50 mg/kg/day in 2 divided doses. >2,000 g: 75 mg/kg/day in 3 divided doses.</p>	<p>Capsules: 250 mg, 500 mg Injection: 125-mg, 250-mg, 500-mg, 1-g, 2-g vials Suspension: 125 mg/5 mL, 250 mg/5 mL</p>

(continued)

Table 1. Medications (continued)

	Dosages	Dosage Forms
Ampicillin (Principen) (continued)	<p>Neonates, age <7 days: <1,200 g: 50 mg/kg/day in 2 divided doses. 1,200–2,000 g: 75 mg/kg/day in 3 divided doses. >2,000 g: 100 mg/kg/day in 4 divided doses. Infants, children, and adults: 50–100 mg/kg/day in 4–6 divided doses to a maximum total dose of 12 g/day.</p> <p>PO (mild to moderate infections): Children <20 kg: 50–75 mg/kg/day in 4 divided doses. Do not exceed adult doses for the same degree of infection. Children >20 kg and adults: 1–2 daily (250–500 mg/dose) in 4 divided doses. Dosage must be adjusted in patients with renal dysfunction.</p>	
Ampicillin and sulbactam sodium (Unasyn)	<p>IV (dosed as ampicillin component): Infants and children: 100–200 mg/kg/day in 4 divided doses (max 8 g amp/day). Adults: 1.5–3 g (1–2 g ampicillin + 0.5–1 g sulbactam) given q6h. Maximum dose is 12 g/day (ampicillin + sulbactam). Dosage must be adjusted in patients with renal dysfunction.</p>	<p>Injection: 1.5 g (1 g ampicillin + 0.5 g sulbactam), 3 g (2 g ampicillin + 1 g sulbactam)</p>
Ascorbic acid	<p>PO, IM, IV (IM preferred over IV): Children: Scurvy: 100–300 mg daily in 3–4 divided doses. Dietary supplementation: 35–100 mg daily. Adults: Scurvy: 200–500 mg daily in 2 divided doses. Dietary supplementation: 50–200 mg daily.</p>	<p>Injection: 250 mg/mL, 500 mg/mL Solution: 90 mg/mL Tablets: 100 mg, 250 mg, 500 mg, 1,000 mg</p>
Aspirin (Anacin, Ascriptin, Bufferin, Easprin, Ecotrin)	<p>PO or rectally: <i>Analgesic, antipyretic:</i> Children: 10–15 mg/kg q4–6h. Adults: 325–1,000 mg q4–6h, up to 4 g/day. <i>Anti-inflammatory:</i> Children ≤25 kg: 60–90 mg/kg/day in 3–4 divided doses initially, with a usual range of 80–100 mg/kg/day. Monitor serum levels. Children >25 kg and adults: 2.4–3.6 g/day in 4 divided doses. Maximum total daily dose usually should not exceed 5.4 g. <i>Kawasaki syndrome:</i> 100 mg/kg/day in 4 divided doses until fever resolves; then 3–5 mg/kg once daily for 6–10 weeks after onset of the disease, or longer.</p>	<p>Suppositories: 300 mg, 325 mg, 600 mg, 650 mg Tablets: 325 mg, 500 mg, 650 mg Tablets, chewable: 81 mg Tablets, extended release: 165 mg, 325 mg, 500 mg, 650 mg, 975 mg Also available in buffered formulation, enteric-coated tablets, and chewing gum.</p>
Atenolol (Tenormin)	<p>PO: Children: Initially 0.8–1 mg/kg/day in a single dose. Dosage may be increased to 1.5 mg/kg/day or a maximum of 2 mg/kg/day if necessary. Adults: Initially 25–50 mg/day, increasing to 50–100 mg/day as needed. The maximum dose for hypertension is 100 mg; for angina, 200 mg.</p>	<p>Tablets: 25 mg, 50 mg, 100 mg</p>
Atomoxetine (Strattera)	<p>PO: Children ≤70 kg: 0.5 mg/kg/day initially to a maximum of 1.2 mg/kg/day. Doses may be given as a single daily dose or as 2 divided doses. Adolescents and adults >70 kg: 40 mg daily initially, increasing to a maximum daily dose of 100 mg.</p>	<p>Capsules: 10 mg, 18 mg, 25 mg, 40 mg, 60 mg, 80 mg, 100 mg</p>
Atropine sulfate	<p>PO or IM: Preoperative: 0.02 mg/kg to a maximum dose of ~1 mg. <i>Bradycardia:</i> 0.02 mg/kg with a minimum dose of 0.1 mg and a maximum dose of 0.5 mg in children, 1 mg in adolescents, and 2 mg in adults. No longer in PALS algorithm, use only if suspicion of vagal stimulation. <i>Ophthalmic:</i> 1–2 drops of 0.5–1% solution in the eye.</p>	<p>Injection: 0.3 mg/mL, 0.4 mg/mL, 0.5 mg/mL, 0.8 mg/mL, 1 mg/mL Ointment, ophthalmic: 0.5%, 1% Solution, ophthalmic: 0.5%, 1%, 2%</p>

Table 1. Medications (continued)

	Dosages	Dosage Forms
Azathioprine (Imuran)	<p>IV or PO: <i>Transplant:</i> Initially 2–5 mg/kg/day as a single dose. Maintenance doses are usually 1–3 mg/kg/day. <i>Lupus:</i> 2–3 mg/kg/day as a single dose. <i>Rheumatoid arthritis:</i> 1 mg/kg/day as a single dose. Note: Metabolism of azathioprine is decreased by allopurinol; decrease dose of azathioprine by 75%.</p>	<p>Injection: 100-mg vial Tablets: 50 mg</p>
Azelastine (Astellin)	<p>Intranasal metered dose spray: Age 5–11 years: 1 spray in each nostril b.i.d. Age ≥12 years: 2 sprays in each nostril b.i.d.</p>	<p>Solution, nasal: 137 mcg/metered spray</p>
Azithromycin (Zithromax)	<p>IV or PO: <i>Otitis media</i> (age ≥6 months): 10 mg/kg (to a maximum of 500 mg) on the first day followed by 5 mg/kg/day (to a maximum of 250 mg) for 4 days. Alternatively, a dose of 30 mg/kg as a single dose (maximum 1,500 mg) or 10 mg/kg/day for 3 days (maximum 500 mg/day) may be used. <i>Pharyngitis/Tonsillitis:</i> Age ≥2 years: 12 mg/kg/day (to a maximum of 500 mg) for 5 days. Adults: 500 mg on the first day followed by 250 mg/day for 4 days. <i>Uncomplicated chlamydia infection:</i> 1 g as a single dose for patients >8 years of age weighing at least 45 kg. <i>Gonorrhea:</i> 2 g for patients weighing at least 45 kg. <i>Chancroid:</i> 20 mg/kg to a maximum dose of 1 g.</p>	<p>Tablets: 250, 500, 600 mg Suspension: 100 mg/5 mL, 200 mg/5 mL, 1-g packet Injection: 2 mg/mL</p>
Aztreonam (Azactam)	<p>IV or IM: Children over age 1 month: 60–100 mg/kg/day in 3–4 divided doses. Doses of up to 200 mg/kg/day have been used in cystic fibrosis patients. Maximum total daily dose is 8 g. Adults: 1–2 g q6–8h, depending on the severity of the infection. Dose adjustment is necessary in renal impairment.</p>	<p>Injection: 500-mg, 1-g, 2-g vials</p>
Bacitracin; bacitracin and polymyxin B (Polysporin); bacitracin, neomycin, and polymyxin B (Neosporin)	<p>Ophthalmic: Apply to eyes q3–4h. If both eyes involved, dispense separate tubes. Topically: Apply to affected area 1–3 times daily.</p>	<p>Ointment, topical (all 3): 15-g, 30-g tubes Ointment, ophthalmic (all 3): 3.5-g tube</p>
Beclomethasone dipropionate (BeconaseAQ, QVAR)	<p>Intranasal aqueous formulation: Age ≥6 years: 1–2 sprays in each nostril b.i.d. Oral inhalation: Age 6–12 years: 40 mcg b.i.d. Do not exceed 8 mcg b.i.d. Age >12 years: 40–80 mcg b.i.d. Do not exceed 320 mcg b.i.d.</p>	<p>Intranasal aerosol spray: 42 mcg/spray Oral inhalation aerosol: 40 mcg/spray, 80 mcg/spray</p>
Betamethasone (Diprolene, Maxivate)	<p>Apply a thin film to the skin 1–3 times daily. Avoid application to the face, groin, or axillae.</p>	<p>Dipropionate, augmented (Diprolene): 0.05% cream, lotion, gel, ointment Dipropionate: 0.05% cream, lotion, ointment Dipropionate with clotrimazole (antifungal) [Lotrisone] Valerate: 0.1% cream, lotion, ointment</p>

(continued)

Table 1. Medications (continued)

	Dosages	Dosage Forms
Bisacodyl (Dulcolax)	<p>PO: (Higher doses for evacuation, lower for laxative): Age 3–12 years: 5–10 mg as a single dose. Age > 12 years: 5–15 mg as a single dose. Tablets are enteric coated and must not be chewed or crushed.</p> <p>Rectally: Age < 2 years: 5 mg/day as a single dose. Age 2–11 years: 5–10 mg/day as a single dose. Age ≥ 12 years: 10 mg/day as a single dose.</p>	<p>Suppositories: 10 mg Tablets, enteric coated: 5 mg</p>
Budesonide (Pulmicort, RhinocortAqua)	<p>Intranasal metered dose spray: Age ≥ 6 years: 2 sprays in each nostril in the morning or as 2 divided doses. Dosage may be decreased to the lowest number of sprays that controls symptoms.</p> <p>Oral inhalation powder: Age 6–12 years: 1–2 puffs b.i.d. Age > 12 years: 2–4 puffs b.i.d.</p> <p>PO inhalation suspension for nebulization: All patients: 0.5–2 mg daily as a single daily dose or in 2 divided doses.</p>	<p>Oral inhalation powder: 200 mcg/actuation Oral inhalation suspension: 0.25 mg/2 mL, 0.5 mg/2 mL Suspension, nasal: 32 mcg/actuation</p>
Bumetanide (Bumex)	<p>PO or IV: Neonates: 0.01–0.05 mg/kg/dose q24–48h. Infants and children: 0.015–0.1 mg/kg/dose q6–24h to a maximum of 10 mg/day. Adults: 0.5–1 mg/dose IV or 0.5–2 mg/dose PO once or twice daily to a maximum of 10 mg/day.</p>	<p>Injection: 0.25 mg/mL Tablets: 0.5 mg, 1 mg, 2 mg</p>
Caffeine	<p>PO or IV: <i>Loading dose:</i> 10 mg/kg caffeine base. If theophylline has been administered within the previous 3 days, a modified dose (50–75% of loading dose) may be given. <i>Maintenance:</i> 2.5 mg/kg caffeine base 24 hours after the loading dose. Dosage may be adjusted based on the patient's response and the results of serum level monitoring. Do not use caffeine and sodium benzoate injection in neonates.</p>	<p>Injection: 10 mg/mL base Solution: 10 mg/mL base</p>
Calcitriol (Calcijex, Rocaltrol)	<p>Individualize to maintain normal serum calcium levels.</p> <p>PO: <i>Hypocalcemia in premature infants:</i> 1 mcg/day for 5 days. <i>Renal failure:</i> Children: 0.25–2 mcg/day (hemodialysis) or 0.014–0.041 mcg/kg/day (no hemodialysis). Adults: 0.25–1 mcg/day.</p> <p>IV: <i>Hypocalcemia in premature infants:</i> 0.05 mcg/kg/day for 4 days. <i>Renal failure:</i> Children: 0.01–0.05 mcg/kg 3 times weekly (hemodialysis). Adults: 0.5–3 mcg 3 times weekly (hemodialysis).</p>	<p>Capsules: 0.25 mcg, 0.5 mcg Injection: 1 mcg/mL, 2 mcg/mL (1-mL ampules) Solution: 1 mcg/mL</p>
Calcium salts	<p>See dosage forms for calcium content of various salts. Dosage should be adjusted based on the desired response and serum calcium levels.</p> <p>IV: <i>Cardiac resuscitation:</i> Calcium gluconate: Children: 60–100 mg/kg/dose to a maximum of 3 g. Adults: 500 mg to 1 g/dose.</p>	<p>Calcium acetate = 25% Ca = 250 mg Ca per 1 g Ca acetate Calcium carbonate = 40% Ca = 400 mg Ca per 1 g Ca carbonate Calcium chloride = 27% Ca = 270 mg Ca per 1 g Ca chloride Calcium citrate = 21% Ca = 210 mg Ca per 1 g Ca citrate Calcium glubionate = 6.5% Ca = 65 mg Ca per 1 g Ca glubionate Calcium gluconate = 9% Ca = 90 mg Ca per 1 g Ca gluconate Calcium lactate = 13% Ca = 130 mg Ca per 1 g Ca lactate</p>

Table 1. Medications (continued)

	Dosages	Dosage Forms
Calcium salts (continued)	<p>Calcium chloride: Children: 20 mg/kg/dose to a maximum of 1 g. Adults: 2–4 mg/kg/dose to a maximum of 1 g. Hypocalcemia (gluconate salt): Neonates: 200–800 mg/kg/day, usually as a continuous infusion. Infants and children: 200–500 mg/kg/day as a continuous infusion or in 4 divided doses. Adults: 2–15 g/day as a continuous infusion or in divided doses.</p> <p>PO (carbonate, glubionate, or lactate salts): Neonates: 20–80 mg elemental calcium/kg/day in 4–6 divided doses. Infants and children: 20–40 mg elemental calcium/kg/day in 4–6 divided doses. Adults: 400 mg to 1.2 g elemental calcium/day or more.</p>	<p>Injection: Chloride salt: 1 g (100 mg/mL) = 27 mg Ca/mL Gluconate salt: 1 g (100 mg/mL) = 9 mg Ca/mL Suspension: Carbonate salt: 1.25 g/5 mL = 500 mg Ca/5 mL Syrup: Glubionate salt: 1.8 g/5 mL = 115 mg Ca/5 mL Tablets: Acetate salt: 667 mg = 169 mg Ca (PhosLo) Carbonate salt: 650 mg = 260 mg Ca; 1.25 g = 500 mg Ca; 1.5 g = 600 mg Ca Citrate salt: 950 mg = 200 mg Ca (Citracal); 2376 mg = 500 mg Ca (Citracal Liquitab) Gluconate salt: 500 mg = 45 mg Ca; 650 mg = 58.5 mg Ca; 975 mg = 87.75 mg Ca; 1 g = 90 mg Ca Lactate salt: 325 mg = 42.25 mg Ca; 650 mg = 84.5 mg Ca</p>
Calfactant (Infasurf)	<p>Intratracheally: 3 mL/kg divided into 2–4 aliquots. Patients should be ventilated and repositioned between aliquots. May be repeated to a total of 3 doses at 12 hour intervals.</p>	<p>Suspension, intratracheal: 3 mL, 6 mL</p>
Captopril (Capoten)	<p>PO: Neonates: 0.01–0.05 mg/kg up to t.i.d., initially. Dose may be increased incrementally to a maximum of 0.5 mg/kg administered as frequently as q6h (2 mg/kg/day). Infants and children: 0.15–0.3 mg/kg up to t.i.d., initially. Dose may be increased incrementally to a maximum of 6 mg/kg/day in divided doses. Adolescents and adults: 12.5–25 mg q8–12h, initially. May be titrated upward to a maximum of 6 mg/kg/day or 450 mg.</p>	<p>Tablets: 12.5 mg, 25 mg, 50 mg, 100 mg</p>
Carbamazepine (Carbatrol, Tegretol, Tegretol-XR)	<p>PO: Initially 5–10 mg/kg/day in 2–4 divided doses, increasing slowly to a maximum of 35 mg/kg/day (1.6–2.4 g in adults). Suspension formulation should be administered in 3–4 daily doses; regular tablet formulations may be administered in 2–3 divided doses, extended release formulations may be administered in 2 divided doses.</p>	<p>Capsules, extended release: 200 mg, 300 mg. Suspension: 100 mg/5 mL Tablets, chewable: 100 mg Tablets: 200 mg Tablets, extended release: 100 mg, 200 mg, 400 mg</p>
Carbamide peroxide (Debrox, Gly-Oxide)	<p>Ear: Instill up to 5–10 drops in the ear and allow to remain for several minutes or longer.</p> <p>PO: Apply several drops to the affected area up to q.i.d.</p>	<p>Drops, oral: 10% (Cank-aid, Gly-Oxide, Orajel Brace-aid Rinse) Drops, otic: 6.5% (Auro Ear Drops, Debrox, Murine Ear Drops)</p>
Cefaclor	<p>PO: 20–40 mg/kg/day in 2–3 divided doses to a maximum of 2 g/24 hr.</p>	<p>Capsules: 250 mg, 500 mg Suspension: 125 mg/5 mL, 187 mg/5 mL, 250 mg/5 mL, 275 mg/5 mL</p>
Cefadroxil	<p>PO: Children: 30 mg/kg/day in 2 divided doses to a maximum of 2 g/day. Adults: 1–2 g/day in a single or 2 divided doses.</p>	<p>Capsules: 500 mg Suspension: 250 mg/5 mL, 500 mg/5 mL</p>
Cefazolin (Ancef)	<p>IV or IM: 50–150 mg/kg/day in 3 divided doses to a maximum of 6 g/day. Usual adult doses are 500 mg to 2 g/dose q8h. Dosing adjustment is necessary in renal impairment.</p>	<p>Injection: 500-mg, 1-g vials</p>
Cefdinir (Omnicef)	<p>PO: Age 6 months to 12 years: 14 mg/kg/day in 1 or 2 divided doses. Age > 12 years or 43 kg: 600 mg daily in 1 or 2 divided doses.</p>	<p>Capsules: 300 mg Suspension: 125 mg/5 mL, 250 mg/5 mL</p>

(continued)

Table 1. Medications (continued)

	Dosages	Dosage Forms
Cefixime (Suprax)	<p>PO: Children: 8–20 mg/kg/day in 1 or 2 divided doses to a maximum of 400 mg/day. Adults: 400 mg/day in 1 or 2 divided doses. <i>Otitis media:</i> Use suspension formula because higher serum levels are reached at the same dose when the suspension is administered.</p>	Suspension: 100 mg/5 mL Tablets: 400 mg
Cefotaxime (Claforan)	<p>IV or IM: <i>Sepsis:</i> Infants and children: 100–150 mg/kg/day in 3–4 divided doses. Adults: 1–2 g q6–8h. <i>Meningitis:</i> Neonates, age < 1 week: 50 mg/kg q12h. Neonates, age ≥ 1 week: 50 mg/kg q8h. Infants, age > 4 weeks and children: 200 mg/kg/day in 4 divided doses. A dose of 300 mg/kg/day in 4 divided doses has been used for the treatment of pneumococcal meningitis. Maximum total daily dose is 12 g. Adults: 2 g q4–6h. Dosing adjustment is necessary in renal impairment.</p>	Injection: 1-g, 2-g vials
Cefoxitin (Mefoxin)	<p>IV or IM: Neonates: 90–100 mg/kg/day in 3 divided doses. Children: 80–160 mg/kg/day depending on the severity of the infection in 4 divided doses. Adults: 1–2 g q6–8h to a maximum total daily dose of 12 g.</p>	Injection: 1-g, 2-g vials
Cefpodoxime (Vantin)	<p>PO (with food to enhance absorption): Children: 10 mg/kg/day in 2 divided doses to a maximum of 800 mg/day. Adults: 200 mg/day in 2 divided doses for upper respiratory or uncomplicated UTI, 400 mg/day in 2 divided doses for lower respiratory tract infection (community-acquired pneumonia), 800 mg/day in 2 divided doses (skin, skin structure infection). Dosage adjustment is necessary in severe renal impairment.</p>	Suspension: 50 mg/5 mL, 100 mg/5 mL Tablets: 100 mg, 200 mg
Cefprozil (Cefzil)	<p>PO: Children: <i>Otitis media:</i> 30 mg/kg/day in 2 divided doses to a maximum total daily dose of 1 g. <i>Pharyngitis, tonsillitis:</i> 15 mg/kg/day in 2 divided doses to a maximum total daily dose of 500 mg. Adults: <i>Lower respiratory tract:</i> 500 mg q12h. <i>Upper respiratory tract and skin:</i> 500 mg q24h. Dosage adjustment is necessary in renal impairment.</p>	Suspension: 125 mg/5 mL, 250 mg/5 mL Tablets: 250 mg, 500 mg
Ceftazidime (Fortaz, Tazicef)	<p>IV or IM: Neonates: <2,000 g: 60 mg/kg/day in 2 divided doses. ≥2,000 g: 90 mg/kg/day in 3 divided doses. Infants and children: 90–150 mg/kg/day in 3 divided doses to a maximum total daily dose of 6 g. Adults: 3–6 g/day in 3 divided doses. Dosage adjustment is necessary in renal impairment.</p>	Injection: 500 mg, 1 g, 2 g
Ceftriaxone (Rocephin)	<p>IV or IM: <i>PPNG (uncomplicated pharyngeal, urethral, endocervical, rectal):</i> <45 kg: 125 mg IM as a single dose. ≥45 kg: 250 mg IM as a single dose. <i>Infants born to a mother infected with PPNG:</i> 50 mg/kg IM to a maximum of 125 mg as a single dose.</p>	Injection: 250-mg, 500-mg, 1-g, 2-g vials

Table 1. Medications (continued)

	Dosages	Dosage Forms
Ceftriaxone (Rocephin) (continued)	<p><i>Other serious infections (not including meningitis):</i> Children: 50–75 mg/kg/day in 2 divided doses. Do not exceed 2 g/day. Adults: Usually 1–2 g as a single daily dose or in 2 divided doses. <i>Otitis media:</i> 50 mg/kg as a single dose to a maximum dose of 1 g. <i>Meningitis:</i> Children: 100 mg/kg/day in 1–2 divided doses to a maximum total daily dose of 4 g.</p>	
Cefuroxime (Ceftin, Zinacef)	<p>PO (administer with food to enhance absorption): <i>Otitis media</i> (all ages): 30 mg/kg/day in 2 divided doses to a maximum total daily dose of 1 g. <i>Other infections</i> (all ages): 20 mg/kg/day in 2 divided doses to a maximum total daily dose of 500 mg.</p> <p>IV: Children: 50–100 mg/kg/day in 3–4 divided doses. A dose of 150 mg/kg/day in 3 divided doses is recommended for bone and joint infections. Do not exceed adult doses below. Adults: 2.25–4.5 g/day in 3 divided doses. Higher dose is necessary for severe infections and bone and joint infections. Dosage adjustment is necessary in renal impairment.</p>	<p>Injection: 750-mg, 1.5-g vials Suspension (axetil): 125 mg/5 mL, 250 mg/5 mL Tablets: 250 mg, 500 mg</p>
Cephalexin (Keflex)	<p>PO: Children: 50–100 mg/kg/day in 4 divided doses for otitis media and serious infections. Doses of 25–50 mg/kg/day in 2–4 divided doses may be used for less serious infections. Do not exceed adult doses. Adults: 1–4 g/day in 4 divided doses. Dosage must be adjusted in patients with renal dysfunction.</p>	<p>Capsules: 250 mg, 500 mg Suspension: 125 mg/5 mL, 250 mg/5 mL</p>
Cetirizine (Zyrtec)	<p>PO: Age 2–5 years: 2.5 mg/day. Dose may be increased to 5 mg/day as a single or 2 divided doses. Age ≥6 years: 5–10 mg/day as a single dose.</p>	<p>Syrup: 1 mg/mL Tablets: 5 mg, 10 mg</p>
Charcoal (Actidose-Aqua, CharcoAid, Liqui-Char)	<p>PO: Usually available as premixed solutions. Solutions containing sorbitol are not indicated for use in children. Do not administer with dairy due to decreased adsorptive capacity of the charcoal. Airway protection must be ensured. Single dose: Children: 1–2 g/kg up to 15–30 g as soon as possible after the ingestion, preferably after emesis. Adults: 30–100 g. Dose should be 5–10 times the amount of the ingested poison. Multiple dose (products without sorbitol): Infants: 1 g/kg q4–6h. Children and adults: 1–2 g/kg (up to 60 g) q2–6h.</p>	<p>Liquid: 25 g/120 mL, 50 g/240 mL</p>
Chloral hydrate (Aquachloral)	<p>PO: <i>Sedation before procedures:</i> 60–75 mg/kg 30 minutes to 1 hour before the procedure. May repeat with a half-dose (30–37.5 mg/kg) if the first dose is ineffective. Do not exceed 120 mg/kg or 2 g total.</p>	<p>Capsules: 500 mg Syrup: 500 mg/5 mL</p>
Chloramphenicol (Chloromycetin)	<p>IV: Infants and children: 50–100 mg/kg/day in 4 divided doses to a maximum total daily dose of 4 g. Adults: 50 mg/kg/day in 4 divided doses to a maximum total daily dose of 4 g. Serum levels must be monitored closely, especially in infants, and patients with renal or hepatic impairment.</p>	<p>Injection: 1-g vial</p>

(continued)

Table 1. Medications (continued)

	Dosages	Dosage Forms
Chlorothiazide (Diuril)	<p>PO: Infants <6 months: 20–40 mg/kg/day in 2 divided doses. Children: 20 mg/kg/day in 2 divided doses. Adults: 0.5–1 g/day in 1 or 2 divided doses.</p> <p>IV: Infants <6 months: 20–40 mg/kg/day in 2 divided doses, but doses of 2–8 mg/kg/day may be sufficient in some patients. Children: 4–20 mg/kg/day in 2 divided doses. Adults: 0.5–1 g/day.</p>	Injection: 500 mg Suspension: 250 mg/5 mL Tablets: 250 mg, 500 mg
Chlorpromazine	<p>IV or PO: <i>Nausea and vomiting or psychosis:</i> Age >6 months: 0.3–0.5 mg/kg IV q6–8h or 0.5–1 mg/kg PO q4–6h or 1 mg/kg rectally q6–8h as needed. Do not exceed adult doses. Adults: 25–50 mg IV q6–8h or 10–25 mg PO q4–6h or 50–100 mg rectally q6–8h. Doses may be increased in the treatment of psychoses; some adults may require as much as 800 mg/day until control is achieved. Dose should then be decreased to the usual maintenance levels of 200 mg/day for adults.</p>	Injection: 25 mg/mL Tablets: 10 mg, 25 mg, 50 mg, 100 mg, 200 mg
Cholestyramine resin (Questran, Questran Light)	<p>PO: Children: 240 mg/kg/day of the resin administered in 3 divided doses. Adults: 3–4 g t.i.d. or q.i.d. Doses should be administered mixed in liquids (4 g in 2–6 oz.) or with pulpy fruits (applesauce or pineapple). Many drugs bind with cholestyramine in the GI tract. Drugs should be administered 1 hour before or 4 hours after cholestyramine. Patients should also be cautioned to ingest plenty of fluids to avoid constipation and fecal impaction.</p>	Powder: 4 g resin/9 g powder (Questran); 4 g resin/5 g powder (Questran Light, contains aspartame)
Cimetidine (Tagamet)	<p>PO or IV: Initial dose: Children: 20–40 mg/kg/day in 4 divided doses daily. Adults: 300 mg q6h. PO, doses of 800 mg at bedtime or 400 mg b.i.d. may be used. A maximum total daily dose of 2.4 g should not be exceeded. Dosage must be adjusted in renal impairment.</p>	Injection: 150 mg/mL Liquid: 300 mg/5 mL Tablets: 200 mg, 300 mg, 400 mg, 800 mg
Ciprofloxacin (Ciloxan, Cipro)	<p>PO (on an empty stomach): Children: 20–30 mg/kg/day in 2 divided doses; up to 40 mg/kg/day may be used for patients with cystic fibrosis. Do not exceed 1.5 g/day. Adults: 500–1,500 mg/day in 2 divided doses.</p> <p>IV (administer over 1 hour at a concentration of 1–2 mg/mL): Children: 15–20 mg/kg/day in 2 divided doses; up to 30 mg/kg/day may be used in patients with cystic fibrosis. Do not exceed 800 mg/day. Adults: 400–800 mg/day in 2 divided doses. Dosage must be adjusted in patients with renal dysfunction.</p> <p>Ophthalmic: Administer 1–2 drops q2h while awake for 2 days and then q4h while awake for 5 days.</p>	Injection: 10 mg/mL Ointment, ophthalmic: 0.3% base Solution, ophthalmic: 0.3% base Suspension: 250 mg/5 mL, 500 mg/5 mL Tablets: 250 mg, 500 mg, 750 mg
Citrate and citric acid (Polycitra, Tricitrates Solution)	<p>PO (dilute in water or juice): Infants and children: 2–3 mEq/kg/day in 3–4 divided doses. Adults: 15–30 mL given q.i.d. Giving doses with meals decreases the saline laxative effect.</p>	Equivalent to potassium 1 mEq, sodium 1 mEq, and bicarbonate 2 mEq per 1 mL

Table 1. Medications (continued)

	Dosages	Dosage Forms
Clarithromycin (Biaxin)	<p>PO: Children: 15 mg/kg/day in 2 divided doses, not to exceed 1 g/day. Adults: 500 mg–1 g/day in 2 divided doses or 1 g daily as 2 extended release tablets</p>	<p>Suspension: 125 mg/5 mL, 250 mg/5 mL Tablets: 250 mg, 500 mg Tablets, extended release: 500 mg</p>
Clindamycin (Cleocin)	<p>IV: Neonates, age <7 days: ≤2,000 g: 10 mg/kg/day in 2 divided doses. >2,000 g: 15 mg/kg/day in 3 divided doses. Neonates, age >7 days: <1,200 g: 10 mg/kg/day in 2 divided doses. 1,200–2,000 g: 15 mg/kg/day in 3 divided doses. >2,000 g: 20 mg/kg/day in 3–4 divided doses. Infants and children: 25–40 mg/kg/day in 3–4 divided doses. Adults: 1.2–2.7 g/day in 2–4 divided doses. Maximum total daily dose should not exceed 4.8 g and should be used for life-threatening infections only.</p> <p>PO: Infants and children: 15–25 mg/kg/day in 3–4 divided doses for moderate to severe infections. Adults: 150–450 mg q6–8h to a maximum total daily dose of 1.8 g.</p> <p>Topically: Apply to the affected area b.i.d. Avoid the eyes, abraded skin, and mucous membranes.</p>	<p>Capsules: 150 mg Injection: 150 mg/mL Solution, oral: 75 mg/5 mL Solution, topical: 1%</p>
Clonazepam (Klonopin)	<p>PO: Age <10 years or weight <30 kg: Initially 0.01–0.03 mg/kg/day in 2–3 divided doses. Dose may be increased gradually (every third day) until seizures are controlled or adverse effects are seen. The usual maintenance dose range is 0.1–0.2 mg/kg/day. Adults, weight >30 kg: Initially 1.5 mg/day in 3 divided doses. Dose may be increased by 0.5–1 mg every third day to a maximum total daily dose of 20 mg. Usual maintenance dose is 0.05–0.2 mg/kg/day.</p>	<p>Tablets: 0.5 mg, 1 mg, 2 mg Tablets, disintegrating: 0.125 mg, 0.25 mg, 0.5 mg, 1 mg, 2 mg</p>
Clonidine (Catapres)	<p>PO: <i>Hypertension:</i> 5–10 mcg/kg/day in 2–3 divided doses. In patients who experience sedation, the doses may be divided such that the patient receives a larger dose at bedtime and a smaller dose in the morning. Dose may be incrementally increased to 25 mcg/kg/day to a maximum dose of 0.9 mg/day, if necessary. <i>Attention deficit/hyperactivity disorder:</i> 5 mcg/kg/day in 4 divided doses has been used in some patients who have failed conventional therapy. Maximum dose is 0.3–0.4 mg/day.</p> <p>TOP: Once oral dose has been titrated to appropriate dose, may transition to patch at equivalent dose. Change every 7 days</p> <p>Injectable: Generally used as a component in epidural solutions at 0.5–2 mcg/kg/hr.</p>	<p>Tablet: 0.1 mg, 0.2 mg, 0.3 mg Patch: 0.1 mg/day, 0.2 mg/day, 0.3 mg/day Injection: 100, 500 mcg/mL</p>
Clorazepate dipotassium (Tranxene)	<p>PO: Age 9–12 years: Initially 3.75–7.5 mg b.i.d. Dose may be increased by 3.75 mg at weekly intervals to a maximum total daily dose of 60 mg. Age >12 years: Up to 7.5 mg up to t.i.d. May be increased by 7.5 mg at weekly intervals to a maximum total daily dose of 90 mg.</p>	<p>Tablets: 3.75 mg, 7.5 mg, 11.25 mg, 15 mg, 22.5 mg</p>
Clotrimazole (Lotrimin, Mycelex)	<p>Vaginal cream: 1 full applicator at bedtime for 7 days (1%) or 3 days (2%).</p> <p>Vaginal suppository: 1 suppository intravaginally at bedtime for 7 days or 2 at bedtime for 3 days or 500 mg as a single dose.</p> <p>Topically: Apply to affected areas b.i.d.</p>	<p>Cream, topical: 1% (30-g tube) Cream, vaginal: 1% (45-g), 2% (21 g) Solution, topical: 1% (10 mL, 30-mL) Suppositories, vaginal: 100 mg, 200 mg</p>

(continued)

Table 1. Medications (continued)

	Dosages	Dosage Forms
Codeine	<p>PO: <i>Analgesic:</i> 0.5–1 mg/kg q4–6h as needed, to a maximum of 60 mg. Usual adult dose is 30 mg. <i>Antitussive:</i> 0.2–0.25 mg/kg q4–6h as needed, to a maximum of 30 mg.</p>	<p>Solution, oral (phosphate): 15 mg/5 mL Tablets (sulfate): 15 mg, 30 mg, 60 mg Also available in various combinations with acetaminophen: Elixir, oral: 12 mg codeine with 120 mg acetaminophen Tablets: 7.5 mg codeine with acetaminophen 300 mg (Tylenol w/Codeine No. 1), 15 mg codeine with acetaminophen 300 mg (Ace taminophon w/Codeine No. 2), 300 mg codeine with acetaminophen 300 mg (Tylenol w/Codeine No. 3), 60 mg codeine with acetaminophen 300 mg (Tylenol w/Codeine No. 4)</p>
Cosyntropin (Cortrosyn)	<p>IV: Age <2 years: 0.125 mg. Age >2 years: 0.25 mg.</p>	<p>Injection: 0.25 mg</p>
Co-trimoxazole (trimethoprim and sulfamethoxazole; Bactrim, Septra)	<p>PO or IV (based on trimethoprim): Age >2 months: <i>Treatment doses:</i> <i>Mild-to-moderate infections (urinary tract or otitis media):</i> 8 mg trimethoprim/kg/day in 2 divided doses. Maximum dose is 320 mg trimethoprim/day. <i>Pneumocystis carinii pneumonitis:</i> 20 mg trimethoprim/kg/day in 4 divided doses. <i>Prophylaxis doses:</i> <i>UTI:</i> 2 mg trimethoprim/kg/day as a single dose. <i>Pneumocystis carinii:</i> 150 mg/m²/day in 1 or 2 divided doses daily on 3 consecutive or alternating days per week. Dosage adjustment is necessary in patients with renal impairment. IV doses must be administered over 60–90 minutes and should be well diluted (1 mL injection in 25 mL infusate). Dosage must be adjusted in patients with renal dysfunction.</p>	<p>Injection: 16 mg trimethoprim and 80 mg sulfamethoxazole per 1 mL Suspension: 8 mg trimethoprim and 40 mg sulfamethoxazole per 1 mL Tablets: 80 mg trimethoprim and 400 mg sulfamethoxazole Tablets, double strength: 160 mg trimethoprim and 800 mg sulfamethoxazole</p>
Cromolyn sodium (Crolom, Intal, Nasal crom, Opticrom)	<p>Children: <i>Metered-dose inhaler:</i> 2 inhalations q.i.d. <i>Nebulizer solution:</i> 20 mg nebulized q.i.d. <i>Intranasal spray:</i> 1 spray in each nostril 3–4 times daily. <i>Ophthalmic:</i> 1–2 drops in each eye 4–6 times daily.</p>	<p>Inhalation, metered dose: 800 mcg/spray Solution, nasal: 5.2 mg/spray Solution, nebulizer: 20 mg/2 mL Solution, ophthalmic: 4%</p>
Crotamiton (Eurax)	<p>Topically: Apply a thin layer to all skin surfaces from the neck to the toes and soles of the feet. Be sure to apply to all surfaces, including skin folds. Avoid the face and mucous membranes, including the urethral meatus. A second coat is applied 24 hours later. A cleansing bath should follow 48 hours after the second application. Treatment may be repeated after 7–10 days if the mites reappear. It is safe for use in infants and young children. If signs of irritation or hypersensitivity appear, remove the product immediately by bathing. Contaminated clothing and bed linens should be washed to avoid reinfestations.</p>	<p>Cream: 10% Lotion: 10%</p>
Cyclosporine (Neoral, Sandimmune, Gengraf)	<p>NOTE: The products are <i>not</i> bioequivalent. Clinical condition and serum levels must be monitored carefully when a patient's therapy is changed from one to the other, especially for patients receiving large doses (> 10 mg/kg/day) of Sandimmune who are changed to Neoral or Gengraf therapy as significant drug toxicity may result.</p> <p>PO (transplant): <i>Sandimmune:</i> Initially 10–18 mg/kg/day (dose dependent on organ being transplanted) in 2 divided doses, tapering over several weeks with frequent monitoring to a maintenance dose usually in the range of 5–10 mg/kg/day. <i>Neoral or Gengraf:</i> Initially ~10 mg/kg/day in 2 divided doses, tapering over several weeks based on clinical condition and serum levels.</p> <p>PO (other conditions): Initially 2.5 mg/kg/day in 2 divided doses, max 4 mg/kg/day <i>Conversion from Sandimmune to Neoral or Gengraf:</i> Consult with pharmacist</p>	<p>Capsules (Neoral, Gengraf): 25 mg, 100 mg Capsules (Sandimmune): 25 mg, 100 mg Injection (Sandimmune): 50 mg/mL Solution, oral (Neoral, Gengraf and Sandimmune): 100 mg/mL</p>

Table 1. Medications (continued)

	Dosages	Dosage Forms
Cyclosporine (Neoral, Sandimmune, Gengraf) (continued)	<p>IV (Sandimmune only): IV dose is ~30% of the oral dose. Initial 5–6 mg/kg/day in 1 or 2 divided doses. Each dose should be administered over at least 2 hours.</p>	
Dantrolene sodium (Dantrium)	<p>PO: <i>Spasticity:</i> Age >5 years: 0.5 mg/kg given b.i.d. initially, but frequency may be increased gradually to t.i.d. or q.i.d. The maximum dose is 100 mg q.i.d. Adults: 25 mg daily initially, with increases in frequency and dose to a maximum of 400 mg/day in 4 divided doses. <i>Malignant hyperthermia prophylaxis:</i> 4–8 mg/kg/day in 3–4 divided doses daily for 1–2 days prior to surgery.</p> <p>IV: <i>Malignant hyperthermia prophylaxis:</i> 2.5 mg/kg administered over 1 hour ~1.25 hours before surgery. Repeat doses may be necessary. <i>Malignant hyperthermia crisis:</i> 1 mg/kg given rapidly. Repeat doses may be necessary, but it is usually not necessary to exceed 2.5 mg/kg. Maximum dose should not exceed 10 mg/kg.</p>	<p>Capsules: 25 mg, 50 mg, 100 mg Injection: 20 mg</p>
Deferoxamine (Desferal)	<p>IV: Children: <i>Acute iron intoxication:</i> 15 mg/kg/hr IV continuous infusion; maximum 6 g/24 hr. <i>Chronic iron overload:</i> 20–25 mg/kg/day IM or 500 mg-2 g IV with each unit of blood transfused, or 20–40 mg/kg/day SC over 8–12 hours up to 1–2 g/day.</p>	<p>Injection: 500-mg vial</p>
Desmopressin acetate (DDAVP)	<p>Intranasally: <i>Nocturnal enuresis in patients over age 6:</i> 20 mcg at bedtime with 1/2 of dose in each nostril. Dose may be increased or decreased depending on the patient's response. Usual range is 10–40 mcg/day. <i>Diabetes insipidus in patients ≥7 years of age:</i> Initially 5 mcg/day as a single dose or in 2 divided doses. Dosage should be titrated to the patient's response. The usual range is 5–40 mcg/day.</p> <p>PO: <i>Diabetes insipidus:</i> Children: Initially, 0.05 mg/dose with careful monitoring to prevent hyponatremia or water intoxication. Age > 12 years: Initially, 0.05 mg b.i.d. Dosage may then be adjusted to maintain normal diurnal water turnover. The usual total daily dosage is in the range of 0.1–1.2 mg and may be administered in 2–3 divided doses. <i>Nocturnal enuresis in children > 12 years:</i> 0.2–0.4 mg/day at bedtime.</p> <p>IV: <i>To increase factor VIII level:</i> 0.3 mcg/kg over 30 minutes. <i>Diabetes insipidus:</i> Adult doses are 2–4 mcg/day in 2 divided doses or ~1/10 of the intranasal dose necessary to control the patient's symptoms, if that is known.</p>	<p>Injection: 4 mcg/mL Solution, nasal: 100 mcg/mL/2.5 mL bottle with calibrated intranasal tube Spray, intranasal: 10 mcg/actuation metered dose Tablets: 0.1 mg, 0.2 mg</p>
Dexamethasone (Decadron, Maxidex)	<p>IV, IM or PO: <i>Bacterial meningitis:</i> 0.6 mg/kg/day in 4 divided doses for the first 4 days of antibiotic therapy. It must be started at the same time or before the first dose of antibiotic. <i>Cerebral edema:</i> 1–1.5 mg/kg/day in 4 divided doses to a maximum total daily dose of 16 mg. <i>Antiemetic therapy (chemotherapy-induced emesis):</i> 20 mg/m²/day in 4 divided doses.</p>	<p>Elixir: 0.5 mg/5 mL Injection: 4 mg/mL, 10 mg/mL Solution, ophthalmic: 0.05%, 0.1% Solution, oral: 1 mg/mL Tablets: 0.5 mg, 0.75 mg, 1 mg, 1.5 mg, 2 mg, 4 mg, 6 mg</p>

(continued)

Table 1. Medications (continued)

	Dosages	Dosage Forms
Dexamethasone (Decadron, Maxidex) (continued)	<p><i>Airway edema or extubation:</i> 0.5–2 mg/kg/day in 4 divided doses beginning 24 hours before and continuing for at least 24 hours after extubation. Maximum dose of 16 mg/day.</p> <p><i>Croup:</i> 0.6 mg/kg PO/IM/IV x 1 dose, max 12 mg.</p> <p>Doses should be tapered when discontinuing long-term therapy.</p> <p><i>Ophthalmic:</i> Instill drops or apply ointment t.i.d. or q.i.d.</p>	
Dextroamphetamine sulfate (Dexedrine)	<p>PO:</p> <p>Age 3–5 years: 2.5 mg/day given in the morning. Dosage may be increased 2.5 mg/day until a response is realized or side effects appear. Usual range is 0.1–0.5 mg/kg/day to a maximum of 40 mg.</p>	Dextroamphetamine: Capsules, sustained release: 5 mg, 10 mg, 15 mg Tablets: 5 mg, 10 mg
Dextroamphetamine mixed salts (Adderall)	<p>Age ≥6 years: 5 mg/day in the morning or at noon. Dosage may be increased in 5-mg increments at weekly intervals. Usual range is 0.1–0.5 mg/kg/day to a maximum of 40 mg.</p>	Dextroamphetamine mixed salts: Capsules, extended release (expressed in mg of salts): 5 mg, 10 mg, 15 mg, 20 mg, 25 mg, 30 mg Tablet (expressed in mg of salts): 5 mg, 7.5 mg, 10 mg, 12.5 mg, 15 mg, 20 mg, 30 mg
Diazepam (Diastat Rectal, Valium)	<p>IV:</p> <p><i>Status epilepticus:</i> 0.05–0.3 mg/kg (usual dose 0.2 mg/kg/dose) administered over 2–3 minutes and repeated q15–30min to a total maximum dose of 0.75 mg/kg or 30 mg, whichever is less. May be repeated in 2–4 hours, if necessary.</p> <p><i>Sedation:</i> 0.04–0.2 mg/kg q2–4h to a maximum of 0.6 mg/kg within an 8-hour period.</p> <p>PO for sedation or muscle relaxant:</p> <p>0.12–0.8 mg/kg/day in 3–4 divided doses to an adult dose of 6–40 mg/day.</p> <p>Rectally (round dose off to closest dose available from manufacturer):</p> <p>Age 2–5 years: 0.5 mg/kg. Age 6–11 years: 0.3 mg/kg Age ≥12 years: 0.2 mg/kg. Dose may be repeated q4–12h as necessary.</p>	<p>Gel, rectal (in rectal delivery system): 2.5 mg, 5 mg, 10 mg, 20 mg Injection: 5 mg/mL Solution, oral: 5 mg/5 mL Solution, concentrated oral: 5 mg/mL Tablets: 2 mg, 5 mg, 10 mg</p>
Diazoxide (Proglycem)	<p>PO:</p> <p><i>(Hypoglycemia due to hyperinsulinism):</i></p> <p>Newborns and infants: Initially 8 mg/kg/day in 2 or 3 divided doses. May be increased incrementally if response is inadequate to a maximum of 15 mg/kg/day.</p> <p>Children and adults: 3 mg/kg/day in 2 or 3 divided doses initially. May be increased to a maximum of 8 mg/kg/day.</p>	<p>Capsules: 50 mg Suspension, oral: 50 mg/mL</p>
Dicloxacillin (Dycill, Dynapen, Pathocil)	<p>PO:</p> <p>Children <40 kg: 25–50 mg/kg/day in 4 divided doses. Doses of 50–100 mg/kg/day in 4 divided doses have been used for osteomyelitis.</p> <p>Children ≥40 kg and adults: 125–500 mg/dose q6h.</p>	<p>Capsules: 250 mg, 500 mg</p>
Digoxin (Lanoxicaps, Lanoxin) (See Table 3)	<p>IV or PO:</p> <p>Should be based on lean body weight. Total digitalizing dose (TDD) is administered as follows: 1/2 TDD initially, then 1/4 TDD 8–12 hours later, then 1/4 TDD 8–12 hours after that. Maintenance doses are administered in 2 divided doses beginning 12 hours after the last digitalizing dose. Patients should be under continuous cardiographic monitoring during digitalization. IM doses are the same as oral doses, but that route of administration should be avoided.[†]</p> <p>Dosage must be adjusted in patients with renal dysfunction.</p>	<p>Capsules, liquid filled (Lanoxicaps): 0.1 mg, 0.2 mg (90–100% bioavailable) Injection: 0.1 mg/mL, 0.25 mg/mL (100% bioavailable IV) Solution: 0.05 mg/mL (75–87% bioavailable) Tablets: 0.125 mg, 0.25 mg (60–80% bioavailable)</p>
Dihydroergotamine (D.H.E.)	<p>IV:</p> <p>Age 6–9 years: 100–150 mcg/dose repeated q6h to a maximum of 8 doses. Age 10–12 years age: 200 mcg/dose repeated q6h to a maximum of 8 doses. Adolescents, age ≤16 years: 250–500 mcg/dose repeated q6h to a maximum of 8 doses. Adults: 500 mcg repeated hourly to a maximum of 2 mg (6 mg/wk) Total dose for entire course must not exceed 6 mg. Do not use ergotamines if patient has received MAOI in past 14 days.</p>	<p>Injection: 1 mg/mL</p>

Table 1. Medications (continued)

	Dosages	Dosage Forms
Dimercaprol [BAL (British anti-lewisite)]	Deep IM: Lead toxicity (in conjunction with calcium EDTA): 4 mg/kg 6 times a day for 3–5 days.	Injection: 100 mg/mL (3-mL ampul)
Diphenhydramine	IV, PO, IM: Children: 5 mg/kg/day in 3 or 4 divided doses to a maximum of 300 mg/day. Adults: 10–50 mg repeated as often as q4h, not to exceed 400 mg/day. The drug may cause paradoxical excitement in children.	Capsules, tablets: 25 mg, 50 mg Elixir, solution, syrup: 12.5 mg/5 mL Injection: 10 mg/mL, 50 mg/mL
Dobutamine hydrochloride (Dobutrex)	Continuous IV infusion: 2–15 mcg/kg/min to a maximum of 40 mcg/kg/min. Start at the lower end of the range and titrate upward based on the patient’s response.	Injection: 12.5 mg/mL
Docusate sodium (dioctyl sodium sulfosuccinate; Colace, D-S-S)	PO: (In 1–4 divided doses with a glass of water): Age <3 years: 10–40 mg/day. Age 3–6 years: 20–60 mg/day. Age >6–12 years: 40–150 mg/day. Age >12 years: 50–500 mg. Do not administer with mineral oil as absorption of the mineral oil may be increased.	Capsules: 50 mg, 100 mg, 240 mg, 250 mg Liquid: 150 mg/15 mL Syrup: 60 mg/15 mL Also available in combination with stimulant laxatives, including senna and casanthranol.
Dopamine hydrochloride (Dopastat, Intropin)	Continuous IV infusion: 2–20 mcg/kg/min, start higher at 5–10 mcg/kg/min in septic shock. Usual a maximum of 20 mcg/kg/min (50 mcg/kg/min has been documented but rarely offers additional support over 20 mcg/kg/min). Consider addition of second agent at 20 mcg/kg/min.	Injection in 5% dextrose: 0.8 mg/mL, 1.6 mg/mL, 3.2 mg/mL (premixed infusions) Injection: 40 mg/mL, 80 mg/mL, 160 mg/mL
Dornase alfa (Pulmozyme)	Inhalation via approved compressor: Age >5 years: 2.5 mg/day. Patients with cystic fibrosis may require 2.5 mg inh BID.	Solution, inhalation: 2.5 mg/2.5 mL
Doxycycline (Doxy-100, Vibramycin)	PO or IV: Age <8 years: Should not be used unless there is no alternative. Age ≥8 years: 2–5 mg/kg/day to a maximum of 200 mg/day in 1 or 2 divided doses. Adults: 100–200 mg/day in 1 or 2 divided doses. Inpatient treatment of PID 100 mg IV b.i.d. with cefoxitin 2 g IV q6h for at least 4 days or 2 days after patient improves, whichever is longer. Doxycycline should be continued PO to complete 10–14 days of therapy.	Capsules or tablets: 50 mg, 100 mg; Liquid: 5 mg/mL; Injection: 100 mg, 200 mg
Edetate calcium disodium (Calcium Disodium Versenate, Calcium EDTA)	IV infusion: <i>Asymptomatic lead toxicity:</i> Initial: Up to 1 g/m ² /24 hr or 50 mg/kg/24 hr in a continuous IV drip if possible or in 2–4 divided doses for 5 days. Subsequent courses: Up to 50 mg/kg/24 hr in a continuous IV drip if possible or in 2–4 divided doses for 3–5 days. <i>Symptomatic lead toxicity or lead encephalopathy:</i> Initial: 50 mg/kg/day or 1–1.5 g/m ² /24 hr in a continuous IV drip if possible or in 4 divided doses for 5–7 days; give with dimercaprol (BAL).	Injection: 200 mg/mL For intravenous infusion, dilute to a maximum concentration of 5 mg/mL with D ₅ W or normal saline. Infusions should be administered either continuously or over 1–2 hours if intermittent doses are used. Rapid infusion may increase intracranial pressure.
Edrophonium (Enlon, Reversol)	IV: Infants: Initially 0.1 mg; if no response, follow with an additional 0.4 mg for a maximum total dose of 0.5 mg. Children: Initial: 0.04 mg/kg followed by 0.16 mg/kg if no response; maximum total dose is 10 mg. Adults: 0.2 mg/kg up to 10 mg. Administer 2 mg initially, then titrate dose. <i>Titration of therapy:</i> 0.04 mg/kg 1 time; if strength improves, an increase in neostigmine or pyridostigmine dose is indicated.	Injection: 10 mg/mL May precipitate cholinergic crisis.

(continued)

Table 1. Medications (continued)

	Dosages	Dosage Forms
Enalapril, enalaprilat (Vasotec)	<p>PO: Initially 0.1 mg/kg/day in 1 or 2 divided doses to the usual adult dose of 2.5–5 mg/kg/day. Dosage may be increased as required to a maximum of 0.5 mg/kg/day or 40 mg.</p> <p>IV: 5–10 mcg/kg (up to 0.625–1.25 mg) may be administered q8–24h as necessary for control of hypertension.</p> <p>Dosage must be decreased in patients with compromised renal function and also should be decreased in patients who are hyponatremic or volume depleted, in severe congestive heart failure, or in those who are receiving diuretics.</p>	<p>Injection: 1.25 mg/mL Tablets: 2.5 mg, 5 mg, 10 mg, 20 mg</p>
Enoxaparin (Lovenox)	<p>SC: <i>Prophylaxis:</i> Age <2 months: 0.75 mg/kg/dose q12h Age ≥2 months: 0.5 mg/kg/dose q12h. Adults >45 kg: 30 mg q12h. <i>Treatment of DVT or PE:</i> Age <2 months: 1.5 mg/kg/dose q12h. Age ≥2 months: 1 mg/kg/dose q12h. Adults >45 kg: 1 mg/kg/dose q12h. Doses should be adjusted based on antifactor Xa levels. Consult pharmacist for dosing in obese patients.</p>	<p>Injection: 100 mg/mL</p>
Epinephrine (Adrenalin)	<p>IV: <i>Asystole, or pulseless arrest:</i> Neonates: 0.01–0.03 mg/kg (0.1–0.3 mL/kg of a 1:10,000 solution) q3–5min as necessary. Infants to adults: An initial dose of 0.01 mg/kg; subsequent doses of 0.1 mg/kg may be repeated q3–5min as necessary. A continuous infusion may be started at a dose of 0.1–1 mcg/kg/min and titrated to effect.</p> <p>IM: <i>Anaphylaxis or respiratory failure:</i> 0.01 mg/kg IM of the 1:1,000 solution. 10–30 kg: 0.15 mg IM, >30 kg: 0.3 mg IM.</p> <p>Nebulization: 0.25–0.5 mL of a 2.25% racemic epinephrine solution diluted in 2.5–3 mL of normal saline for inhalation.</p>	<p>Injection: 1:10,000 (0.1 mg/mL), 1:1,000 (1 mg/mL) Injection pre-filled automatic syringe: EpiPen delivers 0.3 mg IM, EpiPen Jr. delivers 0.15 mg IM Solution, racemic for inhalation: 2.25%</p>
Epoetin alfa (erythropoietin; Epogen, EPO, Procrit, r-HuEPO)	<p>IV or SC: Initially 50–100 Unit/kg administered 1–3 times weekly until the hematocrit reaches 30–33%. Dosage should be lowered if the hematocrit exceeds that range or increases by >4 points in a 2-week period. It may be increased if the hematocrit does not reach the target range or fails to increase by 5–6 points in an 8-week period. The usual maintenance dose is 25 Unit/kg 3 times weekly. Hematocrit and serum iron levels should be monitored frequently. BP should also be monitored frequently.</p>	<p>Injection: 2,000 Unit/mL, 3,000 Unit/mL, 4,000 Unit/mL, 10,000 Unit/mL, 20,000 Unit/mL, 40,000 Unit/mL</p>
Ergocalciferol (vitamin D₂, activated ergosterol; Calciferol, Drisdol)	<p>PO: Healthy infants and children: 400 Units/day. Infants and children with malabsorption syndromes: 1,000 Units/day. Children with liver disease: 4,000–8,000 Units/day. Children with vitamin D–dependent rickets: 3,000–5,000 Units/day. Nutritional rickets with normal absorption: 1,000–5,000 Units/day; with malabsorption: 10,000–25,000 Units/day.</p> <p>IM: Should be retained for patients with rickets due to severe vitamin D deficiency. The dose for vitamin D–resistant rickets ranges from 50,000–500,000 Units/day, for hypoparathyroidism from 50,000–200,000 Units/day, and for familial hypophosphatemia from 10,000–80,000 Units/day. The range between therapeutic and toxic doses is narrow. Patients must be closely monitored.</p> <p>1 mcg = 40 Units.</p>	<p>Capsules: 50,000 Units (1.25 mg) Injection (in sesame oil): 500,000 Units/mL (12.5 mg/mL) Solution, oral: 8,000 Units/mL (200 mcg/mL)</p>

Table 1. Medications (continued)

	Dosages	Dosage Forms
Erythromycin (Ery-Tab, Eryc, Erythrocin, E.E.S.)	<p>PO: Infants and children: Base, ethylsuccinate or stearate: 30–50 mg/kg/day in 3 or 4 divided doses do not exceed 2 g/day. Adults: Base: 250–500 mg q6–12h. Ethylsuccinate: 400–800 mg q6–12h. <i>Endocarditis prophylaxis</i> (penicillin-allergic patients): 20 mg/kg to a maximum of 1 g 2 hours before the procedure and 10 mg/kg to a maximum of 500 mg 6 hours later. <i>Bowel preparation</i> (erythromycin base, only): 20 mg/kg to a maximum of 1 g administered at 1:00, 2:00, and 11:00 P.M. on the day before surgery, usually combined with neomycin and mechanical cleansing of the bowel.</p> <p>IV: 15–50 mg/kg/day to a maximum of 4 g/day administered in 4 divided doses.</p> <p>Ophthalmic ointment: <i>Prophylaxis of neonates:</i> Apply a 0.5–1 cm ribbon of the ointment to each conjunctival sac.</p> <p>Topically for acne: Apply to the affected areas b.i.d. The skin should be washed, rinsed well, and dried before applying the erythromycin. Keep away from the eyes, nose, and mouth.</p>	<p>Base: Capsules, enteric-coated pellets: 250 mg Ointment, ophthalmic: 0.5% Gel, topical: 2% Solution, topical: 1.5%, 2% Tablets, enteric coated: 250 mg, 333 mg, 500 mg Tablets, film coated: 250 mg, 500 mg Ethylsuccinate: Suspension: 200 mg/5 mL, 400 mg/5 mL Tablets: 400 mg Stearate: Tablets: 250 mg, 500 mg</p>
Erythromycin and sulfisoxazole	<p>PO (based on the erythromycin content): Age ≤2 months: 40–50 mg/kg/day in 3 or 4 divided doses to a maximum of 2 g/day.</p>	<p>Suspension: 200 mg erythromycin and 600 mg sulfisoxazole per 5 mL</p>
Etanercept (Enbrel)	<p>SC: <i>The treatment of rheumatoid arthritis:</i> 0.4 mg/kg to a maximum dose of 25 mg given twice weekly 72–96 hours apart. Alternatively, 0.8 mg/kg to a maximum dose of 50 mg as a weekly dose may be used.</p>	<p>Injection, powder for reconstitution: 25 mg</p>
Ethacrynic acid (Edecrin)	<p>PO: 1 mg/kg administered 1–2 times daily. Do not exceed the usual adult dose of 50–200 mg/day.</p> <p>IV: 0.4–1 mg/kg up to 50 mg administered 1 or 2 times daily. Serum electrolytes must be closely monitored during ethacrynic acid therapy.</p>	<p>Injection: 50 mg Tablets: 25 mg</p>
Ethambutol (Myambutol)	<p>PO: <i>(Patient should be old enough to cooperate with an eye exam to detect optic neuritis):</i> Children: 15–20 mg/kg/day in a single dose. Adolescents and adults: 15–25 mg/kg/day in a single dose. Do not exceed 1.6 g/day.</p>	<p>Tablets: 100 mg, 400 mg</p>
Ethosuximide (Zarontin)	<p>PO: Age <6 years: 15 mg/kg/day in 2 divided doses to a maximum of 250 mg/dose. Age ≥6 years: 250 mg b.i.d. Dose may be increased by 250 mg/day q4–7 days to a maximum of 1.5 g/day or 40 mg/kg/day.</p>	<p>Capsules: 250 mg Syrup: 250 mg/5 mL</p>
Famotidine (Pepcid)	<p>PO, IV: Age >3 months to 1 year: 1 mg/kg/day in 2 divided doses may be used for GERD. Children and adults: 1 mg/kg/day in 2 divided doses up to 80 mg/day may be used for GERD. A dose of 0.5 mg/kg up to 40 mg may be used for peptic ulcer or esophagitis.</p>	<p>Injection: 10 mg/mL Powder for oral suspension: 40 mg/5 mL Tablets: 10 mg, 20 mg, 40 mg</p>

(continued)

Table 1. Medications (continued)

	Dosages	Dosage Forms
Fentanyl citrate (Sublimaze)	<p>IV: (Slowly over a period of 3–5 minutes to avoid chest wall rigidity and to titrate to effect): Children: 1–2 mcg/kg may be repeated at 30–60-minute intervals. For continuous therapy, after a bolus dose, a dose of 1 mcg/kg/hr initially may be increased or decreased as necessary to response. Older children and adults: 0.5–1 mcg/kg (25–50 mcg) may be repeated at 30–60-minute intervals.</p> <p>Intranasal: 1–2 mcg/kg intranasal x 1 dose if no IV access The doses listed are analgesic/sedation doses. Doses used for general anesthesia may be higher.</p> <p>Transdermal: Children >2 yrs who are receiving at least 60 mg in morphine equivalents/day may be transitioned to fentanyl patch. Consult pharmacist for conversion.</p>	<p>Injection: 50 mcg/mL Transdermal: 12.5 mcg/day, 25 mcg/day, 50 mcg/day, 75 mcg/day, 100 mcg/day</p>
Ferrous sulfate (Feosol, Fer-In-Sol)	<p>PO (doses are expressed as elemental iron): <i>Iron deficiency anemia:</i> Children: 3–6 mg/kg/day depending on the severity of the deficiency. Higher doses should be administered in 3 divided doses; moderate doses may be administered in 2 divided doses to avoid GI upset. For prophylaxis, 1–2 mg/kg/day in a single dose may be used. Adults: 120–240 mg iron daily in 2–4 divided doses. For prophylaxis, 60 mg iron daily as a single dose. Administration between meals increases absorption, but may result in more GI upset. Do not administer with antacids, eggs, or milk because they may decrease absorption of the iron. Many concentrations available, use caution. Ferrous sulfate contains 20% iron</p>	<p>Drops: 75 mg/0.6 mL (15 mg elemental Fe/0.6 mL) OR 75 mg/mL (15 mg elemental Fe/mL) Elixir: 220 mg/5 mL (44 mg elemental Fe/5 mL) Liquid 300 mg/5 mL (60 mg elemental Fe/5 mL) Suspension: 75 mg/1.5 mL (15 mg elemental Fe/1.5 mL) Tablets: 325 mg (65 mg elemental Fe); Tablet, slow release: 160 mg (50 mg elemental Fe), 140 mg (45 elemental Fe)</p>
Fexofenadine (Allegra)	<p>PO: Age 2–11 years: 30 mg b.i.d. Age > 12 years: 60 mg b.i.d. or 180 mg daily.</p>	<p>Liquid: 6 mg/mL, Tablet: 30 mg, 60 mg, 180 mg, Tablet, orally disintegrating: 30 mg</p>
Fluconazole (Diflucan)	<p>PO or IV: Oropharyngeal or esophageal candidiasis: 6 mg/kg (up to 200 mg) on the first day; then 3 mg/kg/day (up to 100 mg). <i>Systemic candidiasis or cryptococcal meningitis:</i> 12 mg/kg (up to 400 mg) on the first day; then 6 mg/kg/day (up to 200 mg). <i>Prevention of candidiasis in bone marrow transplant:</i> 12 mg/kg/day (up to 400 mg) beginning several days before anticipated onset of neutropenia and continued until 7 days after neutrophil count is > 1,000/mm³. <i>Vaginal candidiasis:</i> 150 mg as a single dose. Dosage should be adjusted in patients with renal dysfunction.</p>	<p>Injection: 2 mg/mL (ready to administer) Suspension: 10 mg/mL, 40 mg/mL Tablets: 50 mg, 100 mg, 150 mg, 200 mg</p>
Flucytosine (Ancobon)	<p>PO: Neonates: 50–100 mg/kg/day in 1–2 divided doses. Children and adults: 50–150 mg/kg/day in 4 divided doses. Dosage must be adjusted in renal impairment.</p>	<p>Capsules: 250 mg, 500 mg</p>
Fludrocortisone (Florinef)	<p>PO: Infants and children: 0.05–0.1 mg/day. Adults: 0.05–0.2 mg/day.</p>	<p>Tablets: 0.1 mg</p>
Flumazenil (Mazicon, Romazicon)	<p>IV: Children: 0.01 mg/kg (to a maximum of 0.2 mg) initially, followed by 0.005 mg/kg (to a maximum of 0.2 mg) every minute until a total cumulative dose of 1 mg has been reached. Adults: <i>Reversal of sedation:</i> 0.2 mg over 15 seconds; may repeat 0.2-mg dose q60sec to a maximum of 1 mg. May repeat doses q20min to a maximum of 3 mg in 1 hour. <i>Benzodiazepine overdose:</i> 0.2 mg over 30 seconds, then 0.3 mg over 30 seconds if desired level of consciousness is not reached. Additional 0.5-mg doses may be given every minute until a cumulative dose of 3 mg has been reached. If a partial response is noted, further 0.5-mg doses may be given until a cumulative dose of 5 mg is reached. Resedation may occur in patients who received long-acting benzodiazepines. Do not use in patients with seizure disorders dependent upon benzodiazepines for seizure control.</p>	<p>Injection: 0.1 mg/mL</p>

Table 1. Medications (continued)

	Dosages	Dosage Forms
Flunisolide (AeroBid, Nasarel)	<p>Intranasal spray: Age 6–14 years: 1 spray in each nostril t.i.d. or 2 sprays in each nostril b.i.d. initially. Maintenance dose is usually 1 spray in each nostril daily. Age > 14 years: 2 sprays in each nostril b.i.d. or t.i.d. initially. After symptoms are controlled, dosage should be decreased to the lowest dose that will prevent symptoms from recurring. That may be as little as 1 spray in each nostril once daily for perennial rhinitis. The maximum dose is 4 sprays to each nostril daily.</p> <p>Oral inhalation: Age 6–15 years: 2 inhalations b.i.d. Adults: 2 inhalations b.i.d. initially, increasing to a maximum of 8 inhalations daily. Improvement in symptoms may take from several days to several weeks to occur, but therapy should not be continued for >3 weeks in the absence of efficacy. Dosage should be decreased to the lowest effective dose when symptoms abate.</p>	<p>Oral inhalation: 250 mcg/spray Spray, intranasal: 29 mcg/metered spray</p>
Fluocinolone acetonide (Synalar)	<p>Topically: Apply a thin layer to the affected area b.i.d. to q.i.d. Use the lowest effective potency product. Absorption is greater if the product is covered by anything that is occlusive (plastic pants, tight diapers).</p>	<p>Cream: 0.01%, 0.025% Ointment: 0.025% Shampoo: 0.01% Solution: 0.01%</p>
Fluoride (Fluoritab, Karidium, Luride, Pediaflor)	<p>PO: Dosage should be based on the fluoride content of the water supply. Long-term supplementation in areas with fluoridated water may result in dental fluorosis and osseous changes. Fluoride content of drinking water <0.3 ppm: Age 0–6 months: Do not supplement. Age >6 months–3 years: 0.25 mg/day. Age >3–6 years: 0.5 mg/day. Age >6–16 years: 1 mg/day. Fluoride content of drinking water 0.3–0.6 ppm: Age 0–3 years: Do not supplement. Age 3–6 years: 0.25 mg/day. Age >6–16 years: 0.5 mg/day. Fluoride content of drinking water >0.6 ppm: Do not supplement. Dental gel: Usually applied by a dentist. Rinses: Over-the-counter rinses may be used for patients over age 6 on a daily basis and contain 0.01–0.02% fluoride.</p>	<p>Most multivitamin combinations are available in formulations containing appropriate amounts of fluoride (Poly-Vi-Flor drops or chewable tablets, Tri-Vi-Flo drops, Vi-Daylin/F drops and chewable tablets). Products containing only fluoride: Drops: 0.25 mg/drop Solution: 0.5 mg/mL, 0.2 mg/mL (may be used PO or as a rinse) Tablets, chewable: 0.25 mg, 0.5 mg, 1 mg</p>
Fluticasone (Flonase, Flovent)	<p>Intranasal metered dose spray: Age ≥4 years: 1 spray in each nostril daily. Dosage may be increased to 2 sprays in each nostril daily if necessary. Adults: 2 sprays in each nostril daily.</p> <p>Oral aerosol inhalation: Age ≥4 years: 88 mcg b.i.d. for patients not previously treated with corticosteroids to a maximum of 440 mcg b.i.d. in patients who were previously treated with inhaled corticosteroids.</p>	<p>Spray oral inhalation: 44 mcg/actuation, 110 mcg/actuation, 220 mcg/actuation Suspension, nasal: 50 mcg/actuation</p>
Fluticasone and Salmeterol (Advair)	<p>Oral powder inhalation: Age 4–11 years: 1 inhalation daily of the fluticasone 100 mcg/salmeterol 50 mcg product. Age ≥12 years: 1 inhalation b.i.d. using the product that most closely matches the patient’s previous steroid dosage. Use the lowest dose product for steroid naïve patients.</p>	<p>Powder for oral inhalation: 100 mcg fluticasone/50 mcg salmeterol/puff, 250 mcg fluticasone/50 mcg salmeterol/puff, 500 mcg fluticasone/50 mcg salmeterol/puff.</p>
Folic acid	<p>PO, IV or IM: Age <1 year: 0.1 mg/day. Age ≥1 year: 1 mg/day initially, then 0.1–0.4 mg/day.</p>	<p>Injection: 5 mg/mL Tablets: 0.4 mg, 0.8 mg, 1 mg</p>

(continued)

Table 1. Medications (continued)

	Dosages	Dosage Forms
Fomepizole (Antizol, 4-MP, 4-methylpyrazole)	<p>IV: (Diluted to <25 mg/mL): Children and Adults: 15 mg/kg loading dose, then 10 mg/kg/dose q12h for 4 doses, then 15 mg/kg/dose q12h until level is <20 mg/dL. Doses should be given q6h in children and q4h in adults during hemodialysis.</p>	Injection: 1 gm/mL
Fosphenytoin See phenytoin Furosemide (Lasix)	<p>PO, IV, or IM: Premature neonates (oral absorption may be poor): 1–2 mg/kg q12–24h. Oral doses up to 4 mg/kg may be used. Infants and children: 1–2 mg/kg q6–12h but not to exceed 6 mg/kg/day. May use as a continuous infusion 0.05–0.3 mg/kg/hr. Titrate to effect. Adults: 20–80 mg/day in divided doses to a maximum of 600 mg/day. Serum electrolyte levels should be monitored closely.</p>	Injection: 10 mg/mL Solution: 10 mg/mL, 40 mg/5 mL Tablets: 20 mg, 40 mg, 80 mg
Gabapentin (Neurontin)	<p>PO: Age 3–12 years: 10–15 mg/kg/day in 3 divided doses. The maintenance dose for patients 3–4 years of age is usually about 40 mg/kg/day and for patients 5 years and older is 25–35 mg/kg/day. Age > 12 years: Initially, 300 mg on day 1, followed by rapid titration to 300 mg t.i.d. The usual maintenance dosage range is 900–1,800 mg/day in 3 divided doses to a maximum daily dose of 3,600 mg. It is not necessary to monitor gabapentin levels or the levels of other antiepileptic drugs the patient may be taking because there are no significant drug interactions. Withdrawal of gabapentin therapy should be accomplished over a period of at least 1 week. Dosage must be adjusted in patients with renal dysfunction.</p>	Capsules: 100 mg, 300 mg, 400 mg Solution: 250 mg/5 mL Tablet: 100 mg, 300 mg, 400 mg, 600 mg, 800 mg
Ganciclovir (Cytovene, DHPG)	<p>IV: (As an infusion over 1 hour): Induction: 10 mg/kg/day in 2 divided doses for 2–3 weeks. Maintenance: 5 mg/kg/day as a single dose for 7 days a week to 6 mg/kg/day for 5 days a week. PO: Maintenance therapy only: In adults, a dose of 1,000 mg t.i.d. with food is used. Valganciclovir is preferred in children when oral dosing required. Dosage must be adjusted in patients with renal dysfunction.</p>	Capsules: 250 mg, 500 mg Injection: 500-mg vial
Gentamicin (Garamycin)	<p>IV or IM: (In obese patients it should be based on ideal, rather than actual, body weight): Age <7 days: <1,000 g: 2.5 mg/kg q24h. 1,000–1,500 g: 2.5 mg/kg q18h. >1,500 g: 2.5 mg/kg q12 h. Age >7 days: 1,200–2,000 g: 2.5 mg/kg q12h. >2,000 g: 2.5 mg/kg q8h. ECMO patients: 2.5 mg/kg q18h. Age <10 years: 2.5 mg/kg q8h OR 7.5 mg/kg s24h. Age >10 years: 5–6 mg/kg/day administered in 3 divided doses. OR as a once daily dose. Note that many different dosing regimens exist. Follow institutional guidelines. If using for synergistic effect, use lower dose of 1–2 mg/kg IV q8h. Dosage must be adjusted in patients with renal dysfunction. Ophthalmic solution: 1–2 drops in the affected eye q2–4h. More frequent application (up to every hour) may be used initially in severe infections. Ophthalmic ointment: Apply a ribbon of ointment to the eye b.i.d. or t.i.d.</p>	Injection: 10 mg/mL, 40 mg/mL Ointment, ophthalmic: 0.3% Solution, ophthalmic: 0.3%

Table 1. Medications (continued)

	Dosages	Dosage Forms
Glucagon	<p>IV, IM, or SC: <i>Hypoglycemia</i> (dose may be repeated in 20 minutes if necessary): Neonates, Infants and Children <20 kg: 0.015–0.03 mg/kg/dose, to a maximum of 1 mg. Children >20 kg and Adults: 0.5–1 mg/dose.</p>	Injection: 1 mg-vial
Glycopyrrolate (Robinul)	<p>IM: <i>Preoperatively:</i> Age <2 years: 4.4–8.8 mcg/kg 30–60 minutes before the procedure. Age ≥2 years: 4.4 mcg/kg 30–60 minutes before the procedure.</p> <p>PO: <i>To control secretions</i> (glycopyrrolate is poorly absorbed from the GI tract): 50–100 mcg/kg administered t.i.d. or q.i.d. <i>Reversal of neuromuscular blockade:</i> 0.2 mg for each 1 mg neostigmine or 5 mg pyridostigmine administered.</p>	Injection: 0.2 mg/mL Liquid: 1 mg/5 mL Tablets: 1 mg, 2 mg
Gonadorelin HCl [Factrel, LHRH (luteinizing hormone-release hormone), GnRH (gonadotropin-releasing hormone)]	<p>IV: 2–5 mcg/kg to a maximum of 100 mcg.</p>	Injection: 100 mcg
Griseofulvin (Microsize products: Grifulvin V, Grisactin; Ultramicrosize products: Fulvicin P/G, Grisactin Ultra, Gris-PEG)	<p>Absorption of griseofulvin from the GI tract is somewhat dependent on the size of the particles of griseofulvin. The ultramicrosize is absorbed ~1.5 times as well as the microsize. Absorption is also increased by administering the dose with a fatty meal. Duration of therapy is dependent on the site of infection and ranges from 2–4 weeks for tinea corporis, to 4–8 weeks for tinea capitis and tinea pedis, to 3–6 months for tinea unguium.</p> <p>Children: Microsize: 15–20 mg/kg/day in 1 or 2 divided doses. Ultramicrosize: 10–13 mg/kg/day in 1 or 2 divided doses.</p> <p>Older children and adults: Microsize: 500 mg to 1 g/day in a single or 2 divided doses. Use higher dose for tinea pedis or tinea unguium. Ultramicrosize: 660–750 mg/day in a single or 2 divided doses.</p> <p>During long-term therapy, renal, hepatic, and hematopoietic function should be monitored.</p> <p>Patients should also be cautioned to avoid sunlight because photosensitivity reactions have occurred.</p>	Microsize: Suspension: 125 mg/5 mL Tablets: 500 mg Ultramicrosize: Tablets: 125 mg, 250 mg, 330 mg
Haloperidol (Haldol)	<p>PO: Age 3–12 years: <i>Agitation or hyperkinesia:</i> 0.01–0.03 mg/kg/day once daily. <i>Tourette disorder:</i> 0.05–0.075 mg/kg/day in 2 or 3 divided doses. <i>Psychotic disorders:</i> 0.05–0.15 mg/kg/day in 2 or 3 divided doses.</p> <p>IM: 1–3 mg q4–8h; maximum, 0.1 mg/kg/day. May use up to 5 mg/dose if > 12 years and an imminent danger to themselves or others. Dose should be individually adjusted to patient. Not recommended for children under age 3. Do NOT interchange the decanoate salt (depot injection) with the lactate (immediate release) salt.</p>	Injection: 5 mg/mL Injection, depot: 50 mg/mL Solution, concentrated oral: 2 mg/mL Tablets: 0.5 mg, 1 mg, 2 mg, 5 mg, 10 mg, 20 mg

(continued)

Table 1. Medications (continued)

	Dosages	Dosage Forms
Heparin sodium	<p>IV: <i>Anticoagulation:</i> Children and adults: Continuous infusion: 50 Units/kg then 15–25 Units/kg/hr. Dose may be increased by 2–4 Units/kg/hr q6–8h based on the results of the APTT. Intermittent infusion: 50–100 Units/kg q4h. This method is less desirable than continuous infusion. <i>Line flushing:</i> Central catheters: May be flushed as infrequently as once daily with 2–3 mL of solution containing 10 Units/mL for patients under age 1 or 100 Units/mL for patients age 1 or older. Peripheral catheters, locks: Usually flushed q6–8h with 10 Units/mL concentration with a volume determined by the length of the catheter, but usually ~1 mL. Lines should be flushed before and after medication or blood administration or if blood is seen in the catheter. Preservative free heparin solutions should be used for all line flushes in children under age 2 months.</p>	<p>Injection: 1,000 Unit, 5,000 Unit, 10,000 Unit, 20,000 Unit, 40,000 Unit/mL Injection, preservative-free: 1,000 Unit, 5,000 Unit, 10,000 Unit/mL Solution, lock flush: 10 Unit/mL, 100 Unit/mL (available preserved and preservative-free)</p>
Hydralazine (Apresoline)	<p>PO: Children: 0.75–1 mg/kg/day in 2–4 divided doses, but not to exceed 25 mg/dose initially. May be increased slowly over 3 or 4 weeks to a maximum of 7.5 mg/kg/day (or 200 mg). Adults: Initially 10 mg q.i.d. May be increased by 10–25 mg/dose q2–5d to a maximum of 300 mg/day. IV (ratio of PO to IV dosing is ~4:1): Children: Initially 0.1–0.2 mg/kg (to a maximum of 20 mg) q4–6h. May be increased to a maximum of 1.7–3.5 mg/kg/day. Adults: Initially 10–20 mg q4–6h. May be increased to 40 mg/dose. Dose must be adjusted in renal impairment.</p>	<p>Injection: 20 mg/mL Tablets: 10 mg, 25 mg, 50 mg, 100 mg</p>
Hydrochlorothiazide (Esidrix, HydroDIURIL, Oretic)	<p>PO: <i>(Chlorothiazide, which is available as a suspension, is usually a better choice for children requiring low doses):</i> Age >6 months: 2 mg/kg/day in 2 divided doses. Adults: 25–100 mg/day in 1 or 2 doses.</p>	<p>Tablets: 25 mg, 50 mg</p>
Hydrocortisone (Cortef, Cortenema, Cortifoam, Solu-Cortef)	<p>PO: <i>Congenital adrenal hyperplasia:</i> Initially 30–36 mg/m²/day divided as 1/3 in the morning and 2/3 in the evening or 1/4 in the morning, 1/4 midday, and 1/2 in the evening. <i>Physiologic replacement:</i> 0.5–0.75 mg/kg/day. <i>Anti-inflammatory:</i> 2.5–10 mg/kg/day in 3 or 4 divided doses. IV: <i>Adrenal insufficiency:</i> Infants and young children: 1–2 mg/kg bolus, then 25–150 mg/day in 3 or 4 divided doses. Older children: 1–2 mg/kg bolus, then 150–250 mg/day in 3 or 4 divided doses. Adults: 15–240 mg/day in 1 or 2 divided doses. <i>Anti-inflammatory:</i> Infants and children: 1–5 mg/kg/day in 2–4 divided doses. Adults: 15–240 mg q12h. <i>Stress coverage (all patients):</i> 100 mg/m² as a single dose followed by 100 mg/m²/day in 6 divided doses. <i>Shock (succinate salt):</i> Children: 50 mg/kg then in 4 hours or q24h as needed. Adults: 500 mg to 2 g q2–6h.</p>	<p>Cream, topical: 0.5%, 1%, 2.5% Enema: 100 mg/60 mL (Cortenema) Foam, intrarectal: 90 mg/full applicator (Cortifoam), rectal/anal 1% (Proctofoam-HC) Injection (sodium phosphate): 50 mg/mL Injection (sodium succinate): 100-mg, 250-mg, 500-mg, 1-g vials Ointment, topical: 0.5%, 1%, 2.5% Suspension (cypionate): 10 mg/5 mL Tablets: 5 mg, 10 mg, 20 mg</p>

Table 1. Medications (continued)

Dosages	Dosage Forms
<p>Hydrocortisone (Cortef, Cortenema, Cortifoam, Solu-Cortef) (continued)</p> <p><i>Rectal retention enemas:</i> 1 enema nightly for 21 days. May be continued for a longer period if effective or discontinued if no effect is seen.</p> <p><i>Intrarectal foam:</i> 1 full applicator rectally nightly or b.i.d. for 2 or 3 weeks. Absorption of hydrocortisone may be greater from the foam formulation than the enema. Discontinue if not effective after 3 weeks.</p> <p>Topically (low-potency corticosteroid in most formulations): Apply a thin layer to the affected area t.i.d. or q.i.d.</p>	
<p>HYDROmorphone (Dilaudid)</p> <p>IV: Young children: 0.015–0.03 mg/kg q3–4h. Older children and adults: 1–4 mg q3–4h. Use lowest effective dose in opiate-naïve patients.</p> <p>PO: Young children: 0.04–0.07 mg/kg q3–4h. Older children and adults: 1–6 mg q3–4h depending on size and pain severity.</p> <p><i>To convert a patient from oral to IV therapy:</i> Start with a ratio of 5:1. Ratios of up to 2:1 may be required in some patients on long-term chronic therapy.</p> <p><i>To convert a patient from IV to oral therapy:</i> In a patient who is receiving a stable dose, use an IV to oral ratio of 1:3.</p> <p>Equianalgesic doses: Oral: 7.5 mg HYDROmorphone = 30 mg morphine. Parenteral: 1.5 mg HYDROmorphone = 10 mg morphine. Use caution when prescribing HYDROmorphone—interchanges with morphine have resulted in severe overdoses.</p>	<p>Injection: 1 mg/mL, 2 mg/mL, 4 mg/mL, 10 mg/mL Solution, oral: 1 mg/mL Suppositories, rectal: 3 mg Tablets: 2 mg, 4 mg, 8 mg</p>
<p>Hydroxychloroquine (Plaquenil)</p> <p>PO: SLE or JRA: 3–5 mg/kg/day in 1 or 2 divided doses to a maximum dose of 6.5 mg/kg/day.</p>	<p>Tablets: 200 mg</p>
<p>Hydroxyzine (Atarax, Vistaril)</p> <p>IM, IV or PO: Children: 2 mg/kg/day in 3 or 4 doses. Adults: 100–400 mg/day in 3 or 4 doses. Use lower doses for pruritus and higher doses for sedation.</p> <p><i>Parenterally:</i> The use of hydroxyzine parenterally (IM, IV, SC) has been associated with severe adverse effects at the site of the injection. The reactions are characterized by local discomfort, sterile abscess, erythema, and tissue necrosis. Phlebitis and hemolysis have been reported after IV administration. The manufacturers recommend administration by deep IM injection into a well-developed large muscle. SC infiltration of the drug from an IM injection or extravasation of an IV injection must be avoided.</p>	<p>Capsule (pamoate): 25 mg, 50 mg, 100 mg Injection for IM use: 25 mg/mL, 50 mg/mL Solution, oral: 10 mg/5 mL Suspension, oral (pamoate): 25 mg/5 mL Tablets: 10 mg, 25 mg, 50 mg, 100 mg</p>
<p>Ibuprofen (Advil, Motrin, Nuprin)</p> <p>IV or PO: <i>Antipyretic:</i> 10 mg/kg/dose PO q6–8h, max 800 mg/dose. <i>Juvenile rheumatoid arthritis:</i> 30–70 mg/kg/day in 4 divided doses to a maximum of 2,400 mg/day. <i>Adult anti-inflammatory dose:</i> 400–800 mg q6–8h to a maximum of 3,200 mg/day.</p>	<p>Drops, concentrated: 40 mg/mL Suspension: 100 mg/5 mL Tablets: 200, 400, 600, 800 mg Tablet, chewable: 100 mg Capsules: 200 mg Injection:</p>
<p>Imipenem and cilastatin (Primaxin)</p> <p>IV infusion over 1 hour (expressed as mg of imipenem): Children: 50–100 mg/kg/day in 4 divided doses to a maximum of 4 g/day. Adults: 2–4 g/day in 3 or 4 divided doses. Dosage must be adjusted in patients with renal dysfunction.</p>	<p>Injection: Imipenem 250 mg and cilastatin 50 mg, imipenem 500 mg and cilastatin 500 mg</p>

(continued)

Table 1. Medications (continued)

	Dosages	Dosage Forms
Imipramine (Tofranil)	<p>PO:</p> <p><i>Enuresis</i> in children under age 6: Initially 25 mg 1 hour before bedtime nightly. Dose may be increased to 50 mg in children age 6–12 or 75 mg in children over age 12 if the initial dose is ineffective.</p> <p><i>Depression:</i></p> <p>Children: 1.5 mg/kg/day in 1–4 divided doses initially. May be increased in increments of about 1 mg/kg/day to a maximum of 5 mg/kg/day.</p> <p>Adolescents: 25–50 mg/day increased gradually to a maximum of 100 mg/day in a single or divided doses.</p> <p>Adults: 75–100 mg/day increased gradually to a maximum of 300 mg/day in a single or divided doses.</p> <p>Dosage should be decreased to the minimum effective dose after symptom control has been achieved.</p> <p>Administration of the total daily dose at bedtime may decrease the daytime sedative effects.</p>	Tablets: 10 mg, 25 mg, 50 mg
Immune globulin, intramuscular	<p>IM:</p> <p><i>Measles prophylaxis:</i> 0.25 mL/kg within 6 days of exposure. In immunocompromised patients, use 0.5 mL/kg (15 mL maximum).</p> <p><i>Hepatitis A pre-exposure prophylaxis:</i></p> <p>Risk of exposure within 3 months: 0.02 mL/kg.</p> <p>Risk of exposure >3 months: 0.06 mL/kg.</p> <p><i>Hepatitis A postexposure:</i> 0.02 mL/kg given within 2 weeks of exposure.</p>	Injection, IM: 165 ± 15 mg (of protein) per mL (2 mL and 10 mL)
Immune globulin, intravenous (Gammagard S/D, Gammar-P IV, Gamunex, Iivegam, Octagam, Polygam S/D)	<p>IV as a slow infusion:</p> <p>The rate of infusion varies from product to product but should always be initiated at a very slow rate and may be increased q30min to the manufacturer’s maximum recommended rate or less as the patient tolerates.</p> <p>Infusion-related reactions usually abate if the rate of infusion is decreased.</p> <p>Anaphylactic hypersensitivity reactions may occur and are more likely in patients with IgA deficiency.</p> <p><i>Immunodeficiency syndromes:</i> 100–400 mg/kg q2–4wks.</p> <p><i>Idiopathic thrombocytopenic purpura:</i> Either 400 mg/kg/day for 2–5 consecutive days or 1 g/kg/day for 1 or 2 consecutive days may be used for induction. Maintenance doses are usually 400 mg/kg/dose q4–6wk but may be increased to 800–1,000 mg/kg if the lower dose is insufficient and are based on platelet counts and clinical response.</p> <p><i>Kawasaki disease:</i> Usually 2 g/kg as a single dose. Alternatively, 400 mg/kg/day for 4 days may be used.</p>	<p>Gammagard S/D: Powder with diluent to make 5% solution</p> <p>Gammar-P IV: Powder with diluent to make 5% solution</p> <p>Gamunex solution 10%</p> <p>Iivegam: Powder with diluent to make 5% solution</p> <p>Octagam solution: 10%</p> <p>Polygam S/D: Powder with diluent to make 5% solution</p>
Indomethacin IV (Indocin IV)	<p>IV push:</p> <p>Further dilution of the reconstituted injection may result in precipitation of insoluble indomethacin. An initial 0.2 mg/kg/dose is followed by 2 doses based on the patient’s postnatal age (PNA) at the time of the first dose:</p> <p>PNA <48 hours: 0.1 mg/kg at 12–24-hour intervals.</p> <p>PNA 2–7 days: 0.2 mg/kg at 12–24-hour intervals.</p> <p>PNA >7 days: 0.25 mg/kg at 12–24-hour intervals.</p> <p>The patient’s renal and hepatic function should be monitored.</p> <p>Oral use in children is generally not recommended.</p> <p>Dosage must be adjusted in patients with renal dysfunction.</p>	Injection (sodium trihydrate): 1 mg
Infliximab (Remicade)	<p>IV infusion:</p> <p>Age ≥8 years: 5 mg/kg administered over 2 hours q2wk for 3 doses, then q4–8wk thereafter. Dosage may be increased to 10 mg/kg/dose if necessary.</p> <p>Infusion reactions common, administer per institutional protocol.</p>	Injection: 100 mg

Table 1. Medications (continued)

	Dosages	Dosage Forms
Insulin	<p>IV: <i>Treatment of diabetic ketoacidosis:</i> start a continuous infusion of 0.1 units/kg/hr (usual range 0.05–0.2 units/kg/hr) to maintain steady, but slow, decrease of serum glucose levels of 50–100 mg/dl/hr. Only regular insulin should be used by this route. Euglycemia in ICU 0.01 unit/kg/hr</p> <p>SC: <i>Maintenance:</i> Most patients require 0.5–1 units/kg/day in 2–4 divided doses depending on how well controlled the patient’s glucose levels have been. Patients should be warned not to change insulins without prior approval of their physicians. If regular insulin is to be mixed with other types of insulin, the regular insulin should always be measured first. Extemporaneously prepared doses of mixed insulins should be used as soon as possible after mixing to minimize the amount of the regular insulin that will be bound by excess protamine or zinc in the other insulin. The activity of regular insulin has a time to onset of 1/2–1 hour, peaks at 2–3 hours, and has a duration of 5–7 hours. The activity of isophane (NPH) insulin has a time to onset of ~1–2 hours, peaks at 4–12 hours, and has a duration of 18–24 hours.</p>	<p>All insulins below are 100 Units/mL</p> <p><i>Rapid acting:</i> Aspart (NovoLog), Lispro (Humalog), Glulisine (Apidra)</p> <p><i>Short acting:</i> Regular insulin</p> <p><i>Intermediate acting:</i> Detemir, Isophane (NPH)</p> <p><i>Long acting:</i> Glargine (Lantus)</p> <p><i>Fixed combinations:</i> regular insulin 30 Units/mL with isophane insulin 70 Units/mL; regular insulin 50 Units/mL with isophane insulin 50 Units/mL; aspart insulin 30 Units/mL with aspart protamine insulin 70 Units/mL; lispro 25 Units/mL with lispro protamine 75 Units/mL</p>
Ipratropium bromide (Atrovent)	<p>Nebulization: non acute: <i>(Evidence lacking for added benefit for maintenance therapy with beta2-agonists):</i> Children: 250–500 mcg q6h</p> <p>Metered inhaler: non-acute: <i>(Evidence lacking for added benefit for maintenance therapy with beta2-agonists):</i> Children and Adults: 1–3 actuations per dose every 6 hrs, not to exceed 12 inhalations per day.</p> <p>Nebulization (acute): Infants: 125–250 mcg t.i.d. Children <12 years (acute asthma in emergency department): 250–500 mcg every 20 minutes for 3 doses, then as needed (not shown to have further benefit in inpatient management per NIH guidelines). Children >12 years and Adults (acute asthma in emergency department) 500 mcg every 30 minutes for 3 doses, then as needed</p> <p><i>Metered inhaler:</i> Children (acute): 4–8 puffs as needed Children >12 years and Adults: 8 puffs as needed</p>	<p>Aerosol HFA, metered dose: 17 mcg/actuation Solution for nebulization: 0.02%, 2.5 mL</p>
Isoniazid (isonicotinic acid hydrazide, isonicotinyl hydrazide; INH)	<p>PO or IM: <i>Treatment:</i> Children: 10–20 mg/kg/day in 1 or 2 divided doses (up to 300 mg/day). Adults: 5 mg/kg/day up to 300 mg; 10 mg/kg should be used for disseminated disease.</p> <p><i>Prophylaxis:</i> Children: 10 mg/kg/day in a single dose up to 300 mg/day. Adults: 300 mg/day.</p> <p>Liver function should be monitored during therapy because hepatitis may occur at any time. Patients whose diets are low in milk or meat should receive pyridoxine supplements at a dose of about 10–50 mg/day (1–2 mg/kg/day).</p>	<p>Solution, oral: 50 mg/5 mL Tablets: 100 mg, 300 mg</p>
Isoproterenol (Isuprel)	<p>Continuous IV infusion: 0.05–3 mcg/kg/min up to 2–20 mcg/min.</p>	<p>Injection: 1:5,000 (0.2 mg/mL, 1 mg/5 mL)</p>
Lansoprazole (Prilosec)	<p>PO or IV: Infants and children: Usual range is 0.4–2 mg/kg/day as a single dose. Adults: 15–30 mg daily. Higher doses may be used for pathological hypersecretory conditions.</p>	<p>Capsules: 15 mg, 30 mg Granules for oral suspension: 15 mg packet, 30 mg packet Tablets, PO disintegrating: 15 mg, 30 mg</p>
Levalbuterol (Xopenex)	<p>Nebulized product for Inhalation (acute asthma exacerbation): Children: 0.075 mg/kg (minimum dose: 1.25 mg) every 20 minutes x 3 doses then 0.075–0.15 mg/kg (maximum dose 5 mg) every 1–4 hours as needed Adults: 1.25–5 mg every 30 minutes x 3 doses, then every 1–4 hours as needed</p>	<p>Solution for inhalation 0.63 mg/3 mL and 1.25 mg/3 mL Solution for inhalation (needs dilution): 0.63 mg/0.5 mL, 1.25 mg/0.5 mL Inhaler (HFA): 45 mcg/actuation</p>

(continued)

Table 1. Medications (continued)

	Dosages	Dosage Forms
Levalbuterol (Xopenex) (continued)	<p>Nebulized product for Inhalation (non-acute): 0 to <5 years: 0.31–1.25 mg/dose every 4–6 hrs as needed Age 6–11 years: 0.31 mg/dose t.i.d. to a maximum dose of 0.63 mg t.i.d. Age > 11 years: 0.63 mg t.i.d. to q.i.d. to a maximum of 1.25 mg t.i.d. with close monitoring for adverse effects.</p> <p>Inhaler (acute): Children: 4–8 puffs every 20 minutes ×3 doses, then every 1–4 hours as needed Adults: 4–8 puffs every 20 minutes for up to 4 hours, then every 1–4 hrs as needed Inhaler: ≥5 years and adults (non-acute): 2 inhalations every 4–6 hours as needed</p>	
Levetiracetam (Keppra)	<p>PO or IV: <i>Status epilepticus</i>: 30 mg/kg over 5–15 min. Age 4–15 years: Initial dose: 10–20 mg/kg/day in 2 divided doses. May be increased to a maximum dose of 60 mg/kg/day. Age ≥16 years: 500 mg b.i.d. May be increased to a maximum daily dose of 1,500 mg b.i.d.</p>	Injection: 100 mg/mL Solution 100 mg/mL Tablets: 250 mg, 500 mg, 750 mg, 1,000 mg
Levothyroxine sodium (Levothroid, Synthroid)	<p>PO: Age 0–6 months: 8–10 mcg/kg or 25–50 mcg/day. Age >6–<12 months: 6–8 mcg/kg or 50–75 mcg/day. Age 1–5 years: 5–6 mcg/kg or 75–100 mcg/day. Age 6–12 years: 4–5 mcg/kg or 100–150 mcg/day. Age > 12 years: 2–3 mcg/kg or > 150 mcg/day.</p> <p>IV: 1/2–3/4 of the oral dose for children or about half the oral dose for adults. The parenteral form of the drug is very unstable and should be used immediately after reconstitution without admixing with other solutions.</p>	Injection: 100 mcg, 500 mcg Tablets: 25 mcg, 50 mcg, 75 mcg, 88 mcg, 100 mcg, 112 mcg, 125 mcg, 137 mcg, 150 mcg, 175 mcg, 200 mcg, 300 mcg
Lidocaine hydrochloride (Xylocaine)	<p>IV: <i>Cardiac arrhythmias</i>: 1 mg/kg loading dose followed by a continuous infusion of 20–50 mcg/kg/min. The loading dose may be repeated twice at 10–15-minute intervals, if necessary. 2 mg/kg RST/ETT</p> <p>Infiltration for local anesthesia: Dose depends on procedure, degree, and duration of anesthesia required and the vascularity of the site. Maximum recommended dose is 4.5 mg/kg (or 300 mg). Doses should not be repeated sooner than 2 hours.</p> <p>Topical: Apply to affected area as needed. Maximum dose should not exceed 3 mg/kg or be repeated within 2 hours. Patients treated with oral lidocaine viscous should be cautioned about the hazards of biting the numbed areas and swallowing difficulties.</p>	Injection: 0.5%, 1%, 1.5%, 2%, 4%; 0.5% with epinephrine 1:200,000; 1% with epinephrine 1:100,000 or 1:200,000; 1.5% with epinephrine 1:200,000; 2% with epinephrine 1:100,000 or 1:200,000 Jelly: 2% Liquid, viscous: 2% Ointment: 2.5%, 5% Solution, topical: 2%, 4%
Linezolid (Zyvox)	<p>IV or PO for VRE infections: Age ≤11 years: 30 mg/kg/day in 3 divided doses. Age ≥12 years: 600 mg/dose q12h.</p>	Injection: 200 mg, 600 mg Suspension: 100 mg/5 mL Tablets: 600 mg
Loperamide (Imodium)	<p>PO: <i>Acute diarrhea</i> (dosage is for the initial 24 hours): Age 2–6 years (13–20 kg): 1 mg t.i.d. Age >6–8 years (20–30 kg): 2 mg b.i.d. Age >8–12 years (>30 kg): 2 mg t.i.d. Adults: 4 mg initially followed by 2 mg after each unformed stool to a maximum of 8 mg in 24 hours (16 mg/24 hr under a physician's care). For subsequent days, use a dose of 0.1 mg/kg for children after each loose stool, but do not exceed dosage guidelines for the first day.</p>	Capsules: 2 mg Solution, oral: 1 mg/5 mL Tablets: 2 mg

Table 1. Medications (continued)

	Dosages	Dosage Forms
Loperamide (Imodium) (continued)	<i>Chronic diarrhea:</i> Children: 0.08–0.24 mg/kg/day in 2 or 3 doses daily to a maximum of 2 mg/dose. Adults: 4 mg followed by 2 mg after each unformed stool until symptoms are controlled, then decreased to the lowest dose that will control symptoms. Usual maintenance dose is 4–8 mg/day.	
Loratadine (Claritin)	PO: Age 2–5 years: 5 mg/day in a single dose. Children ≥ 6 years and Adults: 10 mg/day in a single dose.	Syrup: 1 mg/mL Tablets: 10 mg Tablets, rapidly disintegrating: 10 mg
Lorazepam (Ativan)	IV: <i>Status epilepticus:</i> Neonates: 0.05 mg/kg over 2–5 minutes. Dose may be repeated in 10–15 minutes. Infants and children: 0.1 mg/kg over 2–5 minutes to a maximum of 4 mg/dose. A second dose may be given. Adolescents: 0.05–0.1 mg/kg over 2–5 minutes to a maximum of 4 mg. Dose may be repeated in 10–15 minutes. Adults: 4 mg over 2–5 minutes. Dose may be repeated in 10–15 minutes. <i>Adjunct to antiemetic therapy:</i> 0.02–0.04 mg/kg up to q6h. Do not exceed a maximum of 2 mg/dose. PO or IV: <i>Anxiety and sedation:</i> Infants and children: 0.02–0.1 mg/kg/dose every 4–8 hours. Adults: 2–6 mg/day, usually PO, in 2 or 3 divided doses.	Injection: 2 mg/mL, 4 mg/mL Solution, oral: 2 mg/mL Tablets: 0.5 mg, 1 mg, 2 mg
Magnesium citrate (Citrates of Magnesia, Evac-Q-Mag)	PO: <i>(Chill for better palatability):</i> Age <6: 2–4 mL/kg. Age 6–12 years: 100–150 mL. Age > 12 years: 150–300 mL.	Solution: 300 mL (carbonated; contains 3.85–4.71 mEq Mg/5 mL)
Magnesium gluconate (Almora, Magonate, Magtrate)	PO: <i>(Expressed in terms of mEq of magnesium):</i> Children: 0.5–0.75 mEq/kg/day in 3 or 4 divided doses. Adults: 2.2–4.4 mEq (500–1,000 mg per dose) administered b.i.d. or t.i.d.	Liquid: 1,000 mg/5 mL (54 mg Mg = 4.4 mEq Mg) Tablets: 500 mg (27 mg Mg = 2.2 mEq Mg)
Magnesium hydroxide (Milk of Magnesia)	PO: Age <2 years: 0.5 mL/kg/dose. Age 2–5 years: 5–15 mL/day. Age 6–12 years: 15–30 mL/day. Age > 12 years: 30–60 mL/day.	Suspension: Contains ~13.7 mEq Mg/5 mL
Magnesium sulfate	IV: <i>[Expressed in terms of magnesium sulfate (and mEq Mg):</i> <i>Hypomagnesemia (monitor serum magnesium levels closely):</i> Neonates: 25–50 mg/kg (0.2–0.4 mEq/kg) q8–12h for 2–3 doses. Infants and children: 25–50 mg/kg (0.2–0.4 mEq/kg) q4–6h for 3 or 4 doses with a maximum single dose of 2,000 mg (16 mEq). Torsades de pointes VT: 25–50 mg/kg/dose up to a maximum of 2 gm/dose Asthma 40 mg/kg over 20 min	Injection: 500 mg/mL (4.06 mEq/mL magnesium Mg)

(continued)

Table 1. Medications (continued)

	Dosages	Dosage Forms
Magnesium sulfate (continued)	<p>Adults: 1 g (8 mEq) q6h for 4 doses. Doses of 2–3 g (16–24 mEq) have been used for severe hypomagnesemia.</p> <p><i>Maintenance dose:</i> 30–60 mg/kg/day (0.25–0.5 mEq/kg/day) in 3 or 4 divided doses.</p> <p><i>Management of seizures or hypertension in children:</i> 25–50 mg/kg (0.2–0.4 mEq/kg) q4–6h as needed. Administer the drug slowly (over 1–2 hours) in a concentration not > 100 mg/mL. BP should be monitored frequently during infusions because hypotension has been reported with rapid administration.</p>	
Mannitol (Osmitol)	<p>IV:</p> <p>Initial dose of 0.5–1 g/kg followed by doses of 0.25–0.5 g/kg q4–6h.</p> <p>A test dose of 0.2 g/kg (to a maximum of 12.5 g) over 3–5 minutes should produce a urine flow of about 1 mL/kg/hr for 2 or 3 hours. It should be used for patients with marked oliguria or inadequate renal function.</p>	Injection: 5%, 10%, 15%, 20%, 25%
Meperidine hydrochloride (Demerol)	<p>PO, IV or IM:</p> <p>Oral doses are about half as effective as IV doses but are generally used for less severe pain; therefore, the doses listed are for all routes of administration, but that should be kept in mind if a patient is being switched from parenteral to oral therapy.</p> <p>Children: 1–1.5 mg/kg q3–4h. A single dose of 2 mg/kg (to a maximum of 100 mg) may be used preoperatively.</p> <p>Adults: 50–150 mg q3–4h.</p> <p>Dosage adjustment is necessary in renal impairment.</p> <p>Long-term or high-dose therapy may result in accumulation of normeperidine, an active metabolite that is a CNS stimulant, especially in patients with renal failure.</p>	Injection: 25 mg/mL, 50 mg/mL, 75 mg/mL, 100 mg/mL Solution, oral: 50 mg/5 mL Tablets: 50 mg, 100 mg
Meropenem (Merrem IV)	<p>IV:</p> <p><i>Mild-to-moderate infections:</i></p> <p>Age ≥ 3 months: 60 mg/kg/day in 3 divided doses to a maximum total daily dose of 3 g.</p> <p><i>Meningitis or severe infections:</i></p> <p>Age ≥ 3 months: 120 mg/kg/day in 3 divided doses to a maximum total daily dose of 6 g.</p>	Injection: 500 mg, 1 g
Mesalamine (Asacol, Pentasa, Rowasa)	<p>PO:</p> <p>Children: 50 mg/kg/day divided every 6–12 hours (capsule) or every 8–12 hours (tablet)</p> <p>Adults: 1 g (capsules) q.i.d. or 800 mg (tablets) t.i.d.</p> <p>Rectally:</p> <p>4 g enema administered at bedtime daily. The enema should be retained overnight (8 hours) for best results.</p> <p>The oral forms of the drug are formulated with an enteric coating to slowly release the drug.</p>	Capsules (Pentasa): 250 mg Suspension, rectal: 4 g/60 mL Tablets (Asacol): 400 mg
Methylene blue (Urolene Blue)	<p>IV:</p> <p><i>Methemoglobinemia:</i></p> <p>1–2 mg/kg injected slowly over a period of several minutes. The dose may be repeated in 1 hour, if necessary.</p> <p>PO:</p> <p><i>Adults with chronic methemoglobinemia:</i></p> <p>100–300 mg/day.</p>	Injection: 10 mg/mL Tablets: 65 mg

Table 1. Medications (continued)

	Dosages	Dosage Forms
Methylphenidate (Concerta, Metadate, Ritalin)	<p>PO: Age >6 years: Initially 0.3 mg/kg/day (2.5–5 mg/dose) before breakfast and lunch. That may be increased to the usual dosage range of 0.5–1 mg/kg/day or a maximum of 2 mg/kg/day or 60 mg. The sustained-release form may be given as a single dose at breakfast.</p>	<p>Capsules, extended release: (Metadate CD) 10 mg, 20 mg, 30 mg, 40 mg, 50 mg 60 mg; (Ritalin LA) 10 mg, 20 mg, 30 mg, 40 mg Tablets: 5 mg, 10 mg, 20 mg Tablets, chewable: 2.5 mg, 5 mg, 10 mg Tablets, extended release: 20 mg Tablets, osmotic extended release (Concerta): 18 mg, 27 mg, 36 mg, 54 mg</p>
Methylprednisolone (A-methaPred, Depo-Medrol, Medrol, Solu-Medrol)	<p>IV: <i>Status asthmaticus:</i> Initial dose: 2 mg/kg, followed by 1 mg/kg q6h. <i>“Pulse” therapy for lupus nephritis multiple sclerosis (MS) in older children and adults:</i> 1 g/day for 3 days. A dose of 30 mg/kg every other day for 6 doses has been used for children.</p> <p>PO: Children: 0.5–2 mg/kg/day in 2–4 divided doses. Adults: 2–60 mg/day in 1–4 divided doses. <i>Intra-articular, intralesional doses (acetate):</i> Adults: 4–40 mg or up to 80 mg for large joints q1–5wk.</p>	<p>Injection (acetate; Depo-Medrol): 20 mg/mL, 40 mg/mL, 80 mg/mL Injection (sodium succinate): 40-mg, 125-mg, 500-mg, 1-g, 2-g vials Tablets: 2 mg, 4 mg, 8 mg, 16 mg, 32 mg</p>
Metoclopramide (Reglan)	<p>PO or IV: <i>Gastroesophageal reflux:</i> Infants and Children: Initially 0.2–0.8 mg/kg/day in 4 divided doses before meals. Adults: 10–15 mg 30 minutes before meals and at bedtime.</p> <p>IV: <i>Antiemetic in chemotherapy-induced nausea:</i> 0.5–2 mg/kg administered 30 minutes before the chemotherapy and q4–6h as necessary. Extrapyramidal reactions are common at this dose and may be treated with diphenhydramine IV (1 mg/kg up to 50 mg) q6h or it may be given as a premedication 30 minutes prior to metoclopramide doses.</p>	<p>Injection: 5 mg/mL Solution, oral: 5 mg/5 mL, 10 mg/5 mL Tablets: 5 mg, 10 mg</p>
Metolazone (Zaroxolyn)	<p>PO: Infants and children: 0.2–0.4 mg/kg/day in 1–2 divided doses. Adults: 2.5–5 mg/day for the treatment of hypertension. Edema due to cardiac or renal disease may require doses of 5–20 mg/day.</p>	<p>Tablets: 2.5 mg, 5 mg, 10 mg</p>
Metronidazole (Flagyl, Protostat)	<p>PO or IV: <i>Anaerobic bacterial infections (IV initially, then PO):</i> Infants other than neonates to adults: 30 mg/kg/day in 3–4 divided doses, not to exceed 4 g/day. <i>Amebiasis (usually PO):</i> Infants and children: 35–50 mg/kg/day in 3 divided doses. Adults: 500–750 mg q8h. <i>Other parasitic infections (usually PO):</i> Infants and children: 15–30 mg/kg/day in 3 divided doses. Adults: 250 mg q8h or a single 2-g dose. <i>Trichomoniasis (adults): 2-g single dose</i> <i>Pelvic inflammatory disease:</i> Adults: 500 mg q12h. <i>Antibiotic-associated pseudomembranous colitis:</i> Infants and children: 30 mg/kg/day in 3 divided doses Max dose: 2 gm per day. Adults: 500 mg t.i.d. Oral doses may be taken with food to minimize stomach upset.</p>	<p>Injection: Available 5 mg/mL ready to infuse solution or 500-mg vial Tablets: 250 mg, 500 mg</p>

(continued)

Table 1. Medications (continued)

	Dosages	Dosage Forms
Midazolam (Versed)	<p>IV (titrate dose slowly to avoid excessive dosing): <i>Conscious sedation:</i> Children: 0.05–0.1 mg/kg just before the procedure to a maximum dose of 2 mg. Dose may be repeated q3 or 4 minutes up to 4 times. Adults: 0.5–2 mg over 2 minutes. Titrate to effect by repeating doses q2–3 minutes to a usual dose of 2.5–5 mg. <i>Infusion for sedation during mechanical ventilation:</i> Administer a loading dose of 0.05–0.2 mg/kg followed by a continuous infusion of 0.05–0.1 mg/kg/hr and titrate to effect.</p> <p>PO: 0.5 mg/kg to a maximum dose of 15 mg.</p> <p>Intranasally: 0.2–0.3 mg/kg/dose. The intranasal route of administration is not FDA approved.</p>	<p>Injection: 1 mg/mL, 5 mg/mL Solution: 2 mg/mL</p>
Mineral oil	<p>PO (do not administer concomitantly with docusate): Children: 5–20 mL/day. Adults: 15–45 mL/day.</p> <p>Rectally (as a retention enema): Children: 30–60 mL. Adults: 60–150 mL.</p>	<p>Enema: 133 mL Liquid</p>
Montelukast (Singulair)	<p>PO: Age 6–23 months: 4 mg once daily given as the granules. Age 2–6 years age: 4 mg once daily. Age >6–14 years: 5 mg once daily. Age >14 years: 10 mg once daily.</p>	<p>Granules: 4 mg packet Tablets, chewable: 4 mg, 5 mg Tablets: 10 mg</p>
Morphine sulfate (Astramorph PF, Duramorph, MSIR, MS Contin, Roxanol)	<p>IV or IM: Neonates and infants under age 6 months: These patients are particularly sensitive to the respiratory depressant effects of opiates; therefore, the doses recommended are lower: 0.03–0.05 mg/kg every 4 to 8 hours. Infusions have been used in neonatal patients at a dose of 0.01 mg/kg/hr. The dose may be increased if necessary but should not exceed 0.03 mg/kg/hr. Infants over 6 months and children: 0.025–0.1 mg/kg q3–6h. Doses of up to 2.5 mg/kg have been used in severe pain such as sickle cell or cancer pain. The usual maximum dose is 10 mg. Adults: 2.5–10 mg q2–6h.</p> <p>Epidurally: 0.5–5 mg in the lumbar region. Dose may be repeated q24h. Maximum dose is 10 mg/24 hr. Use preservative free formulations.</p> <p>Intrathecaly: 1/10 of epidural dose or about 0.2–1 mg/dose. Repeat doses are not recommended. Use preservative free formulations.</p> <p>PO: Prompt-release preparations are administered every 3 or 4 hours; controlled-release preparations are administered q8–12h. Oral doses are ~1/3 as effective as IV doses. Infants over 6 months and children: 0.2–0.5 mg/kg every 3 or 4 hours (prompt release) or 0.3–0.6 mg/kg q8–12h (extended release). Adults: 10–30 mg q3–4h (prompt release) or 15–30 mg q8–12h (extended release).</p>	<p>Injection: 0.5 mg/mL, 1 mg/mL, 2 mg/mL, 3 mg/mL, 4 mg/mL, 5 mg/mL, 8 mg/mL, 10 mg/mL, 15 mg/mL Solution: 10 mg/5 mL, 20 mg/5 mL, 20 mg/mL Suppositories: 5 mg, 10 mg, 20 mg, 30 mg Tablets: 15 mg, 30 mg Tablets, controlled release: 15 mg, 30 mg, 60 mg, 100 mg</p>

Table 1. Medications (continued)

	Dosages	Dosage Forms
Mupirocin (pseudomonic acid A; Bactroban)	<p>Topically: <i>Impetigo:</i> Apply ointment to affected area t.i.d. for 5–10 days. <i>Lacerations, minor suture infections or abrasions:</i> Apply cream to the affected area t.i.d. for 10 days. <i>Intranasal Staphylococcus aureus infection:</i> Apply 1/2 of the contents of a unit-dose tube of intranasal cream into each nostril 2–4 times daily for 5–14 days.</p>	<p>Cream (as mupirocin calcium): 2% mupirocin Cream, intranasal (as mupirocin calcium): 2% Ointment: 2%</p>
Nalbuphine (Nubain)	<p>Parenterally: <i>Reversal of morphine infusion side effects:</i> 0.025–0.05 mg/kg repeated q6h as necessary. <i>Analgesia:</i> Children, age > 10 months: 0.1–0.14 mg/kg q3–6h as necessary to a maximum dose of 10 mg. Adults: 10–20 mg q3–6h.</p>	<p>Injection: 10 mg/mL, 20 mg/mL</p>
Naloxone (Narcan)	<p>IV (preferred), IM, or SC: <i>Neonatal opiate depression:</i> 0.01 mg/kg q2–3min until the desired response is obtained. Additional doses may be necessary at 1–2-hour intervals. <i>Opiate overdosage:</i> 0.1 mg/kg to a dose of 2 mg administered q2–3min until 5 doses (up to 10 mg) have been given. If the depressive condition is not reversed, causes other than opiate ingestion should be considered. Additional doses may be necessary because the duration of effect of the opiate is generally longer than that of naloxone. The drug may also be administered via continuous infusion, especially if higher doses are necessary. <i>Postoperative narcotic reversal (partial reversal):</i> 0.005–0.01 mg/kg q2–3min until the desired degree of reversal is achieved.</p>	<p>Injection: 0.4 mg/mL, 1 mg/mL</p>
Naproxen (Aleve, Naprosyn)	<p>PO: 5–15 mg/kg q8–12h to a maximum daily dose of 1 g. Lower dose is used for analgesia, higher for inflammatory diseases.</p>	<p>Suspension: 125 mg/5 mL Tablets: 250 mg, 375 mg, 500 mg</p>
Neomycin, polymyxin B, and hydrocortisone (Cortisporin)	<p>Ophthalmic: 1–2 drops to the affected eye q4–6h; apply finger pressure to the lacrimal sac for 1 minute after instillation. Otic (both a suspension and a solution formulation are available.) The solution form may sting when instilled, but allows the ear canal to be examined easily): Instill 3–4 drops into the affected ear t.i.d. or q.i.d.</p>	<p>Solution or suspension, otic: Neomycin 5 mg/mL, polymyxin B 10,000 U/mL, and hydrocortisone 1% Suspension, ophthalmic: Neomycin 0.35%, polymyxin B 10,000 U, and hydrocortisone 1%</p>
Neomycin sulfate (Neo-Fradin, Neo-Rx)	<p>PO: <i>Bowel preparation:</i> 25 mg/kg (up to 1 g) at 1 P.M., 2 P.M., and 11 P.M. on the day before surgery (with erythromycin, cleansing enemas). <i>Hepatic coma:</i> 50–100 mg/kg/day in 3 or 4 divided doses up to 12 g/day.</p>	<p>Solution, oral: 125 mg/5 mL Tablets: 500 mg</p>
Neostigmine (Prostigmin)	<p>IM: <i>Myasthenia gravis test:</i> 0.04 mg/kg single dose IV: <i>Reversal of nondepolarizing neuromuscular blockade after surgery in conjunction with atropine or glycopyrrrolate:</i> Infants: 0.025–0.1 mg/kg/dose. Children: 0.025–0.08 mg/kg/dose. Adults: 0.5–2.5 mg, total dose not to exceed 5 mg.</p>	<p>Injection: 0.5 mg/mL, 1 mg/mL</p>

(continued)

Table 1. Medications (continued)

	Dosages	Dosage Forms
Nitrofurantoin (Furadantin, Macrochantin)	<p>PO: <i>Active infection:</i> Children (Furadantin): 5–7 mg/kg/day in 4 divided doses to a maximum of 400 mg/day. Adults: 50–100 mg every 6 hours Children > 12 years and Adults (Macrochantin): 100 mg every 12 hours <i>Chronic suppression therapy:</i> Children: 1–2 mg/kg/day in 1 or 2 divided doses. Adults: 50–100 mg at bedtime daily. Administer with food or milk to decrease rate of absorption because high peak levels are associated with increased GI upset.</p>	<p>Capsules (macrocrystals): 25 mg, 50 mg, 100 mg Suspension: 25 mg/5 mL</p>
Nitroprusside sodium (Nipride, Nitropress)	<p>IV as a continuous infusion: 0.3–0.5 mcg/kg/min initially, then titrate to effect. Usual dose is 3 mcg/kg/min. The maximum dose is 10 mcg/kg/min. Cyanide toxicity may occur during prolonged therapy or in patients with hepatic dysfunction. Administration of sodium thiosulfate may decrease blood cyanide levels. Thiocyanate may accumulate in patients with renal impairment.</p>	<p>Injection: 50 mg vial Protect solutions from light. Do not use if highly colored (blue, green, or red).</p>
Norepinephrine (Levarterenol, Levophed, Noradrenalin)	<p>IV as a continuous infusion: Initially 0.05–0.1 mcg/kg/min, titrated to response. Maximum dose: 1–2 mcg/kg/min.</p>	<p>Injection: 1 mg/mL</p>
Nystatin (Mycostatin, Nilstat)	<p>PO: Neonates: 100,000 Units administered q.i.d. Infants: 200,000 Units administered q.i.d. Children and adults: 400,000–1 million Units administered q.i.d. Topically: Apply ointment or cream to the affected area t.i.d. or q.i.d.</p>	<p>Cream: 100,000 Units/g [also available with triamcinolone, a topical steroid (Mycolog)] Ointment: 100,000 Units/g [also available with triamcinolone, a topical steroid (Mycolog)] Suspension: 100,000 Units/mL Tablets: 500,000 Units (intestinal infections only)</p>
Octreotide (somatostatin analog; Sandostatin)	<p>IV or SC: The SC route is generally preferred because absorption is not immediate and the activity is somewhat prolonged. The drug may also be administered as a continuous infusion at a initial rate of 1 mcg/kg/hr. Pediatric experience is limited, but initial IV or SC doses of 1–10 mcg/kg with total daily doses of 2–50 mcg/kg in 2–4 divided doses have been used based on clinical response. Usual adult doses are 50 mcg 1 or 2 times daily initially, then titrate dose to the patient’s response.</p>	<p>Injection: 50 mcg/mL, 100 mcg/mL, 200 mcg/mL, 500 mcg/mL, 1,000 mcg/mL</p>
Ofloxacin (Floxin Otic, Ocuflax)	<p>Ophthalmic infections: <i>Bacterial conjunctivitis:</i> 1–2 drops in the affected eye q2–4h while awake for 2 days, then q.i.d. for up to 5 more days. <i>Bacterial keratitis:</i> 1–2 drops in the affected eye q30min while awake and 4–6 hours after retiring for 2 days, then every hour while awake for up to 4–6 more days, then q.i.d. until cure is attained. Otic infections: <i>Otitis externa:</i> Age 6 months–13 years: 5 drops in the affected ear canal daily for 7 days. Age > 13 years: 10 drops in the affected ear canal daily for 7 days. <i>Suppurative otitis media in patients with perforated tympanic membranes:</i> 10 drops in the affected ear b.i.d. for 14 days. The tragus of the ear should be pumped several times to make sure the solution is in the ear canal and the patient should remain in a position with the ear up for 5 minutes.</p>	<p>Solution, ophthalmic: 0.3% Solution, otic: 0.3%</p>

Table 1. Medications (continued)

	Dosages	Dosage Forms
Ofloxacin (Floxin Otic, Ocuflax) (continued)	<i>Otitis media in patients with tympanostomy tubes:</i> 5 drops in the affected ear b.i.d. for 10 days. The tragus of the ear should be pumped as above and the patient should remain in a position with the ear up for 5 minutes.	
Olopatadine (Patanol)	Ophthalmic: Age ≥3 years: 1–2 drops in each eye b.i.d. at 6–8h intervals.	Solution, ophthalmic: 0.1%
Omeprazole (Prilosec)	PO with food or a meal: Children: While safety and efficacy in children has not been established, a dose of 0.6–0.7 mg/kg/day as a single dose in the morning has been used. If necessary, a second dose may be given 12 hours later. The usual range of doses used is 0.3–3.3 mg/kg/day. Adults: 20 mg daily. Higher doses may be used for pathologic hypersecretory conditions. The usual starting dose is 60 mg daily, but doses of up to 360 mg daily have been used. Doses >80 mg/day should be given in 2–3 divided doses.	Capsules: 10 mg, 20 mg, 40 mg. The capsules contain enteric coated spheres. If the patient is unable to swallow capsules, the spheres may be put into an acidic juice, such as apple juice, for administration. Do not crush the spheres. Pediatric compounded liquids have been made as 2 mg/ml using a base of sodium bicarbonate 8.4% injectable solution.
Osetamivir (Tamiflu)	PO (within 2 days of onset of symptoms and continue for 5 days): Treatment Age <1 year: 3 mg/kg/dose b.i.d. (not FDA-approved under 1 year, but dosing available from CDC) Age 1–12 years: ≤15 kg: 30 mg/dose b.i.d. 15 kg–23 kg: 45 mg/dose b.i.d. 23 kg–≤40 kg: 60 mg b.i.d. Age ≥13 years or >40 kg: 75 mg b.i.d.	Capsules: 75 mg. Powder for suspension: 6 mg/mL
Oxacillin	IV: Neonates, age <7 days: <2,000 g: 50–100 mg/kg/day in 2 divided doses. ≥2,000 g: 75–150 mg/kg/day in 3 divided doses. Neonates, age >7 days: <1,200 g: 50 mg/kg/day in 2 divided doses. 1,200–2,000 g: 75–100 mg/kg/day in 3 divided doses. >2,000 g: 100 mg/kg/day in 4 divided doses. Infants and children (depends on severity and site of infection). <i>Mild-to-moderate infections:</i> 100–150 mg/kg/day in 4 divided doses. <i>Severe infections, including osteomyelitis:</i> 100–200 mg/kg/day in 4–6 divided doses. Total maximum dose is 12 g/day. Adults: <i>Mild-to-moderate infections:</i> 500–1,000 mg q6h. <i>Severe infections:</i> 1–2 g q4–6h.	Injection: 1 g, 2 g
Oxcarbazepine (Trileptal)	PO: Age 2–16 years: 8–10 mg/kg/day (to a maximum of 600 mg daily) initially, with increases over a 2 week period to a target maintenance dose of 900 mg daily for patients weighing 20–29 kg, 1,200 mg daily for patients weighing >29–39 kg and 1,800 mg daily for patients weighing >39 kg. Doses of 6–60 mg/kg/day have been used in clinical trials, with patients in the age range of 2–4 years potentially needing the higher dosing range, achieved over at least 2–4 weeks. Adults: 600 mg daily in 2 divided doses initially, increasing over 1 week to the usual maintenance dose of 1,200 mg daily in two divided doses. Maximum daily dose is 2,400 mg.	Suspension: 60 mg/mL Tablets: 150 mg, 300 mg, 600 mg
Oxybutynin (Ditropan)	PO: Age ≤5 years: 0.2 mg/kg/dose given 2–3 times daily. Children, age >5 years: 5 mg administered b.i.d. or t.i.d. Adults: 5 mg b.i.d. or t.i.d., to a maximum of q.i.d.	Solution, oral: 5 mg/5 mL Tablets: 5 mg

(continued)

Table 1. Medications (continued)

	Dosages	Dosage Forms
Oxycodone	PO (oxycodone component for combination products): Children: 0.05–0.15 mg/kg/dose q4–6h. Adults: 5 mg q6h initially; may be increased to 10 mg q4h if necessary. Higher doses may be necessary for severe pain, using a plain oxycodone product.	Capsule: 5 mg Solution: 1 mg/mL Solution (concentrate): 20 mg/mL Tablets: 5 mg, 15 mg, 30 mg Also available in fixed combinations with acetaminophen or aspirin in capsule, liquid and tablet dosage forms.
Palivizumab (Synagis)	IM: Age ≤2 years: 15 mg/kg/dose given every month during RSV season, which is November through March in most of North America. Follow American Academy of Pediatrics' dosing and candidate selection recommendations.	Injection, lyophilized powder: 50 mg and 100 mg
Pancrelipase (Creon, Zenpep, Pancreaze)	PO: Depends on the condition being treated and the dietary content of the patient. Dosage is usually determined by the fat content of the diet. The usual starting dose is 4,000–8,000 Units of lipase activity before or with each meal or snack for children age 1–7, 4,000–12,000 Units for children age >7–12 years, or 4,000–33,000 Units for adults. Further dosage adjustments may be made based on the patient's symptoms. Typical dose: 1,000–2,500 units/kg/dose (of lipase activity per meal). The newer, enteric-coated products are designed to release the enzymes at pH >6 and are therefore more resistant to destruction by gastric acids.	Capsules, delayed release, containing enteric-coated spheres, microspheres, or microtablets Expressed in lipase USP units: Zenpep 5,000 units, 10,000 units, 15,000 units, 20,000 units Pancreaze 4,200 units, 10,500 units, 16,800 units, 21,000 units Creon 6,000 units, 12,000 units, 24,000 units
Penicillamine (Cuprimine, Depen)	Do not exceed a dose of 30 mg/kg/day. Rheumatoid arthritis: Children: Initial: 3 mg/kg/day (≤250 mg/day) for 3 months, then 6 mg/kg/day (≤500 mg/day) in divided doses b.i.d. for 3 months. Maximum: 10 mg/kg/day in 3 or 4 divided doses. Wilson's disease: Children: 20 mg/kg/day in 2–3 divided doses to a maximum of 1 g daily. Round dose off to the nearest 250 mg. Administer with pyridoxine supplementation	Capsules: 250 mg Tablets: 250 mg
Penicillin G, aqueous (potassium or sodium salt)	IV: Neonates, age <7 days: <2,000 g: 25,000 Units/kg/dose q12h. For meningitis, use 50,000 Units/kg/dose q12h. >2,000 g: 25,000 Units/kg/dose q8h. For meningitis, 50,000 Units/kg/dose q8h. Neonates, age >7 days: <1,200 g: 25,000 units/kg/dose q12h. For meningitis: 50,000 units/kg/dose q12h 1,200 g to <2,000 g: 25,000 Units/kg q8h. For meningitis, 50,000 Units/kg/dose q8h. >2,000 g: 25,000 Units/kg/dose q6h. For meningitis, 50,000 Units/kg/dose q6h. Infants and children: 100,000–250,000 Units/kg/day in 6 divided doses. Up to 400,000 Units/kg/day may be used for severe infections to a maximum of 24 million Units/day. Adults: 2–4 million Units/dose every 4–6 hours. The potassium salt contains 1.7 mEq of potassium and 0.3 mEq of sodium per 1 million Unit. The sodium salt contains 2 mEq of sodium per 1 million Unit. The potassium salt must be administered slowly at high doses due to the effect of the potassium.	Injection, potassium salt: 1 million Unit, 5 million Unit, 10 million Unit Injection, sodium salt: 5 million Unit
Penicillin G procaine, benzathine	Deep IM: Results in low but prolonged serum levels. May be given as a single daily dose. A dose of penicillin G benzathine will result in low serum levels for up to 4 weeks.	Injection, benzathine: 600,000 Units/mL Injection, benzathine and procaine: Combined equal parts of each in 300,000 Units, 600,000 Units, 1.2 million Units, 2.4 million Units; 900/300 (900,000 Units benzathine, 300,000 Units procaine)

Table 1. Medications (continued)

	Dosages	Dosage Forms
Penicillin G procaine, benzathine (continued)	<p>Newborns: Avoid use in these patients because sterile abscess and procaine toxicity are of greater concern.</p> <p>Neonates > 1,200 g: 50,000 Units/kg as a single dose for asymptomatic congenital syphilis.</p> <p>Infants, Children and adults: 600,000–1.2 million Units/day. Maximum dose is 2.4 million U.</p>	Injection, procaine: 600,000 Units/mL
Penicillin V potassium	<p>PO:</p> <p>Children: 25–50 mg/kg/day in 3–4 divided doses.</p> <p>Adults: 125–500 mg/dose q6h.</p> <p>Prophylaxis against pneumococcal infections: Sickle Cell Disease or Asplenia up to age 5 years (assuming adequate vaccination by age 5)</p> <p>Age 2 months–3 years: 125 mg b.i.d.</p> <p>Age >3 years: 250 mg b.i.d.</p> <p>Prophylaxis of rheumatic fever: 250 mg b.i.d.</p>	<p>Liquid, oral: 125 mg/5 mL, 250 mg/5 mL</p> <p>Tablets: 250 mg, 500 mg</p>
Pentobarbital (Nembutal)	<p>PO, IM:</p> <p><i>Sedation before surgery:</i></p> <p>Children: 2–6 mg/kg to a maximum of 100 mg.</p> <p>IV:</p> <p><i>For sedation before procedures:</i> Dose should be administered slowly and incrementally to avoid oversedation. Patients must be closely observed. Dosing is very patient-specific. The rate of injection should not exceed 1 mg/kg/min (50 mg/min in adults). Allow at least 1 minute to reach full effect.</p> <p>Children: Initially 2 mg/kg to a maximum of 100 mg. Incremental doses of 1–2 mg/kg may be used to a maximum total dose of 200 mg.</p> <p>Adults: Initially 100 mg. Incremental doses of 100–200 mg may be given to a maximum dose of 500 mg for healthy adults.</p> <p><i>Barbiturate coma:</i> 10–15 mg/kg administered over 1–2 hours, followed by a maintenance infusion of 1 mg/kg/hr. Dosage may be increased to 2–3 mg/kg/hr to maintain burst suppression on EEG. Hypothermia may necessitate a decrease in dosage.</p>	Injection: 50 mg/mL
Permethrin (Elimite Cream, Nix Cream Rinse)	<p><i>Scabies:</i></p> <p>Age > 2 months: Apply cream from head to toe. Wash cream off after 8–14 hours. May be reapplied after 1 week if live mites appear.</p> <p><i>Head lice:</i> Apply cream rinse to hair that has been thoroughly washed, rinsed and towel dried. Saturate hair and scalp with cream rinse. Also apply to the ears and hairline at the nape of the neck. Rinse off after 10 minutes and remove remaining nits with the comb provided. May be repeated after 1 week if necessary.</p>	<p>Cream, topical: 5%</p> <p>Cream rinse: 1%</p>
Phenobarbital	<p>IV or PO:</p> <p><i>Loading doses (usually IV for status epilepticus):</i></p> <p>Neonates: 20 mg/kg in a single or 2 divided doses.</p> <p>Infants, children, and adults: 15–18 mg/kg a single or 2 divided doses.</p> <p>Allow 15–30 minutes for the drug to distribute into the CNS and for the seizures to stop.</p> <p><i>Maintenance doses:</i></p> <p>Neonates: 5 mg/kg/day in 2 divided doses.</p> <p>Infants: 5–6 mg/kg/day in 2 divided doses.</p> <p>Age 1–5 years: 6 mg/kg/day in 2 divided doses.</p> <p>Age > 5–12 years: 4 mg/kg/day in 1 or 2 divided doses.</p> <p>Age > 12 years: 1–2 mg/kg/day in 1 or 2 divided doses.</p>	<p>Elixir: 20 mg/5 mL</p> <p>Injection (sodium): 65 mg/mL, 130 mg/mL</p> <p>Tablets: 15 mg, 30 mg, 32 mg, 60 mg, 65 mg 100 mg</p>

(continued)

Table 1. Medications (continued)

	Dosages	Dosage Forms
Phenylephrine (Neo-Synephrine, Mydrfrin ophthalmic)	<p>Intranasally (do not use for longer than 3–5 days): Age 1 to <6 years: 0.125% solution 2–3 drops q4h as needed. Age 6–12 years: 0.25% solution 2–3 drops or 1–2 sprays q4h as needed. Age > 12 years: 0.5% solution 2–3 drops or 1–2 sprays q4h as needed. 1% solution may be used in adults with extreme congestion.</p> <p>Ophthalmic: Neonates: Avoid 2.5% and use 1% phenylephrine combination products such as cyclopentolate/phenylephrine combination Infants: 1 drop of 2.5% solution 15–30 minutes before procedure. Children and adults: 1 drop of 2.5% or 10% solution; may repeat in 15–30 minutes.</p> <p>IV for severe hypotension or shock: A bolus dose of 5–20 mcg/kg (2–5 mg in adults) may be repeated q10–15 minutes. For infusion, initial doses of 0.1–0.5 mcg/kg/min are titrated to effect.</p>	<p>Injection: 10 mg/mL Solution, nasal drops or spray: 0.25%, 0.5%, 1% Solution, ophthalmic: 2.5%, 10%</p>
Phenytoin (Dilantin)/ Fosphenytoin (Cerebyx)	<p>Care must be taken when changing from one dosage form of the drug to another because some contain phenytoin sodium and some contain the free acid form of the drug. The free acid form is used for the Infatabs and the suspension. Phenytoin sodium is used for the injection and capsules. Phenytoin sodium contains 92% phenytoin. Injection labeled as 50 mg/mL phenytoin sodium contains 46 mg of phenytoin and capsules labeled 100 mg contain 92 mg phenytoin.</p> <p>Fosphenytoin should be ordered in terms of phenytoin equivalents. The patient's serum levels should be monitored whenever the dosage form is changed. In addition, the different brands of phenytoin capsules have different dissolution characteristics. Dilantin capsules are considered extended and may be dosed in adults as a single daily dose. The serum level range usually associated with clinical effectiveness is 10–20 mcg/mL; that associated with mild-to-moderate toxicity may be as low as 25–30 mcg/mL.</p> <p><i>Loading dose (IV or PO):</i> 15–20 mg/kg in a single or divided doses. <i>Maintenance dose (IV or PO):</i> 5 mg/kg/day in 2 or 3 divided doses initially and then adjusted to response and serum levels. Usual ranges based on age (divided into 2 or 3 doses daily). Neonates: 5–8 mg/kg/day. Age 6 months to 3 years: 8–10 mg/kg/day. Age 4–6 years: 7.5–9 mg/kg/day. Age 7–9 years: 7–8 mg/kg/day. Age 10–16 years: 6–7 mg/kg/day. Adults: 5–6 mg/kg/day may be given as a single dose if extended-capsule preparation is used (usual dose = 300 mg daily). Higher doses are required in infants and young children due to lower absorption of the drug from the GI tract.</p> <p>IV doses of phenytoin should be administered at a maximum rate of about 1 mg/kg/min (50 mg/min in adults) to avoid cardiovascular side effects. The injection is not compatible with many solutions or medications. The line must be flushed well with saline before administration to avoid precipitation of phenytoin in the line. Extravasation of the drug must also be avoided because it is very alkaline and may cause severe tissue necrosis. Thorough flushing of the vessel after phenytoin administration will also decrease the incidence of local tissue inflammation that may occur even in the absence of extravasation.</p> <p>Fosphenytoin injection should be diluted with either 5% dextrose or normal saline to a concentration of 1.5–25 mg of phenytoin equivalents (2.3–37.5 mg fosphenytoin) per mL of diluent and may be administered at a rate of 2–3 mg phenytoin equivalents/kg/min (100–150 mg phenytoin equivalents/min in adults).</p>	<p>Capsule, phenytoin sodium, extended: 30 mg, 100 mg Injection, (fosphenytoin): 75 mg/1 mL (equivalent to 50 mg phenytoin sodium) Injection, phenytoin sodium: 50 mg/mL Suspension, phenytoin: 125 mg/5 mL Tablet, chewable, phenytoin: 50 mg</p>
Phosphate (potassium and/or sodium)	<p>Should be guided by the patient's serum phosphorus and potassium or sodium levels. Severe deficits should be replaced by the IV route because the oral route may result in diarrhea and oral absorption is unreliable. In general, the deficit should be made up by incorporating it into the patient's maintenance fluids.</p>	<p>Injection (potassium phosphate): 3 mmol (94 mg) phosphorus and 4.4 mEq potassium per milliliter Packets or capsules (Neutra-Phos): 250 mg (8 mmol) phosphorus, 7 mEq potassium, and 7 mEq sodium Packets or capsules (Neutra-Phos K): 250 mg (8 mmol) phosphorus, 14.25 mEq potassium</p>

Table 1. Medications (continued)

	Dosages	Dosage Forms
Phosphate (potassium and/or sodium) (continued)	<p>IV maintenance: Neonates: 0.5 mmol/kg up to 1–2 mmol/kg/day. Children: 0.5–1.5 mmol/kg/day Adults: 15–30 mmol/day</p> <p>Intermittent infusions should follow the guidelines outlined below for potassium infusions or sodium infusions because the 2 IV forms available are potassium phosphate (each 3 mmol of phosphate will also deliver 4.4 mEq of potassium) or sodium phosphate (each 3 mmol of phosphate will deliver 4 mEq of sodium). The guidelines below are meant for use in patients with severe hypophosphatemia (<1 mg/dL in adults; low values in children vary with age):</p> <p>Children: 0.08–0.3 mmol/kg with subsequent doses only after serum levels are checked and if the patient is symptomatic. Adults: 0.08 mmol/kg (uncomplicated hypophosphatemia) or 0.16 mmol/kg for prolonged deficits. Do not exceed 0.24 mmol/kg/dose (serum phosphorus ≥0.5 mg/dL) or 0.36 mmol/kg/dose (serum phosphorus <0.5 mg/dL).</p> <p>IV doses should be administered over a 6-hour period. Sodium phosphate doses should be diluted to be normal saline in component while potassium phosphate doses should be diluted according to presence of a peripheral line (<80 mEq/L potassium) or central line (diluted to <150 mEq/L potassium)</p> <p>PO: Should be taken with food to increase GI tolerance. Each packet or capsule should be mixed in 75 mL of water. Tablets should be taken with a full glass of water. IV formulations have also been administered as oral in small children or infants who cannot take oral capsules or packets.</p> <p><i>Maintenance doses:</i> Children: 2–3 mmol/kg/day in 4 divided doses. Adults: 32–64 mmol/day (4–8 packets) in 4 divided doses. Do not administer at the same time as aluminum- and/or magnesium-containing antacids, sucralfate, or calcium because they may act to bind phosphorus.</p>	<p>Tablets (K-Phos Neutral): 250 mg (8 mmol) phosphorus, 1.1 mEq potassium, and 13 mEq sodium Tablets (Uro-KP-Neutral): 250 mg (8 mmol) phosphorus, 1.27 mEq potassium, and 10.9 mEq sodium</p>
Phytonadione (vitamin K, Mephyton)	<p>IM or SC: <i>Hemorrhagic disease of the newborn, prophylaxis:</i> 0.5–1 mg within 1 hour of birth and again 6–8 hours later, if needed. <i>Treatment:</i> 1–2 mg/day. <i>Treatment of deficiency caused by malabsorption or decreased synthesis or due to drugs (administer IV cautiously and slowly):</i> Children: 1–2 mg/day. Adults: 10 mg/day. <i>Treatment of oral anticoagulant overdose (highest doses used if bleeding or lack of need to continue anticoagulation):</i> Infants: 1–2 mg repeated q4–8h. Children and adults: 2.5–10 mg, may be repeated in 6–8 hours.</p> <p>PO: <i>Prevention of deficiency in malabsorption:</i> Children: 2.5–5 mg every other day or daily. Adults: 5–25 mg/day.</p>	<p>Injection: 1 mg/0.5 mL, 10 mg/mL Tablets: 5 mg</p>
Piperacillin	<p>IV: Neonates: 75 mg/kg/dose q8h. Infants and children: 200–300 mg/kg/day in 4–6 divided doses. Patients with cystic fibrosis may need doses of 350–500 mg/kg/day. Maximum dose is 24 g daily. Adults: 2–4 g/dose q4–6h to a maximum of 24 g daily.</p>	<p>Injection: 2 g, 3 g, 4 g</p>

(continued)

Table 1. Medications (continued)

	Dosages	Dosage Forms
Piperacillin/Tazobactam (Zosyn)	<p>IV: Neonates: 75 mg/kg/dose q8h (dosed on piperacillin component) Age 1 <6 months: 150–300 mg/kg/day of piperacillin component in divided doses every 6–8 hours Age ≥6 months: 240–400 mg/kg/day (piperacillin component) in 4 divided doses daily to a maximum of 18 g of piperacillin. Adults: 2–4 g q6h to a maximum of 18 g of piperacillin.</p>	<p>Injection: 2 g piperacillin + 0.25 g tazobactam, 3 g piperacillin + 0.75 g tazobactam, 4 g piperacillin + 1 g tazobactam</p>
Piroxicam (Feldene)	<p>PO: Children: 0.2–0.3 mg/kg/day in a single daily dose to a maximum of 15 mg/day. Adults: 10–20 mg/day in a single dose.</p>	<p>Capsules: 10 mg, 20 mg</p>
Polyethylene glycol electrolyte solution (Colyte, GoLYTELY, Nulytely)	<p>PO or NG after a 3–4-hour fast for bowel cleansing: Children: 25–40 mL/kg/hr. Adults: 240 mL q10min. The patient should continue to drink the solution until the rectal effluent is clear. Rapid drinking of each portion is more effective than slow consumption. The first bowel movement should occur about an hour after starting. The solution is more palatable if chilled, but must not be poured over ice. Nothing, including other flavorings, should be added to the solution.</p>	<p>Powder for oral solution to make 4 L (GoLyteLy): PEG3350 236 g, sodium sulfate 22.74 g, sodium bicarbonate 6.74 g, sodium chloride 5.86 g, and potassium chloride 2.97 g Powder for oral solution to make 4L (Colyte): PEG3350 227.1 g, sodium sulfate 21.5 g, sodium bicarbonate 6.36 g, sodium chloride 5.53 g, and potassium chloride 2.82 g. Powder for oral solution to make 4L (Nulytely): PEG3350 420 g, sodium bicarbonate 5.72 g, sodium chloride 11.2 g, potassium chloride 1.48 g</p>
Polyethylene glycol powder (GlycoLax, Miralax)	<p>PO: Children 10–20 kg: 8.5 g mixed in 4 oz of water or juice daily. Alternative: 0.5–1.5 g/kg/day not to exceed 17 gm per dose. Children >20 kg and adults: 1 capful (17 gm) mixed in 8 oz of water or juice daily.</p>	<p>Powder (PEG3350): 255 g, 527 g</p>
Potassium chloride	<p>PO: Liquid doses must be well diluted before administration to avoid GI adverse effects. Capsules or tablets should be taken with a full glass of water. Capsules may be opened and emptied onto a soft food, but the beads should not be crushed or chewed. Total daily dose may be given in 1 or 2 divided doses if tolerated, or may be given in 3 or 4 divided doses to decrease GI upset. Dose is usually based on each patient's requirements and may depend on concurrent medications or medical conditions that result in potassium losses. The following may be used as general guidelines: <i>Normal daily requirement for either PO or IV replacement:</i> Newborn: 2–6 mEq/kg/day. Children: 2–3 mEq/kg/day. Adults: 40–80 mEq/day. <i>During diuretic therapy:</i> Children: 1–2 mEq/kg/day. Adults: 20–40 mEq/day. <i>For treatment of hypokalemia:</i> Children: 2–5 mEq/kg/day (individual doses should not exceed 1–2 mEq/kg/dose) Adults: 40–100 mEq/day.</p> <p>IV: Doses should be well diluted. Usually they are incorporated into the patient's daily fluid requirement. The maximum desirable concentration is 80 mEq/L. Greater concentrations up to 150 mEq/L in fluids should be used cautiously and only in patients with documented hypokalemia and if the patient has central intravenous access. Rates of infusion of potassium in fluids should not exceed 0.25 mEq/kg/hr in non-cardiac monitored areas.</p>	<p>Capsules, controlled release: 8 mEq (600 mg), 10 mEq (750 mg) Infusions diluted in D5W, NS or SWFI: 10 mEq, 20 mEq, 30 mEq, 40 mEq Injection, concentrated: 2 mEq/mL, 3 mEq/mL Liquids: 20 mEq/15 mL (10%), 40 mEq/15 mL (20%) Powders, effervescent packets: 20 mEq, 25 mEq Tablets, extended release: 8 mEq (600 mg), 10 mEq (750 mg), 20 mEq (1,500 mg) Other potassium salts are also available and may be desirable in patients who are acidotic. They include bicarbonate, citrate, acetate, and gluconate salts.</p>

Table 1. Medications (continued)

Medication	Dosages	Dosage Forms
Potassium chloride (continued)	<p>In the case of a patient in whom a shorter infusion of potassium is necessary (potassium rider), the following guidelines may be used: Maximum concentration of the solution must not exceed 30 mEq/100 mL. The solutions should be infused using a pump to control the infusion rate. Infusion over 2–3 hours (0.3–0.5 mEq/kg/hr) is preferred. Rate of infusion of potassium should never exceed 1 mEq/kg/hr in children or 30 mEq/hr in adults. Administration of doses >0.3 mEq/kg/hr (riders) should be done only if the patient has an ECG monitor in place. Solutions should be mixed well to prevent layering of the potassium chloride, which may result in inadvertent rapid administration.</p>	
Prednisolone Prednisone	<p>PO: Depends on the condition being treated and the patient’s response. The lowest dose possible should be used. Withdrawal of long-term therapy must be accomplished slowly by gradually tapering the dose. The guidelines below may be used for initial dosing.</p> <p>Children: <i>Anti-inflammatory or immunosuppressive:</i> 0.1–2 mg/kg/day in 1–4 divided doses. <i>Acute asthma:</i> 1 mg/kg/dose q6–12h depending on the severity of the attack. Every q6h dosing should be limited to 48 hours and then should be decreased to q12h. <i>Inflammatory bowel disease:</i> 1–3 mg/kg/day in 1–2 divided doses. <i>Nephrotic syndrome:</i> 2 mg/kg/day in 3 or 4 divided doses. <i>Organ transplants:</i> 1 mg/kg/day in 2 divided doses, tapering gradually to 0.15 mg/kg/day or lowest effective dose.</p>	<p>Liquid, as sodium phosphate: 5 mg/5 mL (Pediapred), 15 mg/5 mL (OraPred) Syrup (Prelone): 15 mg/5 mL Tablets: 5 mg Prednisone: Solution: 1 mg/mL, 5 mg/mL Syrup (Liquid Pred): 5 mg/5 mL Tablets: 1 mg, 2.5 mg, 5 mg, 10 mg, 20 mg, 50 mg</p>
Primidone (Mysoline)	<p>PO: Age <8 years: Initially 50–125 mg/day at bedtime or in 2 divided doses. Increase dose by 50–125 mg/day at weekly intervals to the normal range of 125–250 mg t.i.d. or 10–25 mg/kg/day. Age >8 years: Initially 125–250 mg/day at bedtime or in 2 divided doses. Increase dose by 125–250 mg/day at weekly intervals to the usual maintenance dose of 250 mg t.i.d. or q.i.d. Do not exceed 500 mg q.i.d. (2 g). Primidone is metabolized to phenobarbital and phenyl-ethylmalonamide (PEMA). Phenobarbital levels should be monitored in addition to primidone levels.</p>	Tablets: 50 mg, 250 mg
Probenecid (Benemid)	<p><i>Prolong penicillin serum levels:</i> Age <2 years: Not recommended. Age 2–14 years: <i>Initial:</i> 25 mg/kg for 1 dose. <i>Maintenance:</i> 40 mg/kg/24 hr in 4 divided doses to a maximum of 2 g daily.</p>	Tablets: 500 mg
Procainamide	<p>IV: Children: Loading dose of 3–6 mg/kg to a maximum of 100 mg over 5 minutes. This may be repeated q5–10min to a maximum of 15 mg/kg (do not exceed 500 mg in 30 minutes). Follow with a maintenance infusion at a dose of 20–80 mcg/kg/min. Adults: Loading dose of 50–100 mg, repeated q5–10min to a maximum of 17 mg/kg or 1 g. Follow with a maintenance infusion at a usual dose of 1–4 mg/min (reduce dose in renal impairment).</p>	Injection: 100 mg/mL, 500 mg/mL
Prochlorperazine (Compazine)	<p>PO or rectally as an antiemetic (avoid use in patients <2 years): 0.4 mg/kg/day in 3 or 4 divided doses or alternatively by the patient’s weight: 9–14 kg: 2.5 mg q12–24h as needed, to a maximum of 7.5 mg/day. >14–18 kg: 2.5 mg q8–12h as needed, to a maximum of 10 mg/day. >18–39 kg: 2.5 mg q8h or 5 mg q12h as needed, to a maximum of 15 mg/day. >40 kg: Rectally: 25 mg q12h. PO: 5–10 mg t.i.d. or q.i.d.</p> <p>IM (avoid use in patients <2 years; IV is not recommended in children): 0.1–0.15 mg/kg; may be repeated if necessary up to t.i.d. or q.i.d. Usual adult dose is 5–10 mg q4h to a maximum of 40 mg/day.</p>	<p>Injection: 5 mg/mL Suppositories: 25 mg Syrup: 5 mg/5 mL Tablets: 5 mg, 10 mg</p>

(continued)

Table 1. Medications (continued)

Medication	Dosages	Dosage Forms
Promethazine (Phenergan)	<p><i>Drug is contraindicated in children under age 2 due to risk of potentially fatal respiratory depression (Black Box Warning)</i></p> <p><i>Antihistamine</i> (usually PO): Children: 0.1 mg/kg q6h (not to exceed 12.5 mg/dose) during the day. A dose of 0.5 mg/kg (not to exceed 25 mg) may be used at bedtime. Adults: 12.5 mg q6h during the day with a 25-mg dose at bedtime.</p> <p><i>Antiemetic</i> (PO, IM, or rectally; avoid IV use due to risk of serious tissue injury, including gangrene—Black box warning): Children: 0.25–1 mg/kg/dose (Not to exceed 25 mg) up to q4h. Adults: 12.5–25 mg q4h as needed.</p> <p><i>Motion sickness</i> (PO): Children: 0.5 mg/kg 30 minutes to 1 hour before traveling; then q12h as needed. Adults: 25 mg 30 minutes to 1 hour before traveling; then q12h as needed.</p> <p><i>Sedation</i> (all routes): Children: 0.5–1 mg/kg q6h as needed. Adults: 25–50 mg q6h as needed.</p>	<p>Injection: 25 mg/mL, 50 mg/mL Suppositories: 12.5 mg, 25 mg, 50 mg Syrup: 6.25 mg/5 mL Tablets: 12.5 mg, 25 mg, 50 mg</p>
Propranolol (Inderal)	<p>PO:</p> <p><i>Arrhythmias:</i> Children: 0.5–1 mg/kg/day in 3 or 4 divided doses. Dosage may be titrated upward at 3–7-day intervals to the usual range of 2–4 mg/kg/day. If higher doses are necessary, up to 16 mg/kg/day (up to 640 mg) may be used. Adults: Usually 10–30 mg q6–8h.</p> <p><i>Hypertension:</i> Children: 0.5–1 mg/kg/day in 2–4 divided doses, increasing at 3–7-day intervals to the usual range of 1–5 mg/kg/day. Adults: 40 mg b.i.d., increasing at 3–7-day intervals to a maximum dose of 640 mg/day (usual range 40–160 mg/day).</p> <p><i>Migraine prophylaxis:</i> Children: 0.6–1.5 mg/kg/day in 3 divided doses. Adults: 80 mg/day in 3 or 4 divided doses. Dose may be increased to a maximum of 240 mg/day in divided doses or use a once daily sustained release capsule formulation.</p> <p><i>Tetralogy spells:</i> Children: 1–2 mg/kg q6h.</p> <p><i>Thyrotoxicosis:</i> Neonates: 2 mg/kg/day in 2–4 divided doses. Children: 1 mg/kg/day q.i.d. Adolescents and adults: 10–40 mg q6h.</p> <p>IV: Reserve for life-threatening arrhythmias. To be administered as an IV bolus <i>slowly over 10 minutes</i> under ECG monitoring. The IV dose is much smaller than the oral dose. Children: 0.01–0.1 mg/kg to a maximum of 1 mg for arrhythmias. For tetralogy spells, 0.15–0.25 mg/kg, which may be repeated once after 15 minutes. Adults: 1–3 mg. A second dose may be given, if necessary, after 2 minutes.</p>	<p>Capsules, sustained release: 60 mg, 80 mg, 120 mg, 160 mg Injection: 1 mg/mL Solution: 4 mg/mL, 8 mg/mL Tablets: 10 mg, 20 mg, 40 mg, 60 mg, 80 mg</p>
Propylthiouracil	<p>PO:</p> <p>Initially: Neonates: 5–10 mg/kg/day in 3 divided doses. Age <10 years: 5–7 mg/kg/day in 3 divided doses. Age ≥10 years: 150–300 mg/day in 3 divided doses. Adults: 300 mg/day in 3 divided doses.</p> <p>After control of symptoms has been achieved, the dose may be decreased to the lowest dose possible, usually 1/3–2/3 of the initial dose, administered in 3 doses daily.</p>	<p>Tablets: 50 mg</p>

Table 1. Medications (continued)

	Dosages	Dosage Forms
Protamine sulfate	<p>IV:</p> <p>1 mg of protamine sulfate neutralizes 90 USP units of lung-derived intravenous heparin or 115 USP Units of intestinal mucosa-derived intravenous heparin or 1 mg of LMWH. Because heparin disappears rapidly from the circulation, the dose of protamine decreases rapidly with time elapsed since the heparin infusion. The dose of protamine necessary after 30 minutes is half the dose above and that necessary after 2 hours is 1/4 the dose above. Because protamine itself is an anticoagulant, avoid overdosing. Protamine should be administered slowly, over a 1-minute period, and the dose should not exceed 50 mg.</p>	Injection: 10 mg/mL
Psyllium (Fiberall, Hydrocil, Konsyl, Metamucil).	<p>PO (each dose should be accompanied by a full glass of water or other liquid):</p> <p>Children: 1/2 the adult dose (1/2–1 packet or 1.7–3.4 g of psyllium) once daily to t.i.d.</p> <p>Adults: 1–2 packets or 3.4–6.8 g of psyllium once daily to t.i.d.</p> <p>Doses should be separated by 2 hours from other medications.</p>	<p>Powder: ~3.4 g/dose</p> <p>Powder, effervescent</p>
Pyrantel pamoate	<p>PO (may be taken with juice or milk and without regard to the ingestion of food):</p> <p>11 mg/kg pyrantel base to a maximum of 1 g.</p>	Suspension: 50 mg/mL pyrantel base
Ranitidine (Zantac)	<p>PO:</p> <p>Children: 2–4 mg/kg/day in 2 divided doses initially. Dose may be higher, up to 10 mg/kg/day in GERD and hypersecretory conditions.</p> <p>Adults: 150 mg b.i.d. or 300 mg at bedtime. Dose may be higher or more frequently administered. Up to 600 mg/day has been used in hypersecretory conditions.</p> <p>IV:</p> <p>Neonates: 1–2 mg/kg/day in 2 divided doses (avoid use in <1,500 g neonates at risk for necrotizing enterocolitis unless compelling need)</p> <p>Children: 1–2 mg/kg/day in 3 or 4 divided doses. Do not exceed 6 mg/kg/day or 300 mg/day.</p> <p>Adults: 50 mg q8h. Do not exceed 400 mg/day.</p> <p>Dosage should be adjusted for renal dysfunction.</p>	<p>Capsule: 150 mg, 300 mg</p> <p>Injection: 25 mg/mL</p> <p>Syrup: 15 mg/mL</p> <p>Tablets: 75 mg, 150 mg, 300 mg</p> <p>Tablets, effervescent: 25 mg, 150 mg</p>
Rifampin (Rifadin, Rimactane)	<p>PO (on an empty stomach):</p> <p><i>Tuberculosis:</i></p> <p>Children: 10–20 mg/kg/day as a single daily dose to a maximum of 600 mg.</p> <p>Adults: 10 mg/kg/day as a single daily dose up to a maximum of 600 mg/day.</p> <p><i>Meningococcal carriers:</i></p> <p>Age <1 month: 10 mg/kg/day in 2 divided doses for 2 days.</p> <p>Infants and children: 20 mg/kg/day in 2 divided doses for 2 days, to a maximum dose of 1,200 mg/day.</p> <p>Adults: 600 mg/dose b.i.d. for 2 days.</p> <p><i>Haemophilus influenzae type b prophylaxis:</i></p> <p>Age <1 month: 10 mg/kg/day as a single dose for 4 days.</p> <p>Age >1 month and children: 20 mg/kg/day as a single dose for 4 days.</p> <p>Adults: 600 mg/day for 4 days.</p> <p><i>Nasal carriers of Staphylococcus aureus:</i></p> <p>Children: 15 mg/kg/day in 2 divided doses in combination with other antibiotics.</p> <p>Adults: 600 mg daily in combination with other antibiotics.</p> <p>IV (over 30 minutes to 3 hours):</p> <p>Same doses as for the oral route. Rifampin may cause a red-orange discoloration of the sweat, urine, tears, and other body fluids; soft contact lenses may be permanently stained.</p>	<p>Capsules: 150 mg, 300 mg</p> <p>Injection: 600 mg</p> <p>Suspension: Not commercially available, but may be made by mixing the powder from the capsules with simple syrup to form a 10 mg/mL suspension. Such suspensions are stable for 4 weeks at room temperature or refrigerated.</p>

(continued)

Table 1. Medications (continued)

	Dosages	Dosage Forms
Salmeterol (Serevent Diskus)	<p><i>Salmeterol is a long acting drug and must not be used for acute exacerbations of asthma, is not a substitute for the use of steroids and should not be used without steroids for the treatment of chronic asthma.</i></p> <p>Powder (Diskus) for oral inhalation: Age ≥ 4 years: 1 inhalation (50 mcg) b.i.d. ~12 hours apart is used for chronic asthma.</p>	Inhalation, powder: 50 mcg/foil blister
Scopolamine (hyoscine; Isopto Hyoscine)	<p>IM, SC, or IV (anti-emetic): Children: 0.006 mg/kg to a maximum dose of 0.3 mg. Adults: 0.3–0.65 mg. Transdermal patch (> 12 years and adults; for motion sickness): Apply 1 patch behind the ear at least 4 hours prior to the exposure and then every 3 days as needed</p> <p>Ophthalmic: Children: 1 drop (up to q.i.d. for uveitis). Adults: 1–2 drops (up to q.i.d. for uveitis).</p>	<p>Injection: 0.4 mg/mL Solution, ophthalmic: 0.25% Transdermal patch, 1.5 mg</p>
Silver sulfadiazine (Silvadene, SSD, Thermazene)	<p>Topically: Applied to a thickness of 1/16-inch under sterile conditions (using a sterile glove) once or b.i.d. to a clean, debrided wound. Wound should always be covered with cream; reapply if it rubs off.</p>	Cream: 10 mg/g
Sodium bicarbonate (NaHCO₃)	<p>IV: <i>Cardiac arrest</i> (only after adequate ventilation has been established): 1 mEq/kg IV push initially; may repeat with a dose of 0.5 mEq/kg. Further doses should not be given until the patient's acid-base status has been determined. In infants, the concentration should not exceed 4.2% (0.5 mEq/mL). <i>Metabolic acidosis</i> (after measurement of blood gases and pH): Children: $\text{mEq HCO}_3 = 0.3 \times \text{weight (kg)} \times \text{base deficit (mEq/L)}$ <i>OR</i> $\text{mEq HCO}_3 = 0.5 \times \text{weight (kg)} \times [24\text{-serum HCO}_3 \text{ (mEq/L)}]$. Adults: $\text{mEq HCO}_3 = 0.2 \times \text{weight (kg)} \times \text{base deficit (mEq/L)}$ <i>OR</i> $\text{mEq HCO}_3 = 0.5 \times \text{weight (kg)} \times [24\text{-serum HCO}_3 \text{ (mEq/L)}]$. Doses should be administered slowly with frequent monitoring of acid-base balance.</p> <p>PO: <i>Urine alkalization</i> (titrate dose to desired pH): Children: 1–10 mEq/kg/day in divided doses. Adults: 48 mEq initially followed by 12–24 mEq q4h. Doses up to 192 mEq/day have been used.</p>	<p>Injection: 4.2% (0.5 mEq/mL), 7.5% (0.9 mEq/mL), 8.4% (1 mEq/mL) Tablets: 325 mg, 650 mg</p>
Sodium polystyrene sulfonate (Kayexalate)	<p>PO: Children: Base the dose on the exchange rate of 1 mEq K⁺/g of resin in smaller children. Alternatively, a dose of 1 g/kg q6h may be used. Adults: 15 g administered once daily to q.i.d.</p> <p>Rectally as a retention enema: Children: 1 g/kg q2–6h. Adults: 30–50 g q6h. Enemas should be retained for as long as possible to increase ion exchange. Evacuation of the enema should be followed by a non-sodium-containing cleansing enema. Sorbitol is frequently used for making solutions because it helps to prevent constipation. Administer cautiously to patients who may be at risk of serum sodium level increases. It is not totally selective for potassium; small amounts of calcium and magnesium may also be lost.</p>	<p>Powder for oral or rectal use Suspension: 15 g/60 mL (with sorbitol) for oral or rectal use</p>

Table 1. Medications (continued)

	Dosages	Dosage Forms
Sodium sulfacetamide (Bleph-10, Blephamide)	<p>Topically to the eye: Solutions: Apply 1–2 drops in the affected eye up to every 2 or 3 hours while awake. Ointment: Apply to the eye once daily to q.i.d. Drops will cause burning or stinging sensation. Ointment will cause blurred vision.</p>	<p>Ointment, ophthalmic: 10% Ointment, ophthalmic: 10% with prednisolone 0.2% Suspension, ophthalmic: 10%, 15%, 30% Solution, ophthalmic: 10% with prednisolone 0.25% Suspension, ophthalmic: 10% with prednisolone 0.2%</p>
Spironolactone (Aldactone)	<p>PO: <i>Edema</i> (response may not be evident for up to 5 days): Children: 1–3 mg/kg/day in 1 or 2 divided doses. Adults: 100 mg/day with a range of 25–200 mg/day. <i>Primary aldosteronism:</i> Children: 125–375 mg/m²/day in divided doses. Adults: 400 mg/day in 1 or 2 divided doses.</p>	<p>Tablets: 25 mg, 50 mg, 100 mg (A stable suspension may be made by crushing tablets and suspending the powder in simple syrup or cherry syrup.)</p>
Streptomycin	<p>IM: Children: 20–40 mg/kg/24 hr in 1 to 2 divided doses. Adults: 1–2 g in 1 or 2 doses daily (doses > 1 gm should be divided). Maximum dose 2 g/24 hr.</p>	<p>Injection: 1 g</p>
Sucralfate (Carafate)	<p>Sucralfate is not absorbed from the GI tract. It may bind with other drugs administered at the same time, lowering their effectiveness; therefore, it should be administered at least 2 hours before or after other drugs.</p> <p>PO: Children: Dosage has not been established, but 40–80 mg/kg/day in 4 divided doses has been used. Adults: 1 g q.i.d. The dose for stomatitis or mucositis is about 250 mg–500 mg of suspension swished around the mouth and then spit out or swallowed, repeated q.i.d.</p>	<p>Suspension: 1 g/10 mL Tablets: 1 g</p>
Sulfasalazine (Azulfidine)	<p>PO: Age > 2 years: Initially 40–60 mg/kg/day in 3–6 divided doses (not to exceed 4 g/day) then decreasing to a maintenance dose of 20–40 mg/kg/day in 4 divided doses to a maximum dose of 2 g/day. Adults: Initially 3–4 g/day in equally divided doses. Although doses as high as 12 g/day have been used, they are generally accompanied by an increased incidence of adverse effects. Maintenance doses are usually 2 g/day in 4 divided doses. The drug may cause a yellow discoloration of urine and skin.</p>	<p>Tablets: 500 mg Tablets, enteric coated: 500 mg</p>
Sumatriptan (Imitrex)	<p>SC: Age ≥ 6 years and ≤ 30 kg: 0.06 mg/kg or 3 mg. Children > 30 kg and adults: 6 mg. A second dose may be given at least 1 hour after the first dose if necessary. Do not exceed 2 doses in 24 hours.</p> <p>PO: Older adolescents and adults: 25 mg, 50 mg or 100 mg taken with fluids. A second dose may be taken after 2 hours. Daily dose should not exceed 200 mg.</p>	<p>Injection: 4 mg/0.5 mL, 6 mg/0.5 mL Tablet: 25 mg, 50 mg, 100 mg</p>
Tacrolimus (FK-506, Prograf)	<p>Patients are usually treated concurrently with an adrenal corticosteroid.</p> <p>PO: Children: 0.15–0.3 mg/kg/day in 2 divided doses. Adults: 0.1–0.2 mg/kg/day in 2 divided doses. Doses may be decreased to a lower maintenance dose.</p>	

(continued)

Table 1. Medications (continued)

	Dosages	Dosage Forms
Tacrolimus (FK-506, Prograf) (continued)	<p>IV (as a continuous infusion): Children: 0.01–0.06 mg/kg/day. Adults: 0.01–0.05 mg/kg/day. Conversion to oral therapy should take place as soon as the patient is able to tolerate oral medication.</p>	<p>Capsules: 1 mg, 5 mg Injection: 5 mg/mL</p>
Terbinafine (Lamisil AF)	<p>Topically: Age ≥ 12 years: Apply to affected area and surrounding skin for at least 1 week, but not more than 4 weeks.</p>	<p>Cream: 1% Solution (topical spray): 1%</p>
Terbutaline (Brethine)	<p>PO: Age < 12 years: Initially 0.05 mg/kg/dose t.i.d., increased gradually as required to a maximum of 0.15 mg/kg/dose t.i.d. or total of 5 mg/24 hr. Age > 12 years: Initially 2.5 mg t.i.d. Maintenance: Usually 2.5–5 mg or 0.075 mg/kg/dose t.i.d.</p> <p>Parenteral, SC: Age < 12 years: 0.01 mg/kg to a maximum of 0.3 mg q15–20min for 3 doses. Age > 12 years: 0.25 mg, repeated in 15–30 minutes if needed once only; a total dose of 0.5 mg should not be exceeded within a 4-hour period. Continuous infusion for status asthmaticus: Option to load IV with 10 mcg/kg (maximum 500 mcg) over 5 minutes, then start infusion of 0.2 mcg/kg/min to 4 mcg/kg/min.</p>	<p>Injection: 1 mg/mL (1-mL ampul) Tablets: 2.5 mg, 5 mg</p>
Tetracycline	<p>PO (should be given on an empty stomach): Age > 8 years: 25–50 mg/kg/day in 4 divided doses not to exceed 3 g/day. Adults: 1–2 g/day in 2–4 divided doses.</p>	<p>Capsules: 250 mg, 500 mg Tablets: 250 mg, 500 mg</p>
Theophylline	<p>IV or PO for apnea in infants: Premature neonates with postconceptional age < 40 weeks: 2 mg/kg/day in 2 divided doses. Term neonates, age < 4 weeks: 5 mg/kg loading dose followed by 2–6 mg/kg/day in 2 or 3 divided doses. Term neonates, age > 4 weeks: 5–7.5 mg/kg loading dose followed by 3–6 mg/kg/day in 3 divided doses.</p> <p>Acute bronchospasm (all dosing should be based on lean body weight): Loading dose: 1 mg/kg will increase serum theophylline concentration by 2 mcg/mL. Patients who have received no theophylline in the previous 24 hours may be given 5–7.5 mg/kg. Patients who have received theophylline within the previous 24 hours should have a serum concentration checked before receiving a partial loading dose. Serum theophylline level should be monitored 30 minutes after the end of a bolus infusion. Loading dose should be administered IV over 30 minutes or PO using an immediate-release product. For patients requiring a continuous IV infusion of theophylline, it should be started at the completion of the bolus dose at the following rate for children: Age 6 months to 1 year: 0.5 mg/kg/hr. Age > 1–9 years: 0.9 mg/kg/hr. Age > 9–12 years and adolescent smokers: 0.8 mg/kg/hr. Age > 12–16 years (nonsmokers): 0.7 mg/kg/hr. Theophylline levels should be monitored 12–24 hours after beginning the infusion and daily while therapy continues.</p> <p>Oral therapy for chronic bronchospasm: Age 6 months to 1 year: 12–18 mg/kg/day. Age > 1–9 years: 20–24 mg/kg/day. Age > 9–12 years and adolescent smokers: 16 mg/kg/day. Age > 12–16 years (nonsmokers): 13 mg/kg/day. Age > 16 years (nonsmokers): 10 mg/kg/day (not to exceed 900 mg/day). Dose reduction should be made with liver dysfunction or cardiac dysfunction.</p>	<p>Immediate release: Elixir: 80 mg/15 mL Injection in D₅W: 0.4 mg/mL, 0.8 mg/mL, 1.6 mg/mL, 3.2 mg/mL, 4 mg/mL</p> <p>Controlled release: Capsules and tablets of various strengths and release properties: Frequency of dosing must be based on the characteristics of the product chosen. Immediate-release products must be administered q6h. Extended-release products may be administered every 8–12h or even q24h in adolescents using products designed for daily administration. Serum levels should be monitored frequently during early therapy to maintain serum levels between 10–20 mcg/mL. After a stable dose is achieved, monitoring should be done at least q6–12 months.</p>

Table 1. Medications (continued)

	Dosages	Dosage Forms
Ticarcillin and clavulanate potassium (Timentin)	<p>IV (may be expressed in terms of ticarcillin content alone or in terms of the fixed ratio (30:1) of the commercially available combination product):</p> <p>Neonates <1,200 g or <7 days and 1,200–2,000 g: 150 mg/kg/day of ticarcillin component divided q12h</p> <p>Neonates 1,200–2,000 g and ≥7 days: 225 mg/kg/day of ticarcillin component divided q8h</p> <p>Neonates ≥2 kg: 225–300 mg/kg/day of ticarcillin component divided q8h</p> <p>Infants ≥3 months and children</p> <p><60 kg: 200–300 mg/kg/day of ticarcillin (207–310 mg of ticarcillin/clavulanic acid) in 4–6 divided doses.</p> <p>≥60 kg: 3 g ticarcillin + 0.1 g clavulanic acid (3.1 g of combination) q4–6h to a maximum of 24 g of ticarcillin daily.</p> <p>Dosage must be adjusted in patients with renal or hepatic dysfunction.</p>	<p>Injection: 3 g ticarcillin + 0.1 g clavulanic acid labeled as a combined total potency of 3.1 g (pharmacy bulk package containing 30 g ticarcillin + 1 g clavulanic acid)</p>
Tobramycin (TobraDex, Tobrex)	<p>IV (assumes normal renal function):</p> <p>Neonates <2 kg and <7 days: 2.5–3 mg/kg/dose q24–q36h</p> <p>Neonates: >2 kg and <7 days: 2.5 mg/kg/dose q12–q24h</p> <p>Neonates: <2 kg and >7 days: 3 mg/kg/dose q24h</p> <p>Neonates: >2 kg and >7 days: 5 mg/kg/day in 2 divided doses</p> <p>Traditional dosing:</p> <p>Term Infants ≥3 months and children <5 years: 7.5 mg/kg/day in 3 divided doses.</p> <p>Children 5–10 years: 6 mg/kg/day in 3 divided doses.</p> <p>Older children and adults: 5 mg/kg/day in 3 divided doses.</p> <p>Patients with cystic fibrosis usually require higher doses (10 mg/kg/day in 3 divided doses).</p> <p>Dosage may be increased based on the results of serum level monitoring.</p> <p>Dosage must be adjusted in patients with renal dysfunction.</p> <p>Ophthalmic:</p> <p>Ointment: Apply a 1-cm ribbon of ointment to the eye b.i.d. or t.i.d.</p> <p>Solution: Apply 1–2 drops into the eye up to q30–60min in severe infections or q3–4h for moderate infections.</p>	<p>Injection: 10 mg/mL, 40 mg/mL</p> <p>Ointment, ophthalmic: 0.3%</p> <p>Ointment, ophthalmic: 0.3% with dexamethasone 0.1%</p> <p>Solution, ophthalmic: 0.3%</p> <p>Solution, ophthalmic: 0.3% with dexamethasone 0.1%</p>
Tolmetin (Tolectin)	<p>PO for rheumatoid arthritis:</p> <p>Age >2 years: initially 20 mg/kg/day in 3 or 4 divided doses, adjusted to the patient's response. Usual maintenance dosage range is 15–30 mg/kg/day.</p> <p>Adults: 600 mg-1.8 g/day in 3 divided doses.</p>	<p>Capsules: 400 mg</p> <p>Tablets: 200 mg, 600 mg</p>
Topiramate (Topamax)	<p>PO:</p> <p>Age 2–16 years: Initially, 1–3 mg/kg/day (or 25 mg) given daily at bedtime for 1 week. Gradually increase dose by 1–3 mg/kg/day and increase frequency to b.i.d. to the usual maintenance dosage range of 5–9 mg/kg/day.</p> <p>Age >16 years: Initially, 50 mg daily in 2 divided doses, then increase at weekly intervals by 50 mg/day to a usual adult dose range of 200–400 mg daily in 2 divided doses.</p>	<p>Capsule, sprinkle: 15 mg, 25 mg</p> <p>Tablet: 25 mg, 50 mg, 100 mg, 200 mg. Tablets should not be crushed since the drug has a very bitter taste. Broken tablets should be used immediately as the drug is not stable.</p>
Trazodone (Desyrel)	<p>PO:</p> <p>Age 6–18 years: 1.5–2 mg/kg/day in 2 divided doses, increasing gradually to a maximum dose of 6 mg/kg/day in 3 divided doses.</p> <p>Adolescents: 25–50 mg/d, increased gradually to a maximum of 150 mg/day in divided doses.</p> <p>Adults: 150 mg/day in 3 divided doses increased gradually to a maximum of 600 mg/day.</p>	<p>Tablets: 50 mg, 100 mg, 150 mg, 300 mg</p>

(continued)

Table 1. Medications (continued)

	Dosages	Dosage Forms
Tretinoin (Avita, Retin-A Micro, retinoic acid; Retin-A)	Topically: Apply to the affected area once daily after cleaning, generally at bedtime. Avoid application to areas not being treated. Use should be discontinued if severe reddening, swelling, or peeling occurs. After healing, therapy may be restarted with the same or a different formulation administered less frequently.	Cream: 0.025%, 0.05%, 0.1% Gel: 0.01%, 0.025% Microsphere gel: 0.04%, 0.1% Solution: 0.05%
Trientine (Syprine)	PO for copper chelation: Age 6 to 12 years: 500–750 mg daily in 2–4 divided doses to a maximum of 1.5 g daily. Adults: 750–1,250 mg daily in 2–4 divided doses to a maximum of 2 g daily. Capsules should be swallowed whole, on an empty stomach.	Capsule: 250 mg
Trifluridine (Viroptic)	Topically to the eye: Apply 1 drop q2h while awake until re-epithelialization has occurred. Maximum daily dose of 9 drops should not be exceeded. After re-epithelialization has occurred, dosage should be reduced to 1 drop q4h for an additional 7 days to prevent recurrence, but the total length of therapy should not exceed 21 days.	Solution, ophthalmic: 1%
Trimethoprim (Primsol, Proloprim)	PO: UTI: Age <12 years: 4 mg/kg/day in 2 divided doses for 10 days. Age ≥12 years: 100 mg b.i.d. or 200 mg once daily for 10 days. <i>Pneumocystis carinii pneumonia treatment (given with dapsone):</i> 15–20 mg/kg/day in 4 divided doses.	Solution: 50 mg/5 mL Tablet: 100 mg
Tropicamide (Mydracyl, Ocu-Tropic, Tropicacyl)	Topically to the eye: 1–2 drops into the eye(s) 15–20 minutes before exam. 0.5% solution is usually sufficient for exam. If cycloplegia for refraction is necessary, 1% solution must be used and repeated in 5 minutes. Exam must take place within 30 minutes because its effect is short.	Solution, ophthalmic: 0.5%, 1%
Ursodiol (Actigall, Urso 250, Urso Forte, Ursodeoxycholic acid)	PO: <i>Cystic fibrosis:</i> 30 mg/kg/day in 2 divided doses. TPN Cholestasis (infants and young children): 30 mg/kg/day in 3 divided doses <i>Gallstones or cholestasis:</i> 8–10 mg/kg/day in 2–3 divided doses primarily in older children or adults.	Capsule: 300 mg Tablet: 250 mg, 500 mg
Valproic acid, valproate sodium, and divalproex sodium (Depacon, Depakene, Depakote, Depakote ER)	PO (expressed in terms of valproic acid): Initially 15 mg/kg/day increasing by 5–10 mg/kg/day at weekly intervals until seizures are controlled or side effects occur. Usual maximum total daily dose is 60 mg/kg/day in 2–3 divided doses. Frequency of administration in part depends on dosage form, but dosage is usually divided. To prevent adverse GI effects, capsules (valproic acid) and solution are usually administered in 2 or 3 divided doses. Divalproex usually may be administered in 2 divided doses or as a single daily dose if the extended release tablet is used. The usual therapeutic serum concentration range is 50–100 mcg/mL. The oral solution has been administered rectally in patients who are NPO by diluting it 1:1 with tap water and administering it as a retention enema.	Capsules, sprinkles (divalproex sodium): 125 mg valproic acid Capsules (valproic acid): 250 mg Injection: 100 mg/mL Solution (valproate sodium): 250 mg valproic acid/5 mL Tablets (divalproex sodium): 125 mg, 250 mg, 500 mg valproic acid Tablets, extended release (divalproex sodium): 250 mg, 500 mg

Table 1. Medications (continued)

	Dosages	Dosage Forms
Valproic acid, valproate sodium, and divalproex sodium (Depacon, Depakene, Depakote, Depakote ER) (continued)	<p>IV (over 1 hour): For patients who are not on valproic acid therapy, use the dosing and frequency of administration guidelines outlined above for oral dosing but monitor trough levels since q6h dosing frequency may be needed. For patients already on valproic acid therapy, use the patient's total oral daily dose and divide with a frequency of dosing of every 6 hours for the IV route. The use of the injectable form for periods of more than 14 days has not been studied. Loading dose in refractory status epilepticus: 20–40 mg/kg.</p>	
Vancomycin (Vancocin)	<p>IV (over at least 1 hour): If normal renal function for age: Neonates, age <7 days: <1,000 g: 10–15 mg/kg q24h. 1,000–2,000 g: 10–15 mg/kg q18h. >2,000 g: 10–15 mg/kg q12h. Neonates, age 7–30 days: <1,000 g: 10–15 mg/kg q18h. 1,000–2,000 g: 10–15 mg/kg q12h. >2,000 g: 10–15 mg/kg q8h. Infants >2 kg, age 31–60 days: 10–15 mg/kg q6–q8h. Age >2 months and >2 kg to Older Children: 40–60 mg/kg/day in 4 divided doses to a maximum dose of 4 g/day. Dose will depend on indication and desired trough level. Serum concentrations should be measured frequently while on therapy. Adults: 0.5 g q6h or 1 g q12h. Dosage adjustment is necessary in renal impairment. Doses of 60 mg/kg/day or more are usually required in children with staphylococcal or streptococcal CNS infections.</p> <p>Intrathecal: Neonates: 5–10 mg/day. Children: 5–20 mg/day. Adults: 20 mg/day.</p> <p>PO (not absorbed; do not use for systemic infections): Children: 40 mg/kg/day in 4 divided doses to a maximum daily dose of 2 g. The injectable form may be used PO. Adults: 0.5–2 g/day in 3 or 4 divided doses.</p>	<p>Capsules: 125 mg, 250 mg Injection: 500 mg, 1 g (5-g, 10-g pharmacy bulk packages)</p>
Verapamil (Calan, Calan SR, Covera-HS, Isoptin SR, Verelan, Verelan PM)	<p>IV (push over 2–3 minutes): Age <1 year: 0.1–0.2 mg/kg (usually 0.75–2 mg). Age 1–16 years: 0.1–0.3 mg/kg to a maximum of 5 mg. May be repeated once in 30 minutes if not effective (maximum dose for second dose is 10 mg). Age >16 years: 0.075–0.15 mg/kg (5–10 mg) with a repeat dose in 30 minutes if necessary.</p> <p>PO (not well established in children and sustained or extended release products are not usually appropriate): Age 1–5 years: 4–8 mg/kg/day in 3 divided doses or ~40–80 mg q8h. Age >5 years: 80 mg q6–8h. Adults: 240–480 mg/day in 3 or 4 divided doses (1–2 doses daily using extended-release products for the treatment of hypertension).</p>	<p>Capsules, extended release: 120 mg, 180 mg, 240 mg Injection: 2.5 mg/mL Tablets: 40 mg, 80 mg, 120 mg Tablets, extended release: 120 mg, 180 mg, 240 mg</p>
Vitamin E [alpha tocopherol, alpha tocopheryl acetate, tocopherol polyethylene glycol succinate (TPGS), Aquasol E]	<p>PO (water miscible or water soluble TPGS products are recommended, especially for patients with malabsorption): <i>Deficiency:</i> Infants: 25–50 units/day. <i>Children with malabsorption:</i> Consider use of a dose that is 2–5 times the RDA requirement for age or 1 mg/kg/day to raise and maintain plasma tocopherol levels. Patients with cystic fibrosis, thalassemia, or sickle-cell disease may require larger daily doses (400–800 U/day). Adults: 60–75 units/day.</p>	<p>Capsules: 100 U, 200 U, 400 U, 600 U, 1,000 U Capsules, water miscible: 100 U, 200 U, 400 U Solution, water miscible: 50 U/mL Solution (TPGS): 400 U/15 mL</p>

(continued)

MEDICATIONS

Table 1. Medications (continued)

	Dosages	Dosage Forms
Warfarin sodium (Coumadin)	<p>PO: Infants and children: Loading dose 0.2 mg/kg (maximum 10 mg) if normal baseline INR. Usual maintenance dose is 0.1 mg/kg/day with a range of 0.05–0.34 mg/kg/day adjusted to achieve the desired PT/INR. Adults: 5–15 mg/day initially for 2–5 days until desired PT is reached. Usual maintenance dosage range is 2–10 mg/day.</p>	Tablets: 1 mg, 2 mg, 2.5 mg, 3 mg, 4 mg, 5 mg, 6 mg, 7.5 mg, 10 mg
Voriconazole (VFEND)	<p>PO: Age < 12 years: Not established. However, in patients < 25 kg, some centers have used 3–5 mg/kg/dose every 12 hours. Age ≥ 12 years or patients ≥ 40 kg: 100–300 mg q12h.</p> <p>IV: Age 2 years to < 12 years: 5–8 mg/kg/dose q12h. Age ≥ 12 years: 6 mg/kg/dose q12h for 2 doses, followed by a maintenance dose of 4 mg/kg q12h. Consider serum trough concentration monitoring in select patients (e.g., in invasive aspergillosis)</p>	Injection: 200 mg Suspension: 200 mg/5 ml Tablets: 50 mg, 200 mg
Zafirlukast (Accolate)	<p>PO on an empty stomach: Age 5–11 years: 10 mg b.i.d. Age ≥ 12 years: 20 mg b.i.d.</p>	Tablet: 10 mg, 20 mg
Zanamivir (Relenza)	<p>Oral inhalation (Treatment of Influenza): Age ≥ 7 years: 2 inhalations (10 mg) b.i.d. for 5 days beginning within 2 days of the onset of symptoms.</p>	Powder for inhalation with device: 5 mg/actuation
Zidovudine (Retrovir)	<p>PO: Age ≥ 4 weeks to < 18 years: 240 mg/m²/dose q12h to a maximum of 300 mg q12h or 160 mg/m² dose every 8 hrs (maximum 200 mg q8h). Alternatively, dosing may be based on weight: 4–8 kg: 12 mg/kg/dose twice daily or 8 mg/kg/dose t.i.d. ≥ 9 to < 30 kg: 9 mg/kg/dose twice daily or 6 mg/kg/dose t.i.d. Children ≥ 30 kg and Adults: 300 mg b.i.d. or 200 mg t.i.d. Dosage may be decreased in patients who develop anemia and/or granulocytopenia.</p> <p>IV: Infants ≥ 6 weeks and Children < 12 years: Continuous infusion: 20 mg/m²/hr Intermittent infusion: 120 mg/m² by infusion over 1 hour q6h. Children ≥ 12 years and Adults: 1 mg/kg q4h 6 times daily.</p> <p><i>Maternal-fetal HIV transmission prevention:</i> Maternal (> 14 weeks of pregnancy): 100 mg q4h while awake (500 mg/day) or 200 mg t.i.d. or 300 mg b.i.d. until the onset of labor. During labor and delivery, 2 mg/kg over 1 hour followed by a continuous IV infusion of 1 mg/kg/hr until the umbilical cord is clamped. Infant (Term): 4 mg/kg PO q12h starting within 12 hours of birth and continuing for 6 weeks. For infants unable to tolerate oral drugs, 6 mg/kg/day IV in 4 evenly divided doses may be used. Dosage adjustment is necessary for premature infants and in severe renal impairment.</p>	Capsules: 100 mg Injection: 10 mg/mL Solution: 50 mg/5 mL Tablets: 300 mg
Zinc	<p>Response may not occur for 6–8 weeks.</p> <p>PO: Infants and children: 0.5–1 mg/kg/day of elemental zinc in 1–3 divided doses. Adults: 25–50 mg elemental zinc t.i.d. <i>Acrodermatitis enteropathica:</i> 10–45 mg/day elemental zinc. Zinc sulfate 4.4 mg = 1 mg elemental zinc (220 mg = 50 mg).</p>	Zinc sulfate (23% zinc): Capsules: 220 mg (50 mg zinc) Injection: 1 mg/mL, 5 mg/mL (zinc) Tablets: 66 mg (15 mg zinc), 110 mg (25 mg zinc), 220 mg (50 mg zinc) Tablets: 10 mg (1.4 mg zinc), 15 mg (2 mg zinc), 50 mg (7 mg zinc), 78 mg (11 mg zinc)

Table 2. Citric Acid and Citrate Dosage Forms (Content per 1 mL)

Product	Sodium Citrate	Potassium Citrate	Citric Acid	Bicarbonate Equivalent
Oracit solution	98 mg (1 mEq Na)	128 mg	1 mEq
Polycitra K solution	220 mg (2 mEq K)		66.8 mg	2 mEq
Polycitra-LC solution	100 mg (1 mEq Na)	110 mg (1 mEq K)	66.8 mg	2 mEq

Table 3. Digoxin Dosing

Age	Total Digitalizing Dose (mcg/kg)		Daily Maintenance Dose (mcg/kg Divided in 2 Doses)	
	PO	IV	PO	IV
Preterm infant	20–30	15–25	5–7.5	4–6
Full-term infant	25–40	20–30	6–10	5–8
1 month to 2 years	35–60	30–50	10–15	7.5–12
2 years to adult	30–40	25–35	7.5–15	6–9
Maximum dose	0.75–1.5 mg	0.5–1 mg	0.125–0.5 mg	0.1–0.4 mg

IV, intravenously; PO, orally.

Calcium	8.9–10.7 mg/dL	CSF	32–82 mg/dL
Ionized	1.12–1.30 mmol/L	Whole blood	60–115 mg/dL
Stool	0–640 mg/24 h	Ham test	
Carbon dioxide	20–26 mmol/L	Acidified	0%–1%
Carboxyhemoglobin	0%–2%	Unacidified	0%–1%
CD3+ and CD8+	17.4%–34.2%	Haptoglobin	13–163 mg/dL
CD14+	0%–10%	Hematocrit	36%–46%
CD45+ and CD14–	90%–100%	Spun	36%–41%
Ceruloplasmin	23–48 mg/dL	Hemoglobin	13.5–17.0 g/dL
CH50	104–356 U/mL	A ₁ C	3.8%–5.9%
Chloramphenicol	5–20 mcg/mL	Total	
Chloride	96–106 mmol/L	Newborn	10–18 g/dL
Sweat	0–40 mmol/L	Child	12–16.0 g/dL
Cholesterol	111–220 mg/dL	HbA ₂ , quantitative	1.8%–3.6%
High-density lipoprotein (HDL)	35–82 mg/dL	HbF, quantitative	0%–1.9%
Low-density lipoprotein (LDL)	59–137 mg/dL	Immunoglobulin A	
Complement		Newborn	0–5 mg/dL
C3		Infant	27–169 mg/dL
Newborn	67–161 mg/dL	Child	70–486 mg/dL
Child	90–187 mg/dL		
C4	16–45 mg/dL		
Copper	67–147 mcg/dL		

NORMAL LABORATORY VALUES

Immunoglobulin E		Protein, total	6.3–8.6 g/dL
Newborn	0–15 IU/mL	Prothrombin time	10–12 seconds
Child	0–200 IU/mL	Protoporphyrin, free RBC	30–80 $\mu\text{mol/mol}$ Hb
Immunoglobulin G		Pyruvate kinase assay	1.8–2.3 IU/mL RBC
CSF	0.5–6 mg/dL	RBC distribution width	11.5%–14.5%
Child	635–1,775 mg/dL	Reptilase	18–22 seconds
Immunoglobulin M		Reticulocyte count	0.5%–1.5%
Child	71–237 mg/dL	Ristocetin cofactor	48%–220%
Iron	50–180 mcg/dL	Salicylate	<35 mg/dL
Urine	0–2.0 mg/24h	Sodium	136–145 mmol/L
Iron-binding capacity	250–420 mcg/dL	Sucrose hemolysis	0%–5%
Lactate		T3 (total T cells)	69%–86%
CSF	0–3.3 mmol/L	T4 (helper T cells)	39%–57%
Plasma	0.6–2.0 mmol/L	T4–T8 ratio	0.7–2.5
Lactate dehydrogenase (LDH)	340–670 U/L	T8 (suppressor T cells)	18%–45%
Latex IgE	0–20 U	T11 (SRBC receptor)	75%–93%
Lead, blood	0–10.0 mcg/dL	Theophylline	10–20 mcg/mL
Lipase	25–110 U/L	Thrombin time	11.3–16.3 seconds
Lyme antibodies (IgG/IgM)	0.00–0.79	Thyroid-stimulating hormone (thyrotropin)	0.5–5.0 $\mu\text{IU/mL}$
Magnesium	1.5–2.5 mg/dL	Thyroxine	
Mean corpuscular hemoglobin (MCH)	26.0–34.0 pg	Newborn	3.0–14.4 mcg/dL
Mean corpuscular volume (MCV)	80.0–100.0 μm^3	Infant	4.6–13.4 mcg/dL
Mean platelet volume	7.4–10.4 fl	Child	4.5–10.3 mcg/dL
Methemoglobin	0.0%–1.9%	Thyroxine-binding globulin	1.8–4.2 mg/dL
Netilmicin		Tobramycin	
Peak	5–10 mcg/mL	Peak	4–10 mcg/mL
Trough	0–2 mcg/mL	Trough	0–2 mcg/mL
Osmolality		Total cell count	100
Urine		Total eosinophil count	100–300 mm^3
Newborn	50–645 mOsm/kg	Total protein	
Child	50–1,500 mOsm/kg	CSF	
Whole blood	275–296 mOsm/kg	Newborn	40–120 mg/dL
Partial thromboplastin time	25.0–38.0 seconds	Child	15–40 mg/dL
Peroxide hemolysis	0%–20%	Urine	0–20 mg/dL
Phenobarbital	15–40 mcg/mL	Triglycerides	34–165 mg/dL
Phenytoin	10–20 mcg/mL	Triiodothyronine	0.9–2.25 ng/mL
Phosphorus	2.7–4.7 mg/dL	Trypsin, stool	80–740 mcg/g
Platelet aggregation, 10 mcgm	> 60.1%	Urea nitrogen	2–19 mg/dL
Platelet count	150–400 $10^3/\mu\text{L}$	Uric acid	2.1–5.0 mg/dL
Potassium	3.8–5.4 mmol/L	Urine pH	4.8–7.8
Prealbumin	22.0–45.0 mg/dL	Urine specific gravity; TS meter	1.003–1.1035
Primidone	5–12 mcg/mL	Valproic acid	50–100 mcg/mL
Procainamide	4–10 mcg/mL	Vancomycin	
Prolactin	2.7–15.2 ng/mL	Peak	20–30 mcg/mL
Protein, 24-hour total	0–150 mg/24h	Trough	0–12 mcg/mL
Protein C		White blood cell count	
Immunologic	50%–122%	Newborn	9–30 $10^3/\mu\text{L}$
Functional	59%–116%	Child	4.5–11.0 $10^3/\mu\text{L}$
Protein S, free	40%–111%	Zinc	68–94 mcg/dL

DEVELOPMENT

Charles Schwartz

Table 1. Scoring System: Draw-a-Person Test

One Point Assigned per Feature:

Head present	Fingers present
Neck present	Correct number of fingers shown
Neck, two dimensions	Opposition of thumb shown (must include fingers)
Eyes present	Hands present
Eye detail: Brows or lashes	Arms present
Nose present	Arms at side or engaged in activity
Nose, two dimensions (not round ball)	Feet: any indication
Mouth present	Attachment of arms to legs I (to trunk or anywhere)
Lips, two dimensions	Attachment of arms and legs II (at correct point on trunk)
Both nose and lips in two dimensions	Trunk present
Both chin and forehead shown	Trunk in proportion, 2 dimensions (if greater than breadth)
Bridge of nose (straight to eyes; narrower than base)	Clothing I (anything)
Hair I (any scribble)	Clothing II (two articles of clothing)
Hair II (more detail)	
Ears present	

Mental Age (yr)	Points Scored by Boys	Points Scored by Girls
3	4	5
4	7	7
5	11	11
6	13	14
7	16	17
8	18	20

Table 2. Receptive Language Development (continued)

Table 3. Expressive Language Development (continued)

Table 4. Developmental Milestones from Birth to 5 Years

Age (Months)	Adaptive/Fine Motor	Language	Gross Motor	Personal-Social
1	Grasp reflex (hands fisted)	Facial response to sounds	Lifts head in prone position	Stares at face
2	Follows object with eyes past midline	Coos (vowel sounds)	Lifts head in prone position to 45°	Smiles in response to others
4	Hands open Brings objects to mouth	Laughs and squeals Turns toward voice	Sits: Head steady Rolls to supine	Smiles spontaneously
6	Palmar grasp of objects	Babbles (consonant sounds)	Sits independently Stands, hands held	Reaches for toys Recognizes strangers
9	Pincer grasp	Says "mama," "dada" nonspecifically, comprehends "no"	Pulls to stand	Feeds self Waves bye-bye
12	Helps turn pages of book	2-4 words Follows command with gesture	Stands independently Walks, one hand held	Points to indicate wants
15	Scribbles	4-6 words Follows command no gesture	Walks independently	Drinks from cup Imitates activities
18	Turns pages of book	10-20 words Points to 4 body parts	Walks up steps	Feeds self with spoon
24	Solves single-piece puzzles	Combines 2-3 words Uses "I" and "you"	Jumps Kicks ball	Removes coat Verbalizes wants
30	Imitates horizontal and vertical lines	Names all body parts	Rides tricycle using pedals	Pulls up pants Washes, dries hands
36	Copies circle Draws person with 3 parts	Gives full name, age, and sex Names 2 colors	Throws ball overhand Walks up stairs (alternating feet)	Toilet trained Puts on shirt, knows front from back
42	Copies cross	Understands "cold," "tired," "hungry"	Stands on one foot for 2-3 sec	Engages in associative play
48	Counts 4 objects Identifies some numbers and letters	Understands prepositions (under, on, behind, in front of) Asks "how" and "why"	Hops on one foot	Dresses with little assistance Shoes on correct feet
54	Copies square Draws person with 6 parts	Understands opposites	Broad-jumps 24 inches	Bosses and criticizes Shows off
60	Prints first name Counts 10 objects	Asks meaning of words	Skips (alternating feet)	Ties shoes

Table 2A. Causes of Failure to Thrive

Age at Onset	Diagnostic Considerations
Before birth (IUGR, prematurity)	Especially in “symmetric” IUGR, consider prenatal infections, congenital syndromes, teratogenic exposures (anticonvulsants, alcohol, etc.)
Neonatal	Incorrect formula preparation; failed breast-feeding; neglect; poor feeding interactions; metabolic, chromosomal, or anatomic abnormality (less common)
3–6 months	Underfeeding (possibly associated with poverty); improper formula preparation; milk protein intolerance; oral-motor dysfunction; celiac disease; HIV infection; cystic fibrosis; congenital heart disease; GE reflux
7–12 months	Autonomy struggles; overly fastidious parent; oral-motor dysfunction; delayed introduction of solids; intolerance of new foods
After 12 months	Coercive feeding; highly distractible child; distracting environment; acquired illness; new psychosocial stressor (divorce, job loss, new sibling, death in the family, etc.)

Reproduced from Frank DA, et al., with permission from the authors.

Table 3. Primitive Reflexes

Primitive Reflex	Age at Disappearance (Months)	Description
Palmar grasp	3–4	Pressing against the palmar surface of the infant’s hand results in flexion of all fingers.
Rooting	3–4	Stroking the perioral skin at the corners of the mouth causes the mouth to open and turn to stimulated side.
Galant	2–3	Stroking along the paravertebral area causes lateral flexion of the trunk with the concavity toward the stimulated side.
Moro	4–6	Sudden movement of the head causes symmetric abduction and extension of the arms followed by gradual adduction and flexion of the arms over the body.
Asymmetric tonic neck	4–6	Turning the head to 1 side leads to extension of extremities on that side and flexion on the contralateral side. This puts the infant in the fencing position.
Tonic labyrinthine	2–3	In supine neck extension leads to shoulder retraction and trunk and lower extremity extension. This is reduced by neck flexion.
Positive support	2–3	Stimulation of the ball of the foot leads to co-contraction of opposing muscle groups, allowing weight to be borne.
Placing/Stepping	Variable	When the dorsal surface of one foot touches the underside of a table, the infant places the foot on the table top.

Table 4. Penile and Clitoral Length in the Newborn Infant

Gestational Age	Length (Mean ± SD) (cm)
Male Measure from pubic ramus to the tip of the glans with gentle traction applied. ^a	
30 wk	2.5 ± 0.4
34 wk	3.0 ± 0.4
Term	3.5 ± 0.4
Female Measure with labia majora separated and the prepuce skin retracted. ^b	
Term infants	4.0 ± 1.24
Preterm infants—The clitoris achieves full size by 24 wk gestation and may appear more prominent relative to the labia in premature infants.	

^aFeldman KW, Smith DW. Fetal phallic growth and penile standards for newborn male infants. *J Pediatr.* 1975;86:395.

^bOberfield S, Mondok A, Shanrivar F, et al. Clitoral size in full-term infants. *Am J Perinatol.* 1989;6(4):453.

Table 5. Tanner Stages in the Female

Stage	Breast	Pubic Hair
1	Prepubertal, elevation of papilla only	Prepubertal
2	Enlargement of areola, elevation of breast and papilla (“breast bud”)	Sparse, long, straight, slightly pigmented hair along labia
3	Further enlargement of breast and areola with no separation of contour	Hair is darker, curlier, and coarser with increased distribution on pubes
4	Areola and papilla form a second mound above the breast	Adult-type hair limited to pubes with no extension to medial thigh
5	Mature breast	Mature distribution of inverse triangle with spread to medial thighs

Table 6. Tanner Stages in the Male

Stage	Genital Development	Pubic Hair
1	Prepubertal	Prepubertal
2	Enlargement of testes (>4 mL volume) and scrotum with reddening of scrotal skin	Sparse, long, straight, slightly pigmented hair at base of penis
3	Growth of penis, primarily length, with further increase in size of testes and scrotum	Hair is darker and curlier with increased distribution on pubes
4	Further increase in length and breadth of penis with development of glans, increase in testes and scrotum	Adult-type hair limited to pubes with no extension to medial thigh
5	Adult size and shape	Mature distribution with spread to medial thighs and lower abdomen

Table 7. Normal Growth Rates

Age	Expected Growth Rate
1st year	25 cm (10 inches)/y
2nd year	12.5 cm (5 inches)/y
Childhood	6.25 cm (2.5 inches)/y
Adolescence, boys	15–38 cm (6–15 inches)
Adolescence, girls	15–25 cm (6–12 inches)

Table 8. Head Growth Velocity

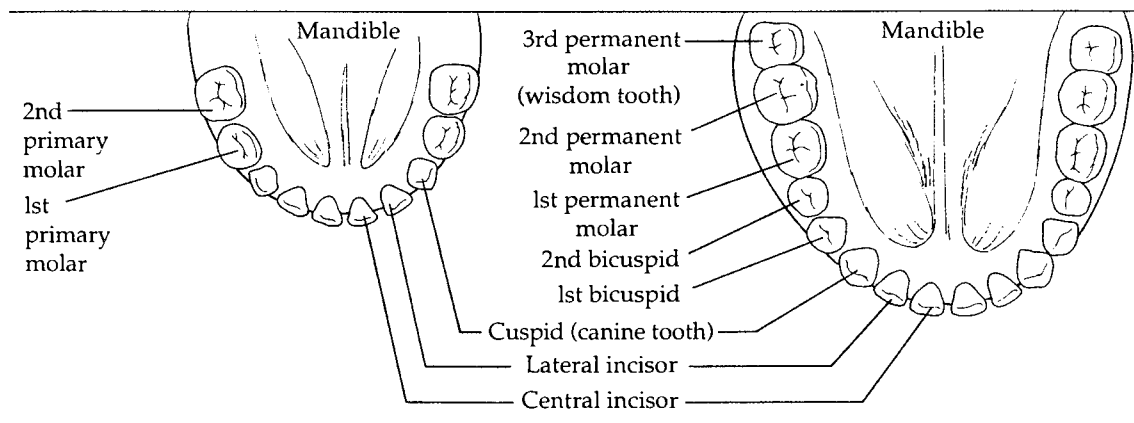

Full-term		Preterm	
2 cm/mo	0–3 months	1 cm/wk	0–2 months
1 cm/mo	3–6 months	0.5 cm/wk	2–4 months
0.5 cm/mo	7–12 months	See full-term	>4 months

Varicella ⁸							Varicella					Varicella
Hepatitis A ⁹							HepA (2 doses)					HepA Series
Meningococcal ¹⁰												MPSV4

Range of recommended ages

Catch-up immunization

Certain high-risk groups

This schedule indicates the recommended ages for routine administration of currently licensed childhood vaccines, as of December 1, 2006, for children aged 0–6 years. Additional information is available at <http://www.cdc.gov/nip/recs/child-schedule.htm>. Any dose not administered at the recommended age should be administered at any subsequent visit, when indicated and feasible. Additional vaccines may be licensed and recommended during the year. Licensed combination vaccines may be used whenever any components of the combination are indicated and

other components of the vaccine are not contraindicated and if approved by the Food and Drug Administration for that dose of the series. Providers should consult the respective Advisory Committee on Immunization Practices statement for detailed recommendations. Clinically significant adverse events that follow immunization should be reported to the Vaccine Adverse Event Reporting System (VAERS). Guidance about how to obtain and complete a VAERS form is available at <http://www.vaers.hhs.gov> or by telephone, 800 822 7967.

1. Hepatitis B vaccine (HepB). (Minimum age: birth)

At birth:

- Administer monovalent HepB to all newborns before hospital discharge.
- If mother is hepatitis surface antigen (HBsAg)-positive, administer HepB and 0.5 mL of hepatitis B immune globulin (HBIG) within 12 hours of birth.
- If mother's HBsAg status is unknown, administer HepB within 12 hours of birth. Determine the HBsAg status as soon as possible and if HBsAg-positive, administer HBIG (no later than age 1 week).
- If mother is HBsAg-negative, the birth dose can only be delayed with physician's order and mother's negative HBsAg laboratory report documented in the infant's medical record.

After the birth dose:

- The HepB series should be completed with either monovalent HepB or a combination vaccine containing HepB. The second dose should be administered at age 1–2 months. The final dose should be administered at age ≥24 weeks. Infants born to HBsAg-positive mothers should be tested for HBsAg and antibody to HBsAg after completion of ≥3 doses of a licensed HepB series, at age 9–18 months (generally at the next well-child visit).

4-month dose:

- It is permissible to administer 4 doses of HepB when combination vaccines are administered after the birth dose. If monovalent HepB is used for doses after the birth dose, a dose at age 4 months is not needed.

2. Rotavirus vaccine (Rota). (Minimum age: 6 weeks)

- Administer the first dose at age 6–12 weeks. Do not start the series later than age 12 weeks.
- Administer the final dose in the series by age 32 weeks. Do not administer a dose later than age 32 weeks.
- Data on safety and efficacy outside of these age ranges are insufficient.

3. Diphtheria and tetanus toxoids and acellular pertussis vaccine (DTaP). (Minimum age: 6 weeks)

- The fourth dose of DTaP may be administered as early as age 12 months, provided 6 months have elapsed since the third dose.
- Administer the final dose in the series at age 4–6 years.

4. *Haemophilus influenzae* type b conjugate vaccine (Hib). (Minimum age: 6 weeks)

- If PRP-OMP (PedvaxHIB® or ComVax® [Merck]) is administered at ages 2 and 4 months, a dose at age 6 months is not required.
- TriHibit® (DTaP/Hib) combination products should not be used for primary immunization but can be used as boosters following any Hib vaccine in children aged ≥12 months.

5. Pneumococcal vaccine. (Minimum age: 6 weeks for pneumococcal conjugate vaccine [PCV]; 2 years for pneumococcal polysaccharide vaccine [PPV])

- Administer PCV at ages 24–59 months in certain high-risk groups.
- Administer PPV to children aged ≥2 years in certain high-risk groups. See *MMWR* 2000;49(No. RR-9):1–35.

6. Influenza vaccine. (Minimum age: 6 months for trivalent inactivated influenza vaccine [TIV]; 5 years for live, attenuated influenza vaccine [LAIV])

- All children aged 6–59 months and close contacts of all children aged 0–59 months are recommended to receive influenza vaccine.
- Influenza vaccine is recommended annually for children aged ≥59 months with certain risk factors, health-care workers, and other persons (including household members) in close contact with persons in groups at high risk. See *MMWR* 2006;55(No. RR-10):1–41.
- For healthy persons aged 5–49 years, LAIV may be used as an alternative to TIV.
- Children receiving TIV should receive 0.25 mL if aged 6–35 months or 0.5 mL if aged ≥3 years.
- Children aged <9 years who are receiving influenza vaccine for the first time should receive 2 doses (separated by ≥4 weeks for TIV and ≥6 weeks for LAIV).

7. Measles mumps and rubella vaccine (MMR). (Minimum age: 12 months)

- Administer the second dose of MMR at age 4–6 years. MMR may be administered before age 4–6 years, provided ≥4 weeks have elapsed since the first dose and both doses are administered at age ≥12 months.

8. Varicella vaccine. (Minimum age: 12 months)

- Administer the second dose of varicella vaccine at age 4–6 years. Varicella vaccine may be administered before age 4–6 years, provided that ≥3 months have elapsed since the first dose and both doses are administered at age ≥12 months. If second dose was administered ≥28 days following the first dose, the second dose does not need to be repeated.

9. Hepatitis A vaccine (HepA). (Minimum age: 12 months)

- HepA is recommended for all children aged 1 year (i.e., aged 12–23 months). The 2 doses in the series should be administered at least 6 months apart.
- Children not fully vaccinated by age 2 years can be vaccinated at subsequent visits.
- HepA is recommended for certain other groups of children, including in areas where vaccination programs target older children. See *MMWR* 2006;55(No. RR-7):1–23.

10. Meningococcal polysaccharide vaccine (MPSV4). (Minimum age: 2 years)

- Administer MPSV4 to children aged 2–10 years with terminal complement deficiencies or anatomic or functional asplenia and certain other high-risk groups. See *MMWR* 2005;54(No. RR-7):1–21.

The Recommended Immunization Schedules for Persons Aged 0–18 Years are approved by the Advisory Committee on Immunization Practices (<http://www.cdc.gov/nip/acip>), the American Academy of Pediatrics (<http://www.aap.org>), and the American Academy of Family Physicians (<http://www.aafp.org>).

Catch-up immunization

Certain high-risk groups

This schedule indicates the recommended ages for routine administration of currently licensed childhood vaccines, as of December 1, 2006, for children aged 7–18 years. Additional information is available at <http://www.cdc.gov/nip/recs/child-schedule.htm>. Any dose not administered at the recommended age should be administered at any subsequent visit, when indicated and feasible. Additional vaccines may be licensed and recommended during the year. Licensed combination vaccines may be used whenever any components of the combination are indicated and other components

of the vaccine are not contraindicated and if approved by the Food and Drug Administration for that dose of the series. Providers should consult the respective Advisory Committee on Immunization Practices statement for detailed recommendations. Clinically significant adverse events that follow immunization should be reported to the Vaccine Adverse Event Reporting System (VAERS). Guidance on how to obtain and complete a VAERS form is available at <http://www.vaers.hhs.gov> or by telephone, 800-822-7967.

- 1. Tetanus and diphtheria toxoids and acellular pertussis vaccine (Tdap).** (Minimum age: 10 years for BOOSTRIX[®] and 11 years for ADACEL[™])
 - Administer at age 11–12 years for those who have completed the recommended childhood DTP/DTaP vaccination series and have not received a tetanus and diphtheria toxoids vaccine (Td) booster dose.
 - Adolescents aged 13–18 years who missed the 11–12 year Td/Tdap booster dose should also receive a single dose of Tdap if they have completed the recommended childhood DTP/DTaP vaccination series.
- 2. Human papillomavirus vaccine (HPV).** (Minimum age: 9 years)
 - Administer the first dose of the HPV vaccine series to females at age 11–12 years.
 - Administer the second dose 2 months after the first dose and the third dose 6 months after the first dose.
 - Administer the HPV vaccine series to females at age 13–18 years if not previously vaccinated.
- 3. Meningococcal vaccine.** (Minimum age: 11 years for meningococcal conjugate vaccine [MCV4]; 2 years for meningococcal polysaccharide vaccine [MPSV4])
 - Administer MCV4 at age 11–12 years and to previously unvaccinated adolescents at high school entry (at approximately age 15 years).
 - Administer MCV4 to previously unvaccinated college freshmen living in dormitories; MPSV4 is an acceptable alternative.
 - Vaccination against invasive meningococcal disease is recommended for children and adolescents aged ≥2 years with terminal complement deficiencies or anatomic or functional asplenia and certain other high-risk groups. See *MMWR* 2005;54(No. RR-7):1–21. Use MPSV4 for children aged 2–10 years and MCV4 or MPSV4 for older children.
- 4. Pneumococcal polysaccharide vaccine (PPV).** (Minimum age: 2 years)
 - Administer for certain high-risk groups. See *MMWR* 1997;46(No. RR-8):1–24, and *MMWR* 2000;49(No. RR-9):1–35.

- 5. Influenza vaccine.** (Minimum age: 6 months for trivalent inactivated influenza vaccine [TIV]; 5 years for live, attenuated influenza vaccine [LAIV])
 - Influenza vaccine is recommended annually for persons with certain risk factors, health-care workers, and other persons (including household members) in close contact with persons in groups at high risk. See *MMWR* 2006;55 (No. RR-10):1–41.
 - For healthy persons aged 5–49 years, LAIV may be used as an alternative to TIV.
 - Children aged <9 years who are receiving influenza vaccine for the first time should receive 2 doses (separated by ≥4 weeks for TIV and ≥6 weeks for LAIV).
- 6. Hepatitis A vaccine (HepA).** (Minimum age: 12 months)
 - The 2 doses in the series should be administered at least 6 months apart.
 - HepA is recommended for certain other groups of children, including in areas where vaccination programs target older children. See *MMWR* 2006;55 (No. RR-7):1–23.
- 7. Hepatitis B vaccine (HepB).** (Minimum age: birth)
 - Administer the 3-dose series to those who were not previously vaccinated.
 - A 2-dose series of Recombivax H is licensed for children aged 11–15 years.
- 8. Inactivated poliovirus vaccine (IPV).** (Minimum age: 6 weeks)
 - For children who received an all-IPV or all-oral poliovirus (OPV) series, a fourth dose is not necessary if the third dose was administered at age ≥4 years.
 - If both OPV and IPV were administered as part of a series, a total of 4 doses should be administered, regardless of the child's current age.
- 9. Measles, mumps, and rubella vaccine (MMR).** (Minimum age: 12 months)
 - If not previously vaccinated, administer 2 doses of MMR during any visit, with ≥4 weeks between the doses.
- 10. Varicella vaccine.** (Minimum age: 12 months)
 - Administer 2 doses of varicella vaccine to persons without evidence of immunity.
 - Administer 2 doses of varicella vaccine to persons aged 13 years at least 3 months apart. Do not repeat the second dose, if administered ≥28 days after the first dose.
 - Administer 2 doses of varicella vaccine to persons aged ≥13 years at least 4 weeks apart.

The Recommended Immunization Schedules for Persons Aged 0–18 Years are approved by the Advisory Committee on Immunization Practices (<http://www.cdc.gov/nip/acip>), the American Academy of Pediatrics (<http://www.aap.org>), and the American Academy of Family Physicians (<http://www.aafp.org>).
SAFER • HEALTHIER • PEOPLE[™]

Table 12. (continued)

Catch-up Immunization Schedule UNITED STATES • 2007

for Persons Aged 4 Months–18 Years Who Start Late or Who Are More Than 1 Month Behind

The table below provides catch-up schedules and minimum intervals between doses for children whose vaccinations have been delayed. A vaccine series does not need to be restarted, regardless of the time that has elapsed between doses. Use the section appropriate for the child's age.

CATCH-UP SCHEDULE FOR PERSONS AGED 4 MONTHS–6 YEARS					
Vaccine	Minimum Age for Dose 1	Minimum Interval Between Doses			
		Dose 1 to Dose 2	Dose 2 to Dose 3	Dose 3 to Dose 4	Dose 4 to Dose 5
Hepatitis B ¹	Birth	4 weeks	8 weeks (and 16 weeks after first dose)		
Rotavirus ²	6 wks	4 weeks	4 weeks		
Diphtheria, Tetanus, Pertussis ³	6 wks	4 weeks	4 weeks	6 months	6 months ³
<i>Haemophilus influenzae</i> type b ⁴	6 wks	4 weeks if first dose administered at age <12 months 8 weeks (as final dose) if first dose administered at age 12–14 months No further doses needed if first dose administered at age ≥15 months	4 weeks ⁴ if current age <12 months 8 weeks (as final dose) ⁴ if current age ≥12 months and second dose administered at age <15 months No further doses needed if previous dose administered at age ≥15 months	8 weeks (as final dose) This dose only necessary for children aged 12 months–5 years who received 3 doses before age 12 months	
Pneumococcal ⁵	6 wks	4 weeks if first dose administered at age <12 months and current age <24 months 8 weeks (as final dose) if first dose administered at age ≥12 months or current age 24–59 months No further doses needed for healthy children if first dose administered at age ≥24 months	4 weeks if current age <12 months 8 weeks (as final dose) if current age ≥12 months No further doses needed for healthy children if previous dose administered at age ≥24 months	8 weeks (as final dose) This dose only necessary for children aged 12 months–5 years who received 3 doses before age 12 months	
Inactivated Poliovirus ⁶	6 wks	4 weeks	4 weeks	4 weeks ^a	
Measles, Mumps, Rubella ⁷	12 mos	4 weeks			
Varicella ⁸	12 mos	3 months			
Hepatitis A	12 mos	6 months			
CATCH-UP SCHEDULE FOR PERSONS AGED 7–18 YEARS					
Tetanus, Diphtheria/ Tetanus, Diphtheria, Pertussis ^{3a}	7 yrs ¹⁰	4 weeks	8 weeks if first dose administered at age <12 months 6 months if first dose administered at age ≥12 months	6 months if first dose administered at age <12 months	
Human Papillomavirus ¹¹	9 yrs	4 weeks	12 weeks		
Hepatitis A	12 mos	6 months			
Hepatitis B ¹	Birth	4 weeks	8 weeks (and 16 weeks after first dose)		
Inactivated Poliovirus ⁶	6 wks	4 weeks	4 weeks	4 weeks ^a	
Measles, Mumps, Rubella ⁷	12 mos	4 weeks			
Varicella ⁸	12 mos	4 weeks if first dose administered at age ≥13 years 3 months if first dose administered at age <13 years			

1. **Hepatitis B vaccine (HepB).** (Minimum age: birth)
 - Administer the 3-dose series to those who were not previously vaccinated.
 - A 2-dose series of Recombivax HB[®] is licensed for children aged 11–15 years.
2. **Rotavirus vaccine (Rota).** (Minimum age: 6 weeks)
 - Do not start the series later than age 12 weeks.
 - Administer the final dose in the series by age 32 weeks. Do not administer a dose later than age 32 weeks.
 - Data on safety and efficacy outside of these age ranges are insufficient.
3. **Diphtheria and tetanus toxoids and acellular pertussis vaccine (DTaP).** (Minimum age: 6 weeks)
 - The fifth dose is not necessary if the fourth dose was administered at age ≥4 years.
 - DTaP is not indicated for persons aged ≥7 years.
4. **Haemophilus influenzae type b conjugate vaccine (Hib).** (Minimum age: 6 weeks)
 - vaccine is not generally recommended for children aged ≥5 years.
 - If current age <12 months and the first 2 doses were PRP-P (PedvaxHIB[™]) or Com 6x[™] (Perck), the third (and final) dose should be administered at age 12–15 months and at least 8 weeks after the second dose.
 - If first dose was administered at age 7–11 months, administer 2 doses separated by 4 weeks plus a booster at age 12–15 months.
5. **Pneumococcal conjugate vaccine (PCV).** (Minimum age: 6 weeks)
 - vaccine is not generally recommended for children aged ≥5 years.
6. **Inactivated poliovirus vaccine (IPV).** (Minimum age: 6 weeks)
 - or children who received an all-IPV or all-oral poliovirus (OPV) series, a fourth dose is not necessary if third dose was administered at age ≥4 years.
 - If both IPV and OPV were administered as part of a series, a total of 4 doses should be administered, regardless of the child's current age.
7. **Measles, mumps, and rubella vaccine (MMR).** (Minimum age: 12 months)
 - The second dose of MMR is recommended routinely at age 4–6 years but may be administered earlier if desired.
 - If not previously vaccinated, administer 2 doses of MMR during any visit with ≥4 weeks between the doses.
8. **Varicella vaccine.** (Minimum age: 12 months)
 - The second dose of varicella vaccine is recommended routinely at age 4–6 years but may be administered earlier if desired.
 - Do not repeat the second dose in persons aged ≥13 years if administered ≥28 days after the first dose.
9. **Hepatitis A vaccine (HepA).** (Minimum age: 12 months)
 - HepA is recommended for certain groups of children, including in areas where vaccination programs target older children. See *MMWR* 2006 55(No. RR-7) 1–23.
10. **Tetanus and diphtheria toxoids and acellular pertussis vaccine (Tdap).** (Minimum ages: 7 years for Td, 10 years for BOOSTRIX[®], and 11 years for ADACEL¹)
 - Tdap should be substituted for a single dose of Td in the primary catch-up series or as a booster if age appropriate. Use Td for other doses.
 - A 5-year interval from the last Td dose is encouraged when Tdap is used as a booster dose. A booster (fourth) dose is needed if any of the previous doses were administered at age 12 months. Refer to ACIP recommendations for further information. See *MMWR* 2006 55(No. RR-3).
11. **Human papillomavirus vaccine (HPV).** (Minimum age: 9 years)
 - Administer the HPV vaccine series to females at age 13–18 years if not previously vaccinated.

Information about reporting reactions after immunization is available online at <http://www.vaers.hhs.gov> or by telephone via the 24-hour national toll-free information line 800-822-7967. Suspected cases of vaccine-preventable diseases should be reported to the state or local health department. Additional information, including precautions and contraindications for immunization, is available from the National Center for Immunization and Respiratory Diseases at <http://www.cdc.gov/nip/default.htm> or telephone, 800-CDC-INFO (800-232-4636).

Table 13. Recommendations for Routine Immunization of HIV-Infected Children in the United States

Vaccine	Known Asymptomatic HIV Infection	Symptomatic HIV Infection
Hepatitis B	Yes	Yes
DTaP (or DTP)	Yes	Yes
IPV ^a	Yes	Yes
MMR	Yes	Yes ^b
Hib	Yes	Yes
Pneumococcal ^c	Yes	Yes
Influenza ^d	Yes	Yes
Varicella ^e	No	No

Adapted from the American Academy of Pediatrics. In Peter G, ed. 1997 Red Book: Report of the Committee on Infectious Diseases, 24th ed. Elk Grove Village, IL: American Academy of Pediatrics, 1997.

DTP, diphtheria and tetanus toxoids and pertussis vaccine; DTaP, diphtheria and tetanus toxoids acellular pertussis vaccine; IPV, inactivated poliovirus vaccine; MMR, live-virus measles, mumps, and rubella; Hib, *Haemophilus influenzae* type b conjugate.

^a Only inactivated polio vaccine (IPV) should be used for HIV-infected children, HIV-exposed infants whose status is indeterminate, and household contacts of HIV-infected patients.

^b Severely immunocompromised HIV-infected children should not receive MMR vaccine.

^c Pneumococcal vaccine should be administered at 2 years of age to all HIV-infected children.

Children who are older than 2 years of age should receive pneumococcal vaccine at the time of diagnosis. Revaccination after 3 to 5 years is recommended in either circumstance.

^d Influenza vaccine should be provided each fall and repeated annually for HIV-exposed infants 6 months of age and older, HIV-infected children and adolescents, and for household contacts of HIV-infected patients.

^e Varicella vaccine is not currently indicated for HIV-exposed or HIV-infected patients, but studies are in progress to determine safety and possible indication.

Table 14. Guide to Tetanus Prophylaxis in Routine Wound Management

History of Absorbed Tetanus Toxoid (Doses)	Clean, Minor Wounds		All Other Wounds ^a	
	TD ^b	TIG ^c	TD ^b	TIG ^c
Unknown or <3	Yes	No	Yes	Yes
≥3 ^d	No ^e	No	No ^f	No

Adapted from the American Academy of Pediatrics. In Peter G, ed. 1997 Red Book: Report of the Committee on Infectious Diseases, 24th ed. Elk Grove Village, IL: American Academy of Pediatrics, 1997.

Td, adult-use tetanus and diphtheria toxoids; TIG, tetanus immune globulin (human).

^a Such as, but not limited to, wounds contaminated with dirt, feces, soil, or saliva; puncture wounds; avulsions; and wounds resulting from missiles, crushing, burns, or frostbite.

^b For children <7 years, diphtheria and tetanus toxoids and acellular pertussis (DTaP) or diphtheria-tetanus-pertussis (DTP) is recommended; if pertussis vaccine is contraindicated, diphtheria-tetanus toxoid (DT) is given. For persons ≥7 years of age, Td is recommended.

^c Equine tetanus antitoxin should be used when TIG is not available.

^d If only 3 doses of fluid toxoid have been received, a fourth dose of toxoid, preferably an adsorbed toxoid, should be given.

^e Yes, if more than 10 years since the last dose.

^f Yes, if more than 5 years since the last dose. (More frequent boosters are not needed and can accentuate side effects.)

Table 15. Suggested Intervals Between Immunoglobulin Administration and Measles Vaccination (MMR or Monovalent Measles Vaccine)

Indication for Immunoglobulin	Preparation	Route	Dose		Interval (Months) ^a
			U or mL	mg IgG/kg	
Tetanus	TIG	IM	250 U	10	3
Hepatitis A prophylaxis	IG				
Contact prophylaxis		IM	0.02 mL/kg	3.3	3
International travel		IM	0.06 mL/kg	10	3
Hepatitis B prophylaxis	HBIG	IM	0.06 mL/kg	10	3
Rabies prophylaxis	RIG	IM	20 IU/kg	22	4
Measles prophylaxis	IG				
Standard		IM	0.25 mL/kg	40	5
Immunocompromised host		IM	0.50 mL/kg	80	6
Varicella prophylaxis	VZIG	IM	125 U/10 kg (maximum, 625 U)	20–39	5
Blood transfusion					
Washed RBCs		IV	10 mL/kg	Negligible	0
RBCs, adenine-saline added		IV	10 mL/kg	10	3
Packed RBCs		IV	10 mL/kg	20–60	5
Whole blood		IV	10 mL/kg	80–100	6
Plasma or platelet products		IV	10 mL/kg	160	7
Replacement (or therapy) of immune deficiencies	IGIV	IV	...	300–400	8
ITP	IGIV	IV	...	400	8
RSV	IGIV	IV	...	750	9
ITP		IV	...	1,000	10
ITP or Kawasaki disease		IV	...	1,600–2,000	11

Adapted from the American Academy of Pediatrics. In: Peter G, ed. 1997 Red Book: Report of the Committee on Infectious Diseases. 24th ed. Elk Grove Village, IL: American Academy of Pediatrics, 1997.

IG, immune globulin; IGIV, intravenous immune globulin; IM, intramuscular; ITP, immune (idiopathic) thrombocytopenic purpura; IV, intravenous; HBIG, hepatitis B immune globulin; MMR, measles-mumps-rubella vaccine; RBCs, red blood cells; RIG, rabies immune globulin; RSV-IGIV, respiratory syncytial virus intravenous immune globulin; TIG, tetanus immune globulin; VZIG, varicella-zoster immune globulin.

^a These intervals should provide sufficient time for decreases in passive antibodies in all children to allow for an adequate response to the measles vaccine. Physicians should not assume that children are fully protected against measles during these intervals. Additional doses of IG or measles vaccine may be indicated after exposure to measles.

FEEDING AND NUTRITION

Table 16. Maternal Drug Use During Lactation

CHO, carbohydrate; CF, cystic fibrosis; FE, iron; LCT, long-chain triglyceride; MCT, medium-chain triglyceride; PRO, protein.

^a Also available as 24 kcal/oz and 27 kcal/oz.

^b Formula with a low renal solute load.

^c Also available as 24 kcal/oz.

^d Also available as 20 kcal/oz.

^e Available only as ready-to-feed.

^f Indications for Special Formulas

Name	Indications
Nutramigen	Cow's milk allergy, severe or multiple food allergies, severe or persistent diarrhea, galactosemia
Pregestimil	Malabsorption, intestinal resection, severe or persistent diarrhea, food allergies
Portagen	Steatorrhea secondary to CF, intestinal resections, pancreatic insufficiency, biliary atresia, lymphatic anomalies, celiac disease
Alimentum	Problems with digestion or absorption, severe or prolonged diarrhea, CF, steatorrhea, food allergies, intestinal resection
Lactofree	Lactose intolerance <i>without</i> cow's milk protein intolerance
Neocate	Cow's milk allergy, soy and protein hydrolysate intolerance, multiple food protein intolerance

SYNDROME AND OBESITY

Table 19. Uncommon Disorders Associated with Obesity

Alström-Hallgren syndrome. Autosomal-recessive trait, obesity, retinal degeneration with blindness in childhood, sensory nerve deafness, diabetes mellitus, small testes in males, and progressive nephropathy in adults.

Carpenter syndrome. Obesity; brachycephaly with craniosynostosis; peculiar facies with lateral displacement of inner canthi and apparent exophthalmos, flat nasal bridge, low-set ears, retrognathism, and high-arched palate; brachydactyly of hands with clinodactyly and partial syndactyly; preaxial polydactyly of feet with partial syndactyly; and mental retardation.

Cohen syndrome. Mild—childhood onset, truncal obesity, persistent hypotonia and muscle weakness, mild mental retardation, characteristic craniofacies with high nasal bridge, maxillary hypoplasia with mild downslant to palpebral fissures, high arched palate, short philtrum, small jaw, open mouth and prominent maxillary central incisors, mottled retina, myopia, strabismus, narrow hands and feet with shortening of metacarpals and metatarsals, simian crease, hyperextensible joints, lumbar lordosis, and mild scoliosis.

Cushing syndrome. Truncal obesity, hypertension, glucose intolerance, hirsutism, oligomenorrhea or amenorrhea, plethora, moon facies, buffalo hump, striae, ecchymoses, increased fatigability and weakness, and personality changes.

Growth hormone deficiency. Short stature, mild-to-moderate obesity.

Hyperinsulinemia. (From an insulin-secreting pancreatic tumor, hypersecretion by pancreatic beta cells or a hypothalamic lesion) Progressive obesity with hyperphagia, normal or excessive growth in stature, and signs and symptoms of hypoglycemia.

Hypothalamic dysfunction. (Due to tumor, trauma, or inflammation) Hyperinsulinemia and hyperphagia may be accompanied by headache, papilledema, impaired vision, amenorrhea or impotence, diabetes insipidus, hypothyroidism, adrenal insufficiency, somnolence, temperature dysregulation, seizures, and coma.

Hypothyroidism. Short stature; delayed sexual maturation; delayed union of epiphyses; lethargy; cold intolerance; hoarse voice; menorrhagia; decreased appetite; dry skin; aching muscles and delayed relaxation phase of deep tendon reflexes; progression to dull expressionless face; sparse hair; periorbital puffiness; large tongue; pale, cool, rough-feeling skin; and presence or absence of goiter.

Laurence-Moon-Biedl (Bardet-Biedl) syndrome. Autosomal-recessive trait, truncal obesity, retinal dystrophy/retinitis pigmentosa with progressively decreasing acuity, mental retardation, hypogenitalism, digital anomalies (polydactyly, syndactyly, or both), and nephropathy.

Polycystic ovary (Stein-Leventhal) syndrome. Irregular or absent menses, moderate hirsutism, weight gain shortly after menarche, increased ratio of luteinizing hormone to follicle-stimulating hormone, hyperandrogenemia, and increased levels of estrone with normal levels of estradiol. May occur in association with congenital adrenal hyperplasia, Cushing syndrome, hyperprolactinemia, or insulin resistance.

Prader-Willi syndrome. Obesity, hypotonia, and feeding problems in infancy; hyperphagia in childhood and adolescence; developmental delay; mental retardation; hypogonadism; short stature; small hands and feet; and strabismus.

Pseudohypoparathyroidism (type I). Short stature, round facies, short metatarsals and metacarpals, subcutaneous calcifications, moderate mental retardation, cataracts, coarse and dry skin, brittle hair and nails, hypocalcemia, and hyperphosphatemia.

Turner syndrome. Short stature, tendency to obesity, ovarian dysgenesis, broad chest with widely spaced nipples, prominent ears, narrow maxilla and small mandible, low posterior hairline, webbed posterior neck, elbow and knee anomalies, nail and skin anomalies, renal anomalies, and hearing impairment.

From Online Mendelian Inheritance in Man.

Adapted from the National Academy of Sciences-National Research Council.

^a The allowances, expressed as average daily intakes over time, are intended to provide for individual variations among most normal persons as they live in the United States under usual environmental stresses. Diets should be based on a variety of common foods to provide other nutrients for which human requirements have been less well defined.

^b The median weights and heights of those younger than 19 years were taken from Hamill PVJ, et al. Physical growth: National Center for Health Statistics percentiles. *Am J Clin Nutr.* 1979;32:607–629. The use of these figures does not imply that the height-to-weight ratios are ideal.

^c RE, retinol equivalent. 1 RE = 1 mcg retinol or 6 mcg beta-carotene.

^d As cholecalciferol. 10 mcg cholecalciferol = 400 IU of vitamin D.

^e TE, alpha-tocopherol equivalents. 1 TE = 1 mg d-alpha-tocopherol.

^f NE, niacin equivalent. 1 NE = 1 mg of niacin or 60 mg of dietary tryptophan.

Table 21. Patient Teaching for Feeding Disorder

General Feeding Guidelines

The Importance of Role Modeling:

- Eat with your child. Young children eat better when adults are around!
- Eat a variety of fruits and vegetables.
- Use the food pyramid as a guide.

Establish a Consistent Mealtime Routine:

- Offer 3 meals and 2–3 snacks per day to help them develop a regular hunger-satiety schedule.
- Have children sit at the table for all meals; this will give them a signal that it is time to eat.
- Avoid asking children to eat, as this gives them the opportunity to refuse. Instead, use directives such as “Take a bite,” or “It’s time to pick up your spoon.”
- Limit distractions during meals to help children focus on eating during mealtimes.
- Limit meal length to ~30 minutes.
- At the end of all meals, teach children to take “1 last bite” to signal the end of the meal. This can be a symbolic “last bite” where a spoon is gently touched to the child’s lips.
- Once children have taken their “last bite,” be sure to praise them to end the meal on a positive note.

Common Mealtime Concerns and Coping Strategies

Tantrums:

- Focus attention on children’s appropriate mealtime behaviors.
- Cheer for children when they take a bite of food or show other appropriate mealtime behaviors. Be specific when praising them (e.g., “Great job taking your bite!” or “I like how you’re picking up your spoon”).
- Ignore refusal behaviors such as crying or throwing food off the table. Avoid responding or reacting to these behaviors. Instead, look away for ~20 seconds, and then remind them that it is time to take another bite. If the child throws food, wait until the end of the meal and have the child help pick up the food they have thrown.

Picky Eater:

- Children need to practice trying new food. It may take 10–15 trials of a new food before a child will learn to like the food.
- Have your child take “1 bite” of a new food at the end of 1 meal each day. Offer the same food every day for 1 week.
- Praise your child when he tastes new foods.

(continued)

Table 21. Patient Teaching for Feeding Disorder (continued)

Common Mealtime Concerns and Coping Strategies (continued)

The Grazer:

- Avoid allowing children to “graze” on small amounts of food and fluid throughout the day. These children do not feel hungry at mealtimes because they snack all day.
- Children who “graze” eat less (fewer calories) than children who have a consistent mealtime.
- Offer 3 meals and no more than 2–3 snacks each day.
- Remember that a snack can be a “mini meal” of nutrient dense foods and not necessarily “snack food.”
- Restrict all snacks and drinks 30 minutes before and after meals. This way, children will not fill up on fluid just prior to or during the meal. By waiting 30 minutes until after the meal to offer fluid, children will not hold out for something to drink instead of eating.

The Short-Order Cook:

- “Short-order cook” caregivers may be preparing 4–5 meals hoping that their child will eat one of the choices.
 - Offer the child a choice between 2 foods. Offer these choices at the start of the meal.
 - If the child is too young or unable to choose, the caregiver may choose the food.
 - When children refuse to eat, wait until the next meal or snack time to offer more food. This will teach children that they will not get a “better” food by refusing what has been offered.
-

INFECTIOUS DISEASES

Table 22. Risk Factors for Group B Streptococcal Infection

Maternal risk factors

- Prolonged rupture of membranes (>18 hours)*
- Premature rupture of membranes (<37 weeks' gestation)*
- Preterm labor (<37 weeks' gestation)*
- Fever >37.9°C (100.2°F)*
- History of previous infant with GBS sepsis*
- Clinical evidence of chorioamnionitis
- GBS bacteriuria*
- Multiple gestation
- Diabetes

Fetal/Neonatal risk factors

- Prematurity
- Meconium passed in utero
- Low 5-minute Apgar score (<6)
- Male gender (sepsis four times more common in boys than in girls)

GBS, group B streptococci.

*Risk necessitating intrapartum antibiotic administration per 1996 Centers for Disease Control (CDC) guidelines.

Table 23. Signs and Symptoms of Sepsis in the Newborn

Respiratory distress	Tachypnea (respiratory rate >60/min), grunting, nasal flaring, retractions; sometimes present even without an oxygen requirement or abnormal chest x-ray
Temperature instability	Fever >37.9°C or hypothermia
Poor feeding	Lack of interest, abdominal distention, vomiting, diarrhea
Altered neurologic status	Lethargy, irritability, hypotonia, seizures (especially if meningitis is present)
Apnea	Especially in preterm infants
Poor perfusion	Mottled, grayish, capillary refill >3 s
Tachycardia	Often a late sign
Bulging fontanelle	Meningitis

Table 24. Neutrophil Indices

Neutrophil Indices	Normal Values
Absolute neutrophil count (ANC) ^a	> 1,800/mm ³
Absolute band count (ABC) ^b	< 2,000/mm ³
I:T ratio ^c	< 0.2

^aANC = % total neutrophils × WBC count.

^bABC = % bands × WBC count.

^cI:T = % immature (bands, metamyelocytes, myelocytes): % total (immature + segmented) neutrophils.

Table 25. Clinical Features Associated with Congenital Infection

- Intrauterine growth retardation
- Hydrops
- Hepatosplenomegaly
- Microcephaly, intracranial calcifications, hydrocephalus
- Anemia, thrombocytopenia, petechiae
- Jaundice (especially conjugated hyperbilirubinemia)
- Pneumonitis
- Cardiac malformations, myocarditis
- Eye abnormalities (chorioretinitis, cataracts)
- Bone abnormalities (osteochondritis, periostitis)

Table 26. Clinical Findings in Congenitally Infected Infants that Suggest a Specific Diagnosis

Infection	Suggestive Findings
Rubella	Cataracts, cloudy cornea, pigmented retina "Blueberry muffin" syndrome Vertical striation
CMV	Malformation (PDA, pulmonary artery stenosis) Microcephaly with periventricular calcifications Inguinal hernias in boys Petechiae with thrombocytopenia
Toxoplasmosis	Hydrocephalus with generalized calcifications Chorioretinitis
Syphilis	Osteochondritis and periostitis Eczematoid skin rash Mucocutaneous lesions (snuffles)
Herpes	Skin vesicles Keratoconjunctivitis Acute CNS findings

Modified with permission from Stagno S, Pass RF, Alford CA. Perinatal infections and maldevelopment. In: Bloom AD, James LS, eds. *The fetus and the newborn*, vol 17, Series 1. New York: Wiley-Liss, 1981.
CMV, cytomegalovirus; CNS, central nervous system; PDA, patent ductus arteriosus.

Table 27. Interpretation of Epstein-Barr Virus (EBV) Serology^a

	IgG-VCA	IgM-VCA	EBV Nuclear Antigens	EBV Early Antigens
No evidence of infection	<10	<10	<2	<10
Acute infection	>10	≥10	<2	≥20
Convalescent infection	>10	Variable	>2	Variable
Remote past infection	≥10	<10	>2	≤20

^aValues are expressed in reciprocal titers as measured by standard immunofluorescence methods.

Table 28. Croup (Laryngotracheobronchitis)—Severity Score for Croup Patients

Indicator of Severity of Illness	Score
Inspiratory stridor	
None	0
At rest, with stethoscope	1
At rest, without stethoscope	2
Retractions	
None	0
Mild	1
Moderate	2
Severe	3
Air entry	
Normal	0
Decreased	1
Severely decreased	2
Cyanosis	
None	0
With agitation	4
At rest	5
Level of consciousness	
Normal	0
Altered mental status	5
Mild Croup	0–3
Moderate to severe croup	>3

ABDOMINAL PAIN

Table 29. Classic Clinical Findings in Disorders Characterized by Abdominal Pain

Disorder	Typical Clinical Picture	Definitive Diagnostic Test
Peptic ulcer disease	Burning or sharp midepigastric pain that occurs 1–3 hours after meals and is exacerbated by spicy food and relieved by antacids; family history of peptic ulcer disease	Endoscopy
Pancreatitis	Episodic left upper quadrant pain that occurs 5–10 minutes after meals, radiates to the back, and is exacerbated by fatty foods	Pancreatic ultrasound or CT scan Serum amylase level (↑)
Urinary tract infection	Suprapubic pain, burning on urination, urinary frequency, urinary urgency	Urine culture Urinalysis
Renal calculi	Severe periodic cramping pain that occurs in the flank and occasionally radiates to the groin; costovertebral angle tenderness; family history of renal calculi	Urinalysis Renal ultrasound
Periappendiceal abscess	Right lower quadrant pain; rebound and direct tenderness; anorexia and vomiting; fever	Barium enema Laparoscopy WBC count (↑)
Gallbladder disease	Right upper quadrant pain that occurs 5–10 minutes after meals and is exacerbated by fatty foods; family history of gallstones	Gallbladder ultrasound
Menstrual pain	Cramping suprapubic pain that occurs during the menses	Trial with NSAIDs
Pelvic inflammatory disease (PID)	Suprapubic pain	Cervical culture
Functional abdominal pain (irritable bowel syndrome)	Cramping periumbilical pain that is exacerbated by eating and relieved by defecation	Trial with Metamucil
Lactose intolerance	Cramping periumbilical pain that increases following ingestion of dairy products and is accompanied by flatulence and bloating	Trial with a milk-free diet Breath hydrogen study for lactose deficiency
Inflammatory bowel disease	Right lower quadrant cramping and tenderness; anemia; guaiac-positive stool	Colonoscopy Barium enema Upper gastrointestinal series ESR (↑), platelet count (↑), WBC count (↑)
Esophagitis	Epigastric and substernal pain that is relieved by lying down; history of iron deficiency; anemia; guaiac-positive stool	Endoscopy
Lead poisoning	Abdominal pain; history of pica; microcytic anemia; basophilic stippling	Serum lead level
Pancreatic pseudocyst	Left upper quadrant pain; recurrent vomiting; history of abdominal pain	Abdominal ultrasound
Sickle cell disease (SCD)	Periumbilical pain that responds to rest and rehydration	Sickle cell preparation Hemoglobin Electrophoresis
Abdominal epilepsy	Periodic severe abdominal pain that is often associated with seizures	Trial with anticonvulsants
Abdominal migraine	Severe abdominal pain; family history of migraine; recurrent headache, fever, and vomiting; unilateral or occipital headache; somatic complaints	Trial with antimigraine medications
Depression	Social withdrawal; decreased activity; irritability; poor attention span; difficulty sleeping	Trial with antidepressant medications
School avoidance	Nonspecific abdominal pain; severe anxiety reaction; pain that is more severe on weekdays and improves on weekends	

Modified with permission from Olson AD. Abdominal pain. In: Stockman JA, ed. *Difficult diagnosis in pediatrics*. Philadelphia: WB Saunders, 1990; p. 253. ESR, erythrocyte sedimentation rate; NSAIDs, nonsteroidal antiinflammatory drugs; WBC, white blood cell; ↑, increased.

Table 30. Abdominal Masses Commonly Associated with Calcification

Neuroblastoma
Teratoma
Ovarian
Sacrococcygeal
Adrenal hematoma
Hepatic hemangioma
Meconium peritonitis

Table 31. Comparison of Functional Constipation and Hirschsprung Disease

	Functional Constipation	Hirschsprung Disease
Symptoms as a newborn	Rare	Almost always
Late onset (after 3 years)	Common	Rare
Difficult bowel training	Common	Rare
Stool size	Large	Small, ribbonlike
Urge to defecate	Rare	Common
Obstructive symptoms	Rare	Common
Enterocolitis	Rare	Sometimes
Failure to thrive	Rare	Common
Abdominal distention	Rare	Common
Stool in rectal ampulla	Common	None
Barium enema	Copious stool No transition zone	Delayed evacuation Transition zone
Rectal biopsy	Normal	No ganglion cells Increased anticholinesterase staining
Anorectal manometry	Distension of rectum causes relaxation of the internal sphincter	No sphincter relaxation

Table 32. Commonly Used Pediatric Medications that May Cause Cholestasis and Hepatotoxicity

Anticonvulsants	Immunosuppressants
Phenobarbital	Cyclosporine
Diphenylhydantoin	Azathioprine
Carbamazepine	Methotrexate
Valproic acid	Steroids
Antimicrobials	Corticosteroids
Tetracycline	Androgens
Erythromycin (estolate preparations)	Oral contraceptives
Sulfonamides	Miscellaneous drugs
Ketoconazole	Acetaminophen
Isoniazid	Salicylates
Rifampin	Chlorpromazine
Griseofulvin	Cimetidine
	Iron preparations (with overdosage)

Table 33. Defects in Hepatic Bilirubin Conjugation

Disease	Defect	Genetics
Gilbert disease	Underactivity of the transferase, defective uptake of albumin-bound bilirubin from the plasma	Autosomal-recessive
Crigler-Najjar syndrome		
Type I	Complete absence of the transferase enzyme	Autosomal-recessive
Type II	Partial absence of the transferase enzyme (less severe than type I)	Autosomal-dominant

A large number of less commonly encountered agents, including antineoplastic agents, antidepressants, antipsychotics, and tranquilizers can also cause cholestasis and hepatotoxicity.

Table 34. Foods and Drugs Mimicking Blood in the Stool

False Hematochezia	False Melena	False Heme-positive Stools
Foods that contain	Spinach	Red meat
Red dye	Blueberries	Cherries
Juice	Licorice	Tomato skin
Candy	Purple grapes	Iron supplements
Kool-Aid	Chocolate	
Jello	Grape juice	
Tomatoes	Bismuth subsalicylate	
Beets	Iron supplements	
Cranberries		

GASTROINTESTINAL

Table 35. Clinical Signs of Dehydration in Children

Parameter	Mild	Moderate	Severe
Activity	Normal	Lethargic	Lethargic to comatose
Color	Pale	Gray	Mottled
Urine output	Decreased (<2–3 mL/kg/hr)	Oliguric (<1 mL/kg/hr)	Anuric
Fontanelle	Flat	Depressed	Sunken
Mucous membranes	Dry	Very dry	Cracked
Skin turgor	Slightly decreased	Markedly decreased	Tenting
Pulse	Normal to increased	Increased	Grossly tachycardic
Blood pressure	Normal	Normal	Decreased
Weight Loss	5%	10%	15%

Hypernatremic dehydration may be accompanied by moderate clinical signs. Reprinted with permission from Rogers MC: Shock. In: Rogers MC, Helfaer MA, eds. *Handbook of pediatric intensive care*, 2nd ed. Baltimore: Williams & Wilkins, 1994:140.

Table 36. Therapy for Hyperlipidemia

Type	Mechanism	Reduction in Cholesterol (%)	Effect on VLDL	Effect on HDL	Side Effect	Dose
Nonpharmacological therapy						
American Heart Association diet	Limits exogenous cholesterol	10–15	Decrease	Decrease		N/A
Exercise	Improves insulin resistance	Some decrease	Decrease	Increase		N/A
Weight Loss	Improves insulin resistance	Some decrease	Decrease	Mild increase		N/A
Pharmacological therapy						
Bile acid resins	Accelerate LDL disposal	20–30	Mild decrease	Mild increase	Epigastric distress, constipation, bloating, interferes with some drug absorption	Up to 24 g/day cholestyramine in divided doses
Nicotinic acid or niacin	Reduces VLDL and LDL synthesis; increases HDL	25	50% decrease	30%–40% increase	Flushing, headache, tachycardia, gastrointestinal distress, activation of peptic ulcer disease and inflammatory bowel disease, hepatic dysfunction	Titrate up to 1 g 3 times/day
Probucol	Increases LDL disposal; reduces HDL/LDL	5–15		Decrease	Nausea, diarrhea, flatulence, eosinophilia, hepatic dysfunction, prolongation of QT interval	0.5 g 2 times/day
Gemfibrozil	Enhances VLDL breakdown; decreases VLDL production	Decrease	40%–50% decrease	20%–30% increase	Rarely myositis; should not be used in patients with renal disease, cholelithiasis, or liver dysfunction	600 mg 2 times/day
HMG CoA reductase inhibitor (lovastatin)	Inhibits cholesterol synthesis; increases LDL disposal	30–40			Elevated liver enzymes, myositis, cataracts in animals	20–40 mg 2 times/day

HDL, high-density lipoprotein; HMG CoA, 3-hydroxy-3-methylglutaryl coenzyme A; LDL, low-density lipoprotein; VLDL, very-low-density lipoprotein.

Table 36A. Expected Liver Span of Infants and Children

Age (yr)	Boys		Girls	
	Mean Estimated Liver Span	Standard Error of Mean	Mean Estimated Liver Span	Standard Error of Mean
6 mo	2.4	2.5	2.8	2.6
1	2.8	2.0	3.1	2.1
2	3.5	1.6	3.6	1.7
3	4.0	1.6	4.0	1.7
4	4.4	1.6	4.3	1.6
5	4.8	1.5	4.5	1.6
6	5.1	1.5	4.8	1.6
8	5.6	1.5	5.1	1.6
10	6.1	1.6	5.4	1.7
12	6.5	1.8	5.6	1.8
14	6.8	2.0	5.8	2.1
16	7.1	2.2	6.0	2.3
18	7.4	2.5	6.1	2.6
20	7.7	2.8	6.3	2.9

From Lawson EE, Grand RJ, Neff RK, et al. *Am J Dis Child* 1978;132:475, with permission.

Table 36B. Review of Liver Function Tests

I. LIVER FUNCTION TESTS

AP	AST	ALT	GGT	5 = NUC
Liver	Hepatocyte	Hepatocyte	Placenta	Biliary
Bone	Muscle	Muscle	Pancreas	
Intestine			Kidney	
Placenta			Bile	
Tumors			Ducts	
			Choroid	

II. "TRUE" LIVER FUNCTION TESTS

- Prothrombin time
- Albumin
- Bile acids and salts
- Factor II, V, VII, IX, X
- Vitamin k-dependent factors: II, VII, IX, X

III. LIVER FUNCTION TESTS

Clinical pearls for daily use:

Low	ALKALINE PHOSPHATASE	γ -GGT
	Zinc deficiency	Bile acid deficiency
	Wilson disease	
High	Cystic fibrosis	
	See other List	Cholestasis, ICP

IV. LIVER FUNCTION TESTS

Clinical pearls for daily use: Elevated transaminases and normal bilirubin, GGT, and alkaline phosphatase

Table 36C. Clinical Disease States and Age of Presentation of Hepatomegaly

Age	Clinical Disease States
Newborn (Birth–2 mo)	Intrauterine and intrapartum acquired infection (TORCH, syphilis, other) Erythroblastosis fetalis Neonatal hepatitis, α_1 -antitrypsin, Alagille syndrome Biliary atresia Congestive heart failure Congenital paroxysmal atrial tachycardia Sepsis
Infant (2–12 mo)	Cystic fibrosis Metabolic disease: glycogen storage, α_1 -antitrypsin deficiency, galactosemia, tyrosinemia, hereditary fructose intolerance, other Neonatal hepatitis, hepatitis B HIV infection (AIDS) Histiocytosis Malnutrition Tumors (intrinsic, metastatic) Cholelithiasis Choledochal cyst
Young child (1–6 yrs)	Viral hepatitis Drug-toxic hepatitis Parasitic Tumor
Older child, adolescent (7–20 yrs)	Leukemia, lymphoma Viral hepatitis Drug-toxic hepatitis Wilson disease Chronic active hepatitis Congenital hepatic fibrosis Focal nodular hyperplasia, adenoma α_1 -Antitrypsin deficiency Reye syndrome Sickle cell anemia Cholelithiasis Juvenile rheumatoid arthritis, lupus erythematosus, sarcoidosis Leukemia, lymphoma Gonococcal perihepatitis Cystic fibrosis Diabetes

Adapted from Walker, WA, Mathia RK. *Pediatr Clin North Am* 1975;22:929.

ELECTROLYTES

Table 37. Assessment of Hypernatremia

Underlying Cause	ECF Volume	Urine Output	Urine Sodium	Specific Gravity
Sodium excess	Increased	Normal or increased	Increased	High
Water loss (DI)	Decreased	Increased	Decreased	High
Sodium and water loss (water > sodium)	Normal or decreased	Decreased	Increased	Low

DI, diabetes insipidus; ECF, extracellular fluid.

Table 38. Assessment of Hyponatremia

If Urine Output Decreased and UNq <20 mEq/L	If Urine Output Decreased and UNq >20 mEq/L	If Urine Output Normal or Increased and UNq >20 mEq/L	If Urine Output Normal or Increased and UNq >20 mEq/L
Effective intravascular volume, consider: CHF, nephrotic syndrome, dehydration, liver disease, third spacing conditions	Renal failure or increased ADH	Water intoxication	Renal NaCl wasting Nonoliguric renal failure, adrenal insufficiency Osmotic diuretic use or osmotic diuresis

Table 39. Conditions Associated with Increased ADH/ADH-Like Effect and Hyponatremia

Pain
Vomiting
CNS disorders: Including injuries, infection, tumors
Intrathoracic disorders: Including infections, mechanical ventilation
Drugs: Narcotics, barbiturates, carbamazepine, NSAIDs, cyclophosphamide, vincristine, others not commonly used in pediatrics

Table 40. Determination of Serum Osmolality

Reliable estimate under most circumstances:
Serum Osm = 2(Na mEq/L) + 10
Estimate when there is hyperglycemia or azotemia
Serum Osm = 2(Na) + glucose/18 + BUN/2.8

Table 41. Drugs Associated with Hyperkalemia

Potassium-sparing diuretics (e.g., spironolactone, triamterene, amiloride)
Potassium supplements (e.g., potassium chloride)
Potassium-containing penicillins
Stored blood
Cyclosporine
Nonsteroidal antiinflammatory drugs (NSAIDs)
Heparin
Angiotensin-converting enzyme (ACE) inhibitors
 β -Adrenergic blockers
Chemotherapeutic agents

Table 42. Treatment of Hyperkalemia

Agent	Indication	Mechanism of Action	Dose	Side Effects/Potential Problems
10% calcium gluconate	ECG changes	Stabilizes membranes	1 mg/kg IV over 5–10 minutes	Hypercalcemia
Sodium bicarbonate	ECG changes or very high K ⁺ level	Shifts K ⁺ to intracellular compartment	1 mg/kg IV over 5–10 minutes	Sodium load
Glucose plus insulin	ECG changes or very high K ⁺ level	Shifts K ⁺ to intracellular compartment	0.25–0.5 gm/kg glucose plus 0.3 U insulin/gm glucose over 30–60 minutes	Hyper- or hypoglycemia
Kayexalate resin	To remove K ⁺ from body	K ⁺ binds to resin in gut	1 gm/kg PO or PR in 50%–70% sorbitol	Constipation
Furosemide	Symptomatic hyperkalemia	Enhances urinary K ⁺ excretion	1–2 mg/kg IV	May not be enough renal function to be effective
Hemo- or peritoneal dialysis	No renal function	Removes K ⁺ in dialysate	...	Risks associated with dialysis
Exchange transfusion	ECG changes or very high K ⁺ level	Donor blood has had most K ⁺ removed	Double volume	Risks associated with exchange transfusion

ECG, electrocardiogram; IV, intravenous; K⁺, potassium; PO, orally; PR, parenterally.

Table 43. Drugs Associated with Hypokalemia**Drugs associated with increased renal loss**

Aminoglycoside toxicity
 Amphotericin B
 Cisplatin
 Penicillins in high doses
 Corticosteroids
 Diuretics (except for potassium-sparing ones)

Drugs associated with increased cellular uptake of potassium

Terbutaline
 Epinephrine
 β -Adrenergic agents (e.g., albuterol)
 Theophylline toxicity
 Barium toxicity
 Insulin

Table 44. Oral Potassium Supplements

Preparation	Formulation	Potassium Supplied
Potassium phosphate	Tablet	1.1, 2.3, or 3.7 mEq
Potassium chloride	Extentabs	10 mEq
	Powder packet	20 mEq
	Effervescent tablets	20 mEq
	Liquid	20 mEq
Potassium citrate	Tablets, crystals, or syrup	1 mEq/mL (Polycitra) or 2 mEq/mL (Polycitra-K)
Potassium gluconate	Liquid	20 mEq/15 mL

Table 45. Commonly Used Calcium Preparations

Preparation	Elemental Calcium Content	Route
Calcium gluconate (10%)	1 mL = 9 mg = 0.45 mEq	IV
Calcium chloride (10%)	1 mL = 27 mg = 1.36 mEq	IV
Calcium glubionate (Neocalglucon)	1 mL = 23 mg = 1.12 mEq	PO

Table 46. Calcium Needs

Maintenance calcium (not precisely known)	20–50 mg/kg/d (elemental calcium)
Emergency calcium (for severe symptoms)	10–20 mg/kg (elemental calcium) slow IV with cardiac monitor

Table 47. Characteristics of Renal Tubular Acidosis

	Type 1	Type 2	Type 3
Renal function?	Normal	Normal	Normal or decreased
Failure to thrive?	Yes	Yes	Yes
Polyuria or polydipsia?	Yes	Yes	No
Potassium level?	Normal or low	Normal or low	Elevated
Bicarbonate leak?	Usually	Significant	Small
Urine maximally acid?	No (pH > 6)	Yes	Yes
Nephrocalcinosis or nephrolithiasis?	Yes	No	No
Fanconi syndrome?	No	Often	No
Osteomalacia or rickets?	Rarely	If Fanconi syndrome is present	No

Table 48. Toxins Removed by Hemodialysis

Toxin	Measured Level Suggestive of Need for Hemodialysis ^a
Acetaminophen	> 100 mcg/mL in conjunction with antidote
Arsenic	Only with coexistent renal failure
Bromide	> 150 mg/dL and severe symptoms
Chloral hydrate	250 mg/dL
Ethanol	600 mg/dL
Ethylene glycol	50 mg/dL
Isopropanol	400 mg/dL
Lithium	4 mEq/L in acute overdose
	As needed for severe symptoms in chronic overdose
Methanol	50 mg/dL
Salicylates	100–120 mg/dL in acute overdose 60–800 mg/dL in chronic overdose

^aThe decision to perform hemodialysis should be based on physical findings as well as drug levels. A repeat measure should be obtained when the drug level is elevated to ensure that a laboratory error has not occurred. In addition, units of measure should be checked before instituting hemodialysis.

Table 49. Toxins Removed by Charcoal Hemoperfusion^a

Toxin	Measured Level Suggestive of Need for Charcoal Hemoperfusion
Amitriptyline	Based on signs and symptoms
Chloral hydrate	250 mg/dL
Digitoxin	50 ng/mL with antidotal therapy
Digoxin	15 ng/mL with antidotal therapy
Ethchlorvinyl	150 mcg/mL
Glutethimide	40 mg/L
Methaqualone	40 mcg/mL
Notriptyline	Based on signs and symptoms
Pentobarbital	50 mg/L
Phenobarbital	100 mg/L
Theophylline	100 mcg/mL in acute overdose 60 mcg/mL in chronic overdose

^aThe decision to perform hemoperfusion should be based on physical findings as well as drug levels. A repeat measure should be obtained when the drug level is elevated to ensure that a laboratory error has not occurred. In addition, units of measure should be checked before instituting hemodialysis.

Table 50. Normal Values for Fractional Excretion of Sodium (Fe_{Na})

	Prerenal ARF	Intrinsic ARF
Adult or child	<1.0	>2.0
Infant (neonate)	<2.5	>2.5

ARF, acute renal failure.

Table 51. Causes of False-Positive Dipstick Reactions for Urinary Protein

Overlong immersion
Placing reagent strip directly in the urine stream
Alkaline urinary pH (pH > 7.0)
Quaternary ammonium compounds and detergents
Pyuria
Bacteriuria
Mucoprotein

Table 52. Drugs that May Cause Hemolytic Anemia in Patients Who Have G6PD Deficiency

Acetanilid	Nitrofurantoin
Doxorubicin	Primaquine
Methylene blue	Pamaquine
Naphthalene	Sulfa drugs

Table 53. Clinical Aids in Distinguishing the Origin of Hematuria

Test For	Glomerular or Renal	Extrarenal
Urine color	Brown, tea or cola colored, cloudy, red	Red, pink
Clots	Usually absent	May be present
RBC casts	Frequently present	Never present
Red cell morphology	Dysmorphic or distorted	Normal RBC shape (eumorphic)
Urine stream	Bloody throughout entire stream	More bloody at initiation (suggesting distal urethral origin) or termination (suggesting trigonitis or cystitis)

PULMONARY

Table 54. Characteristics of the Three Stages of Parapneumonic Pleural Effusions

	Exudative Stage	Fibrinolytic Stage	Organizing Stage (Empyema)
Appearance	Nonpurulent, not turbid	Nonpurulent, not turbid	Purulent, turbid
Fluid consistency	Free flowing	Loculated	Organized
Gram stain and culture results	Negative	Transitional	Positive (before antibiotic treatment)
Glucose	> 100 mg/dL	< 50 mg/dL	< 50 mg/dL
Protein	< 3 g/dL	> 3 g/dL	> 3 g/dL
pH	> 7.30	< 7.30	< 7.30
WBCs	Few	PMNs	PMNs

PMNs, polymorphonuclear neutrophils; WBCs, white blood cells.

Table 55. Pleural Fluid Diagnostic Studies

Study	Transudate	Exudate
<i>Biochemical</i>		
Pleural LDH	< 200 IU	≥ 200 IU
Pleural fluid/serum LDH ratio ^a	< 0.6	≥ 0.6
Pleural fluid/serum protein ratio ^a	< 0.5	≥ 0.5
Specific gravity	< 1.016	≥ 1.016
Protein level	< 3.0 g/dL	≥ 3.0 g/dL
<i>Other studies</i>		
Glucose	Usually > 40 mg/dL	Typically < 40 mg/dL
Amylase	May be elevated in some neoplasms, GI trauma, or surgery	
Rheumatoid factor, LE prep, ANA	Are occasionally helpful if collagen vascular disorders are within the differential	
<i>Hematologic</i>		
WBC count	Although high counts (> 100/mm ³) are suggestive of an exudate, the results are quite variable	
WBC differential	May actually provide more useful information	
Lymphocyte count	May be elevated in neoplasms, tuberculosis, and some fungal infections	
Segmented neutrophils	May be elevated in bacterial infections, connective tissue disease, pancreatitis, or pulmonary infarction	
Eosinophil count	May be elevated in bacterial infections, neoplasms, and connective tissue diseases	
RBC count	If > 100,000/mm ³ , is suggestive of trauma, neoplasms, or pulmonary infarction	
Cytology and chromosomal studies	May show evidence of malignant cells or chromosomal abnormalities	
<i>Microbiology</i>		
Gram stain		
Fluid culture for aerobes and anaerobes		
Acid-fast stain (if tuberculosis is in the differential)		
Fungal culture		
Viral culture		
Counterimmune electrophoresis	may aid in the detection of a bacterial infection)	

^a These tests are more reliable in differentiating transudate from exudate than specific gravity or protein level.

Table 56. Normal Blood Gas Values from the Children's Hospital of Philadelphia Blood Gas Laboratory

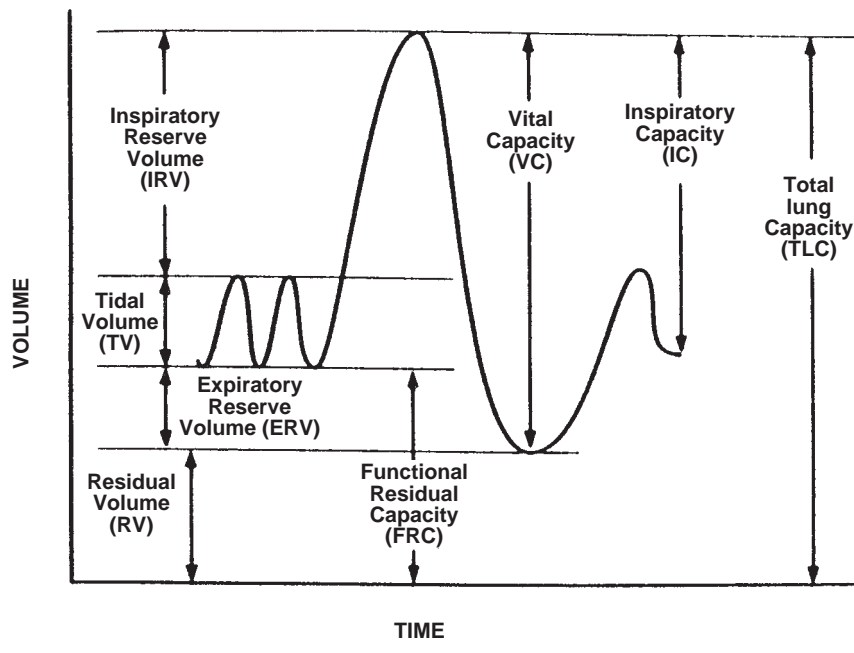

Parameter	Age of Patient	Normal Value
pH	1 day	7.29–7.45
	3–24 months	7.34–7.46
	> 7 years	7.37–7.41
Pco ₂	1 day	27–40 mm Hg
	3–24 months	26–42 mm Hg
	> 7 years	34–40 mm Hg
Po ₂	1 day	37–97 mm Hg
	3–24 months	88–103 mm Hg
	> 7 years	88–103 mm Hg
Base excess	1 day	>8–(-2)
	3–24 months	-7–0
	> 7 years	-4-(+2)
HCO ₃	1 day	19 mmol/L
	3–24 months	16/24 mmol/L
	> 7 years	22–27 mmol/L
α ₂ saturation	...	94%–99%
Venous pH	...	7.32–7.42
Venous CO ₂		25–47 mm Hg
Venous O ₂		25–47 mm Hg

CO₂, carbon dioxide; HCO₃, bicarbonate; O₂ = oxygen; Pco₂, carbon dioxide tension; Po₂, oxygen tension.

Table 57. Signs of Inhalation Injury

Pulmonary	CNS	Skin
Tachypnea	Confusion	Facial burns
Stridor	Dizziness	Singed nasal hairs
Hoarseness	Headache	Cyanosis
Rales	Hallucinations	Cherry red color
Wheezing	Restlessness	
Cough	Coma	
Retractions	Seizures	
Nasal flaring		
Carbonaceous sputum		

Table 58. Pulmonary Function Test

CARDIOVASCULAR

Table 59. Common Causes of Abnormally Wide Splitting of the Second Heart Sound (S₂)

Atrial septal defect (ASD)
Mild pulmonic stenosis
Complete right bundle branch block
Left ventricular paced beats
Massive pulmonary embolus

Table 61. Conditions Causing a Prominent Fourth Heart Sound (S₄)

Left ventricular outflow tract obstruction (e.g., aortic stenosis)
Right ventricular outflow tract obstruction (e.g., pulmonic stenosis)
Hypertrophic cardiomyopathy
Heart block (atrium contracting against a closed valve)

Table 62. Drugs Associated with Rapid Heart Rates

Prescription drugs
β-adrenergic agonists (e.g., albuterol)
Methylxanthines (e.g., theophylline)
Tricyclic antidepressants (e.g., imipramine)
Nonsedating histamines (e.g., terfenadine)
Over-the-counter drugs
Decongestants (e.g., pseudoephedrine)
Diet aids (phenylpropanolamine)
Inhaled bronchodilators (e.g., albuterol)
Caffeine-containing products
Drugs of abuse
Nicotine
Cocaine
Amphetamines
Alcohol
Marijuana
LSD
Phencyclidine
Amyl nitrate

Table 60. Conditions Causing a Prominent Third Heart Sound (S₃)

Physiologic (infants and children)
Congestive heart failure (CHF)
Ventricular septal defect, with large pulmonary to systemic flow ratio
Mitral insufficiency
Tricuspid insufficiency
Hyperdynamic ventricle with high output (e.g., anemia, thyrotoxicosis, arteriovenous fistula)

Table 63. Causes of Prolonged QT Interval

Congenital
Hereditary
Jervell and Lange-Nielsen syndrome: Long QT interval, stress-induced syncope, congenital nerve deafness, autosomal-recessive inheritance
Romano-Ward syndrome: Long QT interval, stress-induced syncope, autosomal-dominant inheritance (usually incomplete penetrance)
Sporadic
Acquired
Electrolyte abnormalities
Hypocalcemia
Hypomagnesemia
Metabolic disturbances
Malnutrition
Liquid protein diets
Drugs
Phenothiazines (e.g., haloperidol)
Tricyclic antidepressants (e.g., imipramine)
Nonsedating antihistamines (e.g., terfenadine)
Class Ia antiarrhythmic agents (e.g., quinidine)
Class III antiarrhythmic agents (e.g., amiodarone)
CNS trauma
Cardiac abnormalities
Ischemia
Mitral valve prolapse
Myocarditis
Intraventricular conduction abnormalities
Bundle branch blocks

Table 64. Structural Heart Disease Associated with Tachycardia

Defect	Type of Tachycardia
Congenital heart disease	
Mitral valve prolapse	SVT, VT
Aortic valve stenosis or regurgitation	VT
Ebstein anomaly of the tricuspid valve	SVT (WPW) commonly, VT less commonly
Tetralogy of Fallot	VT
Mustard/Senning repair of D-TGA	SVT (particularly atrial flutter)
Fontan repair of single ventricle	SVT (particularly atrial flutter)
Cardiomyopathy	
Hypertrophic cardiomyopathy	SVT, VT
Dilated cardiomyopathy	SVT, VT
Arrhythmogenic right ventricular dysplasia	VT (monomorphic, left bundle branch block)
Miscellaneous causes	
Cardiac tumor (atrial myxoma, rhabdomyosarcoma)	VT
Eisenmenger complex (pulmonary vascular disease and pulmonary hypertension)	SVT, VT (depending on tumor site)

D-TGA, D-transposition of the great arteries; SVT, supraventricular tachycardia; VT, ventricular tachycardia; WPW, Wolff-Parkinson-White syndrome.

Table 65. Poisons Causing Tachycardia

Tachycardia and hypertension
 Amphetamines
 Antihistamines
 Cocaine
 LSD/PCP
 Tachycardia and hypotension
 β_2 -Adrenergic agonists
 Albuterol
 Terbutaline
 Carbon monoxide
 Cyclic antidepressants
 Hydralazine
 Iron
 Phenothiazines
 Theophylline
 Any agent causing vomiting, diarrhea, or hemorrhage

LSD, lysergic acid diethylamide; PCP, phencyclidine hydrochloride.

Table 66. Poisons Causing Bradycardia

Bradycardia and hypertension
 α -Adrenergic agonists
 Phenylpropanolamine
 Ephedrine
 Clonidine
 Ergotamine
 Bradycardia and hypotension
 α_1 -Adrenergic antagonists
 Phentolamine
 Prazosin
 α_1 -Adrenergic agonists
 Clonidine
 Tetrahydrozoline
 β -Adrenergic antagonists
 Propranolol
 Atenolol
 Metoprolol
 Calcium channel blockers
 Digitalis-containing drugs and plants
 Narcotics
 Organophosphate pesticides
 Sedative/Hypnotics

Table 67. Poisons Causing Cardiac Arrhythmias

Atrioventricular block
 Astemizole
 β -Adrenergic antagonists
 Calcium channel blockers
 Clonidine
 Cyclic antidepressants
 Digitalis-containing drugs and plants
 Ventricular tachycardia
 Amphetamines
 Carbamazepine
 Chloral hydrate
 Chlorinated hydrocarbons
 Cocaine
 Cyclic antidepressants
 Digitalis-containing drugs or plants
 Phenothiazines (especially thioridazine)
 Theophylline
 Type Ia antiarrhythmic agents
 Quinidine
 Procainamide
 Type Ic antiarrhythmic agents
 Flecainide
 Encainide
 Torsades de pointes (multifocal ventricular tachycardia)
 Amantadine
 Cyclic antidepressants
 Lithium
 Nonsedating antihistamines
 Astemizole
 Terfenadine
 Quinidine
 Phenothiazines
 Sotalol

Table 68. Revised Jones Criteria for Diagnosis of Acute Rheumatic Fever

Major Criteria	Minor Criteria
Carditis	Fever
Arthritis	Arthralgia
Rash (erythema marginatum)	Elevated ESR, CRP
Chorea (Sydenham)	Prolonged PR interval on ECG
Subcutaneous nodules	History of prior attack of rheumatic fever or rheumatic heart disease

Diagnosis is likely with the presence of two major and one minor criteria, or one major and two minor criteria. Supporting evidence of a preceding streptococcal infection includes a history of recent scarlet fever, a positive throat culture for group A *Streptococcus*, and an increased antistreptolysin O (ASO) titer (or titers for other streptococcal antibodies). Adapted from the Report of the Ad Hoc Committee of the American Heart Association Council on Rheumatic Fever and Congenital Heart Disease. *Circulation*. 1984;69:204A–208A. CRP, C-reactive protein; ECG, electrocardiogram; ESR, erythrocyte sedimentation rate.

MUSCULOSKELETAL

Table 69. Range of Motion of Major Joints

	Flexion	Extension	Abduction	Adduction	Internal Rotation	External Rotation
Hip	120°	30°	50°	30°	35°	45°
Knee	135°	5°	0°	0°	10°	10°
Ankle	50°	20°	10°	20°	5° (eversion)	5° (inversion)
Shoulder	90°	45°	180°	45°	55°	45°
Elbow	135°	5°	0°	0°	90° (supination)	90° (pronation)
Wrist	80°	70°	20° (radial)	30° (lunar)	0°	0°

Table 70. Characteristics of Synovial Fluid

	Appearance	WBC/mm ²	% Neutrophils	% Glucose Synovial Blood
Normal	Clear	<2,000	<40	>50
Infectious	Turbid	>75,000	>75	<50
Inflammatory (JRA, SLE)	Clear/Turbid	5,000–75,000	50	≥50
Traumatic	Bloody/Clear	<5,000	<50	>50

Table 71. Relationship Between Short Stature, Bone Age, and Growth Velocity^a

Bone age delayed—normal growth velocity	Constitutional short stature
Bone age normal—normal growth velocity	Genetic short stature
Bone age delayed—delayed growth velocity	Organic diseases

^aVelocity = the rate of growth during a year.

Table 72. Clinical and Biochemical Features of Congenital Adrenal Hyperplasia (CAH)

Enzyme defect	Sexual Ambiguity		Additional Clinical Manifestations	Predominant Steroids
	Female	Male		
Desmolase	—	+	Salt wasting	...
3 β -Hydroxysteroid dehydrogenase	+	+	Salt wasting	17-OH-pregnenolone, DHEA
21-Hydroxylase	+	—	Salt wasting	17-OH-progesterone, androstenedione
11-Hydroxylase	+	—	Hypertension	11-Deoxycortisol
17-Hydroxylase	—	+	Hypertension	DOC, corticosterone

DHEA, dehydroepiandrosterone; DOE, deoxycorticosterone.

Table 73. Normal Serum Adrenal Steroid Levels in Newborn Infants

Steroid	Preterm Sick		Preterm Well	Full Term
	24–28 Weeks	31–35 Weeks	31–35 Weeks	
Cortisol (mcg/dL)	7.5 \pm 4	6 \pm 2.7	6.9 \pm 3.8	6.2 \pm 3.9
17-OH-Preg (ng/dL)	1794 \pm 1818	1395 \pm 694	942 \pm 739	245 \pm 291
17-OH-Pro (ng/dL)	651 \pm 661	373 \pm 317	169 \pm 95	36 \pm 13 ^a
11-deoxycortisol (ng/dL)	662 \pm 548	294 \pm 239	111 \pm 62	87 \pm 42
DHEA (ng/dL)	1872 \pm 4038	675 \pm 502	920 \pm 1227	286 \pm 238
DHEAS (mcg/dL)	467 \pm 312	459 \pm 209	341 \pm 93	162 \pm 88
Androstenedione (ng/dL)	479 \pm 1032	206 \pm 86	215 \pm 134	149 \pm 67

Data based on information in Lee MM, Rajabopalan L, Berg G, et al. Serum adrenal steroid concentrations in premature infants. *J Clin Endocrinol Metab.* 1989;69:1133–1136, and in Wiener D, Smith J, Dahlem S, et al. Serum adrenal steroid levels in healthy term 3-day-old infants. *J Pediatr.* 1987;110(1):122–124.

17-OH-Preg, 17-OH-pregnenolone; 17-OH-Pro, 17-OH-progesterone; DHEA, dehydroepiandrosterone; DHEAS, dehydroepiandrosterone sulfate. ^a 17-OH-Pro values in full-term sick newborns may be double or triple the baseline values. No data are available for other steroid hormones in sick full-term infants.

Table 74. Pharmacokinetics of Common Insulin Preparations

Insulin Preparation	Onset (Hours)	Peak (Hours)	Duration of Action (Hours)
Ultra-rapid-acting (Lispro)	0.25–0.50	1–2	2–3
Short-acting (Regular, Semilente)	0.5–1.0	2–4	4–6
Long-acting (NPH, Lente)	2–4	6–12	18–24
Very long-acting (Ultralente)	6–10	18–24	24–36

NPH, neutral protein Hagedorn insulin.

Table 75. Normal Thyroid Hormone Levels

T ₄	Total	7.0–15.0 mcg/dL
	Free	0.8–2.3 ng/dL
T ₃		100–250 ng/dL
TSH		0.5–5.0 mcg/dL

Table 76. Normal Ranges for Gonadotropin and Sex Steroid Levels: Females

	LH (mLU/mL)	FSH (mLU/mL)	Estradiol (ng/dL)	Testosterone (ng/dL)
0–1 year	0.02–7.0	0.24–14.2	0.5–5.0	<10
Prepubertal	0.02–0.3	1.0–4.2	<1.5	<3–10
Tanner 2	0.02–4.7	1.0–10.8	1.0–2.4	7.0–28
Tanner 3	0.10–12.0	1.5–12.8	0.7–6.0	15–35
Tanner 4	0.4–11.7	1.5–11.7	2.1–8.5	13–32
Tanner 5	0.4–11.7	1.0–9.2	3.4–17.0	20–38
Adult	10–55
Follicular phase	2.0–9.0	1.8–11.2	3.0–10.0	...
Midcycle	18.0–49	6.0–35.0
Luteal phase	2.0–11.0	1.8–11.2	7.0–30.0	...

FSH, follicle-stimulating hormone; LH, luteinizing hormone.

Table 77. Normal Ranges for Gonadotropin and Sex Steroid Levels: Males

	LH (mLU/mL)	FSH (mLU/mL)	Estradiol (ng/dL)	Testosterone (ng/dL)
0–1 year	0.02–7.0	0.16–4.1	1.0–3.2	<10
Prepubertal	0.02–0.3	0.26–3.0	<1.5	<3–10
Tanner 2	0.2–4.9	1.8–3.2	0.5–1.6	18–150
Tanner 3	0.2–5.0	1.2–5.8	0.5–2.5	100–320
Tanner 4	0.4–7.0	2.0–9.2	1.0–3.6	200–620
Tanner 5	0.4–7.0	2.6–11.0	1.0–3.6	350–970
Adult	1.5–9.0	2.0–9.2	0.8–3.5	350–1,030

FSH, follicle-stimulating hormone; LH, leuteinizing hormone.

Table 78. Classification of Total and LDL Cholesterol Levels in Children and Adolescents from Families with Hypercholesterolemia or Premature Cardiovascular Disease

Category	Total Cholesterol, mg/dL	LDL Cholesterol, mg/dL
Acceptable	<170	<110
Borderline	170–199	110–129
High	≥200	≥130

Table 79. Causes and Management of Rickets

Cause	Management
Calcium Deficiency	
Low intake	<6 months of age 400 mg/d 6–12 months of age 600 mg/d 1–10 years of age 800 mg/d
Extreme prematurity (birth weight <1,500 g) Steatorrhea	Adjust intake to 200 mg/kg/d 25-OH-D ₃ (5–7 mcg/kg/d) if serum levels are low and supplement dietary calcium between 25 and 100 mg/kg/d
Anticonvulsant (Phenobarbital or phenytoin)	Calcium <6 months of age 400 mg/d 6–12 months of age 600 mg/d 1–10 years of age 800 mg/d Vitamin D 200 IU/d of ergocalciferol Base supplement: 3–10 mM/kg/d as NaHCO ₃ or citrate
Renal tubular acidosis	
Vitamin D Deficiency	
Insufficient UV light exposure	200 IU/d of vitamin D of ergocalciferol
Breastfeed infants who are not supplemented with vitamin D	200 IU/d of vitamin D of ergocalciferol
Liver disease	4,000–8,000 IU/d ergocalciferol
Renal disorders	4,000–40,000 IU/d of Calcitriol
Nutritional rickets and osteomalacia	1,000–5,000 IU/day of ergocalciferol
Vitamin D–dependent rickets	3,000–5,000 IU/d of Calcitriol
Vitamin D–resistant rickets	40,000–80,000 IU/d of ergocalciferol with phosphate supplements, daily dosage is increased at 3–4 month intervals in 10,000–20,000 IU increments
Phosphorus Deficiency	
Diet (limited to premature infants)	Adjust formula or parenteral source to give 10 mg/kg/d
Antacid excess	Alternative gastric acid control
Excessive phosphaturia from tubular dysfunction	Supplemental P and calcitriol if low

Table 80. Classification of Rickets and Vitamin D Metabolite Levels

	Calcium	Phosphorus	Alkaline Phosphate	25 (OH)D
Deficient synthesis and supply	N or ↓	↓	↑	↓
No sunlight				
Poor diet				
Immaturity				
Malabsorption	N or ↓	↓	↑	↓
Liver disease	N or ↓	↓	↑	↓
Chronic renal failure	N or ↓	↑	↑	N
Vitamin D–dependent rickets (recessively inherited)	↓	↓	↑	N
Vitamin D–resistant rickets (sex-linked dominant)	N	↓	↑	N
Renal tubular disorders (defect of phosphate reabsorption)	N	↓	↑	N

N, normal; ↓, decreased; ↑, increased.

Table 81. Causes of Ataxia

Form of Ataxia	Major Causes	Other Causes
Acute ataxia	Ingestion Postinfectious cerebellitis	Migraine Neuroblastoma
Acute recurrent ataxia	Migraine Metabolic disease	...
Chronic ataxia	Congenital disorders with mental deficiency	...
Chronic progressive ataxia	Brain tumors Neuroectodermal tumors	Ataxia-telangiectasia Friedreich ataxia

Table 82. Glasgow Coma Scale

Eyes open		Best motor response	
Spontaneously	4	Obey commands	6
To speech	3	Localize pain	5
To pain	2	Withdrawal	4
None	1	Flexion to pain	3
Best verbal response		Extension to pain	2
Oriented	5	None	1
Confused	4		
Inappropriate	3		
Incomprehensible	2		
None	1		

Adapted from Fleisher G, Ludwig S, eds. *Textbook of pediatric emergency medicine*, 3rd ed. Baltimore: Williams & Wilkins, 1993:272.

Table 83. Glasgow Coma Scale (GCS) for Adults and Children and Modified Score for Infants

	Glasgow Coma Score (Adults/Older Children)	Modified Glasgow Coma Score (Infants)
Eye Opening	Spontaneous 4 To verbal stimuli 3 To pain 2 None 1	Spontaneous To speech To pain None
Best Verbal Response	Oriented 5 Confused speech 4 Inappropriate words 3 Nonspecific sounds 2 None 1	Coos and babbles Irritable, cries Cries to pain Moans to pain None
Best Motor Response	Follows commands 6 Localizes pain 5 Withdraws to pain 4 Flexes to pain 3 Extends to pain 2 None 1	Normal spontaneous movements Withdraws to touch Withdraws to pain Abnormal flexion Abnormal extension None

Table 84. Drugs that Can Cause Delirium or Coma

Drug	Physical Findings
Barbiturates	Small, reactive pupils; hypothermia; flaccidity; doll's eye reflex may be absent
Opiates	Pinpoint, reactive pupils; hypothermia; hypotension; hypoventilation; bradycardia
Psychedelics	Small, reactive pupils; hypertension; hyperventilation; dystonic posturing
Amphetamines	Dilated pupils, hyperthermia, hypertension, tachycardia, arrhythmia
Cocaine	Dilated pupils, hyperthermia, tachycardia
Atropine-scopolamine	Dilated pupils; hyperthermia; flushing; hot, dry skin; supraventricular tachycardia
Glutethimide	Midposition, irregular fixed pupils; hypothermia; flaccidity
Tricyclic antidepressants	Hyperthermia, hypotension, supraventricular tachycardia
Phenothiazines	Hypotension, arrhythmia, dystonia
Methaqualone	Same as with barbiturates; if severe tachycardia, dystonia

From Packer RJ, Berman PH. Coma. In: Fleisher GR, Ludwig S, eds. *Textbook of pediatric emergency medicine*, 3rd ed. Baltimore: Williams & Wilkins, 1993:126, with permission.

Table 85. Prognostic Indicators of Poor Neurologic Outcome in Near-Drowning Victims^a

At the scene
Submersion time >4–10 minutes
Delay in beginning CPR
Resuscitation >25 minutes
In the emergency department
Necessity for CPR
Fixed, dilated pupils
pH <7.0
GCS score <5
After initial resuscitation
Persistent GCS score <5
Persistent apnea

CPR, cardiopulmonary resuscitation; GCS, Glasgow Coma Scale.
^aApplies to victims of warm water near-drownings only. Hypothermic victims of cold water near-drownings may have a better prognosis.

Table 86. Relationship of the Lesion to the Physical Findings

Lesion	Findings
Upper motor neuron involving corticospinal tract, thalamus, centrum, semiovale, motor cortex	Altered, normal or increased reflexes, bulk normal; strength normal or decreased
Cerebellum	Uncoordinated
Spinal (upper and lower motor)	Local pain, bowel and bladder dysfunction, if anterior horn cells involved, weakness and bulk, decreased absent reflexes, fasciculations
Peripheral	Loss of distal muscles, fasciculations less than spinal lesions; sensation is affected
Muscle	Weakness, muscle atrophy, decreased reflexes, pain, cramping, stiffness
Corticospinal tract	Increased tone, clasp knife character in flexion of arms and extension of legs
Extrapyramidal (basal ganglia)	Rigidity, normal reflexes, absent Babinski, voluntary movement is preserved, may have tremor, chorea, athetosis or dystonia

Table 87. Poisons Causing Coma

Coma with miosis
 Barbiturates and other sedative/hypnotics
 Bromide
 Chloral hydrate
 Clonidine
 Ethanol
 Narcotics
 Organophosphates
 PCP
 Phenothiazines
 Tetrahydrozoline
 Coma with mydriasis
 Atropine/diphenoxylate
 Carbon monoxide
 Cyanide
 Cyclic antidepressants
 Glutethimide
 LSD

LSD, lysergic acid diethylamide; PCP, phencyclidine hydrochloride.

Table 88. Poisons Causing Seizures

Amoxapine
 Amphetamines
 Anticonvulsants
 Phenytoin
 Carbamazepine
 Antihistamines and anticholinergic drugs or plants
 Camphor
 Carbon monoxide
 Chlorinated hydrocarbons
 Cocaine
 Cyanide
 Cyclic antidepressants
 Isoniazid
 Lead
 Lidocaine
 Meperidine
 PCP
 Phenothiazines
 Phenylpropanolamine
 Propoxyphene
 Propranolol
 Theophylline

PCP, phencyclidine hydrochloride.

Table 89. Differential Diagnosis of Metabolic Neurologic Dysfunction

Prominent Symptom	Diagnoses to Consider	Diagnostic Test	Metabolic Therapy
Myoclonic seizures	Ceroid	DNA, tissue EM	
	Lafora body disease	Muscle biopsy	
	Prion (GSS)	DNA	
	Mitochondrial	DNA, muscle biopsy	CoQ, other vitamins
	Aminoacidopathies	Blood biochemistry	Dietary
	Biotinidase deficiency	Blood biochemistry	Biotin supplement
Stroke	Organic acidurias	Blood biochemistry	Dietary, vitamins
	Homocystinuria	Blood/Urine test	B vitamins, betaine
Coma	Mitochondrial	DNA, muscle biopsy	
	Organic aciduria	Blood/Urine test	
Spasticity	MSUD	Blood/Urine test	
	Hyperammonemias	Blood test	Dietary
Visual loss	Leukodystrophy	MRI, fibroblast analysis	Dietary
	Mitochondrial	DNA, muscle biopsy	
Psychosis	Leukodystrophy	MRI, blood biochemistry, DNA, fibroblast analysis	
	Porphyria	Blood/Urine Biochemistry	Avoid precipitants
	Wilson disease	Copper excretion, DNA	Penicillamine (See above)
Microcephaly	Homocystinuria	Blood biochemistry	
	Ceroid	DNA, tissue electron microscopy	
	Huntington disease	DNA	
	Ceroid	DNA, tissue EM	
Macrocephaly	Rett syndrome	(Clinical features)	
	Krabbe disease	Blood biochemistry	
	Storage disorders	DNA, blood biochemistry	
Neuropathy	Canavan disease	Urine biochemistry, DNA	
	Krabbe disease	MRI and blood biochemistry	
Myopathy	Metachromatic leukodystrophy		
	Porphyria	Blood/Urine biochemistry	
	Mitochondrial	DNA, muscle biopsy	
	Friedreich ataxia	(Clinical features)	
	Abetalipoproteinemia		
	Disorders/deficiency of vitamin E	Blood biochemistry	Vitamin E
Ataxia	Mitochondrial	Vitamin E level	Vitamin E
	Neuroaxonal dystrophy	DNA, muscle biopsy	
Myopathy		MRI, nerve biopsy	
	Fukuyama disease	MRI	
Ataxia	Mitochondrial	DNA, muscle biopsy	
	Lactic acidoses	Blood biochemistry	
	Ataxia telangiectasia	DNA	
	Leukodystrophies	MRI, blood biochemistry	
	Friedreich		
	Mitochondrial	(Clinical features)	
	Hartnup	DNA, muscle biopsy	
	Hyperammonemias	Blood biochemistry	
	Abetalipoproteinemia	Blood biochemistry	
	Sphingolipidoses	Blood biochemistry	
Machado-Joseph, SCA-1 (hereditary ataxias)	Blood biochemistry, fibroblast analysis, DNA		

Table 90. Acquired Disorders Associated with Progressive Neurologic Dysfunction

Structural	Hormonal	Infectious	Environmental	Toxic	Immunologic
Hydrocephalus Brain tumor Vascular anomalies	Hypothyroidism Congenital adrenal hyperplasia (visuospatial deficits)	SSPE HIV Spirochetes	Malnutrition/Malabsorption syndromes Vitamin/Trace element deficiency (niacin, thiamine, folic acid, vitamin E, B ₁₂ , essential fatty acids) Physical abuse/neglect	Lead Organic chemicals Carbon monoxide Cocaine, hallucinogens, hypnotics Phenytoin (cerebellar degeneration)	Demyelination/Multiple sclerosis Opsoclonus/Myoclonus or cerebellar ataxia (neuroblastoma) Sydenham chorea Rasmussen encephalitis

Table 91. Epidural versus Acute Subdural Hematoma

	Epidural Hematoma	Subdural Hematoma
Common mechanism	Blunt direct trauma, frequently to parietal region	Acceleration-deceleration injury
Etiology	Arterial or venous	Venous (bridging veins below dura)
Incidence	Uncommon	Common
Peak age	Usually >2 years	Usually <1 year Peak at 6 months 75% bilateral
Location	Unilateral Commonly parietal	Diffuse, over cerebral hemispheres
Skull fracture	Common	Uncommon
Associated seizures	Uncommon	Common
Retinal hemorrhages	Rare	Common
Decreased level of consciousness	Common	Almost always
Mortality	Rare	Uncommon
Morbidity in survivors	Low	High
Clinical findings	Dilated ipsilateral pupil, contralateral hemiparesis Period of lucidity prior to acute decompensation and rapid progression to herniation	Decreased level of consciousness Irritability, lethargy
Onset	Acute	Acute (within 24 hours), subacute (within 1 day–2 weeks), or chronic (after 2 weeks)
Findings on CT	Convex "lens-shaped" cerebral hemisphere	Concave, diffusely surrounding cerebral hemisphere

CT, computed tomography.

Table 92. Age-Related Prevalence of Principal Laparoscopic Findings in 121 Adolescent Females 11 to 17 Years Old with Acute Pelvic Pain (The Children’s Hospital, Boston, 1980–1986)

Diagnosis	Number of Patients		
	Age 11–13	Age 14–15	Age 16–17
Ovarian cyst	12 (50%)	16 (35%)	19 (37%)
Acute pelvic inflammatory disease	4 (17%)	7 (16%)	10 (19%)
Adnexal torsion	0 (0%)	7 (16%)	2 (4%)
Endometriosis	0 (0%)	2 (4%)	4 (7%)
Ectopic pregnancy	0 (0%)	3 (7%)	1 (2%)
Appendicitis	3 (13%)	4 (9%)	6 (12%)
No pathology	5 (20%)	6 (13%)	10 (19%)
Total	24 (20%)	45 (37%)	52 (43%)

From Goldstein DP. Acute and chronic pelvic pain. *Pediatr Clin North Am.* 1989;36(3):576.

Table 93. Key Characteristics of Vaginal Discharges

	Presenting Symptoms	Discharge	Nonmenstrual pH	Amine/Whiff Test	Vaginal Smear	Treatment
Nonspecific vaginitis	Foul-smelling discharge Itching	Scant to copious Brown to green in color	Variable	Negative	Leukocytes Bacteria and other debris	Improved perineal hygiene
Physiologic leukorrhea	None	Variable Scant to moderate Clear to white	<4.5	Negative	Normal epithelial cells Lactobacilli predominate	None
Bacterial vaginosis	Foul-smelling discharge	Gray-white	>4.7	Positive	Epithelial cells with bacteria (“clue cells”) Gram-negative rods	Metronidazole Clindamycin
Candidiasis	Severe itching Vulvar inflammation	White, “curd-like”	<4.5	Negative	Fungal hyphae and buds	Topical or intravaginal imidazoles, triazoles Oral ketoconazole Metronidazole
Trichomonal vaginitis	Copious discharge Itching	Profuse Yellow to green	5.0–6.0	Occasionally present	Motile flagellated organisms	
Foreign body	Foul-smelling discharge	Foul-smelling Purulent Dark brown	Variable (usually >4.7)	Occasionally present	Leukocytes Epithelial cells with bacteria and debris	Remove foreign body Irrigate vagina
Contact vulvovaginitis	Vulvar inflammation Itching Edema	Scant White to yellow	Variable (usually <4.5)	Negative	Leukocytes Epithelial cells	Remove irritant Topical steroids

Table 94. Emergency Contraceptive Pills

Instructions for Use

Any of the birth control pills listed below can be used as ECPs. Use only the type of pill your health care provider prescribed for you. Use only one type of pill.

If You Are Taking	Number of Pills to Swallow as Soon as Possible (1st Dose)	Number of Pills to Swallow 12 Hours Later (2nd Dose)
Ovral	2 white pills	2 white pills
Lo/Ovral	4 white pills	4 white pills
Levlen	4 light-orange pills	4 light-orange pills
Nordette	4 light-orange pills	4 light-orange pills
Tri-Levlen	4 yellow pills	4 yellow pills
Triphasil	4 yellow pills	4 yellow pills
Alesse	5 pink pills	5 pink pills

- To reduce the chance of nausea, take an antinausea medicine (like Dramamine II or Benadryl) 1 hour **before** the first ECP dose; repeat according to labeled instructions. This may make you feel tired, so don't drive or drink any alcohol.
- Take the first ECP dose as soon as convenient **WITHIN 3 DAYS (72 HOURS)** after unprotected sex. Try to time the first dose so that the timing of the second dose will be convenient.
- Take the second ECP dose **12 hours after the first dose**.

IMPORTANT: Do not take any extra ECPs. More pills will probably not make the treatment work better. More pills will increase your risk of feeling sick to your stomach.

- Use condoms, spermicides, or a diaphragm if you have sex after taking ECPs until you get your period. Talk to your health care provider about other regular birth control methods you can use in the future.
- Your next period may be a few days early or late.

IMPORTANT: Do a home pregnancy test or see your health care provider if your period has not started **within 3 weeks** after ECP treatment. You may be pregnant.

Source: Program for Applied Technologies (PATH). *Emergency contraception: Resources for providers*. Seattle, 1997. This patient handout may be reproduced without permission of the publisher.

Table 95. Classification of Burns

Type of Burn	Affected Skin Layer	Appearance
First degree	Epidermis	Erythema, hypersensitivity
Second degree		
Superficial	Upper (papillary) dermis	Erythema, blistering, intact hairs, exquisite pain
Deep	Deep (reticular dermis)	Skin may be white or mottled and nonblanching, or blistered and moist; pain may or may not be present; hairs easily pulled
Third degree	Entire dermis	Dry, white or charred skin; leathery appearance, painless, no hair
Fourth degree	Subcutaneous tissue	Same as third degree; may have exposed muscle and bone

Table 96. "Rule of Nines"

Body Part	Percent of BSA		
	Infant	Child	Adolescent/Adult
Head	18%	13%	9%
Anterior trunk	18%	18%	18%
Posterior trunk	18%	18%	18%
Upper extremity (each)	9%	9%	9%
Lower extremity (each)	14%	16%	18%
Genitalia	1%	1%	1%

For small burns, a rough estimate of the affected BSA can be made by comparing the burn with the size of the child's palm (which represents approximately 1% of the BSA).
BSA, body surface area.

TOXICOLOGY

Table 97. Agents with Limited or Uncertain Binding to Activated Charcoal

Iron	Gasoline
Lithium	Mineral seal oil
Heavy metals	Caustics ^a
Arsenic	NaOH
Mercury	KOH
Lead	HCL
Thallium	H ₂ SO ₄
Alcohols	Low-molecular-weight compounds
Methanol	Ethanol
Isopropanol	Pesticides
Ethylene glycol	Organophosphates
Hydrocarbons	Carbamates
Kerosene	

^a Administration of activated charcoal may also impede further management.

Table 98. Agents Causing Hypoglycemia in Overdosed Children

Ethanol
Salicylates
Oral hypoglycemic agents
Propranolol
Insulin

Table 99. Poisons Not Detected on the Comprehensive Drug Screen^a

β -Adrenergic antagonists
Calcium channel blockers
Carbon monoxide
Clonidine
Cyanide
Iron
LSD
Many benzodiazepines (alprazolam, midazolam, lorazepam)
Most plants and mushrooms

^a Partial listing of some of the most common poisons.

Table 100. Poisons Causing Respiratory Depression or Apnea^a

Antipsychotic agents	Exotic snake envenomation
Carbamate pesticides	Cobras
Chlorinated hydrocarbons	Sea snakes
Trichloroethylene	Mambas
1,1,1-trichloroethane	Mojave rattlesnake envenomation
Clonidine	Narcotics
Coral snake envenomation	Nicotine
Cyclic antidepressants	Organophosphate pesticides
Ethanol (especially when combined with sedative/hypnotics)	Sedative/Hypnotics

^a Partial list of representative poisons.

Table 101. Poisons Causing an Abnormal Anion Gap^a

<i>Increased anion gap with metabolic acidosis</i>	Methanol ^b
Carbon monoxide ^b	Salicylates ^b
Cyanide	Theophylline ^b
Ethanol ^b	<i>Decreased anion gap</i>
Ethylene glycol ^b	Bromide
Iron ^b	Lithium ^b
Isoniazid	Hypermagnesemia ^b
	Hypercalcemia ^b

^a Partial list of representative poisons; anion gap = $\text{Na}^+ - (\text{Cl}^- + \text{CO}_2^-)$.

^b Specific levels rapidly available.

Table 102. Common Poisons and Antidotes

Poison	Antidote	Administration
Acetaminophen	<i>N</i> -Acetylcysteine	Loading dose 140 mg/kg, then 17 doses at 70 mg/kg/dose. Dilute 20% solution to 5%–10% with juice or soda to improve palatability.
Anticholinergics	Physostigmine	
Benzodiazepines	Flumazenil	
β -Adrenergic antagonists	Glucagon	
Calcium channel blockers	Glucagon	0.3–0.6 mL/kg (8–16 mEq calcium/kg)
	Calcium gluconate 10%	
Carbon monoxide	Hyperbaric oxygen	
	Sodium thiosulfate 25% ^a	
Cyanide	Sodium nitrate 3%	Dose depends on hemoglobin (see cyanide antidote kit package insert). Do not exceed recommended dosage. Do not give to patients suffering from concomitant carbon monoxide exposure.
	Sodium thiosulfate 25%	Dose depends on hemoglobin (see cyanide antidote kit package insert).
Digitalis	Digitalis Fab fragments	Calculate dose based on level or dose ingested or 10 vials if acute overdose, 5 vials if chronic overdose.
Ethylene glycol	Ethanol	0.6 g/kg load over 1 hour followed by 100 mg/kg/hr infusion
	Pyridoxine	2 mg/kg and thiamine 0.5 mg/kg
Iron	Deferoxamine	5–15 mg/kg/hr IV infusion
Isoniazid	Pyridoxine	
Lead	Lead level 45–69 mcg/dL	
	Dimercaptosuccinic acid or	10 mg/kg PO three times daily for 5 days, then twice daily for 14 days (may be useful at lower levels)
	Calcium NaEDTA	50–75 mg/kg/day divided, every 6 hours either IM or by slow IV infusion (IV use not FDA-approved)
	Lead level \geq 70 mcg/dL	
	Calcium NaEDTA and British anti-lewisite (BAL)	Administer as described above
Methanol	Folate	3–5 mg/kg IM every 4 hours for 5 days
	4-Methylpyrazole (investigational)	50–100 mg over 6 hours
Methemoglobinemia	Methylene blue 1%	1–2 mg/kg (0.1–0.2 mL/kg)
Narcotics	Naloxone	
Organophosphates	Atropine	0.1–0.5 mg/kg initial dose with additional doses as needed to counteract bronchorrhea
	Pralidoxime	25–50 mg/kg (up to 1 g); for severe cases, consider 10–15 mg/kg/hr infusion
Phenothiazines (dystonia)	Diphenhydramine	1–2 mg/kg IM or IV
	Benzotropine	1–2 mg/kg IM or IV

IM, intramuscularly; IV, intravenously; FDA, Food and Drug Administration; NaEDTA, sodium ethylenediaminetetraacetic acid; PO, orally.

^a Consider for possible cyanide inhalation if the patient suffers from smoke inhalation.

Table 103. Epidemiologic Aspects of Food Poisoning

Organism	Pathogenesis	Source	Prevention
<i>Salmonella</i>	Infection	Meats, poultry, eggs, dairy products	Proper cooking and food handling, pasteurization
<i>Staphylococcus</i>	Preformed enterotoxin	Meats, poultry, potato salad, cream-filled pastry, cheese, sausage	Careful food handling, rapid refrigeration
<i>Clostridium perfringens</i>	Enterotoxin	Meats, poultry	Avoid delay in serving foods, avoid cooling and rewarming foods
<i>Clostridium botulinum</i>	Preformed neurotoxin	Honey, home-canned foods, uncooked foods	Proper refrigeration (see text)
<i>Vibrio parahaemolyticus</i>	Infection enterotoxin	Sea fish, seawater, shellfish	Proper refrigeration
<i>Bacillus cereus</i>			
Diarrheal type	Sporulation enterotoxin	Many prepared foods	Proper refrigeration
Vomiting type	Preformed toxin	Cooked or fried rice, vegetables, meats, cereal, puddings	Proper refrigeration of cooked rice and other foods
Enterohemorrhagic <i>E. coli</i> 0157-H7	Cytotoxins	Milk, beef	Thorough cooking of beef, consumption of pasteurized milk products
Enterotoxigenic <i>E. coli</i> (traveler's diarrhea)	Enterotoxin	Food or water	Prognosis is not recommended for infants and young children

Table 104. Clinical Aspects of Food Poisoning

Organism	Incubation	Symptoms	Duration	Treatment
<i>Bacillus cereus</i>	Vomiting toxin 1–6 hr Diarrhea toxin 6–24 hr	Vomiting ± diarrhea; fever uncommon	8–24 hr	None
<i>Brucella</i>	Several days to months; usually >30 days	Weakness, fever, headache chills, arthralgia, weight loss; splenomegaly		Bactrim, tetracycline
<i>Campylobacter</i>	2–10 days; usually 2–5 days	Diarrhea (often bloody), abdominal pain, fever		Severe infection or immunocompromised; erythromycin, Cipro, or Norfloxacin
<i>Clostridia botulinum</i>	2 hr–8 days; usually 12–48 hr	Poor feeding, weak cry, constipation, diplopia, blurred vision, resp weakness; symmetric descending paralysis		Supportive, trivalent equine antitoxin to prevent further paralysis
<i>Clostridia perfringens</i>	6–24 hr	Diarrhea, abdominal cramps, vomiting and fever uncommon	<24 hr	None
<i>Escherichia coli</i> <i>E. coli</i> 0157:H7	→ 1–10 days; usually 3–4 days	→ Diarrhea (often bloody), abdominal cramps, little or no fever. Can cause HUS.	5–10 days	Antibiotics in systemic infections Supportive
ETEC	6–48 hr	Diarrhea, abdominal cramps, nausea, fever, and vomiting; uncommon	5–10 days	Supportive
<i>Listeria monocytogenes</i> Nontyphoidal <i>Salmonella</i>	2–6 wk 6–48 hr	Meningitis, neonatal sepsis, fever Diarrhea often with fever and abdominal cramps	Variable <7 days	Ampicillin and gentamicin None unless <3 months or immunocompromised
<i>Salmonella typhi</i>	3–60 days; usually 7–14 days	Fever, anorexia, malaise, headache, myalgias, ± diarrhea or constipation	3–4 wk	Chloramphenicol, ampicillin, amoxicillin, Bactrim, Cefotaxime, Ceftriaxone
<i>Shigella</i>	12 hr–6 days; usually 2–4 days	Diarrhea (often bloody), frequently fever, abdominal cramps	1 day–1 month	Bactrim, Cipro
<i>Staphylococcus aureus</i>	30 min–8 hr; usually 2–4 hr	Vomiting, diarrhea	<24 hr	None
<i>Vibriosis</i>	4–30 hr	Diarrhea, cramps, nausea, vomiting	Self limited	Usually none. Treatment for patients with liver disease or immunocompromised: Cefotaxime, gentamicin, Chloramphenicol, Tetracycline
<i>Yersinia enterocolitica</i>	1–10 days; usually 4–6 days	Diarrhea, abdominal pain (often severe), mesenteric adenitis, pseudo-appendicular syndrome	1–3 wks	Septicemia or enterocolitis in immunocompromised: Cefotaxime, aminoglycosides, tetracycline, Bactrim, chloramphenicol

Table 105. Nomogram for Estimating Severity of Acute Poisoning

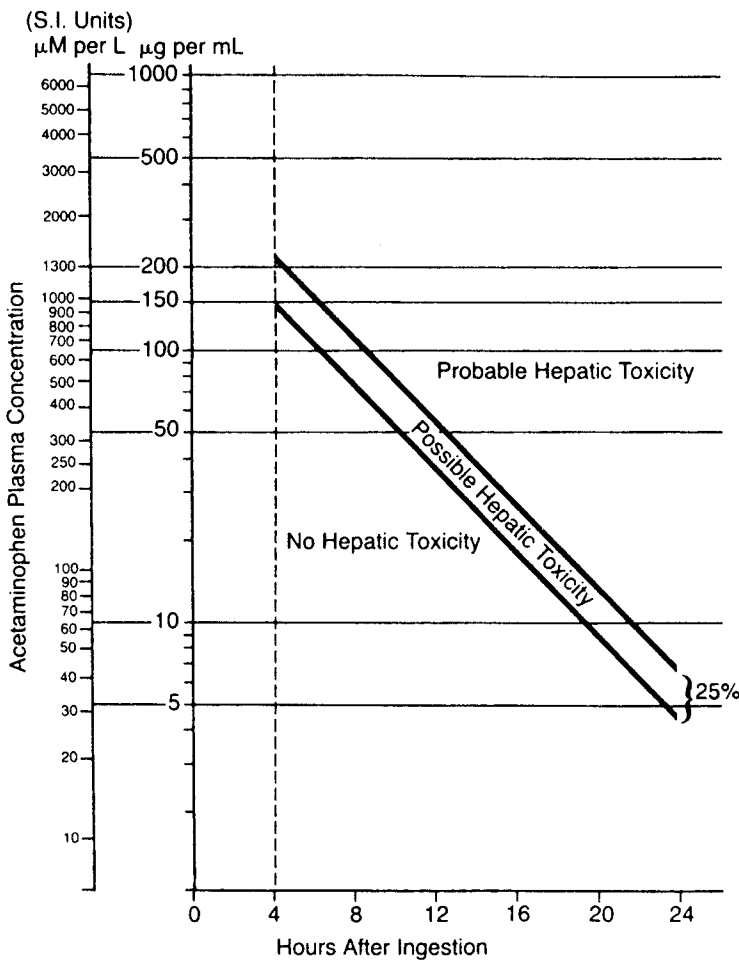

Table 106. Poisonous Plants

The following are a few common plants that are toxic:

Azalea	Laurel
Buttercup	Lily-of-the-valley
Calla lily	Mistletoe
Creeping Charlie—	Morning glory
ground ivy	Nightshade
Daffodil	Periwinkle
Delphinium	Philodendron
Elderberry	Poison ivy
Holly berries	Poison oak
Hyacinth bulbs	Rhododendron
Hydrangea	Sweet pea
Iris	Tomato vines
Ivy (Boston and	Tulip
English)	Wisteria
Jimson weed	Yew
Larkspur	

Table 107. Helpful Specific Drug Levels

Drug	Time to Peak Blood Level (Hours Postingestion)	Potential Intervention
Acetaminophen	4	N-Acetylcysteine administration
Carbamazepine	2–4 ^{a,b}	...
Carboxyhemoglobin	Immediate	Hyperbaric oxygen therapy
Digoxin	2–4	Fab (digoxin antibody) fragment
Ethanol	1/2–1 ^b	...
Ethylene glycol	1/2–1	Ethanol infusion and hemodialysis
Iron	2–4	Deferoxamine administration
Isopropanol	1/2–1 ^b	...
Lead	5 weeks ^a	Chelation and environmental abatement
Lithium	2–4	Hemodialysis
Methanol	1/2–1	Ethanol infusion and hemodialysis
Methemoglobinemia	Immediate	Methylene blue administration
Phenobarbital	2–4	Alkaline diuresis, multiple-dose activated charcoal
Phenytoin	1–2 ^a	Multiple-dose activated charcoal
Salicylates	6–12 ^a	Alkaline diuresis, multiple-dose activated charcoal, hemodialysis
Theophylline	1–3 ^a	Multiple-dose activated charcoal, whole-bowel irrigation, charcoal hemoperfusion, hemodialysis

^a Repeated measurement of levels is necessary because of significant variation in time to reach to peak level.

^b The peak level is predictive of toxicity and clinical course. Adapted from Weisman RS, Howland MA, Verebey K. The toxicology laboratory. In: Goldfrank LR, Flomenbaum NE, Lewin NA, et al., eds. *Goldfrank's toxicologic emergencies*, 5th ed. East Norwalk, CT: Appleton & Lange, 1994:105.

GONOCOCCAL INFECTIONS

Table 108. Regimens for the Treatment of Pelvic Inflammatory Disease (PID) in Adolescents

Outpatient regimens

Regimen A
Ofloxacin, 400 mg PO twice daily for 14 days
PLUS
Metronidazole, 500 mg PO twice daily for 14 days

Regimen B
Ceftriaxone, 250 mg IM once
OR
Cefoxitin (2 mg IM) plus probenecid (1 g PO) in a single dose concurrently once
OR
Another parenteral third-generation cephalosporin (e.g., ceftizoxime or cefotaxime)
PLUS
Doxycycline, 100 mg orally twice daily for 14 days

Inpatient regimens

Parenteral regimen A
Cefotetan, 2 g IV every 12 hours
OR
Cefoxitin, 2 g IV every 6 hours
PLUS
Doxycycline, 100 mg IV or PO every 12 hours

Parenteral regimen B
Clindamycin, 900 mg IV every 8 hours
PLUS
Gentamicin loading dose IV or IM (2 mg/kg of body weight), followed by a maintenance dose (1.5 mg/kg) every 8 hours; single daily dosing may be substituted

The safety and effectiveness of fluoroquinolones (e.g., ciprofloxacin, ofloxacin, norfloxacin, enoxacin) in patients younger than 18 years, pregnant women, and lactating women has not been established; therefore, fluoroquinolones are presently not recommended in these patients.
IM, intramuscularly; IV, intravenously; PO, orally.

Table 109. Uncomplicated Gonococcal Infection: Treatment in Children Beyond the Newborn Period and in Adolescents. Recommended Antimicrobial Regimens Include Therapy for Presumed Concomitant Infection with *Chlamydia trachomatis*^a

Disease	Prepubertal Children Who Weigh <100 LB (45 kg)	Disease	Patients Who Weigh >100 LB (45 kg) and Are 9 Years or Older
Uncomplicated vulvovaginitis, urethritis, proctitis, or pharyngitis	Ceftriaxone, 125 mg IM, ^b in a single dose OR Spectinomycin ^c (max 2 g), IM, in a single dose	Uncomplicated endocervicitis, or urethritis	Ceftriaxone, 125 mg IM, ^b in a single dose OR Ciprofloxacin, ^d 500 mg orally, in a single dose OR Cefixime, 400 mg orally, in a single dose OR Ofloxacin, ^d 400 mg orally, in a single dose OR Spectinomycin, ^c 2 g IM, in a single dose PLUS Doxycycline, 100 mg orally, twice daily for 7 d ^f OR Azithromycin, 1 g orally, in a single dose
	PLUS Erythromycin, ^e 40 mg/kg/d in divided doses for 7 d		

^a Hospitalization should be considered, especially for patients who have been treated as outpatients and have failed to respond, and for those who are unlikely to adhere to treatment regimens.

^b Some clinicians believe the discomfort of an IM injection can be reduced by using 1% lidocaine as a diluent.

^c Spectinomycin is not recommended for treatment of pharyngeal infections; in persons who cannot take a cephalosporin, a quinolone, or spectinomycin, a 5-d oral regimen of trimethoprim-sulfamethoxazole may be given.

^d Quinolones are contraindicated for persons younger than 18 years, pregnant women, and nursing women.

^e Doxycycline can be given instead of erythromycin if the child is 9 years or older.

^f Tetracycline, 500 mg, four times daily, can be substituted for doxycycline.

From American Academy of Pediatrics. In: Peter G, ed. 1994 Red book: Report of the Committee on Infectious Diseases, 23rd ed. Elk Grove Village, IL: American Academy of Pediatrics, 1994:199, with permission.

Table 110. Complicated Gonococcal Infection: Treatment for Children Beyond the Newborn Period and for Adolescents^a

Disease	Prepubertal Children Who Weigh <100 LB (45 kg)	Disease	Patients Who Weigh >100 LB (45 kg) and Are 9 Years or Older
Ophthalmia, peritonitis, bacteremia, or arthritis	Ceftriaxone, 50 mg/kg/d (max 1 g/d) IV or IM, ^c once daily for 7 d	Gonococcal pharyngitis Pelvic inflammatory disease	Ceftriaxone, 125 mg IM, ^c in a single dose See Table 86

^a In all cases, in addition to the recommended treatment for gonococcal infection, doxycycline (100 mg orally, twice daily for 7 d), tetracycline (500 mg, 4 times daily for 7 d), or azithromycin (1 g orally, in a single dose) is recommended on the presumption that the patient has concomitant infection with *Chlamydia trachomatis*, for children younger than 9 y and pregnant women, erythromycin is recommended.

^b Hospitalization is required; follow-up cultures are necessary to ensure that treatment has been effective.

^c Some clinicians believe the discomfort of IM injection can be reduced by using 1% lidocaine as a diluent.

^d Such as the arthritis-dermatitis syndrome.

^e Spectinomycin is not recommended for treatment of pharyngeal gonococcal infection. For patients who cannot take a cephalosporin, spectinomycin, or a quinolone, a 5-d oral regimen of trimethoprim-sulfamethoxazole may be given.

^f Alternatively, parenteral therapy can be discontinued 24–48 h after improvement begins and a 7-d course is completed with an appropriate oral antimicrobial. Some experts advise a 10- to 14-d course of therapy.

From American Academy of Pediatrics. In: Peter G, ed. *1994 Red Book: Report of the Committee on Infectious Diseases*, 23rd ed. Elk Grove Village, IL: American Academy of Pediatrics, 1994:200, with permission.

MISCELLANEOUS

Table 111. Late Effects of Chemotherapy and Radiation

Chemotherapy Agent	Possible Late Effects
Cyclophosphamide	Azoospermia, amenorrhea, hemorrhagic cystitis, secondary malignancies
Doxorubicin, daunomycin	Cardiomyopathy/Pericarditis, secondary leukemia
Methotrexate, actinomycin	Avascular necrosis, hepatitis or cirrhosis, learning disabilities with intrathecal use
Vincristine	Neuropathies
Steroids	Obesity, avascular necrosis, osteoporosis, cataracts
Cisplatin	Gynecomastia, nephritis, thrombotic thrombocytopenic purpura
Etoposide	Secondary leukemia
Radiation	
Cranium/Brain	Short stature or short trunk, obesity, learning disabilities, leukoencephalopathy, cranial neuropathies, alopecia, cataracts, hypothyroidism, second malignancies (brain, thyroid)
Head and neck	Nasolacrimal duct obstruction, chronic conjunctivitis, chronic otitis media, alopecia, cataracts, dental abnormalities, voice changes, facial deformities, neuropathies, esophagitis, second malignancies (thyroid, soft tissue sarcomas, bone tumors)
Mediastinum	Cardiomyopathy, hypothyroidism, second malignancies (thyroid, acute myeloid leukemia, breast cancer), pneumonitis/fibrosis, reduced cell-mediated immunity
Lungs	Pneumonitis or fibrosis
Spine	Short stature or short trunk, scoliosis, hypothyroidism, second malignancies (thyroid), delayed puberty
Bones	Atrophy or hypoplasia, avascular necrosis, osteoporosis, second malignancies (bone and soft-tissue sarcomas), osteochondromas
Total nodes	Reduced cell-mediated immunity, bone marrow dysfunction

Table 112. Red Eye: Common Causes by Location

Conjunctiva	Adnexa	Globe
Infectious conjunctivitis	Chalazion/Hordeolum	Corneal abrasion
Neonatal conjunctivitis	Dacryocystitis	Foreign body
Allergic conjunctivitis	Orbital cellulitis	
Periorbital cellulitis		

Table 113. Human Papilloma Viruses: Preferred Sites of Infectivity

Clinical Type	HPV Type
Verruca vulgaris (common warts)	1, 2, 4, 7, 26, 27, 29
Verruca plana (flat warts)	3, 10, 28, 41
Verruca plantaris (plantar warts)	1, 2, 4
Anogenital warts	1–6, 10, 11, 13, 16, 18, 31, 33, 35, 39, 41, 42
Laryngeal warts	6, 11, 13, 30, 40
Anogenital carcinoma	11, 16, 18, 31, 33, 42, 47
Bowenoid papulosis	16, 18, 30
Epidermodysplasia verruciformis	5, 8–10, 12, 14, 15, 17, 19–25, 16–38, 40

Table 114. Proper Child Safety Seat Use Chart: Buckle Everyone; Children Age 12 and Under Sit in Back!

	Infants	Toddler	Young Children
Weight	Birth to 1 year up to 20–22 lbs	Over 1 year and >20–40 lbs	>40–80 lbs
Type of seat	Infant only or rear-facing convertible	Convertible/forward-facing	Belt positioning booster seat
Seat position	Rear-facing only	Forward facing	Forward facing
Guidelines	Children to 1 year and at least 20 lbs in rear-facing seats Harness straps at or below shoulder level	Harness straps should be at or above shoulders Most seats require top slot for forward-facing	Belt positioning booster seats must be used with both lap and shoulder belts Make sure the lap belt fits low and tight across the lap/upper thigh area and the shoulder belt fits snug crossing the chest and shoulder to avoid abdominal injuries
Warning	All children age 12 and under should ride in the back seat	All children age 12 and under should ride in the back seat	All children age 12 and under should ride in the back seat

From National Highway Traffic Safety Administration, www.nhtsa.dot.gov.

Table 115. Pruritus**Causes of Pruritus in Children**

Most Common	Less Common	Rare
Atopic dermatitis (eczema)	Anaphylaxis	Collagen-vascular disorders: Systemic lupus erythematosus, juvenile rheumatoid arthritis
Contact dermatitis	Cholestasis: Drug-induced (e.g., total parenteral nutrition, estrogens, phenothiazines, allopurinol)	Congenital ectodermal disorders
Allergens: Plants (Rhus dermatitis: "Poison ivy"), cosmetics, dyes, systemic and topical medications (see "Differential Diagnosis")	Extrahepatic biliary obstruction, biliary cirrhosis	Systemic infections: HIV/AIDS, Parvovirus B19, Giardiasis, Ascariasis
Contact irritants (see table)	Cutaneous infections: Cutaneous larva migrans "creeping eruption"	Endocrinologic disorders: Carcinoid syndrome, diabetes mellitus, hyper/hypothyroidism, hypoparathyroidism
Cutaneous infections: Varicella-zoster virus (chicken pox), tinea infections, pinworm	Hookworm, Cercariasis, Trichinosis	Neurologic syndromes: Cerebral abscess or tumor, multiple sclerosis
Papular urticaria: Bites of fleas, mosquitos, etc.	Myiasis (maggots)	Erythropoietic protoporphyria
Pediculosis (lice)	Neurotic excoriations	Psychosomatic disorders
Mites: Scabies, chiggers	Chronic renal failure—with or without "uremic frost"	Solid organ neoplasms
Seborrheic dermatitis	Hepatic disease	Polycythemia vera
Xerosis (dry skin): Excess bathing	Hematopoietic neoplasms: Hodgkin disease, leukemia, lymphoma	Mastocytosis
Low humidity	Iron deficiency anemia

 for abdominal migraines, 5
 for ankylosing spondylitis, 51
 for avascular necrosis of femoral head, 95
 for back pain, 99
 for breast abscess, 125
 for diskitis, 281
 for dysmenorrhea, 295
 for erythema nodosum, 323
 for frostbite, 348
 for Henoch-Schönlein purpura, 409
 for intestinal polyps, 673
 for juvenile idiopathic arthritis, 63
 in juvenile idiopathic arthritis, 63
 for lupus erythematosus, 511
 for pericarditis, 631
 for Perthes disease, 645
 for premenstrual syndrome, 685
 for serum sickness, 783
 for tendonitis, 864
 for transient synovitis, 855
 Nontropical sprue. See Celiac disease (CD)
 Nontuberculous mycobacterial infections. See
 Atypical mycobacterial (ATM) infection
 Noonan syndrome, 963
 Norfloxacin, for peritonitis, 639
 Nortriptyline, for attention-deficit/hyperactivity
 disorder (ADHD), 87
 Norwood procedure, 977
 Nosebleeds, 594–595
 N-palmitoylethanolamine cream, for atopic
 dermatitis, 83
 NS. See Nephrotic syndrome (NS)
 NSAIDs. See Nonsteroidal anti-inflammatory
 drugs (NSAIDs)
 NTD. See Neural tube defects (NTD)
 Nucleoside analog reverse transcriptase
 inhibitors (nRTIs), for viral hepatitis, 935
 Nummular eczema, 221
 Nutritional therapy, for Crohn disease, 233
 Nystatin cream
 for candidiasis, 147, 353
 for diaper rash, 275
- O**
 Obesity, 596–597
 disorders associated with, 1050t
 and gallstones, 178
 hyperinsulinemia and, 1050t
 and type 2 DM, 270
 Obsessions, definition of, 598
 Obsessive compulsive disorder (OCD),
 598–599
 Obstructive sleep apnea syndrome (OSAS),
 802–803
 Occult spinal dysraphism, 585
 Occupational therapy, for juvenile idiopathic
 arthritis, 63
 OCD. See Obsessive compulsive disorder
 (OCD)
 OCPs. See Oral contraceptive pills (OCPs)
 Octreotide, 443
 for diarrhea, 183
 for hyperinsulinism, 443
 for pancreatic pseudocyst, 617
 for short-bowel syndrome, 794
 Oculocerebrorenal syndrome. See Lowe
 syndrome
 Odansetron, for abdominal migraines, 5
 Ofloxacin
 for otitis externa, 611
 for pelvic inflammatory disease, 627
 OI. See Osteogenesis imperfecta (OI)
 Olanzapine, for tics, 879
 Oligoarticular arthritis, 62. See also Juvenile
 idiopathic arthritis (JIA)
 Oliguria, 18. See also Acute kidney injury
 (AKI)
 Olopatadine
 for allergic rhinitis, 745
 for conjunctivitis, 217
 Omeprazole
 for gastritis, 354
 for gastroesophageal reflux, 357
 for hiccups, 423
 Omphalitis, 602–603
 Omphalocele, 977
 Oncovin. See Vincristine
 Ondansetron
 for bulimia nervosa, 141
 for headache and migraine, 391
 for pruritus, 701
 Onion juice, for alopecia areata, 31
 Onlay island flap, 977
 Ophthalmia neonatorum, 216–217
 Opioids, withdrawal from, 16–17
 Oral allergy syndrome, 343. See also Food
 allergy
 Oral antibiotics, for acne, 13
 Oral contraceptive pills (OCPs), 222, 223.
 See also Contraception
 and acne, 13
 for dysmenorrhea, 295
 Oral contraceptives, for polycystic ovary
 syndrome, 669
 Oral decongestants, for barotitis, 100
 Oral nystatin solution, 127
 Oral rehydration fluids, 1048t
 Oral rehydration therapy (ORT), 256
 for cholera, 181
 for dehydration, 256
 for diarrhea, 279
 for vomiting, 939
 Oral viscous budesonide (OVb), for
 eosinophilic esophagitis, 315
 Orchiopexy, 241, 977
 Orlistat (Xenical), for obesity, 597
 Ornithosis. See Psittacosis
 Oropharyngeal candidiasis (thrush), 146
 Orthoplasty, 977
 Orthotopic liver transplantation (OLT), for
 refractory ascites, 68
 OSAS. See Obstructive sleep apnea syndrome
 (OSAS)
